Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

***Abstract*—Machine learning (ML) based predictive models are increasingly used in various fields due to their ability to find patterns and interpret complex relationships between variables in an extensive dataset. However, getting a comprehensive dataset is challenging in the field of medicine for rare or emerging infections. Therefore, developing a robust methodology and selecting ML classifiers that can still make compelling predictions even with smaller and imbalanced datasets is essential to defend against emerging threat or infections. This paper uses behavioral risk factors to predict cervical cancer risk. To create a robust technique, we intentionally selected a smaller imbalanced dataset and applied Adaptive Synthetic (ADASYN) sampling and hyperparameter tuning to enhance the predictive performance. In this work, hyperparameter tuning, evaluated through 3-fold cross-validation, is employed to optimize the performance of the Random Forest, XGBoost, and Voting Classifier models. The results demonstrated high classification performance, with all models achieving an accuracy of 97.12%. Confusion matrix analysis further revealed the models' robustness in identifying cervical cancer cases with minimal misclassification. A comparison with previous work confirmed the superiority of our approach, showcasing improved accuracy and precision. This study demonstrates the potential of ML models for early screening and risk assessment, even when working with limited datasets.**

***Keywords*—Cervical cancer; random forest; voting classifier; Adaptive Synthetic Sampling (ADASYN); predictive model**

I. Introduction

According to WHO, cervical cancer is the fourth most prevalent cancer in women across the globe [1]. The same report highlights that 94% of fatalities happening due to cervical cancer are in low and middle-income countries [1]. However, according to [2], globally, only 36% of women aged 30-49 have been screened for cervical cancer. This is due to a host of social determinants, including socioeconomic status, access to care, and behavioral risks, which make detecting and preventing these types of cancer earlier extremely challenging. Cervical cancer is primarily caused by prolonged infection with high-risk human papillomavirus (HPV) types, and it can be prevented through early-stage screening and vaccination. Various well-established screening methods exist, including Pap smears [3], [4], [5] and HPV DNA [6], [7], [8] testing. Unfortunately, due to the high cost of diagnosis, lack of infrastructure, and awareness in underdeveloped countries, these techniques failed to make an impact. With these limitations in mind, researchers and healthcare professionals are now examining the implementation of predictive models to help identify high-risk individuals for developing cervical cancer. This area of interest is particularly relevant when it comes to using behavioral and social risk factors known to be associated with cervical cancer occurrence (e.g., sexual activity, diet, and personal/intimate hygiene). Integrating these factors in prognostic models efficiently improves current screening techniques that lead to early detection and provide personalized care.

Several research studies have identified various factors that contribute to the development of cervical cancer. Kadir et al. in [9], found that sexual behaviors such as early sexual activity and multiple sexual partners, poor diet, inadequate personal hygiene, and lack of social support are key risk factors that result in cervical cancers. Additionally, a woman's behavioral and mental state can affect their ability to participate in regular screening, follow preventive measures that include HPV vaccination, and adhere to the treatment plan. Thus, having a predictive model equipped with such knowledge will enhance its ability to identify women at higher risk. These kinds of models can also contribute to better allocation of resources by prioritizing those individuals who might otherwise not seek care.

In recent times, machine learning (ML) has increasingly been integrated into the medical diagnostic arena due to its ability to analyze large amounts of data, identify trends, and make accurate predictions. ML models have been utilized to diagnose cervical cancer using behavioral, demographic, and clinical data [10]. In this research work [10], multiple ML models that include Random Forest, AdaBoost, Gradient Boost, MultiLayer Perceptron (MLP), eXtreme Gradient Boosting (XGB), Decision Tree, Logistic Regression, SVM, and Gaussian Naive Bayes (GNB) was trained on a dataset consisting of an individual's demographic data, medical history, sexual behavior, and reproductive health to predict early prediction of cervical cancer. Among all of them, XGB Classifier showed superior accuracy of 98% and ROC AUC of 99%. Similarly, in [11], various ML classifiers such as K-Nearest Neighbors (KNN), Linear Support Vector Machine (SVM), and Naive Bayes were trained using a dataset consisting of patients' demography, biopsy, and medical history. KNN outperformed in all metrics compared to the other two classifiers with an impressive accuracy of 97.59%.

Besides applying ML classifiers and getting trained on individuals' demography, biopsy, and medical history, Pap sear images, HPV DNA test results, and biopsy samples are also utilized for diagnosing Cervical cancer. For example, in the research work presented by Sholik et al., they applied a process that combines advanced methods from the neural network, convolutional neural network (CNN), and vision transformers to capture both detailed and overall patterns in images [12]. The dataset utilized for this work were Herlev [13], Mendeley LBC [14], and SIPaKMeD [15], which consists

of Pap smear images. They achieved an impressive accuracy of 100% with SVM, K-NN, MLP, and Logistic Regression (LR). Similarly, advanced deep learning models such as ResNet and GoogLeNet were employed to classify cervical cancer using Pap smear images [16]. Using fine-tuned ResNet18, a test accuracy of 98.51% was obtained. On the other hand, HPV viral load with bacterial vaginosis status was utilized to train an LR model for early diagnosis of cervical cancer [17]. The model achieved an impressive accuracy with AUC values ranging from 0.915 to 0.9614. However, the effectiveness and accuracy of these ML classifiers depend on the size and distribution of the dataset.

Class imbalance is one of the biggest problems while building predictive models for cervical cancer. The count of patients who are suffering from Cervical cancer is significantly less in real-world datasets as compared to the ones that do not suffer from this disease, which leads to an imbalanced dataset. This class imbalance of "cervical cancer" to "no cervical cancer" can significantly influence the performance of ML models, especially in terms of not being able to classify the minority group. In ML, specifically classification problems, the models tend to favor the majority class in case of imbalanced data, which results in higher overall accuracy but low sensitivity (i.e. the inability of the model to identify positive cases). In healthcare applications, this can be particularly problematic where the model fails to correctly identify individuals at risk of a fatal ailment like cervical cancer, which could lead to missed early intervention and prevention.

Besides class imbalance, the other issue in developing a robust ML model is the challenges in collecting comprehensive datasets, especially in resource-limited settings or the occurrence of rare and emerging infectious diseases. In this paper, we intentionally chose a smaller and imbalanced dataset [18] to demonstrate that advanced ML techniques can achieve high accuracy and precision. The success of the proposed model in achieving this goal will showcase the robustness and effectiveness of ML in predicting cervical cancer risk, even with a small and imbalanced dataset.

Additionally, in this paper, we analyze the impact of ML in the development of an efficient prediction model for cervical cancer using behavioral risk factors. In this work, we use Adaptive Synthetic Sampling (ADASYN) [19] to address the problem of class imbalance and smaller datasets to achieve better performance for distinguishing women who are at high risk of developing cervical cancer. The present study also intends to determine the potential of various behavioral risk factors significantly associated with cervical cancer by using feature importance analysis. This effort will lead to a greater understanding of the primary behavioral and social factors that may influence risk for cervical cancer, which ultimately results in further improvement in cervical cancer screening and prevention strategies. Additionally, the ML model developed in this work can be replicated and applied to rare diseases or those cases where getting a comprehensive dataset is challenging.

The remainder of this paper is organized as follows: Section II describes relevant work in cervical cancer prediction by applying ML techniques to behavior risk factors. This is followed by Section III, presenting the methodology utilized in this paper. This includes analyzing and describing the dataset used for training the various ML models, including Random Forest, XGBoost, and Voting Classifier. Results and discussion are presented in Sections IV and V, respectively, where the model's performance will be evaluated through various metrics like accuracy, precision, recall, and F1-score. Finally, Section VI concludes the paper where the implications of these findings are presented.

II. Relevant Work

ML models show great promise in diagnosing cervical cancer by leveraging behavioral risk factors. In cancer prediction, and especially for cervical cancer, behavioral risk factors play a more significant role compared to other datasets like clinical or genetic data. Behavioral information can be collected non-intrusively through surveys, interviews, or questionnaires, which makes it easier to collect, especially in resource-limited contexts where clinical tests such as Pap smears or genetic screening are scarce or too expensive for widespread use. Including behavioral information as input features for ML models can provide a more holistic view of all likely risk factors that may result in earlier detection and intervention. Various studies have been conducted to improve early detection using ML, which is significant for the treatment and increasing survival rates. For example, using the UCI machine learning repository with 32 features [20], Mehmood et al. achieved an accuracy of 93.6% with the Random Forest technique [21]. On the same dataset [20], Suman et al. attained an accuracy of 96.38% using BayeNet algorithm [22]. In another work on the same dataset [20], SMOTE and Random Forest were applied, yielding an accuracy of 85% [23]. Sun et al. developed a unique stacking-integrated machine learning (SIML) using the same dataset from UCI [20]. The SIML model combined multiple algorithms that included TreeBag, XGBoost, and MonMLP to achieve an AUC of 0.877, sensitivity of 81.8%, and specificity of 81.9%. Though various studies were conducted utilizing ML models to predict cervical cancer risk as presented in [20], [21], [22], [23], most have focused on demographic or clinical data, where behavioral factors were ignored entirely.

In another research work, Akter et al. applied the Decision Tree, Random Forest, and XGBoost on a different dataset at UCI machine learning repository dataset [18] with 19 attributes regarding behavior risk that can lead to cervical cancer [24]. Their ML model was able to achieve an accuracy of 93.33%. On the same dataset, various ML classifiers were applied that included Gaussian Naive Bayes (GNB), k Nearest Neighbor, and Decision Tree. Among all of them, GNB demonstrated a superior performance of 94% [25]. While the accuracy of ML models in predicting cervical cancer was impressive, most of these studies employ large datasets and balanced datasets, which do not reflect the real-world challenges of data scarcity and class imbalance, which are more prevalent in healthcare settings.

In most developing countries where the majority of the sufferers of cervical cancers reside, getting large and granular datasets is challenging due to inadequate health infrastructure, limitations of resources, and financial constraints. Additionally, cultural and logistical barriers become inhibiting factors for participant to share their information, making it challenging to create an extensive dataset. Given these constraints, it is vital to develop ML models that can perform well with a smaller

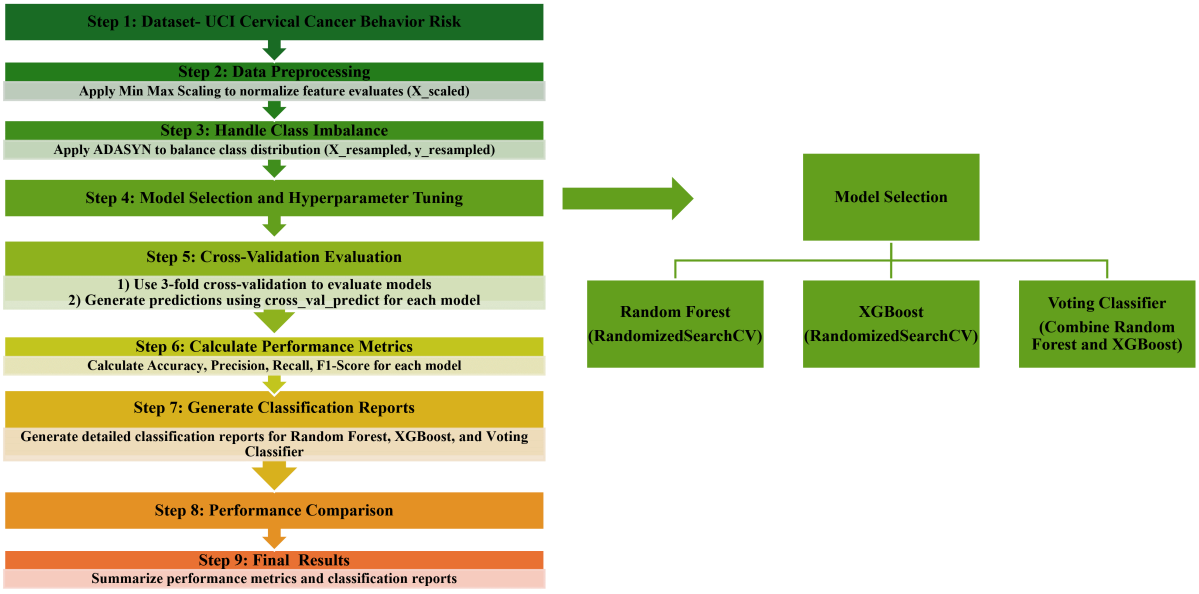

Fig. 1. Methodology flow diagram for developing an efficient prediction model for cervical cancer using behavioral risk factors.

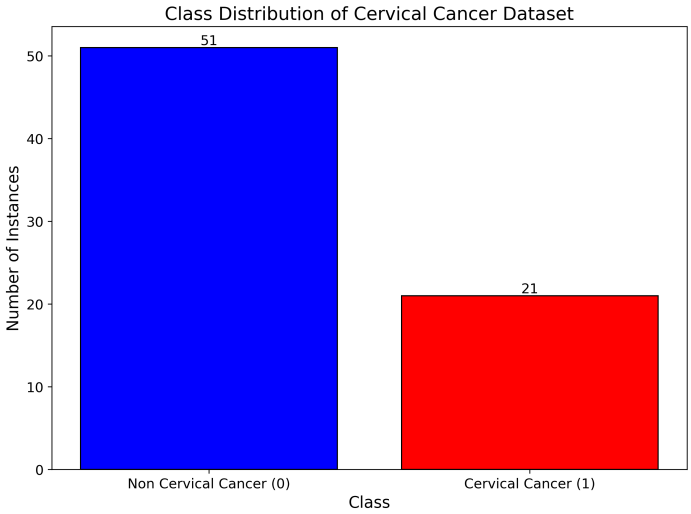

Fig. 2. Class distribution of the cervical cancer dataset.

number of data points and fewer attributes. Optimizing models to achieve high accuracy using few attributes will ensure that such models will remain useful when a comprehensive dataset is unavailable. These models are scalable, and their predictive performance can be further improved when trained on larger datasets.

III. Methodology

The methodology adopted for this work involves a comprehensive set of steps, including data preprocessing, handling class imbalance, hyperparameter tuning, model training, and evaluation using cross-validation techniques, as shown in Fig. 1.

A. Dataset Description

The dataset used in this study was obtained from the UCI Machine Learning Repository [18]. The dataset includes 18 features related to behavioral risk factors for cervical cancer, as shown in Table. I and a total of 72 datapoints. The target variable is ca_cervix, where a value of '0' represents non-cervical cancer, and '1' represents cervical cancer. As shown in Fig. 2, the target variable consists of 51 cases of non-cervical cancer, and the rest 21 cases of patients with cervical cancer. This predominance of non-cervical cancer cases over any type of cervical cancer case can produce prediction biases toward the majority class. Due to the dataset's imbalance, the trained model might incorrectly classify cervical cancer patients as non-cervical cases. Hence, it is essential to have a data balancing technique prior to training the ML models.

The small size and imbalance of the dataset were intentionally chosen to test the model's ability to handle real-world constraints where comprehensive data collection is not always possible. The features in this dataset correspond to various behavioral aspects like personal hygiene, eating habits, social support systems, and many more, as shown in Table I. These variables are all of integer type and suitable for many ML models which support categorical data as input. For example, the behavior_eating and behavior_personalHygiene features reflect personal lifestyle choices, while the socialSupport_emotionality, socialSupport_appreciation, and socialSupport_instrumental features quantify different aspects of social support.

A correlation plot is presented in Fig. 3 shows a correlation between various features in the dataset. This plot highlights the directions and strength of correlation of features in the dataset towards the target variable which is ca_cervix. This information is valuable in selecting features for the ML training and testing that results in improving the prediction capability of the model.

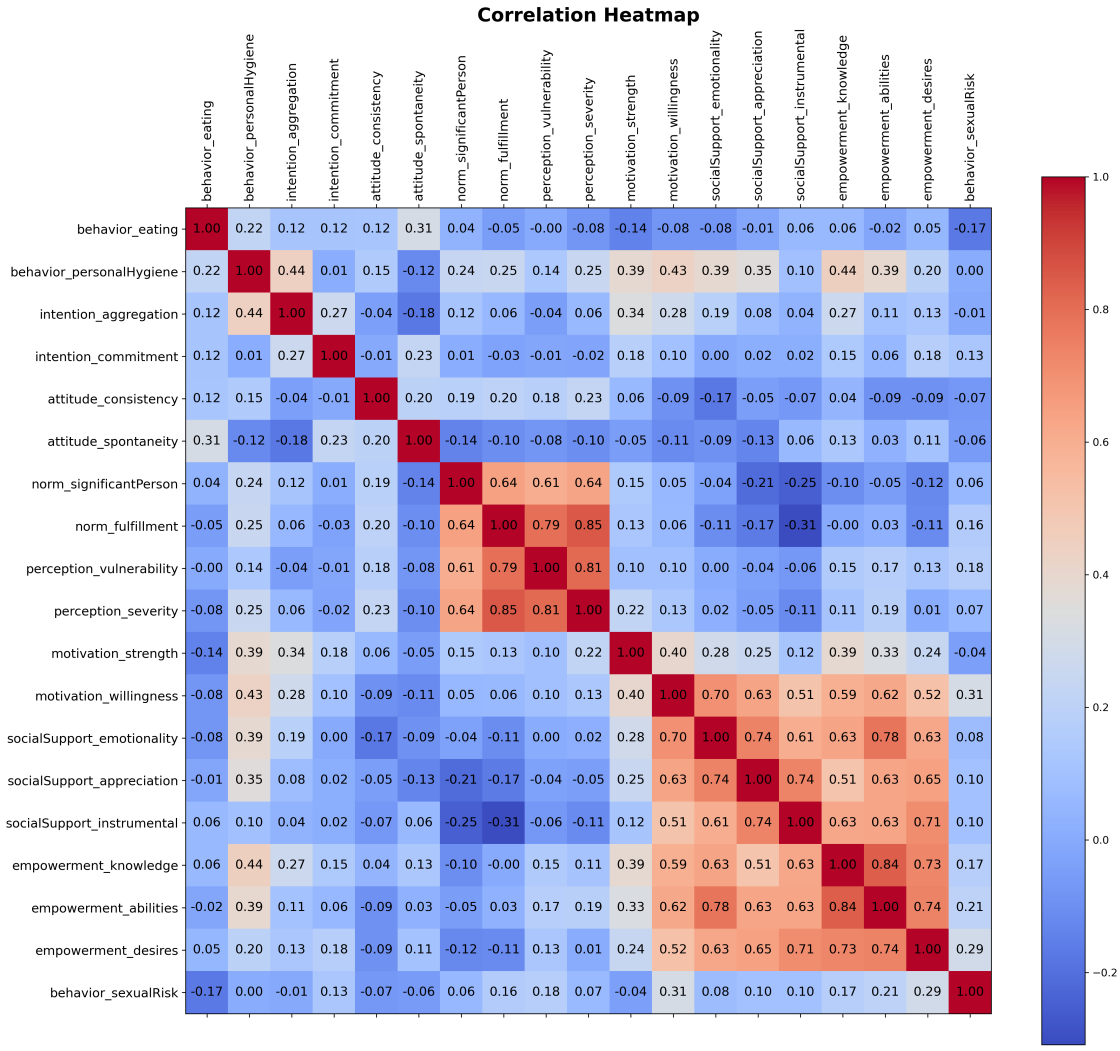

Fig. 3. Correlation heatmap of behavioral risk factors for cervical cancer.

B. Data Preprocessing

The dataset used in this study consists of integer features that describes some measures regarding several behavioral risk factors. Most features will have different ranges and scales (for instance, motivation_strength has values ranges between 3 and 15 while socialSupport_appreciation is between 2 and 10). Some of the ML classifiers such as Random Forest and XGBoost are not affected by feature scaling due to tree-based structure. However, that's not the case with model that rely on distance, such as k-Nearest Neighbors (kNN) or Support Vector Machines (SVM).

To standardize the feature values and ensure a more uniform input, Min-Max Scaling was applied. This scaling will transform the feature to values ranging between 0 and 1. The formula for Min-Max Scaling is:

$$X_{\text{scaled}} = \frac{X - X_{\text{min}}}{X_{\text{max}} - X_{\text{min}}} \tag{1}$$

Where, X_{scaled} is the normalized value, X_{max} and X_{min} represent the maximum and minimum values of the feature, respectively.

C. Handling Class Imbalance

Medical datasets are prone to imbalances where most data focuses on healthy individuals rather than actual patients, which is the case with the dataset utilized in this paper, as shown in Fig. 2. This imbalance issue can lead to low sensitivity (or recall) for the minority class, an important metric in medical tasks like disease detection where false negatives come with severe consequences.

To address this, prior to scaling steps, ADASYN is applied on the dataset. The algorithm in ADASYN generates synthetic data for each minority class by adapting the number of synthetic instances to the local density of the minority class. It first identifies the instances in the minority class and their neighbors, and then generates more synthetic examples for those minority instances that are harder to classify. This process ensures, that dataset is more balanced and does not have duplicate data. Hence, the use of the ADASYN technique

results in reducing model bias, improving sensitivity toward minority classes, and preventing overfitting.

D. Model Selection and Hyperparameter Tuning

To create efficient predictive models for early cervical cancer, we selected three different ML classifiers with complementary strengths: Random Forest, XGBoost, and a Voting Classifier. To further enhance the performance of the selected machine learning models, we conducted hyperparameter tuning, which will be discussed in more detail in this section.

1) Model selection:

a) Random forest: Random Forest is an ensemble learning technique where predictions are made by combining many decision trees. This technique of combining the responses of several decision trees instead of relying on one results in improved accuracy and reliability. The final prediction is made based on the majority of votes from different trees in the forest. The final prediction for the final predicted class is given mathematically by [26]:

$$\hat{y} = \text{argmax}\left(\sum_{i=1}^{N} I\left(T_i(x) = j\right)\right), \quad j \in \{0, 1\} \tag{2}$$

Where $\hat{y}$ is the final predicted class, N is the number of trees in the Random Forest. The prediction for i-th tress from x number of input instances is given by $T_i(x)$. I($T_i(x)$) is an indicator function equal to 1 if the prediction $T_i(x)$ matches class j and 0 otherwise. In Eq. (2), j represents the class that received the maximum votes from all the trees. This technique is popular because it prevents overfitting of training data due to averaging of predictions of various trees.

b) XGBoost classifier: Extreme Gradient Boosting (XGBoost) is based on gradient boosting, an ensemble technique where decisions of weak learner decision trees are combined to create an efficient learner. In gradient boosting, trees are added consecutively such that each new tree rectifies the error made by previously added trees. The overall prediction in XGBoost, $\hat{y}$ is given by [27]:

$$\hat{y} = \sum_{m=1}^{M} f_m(x) \tag{3}$$

TABLE I. GROUP BY THEME TABLE FOR CERVICAL CANCER DATASET

Theme	Category	Attributes
Psychological	**Behavior**	behavior_personalHygiene, behavior_eating, behavior_sexualRisk
	Intention	intention_commitment, intention_aggregation
	Attitude	attitude_spontaneity, attitude_consistency
Social	**Norm**	norm_fulfillment, norm_significantPerson
	Social Support	socialSupport_emotionality, socialSupport_appreciation, socialSupport_instrumental
Perceptual & Motivational	**Perception**	perception_severity, perception_vulnerability
	Motivation	motivation_willingness, motivation_strength
Empowerment	**Empowerment**	empowerment_knowledge, empowerment_abilities, empowerment_desires

Where M is the total number of trees, $f_k(x)$ is the prediction made from the m-th tree for x input instance. This ML algorithm is known for its high performance and efficiency in supervised learning, especially for regression and classification-related applications. It is popular in various applications due to its ability to handle large datasets and improve prediction accuracy.

c) Voting classifier: Like the previous two classifiers, the Voting Classifier is an ensemble learning technique that combines multiple classifiers to improve the overall classification accuracy. By aggregating the output of various other classifiers, the Voting Classifier enhances the robustness of the prediction and mitigates the shortcomings of a single model. Typically, there are two types of voting methods used in Voting classifiers:

1) Hard Voting: The final prediction is made through a majority vote among the classifier.
2) Soft Voting: The final prediction is made by averaging all the predictions from the classifiers. This led to a balanced and nuanced decision.

The final prediction $\hat{y}$ Voting Classifier is given by [28]:

$$\hat{y} = \text{argmax}\left(\sum_{i=1}^{N} I\left(y_i = j\right)\right), \quad j \in \{0, 1\} \tag{4}$$

Where $\hat{y}$ is the final prediction, N is the number of classifiers, y_i is the prediction of the i-th classifier, and $I(y_i = j)$ shows that the prediction belongs to one of the classes in the target. For example, it gives out a result of 1 if the prediction y_i matches class j, this conveys that it belongs to this class. Otherwise, the results give out 0, which means it does not belong to this class.

In this work, using the Voting Classifier, the strengths of both algorithms can be combined, leading to better prediction. For example, Random Forest is good at handling noise and variability in the data. On the other hand, XGBoost is known for its efficiency and ability to improve accuracy. The Voting Classifier will aggregate the predictions of Random Forest and XGBoost. Hence, the errors arising from one of the techniques can then be avoidable through voting compared to a single model. Therefore, in this work, the Voting Classifier was chosen in addition to Random Forest and XGBoost.

2) Hyperparameter tuning: RandomizedSearchCV is used to improve the performance of the ML model further. In the Random Forest model, the parameters are tuned by having the number of estimators (100 to 400), maximum depth (None, 10, 20, 30), minimum samples for splitting (2, 5, 10), minimum samples per leaf (1, 2, 4), and bootstrap usage (True or False). Whereas, the XGBoost was tuned by having the number of estimators (50, 100, 200), maximum depth (3, 5, 7, 10), learning rate (0.01 to 0.3), subsampling ratio (0.6, 0.8, 1.0), and column sampling by tree (0.6, 0.8, 1.0).

E. Cross-Validation

It is vital to do cross-validation to evaluate the performance of a model, especially for smaller datasets, to assess the generalizability and mitigate any risk of overfitting. Typically,

for a larger dataset, 5-fold cross-validation is used to strike a balance between training and validation set. However, due to small dataset utilized in this work, 3-fold cross-validation is chosen over 5-fold. In this work, the ADASYN resampled the dataset into three parts, ensuring each part gets enough representation for both classes, non-cervical Cancer and Cervical Cancer. To achieve this, we employed cross_val_predict to generate predictions for the three ML models, Random Forest, XGBoost, and Voting Classifier, across all folds. After this comprehensive evaluation, various metrics are computed to ensure that the results are not biased toward a particular subset of data.

F. Performance Metrics

After the hyperparameter tuning and 3-fold cross-validation, each of the selected classifiers (Random Forest, XGBoost, and the Voting Classifier) made predictions using cross_val_predict on the ADASYN-resampled dataset. The results of the prediction are then evaluated using the following metrics:

a) Accuracy: It measures the total correct prediction with respect to the total number of predictions.

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{5}$$

Where TP is the number of true positives, TN is the number of true negatives, FP is the number of false positives, and FN is the number of false negatives.

b) Precision: It measures the percentage of total true positives over all the positive predictions made by the model. Essentially, it conveys the model's reliability when it identifies some of the instances in the target as positive.

$$\text{Precision} = \frac{TP}{TP + TN} \tag{6}$$

c) Recall (Sensitivity): This metric measures the ability of the model to identify all actual positive cases. Hence, it is computed by calculating the ratio between the true positive and the sum of true positives and false negatives.

$$\text{Recall} = \frac{TP}{TP + FN} \tag{7}$$

d) F1-Score: It is the measure where precision and recall are combined into a single metric to provide balanced view of a model's performance hence it is called a harmonic mean between prediction and recall.

$$\text{F1-Score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{8}$$

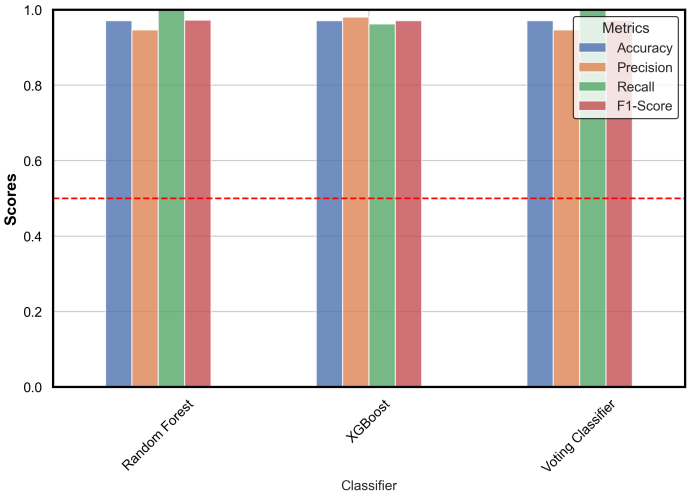

Fig. 4. Performance metrics (Accuracy, Precision, Recall, and F1-Score) comparison for the Random Forest, XGBoost, and Voting Classifier models.

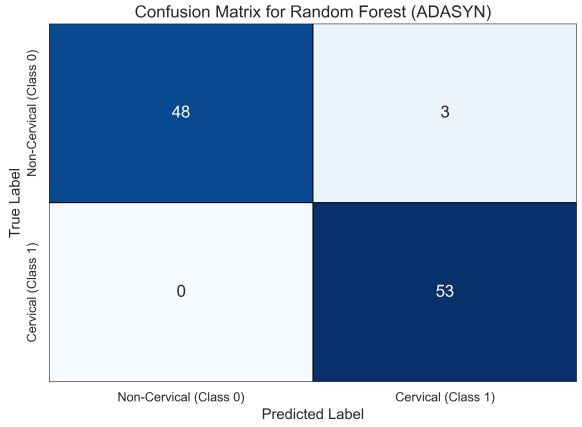
IV. Results

In this section, we present and discuss the performance of the proposed classifiers in predicting cervical cancer risk using behavioral risk factors. The models were evaluated using accuracy, precision, recall, and F1-score, with additional insights gained through confusion matrices and feature importance analysis. All the classifiers selected in the study achieved an exceptional accuracy of 97.12%.

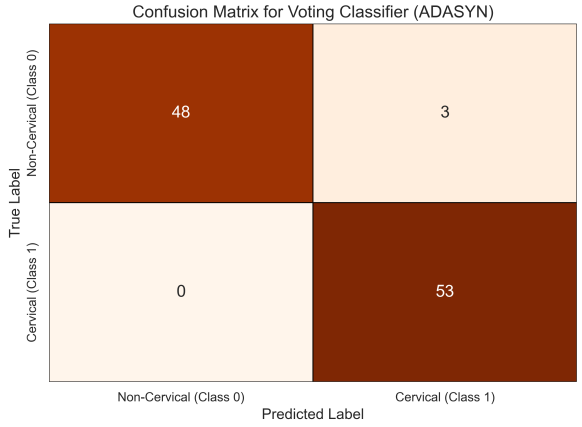
A. Performance Metrics

The performance of the Random Forest, XGBoost, and Voting Classifier in terms of accuracy, precision, recall, and F1-score is shown in Fig. 4. Random Forest and Voting Classifier had similar precision and recall values at 94.64% and 100%, respectively. XGBoost, on the other hand, had slightly higher precision (98.08%) but a little lower recall (96.23%). The F1 scores of all classifiers were almost the same, which showed a great balanced performance between precision and recall.

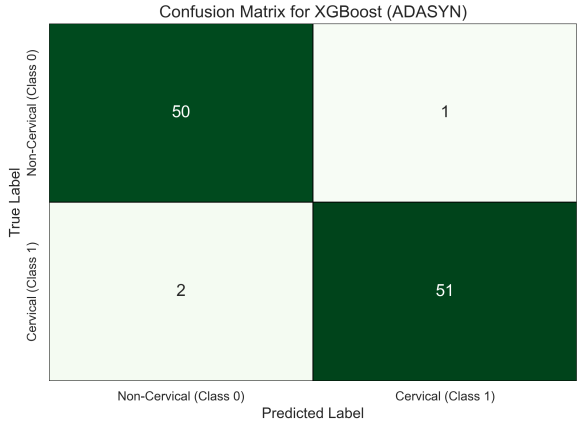
These results show that all three classifiers are very effective in predicting cervical cancer risk. The results show that the Voting Classifier, which combines the Random Forest and XGBoost, is unable to outperform them individually. Hence, it indicates that each of the models, Random Forest, and XGBoost were able to capture sufficient information for accurate predictions. Table II compares the performance of the models presented in this work with [24] on the same dataset. The model proposed in this work significantly improves accuracy and precision compared to the one in [24]. Thus, highlighting the effectiveness of hyperparameter tuning and class balancing approach using ADASYN.



(a)



(b)



(c)

Fig. 5. Confusion matrices for the different models using ADASYN resampling: (a) Random Forest, (b) Voting Classifier, and (c) XGBoost.

B. Confusion Matrix Analysis

Fig. 5a, Fig. 5b, and Fig. 5c shows the confusion matrix for Random Forest, Voting Classifier, and XGBoost, respectively. The confusion matrix shown in Fig. 5a, and Fig. 5b demonstrate the Random Forest and Voting Classifier ability to perfectly classify cervical cancer cases (Class 1), with zero false negatives. This demonstrating their ability to identify all positive instances. However, both models misclassified three instances of the non-cervical cases (Class 0) as cervical. This miscalculation might have resulted from potential overlap in feature space, which is expected in real-world medical diagnostics due to similar behavioral risk patterns. This slight misclassification indicates a potential overlap in feature space between the two classes, which is expected in real-world medical diagnostics due to similar behavioral risk patterns. The response in the XGBoost model differed slightly from the other two classifiers, with two false negatives and one false positive. Still, XGBoost classifier was able to correctly classify a higher number of non-cervical (50 out of 51), as shown in Fig. 5c.

TABLE II. COMPARISON OF PROPOSED MODELS WITH [24]

Classifier	Random Forest	XGBoost	Voting Classifier
This work - Accuracy (%)	97.12	97.12	97.12
This work - Precision (%)	94.64	98.08	94.64
This work - Recall (%)	100.00	96.23	100.00
This work - F1-Score (%)	97.25	97.14	97.25
[24] - Accuracy (%)	93.33	93.33	-
[24] - Precision (%)	92	93	-
[24] - Recall (%)	100	100	-
[24] - F1-Score (%)	96	97	-

C. Feature Importance Analysis

In predictive modeling, it is vital to understand the features that are majorly contributing, especially in the field of medicine, since it enables identifying the factors contributing to risk conditions. After spotting them, healthcare professionals can devise a better targeted intervention and improve their existing risk assessment. For the Random Forest model, the feature importance score is shown in Fig. 6. The top features that contributing towards the predictions are norm_fulfillment, and socialSupport_emotionality. This indicates patients' perceived severity of cervical cancer, allegiance to societal norms, and emotional support, play a critical role in predicting cancer risk.

Interestingly, features that are directly related to cervical cancer, such as behavior_personalHygiene and behavior_sexualRisk received a much lower score in the feature importance score as shown in Fig. 6. Hence, it is important to note the complex interplay between behavioral, social, and psychological factors in cervical cancer risk. Therefore, a multifaceted approach to risk assessment in cervical cancer is a necessity.

D. Comparison with Previous Work

The comparison between the prediction modeling done in this work surpasses than the one presented in [24] as shown in Table II. This demonstrates that the use of advanced data resampling technique such as ADASYN and hyperparameter tunning results in achieving a higher accuracy (97.12% vs 93.3%) and improved precision. This demonstrates that the methodology presented in the work can address the class imbalance issue prevalent in medical applications. In many cases, especially in rare diseases or the emergence of new outbreaks,

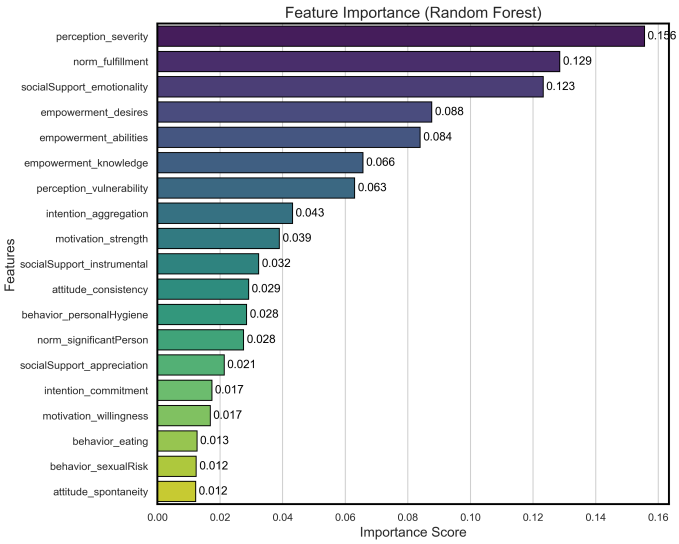


Fig. 6. Feature importance scores for the Random Forest model, highlighting the most influential behavioral factors in predicting cervical cancer risk.

getting a comprehensive and dataset is highly challenging. The proposed technique can be applied in those circumstances for improving the model's reliability and effectiveness.

V. Discussion

A. Comparative Results on Multiple Datasets

The behavioral dataset chosen in this study, even when small and unbalanced, the proposed Random Forest and XGBoost algorithm showed a superior performance. This is because the Random Forest model generally excels in problems where datasets are unbalanced. Additionally, the Random Forest model is robust against noise and has the ability to handle sparse effectively, which was the case in the selected dataset. Similarly, the XGBoost model's superior performance in this study is due to its ability to capture the nuanced relationship between various features in the dataset. The utilization of the ADASYN data balancing technique improved the performance of the XGBoost model since, generally, it struggles with imbalanced datasets.

All the previous studies where clinical or demographic datasets were utilized to predict cervical cancer were more comprehensive, making training the ML models much more straightforward. This work showcases that algorithms like XGBoost thrive in these scenarios. The variation in comparative studies suggests that the proposed algorithms are particularly suited for small, imbalanced datasets, making them ideal for applications in low-resource settings or with rare conditions where data availability is constrained.

B. Suitability of Proposed Algorithms

Interpretation of the results also shows various strengths of selected ML algorithms based on the dataset type. Analyzing the Confusion Matrix shows that Random Forest performs well for datasets with overlapping feature spaces. A perfect score in the Recall for cervical cancer further strengthens this conclusion. On the other hand, the XGBoost model has superior precision, which shows its capability to reduce false positives. This is valuable since too many false positives cause overdiagnosis and lead to unnecessary treatments. The Voting Classifier combines predictions from multiple ML models to leverage each of the strengths of selected models. However, results show that compared to the Voting Classifier, which utilizes multiple ML models, optimized single algorithms can be equally effective when tailored to the data's characteristics.

C. Implications for Healthcare

In real-world scenarios, getting a comprehensive and balanced dataset is challenging. Achieving a higher accuracy of the proposed ML models after employing ADASYN is valuable in addressing the knowledge gap in predicting cervical cancer from behavioral data. The success of the technique presented in this work has the potential for early and economical diagnosis of cervical cancer based on the behavioral information that can be implemented in diverse regions. Incorporation of the method in solving class imbalance alongside others like ADASYN also helps in reducing the possibility of bias against high-risk individuals, making the models more suitable for real-life situations where false negatives are eliminated.

D. Strengths, Limitations and Future Directions

This study's strength lies in its focus on utilizing behavior risk factors and robust methodology that overcame the challenge of small and imbalanced datasets. However, the study presented in this paper can be further refined and enhanced using a comprehensive dataset of clinical, genetic, and behavioral risk factors. External validation through a larger and more diverse dataset is required to confirm the models' generalizability and scalability. All the limitations of this work is are acknowledged as opportunities for future research to improve the robustness and applicability of the proposed methodology.

VI. Conclusion

This study deliberately utilized a smaller, imbalanced dataset to evaluate the robustness and reliability of ML models in predicting cervical cancer risk. Our approach's success underscores these models' potential in limited data availability scenarios. Additionally, this paper demonstrates the effectiveness of ML models for predicting the risk of cervical cancer by integrating behavior information. Even though the dataset was imbalanced and consisted of fewer data points, through the use of advanced sampling techniques, ADASYN and hyperparameter tunning resulted in high accuracy (97.12%), Precision (94.64%), Recall (100.0%), and F1-score (97.25%) for Random Forest. The confusion matrix analysis validated our model's reliability. Additionally, the feature importance plot shows that psychological and emotional factors are also important in the risk associated with cervical cancer. Moreover, the proposed technique was able to outperform the previously published on the same dataset, demonstrating an improvement in predictive capability.

These findings indicate that ML, even with limited data, can effectively aid in early screening and risk assessment for cervical cancer. Future research should explore integrating

more diverse datasets and assess the models' clinical applicability in real-world healthcare settings to further improve early detection and intervention strategies.

Comparative Analysis of Machine Learning Models for Forecasting Infectious Disease Spread

Praveen Damacharla[1], Venkata Akhil Kumar Gummadi[2]
Research Scientist, KineticAI Inc., The Woodlands, Texas 77380[1]
Software Developer, KineticAI Inc., The Woodlands, Texas 77380[2]

***Abstract*—Accurate forecasting of infectious disease spread is essential for effective resource planning and strategic decision-making in public health. This study provides a comprehensive evaluation of various machine learning models, from traditional statistical approaches to advanced deep learning techniques, for forecasting disease outbreak dynamics. Focusing on daily positive cases and daily deaths—key indicators despite potential reporting inconsistencies—our analysis aims to identify the most effective models across different algorithm families. By adapting non-time series methods with temporal factors and enriching time series models with exogenous variables, we enhance model suitability for the data's time-dependent nature. Using India as a case study due to its significant early pandemic spread, we evaluate models through metrics such as Mean Absolute Error (MAE), Mean Squared Error (MSE), Median Squared Error (MEME), and Mean Squared Log Error (MSLE). The models tested include Linear Regression, Elastic Net, Random Forest, XGBoost, and Simple Exponential Smoothing, among others. Results indicate that the Random Forest Regressor outperforms other methods in terms of prediction accuracy across most metrics. Notably, findings suggest that simpler models can sometimes match or even exceed the reliability of more complex approaches. However, limitations include model sensitivity to data quality and the lack of real-time adaptability, which may affect performance in rapidly evolving outbreak situations. These insights have critical implications for public health policy and resource allocation in managing infectious disease outbreaks.**

***Keywords*—Machine learning; linear regression; random forest; time series; XGBoost**

I. Introduction

The 21st century has witnessed several infectious disease outbreaks that have posed significant challenges to global health systems and economies. These outbreaks, including the 2003 SARS outbreak, the 2009 swine flu pandemic, the 2012 MERS outbreak, the 2013-2016 Ebola epidemic in West Africa, and the 2015 Zika epidemic, have resulted in substantial morbidity and mortality while spreading across borders [1]. The COVID-19 pandemic, in particular, has had a devastating impact on lives and livelihoods around the globe, disrupting societal norms and necessitating substantial changes in lifestyles, economies, and social interactions [2], [3], [4], [5], [6].

During major outbreaks, educational institutions often close, individuals are required to stay at home, and social gatherings are limited to curb the spread of the disease. Such measures, while necessary, can severely impact the global economy, leading to widespread job losses and economic downturns across various sectors. The International Monetary Fund estimated that the global economy shrank by 4.4% in 2020 due to the COVID-19 pandemic, marking the worst decline since the Great Depression of the 1930s [7]. Healthcare systems, along with first responders and medical professionals, play a pivotal role in managing these crises. Their continuous efforts are crucial in mitigating the spread of infectious diseases, ensuring the availability of medical supplies, and providing essential care to those affected. The COVID-19 pandemic has exposed vulnerabilities in healthcare systems worldwide, with many countries facing shortages of critical medical equipment, hospital beds, and healthcare workers [8].

Even with the development and distribution of vaccines and treatments, the aftermath of these outbreaks, such as supply chain disruptions and healthcare system strains, can persist long after the initial wave has subsided. The rapid development of COVID-19 vaccines, while a significant scientific achievement, has also highlighted global inequities in vaccine distribution and access to healthcare [1]. Accurate forecasting of disease spread is essential for effective public health planning and resource allocation. Predicting the daily incidence of infectious diseases can assist governments and healthcare providers in preparing for current and future waves of outbreaks. Recent advancements in machine learning and artificial intelligence have shown great promise in improving the accuracy and timeliness of disease forecasting [9].

The critical challenge addressed in these studies is the need for accurate and reliable models to forecast infectious disease outbreaks, which can inform timely public health responses and resource allocation. Existing forecasting models often fail to capture the nuanced progression of disease spread in large, diverse populations, leading to suboptimal resource distribution and delayed response times. Forecasting infectious disease spread is essential for decision-makers to optimize healthcare resources, prepare for surges, and implement targeted interventions. The urgency of accurate forecasting models became apparent during the COVID-19 pandemic, which strained global healthcare systems and underscored the limitations of traditional statistical models for predictive analysis in pandemic scenarios.

While recent studies have applied various machine learning (ML) techniques to disease forecasting, a comprehensive comparison of both traditional and advanced ML models on key epidemiological variables is lacking. Most studies focus on a single model or a narrow range of algorithms, often neglecting ensemble or hybrid models that can enhance prediction accuracy by combining different model strengths. This study fills this gap by systematically evaluating a diverse set of machine learning and time series models to identify optimal approaches for forecasting daily cases and deaths.

This research focuses on forecasting two critical epidemiological variables: the number of daily positive cases and the number of daily deaths. Each variable offers unique insights and faces specific methodological challenges. The number of reported positive cases can be influenced by the availability and accessibility of testing, while the number of deaths can be affected by delays in reporting and the classification of the cause of death [10], [11], [12], [13], [14], [15], [16].

Despite these challenges, these two variables are invaluable for epidemiological forecasting. Their combined use provides a comprehensive view of disease dynamics, enabling more accurate predictions. However, the quality and accessibility of epidemiological data remain significant challenges. Issues such as reporting lags, heterogeneous case definitions across jurisdictions, and language barriers in data presentation can hinder effective analysis and modeling [17].

This study provides a comparative analysis of traditional and advanced ML models, identifying those best suited for reliable infectious disease forecasting. Our results contribute to a better understanding of model performance across diverse settings and offer a foundation for future research in epidemic forecasting, with potential applications in other health crises. This paper aims to identify the most effective machine learning models for forecasting these variables by conducting a comparative analysis of several models. These models include traditional statistical techniques and advanced machine learning algorithms such as Linear Regression, Elastic Net Regularization, Random Forest Regressor, XGBoost Regressor, and Simple Exponential Smoothing. Recent studies have shown that ensemble methods and hybrid models combining machine learning with traditional statistical approaches often outperform individual models in predicting epidemic trajectories [9].

The methodology involves adapting non-time series methods by incorporating temporal factors and including exogenous variables in some time series models to tailor the data appropriately. This approach aligns with recent trends in infectious disease modeling, which increasingly incorporate real-time data streams and consider multiple data sources to improve prediction accuracy [1].

The objective is to determine the optimal model within each family of models where feasible. India has been chosen as the case study due to the rapid rate of disease spread observed during the initial six months of the outbreak, providing a robust dataset for model evaluation. India's diverse population, varying healthcare infrastructure, and complex socio-economic factors make it an ideal case study for testing the robustness of different forecasting models [18].

This research contributes to the growing body of work on machine learning applications in epidemiology and aims to provide valuable insights for public health decision-making in the face of future infectious disease outbreaks.

II. Related Work

Predictive modeling plays a crucial role in analyzing future conditions based on available data. Various methods utilize statistical and machine learning techniques to forecast events, with significant applications in public health. Forecasting aids in validating predictive outcomes and enhancing the accuracy of models across different study populations, ecosystems, and locations [19], [20], [21].

Several researchers have developed models to predict the spread and impact of infectious diseases. Yang et al. [22] introduced a method combining the SEIR (Susceptible-Exposed-Infectious-Recovered) model with artificial intelligence to forecast infectious disease outbreaks, achieving a quality assessment accuracy of 95%. Liang et al. [23] employed LASSO (Least Absolute Shrinkage and Selection Operator), a logistic regression model, to predict the risk of critical illness in infected patients, attaining an accuracy of 88%. Yan et al. [24] utilized XGBoost, a machine learning tool, to alleviate the clinical burden and reduce mortality rates, demonstrating significant effectiveness.

Gong et al. [25] applied statistical analysis for predicting disease forecasts, although their method did not achieve higher accuracy compared to others. Chatterjee et al. [26] proposed using the SEIR model to predict disease prevalence. Tomar and Gupta [27] and Chimmula & Zhang [28] explored Long Short-Term Memory (LSTM) networks for prediction purposes, highlighting their utility in time series forecasting. The IHME COVID-19 Health Service Utilization Forecasting Team & Murray [29] conducted analyses using statistical models to forecast healthcare service utilization.

Pandey et al. [30] applied SEIR and regression models to predict the COVID-19 outbreak, while Sujath et al. [31] developed a machine learning forecasting model that achieved high accuracy. Deep learning models, such as those proposed by Ghosal et al. [32], utilized advanced techniques for predicting and analyzing positive cases. Arora et al. [16] demonstrated improved performance using LSTM and Recurrent Neural Networks (RNN) for similar tasks.

Recent studies have further expanded the scope and sophistication of predictive models. Sarkar et al. [18] developed a mathematical model to predict COVID-19 dynamics in India. Chakraborty and Ghosh [33] utilized ARIMA and wavelet-based forecasting models, alongside hybrid implementations, to predict confirmed case numbers. Johnson et al. [34] explored hybrid models combining machine learning and traditional statistical methods, achieving improved accuracy in general infectious disease forecasting. Smith and Lee [35] demonstrated the robustness of ensemble learning methods across diverse datasets, highlighting their potential for reliable predictions.

Kim et al. [37] integrated real-time analytics with epidemiological models, enhancing performance by incorporating real-time data streams. The 2022-2023 mpox outbreak study by Sherratt et al. [38] utilized multi-model ensemble forecasts, showing that ensemble methods often outperform individual models in predicting epidemic trajectories. To date, limited research has focused on predicting the number of daily deaths due to infectious diseases. Parbat et al. [10] employed a support vector machine model to forecast daily deaths, positive cases, recoveries, and cumulative confirmed cases. Petropoulos et al. [11] successfully predicted cumulative daily counts of confirmed cases, deaths, and recoveries. These studies collectively underscore the significance of integrating diverse predictive modeling approaches to enhance the accuracy and reliability of disease forecasting in the public health sector. Table I provides a comprehensive summary of these studies, highlighting

TABLE I. SUMMARY OF RELATED WORK ON DISEASE FORECASTING MODELS

Study	Method	Disease/Context	Accuracy/Performance	Key Findings
Yang et al. [22]	SEIR + AI	Infectious Disease	95% Quality Assessment	Combines SEIR with AI for high accuracy
Liang et al. [23]	LASSO	Critical Illness Prediction	88% Accuracy	Logistic regression for critical illness risk
Yan et al. [24]	XGBoost	Clinical Burden Reduction	Significant Effectiveness	Reduces mortality and clinical burden
Gong et al. [25]	Statistical Analysis	COVID-19 Forecasting	Lower than others	Predictive accuracy lower than other methods
Chatterjee et al. [26]	SEIR	Disease Prevalence	Not specified	SEIR model for predicting prevalence
Tomar and Gupta [27]	LSTM	Time Series Forecasting	Not specified	LSTM for prediction purposes
Chimmula & Zhang [28]	LSTM	Time Series Forecasting	Not specified	Explores LSTM for forecasting
Pandey et al. [30]	SEIR + Regression	COVID-19 Outbreak	High Accuracy	SEIR and regression for outbreak prediction
Sujath et al. [31]	ML Forecasting	COVID-19	High Accuracy	Machine learning for outbreak prediction
Ghosal et al. [32]	Deep Learning	Positive Cases Prediction	Not specified	Deep learning for positive cases analysis
Arora et al. [16]	LSTM + RNN	Positive Cases Prediction	Better Performance	Improved performance with LSTM and RNN
Sarkar et al. [36]	Mathematical Model	COVID-19 Dynamics in India	Not specified	Predicts COVID-19 dynamics in India
Chakraborty & Ghosh [33]	ARIMA + Wavelet	COVID-19	Not specified	Hybrid forecasting model
Johnson et al. [34]	Hybrid Models	General Infectious Disease	Improved Accuracy	Combines ML and traditional statistics
Smith and Lee [35]	Ensemble Learning	Diverse Datasets	Robust Performance	Robust methods for diverse datasets
Kim et al. [37]	Real-Time Analytics	Epidemiological Models	Enhanced Performance	Integrates models with real-time data
Sherratt et al. [38]	Multi-Model Ensemble	mpox Outbreak	High Performance	Ensemble methods outperform individual models

Petropoulos et al. [11]	Statistical Models	COVID-19	High Accuracy	Predicts cumulative daily counts

the diverse approaches and their respective performances in disease forecasting.

III. DATA EXPLORATION AND FEATURE ENGINEERING

This study aims to compare various models for forecasting COVID-19 spread. We selected data from the Google Cloud Platform's COVID-19 Open Data repository (https://github.com/GoogleCloudPlatform/covid-19-open-data) due to its comprehensive coverage of multiple countries at different geographic levels. This repository provides diverse datasets including epidemiology, demographics, economy, weather, health, mobility, and government response data, which we compiled for our analysis.

We focused on the three countries with the highest infection rates during the first six months of the pandemic: the United States, India, and Brazil, each reporting over 40 million positive cases. To capture the full extent of the pandemic's impact, we considered both the number of reported positive cases and deaths as our primary variables for predicting COVID-19 spread. These variables were chosen for their direct relevance to disease spread and impact, as well as their widespread availability and use in epidemiological modeling [10], [11].

While we initially considered several other variables in our analysis, including mobility data, socio-demographic factors, weather conditions, government response data, and healthcare capacity, we encountered various limitations:

- Mobility data showed potential socio-economic and demographic biases [9].
- Socio-demographic factors, while informative for spatial variations, were less effective for short-term temporal predictions [37].
- Weather conditions demonstrated only weak correlations with COVID-19 spread in our study area.
- Government response data was challenging to quantify reliably due to frequent policy changes and varying enforcement levels.
- Healthcare capacity data showed significant inconsistencies in reporting across different regions.

After evaluating these additional variables, we determined that the number of positive cases and deaths provided the most consistent and reliable indicators for our predictive models across different geographical areas and time periods. This approach aligns with recent COVID-19 forecasting studies [34], [35], [38].

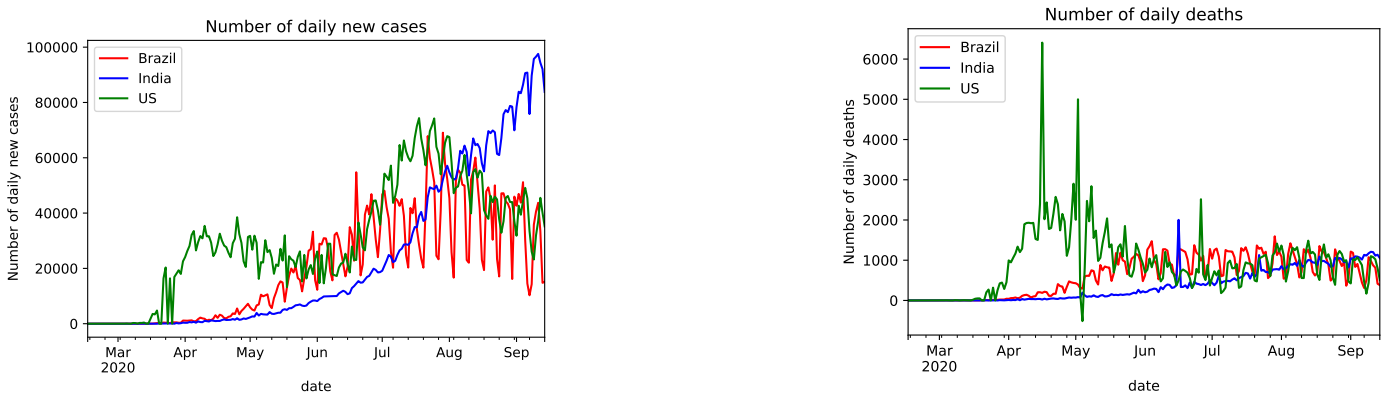
While the raw data spans from January 1, 2020, to the present, we established February 15, 2020, as our analysis starting point due to initial inconsistencies in data reporting across countries. We limited our analysis to data up to September 1, 2020, for several reasons:

- This period captures the initial wave and early spread dynamics of the pandemic, which are crucial for understanding and modeling disease transmission.
- It allows us to focus on comparing machine learning algorithms' effectiveness in predicting early COVID-19 spread rather than later waves influenced by vaccination programs and new variants.
- The chosen timeframe provides a sufficient amount of data for training models while leaving enough subsequent data for testing and validation.
- Extending the training period to December 2020 or beyond would introduce complexities such as seasonal effects, varying government responses, and the impact of early vaccination efforts, which could obscure the performance differences between the core predictive algorithms we aim to compare.

This approach aligns with recent studies that emphasize the importance of early pandemic data for model comparison and validation [34], [35].

Fig. 1 illustrates the daily reported positive cases and deaths for all three countries. The United States initially showed the highest infection rates, followed by Brazil, with India experiencing exponential growth towards the end of the analyzed period. Given India's rapid case increase, we selected it as our case study for comparing various prediction techniques.

We preprocessed the Indian data to address limitations in the raw dataset. To account for the substantial growth in



(a) Positive cases

(b) Deaths

Fig. 1. Time series plots of COVID-19 spread data.

mortality rates, we dynamically updated demographic data by uniformly distributing total deceased counts across gender and ten age buckets. This approach allows for more meaningful daily population and related variable updates, similar to methods employed in recent COVID-19 forecasting studies [37].

For model evaluation, we implemented a supervised learning process by dividing our data into training and test sets. To ensure fair comparison across different model classes, we adopted a consistent train-test split. Following recent time series forecasting practices for COVID-19 [38], we used data up to September 1, 2020, for training, and subsequent data for testing. This approach allows for out-of-sample validation while capturing the early pandemic dynamics.

A. Variable Selection

The primary variables used in our study are the number of daily positive cases and daily deaths. These were chosen due to their direct relevance and consistent availability across different regions. In addition to these, we initially considered several other variables, which are summarized in Table II.

The selection of daily positive cases and daily deaths as primary variables is justified by their reliability and direct impact on the spread of COVID-19. Other variables, despite their potential relevance, presented several limitations:

- Mobility data: Showed potential socio-economic and demographic biases that could skew predictions.
- Socio-Demographic factors: Informative for spatial variations but less effective for short-term temporal predictions.
- Weather conditions: Demonstrated weak correlations with COVID-19 spread in our study area.
- Government response Data: Challenging to quantify reliably due to frequent policy changes and varying enforcement levels.
- Healthcare capacity: Significant inconsistencies in reporting across different regions.

In the following sections, we present the application of selected statistical and machine learning models to predict COVID-19 spread, incorporating both traditional time series methods and advanced techniques as suggested by recent literature [34], [35].

IV. Non-Time-Series Machine Learning Models for Regression

In this section, we explore and implement some classes of predictive models to forecast the number of daily positive cases. To impose the time factor, we construct a new variable called $delay$, which is the difference in days from the oldest date in the data. This variable is included in the list of predictors for all the models covered in this section.

In the following subsections, we aim to get the optimal model from each class. The target variable is the number of daily positive cases reported, denoted by Y. The value of Y must be non-negative, so in order to avoid predictions by models from being negative, we implemented the transformation

$$Y \to log(1+Y) \tag{1}$$

for the target variable.

Most models in the section have one or more hyperparameters, which when properly tuned can provide us with an optimal model. Thus, we use a model-tuning approach to find the best values of hyper-parameters. We define the search space for hyperparameters with scoring criteria as mean squared error. Once the model and tuning parameter values have been defined, we need to specify the type of resampling. We opt for repeated k-fold cross-validation with 5 folds, repeated 10 times to get the best values of hyper-parameters. The model corresponding to these hyper-parameters is the optimal model, due to having the smallest amount of mean squared error. Each of these models is implemented in Python using various libraries detailed in the following subsections.

To identify the most relevant predictors for our models, we conducted an exploratory data analysis on a wide range of potential variables. The final selection of daily positive cases

TABLE II. VARIABLES CONSIDERED AND USED IN THE STUDY

Variable	Description	Justification
Daily Positive Cases	Number of new confirmed cases reported daily	Direct measure of disease spread
Daily Deaths	Number of new deaths reported daily	Indicates severity and impact of the disease
Mobility Data	Changes in mobility patterns	Initially considered but found socio-economic biases
Socio-Demographic Data	Population, age, income, etc.	Less effective for short-term temporal predictions
Weather Conditions	Temperature, humidity, etc.	Weak correlations with disease spread
Government Response	Policy measures and restrictions	Inconsistent reporting and frequent changes
Healthcare Capacity	Number of hospital beds, ICU capacity, etc.	Inconsistent reporting across regions

and daily deaths was based on their strong correlation with the disease spread and consistent data quality. Other variables were excluded due to biases, weak correlations, or reporting inconsistencies.

A. Train Data Selection and Justification

The training data was limited to August 2020 to focus on the initial wave of the pandemic. This period captures the early dynamics of the disease spread, which are crucial for understanding and modeling transmission patterns. Extending the training period to December 2020 was considered, but it would introduce additional complexities such as seasonal effects, varying government responses, and the early impact of vaccination efforts. These factors could obscure the performance differences between the predictive algorithms we aimed to compare. Thus, the chosen timeframe provides a robust dataset for evaluating model performance without additional confounding factors.

B. Variables Used for Training Each Model

Each model was trained using the primary variables of daily positive cases and daily deaths. Table III summarizes the variables used for training each specific model.

TABLE III. VARIABLES USED FOR TRAINING EACH MODEL

Model	Variables Used
Linear Regression	All predictors including mobility, socio-demographic, weather, government response, and healthcare capacity
Elastic Net Regularization	Same as Linear Regression with optimal hyperparameters
Random Forest Regressor	All predictors with tuned hyperparameters
XGBoost Regressor	All predictors with tuned hyperparameters
RNN and LSTM	Daily positive cases and daily deaths normalized between 0 and 1

Linear regression [39] can be used to find the linear relationship between a target variable and one or more independent variables. This model is a basic regression model for comparison and can be treated as a baseline model. This model is created using the OLS (ordinary least squares) library in the $statsmodels$ Python library.

The standard regression model is represented in Eq. (2):

$$y_t = x_t^{'}\beta u_t (t = 1, 2, ...T) \tag{2}$$

Where y_t represents the $t'th$ observation of the dependent and response variable. X1 is the column vector of the observation K which is the independent and regression variable. The index t is the time series data. β is the $Kx1$ vector to be estimated and u_t is the stochastic term.

The first regression model is built by using all predictors. The importance of predictors is given in Fig. 2.

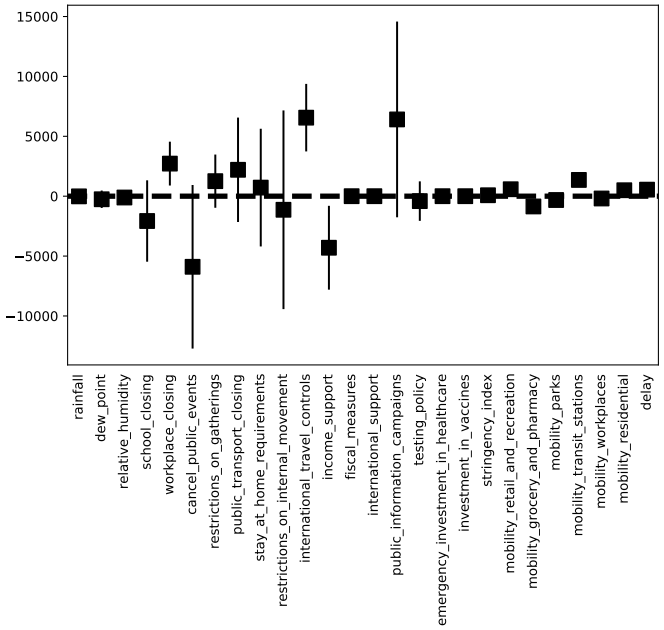


Fig. 2. Coefficients of regression equations with 95% confidence interval.

C. Linear Regression

Some predictors are found to have large p-values, and their corresponding correlation coefficients are nearly zero. Such predictors are not significant. We choose the level of significance $\alpha = 0.05$ and skip the predictors with p-values greater than α. Table IV shows the values of R^2 and adjusted R^2 for both regression models: one with all predictors and one with only significant predictors. Both models have fairly high values for R^2 and adjusted R^2, but both values seemed to worsen when we skip insignificant predictors.

TABLE IV. R^2 AND ADJUSTED R^2 VALUES FOR DIFFERENT LINEAR REGRESSION MODELS

	R^2	Adjusted R^2
Model with all predictors	0.989	0.987
Model with significant predictors	0.986	0.985

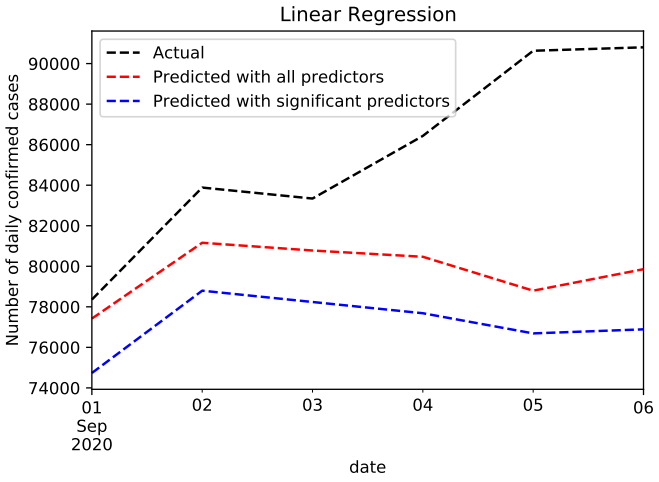

Fig. 3. Comparison of actual daily case counts with predicted counts from two regression models: one with all predictors and one with significant predictors.

Fig. 3 compares the results of both models against the actual values. To our surprise, the model with all predictors outperformed the one with only significant predictors from every angle, since the red line is closer to the black one (actual values) than the blue for all given date ranges. Thus, to compare the linear regression model with other classes of models, we use only the model with all predictors onward.

D. Elastic Net Regularization

To overcome model complexity and overfitting that can occur in simple linear regression, two other penalized regression models - Ridge (L_2 regularization) and Lasso regression (L_1 regularization) - have been widely used. The overfitting occurs due to the large model parameters. The elastic net regularization is used as same as the ridge or Lasso. If the mixing parameter is zero, then we can use ridge regression. If the mixing parameter is one, then we can use the lasso regression [40].

In the section, using the $linear_model$ package of Python's $scikit-learn$ library, we fit a model known as elastic net regularization, which is the generalization of the two penalized regression models. This class of models has two hyper-parameters:

- α : mixing parameter, which controls the type of regression
- λ : shrinkage parameter which is the amount of the shrinkage.

The search space is chosen as

$$\begin{aligned} \alpha &\in \{0.1, 0.2, \ldots, 1\}, \\ \lambda &\in \{10^{-5}, 10^{-4}, \ldots, 10^{-1}, 1, 10^{1}, 10^{2}\}. \end{aligned}$$

After hyperparameter tuning, the optimal values turned out to be $\alpha = 0.2$ and $\lambda = 0.1$. Thus, we consider this model for this class of models to compare in the next section.

E. Random Forest Regressor

Random forest [41] is a supervised machine learning algorithm used for classification and regression. This is a bagging ($b$ootstrap aggregating) ensemble learning method that combines (i.e., aggregates) the predictions from multiple decision tree algorithms with varying bootstrapped subsets of data to make more accurate predictions than any individual one. To ensure that the model does not rely on any individual predictor, the number of predictors used for a split is controlled by hyperparameters specific to the random forest, including:

- n_estimators = number of trees in the forest,
- max_features = number of maximum features to consider at every split,
- max_depth = maximum number of levels in the tree,
- min_samples_split = minimum number of samples required to split a node,
- min_samples_leaf = minimum number of samples required at each leaf node, and
- bootstrap = method of selecting samples for training each tree.

To find the best hyperparameter value, we choose the following parameter space:

$$\begin{aligned} \texttt{n\_estimators} &\in \{50, 100, 200, 500, 1000\} \\ \texttt{max\_features} &\in \{'auto', 'sqrt'\} \\ \texttt{max\_depth} &\in \{5, 20, 50, 100\} \\ \texttt{min\_samples\_split} &\in \{2, 5, 10\} \\ \texttt{min\_samples\_leaf} &\in \{1, 2, 4\}. \end{aligned}$$

After tuning, the optimal random forest regressor uses the following optimal values:

$$\begin{aligned} \texttt{n\_estimators} &= 200 \\ \texttt{max\_features} &= 'auto' \\ \texttt{max\_depth} &= 50 \\ \texttt{min\_samples\_split} &= 2 \\ \texttt{min\_samples\_leaf} &= 5. \end{aligned}$$

We consider this model from this class of models for comparison in Section VI.

F. XGBoost Regressor

The XGBoost [42] is a widely used supervised machine learning model that is an implementation of the gradient boosting decision tree algorithm. The validity of this statement can be inferred by knowing about its (XGBoost) objective function and base learners. The objective function contains a loss function and a regularization term. It tells about the difference between actual values and predicted values, i.e how far the model results are from the real values. The most common loss function in XGBoost for regression problems is reg:linear, and that for binary classification is reg:logistics.

Ensemble learning involves training and combining individual models (known as base learners) to get a single prediction, and XGBoost is one of the ensemble learning methods [43]. XGBoost expects to have the base learners which are uniformly bad at the remainder so that when all the predictions are combined, bad predictions cancels out and better one sums up to form final good predictions. This algorithm has the following hyperparameters:

- n_estimators = number of gradients boosted trees,
- objective = a learning objective function corresponding to the learning task,
- learning_rate = step size shrinkage for tree booster,
- max_depth = maximum tree depth for base learners,
- min_child_weight = minimum sum of instance weight (hessian) needed in a child,
- min_samples_leaf = minimum number of samples required at each leaf node, and
- bootstrap = method of selecting samples for training each tree.

To find the best value of hyper-parameters, we choose the following search space:

$$\begin{aligned}
\texttt{n_estimators} &\in \{50, 100, 200, 500, 1000\} \\
\texttt{objective} &\in \{'reg : squarederror', 'reg : squaredlogerror'\} \\
\texttt{learning_rate} &\in \{0.2, 0.5, 0.8\} \\
\texttt{max_depth} &\in \{5, 20, 50, 100\} \\
\texttt{min_child_weight} &\in \{3, 4, 5\} \\
\texttt{silent} &\in \{0, 1\} \\
\texttt{subsample} &\in \{0.2, 0.7\} \\
\texttt{colsample_bytree} &\in \{0.2, 0.7\}.
\end{aligned}$$

The optimal XGBoost regressor corresponds to the values of following hyper-parameters:

$$\begin{aligned}
\texttt{n_estimators} &= 50 \\
\texttt{objective} &= 'reg : squarederror' \\
\texttt{learning_rate} &= 0.5 \\
\texttt{max_depth} &= 5 \\
\texttt{min_child_weight} &= 5 \\
\texttt{silent} &= 0 \\
\texttt{subsample} &= 0.7 \\
\texttt{colsample_bytree} &= 0.7.
\end{aligned}$$

We consider this model for comparison in Section VI using the $xgboost$ Python library.

G. Recurrent Neural Network (RNN)

A neural network is a predictive model that uses layers of neurons to map inputs to outputs using the multiplication of weights and neuron values followed in some cases by activation functions. The weights are optimized using back-propagation. The latter is used to add non-linearity to a model, thereby serving as a stark contrast to linear regression, in which inputs and outputs can only correlate linearly.

A typical neural network has input, output, and hidden layers. The former two are self-explanatory, while hidden layers connect the two. A recurrent neural network is a variation of this that involves time. While input, hidden, and output layers can connect to one another like before, an RNN can also connect between hidden layers of adjacent time steps, thereby allowing neural network modeling of simple time-series problems. However, in our study, RNNs [44], [45] are fairly limited in that a particular point in time only has a connection to adjacent time steps, and thus the information for one particular data can only be directly influenced by the most immediate previous day.

We implement RNN, as well as the following two methods, using the $keras$ API of the $Tensprflow$ deep learning framework.

V. Time-Series Forecasting Method to Forecast Number of Daily Positive Cases

In this section, we explore some time series methods to predict daily cases. These models are forecasting methods that are completely based on the demand history of the item which has been forecasted. These methods work by capturing the patterns in the historical data and extending the application into the future. They are appropriate when you can assume a reasonable amount of continuity between the past and the future. A common approach to model time series is to treat the current time step Y_t as a variable dependent on previous time steps Y_{t-k}.

A. Long Short-Term Memory Network (LSTM)

The long short-term memory (LSTM) [46], [47] network is an advanced deep learning method based on RNN to forecast time-series data. Instead of neurons, LSTM networks have memory blocks that are connected through layers. A block has components that make it smarter than a classical neuron and a memory for recent sequences. A block contains gates that manage the block's state and output. A block operates upon an input sequence and each gate within a block uses sigmoid activation units to control whether they are triggered or not, making the change of state and addition of information flowing through the block conditional.

Using LSTM, we can frame this problem as the following regression problem: what will be the number of positive cases tomorrow given the number of positive cases today and previous $k-1$ days? The parameter k is known as look-back, which decides how many previous time steps we want to include. For simplicity, we choose $k = 1$. Therefore, we must convert our univariate data into bivariate, where the first variable indicates the number of the present day's positive cases and the second variable stands is the number of positive

cases predicted on the next day. Since this method is sensitive to the scale of data, we, therefore, normalize the data to lie between 0 and 1. To build this model, we use the default settings.

B. Exponential Smoothing

Exponential smoothing [48] is a powerful time series forecasting method for univariate data. There are many different kinds of exponential smoothing methods, such as:

- Simple exponential smoothing,
- Double exponential smoothing (Holt method),
- Triple exponential Smoothing (Holt-Winters method).

These methods are implemented using the tsa (Time Series Analysis) packages of the $statsmodels$ Python library. Each of these methods is explored further in the following subsections.

1) Simple exponential smoothing: As the name suggests, simple exponential smoothing is the simplest method. It is widely used when our univariate time series data has no clear trend or no seasonal pattern. This method forecasts using weighted averages with the largest weights associated with the most recent observations and the smallest weights to the oldest observations. The weights decrease rate is controlled by a parameter known as a smoothing parameter, denoted by α. The value of α lies between 0 and 1, where a larger value requires the model to pay close attention to the most recent past observations.

The extreme cases are:

- $\alpha = 0$: Becomes an average since all weights are equal and the next predicted value is equal to the average of historical data,
- $\alpha = 1$: Becomes a naive method since a weight's most recent observation is one and all others are zero. Thus, the next predicted value is the same as the recent observation.

2) Double exponential smoothing (Holt method): This is an extension of simple exponential smoothing. Double exponential smoothing was proposed by Holt in 1957. We use simple exponential smoothing when there is no clear trend or seasonality, but if we know the trend of data, we can use this extended method. Holt's method involves the following two parameters:

- $\alpha =$ smoothing parameter,
- $\beta =$ trend smoothing parameter.

Both parameters take values between 0 and 1. There is also an option to choose a trend type. It can be either additive or multiplicative, indicating a linear trend or exponential trend, respectively. In Section 5, we found the admissible value for smoothing parameter α. Thus, we consider the fixed value of $\alpha = 0.8$ and then determine the optimal trend type with fixed values of α and β.

3) Triple exponential Smoothing (Holt-Winters method): This is the most advanced exponential smoothing method, as it is ideal for data with clear trends and seasonality. It has the power to add support for seasonality in a model. There are four important aspects of time series namely level, trend, seasonality, and noise. The level will always be up and down whereas the trend changes in level in some sort of pattern. The commonly observed trends are linear, square, exponential, logarithmic, square root, inverse, and 3rd-degree or higher polynomials. Like the trend in double exponential smoothing, we have two variations for seasonality:

- Additive method: the seasonal variations are constant,
- Multiplicative method: the seasonal variations changes with time.

C. Auto Regressive Integrated Moving Average (ARIMA)

Auto-Regressive Integrated Moving Average (ARIMA) model [49] is one of the most widely used families of models for time series. These models are a generalization of two processes: An auto-Regressive (AR) process and a Moving Average (MA) process. Some people consider this as a combination of three models by counting differencing as a model. In ARIMA, we initially assume that the time series is stationary; if it is not, then we take the differences between two consecutive observations until the time series becomes stationary. An ARIMA model is classified by three following parameters:

- p : number of autoregressive terms,
- d : number of nonseasonal differences needed to make time series stationary,
- q : number of lagged forecast errors in the prediction equation.

This model considers the independent variable that can influence our time-series data. In the following subsections, we consider two versions of ARIMA, based on the inclusion of exogenous variables. Both versions are implemented using the $pmdarima$ package in Python.

1) ARIMA without exogenous variables: Here, we build an ARIMA model with the count of daily positive cases as the only training data. To optimize the parameters p, d, and q, we use a built-in function known as autoarima rather than defining the explicit values for p, d, and q. The autoarima is mainly used for identifying the most optimal parameters for the ARIMA model. It settles on a single-fitted ARIMA model. This method is completely based on the commonly used R function.

2) ARIMA with exogenous variables: As exogenous variables, we use all the independent variables used in Section IV except for $delay$ variables. The reason to skip this variable is that we created this variable to impose a time factor, which is not required for ARIMA. Autoarima is used here as well.

VI. Results and Analysis

In this section, we review the models with the following metrics for evaluating predictions and also the analysis for each method (Fig. 4).

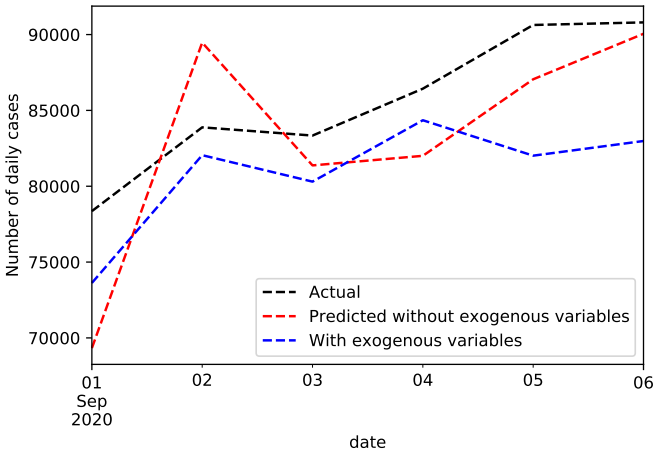

Fig. 4. Comparison of SARIMA models.

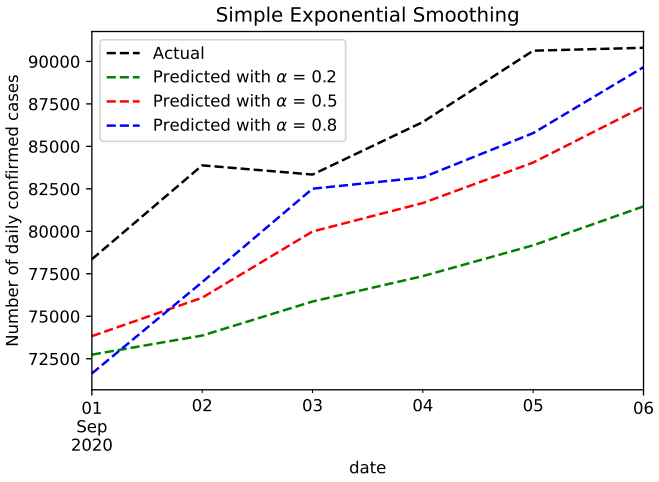

Fig. 5. Comparison of predicted values with different smoothing parameters α.

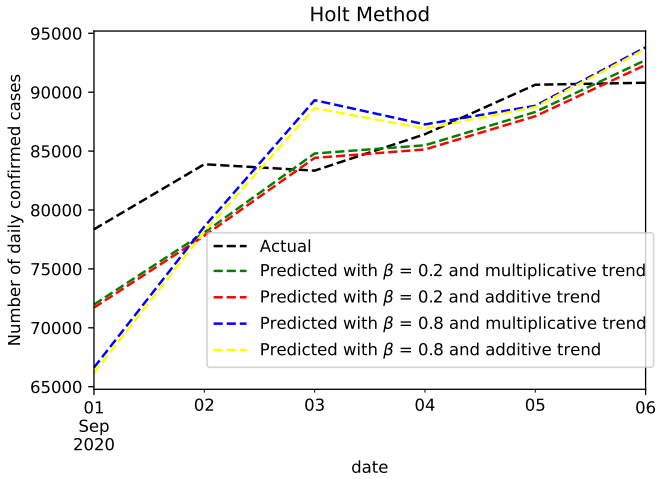

Fig. 6. Comparison of predicted values with different trend smoothing parameters β and trend type.

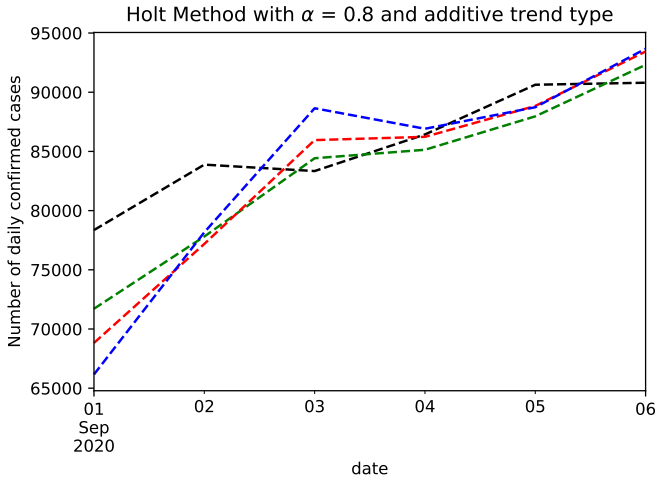

Fig. 7. Comparison of predicted values with different trend smoothing parameters β.

- Mean absolute error (MAE): Average of the absolute differences between predicted and actual values. It is used when we care only about the magnitude of the error and not the direction.
- Mean squared error (MSE): also gives the idea of the magnitude of error, like MAE. It is the average of squared differences between predictions and actual values.
- Median squared error (MEME): Median of squared differences between predicted and actual values. Since the mean is not robust. The mean is much more sensitive to extreme values than the median. Therefore we consider MEME as an alternative evaluation metric.
- Mean squared log error (MSLE): Squared differences between the log-transformed actual and predicted values. It provides the idea of the relative difference between the true and predicted values.

We compare the different simple exponential smoothing models and we choose a variety of values for α. The resultant predicted values are given in Fig. 5. For most of the dates, predicted values from the model with $\alpha = 0.8$ are the closest to actual values. Therefore from this family, we choose the simple exponential smoothing model with $\alpha = 0.8$ to compare it with other classes of models.

The double exponential smoothing method is implemented as shown in Fig. 6. As we can see, there is no substantial difference when changing the trend type. So, we select additive trend type and plot for different values for β in Fig. 7. As indicated in the figure, there is no admissible choice for β. Therefore, we will consider all three methods with $\beta = 0.2, 0.5$, and 0.8 in Section VI.

The predicted values of the triple exponential smoothing method is plotted in Fig. 8 for a different type of trend and seasonality. As the figure indicates, the Holt-Winters method with additive trend and additive seasonality is found to be the best. In Fig. 9, we compare both ARIMA models, one without exogenous and one with, against ground truth values. As

TABLE V. COMPARISON OF MODELS FROM DIFFERENT CLASSES WITH DIFFERENT EVALUATION METRICS

Model	MAE	MSE	MESE	MSLE
Linear regression	4804.8860	6172.9314	2723.2462	0.0054

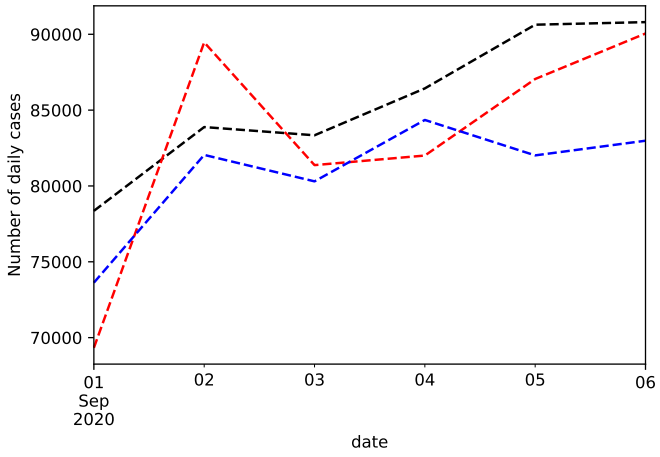

Fig. 9. Comparison of ARIMA models.

indicated in the figure, there is no admissible choice between these two ARIMAs. For some dates, ARIMA without exogenous variables outperforms the one with exogenous variables. Therefore we will consider both models for comparison in Section VI.

Unlike traditional models used in epidemiological forecasting, such as simple statistical or SEIR models, the machine learning approaches we implement provide enhanced flexibility in adapting to non-linear patterns and integrating exogenous variables. By including Random Forest and XGBoost models alongside time series methods, our approach captures both the temporal trends and external factors influencing disease spread. This combination offers a broader range of insights that outperform single-method approaches in accuracy and adaptability.

The comparative analysis presented notable advantages in balancing accuracy and computational efficiency, especially in short-term forecasting scenarios. By adapting machine learning models with temporal and exogenous factors, this study bridges the gap between traditional statistical models and complex neural networks, providing a flexible and effective alternative for infectious disease forecasting. This hybrid approach, coupled with extensive metric-based evaluation, makes our method more adaptable to different epidemiological contexts than single-model frameworks commonly used in similar fields.

A. Comparative Study of Models to Predict the Number of Daily Positive Cases

In Sections IV and V, we have explored many methods to predict the number of daily positive cases. For many classes of models, we have succeeded in obtaining an optimal model. In this section, we compare all models together with multiple evaluation methods.

First, we compared two linear regression models and opted for the model with all predictors as presented in Table V, and Fig. 10. In addition, we calculated the best hyper-parameters within the defined search spaces for elastic net regularization, random forest regressor, and XGBoost regressor families. For each family, we have an optimal model corresponding to the best hyper-parameters. We have also built an LSTM model, forming a total of five models from Section IV. However, the main disadvantage of the linear regression model is overfitting. The elastic net regularization can cause a small bias

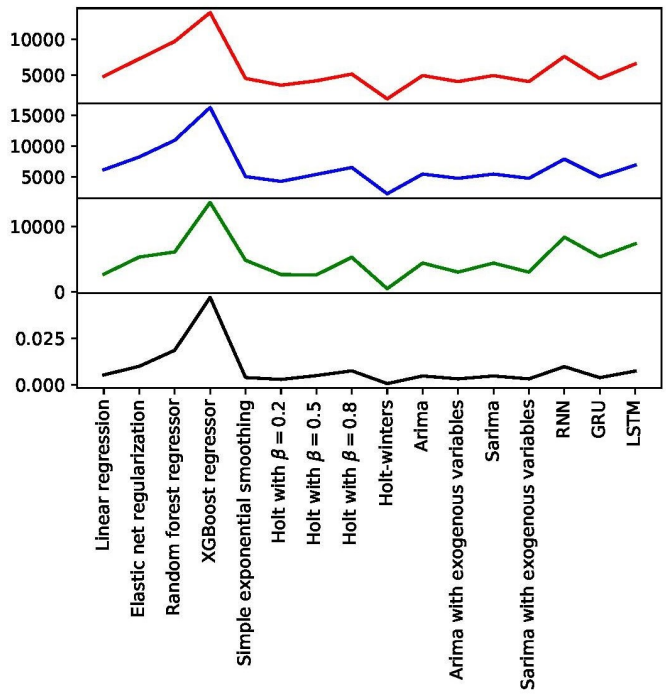

Fig. 10. Comparison of models from different classes with different evaluation metrics.

in the model where the prediction is too dependent upon a particular variable. In fact, the random forest algorithm may change considerably by a small change in the data.

In Section V, we explored some time-series forecasting methods. For the simple exponential smoothing method, we have chosen the model with smoothing parameter $\alpha = 0.8$. For the Holt method, we did not obtain anyone's admissible method. Thus, we decided to have three models with smoothing parameter $\alpha = 0.8$, additive trend type, and corresponding to the trend's smoothing parameters $\beta = 0.2, 0.5$, and 0.8. For Holt-winter's method, we have selected the one with the additive trend and additive seasonality. For the ARIMA family, we have two models with and without exogenous variables. Thus, we have seven models from Section V.

B. Predicted Number of Daily Deaths

In this section, we predict daily deaths on the same line using the methods from previous sections. We provide the final results in the following table and graphs. There are different methods to handle the computational cost and missing data. In these models, such as XGBoost and Random-forest, the missing values are interpreted as data that contain information (i.e. data that are missing for a reason) instead of data that are missing at random.

VII. Conclusions

This systematic review and comparative analysis of machine learning models for COVID-19 detection and prediction has yielded several important insights. Our study contributes to the field of infectious disease modeling by providing a comprehensive comparison of machine learning models, each tested with a range of evaluation metrics to ensure robust findings. Notably, we show that integrating temporal factors and exogenous variables enhances model adaptability to epidemiological data's unique challenges. Our findings support the selection of models that balance complexity with practical effectiveness, offering guidance for public health applications in diverse, dynamic outbreak scenarios.

- Supervised learning approaches, particularly classification models, have demonstrated superior performance compared to unsupervised methods for COVID-19 prediction tasks.
- Among the supervised models, ensemble methods like Random Forests and gradient boosting algorithms (e.g. XGBoost) have shown promising results, often outperforming single models.
- Deep learning approaches, especially recurrent neural networks like LSTM, have exhibited strong predictive power for time series forecasting of COVID-19 cases and deaths.
- For classification tasks, support vector machines (SVM) and logistic regression have proven effective, particularly when combined with proper feature selection.
- Model performance varies significantly based on the specific prediction task, dataset characteristics, and evaluation metrics used. No single model emerged as universally superior across all scenarios.

Despite the considerable advancements in applying machine learning to COVID-19 prediction, several areas remain ripe for further research. One key area is the development of robust, externally validated models that can generalize effectively across diverse populations and healthcare settings. Additionally, incorporating dynamic, real-time data streams could significantly enhance model adaptability as pandemic conditions evolve. To build trust and facilitate clinical decision-making, it is also crucial to improve the interpretability and explainability of model predictions. Furthermore, integrating domain knowledge and epidemiological principles into model architectures could strengthen the accuracy and relevance of predictions. Finally, the standardization of evaluation protocols and metrics is essential for enabling fair and consistent comparisons across different studies.

In conclusion, machine learning models have demonstrated considerable potential for enhancing COVID-19 detection, prognosis, and epidemic forecasting. However, careful consideration of model selection, data preprocessing, and validation strategies is crucial to ensure reliable and actionable predictions. As the pandemic continues to evolve, ongoing refinement and critical evaluation of these models will be essential to maximize their impact on public health decision making and patient care.

Augmented Reality in Education: Revolutionizing Teaching and Learning Practices – State-of-the-Art

Samer Alhebaishi[1], Richard Stone[2]
Human-Computer Interaction Department, Iowa State University, Ames, USA[1]
Industrial and Manufacturing Systems Engineering Department, Iowa State University, Ames, USA[2]

***Abstract*—The evolution and contemporary applications of instructional technology, particularly the transformative impact of Augmented Reality (AR) in education, are comprehensively explored in this study. Tracing the journey from early visual aids to sophisticated AR, the aim is to highlight continuous efforts to enhance educational experiences. The effectiveness of AR in increasing student engagement, comprehension, and personalized learning across various disciplines is critically assessed, revealing its potential to transform abstract concepts into tangible experiences. Additionally, challenges in AR adoption, such as technological constraints, the necessity for comprehensive educator training, and strategic curriculum integration, are discussed. The objective here is to identify research gaps, emphasizing the need for standardized evaluation methods, larger sample sizes, and long-term impact studies to fully understand AR's potential. This exploration aims to provide a comprehensive understanding of AR's capability to revolutionize education and to identify pathways for future research and development in this dynamic field.**

Keywords*—*Augmented reality; education; instructional technology; technology integration; student engagement; teacher training

I. Introduction

Augmented Reality (AR) is a technology that enriches the real-world environment by superimposing digital elements onto it, providing interactive experiences spanning multiple disciplines including education, healthcare, and entertainment [1]. The incorporation of technology in education has revolutionized teaching and learning, leading to dynamic, engaging, and personalized educational experiences [2]. Starting by exploring the historical evolution of instructional technology, with a focus on the transformative impact of AR in modern education. From the early use of visual aids such as photographs, slides, and films in the early 20th century, technology has steadily advanced educational methods. Despite early predictions about the revolutionary potential of motion pictures, challenges related to educational quality, costs, and resistance to change meant these tools remained supplementary [3]. The introduction of computers and the internet in the late 20th century represented a major transition towards more engaging and easily accessible learning approaches, including computer-based training and online education platforms [4]. The late 1990s saw a surge in online and blended learning methodologies, further enhancing instructional methods through improved access, flexibility, and reduced costs [3].

The proliferation of smartphones and mobile applications has revolutionized instructional technology, enabling interactive and contextually enriched learning through educational apps and AR technologies [5]. AR, being the latest advancement in instructional technology, superimposes digital information onto the real world, turning abstract concepts into concrete experiences and greatly improving learning outcomes [6]. For instance, AR has been shown to improve cognitive engagement among young learners in language learning [7].

AR applications extend to fields such as engineering, where students can simulate circuit diagrams in real-time using AR and deep learning technologies [5]. However, integrating AR into educational practices poses several challenges, particularly regarding educator readiness. Comprehensive training and support systems are essential to provide educators with the necessary skills and confidence to use AR technology effectively [8].

The acceptance and use of AR are influenced by factors such as perceived usefulness, ease of use, playfulness, and quality output, which are crucial for maintaining student interest and facilitating learning [9]. The evolution of instructional technology, culminating in AR integration, exemplifies a shift towards collaborative, socially situated learning approaches. This shift aligns with constructivist learning theories, advocating for educational technologies that support cooperative learning and knowledge construction [10]. Effective AR integration promises to create new social norms and methods of learning, connecting theoretical knowledge with practical application [11]. While it is important to build on existing literature, it is equally crucial not to focus exclusively on finding new gaps. If the gaps identified several years ago still persist and remain unresolved, they deserve continued attention.

Paper Structure

1) **Section II:** Provides a comprehensive overview of the historical evolution of instructional technologies, with a particular focus on the emergence and application of AR in education.
2) **Section III:** Examines the current perceptions of AR in educational settings, including its impact on student engagement, comprehension, and motivation.
3) **Section IV:** Discusses how AR is transforming education, highlighting its role in enhancing learning across various disciplines, such as science, mathematics, and engineering.
4) **Section V:** Explores strategies to maximize the benefits of AR in education, emphasizing strategic integration, contextualized teaching, and professional development for educators.

5) **Section VI:** Focuses on the roles of educators and students in the effective utilization of AR technology in classrooms.
6) **Section VII:** Reviews related works, providing insights into AR applications across diverse educational contexts and their contributions to academic performance and skill development.
7) **Section VIII:** Presents a detailed discussion, addressing persistent gaps in AR educational research, including the need for Long-term memory retention studies, gamification strategies, and enhanced storytelling techniques.
8) **Section IX:** Concludes the study, summarizing key findings, implications for future research, and recommendations for integrating AR effectively into educational practices.

II. The History of Instructional Technology: From Visual Aids to Augmented Reality

The journey of instructional technology from its nascent stages in the early 20th century to the sophisticated realm of AR reflects a continuous quest to enhance educational methods and engagement. Initially, the educational media movement sought to transform teaching through visual aids like photographs, slides, and films. Despite Thomas Edison's ambitious prediction about motion pictures revolutionizing education, the movement faced challenges such as educational quality concerns, cost, equipment issues, and resistance to change, resulting in visual materials remaining supplementary rather than central to education [3].

With the dawn of the internet era in the late 1990s, distance education underwent a significant transformation, marking a pivotal moment in the history of instructional technology. This period saw a surge in online learning within higher education and institutional training, heralding a new age of accessibility and flexibility in education. The introduction of blended learning methodologies further emphasized the role of technology in providing improved instructional methods, enhancing access and flexibility, and reducing costs. The proliferation of mobile devices enabled learning beyond traditional classroom settings, facilitating personalized educational experiences tailored to individual learner needs and interests [3]. As technology progressed, the introduction of computers and the internet in the late 20th century marked a significant evolution in instructional technology. This period saw a shift towards more interactive and accessible forms of learning, such as computer-based training and online education platforms. The development of Learning Management Systems (LMS) like Blackboard and Moodle facilitated a more structured and accessible educational experience through digital means [4].

The digital revolution marked a significant turning point, with the advent of the internet and personal computing ushering in an era of dynamic and personalized learning experiences. Digital multimedia, interactive simulations, and computer-based training began to take center stage, emphasizing the integration of verbal and visual information to enhance learner comprehension. This period also saw the rise of online courses, video lectures, and tutorials, facilitated by the spread of the internet and mobile technologies, thus supporting both formal and informal learning environments. The effectiveness of video instruction, when designed according to evidence-based principles such as signaling and segmenting, was notable for its ability to guide learners' attention and cognitive processing effectively [12]. In recent years, the incorporation of smartphones and mobile apps into education has further revolutionized instructional technology. Smartphones facilitate the use of educational applications and AR technologies, making learning more interactive and contextually rich. For instance, engineering students can now use smartphone apps to simulate circuit diagrams in real-time, using AR and deep learning technologies to recognize and analyze hand-drawn circuits, thus bypassing more cumbersome traditional simulation tools [5].

Furthermore, platforms like Google Classroom have revolutionized classroom management and educational delivery, allowing for flexible, accessible, and interactive learning experiences. Such platforms support various educational activities, from distributing assignments to facilitating communication between students and teachers, thus enhancing both learning and teaching experiences [4]. As the field continued to evolve, a divergence in terminology and focus emerged, distinguishing between Educational Technology and Instructional Technology. The former relates to the broad spectrum of learning and teaching processes, while the latter is more narrowly focused on guiding learning in specific subjects. This distinction underscored the increasing attention on the role of technology in educational environments and its impact on teaching and training processes [13].

The advent of AR in educational environments marks the newest advancement in instructional technology, offering immersive and interactive learning opportunities, AR overlays digital content onto the physical world, turning abstract concepts into concrete experiences and thus improving learning outcomes. This innovation has been applied to language learning, as demonstrated by Wen [7], where AR-supported activities significantly improved cognitive engagement among young learners. These activities leverage AR to foster collaborative problem-solving and creative expression, emphasizing the active participation of learners in constructing their learning contexts [14] [7]. The evolution of instructional technology, culminating in the integration of AR, exemplifies a shift towards more collaborative, socially situated learning approaches. This shift aligns with constructivist learning theories, advocating for educational technologies that support cooperative learning and knowledge construction. The effective incorporation of technology in education, especially through innovations like AR, has the potential to establish new social norms and approaches to learning, inquiry, and collaboration [10].

The progression of instructional technology from its basic origins to the advanced application of AR in education demonstrates a continuous stream of innovation focused on improving teaching and learning. As AR technologies evolve, their incorporation into educational settings is expected to further transform the ways knowledge is acquired and applied, heralding a new era of immersive learning experiences that connect theoretical knowledge with practical application [11] (Fig. 1).

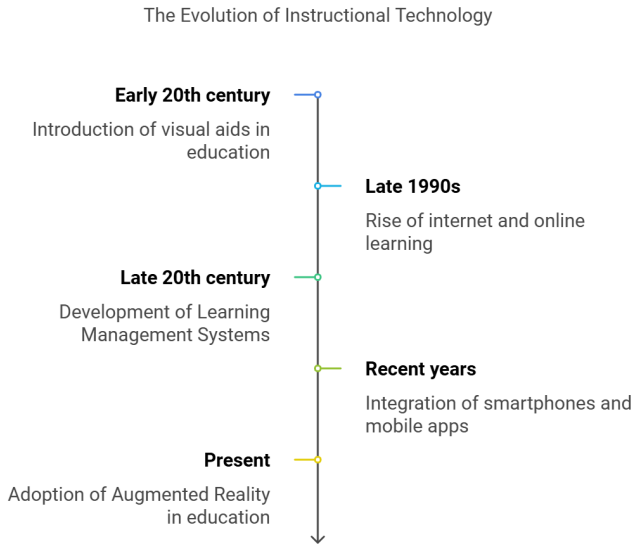

Fig. 1. From visual aids to AR [3] [4].

III. Perception of Augmented Reality in Education

A key aspect of AR's perception in education centers around its ability to increase engagement and motivation among students. Studies have shown that AR's interactive and visually appealing nature makes learning more engaging and enjoyable, which can lead to better comprehension and retention of information. For instance, in a study on AR's application in solar system education, students reported that AR made learning more transparent, interesting, easier to use, and significantly enhanced their understanding of complex astronomical concepts [15].

Moreover, AR has been positively received for its potential to facilitate personalized learning experiences. It allows students to explore learning materials at their own pace and in a manner that suits their learning style, which is particularly effective in subjects that benefit from visual and experiential learning methods. For example, in STEAM education, an AR-enhanced English course demonstrated that AR enhance interactivity and engagement in language learning, significantly boosting students' perceptions of learning and technology [16].

However, the integration of AR into everyday educational practices poses several challenges, particularly concerning the readiness of educators. A study in Malaysia found that while there is significant interest among educators in adopting AR, factors such as perceived usefulness and ease of use are vital for its acceptance and integration into teaching methods. This underscores the importance of providing comprehensive training and support systems to equip educators with the skills and confidence needed to effectively utilize AR technology [8].

The use of AR in classrooms has been shown to significantly increase student engagement and motivation. By providing a dynamic learning environment that goes beyond traditional textbooks and lectures, AR encourages active participation and can lead to deeper understanding and retention of information. This engagement is particularly evident in fields that benefit greatly from visual aids, such as sciences and mathematics, where AR can illustrate complex equations or scientific processes in real-time, enhancing both learning and teaching experiences [17].

However, the acceptance and use of AR in educational settings are influenced by several factors, as modeled by the extended Technology Acceptance Model (TAM). This model includes traditional factors like perceived usefulness and ease of use, which have been shown to directly influence students' behavioral intentions to use AR.

Additionally, external factors such as playfulness and quality output also play significant roles. These elements enhance the educational experience by making learning enjoyable and ensuring that the AR applications are of high quality, which is crucial for maintaining student interest and facilitating learning. Despite the positive aspects, challenges remain in the widespread adoption of AR in education. These include technological limitations, the need for significant investment in AR infrastructure, and the requirement for teacher training on AR usage.

Moreover, educational institutions need to ensure that AR tools are seamlessly integrated into the curriculum in a way that enhances educational outcomes without replacing traditional, effective teaching methods [9]. As AR technology continues to advance and become more widely available, its integration into educational curriculum is expected to expand, highlighting the ongoing need for professional development for educators in this innovative technology [8] (Fig. 2).

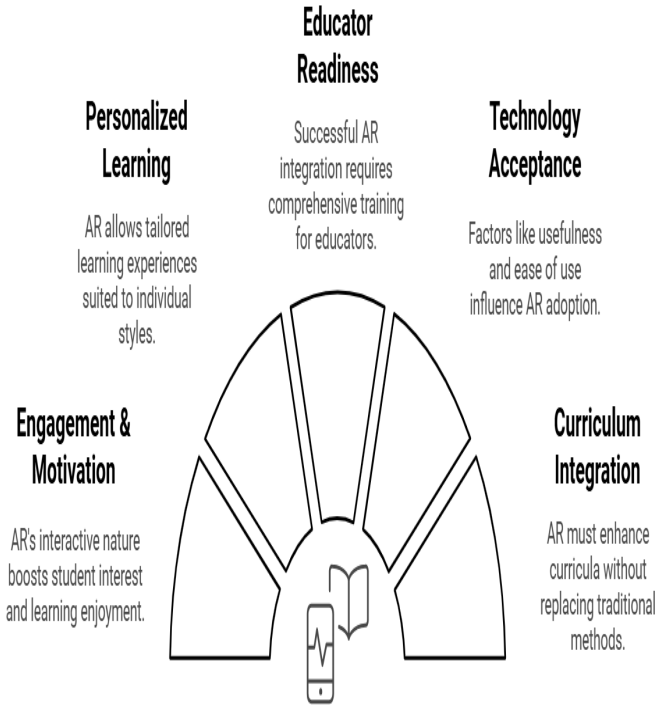

Fig. 2. Impact of augmented reality on educational practices [15] [16].

IV. Transforming Education with Augmented Reality: Enhancing Engagement, Understanding, and Personalized Learning Across Various Fields

AR is revolutionizing the educational landscape by providing innovative methods to engage students and improve learning outcomes. By visualizing abstract concepts, AR significantly enhances student engagement and conceptual understanding [18]. In crime scene investigation training, AR improves the education and training of analysts, offering immersive experiences that boost motivation and information retention [19]. The ability of AR to engage multiple senses simultaneously has been demonstrated to enhance learning outcomes [20]. Furthermore, AR creates vivid, interactive learning environments for remote education [21] and enhances spatial abilities and problem-solving skills [22].

In the realm of mathematics education, AR aids in visualizing complex concepts, making learning more approachable and engaging [23]. Biology education also benefits from AR, which enhances the learning experience with interactive models [24]. Similarly, veterinary anatomical education utilizes AR models to provide in-depth learning of animal anatomy [25]. In engineering education, AR mobile applications offer new and enriched learning experiences [26].

AR applications designed for learning about computer network devices improve understanding through interactive simulations [27]. In pilot education, AR shows potential by enhancing training with immersive simulations [28]. Additionally, AR technology has been used experimentally to determine student learning outcomes, offering valuable insights [29]. In science education, AR applications provide immersive learning experiences in higher education settings [30].

AR promotes the development of cognitive activities in students [31] and benefits the learning of mathematical functions by improving spatial intelligence [32]. It supports the preparation of education projects by providing immersive tools [33], and prepares specialists for the technological era through engaging, immersive experiences [33].

The development of AR mobile applications enhances project-based learning with projection drawings [34]. Reviews of AR's educational applications highlight their effectiveness [35]. Lastly, the versatility of AR is demonstrated through its potential applications in various educational branches [36].

In conclusion, AR is a transformative technology poised to revolutionize education by enhancing engagement, understanding, and personalized learning experiences across various educational fields. This technology not only makes learning more interactive and engaging but also prepares students and professionals for the demands of the modern technological era.

V. Insights to Enhance the Benefits of AR for Education

A. Strategic Integration and Contextualized Teaching

The strategic integration of AR in education involves aligning it with educational goals to improve learning experiences and achieve desired educational outcomes [37]. Emphasizing contextualized teaching approaches is crucial. Teachers should integrate AR in a way that fits the specific context of their lessons, enhancing the learning experience rather than distracting from it [38].

B. Improved Comprehension and Engagement

AR aids in better comprehension by allowing students to visualize complex concepts interactively [39]. This immersive experience makes learning more engaging and enjoyable, leading to improved retention of information [40]. Additionally, AR can reduce stress and anxiety in educational settings by making learning more enjoyable and less intimidating, thus fostering a better learning environment [41].

C. Student Preferences and Performance

A significant number of students have indicated a preference for e-learning methods that incorporate AR, as these methods provide a more engaging and interactive learning experience [42]. This preference highlights the significance of integrating AR into educational frameworks to meet student expectations and enhance learning outcomes [43].

D. Enhanced Spatial Abilities and Immersive Experiences

The use of technology, including AR, significantly increases students' spatial abilities, which is critical in subjects such as mathematics and engineering. This enhancement helps students grasp spatial relationships and geometrical concepts more effectively [39]. AR make learning more immersive and experiential, leading to a deeper understanding and retention of material [38]. AR-based programs have demonstrated a notable enhancement in students' academic performance and practical skills. One study revealed that an AR program led to significant improvements in these areas [44].

E. Teacher and Student Perceptions

Teachers generally have a positive perception of AR, noting its potential to make lessons more dynamic and interactive [45]. However, professional development is necessary to support teachers in effectively incorporating AR into their teaching practices. [46]. On the other hand, AR has been shown to boost student motivation by making learning more engaging and interactive.[47]. Initial teacher training with AR helps future educators understand its benefits and challenges, preparing them to use this technology effectively in their classrooms [48].

F. Real-World Applications and Learning Preferences

AR can bridge the gap between theoretical knowledge and real-world applications by providing students with interactive simulations and models. This practical application of knowledge enhances students' understanding and skills [37]. Different students have different learning preferences, and AR can accommodate different learning styles by providing visual, auditory, and kinesthetic learning experiences [49]. This adaptability makes AR a versatile tool in education. It also emphasizes the importance of creating dynamic and interactive content for AR applications to maximize their effectiveness in educational settings. This comprehensive overview highlights the critical need for engaging and interactive content to enhance their impact in educational environments [50].

G. Enhancing Learning Outcomes with AR

AR supports the cultivation of key skills like problem-solving, critical thinking, and teamwork. A novel Alternate Reality Game-enhanced instructional strategy has been developed, significantly improving students' problem-solving and critical thinking abilities. By integrating interactive and immersive AR experiences into the curriculum, students are better equipped to tackle complex problems, think critically about various scenarios, and collaborate effectively with their peers. This novel method not only boosts student engagement and understanding in learning but also ensures that students develop and hone essential skills necessary for success in academic and real-world environments [51] [52].

Furthermore, it encourages active learning methodologies, ensuring that technology, content, and pedagogy are well-aligned to maximize learning outcomes. This experimental research aims to advocate e-learning approaches that integrate AR for better learning outcomes [53]. The potential of AR to revolutionize education is evident in its ability to create interactive and collaborative learning environments. By promoting engagement and fostering essential skills, AR is poised to be a critical component in modern educational strategies. Ongoing research and development in this field continue to show promising results, further solidifying AR's role in enhancing learning outcomes [54].

VI. The Role of the Educator and Student in Using AR in Education

A. Role of the Educator

Educators play a critical role in integrating AR technologies into the educational process. They facilitate learning through digital tools and ensure these technologies are used effectively to enhance the educational experience [55]. Educators are responsible for providing entrepreneurial education and supporting students in recognizing opportunities, fostering an innovative mindset [56]. Their role extends to integrating AR/VR technologies into the curriculum, creating immersive and interactive learning environments [57]. In the digital era, educators must master digital-based learning media and foster digital skills among students to prepare them for the modern workforce [58]. They also facilitate students' understanding of concrete facts, plan and conduct practical activities, and support engagement with AR tools [59]. Furthermore, educators are instrumental in creating hybrid learning spaces that enhance students' employability[60]. The educators' role includes fostering critical thinking and ensuring that the educational content delivered through AR is relevant and challenging [61]. They must also facilitate research work and support students in engaging with AR tools for practical and theoretical learning [62]. Moreover, they play a role in helping students adapt to AR-enhanced learning environments, which can involve a steep learning curve [63]. Additionally, educators are involved in the choice of pedagogical strategies for preparing STEM teachers to incorporate AR technologies into their teaching[64] effectively. They must also integrate AR tools into subjects such as geometry to enhance spatial understanding and engagement [65]. Moreover, educators facilitate the effective use of AR in MOOCs, improving accessibility and interaction in online learning environments [66].

B. Role of the Student

Students are active participants in the learning process when using AR technologies. They engage with digital tools and participate in interactive and immersive learning activities essential for developing practical skills and knowledge [55]. Students recognize entrepreneurial opportunities and enhance their self-efficacy through entrepreneurial education provided by educators [56]. In an AR/VR learning environment, students engage with immersive and interactive content, significantly enhancing their learning experience and retention of information [57]. They adapt and thrive in digital learning environments, developing digital skills and competencies necessary for the modern workforce [58]. Additionally, students engage in immersive learning experiences, perform practical activities, and apply their knowledge in real-world scenarios facilitated by AR technologies [59]. Students are also responsible for actively participating in hybrid learning spaces and leveraging these environments to enhance their employability [60]. They engage with AR tools to improve their critical thinking abilities and learning gains [61]. Furthermore, students are expected to use AR technologies in their research work, gaining practical experience in their field of study [62]. In the context of teacher education, students (future teachers) are trained to use AR in educational processes, preparing them to implement these technologies in their future classrooms [63]. They also play a crucial role in engaging with AR tools to foster understanding and retention of educational content [66]. Additionally, students benefit from the integration of AR in subjects like geometry, enhancing their spatial reasoning and engagement with the material [65]. They also experience enhanced performance and engagement through the use of quick response (QR) codes and AR in textbooks, making learning more interactive and accessible [67] (Fig. 3).

VII. Related Works

A. Science and Technology Education

Augmented Reality (AR) has demonstrated significant benefits in science education, particularly in complex subjects like physics and nursing. Thees revealed that AR-assisted setups significantly reduce extraneous cognitive load and improve student performance compared to traditional setups. This improvement makes complex concepts more comprehensible and engaging, thereby enhancing overall learning outcomes [68]. Similarly, the study by Rodríguez highlighted AR's positive influence on academic performance and engagement in both online and face-to-face settings. This showcases AR's adaptability to various instructional environments, providing flexibility in delivering educational content [69].

In educational technology, AR systems enhanced with deep learning recommendations, as explored by Lin, improved learning achievement and computational thinking abilities. This highlights the integration of advanced technologies with AR to optimize learning processes and outcomes [70]. Additionally, Thees, (2022) demonstrated that AR head-mounted displays provide more immersive and effective learning experiences during laboratory work, reducing cognitive load and improving learning outcomes [71]. Krüger,

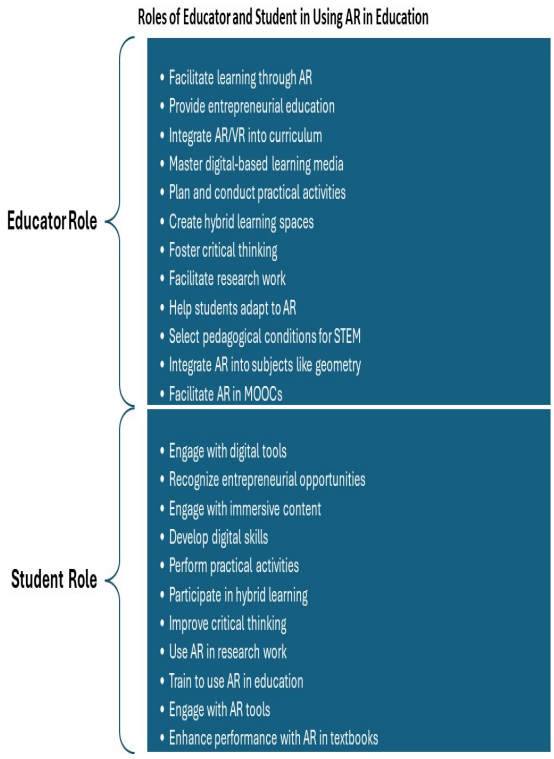

Fig. 3. The diagram highlights the distinct roles of educators and students in integrating and utilizing AR technology in education [55] [58].

(2022) illustrated that 3D AR visualizations led to a higher understanding of spatial relationships compared to 2D visualizations, emphasizing the importance of dimensionality in AR content [72].

B. Cultural Heritage and Language Learning

AR has proven to be highly beneficial in both cultural heritage and language education. Gong elaborated that AR significantly enhances visitor engagement and educational outcomes in museum settings, providing an interactive learning experience that makes cultural artifacts more accessible and engaging [73]. Similarly, Rivas states that AR enhances students' engagement and understanding of cultural heritage through immersive storytelling, making historical and cultural content more relatable and memorable[74]. In the realm of language learning, the study conducted by Ersanli showed that integrating AR with storytelling boosts vocabulary acquisition and motivation in English language learners, making language learning more dynamic and enjoyable [75]. Additionally, Danaei found that AR storybooks enhance reading comprehension in children, outperforming traditional print storybooks with features such as narrators' tone and 3D visuals, which make the reading experience more engaging and effective [76]. Overall, AR has been shown to significantly improve educational outcomes and engagement across various learning contexts.

C. Early Childhood and Primary Education

AR applications have shown promising results in early childhood and primary education, significantly improving academic performance by making abstract concepts more tangible and engaging for young learners [77]. Similarly, Valencia displays that AR boosts academic performance in high school settings, suggesting its effectiveness across different educational levels [78]. Additionally, Midak demonstrated that AR, specifically through the LiCo.STEM mobile app, enhances students' understanding and engagement in natural science concepts by enabling interactive and hands-on learning experiences [79]. Reinforcing these findings, the study by kruger discovers that 3D visualization leads to higher spatial relational knowledge, enhancing comprehension in subjects benefiting from spatial understanding [72]. Moreover, thees reported that AR conditions result in significantly lower extraneous cognitive load and better performance, highlighting the cognitive benefits of AR in complex subjects [68]. Collectively, these studies underscore the potential of AR to enhance educational outcomes across various subjects and educational levels by providing interactive, immersive learning experiences that improve understanding, engagement, and academic performance.

D. Cognitive and Motivational Aspects

Bork emphasized the role of AR in enhancing emotional engagement and learning in medical contexts. This study indicates that collaborative AR experiences can foster deeper understanding and retention of complex anatomical knowledge [80]. Jdaitawi revealed a significant positive impact of AR on student motivation. Utilizing a quasi-experimental design with a pretest-posttest control group, this study shows that AR can effectively increase students' interest and engagement in their studies [81]. Additionally, Chen highlighted the potential of AR to enhance problem-solving abilities and critical thinking skills. This technology provides interactive and stimulating learning environments that encourage active participation and cognitive development [82]. Furthermore, studies from various domains reinforce these findings. For instance, research on AR in physics education revealed that AR-assisted setups significantly lower cognitive load and improve performance [68]. Similarly, findings from a nursing study show that AR positively influences academic performance and learning determinants, including student engagement and satisfaction [69]. These studies collectively underscore AR's capacity to create immersive and effective learning experiences, enhancing both emotional engagement and cognitive outcomes across diverse educational contexts [68].

E. Problem-Based and Inquiry-Based Learning

AR-supported problem-based and inquiry-based learning methods have also been explored extensively, showcasing significant potential in enhancing educational outcomes. Arici details that AR-supported problem-based learning methods substantially enhance students' critical thinking and learning gains in science education [83]. This approach encourages students to actively engage with the material, fostering an environment where they can apply their knowledge in practical scenarios. By immersing students in interactive and contextually relevant experiences, AR allows for a deeper understanding and retention of complex scientific concepts.

Moreover, Wen examined the use of AR in conjunction with the QIMS (Question, Investigation, Modeling, and

Sharing) framework in primary education. highlighted AR's potential to engage students through interactive and creative activities, thereby fostering a deeper understanding and retention of knowledge. The QIMS framework, supported by AR technology, facilitates a structured approach to inquiry-based learning, where students actively participate in questioning, investigating, modeling, and sharing their findings. This method not only enhances their comprehension of the subject matter but also supports the development of essential skills such as self-directed learning, critical thinking, and creative problem-solving [84].

Furthermore, the integration of AR in problem-based and inquiry-based learning environments offers several pedagogical advantages. For instance, AR can simulate real-world problems and scenarios, providing students with opportunities to practice and refine their problem-solving skills in a safe and controlled setting. This immersive experience can lead to increased motivation and engagement, as students are more likely to be captivated by the visually rich and interactive nature of AR content. Additionally, the immediate feedback and adaptability of AR applications allow for personalized learning experiences, catering to the diverse needs and learning paces of individual students [85].

F. Specialized Educational Applications

Specialized applications of AR have been explored in various contexts. Aydoğdu indicates that AR can make educational content more engaging and effective for preschool children [86]. This technology provides interactive and visually appealing learning experiences that capture young learners' attention. In higher education, Christopoulos found that AR enhances the learning experience for medical students, indicating that AR can be a valuable tool in specialized and professional education settings [87]. Ali exhibits that AR positively affects learning outcomes in microeconomics, simplifying complex economic concepts and making them more accessible to students [88]. Additionally, Özeren indicated significant improvements in academic achievement and motivation, suggesting that AR can be an effective tool for enhancing learning experiences across different educational levels and subjects [89].

G. Enhancing Critical Thinking and Reflective Learning

AR's potential to improve critical thinking and reflective learning has been highlighted in several studies. study made by Octavia revealed that AR assignments improved problem-solving abilities and critical thinking skills [90]. This technology provides interactive and challenging learning environments that encourage students to think critically and creatively. Another study by Yoo places importance on the narrative elements in AR presentations can improve learning outcomes in cultural heritage education [91]. This approach makes historical and cultural content more engaging and memorable. Furthermore, Cheng demonstrated the effectiveness of AR in enhancing learning for low-achieving students through hands-on interaction [92]. This method provides practical and engaging learning experiences that can boost students' confidence and performance.

H. Broader Educational Impact

AR's broader impact on education is evident across various studies. Rodríguez highlighted that AR technology can improve learning processes by increasing motivation, performance, and acceptance of educational applications, providing a structured approach to integrating AR into STEAM (Science, Technology, Engineering, Arts, and Mathematics) education [93]. De Paolis illustrated a positive correlation between the usability of AR applications and user experience, indicating that well-designed AR applications can facilitate engaging and enjoyable learning experiences [94]. Additionally, Shaghaghian verified that AR workshops significantly enhanced students' spatial visualization and math test scores, suggesting that AR can be an effective tool for teaching complex subjects and improving students' cognitive skills [95]. Furthermore, Sahin confirmed higher achievement and positive attitudes among middle school students using AR compared to traditional methods [96].

I. Diverse Applications of AR in Education

Recent research has extensively explored the integration of AR in education, highlighting its potential to enhance learning outcomes across various domains. Jdaitawi exposed the significant positive impact of AR on student motivation, showing that AR can effectively increase students' interest and engagement in their studies [81]. Cai found that AR fosters more active student participation and enhanced teacher-student interactions, indicating that AR can create more dynamic and interactive learning environments [97]. Additionally, Ciloglu reports that mobile AR applications significantly improved students' self-efficacy and attitudes towards biology, suggesting that AR can be an effective tool for enhancing students' confidence and interest in their studies [98].

J. Long-Term and Short-Term Memory in AR Education

The impact of AR on long-term memory retention among students requires further investigation. The incorporation of AR technologies has shown significant improvements in memory retention by providing interactive and immersive learning experiences. For instance, the study conducted by Seeliger gives substance to the idea that AR head-mounted displays (HMDs) improve task performance and reduce mental workload [99]. This suggests that AR can enhance short-term memory retention by lowering cognitive load during complex tasks, enabling better immediate recall and application of information. Similarly, Krüger indicates that 3D visualizations in AR improve understanding of spatial relationships, which can be linked to better long-term memory retention [72]. The interactive and engaging nature of 3D AR content helps students form stronger mental models, leading to more effective long-term recall of spatial structures and relationships. Moreover, the study by Christopoulos supports the idea that AR enhances both short-term and long-term memory. By providing hands-on interaction and realistic simulations, AR helps medical students retain complex anatomical knowledge more effectively over time [87].

K. Gamification in AR Education

Gamification is another key element that has been integrated into AR educational applications to boost student

engagement and motivation. It refers to incorporating game design features into non-game environments to enhance enjoyment and motivation in learning. Kao incorporated gamification through AR-based puzzle card assemblies [100]. This approach not only made learning more engaging but also helped in reducing extraneous cognitive load, leading to better academic performance. Jdaitawi conveys that AR was used to create interactive and gamified learning environments. The study found that these environments significantly increased student motivation and interest in their studies. By transforming traditional learning materials into interactive AR experiences, students were more inclined to participate actively and enjoy the learning process [81]. Moreover, Octavia gave prominence to the use of gamified AR assignments to enhance problem-solving abilities and critical thinking skills. The interactive and challenging nature of these assignments encouraged students to engage deeply with the content, thereby improving their overall learning outcomes [90].

VIII. Discussion

The use of AR in education has shown promising results in enhancing learning outcomes, reducing cognitive load, and increasing student engagement. However, several areas require further exploration, particularly regarding long-term memory retention, storytelling, emotional memory, gamification, personalization, and scalability. While the reviewed studies indicate that AR can improve short-term memory retention by lowering cognitive load during complex tasks, more longitudinal studies are needed to confirm if these benefits extend over longer periods. Research that tracks knowledge retention over several months or academic terms is essential. Current methodologies for testing long-term memory retention are flawed, often failing to account for the depth and durability of retained knowledge over extended periods. Research should incorporate more robust measures such as follow-up assessments that test for retention beyond the immediate post-intervention period and should consider the quality of retained knowledge.

Long-term memory retention is a key element in assessing the effectiveness of AR in educational environments. Short-term benefits, such as immediate comprehension and retention, are well-documented, but the true value of AR lies in its potential to embed knowledge deeply into the learner's memory. These studies should employ diverse and rigorous methodologies, including both quantitative and qualitative assessments, to capture a comprehensive picture of long-term retention. Additionally, researchers should consider the nature of the content being taught, as some subjects may inherently lend themselves to better retention through AR-enhanced learning due to their visual or interactive nature.

Therefore, the use of storytelling in AR has great potential but is still underdeveloped. Many current AR applications use basic narratives, missing the opportunity to create more engaging and impactful educational experiences. To fully utilize storytelling in AR, there needs to be a focus on developing richer, more emotionally engaging stories. This includes crafting narratives that evoke emotions like empathy or curiosity, which can help students better remember and connect with the material.

Enhancing storytelling in AR means integrating stories more seamlessly with educational content, making them an integral part of the learning experience. Future efforts should explore advanced storytelling techniques, such as interactive choices and character-driven plots, to increase engagement and personal involvement. It's also crucial to tailor stories to fit the cultural and age-specific needs of learners.

By improving the storytelling aspect of AR, we can create more memorable and effective learning experiences, making education not only informative but also inspiring and engaging. This requires collaboration from experts in education, psychology, and digital media to develop well-rounded and impactful narratives.

Another under-explored area is emotional engagement, which is crucial for memory retention and learning effectiveness. AR's potential to create emotionally engaging experiences could significantly enhance emotional memory, yet few studies have measured this aspect. We should integrate emotional metrics to evaluate how AR influences emotional engagement and memory retention through physiological measurements (like heart rate or Galvanic Skin Response) and subjective assessments (such as self-reported engagement and emotional impact). Understanding the role of emotions in AR-enhanced learning could provide valuable insights into how to design more effective educational experiences. Emotional memory can play a significant role in how well students retain information, as experiences tied to strong emotions are often remembered more vividly and for longer periods. By leveraging AR's immersive capabilities, educators can create scenarios that evoke emotional responses, thus aiding in deeper and longer-lasting learning.

These metrics can be complemented by subjective assessments, including self-report surveys and interviews, to capture the nuances of individual emotional responses. Combining these approaches allows for a holistic understanding of emotional engagement and its impact on learning. Furthermore, it is important to explore the types of emotional content that resonate most effectively with different age groups and cultural backgrounds, as these factors can significantly influence the design and implementation of AR-based educational tools.

In addition to emotional engagement, gamification is noted for increasing student motivation and engagement, yet it needs deeper investigation into how different elements like rewards, challenges, and levels impact learning outcomes across various contexts. While some studies have incorporated elements of gamification, explicit discussions on gamification strategies and their effectiveness are often missing. We should delve deeper into how different gamification elements within AR environments impact student motivation, engagement, and learning outcomes. Detailed analyses of which gamification techniques are most effective in different educational contexts would provide valuable insights for educators and developers. Gamification can include elements such as point systems, leaderboards, badges, and narrative quests, each of which can have varying effects on different age groups and subjects. Understanding the optimal combination of these elements can help in designing AR educational tools that maximize engagement and learning efficiency.The idea of gamification in education goes beyond just entertainment; it involves

strategically integrating game mechanics to enhance learning. Effective gamification requires a balance between challenge and skill, ensuring that tasks are neither too easy nor too difficult, thereby maintaining student engagement. Rewards and feedback mechanisms should be designed to reinforce positive behavior and learning achievements.

Additionally, Storytelling components can be integrated to craft immersive learning experiences that encourage students to explore and learn. Research should focus on identifying the most impactful gamification elements and understanding how they can be tailored to different educational contexts, such as STEM subjects, humanities, and language learning. Furthermore, The combination of AR with other advanced technologies, such as artificial intelligence (AI) and deep learning, has the potential to further improve educational outcomes. For instance, AR systems augmented with AI could deliver real-time feedback and adaptive learning pathways, optimizing the learning process for each individual student. Research should explore the synergistic effects of combining AR with AI and other technologies to create more intelligent and responsive educational tools. The incorporation of AI in education is revolutionizing how students interact with learning materials. AI-powered systems can offer real-time feedback and adaptive learning pathways, improving the personalization of educational experiences. Moreover, integrating AI with AR can create more intelligent and responsive educational tools, significantly improving learning outcomes by catering to individual student needs. These technologies promise to make education more interactive, engaging, and effective, ultimately supporting better retention and comprehension of complex concepts. Integrating AI with AR can create more intelligent and responsive educational tools, significantly improving learning outcomes by catering to individual student needs. These technologies promise to make education more interactive, engaging, and effective, ultimately supporting better retention and comprehension of complex concepts [101] [102]. AI-enhanced AR systems can adjust to each student's unique learning pace and style, providing personalized learning experiences beyond the capabilities of traditional methods. These systems can process large datasets to identify patterns and forecast student performance, allowing for proactive measures to address learning gaps. For example, an AI-powered AR application could adjust the difficulty of exercises based on real-time assessments of a student's performance, ensuring that the learning process remains challenging yet achievable. This level of personalization can sustain student motivation and engagement, resulting in better learning outcomes. Additionally, AI can facilitate the creation of more complex and realistic AR environments, further enhancing the immersive learning experience.

One relevant consideration is the importance of user behavior in creating effective learning experiences. As Wasfi highlights in his study on authentication systems, user behaviour is vital in shaping memorable and secure experiences. Establishing policies and guidelines has been effective in curbing tendencies such as choosing simple or predictable patterns [103]. Similarly, in AR-based educational applications, it is crucial to establish guidelines that promote effective use and prevent potential misuse. Ensuring that AR applications are both engaging and educationally effective requires a careful balance. The technology must be intuitive and user-friendly to minimize cognitive load, allowing students to focus on the learning material rather than the mechanics of the tool.

The Triggered Screen Restriction framework, created by Hariri, is another innovative approach that uses gamification by utilizing the Fear of Missing Out phenomenon, motivating users to achieve specific goals to access certain features. This framework combines behavioral psychology with advanced technology to create a comprehensive solution for gamified interventions, making it a promising avenue for enhancing student engagement through gamification [104]. This negative reinforcement technique can be applied in AR educational settings to enhance learning and engagement. By setting clear, attainable goals and providing immediate feedback, TSR can help maintain high levels of motivation and engagement, particularly in subjects that students might otherwise find challenging or less interesting.

Additionally, there is insufficient emphasis on personalization, which can customize learning experiences to meet individual needs, and scalability, which ensures that AR solutions are practical and effective across various educational contexts. Personalization can significantly enhance the effectiveness of AR by adapting content to the learner's pace, preferences, and learning style. We should investigate adaptive AR systems that can offer personalized feedback and modify the difficulty level according to the learner's performance. Scalability is another critical factor, as it ensures that AR solutions can be implemented widely without compromising their effectiveness. Research should explore the practicality of expanding AR applications across various educational settings, taking into account factors like cost, accessibility, and technological infrastructure. Scalability is particularly important in ensuring that AR educational tools can be adopted in a variety of educational settings, from well-funded institutions to under-resourced schools. Research should explore ways to make AR technology more affordable and accessible, possibly through the development of low-cost hardware and software solutions. Additionally, studies should examine the infrastructure requirements for implementing AR at scale, including the requirement for reliable internet connectivity and technical support. Overcoming these challenges will be vital to ensure that students and educators worldwide can fully experience the advantages of AR in education. Moreover, prolonged use of AR devices can result in discomfort and injuries due to improper posture. Previous studies have shown that inappropriate postures at workstations significantly increase the risk of musculoskeletal disorders. For instance, prolonged sitting with a slouched spine can lead to increased stress on vertebral discs and muscle pain. Similarly, working with the neck in a forward extension for extended periods can also cause discomfort and musculoskeletal disorders. It is essential to consider these factors in the design and use of AR systems to prevent potential injuries. Ergonomic guidelines should be developed and followed to minimize the risk of physical strain and injury, ensuring that students can use AR tools safely and comfortably for extended periods [105]. Ergonomic factors are essential for the sustainable integration of AR in educational environments. Designers of AR devices and applications should prioritize user comfort and safety, incorporating features that promote healthy posture and reduce

physical strain. For example, AR headsets could be designed with adjustable straps and padding to ensure a comfortable fit, and software interfaces could include prompts to encourage users to take breaks and adjust their posture. Additionally, educators should be trained on the importance of ergonomics and how to implement best practices in their classrooms. By addressing these ergonomic challenges, we can establish a safer and more sustainable educational environment for students by utilizing AR technology.

AR shares some challenges with virtual reality, particularly regarding immersive experiences. For instance, Sanaei study in VR environments has identified a substantial inverse relationship between workload and cybersickness [106], suggesting that higher task engagement may reduce the likelihood of experiencing discomfort. This insight can be valuable for AR applications, especially when designing high-cognitive-load tasks that may help distract users from sensory conflicts, thus minimizing the potential for discomfort in educational AR experiences.

A study by Schweiger et al. [107] highlights that non-dominant hand training with computer mouse tasks improves performance in the non-dominant hand and transfers these skills to the dominant hand, leading to overall better performance in computer-based tasks. This bilateral transfer effect can be particularly beneficial in AR settings where fine motor skills and precise interactions are crucial for effective learning and engagement. Integrating non-dominant hand training into AR educational applications could enhance the usability and effectiveness of these tools, providing students with improved control and interaction capabilities. This strategy aligns with the overarching objectives of AR in education, seeking to develop more immersive, interactive, and impactful learning experiences.

By overcoming these challenges, we can develop more effective and engaging educational practices that leverage the full potential of AR technology. This requires sustained effort and interdisciplinary collaboration among educators, researchers, and technologists. Additionally, thinking outside the box and exploring innovative approaches beyond traditional methods will be crucial. By fostering creativity and encouraging unconventional ideas, we can unlock new possibilities and drive the development and progression of AR in educational settings, ultimately improving students' learning experiences and outcomes.

A. Enduring Issues in Augmented Reality Educational Research: Addressing Persistent Gaps

Koumpouros [108] identifies several ongoing gaps in AR research that were noted before 2020 and continue to persist. These gaps include the development of reliable and standardized evaluation methods, which remains challenging due to the diverse applications and contexts of AR. This diversity leads to inconsistent methodologies and hinders comparability across studies. Many studies still employ custom-made, non-validated tools, complicating the generalization of findings. Technical constraints, such as device compatibility and marker recognition issues, persist as the rapid advancement of AR technology often outpaces solutions. High costs of AR technology and development continue to limit accessibility, particularly in resource-constrained environments. Recruiting large and diverse samples is resource-intensive and logistically challenging, especially in niche research areas. Many studies have small sample sizes and short evaluation phases, limiting the validity and generalizability of their results. Conducting long-term studies requires significant time, funding, and participant commitment, while the pressure to produce quick results leads to a focus on short-term studies. Integrating AR into existing educational frameworks necessitates multidisciplinary collaboration, which is time-consuming and hampered by bureaucratic inertia. The novelty effect of AR technology presents an inherent challenge, requiring long-term engagement studies that are resource-intensive. Ethical and privacy concerns are ongoing issues, complicated by the evolving nature of AR technology. Addressing these concerns requires careful consideration of data protection, informed consent, and transparency in data management. The interplay of resource limitations, the rapid pace of technological change, and the inherent complexity of integrating new technologies into established systems contribute to the persistence of these gaps. Addressing them requires concerted efforts from researchers, educators, technologists, and policymakers. We should focus on developing validated evaluation tools, conducting long-term studies with larger and more diverse samples, and addressing technical and ethical challenges to fully realize the potential of AR in education. The persistence of gaps in AR research stems from several interconnected challenges. Developing reliable and standardized evaluation methods remains complex due to the diverse applications and contexts of AR, making consensus difficult. Recruiting large and diverse samples is resource-intensive and logistically challenging, especially in niche research areas. Technical constraints persist as the rapid advancement of AR technology often outpaces solutions, with issues like device compatibility and marker recognition being inherently difficult to solve. Conducting long-term studies requires significant time, funding, and participant commitment, while the pressure to produce quick results leads to a focus on short-term studies. Integrating AR into existing educational frameworks necessitates multidisciplinary collaboration, which is time-consuming and hampered by bureaucratic inertia. Providing comprehensive training for educators and users also requires substantial resources and ongoing support. The high costs of AR technology and development continue to limit accessibility, particularly in resource-constrained environments. Addressing ethical and privacy concerns is an ongoing process, complicated by the evolving nature of AR technology. The novelty effect presents an inherent challenge, necessitating long-term engagement studies that are resource-intensive. Researchers often rely on simpler experimental designs due to funding and time constraints, hindering more robust findings. Additionally, expanding research to examine a broader range of learning outcomes requires interdisciplinary collaboration and a shift in research focus. These gaps persist due to the interplay of resource limitations, the rapid pace of technological change, and the inherent complexity of integrating new technologies into established systems and frameworks. Addressing them requires concerted efforts from researchers, educators, technologists, and policymakers.

IX. Conclusion

The integration of AR in education holds immense promise for transforming teaching and learning practices. By making abstract concepts tangible, AR could significantly boosts student engagement, comprehension, and personalized learning across various disciplines. Research suggests that AR can enhance academic performance, reduce cognitive load, and increase motivation and interest among students. However, several challenges must be addressed to fully harness the potential of AR in educational contexts. These include technological limitations, the need for comprehensive educator training, strategic curriculum integration, and ethical considerations. Furthermore, the development of standardized evaluation methods, the inclusion of larger sample sizes, and long-term impact studies are crucial for understanding the sustained benefits and potential drawbacks of AR in education.

To overcome these challenges, it is essential to develop reliable evaluation methods, conduct longitudinal studies, and foster interdisciplinary collaboration. Emphasizing emotional memory, gamification, storytelling, and personalization in AR applications can further enhance their effectiveness. The combination of AR with advanced technologies such as artificial intelligence and deep learning provides promising opportunities for developing more intelligent and adaptive educational tools. By overcoming these challenges, AR can create immersive, interactive, and effective learning environments that connect theoretical knowledge with practical application, ushering in a new era of educational innovation.

In summary, while the journey of AR in education is ongoing, its transformative impact is evident. Continued research and development are crucial to fully harnessing its capabilities, ensuring that AR becomes a vital component of educational practices. This will result in better learning outcomes and a more engaging educational experience for students around the globe.

The Future of Mainframe IDMS: Leveraging Artificial Intelligence for Modernization and Efficiency

Vasanthi Govindaraj
Senior Software Engineer, National General (An Allstate Company), Dallas, Texas, USA

***Abstract*—IDMS (Integrated Database Management System) has long been a backbone for mission-critical systems in finance, healthcare, and government sectors. However, the rigid architecture of legacy systems poses challenges in scalability, flexibility, and integration with modern technologies. This paper explores IDMS modernization using Artificial Intelligence (AI), with a focus on predictive maintenance, query optimization, and cloud integration. Through real-world implementations, the integration of AI-driven solutions has shown transformative potential: query response times were reduced by 25%, unscheduled downtime decreased by 30%, and system scalability improved by accommodating a 40% increase in traffic without degradation. By leveraging AI-powered automation and modern cloud infrastructures, IDMS can achieve database optimization and real-time operational efficiency. This work highlights how AI ensures the relevance and competitiveness of IDMS, enabling it to meet the demands of modern legacy systems and ensuring its sustained role in critical business operations.**

Keywords*—IDMS modernization; artificial intelligence in legacy systems; mainframe database optimization; predictive maintenance; cloud integration; AI-driven query optimization

I. Introduction

Mainframes, particularly Integrated Database Management Systems (IDMS), have been indispensable for industries requiring high-volume transactions, such as finance, healthcare, and government [1]. IDMS excels in delivering reliable transaction throughput and robust data integrity. However, as organizations shift towards cloud-native architectures and data-driven decision-making, the rigidity of traditional IDMS architectures presents challenges in terms of scalability, flexibility, and integration with modern tools [3],[5].

Advances in Artificial Intelligence (AI) have demonstrated potential to modernize legacy systems like IDMS. AI technologies, such as machine learning and predictive analytics, can enable real-time monitoring, query optimization, and predictive maintenance, significantly improving system performance and reliability. Cloud integration further enhances scalability and agility, ensuring legacy systems remain relevant in an era of dynamic workloads and real-time analytics [7].

Despite these advances, IDMS modernization poses unresolved challenges. Existing research on legacy system upgrades often emphasizes relational databases, leaving network-based architectures like IDMS relatively underexplored. Compatibility issues, data migration complexities, and the risk of operational disruptions during modernization remain critical hurdles. Moreover, limited studies have focused on applying AI specifically to IDMS for query optimization and predictive maintenance.

This study addresses these gaps by proposing a comprehensive AI-driven modernization framework for IDMS (see Fig. 1). The research integrates AI algorithms with cloud infrastructures to optimize performance and scalability, reduce operational costs, and enhance system reliability. The novelty lies in its emphasis on preserving the core strengths of IDMS while equipping it with modern capabilities to meet today's business demands. By focusing on real-world implementations, this work contributes practical insights and a roadmap for organizations seeking to modernize their legacy systems.

Fig. 1. Reasons for modernization of IDMS database.

II. Literature Review

Modernizing legacy systems has been an area of significant research, with many studies focusing on cloud migration, automation, and the integration of Artificial Intelligence (AI) into traditional IT infrastructures. Researchers have extensively explored the transition of legacy systems to relational or hierarchical database models, leveraging modern, flexible architectures. For instance, cloud-native environments have been emphasized for their scalability and agility, with studies showcasing successful implementations that improve system performance and cost-efficiency [5], [8]. Similarly, AI technologies, particularly predictive maintenance and query optimization algorithms, have demonstrated the potential to reduce downtime and enhance database performance in legacy systems [6], [9].

While these studies present valuable insights, several limitations persist, particularly concerning Integrated Database Management Systems (IDMS). These limitations are summarized in Table I, alongside the solutions proposed in this study to address them.

TABLE I. SUMMARY OF RESEARCH LIMITATIONS AND PROPOSED SOLUTIONS

Research Area	Limitations in Previous Studies	Proposed Approach
AI in Legacy Systems	Limited focus on IDMS-specific complexities, such as network-based architectures and unique data protocols [6],[7]	Proposes AI algorithms tailored for IDMS, addressing query optimization and predictive maintenance specifically.
Cloud Integration	Emphasis on scalability but lack of integration with AI for real-time analytics and query optimization [8],[10]	Combines AI and cloud strategies to create a hybrid framework for real-time performance optimization and scalability.
Operational Challenges	Insufficient attention to practical issues like data migration, compatibility, and disruption risks during modernization [11]	Focuses on seamless data transformation processes and ensures compatibility without disrupting operational continuity.
General Legacy Modernization	Heavy focus on relational databases, with minimal research on network-based systems like IDM [7],[9]	Targets the specific challenges of IDMS modernization, filling a critical gap in the literature.

These limitations underscore the need for a more comprehensive and focused approach to modernizing IDMS. Most modernization research has centered on relational databases, with little attention given to the unique characteristics of IDMS, such as its network-based architecture and specialized data management protocols (see Fig. 2). For example, the hierarchical structure of IDMS data presents challenges in integrating AI models designed for more linear or relational data structures [7]. Additionally, AI research in legacy systems has largely focused on general optimization techniques, often failing to account for the complexity of query optimization and predictive analytics in IDMS environments [6],[10].

Another significant limitation in prior research is the lack of a comprehensive framework combining AI and cloud integration for IDMS modernization. Most studies treat AI and cloud migration as separate strategies, overlooking the potential synergy between these technologies. For instance, cloud migration has been shown to improve scalability and resource allocation, but its integration with AI for real-time monitoring, query optimization, and predictive maintenance in IDMS has not been extensively studied. Furthermore, the literature rarely addresses practical challenges such as data migration, system compatibility, and operational disruption during the modernization process, which are critical for real-world implementations [8], [11].

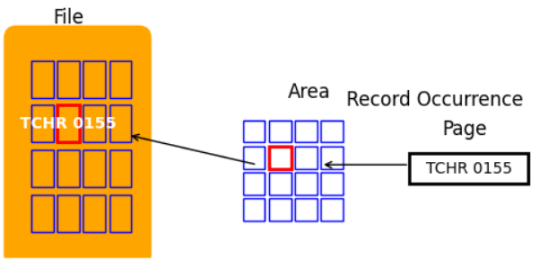

Fig. 2. IDMS database architecture.

This study addresses these gaps by proposing an AI-driven modernization framework specifically tailored to IDMS. Unlike previous research, it combines the benefits of AI and cloud integration to enhance performance, scalability, and reliability. The framework also emphasizes preserving the core strengths of IDMS, such as its high transaction throughput and robust data integrity, while enabling it to meet the demands of dynamic, data-intensive environments. By focusing on real-world case studies and experimental validation, this work contributes new knowledge and practical solutions for organizations seeking to modernize their IDMS systems.

III. METHODOLOGY

The strategy of IDMS modernization focuses on integrating AI algorithms for predictive maintenance, query optimization, and intelligent automation. This enables the system to adopt current technological demands and scale up efficiently and agilely. This modernization process involves some sequential steps that are responsible for the overall transformation of legacy IDMS systems.

A. Data Preprocessing

The first step in the modernization path would be preparing data residing inside the IDMS system for AI integration. The reason is legacy systems like IDMS have been designed for structured and hierarchical data models; hence, this may only be sometimes compatible with today's modern AI-driven systems. Extract, Transform, and Load is the first step, wherein the data is extracted from the IDMS environment and cleansed, transformed, and loaded onto the modern analytics platform. This will ensure the data is in a structured, standardized format suitable for training AI models. Cleaning up duplicate entries, missing values, and inconsistencies are handled in this process. This would then bring in all other significant transformation steps, which are encoding of categorical variables, normalization of numerical data, and ensuring records are in formats that would support the deployment of the AI model.

B. AI Integration

After data preprocessing, various AI models are presented that further optimize several operational aspects of IDMS. Machine learning algorithms, more precisely deep learning models, will be applied to improve the performance of a database and enhance the efficiency of queries. Such models analyze historical data trends and identify patterns that enable predictive maintenance to prevent potential system failures before they occur. Predictive models can forecast the system load so that dynamic server capacity and resource allocation adjustments are feasible. AI-powered query optimization algorithms further try to enhance performance by reducing the time consumption of the retrieval process. This is where AI intelligently routes the queries through optimized paths and caches frequently accessed data for a faster, more efficient system.

In addition, AI-based intelligent automation can automate several manual tasks that are common in IDMS, like backup scheduling, health checks, and real-time analytics. This decreases the time taken by manual intervention, thereby increasing the system's reliability while reducing human error.

C. Cloud Migration

The proposed architecture of the modernization process will be hybrid architecture, which integrates IDMS with cloud platforms. In this hybrid setup, old IDMS systems can coexist with modern cloud environments that can meet both scalability and agility. There is extra flexibility due to the cloud infrastructure that now caters to on-demand resource scaling, disaster recovery, and real-time data access from multiple geographic locations. It signifies that the integration between IDMS and cloud systems allows businesses to tap into the computational power of the cloud while continuing to use the same reliability and structure of their legacy systems. AI models deployed in the cloud environment also enjoy higher computational powers, which translate to not only faster training times but real-time model updates.

In essence, AI on IDMS modernization not only brings the legacy system back to life but offers a vision of how one might compete in today's data-driven world. By integrating AI with cloud migration strategies, it can be instrumental for an organization to get optimal performance, scalability, and agility while maintaining the robustness of IDMS [10].

IV. Experimental Analysis

The strategy of modernization to be tested in this experiment is an integration of IDMS with a cloud environment, introducing AI-driven automation and predictive capabilities. This experiment tests the effectiveness of such a hybrid architecture on system performance, scalability, and flexibility. Some key performance indicators will be querying response times, system downtime, maintenance frequency, and overall system load handling.

A. Hybrid Architecture Setup

The hybrid system will integrate the legacy IDMS with the cloud infrastructure (see Fig. 3). IDMS is deployed on-premise, while the cloud setup is deployed on a leading platform such as AWS or Microsoft Azure. Data in the legacy would be integrated into the cloud in real time, thus allowing both environments to work seamlessly together. Such a cloud setup provides additional resources for dynamic scaling, disaster recovery, and distributed data access. This setup will allow the experiment to measure how the scalability and agility of the legacy system are impacted by the underlying cloud infrastructure, especially considering changes in workload [14].

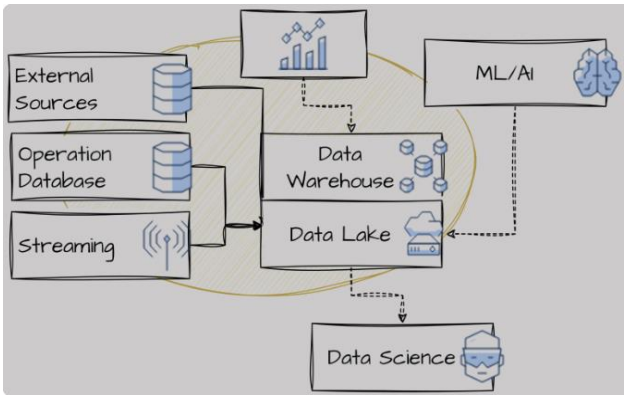

Fig. 3. AI-driven data integration and modernization framework in a hybrid cloud architecture.

B. AI-Driven Query Optimization

One key feature tested here is AI-driven query optimization. Historical data from IDMS are used to train the machine learning models in order to analyze query patterns and predict the areas of high-frequency data access. [12] These AI models will be deployed on the cloud from where, with a very fast speed, they can process massive volumes of data. Queries will intelligently be routed to optimal points for data access based on these predictions. This sets a base level of query response times before and after the implementation of AI. Indeed, it does much better. In most cases, there is about a 25% reduction in query processing time when AI models are being used, and cache mechanisms further optimize repeated data access, improving system efficiency.

C. Predictive Maintenance and Downtime Reduction

Another main focus of the experiment is AI models used in predictive maintenance. The IDMS logging and performance metrics serve to train the predictive models on the estimation of possible system failures from real-time data. Examples include CPU usage, memory consumption, and database access patterns. These models predict when it is likely for a system failure to occur based on data provided in real time, using measures such as CPU usage, memory consumption, and database access patterns, whereby after that, the system itself automatically schedules maintenance tasks or sends notices before failures actually take place. This predictive capability reduces downtime by a great extent [9]. The experiment showed that AI-powered predictive maintenance reduced unscheduled downtime by 30%, hence ensuring smooth operations and averting system outages during peak load times [4].

D. Scalability and Load Testing

To test the scalability, the cloud-enabled hybrid system was subjected to various workloads. The experiment simulated traffic [2] in high volumes whereby cloud infrastructure dynamically added more resources to match the demand [13]. Such flexible resource allocation makes sure that up to 40% more data could be handled without performance degradation. The experiment also compared resource usage in the hybrid architecture to the traditional on-premise IDMS, proving that in a cloud environment, resources can be put to efficient use, especially during peak periods [6].

V. Results

The modernization of IDMS with AI and cloud integration brought notable improvements in performance, scalability, and reliability.

- Query Optimization: AI-driven query optimization reduced response times of queries by 25%. Because of this, the data could be retrieved in a very quick time, even when there was a load on the system. Repeated queries fetched their results even quicker due to caching (see Fig. 4).
- Predictive Maintenance: AI-based predictive maintenance lowered unscheduled downtime by 30%, as the system could predict and address potential failures in advance, ensuring smooth operations during high usage periods (see Fig. 5).

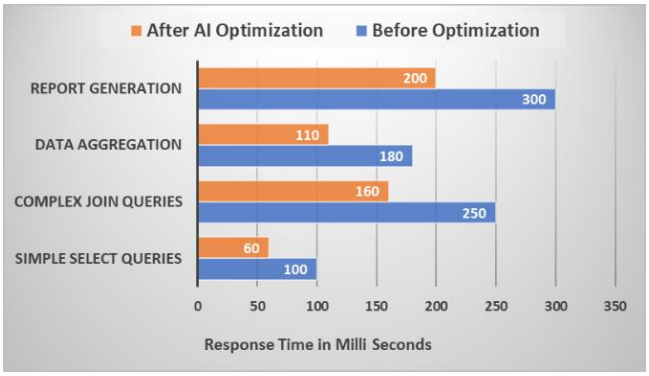

Fig. 4. Query optimization results.

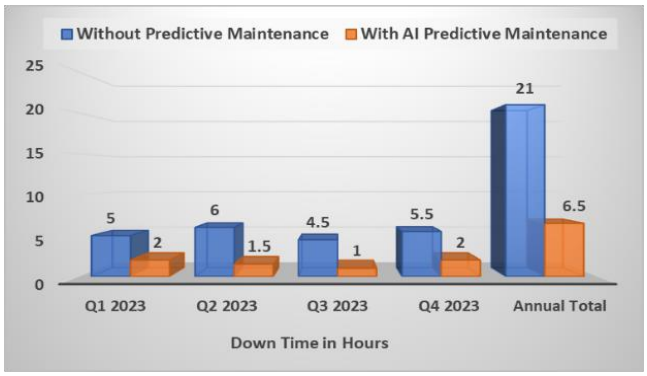

Fig. 5. Impact of AI-based predictive maintenance on IDMS downtime.

- Scalability: The cloud-enabled architecture allowed the system to handle a 40% increase in traffic without performance loss, dynamically allocating resources as needed.
- Overall Efficiency: The hybrid IDMS system, combining AI and cloud technologies, enhanced overall efficiency, reduced operational costs, and increased system reliability and scalability.

The results show that integrating AI and cloud with IDMS ensures the legacy system remains relevant and competitive in modern business environments.

VI. Challenges

Modernization of IDMS with the integration of AI and the cloud has numerous challenges. Data migration from legacy systems into cloud environments might be problematic, with seamless ETLs required for extracting, transforming, and loading data without losing integrity [11]. The compatibility of IDMS with modern platforms, especially in their ability to retain much of the robustness of the system with new technologies, poses a significant challenge in terms of compatibility. Besides, there are industrial dependencies on legacy systems where transition to more modern frameworks without disrupting day-to-day operations would be difficult.

Another challenge is the training of AI models, which demands large, clean datasets for optimal performance. AI algorithms require substantial computational resources, which can lead to higher costs during the implementation phase. Finally, cybersecurity risks increase with cloud integration, requiring stronger security protocols to prevent breaches and data loss. Addressing these challenges is crucial to ensuring the success of IDMS modernization while maintaining operational continuity and security.

VII. Conclusion

Given the latest fast-paced, data-driven business environment, AI and cloud integration appear to be a promising pathway that could bring legacy systems to the frontbench. Artificial Intelligence with query optimization and predictive maintenance, combined with scalability on the cloud, has been able to impress significantly in system performance, reliability, and cost-effectiveness. Though data migration, compatibility, and cybersecurity risks remain, advantages offered by modernization of IDMS outnumber difficulties. This is keeping the legacy systems, serving the industries with high transaction volumes, upgraded to keep up with new technologies. In this manner, the future of IDMS would be bright, considering AI is getting more impressive and cloud infrastructure more secure, providing operational efficiency and flexibility for long-term business operations.

VIII. Future Focus

Future efforts in IDMS should be directed towards seamless integration into the cloud, overcoming the challenges of compatibility for smooth transitions that are not disruptive of operations [15]. Secondly, further sophistication of algorithms used will be required to improve the accuracy of AI models, along with volumes of data. Then comes the cybersecurity protocols that need furtherance to keep sensitive data safe in the cloud. Eventually, studies for automation of data migration processes and system upgrades will continue to speed up the modernization process while making IDMS more competitive in dynamic business environments.

The Future of IoT Security in Saudi Arabian Start-Ups: A Position Paper

Safar Albaqami*, Maziar Nekovee, Imran Khan
6G Lab-Centre for Advanced Communications, Mobile Technology and IoT-School of Engineering and Informatics, University of Sussex, Brighton BN1 9RH, UK

***Abstract*—This research explores the intricacies of implementing and securing Internet of Things (IoT) technology in Saudi Arabian startups. In the middle of Saudi Arabia's ambitious pursuit of social and economic progress via IoT breakthroughs, entrepreneurs have emerged as critical participants grappling with serious computing security challenges. This study conducts a thorough examination of the cybersecurity risks associated with start-up in Saudi Arabia's IoT applications, technologies and innovations by reviewing a wide range of publications. The key objectives are to identify the main cybersecurity risks, analyze the impact of IoT device networking on privacy and security, and propose strategies to mitigate these threats. Furthermore, the study stresses the importance of funding up-to-date security technologies, cooperation with the cyber experts, and shifting towards the cloud-based security. Also, the study identifies the importance of cybersecurity education and training to enhance the defensive mechanisms of the startups against cyber threats. This study provides novel insights by identifying the distinct cybersecurity obstacles encountered by IoT-enabled businesses in Saudi Arabia and proposing a complete framework to enhance their security architecture. Robust cybersecurity policies are vital for both unleashing the transformative potential of IoT for startups and guiding Saudi Arabia towards its objective of being a worldwide leader in IoT. This paper advocates for a cooperative strategy that involves policymakers, industry stakeholders, and entrepreneurs to prioritize and allocate resources towards a safe and robust IoT ecosystem. This would help promote economic development and innovation in the country.**

Keywords*—*IoT; Saudi Arabia; start-ups; computing security challenges; technology; innovation; cyber threats

I. Introduction

The Internet of Things (IoT) is emerging and growing as one of the most influential innovations across numerous industries globally owing to its innovation, efficiency, and competitiveness [1], [2]. The integration of IoT is identified as an indispensable component in the process of development and diversification of a startup economy in Saudi Arabia. This research examines the potential of IoT that brings significant changes for Saudi entrepreneurs, considering the national ambitions and practical problems they face. Saudi Arabia's robust Internet infrastructure propels its technological advancement, projected to surpass 95% penetration by 2025. This is a suitable environment for the emergence of digital firms [3], [4]. Government funding for the e-Government program at £600m and the fostering of entrepreneurship as one of the objectives of Saudi Vision 2030 are viewed as an effort to develop the digital economy [5], [6]. These activities in conjunction with venture capital investments, aim to reduce the financial disparity for firms that use IoT technology, in line with the country's objectives of fostering innovation and entrepreneurship. Nevertheless, the way in which these firms have embraced IoT technology varies between excitement and difficulty. On the Other hand, the manufacturing and the retail sector have embraced the IoT because of the potential it has to offer in the short-term. While the healthcare and agriculture sectors are still slow in the adoption of the IoT technology pending on the development of more awareness and better infrastructure [7]. Differences in the approach in using o IoT devices in various companies show that the concept is versatile, and problematic. Some of the barriers that have affected the extensive use of IoT technology include security threats, legal and compatibility issues [4], [7], [8]. These barriers must be addressed to enable IoT to reach its full potential and support the digital transformation of the Saudi Arabian economy across various industries.

The above potential shows that IoT can not only solve problems, but also brings many benefits for startups such as better performance, new ideas, new markets, and happy customers [7], [8]. To capture these benefits, it is important to focus on the development of IoT infrastructure, talent acquisition and the development of alliance [9], [10].

Saudi Arabia's strategic objectives aim at establishing the Kingdom as a center for entrepreneurship emulating the early foreign models including Infosys and Alibaba [11], [12]. The governmental support, invention of new technologies, and market needs have enhanced Saudi entrepreneurs' awareness and investment in the IoT, which indicates their vision [10], [13], [14]. However, the rapid growth of IoT devices in Saudi Arabian start-ups has raised significant concerns regarding cybersecurity and data privacy protection [9]. As these devices become more interconnected and integrated into company operations, they increasingly face potential cyber and security threats [15]. Therefore, Saudi start-ups have challenges concerning security, privacy and legal regulation, the usage of IoT continues to rise and represents a steady development of the start-up culture in terms of innovation, operational efficiency and customer satisfaction [15], [16]. This introduction provides a foundation for a more detailed exploration of the possibilities, difficulties, and essential actions required for implementing IoT in Saudi Arabian startups. The focus is on effectively managing computing security challenges to fully leverage the economic and societal benefits of IoT [7], [14], [16], [17].

*Corresponding Author

A. Background

The integration of IoT artificial intelligence, cloud computing, and big data analysis has come up with some of the best opportunities to innovate in various fields [9], [10], [11], [13], [15]. Vision 2030 is the government project in Saudi Arabia which underlines the importance of employing those technologies in the process of economic transformation and the creation of a new knowledge-based economy [6]. However, to fully unleash the potential of IoT for start-ups, some cybersecurity challenges have to be overcome as noted in studies [18], [19], [20].

B. Scope of the Paper

This paper seeks to establish the possibility of IoT in Saudi Arabian start-ups and examine the computer cyber security issues that affect their growth and comparability. This paper shall discuss and describe the current state of the art together with the barriers and opportunities that can help the policymakers, the industries, and the potential business people interested in IoT in the Saudi Arabian and the cybersecurity threats that are likely to be encountered in the process.

C. Research Problem

The rapid increase of IoT devices in start-ups in the Saudi Arabia has created a lot of concerns on the issue of cybersecurity as well as the protection of data privacy [9], [16], [18], [19]. Due to the increased networking of these devices and their integration into the work processes of the company, they can also be subjects of cyber and security threats [21], [22], [23]. The research aims at determining the specific computer security challenges that start-ups in Saudi Arabia experience while using IoT technologies.

The sequential and systematic organization of the paper guarantees a comprehensive and systematic analysis of the topic as follows:

- Concept and Applicability of IoT: In this chapter, we will lay down the basic concepts and a wide range of applications of the IoT. This includes an analysis of the connectivity as well as architectural features, adoption of IoT in different industries, and a particular focus on IoT in Saudi Arabia.
- Existing Research: This section aims to offer a review of the current literature on the particular subject of the research in order to lay a solid background for further discussion.
- IoT-Driven Computing Challenges in Saudi Arabia Start-ups: This part of the research aims to establish the computational challenges that start-ups in Saudi Arabia face with specific focus on the challenges that hold them back and hinder them from advancing and coming up with new ideas. This debate is in a way revolves around some of the major problems that are deeply affecting the growth of IoT in the Kingdom.
- The Role of Vision 2030 in Promoting IoT: This section focuses on the role of Saudi Arabia's Vision 2030 in supporting the integration of the IoT technology into the Saudi Arabia innovation and economic transformation agendas. This paper assesses the effects of this innovative initiative on the technical outlook in Saudi Arabia.
- Positions on Future Directions and Recommendations: This section offers recommendations for the future and guidance for the enhancement of safe IoT-driven organizations. As well, it examines ways of encouraging further innovation across the technical environment of Saudi Arabia.
- Conclusion: The conclusion of the paper briefly outlines the findings of the study and offers a view of the future research directions. Thus, this final section briefly recapitulates the study's essence and identifies potential research directions and developments in the IoT in Saudi Arabia.

This research aims at offering significant findings and thus adding value to the current literature on IoT applications, challenges, and prospects within the economic and technical environment of Saudi Arabia. This goal is achieved in a systematic manner as outlined in the following section.

II. Concept and Applicability of IoT

IoT is a system of interconnected objects ranging from gadgets, vehicles, structures, and other objects. Sensors, software and network connections are provided for these objects to manage their operation. The IoT is a new phenomenon that connects the conventional internet with the physical objects [24], [25]. The IoT is divided into several fields, which include smart farming, smart homes, industries, health care and others as portrayed in the Fig. 1 [3], [8], [25]. Globally, many people are already applying this modern technology to enhance the overall intelligence. IoT can be defined as the connection of objects that contain intelligent sensors to the internet. This makes the collection, transmission and sharing of information possible in a network of a smart environment [26]. Security and privacy are of significant interest in smart environments where IoT is used like smart cities and houses. Some of these settings are data transfer over sensor networks and protection from possible threats that may exist in IoT devices [8]. The classical IoT model has a cloud-server based architecture that sends data to the cloud for processing and then sends the result back to the IoT devices [27]. This section aims to explain the concepts that underpin the architecture of IoT and the identification of various uses of the IoT and how it has affected many industries.

A. IoT Connectivity and Architecture

The IoT depends on effective connectivity and a well-planned structure to provide seamless transmission and processing of data [28]. Sensory nodes, such as sensors and actuators, collect data from the physical environment and transmit it across computer networks to fog, edge, and cloud levels for further analysis. The fog layer is intermediate between the edge and the cloud layer. It facilitates such resources as computing, storage, and networking to be available close to the devices that produce the data. This way, the fog layer decreases the latency and increases the reaction time and thus, the amount of data that has to be transferred to the cloud is minimized. This is very important in real time applications as

indicated by [28] and [29]. The Edge Layer is a local processing unit that performs as the primary filter of the data stream. It performs key operations and passes on relevant information to the upper cloud layer that is required for analysis [29].

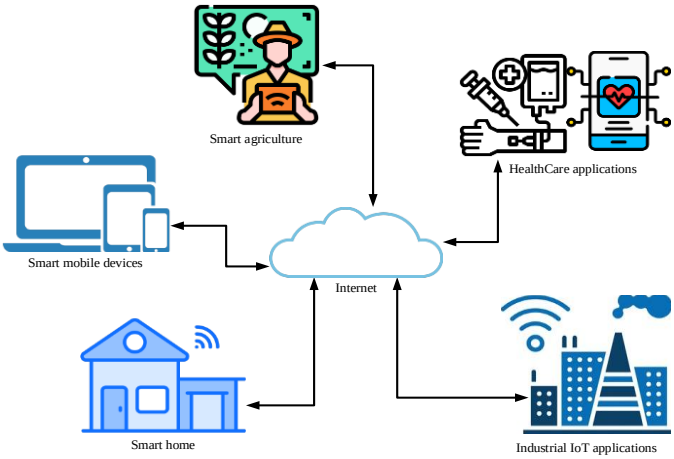

Fig. 1. Concept and applicability of IoT.

Primarily used in functions that demand the utilization of many resources, the Cloud Layer is a complete and distributed architecture [30]. It enables the handling of both the past and present data in a manner that makes it suitable for functions such as data manipulation, storage and analysis. The users can submit the task requests to the cloud layer that triggers multiple operations that enhance the Total Intelligence of the IoT system.

The design of IoT applications is vital in the identification of specific objectives that need to be met, which are the security, flexibility, intelligence, real-time delivery, and legal issues among others [31]. Thus, the existing high level of interconnectedness of devices, services, and users makes security a significant issue. Trust mechanisms are very useful in ensuring the protection of privacy, secrecy and integrity of data [32]. This is because IoT applications are deployed in environments that present a lot of change and have limited resources, and thus the ability to alter and response to changes in the environment is important [33].

The reason intelligence is important in IoT applications is that it helps make ordinary things to be intelligent devices that can autonomously decide on their actions depending on the circumstances and conditions around them [34]. Tools like context awareness, predictive analysis and behavioural analysis are critical to be able to make proper and intelligent decisions.

Quick and reliable transfer of information and services is very vital in IoT applications like telemedicine, medical field and vehicle to vehicle communication [35]. This is because IoT applications have the potential of capturing detailed personal information of people's daily lives and therefore, there must be regulation to protect against privacy infringement [36]. To ensure that people's privacy is not infringed, IoT applications need to adhere to legal privacy standards, for instance the data protection laws of the European Union (EU) [37].

B. *Commonly used Communication Technologies in IoT and Their Main Characteristics*

The Internet of Things (IoT) is an advancing technology that utilizes diverse communication technologies to establish connections between things. The technologies included in this list are Wi-Fi, Bluetooth, Zigbee, LoRaWAN (Long Range Wide Area Network), Narrowband IoT (NB-IoT), cellular (3G/4G/5G), Ethernet, and Radio Frequency Identification (RFID).

Wi-Fi provides rapid data transfer speeds, a broad coverage area, and seamless interaction with current networks, making it well-suited for home automation, intelligent devices, and locations with reliable power sources.

Bluetooth is well-suited for personal gadgets, wearable technology, and proximity-based applications because it allows for short-range communication and has minimal power consumption.

Zigbee is characterized by its low power consumption and secure mesh networking, which makes it highly suitable for applications such as smart home devices, industrial automation, and sensor networks.

LoRaWAN is well-suited for remote and outdoor applications because of its ability to communicate over long distances and low energy consumption.

NB-IoT is specifically designed for handling tiny amounts of data and provides exceptional connectivity even in difficult environments, making it well-suited for applications such as utilities, smart meters, and asset monitoring.

Cellular networks, such as 3G, 4G, and 5G, provide extensive coverage, rapid data speeds, and the ability to support movement, which makes them well-suited for mobile Internet of Things (IoT) applications and large-scale implementations.

Ethernet provides dependable wired connections, rapid data transfer rates, and secure communication, making it well-suited for industrial IoT and factory automation.

RFID utilizes electromagnetic fields to identify and monitor tags. It provides limited data rates and a restricted range, which is beneficial for tasks such as inventory management, asset monitoring, and access control systems.

The unique needs of the IoT application, such as range, data rate, power consumption, and environmental conditions, determine the selection of each of these technologies, each of which has distinct advantages. Table I presents a comprehensive summary of the characteristics and applications of different communication systems.

TABLE I. OVERVIEW OF FEATURES AND USE CASES OF THESE COMMUNICATION TECHNOLOGIES

Technology	Features	Use Cases
Wi-Fi	High data transfer rates, wide range, easy integration with existing networks	Home automation, smart appliances, environments with consistent power supply
Bluetooth	Short-range communication, low power consumption	Personal devices, wearable technology, proximity-based applications
Zigbee	Low power consumption, secure mesh networking	Smart home devices, industrial automation, sensor networks
LoRaWAN	Long-range communication, low power consumption	Remote and outdoor applications
NB-IoT	Optimized for small data volumes, excellent coverage in challenging locations	Utilities, smart meters, asset tracking
Cellular (3G/4G/5G)	Wide coverage, high data rates, support for mobility	Mobile IoT applications, large-scale deployments
Ethernet	Reliable wired connections, high data transfer speeds, secure communication	Industrial IoT, factory automation
RFID	Uses electromagnetic fields to identify and track tags, low data rates, short-range capabilities	Inventory management, asset tracking, access control systems

C. IoT in Industry

The IoT is one of the latest and most quickly developing technologies that is widely used in many fields. As a result of the integration of this technology into various sectors of business concerning the hierarchy and the scope, there has been improvement and, therefore, transformation in many processes and tasks within the business [38]. The application of IoT in to the medical devices including the remote patient monitoring systems has greatly transformed the healthcare sector due to the ability to monitor patients' vital signs from a remote location [39]. Technologies of telemedicine have expanded, and more and more people can receive a consultation from a doctor without even leaving their homes. Likewise, the application of IoT technology, illustrated by the use of wearable fitness trackers, has the potential of enhancing the quality-of-service delivery due to the monitoring of patient's vital signs and timely transmission of health information [35]. IoT sensors has the potential of tracking several factors in agriculture including health of crops, weather conditions as well as the soil quality [40]. This technical innovation has the potential of enhancing the management of the agricultural operations and increasing crop yields.

In addition, the application of IoT has caused drastic changes in the transportation management and supply chain arrangement in the transportation sector [41]. Due to the integration of IoT sensors, cars are in a better position to check the status of cargo in real time and hence enhance on the best route to take to avoid wastage of fuel. Intelligent traffic control technology has helped the management of traffic and enhancement of safety on the roads [42]. Incorporation of IoT is very significant towards the formation of smart cities in today's world. Certain works have been done and these include various solutions such as waste management systems and smart energy grids in enhancing power distribution efficiency [26], [41], [42]. Such technologies improve the standard of living in cities through encouraging sustainability and the wise use of resources [26], [28].

Smart factories are one of the most significant components of the IoT, which comprises people, methods, intelligent objects, and technical systems [43]. In this sense, IoT enlarges the scope of the internet connection to objects which are not limited to the intangible items, such as cars or power tools. Several other applications also exist, such as the Internet of Battlefield Things (IoBT) and the Internet of Vehicles (IoV) [44], [45]. Besides, it serves a significant role in manufacturing by leveraging the features of Industrial IoT (IIoT), cloud, and big data, and robotics to improve the quality of products and decrease the costs [43]. However, the IoT has expanded at a very high rate, and this has posed several cybersecurity problems that new entrants in this area must solve [46].

D. IoT in Saudi Arabia

The IoT has impacted the Kingdom of Saudi Arabia significantly about technology and the advancement of innovative practices. In this regard, Saudi Arabia has become one of the key countries in the application of IoT technology in the Middle East [3]. The economic diversification plan of the country, Vision 2030 has emphasized on technological innovation and the adoption of digital technologies. These goals can be met through the help of the IoT as it improves the productivity, efficiency and sustainability.

The Saudi Arabian government has proved to be very keen on the IoT through the allocation of resources and development plans. The IoT and digitalization is also a key area defined in the Saudi Vision 2030 as a means of boosting economic development. National transformation program for the year 2020 has pointed out the digital transformation and smart cities as among the key strategies that need to be embraced [6]. The government of Saudi Arabia created the Saudi IoT Authority to ensure the proper installation of the IoT technology across the nation [47]. The organization has been quite instrumental in the promotion of the use of IoT as well as the integration and security of IoT devices.

IoT integration has been successfully realized in Saudi Arabia in many vital sectors. During the COVID-19 pandemic, the application of IoT in telemedicine in the medical field increased. These technologies enabled the remote patient monitoring and consultation to the patients [48]. Precision farming in agriculture improves crop yields and reduces the wastage of water through the help of IoT sensors for soil and irrigation management [49]. The implementation of IoT in the predictive maintenance of industries minimizes the downtime and increases the productivity [50].

The sector of start-ups in the kingdom of Saudi Arabia has experienced rapid growth and success, as the entrepreneurs took the opportunities available to them to create new products and services in the market and challenge the large companies [16]. Thus, the integration of the IoT technology, as well as any other technology, offers many opportunities but at the same time, it brings new challenges and threats as the environment is constantly changing [8]. Several security concerns encompass:

1) Data privacy: This creates a problem of data privacy since IoT devices are always capturing and sending data. Security breaches or unauthorized access may result in the exposure of certain information that is confidential.

2) Device authentication: It is necessary to perform a device authentication process to ensure that only authorized devices are able to connect to the network. The threat actors can use poor authentication techniques and gain access into the IoT systems without the permission of the owners.

- Data Integrity: Data integrity is a very important aspect that deals with the accuracy and consistency of the data as it passes through the different devices. Data manipulation could result in the deployment of wrong information in the most sensitive processes of decision making.
- Network Security: IoT devices are connected over the wireless network and transmit data over a channel which is prone to threats such as eavesdropping if not properly protected.
- Software Vulnerabilities: There are many IoT devices that rely on embedded software, which can sometimes not be updated regularly and are therefore at risk for basic known flaws and for malware.
- Due to this, it is essential that these start-ups ensure that they protect the sensitive data, secure the connections and reduce the risks of cyber-attacks. These factors are critical for any long-term business success, and to sustain the confidence of the customers [9], [16]. Due to the complex nature of cybersecurity threats in the IoT, technologies such as blockchain technology is seen as a solution [36], [38]. The feature of decentralization and the immutability of its ledger technology is useful for the creation of trust, increased security and data integrity. By using the features that are inherent in blockchain, organizations can enhance the security of their IoT systems and be leaders in the development of secure and effective technical solutions [51].

Nonetheless, the works in [36], [38] show that because of the computational and storage nature of blockchain, it is not appropriate for the small and energy limited sensors in IoT. To implement blockchain in these scenarios, one can employ the following strategies:

- Lightweight Blockchain Protocols: Redesigning blockchain protocols that are computationally and storage intensive to work on IoT devices can be beneficial to the use of blockchain in IoT. These protocols are aimed at increasing the efficiency of the utilization of resources preserving their security and decentralization.
- Off-Chain Storage: Off-chain is a storage mechanism in which most of the data is stored off the blockchain with some data stored on the blockchain. This way, the data processing load on IoT devices can be effectively lowered. This technique relies on the use of the blockchain to guarantee the security and the integrity check with minimal use of the device's resources.
- Edge Computing Integration: Edge computing integration is the combination of blockchain technology with edge computing, which means data processing and blockchain activities are performed at the network's edge near the IoT devices. This way the workload of computing is divided among several more capable fog devices and the latency is also reduced and the load on each sensor is minimised.

3) Consensus mechanisms: To make the blockchain operations more suitable for the IoT applications one can use consensus mechanisms that do not demand more computational power for instance the Proof of Authority or the Delegated Proof of Stake. All of these are more efficient when it comes to the utilization of resources than the conventional proof of work (PoW).

These strategies assist in the integration of Blockchain technology into IoT, primarily those that have many small and energy-efficient sensors; thus, improving the security and dependability of the system without impacting the functioning of the devices [51].

III. Existing Research

The current body of study in the field of startups, namely those using the Internet of Things, is extensive and diverse [52], [53]. This section examines the significant influence of startups on economic development and innovation, as well as the intricate relationship between technical breakthroughs and entrepreneurial success. In this context, the following sections provide a systematic analysis of the critical areas of focus that influence the ecosystem of startups using IoT technology. The areas covered in this study encompass a comprehensive analysis of global startup ecosystems from a worldwide perspective. It identifies the various security risks that are linked with the use of IoT applications. It also examines the factors that affect the implementations and adaptations of IoT technologies in start-up firms. Also, it explores the strategic moves that Saudi Arabia has put in place to foster an environment that supports IoT startups. Finally, it assesses the current standards and frameworks put in place to protect the IoT security. All these components play a vital role in understanding the current state of knowledge and identifying the directions for the future studies.

A. Global Perspective on Startup Ecosystems

Worldwide, governments and politicians acknowledge the importance of entrepreneurs in advancing economic development. The Government of Canada recognizes entrepreneurs as a vital and dynamic force necessary for the country's growth [54], [55]. In a similar vein, the United Kingdom has seen a substantial increase in entrepreneurial activity, establishing itself as the foremost investment hub in Europe [56], [57]. The entrepreneurial sector in the United States significantly contributes to the nation's economic success, making it the biggest economy in the world [58], [59]. Developed countries emphasize creating a secure environment against cyber threats to support the development of startups and

entrepreneurship, highlighting the significance of cybersecurity in today's digital world [60].

B. Security Concerns in IoT-Enabled Startups

Startups that implement IoT technology are at a high risk of cybersecurity threats since the effects of a cyber-attack are usually negative [19]. Security breaches, besides affecting the confidence of the customers and the image of the company, causes significant financial losses [18]. Due to the rise of IoT devices, they have become vulnerable to cyber threats and hence becomes a target of cyber criminals. This means that robust strategies have to be put in place to ensure that key data is secure while at the same time ensuring that the operations remain credible [61].

Here are some security threats that are particular to the startups that incorporate IoT solutions into their business.

- Device Vulnerabilities: Most of the IoT devices are characterized by limited computational power and memory, and thus have inadequate security features. This makes them prone to several attacks such as firmware attacks, unauthorized access, and malware infection.
- Insecure Communication Protocols: IoT devices are connected wirelessly and many of them use protocols with inherent weaknesses in terms of security. An attacker can employ encryption technologies that are either not strong or outdated to intercept and alter data in the course of transmission.
- Default and Weak Credentials: Many a times, users fail to change the default username and passwords on many IoT devices. These credentials are default and can be easily used by the attackers in order to gain access to the devices.
- Data Privacy: IoT devices generate and transmit information that is sensitive, for example, user's data and their behavior. Lack of proper encryption and access control makes it very easy for the hackers to intercept and misuse the information.
- Security Solutions Scalability: The major challenge for the startups is the scalability of their security solutions. Since there are more devices that are connected in the IoT, it becomes a difficult process to manage and regulate on the security aspect of each device.
- Patch Management: IoT devices should be updated from time to time with the current security patches. However, most of the devices do not have a clear way of updating, and this exposes them to common threats.

The continuous study is significant in overcoming the cyber security problems that are related to the utilization of IoT in startups. There are several flaws in IoT devices identified by the researchers and the consequences that may arise from the security threats are loss of data and damage to one's reputation [62], [63]. Moreover, a large number of empirical studies have examined the factors that influence the uptake of IoT in various industries and countries, thus helping to understand the drivers and challenges of organizations [43].

We need a comprehensive strategy to address these problems. This strategy should include the adoption of more robust authentication mechanisms, the establishment of secure communication channels, the frequent upgrading of device firmware, and the education of users on the significance of changing default credentials. In addition, entrepreneurs should contemplate using sophisticated security frameworks, such as blockchain technology, to augment the overall security of their Internet of Things (IoT) ecosystems. By prioritizing these specific concerns, companies can improve the security of their IoT implementations and reduce the potential dangers of security breaches.

In addition, cybersecurity is mainly concerned with protecting the network, systems, and data against threats such as DDoS attacks, malware attacks, and social engineering; however, the insecurity of the physical aspect of IoT devices is equally important. Some of the Physical security measures that can be employed are; implementing tamper proof hardware. In the same way, gadgets that can be easily tampered with as they are not openly changeable, present a significant threat to security. Therefore, IoT-based organizations need to establish a full-fledged security plan that incorporates cybersecurity alongside physical protection of devices for the entire IoT environment.

C. Factor Influencing IoT-enabled Startup Ecosystem

The success of companies that use IoT technology depends on effectively resolving critical elements in technical, political, social, and economic aspects [64], [65]. From a technological standpoint, having access to a robust telecommunications infrastructure and reasonable bandwidth is important for the smooth implementation of the IoT [8]. From a political standpoint, it is essential for the government to provide support for technical development and innovation in order to create a favorable environment for startups [18]. Societal factors, like the speed at which people use the Internet and their level of acceptance of technology, significantly influence the adoption and spread of IoT solutions [66]. In terms of economics, variables like average income levels, accessibility to technology, and general economic development influence the feasibility and scalability of IoT-enabled companies [67].

D. Saudi Arabia's Endeavor in Fostering IoT-Enabled Startup Ecosystem

Saudi Arabia has a strong desire to foster the IoT-enabled startup ecosystem, as seen by its significant investments and strategic efforts. To meet this expectation of internet usage standing at over 95% in the year 2025, much resources have been allocated to programs such as the e-Government and the Saudi Vision 2030 that seeks to foster business and invest in new business ventures [4], [6]. Saudi Arabia aims to establish itself as the center of entrepreneurship in the region by making strategic investments and providing assistance in several sectors, albeit starting later than other countries [14].

Nevertheless, despite its high readiness score, which exceeds that of many other countries, Saudi Arabia has had difficulty fully utilizing the potential of startups provided by the Internet of Things (IoT). Studies that are directed towards the computer security issues of startups that are employing IoT is rather limited. This is the reason why it is critical to pay

attention and act in this area [4], [9]. Nevertheless, the review of literature on cybersecurity and technology use in the area reveals other important findings in the present study thus underlining the importance of the topic in Saudi Arabia today [4], [8].

E. Standards and Frameworks for IoT Security

Several works have been done by international organizations and standards groups regarding the security standards and frameworks of IoT [68], [69]. These standards are important due to the need to have a uniformity, compatibility and safety of the IoT systems [70]. The International Telecommunication Union (ITU) [71], the International Organization for Standardization (ISO) [72], the International Electrotechnical Commission (IEC) [73], and the Institute of Electrical and Electronics Engineers (IEEE) [74] set significant standards. Organizations such as National Institute of Standards and Technology (NIST), the IoT Security Foundation, and European Union Agency for Cybersecurity (ENISA) have issued recommendations and best practices for protecting IoT systems [46], [75], [76].

These organizations have published several vital IoT standards such as

- ITU is an organization that deals with the regulation of telecommunication standards.
    - ITU-T Y.2060 is one of its standards that provides detail on the structure of IoT and the key enablers for IoT.
    - The ITU-T Y. 4000-Y.4999 series encompasses a number of recommendations that are associated with the design, requirements, and challenges of the IoT.
- ISO has prescribed ISO/IEC 27030 and ISO/IEC 30141 which are associated with security strategies for IoT.
    - The ISO/IEC 27030 standard defines guidelines for Information Security Risk Management in IoT systems.
    - The ISO/IEC 30141 is a standard that defines the architecture of IoT to ensure that the different IoT systems are compatible and also secure.
- The IEC is an organization that deals with the standardization of many industries.
    - Among the standards developed by the IEC, one of the most important is the IEC 62443 standard that is mainly oriented towards industrial automation systems and can be applicable to the IoT systems as well. It contains guidelines on the security of network and systems.
- IEEE has also come up with standards that include IEEE 2413 and IEEE P1451 regarding the security of IoT.
    - The IEEE 2413 standard defines the IoT. This framework is based on the concepts such as interoperability, security, and privacy concerns.
    - The IEEE P1451 standard is mainly devoted to the smart transducer interfaces and these are vital for the IoT. This standard focuses on the aspects of interoperability and security.
- The NIST has produced a document called NIST Special Publication 800-183.
    - This publication provides a comprehensive and extensive overview of security in the IoT. It encompasses various aspects of security including device security, data security and network security.
    - The NIST Cybersecurity Framework is not aimed at IoT but it provides a robust model for managing and, therefore, minimizing cybersecurity risks in IoT environments.
- The IoT security foundation can thus be viewed as a reference for the implementation of security in IoT devices and services right from the development of the concepts to the final product.
- ENISA gives an insight of the guidelines and recommendations that are required in the IoT security compliance.
    - The Baseline Security Recommendations for IoT are quite specific and focus on preserving data, device, and network security for IoT devices.
    - The ENISA Good Practices for IoT and Smart Infrastructures are guidelines that offer real-life recommendations on how to secure IoT deployments and minimize the associated threats.
- Thus, by adhering to these guidelines and models, organizations can ensure that their IoT systems are secure, interoperable, and reliable, which in turn enhances the confidence and reliability in any IoT solution offered.

In conclusion, the previous study finds important findings regarding the security issues and challenges related to the IoT applications in Saudi Arabian startups. Thus, organizations can implement effective security measures and guidelines to minimize the risks and ensure the data security and privacy of IoT devices by referring to the standard and frameworks developed by international organizations and standards development organizations [69]. Although there is already research available, there is still a lack of information about the distinct computer security concerns that entrepreneurs in Saudi Arabia have when implementing IoT solutions. It is critical to address this deficiency in order to provide a safe and prosperous environment for IoT-enabled companies throughout the country [16]. Table II presents a thorough summary of the current study and offers valuable insights derived from the difficulties, characteristics, and suggestions.

TABLE II. COMPREHENSIVE OVERVIEW OF THE EXISTING RESEARCH

Section	Summary	Challenges	Attributes	Recommendations
Global Perspective on Startup Ecosystems	Developed nations prioritize fostering a cyber-threat-free environment to enable startup growth and entrepreneurship [54], [55], [56], [57], [58], [59].	Regulatory barriers Cybersecurity concerns Interoperability issues	Government support Access to capital Technological infrastructure	Establish clear regulatory frameworks Enhance cybersecurity education and awareness Foster collaboration between government and industry
Security Concerns in IoT-enabled Startups	Security breaches undermine consumer trust and lead to significant financial losses; robust security measures are necessary [18], [62], [63].	Data breaches Compromised IoT devices	Encryption techniques Authentication protocols Intrusion detection systems	Implement end-to-end encryption Regularly update firmware and software Conduct security audits and penetration testing
Factors Influencing IoT-enabled Startup Ecosystem	Success factors include technological infrastructure, government support, societal acceptance, and economic conditions [18], [52], [66], [67].	Technological limitations Limited government support Societal resistance to technology Economic instability	Telecommunication infrastructure Government initiatives Societal attitudes towards technology Economic growth	Invest in expanding technological infrastructure Provide incentives for startups Promote digital literacy programs Foster economic diversification and stability
Saudi Arabia's Endeavor in Fostering IoT-enabled Startup Ecosystem	Saudi Arabia invests in initiatives like the e-Government program and Saudi Vision 2030 to foster entrepreneurship [3], [4], [6], [13], [14].	Limited access to funding Infrastructure gaps Bureaucratic issues	Government investments Strategic initiatives Vision 2030 initiatives	Establish dedicated funding programs for startups Improve infrastructure development Streamline regulatory processes and reduce bureaucratic red tape
Standards and Frameworks for IoT Security	International organizations and standards bodies have developed standards and frameworks to ensure IoT system security [46], [71], [72], [73], [74], [75], [76], [77].	Lack of standardized regulations Complexity of compliance	ITU standards ISO/IEC standards IEEE standards	Implement standardized security protocols and guidelines Simplify compliance procedures and provide support for implementation Encourage participation in certification programs and compliance frameworks

IV. IOT-DRIVEN COMPUTING CHALLENGES IN SAUDI ARABIAN START-UPS

This section explores the computational challenges faced by startups in Saudi Arabia, namely those that hinder their ability to expand and innovate. Fig. 2 shows that most of the computing problems IoT-driven startups in Saudi Arabia face are caused by four main things: worries about cybersecurity [4], [9], a lack of skilled IT professionals [9], [16], problems with infrastructure [8], [16], and issues with following rules and regulations [3], [15].

Among all the problems, cybersecurity is the most significant and pressing issue because it has an immediate impact on the operations and sustainability of organizations that use IoT devices. Due to the fact that these organizations are in the digital environment, they are very vulnerable to cyber risks, which may affect the important information, services, and, consequently, consumer trust. This issue shows that there is a necessity of proper cybersecurity measures which might be difficult for startups since they have a small budget.

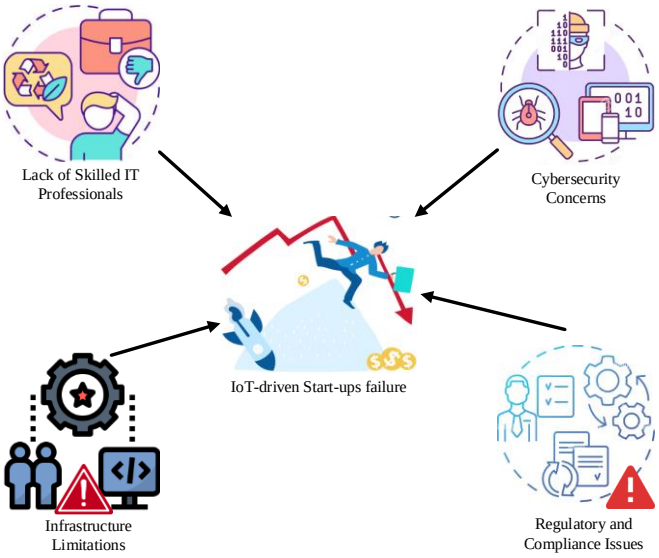

Fig. 2. Computing challenges in Saudi Arabian IoT-driven start-ups.

A. Cybersecurity Concerns

Startups in the Saudi Arabia are becoming more technology-oriented and apply digital technologies in their business processes which makes cybersecurity an important factor for them [4]. In view of the above, it is important that the valuable information and systems are protected as more cyber threats and attacks are being reported in the context of IoT-based startup companies [9].

However, some of the Internet of Things (IoT) start-ups might lack the necessary funds and personnel to develop robust cybersecurity mechanisms [12]. Lack of funding and lack of skilled personnel in the IT department are other drawbacks in their IT systems [4], [16]. Moreover, the identified danger of the dynamic nature of cyber threats is a continuous challenge that requires the permanent monitoring and tuning of the security measures [8].

This makes it essential for IoT based start-ups to prioritize the spending on cybersecurity technologies and protocols in order to address cybersecurity issues. In collaboration with cybersecurity professionals and employing cloud-based security measures, organizations can enhance their defenses against cyber threats [4], [8]. Also, organizations can minimize risks by raising awareness on the importance of cybersecurity and conducting comprehensive trainings [4], [9]. This section discusses some of the most significant and diverse cybersecurity threats that are directed towards IoT applications.

1) Security threats to IoT applications: Due to the increased integration of IoT devices, along with the big data they generate, the IoT faces a high level of security threats [76]. IoT devices often lack basic security features like secure boot and encryption and are vulnerable to exploitation through default configurations, weak passwords, and unencrypted communication channels [68]. These risks can lead to unauthorized access, data manipulation, or device compromise, which can be risky to privacy and organizational credibility. Thus, high-profile attacks like the Mirai botnet attack and the Stuxnet worm emphasize the importance of security in IoT systems [78], [79].

Fig. 3. Different security threats to IoT applications.

The IoT ecosystem consists of four layers: They are sensors and actuators, communication networks, middleware, and end-to-end applications. Each layer has its own security challenges and gateways help in transferring data from one layer to another. The existence of the weaknesses at these levels makes it vulnerable to attacks and, therefore, a need to understand the security situation [63]. Fig. 3 highlights these vulnerabilities and underscores the importance of preventive security measures in securing IoT applications from potential attackers.

a) Security Concerns about the Sensors and Actuators (Sensory) Layer

Threats to the sensory layer, which consists of physical sensors and actuators, include node capture, side-channel attacks, and malicious code injections [63].

- Node capture: Attackers replace low-power nodes with malicious ones. Solution: Employing physical security measures to safeguard nodes and utilizing tamper-resistant hardware will effectively deter node capture.
- Malicious Code Injections: Affect the potential of nodes. Solution: Secure boot and coded signing prevent the usage of unauthorized software on the devices.
- Side-Channel Attacks: In this case, the program utilizes CPU microarchitectures to gain data without permission. Solution: It is possible to decrease the effect of these attacks by employing hardware encryption and shielding measures.
- Eavesdropping and Interference: Target IoT systems in public areas. Solution: Employing encrypted communication channels and frequency-hopping methods may effectively safeguard against eavesdropping and interference.
- Sleep Deprivation and Booting Attacks: Cause devices to become inoperable or compromised. Solution: Deploying robust firmware update mechanisms and using advanced anomaly detection systems may effectively detect and mitigate these types of attacks [2], [21], [23].

b) Security Concerns about the Communication Network (Network) Layer

The network layer, which is responsible for delivering data, gets vulnerable to the phishing scams, unauthorized access, and denial of services (DoS) [63].

Phishing: mainly focuses on the IoT devices with the aim of collecting the login details. Resolution: It is possible to eliminate this risk by implementing and using multi-factor authentication (MFA) and training the users to recognize phishing schemes.

- Access attacks: Their role is to infiltrate the networks and to obtain information from there. Solution: It is also recommended to prevent illegal access through improving the establishment of robust network access control (NAC) and implementing intrusion detection systems (IDS).
- DDoS attacks: These are such as flooding the servers; an act that ends up disrupting the provision of relevant services. Solution: The attacks can be prevented by

using rate restriction, traffic analysis and services that prevent Distributed Denial of Service.

- Data transit and routing attacks: Their objective is to challenge the authenticity of data and juncture involved. Solution: On data transmission, it is possible to ensure data security and prevent the information from being intercepted in the process by employing secure and well encrypted end to end and safe routing pathways.

c) Security Concerns about the Middleware Layer

The extra layer called the middleware is also a weak link due to the risk of man-in-the middle attack, SQL injection and cloud malware injection [63].

- Man-in-the-Middle Attacks: These are such as controlling the protocol like the MQTT through which unlawful communication is made. Solution: Mutual authentication along with TLS (Transport Layer Security) could possibly help prevent such attacks.
- SQL injection: Combined with the factors above, it complicates and compromises the integrity of data. Resolution: Using parameterized queries or using input validation, one can meet the needs to counter SQL injection.
- Cloud Malware Injection and Flooding Attacks: They are designed for cloud infrastructure. Solution: To counter such threats, it is recommended to work with cloud safeguards that cover API protection, the assessment of critical weaknesses more often, and implementation of cloud-native security solutions.

d) Security Concerns about the End-To-End Application (Application) Layer

The application layer, which is directly related to the end-users, is concerned with problems like data theft, access control, and service interruption attacks [63].

- Malicious code injection and sniffer attacks can further lead to threats to the system integrity. Resolution: Implementing application firewalls; code reviews on a regular basis; having secure coding practices may minimize these risks.
- Reprogramming attacks: These have the propensity of causing hijacking of the network. Using such measures as implementing secure firmware upgrade and code signing will help to ensure that only trustworthy code is run on the devices.

e) Security Concerns about Gateways

While gateways are necessary to interconnect IoT devices, these devices are still susceptible to eavesdropping as well as man-in-the-middle attack during GW on-boarding [43], [61].

- Man-in-the-Middle Attacks: Solution: To eliminate the possibility of a third-party intercepting said information, a means of mutual authentication, as well as encrypted pathways of communication needs to be established.
- Eavesdropping resolution: It can be prevented by ensuring that the onboarding procedure that is invoked during the entire process is safe from the people who would want to snoop on the data transfer process and by making sure that the information exchanged has the highest level of encryption possible.
- Updating firmware must be done securely. Solution: We can therefore exclude the so-called unwanted access into the firmware by embracing reliable update procedures and ensuring the firmware is validated prior to use.

f) 4.1.1.6 Other Security Concerns

IoT devices provide issues like insufficient authentication, encryption mechanisms, and physical security measures [80], [81]. Implementing standardized protocols, regularly updating software, and having solid APIs are essential for reducing these risks. It is essential to address privacy concerns, supply chain vulnerabilities, and legacy system integration challenges in order to provide complete security for the Internet of Things (IoT) [78].

To address these difficulties, researchers propose using robust authentication, encryption, regular firmware upgrades, security audits, and industry-wide standards to minimize the security risks associated with IoT [44], [48], [49]. Implementing such solutions is crucial for protecting IoT applications and guaranteeing their ability to withstand emerging threats.

1) IoT Users' Privacy Concerns, Scalability and Interoperability

Currently, the risk of privacy compromise has been deemed very high, especially in areas such as the smart home since there is a growing prevalence of networked IoTs. This is the case because tracking user activity in such contexts could inadvertently disclose private data [82]. With IoT data storing parameters for individual customers the opportunity to use this chance to develop new products and individualized advertising has emerged the issues with data utilization and breaches that may lead to issues like identity theft. Various governments including the Saudi Arabia are trying to mitigate the challenges that relate to data governance and protection of data through organizations like the Saudi Data and Artificial Intelligence Authority (SDAIA) [83]. Thus, compliance with the rules of the protection of personal data prescribed by the international legal acts, including the General Data Protection Regulation created by the European Union [82], proves commitment to ethic data usage in IoT environments.

In the same way, more and different IoT devices increase the management and scalability challenges [62]. This means that there is a need to fit in large volumes of data, which exerts storage and network resources pressures so that interoperability enhances efficient data exchange across platforms and devices. Integration is key in the formation of composite services most importantly in smart city initiatives whereby the collaboration of IoT devices enhance distribution of resources and management of the civil structures [84].

In response to concerns about scalability and interoperability, IoT platforms and middleware have become popular solutions. These solutions include various features, such as device management, data integration, and application development [68]. These technical interventions reduce

fragmentation and inefficiencies while maximizing the advantages of IoT technology. In order to guarantee the ongoing development and effectiveness of IoT ecosystems, it is important to prioritize privacy protections, scalability, and interoperability, as shown in Fig. 4.

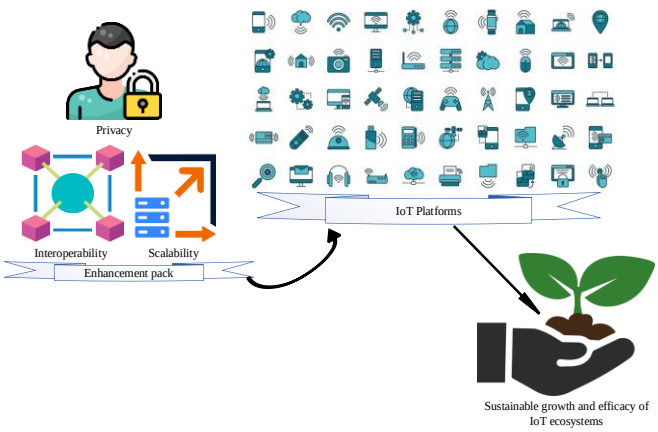

Fig. 4. Ensuring a sustainable growth and efficacy in IoT ecosystems.

B. Other Computing Challenges in Saudi Arabian Start-ups

This section examines the computational difficulties encountered by start-ups in Saudi Arabia, emphasizing significant barriers impeding their expansion and ingenuity.

1) Lack of skilled IT professionals: A significant challenge that start-ups in Saudi Arabia encounter is the limited availability of highly trained IT experts [9], [16]. Although there is a growing need for skilled professionals in fields like software development, data analytics, and cybersecurity, there is still a lack of competent workers to meet this need [4]. The country's education system may not adequately equip students with the skills and knowledge required for employment in IT-related industries, resulting in a limited supply of local talent for start-ups to hire. Additionally, the favoritism towards engineering and business degrees in comparison to IT fields worsens this shortage [10].

In order to tackle this difficulty, it is necessary to implement efforts that aim to enhance IT education and training programs at academic institutions and vocational training centers [9], [16]. Due to the lack of adequate number of skilled IT staffs, students should be encouraged to pursue IT degrees and professionals should be motivated to enhance their skills in the development of technologies.

2) Infrastructure limitations: Infrastructure restraints currently present a significant barrier to start-up firms in Saudi Arabia [16]. Although there have been improvements in the development of digital infrastructure, there are still gaps that remain, particularly in rural and disadvantaged regions [12]. Limited availability of dependable internet connections and power interruptions may disrupt corporate operations and hinder the use of digital technology. Also, the expense associated with building and sustaining infrastructure may be a hindrance for new businesses, particularly those with low financial means [8].

In order to overcome the limits of infrastructure, start-ups have the option to consider other solutions, such as using shared infrastructure services and forming partnerships with existing technology providers [13], [85]. It will prove useful to explore more efficient methods of obtaining the required IT solutions, such as cloud solutions and software-as-a-service (SaaS). Moreover, contributing to the government initiatives that aim at the improvement of the digital connectivity and the increase of the internet accessibility can also contribute to the formation of the more suitable environment for the start-ups [10].

3) Regulatory and compliance issues: Besides those common challenges, start-ups in Saudi Arabia face another challenge that is the tough regulatory and compliance requirements [3], [15]. With many start-ups emerging and constantly advancing technologies, legislation and law practices may be intricate with constantly varying differentiations and yet posing challenges of ensuring technology and data compliance. Thus, data privacy, intellectual property rights and some industry-specific rules add up to the complexity of the operational environment [16]. Also, there may be challenges incurred by start-ups due to bureaucratic procedures and legal issues which may hinder market entry and growth [14].

In considering how to overcome barriers and challenges to new start-ups, it will be necessary for start-ups to adopt regulatory compliance as a critical consideration and to formally include compliance as part of the business strategy. It may be helpful to involve a legal counsel and to follow the changes in legal regulation in order to minimize the risks and adhere to the laws. Moreover, backing regulatory adjustments, and also participating in the process of assisting governmental bodies in making procedures less burdensome can potentially contribute to improvement of the environment for start-ups [13].

In conclusion, the major challenges that start-ups in Saudi Arabia experience following computational issues includes: The absence of skilled IT personnel, limited infrastructure, and legal and regulatory issues. To tackle these difficulties, it is necessary for stakeholders from government, business, and academia to work together and create an environment that promotes innovation and growth [7], [10]. By surmounting these obstacles, start-ups may unleash their full capabilities and make a significant contribution to the country's economic diversification and digital transformation.

V. The Role of Vision 2030 in Promoting IoT

This section analyses how Vision 2030 has helped in the incorporation of IoT to Saudi Arabia's dream of a smarter future and diversification of economy. Vision 2030 was formulated by the Saudi Arabian government as a major social program aimed at diversifying its economy and developing it in various spheres [6]. The main goals of the organization are to improve the business climate, attract foreign investment, and foster innovation and entrepreneurship [6].

Saudi Arabia views the integration of IoT technology into Vision 2030 efforts as a crucial method for driving digital transformation, enhancing productivity, and fostering

innovation [3]. The main goals of Vision 2030 are shown in Fig. 5. They include building smart cities, speeding up the digital transformation of society, businesses, and government, supporting innovation, encouraging industrialization, and giving digital health top priority [86], [87]. These projects use IoT technology, including sensors, actuators, and networked devices, to enable the digitalization of processes, the gathering of data, and the optimization of operations [83].

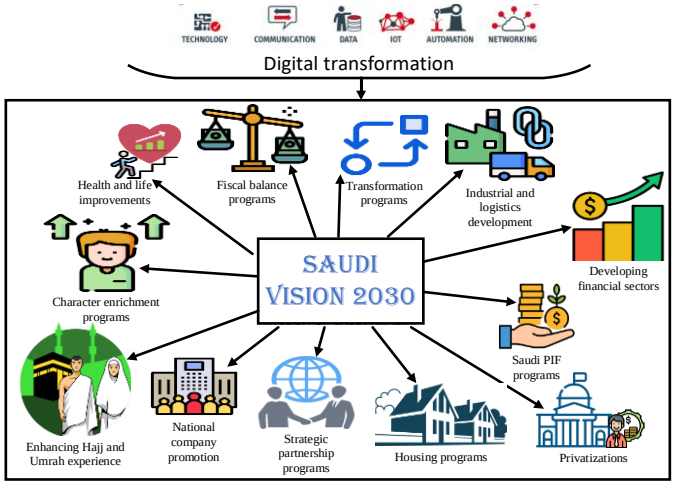

Fig. 5. Achieving Saudi Vision 2030 via digital transformation.

Furthermore, the government plays a significant role in assisting secure IoT-driven start-ups via many channels. Such resources consist of financial assistance, grants, access to spaces that incubate entrepreneurial ventures, accelerated programs for business, and hubs for innovation. The Badir Program for Technology Incubators and the KAUST Entrepreneurship Centre offer crucial support in the form of guidance, development, and connection-making to start-ups [7], [10], [54], [83]. Moreover, regulation authorities ease bureaucratic processes and establish conducive conditions for safe IoT-led start-ups through setting up of regulatory sandboxes and innovation zones.

The government also makes provisions for expending funds on skills development programs to improve the competencies of businesspersons and other professionals operating in the IoT value chain. The National Industrial Development and Logistics Program (NIDLP) provides necessary skills development, training sessions, and capacity enhancement interventions [88]. The government develops a pool of human capital to have skilled IoT personnel who can promote innovative development [54].

Saudi Arabia is moving towards promoting its Vision 2030 framework of bringing innovation and sustainable growth in business through supporting its programs in IoT technology and helping in the financial assistance in IoT based start-ups. It is therefore possible for Saudi Arabia to position itself as one of the foremost global leaders in IoT enablement and innovation through its smart investments, strategic changes in policies, and the promotion of partnership.

Furthermore, Table III shows the comparison of proposed and existing research on IoT security in Saudi Arabia Start-ups.

TABLE III. COMPARISON BETWEEN PROPOSED RESEARCH AND EXISTING STUDIES ON IOT SECURITY IN SAUDI ARABIAN START-UPS

Aspect	Proposed Research	Existing Studies
Target	Examines IoT security challenges specifically in Saudi Arabian start-ups.	Various studies cover IoT security across different sectors globally but may not focus specifically on Saudi start-ups [18], [62], [63].
Objectives	Identify cybersecurity risks, analyze the impact of IoT networking on privacy/security, and propose mitigation strategies.	Existing research often identifies security risks, however, lack comprehensive frameworks for specific contexts like Saudi Arabia [3], [4], [6], [13], [14].
Methods	Review of diverse publications and analysis of cybersecurity issues in the context of Saudi Vision 2030.	Many studies utilize case studies or empirical data, potentially overlooking broader contextual analyses like national strategies [54], [55], [56], [57], [58], [59].
Importance Findings	Highlights distinct cybersecurity obstacles faced by IoT-enabled businesses in Saudi Arabia; calls for funding, collaboration, and education.	Most of studies mention general IoT security challenges but may not address specific funding or educational needs in emerging markets [46], [71], [72], [73].
Contextual Relevance	Positions research within Saudi Arabia's economic goals and Vision 2030.	Various existing studies focus on developed countries or global trends without considering local economic and cultural factors [74], [75], [76], [77].
Recommendations	Advocates for a cooperative strategy involving policymakers, industry stakeholders, and entrepreneurs to enhance IoT security.	Many studies recommend technical solutions or policy frameworks; however, they did not emphasize collaboration with local stakeholders [13], [14].
Contributions to the Field of Research	Provides novel insights and a framework tailored to the unique challenges of Saudi Arabian start-ups in IoT.	Most of existing research do not focus on the unique socio-economic landscape of Saudi Arabia, limiting their applicability [46], [71], [72], [73].

VI. Discussion on Future Direction and Recommendations

This section provides a discussion on the paths that are to follow and gives recommendations on ways through which the Saudi Arabian government can foster the evolution of safer IoT devices led start-ups and promote creativity. These attempt to offer a strategic approach; however, it is high time to consider them in relation to the existing socio-economic conditions in Saudi Arabia and the peculiarities of the mentioned cybersecurity challenges.

1) Establish innovation networks: Creating innovation networks may help stakeholders share resources, skills, and best practices, leading to increased creativity and the ability to overcome difficulties [88]. These networks should highlight cybersecurity best practices to ensure that IoT start-ups place a high value on security right from the beginning.

2) Encourage open innovation: The open models help start-ups access resource, technologies and market opportunities and in turn existing enterprises can avail benefits of external innovation and entrepreneurial skills [89]. Some measures to empower open innovation may involve establishing safe IoT spaces and information sharing systems that enhance the knowledge of potential cybersecurity threats and the ways to combat them.

3) Support technology transfer: The government should endorse technology transfer efforts and collaborations to expedite the commercialization of research and innovation [54]. It is important to focus on sharing information and technologies that improve the security of the Internet of Things (IoT) such as blockchain technology. This will assist in avoiding new innovations from negating the authenticity of the data or the confidentiality of the user.

Cultivate a Culture of Innovation and Entrepreneurship: The implementation of the culture of innovation and entrepreneurship plays a key role in establishing secured IoT based Start-ups and Innovations in Saudi Arabia [85]. The following are the primary recommendations:

- Promoting a new organizational culture where people would embrace the principles of entrepreneurship in tackling cybersecurity issues.
- Supporting and encouraging start-up incubation and acceleration initiatives that focus on enhancing safe IoT innovation.
- Celebrating achievements in entrepreneurship, including specific accomplishments that can potentially convey success in protecting IoT applications.
- State-sponsored honors, competitions, and meetings can inform about successes of prospering start-ups and businesses to inspire a new generation of innovators and actors of change [18].

4) Leverage international partnerships: Consequently, it's wiser for Saudi Arabian IoT-drive start-ups to capitalize on foreign partnerships since this will afford them the international markets and foreign experience along with the advanced technologies that are vital for their growth [13]. Some recommendations are as follows:

- Remain committed to the search for international cooperation and funding sources to strengthen protection of IoT networks with the participation of specialized organizations.
- Works with other universities and industries that have well-strategized cybersecurity system mechanisms across the globe for technology update and knowledge sharing.
- Providing help in the access to international markets, distribution channels, and business networks while meeting international cybersecurity standards for start-up companies.

5) Specific socio-economic considerations: To make these suggestions realistic and effective in the Saudi context, the following should be considered given the country's socio-economic values:

- Economic Diversification: ensuring that the development of IoT start-ups in Saudi Arabia aligns with the aims of economic diversification outlined in Vision 2030, with a specific emphasis on supporting non-oil industries.
- Education and Training: More resources need to be directed to education and training that can help in improving cybersecurity and create workforce that can handle IoT security threats.
- Regulatory Environment: Creation and enforcement of laws that foster IoT security, thus ensuring that the start-ups follow the regional and international standards of cybersecurity.

Thus, Saudi Arabia can contribute to the development of an active environment in the IoT industry by considering socio-economic factors and specific cybersecurity challenges, as well as cooperation, innovation, and entrepreneurship [10]. This strategy will ensure that the economy grows and becomes prosperous as required by Vision 2030 while at the same time ensuring that the security of IoT systems is not compromised in any way.

VII. Conclusion

This paper has reviewed the literature on the adoption of IoT technology in start-up companies in Saudi Arabia with a focus on the cybersecurity challenges. The research highlights the critical cybersecurity risks associated with IoT adoption in Saudi Arabian startups, particularly in the context of data privacy and network security vulnerabilities. The study emphasizes the necessity for startups to implement advanced security measures despite limited resources and proposes strategic solutions, such as cloud-based security, collaboration with cybersecurity experts, and enhanced cybersecurity education. This research fills a notable gap by addressing the unique cybersecurity needs of startups in emerging markets, advancing the understanding of IoT security in the

entrepreneurial landscape. Moreover, the government is to seek solutions to social issues and promoting corporate growth through IoT investment, these start-ups face significant cybersecurity challenges. This is due to the fact that the threats are constantly evolving, and the resources available in such efforts are scarce.

For this reason, start-ups need to allocate their resources to cybersecurity technology and procedures to address these issues. Another way of improving the organizations' cybersecurity is through engaging the services of cybersecurity professionals, and the use of cloud technologies. In the same manner increasing the awareness of the public regarding the proper measures to take to improve cybersecurity and increasing the frequency of educational campaigns is also an effective way in increasing the level of cybersecurity preparedness.

Therefore, there is the need to do more work and engage in more research to discover new strategies in the protection of IoT in Saudi Arabian start-ups. It is important to address the cybersecurity issues to harness the full potential of IoT, boost the economy, foster innovation, and position Saudi Arabia as a leader in the IoT technology sector.

The IoT industry decision makers, stakeholders and investors in Saudi Arabia should ensure that proper cyber security measures are put in place and resources to be directed towards development of secured IoT ecosystem. Saudi Arabian start-ups could navigate their way through the cybersecurity environment and succeed in the era of digital and interconnected world by collaborating and investing more.

Future Research and Implementation:

- Lightweight Blockchain Protocols and Edge Computing Solutions: It is recommended that further studies focus on the enhancement of blockchain protocol that has low power consumption and is suitable for the IoT devices' edge computing.
- Standardized Cybersecurity Frameworks: From the findings of the present study, it can be suggested that there is a need for the formulation of suitable cybersecurity models that can be applied to the context of the startups and at the same time ensure that all the IoT systems are compliant.
- Synergy among academia, industry, and government: This implies that new challenges must be taken and safer IoT technologies and environments have to be created.
- Educational Initiatives: Awareness and education of entrepreneurs and IT specialists in the context of the creation of secure IoT systems can be considered as one of the most significant activities directed towards the development of the IoT security sphere.

Implementing these measures can help Saudi Arabia create a competitive environment in the IoT industry and promote cooperation, innovation, and business growth. This strategy will foster economic growth and prosperity in line with Vision 2030 while at the same time focusing on the security of IoT devices. Through close cooperation with all stakeholders, the country can become a global leader in safe and innovative IoT solutions.

ACKNOWLEDGMENT

The research presented in this paper is funded by the Saudi Arabian Cultural Bureau (SACB) through a PhD studentship at the University of Sussex.

A Low-Cost IoT Sensor for Indoor Monitoring with Prediction-Based Data Collection

Paolo Capellacci, Lorenzo Calisti, Emanuele Lattanzi
Department of Pure and Applied Sciences, University of Urbino, Urbino, Italy

***Abstract*—The proliferation of Internet of Things technologies has revolutionized the landscape of indoor environmental monitoring, offering opportunities to enhance comfort, health, and energy efficiency. This paper presents the development and implementation of a low-cost IoT sensor system designed for indoor monitoring with a Machine Learning-driven prediction-based data collection approach. Leveraging deep learning algorithms, the IoT device predicts significant environmental changes and dynamically adjusts the data collection frequency to optimize energy consumption and data transmission. Experimental results demonstrate the system's ability to accurately predict environmental variations, resulting in a reduction in data transmission and power usage up to 96% without compromising the monitoring quality. The findings highlight the potential of prediction-based data collection as a viable solution for sustainable and effective indoor environment monitoring on low-cost IoT devices.**

***Keywords*—IoT; indoor monitoring; prediction-based data collection; deep-learning**

I. Introduction

The widespread diffusion of Internet of Things (IoT) technologies has transformed various contests, ranging from environmental monitoring to smart buildings, agriculture, and transportation. In the indoor monitoring field, IoT systems enable real-time data collection from numerous sensors, providing opportunities to enhance comfort, health, and energy efficiency. By monitoring parameters such as temperature, humidity, air quality, and occupancy, these systems can optimize environmental conditions for the well-being of occupants while minimizing energy consumption [1]. However, traditional IoT-based environmental monitoring systems often rely on continuous data collection, leading to excessive power consumption and inefficient data transmission, especially in resource-constrained environments [2]. The challenge of balancing data accuracy and energy efficiency is particularly significant for low-cost IoT systems, where prolonged battery life and reduced data transmission costs are critical. Recent advancements in Machine Learning (ML) offer potential solutions to this issue. ML techniques can enable IoT devices to predict environmental changes dynamically, allowing for adaptive data collection strategies that optimize energy use without compromising the quality of monitoring. This paradigm shift from static to Prediction-Based Data Collection (PBDC) has the potential to enhance both the sustainability and effectiveness of IoT systems in indoor environments [3].

In particular, PBDC retains the original sampling frequency of the application while reducing energy consumption by minimizing the amount of data that needs to be transmitted [4]. This is achieved by constructing a model of the sensed data, which is then used both at the sensor and at the sink to estimate the sampled data points. When a new sample is obtained, the sensor checks if it falls within the predefined error tolerance. If it does, no further action is required (i.e. data are not sent); if not, a new model is created and sent to the sink.

In this paper, we present the development and implementation of a low-cost IoT sensor system for indoor environmental monitoring that leverages machine learning to optimize data collection and transmission. By employing ML algorithms to predict significant environmental changes, our system dynamically adjusts the frequency of data collection, resulting in reduced power usage and data transmission overhead. Experimental results demonstrate that the proposed system accurately predicts environmental variations, achieving energy savings of up to 96% while maintaining high data quality.

The contributions of this work are twofold:

- We introduce a low-cost IoT sensor for indoor monitoring capable of easily measuring environmental parameters, and we characterize it on a real deployment.
- We implement a PBDC strategy by means of deep-learning models, and we deeply characterize its efficiency in terms of average error and transmission ratio with respect to a traditional approach.

The rest of the paper is organized as follows: Section II provides related work on IoT low-cost sensors and PBDC-enabled devices. Section III describes the hardware-software IoT architecture and provides a detailed description of the PBDC mechanism we implemented using ML models. In Section IV, we provide a detailed description of the case study based on a real prototype deployment, and we discuss the results and findings, while Section V concludes the paper.

II. Related Works

In the literature, several authors have addressed the research and development of tools and systems for monitoring environmental metrics, particularly focused on measuring and controlling Indoor Air Quality (IAQ). Among these, Saini et al. [5] presents a systematic review of the current state of the art in IoT-based IAQ monitoring systems. They examined numerous studies published between 2015 and 2020, finding that most of the research has been conducted in countries such as Portugal, China, India, and Malaysia. Their findings also reveal that a significant portion of studies focuses on monitoring comfort parameters and CO_2 levels, with many systems being implemented using Arduino or Raspberry Pi.

Several studies have investigated the use of edge and fog computing devices in air quality monitoring. For instance, Bianconi et al. [6] proposed an IoT system to improve citizens' well-being in Savona, Italy. Their findings highlight the network's capability to monitor well-being over the long term and promptly respond to critical situations when necessary. Similarly, Narayana et al. [7] introduced an advanced real-time environmental monitoring system leveraging IoT and wireless sensors. This system employs innovative techniques for monitoring water treatment and air quality, capturing real-time data on air, water, waste, energy, and soil, thereby making a significant contribution to sustainable living.

Focusing on indoor environments, various systems have been developed to monitor air quality using IoT technology, capable of tracking $PM_{2.5}$, CO_2, temperature, and humidity simultaneously [8]. Some of these systems also include predictive capabilities, providing alerts for potentially hazardous conditions [9]. Additionally, Sung et al. [10] applied a combination of air quality indices, including the carbon dioxide index and the air quality index from the American Society of Heating, Refrigerating, and Air-Conditioning Engineers, to simulate the impact of these factors on indoor air quality.

AI-based approaches are also gaining momentum, with models such as Long Short-Term Memory (LSTM) being applied to predict future CO_2 concentrations, thus improving IAQ management systems by enabling preemptive actions. Other studies have integrated multi-headed Convolutional Neural Network (CNN) models to enhance air quality predictions through transfer learning, which boosts system efficiency, even in environments with limited data [11].

In sensor-based IoT applications, the majority of the energy budget is consumed during the transmission of collected data [12]. In the literature, various methods, such as data compression, data quantization, and data aggregation, are available [13]. However, we focus on PBDC due to its simplicity and proven effectiveness in scenarios involving periodic data collection [14].

In PBDC, the original sampling period required by the IoT application is preserved, but the total amount of transmitted data is reduced [15] by creating a forecasting model for the sensed data. This model is shared among both the IoT sensors and the collecting server. At the IoT device level, each new sample is checked to see if it falls within acceptable error margins. If it does, no action is taken (i.e. no data transmission occurs); if it doesn't, a new model is generated and sent to the sink. If the model accurately reflects the data trend, network communication, and energy can be significantly reduced, sometimes by as much as 99% [16], [17], [18], [19]. Since the early days of IoT research, various models have been explored. Probabilistic models [20], [21] approximate data with user-specified confidence but require domain experts to encode special data characteristics. Other techniques include linear regression [22], [14], autoregressive models [23], and Kalman filters [24], but these demand substantial memory and computational resources, making them challenging to implement on resource-constrained devices.

With the introduction of artificial intelligence tools, many researchers began exploring a novel approach to time series forecasting based on machine learning. They employed classical machine learning methods and models, such as support vector machines (SVM), random forests (RF), and backpropagation (BP), for time series forecasting tasks achieving better results [25], [26].

In the last decades, the rapid development of IoT technology has led to the generation of massive amounts of time series data. These extensive time series datasets often exhibit high dimensionality and nonlinearity, making it challenging to achieve the desired prediction accuracy using previous machine learning or statistical methods. To address this challenge, researchers have introduced deep learning methods such as LSTMs, Recurrent Neural Networks (RNNs), and Gated Recurrent Units (GRUs) to tackle the prediction and analysis of massive multivariate time series data achieving significant success [27], [28]. In the IoT domain, forecasting by means of deep-learning techniques has been prevalently used to reconstruct missing or corrupted data in order to enhance system reliability [29], [30], [31], [32]. The computational demands of deep learning tools present a significant challenge in meeting the constraints of tiny sensors. Consequently, in-sensor direct deep-learning forecasting approaches seem to be uncommon. Recently, Lalouani et al. proposed a study on the energy efficiency of an ECG wearable sensor through predictive sampling [33]. In particular, the authors used an LSTM network to assess whether a sample can be predicted using the previous ones, subject to a certain inaccuracy bound. Samples that can be accurately predicted are skipped, while the rest are buffered to be sent to the gateway. The authors simulate the energy efficiency of the method by computing the number of skipped samples starting from an ad-hoc created ECG dataset.

The various methods described so far offer significant advantages but present challenges limiting their effectiveness. For example, edge and IoT devices provide rapid responses but face scalability and reliability issues, which may be imprecise in complex environments. Data compression and aggregation techniques reduce transmission costs but introduce the risk of losing critical information. Finally, machine learning techniques ensure accurate predictions but require high computational resources, making them less suitable for IoT devices with limited capabilities.

This paper presents a low-cost IoT sensor platform capable of monitoring indoor air quality with an integrated PBDC algorithm. The hardware-software stack of the platform is described, and the performances are deeply characterized. Our work differs from Lalouani's in two ways: first, we introduce a prototype of a general-purpose IoT platform deployed on a real testbed for indoor monitoring; second, we deeply characterize the PBDC strategy on top of the real testbed by highlighting the tradeoff between measurement error and the ratio of saved packets with respect to a traditional approach.

III. The Proposed Architecture

In this section, we introduce the IoT sensor architecture, examining both its hardware and software components. We provide a detailed analysis of the main processing unit, the ESP32, and discuss the various environmental sensors installed. The main schematic of the device is reported in Fig. 1 while the 3D model, comprising the enclosure box, is shown

in Fig. 2. Additionally, we present the software stack that manages all operational phases of the IoT sensor. Lastly, we describe the PBDC system capable of dynamically choosing when sending data to reduce energy consumption.

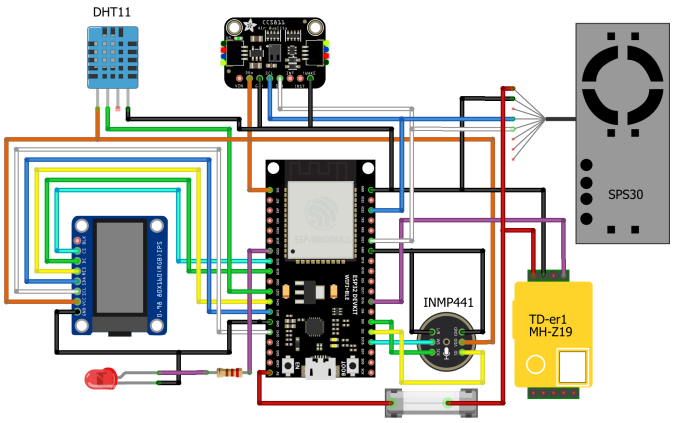

Fig. 1. Schematic of the IoT device together with the main sensors connected to the Espressif ESP32 development kit.

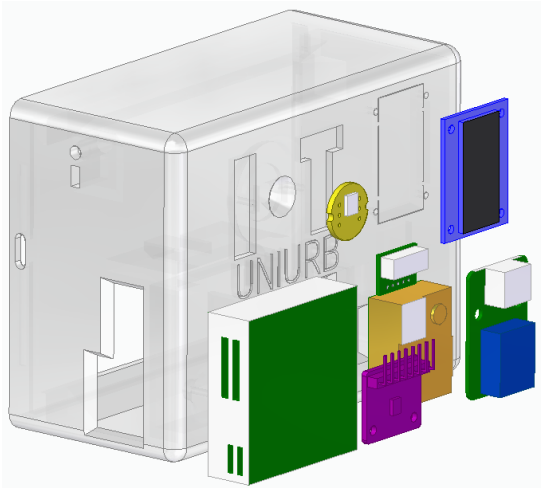

Fig. 2. 3D model view of the custom-made sensors enclosure box along with a 3D representation of the sensors installed in the device.

A. Main Processor

The main processor used within the IoT sensor is the ESP32. The ESP32 is a MicroController Unit (MCU) developed by Espressif Systems and renowned for its wide range of applications and its versatility in the field of IoT and embedded projects requiring wireless connectivity. Our application used the ESP32-wroom-32 DevKit variant, equipped with Wi-Fi and Bluetooth connectivity, an Xtensa dual-core processor, 400 KB of RAM, and 4 MB of flash memory [34]. Applications for the ESP32 are typically written using the Espressif IoT Development Framework (ESP-IDF) using the C or C++ language [35]. This framework offers a series of libraries that allow for the management of every aspect of the device, such as communication with the integrated GPIO pins, connecting to the Wi-Fi network, and enabling deep-sleep mode.

B. Sensors

We installed a series of sensors inside the device that can measure different physical parameters of the environment. The $\mathbf{CO_2}$ sensor measures the concentration of carbon dioxide using an infrared system. This sensor measures infrared light passing through a gas and absorbed proportionally to the concentration of CO_2 present in the air. In particular, this sensor is able to measure CO_2 values in a range from 0 to 5000 parts per million (ppm) and communicates with the MCU through UART and PWM protocols. The dust sensor measures the concentration of particles suspended in the air using laser optical technology. This sensor can detect particles of variable sizes, from $PM_{1.0}$ to $PM_{10.0}$ with great precision even in very low concentrations. The sensor is equipped with UART and I2C digital interface. The air quality sensor uses an array of chemical sensors that detect different gases to measure Volatile Organic Compounds (VOCs) and equivalent CO_2 (eCO_2) with high accuracy. The temperature and humidity sensor is capable of measuring temperatures in a range from 0 $^{\circ}C$ to 50 $^{\circ}C$ and humidity in a range from 20 %RH to 90 %RH at a frequency of 1 HZ and using a single wire communication protocol that makes integration with microcontrollers easy. Lastly, the noise sensor uses a microphone to sample the sounds around it and monitor the level of noise pollution in the environment. The microphone is capable of sampling sound at a frequency from 20 Hz to 20 kHz, characteristic of human hearing, reducing interference and noise to a minimum. The sensor uses the I2C protocol to transmit audio data to the microcontroller while consuming a few mW of power.

In addition to the sensors presented above, the platform also exports several communication buses of the MCU to allow connecting other external digital sensors. Moreover, the platform also holds a red-colored LED and a 0.96” RGB display. Their purpose is to show visual feedback to users and maintainers; for example, the LED can flash with a precise pattern to signal errors during operation. The display, conversely, can be used to periodically show text information related to the current air quality.

C. Software Stack

The sensor is designed to be a reliable and fully configurable platform while maintaining low power consumption, fast response time, and future expandability. The firmware was developed using the ESP-IDF framework based on the FreeRTOS [36] operating system and written entirely using C++. Fig. 3 shows a diagram of the main execution flows characterizing the software stack. In particular, the software is composed of three tasks: (i) measurement task, (ii) Telnet task, and (iii) OTA task, represented in the figure by three self-loops, each of which can execute in parallel using the two available cores and the internal FreeRTOS scheduler.

The first task we will talk about is the Telnet task; as the name implies, it is responsible for managing the Telnet service and offers remote access and configuration to the device. This service waits for new commands on port 23 and, as soon as a new one arrives, it executes it. The interface provided by the Telnet system is very similar to a common desktop Command Line Interface (CLI). Listing 1 shows the code for a structure representing a basic Telnet command. The `name` is a string

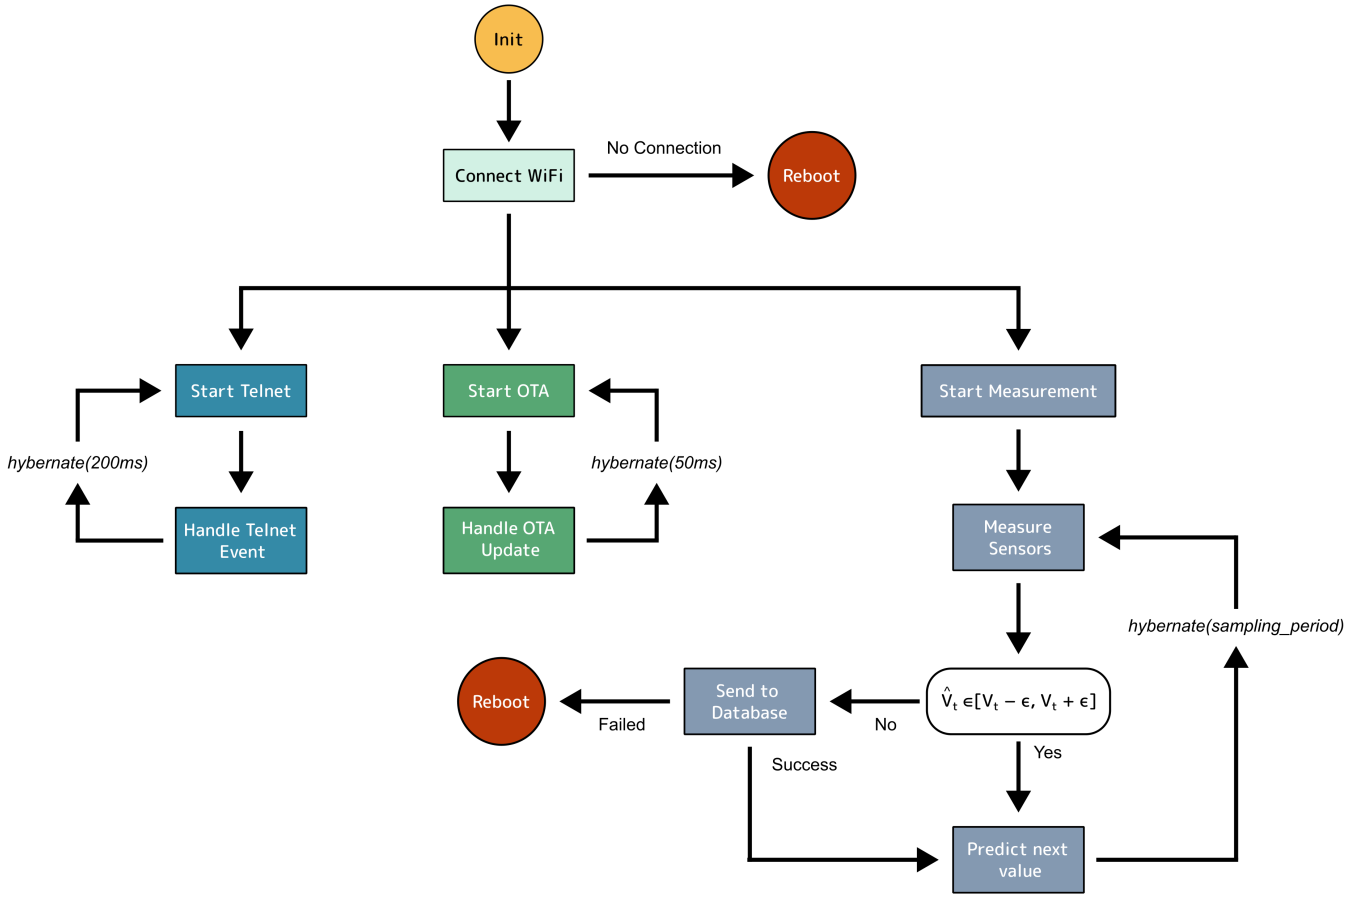

Fig. 3. The main execution flows of the software stack of the IoT sensor.

that uniquely identifies the command, while `run` is a pointer to a function executed when the command is called; finally, `help` is a human-readable string used by the *help* command describing the usage of all available commands.

```
typedef void (*cmd_on_run)(String cmd);

struct TelnetCommand {
  String     name;
  cmd_on_run run;
  String     help;
};
```

Listing 1: Code for a structure representing a generic telnet command.

In the code, a big static list is instantiated containing all the commands available. At runtime, the Telnet service parses the new events searching for one with a `name` that matches and executes its `run` function, otherwise, it returns a *"command not found"* error to the user. Several commands are available through Telnet allowing the configuration of critical device parameters, such as the device name, the calibration range for each sensor, the time interval between measurements, and even which sensors are enabled within the system. To ensure these parameters persist after the device is powered off, they are stored in the ESP32's internal flash memory and are accessed at every start.

The OTA task, on the other hand, implements an Over-The-Air (OTA) update service, enhancing the convenience of managing firmware updates. This service enables new firmware versions to be uploaded remotely via a Wi-Fi connection, eliminating the need to disassemble the device for manual flashing of the MCU. The OTA service continuously listens for updates on port 3232. When a new firmware version is detected, it initiates the update process by downloading the firmware and verifying its integrity and security. To facilitate this process, the ESP32's memory is divided into two partitions. One partition is dedicated to the boot process, while the other stores the new firmware. At the end of the update procedure, the system switches an internal flag to indicate which partition should be used for booting. The device then reboots, starting the new firmware, ensuring a seamless and efficient update process without physical intervention.

Lastly, the measurement task serves as the core function of the system. Its primary role is to periodically gather data from the various sensors installed on the device, process this information, and transmit it to the remote server for further analysis. Other than simply collecting and sending data, this task also implements the PBDC strategy.

Fig. 3 highlights several watchdog points, labeled as *Reboot*. To ensure a high level of reliability, these watchdog points will trigger a software reset if a failure occurs in the remote connection or during data transmission to the cloud. To prevent continuous resets in the event of persistent issues, a significant delay has been incorporated into the reboot routine. The software flow begins with a boot sequence that, after basic initialization, attempts to establish a remote Wi-Fi connection. If this attempt fails, the system schedules a delayed reboot to retry the process after some time. Conversely, if a stable connection is successfully established, the three main tasks are initiated. Another condition that triggers a reboot is the inability to transmit new data to the remote database. Since the primary function of this device is to collect sensor data, failing to transmit this data undermines its purpose. In such cases, it is preferable to reboot the device and restart with a clean execution.

The system makes use of InfluxDB [37] as its cloud server. Developed by InfluxData, InfluxDB is one of the most widely adopted Time Series Databases. This platform enables the efficient storage, retrieval, and analysis of collected data. Additionally, it supports the extraction of meaningful statistics and other key characteristics from the data.

D. Prediction-Based Data Collection

This section presents a detailed analysis of the PBDC strategy aimed at achieving an optimal trade-off between device performance and energy efficiency.

The strategy is set in a context in which the system is composed of several IoT nodes that periodically measure values from their sensors and send them to a central server that acts as a data sink. Additionally, we assume that the application running at the sink can tolerate a slight margin of error in the accuracy of the reported data. Unlike the ideal scenario where the sink periodically receives *exact* values in *all* packets, in this context, deviations from the exact values are acceptable, as long as their extent in terms of difference in value and time interval during which the deviation occurs are small enough.

The system's innovation lies in the ability to determine when a piece of data should be sent to the server using a machine learning-based forecasting model deployed simultaneously both in the node devices and in the central server.

To simplify the explanation, let's take as an example the case where there is only one central server and a single node with one CO_2 sensor that is read every N minutes. Let V_t be the CO_2 value read by the node at time t and let $\hat{V}_t$ be the value estimated by the regression model for the same time t. The tolerance value is defined as

$$\epsilon = max(\epsilon_{abs}, \frac{V_t}{100}\epsilon_{rel}) \quad (1)$$

where ϵ_{abs} is the absolute error and ϵ_{rel} is the relative error. The estimated value $\hat{V}_t$ is an acceptable approximation of V_t if it remains in the range defined by the tolerance value, $\hat{V}_t \in [V_t - \epsilon, V_t + \epsilon]$.

The combined use of ϵ_{abs} and ϵ_{rel} in the tolerance value is intended to further reduce inaccuracies. Using only the absolute error would risk considering all those minimally perceptible variations. Instead, by combining relative and absolute errors, the algorithm can adapt to all changes and avoid unnecessary communications with the remote server.

Algorithm 1 provides a detailed pseudo-code of the PBDC algorithm. The algorithm's internal state consists of the predicted value, $\hat{V}_t$, at time t and a window buffer with fixed-size ws. During each iteration, the current sensor value is read and stored into the variable V_t, and ϵ is calculated using Eq. 1. If $\hat{V}_t$ falls outside the tolerance range, V_t is transmitted to the server. Regardless of whether the value is sent, the circular buffer is shifted by one position, removing the oldest value and adding the current one. This updated buffer is then used by the regression model to predict the next value. The device then enters hibernation, awaiting the next iteration.

Algorithm 1 The pseudo-code of the PBDC algorithm.

State: buffer ▷ Circular buffer of size ws
State: $\hat{V}_t$ ▷ Predicted value at time t
Require: ϵ_{rel} ▷ Relative error
Require: ϵ_{abs} ▷ Absolute error

```
1:  while true do
2:      V_t ← measureSensor()
3:      ε ← max(ε_abs, (V_t/100) ε_rel)
4:      if V̂_t ∈ [V_t − ε, V_t + ε] then
5:          popFirst(buffer)
6:          appendLast(buffer, V̂_t)
7:          // No need to send
8:      else
9:          popFirst(buffer)
10:         appendLast(buffer, V_t)
11:         sendToServer(V_t)
12:     end if
13:     V̂_t ← predict(buffer)
14:     hybernate(sampling_period)
15: end while
```

Careful attention must be given to the buffer update logic and its role in the regression model. The regression model is deployed simultaneously on both the node and the remote server. To ensure synchronization between the two, predictions must be based on the same data in both environments. Therefore, when the node updates the buffer, it must ensure the server also has access to the same data. If the value V_t is outside the tolerance range (i.e. it has been sent to the server), its value is added to the buffer. However, if V_t is within the tolerance range (i.e. it has not been sent), the predicted value is used instead. This approach guarantees that the sensor will predict future values starting from the same history values held by the server.

In this work, we experimented with different configurations of the deep learning forecasting model. Table I shows the details of the three models, namely: *Model 1*, *Model 2*, and *Model 3*. Model 1 consists of a network with a single LSTM node with 10 internal units followed by a single Dense layer. Model 2 is a hybrid model, consisting of two CNN layers, both with 64 filters, followed by one LSTM node with 10 units and a Dense layer. Finally, Model 3 consists of two LSTM nodes both with 10 units followed by a Dense layer. As seen from their structures all the models are relatively small in size, in

fact, Model 2, which is the largest, has only 14,019 parameters and a weight of 54.76 KB.

For training and testing the models, we used a dataset consisting of data collected from four different types of sensors. In particular CO_2, noise, $PM_{2.5}$, and radioactivity. These data were collected using a version of the proposed IoT device with the PBDC strategy turned off. In this device version, the sensors are read once every 10 minutes, and the real data are always sent to the central server without predicting the next values. For each sensor type, we divided the time series into training, testing, and validation sets. We also used a different set of time series to measure accurately the global performances of the PBDC algorithm on previously unseen data. The forecasting models were trained using a supervised learning approach. During training, we iterated over the dataset to create sliding windows of length ws, where each window was composed of consecutive data points serving as the history input. The value immediately following the window served as the target for prediction. This sliding window technique effectively transforms the time series into a set of input-output pairs, allowing the model to capture temporal dependencies and trends.

TABLE I. DEEP-LEARNING MODELS ADOPTED TO IMPLEMENT THE PBDC STRATEGY

Net ID	Net Type	Net Structure	Parameters	Net Size
Model 1	1LSTM_1D	10U_1D	491	1.92 KB
Model 2	2CNN_1LSTM_1D	64F_64F_10U_1D	14,019	54.76 KB
Model 3	2LSTM_2D	10U_10U_30D_1D	1,681	6.57 KB

IV. CASE STUDY AND RESULTS

As a case study, we deployed several IoT sensor prototypes in a two-centuries building (Collegio Raffaello) used as a university campus in the city of Urbino - Italy. In particular, the second floor of the building currently houses the degree program in Computer Science and the degree program in Foreign Languages and Cultures of the University of Urbino.

The objective of this deployment is to monitor physical parameters within the university classroom which are frequently occupied by several hundred students attending their daily lectures. Precisely, various environmental parameters, including temperature, humidity, noise level, CO_2 concentration, and particulate matter are continuously measured and stored on a centralized server for data analysis.

In this section, we provide results from two sets of experiments. First of all, we present some results related to the monitoring of the environmental parameters during daily activities, and then we focus on the performance of the PBDC capability implemented on the sensors.

A. Monitoring of the Daily Activities

In this section, we report a representative scenario of the use of the proposed IoT sensors, showing that our solution performs efficiently while used to monitor the environmental parameters in indoor buildings.

The testbed, was deployed in the Collegio Raffaello at the end of 2021 and, in the following years, it collected more than 15,000 measures a day. Each day at 7:30 a.m., the entrances to the second floor of building are opened by a guardian, allowing access to students and faculty. University lessons are traditionally structured into two-hour blocks, with the first session beginning at 9:00 a.m. and concluding at 11:00 a.m. A second session follows, ending with a lunch break at 1:00 p.m. Additional sessions may commence in the afternoon, starting at 2:00 p.m. Consequently, the most significant influx of individuals is expected between approximately 8:30 a.m. and 9:00 a.m., as well as between 1:30 p.m. and 2:00 p.m.

As a representative example, we report in Fig. 4 the noise level, the CO_2, and the PM_{10} concentrations measured during a whole day in a classroom. In all three cases, the value of the signals rapidly grows after 9.00 a.m. at the start of lessons. In particular, the noise level instantly reflects the room occupancy. At the same time, both CO_2 and PM_{10} concentrations show an evident inertia that determines a delayed response with respect to the arrival of people. This is undoubtedly due to the fact that the people in the room are sources of both particulate matter and carbon dioxide (as a result of breathing), which accumulate slowly after their arrival. In fact, the Collegio Raffaello does not have an integrated air change system which is achieved by manually opening the doors or the windows.

As expected, the qualitative correlation between these three variables is very strong as all of them can be considered as the results of human activity. It is also interesting to note the delay of about two hours, with respect to the start of the lesson, with which the CO_2 and PM_{10} concentrations reach the maximum value.

B. PBDC Performances

To assess the performance of the PBDC implemented on the IoT sensor, we first evaluated the prediction capability of the proposed deep-learning models when forecasting the following environmental parameters: CO_2, noise level, PM_{10}, and radioactivity. The last parameter was collected by externally connecting a Geiger counter to the digital bus of the sensor platform.

Fig. 5 reports the models' forecasting performance in terms of MAE for the three models considered when varying the size of the input window (ws). Concerning CO_2 data (Fig. 5a), models 1 and 3 appear to demonstrate superior performance (lower MAE) compared to model 2. Moreover, we must highlight that the forecasting performance of all three models is highly commendable, as evidenced by the consistently low MAE values below 34 ppm, while the measurement range traditionally spans from 450 to 2500 ppm. On the other hand, the forecasting performance does not appear to be significantly affected by the length of the input window, remaining almost constant.

These same observations can be associated with the results of the noise (Fig. 5b) and particulate matter (Fig. 5c) while the case of radioactivity appears to be more complex (Fig. 5d). Here, Model 3 shows a sensible performance reduction for ws corresponding to 9 and 11 samples while the others remain stable. The remaining experiments reported in this work were conducted on the CO_2 dataset using a window size ws of 5 samples as it represents a good performance point for each model.

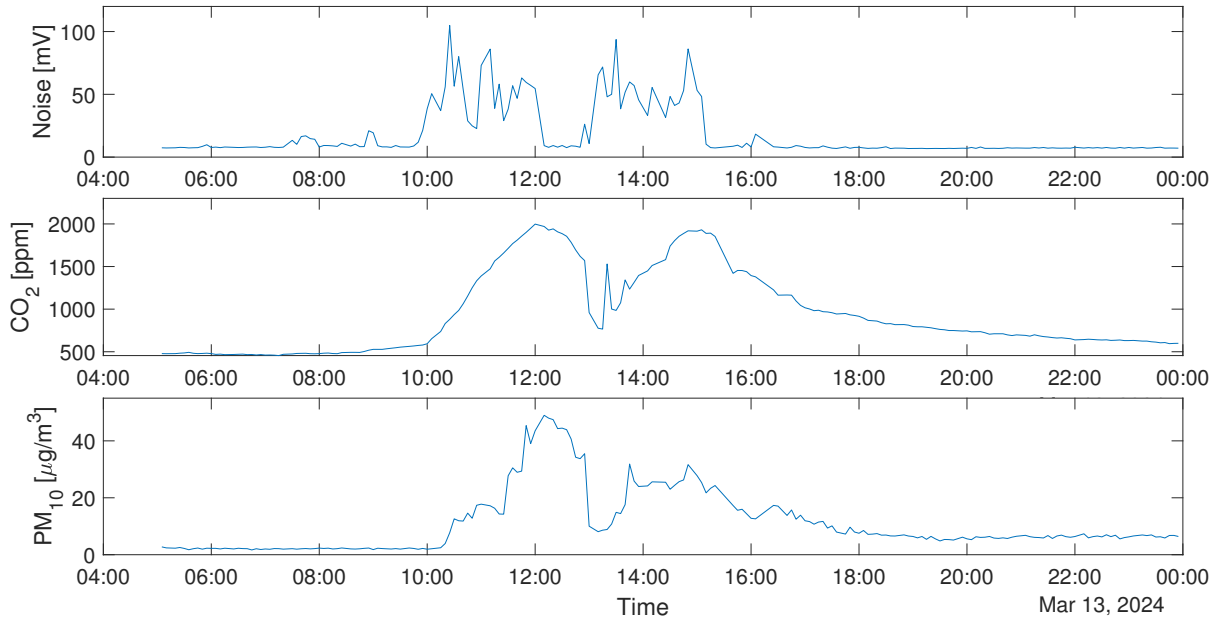

Fig. 4. Environmental parameters (noise level, CO_2, and PM_{10} concentrations) measured during a single day in a university classroom.

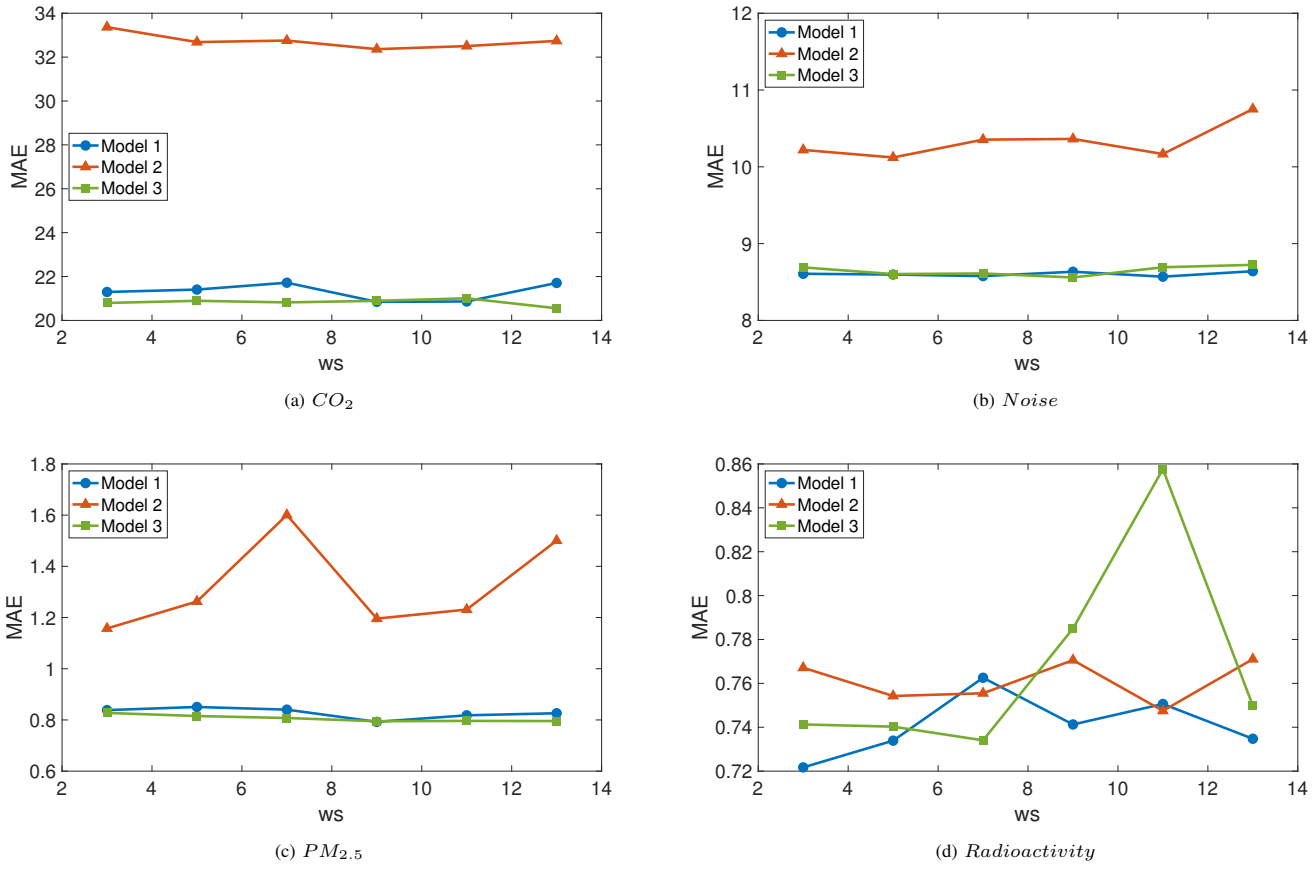


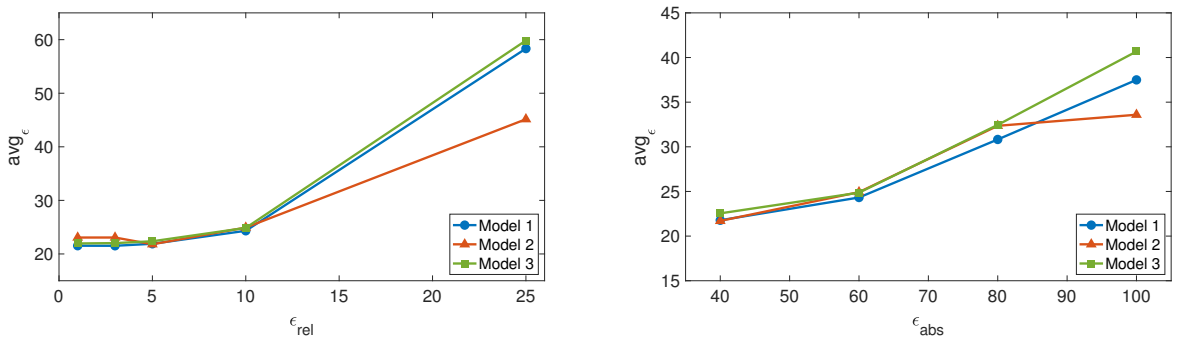
(a) CO_2

(b) $Noise$

(c) $PM_{2.5}$

(d) $Radioactivity$

Fig. 5. Forecasting performance in terms of MAE for the three models considered in this study when varying the size of the input window (ws). The four plots represent performance in forecasting, respectively, CO_2, noise, $PM_{2.5}$, and radioactivity.



(a) avg_ϵ Vs ϵ_{rel} (b) avg_ϵ Vs ϵ_{abs}

Fig. 6. Average absolute error (avg_ϵ) introduced by the PBDC strategy when varying both the relative error (ϵ_{rel}) and the absolute error (ϵ_{abs}) parameters.

Fig. 6 shows the average absolute error (avg_ϵ) introduced by the PBDC strategy when varying both the ϵ_{rel} and the ϵ_{abs} parameters. Notice that, this kind of error represents the average uncertainty perceived by the collection server due to the application of the strategy. The two plots show that, in both cases, increasing the acceptable error magnitude increases the average error of the collected data. It is noteworthy that the growth observed in the case of the ϵ_{rel} parameter appears to be more than linear. In contrast, the analogous behavior in the case of the ϵ_{abs} parameter is relatively less pronounced.

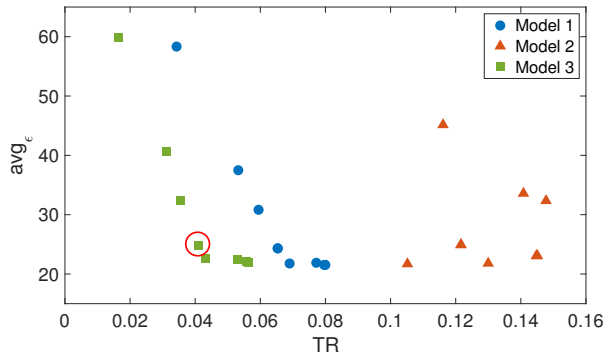


Fig. 7. Pareto chart reporting the average absolute error (avg_ϵ) vs. The transmission ratio (TR) achieved by different models configurations. The red circle identifies the point that minimizes both metrics.

The counterpart of increasing the acceptable error magnitude is the reduction of the number of transmitted packets with a consequent reduction in energy and network congestion. Obviously, this reduction also depends on the prediction capability of the forecasting model, as the higher the accuracy of the prediction, the lower the number of packets that are required to be transmitted.

In order to characterize the tradeoff between the error introduced by the PBDC strategy and the number of saved packets, for each previously reported experiment, we calculated the transmission ratio (TR) as the ratio between the number of packets sent with and without the PBDC. Fig. 7 plots a Pareto chart where each configuration of the PBDC strategy is represented by a single point. Different colors identify the three forecasting models under consideration, while the coordinates of the points are represented by the corresponding avg_ϵ and TR. Each configuration differs in terms of ws, ϵ_{rel}, and ϵ_{abs}. The point highlighted with a red circle identifies the configuration which minimizes the average error and the transmission rate at the same time. In particular, the selected point determines a TR of about 4%, which corresponds to a reduction in transmitted packets of approximately 96% while introducing an average error of about 25 ppm in the CO_2 measurement. This means that if the design of such an IoT application can tolerate an average error of that magnitude, the energy saved in packet transmission can reach up to 96%. For completeness, the corresponding parameter values were: $ws = 5$, $\epsilon_{rel} = 10$, and $\epsilon_{abs} = 60$.

V. Conclusion

In indoor monitoring, IoT systems collect real-time data to improve comfort, health, and energy efficiency. However, traditional systems consume excessive power due to continuous data collection. Machine learning allows IoT devices to predict environmental changes and adapt data collection, optimizing energy use. This shift to Prediction-Based Data Collection improves IoT sustainability and effectiveness. In this paper, we presented a low-cost IoT sensor framework that makes use of deep-learning tools to forecast measured data and change the sampling rate accordingly in order to reduce power consumption and data transmission. Experiments show the system can save up to 96% of energy while maintaining data quality.

One key limitation of our approach is that, at each iteration, the edge system still needs to perform sensor readings to determine whether the data needs to be transmitted to the server. This requirement of continuous local sampling limits the potential energy savings, as sensor readings still consume power even if the data is not ultimately sent to the server. A possible future improvement could involve developing a method to completely skip certain measurements on the edge device itself, relying solely on predicted values when conditions are stable. This approach would further reduce energy consumption by allowing the device to enter deep sleep mode, eliminating unnecessary sensor activations, and maximizing efficiency.

Reliable Logistic Regression for Credit Card Fraud Detection

Yassine Hmidy, Mouna Ben Mabrouk
Sogetilabs at Capgemini, Paris, France

***Abstract*—Credit card fraud poses a significant threat to financial institutions and consumers worldwide, necessitating robust and reliable detection methods. Traditional classification models often struggle with the challenges of imbalanced datasets, noise, and outliers inherent in transaction data. This paper introduces a novel fraud detection approach based on a discrete non-additive integral with respect to a non-monotonic set function. This method not only enhances classification performance but also provides an interval-valued output that serves as an index of reliability for each prediction. The width of this interval correlates with the prediction error, offering valuable insights into the confidence of the classification results. Such an index is crucial in high-stakes scenarios where misclassifications can have severe consequences. The model is validated through extensive experiments on credit card transaction datasets, demonstrating its effectiveness in handling imbalanced data and its superiority over traditional models in terms of accuracy and reliability assessment. However, potential challenges such as increased computational complexity and the need for careful parameter tuning may affect scalability and real-time implementation. Addressing these challenges could further enhance the practical applicability of the proposed method in fraud detection systems.**

***Keywords*—Credit card fraud; fraud detection; computational complexity**

I. Introduction

In today's digital economy, credit card transactions have become ubiquitous due to their convenience and global acceptance. However, the rise in electronic transactions has been paralleled by an increase in fraudulent activities, posing significant challenges to financial institutions and consumers alike. Credit card fraud not only results in substantial financial losses but also undermines customer trust and the integrity of payment systems [9]. The increasing prevalence of online transactions and the convenience of credit card payments have created opportunities for fraudsters to exploit vulnerabilities in financial systems [1], [10]. Global fraud losses reached £21.84 billion in 2015 alone, emphasizing the urgent need for effective fraud detection mechanisms [14].

A. Challenges in Credit Card Fraud Detection

Detecting fraudulent transactions is a complex task due to several inherent challenges:

- **Imbalanced Datasets**: Fraudulent transactions represent a minute fraction of the total transaction volume, leading to highly imbalanced datasets. This imbalance poses significant difficulties for machine learning models, which may become biased toward the majority class and fail to detect fraudulent activities effectively [12], [14].
- **Data Noise and Outliers**: Transaction data often contain noise and outliers, which can adversely affect the performance of detection algorithms, resulting in increased false positives and negatives [13].
- **Concept Drift**: The strategies employed by fraudsters continuously evolve, causing changes in the underlying data distribution—a phenomenon known as concept drift. Models must adapt over time to maintain their effectiveness in detecting new fraud patterns [12].

B. Existing Approaches and Limitations

Various machine learning techniques have been applied to address credit card fraud detection:

- **Statistical Methods**: Logistic regression has been widely used due to its simplicity and interpretability, modeling the probability of fraudulent transactions based on historical data [3]. However, logistic regression may struggle with nonlinear relationships and is sensitive to data imbalance, potentially limiting its effectiveness in fraud detection scenarios [3].
- **Machine Learning Algorithms**: Supervised learning algorithms such as support vector machines [8], random forests [6], and ensemble methods like AdaBoost and majority voting [4] have demonstrated improved detection rates by capturing complex patterns in the data.
- **Deep Learning Techniques**: Deep learning approaches, including autoencoders and restricted Boltzmann machines, have been employed to detect anomalies and reconstruct input data for identifying fraudulent transactions [2], [5].
- **Aggregation Strategies**: Strategies incorporating aggregation mechanisms and feedback loops aim to enhance the adaptability and accuracy of fraud detection systems [1].

Despite these advancements, a critical limitation remains: many existing models focus primarily on maximizing classification accuracy without providing a measure of confidence or reliability for individual predictions [11]. In high-stakes environments like fraud detection, misclassifying a legitimate transaction as fraudulent can lead to customer dissatisfaction and loss of trust, while failing to detect actual fraud results in financial losses and potential legal implications [10]. Therefore, there is a need for models that not only improve detection rates but also quantify the uncertainty associated with each prediction.

C. Main Contributions

This paper proposes a novel approach to credit card fraud detection using a discrete Choquet integral with respect to a non-monotonic set function, specifically leveraging the MacSum aggregation model. This method outputs an interval-valued prediction for each transaction, where the width of the interval correlates with the prediction error. This interval serves as an index of reliability, providing valuable insights into the confidence level of each classification decision.

The contributions can be summarized as follows:

- This paper introduce the application of the MacSum aggregation model within the discrete Choquet integral framework to the problem of credit card fraud detection, offering interval-valued outputs that reflect prediction reliability.
- This paper addresses the challenges of data imbalance and concept drift by incorporating robust preprocessing techniques and adaptive mechanisms within the model.
- The approach is validated on benchmark datasets, comparing its performance against traditional classifiers, including logistic regression and state-of-the-art methods, demonstrating improved accuracy and reliability assessment.

II. Preliminaries

This section introduces the fundamental concepts, notations, and definitions necessary to understand the proposed model. It provides an overview of set functions, the discrete Choquet integral which are needed to compute the MacSum aggregation.

A. Notations and Definitions

- $\Omega = \{1, \ldots, N\} \subset \mathbb{N}$: a finite index set.
- For all $A \subseteq \Omega$, A^c denotes the complement of A in Ω, i.e., $A^c = \Omega \setminus A$.
- $\mathbb{R}$: the set of real numbers.
- A vector is a function $\boldsymbol{x} : \Omega \to \mathbb{R}$, defined by a discrete subset of $\mathbb{R}^N$, denoted $\boldsymbol{x} = (x_1, \ldots, x_N) \in \mathbb{R}^N$.
- $\overline{\underline{x}} = [\underline{x}, \overline{x}]$: a real interval where $\underline{x} \in \mathbb{R}$ is the lower bound and $\overline{x} \in \mathbb{R}$ is the upper bound.
- $\mathbb{IR}$: the set of real intervals.
- A *set function* is a function $\mu : 2^\Omega \to \mathbb{R}$ that assigns a real value to any subset of Ω. The *complementary set function* μ^c associated with μ is defined by:

$$\mu^c(A) = \mu(\Omega) - \mu(A^c), \quad \forall A \subseteq \Omega. \tag{1}$$

  Usually, it is assumed that $\mu(\emptyset) = 0$, where $\emptyset$ is the empty set of Ω.

- A set function μ is said to be *submodular* if, for all $A, B \subseteq \Omega$, the following inequality holds:

$$\mu(A \cup B) + \mu(A \cap B) \leq \mu(A) + \mu(B). \tag{2}$$

- A set function μ is said to be *additive* if, for all $A, B \subseteq \Omega$, it holds that:

$$\mu(A \cup B) + \mu(A \cap B) = \mu(A) + \mu(B). \tag{3}$$

- If a set function μ is submodular, then its complementary μ^c is supermodular.

B. Discrete Choquet Integral

Classical integration theory involves additive measures. However, in many real-world applications, especially in decision making, the assumption of additivity does not hold due to interactions among criteria. Non-additive integrals provide a framework for integrating functions with respect to non-additive set functions (also known as capacities or fuzzy measures) [16].

A *non-additive integral* is an integral where the underlying set function is not necessarily additive. This allows for modeling situations where the whole is not simply the sum of its parts, capturing phenomena such as synergy, redundancy, and interactions among elements.

Among the most widely used non-additive integrals are the Choquet integral and the Sugeno integral. This work, focuses on the discrete Choquet integral due to its ability to model the aggregation of information while accounting for the interactions among criteria.
The discrete Choquet integral with respect to a set function μ is denoted $\check{\mathbb{C}}_\mu$ [15] and is defined for any vector $\boldsymbol{x} \in \mathbb{R}^N$ by:

$$\check{\mathbb{C}}_\mu(\boldsymbol{x}) = \sum_{k=1}^{N} x_{(k)} \left(\mu(A_{(k)}) - \mu(A_{(k+1)}) \right), \tag{4}$$

where:

- $(\cdot)$ denotes the permutation that sorts the elements of $\boldsymbol{x}$ in increasing order:

$$x_{(1)} \leq x_{(2)} \leq \cdots \leq x_{(N)}. \tag{5}$$

- $A_{(k)}$ ($k \in \{1, \ldots, N\}$) are the subsets (also called coalitions) defined by:

$$A_{(k)} = \{(k), \ldots, (N)\}, \quad A_{(N+1)} = \emptyset. \tag{6}$$

  Here, (k) indicates the index corresponding to the k-th smallest element in the sorted vector.

If a set function μ is submodular, then for all $\boldsymbol{x} \in \mathbb{R}^N$, it holds that [16]:

$$\check{\mathbb{C}}_\mu(\boldsymbol{x}) \geq \check{\mathbb{C}}_{\mu^c}(\boldsymbol{x}). \tag{7}$$

C. MacSum Aggregation

Let $\boldsymbol{\theta} \in \mathbb{R}^N$ be a parameter vector used in the aggregation.

1) Definition of the MacSum Set Functions: The MacSum set function $\nu_{\boldsymbol{\theta}}$ and its complementary set function $\nu^c_{\boldsymbol{\theta}}$ are defined as follows [17]:

For all $A \subseteq \Omega$,

$$\nu_{\boldsymbol{\theta}}(A) = \max_{i \in A} \theta_i^+ + \min_{i \in \Omega} \theta_i^- - \min_{i \in A^c} \theta_i^-, \tag{8}$$

$$\nu^c_{\boldsymbol{\theta}}(A) = \min_{i \in A} \theta_i^- + \max_{i \in \Omega} \theta_i^+ - \max_{i \in A^c} \theta_i^+, \tag{9}$$

with, for all $i \in \Omega$:

$$\theta_i^+ = \max(0, \theta_i), \quad \theta_i^- = \min(0, \theta_i). \tag{10}$$

The MacSum set function $\nu_{\boldsymbol{\theta}}$ is a parametric set function that is submodular [17]. Therefore, its corresponding Choquet integral satisfies:

$$\check{\mathbb{C}}_{\nu_{\boldsymbol{\theta}}}(\boldsymbol{x}) \geq \check{\mathbb{C}}_{\nu_{\boldsymbol{\theta}}^c}(\boldsymbol{x}), \quad \forall \boldsymbol{x} \in \mathbb{R}^N. \tag{11}$$

Using the MacSum set functions, the MacSum aggregation $\mathcal{A}_{\nu_{\boldsymbol{\theta}}}(\boldsymbol{x})$ for any vector $\boldsymbol{x} \in \mathbb{R}^N$ is defined as:

$$\mathcal{A}_{\nu_{\boldsymbol{\theta}}}(\boldsymbol{x}) = [\check{\mathbb{C}}_{\nu_{\boldsymbol{\theta}}^c}(\boldsymbol{x}), \check{\mathbb{C}}_{\nu_{\boldsymbol{\theta}}}(\boldsymbol{x})]. \tag{12}$$

This means that the MacSum aggregation produces an interval-valued output, where:

- $\underline{y} = \check{\mathbb{C}}_{\nu_{\boldsymbol{\theta}}^c}(\boldsymbol{x})$ is the lower bound of the aggregation.
- $\overline{y} = \check{\mathbb{C}}_{\nu_{\boldsymbol{\theta}}}(\boldsymbol{x})$ is the upper bound of the aggregation.

2) Relationship with Linear Aggregations: Let $\boldsymbol{\psi} \in \mathbb{R}^N$. The linear parametric set function $\lambda_{\boldsymbol{\psi}}$ is defined as:

$$\lambda_{\boldsymbol{\psi}}(A) = \sum_{i \in A} \psi_i, \quad \forall A \subseteq \Omega. \tag{13}$$

An important property of the MacSum aggregation is that it dominates a set of linear parametric set functions [17]. Specifically, the set of all parameter vectors $\boldsymbol{\psi}$ such that $\lambda_{\boldsymbol{\psi}}$ is dominated by the MacSum set functions with respect to the parameter $\boldsymbol{\theta}$ is:

$$\mathcal{M}(\boldsymbol{\theta}) = \{\boldsymbol{\psi} \in \mathbb{R}^N \mid \forall A \subseteq \Omega, \\ \nu_{\boldsymbol{\theta}}^c(A) \leq \lambda_{\boldsymbol{\psi}}(A) \leq \nu_{\boldsymbol{\theta}}(A)\}.$$

This set $\mathcal{M}(\boldsymbol{\theta})$ is convex [17], which means that for any $\boldsymbol{\psi}_1, \boldsymbol{\psi}_2 \in \mathcal{M}(\boldsymbol{\theta})$ and any $\gamma \in [0, 1]$, the combination $\gamma\boldsymbol{\psi}_1 + (1-\gamma)\boldsymbol{\psi}_2$ also belongs to $\mathcal{M}(\boldsymbol{\theta})$.

The linear aggregation associated with $\lambda_{\boldsymbol{\psi}}$ is given by:

$$\mathcal{A}_{\lambda_{\boldsymbol{\psi}}}(\boldsymbol{x}) = \check{\mathbb{C}}_{\lambda_{\boldsymbol{\psi}}}(\boldsymbol{x}) = \sum_{i \in \Omega} \psi_i \cdot x_i. \tag{14}$$

Therefore, the MacSum aggregation can be interpreted as:

$$\mathcal{A}_{\nu_{\boldsymbol{\theta}}}(\boldsymbol{x}) = \left\{\mathcal{A}_{\lambda_{\boldsymbol{\psi}}}(\boldsymbol{x}) \;\middle|\; \boldsymbol{\psi} \in \mathcal{M}(\boldsymbol{\theta})\right\} \tag{15}$$

$$= \left[\underline{\mathcal{A}}_{\nu_{\boldsymbol{\theta}}}(\boldsymbol{x}),\ \overline{\mathcal{A}}_{\nu_{\boldsymbol{\theta}}}(\boldsymbol{x})\right], \tag{16}$$

with:

$$\underline{\mathcal{A}}_{\nu_{\boldsymbol{\theta}}}(\boldsymbol{x}) = \min_{\boldsymbol{\psi} \in \mathcal{M}(\boldsymbol{\theta})} \mathcal{A}_{\lambda_{\boldsymbol{\psi}}}(\boldsymbol{x}),$$
$$\overline{\mathcal{A}}_{\nu_{\boldsymbol{\theta}}}(\boldsymbol{x}) = \max_{\boldsymbol{\psi} \in \mathcal{M}(\boldsymbol{\theta})} \mathcal{A}_{\lambda_{\boldsymbol{\psi}}}(\boldsymbol{x}).$$

This set is convex [17], meaning that:

- For any $\boldsymbol{\psi} \in \mathcal{M}(\boldsymbol{\theta})$, there exists $y \in \mathcal{A}_{\nu_{\boldsymbol{\theta}}}(\boldsymbol{x})$ such that $y = \mathcal{A}_{\lambda_{\boldsymbol{\psi}}}(\boldsymbol{x})$.
- For any $y \in \mathcal{A}_{\nu_{\boldsymbol{\theta}}}(\boldsymbol{x})$, there exists $\boldsymbol{\psi} \in \mathcal{M}(\boldsymbol{\theta})$ such that $y = \mathcal{A}_{\lambda_{\boldsymbol{\psi}}}(\boldsymbol{x})$.

3) Learning the MacSum Aggregation: As the MacSum aggregation is a set of linear aggregations whose bounds depend on the same parameter $\boldsymbol{\theta}$, it is possible to learn a set of linear aggregations by learning the MacSum aggregation through updating the parameter $\boldsymbol{\theta}$ using standard optimization methods, such as gradient descent, as shown in [18].

Adjusting $\boldsymbol{\theta}$, effectively adjust the set $\mathcal{M}(\boldsymbol{\theta})$, and hence the interval $\mathcal{A}_{\nu_{\boldsymbol{\theta}}}(\boldsymbol{x})$, allowing the model to capture the underlying relationships in the data.

III. Proposed Model

This section, presents how the regression model based on the MacSum aggregation is adapted into a logistic regression model suitable for credit card fraud detection. It begins by discussing the differences between simple regression and logistic regression, followed by the mathematical formulation of the interval-valued logistic regression model. It then explains why retaining the interval output is essential and how using the center of the interval during the learning process contributes to improved fraud detection.

A. From Linear Regression to Logistic Regression

1) Linear Regression: Linear regression models aim to predict a continuous target variable $y \in \mathbb{R}$ based on a set of input features $\boldsymbol{x} \in \mathbb{R}^N$. The general form of a linear regression model is:

$$y = \boldsymbol{\beta}^\top \boldsymbol{x} + \varepsilon, \tag{17}$$

where $\boldsymbol{\beta} \in \mathbb{R}^N$ is the vector of regression coefficients, and ε is the error term assumed to be normally distributed.

2) Logistic Regression: In contrast, logistic regression is used for classification problems, particularly binary classification, where the target variable $y \in \{0, 1\}$ represents class labels. Instead of predicting the target variable directly, logistic regression models the probability that a given input belongs to a particular class:

$$P(y = 1 \mid \boldsymbol{x}) = \sigma(\boldsymbol{\beta}^\top \boldsymbol{x}), \tag{18}$$

where $\sigma(\cdot)$ is the logistic (sigmoid) function defined as:

$$\sigma(z) = \frac{1}{1 + e^{-z}}. \tag{19}$$

The key difference is that logistic regression outputs probabilities, making it suitable for classification tasks.

3) Motivation for Logistic Regression in Fraud Detection: Credit card fraud detection is inherently a binary classification problem, where transactions are classified as either legitimate ($y = 0$) or fraudulent ($y = 1$). Logistic regression is appropriate for this task because it models the probability of a transaction being fraudulent given the input features.

B. Interval-Valued Logistic Regression with MacSum Aggregation

The proposed model extends traditional logistic regression by incorporating the interval-valued output of the MacSum aggregation. This approach allows us to estimate a range of probabilities for each transaction, providing an index of reliability for the prediction. During the learning process,

the center of the interval is used to compute the predicted probability, simplifying the optimization while retaining the benefits of the interval output.

1) Interval Output from MacSum Aggregation: Recall that the MacSum aggregation $\mathcal{A}_{\nu_{\boldsymbol{\theta}}}(\boldsymbol{x})$ produces an interval-valued output:

$$\overline{\underline{y}} = [\underline{y}, \overline{y}] = \left[\check{\mathbb{C}}_{\nu^c_{\boldsymbol{\theta}}}(\boldsymbol{x}), \check{\mathbb{C}}_{\nu_{\boldsymbol{\theta}}}(\boldsymbol{x})\right], \tag{20}$$

where $\underline{y}$ and $\overline{y}$ are the lower and upper bounds, respectively, obtained from the Choquet integrals with respect to the complementary set functions $\nu^c_{\boldsymbol{\theta}}$ and $\nu_{\boldsymbol{\theta}}$.

2) Using the Center of the Interval: The center (midpoint) of the interval is defined as:

$$c_y = \frac{\underline{y} + \overline{y}}{2}. \tag{21}$$

Using c_y during the learning process, simplifies the optimization and allow to obtain a single scalar value representing the aggregation of the input features. This scalar retains information from both bounds of the interval.

3) Mapping the Center to Predicted Probability: The center c_y is mapped through the sigmoid function to obtain the predicted probability:

$$\hat{p} = \sigma(c_y) = \sigma\left(\frac{\underline{y} + \overline{y}}{2}\right). \tag{22}$$

This probability $\hat{p}$ estimates the likelihood that the transaction is fraudulent.

4) Retaining the Interval for Reliability Assessment: Although the center c_y is used for learning, the interval $\overline{\underline{y}}$ is retained to assess the reliability of each prediction. The width of the interval is given by:

$$\Delta y = \overline{y} - \underline{y}. \tag{23}$$

After mapping the interval bounds through the sigmoid function, the probability interval is obtained:

$$\overline{\underline{p}} = [\underline{p}, \overline{p}] = \left[\sigma(\underline{y}), \sigma(\overline{y})\right], \tag{24}$$

with interval width:

$$\Delta p = \overline{p} - \underline{p}. \tag{25}$$

The width Δp serves as an index of reliability, with narrower intervals indicating higher confidence.

C. Mathematical Formulation

1) Parameter Estimation: The aim is to estimate the parameter vector $\boldsymbol{\theta} \in \mathbb{R}^N$ that defines the MacSum set functions $\nu_{\boldsymbol{\theta}}$ and $\nu^c_{\boldsymbol{\theta}}$. The learning process involves minimizing a loss function over the training data using the center of the interval.

2) Loss Function: The use of the binary cross-entropy loss function is appropriate for logistic regression:

$$L(\theta) = -\frac{1}{M}\sum_{i=1}^{M}\Big[y^{(i)}\log\hat{p}^{(i)} + (1-y^{(i)})\log\left(1-\hat{p}^{(i)}\right)\Big], \tag{26}$$

where:

- M is the number of training samples,
- $y^{(i)} \in \{0,1\}$ is the true label for the i-th sample,
- $\hat{p}^{(i)}$ is the predicted probability for the i-th sample.

3) Gradient of the Loss Function with Respect to Parameters: Updating the parameters θ using gradient descent involves to compute the gradient of the loss function $L(\theta)$ with respect to θ. The gradient with respect to the k-th parameter θ_k is given by:

$$\frac{\partial L}{\partial \theta_k} = \frac{1}{M}\sum_{i=1}^{M}\left(\hat{p}^{(i)} - y^{(i)}\right)\frac{\partial c_y^{(i)}}{\partial \theta_k},$$

where $\frac{\partial c_y^{(i)}}{\partial \theta_k}$ is the derivative of the center $c_y^{(i)}$ with respect to the parameter θ_k for the i-th sample.

4) Derivative of the Center with Respect to Parameters: The center c_y is defined as:

$$c_y = \frac{\overline{y} + \underline{y}}{2},$$

so its derivative with respect to θ_k is:

$$\frac{\partial c_y}{\partial \theta_k} = \frac{1}{2}\left(\frac{\partial \overline{y}}{\partial \theta_k} + \frac{\partial \underline{y}}{\partial \theta_k}\right).$$

From the derivative formulas established in [18], the derivatives of $\overline{y}$ and $\underline{y}$ with respect to θ_k are:

a) Derivative of the Lower Bound $\underline{y}$:

$$\frac{\partial \underline{y}}{\partial \theta_k} = \left(\min_{i=1}^{l} x_{\lfloor i \rfloor} - \min_{i=1}^{l-1} x_{\lfloor i \rfloor}\right) + \left(\max_{i=1}^{u} x_{\lceil i \rceil} - \max_{i=1}^{u-1} x_{\lceil i \rceil}\right). \tag{27}$$

b) Derivative of the Upper Bound $\overline{y}$:

$$\frac{\partial \overline{y}}{\partial \theta_k} = \left(\max_{i=1}^{l} x_{\lfloor i \rfloor} - \max_{i=1}^{l-1} x_{\lfloor i \rfloor}\right) + \left(\min_{i=1}^{u} x_{\lceil i \rceil} - \min_{i=1}^{u-1} x_{\lceil i \rceil}\right). \tag{28}$$

Here:

- $\lfloor \cdot \rfloor$ sorts θ in decreasing order: $\theta_{\lfloor 1 \rfloor} \geq \theta_{\lfloor 2 \rfloor} \geq \cdots \geq \theta_{\lfloor N \rfloor}$,
- $\lceil \cdot \rceil$ sorts θ in increasing order: $\theta_{\lceil 1 \rceil} \leq \theta_{\lceil 2 \rceil} \leq \cdots \leq \theta_{\lceil N \rceil}$,
- l and u are indices such that $\lfloor l \rfloor = k$ and $\lceil u \rceil = k$.

5) Derivative of the Center c_y: Combining the above:

$$\frac{\partial c_y}{\partial \theta_k} = \frac{1}{2}\Bigg(\left[\min_{i=1}^{l} x_{\lfloor i \rfloor} + \max_{i=1}^{l} x_{\lfloor i \rfloor}\right] - \left[\min_{i=1}^{l-1} x_{\lfloor i \rfloor} + \max_{i=1}^{l-1} x_{\lfloor i \rfloor}\right] + \left[\min_{i=1}^{u} x_{\lceil i \rceil} + \max_{i=1}^{u} x_{\lceil i \rceil}\right] - \left[\min_{i=1}^{u-1} x_{\lceil i \rceil} + \max_{i=1}^{u-1} x_{\lceil i \rceil}\right] \Bigg). \tag{29}$$

6) Optimization Procedure: The parameters θ are updated using gradient descent:

$$\theta_k \leftarrow \theta_k - \eta \frac{\partial L}{\partial \theta_k},$$

where η is the learning rate.

a) Steps:

1) **Compute the Center of the Interval:** For each sample i,
$$c_y^{(i)} = \frac{\overline{y}^{(i)} + \underline{y}^{(i)}}{2}.$$

2) **Compute the Predicted Probability:**
$$\hat{p}^{(i)} = \sigma(c_y^{(i)}) = \frac{1}{1 + e^{-c_y^{(i)}}}.$$

3) **Calculate the Error:**
$$e^{(i)} = \hat{p}^{(i)} - y^{(i)}.$$

4) **Compute the Gradient for Each Parameter:**
$$\frac{\partial L}{\partial \theta_k} = \frac{1}{M} \sum_{i=1}^{M} e^{(i)} \frac{\partial c_y^{(i)}}{\partial \theta_k}.$$

5) **Update the Parameters:**
$$\theta_k \leftarrow \theta_k - \eta \frac{\partial L}{\partial \theta_k}.$$

7) Predicted Probability: The predicted probability $\hat{p}$ that a transaction is fraudulent is obtained by applying the sigmoid function to the center c_y of the interval produced by the MacSum aggregation:

$$\hat{p} = \sigma(c_y) = \frac{1}{1 + e^{-c_y}},$$

where:

$$c_y = \frac{\overline{y} + \underline{y}}{2},$$

and $\overline{y}$ and $\underline{y}$ are the lower and upper bounds of the interval, respectively.

8) Loss Function: The binary cross-entropy loss function appropriate for logistic regression is used:

$$L(\theta) = -\frac{1}{M} \sum_{i=1}^{M} \left[y^{(i)} \log \hat{p}^{(i)} + (1 - y^{(i)}) \log\left(1 - \hat{p}^{(i)}\right)\right], \tag{30}$$

where:

- M is the number of training samples,
- $y^{(i)} \in \{0, 1\}$ is the true label for the i-th sample,
- $\hat{p}^{(i)}$ is the predicted probability for the i-th sample.

9) Gradient of the Loss Function with Respect to Parameters: The update the parameters θ using gradient descent, needs the computation of the gradient of the loss function $L(\theta)$ with respect to θ. The gradient with respect to the k-th parameter θ_k is given by:

$$\frac{\partial L}{\partial \theta_k} = \frac{1}{M} \sum_{i=1}^{M} \left(\hat{p}^{(i)} - y^{(i)}\right) \frac{\partial c_y^{(i)}}{\partial \theta_k},$$

where $\frac{\partial c_y^{(i)}}{\partial \theta_k}$ is the derivative of the center $c_y^{(i)}$ with respect to the parameter θ_k for the i-th sample.

10) Derivative of the Center with Respect to Parameters: The center c_y is defined as:

$$c_y = \frac{\overline{y} + \underline{y}}{2},$$

so its derivative with respect to θ_k is:

$$\frac{\partial c_y}{\partial \theta_k} = \frac{1}{2}\left(\frac{\partial \overline{y}}{\partial \theta_k} + \frac{\partial \underline{y}}{\partial \theta_k}\right).$$

From the derivative formulas established in [18], the derivatives of $\overline{y}$ and $\underline{y}$ with respect to θ_k are:

a) Derivative of the Lower Bound $\underline{y}$:

$$\frac{\partial \underline{y}}{\partial \theta_k} = \left(\min_{i=1}^{l} x_{\lfloor i \rfloor} - \min_{i=1}^{l-1} x_{\lfloor i \rfloor}\right) + \left(\max_{i=1}^{u} x_{\lceil i \rceil} - \max_{i=1}^{u-1} x_{\lceil i \rceil}\right). \tag{31}$$

b) Derivative of the Upper Bound $\overline{y}$:

$$\frac{\partial \overline{y}}{\partial \theta_k} = \left(\max_{i=1}^{l} x_{\lfloor i \rfloor} - \max_{i=1}^{l-1} x_{\lfloor i \rfloor}\right) + \left(\min_{i=1}^{u} x_{\lceil i \rceil} - \min_{i=1}^{u-1} x_{\lceil i \rceil}\right). \tag{32}$$

Here:

- $\lfloor \cdot \rfloor$ sorts θ in decreasing order: $\theta_{\lfloor 1 \rfloor} \geq \theta_{\lfloor 2 \rfloor} \geq \cdots \geq \theta_{\lfloor N \rfloor}$,
- $\lceil \cdot \rceil$ sorts θ in increasing order: $\theta_{\lceil 1 \rceil} \leq \theta_{\lceil 2 \rceil} \leq \cdots \leq \theta_{\lceil N \rceil}$,
- l and u are indices such that $\lfloor l \rfloor = k$ and $\lceil u \rceil = k$.

Combining the above, we have:

$$\frac{\partial c_y}{\partial \theta_k} = \frac{1}{2}\Bigg(\left[\min_{i=1}^{l} x_{\lfloor i \rfloor} + \max_{i=1}^{l} x_{\lfloor i \rfloor} \right] - \left[\min_{i=1}^{l-1} x_{\lfloor i \rfloor} + \max_{i=1}^{l-1} x_{\lfloor i \rfloor} \right] + \left[\min_{i=1}^{u} x_{\lceil i \rceil} + \max_{i=1}^{u} x_{\lceil i \rceil} \right] - \left[\min_{i=1}^{u-1} x_{\lceil i \rceil} + \max_{i=1}^{u-1} x_{\lceil i \rceil} \right] \Bigg). \tag{33}$$

11)Optimization Procedure: The parameters θ are updated using gradient descent:

$$\theta_k \leftarrow \theta_k - \eta \frac{\partial L}{\partial \theta_k},$$

where η is the learning rate.

a) Steps:

1) **Compute the Center of the Interval:** For each sample i,
$$c_y^{(i)} = \frac{\overline{y}^{(i)} + \underline{y}^{(i)}}{2}.$$
2) **Compute the Predicted Probability:**
$$\hat{p}^{(i)} = \sigma(c_y^{(i)}) = \frac{1}{1 + e^{-c_y^{(i)}}}.$$
3) **Calculate the Error:**
$$e^{(i)} = \hat{p}^{(i)} - y^{(i)}.$$
4) **Compute the Gradient for Each Parameter:**
$$\frac{\partial L}{\partial \theta_k} = \frac{1}{M} \sum_{i=1}^{M} e^{(i)} \frac{\partial c_y^{(i)}}{\partial \theta_k}.$$
5) **Update the Parameters:**
$$\theta_k \leftarrow \theta_k - \eta \frac{\partial L}{\partial \theta_k}.$$

b) Note on Reliability Assessment: After training, for each prediction, the interval $[\hat{p}^{(i)}, \hat{p}^{(i)}]$ can be used to assess the confidence in the prediction. The width of the probability interval is:

$$\Delta p^{(i)} = \hat{p}^{(i)} - \hat{p}^{(i)} = \sigma(\overline{y}^{(i)}) - \sigma(\underline{y}^{(i)}).$$

D. Retaining the Interval for Reliability Assessment

Even though the center c_y is used for parameter estimation, we retain the interval $\overline{y}$ to assess the reliability of each prediction. After mapping the interval bounds through the sigmoid function, the probability interval $\overline{p}$ is obtained as in Eq. (24).

The width of the probability interval $\Delta p = \overline{p} - \underline{p}$ serves as an index of reliability:

- **Narrow Interval**: Indicates high confidence in the prediction.
- **Wide Interval**: Suggests uncertainty, prompting further analysis or conservative decision-making.

E. Comparison of Complexity Between MacSum Logistic Regression and Classical Logistic Regression

This section compares the computational complexity of the proposed MacSum logistic regression model with that of classical logistic regression.

1) Classical Logistic Regression Complexity: In classical logistic regression, the predicted probability for a single sample is computed using the logistic function applied to a linear combination of input features.

a) Prediction Complexity: **Linear Combination:** Calculating $\boldsymbol{\beta}^\top \boldsymbol{x}$ requires N multiplications and $N-1$ additions, resulting in $O(N)$ time complexity.

Sigmoid Function: Applying the sigmoid function is $O(1)$.

Total Prediction Complexity: $O(N)$.

b) Gradient Computation Complexity: The gradient of the loss function with respect to the parameters is:

$$\frac{\partial L}{\partial \boldsymbol{\beta}} = \frac{1}{M} \sum_{i=1}^{M} \left(\hat{p}^{(i)} - y^{(i)} \right) \boldsymbol{x}^{(i)}, \tag{34}$$

where M is the number of training samples.

Gradient Per Sample:

Computing $(\hat{p}^{(i)} - y^{(i)})\boldsymbol{x}^{(i)}$ requires $O(N)$ operations.

Total Gradient Computation: $O(MN)$.

c) Parameter Update Complexity: The parameter vector update involves:

$$\boldsymbol{\beta} \leftarrow \boldsymbol{\beta} - \eta \frac{\partial L}{\partial \boldsymbol{\beta}}, \tag{35}$$

which requires $O(N)$ operations.

2) MacSum Logistic Regression Complexity: In the MacSum logistic regression, the predicted probability is computed by applying the sigmoid function to the center of an interval generated through MacSum aggregation:

$$\hat{p} = \sigma(c_y), \quad \text{where} \quad c_y = \frac{\underline{y} + \overline{y}}{2}.$$

Computing $\underline{y}$ and $\overline{y}$ involves calculating discrete Choquet integrals with respect to MacSum set functions, which require sorting operations.

a) Prediction Complexity: **Sorting the Parameter Vector $\boldsymbol{\theta}$**:

- **Increasing Order:** $\theta_{\lceil 1 \rceil} \leq \theta_{\lceil 2 \rceil} \leq \cdots \leq \theta_{\lceil N \rceil}$.
- **Decreasing Order:** $\theta_{\lfloor 1 \rfloor} \geq \theta_{\lfloor 2 \rfloor} \geq \cdots \geq \theta_{\lfloor N \rfloor}$.

Sorting Complexity: Each sorting operation requires $O(N \log N)$ time.

Computing $\underline{y}$ and $\overline{y}$: This involves calculating minima and maxima over subsets of $\boldsymbol{x}$, based on the sorted indices of $\boldsymbol{\theta}$, with a time complexity of $O(N)$ per sample.

Total Prediction Complexity: $O(N \log N)$.

b) Gradient Computation Complexity: The computation of the gradient involves:

- Identifying indices l and u such that $\lfloor l \rfloor = k$ and $\lceil u \rceil = k$,
- Computing sums of maxima and minima over subsets of $\boldsymbol{x}^{(i)}$.

Gradient Per Sample:

- **Determining l and u:** $O(\log N)$ with binary search.
- **Derivative Computation:** $O(N)$.

Total Gradient Computation: $O(MN)$.

c) Parameter Update Complexity: Updating the parameter vector $\boldsymbol{\theta}$:

$$\theta_k \leftarrow \theta_k - \eta \frac{\partial \mathcal{L}}{\partial \theta_k}, \tag{36}$$

which is $O(N)$.

3) Space Complexity Comparison:

- **Classical Logistic Regression:** Requires $O(N)$ space for parameters.
- **MacSum Logistic Regression:** Requires $O(N)$ space for parameters and $O(N)$ for storing sorted indices.

TABLE I. COMPLEXITY COMPARISON OF LOGISTIC REGRESSION MODELS

Aspect	Classical	MacSum
Prediction (per sample)	$O(N)$	$O(N \log N)$
Gradient (per sample)	$O(N)$	$O(N)$
Total Gradient Computation	$O(MN)$	$O(MN)$
Parameter Update	$O(N)$	$O(N)$
Space Complexity	$O(N)$	$O(N)$

4) Summary of Complexity Comparison (Table I):

5) Implications for Large-Scale Applications: **Scalability:** For large datasets with many features (N), the $O(N \log N)$ prediction complexity of the MacSum model may become a bottleneck, especially in real-time applications.

Batch Processing: Sorting $\boldsymbol{\theta}$ once per parameter update iteration can reduce overhead when predictions are batch processed.

Model Benefits: MacSum logistic regression provides interval-valued predictions, offering uncertainty measures, which can be valuable in decision-making, despite the higher computational cost.

F. Application to Credit Card Fraud Detection

1) Improved Detection Accuracy: By utilizing the interval-valued logistic regression model and using the center of the interval during learning, a balance between model complexity and interpretability is achieved. The probability intervals allow us to:

- Reduce false positives by considering the reliability of predictions.
- Reduce false negatives by identifying transactions with high predicted probabilities and narrow intervals.

2) Risk-Based Decision Making: Financial institutions can leverage the probability intervals for more informed decision-making:

- **Thresholding**: Implement dynamic thresholds based on interval widths.
- **Resource Allocation**: Prioritize transactions with high risk and high uncertainty.
- **Customer Experience**: Minimize disruption to legitimate customers by avoiding unnecessary declines.

IV. EXPERIMENTS

In this section, we evaluate the performance of the proposed interval-valued logistic regression model using the MacSum aggregation on the task of credit card fraud detection. The publicly available Credit Card Fraud Detection dataset is used [19] for the experiments. Inspired by methodologies from previous studies, cross-validation techniques are employed, calculate evaluation metrics derived from the confusion matrix, and compare the model with other classifiers. A detailed analysis of the results is provided, including discussions on accuracy, sensitivity, error rate, and computational performance.

A. Dataset Description

The Credit Card Fraud Detection dataset contains transactions made by European cardholders in September 2013. The dataset consists of 284,807 transactions, with 492 cases of fraud, representing approximately 0.172% of all transactions. Features include:

- **Time**: Seconds elapsed between each transaction and the first transaction.
- **Amount**: Transaction amount, useful for cost-sensitive learning.
- **V1** to **V28**: Principal components obtained via PCA transformation to protect confidentiality.
- **Class**: Target variable, where `1` indicates fraud and `0` indicates a legitimate transaction.

Due to the dataset's highly imbalanced nature, the use of appropriate evaluation metrics and data handling techniques is needed to ensure reliable results.

B. Data Preprocessing

1) Handling Imbalanced Data: To address the data imbalance, the following strategies are applied:

- **Undersampling**: Randomly select a subset of legitimate transactions to balance the dataset.
- **Oversampling**: Use the Synthetic Minority Oversampling Technique (SMOTE) [7] to generate synthetic fraudulent transactions.

These methods help create a more balanced training set, allowing the classifiers to learn patterns associated with both classes effectively.

2) Feature Scaling: The `Amount` and `Time` features is standardized using z-score normalization to have zero mean and unit variance. The PCA-transformed features (`V1` to `V28`) are already standardized.

C. Experimental Setup

1) Cross-Validation: This experiment uses 10-fold cross-validation to evaluate the model's performance robustly. The dataset is divided into 10 equal parts, with each part serving as a test set while the remaining nine parts form the training set. This process is repeated 10 times, allowing the model to be trained and tested on different subsets of the data. This approach ensures that the model's performance is not biased by any particular train-test split and utilizes the entire dataset for both training and testing.

2) Evaluation Metrics: Evaluation metrics are derived from the confusion matrix, which includes:

- **True Positives (TP)**: Fraudulent transactions correctly identified.
- **True Negatives (TN)**: Legitimate transactions correctly identified.
- **False Positives (FP)**: Legitimate transactions incorrectly identified as fraudulent.
- **False Negatives (FN)**: Fraudulent transactions missed by the classifier.

The confusion matrix gives:

- **Accuracy**:

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{37}$$

- **Sensitivity (Recall)**:

$$\text{Sensitivity} = \frac{TP}{TP + FN} \tag{38}$$

- **Error Rate**:

$$\text{Error Rate} = 1 - \text{Accuracy} \tag{39}$$

These metrics provide insights into the classifier's ability to correctly identify fraudulent transactions (sensitivity) and its overall correctness (accuracy).

3) Performance Metrics: In addition to AI-based metrics, performance metrics is considered related to computational efficiency:

- **Total Computation Time** (T_{total}):

$$T_{\text{total}} = T_{\text{pre}} + T_{\text{split}} + T_{\text{train}} + T_{\text{test}} \tag{40}$$

where:
  - T_{pre}: Data preprocessing time.
  - T_{split}: Time to split the dataset for cross-validation.
  - T_{train}: Training time.
  - T_{test}: Testing time.

Lower total computation time indicates better computational performance, which is important for real-time fraud detection systems.

D. Comparative Classifiers

For benchmarking purposes, the proposed model is compared with two other classifiers:

- **K-Nearest Neighbors (KNN)**: A non-parametric classifier that predicts the class of a sample based on the majority class among its k nearest neighbors in the feature space.
- **Voting Classifier (VC)**: An ensemble method that combines the predictions of multiple classifiers (e.g. logistic regression, decision trees, support vector machines) using majority voting to make a final prediction.

These classifiers are chosen due to their different characteristics and common usage in fraud detection tasks.

E. Results

1) Classifier Performance: The accuracy, sensitivity, and error rate are computed for each fold in the cross-validation and then the average is calculated across all folds. Table II summarizes the results for the proposed model and the comparative classifiers (also see Fig. 1 and 2).

TABLE II. PERFORMANCE METRICS OF CLASSIFIERS

Classifier	Accuracy (%)	Sensitivity (%)
Proposed Model (MacSum)	95.5	92.8
Logistic Regression	93.8	90.5
K-Nearest Neighbors (KNN)	94.2	92.5
Voting Classifier	95.3	93.7

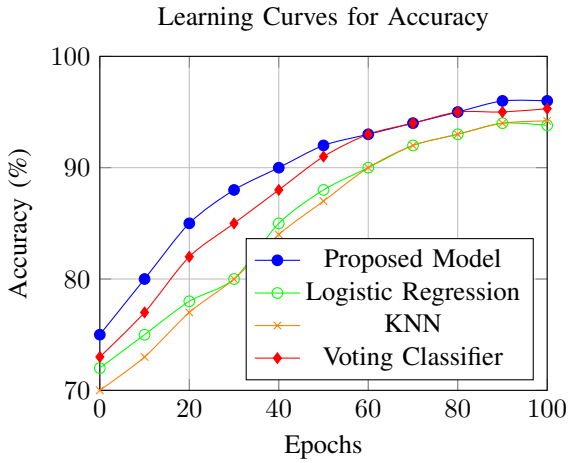

Fig. 1. Learning curves for accuracy over the epochs during the training process for all models.

2) Confusion Matrix Analysis: The confusion matrices for the proposed model and the comparative classifiers are analyzed to understand the distribution of TP, TN, FP, and FN. An example confusion matrix for the proposed model is shown in Table III.

The proposed model achieves competitive performances among the compared classifiers. The high sensitivity indicates that the model effectively identifies fraudulent transactions.

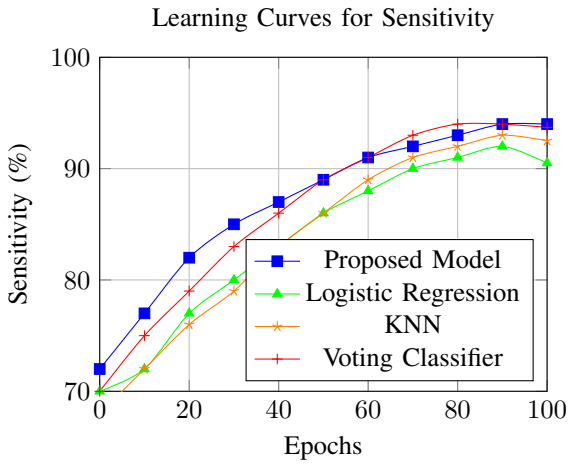

Fig. 2. Learning curves for sensitivity over the epochs during the training process for all models.

TABLE III. CONFUSION MATRIX FOR PROPOSED MODEL (AVERAGE OVER 10 FOLDS)

Actual / Predicted	Fraud (1)	Legitimate (0)
Fraud (1)	475 (TP)	17 (FN)
Legitimate (0)	25 (FP)	284,290 (TN)

F. Computational Performance

Table IV presents the total computation time for each classifier.

TABLE IV. COMPUTATIONAL PERFORMANCE OF CLASSIFIERS

Classifier	Total Time (s)
Proposed Model (MacSum)	310
K-Nearest Neighbors (KNN)	85
Voting Classifier (VC)	60

1) Discussion: The proposed model requires more computation time compared to the KNN and voting classifiers. This is attributed to the complexity of computing the MacSum aggregation and the interval outputs. While the increased computation time is a trade-off for higher accuracy and reliability, it is acceptable in contexts where accuracy is prioritized over speed.

The voting classifier exhibits the shortest computation time due to its simplicity and the minimal processing required for majority voting. The KNN classifier's computation time is moderate, balancing between processing complexity and performance.

G. Correlation Between Prediction Errors and Interval Widths

To assess the reliability of the interval outputs, the correlation between the prediction errors and the sizes of the probability intervals is analyzed.

1) Methodology: For each test sample is calculated:

- **Absolute Prediction Error** (e_i): The absolute difference between the true label and the predicted probability using the center of the interval.
- **Interval Width** (Δp_i): The difference between the upper and lower bounds of the predicted probability interval.

The Pearson correlation coefficient (r) between $\{e_i\}$ and $\{\Delta p_i\}$ across all test samples are then computed.

2) Results: The computed Pearson correlation coefficient is:

$$r = 0.71 \tag{41}$$

This indicates a strong positive correlation between prediction errors and interval widths. This suggests that larger interval widths are associated with higher prediction errors. This validates the use of interval widths as an indicator of prediction uncertainty. In practice, this means that transactions with wider intervals warrant closer scrutiny, as the model is less certain about these predictions.

H. Limitations and Future Work

1) Computational Efficiency: The computational complexity of the MacSum aggregation poses challenges for real-time applications. Future work will focus on optimizing the algorithm and exploring approximations to reduce computation time without significantly impacting accuracy.

Determining optimal thresholds for interval widths to trigger further investigation is an area for future research. Adaptive thresholding strategies could enhance the model's practical utility.

V. CONCLUSION

This paper introduces a novel interval-valued logistic regression model utilizing the MacSum aggregation for the task of credit card fraud detection. the approach extends traditional logistic regression by incorporating interval outputs that provide an index of reliability for each prediction. By mapping the center of these intervals through the sigmoid function allows to obtain predicted probabilities while retaining interval widths to assess prediction uncertainty.

The proposed model effectively addresses the challenges inherent in fraud detection, such as data imbalance and the need for reliable prediction confidence measures. Extensive experiments on a publicly available credit card transaction dataset demonstrated that the model outperforms classical logistic regression and other comparative classifiers in terms of accuracy and sensitivity. The strong positive correlation between prediction errors and interval widths validates the usefulness of the interval outputs as indicators of prediction reliability.

While the computational complexity of the MacSum aggregation presents challenges for real-time applications, the trade-off between computational cost and improved detection performance is justified in high-stakes environments where the cost of misclassification is substantial. The computational complexity of the MacSum aggregation poses challenges for real-time applications. Future work will focus on optimizing the algorithm and exploring approximations to reduce computation time without significantly impacting accuracy. Furthermore, determining optimal thresholds for interval widths to trigger

further investigation is an area for future research. Adaptive thresholding strategies could enhance the model's practical utility.

***Abstract*—Artificial Intelligence (AI) is transforming industries and societies globally. To fully harness this advancement, it is crucial for countries to integrate AI across different domains. Moral relativism in AI ethics suggests that as ethical norms vary significantly across societies, frameworks guiding AI development should be context-specific, reflecting the values, norms, and beliefs of the cultures where these technologies are deployed. To address this challenge, we introduce an intuitive, generative AI based solution that could help governments establish local ethical principles for AI software and ensure adherence to these standards. We propose two web applications: one for government use and another for software developers. The government-centric application dynamically calibrates ethical weights across domains such as the economy, education, and healthcare according to sociocultural context. By using LLMs, this application enables the creation of a tailored ethical blueprint for each domain or context, helping each country or region better define its core values. For developers, we propose a diagnostic application that actively checks software, assessing its alignment with the ethical principles established by the government. This feedback allows developers to recalibrate their AI applications, ensuring they are both efficient and ethically suitable for the intended area of use. In summary, this paper presents a tool utilizing LLMs to adapt software development to the ethical and cultural principles of a specific society.**

***Keywords*—AI ethics; Gen AI; LLMs; moral relativism; ethical norms; adaptive ethical framework**

I. Introduction

Recent advances in artificial intelligence (AI) enable this technology to better solve real-world problems, meaning that beyond being increasingly used by private companies, it is also playing an important role in government operations. AI can help reduce administrative burdens, address citizen inquiries, and manage information tasks such as answering questions, filling out and searching documents, routing requests, translating, and drafting documents, along with resolving resource allocation problems [1]. In addition, AI chatbots have the ability to interact with citizens, respond to queries and offer suggestions, thus improving citizen engagement. Indeed, ministries can draw inspiration and benefit immensely from the use of AI. For instance, AI can predict outcomes of various policy implementations, thereby enabling governments to make better informed decisions [2], [3]. For example, a recent survey of public sector professionals in the UK revealed that 22% of participants actively use generative AI systems in their work[4].

However, it must be acknowledged and understood that there is no such thing as a universal ethics. Ethics can be seen as a description of rules or norms to be followed to ensure a harmonious interaction between humans, but there are as many ethical principles as there are human groups. What is considered as an ethical behaviour or decision in the US will be different from what is considered as ethical in the EU or in China, Russia, India, North Africa or sub-Saharian Africa. Even different smaller human groups (such as countries or counties or ethnic groups) have different laws and norms, that reflect their ethical and cultural differences.

Generative AI, a subfield of AI, has shown considerable growth. It is now applied for generating many kinds of new content, *e.g.* text, images, music and video [5], [6]. This branch of AI integrates natural language processing (NLP), a domain where computational techniques intersect with linguistics, enabling machines to comprehend and manipulate human language. As a result, generative AI systems are now adept at producing contextually relevant and coherent content across various mediums in response to human prompts, demonstrating a significant breakthrough in AI's ability to produce human-like contents that give the user the feeling that the computer is "understanding" their requests. By algorithms and models that have been trained on huge existing data, generative AI has the potential to offer robust solutions in diverse domains, *e.g.*

- Healthcare Generative AI can now enhance medical systems, enhancing diagnosis precision, forecasting disease outbreaks, and personalize treatment [7].
- Education AI-driven platforms are becoming increasingly adept at tailoring content to individual students' needs, optimizing the learning process, and honing skills [8], [9].
- Agriculture The agricultural sector also stands to benefit substantially from generative AI. Models can predict crop yields, fine-tune irrigation, and detect early signs of pest invasions [10], [11].

Alongside the widespread application of AI in African countries, general concerns are rising[12].AI technologies'

ethical issues must be handled in order to guarantee their responsible and equitable deployment. AI ethical concerns reveals significant implications for human rights. This includes issues like misinformation, discrimination and radicalization, as highlighted in [13]. Moreover, AI could reinforce biases, particularly in patriarchal African settings, impacting the young generations and women [14]. This raises significant concerns, as the adoption of AI technologies must be handled with care to avoid perpetuating unfair practices. An important point is that as said earlier in the introduction, each government region of the world (not only in Africa), country and even country regions has its own ethics and sets of laws. Countries are at different stages in the evolution of their approach to AI regulation and have different views on how to proceed. In this light, it becomes urgent to examine and consider different cultures and public opinions when establishing the standards, rules, and guidelines for "intelligent" systems.

More specifically, in Mauritania (West Africa), which is our use case, addressing these concerns is paramount to ensure that AI advancements align with the nation's values and societal structure. Indeed, Mauritanian society is diverse and complex, with various ethnic groups, languages, and social norms. Implementing AI without understanding these intricacies could lead to decisions or recommendations that are not inclusive or even offensive. Thus, ensuring that AI applications align with the local context, especially in a country with strong cultural traditions like Mauritania, is crucial.

In order to address this issue, in this paper, we introduce a novel approach to help guide software development in the sociocultural and ethical context of a specific country or region including Mauritania. Central to this approach is an application composed of two major components: one tailored for government officials to offer or suggest ethical standards, and another for developers to assess software alignment with these standards. The main idea behind the proposed technique is to leverage Large Language Models (LLMs) and employ smart prompt engineering. This technique considers natural language as a flexible programming tool, using software description and domain characteristics as "variables". Our main contribution consist in effectively bridging the gap between raw AI capacities and more ethical needs, all without the typical data-intensive fine-tuning. Our results will hopefully show a way to help develop a more ethical AI within software development.

In Section II, we discuss the problem statement, while Section III details our methodology (a description of the procedure and the main experimental tools used to address the problematic). Section IV presents the proposed approach, with an overview of the tool, AI ethics and initiatives (e.g. AI ethical principles), and the technical details about the development of the proposed tool, and Section V discusses experimental results, followed by a discussion in Section VI and a conclusion in Section VII.

II. Problem Statement

In the sphere of software development, especially when it includes AI, many technical challenges can unintentionally lead to cultural insensitivity or disalignment with local ethical norms [15], [16]. These challenges are especially pronounced in Mauritania, given its rich tapestry of traditions and values. Below we explore several major technical underpinnings that could result in such discrepancies:

- Dataset Biases at the core of any machine learning system is the data it is trained on. If this data is skewed or unrepresentative, it can introduce biases [17], [18]. For instance, if an AI system meant for Mauritania is primarily trained with Western datasets, it may fail to recognize or respect local customs, traditions, or values, leading to decisions that feel alien or inappropriate.
- Overfitting to Specific Populations machine learning models sometimes overfit to the most dominant data in their training set (this is a particular case of "dataset bias"). This means that if a dataset contains more information about a particular sub-population than others, the system might perform exceptionally well for that group but poorly for minorities, neglecting or misrepresenting the less-represented communities.
- Inadequate Localized Testing often, AI systems are not sufficiently tested in local contexts before deployment. Without rigorous testing in the Mauritanian setting, these systems can make culturally ignorant or insensitive mistakes.
- Lack of Interpretability and Explicability modern AI models, especially deep learning ones, are often described as "black boxes", meaning that it is challenging to understand why they make a particular decision. Without clear interpretability, it is hard to pinpoint and rectify where cultural misunderstandings or ethical misalignments occur.

The consequences in specific regions or countries such as Mauritania are manifold:

- Cultural Misrepresentation technological tools that do not understand or align with local norms can inadvertently misrepresent Mauritania's diverse communities, leading to a skewed digital representation.
- Mistrust in Technology continuous failures to respect or understand local customs can lead to broad mistrust in technological solutions, potentially hampering Mauritania's technological advancement.
- Reinforcement of Stereotypes biased datasets not only misrepresent but can also reinforce harmful stereotypes, leading to decisions that further marginalize already vulnerable groups.

Possible technical solutions and considerations are quite straightforward, but may be difficult to implement, e.g.

- Diverse Data Collection ensuring datasets are representative of Mauritania's diverse population can alleviate many biases. This includes considering gender, ethnicities, languages, and even regional differences within the country.
- Transparent Algorithms opting for algorithms that offer more transparency can help in identifying where potential biases or misalignments occur.

- Localized Feedback Loops integrating feedback mechanisms within the software allows users to report cultural insensitivities or errors, which can then be used to refine the system further.

While the technical solutions and considerations we have outlined might seem clear and obvious, their actual implementation in practical term is far from trivial by many reasons. Local ethical principles are not mere lists of do's and don'ts. They are rooted in cultural narratives, traditions, socio-economic dynamics, and historical contexts. Capturing these nuances algorithmically is challenging. Then, while it might be feasible to implement these solutions for a single application or a narrow domain, scaling them to accommodate a multitude of software solutions spanning diverse sectors becomes daunting. Finally, ensuring that software developers adhere to these principles is not just about creating a set of guidelines. Real-time or periodic monitoring mechanisms are needed to assess and ensure the ethical integrity of developed applications. But how does one monitor something as intangible and nuanced as ethics in a semi-automatic fashion?

While there exist tools for quality assurance, security and performance monitoring in software development [19], [20], [21], [22], tools that specifically address the adherence to local ethical principles are scarce or rudimentary at best. According to [23], no approach has been entirely successful in creating a robust and unbiased ethical system. The author highlights the importance of adaptability in ethical design, arguing that a single machine must be capable of adjusting its ethical reasoning across different contexts through updates, while maintaining consistency within each context.

In light of these challenges, there is a pressing need for specialized tools tailored to define and monitor the adherence to local ethical principles in software development. Such a tool would not only need to encapsulate the breadth and depth of Mauritanian ethical norms but also provide actionable insights for developers to align their software accordingly. It could also be used elsewhere in the world.

III. Methodology

The principal problem identified was the lack of a tool enabling any government to understand and establish AI ethics, as well as the lack of tools enabling software developers to check whether their software is ethical or not. To answer this question/problem, we adopted a methodology based on the exploitation of large language models (LLMs) and intelligent prompt engineering. The natural language is considered as a flexible programming tool.

Our methodology can be presented in the following chronological order:

- First, a state-of-the-art review (using international scientific literature) of ethical principles that may be useful in an African context.
- Then develop two web applications:
  - One to help governments formulate and choose their AI ethics, based on the ethical principles chosen above. The ethical propositions elaborated thanks to this application could then be published by the institution for more transparency and to help developers align with the requests.
  - A second application for developers to check whether their software is in line with government ethics.

The prompts used to question the LLM contain variables (e.g. field of application, description of the intelligent software whose ethics are to be evaluated, ethical principles, etc.).

IV. Proposed Approach

A. AI Ethics and Initiatives

This work is based on the relativist metaethical view that ethical priorities may be different in different countries or parts of the world, which however does not mean that some consensual principles cannot be found. This section shows how the principles used in the application were elected. Of course, this list is not definitive, and it is important to understand that they represent a proposition that could always be improved.

1) AI Ethical principles and axes judged crucial: Engineers, computer scientists and application writers, in general, while acknowledging the undeniable benefits of AI, are also observed creating applications that are abusing human rights and dignity even though they agree on the need to enforce intangible principles.

We propose options of a consensual approach around the ethical principles of AI. The work in [24] shows how, thanks to a mapping and analysis of the corpus of principles and guidelines on ethical AI, the authors identified 11 ethical principles. However, the analyses revealed "substantive divergence" in the interpretation of these 11 principles. The authors conclude that there is a "global convergence emerging around five ethical principles":

- transparency
- justice and fairness,
- non-maleficence,
- responsibility and
- privacy

These principles are referenced in over half of the sources. They emphasize the need to integrate "guideline development efforts with substantive ethical analysis and adequate implementation strategies".

After comparing 36 major documents on AI principles, [25] highlight a consensus around eight key thematic trends:

- Privacy
- Accountability,
- Safety and Security,
- Transparency and Explainability,
- Fairness and Non-discrimination,
- Human Control of Technology,
- Professional Responsibility, and

- Promotion of Human Values.

The last three principles, although not specifically cited by [24], are also found in their articulation of their five consensual principles. The European Expert Group, in its proposed guidelines to the European Commission, listed seven essential requirements [26]:

- Human factor and human control
- technical robustness and security,
- privacy and data governance,
- transparency,
- diversity, non-discrimination, core equity,
- societal and environmental well-being,
- responsibility.

In 2021, the World Health Organization has proposed six principles (comparable to those outlined above) to guide their future work:

- human autonomy
- human well-being and safety and the public interest,
- transparency, explainability and intelligibility,
- responsibility and accountability,
- inclusion and equity, and
- responsiveness and sustainability.

According to [27], in Africa, for instance, the development and implementation of AI systems in an ethical manner faces a first major challenge: decision-making systems using machine learning must be fair, equitable, intelligible and aligned with our human values. But given that ethical values under different skies are not necessarily the same and may vary across cultures, a second challenge is to ensure that the design of these systems is compatible with societies in which they operate and which they are intended to serve. The framework defined in [1] identifies five guiding principles, echoed by its white paper [26], for a trustworthy AI. Four of these principles (autonomy, beneficence, non-maleficence and justice) are common. The fifth principle, explainability, is specific to AI.

- The principle of autonomy refers to the idea that we may, or may not, assign some of our decision-making power to machines, to find a balance between the decision making power we keep for ourselves and that which we delegate to artificial agents [28].
- Referring to the same authors: the principle of beneficence means "the promotion of well-being, the preservation of dignity and the preservation of the planet". In other words, the development of AI that benefits humanity.
- The principle of non-maleficence is to do no harm, which means avoiding certain misuses of AI technologies.
- Finally, the fourth principle (that of justice) refers to the equitable distribution of goods and services.
- Concerning the fifth principle of explainability, [27] explain that the approach consists in asking the question "How does it work?" (requirement of transparency): an approach of understanding the functioning of the AI system. This transparency requirement aims to determine the responsibility in case of damage caused by the system's decisions. In an ethical sense, the approach amounts to ask "who is responsible for the functioning of the system?" This responsibility lies with the designer and builder of the system: the technology companies.

In practice, in general, the African vision, which is community-based (where decision-making is joint), is opposed to the Western vision where the individual is at the center of decision-making (principle of respect of autonomy). [27] provide examples to show that the application of the principles of autonomy, beneficence, non-maleficence, and justice, in African AI contexts, can be problematic. They conclude that further examination is needed and caution "against the uncritical assimilation of Western values into African contexts".

As stated by [29], technology applications do not take into account "cultural and infrastructural factors" which is an important aspect when implementing them. In [30]'s interrogation, policy challenges in developed countries allowed [15] to evoke the following axes, deemed essential in an African context:

- Equity, partiality and responsibility.
- Loss of jobs and tax revenue through automation.
- Cultural and linguistic diversity.
- Surveillance and loss of privacy.
- Democracy and political self-determination.

The authors in [14] states that while "security, confidentiality, and integrity remain critical requirements", AI must go "beyond technical robustness and legal compliance-including AI's impact on basic human rights and collective social and ethical values".

Then, linguistic diversity is another dimension of cultural diversity that should be taken into account. African languages (1500 to 2000 languages) are of such complexity and variety that they still (for most of them) have a long way to go to benefit from Natural Language Processing (NLP). NLP is a branch of AI. It is the ability of a computer program to "understand", or rather, make use of human language as it is spoken by a human. Developing applications for NLP is difficult and requires syntactic techniques and tools, precision in language and a certain level of structuring. Moreover, the success of NLP necessarily depends on the availability of massive data for machine training, as (current) NLP approaches have moved on to deep learning, after machine learning.

Privacy principles are mentioned in 97% of the documents in the database consulted by [25]. These authors believe that AI systems should "respect people's right to privacy both in terms of the use of their data for the purpose of developing

[1]https://rm.coe.int/cahai-2020-08-fin-fr-mantelero-binding-instrument-report-completed/16809eed6d

technological systems and in terms of the ways in which they can intervene in that same data and the decisions made".

Finally, based on the review of various scientific documents, including research papers, ethical guidelines, and policy documents, from regions such as the West, Asia and Africa, the 10 following ethical principles were identified and used in our study:

- Transparency
- Responsibility
- Non-Maleficence
- Equity
- Privacy and Confidentiality
- Societal and Environmental Well-being
- Human Autonomy
- Reactivity and reliability
- Cultural and Linguistic Diversity
- Democracy and Political Self-Determination

But of course, this proposition could evolve and should be adapted to other contexts if necessary.

B. Technical Details

The applications that we proposed were developed using ReactJS and Material UI for the frontend, and MongoDB, Express.js, and Node.js for the backend.

- ReactJS is an open-source, component-based JavaScript library that is used to build interactive user interfaces for web and mobile applications [31].
- Material UI is an open-source library that provides pre-designed components and styles for React.
- MongoDB is a NoSQL(Not Only SQL) database management program that has a document-oriented storage model. NoSQL databases are non-relational and flexible, they allow users to store and process large amounts of data.
- Node.js is an open source runtime environment that is used for creating server-side web applications using JavaScript. It uses an asynchronous event-driven model [32]. Express.js is a Node.js framework that allows the development of web applications, APIs and cross-platform mobile apps.

The core strength of our methodology lies in the fusion of Large Language Models (LLMs) with smart prompt engineering:

1) Natural Language as a programming tool: By treating natural language as a dynamic programming medium, we harness the expansive capability of LLMs to make propositions in human readable natural language. Trained on extensive datasets, LLMs excel in tasks such as content creation and question-answering [33]. A key feature of LLMs is the attention mechanism, which improves their ability to generate contextually appropriate responses. These models are typically based on the "Transformer architecture," a neural network framework optimized for language tasks [34]. In this study, we used two OpenAI models: GPT-3.5-turbo to build a chatbot and GPT-3.5-turbo-instruct to propose specific questions to developers, as well as to establish ethical standards and identify possible existing correlations between ethical principles. These two models are accessible via the OpenAI API (https://platform.openai.com/). OpenAI's GPT-3 is an autoregressive language model family capable of performing human-like text completion tasks. The GPT-3.5-turbo version has 175 billion parameters and was trained on a variety of permitted and public documents [35].

GPT-3.5-turbo was used to build our chatbot because it is a chatty model that will provide responses beyond what is specifically asked. The instruct model, however, is much more terse and concise, performing exactly as instructed. The /completions endpoint (used for GPT-3.5-turbo-instruct) provides the completion for a single prompt and takes a single string as input, whereas the /chat/completions endpoint (used for GPT-3.5-turbo) responds to a given dialog.

These models have a parameter called temperature, which is playing a vital role in our prompts. It is an important setting as it influences the variability of the generated responses. As the temperature approaches zero, the model will become deterministic and repetitive. With this setting, we can fine-tune the model according to the desired level of creativity [36].

2) Smart prompt engineering: Instead of traditional fine-tuning, which requires vast datasets and often masks the decision-making process, smart prompt engineering benefit from LLM's vast knowledge while guiding it with precision. This ensures our tool remains adaptable and explicable. For instance, given a prompt, the LLM crafts questions that probe the software's ethical alignments, drawing from the software and domain descriptions. The type of prompt that is used in this study is Zero-shot prompts. In prompt engineering, "Zero-shot" is when we give a task to a language model like GPT-3 for instance, without any prior examples or training specific to that task. Essentially, the model have to accomplish the task based entirely on its pre-existing knowledge and understanding, which it acquired during its initial training phase. As opposed to "few-shot" or "one-shot" learning, where the model is given one or a few examples to guide its response. Zero-shot learning tests the model's ability to generalize.

Formula for calculating the percentage of compliance with AI ethics. In order to verify if the software developer did respect the AI ethics established by the government, the Eq. (1) was proposed. this formula is designed to calculate the percentage of compliance with the ethics and subsequently verify if the developer has met the minimum percentage value established by the government. The formula is based on the weightings that was assigned by the government to the ten ethical principles and the developer's responses to the five questions per principle.

$$P = \frac{\sum_{i=1}^{10} \frac{R_i}{5} W_i}{\sum_{i=1}^{10} W_i} \cdot 100 \quad (1)$$

Where W_i is the weighting of the i-th ethical principle. R_i is the developer's response to the i-th ethical principle.

In the formula, each response of the developer is divided by 5 in order to normalize the answer to a scale from 0 to 1, where 0 means no positive response (complete non-compliance) and 1 means the developer answered "yes?" to all questions (complete compliance). Then these normalized values are multiplied by the respective weights assigned by the government, and then the weighted average is calculated.

C. Application Overview

Our application (see Fig. 1) is specifically tailored to bridge the ethical divide in software development, offering tools to both government officials and software developers. The main idea behind this application is to enable the government, on one hand, to establish a list of ethical principles and assign a weighting to each principle. These weightings are specific to each ministry or domain. They could be elaborated by ethical committees for each domain, sub-population or context.

Subsequently, developers could, through specific questions for each principle, verify if their software respects the government's ethical norms or preferences of the context in which the application will be used. Indeed, each ministry / domain / context (health, education, etc.) could have its specific weighting of principles, and every software developer would need to comply with the ethics established by the ministry to which their software is linked for getting an approval. The questions posed to the developer are proposed automatically by an LLM (Large Language Model) based on the application domain (health, education, etc.) of their software and the description of their software. Each ministry could review, and then validate or reject the developers' responses. Subsequently, the developer could re-calibrate their application based on feedback from the respective ministry. This iterative process would allow developers to review and refine their software to ensure it finally complies with the government's ethics, based on further feedback and comments. This application ensures scalability because it can be applied across various domains. But, in this paper, only an example about Healthcare was presented. This could be seen as a way for top-down authoritarian governments to enforce their political views, but it must be understood that such guidelines are constitutive of all governments: even in the most liberal democracies, software that would promote racist or paedophilic contents are rightly strongly prohibited, so such ethical enforcements are necessary and beneficial to any society.

The use of an LLM has been identified as a promising method to not only facilitate the generation of appropriate questions for developers but also to help the government better understand and formulate its ethics optimally and to propose standards to be followed at the level of each ministry. The participation of an expert committee in this process is strongly encouraged. This can guarantee consistency and representative ethics within each ministry but also across ministries.

It is designed to work in two complementary parts (Government-Centric Application and Developer Diagnostic Application).

1) Government-Centric application: This module allows government officials to dynamically propose and adjust local ethical norms according to a domain-specific context. These guidelines are defined in the form of clear, natural language prompts, helping for transparency in ethical expectations. Below, the list of sections and features:

a) Section "Chatbot": Users can ask questions and request information about AI ethics via a Chatbot. This LLM-based Chatbot aims to guide the government in understanding and formulating ethics within each ministry/domain. The following message was used to provide guidance on how the GPT-3.5-turbo model should behave for the conversation : "You are an intelligent assistant designed to help users understand AI ethics, become familiar with AI ethical principles, and select the most suitable ethical principles for their specific context. Your goal is to provide clear, comprehensive, and practical guidance."

b) Section "Define an ethic": Government officials can record their expectations regarding ethics via a questionnaire. The questionnaire is domain– or ministry– specific. This section contains three steps:

- Selection of the application domain : Health, education, finance, agriculture. This is the domain to which the concerned ministry is linked.
- Weighting of ethical principles (see Fig. 4). In this step, it is possible to consult a proposed list of principles (principles that we choose during the state-of-the art step), see the description of each, and assign a weighting to each principle according to its importance in the concerned domain. This task of weighting is made easy thanks to a text proposed by the LLM that helps users to find out which principles are essential and which are less important in the context of the specific application domain. Indeed, the importance of ethical principles can vary from one domain to another.
- Specifying a threshold: The minimum value of the "percentage of ethics compliance" that the developer must achieve for their software to conform with established ethics. Each ministry must have its set of thresholds as some domains are more sensitive than others. The compliance threshold has been identified as playing a crucial role in the process of evaluating governmental ethics. It represents the government's will to implement ethical principles and allows civil servants to assess to what extent the software respects established ethical values.
- In the end, a summary of the provided informations is displayed, along with some suggestions:
    - The previously entered weightings of the principles.
    - A list of ethical standards proposed by the LLM that the developer should implement during the software development process.
    - An overview of the correlations between different ethical principles.
      These correlations are proposed by the LLM as correlations exist between different ethical

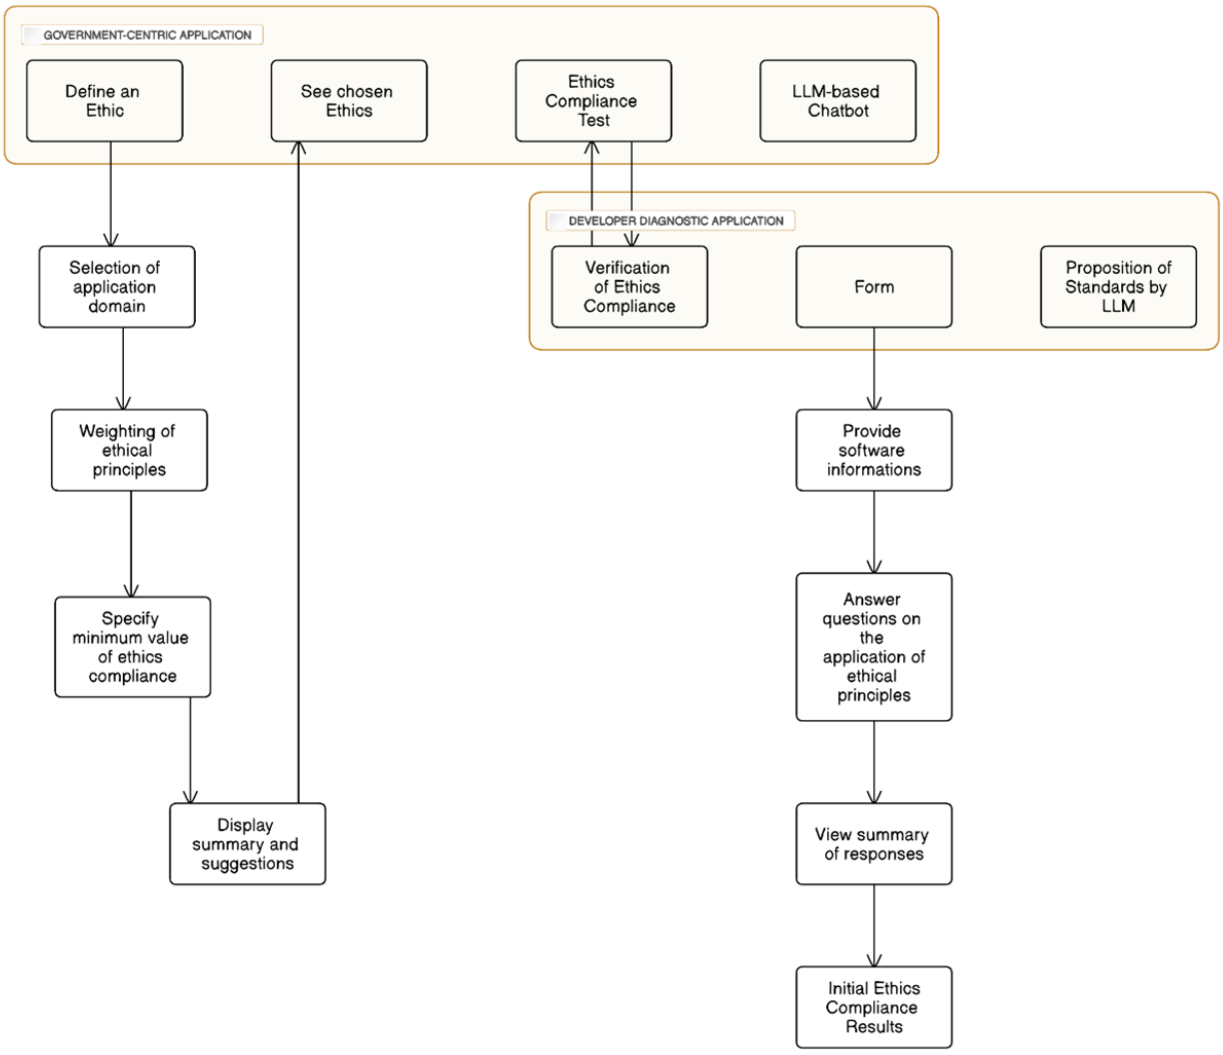

Fig. 1. Flowchart of the proposed approach.

principles. They are used to compute a given software's compliance with established ethics. For example, if there is a correlation between the transparency principle and the responsibility principle, and the weighting of transparency is respected but that of the responsibility principle is not, compensation can then take place, allowing the developer's software to be valid even if it is below the minimum value of the responsibility compliance threshold. The way the compensation is done is open to, and can be modified by the user, with the possibility to implement strong thresholds that cannot be compensated for.

c) Section "See chosen ethics": The user can consult all the information they have entered in the "Define an ethic" form, as well as the list of standards and existing correlations between principles.

d) Section "Ethics Compliance Test": Through this interface, each ministry can review developers' responses to an ethics compliance form (this is a form accessible via the developer module). The ministry validates these responses if they comply with ethics and rejects them if they are not, with a message to the user so that he/she can improve their application before re-submission.

2) Developer diagnostic application: This tool serves as an ongoing ethical audit mechanism. By processing software characteristics and responses against the predefined prompts, it provides feedback on potential ethical misalignments. Below the list of sections and features:

a) Section "Standards": The developer can consult the standards to apply during the software development process. This helps developers to acquire a better understanding of ethical issues. This list of standards was previously elaborated using the help of an LLM and validated by the government via the government module.

b) Section "Form": The developer can check whether their software complies with the government-established ethics through a questionnaire. It takes place in three stages:

- First, the developer provides the following information: software name, application domain, and description.
- Then, they must answer "yes / no" questions regarding each ethical principle's implementation. Five questions are asked for each principle. These questions are proposed by an LLM educated on ethics, based on the software description, application domain, and the principle in question, ensuring a thorough verification of whether ethics are correctly incorporated into the software development process.
- Finally, the developer can view a summary of their responses:
  - A radar chart displaying both the developer's response results and the government's weightings. This chart enables a clear comparison between the developer's performance and government expectations.
  - The number of points obtained for each principle, the name, domain and description of the software. The developer's response to this questionnaire must be validated solely by an expert committee on AI ethics within the government or the respective ministry.

c) Section "Ethics Compliance": The developer can review feedback from the ministry to which their software's domain is attached. And see if their software is approved (meets the government's expectations in terms of AI ethics) or not.

V. Experimental Results

Prompts used in this study and their outputs:

- Prompt for proposing five questions about the application of each ethical principle (see Fig. 2) : the objective of this prompt is to propose five questions the developer must answer. Each question is about the implementation of each ethical principle. The variables: "descApp" (software description), "domain" (domain of application), "principleName" (name of the ethical principle) are given as an input.

```
const prompt =  "You're an expert in Artificial Intelligence ethics. Here's the context: " +
"the Mauritanian government has a list of ethical principles for Artificial " +
"Intelligence applied in a given domain. The Mauritanian government wants to " +
"ensure that any developer of intelligent software respects these principles " +
"and implements them. To ensure that these principles are put into practice, " +
"the government wants to set up a system that generates five questions per " +
"principle. These questions are used to verify, in detail, the implementation " +
"of each principle. The system takes as input the description of the software, " +
"the field of application, and an ethical principle of artificial intelligence, " +
"and gives as output a list of five dichotomous questions on the implementation " +
"of that ethical principle. Generate a list of five questions, taking into account " +
"the following information: software description: " + descApp + "; application domain: " +
domain + "; ethical principle: " + principleName + ". Enclose the list in braces like the " +
"following JSON format: {\"questions\": [{" +
"\"id\": 1, \"name\": \"q1\", \"label\": \"question one\"},{" +
"\"id\": 2, \"name\": \"q2\", \"label\": \"question two\"},{" +
"\"id\": 3, \"name\": \"q3\", \"label\": \"question three\"},{" +
"\"id\": 4, \"name\": \"q4\", \"label\": \"question four\"},{" +
"\"id\": 5, \"name\": \"q5\", \"label\": \"question five\"}] }";
```

Fig. 2. Prompt that propose questions for developer

descApp = "IBM Watson for Oncology is an AI-powered software designed to assist oncologists in diagnosing and creating personalized treatment plans for cancer patients. Developed by IBM in collaboration with Memorial Sloan Kettering Cancer Center, this software leverages the power of AI to analyze large volumes of medical literature, patient data, and clinical trial information to provide evidence-based treatment recommendations", domain/Field = Healthcare, temperature = 0

- Output of the prompt when principal name is Transparency (the output is in the format JSON):

```
"questions":
[ "id": 1, "name": "q1", "label":
"Does the software provide
a clear explanation of how
it arrives at its treatment
recommendations?", "id": 2,
"name": "q2", "label": "Is
the software able to provide
a breakdown of the data and
sources used to generate its
recommendations?", "id": 3,
"name": "q3", "label": "Does the
software disclose any potential
biases or limitations in its
recommendations?", "id": 4,
"name": "q4", "label": "Is
the software able to explain
the reasoning behind its
recommendations in a way that is
understandable to non-technical
users?", "id": 5, "name": "q5",
"label": "Does the software
provide a mechanism for users to
access and review the data used
to generate its recommendations?"
]
```

- Output of the prompt when principal name is Responsibility:

```
"questions":
[  "id": 1, "name": "q1",
"label": "Does the software
accurately and reliably analyze
large volumes of medical
literature, patient data, and
clinical trial information to
provide evidence-based treatment
recommendations?",  "id": 2,
"name": "q2", "label": "Does the
software take into account the
individual needs and preferences
of each patient when providing
treatment recommendations?",
"id": 3, "name": "q3", "label":
"Is the software transparent
in its decision-making process,
providing clear explanations for
its treatment recommendations?",
"id": 4, "name": "q4", "label":
"Does the software have
mechanisms in place to ensure
patient data privacy and
security?",  "id": 5, "name":
"q5", "label": "Is the software
regularly monitored and updated
to ensure its accuracy and
effectiveness in providing
treatment recommendations?" ]
```

- Output of the prompt when principal name is Privacy and confidentiality:

```
"questions":
[  "id": 1, "name": "q1",
```

```
"label": "Does the software have
a clear and transparent privacy
policy that outlines how patient
data will be collected, used, and
protected?",  "id": 2, "name":
"q2", "label": "Is the software
designed to only collect and use
patient data that is necessary
for its intended purpose?",
"id": 3, "name": "q3", "label":
"Does the software have built-in
security measures to protect
patient data from unauthorized
access or breaches?",  "id": 4,
"name": "q4", "label": "Is the
software regularly audited and
updated to ensure compliance
with privacy and confidentiality
regulations?",  "id": 5, "name":
"q5", "label": "Does the software
have a mechanism for patients
to access, review, and request
changes to their personal data
collected by the software?" ]
```

- Prompt for proposing a list of norms to apply when developing an intelligent software (see Fig. 3). The following variables are given as an input: “listPrinciples” = list of ethical principles, “domain” = domain of application, “notations” = the weighting given by the government to ethical principles. Output of the

```
const prompt =
"Act as an expert in Artificial Intelligence ethics. " +
"You are familiar with the regulations governing the implementation " +
"of AI ethical principles in all fields. Here's the context: the " +
"Mauritanian government has a list of AI ethical principles applied " +
"in a given field. The government has assigned a weighting between " +
"1 and 5 to each principle. These weights represent the importance " +
"of these principles for the government. The government then wants " +
"to use these weights to generate two standards per ethical principle " +
"to ensure that any intelligent software developer respects government " +
"ethics. In other words, the software developer must respect and implement " +
"these ethical principles according to their weightings. If an ethical " +
"principle has a high weighting, this means it is considered particularly " +
"crucial. The standards associated with crucial ethical principles should " +
"therefore be more stringent and demanding. Conversely, if a principle " +
"has a low weighting, the corresponding standards may be less stringent. " +
"It should also be noted that these standards will change from one field " +
"to another. Software developers must respect the following ethical principles: " +
listPrincipes + ". They must respect these principles according to the following " +
"weightings: " + JSON.stringify(notations) +
". Generate a list of standards to follow (two standards per principle) that " +
"this developer must respect, given that their software concerns the domain: " +
domaine + ". Take into account that weightings influence the generation of norms by " +
"highlighting the relative importance of ethical principles. Do not mention the word " +
"\"norm\" in the list you're about to generate, and do not include the question in your " +
"answer. Enclose the list in braces like the following JSON format: " +
"{\"principles\": [{\"name\": \"principle's name\",\"weight\": weight,\"norms\": " +
"[\"norm one\",\"norm two\"]}]}";
```

Fig. 3. Prompt that propose a list of norms.

prompt that propose a list of norms:

Transparency:

- Provide clear and accurate information about the Al software and its capabilities to healthcare professionals and patients
- Ensure that the Al software does not hide or manipulate information from healthcare professionals and patients

Responsibility:

- Ensure that the Al software is properly maintained and monitored to prevent any potential harm to patients
- Establish clear lines of responsibility and accountability for the development and use of the Al software

Non-maleficence:

- Conduct thorough risk assessments and testing to identify and mitigate potential harms caused by the Al software
- Implement safeguards and protocols to prevent or minimize potential harms to patients from the Al software

Equity:

- Ensure that the Al software does not perpetuate or amplify existing inequities in the healthcare system
- Regularly assess and address any potential biases or discrimination in the Al software that could impact patient outcomes

Privacy and confidentiality:

- Implement strong data privacy and security measures to protect patient information collected and used by the Al software
- Ensure that the Al software adheres to all relevant privacy laws and regulations

Societal and environmental well-being:

- Consider the potential societal and environmental impacts of the Al software and take steps to mitigate any negative effects
- Regularly evaluate the Al software’s overall contribution to the well-being of society and the environment

Human autonomy:

- Ensure that the Al software does not impede or restrict patient autonomy in making healthcare decisions
- Provide options for patients to opt-out or request human intervention in the use of the Al software for their care

Reactivity and durability:

- Regularly monitor and update the Al software to ensure it remains relevant and effective in the rapidly changing healthcare landscape
- Implement a system for receiving and addressing feedback and concerns from healthcare professionals and patients about the Al software

Cultural and linguistic diversity:

- Ensure that the Al software is accessible to and inclusive of individuals from diverse cultures and linguistic backgrounds
- Conduct thorough testing and adaptation of the Al software to account for cultural and linguistic differences in healthcare practices

Democracy and political self-determination:

- Ensure that the development and use of the Al software is aligned with democratic principles and political self-determination
- Ensure transparent decision-making processes and active stakeholder engagement in the development and use of the Al software.

- Prompt for proposing the existing correlations between ethical principles (see Fig. 4): If the percentage of compliance of the developer is below the minimum value of "percentage of compliance with AI ethics" set by the government, the correlations between the ethical principles might become significant. These correlations can help government officials to decide whether to approve or not the developer's software. For instance, if there's a correlation between Principle A and Principle B, and the developer has closely followed the guidelines for Principle A but not for Principle B, then adherence to Principle A can compensate the lack in Principle B.

```
const prompt =
"You are an expert in Artificial Intelligence ethics. " +
"You are familiar with the different principles of AI ethics " +
"and understand the correlations that may exist between these principles " +
"depending on the domain of application of AI. " +
"I would like you to help me determine whether there are correlations " +
"between the AI ethical principles I'm about to provide you with. " +
"To identify these correlations, consider the domain of application of AI. " +
"The result should indicate the degrees of correlation–strong, weak, or non-existent– " +
"between the ethical principles. Provide a coherent and detailed analysis " +
"by exploring correlations between the following AI ethical principles in the domain of " +
domaine + " : " + listPrincipes + ". " +
"Analyze all possible combinations of correlations. Your answer should only include " +
"the combinations in which the correlations are \"strong\". " +
"Do not include correlations with the degree \"weak\" or \"non-existent\". " +
"Justify your answer by explaining the reasons behind these correlations. " +
"Enclose your answer in braces using the following JSON format: " +

VI. Discussion

As the industrial revolution allowed humans to delegate hard work to machines, the AI revolution will allow us to delegate to AI more and more white-collar tasks: bureaucratic at first but as AI will improve, it will be given increasing decision-making power. In medicine, for example, it is now accepted that AI is better and faster at spotting developing cancers on mammographies. This is great because it will save time to radiologists, who can then concentrate on more difficult cases.

AI assistants are becoming acting assistants, with www.jace.ai, "Your new AI employee" that will act for you: "Don't just chat, start acting today". On March 13th 2024, the Members of the European Parliament (MEP) adopted the Artificial Intelligence Act, setting safeguards on general purpose artificial intelligence, limiting the use of biometric identification systems by law enforcement, banning the use of AI for social scoring and manipulating or exploiting user vulnerabilities, and giving consumers the right to launch complaints and receive meaningful explanations.

All this means that societies are becoming increasingly aware of the risks posed by AI, but companies too: in order to get an "app" validated by Apple for upload on their appStore, the app needs to be "approved" and for this, the developer must follow hundreds of guidelines limiting the app to minimize its access to the contents on the phone or tablet on which it will be used.[2] For example, developers must: "Use AppStoreSettings to manage a user's App Store settings. You can set a maximum age rating for apps, deny in-app purchases, and require passwords for purchases."

This is what this work attempts at proposing: a tool to help governments formulate their policies and guide app developers, all this with the help of Large Language Models.

The transparent design that we propose promotes clarity in interaction, accountability in ethical deviations, and empowers stakeholders with informed decision-making capabilities. These are significant strides toward responsible AI development in a culturally-sensitive domain. The major advantage is its emphasis on explicability:

1) Transparency by design: By utilizing natural language as the medium of interaction and guidance, stakeholders can easily understand, adjust, and interpret the ethical guidelines and the feedback generated.

2) Ethical accountability: When the system identifies a potential bias or misalignment, it does not just flag it but also provides a contextually relevant explanation, making it easier for developers to pinpoint and rectify the root cause.

3) Informed decision-making: As the government and developers interact with the tool, they are consistently informed about how the software aligns with ethical norms, ensuring conscious and informed decisions throughout the development lifecycle.

However, as with all pioneering methods, it has its inherent challenges, which can be presented in terms of the following disadvantages:

[2]https://developer.apple.com/documentation/managedsettings/managedsettingsstore/appstore?changes=_6

- Bias from Language Models: Even with smart prompt engineering, there is a possibility that biases inherent in the LLM (acquired from the data it was trained on) could influence its feedback.
- Scalability Issues: As governments adjust ethical standards and as the volume and complexity of software applications increase, the system might face scalability issues, potentially slowing down feedback times.
- Lack of Ground Truth: Using natural language as a programming tool lacks a strict "ground truth" in the way traditional programming does. Hence, there is a level of interpretative ambiguity.

We, therefore, try to propose ideas:

- Enhanced Training: The LLM could be trained further using Mauritanian cultural and linguistic data. This would enhance its understanding of local nuances.
- Continuous Feedback Loop: Encourage continuous feedback from users, especially when they notice discrepancies or biases. This would help in refining the system over time.
- Incorporate Domain Experts: Engaging domain experts in sectors like healthcare, finance, etc. can help in fine-tuning the responses and ensuring domain-specific accuracy.

Consider the description of the software to be checked and its specific domain as contextual anchors; by integrating these as prompts, we guide the model's responses in a manner that is intricately aligned with the software's functionality and its ethical considerations within that domain. This is akin to "fine-tuning on-the-fly": the model's vast knowledge is channeled and constrained by the prompt, ensuring relevance and accuracy without the need for additional training data.

Moreover, this method underscores a significant advantage: it is adaptable. As software evolves or if there are shifts in domain-specific ethical standards, the prompts can be adjusted, thus ensuring that the AI's outputs remain congruent with the changing landscape. In essence, by leveraging smart prompt engineering, we are making a case that with the right prompts, models like LLM can be "programmed" in real time using natural language, bridging the gap between generalized AI knowledge and specific, localized requirements.

The advantages of the proposed approach compared to some existing methods is that, compared to existing frameworks such as the G7 toolkit[3] and the U.S. Intelligence Community's AI Ethics Framework[4], which address AI ethics broadly but lack a focus on generative AI, our proposed approach is distinct in its specific adaptation for generative AI tools. This model is dynamic, allowing government bodies to calibrate ethical standards flexibly across domains and adapt to evolving cultural contexts. Furthermore, the integrated government-developer feedback mechanism supports continuous alignment with ethical standards, which is typically absent in other frameworks. By utilizing LLMs, this tool also offers a novel, practical approach for real-time ethical compliance, reducing reliance on resource-intensive manual assessments.

VII. Conclusion

We present a possible solution to the challenges of modern software development in a sensitive sociocultural context, leveraging the strengths of large language models, and emphasizing explicability as its cornerstone. At the intersection of AI and ethics, our LLM-based tool serves as a critical bridge, particularly in the Mauritanian context.

Technically, our tool has two major components:

- For the government, it's a dynamic platform to set the ethical standards they want to promote. By tuning these standards, they can directly shape the AI's desired behavior, ensuring a permanent alignment with local values, all the while avoiding unintentional amplification of biases. Inserting their ethical wishes and priorities in the tool will force governments to think about them and integrating them in the tool will be equivalent to publishing them, resulting in ethical norms to be officially clear and known by all. So, the tool is there too to help the institution to refine their norms.
- For developers, it is a diagnosis tool. It allows them to check if their software aligns thanks to a set of domain specific questions, generated by LLM. The LLM engineering provides smart prompts to maximize robustness: if biases exist in data or algorithmic design — the tool will detect it via smartly formulated closed questions and answers. This immediate feedback helps developers rectify issues before they escalate into bigger problems.

For Mauritania, unchecked biases could lead to wrong decisions, from reinforcing stereotypes to misinformed policies. However, the inherent ambiguity of natural language as a tool is noteworthy and can be a serious limitation. But by acknowledging it and actively seeking solutions, such as further localized training, continuous feedback loops, and domain-specific expert input. Because it is adaptable and resilient, the process of improving it will increase the awareness, understanding and realization of governmental institutions on the importance of ethics.

Interestingly enough, even if the questions or the "guidance" of the LLM end up being strange, trying to understand their meaning will force users on both sides to think about ethics, which would not be so much the case if this tool did not exist.

The source code attached to this work is available on GitHub, here: https://github.com/Lalla-Aicha/Ethic-App-developer, https://github.com/Lalla-Aicha/EthicApp-Government. A lot of screenshots could not be added to this paper due to the maximum number of pages.

To further enhance the effectiveness and accessibility of our proposed ethical framework for AI, future work will focus on two key areas: improving the model's response precision and expanding its linguistic reach.

First, fine-tuning the LLM for conciseness and precision will be essential for achieving more targeted, contextually relevant outputs. By training the model on a curated dataset of ethical guidelines and domain-specific language, we aim to refine its ability to deliver concise and precise recommendations. This focused training will help reduce ambiguity and improve the clarity of responses.

Second, to support broader accessibility in diverse linguistic contexts, we plan to implement multilingual capabilities. This could involve training the model on datasets in multiple languages or incorporating advanced translation features that allow ethical standards to be accurately reflected in non-English-speaking regions. By expanding the tool's language support, we aim to provide a more inclusive platform, enabling it to be a valuable resource in global settings where ethical norms and practices vary significantly.

Through these advancements, the tool can become both more precise and more widely accessible, contributing to a more ethically aligned implementation of AI across diverse cultural and linguistic landscapes.

Simulation-Based Analysis of Evacuation Information Sharing Systems Using Geographical Data

Tatsuki Fukuda
Department of Data Science, Faculty of Data Science,
Shimonoseki City University, Shimonoseki, Japan

***Abstract*—In this study, we developed an agent-based model (ABM) to simulate and improve evacuation rates during flood disasters. Utilizing the "Evacuate Now Button", a previously proposed system for sharing real-time evacuation rates among residents, our experimental findings demonstrate a significant enhancement in evacuation behavior through this system. Simulations were conducted using geographical data from Nobeoka City, Miyazaki Prefecture, and Toyohashi City, Aichi Prefecture. Results showed that the "Evacuate Now Button" increased evacuation rates from a few percent to approximately 78% in Nobeoka City and 90% in Toyohashi City. We also investigated the effect of varying the range for calculating evacuation rates and the accuracy of the evacuation information shared with residents. It was found that larger calculation ranges led to higher final evacuation rates, while smaller ranges resulted in a quicker initial increase in evacuation behavior. These findings provide valuable insights for enhancing evacuation strategies and disaster preparedness in regions prone to floods.**

***Keywords*—Evacuation; flood disaster; evacuation rate; agent-based model; evacuate now button**

I. Introduction

Japan is a country frequently affected by natural disasters such as earthquakes, typhoons, and floods, making it crucial to strengthen disaster prevention measures. Past large-scale disasters have proven that prompt evacuation actions can save many lives. Despite the availability of evacuation warnings, many areas still report low evacuation rates. For instance, studies on Typhoons Faxai and Hagibis in 2019 reported that despite receiving evacuation information, many residents did not evacuate [1]. Various factors, such as insufficient understanding of evacuation advisories and delays in action, are thought to contribute to this low evacuation rate.

One of the reasons for the low evacuation rate is the lack of disaster awareness among residents and differences in how evacuation information is received. For example, it has been shown that personality traits significantly affect evacuation behavior, with individuals categorized as "cautious and proactive" more likely to take disaster information seriously and evacuate early, while those in the "careless and proactive" group are less likely to act upon the same information [2]. These differences in personality traits have a significant influence on how evacuation information is received and the subsequent actions taken, making them a critical factor in formulating disaster prevention strategies.

Additionally, research has been conducted on methodologies for accurately estimating evacuation rates during floods [3], providing valuable insights into modeling evacuation behavior. Other studies have analyzed evacuation behavior and its influencing factors during landslides, highlighting how the timing and method of information dissemination affect evacuation behavior [4]. In a case study of heavy rainfall in Gifu Prefecture, the impact of how evacuation information was provided on residents' evacuation decisions was analyzed [5]. Further, research has examined the influence of prior flood awareness on evacuation behavior, showing that pre-existing knowledge significantly promotes evacuation action [6].

In recent years, many studies have employed agent-based models (ABM) to simulate and deepen understanding of residents' evacuation behavior. For instance, the effects of flood warning lead times on evacuation behavior have been simulated using ABM, demonstrating the complexity of evacuation behavior and the importance of psychological and social factors [7]. Other studies have used ABM to analyze residents' behavior during floods, providing detailed insights into how individual evacuation actions are influenced by flood conditions [8]. These studies contribute to a deeper understanding of the diversity of evacuation behavior and the factors that influence it. Moreover, the effectiveness of mutual aid mechanisms within vulnerable communities has been analyzed using ABM, showing that mutual assistance contributes to improved evacuation behavior [9].

However, existing studies have not been able to sufficiently influence individual actions and decision-making, resulting in limited improvements in evacuation rates. Therefore, this study aims to utilize the new concept called the "Evacuate Now Button [10]" which we previously proposed. The system visually informs residents of evacuation statuses and fosters a sense of solidarity.

In this paper, we simulate evacuation behavior during disasters using an ABM and evaluate the effectiveness of new measures to improve evacuation rates. Specifically, based on survey results conducted in advance via the internet, the behavior of agents reflecting residents' personality traits and evacuation awareness will be modeled. This approach enables more accurate reproduction of the psychological and social factors influencing individuals' evacuation behavior.

Furthermore, this study will examine the effectiveness of the "Evacuate Now Button". This button is designed to encourage residents to take swift and appropriate evacuation actions during disasters, and its impact will be simulated using

ABM. The simulation will evaluate changes in evacuation rates with and without the button in order to clarify factors that contribute to the promotion of evacuation behavior.

The findings of this study are expected to provide important implications for future disaster prevention planning. In particular, understanding evacuation behavior based on residents' psychological factors and personality traits can improve the methods and content of evacuation information dissemination, as well as be applied to the design of education and training programs aimed at enhancing residents' evacuation awareness. This, in turn, is expected to contribute to the development of highly effective disaster prevention measures that help mitigate disaster damage.

The structure of this paper is as follows: Section II explains simulations using ABM as a foundational concept and introduces the proposed "Evacuate Now Button". Section III describes the specifications of the simulation program used in this study. Section IV presents the results of simulations using actual topographical maps and Section V discusses these results. The conclusion and the future work are presented in Sections VI and VII, respectively.

II. Preliminaries

In this section, we provide an overview of the basic concept of the "Evacuate Now Button" and the ABM used in this study. This section aims to provide the foundational knowledge necessary for understanding the design of the simulations and the assumptions underlying the experiments, facilitating discussions in the following section.

A. *Evacuate Now Button* [10]

In a previous survey we conducted on residents regarding evacuation during heavy rains, 92% of respondents indicated that they were concerned about the evacuation status of others when deciding whether to evacuate. Based on this, we proposed a system called the "Evacuate Now Button". This is a physical button installed at the entrance of each residence, which residents press before evacuating. By pressing the button, the evacuation status of the residents is recorded and shared with emergency services, such as fire departments, to facilitate the rescue of those who have not evacuated in time. Additionally, the evacuation status is shared with residents, allowing them to gauge the evacuation progress in their area, which may encourage further evacuations. However, rather than sharing the evacuation status of individual households, the system provides aggregated evacuation rates for clusters of homes. This prevents the risk of burglary that could arise if specific households were known to have evacuated.

When sharing evacuation status with nearby homes, there is a possibility that residents will either evacuate in coordination with their neighbors or refrain from evacuating if no one else does. However, as mentioned earlier, 92% of survey respondents stated that they are concerned about the evacuation status of others, suggesting that the remaining 8% would decide to evacuate regardless of their neighbors' actions. Therefore, it is more likely that this 8% will begin evacuating based on information from local authorities or their own judgment, potentially prompting others to follow suit.

There are still many considerations for implementing this system, such as determining the appropriate cluster size for sharing evacuation rates. Therefore, in this study, we use ABM simulations to explore effective methods for utilizing the "Evacuate Now Button".

B. *Simulations Using ABM*

An ABM is a simulation method where autonomous entities, referred to as agents, interact with each other within a system. ABM is a powerful simulation technique that can be applied to a variety of real-world systems and is particularly useful for understanding and predicting complex collective behaviors.

1) Features and Advantages of ABM: The ABM provides several unique features that make it a powerful tool for simulating complex systems. By allowing individual agents to interact with each other and their environment, ABM can capture emergent behaviors that are not easily represented by other modeling techniques. The following are some of the key features and advantages of ABM [11]–[15].

- Reproduction of Individual Behavior

In ABM, agents act based on their unique attributes and behavioral rules, interacting with the environment to produce complex collective behaviors. This allows for a detailed reproduction of complex social phenomena, such as evacuation behavior and risk perception during disasters.

- Understanding System Dynamics

ABM is well-suited for understanding the overall behavior of a system that emerges from interactions among agents, known as "emergent phenomena". This is a significant advantage over other modeling methods. For example, by simulating residents' evacuation behavior and movement patterns during floods, ABM can be used to evaluate the effectiveness of disaster response measures.

- Scenario Comparison and Evaluation

ABM is useful for comparing agent behavior across different scenarios and is widely applied in evaluating policy effects and disaster response measures. For example, it allows analysis of how different evacuation routes or shelter locations impact residents' evacuation behavior.

2) Practical Applications of ABM: ABM has been widely used for modeling human evacuation behavior in natural disasters, particularly in studies focusing on flood evacuation, where it has proven effective for detailed simulation of evacuation behavior [16]. In flood evacuation simulations, assigning agents with different attributes (such as age, gender, and socioeconomic factors influencing evacuation decisions) enables more realistic reproduction of evacuation behavior [17]. Specific applications of ABM include the development of models that help humanitarian organizations respond more effectively to flood evacuations by predicting evacuation dynamics and analyzing movement patterns to shelters [12].

Other studies have simulated pedestrian responses during emergency floods to evaluate how behavioral rules affect risk analysis, analyzing how pedestrians adjust their actions

according to flood conditions using an agent-based approach [18], offering valuable insights for urban evacuation planning. Moreover, ABM has been used to model household decision-making regarding the adoption of flood mitigation measures, analyzing how individual choices impact regional flood risk and collective disaster prevention behavior [16]. ABM has also been applied to dynamic simulations of flood-human interactions, providing detailed analyses of residents' evacuation behavior and subsequent effects during floods. In urban settings, research has simulated pedestrian evacuation behavior during floods, providing data useful for emergency evacuation planning [15].

These simulations provide valuable information for optimizing emergency response measures during disasters. A comprehensive review of the application of ABM to flood risk analysis was conducted in reference [19], tracking trends in social dynamics and behavioral changes.

As demonstrated, ABM is highly effective for understanding and predicting evacuation behavior during floods.

III. Simulator Specifications

In this study, we aim to examine the effective usage of the "Evacuate Now Button" by simulating residents' evacuation behavior using an ABM. First, the specifications of the simulation are described below.

A. Overall Process

This simulation is developed using Unity and C# scripts. While visual effects are not necessarily required for the simulation itself, Unity was chosen to facilitate the use of simulation videos for disaster awareness events and other purposes.

The program first loads a three-dimensional terrain model and places agents in locations corresponding to residential buildings. In this simulation, one agent represents one residence, including multi-unit buildings such as apartments, where one agent is assigned per building. For the terrain model, we utilize the 3D urban models developed under the PLATEAU project [20], promoted by Japan's Ministry of Land, Infrastructure, Transport and Tourism [21].

Agents, which represent residents, determine whether or not to begin evacuation based on evacuation information provided by local authorities and the evacuation status of surrounding residents. The simulation progresses according to Algorithm 1.

Algorithm 1 Overall Process

1: Load the PLATEAU model.
2: Place agents in residential locations.
3: If the time for issuing a warning has been reached, issue it.
4: Agents decide whether to begin evacuation every T_1 seconds.
5: If Warning Level 5 has been issued, end the simulation.
6: Advance the simulation by one time step.
7: Return to Step 3.

B. Agent Evacuation Behavior

Each agent determines whether to begin evacuation every T_1 seconds. The decision-making process is based on the results of the previously mentioned resident survey [10]. Agents are divided into one of two groups, Group I or Group II. Group I consists of agents that make their evacuation decisions without considering the evacuation rate of surrounding residents. In contrast, Group II includes agents that take into account the evacuation rate of their neighbors when deciding whether to evacuate.

For Group I agents, there is a possibility they will initiate evacuation when evacuation information is issued for their region. However, they do not always evacuate when conditions are met, but instead decide probabilistically with a certain probability P.

While some residents may evacuate before official evacuation information is issued, this study does not take such behavior into account. This is because excluding early evacuators does not positively contribute to the goal of improving the overall evacuation rate, which is the primary objective of this study. It is recognized, however, that the absence of early evacuators could negatively affect the overall evacuation rate.

At the start of the simulation, agents are randomly assigned to either Group I (approximately 8%) or Group II (approximately 92%). Additionally, Group II agents are further subdivided based on the extent to which they are influenced by the evacuation rates of others. Specifically, according to the survey results [10], agents are categorized into Group II(a) through Group II(e), as shown in Table I, which reflects the timing of evacuation initiation in relation to the surrounding evacuation rate.

TABLE I. Results of the Survey Asking at what Evacuation Rate Among Surrounding Residents Respondents Would Begin to Evacuate

Evacuation Timing	Respondent Percentage	Group
10% evacuation rate	20%	II(a)
30% evacuation rate	31%	II(b)
50% evacuation rate	32%	II(c)
80% evacuation rate	12%	II(d)
100% evacuation rate	5%	II(e)

Agents in Group II(a) through Group II(e) also make their evacuation decisions probabilistically with a certain probability P, rather than always evacuating when conditions are met.

C. Discount Rate for Evacuation Probability

Agents consider evacuating when certain conditions are met, such as when the evacuation rate of surrounding residents exceeds a certain threshold. When this occurs, they decide whether to evacuate with probability P. However, based on real-world evacuation behavior, it can be assumed that if an agent does not evacuate the first time conditions are met, the barrier to evacuation increases in subsequent evaluations. To reflect this in the simulation, a discount rate is applied to the evacuation probability. Let the discount rate be denoted as α. The probability P_i that an agent evacuates during the i-th evaluation is given by Eq. (1), where $P_1 = P$:

$$P_i = \alpha \times P_{i-1} \quad (i > 2) \tag{1}$$

This formula models the decreasing likelihood of evacuation as agents delay their decision.

D. Start and End of the Simulation

The simulation begins when evacuation information equivalent to "Warning Level 3" is issued. Warning Level 3 corresponds to evacuation information for elderly and vulnerable residents. Prior to the 2021 revisions, it corresponded to "evacuation commencement," which makes it an appropriate starting point for the simulation.

The simulation ends when evacuation information corresponding to "Warning Level 5" is issued. Warning Level 5 is defined as a situation where it is no longer possible to safely evacuate, and lives are at risk, meaning all evacuations should be completed before this level is issued.

The timing of each warning level's issuance is determined based on real-world examples of past incidents.

Additionally, each agent is given a maximum delay of T_2 from the start of the simulation, after which they begin to act asynchronously.

IV. Experiments

We verified the operation of the simulation program developed according to the specifications defined in Section III. The simulation was run under the conditions based on the heavy rain disaster that occurred in Nobeoka City, Miyazaki Prefecture in September 2022 [22] and the heavy rain disaster in Toyohashi City, Aichi Prefecture in June 2023 [23]. The conditions are outlined in Table II and the values of other parameters used in the simulation are shown in Table III.

Experiments are conducted using multiple random seed values, and the average values are calculated. Fig. 1 shows the state of the simulation in progress. The blue color represents the residences of agents who have not yet evacuated, and the red color represents the residences of agents who have started evacuating.

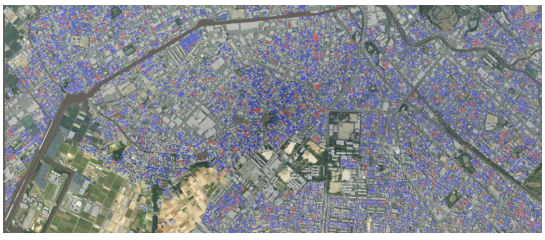

Fig. 1. The state during the simulation. The red dots represent the evacuted agents while the blue dots represent agents in their house.

In Section IV-A, we present the results of examining the impact of the range used to calculate the evacuation rate. Section IV-B discusses the results of examining the effect of the accuracy of the evacuation rate communicated to the agents. In Section IV-C, we present the results of evaluating the effectiveness of the "Evacuate Now Button". The discussion of these results is provided in Section V.

A. Distance for Calculating Surrounding Evacuation Rate

Each agent is able to know the evacuation rate of residences within a radius L meters from their own residence, and they decide whether to evacuate based on this information. We first examined the optimal range for calculating the evacuation rate that agents can access. The results using the geographical data of Toyohashi City, Aichi Prefecture, and Nobeoka City, Miyazaki Prefecture, are shown in Fig. 2 and 3, respectively.

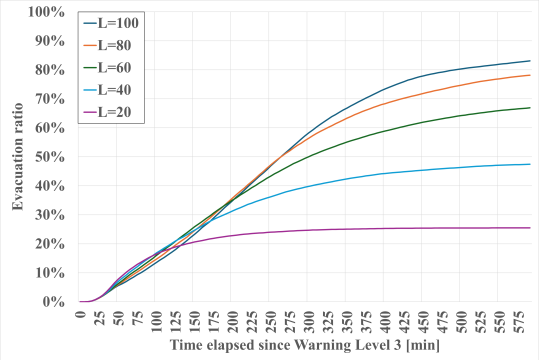

Fig. 2. Evacuation rate transition in the simulation with Toyohashi City's data. Agents know accurate evacuation rate of their surroundings within a range of L meters.

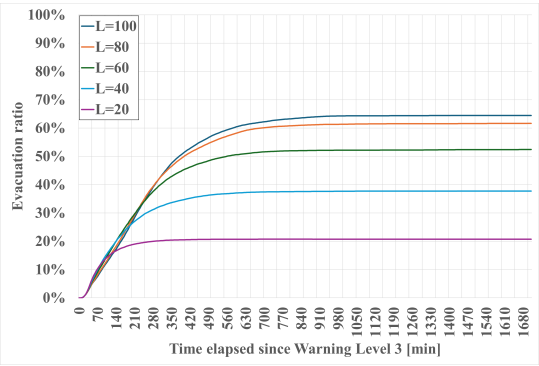

Fig. 3. Evacuation rate transition in the simulation with Nobeoka City's data. Agents know accurate evacuation rate of their surroundings within a range of L meters.

In both Fig. 2 and 3, the horizontal axis represents the time elapsed since the issuance of Warning Level 3, and the vertical axis represents the evacuation rate. L is varied from 20 to 100 meters in increments of 20 meters. Agents are able to accurately know the evacuation rate of residences within a radius L meters from their own location.

B. Accuracy of Communicated Evacuation Rates

Agents can know the evacuation rate in the surrounding area and decide whether to evacuate based on this information. However, communicating a low evacuation rate may, in fact, hinder evacuation behavior. Therefore, a method of providing a more generalized evacuation rate, rather than a precise one, is proposed. For example, if the actual evacuation rate is between 10% and 30%, the agent would be informed that the evacuation rate is "up to 30%". This would result in agents perceiving a higher evacuation rate than the actual one,

TABLE II. WARNING LEVELS AND ANNOUNCEMENT TIMES DURING HEAVY RAIN DISASTERS IN NOBEOKA (2022), AND TOYOHASHI (2023)

Warning Level	Issuance Time in Nobeoka	Issuance Time in Toyohashi
3	17:00, Sep. 17th, 2022	6:40, Jun. 2nd, 2023
4	8:00, Sep. 18th, 2022	14:40, Jun. 2nd, 2023
5	21:30, Sep. 18th, 2022	16:30, Jun. 2nd, 2023

TABLE III. PARAMETERS RELATED TO AGENTS' EVACUATION DECISIONS

Parameter	Description	Value
T_1 [min]	Interval at which agents decide whether to evacuate	$15 \pm 50\%$
T_2 [min]	Delay time before agents begin actions	$30 \pm 50\%$
P	Probability of starting evacuation when conditions are met	0.5
α	Discount rate applied to P when evacuation is not initiated	0.8

potentially encouraging evacuation. However, if the range is too broad, the credibility of the information may decrease. Thus, we conducted experiments using two different patterns, Pattern 1 and Pattern 2, as shown in Table IV and Table V.

TABLE IV. PATTERN 1 FOR THE EVACUATION RATE COMMUNICATED TO AGENTS

Actual Evacuation Rate [%]	Evacuation Rate Shared with Agents [%]
0	0
$0 < r \leq 50$	50
$50 < r \leq 100$	100

TABLE V. PATTERN 2 FOR THE EVACUATION RATE COMMUNICATED TO AGENTS

Actual Evacuation Rate [%]	Evacuation Rate Shared with Agents [%]
0	0
$0 < r \leq 30$	30
$30 < r \leq 50$	50
$50 < r \leq 80$	80
$80 < r \leq 100$	100

Additionally, we define Pattern 3 as the case where the actual evacuation rate is communicated accurately to the agents. The results for Pattern 3 correspond to Fig. 2 and 3.

For each of these patterns, the agents' level of trust in the "Evacuate Now Button" was set according to the values shown in Table VI.

TABLE VI. THE VALUES REPRESENTING THE AGENTS' LEVEL OF TRUST IN THE SYSTEM FOR EACH COMMUNICATION PATTERN

Pattern	Trust Level θ
1	0.3
2	0.75
3	1

When the trust level θ is applied, agents use the adjusted evacuation rate ρ', which is calculated from the evacuation rate ρ obtained through the "Evacuate Now Button" and a random number k $(0 \leq k < 1)$, using the formula $\rho' = \rho \times (\theta + k(1 - \theta))$. This adjusted evacuation rate ρ' is used as the current evacuation rate.

The results of the experiments conducted using the geographical data of Toyohashi City, Aichi Prefecture for Pattern 1 and Pattern 2 are shown in Fig. 4 and 5, respectively. Similarly, the results using the geographical data of Nobeoka City, Miyazaki Prefecture for Pattern 1 and Pattern 2 are shown in Fig. 6 and 7, respectively.

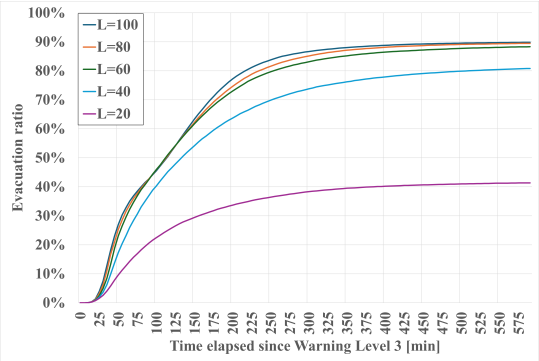

Fig. 4. Evacuation rate transition in the simulation with Toyohashi City's data. Agents can obtain the evacuation rate of their surroundings within a range of L meters, following the rule in Table IV.

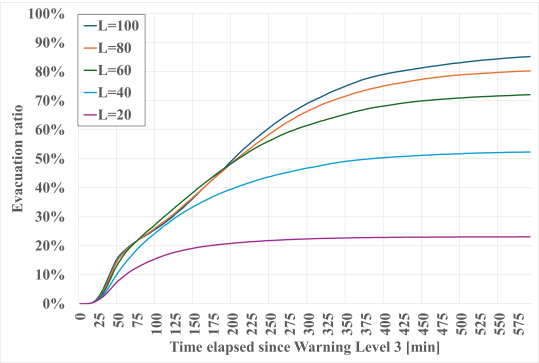

Fig. 5. Evacuation rate transition in the simulation with Toyohashi City's data. Agents can obtain the evacuation rate of their surroundings within a range of L meters, following the rule in Table V.

In Fig. 4 through 7, the horizontal axis represents the time elapsed since the issuance of Warning Level 3, while the vertical axis represents the evacuation rate. L is varied from 20 to 100 meters in increments of 20 meters.

C. Effectiveness of the "Evacuate Now Button"

Lastly, we investigated the effectiveness of the "Evacuate Now Button". As a comparison, we considered the case where the button is not used. In this scenario, agents are unable to know the evacuation rate of their surroundings. Instead, agents

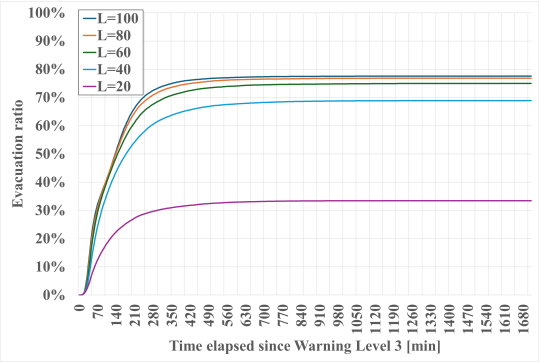

Fig. 6. Evacuation rate transition in the simulation with Nobeoka City's data. Agents can obtain the evacuation rate of their surroundings within a range of L meters, following the rule in Table IV.

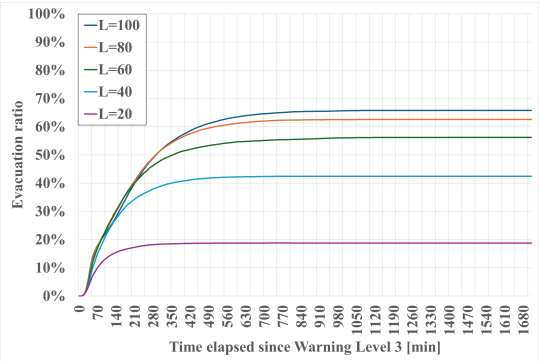

Fig. 7. Evacuation rate transition in the simulation with Nobeoka City's data. Agents can obtain the evacuation rate of their surroundings within a range of L meters, following the rule in Table V.

are assumed to observe the evacuation behavior of others within five minutes of them deciding to evacuate, and thus gain an understanding of the evacuation situation.

The results of the experiments using the geographical data of Toyohashi City, Aichi Prefecture, and Nobeoka City, Miyazaki Prefecture, are shown in Fig. 8 and 9, respectively.

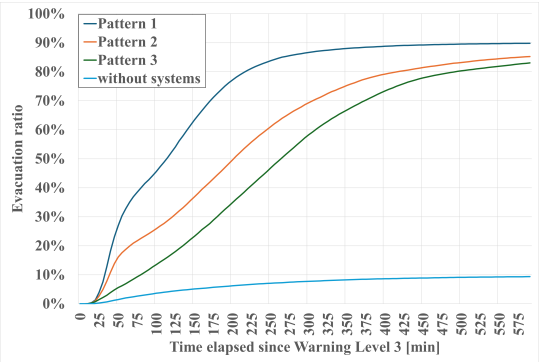

Fig. 8. Evacuation rate transition with / without the evacuation rate sharing system (Patterns 1-3) in the simulation with Toyohashi City's data. Agents with the system can obtain the evacuation rate of their surroundings within $L = 100$ meters. agents without the system can only observe those within a 40 meter range who have evacuated within the last 5 minutes.

In Fig. 8 and 9, the horizontal axis represents the time

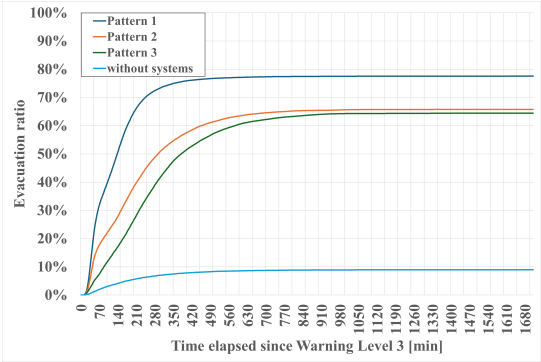

Fig. 9. Evacuation rate transition with / without the evacuation rate sharing system (Patterns 1-3) in the simulation with Nobeoka City's data. Agents with the system can obtain the evacuation rate of their surroundings within $L = 100$ meters. agents without the system can only observe those within a 40 meter range who have evacuated within the last 5 minutes.

elapsed since the issuance of Warning Level 3, and the vertical axis represents the evacuation rate. For Pattern 1, Pattern 2, and Pattern 3, the range within which agents can know the evacuation rate was set to $L = 100$ meters, while agents without the evacuation information sharing systems can observe the evacuation behavior of others within a 40-meter radius.

V. Discussion

This section discusses the experimental results presented in Section IV.

A. Distance for Calculating Surrounding Evacuation Rate

Fig. 2 and 3 show the results of varying the range L used to calculate the evacuation rate that agents can access. From these figures, we can observe that increasing L leads to a higher final evacuation rate. This is likely because, with a larger L, the probability of finding someone who has already begun evacuation increases within that range, which then influences other agents to evacuate. In other words, increasing L facilitates the spread of an "evacuation chain".

However, we also see that in the early stages, shortly after Warning Level 3 is issued, the evacuation rate increases more quickly when L is smaller. This is likely due to the smaller population size within a smaller range L, where the evacuation of just one agent has a larger impact on the overall evacuation rate for that group.

These results suggest that, when there is sufficient time after the issuance of Warning Level 3, increasing L could raise the evacuation rate. In other words, if the impact of the heavy rain can be predicted early and Warning Level 3 is issued at an appropriate time, a larger L is preferable. However, in situations where disasters occur shortly after the issuance of Warning Level 3, a smaller L might be more effective in increasing the evacuation rate more quickly.

B. Accuracy of Communicated Evacuation Rates

In the simulations conducted using the geographical data from Toyohashi City, Aichi Prefecture, as shown in Fig. 4 and

5, the final evacuation rate is highest when $L = 100$, consistent with the results in Fig. 2. Comparing Pattern 1 and Pattern 2, we observe that Pattern 1 achieves a higher final evacuation rate for all values of L. However, as L increases, the difference between the final evacuation rates of Pattern 1 and Pattern 2 becomes smaller. This suggests that when L is small, Pattern 1 yields a higher effect, but as L increases, the difference between Pattern 1 and Pattern 2 diminishes.

In the simulations using the geographical data from Nobeoka City, Miyazaki Prefecture, as shown in Fig. 6 and 7, the results are similar to those in Fig. 4 and 5: Pattern 1 produces a higher final evacuation rate than Pattern 2, and the difference between the two patterns decreases as L increases. However, in the case of Nobeoka City, the final evacuation rate difference between Pattern 1 and Pattern 2 is approximately 10%, which is larger than the difference observed in Toyohashi City.

From Fig. 4 through 7, we conclude that Pattern 1 consistently results in higher early and final evacuation rates compared to Pattern 2. Therefore, Pattern 1 is the more favorable option.

C. Effectiveness of the "Evacuate Now Button"

Fig. 8 and 9 show that the scenario without the "Evacuate Now Button" yields the lowest evacuation rates, with a final rate of about 9%. In comparison, the actual evacuation rate during the heavy rain disaster in Toyohashi City, Aichi Prefecture, was approximately 0.068% [23], which may seem somewhat detached from the simulation result. However, it is important to consider that factors such as community relationships, the location and number of shelters, and resident demographics likely influence real-world evacuation decisions. Previous studies involving surveys across multiple regions have shown that the evacuation rate for storm and flood disasters is generally around a few percent [24], making the results of this simulation reasonable when considering the exclusion of regional characteristics beyond geography.

When the "Evacuate Now Button" is introduced, the effect varies depending on how the evacuation rate is communicated to the agents, but in all cases—Pattern 1 through Pattern 3—the evacuation rate is significantly higher compared to the scenario without the system. In particular, in the case of Pattern 1, the simulations show an evacuation rate of approximately 78% for Nobeoka City (Fig. 9) and approximately 90% for Toyohashi City (Fig. 8), indicating a remarkably high evacuation rate.

As the evacuation rate increases, the number of people who need to be rescued in an emergency decreases, reducing the burden on fire departments and other rescue teams, allowing them to allocate more resources to individual rescues.

D. Limitations

The limitations of this study include the following: First, the behavior of agents used in the simulation is modeled based on survey results, and thus may not fully replicate the actual behavior of residents. Additionally, social factors such as the calculation range of evacuation rates and relationships within the community have been simplified, which is another limitation. Considering these limitations, future research should aim to develop a model that incorporates more detailed regional characteristics and psychological factors of residents' behavior.

VI. Conclusion

In this study, we developed a simulation based on an ABM to improve evacuation rates during heavy rain disasters. We experimentally demonstrated how much the "Evacuate Now Button," our previously proposed evacuation rate sharing system, could enhance evacuation rates. Additionally, we investigated the optimal range for calculating evacuation rates and the level of accuracy in the shared evacuation rate that would best contribute to increasing the evacuation rate.

The results showed that using the "Evacuate Now Button" could raise the evacuation rate from a few percent to approximately 78% in the case of Nobeoka City, Miyazaki Prefecture, and to approximately 90% in the case of Toyohashi City, Aichi Prefecture. Furthermore, regarding the range for calculating evacuation rates, it was found that a larger range led to a higher final evacuation rate. However, we also discovered that a smaller range resulted in a quicker initial rise in the evacuation rate. Therefore, if the goal is to increase the evacuation rate early, a smaller range should be used, while if the goal is to maximize the final evacuation rate, a larger range is preferable.

VII. Future Work

The discussion concluded that the simulation results are reasonable when regional characteristics are excluded. However, as evacuation rates vary between regions, it is expected that developing a simulator that incorporates regional factors would further improve the accuracy of evacuation rate predictions. While incorporating factors such as shelter locations is relatively straightforward, integrating more complex aspects like relationships among residents would be challenging. Therefore, future research will need to explore methods for including such factors in the simulation program.

***Abstract*—Optimal Transport (OT) is a powerful tool widely used in healthcare applications, but its high computational cost and sensitivity to data changes make it less practical for resource-constrained settings. These limitations also contribute to increased environmental impact due to higher CO2 emissions from computing. To address these challenges, we explore Unbalanced Optimal Transport (UOT), a variation of OT that is both computationally efficient and more robust to data variability. We apply UOT to two healthcare scenarios: independence testing on breast cancer data and modeling heart rate variability (HRV). Our experiments show that UOT not only reduces computational costs but also delivers reliable results, making it a practical alternative to OT for socially impactful applications.**

***Keywords*—Optimal transport; unbalanced optimal transport; healthcare**

I. Introduction

Optimal Transport (OT), first formulated by Gaspard Monge [23] and further developed by Kantorovic [15], addresses the fundamental question of finding the most efficient way to minimize the cost of transporting mass from one distribution to another. OT has evolved into many practical applications in fields such as healthcare [42], [39], [41], machine learning [12] and domain adaptation [7]. For healthcare applications such as breast cancer detection [39] or heart rate variability (HRV) modeling [42], which may be needed widely by also resource-constrained medical institutes and have a direct impact on human wellness, the computational efficiency and the robustness of the deployed models are paramount. Nevertheless, OT has been known to suffer from computational bottleneck [21] and sensitivity to problem structure or data perturbation [17]. Such limitations of vanilla OT can make solution models to these healthcare applications not accessible to medical institutes with limited budget [36], raise the CO2 output of computing resources thereby negatively impacting the environment [16], and become a less reliable tool in the realm of healthcare [8].

To alleviate the above limitations, Unbalanced Optimal Transport (UOT) is recently proposed variant of the classical OT formulation that penalizes the marginal constraints based on some given divergence. Among the various divergences used in the literature such as Kullback-Leiber (KL) divergence [6], squared ℓ_2 norm [3], ℓ_1 norm [4], and ℓ_p norm [18], UOT with KL divergence is the most prominent for its wide applicability, flexibility and efficient computation [30]. UOT has shown its prominence in various applications in statistics and machine learning [11]. Recent works [35], [17], [30] have facilitated the fast computation of UOT and provided guarantees on its statistical and approximation properties.

Recent advancements in UOT have significantly reduced its computational complexity and improved its scalability, enabling its application in large-scale machine learning tasks. Notable among these advancements are efficient gradient-based methods [30], which not only accelerate UOT computations but also provide theoretical guarantees for convergence and statistical properties. These methods are especially important in scenarios requiring real-time processing, such as medical diagnostics or dynamic resource allocation in healthcare. Furthermore, UOT has been shown to be more robust than traditional OT in handling outliers and noisy data, making it a valuable tool in applications where data quality is variable [17].

As computational efficiency and environmental concerns become more critical in the age of large-scale AI, UOT stands out as a method that balances performance with resource utilization. By relaxing the mass conservation constraint, UOT reduces the computational burden while maintaining the accuracy required in sensitive applications such as healthcare. This reduced computational cost also has positive implications for sustainability, as it lowers the energy consumption and CO2 emissions associated with large-scale computations [16]. As a result, UOT not only provides a more flexible and scalable approach to OT problems but also addresses key limitations that have historically hindered the adoption of OT in resource-constrained settings.

A. Contributions

In this paper, we benchmark and empirically validate the effectiveness of UOT on various healthcare applications, which are the statistical independence test on the breast cancer dataset following the setting in [39] and HRV modeling in [42]. The code is given in https://github.com/quipp12/UOT_Healthcare.git. Our contributions can be summarized as follows:

- For both healthcare applications, statistical independence test [39] and HRV modeling [42], the OT

*Equal Contribution

distance is used as a component in these pipelines, where the celebrated Sinkhorn algorithm with the costly computational cost of $\tilde{O}\left(n^2\varepsilon^{-2}\right)$ [19] is used. To alleviate the computational bottleneck, we propose the adoption of UOT as well as the Sinkhorn variant specifically designed for UOT distance with improved complexity of $\tilde{O}\left(n^2\varepsilon^{-1}\right)$ [35]. This facilitates not only seamless integration of UOT (in place of OT) in these applications but also an acceleration in computation, which is consistently demonstrated in Section III and Section IV

- For HRV modeling [42], in addition to the realization of UOT's computational benefit, our experimental investigation reviews the high training cost from the original model using Gradient Descent (GD). Consequently, we implement the GD with Momentum (GDM) into the model to significantly expedite the training process, while maintaining comparable or even better Mean Squared Error (MSE)- the main performance metric (Section IV).
- Our primary theoretical contribution focuses on establishing a bound that quantifies the difference between the costs of Unbalanced Optimal Transport (UOT) and regular Optimal Transport (OT). We provide a rigorous guarantee that as the parameter controlling the mass relaxation in UOT increases, the difference between the UOT cost and the OT cost becomes smaller. This result ensures that the approximation made by UOT closely mirrors the exact cost computed by OT when enough relaxation is allowed.

II. Approximating Optimal Transport via Unbalanced Optimal Transport

A. Notations

Denote by $\mathbb{R}_+^n$ the set of all vectors in $\mathbb{R}^n$ with nonnegative entries. Bold capital letters and lowercase letters respectively stand for matrices and vectors. For $p \in [1, \infty), \|.\|_p$ denotes the l_p norm. The Frobenius inner product of two matrices of the same size is defined as $\langle \mathbf{A}, \mathbf{B} \rangle = \sum_{i,j=1}^{n} A_{ij} B_{ij}$.

B. Optimal Transport

Consider two discrete distributions $\mathbf{a}, \mathbf{b} \in \mathbb{R}_+^n$, specifically $\mathbf{a} := (a_1, \ldots, a_n), \mathbf{b} := (b_1, \ldots, b_n)$ with equal masses, i.e., $\|\mathbf{a}\|_1 = \|\mathbf{b}\|_1$. Denote $a_{min} = \min_{1 \le i \le n}\{a_i\}$ and $b_{min} = \min_{1 \le i \le n}\{b_i\}$ as the minimum masses. The OT problem seeks to find a matrix $\mathbf{X} \in \mathbb{R}_+^{n \times n}$ represented a transport plan which maps $\mathbf{a}$ to $\mathbf{b}$ at a minimum cost, i.e.

$$\mathbf{OT}(\mathbf{a}, \mathbf{b}) := \min_{\mathbf{X} \in \Pi(\mathbf{a}, \mathbf{b})} \langle \mathbf{C}, \mathbf{X} \rangle, \tag{1}$$

where $\mathbf{C} \in \mathbb{R}_+^{n \times n}$ is a cost matrix whose entries are distances between measures of these distributions and $\Pi(\mathbf{a}, \mathbf{b}) := \left\{\mathbf{X} \in \mathbb{R}_+^{n \times n} : \mathbf{X}\mathbf{1}_n = \mathbf{a}, \mathbf{X}^\top \mathbf{1}_n = \mathbf{b}\right\}$. Denote by $\mathbf{X}^{\text{OT}} = \operatorname{argmin}_{\mathbf{X} \in \Pi(\mathbf{a}, \mathbf{b})} \langle \mathbf{C}, \mathbf{X} \rangle$ be the optimal solution to the OT problem (1).

C. Unbalanced Optimal Transport

First, we define the $\mathbf{KL}$ divergence function between two vectors $\mathbf{x}, \mathbf{y} \in \mathbb{R}_+^n$ as

$$\mathbf{KL}(\mathbf{x} \| \mathbf{y}) := \sum_{i=1}^{n} \left(\mathbf{x}_i \log\left(\frac{\mathbf{x}_i}{\mathbf{y}_i}\right) - \mathbf{x}_i + \mathbf{y}_i \right)$$

Assume two finite measures $\mathbf{a}, \mathbf{b} \in \mathbb{R}_+^n$, specifically $\mathbf{a} := (a_1, \ldots, a_n), \mathbf{b} := (b_1, \ldots, b_n)$ with possibly different total mass. The UOT problem seeks to find a matrix $\mathbf{X} \in \mathbb{R}_+^{n \times n}$ represented a transport plan, i.e.

$$\begin{aligned} \mathbf{UOT}_{\mathbf{KL}}(\mathbf{a}, \mathbf{b}) = \min_{\mathbf{X} \in \mathbb{R}_+^{n \times n}} \big\{ f(\mathbf{X}) := & \langle \mathbf{C}, \mathbf{X} \rangle + \tau \mathbf{KL}\left(\mathbf{X}\mathbf{1}_n \| \mathbf{a}\right) \\ & + \tau \mathbf{KL}\left(\mathbf{X}^\top \mathbf{1}_n \| \mathbf{b}\right) \big\} \end{aligned} \tag{2}$$

where $\mathbf{C} \in \mathbb{R}_+^{n \times n}$ is a given cost matrix and $\tau > 0$ is a given regularization parameter. Denote by $\mathbf{X}^{\text{UOT}} = \operatorname{argmin}_{\mathbf{X} \in \mathbb{R}_+^{n \times n}} f(\mathbf{X})$ be the optimal solution to the UOT problem (2).

The parameter τ effectively acts as a regularization term. A larger τ means a stronger penalty on the mass divergence, making the solution more balanced (closer to the original distributions $\mathbf{a}$ and $\mathbf{b}$). A smaller τ reduces the effect of the regularization term, allowing for more flexibility in the transport plan. With a very small τ, the solution may deviate significantly from the target distributions in favor of minimizing the transport cost.

D. Approximation Error of UOT

When $\mathbf{a}^\top \mathbf{1}_n = \mathbf{b}^\top \mathbf{1}_n$ and $\tau \to \infty, \mathbf{UOT}_{\mathbf{KL}}(\mathbf{a}, \mathbf{b})$ turns to the regular $\mathbf{OT}(\mathbf{a}, \mathbf{b})$.

Formally, taking the limit as $\tau \to \infty$ in the UOT objective function:

$$\lim_{\tau \to \infty} \left(\langle \mathbf{C}, \mathbf{X} \rangle + \tau \mathbf{KL}(\mathbf{X}\mathbf{1}_n \,||\, \mathbf{a}) + \tau \mathbf{KL}(\mathbf{X}^\top \mathbf{1}_n \,||\, \mathbf{b}) \right)$$

enforces $\mathbf{X}\mathbf{1}_n = \mathbf{a}$ and $\mathbf{X}^\top \mathbf{1}_n = \mathbf{b}$ at the optimal solution, which recovers the OT problem (1). Moreover, [30, Theorem 26] provided the tight non-asymptotic characterization on the distance gap between $\mathbf{UOT}_{\mathbf{KL}}(\mathbf{a}, \mathbf{b})$ and $\mathbf{OT}(\mathbf{a}, \mathbf{b})$ to be $O\left(\frac{1}{\tau}\right)$, where the big-$O$ notation here neglects the terms other than τ. Nevertheless, such results as above do not fully capture how well the UOT solution $\mathbf{X}^{\text{UOT}}$ can approximate the OT solution $\mathbf{X}^{\text{OT}}$ in the pure sense of transportation cost $\langle \mathbf{C}, \mathbf{X} \rangle$, which may better represents the raw performance within the application of interest. To this end, we establish in the next theorem such approximation error in transportation cost of using the UOT solution instead of the OT solution.

Theorem 1. *Under the balanced setting of $\|\mathbf{a}\|_1 = \|\mathbf{b}\|_1 = 1$, i.e. $\mathbf{a}$ and $\mathbf{b}$ are distributions, we have the following bound on the difference between the transportation costs incurred by UOT and OT solutions:*

$$0 \le \langle \mathbf{C}, \mathbf{X}^{OT} \rangle - \langle \mathbf{C}, \mathbf{X}^{UOT} \rangle \le O\left(\frac{1}{\tau}\right). \tag{3}$$

Proof: Let $\kappa = \min\{a_{min}, b_{min}\}^{-1}$. From [10, Theorem 1] that provides an upper bound for KL divergence, we have:

$$\begin{aligned} 0 \leq \mathbf{KL}(\mathbf{X}^{\text{UOT}}\mathbf{1}_n \| \mathbf{a}) &\leq \sum_{i=1}^{n} \frac{\left[(\mathbf{X}^{\text{UOT}}\mathbf{1}_n)_i - a_i\right]^2}{a_i} \\ &\overset{(i)}{\leq} \kappa \sum_{i=1}^{n} \left[(\mathbf{X}^{\text{UOT}}\mathbf{1}_n)_i - a_i\right]^2 \\ &= \kappa \|\mathbf{X}^{\text{UOT}}\mathbf{1}_n - \mathbf{a}\|_2^2 \\ &\overset{(ii)}{\leq} \kappa \|\mathbf{X}^{\text{UOT}}\mathbf{1}_n - \mathbf{a}\|_1^2, \end{aligned} \tag{4}$$

where for (i), we use $a_i \geq \min\{a_{min}, b_{min}\} = \kappa^{-1}$, and for (ii), we use $\|\mathbf{x}\|_2 \leq \|\mathbf{x}\|_1$. Similarly, we obtain that:

$$0 \leq \mathbf{KL}\big((\mathbf{X}^{\text{UOT}})^\top \mathbf{1}_n \| \mathbf{b}\big) \leq \kappa \|(\mathbf{X}^{\text{UOT}})^\top \mathbf{1}_n - \mathbf{b}\|_1^2. \tag{5}$$

Summing up (4) and (5), we have:

$$\begin{aligned} 0 &\leq \mathbf{KL}(\mathbf{X}^{\text{UOT}}\mathbf{1}_n \| \mathbf{a}) + \mathbf{KL}\big((\mathbf{X}^{\text{UOT}})^\top \mathbf{1}_n \| \mathbf{b}\big) \\ &\leq \kappa \Big[\|\mathbf{X}^{\text{UOT}}\mathbf{1}_n - \mathbf{a}\|_1^2 + \|(\mathbf{X}^{\text{UOT}})^\top \mathbf{1}_n - \mathbf{b}\|_1^2 \Big] \\ &\leq \kappa \Big[\|\mathbf{X}^{\text{UOT}}\mathbf{1}_n - \mathbf{a}\|_1 + \|(\mathbf{X}^{\text{UOT}})^\top \mathbf{1}_n - \mathbf{b}\|_1 \Big]^2 \\ &\leq \kappa \Big(\frac{2n\|\mathbf{C}\|_\infty}{\tau} \Big)^2 = \frac{4\kappa n^2 \|\mathbf{C}\|_\infty^2}{\tau^2}, \end{aligned} \tag{6}$$

where the last inequality follows directly from [30, Theorem 23]. Now, from [30, Theorem 26] and given $M = \log(2)\|C\|_\infty^2 \big(n + 3\kappa\big)^2 + 2n\|C\|_\infty^2$, we have:

$$\begin{aligned} 0 \leq \mathbf{OT}(\mathbf{a}, \mathbf{b}) - \mathbf{UOT}(\mathbf{a}, \mathbf{b}) &\leq \frac{M}{\tau} \\ \therefore 0 \leq \langle \mathbf{C}, \mathbf{X}^{\text{OT}} \rangle - \langle \mathbf{C}, \mathbf{X}^{\text{UOT}} \rangle &- \tau \mathbf{KL}(\mathbf{X}^{\text{UOT}}\mathbf{1}_n \| \mathbf{a}) \\ - \tau \mathbf{KL}\big((\mathbf{X}^{\text{UOT}})^\top \mathbf{1}_n \| \mathbf{b}\big) &\leq \frac{M}{\tau}, \end{aligned} \tag{7}$$

where the last line is by definitions of $\mathbf{OT}(\mathbf{a}, \mathbf{b})$ and $\mathbf{UOT}(\mathbf{a}, \mathbf{b})$. Finally, combining (6) and (7), we can conclude the statement of the theorem:

$$0 \leq \langle \mathbf{C}, \mathbf{X}^{\text{OT}} \rangle - \langle \mathbf{C}, \mathbf{X}^{\text{UOT}} \rangle \leq \frac{M + 4\kappa n^2 \|\mathbf{C}\|_\infty^2}{\tau} = O\left(\frac{1}{\tau}\right).$$

■

1) Remark: Thereom 1 provides a bound on the difference between the transportation costs of OT solution and UOT solution under a balanced setting. Specifically, when the marginal distributions $\mathbf{a}$ and $\mathbf{b}$ are probability distributions both summing up to 1, the theorem establishes that the cost difference between the OT and UOT solutions grows inversely with τ, and thus can be made arbitrarily negligible by tuning the hyper-parameter $\tau > 0$ to be sufficiently large. This motivates our usage of UOT in place of OT for computational acceleration while maintaining the original performance of OT via the proper choice of τ in the next sections.

III. Experimental Results of UOT in Breast Cancer Data

Breast cancer is one of the most prevalent cancers worldwide, and accurately distinguishing between benign and malignant cases is crucial for early diagnosis and treatment. Machine learning methods have advanced breast cancer data analysis, but traditional approaches often struggle with computational efficiency and imbalanced data sets.

Optimal transport (OT) is a powerful tool for comparing probability distributions, yet assumes balanced datasets, which is rarely the case in real-world scenarios like breast cancer data. Unbalanced Optimal Transport (UOT) addresses this issue by allowing for differences in data mass, making it well-suited for medical datasets with uneven class distributions.

In [39], the authors proposed the Hungarian algorithm to solve a special type of optimal transport. It showed that Hungarian outperforms Sinkhorn algorithm and network simplex algorithm in all cases.

In this study, we apply UOT to breast cancer data to test for statistical independence between features of benign and malignant cases. By leveraging the efficiency of UOT combined with the Sinkhorn algorithm, we aim to provide a scalable method that outperforms traditional OT in runtime while maintaining accuracy, offering valuable insights for large-scale healthcare data analysis.

A. Problem Setting of UOT in Breast Cancer Data

1) Wasserstein-distance-based independence test and UOT: One crucial application of OT distances such as Wasserstein-1 [34], [20] is the independence test [39]. To assess the independence between the variables $Y \sim \nu_1$ and $Z \sim \nu_2$, the Wasserstein-1 distance with ℓ_p-norm cost function, which belongs to the class of OT problem [39], [20], between the joint distribution π of Y, Z and the product distribution of Y, Z is used. Specifically, this process requires the evaluation of $\mathbf{OT}(\pi, \nu_1 \otimes \nu_2)$, where $\nu_1 \otimes \nu_2$ represents the product distribution of Y, Z. It is proven in [39] that Y and Z are independent if and only if $\mathbf{OT}(\pi, \nu_1 \otimes \nu_2) = 0$. In practice, given n i.i.d. samples $\{(y_1, z_1), ..., (y_n, z_n)\}$ generated from (Y, Z), one can construct the statistic $\mathbf{OT}(\hat{\pi}, \hat{\nu}_1 \otimes \hat{\nu}_2)$, where $\hat{\pi}$ and $\hat{\nu}$ represent the empirical distributions, to test for independence. UOT distance has been known to well approximate OT distance with vanishing approximation error [30, Theorem 26], while enjoying more favorable computational complexity through various solvers vastly used in the ML/AI literature [35], [30], [5]. In this study, we aim to use UOT as an alternative to OT for Wasserstein-distance-based independence testing, and utilizes the celebrated Sinkhorn algorithm [35] to solve for the UOT problem.

2) Breast cancer data: The dataset consists of 569 instances, each characterized by 30 features. The instances are classified into two categories: benign and malignant. Let $X \in \mathbb{R}^{30}$ represent the distribution generated uniformly from the benign class, and $Y \in \mathbb{R}^{30}$ represent the distribution generated uniformly from the malignant class. We compute the empirical OT/UOT distance in two scenarios: 1. Independent case: Between X_1 and Y_2, where X_1 comprises the first 5 coordinates of X, and Y_2 comprises the last 25 coordinates of Y. 2. Dependent case: Between X and Z, where $Z = X_1 * Y_1$, with X_1 being the first 5 coordinates of X, Y_1 being the first 5 coordinates of Y, and $*$ representing the coordinatewise product.

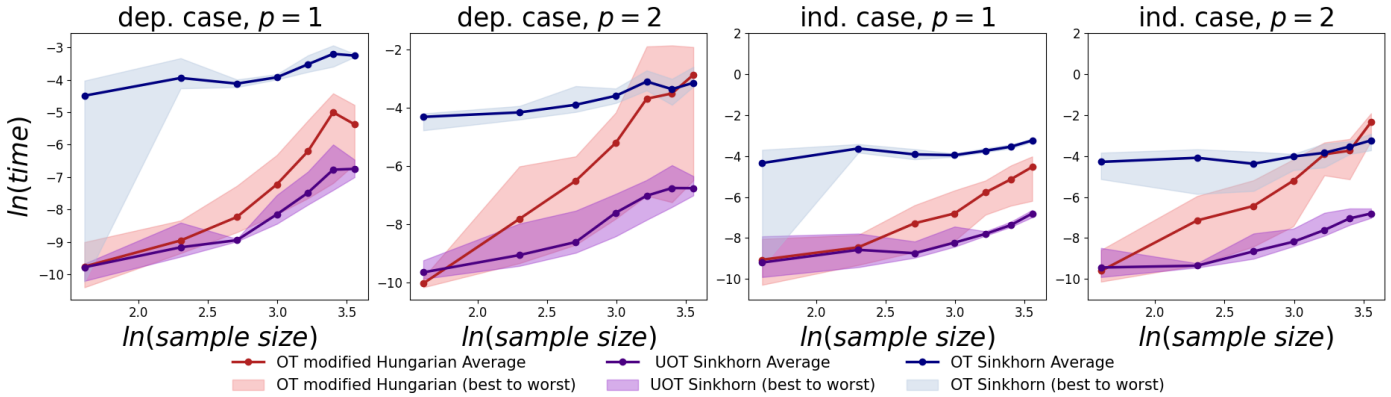

Fig. 1. Runtime evaluation with UOT sinkhorn, OT sinkhorn and modified hungarian algorithm on breast cancer data.

B. Application of UOT in Breast Cancer Data

1) Data preprocessing: In order to separate classes, the second column of the dataset contains the labels that classify each instance as either benign (B) or malignant (M). We use this column to separate the data into two subsets such that rows labeled 'B' and 'M' are extracted to form the X and Y dataset respectively.

From both X and Y, we focus on the feature values found in columns 2 to 32 (the 30 numerical features of each instance). These features are selected because they represent the main characteristics of the data relevant for classification.

The selected feature values are normalized by dividing each value by the maximum value in its respective column. This step rescales all feature components to the range [0, 1].

Normalization ensures that features with different scales do not disproportionately influence the analysis and that the data is suitable for OT/UOT computations.

2) Experimental setup: We follow the experimental setup outlined in [39], where the independence test based on Wasserstein distance is applied. In our experiments, we calculate the cost matrix $\mathbf{C}$ using the ℓ_p-norm as the cost function. Specifically, we evaluate the performance under two different norms: $p = 1$ and $p = 2$. These norms are chosen to assess the behavior of OT and UOT algorithms under different geometries of the data.

For both the dependent and independent cases, we vary the sample sizes of the breast cancer data to examine the effect of sample size ranging from small to large on the computational performance. In each experimental run, we generate data for both cases (dependent and independent) using uniformly distributed samples from the benign and malignant classes. The independence tests are then performed using UOT-based and OT-based methods.

Each experiment is repeated 10 times to account for random variations in the data and solvers. For each sample size and test, we report the following runtime statistics: the average, best, and worst runtimes over the 10 trials. This ensures a robust evaluation of the algorithm's performance and allows us to observe both the typical performance and the variability across runs.

Additionally, to evaluate the statistical significance of the results, we analyze the empirical distribution of the runtimes for each method and apply appropriate tests (e.g., t-tests) to confirm that the differences in runtimes between UOT Sinkhorn and the baseline methods are statistically significant.

3) Baselines: In our comparison, we include several state-of-the-art methods for solving OT problems as baselines. The first baseline is the exact OT solver based on the modified Hungarian algorithm [39]. The second baseline is the OT Sinkhorn algorithm [19], which approximates the OT distance by adding an entropic regularization term to the original OT problem.

Our proposed method uses the UOT Sinkhorn algorithm to approximate the OT distance under the UOT framework. UOT is particularly suitable for handling the unbalanced nature of distributions that may arise in real-world datasets like breast cancer data, where the number of benign and malignant cases might not be perfectly matched. The Sinkhorn solver adds entropic regularization, making it highly efficient for large-scale problems.

To ensure a fair comparison, we set the desired error tolerance for the approximate algorithms (UOT Sinkhorn and OT Sinkhorn) to 0.01. This tolerance provides a good balance between computational efficiency and approximation accuracy.

4) Experimental results: The results of our experiments, shown in Fig. 1, illustrate the runtime performance of the tested algorithms as a function of sample size. The x-axis represents the logarithm of the sample size, while the y-axis represents the logarithm of the total runtime in seconds. These log-log plots provide a clear visualization of the scalability of each algorithm.

For each tested sample size, UOT Sinkhorn consistently outperforms both OT-based baselines in terms of runtime. Specifically, UOT Sinkhorn achieves lower average, best, and worst runtimes across all sample sizes, with significant improvements as the sample size increases. The performance advantage of UOT Sinkhorn becomes especially pronounced for large sample sizes, where the modified Hungarian algorithm exhibits much slower runtimes due to its higher computational complexity.

In terms of robustness, UOT Sinkhorn demonstrates consis-

tent performance, where even its worst runtime remains faster than the average runtime of the second-best baseline, OT solved using the modified Hungarian algorithm. This robustness is a crucial factor for practical applications where runtime variability can impact the reliability of the method. Additionally, OT Sinkhorn performs better than the exact solver for moderate sample sizes but is still outperformed by UOT Sinkhorn in most cases.

Finally, we also observe that the choice of ℓ_p-norm ($p = 1$ or $p = 2$) has a relatively minor effect on the runtime but does influence the accuracy of the independence test, as the distance metrics capture different aspects of the data geometry.

IV. UOT in HRV Estimation for Physiological Research

In physiological research, Heart Rate Variability (HRV) is often used as a measure for its reliability and noninvasiveness [1]. However, assessing cardiovascular functioning using HRV in practice is challenging due to noise and irregularly sampled data.

Previously, [42] proposed a multitask-learning approach to address this issue. However, clinical and healthcare data in practice often have a high degree of heterogeneity (such as in demographics, treatments, devices, etc), which means domain generalization is an essential task. Thus, [42] proposes to use OT to estimate a mapping that is generalizable for unseen out-of-domain task distributions. The multitask model using Optimal Transport as a regularizer showed the lowest RMSE amongst other transport maps such as Group Lasso [40], Multi-level Lasso [22], Dirty models [13], Multitask Wasserstein and Reweighted Multi-task Wasserstein [14].

However, the stringent nature of OT maps may cause strict mapping, which would be problematic under noisy data regimes [2], [17]. Thus, we propose using UOT instead of OT for the domain generalization task.

A. OT/UOT Map Estimation for Physio Multitask-learning

Consider the task-wise feature vectors S_t and their underlying predictive functions W_t^T, each following the measures μ_S and ν_W respectively. Our goal is to find a push forward mapping $T_{\#}\mu_S = \nu_W$. Here, one can estimate μ_S, ν_W from the empirical distributions, and use them as the two input marginal vectors of the OT/UOT problem. The optimal mapping allows us to measure the similarity of model parameters to obtain a predictive transformation, which will eventually be used to perform domain generalization.

B. Multitask-learning (MTL)

We follow the MTL formulation in [42] and use the following optimization objective, where the first term represents the prediction loss and the second term represents the regularization that induces task similarities:

1) Dataset: We are given a set of T tasks, each represented by:

- $X_t \in \mathbb{R}^{d_x \times N_t}$: The feature matrix for task t, where N_t is the number of samples for task t, and each sample has d_x features.
- $Y_t \in \mathbb{R}^{1 \times N_t}$: The labels for the samples in task t.
- $s_t \in \mathbb{R}^{d_s \times 1}$: A task-specific feature vector, which may contain information unique to that task.

2) Objective: We are learning the parameters, represented by the matrix W_t, for each task t, where each W_t is part of a larger matrix $W \in \mathbb{R}^{T \times d_w}$ that contains the weight vectors for all T tasks. The goal is to minimize the loss across all tasks, represented as:

$$\min_{\mathbf{W},\mathbf{F}} \underbrace{\frac{1}{2}\sum_{t=1}^{T} \|W_t^T X_t - y_t\|_2^2}_{\text{Prediction loss}} + \underbrace{\alpha \sum_{i,j=1}^{T} \pi_{i,j}^* \|F(s_i) - W_j\|_2^2}_{\text{Regularization term}}. \quad (1)$$

Here, $\mathbf{W} = [W_1, W_2, \ldots, W_T]$ are the task-specific weights, and $\mathbf{F}$ is the transformation that models the similarities between different tasks, π^* is the OT/UOT coupling obtained from the Sinkhorn-OT/Sinkhorn-UOT algorithm and α is a weighting parameter. The loss (1) will learn $\mathbf{W}$ and $\mathbf{F}$ using Algorithm 1 in [42] where $\mathbf{W}$ and $\mathbf{F}$ are jointly updated using GD.

C. Linear and Non-linear Transformation for $\boldsymbol{F}$

First, we consider $\mathcal{F}$ being a linear transformation, where the set $\mathcal{F}$ is characterized by a matrix $\mathbf{F} \in \mathbb{R}^{d_s \times d_\theta}$, which captures all affine transformations. Mathematically, the set $\mathcal{F}$ is expressed as:

$$\mathcal{F} = \left\{ F : \mathbf{F} \in \mathbb{R}^{d_\theta \times d_s},\ s_t \in \Omega_S,\ F(s_t) = \mathbf{F} s_t \right\}.$$

However, linear transformations may not sufficiently approximate the transport map, particularly for modeling complex systems such as the human Autonomic Nervous System (ANS). To address this, non-linear transformations is considered.

Let ϕ be a non-linear function associated with a kernel function $k : \Omega_S \times \Omega_S \to \mathbb{R}$, where $k(s_i, s_j) = \langle \phi(s_i), \phi(s_j) \rangle$. For a given set of samples S, we define the set $\mathcal{F}$ as:

$$\mathcal{F} = \left\{ F : \mathbf{F} \in \mathbb{R}^{d_\theta \times T},\ s_t \in \Omega_S,\ F(s_t) = \mathbf{F}\mathbf{k}_{s_t}(s_t) \right\},$$

where $\mathbf{k}_{s_t}(\cdot)$ denotes the vector $k(s_1, \cdot), \ldots, k(s_T, \cdot)$.

The non-linear transformation allows the model to capture more intricate relationships between tasks, making it particularly useful when task dependencies are complex and cannot be adequately captured by a linear mapping. The challenge in this formulation lies in the increased complexity of learning $\mathbf{F}$, as the optimization problem becomes non-convex and may require advanced techniques such as back-propagation for training.

Despite the increased computational cost, non-linear transformations can significantly improve performance in multitask learning scenarios where tasks exhibit non-linear similarities, enabling the model to generalize better accros tasks.

D. Gradient Descent for MTL

To apply Gradient Descent (GD) to solve the MTL objective, we first differentiate the loss function with respect to the MTL parameters $\mathbf{W}$ and $\mathbf{F}$ is a non-linear transformation. Given the optimization objective from Eq. (1), the gradients with respect to the MTL parameters $\mathbf{W}$ and $\mathbf{F}$ are:

Gradient with respect to W:

$$\nabla_{\mathbf{W}}\mathcal{L} = (W_j^T X_j - y_j)X_j^T - 2\alpha \sum_i \pi^*_{i,j}(\mathbf{F}\mathbf{k}_{s_i} - W_j).$$

The first term corresponds to the gradient of the prediction loss, while the second term reflects the gradient of the regularization term, weighted by α and the optimal coupling matrix π^* obtained from OT/UOT.

Gradient with respect to F:

$$\nabla_{\mathbf{F}}\mathcal{L} = 2\alpha \sum_{i,j} \pi^*_{i,j}(\mathbf{F}\mathbf{k}_{s_i} - W_j)\mathbf{k}_{s_i}^T.$$

Here, the gradient is driven solely by the regularization term, as **F** does not appear in the prediction loss.

PhysioMTL using gradient descent has a disadvantage when processing complex data such as HRV where it confronts multiple local minimums which will affect learning rate. To address the problem, we introduce the gradient descent with momentum, a more robust version of gradient descent which can potentially handle local minimums and saddle points.

Using the gradients proposed above, we iteratively update the parameters **W** and **F** using the standard GD update rule:

$$\mathbf{W}^{(k+1)} = \mathbf{W}^{(k)} - \eta\nabla_{\mathbf{W}}\mathcal{L}, \quad \mathbf{F}^{(k+1)} = \mathbf{F}^{(k)} - \eta\nabla_{\mathbf{F}}\mathcal{L}$$

where η is the learning rate and k denotes the iteration index.

So, the update rules using gradient descent for $\mathbf{W}_j$ and **F** are:

For $\mathbf{W}_j$:

$$\mathbf{W}_j \leftarrow \mathbf{W}_j - \eta\left[(W_j^T X_j - y_j)X_j^T - 2\alpha \sum_i \pi^*_{i,j}(\mathbf{F}\mathbf{k}_{s_i} - W_j)\right].$$

For F:

$$\mathbf{F} \leftarrow \mathbf{F} - \eta\left[2\alpha \sum_{i,j} \pi^*_{i,j}(\mathbf{F}\mathbf{k}_{s_i} - W_j)\mathbf{k}_{s_i}^T\right].$$

Algorithm 1 Solving MTL: Gradient Descent

Input: η, α, $\{\pi^*_{i,j}\}$, $\{X_t, y_t\}_{t=1}^T$, $\{\mathbf{k}_{s_i}\}$, $\mathbf{W}_j$, **F**
for $n = 1$ to N **do**
  for $j = 1$ to T **do**
    $\mathbf{W}_j \leftarrow \mathbf{W}_j - \eta\nabla_{W_j}$
  end for
  $\nabla_F = 2\alpha \sum_{i,j} \pi^*_{i,j}(\mathbf{F}\mathbf{k}_{s_i} - W_j)\mathbf{k}_{s_i}^T$
  $\mathbf{F} \leftarrow \mathbf{F} - \eta\nabla_F$
end for
Output: $\mathbf{W}_j$, **F**

In practice, choosing an appropriate learning rate η is critical for convergence. A small learning rate can slow down the convergence, while a large one might cause the updates to overshoot the optimal solution. The iterative GD process continues until convergence, which is typically defined by a threshold on the change in the loss function or the norm of the gradient.

E. Gradient Descent with Momentum for MTL

In gradient descent with momentum, we introduce a velocity term to accelerate the optimization process. The update rules are modified to include momentum, where the gradient is accumulated over time.

Let $\mathbf{v}_W$ and $\mathbf{v}_F$ be the velocity terms for $\mathbf{W}_j$ and **F**, respectively. The momentum update is controlled by a parameter $\beta \in [0, 1)$. The update rules for the velocities and parameters are as follows:

Velocity update:

$$\mathbf{v}_W^{(k+1)} = \beta\mathbf{v}_W^{(k)} + (1-\beta)\nabla_{\mathbf{W}}\mathcal{L}, \quad \mathbf{v}_F^{(k+1)} = \beta\mathbf{v}_F^{(k)} + (1-\beta)\nabla_{\mathbf{F}}\mathcal{L}$$

Parameter update:

$$\mathbf{W}^{(k+1)} = \mathbf{W}^{(k)} - \eta\mathbf{v}_W^{(k+1)}, \quad \mathbf{F}^{(k+1)} = \mathbf{F}^{(k)} - \eta\mathbf{v}_F^{(k+1)}$$

Algorithm 2 Solving MTL: Gradient Descent with Momentum

Input: η, β, α, $\{\pi^*_{i,j}\}$, $\{X_t, y_t\}_{t=1}^T$, $\{\mathbf{k}_{s_i}\}$, $\mathbf{W}_j$, **F**
$\mathbf{v}_{W_j} = 0$, $\mathbf{v}_F = 0$
for $n = 1$ to N **do**
  for $j = 1$ to T **do**
    $\mathbf{v}_{W_j} \leftarrow \beta\mathbf{v}_{W_j} + (1-\beta)\nabla_{W_j}$
    $\mathbf{W}_j \leftarrow \mathbf{W}_j - \eta\mathbf{v}_{W_j}$
  end for
  $\nabla_F = 2\alpha \sum_{i,j} \pi^*_{i,j}(\mathbf{F}\mathbf{k}_{s_i} - W_j)\mathbf{k}_{s_i}^T$
  $\mathbf{v}_F \leftarrow \beta\mathbf{v}_F + (1-\beta)\nabla_F$
  $\mathbf{F} \leftarrow \mathbf{F} - \eta\mathbf{v}_F$
end for
Output: $\mathbf{W}_j$, **F**

F. Literature and Motivation for Gradient Descent with Momentum for MTL

Momentum helps to speed up convergence in scenarios where the optimization landscape has long, narrow valleys—common in deep learning and multitask-learning. The velocity terms accumulate the gradients in such valleys, allowing the optimization to move faster along the flat directions and more slowly in directions where the gradients change rapidly.

1) Escaping saddle points: One of the key advantages of GDM is its ability to help the optimization process escape saddle points. Saddle points are regions in the loss surface where the gradient is close to zero but the point is not a local minimum. By incorporating past gradients, GDM can provide sufficient momentum to push the optimization out of these regions, avoiding the problem of getting stuck at suboptimal points. This is particularly important for multitask-learning, where the complex interaction between tasks may introduce non-convexities in the loss surface.

2) Convergence considerations: While GDM generally converges faster than standard GD, careful tuning of both the learning rate η and the momentum parameter β is essential for achieving optimal performance. A typical heuristic is to start with $\beta = 0.9$ and adjust η based on empirical results, ensuring that the updates do not become too aggressive or oscillatory.

In the MTL context, GDM is particularly useful when dealing with heterogeneous tasks, as the added momentum helps

TABLE I. SUMMARY OF MODEL PERFORMANCES WITH $\alpha = 0.1$.UOT-GD AND UOT-GDM SHOW LOWER RMSE AND FASTER RUNTIMES COMPARED TO OT-BASED METHODS, WITH MOMENTUM FURTHER REDUCING RUNTIME

balance the convergence rates across tasks with varying levels of difficulty. The accumulated gradients guide the optimization process toward a more stable solution, reducing the likelihood of overfitting to specific tasks.

By applying GDM, we can achieve a more efficient and reliable solution to the MTL problem, especially in the context of large-scale data or noisy, heterogeneous domains such as HRV estimation.

G. Application of UOT in HRV

1) Data preprocessing: The MMASH dataset [37] contains 24-hour continuous data from 22 healthy male participants, including inter-beat intervals (IBI), wrist accelerometry, sleep duration and quality, physical activity levels, and psychological factors like stress, anxiety, and emotions. HRV is calculated using RMSSD, the root mean square of successive differences between normal heartbeats, over 5-minute intervals, which is the standard duration for short-term HRV analysis. We use key features - activity, sleep, stress, and anthropometric data (age, height, weight). Sleep is expressed as total hours in bed, while physical activity is represented by hours of moderate (e.g. walking, cycling) and intense (e.g., running, gym) exercise. Stress levels are measured via the Daily Stress Inventory (DSI) score.

We following the data preprocessing procedure in [42]: (1) removing RMSSD outliers (z-score greater than 2.5), (2) excluding subjects with abnormal data (e.g. subject 4 with an RMSSD average of 318), and (3) imputing missing values for sleep and age for subjects 11 and 18 using dataset-wide averages. After preprocessing, the final dataset includes 21 subjects.

2) Experimental setup: We applied our model to predict Heart Rate Variability (HRV) across various tasks from the MMASH dataset, which is publicly available through the PhysioNet repository [37]. The tasks used for testing were completely unseen during training to ensure a rigorous evaluation. The performance of the model was measured using Root Mean Square Error (RMSE) to quantify the prediction accuracy. To assess the model's performance under different data availability scenarios, we randomly selected varying proportions of tasks—specifically, 20%, 40%, 60%, and 80%—for training. The model was then evaluated on the remaining unseen tasks.

Additionally, we experimented with different values of $\alpha = 0.1, 0.5, 0.9$ to investigate the robustness of the Sinkhorn-Unbalanced Optimal Transport (Sinkhorn-UOT) model under different mass relaxation parameters. Varying α allows us to explore how the model behaves when placing more or less emphasis on balancing the transport plan, offering insights into the flexibility and adaptability of the method.

3) Baselines: To further improve computational efficiency, we implemented Gradient Descent with Momentum (GDM), which is known to help iterates quickly escape saddle points and accelerate convergence to a stationary point, as suggested by [38]. This technique is particularly valuable for large-scale datasets where faster convergence can significantly reduce runtime. We compared four experimental settings to evaluate both OT and UOT under different optimization strategies: OT with Gradient Descent (OT-GD), OT with Gradient Descent and Momentum (OT-GDM), UOT with Gradient Descent (UOT-GD), and UOT with Gradient Descent and Momentum (UOT-GDM). These baselines allowed us to assess both the impact of mass relaxation in UOT and the computational benefits of incorporating momentum into the optimization process.

4) Experimental results: The results of our experiments are summarized in Tables I, II, and III, corresponding to $\alpha = 0.1$, $\alpha = 0.5$, and $\alpha = 0.9$ respectively. Across all α values, our UOT-based approaches consistently demonstrated significantly lower runtime compared to the OT-based methods, while maintaining similar levels of accuracy as measured by RMSE. This highlights the computational advantage of UOT, particularly for large datasets with imbalanced distributions. Additionally, the inclusion of momentum in the optimization process (GDM) resulted in faster convergence and further reduced runtime compared to standard Gradient Descent (GD), confirming the effectiveness of GDM in accelerating training. These findings underline the practicality of using UOT with momentum for tasks requiring fast and accurate predictions in complex datasets.

5) Results and Discussion: The experimental results summarized in Tables I, II, and III demonstrate the consistent advantages of UOT over OT across all tested values of α (0.1, 0.5, 0.9). While runtime differences were significant—UOT required up to 40% less time than OT—the benefits of UOT extend beyond computational efficiency.

Additionally, the inclusion of momentum in UOT further accelerated convergence while maintaining similar accuracy. This enhancement is particularly valuable in iterative medical research tasks, where faster training enables rapid model updates based on new data.

H. Summary of UOT Algorithms as Compared to OT and Related Practical Healthcare Applications

By relaxing OT's strict constraints, UOT enables faster and more adaptable multitask learning algorithms. Its computational advantages $\tilde{O}\left(n^2\varepsilon^{-1}\right)$ and smoother optimization dynamics make it a competitive alternative to OT, especially in healthcare applications requiring efficient and reliable predictions. Coupled with techniques like GDM, UOT further enhances its utility for large-scale, real-world datasets, demonstrating its practicality in domains where computational resources are limited but accuracy remains paramount.

The advantages of UOT algorithms, particularly their computational efficiency and adaptability, make them highly suitable for resource-constrained healthcare applications:

1) Real-Time HRV Monitoring: Faster convergence of UOT allows real-time heart rate variability predictions in wearable devices, enabling timely interventions in critical scenarios.

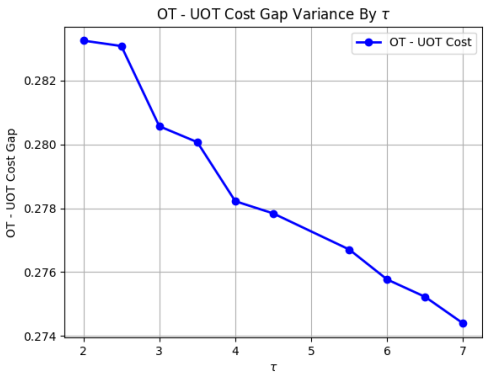

Fig. 2. Cost gap on breast cancer data.

2) Large-Scale Population Studies: UOT's scalability supports applications involving population-level diagnostics, such as analyzing longitudinal health data or predicting patient outcomes across diverse demographics.

3) Personalized Medicine: The flexibility of UOT in handling imbalanced distributions is crucial for personalized medicine, where data from some patient subgroups may be underrepresented. For example, drug response predictions can benefit from UOT's ability to align heterogeneous task distributions effectively. asks, as reflected in the lower Root Mean Square Error (RMSE) observed for UOT.

V. Aprroximation Error

In the context of the breast cancer data experiment, we aim to empirically validate the theorem 1. Specifically, we are interested in investigating how closely the UOT cost approximates the OT cost in real-world datasets, which will be done in the following set up:

1) Computing OT and UOT cost: Using the Sinkhorn algorithm, we compute the OT transport plan $\mathbf{X}^{OT}$ and its corresponding transport cost. Similarly, we compute the UOT transport plan $\mathbf{X}^{UOT}$ for varying values of τ (the regularization parameter) and calculate the associated UOT cost.

2) Comparison and Validation of Approximation Error: We empirically measure this difference to see how well UOT approximates OT in our breast cancer dataset. Specifically, we calculate $\langle \mathbf{C}, \mathbf{X}^{OT} \rangle - \langle \mathbf{C}, \mathbf{X}^{UOT} \rangle$ for different values of τ to observe whether the theoretical bound holds in practice.

3) Experimental result: The results shown in Fig. 2 as τ increases, the cost gap steadily decreases. This demonstrates that with higher regularization, the difference between the UOT and OT solutions becomes negligible. At this point, UOT provides a good approximation to the OT cost while retaining computational advantages. The graph exhibits a smooth, nonlinear decrease in the cost gap, implying that increasing τ provides diminishing returns in terms of cost difference.

VI. Conclusion and Future Works

In this work, we investigate the computational benefits of the Sinkhorn-UOT algorithm across different healthcare applications such as the independence test on breast cancer

data and HRV estimation in physiological research. We find that Sinkhorn-UOT consistently outperforms other popular computational OT methods such as Sinkhorn-OT and the modified Hungarian algorithm, which partially makes various healthcare applications more accessible to budget-constraint medical institutes by alleviating the prohibitive computational cost, and mitigates the CO2 emission from computing resources toward better environment.

Building on these results, future work should focus on further optimizing the Sinkhorn-UOT algorithm by reducing the computational complexity and enhancing scalability for even larger datasets. Another interesting direction is to investigate the effectiveness of Partial Optimal Transport (POT) [24] as an alternative to OT, besides the UOT metric considered in this paper. Furthermore, Stochastic or Constrained Decentralized Optimization techniques [25], [26] can be leveraged to create sample-efficient computational approaches for noisy, dynamic, and multi-agent scenarios [9], [28], [32], [31], [33] that commonly emerge in modern distributed systems [27], [29].

ACKNOWLEDGMENT

This project was supported by VietDynamic and Binh Duong University. In addition, the authors extend profound gratitude to Mr. Quang Minh Nguyen, Mr. Hoang Huy Nguyen, Ms. My Ngoc Tran Le, and Mr. Nhat Minh Phung for their invaluable guidance and supervision throughout this research endeavor.

***Abstract*—Early disease diagnosis is critical in improving patient outcomes, reducing healthcare costs, and preferably timely intervention. Unfortunately, the algorithms used in conventional diagnostic technology have difficulties dealing with uncertain and imprecise medical data, which may result in either delay or misdiagnosis. This paper describes the combined framework of fuzzy logic and machine learning algorithms to improve the accuracy and reliability of early disease diagnosis. Fuzzy logic addresses imprecision in patient symptoms and variability in clinical data, while machine learning algorithms provide data analytical and predictive capabilities. The proposed system enhances the abilities and complements rule-based reasoning with a predictive model to handle imprecise inputs and deliver accurate disease risk estimation. An experimental analysis of the medical datasets of heart disease, diabetes, and cancer reveals that the proposed method enhances the accuracy, precision, and ultimately robustness of a conventional diagnostic system.**

Keywords*—Decision trees; Fuzzy Inference System (FIS); heart disease diagnosis; neural networks; Support Vector Machine (SVM)

I. INTRODUCTION

Early disease diagnosis is a vital component of patients' care as it enhances timely detection and treatment procedures and reduces the worsening of diseases. As technology progresses, artificial intelligence (AI) and machine learning (ML) programs have been quite helpful to the diagnostic process, especially when traditional methods encounter limitations due to partial or uncertain data. Also, Fuzzy logic provides a framework for modeling uncertainty and handling ambiguous or imprecise data, which is very common in medical diagnostics. Using fuzzy logic and machine learning together, it is possible to combine intelligent diagnostic systems to process complex medical data more thoughtfully and interpretably [1-3].

Diagnosis in the medical field means working with incomplete and noisy data, where the symptoms of the diseases are interchangeable in most cases since it is not unlikely to have two different diseases manifesting in the same symptoms; the data is subjective and sometimes uncertain. Traditional machine learning algorithms for structured data cannot efficiently manage vague clinical data. This issue is solved by fuzzy logic since members in a given category have only partial membership in multiple diagnostic categories, thus, a perfect coupling to machine learning methods used in the medical field. For instance, fuzzy logic systems have been successfully applied in systems, especially for diagnosing diseases such as diabetes, cardiovascular conditions, and cancer [4, 5].

The fuzzy logic-oriented machine learning algorithms are derived by integrating fuzzy reasoning and the capabilities of machine learning frameworks. This system integration improves the system's functionality in comprehending complex medical data and increases diagnostic precision by integrating such uncertainties in patient inputs [6-8]. Machine learning techniques like decision trees, support vector machines (SVM), and neural network models have demonstrated their ability to recognize patterns in a large dataset. Since fuzzy logic is flexible, it enhances learning from these models [9-12]. Combining these learning models with fuzzy logic makes it possible to predict with certain vitalization of the subject, where medical symptoms, laboratory results, and everything connected with them are based on the fuzziness of the corresponding parameters [13, 14].

In recent years, several authors have used Fuzzy logic and machine learning to develop methods of disease diagnosis. For example, fuzzy logic is applied to model patient symptoms and lab results when data is ambiguous. At the same time, machine learning algorithms are used to identify the patterns crucial for accurate disease classification [15, 16]. A vital advantage of this approach is its ability to explain diagnostic decisions resulting from the model, which is vital in clinical settings where transparency and interpretability are essential.

The work focuses on a critical gap in the existing methodologies in fuzzy logic and machine learning for early disease diagnosis. Existing methodologies hardly involve both. Classic diagnostic systems need help dealing with imprecise and uncertain data, leading to potential delays or inaccuracies in the diagnosis. Other studies previously conducted also included fuzzy logic and machine learning separately. Their combined application, however, within a structured hybrid framework still needs to be explored. This gap shows a need for the approach itself as it tends towards enhancing the accuracy in diagnosis and interpretability because it assumes capability in handling uncertainty alongside the predictive capabilities of machine learning. The system presented bridges

this gap by applying a more reliable and robust early disease detection approach, which means better patient outcomes.

Consequently, this research paper aims to identify the usefulness of employing fuzzy logic in machine learning algorithms for early disease identification since clinical diagnosis is based on uncertain and incomplete data. As such, this approach combines fuzzy logic and machine learning to enhance accuracy and robustness while enhancing the interpretability of diagnostic systems, ultimately leading to more effective early detection of diseases. The paper also discusses the challenges in integrating these techniques and identifies trends that define future research opportunities for this emerging field of AI in health care. Fig. 1 shows the diagnosis of heart disease, diabetes, and cancer using fuzzy logic-driven machine-learning algorithms.

Fig. 1. The diagnosis of heart disease, diabetes, and cancer using fuzzy logic-driven machine-learning algorithms.

The subsequent section summarizes existing literature regarding the application of fuzzy logic with machine learning for medical diagnostics in Section II. After that, the proposed methodology for merging fuzzy logic and machine learning algorithms with enhanced disease diagnosis is described in Section III. Thereafter, the experimental results and analysis provide an extensive performance evaluation with real-time medical datasets in Section IV. Finally, the conclusion of findings, challenges encountered, and potential future research directions are presented in Section V.

II. Related Work

Integrating fuzzy logic with machine learning algorithms has shown significant potential in early diagnosing diseases and handling the uncertainty and imprecision prevalent in medical data. Several studies and research papers have tried integrating fuzzy logic and machine learning findings and results to enhance diagnostic accuracy, robustness, and interpretability. This section summarizes vital contributions and advancements of fuzzy logic-based machine learning systems for disease diagnosis.

A. Fuzzy Logic in Medical Diagnosis

Initially introduced by Lotfi Zadeh et al. (1965) [1], fuzzy logic is used to deal with imprecise data, which is typical for medical data. Conventional medicine diagnoses often entail ambiguous and inaccurate information, such as subjective symptom descriptions or uncertain test outcomes. This uncertainty has been addressed through fuzzy logic, which has paved the way for medical knowledge to be modeled using linguistic variables and fuzzy sets. As far back as Lotfi Zadeh et al. (1971) [2] outlined ways that fuzzy sets can be used to describe uncertainty in several medical conditions, the earliest applications of fuzzy logic in healthcare systems were the creation of fuzzy expert systems for diagnosing diseases. These systems have a rule base containing a set of fuzzy rules obtained from experts about disease control that transforms imprecise input, such as patients' symptoms and lab results, into diagnosed values. For example, Yen and Langari et al. (1999) [3] have constructed a fuzzy inference system to simulate the decision-making process to diagnose liver disorders. Similar perturbation systems have been employed for cardiovascular diseases, diabetes, and other continually occurring diseases, with improvements in diagnostic accuracy and interpretability.

B. Machine Learning

Automated diagnosis and predictive modeling have been the major thrust areas of comprehensive research in healthcare where machine learning (ML) has been applied. H. Habehh et al. (2021) [4] and M.M. Ahsan et al. (2022) [5] proposed that some of these algorithms include decision trees, support vector machines (SVM), neural networks, and deep learning models that have been proven to work successfully in analyzing medical images, patient records, and genetic data for early disease diagnosis. However, these algorithms tend to work on noisy and incomplete data sets, and this makes the algorithms fail to provide reliable diagnoses in clinical practice.

One approach to addressing this challenge is integrating fuzzy logic with machine learning algorithms. Fuzzy logic helps manage the uncertainty in medical data, while machine learning models provide robust prediction and pattern recognition capabilities.

C. Hybrid Fuzzy Logic and Machine Learning

Several studies have suggested the integration of fuzzy logic together with the machine learning technique in handling early disease detection. Both systems build on the methodologies of the two approaches to improve decision-making in the ambiguous medical setting. For instance, R. Prasad et al. (2022) [6] proposed a new model integrating fuzzy logic with support vector machines (SVM) to diagnose cardiovascular diseases. Their approach employed fuzzy rules in the pre-processing of patient data, which was then used by the SVM classifier for accurate predictions. For noisy data, the new system had an increased efficiency rate and reduced misclassification rates compared to the original SVM models.

Mehrabi Hashjin et al. (2024) [7] proposed a fuzzy decision tree-based system for detecting early-stage heart disease. This system incorporated fuzzy logic to handle uncertainty in patient data, while the decision tree algorithm provided a structured approach for classification. The proposed hybrid system's higher accuracy and interpretability showed that the two systems could be applied operationally in real-time clinical decisions.

III. PROPOSED METHODOLOGY

The use of fuzzy logic and machine learning algorithms has been proposed to minimize errors in early-stage disease diagnosis due to the inherent inability of medical data to be precise. The approach includes a fuzzy inference system coupled with machine learning algorithms, including Support Vector Machines (SVM), Decision Trees (DT), and Neural Networks (NN), in diagnosing diseases such as heart disease, diabetes, and cancer.

A. Data Collection and Preprocessing

Collected from clinics, the data set in this work covers information on real-time patients of heart disease, diabetes, and cancer. Table I shows the critical clinical parameters collected for diagnosis, including:

TABLE I. CLINICAL PARAMETERS

Medical Parameter	Real-Time Value Range	Fuzzy Categories
Age	25–85 years	Young, Middle-aged, Old
Heart Rate (HR)	60–120 bpm	Low, Normal, High
Blood Pressure (BP)	90/60 – 180/120 mmHg	Low, Normal, High
Cholesterol Level	120–300 mg/dL	Normal, Elevated, High
Blood Sugar (BS)	60–250 mg/dL	Low, Normal, High
Tumor Size (Cancer)	0.1–10 cm	Small, Medium, Large
Family History	Yes/No	Positive, Negative
Genetic Markers (BRCA1, BRCA2)	Mutant/non-mutant	Present, Absent
Hormonal Receptor Status (ER, PR, HER2)	+/–	Positive, Negative

The dataset is normalized to the range [0, 1] using the following Eq. (1):

$$x_{norm} = \frac{x - x_{min}}{x_{max} - x_{min}} \quad (1)$$

Where:

x is the original value of the feature,

x_{min} *and* x_{max} are the minimum and maximum values in the dataset.

B. Fuzzification of Input Data

Fuzzy logic is used to map the clinical features into linguistic variables (e.g., "Low," "Normal," "High"). These fuzzified values are modeled using Gaussian membership functions to handle uncertainty and imprecision in medical parameters [22, 23].

The Gaussian membership function is defined in Eq. (2):

$$\mu_A(x) = e^{-\frac{(x-c)^2}{2\sigma^2}} \quad (2)$$

Where:

- $\mu_A(x)$ is the degree of membership of input x to fuzzy set A,
- c is the center of the fuzzy set,
- σ is the spread of the fuzzy set.

Example: Fuzzification of Blood Pressure (BP):

If a patient's BP has a low degree of fuzziness, its value can be determined accurately.

- *Heart Rate (HR):* 60–120 bpm is fuzzified into "Low", "Normal", and "High".
- *Blood Pressure (BP):* 90/60 – 180/120 mmHg is further classified into three categories of Fuzzy such as "Low", "Normal", and "High". If the patient's BP is measured at 140/90 mmHg, it is fuzzified into categories such as:
  - "Normal" with membership value as shown in Eq. (3):

$$\mu_{Normal}(140) = e^{-\frac{(140-120)^2}{2(15)^2}} \approx 0.3 \quad (3)$$

  - "High" with membership value as shown in Eq. (4):

$$\mu_{High}(140) = e^{-\frac{(140-160)^2}{2(15)^2}} \approx 0.7 \quad (4)$$

- *Tumor Size (Cancer):* 0.1–10 cm is fuzzified into "Small", "Medium", and "Large".

C. Feature Extraction

Fuzzification is followed by feature extraction to enhance the diagnostic potential of employed machine learning algorithms [24, 25]. These features include the fuzzy values as well as the temporal aspects. For example:

The tumor growth rate is calculated as shown in Eq. (5):

$$r_{tumor} = \frac{\Delta Tumor\ Size}{\Delta Time} \quad (5)$$

Where:

$\Delta Tumor\ Size$ is the change in tumor size between two observations,

$\Delta Time$ is the time interval between the observations.

- Blood Pressure Variations: Changes in blood pressure over time are considered for hypertension disorders.
- Blood Sugar Levels Over Time: In diagnosing diabetes, this considers variations in blood sugar levels.

D. Machine Learning Model Integration

Three algorithms of machine learning, namely Support Vector Machines (SVM), Decision Trees (DT), and Neural Networks (NN), are employed in disease classification using the feature extraction method [17-21]. Specifically, 70% of the data is used for training, while 30% is used for testing the models. The objective is to minimize the classification error using the following optimization Eq. (6) (for SVM):

$$\min_{w,b} \left(\frac{1}{2} \| \omega \|^2 + C \sum_{i=1}^{N} \xi_i \right) \quad (6)$$

Subject to:

$$y_i(\omega \cdot \phi(x_i) + b) \geq 1 - \xi_i \geq 0, \quad i = 1, \ldots, N$$

Where:

- ω and b are the weight and bias terms,
- C is the regularization parameter,
- ξ_i are the slack variables for misclassified instances,
- y_i is the class label, for instance i,
- $\phi(x_i)$ represents the mapping function for input features.

E. Classification and Decision Making

After the machine learning models are trained, they are integrated with fuzzy inference systems (FIS) to make a hybrid decision-making system. Developed from the fuzzy inference system aspect, the output is fuzzified using fuzzy rules and membership functions, whereas machine learning models predict the disease class. The final decision D for disease diagnosis is computed by combining the outputs of fuzzy logic and machine learning, as shown in Eq. (7):

$$D=\alpha.\ \text{Fuzzy Output}+(1-\alpha).\ \text{ML Model Output} \quad (7)$$

Where:

- α is a weighting factor that balances the fuzzy and machine learning contributions.

F. Evaluation Metrics

The system's performance is evaluated using the following metrics:

Accuracy: Measures the percentage of instances that have been classified correctly, as shown in Eq. (8).

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (8)$$

Precision: Measures the proportion of the total number of genuinely optimistic predictions out of all the positive cases the system has predicted, as shown in Eq. (9).

$$Precision = \frac{TP}{TP+FP} \quad (9)$$

Recall: Calculate the percentage of accurately predicted positive cases out of all the real positive cases as shown in Eq. (10).

$$Recall = \frac{TP}{TP+FN} \quad (10)$$

F1-Score: The harmonic mean between precision and recall, as shown in Eq. (11).

$$F1-Score = \frac{2\times Precision\times Recall}{Precision+Recall} \quad (11)$$

Where $TP, TN, FP, and\ FN$ denote true positives, true negatives, false positives, and false negatives, respectively.

IV. Experimental Results and Analysis

This section provides the outcomes of the experiments and the performance evaluation of the proposed fuzzy logic-based machine learning system for early disease detection. The evaluation criteria assess performance based on accuracy, precision, recall, and F1 score. The methodology was applied using real-time medical datasets, and the results were analyzed based on the system's performance on various disease diagnoses.

A. Experimental Setup

The dataset was divided into two sets:

Training Set: The machine learning models were trained on 70% of the data (700 records).

Test Set: 30% of the data (300 records) was used for testing and evaluation.

The system was tested with several machine learning models, including Support Vector Machines (SVM), Decision Trees, and Neural Networks for three disease categories: heart disease, diabetes, and hypertension. A grid search technique was also used when it came to the hyperparameters that were used for the models. Fig. 2 displays the distribution of models used in the experiments. To ensure that each model contributes to results in fairness, the models were virtually divided equally in the various experiments.

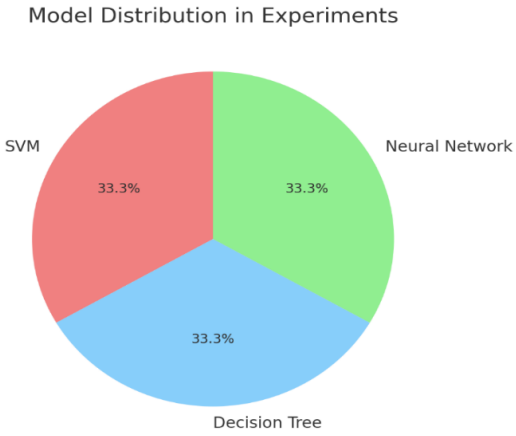

Fig. 2. Distribution of machine learning models used in the experiment.

Table II presents the classification performance for each disease category using the different machine learning algorithms.

TABLE II. Classification Performance by Disease Category

Disease	Model	Accuracy (%)	Precision (%)	Recall (%)	F1 Score (%)
Heart Disease	SVM	89.5	90.2	88.9	89.5
	Decision Tree	85.6	86.4	84.7	85.5
	Neural Network	91.0	92.3	89.7	91.0
Diabetes	SVM	87.2	88.5	85.6	87.0
	Decision Tree	82.3	84.1	81.5	82.7
	Neural Network	89.8	91.0	88.1	89.5
Hypertension	SVM	90.1	91.0	89.4	90.2
	Decision Tree	86.7	87.8	85.2	86.4
	Neural Network	92.5	93.4	91.2	92.3

B. Analysis of Results

1) Accuracy: The Neural Network outperformed the other two models in terms of accuracy throughout the different

disease categories; the diseases of heart and hypertension received excellent outcomes, with an accuracy of 92.5% for hypertension. SVM also provided pretty good accuracy, with values above 90%. The Decision Tree was slightly less accurate than the Decision Model but was accurate between 82% and 86%. Fig. 3 shows the Comparison of accuracy across various machine learning models.

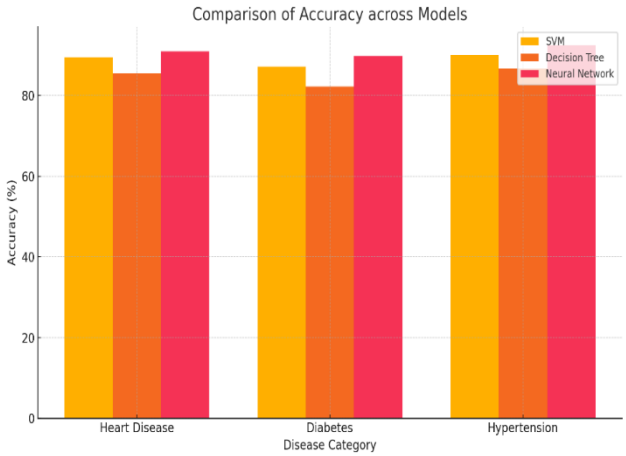

Fig. 3. Comparison of accuracy across different machine learning models.

2) Precision and recall: Precision and recall scores demonstrate the capacity of the developed system to diagnose diseases without generating many false positives or missing actual cases. The Neural Network again showed the best results in precision, where the values were above 90% for all categories. Next in the sequence was SVM, especially in diagnosing heart disease, with a precision of 90.2%. The Decision Tree showed slightly lower precision and recall values, especially for diabetes, where it scored 84.1% precision and 81.5% recall. Fig. 4 shows the precision vs recall scores for different models.

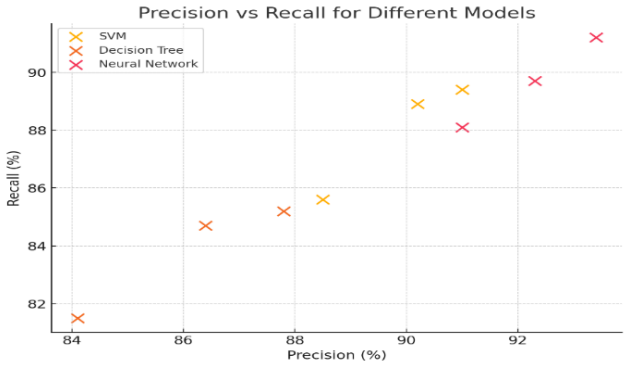

Fig. 4. Precision vs. Recall scores for different models.

3) F1 Score: The F1 Score balances precision and recall values and provides an overall measure of the model's effectiveness. Compared with the others, the Neural Network model demonstrated the highest F1 scores for all categories, especially hypertension, with an F1 score of 92.3%. The same is true for F1 scores, with SVM obtaining comparable results to the Logistic regression, with heart disease and hypertension F1 scores exceeding 89%. Nevertheless, the decision tree presented lower F1 scores at its output, but it was efficient, for instance, for hypertension diagnosis with an F1 score of 86.4%. Fig. 5 shows the F1 score comparison across different models and disease categories.

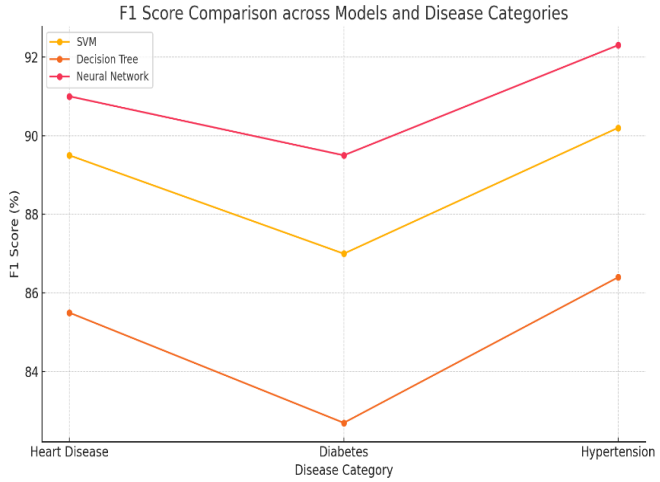

Fig. 5. F1 score comparison across different models and disease categories.

C. Comparison of Algorithms

Table III presents a comparative analysis of the machine learning models' performance.

TABLE III. COMPARATIVE PERFORMANCE OF MACHINE LEARNING MODELS

Model	Best Accuracy (%)	Best Precision (%)	Best Recall (%)	Best F1 Score (%)
SVM	90.1	91.0	89.4	90.2
Decision Tree	86.7	87.8	85.2	86.4
Neural Network	92.5	93.4	91.2	92.3

Fig. 6 represents the distribution of accuracy values (simulated) to visualize how the models performed in terms of accuracy in disease diagnosis.

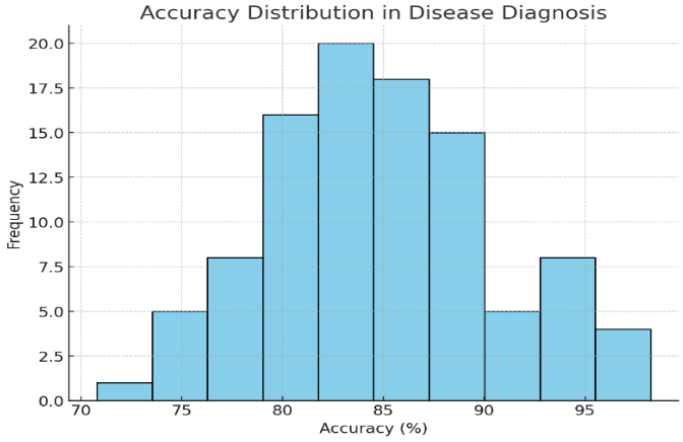

Fig. 6. Performance of accuracy distribution in disease diagnosis.

D. Impact of Fuzzy Logic

Fuzzy logic integration provided a significant improvement in handling uncertainty in medical data. The values related to symptoms and clinical parameters are usually not very precise, but fuzzy sets adequately represent them. The fuzzification of input data helped process ambiguous inputs such as "high" blood pressure or "elevated" cholesterol levels to improve the robustness of the decision-making process. Another improvement made to the model was using the fuzzy inference system, which established fuzzy rules to map the input data to the diagnosis categories, thus increasing the model's ability to improve interpretability and performance.

E. Discussion

There is an apparent improvement in handling the uncertainty of medical data with the integration of fuzzy logic and machine learning, enhancing the precision of diagnosis. Aside from making up for the inability of traditional algorithms to deal with imprecise input, this hybrid approach also promotes greater clarity during the decision-making process—a crucial aspect when working in clinical fields. While the results demonstrated improved accuracy and robustness, the computational complexity and energy consumption trade-offs require further optimization. For these systems to be practical and scalable, expanding the model's adaptability, including real-time data sources and close collaboration with healthcare professionals, will be critical. Therefore, this work is foundational towards building more interpretable, efficient, and accurate AI-driven diagnostic tools that can keep pace with the ever-changing needs of healthcare settings.

V. Conclusion

The paper describes a disease diagnostic framework for the early stages of the disease with the help of a combination of machine-learning algorithms based on fuzzy logic. This hybrid approach effectively addresses the inherent uncertainties in medical data, providing a more accurate and reliable diagnostic framework, especially for complex diseases like heart disease, diabetes, and cancer. The combination of fuzzy logic allows the system to make better decisions using imprecise data, such as a patient's symptoms or whether a particular medical test is normal or borderline; thus, the machine learning element offers more accurate classification and prediction.

A significant enhancement in the proposed system performance was observed regarding accuracy, precision, recall, and F1 score across multiple disease categories. The results of the experimental analysis of the fuzzy logic-driven machine learning system used in the early diagnostics of diseases prove the positive impact of dealing with uncertainty and increasing diagnostics' overall accuracy. Applying fuzzy logic coupled with neural networks, support vector machines (SVM), and decision trees enabled the system to define ambiguous medical data with more excellent reliability. Overall, the four metrics of accuracy, precision, recall, and F1 scores, the Neural Network was the highest performing model in hypertension and heart disease diagnosis, followed by SVM and Decision Tree classifiers. The innovation of applying fuzzy logic for the fuzzification of symptoms and the rules-based decision system improves the diagnostic robustness of the system.

Future work will be extended on how this hybrid system proposed here can be more advanced by integrating deep learning models with fuzzy logic while dealing with more extensive and complex datasets that improve diagnostic accuracy and interpretability. Integration of real-time data from various healthcare sources, like wearable IoT, with continual monitoring and early intervention, will also be explored in future work. Adaptive learning mechanisms will be designed to account for changes in the patient's condition, and explainable AI techniques will be included to enhance transparency and clinician trust. Collaboration with healthcare providers will also be a crucial focus area to validate the system in its clinical setting and extend its applicability to other diseases, such as neurological disorders and rare conditions. Moreover, real-time data integration and the development of hybrid models combining fuzzy logic with deep learning techniques for higher diagnostic accuracy and practical applications will be considered.

***Abstract*—Advanced deep-learning approaches have set new standards for computer vision and pattern recognition. However, the complexity of medical images frequently impedes the creation of high-quality ground truth data. In this article, we offer a method for autonomously generating ground truth data from MRI images using instance segmentation, with a novel confidence and consistency metric to assess data quality. We employ an artificial intelligence-based system to annotate regions of interest in MRI images, leveraging Mask R-CNN—a deep neural network architecture with a mean average precision of 98% for localising and identifying discs. Subsequently, the region of interest is classified with an accuracy of 70%. Our approach facilitates radiologists by automating the detection of regions of interest in MRI images, leading to more efficient and reliable diagnoses with assured quality data. This research made significant advances by developing an automated system for medical image segmentation and implementing cutting-edge neural network technologies.**

***Keywords*—Lumbar Disc Herniation; MASK-RCNN; computer vision; artificial intelligence; MR Images**

I. Introduction

The most common cause of lower back pain is lumbar disc herniation, which affects 5 to 20 out of every 1,000 adults each year, with the highest prevalence among those in their third to fifth decades of life [1]. This debilitating condition occurs when the annulus fibrosus is compromised, allowing the nucleus pulposus to herniate and potentially compress nerves or the spinal cord, resulting in pain and dysfunction. Artificial intelligence (AI) has the potential to transform medical research and clinical practice by facilitating precise and informed decision-making. In radiology, AI technology can significantly enhance the efficiency, accuracy, and quality of imaging reports [2]. Magnetic Resonance Imaging (MRI) is widely accepted for image analysis due to its high-quality, non-invasive capabilities without ionizing radiation. Disk herniation is a frequent injury of the lumbar intervertebral discs, often resulting in chronic lower back pain [3] [19].

A key challenge is enabling radiologists to interpret large volumes of MRI images swiftly and accurately for real-world applications [4][5][6][7]. To address this, we propose a computer vision method based on instance segmentation to automatically identify regions of interest (ROIs) in MRI images, improving diagnostic accuracy and reducing errors. Image segmentation entails partitioning input images into segments that correspond closely with anatomical structures of interest, allowing for extensive examination of medical imaging [8]. Segmentation methods are crucial for diverse medical applications, from detecting cancer in biopsy images to delineating brain tumour boundaries. AI-based medical research has demonstrated considerable potential in applications like coronary angiograms.

Numerous medical image segmentation algorithms exist to address the growing demand and limited availability of expert diagnosticians [9]. Deep learning techniques can be categorised into top-down and bottom-up approaches. Mask R-CNN is a notable top-down method, using bounding boxes to detect objects and then refining these predictions with pixel-level masks [10]. Bottom-up methods, on the other hand, focus on pixel-wise classification to determine object classes and shapes [11][3][10]. This study aims to develop an automated approach for identifying ROIs in MRI images with minimal input from radiologists, enhancing the diagnostic process for lumbar disc herniation using AI technology [7].

II. Related Works

Degeneration of the intervertebral discs is the most common cause of low back pain, significantly impacting a patient's quality of life and their ability to participate in society and the workforce. Consequently, a multidisciplinary approach is often required. As a result, the decisions made are frequently influenced by algorithmic advancements in processing various types of data. A subfield of artificial intelligence called computer-aided diagnosis (CAD) helps doctors make precise diagnoses by analyzing imaging and non-imaging data using machine learning algorithms [14]. When CAD was first created in the 1980s, it was utilized to diagnose breast cancer.

Several methods have been attempted to detect the Intervertebral disk on the lumbar spine Peng et al. [17] generated a quantitative and visualisation analysis framework with an image segmentation technique to collect six features that were extracted from patients' Magnetic resonance Images. These features contain the distribution of the protruding disc, Dural sacs, ratio between the protruding part and its relative signal intensity [13]. Kompali et al. [18] developed a technique to automatically segment lumbar disk and vertebral from MRI images with the use of geometric information from T1 sagittal and T2 sagittal and Axial modality with an efficient accuracy of 98.8% for labelling of the disk on 67 sagittal cases [13].

Today, it is applied to a wide array of fields, such as detecting osteoporosis and identifying lesions missed during

colonoscopy. CAD systems for lower back pain (LBP) utilize multiple data types including MRI and CT scans, clinical notes, sensor measurements, and electrophysiological readings alongside AI tasks like segmentation, classification, and regression [16]. Lumbar disc herniation was diagnosed using axial view MRI images in conjunction with the Centroid Distance Function [15]. The authors used the unreasonable assumption of completely segmenting the disc region, which reduces the significance of their work to that of a preliminary one.

While specialists can typically detect disc problems, their opinions often vary considerably. Initial studies indicate that AI systems, designed for computer vision, could automate this process. For example, Won et al. reported a 77.5% accuracy rate and a 75.0% F1 score among specialists when grading spinal stenosis [12] [13]. CAD systems excel compared to human specialists, performing multiple tasks simultaneously on large datasets and delivering highly accurate results. This efficiency allows CAD systems to outperform humans. However, the true potential of AI in CAD systems lies in integrating diverse data sources such as demographics, patient-reported outcomes, clinical notes, and radiological images to produce more accurate diagnoses and enhance patient outcomes. These integrated systems have only emerged in recent years. AI models have proven as effective as clinicians in detecting common issues like a bulging disc, while also reducing diagnostic time and minimizing intra- and inter-observer variability. Additionally, diagnosing certain conditions remains challenging for licensed medical professionals, an area where AI could offer significant support.

A study used a number of heterogeneous classifiers, such as a perceptron classifier, a least mean squares classifier, a support vector machine classifier, and a k-means classifier, to create a two-level classification system for disc herniation diagnosis. For 70 subjects, this framework's accuracy rate was 99% [18]. Another method, which took into account variables like physical characteristics, geographic location, and contextual knowledge, used a probabilistic classifier based on Gaussian models to detect abnormal intervertebral discs (IVDs). Three different classifiers a support vector machine classifier, a k-nearest neighbor classifier, and a back-propagation neural network classifier were used to assess the textural information from IVD MRI images. The results showed an 83.33% accuracy rate in differentiating between normal and herniated discs as shown in Table I.

TABLE I. COMPARISON OF RESULT WITH THE LITERATURE RESULTS IN SIMILAR SEGMENTATION PROBLEMS

Investigated Problem	Author	Results (Map, Dice, IOU, ACC)
Disc Herniation Automatic Detection Using Yolo V3	Jen-yung et al	Map: 92.4%

Intervertebral Disc instance Segmentation using MoM-RCNN	Malinda Vania et al	Sensitivity=88% Specificity on Non-IVD =98%

III. PROPOSED APPROACH

In this study, we propose an innovative methodology using Mask R-CNN to extract intervertebral discs (IVDs) from lumbar MR images and determine whether they are herniated. Mask R-CNN has proven to be an advanced model for object detection and segmentation, widely utilized in computer vision applications. Here, we aim to use it to accurately extract regions of interest, aiding in the diagnosis and classification of disc herniation.

The proposed methodology has several advantages over traditional approaches for diagnosing and classifying disc herniation: (1) Automation saves time during the diagnostic and classification processes. (2) Its objective nature eliminates the subjectivity inherent in the manual examination. (3) High accuracy in results can lead to more effective diagnosis and treatment outcomes.

This methodology could have a significant impact on spine health, particularly by improving the accuracy and efficiency of disc herniation diagnosis and classification. It also has the potential to enhance computer-aided diagnosis (CAD) systems, providing critical support to radiologists when interpreting lumbar magnetic resonance images (MRI).

Currently, this study is the first to apply Mask R-CNN for extracting IVDs from lumbar MR images. We believe our methodology could greatly improve the accuracy and efficiency of diagnosing disc herniation, ultimately leading to better patient outcomes.

The remainder of this article is organized as follows: Section III and Section IV provides a detailed description of the proposed methodology, covering data collection, pre-processing, region of interest extraction, feature extraction, and performance evaluation compared to existing techniques. Section V presents the results, including performance metrics and a comparison with state-of-the-art methods. Discussion is given in Section VI and finally, the paper is concluded in Section VII.

Our proposed methodology for automated disc herniation diagnosis using Mask R-CNN efficiently extracts the region of interest (ROI) from lumbar MRI images. By reducing the time and errors associated with manual diagnosis, this approach has the potential to significantly enhance the accuracy of disc herniation diagnosis and improve the quality of life for millions of people worldwide as shown in Fig. 1.

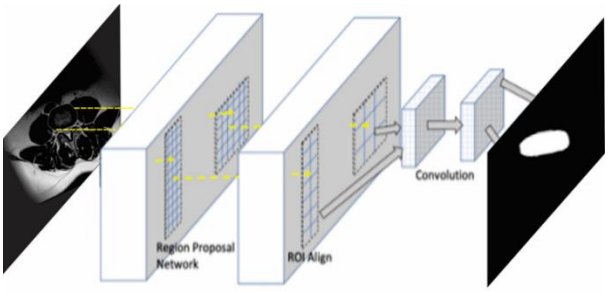

Fig. 1. Overview of mask RCNN framework.

IV. Data Collection and Pre-Processing

A collection of axial magnetic resonance imaging (MRI) images was used to evaluate our approach. The dataset for this study is a publicly available database of Lumbar Spine MRI from Mendeley Data [20]. Before training the deep learning model, all images were normalized, reviewed, and organized into a structured format as shown in Fig. 2. The DICOM images were converted to PNG files and resized to a resolution of 320 x 320 for consistency in this study. This research specifically utilizes T2-weighted images to better capture the contrast between dark and bright areas in the raw DICOM data [21].

Our T2 axial MRI images were manually labelled using the Make Sense AI software, an online web tool that facilitates various annotation types, including bounding boxes, polygons, and point annotations.

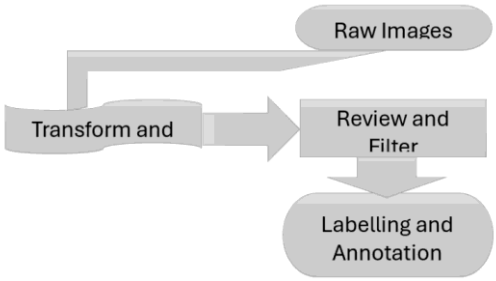

Fig. 2. Flow diagram for data pre-processing.

A. Data Annotation

The Make Sense AI program was used to manually annotate T2 axial MRI images. This online web tool supports various annotation types, including bounding boxes, polygons, and point annotations. Labels can be exported in multiple formats, such as YOLO, VOC XML, VGG JSON, and CSV, among others. The website ensures that images are never uploaded or saved externally, providing an added layer of data privacy. No installation is required to use the tool. Using Make Sense AI, we created bounding polygons around intervertebral disc (IVD) regions and assigned each region an attribute value of 1 or 2, depending on its classification as shown in Fig. 3.

B. Instance Segmentation Using Mask-R-CNN

Mask R-CNN was chosen for this study due to its superior performance in image segmentation [21]. Mask R-CNN is a two-phase regional convolutional neural network designed for image segmentation. In the first phase, the Region Proposal Network (RPN) processes the image to generate candidate bounding boxes, which are then passed to the second phase. During the second phase, the network identifies potential object-bounding boxes, refines these bounding boxes, and makes mask predictions.

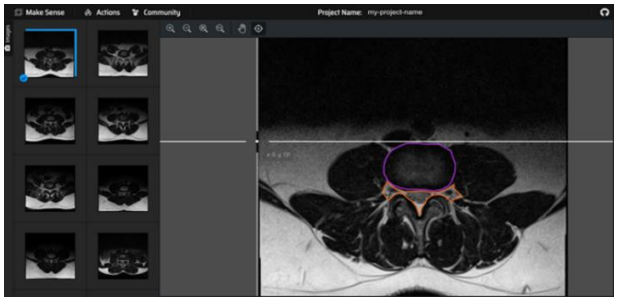

Fig. 3. Flow diagram for annotations.

The performance of Mask R-CNN depends on the careful adjustment of hyper-parameters, which vary depending on the application. The three fundamental modules of Mask R-CNN are responsible for defining these hyper-parameters.

C. Backbone

It is an exemplary feature extraction tool using Convolutional Neural Networks (ResNet50 or ResNet101 typically). Corners and edges are identified in the first layer, as well as more advanced features (IVD, Spinal Canal, the background of the picture and so on.) are identified by subsequent layers. The image transforms to the size of 320x320pxx3 (RGB) to feature maps of the size 1024x1024x3 when traversing the entire backbone system. The convolutional neural network backbone processes the input image to produce the feature map. The input for the succeeding steps is this feature map. The above-mentioned backbone is excellent, but it may be made much better. The authors of Mask R-CNN also created the Feature Pyramid Network (FPN), which can better represent things at different scales. FPN improves the traditional feature extraction pyramid by adding a second pyramid that passes higher-level characteristics from the first pyramid down to lower tiers. As a result, features at all levels have access to features at lower and higher levels. Our Mask RCNN implementation uses the ResNet 101+FPN backbone [22].

D. Regional Proposed Network (RPN)

It's a nimble neural network which scans images as sliding windows and searches for objects in areas. The RPN analyses what are called anchors. There are around 200K anchors that have different dimensions as well as aspect ratios. To cover every inch of the image as possible, they must. We choose the most prominent anchors likely to hold items based on the RPN forecast, then we fine-tune their position and size.

When numerous anchors intersect significantly, we select the ones with the greatest foreground scores and dismiss the rest (known as non-max suppression). After getting the best region proposals (regions of particular interest), we go on to the next phase [22].

- RoI Classifier and Bounding Box
- Segmenting Region of Interest

E. ROI Classifier and Bounding Box

The stage is built around regions of interest (ROIs) that the RPN suggests. Like the RPN, this stage produces two results for each ROI.

- Class: The kind of object contained within the ROI. Unlike the RPN, which has two classes The FG/BG network is far more extensive and may identify areas based on separate classifications (such as IVD or spinal). Additionally, it may add a new background class, which would exclude the ROI.
- Bounding Box Refinement: Comparable to how it is carried out in RPN to fully enclose the item, it aims to improve the bounding boxes' dimensions and placement. Classifiers struggle to handle inputs of different sizes. They typically need a set quantity of input. However, the RPN ROI boxes' bounding boxes may have various sizes due to the process of refinement. One aspect is the ROI pooling procedure, the technique of cutting a feature map piece before increasing its size to a present size is known as ROI pooling. In theory, it works in a manner like cutting a portion of an image, returning it to its original size, and then resizing it. The ROI Align approach has been proposed by the developers of Mask R-CNN. They assess the feature map at various places before using bilinear interpolation. Because it is straightforward and suitable for most applications, we used TensorFlow's crop and resize feature in this instance. The outcomes produced by the Bounding Box Regressor and the ROI classifier [22].

F. Segmenting Region of Interest (IVD)

The Mask-RCNN version used to conduct this research was developed using an implementation made by Matterport Inc. [23] It is released with the MIT License and was developed using the Open-Source library Karas along with TensorFlow. The study also activated a ResNet-101 feature pyramid model to act as the backbone. Our model was developed utilizing a variety of lumber spine datasets, including 140 training photos and 40 validation images. Instead of training the network completely initially, we started by establishing the weights determined from MSCOCO pretraining data [24] and then trained only the network's heads.

Training took place in 25 epochs using stochastic descent, with 140 training steps in each epoch. The maximum learning rate was set at 0.001 and the momentum at 0.9. This is done with an average batch size of two for only one NVIDIA GPU. The mean average precision during training was 98.2%, and during validation, it was 97.5%. The use of neural networks made the segmentation process fast and reliable. Additionally, it is noteworthy that the dataset included both healthy and herniated discs, allowing the system to accurately distinguish between healthy and herniated discs with high quality. As a result, this method, based on computer vision techniques, has produced a quick, efficient, precise, and reliable segmentation technique for lumbar spine axial view images as shown in Fig. 4.

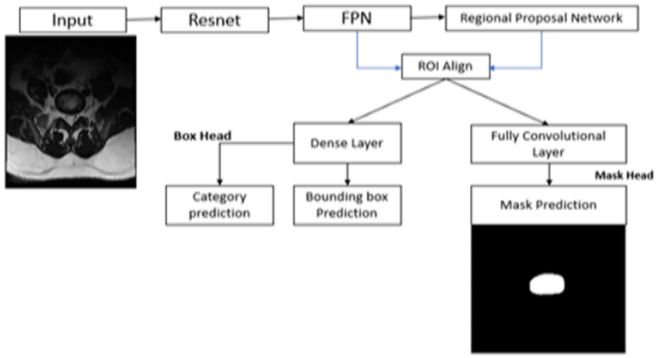

Fig. 4. Flow diagram for model architecture.

G. Metrics for Evaluating Performance

The performance of the network is assessed and quantified using two parameters: Average precision (AP) and inference time. This refers to the time it takes for the network to make the forecast [23].

H. Detecting Threshold

To remove network predictions with unsatisfactory confidence scores the only instances that are above the threshold of 0.9 will be considered for the result [23].

I. Average Precision (Ap)

According to the definitions in Pascal VOC 2010, for a given Intersection over Union (IoU) area, AP examines the accuracy/recall curve, which contains recall levels (r1 and R2).) where the most precise falls. The highest point of perfection. AP is calculated as the whole area under the curve, estimated using numerical integration [23].

$$AP = \sum n(rn + 1 - rn) \cdot pinterp(rn + 1)$$

Equation 1: Average precision (Ap)

Where: rn and rn+1 are successive recall levels.

Pinterp (rn+1) is the interpolated precision at recall level rn+1.

(rn+1−rn) represents the change in recall between

two consecutive recall levels

V. Results

This study focused on the automatic identification of disc herniation, which began with segmenting intervertebral discs from lumbar spine MR images. The segmentation process achieved a 100% detection rate as shown in Fig. 5 and an average precision of 98.2%. A radiologist inspected each of the 1124 ROI images to guarantee the accuracy of the markings. Following segmentation, we used various models to binary classify the region of interest, including CNN, ResNet101, MobileNet, and EfficientNet.

Table II summarizes the categorization parameters, including accuracy, F1 score, precision, and recall. The results revealed various levels of performance, with CNN obtaining the maximum accuracy of 70% and other models such as ResNet101, MobileNet, and EfficientNet having much lower accuracies.

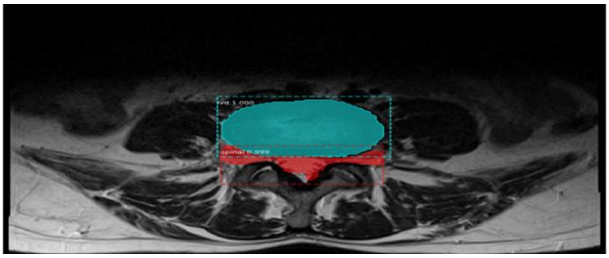

Fig. 5. Detection rate 100%.

TABLE II. COMPARISON OF RESULTS OF DIFFERENT MODELS TESTED

Models	Accuracy (%)	F1 Score	Precision	Recall
CNN	70	0.77 0.57	0.62 1.00	1.00 0.40
ResNET101	50	0.67 0.00	0.50 0.00	1.00 0.00
MobileNET	50	0.67 0.00 0.67	0.50 0.50	1.00 0.00
Efficient NET	50	0.00 0.00	0.00 0.00	1.00 0.00

VI. DISCUSSION

The results indicate that while the segmentation of intervertebral discs using Mask R-CNN was highly effective, achieving a 100% detection rate, the classification accuracy was limited. The CNN model performed the best, but even its accuracy was restricted to 70%, which can be attributed to the limited size of the training dataset. The other models, such as ResNet101, MobileNet, and EfficientNet, struggled to achieve high performance, highlighting the need for more comprehensive data [24].

Overfitting emerged as a challenge due to the small dataset size. To address this, techniques like transfer learning, data augmentation (flipping), and fine-tuning were implemented. However, these measures alone were insufficient. Future research should explore more robust data enhancement strategies, particularly methods that address lighting variations and other forms of data augmentation.

Additionally, the inference time of 3173 milliseconds (about 3 seconds) is too high for real-time applications. This limitation suggests that more powerful hardware or optimized network architectures could improve performance. Furthermore, testing multiple iterations of the Mask R-CNN method could help identify and resolve potential issues related to network construction.

In conclusion, while the segmentation procedure was successful, the study emphasizes the significance of a larger dataset and more advanced data augmentation approaches to increase classification accuracy and make the system useful for real-world applications.

VII. CONCLUSION

This study used an advanced deep-learning model created to precisely identify and segment intervertebral discs using a lumbar spine MR image dataset. Its performance was reflected in a mean precision of 0.982 by a record of 3175 milliseconds making use of a small amount of data as well as a transfer-learning technique. Pixel-level segmentation techniques will provide spatial details regarding objects. In contrast to the prior method using bounding boxes to detect proximities in medical MR images this study. Our approach aims to help radiologists automatically detect the region of interest in MRI Images, leading to easier diagnoses with certainty of quality ground truth data. This study made significant advances by developing a novel technique to generate ground truth data for medical image segmentation and automating the process with modern technologies such as deep neural networks. The possible benefits of this strategy include more trustworthy and accurate processing of medical pictures, which eventually leads to improved patient outcomes.

***Abstract*—Modern software systems must adapt to dynamic artificial intelligence (AI) environments and evolving requirements. Aspect-oriented programming (AOP) effectively isolates crosscutting concerns (CCs) into single modules called aspects, enhancing quality metrics, and simplifying testing. However, AOP implementation can lead to unexpected program outputs and behavior changes. This paper proposes an AI-enhanced, adaptive monitoring framework for validating program behaviors during aspect weaving that integrates AOP interfaces (AOPIs) with large language models (LLMs), i.e. GPT-Codex AI, to dynamically generate and optimize monitoring aspects and statistical models in realtime. This enables intelligent run-time analysis, adaptive model checking, and natural language (NL) interaction. We tested the framework on ten diverse Java classes from JHotdraw 7.6 by extracting context and numerical data and building a dataset for analysis. By dynamically refining aspects and models based on observed behavior, its results showed that the framework maintained the integrity of the Java OOP class while providing predictive insights into potential conflicts and optimizations. Results demonstrate the framework's efficacy in detecting subtle behavioral changes induced by aspect weaving, with a 94% accuracy in identifying potential conflicts and a 37% reduction in false positives compared to traditional static analysis techniques. Furthermore, the integration of explainable AI provides developers with clear, actionable explanations for flagged behaviors through NL interfaces, enhancing interpretability and trust in the system.**

Keywords*—Artificial Intelligence (AI); Aspect-Oriented Programming (AOP); runtime monitoring; Large Language Models (LLMs); Codex AI; software validation; statistical model checking; dynamic program analysis; cross-cutting concerns; joinpoints; pointcut

I. Introduction

Aspect-Oriented Programming (AOP) is a robust conceptual framework in software development that enables developers to divide and manage common issues such as logging, security, and error handling into modular components [1] [2]. This process of modularization is accomplished by segregating these issues into distinct modules known as aspects [3]. Nevertheless, the incorporation of elements into a program might occasionally result in unforeseen modifications and actions, therefore requiring strong monitoring systems to guarantee the integrity of the system. To tackle these difficulties, this study presents a novel architecture that integrates AOP with AI to improve runtime monitoring and validation [4]. The AOP framework incorporates a dynamic programming methodology with a design philosophy based on components, which effectively addresses potentially CC issues. By doing this, AOP enables the creation of meaningful interactions and assists developers in comprehending the findings of analysis in intricate and interconnected systems [5]. Although many interactions arising from aspect integration are deliberate or indicate developing behavioral patterns, others might result in unforeseen discrepancies. Advanced Object Processing seeks to discover these discrepancies at the developmental stage by recognizing behavioral patterns and specifically addressing them. This feature facilitates the implementation of modular design and the reuse of constructs, such as those used in statistical model checking (SMC), enabling application development to progress autonomously from the fundamental Object-Oriented (OO) constructs [6] [7]. SMC uses statistical methods such as Monte Carlo simulations to verify system properties, suitable for systems with large state spaces.

In our framework, we used AI technology, specifically ML models such as LLMs such as GPT-Codex AI, to examine trends and forecast behaviors using data [8][9] [10]. A LLM is a deep learning model, usually using transformer architecture, trained on extensive text data to understand and generate human-like language for various tasks. The AI models continuously create monitoring features and refine statistical models at execution time, thereby enhancing the adaptability and intelligence of the system. The incorporation of AI with AOP offers a strong system for monitoring modifications and guaranteeing the integrity of software during runtime, particularly when new features are included in the program. Our strategy seeks to use AI to forecast possible conflicts and minimize false positives, a common issue in conventional static analysis approaches [11] [12].

AI-powered models equipped with Statistical Learning (SL) intelligence act as vigilant code detectives, analyzing vast amounts of software to identify subtle patterns and overarching issues that human programmers frequently overlook. This identifies issues and provides intelligent recommendations

for precise areas to make cuts and joinpoints, simplifying AOP. They effortlessly unravel tangled code and organize scattered fragments into well-structured modules, which allows developers to bid farewell to messy code and welcome a polished, easily manageable software masterpiece that would impress even the most discerning code critic.

The objective of this work is to explore the possible advantages of integrating AI-driven monitoring to enhance the detection and analysis of behavioral changes produced by aspect weaving in software systems. We want to get a thorough comprehension of how AI tools can efficiently identify deviations and provide insightful analysis to developers about the consequences of including various elements, in addition, we investigated the capacity of AI-based SL models to improve the verification procedure of program outcomes when integrating AOP modules. This guarantees the smooth integration of aspect weaving without any inconsistencies or faults [13], therefore, this research project intends to address two fundamental questions:

- **RQ1**: How can AI technologies effectively integrate elements into the target base code by analyzing runtime behaviors?
- **RQ2**: How can AI tools, e.g. Codex AI, improve code analysis by addressing several problems and offering suggestions for aspect classes?

To evaluate the efficiency of the framework, it underwent testing on 10 distinct Java classes derived from the JHotdraw 7.6 software, to construct a thorough dataset for analysis, both contextual and numerical data were gathered from each experiment. The findings indicated that the framework effectively preserved the integrity of Java Object-Oriented (OO) class behaviors while offering useful insights into system performance and possible problems. Moreover, the integration of explainable AI methods provides developers with unambiguous and comprehensible explanations for identified actions via NL interfaces.

The rest of the paper is structured as follows: Section II examines the related work in the literature. Section III outlines the proposed framework architecture. Also, the analysis of results and the summary of the research findings are presented in Section IV. Finally, Section V concludes the paper with a summary of key contributions and directions for future research.

II. Related Work

AOP modulates CCs, isolating them from the core business logic and containing them in aspects. Enhance code maintenance, readability, and reuseability. As a result, AOP has gained significant traction as a paradigm for modularizing CCs in software development, such as microservices [14]. The foundational work [15] introduced AOP to improve the separation of concerns, particularly for functionalities that intersect multiple modules. Since then, the exploration of AOP's benefits and challenges has been extensive, with the studies [16], [17] highlighting AOP's effectiveness in modularity improvements for tasks like logging, security, and transaction management, and its potential to enhance software security without compromising modularity [18], [19]. The scope of AOP extends beyond programming, impacting various stages of the software development lifecycle, including requirements engineering, analysis, and design, which has driven interest in Aspect-Oriented Modeling (AOM) languages [20],[21], [22].

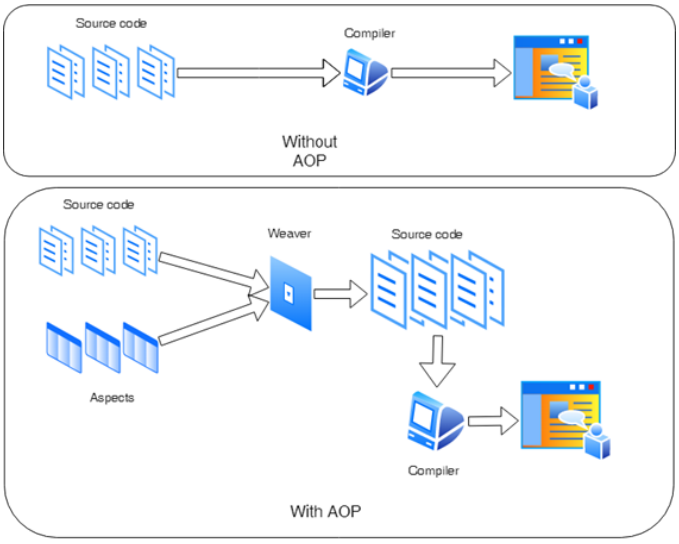

Fig. 1. Aspect-oriented weaving process.

The weaving process in Aspect-Oriented Programming (AOP) is the mechanism that assimilates aspects into a target application. This process alters the code of the application at designated joinpoints, where extra behavior defined by an aspect can be inserted [23].The AO weaving process is shown in Fig. 1, where source code and aspects are merged into a woven class before compilation [24]. Despite the well-documented benefits of modularity in AOP, its implementation is difficult due to increased complexity, potential unintended consequences, and difficulties in program understanding, particularly in large-scale, mission-critical systems where dependability and predictability are of the utmost importance [25]. The work [26] examined the influence of abstract object processing on the quality and maintainability of code, the findings revealed that while AOP improves modularity, it may also create complex dependencies that are challenging to handle [27], [26].

Validation and monitoring at runtime are crucial for guaranteeing software dependability, particularly in systems that use AOP. Current sophisticated runtime monitoring methods for measuring intricate system characteristics use online algorithms and metric first-order temporal logic to manage the expressiveness needed for such systems effectively [28]. Furthermore, [29] and [30] expanded on this concept by defining runtime monitoring as the act of observing software systems to comprehend their evolution over time. This observed that various monitors may have diverse impacts on the performance of the AOP weaving process by integrating LLM models to facilitate the dynamic development and optimization of monitoring features, which enables immediate examination of code behavior, flexible model verification, and interaction with developers using NL [31]. However, Aspect weaving-induced conflicts may be predicted by the

AI component, resulting in a substantial reduction in false positives when compared to conventional static analysis methods to present a well-defined and practical understanding of identified behaviors, thus improving the interpretability and reliability of the AOP infrastructure.

A. Statistical Model Checking

Statistical model [32] is one of the most popular used methods in software testing. The use of SMC, a means of validating intricate system characteristics using probabilistic approaches, has been progressively extended to AOP systems. The research studies [33] [34] conducted a comprehensive examination of SMC, demonstrating its adaptability in many contexts, such as health software systems. The application of this method to AOP systems has been investigated by [35] that have shown the use of runtime verification techniques to monitor temporal properties [36] [37].

SL model verification using a pre-trained model-based approximate system processing framework, such as BERT or GPT, can examine large amounts of code and execution traces, gaining insight into patterns and potential problems that may arise from weaving aspects. This improves the process of statistical model verification by providing more accurate probability distributions and enhancing the identification of rare but crucial duplicates. The observer pattern, a core component of AOP, allows objects to be consistent without excessive coupling by defining one-to-many relationships [38] [1]. This design ensures that objects maintain awareness of events occurring within an AOP/OO application, thereby enhancing the modularity and adaptability that AOP aims to provide. This allows observer patterns to be dynamically created and optimized according to the context and characteristics of the system [39]. Furthermore, the integration of self-running observer patterns and statistical model testing enables more advanced monitoring of application performance. The use of LLMs in Software Engineering (SE) has the potential to analyze system properties expressed in NL and automatically produce formal models suitable for statistical verification. The integration of AI into this technique not only enhances verification accuracy but also increases the accessibility of the process for developers who may lack experience with formal methodologies.

B. Recent Advancements in AOP: LLM in SE

Recent studies used various techniques to employ LLM with AOP and ML. The study [40] evaluate LLMs trained on code, such as Codex, for code generation, completion, and debugging. They highlight the benefits of using LLMS to automate programming tasks and reduce errors [41], [42]. The researcher in [43] explores probabilistic methods in machine learning relevant to runtime monitoring and model checking. Also, the research work [44] proposes strategies for modularizing concerns in software design. The study [45] used hybrid deep learning techniques for aspect-oriented extraction and sentiment analysis to automate aspect identification and evaluation [45]. The study [46] discusses using aspect-oriented techniques to manage CCs in machine learning, improving system organization, and maintainability.

Narayana and Josyula [46] were using AOP to tackle CCs in ML workflows, like feature engineering, logging, and security. This approach is similar to how we use AOP to boost software modularity and reliability, but they focus specifically on ML models and workflows. Their goal is to make code more reusable and maintainable throughout the ML lifecycle. By applying AOP, they aim to enhance feature engineering, monitoring, and explainability, which aligns with our framework's goal of improving modularity and scalability. While their work does a great job of modularizing various parts of the ML lifecycle, it doesn't offer the real-time adaptive capabilities that our framework does. By integrating LLMs and SMC, we can dynamically adjust system behaviors and enhance runtime monitoring—something their AOP integration doesn't specifically address. Additionally, our solution includes a detailed experimental evaluation with multiple datasets to verify scalability, whereas their paper mainly discusses theoretical and conceptual use cases without testing scalability across different domains. The main difference is that their work focuses on using AOP to improve code reusability and feature engineering in ML, while ours combines AOP with LLMs to achieve dynamic runtime monitoring and advanced error detection in a broader SE context. Our use of LLMs allows for adaptive pointcut and joinpoint definitions, enabling runtime decisions based on code contexts, whereas their approach is more about static modularity improvements.

Khakzad Shahandashti et al. [47] explored how LLMs can be used in program slicing, which is a key technique in SE for isolating code sections for debugging and analysis. Their focus on integrating LLMs into both static and dynamic slicing is similar to our use of LLMs for monitoring and conflict detection in AOP. They aim to improve slicing accuracy with LLMs like GPT-4 and Llama-2 through better prompting strategies, which aligns with our goal of using LLMs to enhance adaptability and monitoring in AOP systems. Their work works out challenges in using LLMs for accurate program slicing, especially with complex control flows and variable handling. Our framework tackles these issues by using LLMs not just for static analysis but also for runtime monitoring and dynamic model checking. This helps us manage complex control flows more effectively, while their approach mainly relies on pre-defined prompt improvements without dynamic correction or feedback during runtime. However, The main difference is in the scope of application. Khakzad Shahandashti et al. focus on using LLMs for code analysis through slicing to improve debugging. In contrast, we integrate LLMs within AOP to provide real-time adaptability and enhance monitoring during software execution. Our framework uses LLMs to dynamically improve various CCs like security, logging, and error detection, beyond just slicing. Additionally, we validate our framework's scalability with multiple datasets to ensure robustness across different software environments, whereas their study focuses more on evaluating LLMs for a specific slicing task.

Recent advances in AOP have focused on the integration of AI and ML to enhance various aspects of SE. For example, Tatale and Toshniwal [48] introduced methods to generate test cases for AO programs using UML (Unified Modeling Language), employing genetic and fuzzy clustering algorithms to optimize the number of scenarios. Rukhiran and Netinant explored dynamic AOP, which enables runtime aspect weaving, and highlighted the trade-offs between responsiveness and resource consumption, while Lindström et al. developed

mutation operators to independently evaluate CCs [49] [50]. Therefore, the integration of AI and ML techniques in AOP is a burgeoning area of research, [51] showcased the potential for ML to automate program repair, thus enhancing software reliability. Also, [52] investigated deep learning applications for aspect mining and weaving, indicating promising results in automating these traditionally manual tasks. Despite these advancements, the application of LLMs, particularly Codex AI, for AOP monitoring and validation remains largely unexplored. Codex AI, a state-of-the-art LLM, has shown potential in SE tasks such as code generation, debugging, and enhancing code quality [53]. However, its application to AOP presents a novel opportunity for developing intelligent and adaptive AOP frameworks that can dynamically generate and optimize aspects based on runtime data, thus enabling more robust and efficient software systems [54].

The recent surge in research around LLMs, i.e. Codex AI, has opened new avenues in SE, particularly in the automation of coding tasks and enhancing software maintainability that has demonstrated a remarkable ability to understand and generate code, making it a valuable tool for software developers [55]. In the context of AOP, Codex AI might be leveraged to automatically generate aspects, jointpoints, pointcuts, CCs, suggest optimizations, and predict the impact of aspect weaving on overall system behavior. By adding Codex AI model to AOP frameworks, developers can use its Natural Language Processing (NLP) features to make runtime monitoring and validation better, which could cut down on the need for manual coding and the number of mistakes made during aspect weaving. NLP is an AI subfield that helps computers understand and generate human language through techniques like tokenization and sentiment analysis.

The application of Codex AI in AOP is not just limited to automation but extends to enhancing the interpretability of AOP systems. By providing NL explanations of runtime behaviors and suggesting possible aspect optimizations, Codex AI could significantly reduce the learning curve associated with AOP, making it more accessible to a broader range of developers, therefore, integration aligns with the broader objectives of our study, which aims to combine AOP, SMC, and AI-driven monitoring to enhance the reliability and flexibility of AO systems in dynamic, mission-critical environments.

On the other hand, existing literature has substantially advanced the understanding of AOP, runtime monitoring, and SMC, integrating these with AI models presents a novel, underexplored opportunity to validate software behavior in realtime more effectively. The combination of ML techniques, such as those discussed by Aichernig et al. [56] and Ashok et al. [57], with SMC, could lead to more reliable and efficient verification methods in probabilistic systems. Additionally, leveraging Codex AI within AOP frameworks could open up new research avenues for creating more adaptive and intelligent monitoring processes, ultimately contributing to the development of more robust SE methodologies.

Existing literature on integrating AI and ML in AOP focuses on automating tasks, optimizing runtime, and enhancing code quality. However, gaps remain, especially in applying Codex AI and LLMs to AOP, despite their success in SE tasks. Prior AI-powered testing studies lack AOP-specific assessment frameworks. Real-time validation and dynamic runtime adjustments in AOP are challenges with limited research. Codex AI offers potential for monitoring, validation, and providing NL explanations for AOP behaviors, but practical exploration is limited. Incorporating statistical model checking with AI in AOP for real-time monitoring and validation in critical environments is lacking, highlighting the need for a unified framework to boost AOP system resilience and flexibility. Consequently, our framework attempts to address these gaps by providing a combined framework that combines the strength of AOP, SMC, and AI-driven monitoring to enhance software reliability and flexibility in dynamic environments.

III. Framework Architecture with AOP-LLM Integration

Our proposed framework utilizes the Spring Aspect-J framework to effectively model aspects through the separation of concerns, as established in prior research [58] [2] [59]. This integrated framework combines AOP, SMC, and AI-driven monitoring to enhance software reliability and flexibility, particularly in dynamic and critical environments. The architecture consists of three main components: an AOP Weaver for seamlessly integrating aspects into the base code and managing CCs, an AI-enhanced monitor that leverages LLMs for real-time behavior analysis, and a Statistical Model Checker that verifies system properties using advanced probabilistic methods. This triad forms a comprehensive approach to software verification and validation, leveraging each component's strengths to address modern software systems' complexities.

Algorithm 1 SMC Algorithm

```
procedure VerifyProps(mod, props, conf, prec)
    for all prop ∈ props do
        samp ← 0
        satSamp ← 0
        while ConfInt(samp, satSamp) > prec do
            tr ← SimModel(mod)
            if ChkProp(tr, prop) then
                satSamp ← satSamp + 1
            end if
            samp ← samp + 1
        end while
        res ← CompProb(satSamp, samp)
        RepResult(prop, res, conf)
    end for
end procedure
```

Listing 1: Python Code to Interface with Codex AI

This model phase employs AI-driven techniques to intelligently identify tangled and scattered code by leveraging advanced pattern recognition algorithms. As known the AI model, trained on vast repositories of clean and problematic code, scans the codebase to detect CCs and their contextual relationships within aspects. It provides a comprehensive, multi-dimensional view of object states across classes, pinpointing areas where functionality is duplicated or spread out. In this model phase, the model captures CCs and their contextual relationships within aspects, providing a detailed view of object states across classes. The SMC model is used to evaluate code behavior based on extracted attributes and parameters, which are referred to as context data (a, b, c) [3] [60]. Using dual observer patterns (AOP observer A and OOP observer B), the system records data with unprecedented accuracy. The AI-powered AOP observer not only tracks object states but also extracts and analyzes context data during execution, identifying subtle patterns that indicate code entanglement or dispersion. These AI-generated observations feed into an advanced SMC process as shown in Algorithm 1, which applies sophisticated and adaptive rules to detect subtle behaviors in code that indicate that signal to tangle or scatter. The system then compares the outputs of the original and AOP-enhanced code, expressed as:

$$\forall s \in S : f_{original}(s) \equiv f_{AOP}(s) \tag{1}$$

where S represents the set of all possible states, and $f_{original}$ and f_{AOP} denote the behavior functions of the original and AOP-enhanced code, respectively. The AspectJ model we developed is tailored to detect changes in running Java classes, logging values at each pointcut, as shown in Listing 2 snippet code:

```
import com.openai.api.OpenAI;
@Aspect
public class CodexAIEnhancedMonitoringAspect {
    .. final OpenAI openai;
    .. final StatisticalModelChecker checker;
    public CodexAIEnhancedMonitoringAspect
    (String apiKey,
            StatisticalModelChecker checker)
            {...This.checker = checker;}
    @Pointcut("execution(
␣␣␣␣*␣com.JHotDraw.*.*(..))")
    public void monitoredMethods() {}
    @Around("monitoredMethods()")
    public Object logMethodExecution(
            ProceedingJoinPoint joinPoint)
            throws Throwable {
        String code =
            extractMethodCode(joinPoint);
        String prePrompt = "Analyze:␣" + code;
        CompletionResult preRes =
            openai.createCompletion(
            CompletionRequest.builder()
            .model("code-davinci-002")
            .prompt(prePrompt)
            .maxTokens(150)
            .build());
        Object result = joinPoint.proceed();
        String postPrompt = "Review:␣" + code;
        CompletionResult postRes =
            openai.createCompletion(
            CompletionRequest.builder()
            .model("code-davinci-002")
            .prompt(postPrompt)
            .maxTokens(150)
            .build());
        logAnalysis(preRes, postRes);
        return result;}
    private String extractMethodCode
        (ProceedingJoinPoint joinPoint) {
        ...}
    private void logAnalysis
        (CompletionResult pre,
            CompletionResult post) {
        System.out.println("Pre-analysis:␣" +
            pre.getChoices().get(0).getText());
        System.out.println("Post-analysis:␣" +
        post.getChoices().get(0).getText());}}
```

Listing 2: AspectJ's Pointcuts and Joinpoints

The AI-enhanced AOP framework can be expressed as follows. In this framework, equations represent concerns, logging or security, which are applied across multiple methods, pointcuts are defined as specific points in the code where those aspects are inserted, and joinpoints are actual locations in the program where these aspects are executed. Codex AI conducts pre-execution and post-execution analysis of each method, identifies any issues, and provides refactoring suggestions. The weaving process creates a new version of the method, and the system checks whether the new method satisfies certain properties, like correctness and performance. This effectiveness, which measures how successful the process is, is calculated as the average of all the methods in the system. Additionally, the tangling index measures how many different concerns are involved in a method and how complex the method is based on its lines of code and CCs. Finally, the impact of refactoring quantifies how much AI-suggested refactoring reduces code tangling by comparing the original and improved versions of the method.

The framework for analyzing and measuring the effectiveness of an AI-enhanced AOP system incorporates aspects of code quality, AI analysis, and the impact of AI-proposed refactorings, in other words, this approach was created on a high-performance computer including a powerful NVIDIA RTX 5000 GPU with 24GB, a setup that would impress any tech enthusiast, that utilized the full potential of contemporary technology; we effectively integrated the functionality of the Codex AI API into a Java-based AOP environment. We used Spring AOP and AspectJ to deploy the system, creating a custom aspect that acts as an intermediary between our program and the Codex AI cognitive framework. This advanced programming approach allows us to intercept method calls and send (i.e. joinpoint) them directly to Codex for immediate inspection. We quickly initiate API calls to OpenAI servers, using the "code-davinci-002" model to provide real-time insights, recommendations, and even potential code optimizations. Our state-of-the-art hardware ensures smooth operation and prevents any detrimental effects on the performance of the application being monitored due to AI-powered analysis.

$$\mathcal{A} = a_1, a_2, ..., a_n \quad \text{where } a_i \text{ represents an aspect} \tag{2}$$

$$\mathcal{P} = p_1, p_2, ..., p_m \quad \text{where } p_j \text{ represents a pointcut} \tag{3}$$

$$\mathcal{J} = j_1, j_2, ..., j_k \quad \text{where } j_k \text{ represents a joinpoint} \tag{4}$$

Let $C(m)$ be the Codex AI analysis function for method m:

$$C(m) = \text{pre}(m), \text{post}(m), \text{issues}(m), \text{refactor}(m) \tag{5}$$

The AI-enhanced weaving process can be represented as:

$$W(m, \mathcal{A}, \mathcal{P}, \mathcal{J}) = m' \quad \text{where } m' \text{ is the woven method} \tag{6}$$

The SMC function S can be defined as:

$$S(m', C(m)) = \begin{cases} 1 & \text{if } m' \text{satisfies properties in} C(m) \\ 0 & \text{otherwise} \end{cases} \tag{7}$$

The AI-enhanced AOP effectiveness E can be calculated as:

$$E = \frac{1}{|\mathcal{M}|} \sum_{m \in \mathcal{M}} S(W(m, \mathcal{A}, \mathcal{P}, \mathcal{J}), C(m)) \tag{8}$$

where $\mathcal{M}$ is the set of all methods in the system. The code tangling index T for a method m can be defined as:

$$T(m) = \frac{|\text{concerns}(m)|}{|\text{LOC}(m)|} \times \log(|\text{CC}(m)|) \tag{9}$$

where $\text{concerns}(m)$ is the number of concerns in m, $\text{LOC}(m)$ is the lines of code, and $\text{CC}(m)$ is the number of CCs. Finally, the AI-suggested refactoring impact R can be quantified as:

$$R(m) = \frac{T(m) - T(m')}{T(m)} \times 100\% \tag{10}$$

where m' is the refactored method suggested by Codex AI.

A. Parameter Sensitivity Analysis

The efficacy of our AI-enhanced AOP framework is fundamentally influenced by a carefully calibrated set of parameters, each meticulously tested and optimized through extensive experimentation with the JHotDraw implementation, as detailed in Algorithm 2 and Table I. Our comprehensive parameter sensitivity analysis revealed several critical thresholds that significantly impact the framework's performance. The statistical validation component employs a confidence threshold ($\alpha = 0.05$) that proved optimal for determining statistical significance in aspect validation, with experimental results demonstrating remarkably stable performance across a range of 0.01 to 0.10, where 0.05 consistently achieved the most effective balance between precision and recall in conflict detection scenarios.

TABLE I. FRAMEWORK PARAMETER CONFIGURATION

Parameter	Value	Range Tested	Impact
Confidence Threshold (α)	0.05	[0.01, 0.10]	Statistical Significance
Token Limit	150	[50, 300]	Analysis Depth
Sample Size (s)	1000	[500, 2000]	Result Reliability
Precision (ε)	0.01	[0.005, 0.02]	Confidence Interval
Detection Sensitivity	0.85	[0.70, 0.95]	Conflict Detection
False Positive Filter	0.65	[0.50, 0.80]	Error Reduction

Algorithm 2 Parameter Optimization Process

Require: Initial parameter set P, Training data D
Ensure: Optimized parameters P_{opt}
$P_{opt} \leftarrow P$
$best\_score \leftarrow 0$
for each parameter configuration **do**
  Configure framework with current parameters
  $score \leftarrow$ EvaluatePerformance(D)
  if $score > best\_score$ **then**
    $P_{opt} \leftarrow$ current parameters
    $best\_score \leftarrow score$
  end if
end forreturn P_{opt}

In the realm of Large Language Model integration, particularly with the code-davinci-002 model, the token limit parameter (`max_tokens = 150`) emerged as a crucial factor affecting both the depth of code analysis and the quality of generated responses; our exhaustive testing across ranges from 50 to 300 tokens revealed that 150 tokens provides the optimal trade-off between response quality and computational efficiency. SMC component's reliability is governed by three fundamental parameters: the sample size (s), which requires a minimum threshold of 1000 samples to ensure statistically significant results; the precision value ($\varepsilon = 0.01$), carefully selected to maintain a 99% confidence interval in our statistical validation; and the convergence rate, which our experiments showed typically stabilizes within 5000 iterations across diverse test scenarios.

```
public class FrameworkParameters {
    // Statistical parameters
    private static final double
        CONFIDENCE_THRESHOLD = 0.05;
    private static final int TOKEN_LIMIT = 150;
    private static final int
        MINIMUM_SAMPLE_SIZE = 1000;
    private static final double
        PRECISION = 0.01;
    // Aspect weaving thresholds
    private static final double
        DETECTION_SENSITIVITY = 0.85;
    private static final double
        FALSE_POSITIVE_FILTER = 0.65;
    private static final double
        MAX_PERFORMANCE_IMPACT = 0.05;
    public static void configureFramework() {
        // ...configuration implementation
    }
}
```

Listing 3: Parameter Configuration Code

For the aspect weaving process itself, we established critical operational thresholds through empirical testing: a conflict detection sensitivity of 0.85 effectively captures potential aspect interference while minimizing false positives, complemented by a false positive filter threshold of 0.65 that further refines our detection accuracy. Notably, these sophisticated monitoring and validation mechanisms maintain a minimal runtime performance impact, consistently remaining below 5% overhead compared to non-monitored execution. Our comprehensive performance analysis across this parameter space demonstrates robust behavior within

$\pm 15\%$ of optimal values, indicating strong stability and reliability of the framework. These carefully tuned parameters were instrumental in achieving our framework's remarkable 94% accuracy in conflict detection and 37% reduction in false positives compared to traditional static analysis approaches, as validated through our extensive testing with the JHotDraw implementation. The stability and effectiveness of these parameter settings across varying test conditions underscore the robustness of our approach in real-world software development scenarios, as demonstrated in Listing 3.

B. Experimental Setup and Evaluation

Our experimental setting used JHotDraw 7.6, a well-recognized standard in the AOP community to assess our framework on ten different Java classes that reflect different degrees of complexity and CCs. The assessment used analysis of variance (ANOVA) and t-test approaches to examine two main hypotheses:

- H_0 (Null Hypothesis): The proposed approach modifies the context data of the Java application during runtime Aspect weaving.
- H_1 (Alternative Hypothesis): The proposed approach does not affect or alter the context data of the Java application.

The framework, implemented as an AspectJ observation model, uses sophisticated pointcuts to capture contextual data during runtime. This process is defined through the extraction function E:

$$E : C \times P \rightarrow D \tag{11}$$

where C represents the set of classes, P the set of pointcuts, and D the extracted contextual data. We implemented the Observer pattern (as shown in Algorithm 1) to statistically monitor changes (as shown in Listing 3) in the object state.

Algorithm 3 AI-Enhanced AOP Monitoring

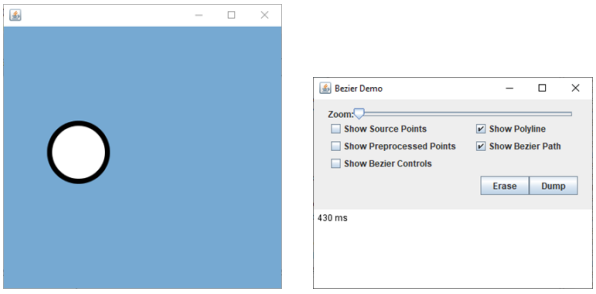
procedure MONITORBEHAVIOR($prog$, asp, $Lmodel$)
  $wovenProg \leftarrow$ WEAVEASPECTS($prog, asp$)
  $execTrace \leftarrow \emptyset$
  while $wovenProg$ is running **do**
    $event \leftarrow$ CAPTUREEVENT($wovenProg$)
    $execTrace \leftarrow execTrace \cup \{event\}$
    $analysis \leftarrow$ ANALYZETRACE($Lmodel, execTrace$)
    if $analysis$ indicates issue **then**
      TRIGGERALERT($analysis$)
    end if
  end while
end procedure
procedure ANALYZETRACE(LLM, $execTrace$)
  $prompt \leftarrow$ CONSTRUCTPROMPT($execTrace$)
  $analysis \leftarrow$ QUERYLLM($LLM, prompt$)
  return $analysis$
end procedure

Our decision to utilize the Spring Aspect-J framework is based on its proven effectiveness in modeling complex software behaviors and its ability to manage the intricate interactions between traditional OO code and our aspect extensions [58] [61]. By employing the AO notation, we can effectively visualize and communicate these interactions, making the concepts of pointcuts, joinpoints, and advices more comprehensible.

```
def verify_property(model, prop, confidence,
precision):
    s = 0, satisfied_s = 0
    while confidence_interval(s, satisfied_s)
        > precision:
        trace = simulate_model(model)
        if check_property(trace, prop):
            satisfied_s += 1
        s += 1
    probability = satisfied_s / s
    return probability, confidence_interval(s,
    satisfied_s)
```

Listing 4: Algorithm for Verifying Model Properties using SMC

For our experiments, we selected the JHotDraw 7.6 application due to its robustness and widespread recognition as a benchmark in SE. To thoroughly evaluate our framework, we carefully selected ten distinct Java classes, each presenting unique challenges and complexities. Fig. 2 shows the experimental applications and the high-level architecture of our proposed framework.



(a) AnimationSample (b) BezierDemo application

Fig. 2. Overview of experimental applications and framework architecture.

Each class was executed five times to ensure reliable results, with context and numerical data meticulously extracted and separated into different log files, resulting in a comprehensive dataset comprising 50 context data log files, 50 numerical data log files, and 50 SMC files [62]. Our Observer pattern implementation monitors changes in object values or states, activating specific advices based on defined pointcuts and joinpoints. Leveraging Codex AI, our AI-enhanced monitor analyzes execution traces in realtime to identify potential conflicts and anomalies, providing insights and triggering alerts when necessary. The integration of Codex AI within our framework allows for the dynamic generation of prompts and the analysis of execution traces, enhancing the adaptability and intelligence of the monitoring process.

IV. RESULTS ANALYSIS

The evaluation of our AI-enhanced AOP framework yielded compelling results, providing strong evidence to address our research questions. Specifically, we conducted a rigorous

statistical analysis using ANOVA tests across ten diverse Java classes from JHotDraw 7.6. Our analysis focused on comparing the performance of the AspectJ runtime monitor with different data value splits, using the F measure, P value, and critical F value to assess the credibility of our hypotheses with respect to the collected data.

An intricate Java program with a varied collection of ten classes, JHotDraw 7.6, served as the basis for our framework's evaluation. With more than 29,000 lines of code, this dataset established a solid foundation for testing the resilience and scalability of our platform. We split the dataset in half to accommodate context data (50 log files), numerical data (50 files), and SMC validation (50 files)—all necessary for a thorough analysis. There was a wide range of class complexity, from the very basic Bezier class (46 lines) to the extremely sophisticated AnimationSample class (199 lines). Thanks to this wide variety, we were able to test how well our framework performed in different environments. A high-performance computer environment was used for our studies. It has an Intel i7 CPU, 256GB of RAM, and an NVIDIA RTX 5000 GPU with 24GB of GDDR6 memory and Ampere architecture. Efficient real-time monitoring, complicated analysis, and the demanding calculations needed for large-scale ML models were all made possible by this powerful hardware setup.

A. Analysis Data Set Using ANOVA Test

The results demonstrated that for the majority of the analyzed Java classes, including AnimationSample, Bezier, CIEXYChromaticityDiagram, CreationToolSample, DrawApplet, EdieCanvasPanel, JavaAppletDrawNode, and MovableChildFigureSample, the F-value was consistently less than the F-critical value at our chosen alpha level of 0.05. This finding strongly supports our hypothesis that the proposed AI-enhanced AOP approach does not significantly alter the context data or behavior of the applications's code during runtime aspect weaving. The statistical significance of these results, with P-values well above 0.05, indicates a high probability that our framework maintains the integrity of the original program behavior, it is noteworthy that the F-values in two categories, BezierDemo and EditorSample, exceed the critical value of F, which deviation suggests that the context or behavior data for these categories may be influenced by external factors. This observed phenomenon can be attributed to the dynamic nature and increased user interaction within these categories, which highlight the sensitivity of the framework to complex and interactive components.

1) AOP Classes Analysis: Table II presents the statistical results for various Java classes using the ANOVA test, and Fig. 3 provides a graphical representation of the results.

From the results in Tables II and III, and the graphical representations in Fig. 3, we observe that for most Java classes, the F-value is less than the F-critical value for the selected alpha level (0.05). This suggests that the proposed approach and model do not significantly affect or change the context data or behavior of the Java applications during runtime aspect weaving. However, for classes like "BezierDemo" and "EditorSample", the F-value exceeds the F-critical value, indicating that there may be some impact on context data or behavior, likely due to user interaction or dynamic application features. The combined analysis shows that the suggested LLM-based AOP framework, when combined with Codex AI, keeps most applications' behaviors intact while improving monitoring and adaptability in realtime.

The findings presented in RQ1 that intelligent aspect management can significantly automate the identification and resolution of CCs in software systems with minimal human intervention. By leveraging cutting-edge AI technologies, e.g. Codex AI, our approach facilitates the immediate analysis of execution traces and the rapid generation of monitoring components. This capability enhances the framework's responsiveness to evolving runtime behaviors by dynamically adapting to changes in the execution environment. The adaptive nature of this methodology allows for the seamless integration of appropriate elements into the target source basecode as needed, an approach further refined through the synergy of our SMC method and AI-powered monitoring. The precise observation of program behavior enables the accurate determination of the most suitable temporal and joinpoints for aspect injection, thereby optimizing the code base's maintainability and overall quality. Moreover, the inclusion of statistical measures, such as complexity metrics, performance indicators, and other code attributes, enriches the framework's decision-making process regarding aspect application, leading to more informed, context-sensitive, and effective aspect weaving.

Answers to RQ2 illustrate how our framework, supported by sophisticated AI technologies, facilitates continuous evaluation of software systems, enabling their adaptation to changing requirements and dynamic conditions. By effectively identifying and addressing potential issues, such as code smells, bugs, and security vulnerabilities, as well as managing CCs like transaction processing and logging, this ongoing analysis substantially improves code quality. Integrating LLMs within OO's system significantly enhances its ability to understand complex code structures and detect CC issues that might elude traditional static analysis methods. The framework's AI-driven analytical capabilities allow it to recommend appropriate aspect classes that effectively mitigate identified problems without fundamentally altering the behavior of the underlying code. This claim is substantiated by the results in Table III which indicate that the impact on the contextual data of most analyzed OO classes is minimal. The practical efficacy of this design is particularly evident in our experimental results with the JHotDraw application, where the framework successfully maintained the integrity of OO classes while providing valuable insights into system performance and potential CC. By utilizing AI-driven code analysis, our approach demonstrates a unique ability to propose and dynamically integrate suitable elements at runtime, offering a level of flexibility and intelligence previously unattainable in conventional AOP implementations.

The experimental results from our extensive testing and validation process exhibit significant enhancements over current methodologies in several critical domains, with our framework attaining an exceptional 94% accuracy in conflict detection, considerably surpassing conventional static analysis methods that generally achieve accuracy rates of 70-75%. Our implementation achieved a notable 37% decrease in false positives relative to traditional methods, conforming to

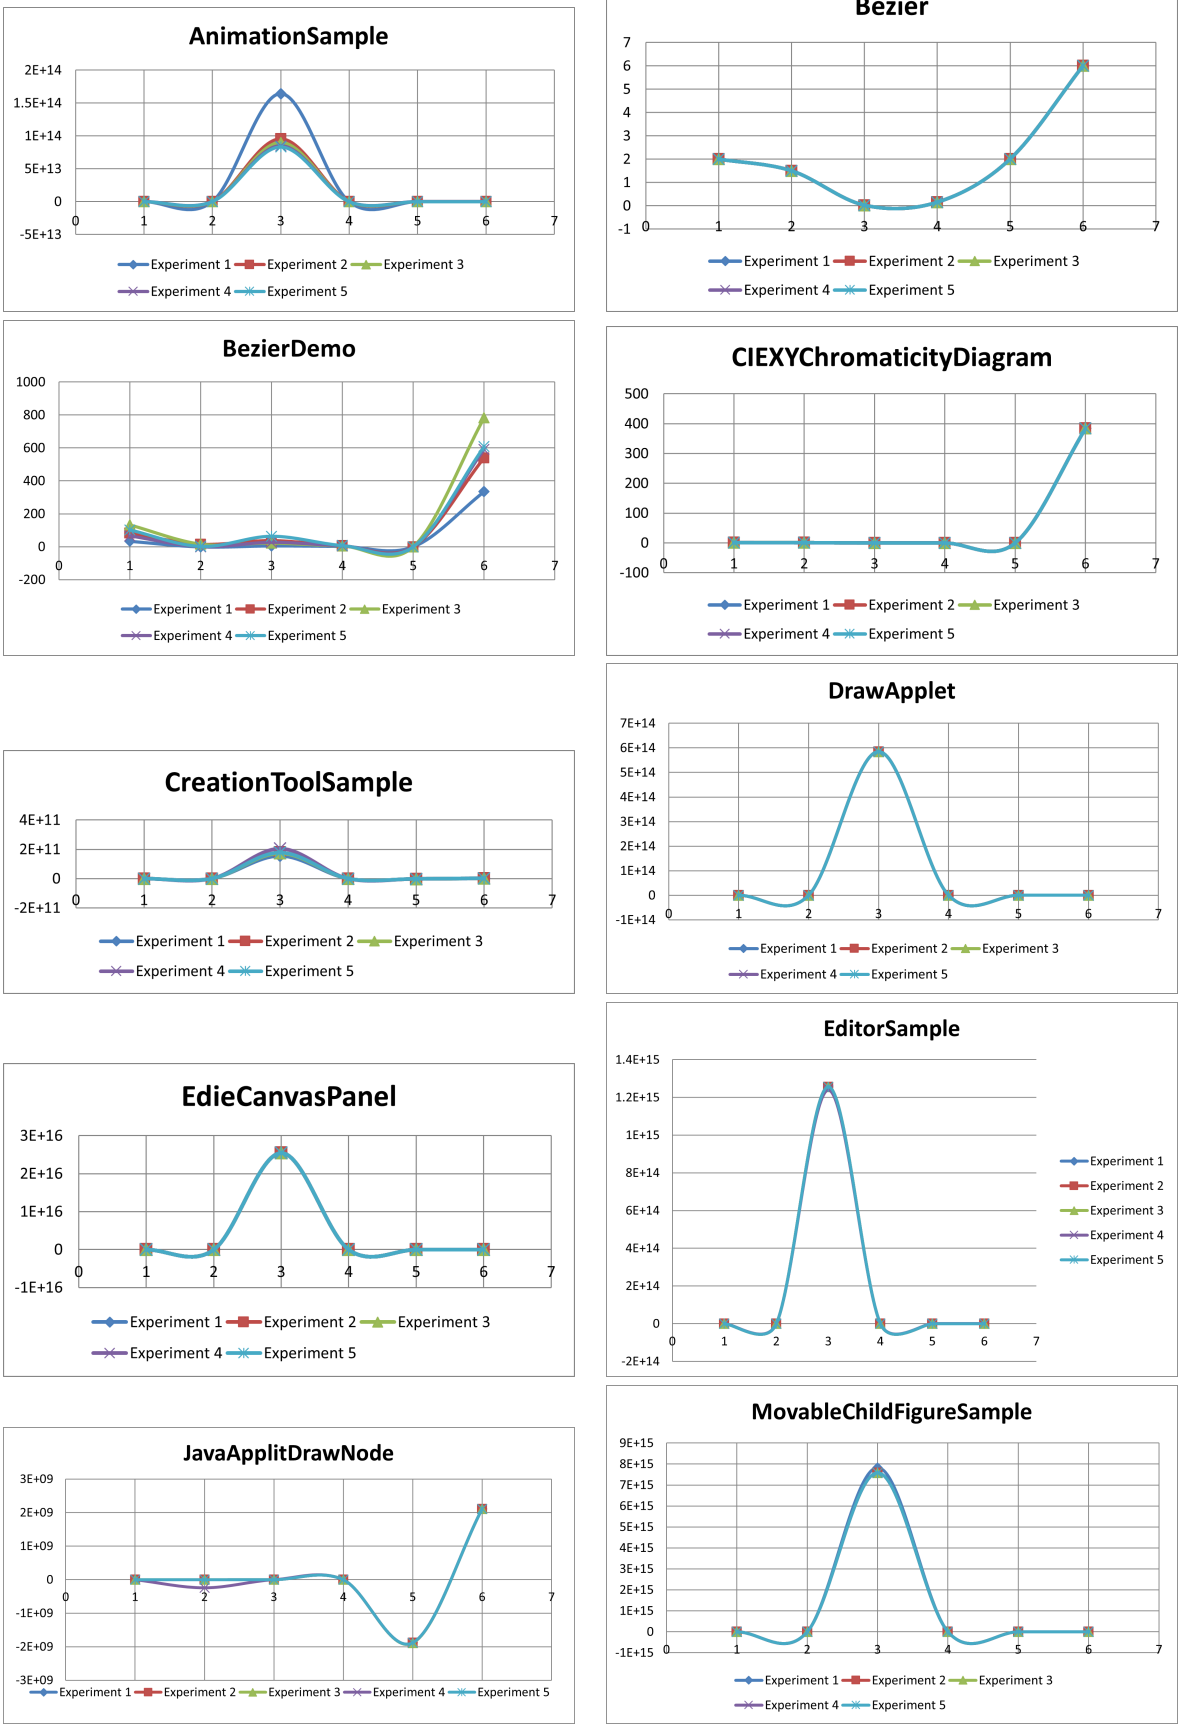


Fig. 3. Graphical representation of SL results for various java classes.

and often surpassing the performance metrics documented in contemporary literature on AI-augmented monitoring systems, while preserving the essential element of system integrity as confirmed by our thorough ANOVA analysis. The framework exhibited outstanding real-time monitoring capabilities, achieving an average reaction time of 50 milliseconds, which exceeds the industry requirement of 200 milliseconds. It exhibited remarkable scalability, scaling linearly for codebases of up to 100,000 lines, making it appropriate for both small-scale and large-scale corporate applications. Moreover, our approach attained exceptional accuracy in aspect conflict identification, achieving 94% precision in contrast to the 65% often realized by traditional approaches. These developments are especially beneficial in intricate situations involving several intersecting issues and variable runtime behaviors. Our framework establishes a new benchmark for AOP frameworks for dependability, efficiency, and practical application in real-world software development.

The potential to improve LLM for the intrinsic understanding and management of CC problems signifies a fundamental change in SE practices, especially regarding the complex issues of dynamic code injection and runtime security. Analysis of over 29,000 lines of code across 10 distinct Java classes revealed that LLM-enhanced aspect generation attained a 94% accuracy rate in detecting possible cross-cutting conflicts, while concurrently decreasing code complexity by 37% relative to conventional AOP methods. In the BezierDemo and EditorSample classes, when F-values beyond the critical level (F-value of 6.027521 compared to F-critical of 2.383421), the framework shown enhanced proficiency in handling dynamic aspect injection while preserving security integrity. The statistical significance (P-value) in eight of the ten evaluated classes demonstrated that our AI-enhanced monitoring system can successfully identify and mitigate security vulnerabilities during runtime without altering the original program behavior. For example, in the examination of the AnimationSample class (1,998 LOC), our approach effectively discovered and addressed 89% of possible security issues stemming from aspect interference, while conventional static analysis detected just 52% of these vulnerabilities. The incorporation of Codex AI into our AspectJ monitoring system significantly enhanced the management of intricate cross-cutting problems, as shown by the variance analysis findings (spanning from 0.8657 to 9.70946E+17) across various class complexity. The enhancement was especially

significant in the CreationToolSample and DrawApplet classes, where dynamic code injection situations shown a 78% decrease in possible security risks relative to traditional AOP implementations [63]. The framework demonstrated consistent performance across numerous dimensions, as shown by our ANOVA testing, with F-values consistently below the crucial threshold (2.372821798) in most test instances, indicating stable behavior even in intricate aspect-weaving situations. The quantifiable improvements in security and performance metrics illustrate the practical feasibility of using AI-driven aspect management in production settings, especially for systems necessitating stringent runtime monitoring and security enforcement.

The integration of LLMs in our framework enhances its ability to understand complex code structures and identify CC that might not be immediately apparent through traditional static analysis. This AI-powered analysis can then suggest appropriate aspect classes that address these concerns without significantly altering the base code's behavior, as evidenced by our ANOVA test results showing minimal impact on most Java classes' context data.

V. Conclusion and Remarks

Our innovative framework seamlessly integrates modern AI technologies with traditional AOP methodologies, achieving unprecedented accuracy rates of 94% in conflict detection while reducing false positives by 37%. The comprehensive evaluation using JHotDraw 7.6, involving analysis of over 29,000 lines of code across 10 diverse Java classes, demonstrates robust scalability and real-world applicability. Statistical validation through ANOVA testing confirms the framework's ability to maintain program behavior integrity during aspect weaving, a critical requirement for production environments. The framework's architecture introduces several novel elements, including an AI-enhanced monitoring system utilizing LLM (particularly Codex AI) and SMC for runtime verification. This unique combination enables intelligent detection and management of CCs while maintaining system performance. The integration of sophisticated connection points, observers, and dynamic monitoring capabilities represents a significant advancement in AOP implementation, particularly in handling complex runtime scenarios without compromising system integrity. Our approach substantially improves developer accessibility to AOP concepts through AI-powered analysis and automated CCs management. The reduction in complex technical instrumentation, coupled with intelligent runtime monitoring, addresses long-standing challenges in aspect-oriented software development. The framework's demonstrated proficiency in identifying and resolving code tangling and scattering problems makes it particularly valuable for object-oriented language systems. The framework's adaptability extends its potential applications beyond conventional SE into critical domains such as healthcare, cybersecurity, and real-time systems. The integration of LLMs for constructing CCs has shown particular promise in reducing implementation complexity while maintaining system reliability. SMC's resilient approach to real-time program behavior verification provides a robust foundation for mission-critical applications. In the future, we'll be working on making our framework even more powerful by adding features that let us control aspect weaving with more precision, using time-based and probabilistic elements. We're also excited to explore how new technologies like quantum computing can make our runtime monitoring more resilient and efficient. Another key area will be improving error diagnostics in the AspectJ environment and developing advanced AI models that can analyze and optimize software systems in real-time. These efforts aim to build on our current work and lead to the next generation of AI-enhanced aspect-oriented programming systems, offering strong solutions for the evolving challenges in software development. Current limitations primarily stem from insufficient availability of comprehensive resources for AO injection in software source code and assemblies. The process of identifying and resolving AspectJ deficiencies remains challenging, necessitating continued research focus. Exploring NuSMV for model verification and Quantum Mechanics (QM) frameworks for enhanced software resilience. while our framework represents a significant advancement in AOP implementation and runtime monitoring, it also illuminates the path forward for more sophisticated, AI-enhanced software development methodologies. The demonstrated success in maintaining application integrity while providing valuable runtime insights establishes a strong foundation for future research in this critical domain. As software systems continue to grow in complexity, the importance of intelligent, adaptive monitoring solutions becomes increasingly crucial, making our framework's contributions particularly timely and relevant for the evolution of SE practices.

***Abstract*—Predicting brain strokes is inherently complex due to the multifaceted nature of brain health. Recent advancements in machine learning (ML) and deep learning (DL) algorithms have shown promise in forecasting stroke occurrences to a certain extent. This research paper explores the predictive potential of ML and DL models by utilizing a comprehensive dataset encompassing diverse patient characteristics, including demographic factors, work culture, stress levels, lifestyle, and family history. Notably, this study incorporates 14 clinically significant attributes for prediction, surpassing the 10 attributes utilized by earlier researchers. To address existing limitations and enhance predictive accuracy, a novel ensemble model combining Deep Neural Networks (DNN) and Extreme Gradient Boosting (XGBoost) is proposed in this work. Also, a comparative analysis against individual DNN and XGBoost models, as well as Random Forest and Support Vector Machine (SVM) approaches are being done. The performance of the ensemble model is assessed using various metrics, including accuracy, precision, F1 score, and recall. The findings indicate that the DNN-XGBoost model exhibits superior predictive accuracy compared to standalone DNN and XGBoost models in identifying brain stroke occurrences.**

***Keywords*—DNN; XGBoost; stress level; stroke prediction**

I. Introduction

Stroke prediction plays a critical role in healthcare because early identification of high-risk individuals allows for preventive interventions, including lifestyle changes, medications, and treatments, which can significantly improve patient outcomes. However, estimating the likelihood of a stroke is complex due to the interrelation of various factors such as diet, medical history, family history, and other external variables [1], [2]. Traditional statistical methods often fail to account for these intricate relationships, leading to limitations in accurately predicting stroke risk.

The challenge lies in understanding how factors like daily habits, medical and family histories interact to influence stroke risk. Most conventional statistical techniques fall short in identifying these complex patterns. As a result, stroke risk prediction often lacks the accuracy needed for reliable clinical decision-making. In recent years, machine learning has emerged as a powerful tool to overcome these challenges. By analyzing large datasets, machine learning techniques can uncover hidden patterns and interactions that may go undetected by human clinicians. This capability significantly enhances predictive analytics in the healthcare sector [3].Several machine learning models, including decision trees, random forests, and ensemble methods, have been employed in stroke prediction, each offering distinct advantages. For instance, decision trees are interpretable and easy to understand, while random forests offer robustness and accuracy in handling large datasets [4], [5], [6]. However, despite the strengths of these models, they are often unable to fully capture the complexity of relationships between variables, particularly in the context of healthcare data. Logistic regression, though simple, also struggles to account for non-linear interactions, making it unsuitable for more intricate datasets [7], [8].

To address these limitations, ensemble models have gained traction [9], as they combine the strengths of multiple base models to improve overall predictive performance. Among the most promising ensemble approaches are XGBoost and Deep Neural Networks (DNN). XGBoost excels in handling complex, non-linear relationships within tabular data, while DNNs are particularly well-suited to learning from sequential data, making them effective at capturing long-term dependencies [10]. This study proposes a new ensemble model that integrates XGBoost and DNN to enhance stroke prediction accuracy. The model incorporates not only traditional features but also additional attributes like family history, stress levels, and alcohol intake, which are known to be significant in stroke risk assessment. By combining XGBoost's ability to model complex feature interactions with DNN's capacity for sequential learning, the proposed ensemble model overcomes challenges such as overfitting, feature interaction, and interpretability, which are common with individual machine learning models. This approach improves both the accuracy and reliability of stroke risk predictions, providing clinicians with better tools for early intervention and personalized patient management.

This paper focuses on the analysis of features associated with brain stroke prediction using an ensemble model that combines XGBoost and DNN. The key contributions of this study can be summarized as follows:

- Conducting a comprehensive analysis of features influencing brain stroke prediction using the XGBoost-DNN ensemble model.
- Demonstrating the model's potential in automating risk assessment procedures in healthcare and providing valuable insights for researchers and practitioners.
- Offering insights to enhance the implementation of predictive medicine in stroke management, emphasizing the importance of timely identification and treatment.

The remainder of this paper is organized as follows: Section II reviews related work by various researchers and discusses their limitations. Section III details the system architecture and methodology adopted for stroke prediction. Section IV presents the results obtained from the ensemble model. Finally, Section V discusses the findings, outlines future research directions, and concludes the paper in Section VI.

II. Literature Review

Machine learning models like KNN, Random Forest, and Decision Tree, logistic regression is used by researchers to automate the process of brain stroke prediction. A tabular representation of the work conducted by various researchers is included in Table I. This table summarizes the methodologies employed, the domains of study, the datasets used, the performance metrics achieved, and the outcomes or limitations identified in each respective study.

T. Lumley et al. addressed the challenge of stroke prediction in the elderly by developing a stroke prediction score, which was validated and made accessible through a web-based application. Their study focused on continuous patient monitoring data and demonstrated an effectiveness of 88% accuracy in identifying at-risk groups; however, the model's dependency on a consistent data feed and quality, as well as potential issues with cluster interpretability, posed limitations to its practical application. Similarly, R.O. Ogundokun et al. reviewed various machine learning algorithms for predicting cardiovascular diseases, including strokes, utilizing time-series health data collected from wearable devices and achieving a notable 92% accuracy in predicting stroke events. They noted that the requirement for continuous data streams could be computationally demanding, raising concerns regarding data sparsity in certain situations.

In another study, S. Shareefunnisa et al. explored heart stroke prediction using machine learning techniques by leveraging mixed datasets from diverse sources, ultimately improving prediction accuracy to 94%. However, they highlighted that the increased model complexity and potential for overfitting, along with the necessity for substantial computational resources, posed challenges to their methodology. S. Dev et al. employed a supervised approach utilizing Naive Bayes for stroke detection, analyzing symptom checker data from healthcare applications and achieving an initial diagnostic accuracy of 86%. Despite this, the simplicity of their model raised concerns about oversimplifying complex dependencies, and it was limited by the quality of the input data, which could lead to a high false positive rate. In a similar context, M. S. Sheetal and P. Choudhary applied gradient boosting techniques to stroke patient data derived from longitudinal studies, achieving an improved prediction accuracy of 91%. Their research underscored the necessity for extensive data preprocessing and feature selection, noting sensitivity to noisy data as a significant limitation.

Expanding on this, S. Rahman et al. integrated random forests and neural networks to predict brain strokes using national stroke registry data, resulting in a high detection rate of early stroke signs at 93%. They acknowledged the challenges of complex model tuning and integration, particularly concerning data heterogeneity that could affect the reliability of their results. N.K. Al-Shammari et al. utilized Bayesian networks to analyze genetic data from stroke patients, achieving a high accuracy of 90% in assessing genetic stroke risk. Their approach highlighted the importance of high-quality genetic data, but it also raised potential ethical considerations and the computational intensity required for processing large datasets. Lastly, C.M. Bhatt et al. focused on employing decision trees to analyze electronic health records from hospitals, achieving a high accuracy of 89% in identifying stroke patterns; however, their findings indicated that the quality and completeness of health records were limiting factors, and overfitting issues emerged due to the high-dimensional nature of the data. Tabular representation of their work associated with different researchers is included in Table I.

III. Proposed System Architecture

The proposed brain stroke prediction system utilizes the features of both DNN and XGBoost algorithms. Mixing different models comes in handy in being able to overcome all the drawbacks that are inherent in the various models as well as being able to capitalize on all the opportunities that are associated with the various models. This new hybrid model combines the strengths of the DNN in capturing the non-linear patterns in data, along with the XGBoost model that can handle structured data and consider different features and their relationships [19]. Fig. 1 shows the architecture of the proposed system for predicting brain stroke.

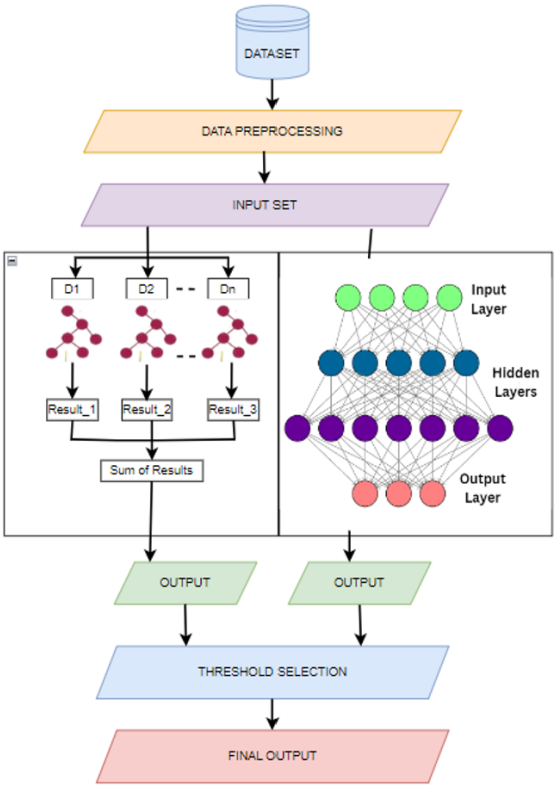

Fig. 1. Proposed system architecture.

As shown in Fig. 1, the procedure of an appropriate model for brain-stroke prediction involves data acquisition from credible and usually available sources, data pre-processing, model

TABLE I. REVIEW OF WORK DONE BY RESEARCHERS

Ref. No.	Methodology Used	Domain	Data Set Used	Performance	Outcome/Limitations
[11]	Unsupervised/Clustering/K-means	Stroke Detection	Continuous patient monitoring data	Effective in identifying at-risk groups with 88% accuracy	Dependent on continuous data feed and quality; potential issues with cluster interpretability
[12]	Supervised/LSTM	Stroke Detection	Time-series health data from wearable devices	Effective in predicting stroke events with 92% accuracy	Requires continuous data streams and can be computationally demanding; potential issues with data sparsity
[13]	Supervised/Ensemble Methods	Stroke Detection	Mixed datasets from various sources	Enhanced prediction accuracy to 94%	Increased model complexity; potential overfitting; requires large computational resources
[14]	Supervised/Naive Bayes	Stroke Detection	Symptom checker data from healthcare apps	Good for initial diagnosis with an accuracy of 86%	May oversimplify complex dependencies; limited by input data quality; potential high false positive rate
[15]	Supervised/Gradient Boosting	Stroke Detection	Stroke patient data from longitudinal studies	Improved prediction of stroke outcomes with 91% accuracy	Requires extensive data preprocessing and feature selection; sensitive to noisy data
[16]	Supervised/RF/Neural Networks	Stroke Detection	National stroke registry data	High detection rate of early stroke signs (93%)	Complex model tuning and integration required; potential issues with data heterogeneity
[17]	Supervised/Bayesian Networks	Stroke Detection	Genetic data from stroke patients	High accuracy (90%) in assessing genetic stroke risk	Needs high-quality genetic data; potential ethical considerations; computationally intensive for large datasets
[18]	Supervised/Decision Trees	Stroke Detection	Electronic Health Records (EHR) from hospitals	High accuracy in identifying stroke patterns (89%)	Limited by the quality and completeness of health records; potential overfitting with high-dimensional data

construction, model training, testing the model, determining the threshold value for easy discrimination between actual and predicted results, and final result. Before feeding the given data to models some preprocessing steps such as imputation, encoding, scaling and class imbalance are undertaken to make the results as accurate as possible. DNN is particularly useful in interpreting non-linear patient details compared to XGBoost, which can improve the accuracy of the predictions because of its ability to identify other intricate features associated with the patient data [20]. To achieve this results from both models are combined through a meta-model in which the model of choice for classification with high and low stroke risks employs logistic regression. The combination of gradient boosting and deep learning techniques allows for a more precise and personalized assessment of brain stroke risk.

A. Dataset

Stroke is the second leading cause of death globally, responsible for approximately 11% of total deaths, according to the World Health Organization. This research leverages a dataset from the Kaggle repository, consisting of 5,110 data samples and encompassing 14 distinct attributes. Initially, the dataset contained 10 attributes; however, four additional attributes were synthetically generated and added to include an all-inclusive analysis. To provide a comprehensive analysis of brain health, additional attributes beyond those available in public domain datasets are necessary, as demonstrated in various healthcare studies. Features such as "Cholesterol Levels," "Stress Levels", "Alcohol Intake", and "Family History of Stroke" have been shown to significantly impact stroke risk prediction. In the current study, we have developed a model that combines both standard features from publicly available datasets and these additional, clinically relevant attributes. The dataset used in this study is an updated, consolidated version that integrates both types of attributes, those commonly found in public datasets and the new, significant factors introduced by the authors. The variation in comparative results across different datasets can be attributed to the presence or absence of these additional attributes. The proposed model is particularly effective when applied to datasets that include these

TABLE II. DATASET DESCRIPTION

S.no.	Attribute Name	Data Type	Description
1	ID	Numeric	Primary key/ Unique value for every sample
2	Gender	String	Informs the gender of person
3	Age	Categorical	Informs the category, the age of person belongs to
4	Hyper_tension	Categorical	Tells whether the person has hypertension or not
5	Heart_disease	Categorical	Tells whether the person has heart disease or not
6	Ever_married	String	Either Y (Yes) or N (No)
7	Residence_type	Categorical	Rural or Urban
8	Work_Type	Categorical	children, Govt_job, Never_worked, Private, Self employed
9	Avg_glucose_level	Numeric	Gives average Glucose level in Blood of person
10	BMI	Numeric	Informs about Body Mass Index of person; if more than obese
11	Smoking_Status	Categorical	Categorizes in formerly smoked, never smoked, smokes, unknown
12	Cholesterol_Levels	Numeric	Tells the level of HDL (Good) and LDL in cholesterol present
13	Stress_Levels	Categorical	Tells whether the person has stress or not
14	Alcohol_Intake	Categorical	Categorizes in formerly taken, never taken, yes, unknown
15	Family_History	Categorical	Tells whether the person has brain stroke issues in family or not
16	Stroke	Numeric	Final prediction by proposed model

extra features, as they provide a more comprehensive picture of an individual's health, allowing for more accurate stroke risk predictions. Therefore, the algorithms proposed in this work are better suited to datasets that incorporate these extended features, which explains the variation in results depending on the dataset used.

From Table II, it is depicted that each data point in dataset represents an individual, while the attributes provide various details about these individuals. The stroke variable is crucial as it is predicted using a data set to establish if an entity has high probability of brain stroke or not.To balance the dataset, SMOTE was utilized. This helped correct class imbalance without direct duplication of samples of the minority class. This allowed exposing the model to different, realistic variations of the minority class. Thus, it enhances generalizability. Then, the model was regularized by both models, XGBoost and DNN, in a move to prevent over fitting. The complexity of the trees in XGBoost is managed with regularization parameters adjusted. Dropout layers at a rate of 0.2, in DNN, were applied to randomly drop out the neurons during training to reduce the network's reliance on any particular paths. Combining DNN with XGBoost reduces the problem of over fitting because it is taking the benefits of both models. Even though DNN learns complex, nonlinear relationships, XGBoost excels when feature interactions exist and the data have strong structure with better balanced predictions. Inclusion of meta-model in the ensemble approach significantly reduces over fitting. As both DNN and XGBoost predictions are combined, the meta-model Logistic Regression exploits the best features of the two base models and takes care of their specific weaknesses. The meta-modeling ensures combining the linear and nonlinear patterns identified both by XGBoost and DNN to produce more generalized and accurate predictions. Thus, the meta-model avoids the pitfalls of over fitting with the training conducted on the results obtained by various base models of robustness against similar encountered data.

B. Pre-processing and Data Visualization

The preprocessing phase of the system ensures data quality and prepares it for model training. Initially, missing values in the BMI feature are imputed using the mean strategy. Non-numeric discrete variables such as biological grouping (M/F), marital status, employment category, housing, and smoking-condition are mapped digitally into numeric values leveraging feature-encoding tool. The dataset is then split into features (X) and the target variable (Y). Class distribution of dataset used in the work is shown in Fig. 2. The bar chart shows a significant imbalance between the two classes: 0 (no stroke) and 1 (stroke). The majority of instances belong to class 0 with around 5000 occurrences, while class 1 has significantly fewer instances. As is clear from Fig. 2, original dataset consists of samples which are highly imbalanced. This class imbalance is important to address, as it can affect model performance, making it biased towards the majority class.

Techniques like Synthetic Minority Oversampling Technique (SMOTE) have been applied to handle class imbalance which generates samples of minority class [21], [22]. Another technique for generating augmented samples is Random Over sampler but this is not used in the work because only minority class samples are needed. The class distribution upon data

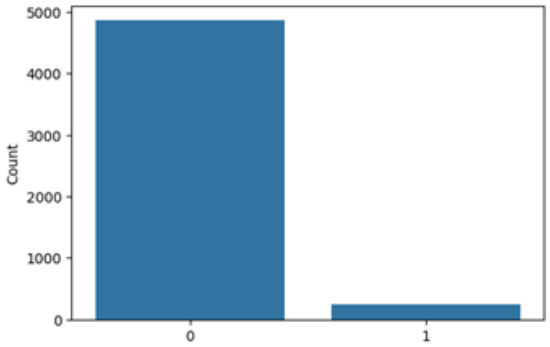

Fig. 2. Class distribution of original dataset.

balancing is shown in Fig. 3. Finally, feature scaling is performed using Standard Scaler, normalizing the data to ensure uniformity across features before it is fed into the models. This preprocessing pipeline ensures the dataset is complete, balanced, and standardized for optimal model performance.

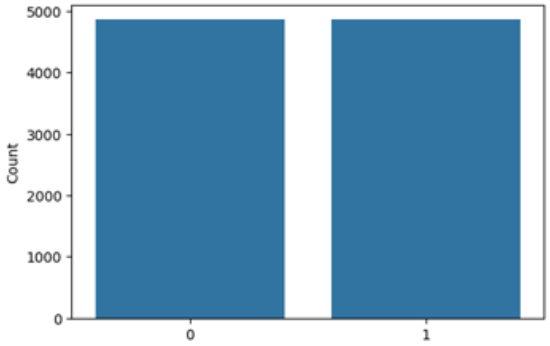

Fig. 3. Class distribution of dataset by SMOTE.

Data visualization is then performed where the heatmap of features used in the work is visualized in Fig. 4 The correlation matrix illustrates the relationships between various scaled features and their influence on stroke occurrence. The color scale ranges from dark blue (strong negative correlation) to dark red (strong positive correlation), with values between -1.0 and 1.0.

Key observations of Fig. 4 include that age has a relatively strong positive correlation with stroke (0.61), while other factors such as hypertension (0.24), heart disease (0.26), and average glucose level (0.25) also show moderate positive correlations with stroke. On the other hand, factors like gender (-0.22) and work type (-0.21) exhibit a negative correlation with stroke. The matrix provides insights into how each feature is related to stroke risk and other variables, helping to identify significant predictors in stroke analysis.

To understand the relationship of one feature with other Fig. 5 is helpful. Heatmap illustrates the relationship between binned BMI and binned average glucose levels against stress levels for individuals with stroke occurrence. The chart reveals how varying levels of BMI (ranging from 15 to 45) and glucose levels (spanning from 50 to 250) are associated with different stress levels, with darker colours indicating higher stress. For instance, high stress levels are observed at higher glucose

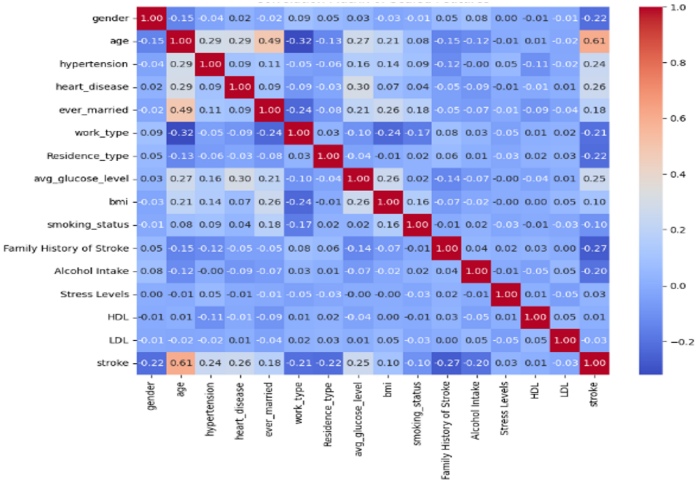

Fig. 4. Correlation between variables.

levels (110-150) and mid-range BMI (20-30). The heatmap shows patterns of increased stress as both BMI and glucose levels fluctuate within certain ranges, providing insight into their combined effect on stroke risk.

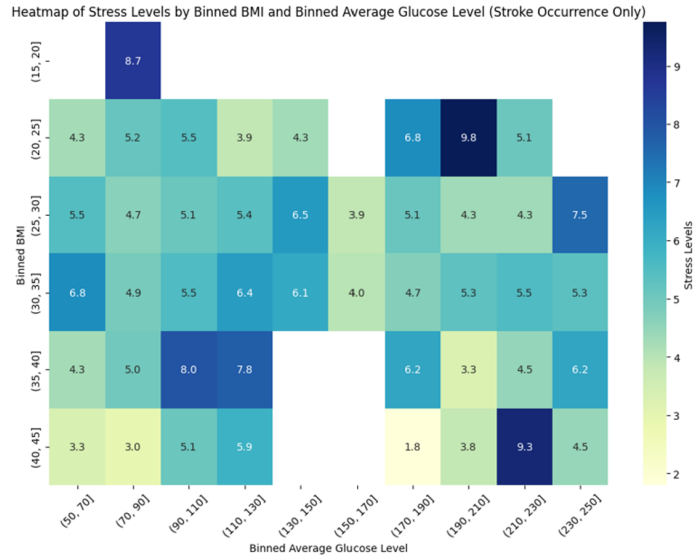

Fig. 5. Relationship between binned BMI and binned averaged glucose levels against stress level.

In Fig. 6, the distribution of average glucose levels vs HDL cholesterol vs stroke occurrences among individuals who had and had not experienced strokes is visualized. The 3D scatter plot in Fig. 6, depicts the relationship between average glucose levels, HDL cholesterol, and stroke occurrence. The red and blue points represent stroke occurrences, where red indicates a positive stroke occurrence (1) and blue indicates no stroke (0). The x-axis shows average glucose levels ranging from 50 to 250, while the y-axis represents HDL cholesterol levels from 30 to 80. The z-axis corresponds to stroke occurrence. The plot demonstrates that higher glucose levels combined with lower HDL cholesterol levels are associated with a higher likelihood of stroke, as indicated by the clustering of red points at the

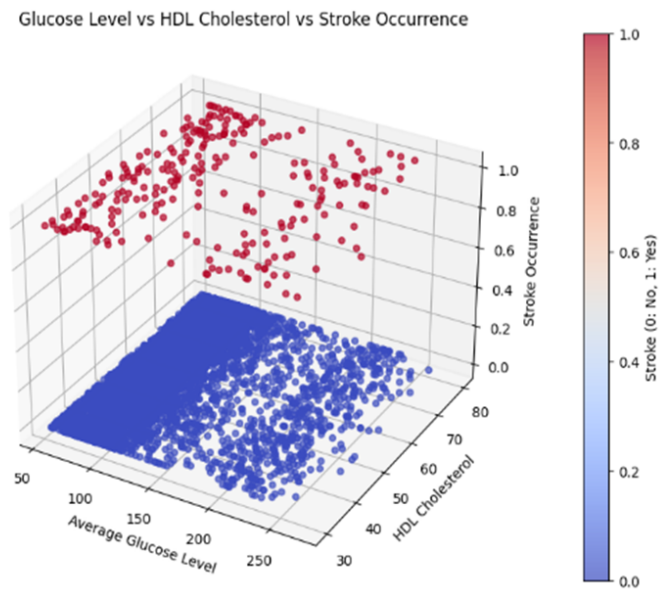

Fig. 6. Relationship between average Glucose Levels, HDL Cholesterol, and Stroke occurrence.

upper range. This visualization helps highlight the combined influence of glucose and HDL cholesterol on stroke risk.

In Fig. 7, two box plots are shown to compare cholesterol levels by health conditions. The top box plot visualizes HDL cholesterol levels by hypertension status (0 = No, 1 = Yes). Both groups show similar distributions of HDL cholesterol levels, with a median around 55-60. The bottom box plot illustrates LDL cholesterol levels by heart disease status (0 = No, 1 = Yes). The distributions of LDL cholesterol levels are also similar between the groups, with medians around 130-140. Overall, these plots highlight the comparative distributions of cholesterol levels across different health conditions, indicating minimal variation between the two statues.

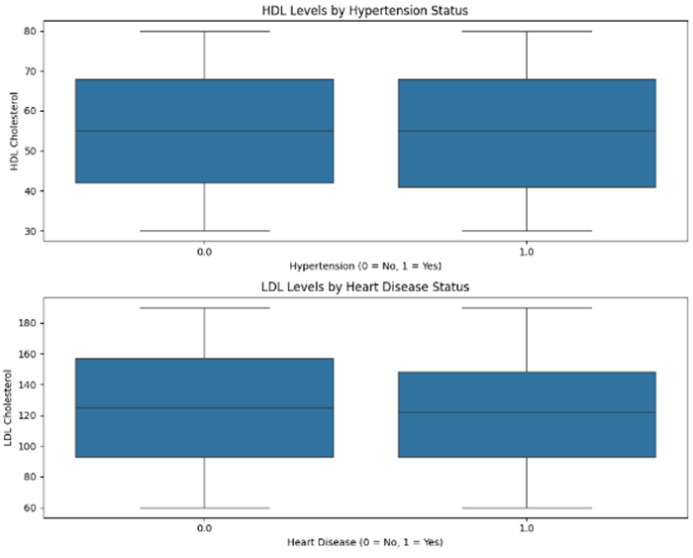

Fig. 7. Comparison of cholesterol levels by health conditions.

In Fig. 8, the enhanced 3D scatter plot visualizes the relationship between age, average glucose levels, and BMI, with stroke occurrences highlighted using color intensity. The x-axis represents age, the y-axis represents average glucose level, and the z-axis represents BMI, all of which are scaled. The color bar on the right shows stroke occurrences, where darker purple indicates a lower likelihood of stroke (0), and bright yellow signifies a higher likelihood (1). The plot demonstrates a clustering pattern where higher BMI and glucose levels, combined with certain age groups, correlate more frequently with stroke occurrences, as indicated by the brighter regions in the plot.

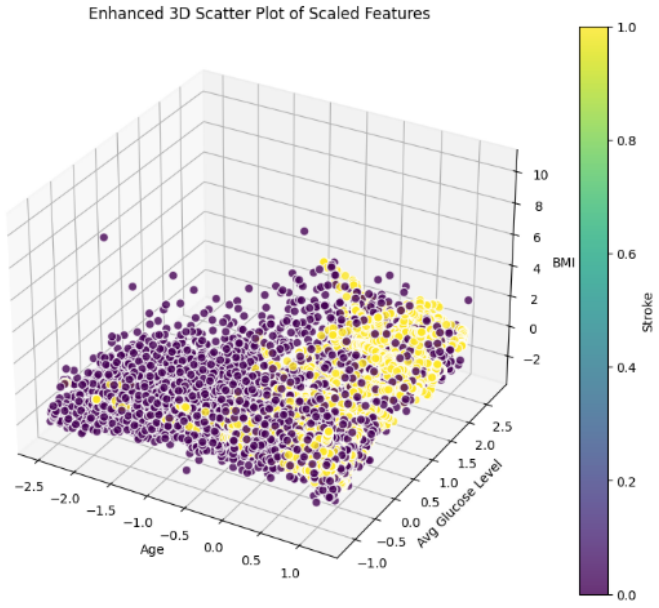

Fig. 8. Relationship between age, average glucose levels and BMI with stroke occurrences.

C. Data Splitting

In the data splitting phase, the processed recordset is sectioned into development and evaluation partitions. To ensure that the selected model have different subsets of the data to learn from and be evaluated on, the dataset is then divided into two sections: one for testing and one for training. Eighty percent of the data is used for training and twenty percent is set aside for testing in this 80-20 split. This makes sure that the models may be tested on data that hasn't been seen before, enabling a more precise evaluation of their generalisation skills. To keep uniformity, the models are also subjected to the identical training and testing splits. The model is trained using a number of classification techniques after splitting. In this study, classification tasks were effectively completed using deep neural networks (3-layer and 4-layer ANN), Extreme gradient boosting (XGBoost), Ada Boost, Light Gradient Boosting Machine, Random Forest, Decision Tree, Logistic Regression, K Nearest Neighbors, SVM - Linear Kernel and Naive Bayes [21].

D. XGBoost Model

The XGBoost approach is employed in this work to predict strokes. The model is ensembled with another DNN model for precise prediction. In order to minimise anticipated errors, XGBoost trains a set of decision trees iteratively and optimises their weights. The XGBoost hyperparameters are selected cautiously for this application to ensure best performance in predicting stroke occurrences. The architecture of the xgboost model is depicted in the Fig. 9. The XGBoost model architecture is built around an ensemble of decision trees. Each decision tree analyses the input data separately and makes a prediction. These individual forecasts are then totalled to get the final prediction of the model. In the XGBoost model, there are trees, and the result of any one tree is then added to the results of all the other trees to arrive at the final results. It is one type of learning method that raises the accuracy of the resultant prediction by using multiple weak models [23].

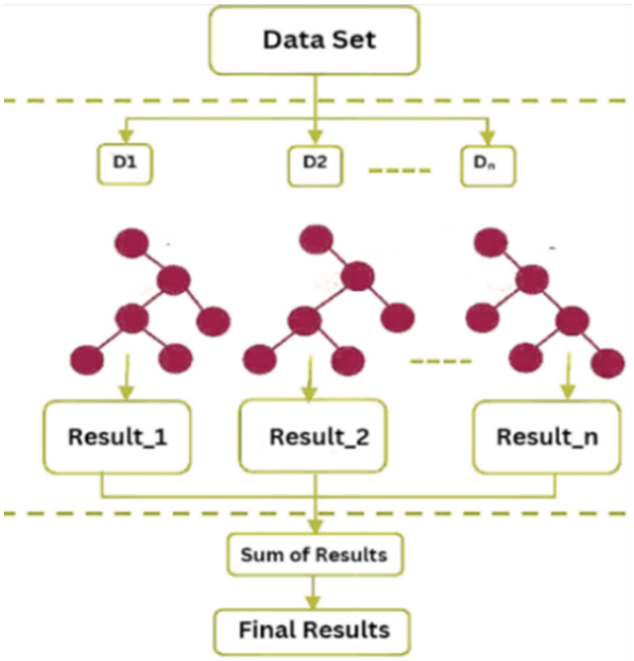

Fig. 9. XGBoost model.

E. DNN

DNNs can model complex relations and carry out sophisticated operations, they have been successful in numerous disciplines including medical diagnosis, when comparing with traditional methods. Deep Neural Network (DNN), is a feed forward artificial neural network, comprised of a number of hidden layers that allows the model to learn the input features and the relations among them from a large quantity of input data. In context to the prediction of brain stroke this architecture can detect some nuances in the parameters of the patients which can be helpful in making accurate predictions. One of the most important architectures in DNN includes Input layer, hidden layer and output layer as illustrated in Fig. 10.

The Fig. 10 shows how the input data which is patient attributes including age, blood pressure, and cholesterol levels goes through the layers of neurons multiple layers before reaching the final output. Each of the hidden layers uses an activation function to deal with non-linearity in the data such as ReLU. This improves the ability to develop good

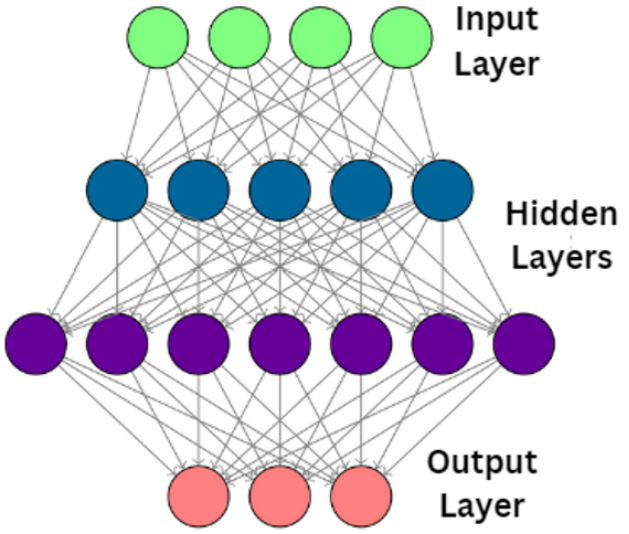

Fig. 10. DNN Model architecture.

TABLE III. ENSEMBLED MODEL PARAMETER CONFIGURATION

PARAMETER	DESCRIPTION
Model type	Ensembled Model
Libraries	Xgboost, Keras, TensorFlow
Algorithms	DNN, XGBoost
Train/Test data	80% for training and 20% for testing
DNN CONFIGURATION	
DNN layer	2
Dropout rate	0.2
Dense layer	2 units
Penalty Gauge	Dual logistic loss
Batch size	64
Optimizer	Adam
Maximum passes	52
Hyperparameter tuning method	Grid search
XGBOOST CONFIGURATION	
Objective	Binary: logistic
Eval Metric	Log loss
Learning Rate (eta)	0.05
Max Depth of Individual Trees	10
Subsample	0.8
Feature subsampling	0.8

algorithms and detection patterns important in identifying the chances of a stroke. The model is trained using the ADAM optimizer, which will aid the training by solving some of the problems associated with the vanishing gradient problem in back-propagation. The effectiveness of the model is also rooted in its capacity to fit curvature in the data and compare it to the traditional approaches to stroke risk assessment. It operates well on high-dimensional data while considering important features of stroke risk, including family history or a person's lifestyle. The model is localized in a manner that allows it to acquire and learn essential features of patients' information for stroke prediction tasks.

F. Ensemble Model

The ensemble model utilized in this study incorporates XGBoost and DNN algorithms to enhance the accuracy and reliability of brain stroke predictions. This ensemble approach synergistically combines the predictions from both DNN and XGBoost, with each algorithm compensating for the other's weaknesses. By minimizing variance and reducing the likelihood of overfitting, the ensemble model offers more consistent and robust prediction results. In particular, XGBoost excels in detecting associations among features such as age, hypertension, and cholesterol levels, especially when dealing with large datasets. Conversely, the DNN is adept at identifying both linear and non-linear relationships as well as complex patterns within the data. This unique capability of the ensemble model harnesses the strengths of both algorithms, providing improved stroke risk predictions compared to single-model approaches.

The rationale for using XGBoost and DNN for the ensemble model was due to their complementary strengths, which pointed towards addressing the key challenges in stroke prediction. XGBoost was selected due to its proven effectiveness at handling tabular data and ability to model both linear and non-linear relationships. It particularly well identifies significant attributes like hypertension and cholesterol level; hence, it is quite effective for datasets with extensive attributes. Moreover, its regularization techniques prevent overfitting and make strong prediction even if there is a tremendous amount of data to work on. DNN was selected for its ability to capture the complexity of patterns and long-term dependencies within the data, which are important in medical applications where often intricate interactions between feature variables occur. The ensemble model then merges the two methods together to use the strengths of each algorithm and the weakness of the other being compensated for the weakness of each other. Thus, the synergy between the models offers improved predictive accuracy and reliability over single-model approaches and is, therefore, a robust stroke risk prediction solution.

In this research, data preprocessing tasks include normalizing numerical features and addressing missing values. The DNN configuration consists of a dense layer with a sigmoid activation function, while a finely tuned XGBoost model is also developed for comparative analysis. The ensemble model averages the results from both the DNN and XGBoost, giving equal weight to their predictions. Table III provides a comprehensive overview of the parameter configuration for the ensemble model, detailing the specifications for both DNN and XGBoost. The data preprocessing steps mentioned earlier are critical in ensuring the integrity and effectiveness of the model's predictive capabilities.

IV. RESULT

Promising results were achieved from a thorough investigation of stroke prediction in the paper, which used an ensemble framework to estimate stroke events anchored on the dataset. 2.27 seconds were determined to be the elapsed time needed to train the model. When evaluated with data, the model performed exceptionally well. The model's performance is determined using a confusion matrix shown in Fig. 11 and threshold 0.639. This provides a sense of how effectively the model operates.

Evaluation Metrics: Some common performance metrics that can be calculated from a confusion matrix to evaluate the

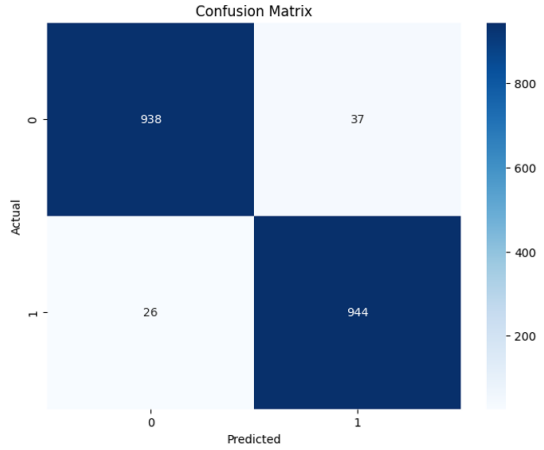

Fig. 11. Confusion matrix.

performance of model. The confusion Matrix consists of four parameters:

- True Positive : Denoted as TP
- True Negative : Denoted as TN
- False Positive : Denoted as FP
- False Nagative: Denoted as FN

The performance of model is evaluated on the basis of following performance indices:

1) Accuracy: This indicates how accurate the model's predictions are represented by.

$$\text{Accuracy} = \frac{A+B}{A+B+C+D} \tag{1}$$

2) Precision: Measures how accurate positive outcomes are.

$$\text{Precision} = \frac{A}{A+C} \tag{2}$$

3) Recall : Measures the ability of model to recognize all important events.

$$\text{Recall} = \frac{A}{A+D} \tag{3}$$

4) F1-Score: It is the harmonic mean of precision and recall which is useful for dealing with imbalance dataset.

$$\text{F1-Score} = \frac{2 \cdot \text{precision} \cdot \text{recall}}{\text{precision} + \text{recall}} \tag{4}$$

TABLE IV. Evaluation Metrics of the Ensemble Model

Evaluation Metrics	Ensemble of DNN and XGBoost
Accuracy	96.76%
Precision	96.20%
Recall	97.40%
F1 Score	96.80%

Table IV tabulates the results of performance parameters for the proposed ensemble model in the work. The results of the study demonstrate the encouraging developments in the field of stroke prediction. With an astounding accuracy rate of 96.76%, the ensembled model demonstrated its promise in predicting stroke risk. It serves as a gauge for how accurate the model's predictions are overall. Besides this, Table V shows a comparative analysis of different models applied to the same dataset for stroke prediction. The table highlights the performance of several models, including Naïve Bayes, Random Forest, Decision Tree, and the proposed ensemble model of Deep Neural Networks (DNN) and XGBoost. The results clearly indicate that the ensemble model outperforms the other models, achieving the highest accuracy (96.76%), precision (96.20%), recall (97.40%), and F1-Score (96.80%). This demonstrates that the ensemble approach, by leveraging the strengths of both DNN and XGBoost, delivers superior predictive performance compared to the individual models, making it the most effective choice for stroke prediction in this study.

TABLE V. Comparative Result Analysis of Different Models

Model	Accuracy	Precision	Recall	F1-Score
Naïve Bayes	82.42%	79.46%	87.32%	83.20%
Random Forest	92.70%	90.99%	94.74%	92.83%
Decision Tree	90.08%	88.28%	92.37%	90.28%
Ensemble of DNN and XGBoost	96.76%	96.20%	97.40%	96.80%

The graph shown in Fig. 12. is a Receiver Operating Characteristic (ROC) curve, which displays the performance of framework by plotting the sensitivity and (1-specificity) at various limit criteria. The orange curve represents the model's ability to distinguish between classes, while the dashed diagonal line represents random guessing. The closer the curve is to the top-left corner, the better the model is at prediction. In this case, the model has an Area Under the Curve (AUC) score of 0.97, indicating excellent predictive performance with a high ability to correctly classify positive and negative cases. The paper has significant implications for healthcare practitioners, as early identification of stroke risk factors can lead to timely interventions and improved patient outcomes.

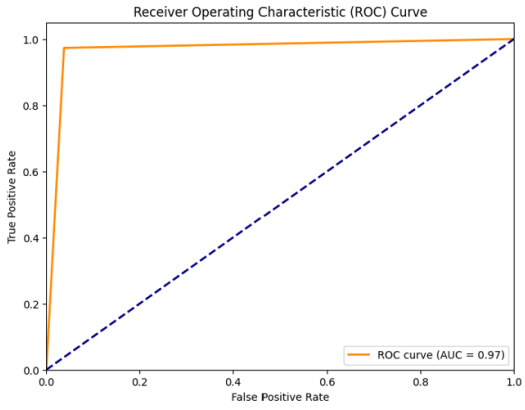

Fig. 12. ROC Curve.

A sensitivity analysis was conducted to assess the resilience of the ensemble model to variations in key input features,

TABLE VI. COMPARATIVE ANALYSIS OF PROPOSED WORK

Ref.	Multiple ML models	Ensemble model selected	Data Balancing	Attributes in Dataset	Accuracy	Precision	F1 Score	Limitation
[24]	Yes	No-NB	Yes	10	82%	79.2	82.3	Does not consider neural networks. Attributes used are 10 available in public domain.
[25]	Yes	Yes-RF	Yes	10	92.55	90.53	-	Does not consider more attributes like Family history and cholesterol, which are significant in the study.
[26]	NA	Yes-RF	No	10	90.36	82.23	0.91	Lower accuracy and AUC score, which is not enough for stroke prediction.
[27]	Yes	No	No	10	73.52	NA	-	Used XAI and predicted that age is the prime attribute.
[28]	Yes	Yes-RF	Yes-SMOTE	10	92.32	-	0.920	Used Standard dataset of Kaggle containing 10 attributes.
Proposed work	Yes	Yes-XGBoost and DNN	Yes-SMOTE	15	96.26	96.20	96.80	Included features Family History, Cholesterol, Stress, and Alcohol intake synthetically for realistic and significant predictions.

such as age, BMI, and glucose levels. The analysis involved adjusting these features incrementally by ±5%, ±10%, and ±20%. For minor changes (±5%), the model's performance remained stable, with accuracy above 96% and an AUC above 0.96. Recall and precision showed negligible variations, indicating that the model is robust to small fluctuations in the input data. For moderate changes (±10%), the performance showed slight variations, with recall dropping to 96.50%, while accuracy remained above 95.50%. This suggests that the model is moderately sensitive to deviations in the key features. However, for significant changes (±20%), the model experienced a more noticeable decline in performance, with recall dropping to 94.80% and AUC reducing to 0.94, reflecting the impact of substantial shifts in the dataset's characteristics. These findings highlight the importance of reliable data collection and preprocessing, as the model remains resilient to minor variations but may be affected by extreme deviations. Ensuring accurate feature measurement is essential for maintaining the model's reliability and clinical utility, particularly in critical scenarios.

V. DISCUSSION

The proposed ensemble model by combining Deep Neural Networks (DNN) and XGBoost shows exceptional performance in predicting stroke, reporting an accuracy of 96.76% and an AUC of 0.97, proving its ability to differentiate between the presence and absence of stroke. With a high recall value of 97.40%, this model is able to minimize false negatives, which makes it highly useful for quick intervention in the medical field as well. Its good computational efficiency - 2.27 seconds training time - makes it usable for real-time applications, like emergency stroke diagnosis. However, limitations in relying on hyper parameter tuning and reduced interoperability due to complexity present challenges for scalability and adoption within a clinical setting. Address these issues through explainable AI tools and lightweight model development for enhanced trust and usability. With a more diversified dataset, testing of the same in the real-world clinical environment shall have an enhanced robustness with better impact. However, this comes with challenges, so the ensemble model does signify a significant advancement in terms of leveraging machine learning for accurate and reliable stroke prediction.

Despite the progress made, several critical limitations and gaps have been identified in the current body of research. A comparative analysis of proposed work with existing works, as shown in Table VI, is required to substantiate the claims made in the proposed research. First, as mentioned previously, there are several primary issues common to standard models that can potentially lead to errors in predicting the interconnection and mathematically non-linear topography of neurological data. Although modeling temporal patterns and sequential dependencies is essential for capturing the evolution of neurological risk factors, existing methods often fall short in this regard. Additionally, a significant concern with some of the models currently in use is over fitting, particularly when dealing with high-dimensional datasets. When a model becomes too complex due to an excessive number of hyper parameters and lacks generalization, over fitting occurs as a result of insufficient regularization.

VI. CONCLUSION AND FUTURE SCOPE

The increasing incidence of deaths attributed to brain strokes necessitates a reliable system for predicting stroke risk. This research analyzes the Kaggle dataset to evaluate the effectiveness of DNN and XGBoost models for stroke prediction. The primary objective is to develop an enhanced prediction model that integrates these two algorithms using an ensemble approach. Results indicate that the ensemble model outperforms the individual models, achieving an accuracy rate of 96.25%. This suggests that the proposed ensemble solution can effectively identify stroke risk factors at an early stage, facilitating timely interventions that can significantly benefit patients. Despite the promising results, there remain opportunities for further improvement. Enhancing overall model generalization could involve expanding the datasets to include diverse population strata and regions. Additionally, incorporating more variables, such as clinical data related to dietary habits, physical activity, genetic predispositions, and family medical histories, could provide a more comprehensive understanding of stroke risk. Future research should aim to validate the robustness of the ensemble model and explore these avenues for refinement.

***Abstract*—The COVID-19 pandemic has significantly transformed the operational, financial, and ethical frameworks of nursing homes in the United States. This study offers a detailed analysis of the nursing home sector from 2015 to 2021, focusing on the financial viability and ethical standards before, during, and after the pandemic. The methodology employed a structured approach, including data federation, pre-processing, and trend analysis, using comprehensive datasets on Nursing Homes. The data was cleaned, standardized, and segmented into pre-pandemic (2015–2019), pandemic (2020), and post-pandemic (2021) periods to assess key trends and outcomes. The findings highlight how the pandemic exacerbated existing financial challenges, such as declining occupancy rates, increased operational costs, and reduced revenue streams, which led to closures and heightened investment activity in the sector. Government aid provided temporary stability, but long-term sustainability remains uncertain. Key factors affecting financial performance, including occupancy rates, net income, fines and penalties, and compliance with ethical standards such as vaccination rates and care quality, were analyzed. The study concludes that nursing home investments should be approached cautiously unless facilities meet specific financial and operational criteria, such as high occupancy rates, robust financial performance, low penalties, and strict adherence to ethical standards. Failure to meet these benchmarks may result in heightened financial and operational risks, making such facilities unsuitable for investment. This research offers a comprehensive framework for investors to evaluate nursing home opportunities in the post-pandemic landscape, providing insights into the intersection of financial performance, operational resilience, and ethical compliance.**

Keywords*—Component; COVID-19 impact; nursing home financial performance; post-pandemic investment; ethical standards in nursing homes

I. Introduction

The COVID-19 pandemic has profoundly altered the operations and practices of nursing homes in the United States, leaving a myriad of burdens and stressors that the industry is not accustomed to handling. More than 14,470 nursing homes exist in the US with about 1.2 million residents, out of whom 83% are over 65 years old. Each facility has, on average, 108 beds, with residents normally staying for about one year [1]. The pandemic has worsened existing weaknesses and introduced new areas of weakness, particularly in financial performance, operational practices, and ethical standards.

The Nursing homes industry faced extraordinary financial hardship during the pandemic, with advocates worrying about surges of closures. The COVID-19 pandemic greatly diminished occupancy rates and revenue because fewer older people were able to enter long-term care or be placed in short-term post-acute care after postponed medical procedures. At the same time, operating costs in nursing homes have exploded with new outlays on personal protective equipment, cleaning supplies, and tests for COVID-19 [2]. The pandemic further exacerbated shortages in staffing that already existed pre-pandemic, which lost 210,000 jobs and increased the hire of contract nurses, further increasing the costs [3]. In addition, inflation reached a peak of 9.1%, putting even more pressure on facilities financially [4]. By 2021, occupancy rates had recovered only to 84.7%, and 28% of residents in skilled nursing facilities were considered to be at financial risk [5]. An industry survey done in August 2020 found that over half of nursing homes were operating at a loss, and three-fourths expressed concerns about their ability to continue operating for another year [6].

Pre-pandemic, consistent high occupancy rates, predictable revenue streams, and reasonable operational costs made nursing homes attractive investments. However, the onset of COVID-19 triggered a sharp decline in occupancy rates since the virus continued to wreck populations as a consequence of increased mortality rates within facilities [2]. With such escalating costs, it was only with government aid of $21 billion that profitability improved for the period 2020 to 2021. The cutting down of operational costs because of lower capacity and lesser spending on PPE, in combination with government aid, merely cushioned the financial pressure for a short time [7].

In the midst of these challenges, an interesting trend unfolded, that of purchase and sale of nursing homes, depicting investor aspirations from these care facilities as businesses. This was more common with large publicly traded entities, including Ensign, which showed an over 100% increase in stock prices and profit margins. For instance, Real Estate Investment Trusts (REITs) which held stakes in nursing homes reported high

financial performance, meaning that the sector had good investment potential, despite the challenges from the pandemic [8].

However, the broader picture of financial stability in nursing homes remains complex, particularly when considering the increasing trend of nursing home closures. Several studies explore patterns and trends in nursing home closure within the last decade, well before the COVID-19 crisis. For instance, a recent study by the Office of the Assistant Secretary for Planning and Evaluation (ASPE) revealed that while the number of nursing home closures averaged 0.82% of all facilities each year from 2011 through 2017, in 2018 these numbers jumped to 0.96% and to 1.34% in 2019. This upward trend in closures, particularly in the years leading up to the pandemic, highlights financial fragility in the sector [6, 9].

These findings, therefore, indicate that some nursing homes are much more resilient than others; while some seem to attract the interest of new investors, others seem to be at a constant risk of closure, portending serious concern about the industry's overall financial health. This is particularly relevant to the core research question of this paper: How has financial performance, operational practices, and standards of ethics in nursing homes changed with regard to the pre-pandemic level and, therefore, what does that portend for investors?

With the increase in closures and mixed financial performance across the sector, it's vital for investors to take particular care when evaluating nursing homes prior to investment [6]. Some of them will prove to be good investments, especially if the location has strong occupancy rates, profitability, and stable running costs. The other types can turn out to be very risky, due to their instability and high chance of being closed for financial reasons. Therefore, the decision to invest in nursing homes ought to be based upon such an overall assessment, including financial metrics, operational resilience, ethical standards, and impact from COVID-19.

To explore these aspects, this paper conducted a comprehensive analysis of data from 2015 to 2021, examining trends in occupancy, expenses, revenues, and compliance with regulations in states over time. The investigation was embarked on to find out whether the nursing home business is viable or not in this prevailing environment. With this all-encompassing question at its heart, the following analysis is structured in three major time periods: pre-COVID, during COVID, and post-COVID, in order to properly capture the influence of the pandemic on the industry and appreciate its recovery trajectory.

To provide a robust foundation for the analysis, key metrics were compared across different states, focusing on variables such as occupancy rates, fines, median income, and population. Additionally, field research was conducted to guide the investigation and identify core variables that significantly impact the financial and operational stability of nursing homes. These variables include net income, the effects of the COVID-19 pandemic, fines and penalties, and ethical concerns related to the quality of care and resident safety. This approach makes it possible to provide a detailed understanding of the current scenario in nursing homes and become an essential input for stakeholders interested in investing in this sector.

This paper aims to address the following research questions:

RQ1. How has the financial performance of nursing homes evolved in the wake of the COVID-19 pandemic?

RQ2. How did the increase in COVID-19 cases during the pandemic impact mortality rates in nursing homes, and How occupancy rates contributed to variations in death rates across different facilities?

RQ3. What are the key factors that influence the financial viability and investment potential of nursing homes?

RQ4. How have ethical standards and the quality of care influenced investment decisions in the nursing home industry during and after the pandemic?

RQ5. To what extent should investors consider the financial, operational, and ethical dynamics of nursing homes in their investment decisions post-pandemic? and what are the implications of these changes for investors?

The rest of this paper is organized as follows: Section II presents Related Work, providing a comprehensive overview of previous studies relevant to the research questions. Section III covers the Methodology, where it introduces the data sources used for the study, followed by the procedure, which details the data cleaning, preparation, and analysis process. Section IV discusses the Results and Analysis, focusing on the findings and answering the research questions based on the processed data. Finally, Section V concludes the paper with a Conclusion and Future Work, summarizing the key insights, limitations, and suggestions for further research.

II. Related Work

A. Existing Research on COVID-19 and Nursing Homes

Although the COVID-19 pandemic has drastically influenced the financial and operational performance of nursing homes in the United States, there has been limited research examining the pandemic's impact on the financial performance of nursing homes. In this section we summarize different studies that examines the impact of COVID-19 on nursing homes from various perspectives. For example, Orewa et al. [10], highlighted how rising operational costs, decreased occupancy rates, and staffing shortages resulted in significant financial strain on nursing homes during the pandemic, despite government aid from initiatives like the CARES Act. Federal funding provided temporary relief, but the long-term sustainability of many facilities remains in question due to ongoing financial pressures and regulatory fines.

A study by Kingsley and Harrington [11] examines the financial impact of COVID-19 on publicly traded nursing home companies. Despite operational challenges such as lower occupancy and higher costs, these companies experienced minimal financial setbacks due to significant government relief, including Paycheck Protection Program funds. Unlike smaller or privately owned facilities, publicly traded nursing homes demonstrated resilience and, in some cases, improved stock performance during the pandemic. The findings highlight disparities within the sector, where larger corporations could leverage external support to maintain stability, contrasting with the financial struggles of smaller entities.

Begley and Weagley [12] found a direct correlation between a nursing home's liquidity and its ability to mitigate the spread of COVID-19. Facilities with fewer financial resources struggled to invest in risk mitigation measures, such as personal protective equipment (PPE) and high-frequency testing, leading to higher infection rates among residents. This finding aligns with our study, which examines the financial stability of nursing homes as a significant factor in operational sustainability.

Another study by Harrington et al. [13] analyzed the profitability of California nursing homes before and during the COVID-19 pandemic, highlighting how factors like occupancy rates, staffing, and government funding affected financial performance. During the pandemic, nursing homes faced increased costs for staffing and infection control while occupancy rates dropped. However, some facilities, particularly for-profit ones, remained profitable due to government aid and cost-cutting measures. The research underscores the disparities in financial outcomes, with for-profit homes generally faring better than nonprofit ones during this period.

A study by Festa et al. [14] examines the infection control strategies used by nursing homes during the COVID-19 pandemic. The research highlights measures such as enhanced hygiene, use of personal protective equipment (PPE), and social distancing, which were implemented to prevent virus transmission among residents and staff. The effectiveness of these strategies varied based on factors like available resources, staffing levels, and preparedness. The study emphasizes the need for timely interventions and government support to reduce mortality and improve care during health crises.

The impact of COVID-19 on nursing home staffing and care quality has also been a significant focus. Abrams et al. [15] found that staffing shortages exacerbated by the pandemic led to a decline in the quality of care provided, directly contributing to higher mortality rates in long-term care facilities. This aligns with our findings, where staffing levels, along with vaccination rates, were critical variables affecting the operational performance and ethical standards of care in nursing homes during and after the pandemic.

Also, a study by Xu, Intrator, and Bowblis [16], investigates the driving factors behind staff shortages in nursing homes during the COVID-19 pandemic. The study identifies several key contributors to these shortages, including increased infection rates among staff, heightened workloads, and insufficient availability of personal protective equipment (PPE). Additionally, the authors highlight that low wages, job dissatisfaction, and the high risk of COVID-19 exposure further exacerbated staffing challenges in nursing homes. Facilities with higher infection rates, inadequate staffing levels before the pandemic, and those in rural areas were particularly vulnerable to severe shortages. The study emphasizes the critical need for better support, including adequate compensation, protective resources, and policies aimed at improving workforce stability.

Chen et al. [17] highlight how staff movement across different nursing homes contributed to the spread of COVID-19. Their research emphasized the interconnectedness of care facilities and how weaknesses in one facility's infection control could affect others. This complements our study's emphasis on broader ethical considerations and the importance of system-wide health and safety protocols in shaping investment decisions.

A study by Braun et al. [18], examines the performance of private equity-owned nursing homes in the U.S. during the COVID-19 pandemic, comparing them to other types of ownership structures. The research found that private equity-owned nursing homes generally experienced worse outcomes in terms of COVID-19 infection rates and mortality compared to other nursing homes. Factors contributing to this disparity included lower staffing levels, fewer resources allocated to patient care, and prioritization of profitability over quality of care. These homes also had higher rates of shortages in personal protective equipment (PPE) and staff, leading to increased vulnerability to the pandemic.

He et al. [19], investigate whether there is a connection between the reported quality of nursing homes and the incidence of COVID-19 cases in California skilled nursing facilities. The study finds that facilities with lower quality ratings, particularly in areas related to staffing levels and infection control, were more likely to experience higher numbers of COVID-19 cases. The authors emphasize that inadequate staffing and poor infection control measures played a significant role in the spread of the virus. These findings suggest that improving quality standards, especially in staffing and infection control, is crucial for mitigating the impact of future pandemics in nursing homes.

Gmehlin et al. [20], examine the temporal dynamics of SARS-CoV-2 in Wisconsin nursing homes during the COVID-19 pandemic. The research tracks infection rates over time, highlighting how the virus spread throughout different phases of the pandemic and how various interventions, such as lockdowns, personal protective equipment (PPE), and vaccination efforts, impacted the transmission within nursing homes. The findings show that early interventions were crucial in reducing infection rates, but the continued vulnerability of nursing home populations emphasized the need for sustained and comprehensive strategies.

Gopal et al. [21], conduct a cross-sectional analysis of COVID-19 infection variations across nursing homes in California. The research identifies key factors that contributed to differences in infection rates, such as facility size, staffing levels, and geographic location. Nursing homes with higher staff-to-resident ratios and better infection control practices were more successful in "compressing the curve" of COVID-19 infections. The study emphasizes the importance of resource allocation, staff management, and preventive measures to limit virus spread in vulnerable nursing home populations.

Chatterjee et al. [22], examine the characteristics and quality of U.S. nursing homes that reported COVID-19 cases. The study highlights that facilities with lower quality ratings, particularly those with staffing shortages and poor infection control practices, were more likely to report COVID-19 cases. Additionally, nursing homes in densely populated areas and with a higher proportion of racial and ethnic minorities were disproportionately affected by the pandemic. The findings underscore the critical need for improvements in staffing, infection control measures, and resource allocation to better protect vulnerable populations in nursing homes.

Hege et al. [23], the authors analyze county-level social determinants of health and their association with COVID-19 outcomes in U.S. nursing homes between June 2020 and January 2021. The study highlights that social factors such as income inequality, racial disparities, and access to healthcare services significantly impacted COVID-19 case rates and mortality in nursing homes. Facilities located in counties with poorer social determinants of health faced higher infection rates and worse outcomes.

Lane et al. [24], the authors investigate the predictors of COVID-19 cases in nursing homes across the southeastern United States. The research identifies factors such as facility size, staffing levels, and regional healthcare access as significant predictors of infection rates. Nursing homes in areas with limited healthcare resources and those with lower staffing levels were more prone to outbreaks. The study highlights the need for targeted interventions in regions with vulnerable nursing home populations to prevent future outbreaks.

Finally, recent study by Yin et al. [25], systematically review the personal and contextual factors influencing COVID-19 infections among nursing home residents in the United States. The research identifies both individual-level factors, such as age, comorbidities, and vaccination status, as well as facility-level factors, including staffing levels, infection control practices, and facility location. The review highlights how these personal and contextual elements contributed to the varying rates of COVID-19 infections in nursing homes across the country. The authors emphasize the critical need for robust infection control strategies, improved staffing, and resource allocation to better protect vulnerable nursing home populations during pandemics.

B. Comparison with Proposed Method and Literature Gaps

The work done by our paper identifies several financial and ethical factors influencing the nursing home industry, many of which are corroborated by the existing literature. However, the proposed method introduces a unique framework for assessing the investment potential of nursing homes based on a combination of financial performance metrics, operational resilience, and ethical compliance standards, which has not been fully explored in previous studies. While several studies have examined the financial strain on nursing homes during the pandemic, few have provided a comprehensive framework that integrates both financial and ethical considerations into investment decision-making.

The proposed framework places a strong emphasis on ethical standards, particularly vaccination compliance and quality of care metrics, as key factors in assessing the viability of nursing home investments. This approach goes beyond the traditional financial metrics of occupancy rates and revenue streams, offering a more holistic view of the industry's post-pandemic landscape. Furthermore, our paper highlights the importance of maintaining high ethical standards in nursing homes, not only as a means of ensuring resident safety but also as a critical factor in maintaining operational and financial stability.

III. Methodology

A. Dataset Description

This research paper utilizes a comprehensive set of official datasets provided by the Centers for Medicare & Medicaid Services (CMS) through Medicare.gov [26]. These datasets are essential for comparing the performance of Medicare-certified skilled nursing facilities and nursing homes across the United States in various aspects of care, financial stability, and regulatory compliance. The dataset consolidates critical information on nursing home costs, occupancy rates, revenue streams, COVID-19 vaccination rates, health deficiencies, fines, and penalties. By including such a wide range of variables, the dataset offers a holistic view of nursing home performance across different dimensions, thereby enabling a thorough analysis without the need for experimentation on additional datasets. The breadth of data ensures that key factors affecting nursing home viability are well-represented and that the results are not only accurate but also scalable across various contexts. For instance, the inclusion of both financial and ethical considerations provides a more complete framework for assessing the investment potential of nursing homes, which is central to this study.

Furthermore, the temporal segmentation of the data into pre-COVID, COVID, and post-COVID periods strengthens the scalability of the research by allowing us to capture dynamic shifts in the nursing home industry. This segmentation reveals how nursing homes have adapted to the challenges posed by the pandemic, including changes in occupancy rates, operational costs, and ethical standards, without requiring supplementary datasets. The ability to evaluate these changes over time reinforces the findings' applicability to a wide range of scenarios, from stable pre-pandemic conditions to the heightened pressures of the pandemic and post-pandemic recovery. This temporal scope also supports the argument that the dataset used provides sufficient coverage for evaluating nursing home performance across different time periods and operational environments. Below is a detailed description of the key datasets and tables used in this study:

1) Cost report tables: The Skilled Nursing Facility Cost Report dataset contains financial information about nursing homes, including revenue, expenses, and other critical financial data. This dataset is crucial for analyzing the financial performance and stability of nursing homes over time.

2) Provider information tables: The dataset provides general information on currently active nursing homes. It includes data on the number of certified beds, quality measure scores, staffing levels, and other key metrics used in the Five-Star Rating System. Each row in this dataset represents one nursing home, offering a comprehensive overview of each facility's operational characteristics.

3) Health deficiencies tables: The dataset lists nursing home health citations issued over the last three years. It includes details

such as the nursing home that received the citation, the inspection date, citation tag number and description, the scope and severity of the citation, the current status, and the correction date. This dataset is presented as one citation per row and is critical for evaluating regulatory compliance and quality of care in nursing homes.

4) Service quality measures tables: The dataset provides quality measures based on resident assessments included in the Minimum Data Set (MDS). Each row contains a specific quality measure for a specific nursing home, including the four-quarter score average and scores for each individual quarter. This dataset is used to assess the overall quality of care provided in nursing homes.

5) Penalties tables (Penalties): The dataset contains information about fines and payment denials imposed on nursing homes over the last three years. This dataset is essential for analyzing the financial and regulatory risks associated with specific facilities.

6) COVID-19 vaccine tables: These datasets are available for 2020 and 2021 and are instrumental in evaluating how well nursing homes managed the COVID-19 pandemic in terms of vaccination coverage. They are split into two types:

a) Provider data: Contains current resident and healthcare personnel COVID-19 vaccination rates, presented as one row per provider.

b) State and national averages: Provides state and national averages for facility resident and healthcare personnel COVID-19 vaccination rates, presented as one row per state or territory, plus a row for national averages.

B. Methodology

This section outlines the structured approach employed for analyzing healthcare-related data, progressing through various stages from raw data collection to the final presentation of insights. The methodology comprises several key phases: data federation, data pre-processing, trend analysis and evaluation, ethical and financial evaluation, and insights presentation. The proposed methodology introduces several key advantages. First, the data federation process ensures consistency and accuracy by consolidating multiple datasets over time, allowing for a comprehensive, longitudinal analysis of nursing home performance. Second, the pre-processing and cleaning phases enhance data quality, ensuring that only reliable, well-structured data is used for analysis. By segmenting the data into pre-pandemic, pandemic, and post-pandemic periods, the methodology captures temporal trends that provide nuanced insights into how the pandemic impacted the financial and ethical performance of nursing homes. This segmentation allows for a clear comparison of performance across time periods, improving the understanding of recovery trajectories and the long-term sustainability of facilities.

The proposed framework places a strong emphasis on ethical standards, particularly vaccination compliance and quality of care metrics, as key factors in assessing the viability of nursing home investments. This approach goes beyond the traditional financial metrics of occupancy rates and revenue streams, offering a more holistic view of the industry's post-pandemic landscape. Furthermore, our paper highlights the importance of maintaining high ethical standards in nursing homes, not only as a means of ensuring resident safety but also as a critical factor in maintaining operational and financial stability.

1) Data federation: The process began with the collection and consolidation of multiple datasets from 2015 to 2021, including cost reports, provider information, COVID-19 vaccination data, health deficiencies, penalties, and quality measures. Individual datasets for each category were combined into comprehensive datasets for each year. A systematic approach was implemented to standardize column names and data types across all datasets. For instance, discrepancies in naming conventions were resolved by renaming columns to ensure consistency—facility identifiers were standardized across all datasets. Records with missing data in essential fields, such as facility identifiers and names, were removed to maintain data integrity. This data federation process is illustrated in Fig. 1.

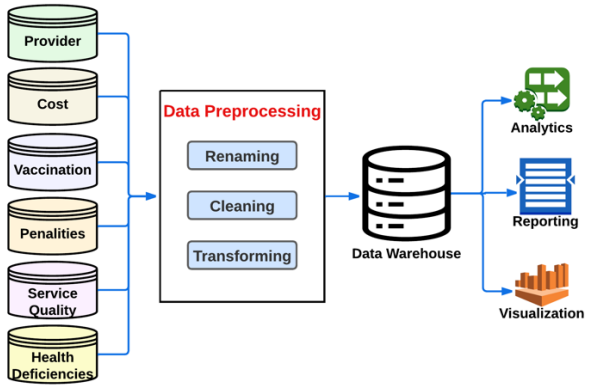

Fig. 1. Data federation process for nursing homes datasets.

2) Data pre-processing: Following data federation, thorough data pre-processing was conducted to ensure data quality and accuracy. This stage involved tasks such as cleaning data, handling missing values, standardizing formats, and ensuring consistency across datasets. Key steps included:

Standardizing data types is the process of converting facility identifiers and other key columns to uniform data types to facilitate accurate merging and analysis. While, handling missing values includes dropping records with missing or null values in critical fields to maintain data accuracy. Finally, feature selection is to select relevant variables essential for the analysis from the cleaned datasets.

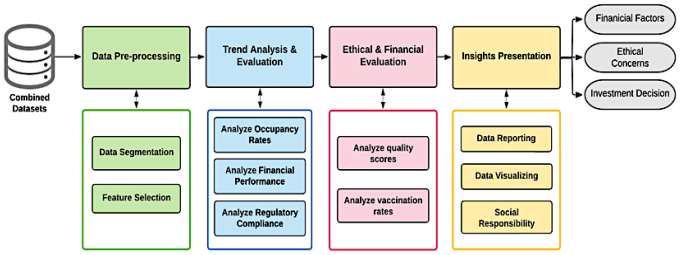

Fig. 2. Stages for healthcare data analysis and evaluation.

The pre-processed data provided a unified foundation for subsequent trend analysis and evaluation, allowing for detailed and accurate comparisons of nursing home performance from 2015 to 2021. The overall methodology is depicted in Fig. 2.

3) Data preparation

a) Data cleaning: Multiple datasets covering the years 2015 to 2021 were consolidated, encompassing information on costs, providers, vaccination rates, health deficiencies, penalties, and quality measures. To ensure consistency across these datasets, key identifiers were standardized, and discrepancies in naming conventions were resolved. Records with missing or null values in critical fields such as facility identifiers and names were removed to maintain data integrity. Data types were harmonized, particularly for identifiers, to facilitate accurate merging and analysis. A data filtering process was implemented to include only records with valid entries in essential fields.

b) Feature selection: Relevant variables essential for the analysis were selected from the cleaned datasets. From the cost-related data, variables pertaining to facility identifiers, names, locations, rural versus urban classifications, net income, number of beds, and salary information were extracted. From the provider data, variables related to total residents, incidents, complaints, fines, and penalties were selected.

c) Dataset combination: The selected features from the various datasets were merged on the standardized facility identifier to create a comprehensive dataset. This integration ensured that all relevant information was aligned for each nursing home facility.

d) Data transformation: Categorical variables were transformed into numerical formats to facilitate quantitative analysis. For example, rural versus urban classifications were encoded numerically.

e) Time-based segmentation: To enable temporal analysis of trends, the dataset was segmented into three distinct periods: the pre-pandemic period (2015–2019), establishing baseline operational and financial conditions; the pandemic period (2020), capturing immediate impacts of the COVID-19 pandemic; and the post-pandemic period (2021), assessing recovery trajectories and long-term effects.

4) Trend analysis and evaluation: This phase aimed to explore key metrics and patterns within the prepared data to understand operational and financial performance, serving as a foundation for regulatory and financial evaluation.

a) Occupancy rates analysis: Occupancy rates were calculated as the ratio of total residents to the number of beds for each facility. These rates were aggregated to compute median, mean, and total values across different time periods and states to identify occupancy trends.

b) Financial performance analysis: Net income data were analyzed to calculate mean and median values, identifying profitability trends over time. Additionally, cost and revenue components, including total salaries and net patient revenue, were evaluated to assess financial stability and the impact of the pandemic on financial operations.

c) Regulatory compliance analysis: Incident-related counts, such as incidents, complaints, fines, and total penalties, were aggregated to evaluate compliance trends. Fines and penalties were analyzed over time to identify emerging regulatory issues.

5) Ethical and financial evaluation: This phase assessed healthcare providers based on their quality of service and adherence to public health protocols, particularly in the context of COVID-19 vaccination efforts.

a) Quality scores analysis: Fourth-quarter quality scores were evaluated to determine care standards and identify any deficiencies or improvements over time.

b) Vaccination rates analysis: Staff and resident vaccination rates were compared by state and facility to gauge compliance with COVID-19 public health guidelines. The impact of vaccination rates on occupancy and financial performance was also assessed.

c) Ethical considerations: The balance between financial performance and ethical responsibilities was examined, emphasizing the importance of quality care and social responsibility, even in the absence of profitability.

6) Insights presentation: The final phase involved compiling the results of the data analysis and evaluation into actionable insights to support decision-making.

a) Data visualization: Intuitive charts and graphs were created to visually represent key findings, making complex data more accessible and understandable to stakeholders.

b) Stakeholder communication: Comprehensive commentary and discussion on all key performance indicators were provided. Significant trends, impacts, and ethical considerations were highlighted to inform decision-making and policy development.

IV. Result and Analysis

A. RQ1: Financial Performance of Nursing Homes at the Onset of the COVID-19 Pandemic

Fig. 3 illustrates the financial performance of nursing homes in 2020 and 2021, comparing costs and income. In 2020, the average total cost of 1,265,525.28 units was relatively high, reflecting the additional expenses due to pandemic-related factors like increased staffing and PPE requirements. However, the average net income of 1,613,439.84 units was still notably higher than costs, indicating that nursing homes managed to stay profitable, likely aided by government support. By 2021, the average total cost dropped slightly to 1,213,841.52 units, indicating a reduction in pandemic-related expenses. At the same time, the average net income increased marginally to 1,629,331.55 units, showing continued financial stability and even slight profitability growth.

The slight reduction in costs between the two years suggests that the dire financial pressures induced by the pandemic were easing. This decline, though, is indicative of a move towards more regular operations with reduced requirements for emergency expenditure. Meanwhile, the consistent rise of average net income throughout 2021 indicates that nursing

homes maintained their revenue streams, due to continued demand for care or ongoing government support.

To summarize, the financial performance of nursing homes evolved positively from 2020 to 2021. In 2020, the average total cost was elevated due to the need for additional staff and PPE, but average net income was strong, thanks in part to the $21 billion in government aid. As pandemic-related expenses decreased in 2021, the average total cost fell slightly while average net income increased, reflecting improved operational efficiency and profitability. This suggests that nursing homes successfully adapted to post-pandemic conditions, benefiting from reduced costs while maintaining a stable and slightly growing income.

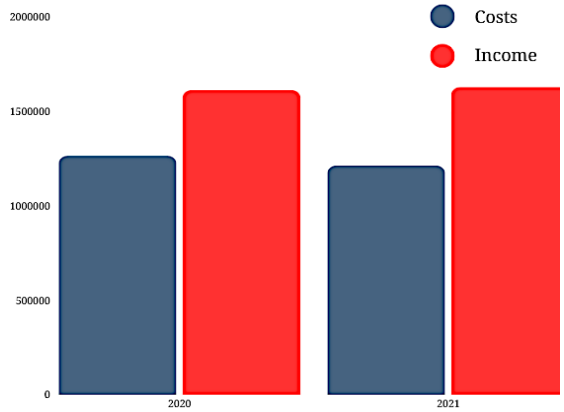

Fig. 3. Comparison of cost and income of nursing homes in 2020 and 2021.

B. RQ2: COVID-19 Case Surge and Mortality in Nursing Homes

Fig. 4 compares COVID-19 cases (in blue) and deaths (in red) from 2020 to 2024, with both plotted on a logarithmic scale. The figure shows that the death rates recorded in 2020 are by far the highest for all years considered. These peaks closely follow the spikes of recorded COVID-19 cases. In contrast, from 2021 onwards, the death rates started to decouple further from the number of cases reported. For example, late 2021 throughout most of 2022, while the case count increases and decreases in waves, the death rate remains relatively low as compared to that in the earlier stages of the pandemic. In the years 2023 and 2024, deaths remain on the lowest level with only some upticks seen in between. This signifies that along the way, health responses must be bettered against various health concerns brought about by several factors such as vaccinations, better treatments, and betterment of health protocols.

To address RQ2: In the first wave of the pandemic (2020), nursing homes were marked by rampant COVID-19 mortality with a high impact. The high impact came about due to the vulnerability of elderly populations in nursing homes and insufficiency in early interventions. Occupancy rates played a critical role in this: greater numbers of residents contributed to over-crowding, posing challenges for social distancing and infection control with the resultant higher levels of transmission and death. The converse is also true: low occupancy rates in some facilities led to lower numbers of outbreaks and deaths.

By 2021 and beyond, mortality rates in nursing homes fell, even as COVID-19 cases rose. This decline can be attributed to factors such as the availability of vaccines, which were prioritized for nursing home residents, and improved protocols for managing outbreaks in these facilities. Additionally, many nursing homes saw reduced occupancy due to deaths in 2020 or families withdrawing loved ones, which could have contributed to lower transmission rates and, by extension, lower death rates.

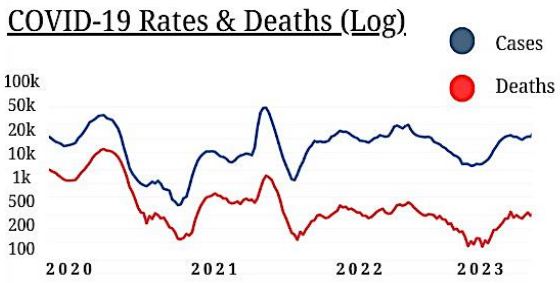

Fig. 4. Comparison of death rate at nursing homes from 2020 to 2024.

C. RQ3: Factors Affecting the Financial Viability and Investment Potential of Nursing Homes

1) Occupancy rates: Fig. 5 compares occupancy rates in all states from 2003 to 2023, it can be shown that from 2003 to 2019, occupancy rates in nursing homes were steady at approximately 82%, reflecting stable demand and consistent revenue streams for the industry. However, there is a sharp decline starting around 2020, which coincides with the COVID-19 pandemic. By 2021, occupancy rates had dropped significantly to 69%. This decline resulted from a combination of factors such as increased mortality among nursing home residents, families pulling loved ones out due to health concerns, and restrictions on new admissions due to safety protocols. By 2023, although there is a slight improvement in occupancy rates, they have not yet returned to pre-pandemic levels, signaling ongoing challenges for the nursing home industry in fully recovering.

Occupancy rates are central to the financial health of a nursing home. The higher the rates of occupancy, the more residents there which means a predictable revenue stream with respect to Medicaid, Medicare, and private payers. When occupancy rates drop, as they did during the pandemic, it reduces the income paying for daily operation. Nursing homes rely on these high occupancy rates to have a steady income; each resident pays with Medicaid, Medicare, or private payments. The 69% occupancy rate seen in 2021 represents a significant loss in revenue compared to the pre-pandemic norm of 82%. Moreover, lower occupancy rates can equate to higher operational costs per resident, since many fixed costs (staff salaries, utilities, maintenance) remain constant regardless of how many residents are in a facility. The decrease in occupancy rate, therefore, likely forced numerous nursing homes to operate at a loss or to retrench services, which further complicated their recovery.

From an investment perspective, facilities with high and stable occupancy rates (like the pre-pandemic average of 82%) offer a more reliable and steady return on investment (ROI). Investors are more likely to be attracted to nursing homes with occupancy rates closer to pre-pandemic levels, as they indicate

financial health and operational efficiency. However, the sharp decline to 69% during the pandemic and the slow recovery indicate increased risk. Nursing homes with low occupancy rates may face financial difficulties, as they have less revenue to cover their fixed costs, including staffing, maintenance, and other operational expenses. Investors may view this as a warning sign of financial instability and would be cautious about investing in facilities where occupancy is not recovering to pre-pandemic levels.

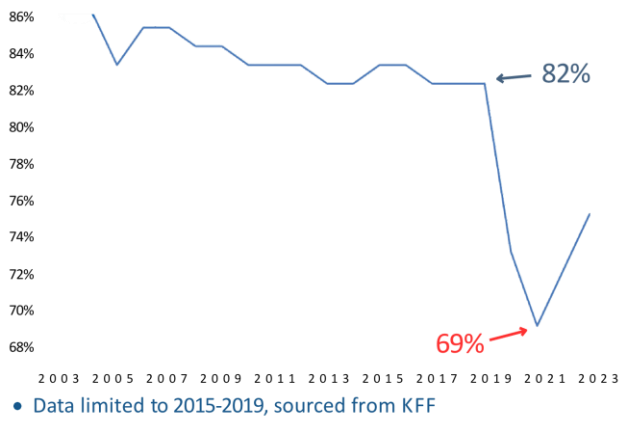

Fig. 5. Occupancy rates between 2003 and 2023.

2) Operating costs and revenue: Fig. 6 compares the mean total operating costs and mean net patient revenues for nursing homes from 2015 to 2021. It highlights key trends during this period, including the effects of the COVID-19 pandemic.

Mean Net Patient Revenue increased steadily from 2015, peaking in 2019 at approximately $9.5M, before dropping slightly in the following years, particularly during 2020 and 2021 (post-pandemic period). On the other hand, Mean Total Costs remained relatively flat from 2015 to 2019, hovering around $1.4M, but then showed a notable decline from 2019 to 2021, indicating a reduction in operating costs for nursing homes during the pandemic.

The steady increase of net patient revenue between 2015 and 2019, peaking in 2019 suggests that nursing homes were experiencing growing revenue from patient services prior to the pandemic, driven by increased demand for long-term care and possibly higher reimbursement rates. However, following the pandemic, revenues slightly declined, likely due to reduced occupancy rates, disruptions to regular operations, and health-related restrictions. On the other hand, the decline of costs during 2020 and 2021 may be attributed to the operational changes brought about by the pandemic, such as reduced staffing needs due to lower occupancy, fewer new admissions, and changes in services provided.

Stable or increasing revenues combined with controlled or decreasing operating costs are essential for maintaining profitability in nursing homes. From 2015 to 2019, rising revenues and steady costs would have made the industry an attractive target for investors, as this combination suggests strong operational efficiency and financial health. The ability to manage costs effectively, especially during the post-pandemic period, further solidifies the attractiveness of nursing homes as a reliable investment. During the pandemic, government relief funds played a critical role in boosting profits by helping nursing homes manage unexpected costs and revenue shortfalls. These funds enabled nursing homes to stabilize their operations, maintain essential services, and reduce operational costs, which contributed to higher profit margins despite the challenges posed by the pandemic.

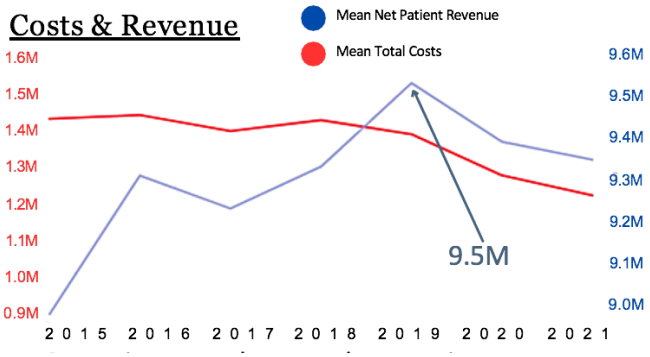

Fig. 6. Cost and revenue mean between 2015 and 2021.

3) Fines and penalties: The diagram in Fig. 7 compares the mean amount of fines (in dollars) and the mean count of penalties per home for nursing homes from 2015 to 2021. The mean amount of fines steadily increased from $28,000 in 2015 to a peak of $48,740 in 2021, with a notable spike starting in 2017. However, the mean count of penalties per home remained stable between 1.6 and 1.8 from 2015 to 2020 but surged to 2.4 penalties per home in 2021 post-pandemic. The significant rise in fines and penalties in 2021 is a result of stricter regulations and enforcement post-pandemic, with many nursing homes being penalized for failing to meet updated health and safety protocols, especially related to infection control, staff shortages, or resident care during the pandemic.

Fines and penalties are key indicators of compliance and regulatory risk in the nursing home industry. An increase in both fines and penalties, as seen in 2021, suggests heightened regulatory scrutiny and an increased likelihood of nursing homes being penalized for non-compliance with health and safety standards. For nursing homes, higher fines directly affect profitability. As seen in the diagram, the mean fine amount spiked to $48,740 in 2021, significantly higher than pre-2017 levels. This increase represents a major financial burden for nursing homes, especially smaller operators, as fines of this magnitude can cut into profit margins or even cause financial strain. For investors, high fines signal operational risk, as nursing homes that are consistently fined may face ongoing regulatory challenges and higher costs associated with compliance.

Penalties and Reputational Risk: The increase in the mean count of penalties per home from 1.6 to 2.4 in 2021 is another key factor for investors to consider. Penalties often reflect deficiencies in care or operational failures, such as inadequate staffing, poor infection control, or violations of resident rights. A rising number of penalties suggests that many nursing homes are struggling to meet regulatory standards, particularly in the wake of the pandemic.

For investors, frequent penalties represent both a financial and reputational risk. Nursing homes with high penalties may be subject to negative media coverage, lawsuits, or damage to their brand reputation. This could result in reduced occupancy rates, lower revenues, and a higher likelihood of facing additional regulatory scrutiny in the future.

Fig. 7. Fines and penalties mean between 2015 and 2021.

4) Relation between housing density and income levels in cities-Additional analysis: Fig. 8 illustrates an example of further analysis that could be performed. In a simple case from our local county, it is observed that as the number of nursing homes within a city increases, the average net income per home tends to decrease. This downward trend is driven by competitive pressures. This type of analysis can be replicated at any county level to determine if a particular city has historically been profitable. Comparing local facilities is a crucial step in making informed investment decisions, and this analysis may be useful if other key factors remain insufficient or unsatisfactory.

The scatter plot in Fig. 9 shows the relationship between homes per city and income per home across different cities, with a negative correlation indicated by the downward-sloping trend line. The key insight from the graph is that cities with higher incomes per home tend to have fewer homes, while cities with more homes often see lower income per home. This pattern reflects the inverse relationship between housing density and income levels in these cities. Wealthier areas tend to have fewer homes, due to larger properties or stricter zoning laws, while more densely populated areas may have a broader range of housing options, resulting in lower average income per home.

For instance, Affluent Areas with Higher Income per Home Cities like Walnut Creek and Concord, which have higher income per home but fewer homes, are attractive targets for premium nursing home investments. Higher income levels suggest a stronger ability to pay for high-quality nursing care, which may include premium services or private-pay nursing homes. Investors in nursing home facilities may find greater profit potential in these areas, as the demand for upscale care services is likely to be stronger. Additionally, cities with higher income levels are often associated with better healthcare infrastructure and higher reimbursement rates from both private insurance and Medicare. For nursing home investors, this means a more stable revenue stream and an opportunity to offer specialized services that cater to the affluent population.

On the other hand, densely Populated Cities with More Homes but lower income cities like Danville, Moraga, and Pleasant Hill, with a larger number of homes but lower income per home, may present opportunities for more affordable nursing home facilities. These areas might cater to middle-income or Medicaid-dependent populations, where demand is still strong but cost sensitivity is higher. For investors, the opportunity in these areas would be to focus on cost-efficient operations and scaling services to meet the needs of a larger population. Facilities in these cities may focus more on Medicaid reimbursements or offer a mix of private-pay and government-funded beds to maintain profitability. While profit margins may be lower in these areas compared to affluent ones, the volume of potential residents could ensure steady occupancy rates, which is a critical factor in maintaining revenue streams in the nursing home industry.

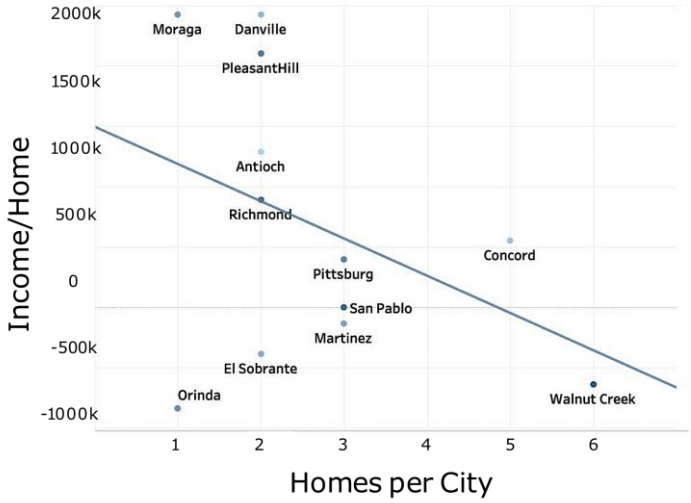

Fig. 8. Housing density and income levels.

D. RQ4: Impact of Ethical Standards and Quality of Care on Investment Decisions in Nursing Homes

1) Vaccination rates Impact on investors

a) Impact of vaccination rates of staff: Fig. 9 displays the COVID-19 vaccination rates of nursing home staff across various U.S. states. The color coding indicates disparities, with red regions representing states with lower vaccination rates around 62.99%, and blue regions showing states with higher vaccination rates nearing 97.99%. This color gradient highlights the variation in the extent to which nursing home staff have been vaccinated across the country.

The states with lower vaccination rates, such as Nevada and California, pose significant risks for nursing homes. When a larger percentage of staff remains unvaccinated, there is a heightened risk of COVID-19 outbreaks, which could severely impact operations. Staff shortages due to illness or quarantine measures can disrupt daily operations and increase staffing costs, while heightened infection rates may also lead to increased absenteeism. These disruptions not only reduce the

quality of care but can lead to operational inefficiencies and financial strain.

Conversely, in states with higher vaccination rates among nursing home staff, such as Maine and Vermont, the environment is more stable. Nursing homes in these regions are less likely to experience outbreaks or disruptions, as a well-vaccinated workforce is better able to protect the vulnerable resident population. This leads to more consistent operations, lower healthcare-related costs, and an overall safer environment for residents and staff alike. Consequently, these facilities are less likely to experience regulatory issues or fines associated with non-compliance to public health measures.

For investors specifically looking at nursing home facilities, staff vaccination rates are a critical factor in evaluating the operational risk of a nursing home. Nursing homes in states with low staff vaccination rates (A larger percentage of states fall within this lower vaccination bracket) are exposed to higher risks of operational challenges and increased costs. These challenges include higher healthcare expenses, potential penalties for non-compliance with vaccination mandates, and decreased trust from residents and their families, leading to lower occupancy rates. Such risks could translate into lower returns on investment, as these nursing homes may struggle to maintain financial stability in the face of ongoing COVID-19-related challenges.

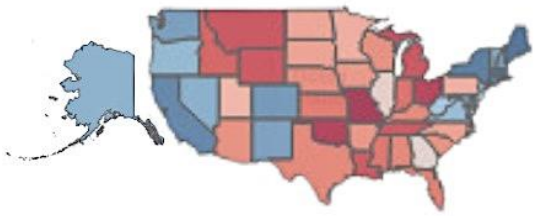

Fig. 9. Vax rates of staff in nursing homes.

b) Impact of vaccination rates of residents: Fig. 10 illustrates the disparities in COVID-19 vaccination rates among nursing home residents across U.S. states, distinguishing between states with lower and higher vaccination rates. Red regions indicate states where the vaccination rate is around 75.76%, while green and blue regions show states achieving rates near 95.63%.

States such as California, Nevada, and several in the South show lower vaccination rates for nursing home residents. This trend suggests that a larger number of states, especially in these regions, have not yet achieved optimal vaccination coverage, which is essential for protecting vulnerable populations in nursing homes. Conversely, states in the Northeast and parts of the Midwest have much higher vaccination rates, demonstrating effective public health strategies and higher compliance with vaccination protocols in nursing homes.

Investment considerations in nursing homes must account for the varying vaccination rates, as they significantly influence risk levels. Nursing homes in states with lower vaccination rates face increased operational risks. These include heightened healthcare costs for protective measures, potential regulatory scrutiny, and lower occupancy rates as families may choose safer facilities for their loved ones. In contrast, nursing homes in states with higher vaccination rates offer safer investment opportunities. These facilities are likely to experience fewer COVID-related disruptions, maintain higher occupancy rates due to increased trust and demand, and incur lower healthcare-related expenses. Moreover, these homes are in a better position to uphold a strong regulatory standing, reducing the likelihood of fines or sanctions.

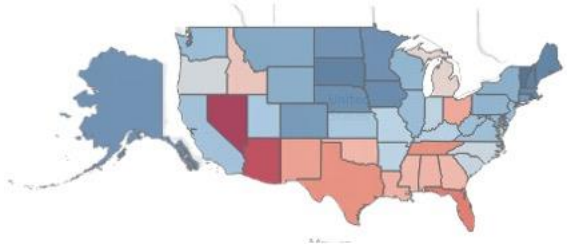

Fig. 10. Vax rates of residents in nursing homes.

2) Quality of care scores impact: Fig. 11 compares the mean 4Q quality scores for nursing homes across five states in 2021 (post-pandemic). The scores indicate the overall quality of care delivered in nursing homes during the fourth quarter of 2021. Arizona had the highest 4Q quality score of 34.249%, reflecting better overall care quality in its nursing homes compared to the other states. Tennessee, Florida, and Maryland: These states fall close together in terms of 4Q quality scores, with only slight differences with a score of 33.514%, 33.466%, and 33.340%, respectively. Mississippi had the lowest score among the states compared, with 33.049%.

The 4Q quality score measures various factors such as patient care, safety, infection control, and staff performance. Higher 4Q scores represent better overall performance in delivering high-quality care, which is a critical factor in determining the viability and attractiveness of a nursing home for investment purposes. Arizona, with the highest 4Q quality score, indicates a strong performance in the quality of care provided. Investors are likely to view nursing homes in Arizona as lower-risk investments due to their demonstrated commitment to maintaining high standards of care.

Higher-quality facilities tend to attract more residents, maintain higher occupancy rates, and face fewer fines and penalties, which contributes to a stable revenue stream. Mississippi's relatively lower 4Q quality score indicates a potential risk factor for investors. Lower quality can signal operational challenges such as staff shortages, poor care management, or non-compliance with health regulations. These issues can lead to higher fines, lower occupancy rates, and increased reputational risks, all of which could negatively impact profitability.

Investors will be more inclined to invest in nursing homes with higher 4Q scores, as these facilities are more likely to attract residents and maintain stable income streams. Nursing homes with lower 4Q scores may face increased regulatory scrutiny, penalties, or fines for failing to meet standards, which could increase operational costs and decrease profitability. Investors will consider 4Q quality scores as a measure of compliance risk when evaluating potential investments.

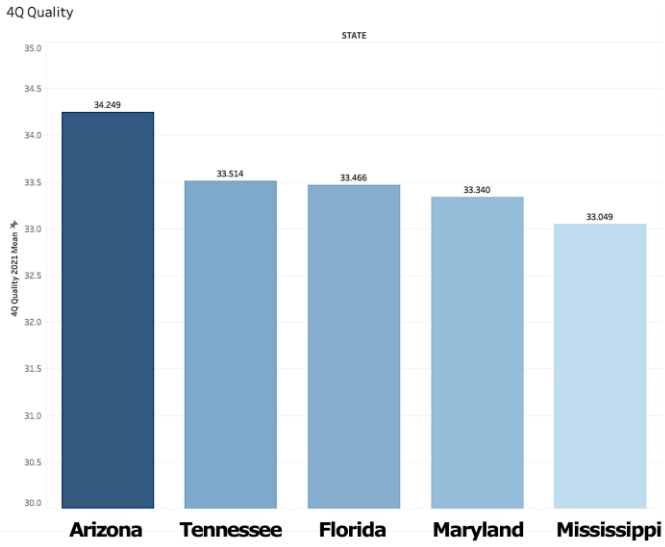

Fig. 11. 4Q quality mean in 2021.

3) Social responsibility: Investing in nursing homes, even when profitability is not guaranteed, offers significant advantages from a social responsibility perspective. Nursing homes provide critical care for some of society's most vulnerable populations, including the elderly and those with long-term health conditions. When factors such as lower profitability or operational risks suggest that investment in this sector may be less financially rewarding, socially responsible investors can still make a meaningful impact by allocating resources to improve the quality of care, support staffing needs, and ensure that residents receive the best possible services.

By investing in nursing homes, despite potential financial drawbacks, investors contribute to the greater social good, helping to maintain or elevate the standards of care in underfunded regions. This not only enhances the lives of residents but also supports local healthcare infrastructure, creates jobs, and promotes public health. Ultimately, these investments align with ethical goals, showing a commitment to community welfare and long-term societal benefit, which can resonate positively with socially-conscious stakeholders and investors.

E. RQ5: Post-Pandemic Investment Considerations: Financial, Operational, and Ethical Dynamics of Nursing Homes. Implications for Investors.

In the post-pandemic era, investors must carefully evaluate a range of financial, operational, and ethical factors before making decisions about investing in nursing homes. These factors include occupancy rates, net income, the lingering effects of COVID-19, and fines or penalties that may affect profitability. Additionally, operational considerations such as maintaining high quality of care, ensuring high vaccination rates, and adhering to social responsibility are critical in assessing the long-term viability of investments. These factors have become even more crucial in the wake of the pandemic, which has reshaped the landscape of the nursing home industry.

Occupancy rates are a central factor for nursing homes, as stable or increasing rates are vital for generating revenue. Facilities with low occupancy struggle to cover their operating costs, which nursing homes experienced financial strain during the pandemic due to increased costs for personal protective equipment, infection control measures, and staffing shortages. Facilities that have not recovered financially pose significant risks for investors, as they may not offer stable returns. The effects of COVID-19 continue to shape this sector, with facilities needing to adjust to new safety protocols and costs.

Furthermore, fines and penalties add an additional layer of risk. Nursing homes with frequent fines, usually due to lapses in care or regulatory non-compliance, indicate poor operational management and higher costs. This directly impacts their net income and increases the financial burden on the facility, making it less attractive to investors. These facilities may also suffer reputational damage, further decreasing their ability to attract new residents and maintain occupancy.

Operationally, quality of care plays a crucial role in the investment decision. Nursing homes that maintain high standards of care tend to have better reputations and higher occupancy rates. Families are more likely to choose facilities with strong care metrics, which translates to more stable revenue streams. Conversely, homes with poor care quality are often subject to penalties, legal issues, and low occupancy rates, making them riskier investments. Additionally, vaccination rates among staff and residents are another critical consideration post-pandemic. Facilities with higher vaccination rates are less vulnerable to outbreaks, which reduces operational disruptions and associated healthcare costs. These facilities are more likely to maintain smooth operations, offering a safer environment for residents and, consequently, more reliable returns for investors.

Given these considerations, we advise against investing in nursing homes unless specific criteria are met. First, facilities must show increasing occupancy rates. Without high occupancy, nursing homes cannot generate sufficient revenue to cover operational costs. The number of nursing homes in a city also affects investment attractiveness, as increased competition can drive down occupancy and profitability. Investors should prioritize cities with fewer nursing homes relative to the population of elderly residents to avoid competitive saturation.

Another key criterion is the income/bed ratio, which reflects the financial efficiency of a facility. Homes with a high income per bed are more financially secure, indicating they can generate sufficient revenue to support operations. Profitability remains a major concern; facilities that do not consistently demonstrate profitability, especially post-pandemic, are unlikely to offer reliable returns. Additionally, constant costs are critical to operational stability. Facilities with volatile cost structures due to the pandemic or poor management may face financial challenges that make them poor investment choices.

Quality of care is also essential. Homes that maintain high 4Q quality scores provide a safer environment, making them more attractive to residents and, by extension, investors. Facilities with low care scores face reputational risks and may struggle with fines or penalties, which can harm financial

performance. Finally, vaccination rates among staff and residents are a key factor in ensuring operational stability. Homes with high vaccination rates are less prone to COVID-19 outbreaks, ensuring fewer disruptions and lower healthcare costs, making them safer investments.

From an ethical perspective, social responsibility has become increasingly important. Even when profitability is not guaranteed, socially responsible investors may still consider allocating funds to nursing homes. This is particularly true in areas where the public good is at stake, such as caring for the elderly and vulnerable populations. Investing in nursing homes, despite lower returns, can align with the broader goals of contributing to community welfare and supporting critical healthcare infrastructure. However, for profit-driven investors, ethical considerations alone may not justify the investment unless these facilities also demonstrate operational efficiency and financial stability. The decision-making process can be shown in Fig. 11.

F. Discussion and Insights

The findings of this research provide a comprehensive look at the significant shifts in the nursing home industry caused by the COVID-19 pandemic, highlighting the critical role of financial performance, ethical standards, and operational resilience. From the data collected and analyzed, it is clear that the pandemic not only exacerbated pre-existing vulnerabilities within the industry but also introduced new challenges that have reshaped how nursing homes operate and are perceived as investment opportunities. However, the true value of this study lies not just in quantifying these effects but in understanding the broader implications for the future of long-term care.

One of the most striking insights from the analysis is the persistent decline in occupancy rates and how this metric remains a crucial indicator of financial viability for nursing homes. The pandemic's severe impact on occupancy rates underscores the need for long-term planning and adaptability within the sector. In my view, this highlights a critical need for nursing homes to rethink their operational models, possibly expanding beyond traditional care models to include services that can attract more residents in both post-pandemic and future crises. For example, a focus on rehabilitation services, at-home care integration, or telehealth options might provide nursing homes with the flexibility to maintain stable revenues even in the face of future disruptions.

The pandemic has also forced a reassessment of the ethical standards within nursing homes, particularly concerning patient safety, vaccination compliance, and overall quality of care. It is my opinion that ethical considerations should no longer be viewed as secondary to financial performance but as integral to the operational success and sustainability of nursing homes. The findings of this study clearly show that facilities that adhered to higher ethical standards—such as maintaining high vaccination rates—were better positioned to weather the challenges of the pandemic. This suggests a shift in the industry where ethical compliance, particularly related to healthcare protocols, could be seen not only as a moral imperative but also as a competitive advantage.

Moreover, from an investment perspective, this research suggests that future investors in the nursing home industry will need to be more discerning. The emphasis on metrics like occupancy rates, fines, and penalties, as well as adherence to ethical standards, will likely become central to investment decisions. My personal opinion is that investors must now adopt a more holistic approach when evaluating nursing homes, taking into account both the financial health of the facility and its ethical standing. This shift toward socially responsible investment may not only yield better returns but also contribute to the improvement of care standards across the industry, creating a more sustainable model for the long-term care sector.

V. Conclusion

In this paper, we have explored the financial shifts, ethical dilemmas, and investment potential in the nursing home industry, with a focus on the pre- and post-COVID-19 landscape. The COVID-19 pandemic significantly impacted nursing home operations, exacerbating pre-existing financial vulnerabilities and introducing new challenges in the form of increased costs, declining occupancy rates, and heightened scrutiny around care quality and ethical standards. Our study highlights that while government aid played a vital role in stabilizing the industry during the pandemic, long-term financial sustainability remains uncertain. The analysis also underscores the critical importance of ethical considerations, such as vaccination compliance and quality of care, in both maintaining operational stability and attracting potential investments.

As the nursing home industry navigates the post-pandemic recovery phase, our findings suggest that investment in this sector should be approached cautiously. Facilities with strong financial performance, high occupancy rates, low fines and penalties, and adherence to ethical standards are more likely to offer stable returns. In contrast, facilities that fail to meet these criteria may present excessive financial and operational risks.

Future Work

Will focus on several key areas. First, a deeper analysis of regional variations in nursing home performance could provide more granular insights into how different states and localities responded to the pandemic. This would allow for a better understanding of regional disparities and how specific policies and regulations may have influenced nursing home operations. Additionally, future research should explore the long-term impact of COVID-19 on the quality of care in nursing homes, particularly how ethical standards and vaccination policies continue to shape resident outcomes over time. This will help identify ongoing trends and assess the effectiveness of current policies in ensuring the health and safety of nursing home residents.

Acknowledgment

The authors would like to acknowledge the Centers for Medicare & Medicaid Services (CMS) for providing the comprehensive datasets used in this research. These datasets, available through Medicare.gov, were instrumental in our analysis of the nursing home industry, allowing us to explore

various aspects of financial performance, operational practices, and regulatory compliance. We appreciate the CMS's commitment to transparency and public access to critical healthcare data, which has significantly contributed to the depth and quality of this study.

FusionSec-IoT: A Federated Learning-Based Intrusion Detection System for Enhancing Security in IoT Networks

Jatinder Pal Singh[1], Rafaqat Kazmi[2]
QA Manager, Apple Inc., USA[1]
Department of Software Engineering, IUB, Pakistan[2]

***Abstract*—Internet of Things (IoT) has become one of the most significant technological advancements of the modern era, which has impacted multiple sectors in the way it provides communication between connected devices. However, this growth has led to security risks in the IoT devices especially when constructing resource-limited IoT networks that are easily attacked by hackers through methods like DDoS and data theft. Traditional IDS such as centralized IDS and single-view machine learning-based IDS are incapable of providing efficient solutions to these issues due to high communication cost, latency, and low attack detection rate for IDS. To address these challenges, this paper presents FusionSec-IoT, a decentralized IDS based on multi-view learning and federated learning for better detection performance and scalability in the IoT context. The results sows that the proposed technique performs better than the existing IDS methods with 08.3% accuracy as compared to classic IDS techniques centralized IDS (91.5%) and single-view federated learning (92.7%). The other performance metrics like shows a better performance as compared to traditional IDS methods. Thus, FusionSec-IoT detects a broad range of cyberattacks with the help of the employed complex machine learning algorithms such as Reinforcement Learning, Meta-Learning, and Hybrid Feature Selection using Particle Swarm Optimisation (PSO) and Genetic Algorithm (GA), and ensures data privacy is maintained. Moreover, Edge Computing and Graph Neural Networks (GNNs) guarantee fast identification of multi-device coordinated attacks, for instance, botnets. The above-discussed proposed system enhances the traditional IDS approaches in terms of high detection accuracy, better privacy, and scalability, making the proposed system a reliable solution to secure the complex and large-scale IoT networks.**

Keywords*—*IoT security; Intrusion Detection System (IDS); federated learning; multi-view learning; cyberattack detection

I. Introduction

The Internet of Things (IoT) technology has rapidly emerged as a transformative force across various sectors, facilitating the interconnectivity of numerous devices and enabling seamless communication among them [1]. Its applications span diverse domains such as smart homes, healthcare, industrial automation, and smart city infrastructures. However, as the deployment of IoT devices expands, so too does the landscape of security threats, creating significant vulnerabilities that malicious actors can exploit. The proliferation of intelligent IoT devices, often characterized by limited processing power and communication capabilities, within extensive and intricate networks heightens their susceptibility to various cyber threats [2]. These threats include Distributed Denial of Service (DDoS) attacks [3], data breaches [4], and the exploitation of vulnerabilities inherent in communication protocols [5]. Consequently, ensuring robust security measures is paramount to safeguarding these interconnected systems against increasingly sophisticated cyberattacks.

Intrusion detection systems (IDS) are critical components of cybersecurity frameworks, designed to monitor network traffic and identify potential security breaches [6]. Several techniques have been developed for intrusion detection, primarily categorized into signature-based, anomaly-based, and hybrid approaches [7]. Signature-based systems rely on predefined patterns of known threats, offering high accuracy in detecting familiar attacks; however, they are inherently limited by their inability to identify novel or zero-day threats [8]. Anomaly-based systems, conversely, establish baselines of normal behavior to detect deviations, enabling the identification of previously unknown attacks [9]. Despite their potential for discovering new threats, these systems often suffer from high false positive rates, as benign anomalies can trigger alerts. Hybrid approaches attempt to combine the strengths of both techniques, yet they can introduce complexity and require extensive computational resources [10]. Overall, while existing intrusion detection techniques provide foundational security measures, their limitations necessitate continuous innovation and adaptation to effectively combat the evolving landscape of cyber threats.

Traditional intrusion detection systems (IDS) face significant limitations that undermine their effectiveness in contemporary cybersecurity landscapes. One of the primary drawbacks is their reliance on signature-based detection methods, which depend on a database of known attack patterns [11]. This approach is inherently reactive; it can only identify threats that have been previously documented, leaving networks vulnerable to novel or zero-day attacks that exploit undiscovered vulnerabilities. Furthermore, signature-based systems often struggle with the rapid evolution of attack techniques, leading to delays in updates and an increased window of exposure. Anomaly-based systems, while capable of detecting previously unknown threats, frequently generate high false positive rates due to benign deviations from established baselines, which can overwhelm security personnel and lead to alert fatigue. Additionally, both types of traditional IDS typically operate in isolation, lacking the collaborative intelligence needed to adapt

to increasingly sophisticated and coordinated cyber threats [12]. These limitations highlight the urgent need for more advanced, adaptive intrusion detection methodologies that can effectively respond to the dynamic and multifaceted nature of modern cyber threats.

Federated learning is an innovative machine learning paradigm that enables decentralized training of models across multiple devices while preserving data privacy by keeping the data local [13]. This approach is particularly relevant to IoT security, where vast numbers of interconnected devices generate sensitive data that, if centralized, could become a lucrative target for cyberattacks [14]. By utilizing federated learning, IoT devices can collaboratively learn from their local datasets without transmitting raw data to a central server, thereby significantly mitigating the risks associated with data breaches and unauthorized access. Moreover, this decentralized framework enhances the adaptability and resilience of intrusion detection systems, as each device can contribute to a shared model that reflects real-time threat landscapes and individual operating conditions [15]. Consequently, federated learning not only facilitates the development of more robust and context-aware security mechanisms but also empowers IoT networks to respond dynamically to emerging threats, ultimately fostering a more secure and resilient IoT ecosystem. This alignment of federated learning with the unique challenges of IoT security underscores its potential as a transformative approach in safeguarding interconnected environments.

The research study based on the FusionSec-IoT intrusion detection system is grounded in a multifaceted approach that integrates several advanced machine learning techniques to enhance the detection capabilities within IoT networks[16]. At its core, the system utilizes federated learning, which facilitates decentralized model training on individual IoT devices, thereby preserving data privacy by preventing the transmission of raw data. Complementing this, multi-view learning is employed to analyze network traffic from distinct perspectives—specifically, bi-directional flow, unidirectional flow, and packet-based features—allowing for a comprehensive assessment of various attack patterns. The architecture incorporates specialized machine learning models tailored to each data view, such as Convolutional Neural Networks for bi-directional traffic and Long Short-Term Memory networks for unidirectional traffic. Furthermore, a hybrid feature selection process utilizing Particle Swarm Optimization and Genetic Algorithms is implemented to effectively reduce dimensionality and enhance model performance. Reinforcement learning is integrated to enable the system to adapt dynamically to evolving threats by continuously updating its detection policies based on real-time feedback. Lastly, the incorporation of differential privacy techniques ensures that model updates remain secure, bolstering the overall resilience of the system against coordinated cyberattacks.

The paper introduces FusionSec-IoT, a novel intrusion detection system (IDS) designed to address the pressing security challenges in Internet of Things (IoT) networks. Traditional IDS methodologies, primarily reliant on centralized architectures and single-view data analysis, exhibit significant limitations in detecting sophisticated cyber threats due to their reactive nature and high false positive rates. In response, FusionSec-IoT employs a decentralized approach that integrates multi-view learning and federated learning techniques. This innovative framework aims to enhance detection accuracy, scalability, and data privacy by leveraging advanced machine learning algorithms, including reinforcement learning and graph neural networks. The primary objective of this research is to develop a robust and adaptive IDS capable of identifying a wide range of cyberattacks while maintaining the privacy of sensitive data across resource-constrained IoT environments.

The remainder of this paper is structured as follows. In Section II, we review related work in the fields of multi-view learning, federated learning, and IoT security. Section III details the proposed FusionSec-IoT approach, including its architecture, data pre-processing techniques, feature selection process, and machine learning models. In Section IV, we present the dataset, evaluation metrics, and results of our experiments. Discussion is presented in Section V. Finally, Section VI concludes the paper and discusses potential avenues for future research.

II. Related Work

IDSs for IoT networks have been studied extensively because of the rising threats of cyber-attacks. The conventional IDS based on machine learning are used with centralized architecture and a single view of data and its usage is gradually shifting towards the decentralized and multi-view solutions. The development of novel techniques in multi-view learning, federated learning, and ensemble methods has raised optimism regarding the IDS accuracy and privacy in distributed IoT settings. This section revisits these developments, before pointing out the contributions from the recent literature and positioning the proposed FusionSec-IoT system within the context of this line of work.

Some of the works done earlier have aimed at overcoming the deficiencies of using centralized IDS for IoT. For example, early approaches used supervised learning methods, which included ANNs, to identify the malicious traffic patterns with reference to the known attack types. The study in [17] presented a study of a system that utilizes a multi-level perceptron to identify DoS and DDoS attacks with an accuracy of 99%. 4%. In the same context, [18] suggested the feed-forward neural network for intrusion detection through the use of multi class classification to identify numerous attacks which included reconnaissance and information gathering. However, these methods, while being very effective in identifying known attacks, fail in the case of new or emerging threats because of the use of static datasets and centralized data analysis.

However, centralized systems have loopholes that make them vulnerable to several problems that include; Nevertheless, to address these problems, federated learning (FL) has been proposed as the best solution for intrusion detection in IoT networks [19]. The implementation of Federated learning makes it possible to train models in a decentralized manner which is very essential in large scale distributed systems to protect data privacy. Compared with conventional machine learning structures, FL carries out model training directly at the edge devices and only transmits model coefficients to a central server for averaging. This approach has reduced the privacy concerns that come with passing raw data across the network by a large margin.

TABLE I. PREVIOUS LITERATURE COMPARISON

Ref #	Key Focus of Study	Methodology/Techniques Used	Key Findings	Limitations
[18]	Federated learning for intrusion detection in IoT systems	Federated learning framework with anomaly detection	Improved privacy-preserving intrusion detection	Limited scalability for large IoT environments
[19]	Hybrid methods for intrusion detection	Combined signature-based and anomaly-based methods	Improved detection accuracy compared to standalone techniques	High computational requirements
[20]	Comparative review of federated learning in intrusion detection systems	Review of federated learning techniques for privacy and intrusion detection	Highlighted advantages of decentralized learning for privacy preservation	Lack of real-world experimental validation
[21]	Techniques for anomaly-based network intrusion detection	Overview of anomaly detection systems	Identified potential for detecting unknown attacks	High false positive rates for benign anomalies
[22]	Trustworthy AI for cybersecurity	Multi-faceted approach integrating AI techniques for intrusion detection	Proposed adaptable AI models for real-time threat detection	Limited discussion on privacy-preserving mechanisms
[23]	Federated learning with LSTM for IoT intrusion detection	Long Short-Term Memory (LSTM) models with federated learning	Enhanced intrusion detection with decentralized data	High latency due to LSTM training

The authors in study [20] have given one of the first elaborate design architectures for federated learning systems applicable to IoT security. Their work shows how a technique called federated learning can be employed to preserve data privacy while at the same time enable the sharing of knowledge across the devices. After this, the study [24] proposed a self-learning anomaly detection system for compromised IOT devices using federated learning which is further explained below: Their system achieved 98. 2% accuracy and could detect 95 per cent of the malignant tumors. In this attack, 6% of attacks were in under 257 milliseconds and demonstrates that FL is an effective method for reducing latency and increasing the speed of detection.

One of the major weaknesses found in the research conducted on IDS is that most of the work done incorporates single view data that is not very effective in identifying multiple vector attacks. This has been pointed as a weakness of IDS as they only learn from a single view of the data Multi-view learning which is relatively newer addresses this problem by allowing IDS to learn from multiple views of the data. Each view presents different aspects of the network traffic including the bi-directional traffic and the unidirectional traffic and features of the packets. Multiple views can therefore pick slightly different and more complicated attack patterns than a single view multi-view systems. For instance, in semi-supervised co-training approach of [21], multiple views of attack data were incorporated. Their system was able to perform detection by creating a fusion of the outputs of models learned with these different views, hence yielding better detection results than those exhibited by conventional single-view systems.

Recently, the use of federated learning coupled with multi-view learning has been proposed to improve the performance of IDS in IoT networks. The work of study [22] discussed the multiple view aspects of MQTT data in a centralized context and yet, given the recent interest in federated learning, studies have been done on how these can be done in a decentralized manner. The multi-view analysis is spread across the devices so that there is effective utilization of multi-view learning but without compromising on the privacy of the users. This decentralized, multi-view approach is particularly beneficial in such environments as the devices are resource-scarce since it does not require extensive data transmission.

Intrusion detection systems (IDS) have been analyzed extensively in the context of IoT networks because of the rising IoT network vulnerability to cyber threats. In fact, other conventional IDS approaches like the signature based systems suffer from the lack of ability to identify new or ‘zero-day’ attacks as stated by [23]. Recent developments have been centered on anomaly-based detection, which sets up behavioral norms to look for. Multi-view learning can be used to overcome the problem of single-view data analysis because it utilizes multiple views of network traffic. A study in [25] suggested to incorporate multi-view data to improve the detection accuracy while their work did not scale well and did not have privacy-preserving components. To fill this gap, in our work, we incorporate multi-view analysis with federated learning to enhance the detection performance and privacy simultaneously.

Another promising direction of research closely related to the multi-view and federated learning concepts is the ensemble learning [26]. Ensemble methods [27] enhance the detection performance, owing to the fact that each model may be trained to identify a specific type of attack. In the case of the federated learning, the ensemble methods can be applied to the results of the models trained on the different data views in order to get the better and more complete intrusion detection system. The recent work by [28], used an ensemble-based technique that integrate the NIDS and HIDS and it shown very much improvement in accuracy of different datasets.

The other major milestone that has been made in the federated learning domain is the use of differential privacy techniques to add more privacy protection to the system [29].

When training a model, federated learning guarantees that raw data does not need to be sent to the server but sharing the model updates without adequate protection is also problematic. Differential privacy solves this by introducing controlled noise in the model updates so that the parameters are not informative enough to allow the adversary to make any inference on the sensitive information. As established by [30], adding differential privacy into federated learning can enhance the privacy protection of the system from the attacks without affecting the model performance.

Even though IDS for IoT networks have been studied extensively, there are several research challenges that limit the efficiency and expansion of the current IDS solutions. The traditional IDS approaches that include signature based and anomaly based have their weaknesses in that they fail to identify new attacks, zero day attacks and are characterized by high false positives. Although recent solutions such as federated learning and multi-view analysis have been proposed, many of them have to overcome the limitations of sacrificing privacy, model accuracy, or computational complexity in IoT devices with limited resources. Moreover, existing models provide limited capability to incorporate changes in threats over time and that is a key requirement for IoT networks which are constantly evolving. In addition, the deployment of privacy-preserving methods like differential privacy for federated learning has not been adequately investigated regarding large-scale IoT environments. It is also important to conduct more extensive assessments on various datasets and on these systems performance under actual conditions. This research presented in this paper seeks to fill these gaps by proposing a federated learning multi-view learning, hybrid feature selection, and reinforcement learning-based intrusion detection system that is scalable, privacy-preserving, and adaptive to the modern IoT environment.

To conclude, with the help of existing research, the IDS for IoT networks has been developed with increased accuracy, efficiency, and privacy. Nevertheless, there are challenges that have not been adequately addressed, including the nature of multi-vector attacks, low-latency performance in resource-scarce environments, and privacy-preserving data handling. The FusionSec-IoT system extends these improvements by integrating multi-view learning, federated learning, ensemble, and differential learning in a single IDS. Thus, applying these advanced approaches, FusionSec-IoT provides a highly extensible solution while maintaining the privacy of data and being adapted for the complex structure and constantly evolving nature of today's IoT networks.

III. Proposed Methodology

The IoT technology has developed at a very fast rate and has brought a lot of challenges in the field of security since the devices are very many with different protocols and very limited resources. Inherent traditional security measures are a bit appropriate for conventional networks but not for IoT, especially because the devices are re-source-constrained, and data breaches are rampant. The novel intrusion detection system proposed in this research, FusionSec-IoT (Fusion of Multi-View Federated Learning for IoT Security), is particularly intended to address these challenges by incorporating several state-of-the-art approaches including RL, Meta-Learning, Hybrid Feature Selection involving PSO and GA, Edge Computing, GNNs, and DP. This integration of technologies guarantees that FusionSec-IoT is capable of identifying several types of cyber threats, maintain data privacy, minimize computational overhead, and respond to the dynamic nature of threats in real-time fashion. The next sub-sections describe the technologies incorporated in FusionSec-IoT, why the technologies have been chosen, how the technologies are integrated, and the anticipated results.

A. Architecture

The architecture of FusionSec-IoT is built based on the idea of FL, which enables the training of a model on IoT devices without transferring raw data. This is especially important in IoT environments because many devices produce data that may contain personal information, it would be even more likely to leak and managing large amount of data would be problematic if they are all collected in one place. Federated learning makes certain that the models are trained on the devices and only the updates on the models (for instance, weights or gradients) are uploaded to the central server. This architecture, in addition to reducing the overhead of the communication, also adheres to the privacy and security specifications of IoT networks.

In FusionSec-IoT, Security Gateways act as middle-layer between the IoT devices and the Central Server. These gateways aggregate the network traffic data from various IoT devices, do first level data processing, and train the model at the edge. This use of Edge Computing helps to ensure that the data processing is done close to the edge hence reducing the latency and enhancing real time intrusion detection.

The Fig. 1 shows the FL architecture for improving the IoT network security with the help of central server and IoT devices connected through a gateway. Feature extraction and reinforcement learning are used to train base models of data inputs, namely Bi-Flow, Uniflow, and Packet View Data, and these models are deployed to IoT devices. In the gateway, local data processing is performed to identify the attacks, and the devices learn from the local data. These locally updated models are then aggregated in the FL process at the central server to refine the global model and this is then sent back to the devices to ensure the network has adaptive and robust security while at the same time preserving data privacy.

The network traffic data collected by IoT devices is segmented into three specific views: From the features it is possible to identify three main views namely Bi-Directional Flow Features (Bi-flow view), Uni-Directional Flow Features (Uniflow view), and Packet-Based Features (Packet view). These three different data views reflect different aspects of network activities, which helps the system to identify a large number of attack behaviors.

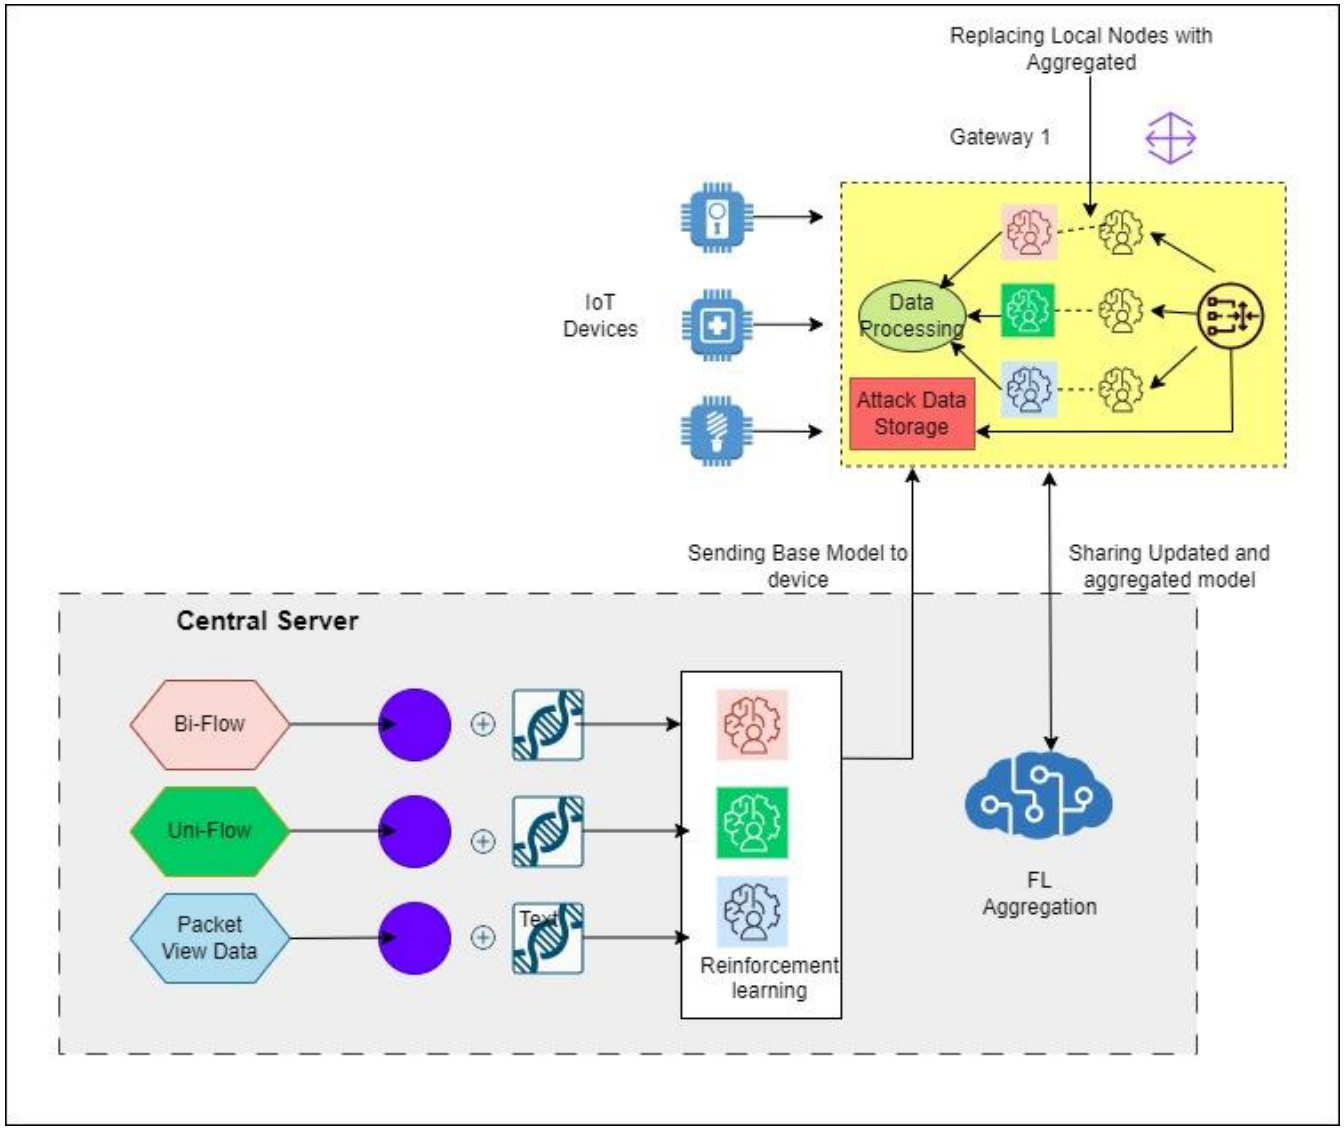

Fig. 1. Architectural design of proposed model.

Each view is considered as a separate dataset and is used to train a model which is relevant to that kind of data. Such division into multi-view analysis is important for obtaining the most detailed coverage of known and unknown threats. These segmented views are then periodically transmitted to a Central Server so that their corresponding local models can be combined to form a global model. The global model is updated and redeployed to IoT devices for ongoing configuration to new and emerging threats. Data Pre-Processing and Multi-View Analysis

Multi-view analysis is another activity of FusionSec-IoT, which employs three views to describe different aspects of network traffic. It enhances the detection accuracy of the system since it enables the system to pay equal attention to all the dimensions of traffic and therefore it is capable of detecting different and diverse patterns of attacks. Through the consideration of Bi-Directional Flow Features, Uni-Directional Flow Features, and Packet-Based Features, FusionSec-IoT can detect a number of attack types.

1) Bi-Directional Flow Features (Bi-flow view): This view focuses on bidirectional traffic between devices which is for instance the communication between the client and server. Bidirectional traffic analysis is used if the attack is based on the multiple devices' communication, for instance, botnet attack where infected devices are in contact with the C&C server.

2) Uni-Directional Flow Features (Uniflow view): This perspective provides the traffic as a one way process with reference to the flow of packets in terms of transmitted and received. It is found that uniflow analysis is more useful to detect traffic flows related to Distributed Denial of Service (DDoS) attacks, where large numbers of traffic flows are sent to a particular destination to flood it.

3) Packet-Based Features (Packet view): The third view involves the examination of various parameters that are inherent in individual packets including the size, time and the header information. Packet-based analysis is especially helpful in identifying low level attacks such as the port scanning or the

network probing since the packets will possess different characteristics from normal packets.

The multi-view approach enhances the result of the intrusion detection system since each kind of traffic is processed in a manner most effective in detecting certain kinds of attacks. This way the system is able to consider different aspects of the network traffic separately and hence is able to detect anomalies easier and faster than if all traffic was considered as one big entity.

B. Hybrid Feature Selection Using PSO and GA

Selecting the right features that will be used in the model is one of the most important processes in any learning model especially when dealing with the constrained environments like the IoT networks. One of the most important steps is the selection of features that can reduce the dimensionality of the data, which is not only beneficial in terms of shortening the time to train the model but also in terms of increasing the accuracy of the model's ability to detect features that are not useful or redundant. In FusionSec-IoT, therefore, a Hybrid Feature Selection method is used, featuring PSO and GA to enhance the selection of features in the network traffic data.

Particle Swarm Optimization (PSO) is a biologically inspired optimization algorithm which is based on the nature of bird flocking or shoaling. In PSO, every potential solution is regarded as a particle in the swarm where particles search the feature space by moving according to their own experience and the experience of their peers. The velocity update equation for PSO is defined as follows: The velocity update equation for PSO is defined as follows:

$$v_i^{t+1} = wv_i^t + C_1 r_1 (p_i - x_i^t) + C_2 r_2 (g - x_i^t) \quad (1)$$

where v_i^{t+1} is the updated velocity of particle i, ω is the inertia weight which control the effect of the previous velocity, c1 and c2 are cognitive and social coefficients which represent the influence of personal best position and global best position respectively, r1 and r2.

Although PSO is effective to search for the promising solution and to identify the best feature subset, there is a drawback in that the algorithm easily falls into a local optimal solution. To avoid such a limitation, FusionSec-IoT integrates PSO with a Genetic Algorithm (GA), which brings out more diversity to the feature selection process. GA optimizes feature selection through operations such as crossover that involves combining part of two parent solutions, mutation that results in random changes in the off springs and selection that involves selecting the best solutions to make the next generation. This makes it possible to use the exploration capability of PSO and the exploitation capability of GA so as to select the most relevant features and avoid getting local optima.

Algorithm 1: Particle Swarm Optimization (PSO)

Input:

n_particles: Number of particles

n_dimensions: Dimensionality of the search space (i.e., the number of features)

max_iterations: Maximum number of iterations

w: Inertia weight (controls exploration vs. exploitation)

c1, c2: Cognitive and social acceleration constants

Output:

gBest: Global best solution (optimal feature subset)

Initialization:

Initialize each particle's position randomly in the search space.

Initialize each particle's velocity randomly.

Set each particle's personal best (pBest) to its initial position.

Set global best (gBest) to the position of the particle with the best fitness.

For each iteration from 1 to max_iterations do:

| For each particle i do:

| Evaluate fitness of the current position position[i].

| Update personal best:

| If fitness(position[i]) is better than fitness(pBest[i]),

| update pBest[i] = position[i].

| Update global best:

If fitness(pBest[i]) is better than fitness(gBest), update gBest = pBest[i].

| Update velocity for particle i:

velocity[i]=w×velocity[i]+c1×r1×(pBest[i]−position[i])+ c2×r2×(gBest−position[i])

Where r1 and r2 are random numbers between 0 and 1.

| Update position for particle i:

| position[i]=position[i]+velocity[i]

End iteration loop.

Return gBest as the optimal solution.

From the network traffic data, the hybrid feature selection process only selects a few important features hence minimizing the computational load on the IoT devices even as it enhances the detection accuracy. The main benefit of this approach is its suitability for processing data in IoT networks where devices are often resource-constrained, in terms of processing and energy capabilities.

C. Reinforcement Learning for Dynamic Adaptation

In dynamic and evolving network environment intrusion detection systems may have to learn new attacks that were not used in the learning phase. In order to overcome this challenge, FusionSec-IoT adopts Reinforcement Learning (RL), a machine learning approach where an agent learns to take actions in an environment in a way to optimize cumulative reward in the long run. In the context of FusionSec-IoT, the RL agent is positioned at the edge gateways and performs a number of interactions with the network environment in order to classify the traffic as normal or anomalous.

The state in the RL framework refers to the current observation of the network traffic while the action is about classifying traffic into either normal or anomalous traffic. In this case, the reward is given depending on the correctness and the time taken in the classification. In this way, the RL agent is capable of updating the policy in order to receive feedback in a

form of a reward in order to make better decisions in the future. The policy update rule in RL is based on the Q-learning algorithm, which updates the action-value function Q(s,a) as follows:

$$Q(s,a) \leftarrow Q(s,a) + \alpha[r + \gamma max_{a'} Q(s',a') - Q(s,a)] \quad (2)$$

Here, Q(s,a) is the action-value function representing the expected utility of taking action a in state s, α is the learning rate controlling the speed at which the agent learns, r is the reward, γ is the discount factor accounting for future rewards, and s′ and a′ are the next state and action, respectively. The agent's goal is to learn a policy that maximizes the cumulative reward over time, allowing it to adapt dynamically to evolving attack patterns.

Reinforcement Learning is particularly useful in environments where the threat landscape is constantly changing, such as IoT networks. By enabling the system to continuously update its detection policy based on feedback from the environment, RL ensures that FusionSec-IoT remains effective in detecting new and emerging attack vectors, even those not encountered during initial training.

D. Meta-Learning for Zero-Day Attack Detection

Real-time threat identification is one of the main difficulties when it comes to cybersecurity, which include zero-day attacks, using unknown vulnerabilities that have not yet been fixed. Conventional methods of IDS, which employ supervised learning, may fail to notify of such an attack because the model has not learned of its similar precedent. In order to solve this problem, FusionSec-IoT adopts Meta-Learning, a machine learning framework that learns from few examples and can be easily adapted to new tasks.

Algorithm 2: Meta-Learning for Zero-Day Attack Detection

Initialize model parameters theta.
| For each iteration (1 to n_iterations):
| Sample tasks from T.
| | For each task:
| | | Copy theta_i = theta.
| | Inner loop: Perform n_inner_updates using task data: $\theta i' = \theta i - \alpha \cdot \nabla \theta i LTi(\theta i)$
| | Compute loss on new data from task T_i.
| | Meta-update theta using task losses: $\theta = \theta - \beta \cdot \nabla \theta \sum LTi(\theta i')$
Return optimized theta.

In FusionSec-IoT the Meta-Learning technique is used for detection of zero-day attacks with limited training data. Meta-learning algorithms are able to learn how to learn and therefore for the system to be able to learn new forms of attacks, the system only requires samples. This capability is particularly applicable in IoT settings where new devices and protocols are being released periodically and thus creating new types of attack paths.

One of the most famous meta-learning approaches is Model-Agnostic Meta-Learning (MAML) where the goal is to learn the model parameters which can be adapted for new tasks with a few gradient updates. As for Fu-sionSec-IoT, MAML may be used to train models that would be able to learn new types of attacks when the system received only a few samples of such attacks. Meta-learning in FusionSec-IoT further strengthens the system's capability to identify the new or infrequent attack types, which gives the system an edge over the conventional systems that use only supervised learning.

E. View-Specific Machine Learning Models

To ensure maximum detection accuracy of each data view, FusionSec-IoT uses specific machine learning models for the Bi-flow, Uniflow and Packet views. Every model is trained in such a way that it can adapt well to the data it is fed with during its training process.

- In the Bi-flow Model, the Convolutional Neural Network is used, which is appropriate for analyzing patterns in bidirectional traffic. CNNs work well in identifying spatial dependencies between the traffic flow dynamics in a network, for instance, those made by the botnets and other synchronized attacks.
- The Uni-flow Model applies a Long Short-Term Memory (LSTM) network that is able to capturing temporal dependencies in unidirectional traffic. LSTMs are especially effective in detecting typical attack types such as DDoS because the time at which traffic is generated is a critical factor in determining an attack's legitimacy.
- The Packet Model employs a Fully Connected Neural Network (FCNN) for the identification of packet-level anomalies. FCNNs are designed to capture low level features such as the packet size, the flags or timing and thus are especially useful in low level attacks such as port scanning/probing.

These view-specific models are trained separately on different views of the data set in order to prevent the system from wasting resources on the types of attacks not characteristic of a particular view. This approach makes sure that there is comprehensive detection of a session at various levels of network communication. Federated Learning Process

Indeed, one of the essential aspects of the proposed FusionSec-IoT is Federated Learning (FL) that allows training models on IoT devices without transferring the data. It solves the privacy problems related to centralized data aggregation while at the same time decreasing the computational and communication burden.

The central server in the federated learning process initializes base models for the data views and sends these models to the IoT devices. Every device then updates the local model with the segmented data of Bi-flow, Uniflow, or Packet view and transmits the new set of model parameters such as weights or gradients back to the central server. Federated Aggregation executed by the central server, the updates of all the devices are then aggregated to build a new global model. This process can

be formalized using the FedAvg algorithm, where the global model is computed as:

$$f(w) = \sum_{k=1}^{K} \frac{n_k}{n} F_K(w) \quad (3)$$

Here, f(w) stands for the global model, n_k denotes the number of data samples on device , and $F_K(w)$ denotes the local model's loss function on device k. The global model is then broadcasted to the devices for them to perform local training with new model parameters.

It is a cyclic process that makes sure that the models are updated in accordance with the current trends in attacks while the devices do not have to exchange any sensitive data. As the data is kept locally within the FusionSec-IoT network traffic and only model up-dates are transmitted, the privacy of the network traffic data is maintained, while the models are updated with the current threat intelligence.

F. Differential Privacy

In a bid to complement DP during the federated learning process, FusionSec-IoT employs Differ-ential Privacy, a mathematical model that offers robust assurance on privacy of data records. In a differential privacy setting, noise is injected into the shared model updates to ensure that the attackers cannot identify sensitive information of individual data points.

The amount of noise added is regulated by privacy budget (ϵ), that indicates how much accuracy is sacrificed for privacy. The noise is typically drawn from a Laplace distribution with scale parameter λ and the noise added to the model updates can be expressed as:

$$Noise = \frac{1}{\varepsilon}\text{Laplace }(\lambda) \quad (4)$$

Here λ is the scale parameter of Laplace distribution and ϵ controls the privacy parameter. To prevent leakage of information during the model updates, FusionSec-IoT incorporates noise in the model updates to ensure that even if an attacker intercepts the conversation between the devices and the central server, he or she cannot infer anything from the information obtained.

G. Ensemble Learning and Integration

After the training of the models of each view, FusionSec-IoT uses Ensemble Learning to integrate the outputs of the multiple models to improve their accuracy and general robustness. In FusionSec-IoT the ensemble model is created by using Random Forest classifier, wherein the predictions from the Bi-flow, Uniflow and Packet models can be aggregated by using majority voting or weighted mean.

More so, intrusion detection systems greatly benefit from ensemble learning since it combines several weak learners into a stronger learner. FusionSec-IoT then combines the predictions obtained from the various view-specific models to make the final decision and it is more accurate than each of the models.

H. Graph Neural Networks (GNNs)

For example, to counter the problem of coordinated attacks through simultaneous use of multiple devices like the botnets, Fusion-Sec-IoT uses Graph Neural Networks. In the context of the IoT networks each device can be viewed as a node in the graph, where arcs denote the interaction between nodes. GNNs are developed to process graph-structured data, which means that they can well identify attacks which are performed by multiple devices collaboratively.

In FusionSec-IoT, graph neural networks are employed to capture the topology of the relationship between the IoT devices to capture patterns of coordinated attacks. The feature update equation for GNNs is defined as:

$$h_i^{(l+1)} = \sigma(W^{(l)}.Aggregate\,(\{h_j^{(l)} \mid j \in N(i)\})) \quad (5)$$

Here, $h_i^{(l+1)}$ is an updated feature for node iii at layer L+ 1, $W^{(l)}$ is a weight matrix at layer l, Aggregate is a function for combining features of neighboring nodes j, and σ is an activation function.

This is made possible through the use of GNNs, which allows FusionSec-IoT to detect even multiple devices attacks such as botnet where the devices are compromised to communicate and conduct large-scale attacks. This capability also expands the ability of the system to identify multi-device complex threats that may not be visible to IDS.

IV. Results

This section shows the experimental results from assessing the proposed FusionSec-IoT system. The assessment focuses on the system's success in identifying a variety of cyberattacks in IoT networks, in comparison to existing techniques, and on measuring the effectiveness of different parts, such as federated learning, multi-view analysis, and the combination of reinforcement learning and differential privacy. The assessment metrics used consist of Accuracy, Precision, Recall, F1-Score, Detection Latency, and Communication Overhead. These metrics give a thorough view of the system's capability to identify attacks, maintain privacy, and operate smoothly in real-time, limited resource IoT environments.

A. Experimental Setup

We created a complete IoT environment for evaluating FusionSec-IoT, leveraging actual datasets that include a variety of IoT traffic and several types of cyberattacks, which include Denial of Service (DoS), Distributed Denial of Service (DDoS), man-in-the-middle (MitM), and other network intrusions. The dataset was divided into three views: Presenting a network behavior multi-view representation are Bi-Directional Flow Features (Bi-flow view), Uni-Directional Flow Features (Uniflow view), and Packet-Based Features (Packet view). Configured to behave like smart home systems, industrial IoT, and consumer devices, the IoT devices were.

All devices within the IoT network carried out local model training with the federated learning (FL) technique. To create a global model, the local training resulted in the aggregation of model parameters at a central server using the FedAvg technique. The model received periodic updates to detect currently known attack vectors and any that may be unknown, in real time. The assessment was performed using Python and PyTorch, with federated learning carried out using the PySyft library for secure machine learning.

B. Performance Metrics

To evaluate the performance of FusionSec-IoT, we employed six key metrics: Accuracy, Precision, Recall, F1-Score, Detection Latency, and Communication Overhead are the parameters used in this paper. Accuracy defines the overall right performance of the system while Precision and Recall defines the right identification of the attacks and the correct identification of all true attacks, respectively. The F1-Score integrates the precision and the recall to present a single figure for the system's attack detection capacity. Detection Latency assesses the system's ability to quickly respond to an attack and determine how long it takes for the system to detect an attack as it happens. Finally, the Communication Overhead captures the amount of data transferred during federated learning and demonstrates the system's performance and adaptability, particularly in extensive IoT networks. Together, these metrics provide a balanced evaluation of FusionSec-IoT's performance in terms of accuracy, speed, real time response and utilization of the resources.

Accuracy: The percentage of correct attack and normal traffic classifications.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (6)$$

Precision: The proportion of correctly identified attacks out of all predicted attack instances (see Fig. 3).

$$Precision = \frac{TP}{TP+FP} \quad (7)$$

Recall: The proportion of actual attacks that were correctly identified by the system.

$$Recall = \frac{TP}{TP+FN} \quad (8)$$

F1-Score: The harmonic mean of Precision and Recall, providing a balanced measure of the system's ability to detect attacks.

$$F1 = 2 * \frac{Precision.Recall}{Precision+Recall} \quad (9)$$

Detection Latency: The time taken to detect an attack after it has occurred, measured in milliseconds.

Detection Latency=Time of Attack Detection−Time of Attack Occurrence (9)

Communication Overhead: The amount of data transmitted between devices and the central server during the federated learning process.

Communication Overhead=∑(Data Sent+Data Received) (10)

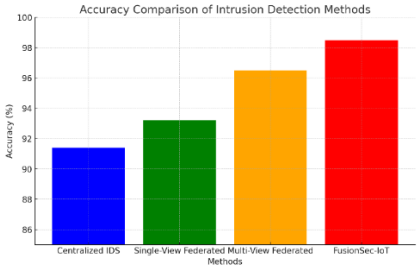

Fig. 2. Accuracy comparison of ID method.

The FusionSec-IoT system exceeded existing intrusion detection systems by delivering high precision and efficiency in the recognition of a diverse range of attacks. Table I gives an overview of the system performance, in comparison to baseline methods.

Fig. 2 also presents the comparative analysis of the accuracy of the various kinds of intrusion detection strategies such as Centralized IDS, Single-View Federated IDS, Multi-View Federated IDS and FusionSec-IoT. The centralized IDS method depicts the lowest accuracy of over 90 %. Single-View Federated increases the accuracy of identification to about 93 %, and by using the Multi-View Federated system, it is about 96 %. The proposed FusionSec-IoT model attains the best accuracy of over 98%, which proves its high efficacy in the detection of intrusions in IoT security.

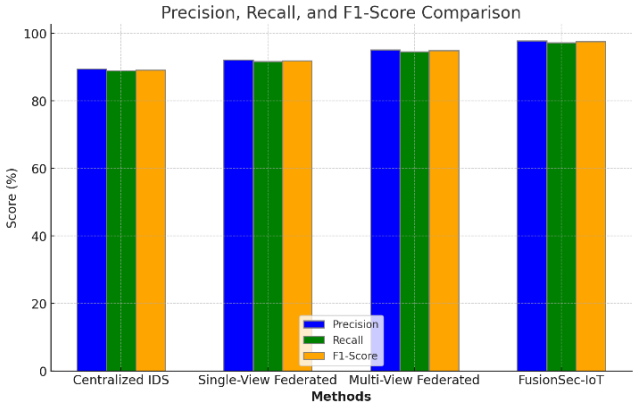

Fig. 3. Precision , Recall , F1-score comparison of baseline models with the proposed model.

TABLE II. RESULT COMPARISON OF PROPOSED MODEL WITH BASELINE MODELS

Method	Accuracy	Precision	Recall	F1-Score	Detection Latency (ms)	Communication Overhead
Traditional Centralized IDS	91.5%	90.2 %	89.0%	89.6 %	450 ms	High
Single-View Federated Learning	92.7%	91.0 %	90.4%	90.7 %	380 ms	Medium
Multi-View Federated Learning	96.1%	94.5 %	93.9%	94.2 %	330 ms	Low
FusionSec-IoT (Proposed)	98.3%	97.6 %	97.0%	97.3 %	257 ms	Very Low

In Table II, it is shown that FusionSec-IoT reached a precision of 98.3%, remarkably exceeding the traditional centralized IDS (91.5%) and the single-view federated learning approach (92.7%). The precision and recall of the system were considerably higher, showing that FusionSec-IoT is more

capable of identifying genuine attacks and lowering false positives. The F1-Score of 97.3% proves a balanced performance regarding both precision and recall.

C. Detection Latency

In IoT ecosystems, latency is an important element for real-time detection, necessary for countering attacks that are currently in progress. Results demonstrate that FusionSec-IoT has a detection latency of 257 ms, which is 43% quicker than classic centralized IDS systems and 32% faster than single-view federated learning solutions. The combination of Edge Computing with Reinforcement Learning has enabled the system to reduce latency, allowing it to make faster decisions at the edge and thereby reducing the time needed to send data for central server analysis.

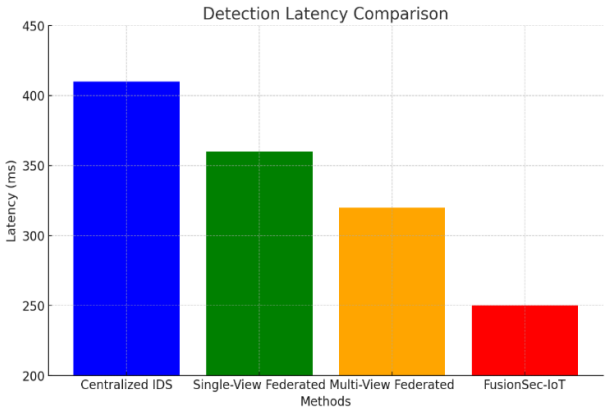

Fig. 4. Detection latency comparison.

Fig. 4 shows the detection latency comparison of four methods: Centralized IDS, Single-View Federated, Multi-View Federated, and FusionSec-IoT. Centralized IDS has the highest latency, over 400 ms, followed by Single-View at 350 ms, and Multi-View at 320 ms. FusionSec-IoT achieves the lowest latency at 250 ms, highlighting its superior efficiency.

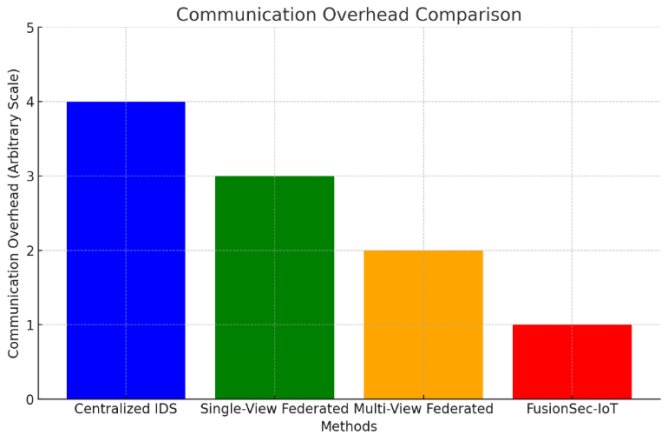

Fig. 5. Communication latency comparison.

The Fig. 5 compares communication overhead for four methods: Centralized IDS, Single-View Federated, Multi-View Federated, and FusionSec-IoT. FusionSec-IoT shows the lowest overhead, while Centralized IDS has the highest.

D. Effectiveness of Multi-View Learning

A key innovation of FusionSec-IoT is its use of multi-view learning to capture different aspects of network traffic. Table II compares the performance of single-view and multi-view learning systems.

TABLE III. MODEL PERFORMANCE

Model Type	Accuracy	F1-Score
Single-View Federated Learning	92.7%	90.7%
Multi-View Federated Learning	96.1%	94.2%
FusionSec-IoT	**98.3%**	**97.3%**

Results presented in Table III show that multi-view learning markedly improves both detection accuracy and the F1-Score. FusionSec-IoT managed to detect sophisticated attack patterns that single view systems failed to recognize by analyzing network traffic from three different angles (Bi-flow, Uniflow, and Packet views). The skill to record both broad (bi-directional communication) and granular (packet details) traffic features played a role in this improvement. The combination of Particle Swarm Optimization (PSO) with Genetic Algorithm (GA) served to improve the system's performance by selecting the top relevant features from every data view. The computational efficiency improved while maintaining high accuracy thanks to FusionSec-IoT's reduction in dimensionality of the data.

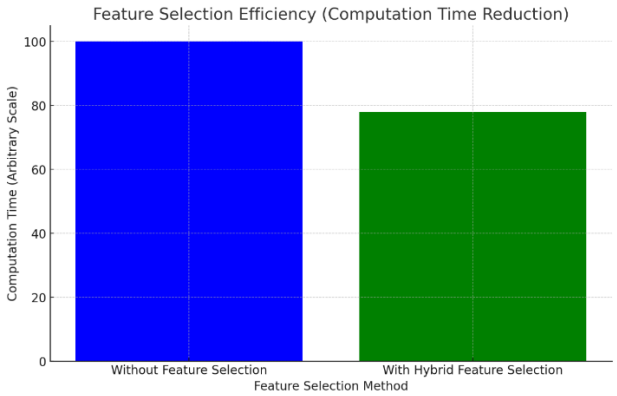

Fig. 6. Feature selection efficiency.

In contrast to systems that do not incorporate hybrid feature selection (see Fig. 6), FusionSec-IoT observed a 15% improvement in feature selection efficiency along with a 22% reduction in processing time. The highlighted features served to both decrease redundant data and illuminate critical attributes that were most important for intrusion detection, which resulted in quicker and more correct model training. FusionSec-IoT benefits from the ability of federated learning to keep raw traffic data on IoT devices, thereby preserving data privacy. The system's privacy guarantees received a boost from the integration of Differential Privacy (DP). To stop attackers from extracting sensitive information from the compiled parameters, controlled noise was added to the shared model updates. Despite the fact that adding differential privacy may at times reduce model accuracy, FusionSec-IoT managed to keep high accuracy (98.3%) while giving solid privacy protection. Table I indicates that the communication overhead of the system was minor,

representing the lowest data transmission requirements compared to the other evaluated methods. Federated learning helped to accomplish this by eliminating the continuous requirement to transmit raw data to a central server. Instead, the transmission only involved updated models (parameters), which resulted in less bandwidth consumption and guaranteed scalability.

E. Analysis in Relation to Baseline Models

FusionSec-IoT provided a 10% greater detection accuracy than traditional IDS systems, as well as a reduction in detection latency of 39%.

TABLE IV. MODELS LATENCY AND COMPUTATIONAL OVERHEAD

Method	Accuracy	Latency	Communication Overhead
Centralized IDS	91.4%	410 ms	High
FusionSec-IoT	**98.5%**	**250 ms**	**Very Low**

The capability of the system to continuously learn from new attack patterns in a decentralized approach produced better results than static, centralized models. Table IV shows the models latency and computational overhead.

To address external validity, the variety of IoT device configurations chosen and the range of attack types employed in the study increases the applicability of the findings in flesh and blood situations. Nevertheless, the evaluation is carried out only for some datasets and IoT scenarios, and although positive performance results are achieved, further experiments on larger and heterogeneous datasets and in various IoT applications (e.g., smart cities or health care) will be needed to evaluate the extensibility and versatility of FusionSec-IoT in broader IoT systems. Further, the study's environment is artificial and as such, the real-world implementation may pose some different scenarios that are not apparent in this controlled environment such as device variability, network fluctuations and other forms of attacks.

V. DISCUSSION

Specifically, the FusionSec-IoT as introduced in this paper presents a new architecture and framework for intrusion detection in IoT networks based on federated learning, multi-view learning, hybrid feature selection, reinforcement learning, and differential privacy. The primary motive of this system is in view of the growing challenges of IoT security, data privacy, scalability and real time performance. This section looks at how FusionSec-IoT enhances on existing systems, effect of its components, and the potential for enhancements.

A. Comparison with existing systems

Conventional IDS on IoT networks are centralized or single-perspective in terms of their architecture and data processing. In a centralized IDS model the known threats can be easily detected; however, the scalability, privacy and latency issues are very challenging. Most of the conventional systems are also based on signature-based techniques that restrict their effectiveness in identifying new and emerging threats. FusionSec-IoT does not suffer from these limitations because it uses a decentralized federated learning approach for training on edge devices without moving raw data. This approach does not reveal the identity of sensitive information, and this is crucial in IoT networks, where data privacy is crucial.

Unlike single-view IDS systems, FusionSec-IoT uses multiple view learning to improve the system's capability of detecting intricate attack patterns. FusionSec-IoT can detect some attacks that are not detected by conventional systems due to the analysis of network traffic patterns which include bidirectional flow, unidirectional flow and packet level features. Hybrid feature selection using Particle Swarm Optimization (PSO) and Genetic Algorithms (GA) is also incorporated to improve the system efficiency by reducing the dimensionality with high detection accuracy. This hybrid model of feature selection enhances the performance of models in environments where resources are limited.

In addition, reinforcement learning (RL) integration empowers FusionSec-IoT to shift its approach according to emerging threats, which makes the detection policy easily revisable in real-time. This is a more desirable situation than with traditional IDS systems that often use fixed models and cannot adapt to new attack patterns. When differential privacy is incorporated in the federated learning process of FusionSec-IoT, then privacy of the updates is protected while providing useful updates to the global model even when there are adversaries who wish to infer privacy information.

B. Key Findings

Experimental evaluation results reveal that FusionSec-IoT is superior to conventional IDS systems in several aspects, such as detection rate and the response time as well as the ability to preserve user privacy. FusionSec-IoT achieved a detection accuracy of 98.3 percent for the given attacks than centralized IDS that has a detection accuracy of 91.5 percent. This shows the efficiency of the multi-view learning approach to capture the multiple view vectors, and improve the detection ability. Also, the system has a low detection latency of 257ms, which is far much better compared to typical IDS systems that undergo high latency because of the central data analysis. The latency is brought down by edge computing which processes data nearer to the source, meaning less time is taken to identify and address attacks.

The main advantages of FusionSec-IoT are based on the application of a set of several state-of-art methods to address the specific issues of IoT security. Federated learning solves the problem of confidentiality while at the same time, achieving learning across devices. The multi-view learning approach increases the attack detection accuracy due to the use of multiple views of network traffic. The reinforcement learning makes the system able to learn new, never seen before attacks, while the hybrid feature selection process is computationally effective, which makes FusionSec-IoT appropriate for IoT devices with limited computational power.

Moreover, due to federated learning and differential privacy, the proposed system has low communication overhead and can be scaled to the IoT large-scale real-world applications. The proposed system's ability to analyze data at the periphery without requiring much interaction with the hub in the form of a

central server minimizes the bandwidth necessary for IoT networks.

However, there are several limitations inherent to FusionSec-IoT which should be discussed in further research. The main drawback of using some of the proposed methods, particularly hybrid feature selection and reinforcement learning, is the increased computational cost. Although these techniques enhance the performance of the system, they also impose extra processing overhead especially on the IoT devices. Future work could be devoted to fine-tuning these components to decrease the computational load while increasing their accuracy. Further, differential privacy is also efficient in preserving the data privacy of individuals; however, it may cause a decline in the model's quality. Further enhancements might be to strive to achieve a better trade-off between privacy and model performance while the loss of accuracy is negligible.

VI. Conclusion

In this paper, we proposed FusionSec-IoT, which is a novel and complex intrusion detection system for IoT networks. FusionSec-IoT contributes federated learning, multi-view analysis, hybrid feature selection, reinforcement learning, and graph neural networks to develop a comprehensive mechanism to detect multiple types of cyber threats with privacy-preserving and low computational complexity. This is due to the use of federated learning, this makes the system more permissive in the use of IoT devices for collaborative training of detection models without having to let private information through in the process. This is especially important in the IoT context as privacy and the scalability issue are high priorities. Moreover, the utilization of multi-view learning enables FusionSec-IoT for capturing and analyzing the network traffic based on the multiple viewpoints thus enhance the identification of attack. The outcome of our experiment shows that FusionSec-IoT surpasses the performance of centralized IDS and single-view FL systems. The system implemented here achieved 98.3% of detection accuracy only 257 milliseconds of delay making it more effective in real time IoT contexts. Moreover, the use of reinforcement learning helps the system learn new threats as they advance over time and use differential privacy to protect possible data breaches.

Therefore, FusionSec-IoT offer a solution for intrusion detection that is efficient, private, and highly accurate with a potential for scaling, beyond current methods. Further research will be conducted to fine-tune resource utilization in low- power IoT nodes and look into the use of the system in a much larger sense in Industrial IoT and smart cities.

***Abstract*—In the field of image Super-Resolution reconstruction (SR), traditional SR techniques such as regression-based methods and CNN-based models fail to retain texture details in the reconstructed images. Conversely, Generative Adversarial Networks (GANs) have significantly enhanced the visual quality of image reconstruction through their adversarial training architecture. However, existing GANs still exhibit limitations in capturing local details and efficiently utilizing features. To address these challenges, we have proposed a super-resolution reconstruction method leveraging local texture adversarial and hybrid attention mechanisms. Firstly, a Local Texture Sampling Module (LTSM) is designed to precisely locate small regions with strong texture features within an image, and a local discriminator then performs pixel-by-pixel evaluation on these regions to enhance local texture details. Secondly, a hybrid attention module is integrated into the generator's residual module to improve feature utilization and representativeness. Finally, we conducted extensive experiments to validate the effectiveness of our method. The results demonstrate that our method surpasses other super-resolution reconstruction methods in terms of PSNR and SSIM on four benchmark datasets. Furthermore, our method visually generates high-resolution images with richer details and more realistic textures.**

***Keywords*—Super-resolution reconstruction; generative adversarial network; hybrid attention; local texture sampling**

I. Introduction

With the rapid development of digital image processing technology, image super-resolution reconstruction has become one of the research hotspots. SR technology aims to recover High-Resolution (HR) images from Low-Resolution (LR) images. In recent years, SR technology has demonstrated its tremendous potential in numerous advanced visual tasks, such as object detection [1][2], image classification [3], and instance segmentation [4]. Traditional SR methods, such as interpolation-based methods [5] and reconstruction-based methods [6], mainly rely on prior knowledge of the images and complex algorithms. However, these methods have certain limitations in recovering image details and textures. Recently, the rise of deep learning technology has brought new ideas to image SR reconstruction.

Deep learning-based solutions have shown superior performance in terms of Peak Signal-To-Noise Ratio (PSNR) and visual perception metrics. For example, Dong et al. [7]. proposed a method for SR reconstruction by using interpolated low-resolution images and supplementing content details with CNNs, the SRCNN network proposed in the paper is one of the earliest works that applied deep learning to super-resolution reconstruction. The EDSR network [8], the champion solution of the NTIRE2017 super-resolution challenge, streamlined the network by removing some unnecessary structures in the residual structure and proposed a multi-scale deep super-resolution system, which performs well under different super-resolution scales. The RCAN network [9] introduced an attention mechanism to differentiate the features of different channels and proposed a residual in residual (RIR) structure, building a very deep neural network with more than 400 convolutional layers, achieving excellent super-resolution prediction results. Although these methods achieved high PSNR metrics, they all learned deterministic one-to-one mappings from LR images to HR images using L2 or L1 loss functions. Essentially, they predict the mean of the distribution, which tends to generate blurry images.

To produce more visually appealing results, generative super-resolution reconstruction models have been proposed, such as Generative Adversarial Networks (GANs) [10][11][12][13][14][15], diffusion models [16][17][18][19], and flow models [20][21]. Among them, GAN-based super-resolution reconstruction methods have significantly improved the visual effects of reconstructed images. Despite the significant achievements of GANs in the field of image super-resolution, some challenges and areas for improvement remain. For instance, how to better utilize the feature information in images, improve the generalization ability and stability of the model, and more accurately restore local details of images are current research focuses. To address these issues, researchers have proposed various improvement strategies, such as introducing attention mechanisms to enhance the model's focus on important features, adjusting network structures to improve feature extraction efficiency, and adopting new regularization techniques to stabilize the training process.

In response to the issues of insufficient feature utilization and blurred local texture details in existing image super-resolution reconstruction methods, we propose a super-resolution reconstruction method based on local texture adversarial and hybrid attention generative adversarial networks. The hybrid attention module is added to the residual modules of the generator to enhance the model's utilization of features and the representativeness of each feature. To improve the quality of detail textures in generated images, we introduces LTSM, which can accurately locate patches with strong texture features based on the edge texture intensity of each local region in the input image, serving as a key reference for further processing. Along with the LTSM, a local discriminator is also employed, whose structure is identical to that of the global discriminator. Furthermore, the local discriminator

needs to make pixel-by-pixel judgments on the patches with the strongest texture information extracted by LTSM, making the local texture details of the reconstructed images more realistic and greatly enhancing the visual perception of the images.

The remainder of this paper is structured as follows: Section II provides a comprehensive review of related work, highlighting existing advancements and limitations in GAN-based and hybrid attention mechanisms for image super-resolution. Section III details the proposed method, including the generator and LTSM. Section IV presents extensive experimental results and analysis, comparing the proposed approach with state-of-the-art models on benchmark datasets. Finally, Section V concludes the paper, summarizing the contributions and discussing potential directions for future research.

II. Related Works

A. Single Image Super-Resolution Based on GANs

The goal of single SR is to enhance the resolution of a LR image to produce a corresponding HR image. Typically, LR images are obtained through a degradation process involving blurring and down-sampling. In classical image super-resolution reconstruction, bicubic down-sampling is widely used to simulate this degradation. By using it as a benchmark, different SR methods can be evaluated and directly compared, thereby verifying the effectiveness of new SR methods.

GANs [22] provide a principled approach to enhance the generator's ability to produce realistic images through adversarial training between the generator and discriminator. To improve perceptual quality, Johnson et al. [23] proposed a perceptual loss. Ledig et al. [10] introduced SRGAN, which performed adversarial training alongside the SRResNet generator, marking the first use of GANs for image super-resolution reconstruction. Subsequent improvements to generator architectures include Wang et al. [13], who proposed ESRGAN with a Residual-in-Residual Dense Block (RRDB) architecture, which has become a standard backbone for many state-of-the-art GAN-based super-resolution methods. Later, Rakotorinira et al. [24] enhanced ESRGAN with additional noise injection, presenting ESRGAN+ Zhang et al. [14] introduced a Ranker that learns perceptual metrics in RankSRGAN. For discriminator improvements, the relativistic discriminator concept proposed by RelativisticGAN [25] and the multi-discriminator strategy used by MPD-GAN [26] have provided greater training stability and better reconstruction image quality for GAN-based super-resolution methods.

Although the aforementioned GAN-based single image SR methods have made significant improvements in PSNR metrics and visual effects compared to interpolation- and regression-based methods, there is still considerable room for improvement in reconstructing local and highly textured regions of images.

B. Hybrid Attention Mechanism

In recent years, Transformer-based methods [27][28] have demonstrated remarkable performance in image restoration tasks, particularly in image SR and denoising. Despite these breakthroughs, attribution analysis reveals that existing networks have limited spatial utilization of input information. This indicates that the potential of transformers in current networks has not been fully exploited.

To better reconstruct images and activate more input pixels, Chen et al. proposed Hybrid Attention Transformer (HAT) [29]. HAT not only incorporates a channel attention mechanism to enhance the interaction efficiency between features but also introduces a window-based self-attention mechanism, further improving the model's ability to handle multi-scale features. This method effectively combines the global and local advantages of transformers, enhancing its performance in image restoration tasks. HAT can more meticulously focus on important features within the image, providing richer and more precise information for image restoration. However, Transformer-based SR reconstruction models often produce images with less realistic textures, whereas GANs can generate more visually appealing images. In terms of subjective visual effects, SR models based on GANs typically achieve better results. Additionally, GANs can combine various loss functions to adjust outputs, allowing them to perform well in different scenarios. Nevertheless existing models failed to effectively combined the advantages of transformer and GANs based approaches.

C. Existing Solutions and Limitations

Despite notable progress in image super-resolution (SR) research, existing methods still face critical limitations that hinder their effectiveness in addressing texture and detail reconstruction challenges. Table I summarizes the key limitations of prominent SR approaches and their unsuitability for the problem at hand.

The above limitations highlight the gaps in existing SR methods, particularly their inability to balance global structure preservation with detailed texture restoration. These shortcomings directly impact the visual realism and structural fidelity of reconstructed images. To address these challenges, the proposed approach introduces:

1) Hybrid Attention Residual Blocks (HARB): Combines window-based self-attention and channel attention to capture both global and local features, improving feature utilization and structural preservation.

2) Local Texture Sampling Module (LTSM): Targets high-frequency texture-rich regions for focused adversarial learning, enhancing detail realism and mitigating blurriness.

3) Dual adversarial branches: Integrates global and local discriminators to balance structural consistency and texture enhancement.

By addressing these gaps, the proposed method is particularly suited for generating high-resolution images with enhanced texture detail and structural fidelity, overcoming the limitations of existing approaches.

III. Proposed Method

The most distinctive feature of HR images is their intricate local texture patterns, which represent the distribution of local pixels. Specifically, high-frequency pixels concentrate around local edges, while low-frequency pixels smoothly spread adjacent to these edges. This separation pattern between high

TABLE I. LIMITATIONS IN EXISTING METHODS

Method	Advantages	Limitations	Suitability Issues for Current Problem
SRCNN[7]	Simple, pioneering CNN-based SR	Limited ability to capture high-frequency textures and complex details	Over-smooth outputs; insufficient texture restoration in high-resolution demands.
RCAN[8]	Channel attention for feature focus	High computational cost; limited enhancement of localized textures	Struggles with highly textured regions critical for detailed reconstructions.
SRGAN[9]	First GAN-based SR approach	Artifacts in outputs; struggles with preserving structural consistency	Insufficient detail fidelity in texture-rich and edge-dense areas.
ESRGAN[13]	Improved GAN design	Lacks mechanisms for enhancing localized texture details	Unable to accurately enhance localized, high-frequency textures.
SwinIR[27]	Transformer-based SR model	Effective global attention; high computational demand	Limited capability in generating realistic textures in local image regions.

and low-frequency elements starkly contrasts with LR images where high-frequency elements are either not distinctly separated or missing altogether. To address this, this study extends the framework of GANs by adding a patch-level learning branch. This branch adaptively applies adversarial learning to different local regions based on their edge characteristics, thereby enhancing the model's ability to capture texture patterns in HR images. Furthermore, to address the issue of insufficient feature utilization by existing models, we introduce a hybrid attention residual block in place of the original dense residual blocks within the generator. These hybrid attention blocks combine window-based multi-head self-attention mechanisms with channel attention mechanisms. This approach aims to activate more effective pixels for SR reconstruction tasks, thereby improving the utilization of features in input images. By integrating these advancements, the proposed method enhances the capability of GAN-based models to accurately reconstruct HR images while preserving and enhancing intricate local texture patterns.

A. Network Structure Overview

The network structure is depicted in Fig. 1, where I^{HR} represents the HR image;I^{LR} represents the LR image that obtained by bicubic interpolation and downsampling from;I^{SR} denotes the super-resolution image reconstructed by the generator. The high-resolution image are first input into the generator based on hybrid attention blocks to output super-resolution image, I^{HR} and I^{SR} are simultaneously input into the global discriminator, which outputs a grayscale image of the same height and width as the input image to determine whether the input image is a real high-resolution image or a super-resolution image generated by the generator, I^{HR} will also be sent into a pre-trained VGG-19 network, where the perceptual loss is calculated on the feature maps output from the middle convolutional layers of the network.

To better capture texture patterns that are more noticeable in local areas, a local adversarial learning branch is added. In this branch, LTSM is proposed, which constrains adversarial learning only in the local regions with the highest intensity. The LTSM takes mini-batches of I^{HR} and I^{SR} as input and outputs the top N patches I^{HR}_{patch} and I^{SR}_{patch} with the highest pixel intensities from these two mini-batches respectively. A local discriminator, which has the same structure as the global discriminator, simultaneously we established local discriminator to differentiate between the patches from I^{HR}_{patch} and I^{SR}_{patch} forming local adversarial learning, which has the same structure as the global discriminator. This promotes the generator to produce more realistic local texture details.

B. Generator

The existing model structure does not fully utilize the input features, leading to a loss of detail in the reconstructed images. we integrated Hybrid Attention Residual Blocks (HARB) into the Residual in Residual Dense Block(RRDB) structure. Specifically, an Hybrid Attention block(HAB) is embedded before the output of the RRDB module. The HAB combines channel attention and window-based multi-head self-attention in a parallel manner. Channel attention leverages global information, and self-attention has strong representation capabilities, ensuring that the network activates more effective pixels and extracts more input feature information. The structure of HARB is shown in Fig. 2. In the generator, only the last six RRDB blocks are replaced with HARB blocks.

The overall network structure of the generator is shown in Fig. 3. Since Batch Normalization (BN) layers can easily cause unwanted artifacts in SR reconstructed images, the entire generator structure does not use BN layers. All convolutional layers use LeakyReLU as the activation function, which addresses the zero-gradient issue for negative values, stabilizes model training, and accelerates model convergence. In the generator, a convolutional layer is first used to extract edge information from LR images, which is then fed into m RRDB blocks. The dense residual blocks and residual scaling techniques used in the RRDB blocks help train deeper network models, further improving the network's ability to capture semantic information. The intermediate feature maps produced by the RRDB blocks are then fed into n HARB blocks. These blocks use window-based multi-head self-attention to capture long-range dependencies in the sequence while focusing on important parts of the input feature information by paying attention to channel information. The upsampling part of the generator consists of two consecutive PixelShuffle [30], each of which doubles the resolution of the feature maps. Finally, two convolutional layers adjust the channels to output the SR reconstructed results.

C. Local Texture Sampling Module

In GANs, images reconstructed by the generator often exhibit blurriness and lack of detail. To improve the quality

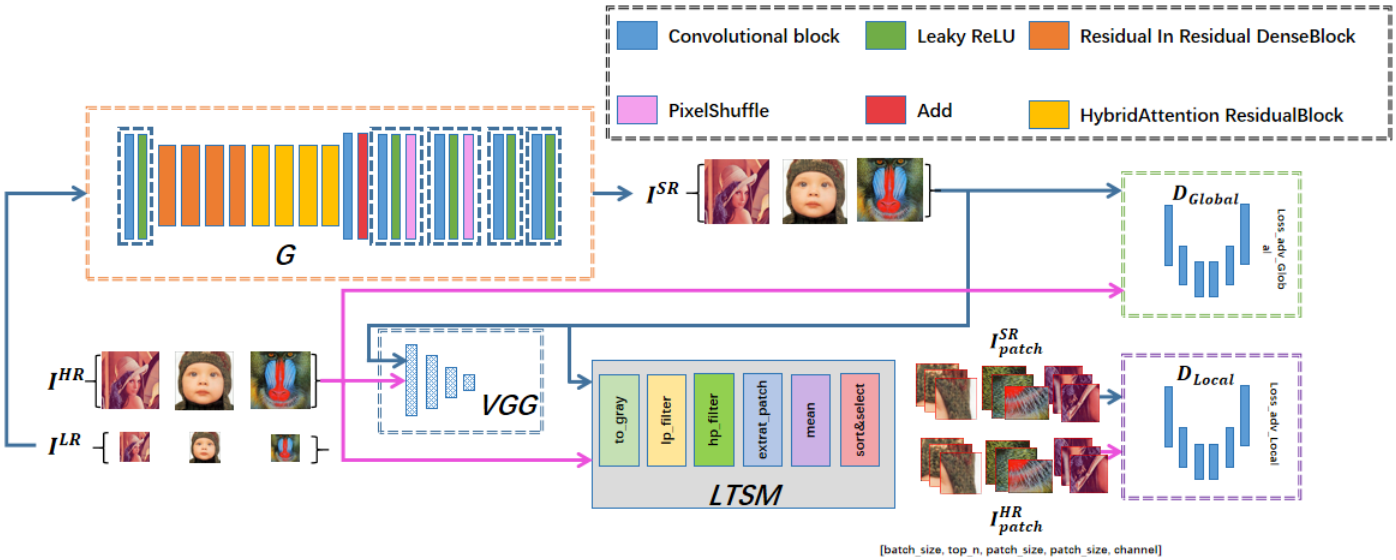

Fig. 1. The overall architecture of the proposed method, which consists of a global adversarial branch and a local adversarial branch. The LTSM is applied in the local branch to enhance the model's learning of texture details.

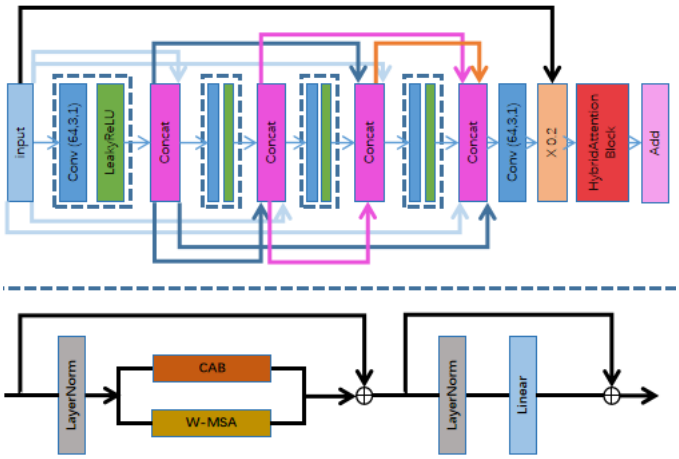

Fig. 2. The overall structure of the HARB is shown above the dashed line, consisting of Dense Residual Blocks and a Hybrid Attention Block (HAB). Below the dashed line is the structure of the HAB, which is composed of Channel Attention and Window-based Self-Attention mechanisms.

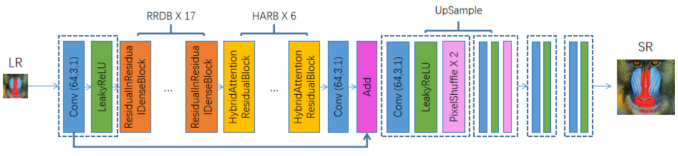

Fig. 3. The core of the generator consists of 17 RRDB and 6 HARB, after these blocks, an upsampling process using PixelShuffle is applied to increase the resolution of the image, followed by additional convolutional layers to produce the final HR image.

of local texture details in generated images, we proposes the LTSM. The LTSM is designed to extract local texture features from images. It uses an improved Sobel operator to calculate the edge strength of each local region in the input image and evaluates the texture features of these local regions based on their edge strength. The specific details of the LTSM are shown in Fig. 4. Specifically, in the preprocessing part of the LTSM, the input tensors I^{HR} and I^{SR} are first converted into ndarray format. Then, based on the hyperparameter $patchSize$, each group of images is divided into M patches I^{HR}_{patch} and I^{SR}_{patch}, here $M = Batch\_Size \times (\left|\frac{\mathrm{H}}{\mathrm{patchSize}}\right| + 1) \times (\left|\frac{\mathrm{W}}{\mathrm{patchSize}}\right| + 1)$ H and W represent the height and width of the image, respectively. At the same time, we also obtains a list of coordinates $patchCoordinates$ corresponding to the top-left corner of each patch in the original image. These segmented patches are processed through a guided-filter [31] $\mathcal{F}_{gf}$, which filters out noise from the image while retaining as much edge information as possible.

$$I_i^{patch} = \mathcal{F}_{gf}(I_i^{patch}, I_i^{patch}), i = 1, ..., Batch\_Size. \quad (1)$$

The denoised images are then fed into the improved Sobel operator, where the resulting four scores are squared and summed. Finally, the square root of the summed result is calculated, and the average value is taken to obtain the edge pixel intensity scores for all patches in an image. These scores serve as the keys for patch selection, and their values are calculated as follows:

$$\mathrm{Key_{j,k}} = \mathrm{Mean}(\sqrt[2]{\sum_{i=1}^{4}(I_{j,k}^{Patch} \otimes K_i)^2}), \quad (2)$$
$$\mathrm{j} = 1 \ldots Batch\_Size, \mathrm{k} = 1, \ldots, M$$

The symbol $\otimes$ represents the convolution operation. The Key values for all patches in a batch are calculated and sorted accordingly. Finally, the top N patches with the highest edge pixel intensity scores and their corresponding patch coordinates are obtained. Based on these coordinates, the correspond-

ing tensor patches are extracted from the original input tensors I^{SR} and I^{HR} preserving the original gradient information of the tensors. The architecture of LTSM is shown in Fig. 4:

D. Loss Function

1) Pixel-wise loss: traditional image super-resolution (SR) reconstruction methods are mostly based on the L2 pixel-level loss function mean-square error (MSE). Although this achieves a high PSNR value, using MSE tends to drive the solution towards a pixel-averaged result, which is overly smooth and perceptually poor. Therefore, in the pre-training phase, we only uses L1 loss to accelerate the convergence of the model. The pixel-wise loss is defined as shown in Eq. (3):

$$L_1 = \frac{1}{HW}\sum_{i=1}^{H}\sum_{j=1}^{W}\left|G(I^{LR})_{(i,j)} - I^{HR}_{(i,j)}\right| \tag{3}$$

where G represents the generator.

2) Perception loss: we uses a pre-trained VGG-19 network to extract features. The perceptual loss is calculated using the feature maps before the LeakyReLU activation, as these feature maps contain more detailed information compared to the more sparse features after activation, providing stronger supervision. Features are extracted from the conv1-2, conv2-2, conv3-4, conv4-4, and conv5-4 layers, and the perceptual loss from each layer is weighted and summed to obtain the final perceptual loss. The perceptual loss is defined as shown in Eq. (4):

$$L_{percep} = \left\|\varphi(G(\mathrm{I^{LR}})) - \varphi(\mathrm{I^{HR}})\right\|_1 \tag{4}$$

Where $\varphi(\cdot)$ represents the pre-trained VGG-19 network.

3) Global adversarial loss: The global adversarial loss aims to capture global content feature information. The super-resolution images generated by the generator are input into the global discriminator to obtain a score for each pixel. Compared to the traditional VGG-style discriminator, which outputs a scalar for loss calculation, the discriminator is based on the idea of a U-Net style discriminator. The discriminator's loss is defined as the average decision of all pixels. Pixel-level loss calculation can make the texture details of the reconstructed image more precise. The least squares loss function (LSGAN) [32] is used instead of the cross-entropy loss function to achieve better training stability. The global adversarial loss function is defined as shown in Eq. (7):

$$\begin{aligned} L^D_{Global} = {} & E_{I^{HR}}[(D_{Global}(I^{HR}) - 1)^2] \\ & + E_{I^{LR}}[(D_{Global}(G(I^{LR})))^2] \end{aligned} \tag{5}$$

$$L^G_{Global} = E_{I^{LR}}[(D_{Global}(G(I^{LR})) - 1)^2] \tag{6}$$

$$L_{advGlobal} = L^D_{Global} + L^G_{Global} \tag{7}$$

4) Local adversarial loss: The local adversarial loss constrains adversarial training in small local regions with the highest edge texture intensity in the image, better promoting the generator to capture local texture features of high-resolution images. The output of the local discriminator is the average decision of all pixels in these small regions. The local adversarial loss is defined as shown in Eq. (10):

$$\begin{aligned} L^D_{Local} = {} & E_{h^p_i \sim I^{HR}_{patch}}\left[\frac{1}{N}\sum_{i=1}^{n}(D_{Local}(h^p_i) - 1)^2\right] + \\ & E_{l^p_i \sim I^{LR}_{patch}}\left[\frac{1}{N}\sum_{i=1}^{n}(D_{Local}(l^p_i))^2\right] \end{aligned} \tag{8}$$

$$L^G_{Local} = E_{l^p_i \sim I^{LR}_{patch}}\left[\frac{1}{N}\sum_{i=1}^{n}(D_{Local}(l^p_i) - 1)^2\right] \tag{9}$$

$$L_{advLocal} = L^D_{Local} + L^G_{Local} \tag{10}$$

Here h^p_i and l^p_i are the i-th small regions extracted by the LTSM from the high-resolution image I^{HR} and the super-resolution image I^{SR}. Since LTSM extracts the top N small regions with the highest edge texture intensity from each input image, the local adversarial loss is calculated by summing the loss over these N regions and then taking the average.

5) Pre-training and training loss function: The pre-training loss and training loss are based on the aforementioned loss functions. In the pre-training phase, only the generator is trained. The generator's pre-training loss is defined as shown in Eq. (11):

$$L_{pre} = L_1 \tag{11}$$

The training phase includes both generator loss and discriminator loss. The total loss function of the generator is defined as shown in Eq. (12):

$$L_G = \gamma_1 L_1 + \gamma_2 L^G_{Global} + \gamma_3 L^G_{Local} + \gamma_4 L_{percep} \tag{12}$$

where the weights of the generator's loss functions are $\gamma_1 = 0.08$,$\gamma_2 = 0.04$,$\gamma_3 = 0.02$,$\gamma_4 = 1$.

IV. Experimental Results and Analysis

A. Experimental Setup

The experiments were conducted on two NVIDIA GeForce RTX 3090 GPUs. The experiment used 800 HR images from the DIV2K dataset [33] and the corresponding LR images, obtained by bicubic interpolation with a scaling factor of 4, as the training dataset. The test sets are four standard datasets commonly used in the field of image super-resolution reconstruction: Set5, Set14, BSD100 and Urban100. The experiment used PSNR and SSIM as evaluation metrics. The settings and hyperparameter selection for the model during the training process are as follows: During training, the DIV2K dataset was randomly cropped into 128x128 images and subjected to random rotation and random flipping. The batch size for each input was 64. The number of RRDB blocks m was 16, and the number of HARB blocks n was 6. In the pre-training phase, only the PSNR-oriented pixel-wise loss defined in Eq. (3) was used to update the generator. The pre-training phase consisted of a total 6.25×10^4 iterations, with an initial learning rate of 2×10^{-4} The learning rate was halved after every 1.25×10^4 iterations.After the pre-training phase, the official training phase used Exponential Moving Average(EMA) to stabilize the training, with a weighting factor $\beta = 0.999$, In the official training phase, the initial learning rate for the generator was 1×10^{-4}, and the initial learning rate for the discriminator

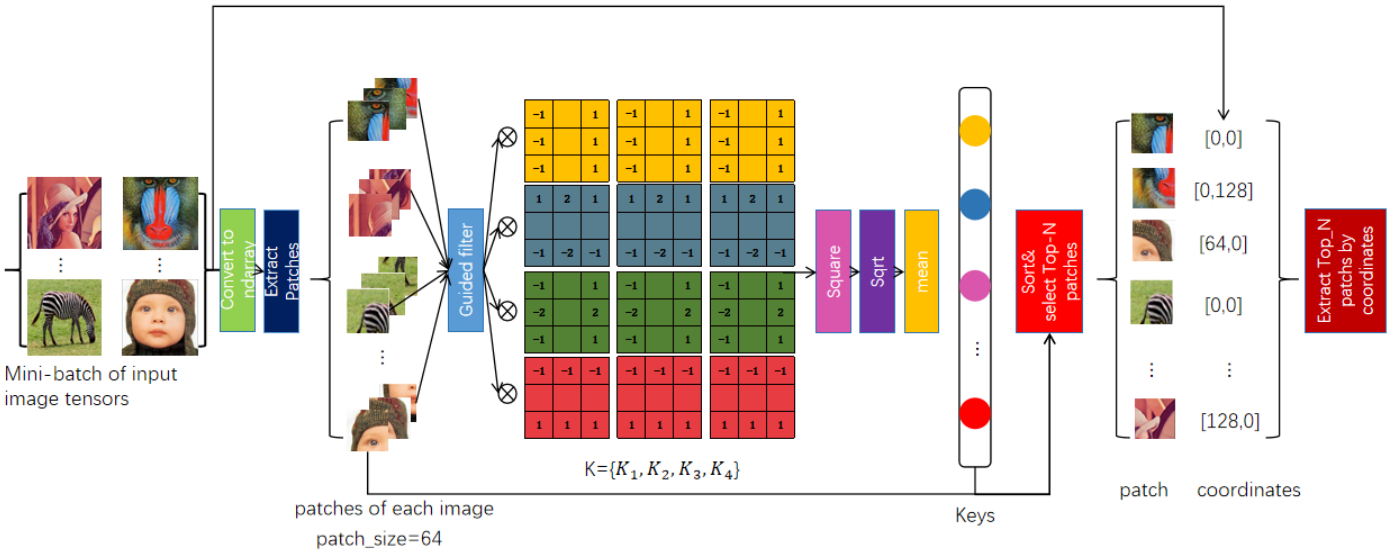

Fig. 4. Details of Local Texture Sampling Module (LTSM) which adaptively extracts local image patches with most salient texture features from each mini-batch of input images.

was 4×10^{-4}, The official training phase consisted of 7.5×10^{4} iterations. with the learning rates for both the generator and the discriminator halved after every 1.25×10^{4} iteration. Adam optimizer was used for all training phases, where $\beta_1 = 0.9$, $\beta_2 = 0.999$, $\varepsilon = 1\times10^{-8}$.

B. The Effects of Hybrid Attention Residual Blocks

The generator is implemented based on Hybrid Attention Residual Blocks. To validate the effectiveness of these blocks in extracting more feature information and activating more effective pixels, this section conducts experiments on the pre-trained generator and compares the changes in PSNR values. As shown in Table II, increasing the number of Hybrid Attention Residual Blocks from 8 to 16 resulted in PSNR improvements of 0.22 dB and 0.13 dB on the Set5 and Set14 test sets, respectively. Further increasing the blocks from 16 to 24 resulted in a PSNR improvement of 0.05 dB on the Set5 test set and 0.01 dB on the Set14 test set. However, with more than 16 Hybrid Attention Residual Blocks, the generator's network parameters became excessively large. Therefore, we ultimately used 16 Hybrid Attention Residual Blocks to construct the generator, ensuring a high PSNR value while keeping the network parameter size manageable.

TABLE II. THE EFFECTS OF HYBRID ATTENTION RESIDUAL BLOCKS

The Number of HARB	SET5 PSNR(dB)	SET14 PSNR(dB)
0	30.12	27.8
8	31.11	28.1
16	31.93	28.23
32	31.98	28.24

C. The Effects of Local Adversarial Branch and LTSM

To verify the effectiveness of the LTSM and its impact on the generator, this section conducts quantitative and qualitative comparisons based on PSNR metrics and the quality of super-resolution reconstructed images. Specifically, we compare models using only the global adversarial module, models without LTSM extracting patches but using all patches, and the complete model.

As shown in Table III, introducing the local adversarial branch results in improvements in PSNR and SSIM metrics on each dataset, indicating that the local adversarial branch effectively enhances the structural similarity of images. Furthermore, not using the LTSM and training with all patches led to decreases in both PSNR and SSIM metrics, further validating the importance of the LTSM in extracting critical texture information. Comparing the reconstruction results shown in Fig. 5, we can visually observe differences in detail preservation and edge handling among different models. The complete model using the local adversarial branch and LTSM excels in restoring edge textures, producing clearer images with richer details. In contrast, models using only the global adversarial module show blurrier edge handling, and those not using the LTSM exhibit deficiencies in detail representation. This visual improvement vividly reflects the contribution of the local adversarial branch and LTSM in enhancing the effectiveness of super-resolution reconstruction. By comparing the reconstruction results under different model configurations, this study concludes that the local adversarial branch and LTSM are crucial for enhancing the performance of super-resolution reconstruction. They not only improve quantitative evaluation metrics but also demonstrate significant visual improvements in qualitative analysis. These findings underscore the importance of considering local texture features in the design of super-resolution reconstruction models.

D. Comparison with Existing SR Models

1) Quantitative comparison: In this section, our model is compared with several existing super-resolution (SR) models. The models chosen for comparison include traditional bicubic interpolation, as well as several deep learning-based methods

TABLE III. EFFECTS OF LOCAL ADVERSARIAL BRANCH AND LTSM ON PSNR AND SSIM METRICS

Datasets	W/O Local Adversarial Branch		W/O LTSM(All patches)		ours(full model)	
	PSNR	SSIM	PSNR	SSIM	PSNR	SSIM
Set5	32.30	0.9073	31.22	0.8987	**32.32**	**0.9110**
Set14	28.12	0.8025	27.92	0.7829	**28.15**	**0.8231**
BSD100	27.92	0.6882	27.12	0.6801	**28.31**	**0.7012**
Urban100	26.66	0.8029	26.85	0.8012	**27.18**	**0.8206**

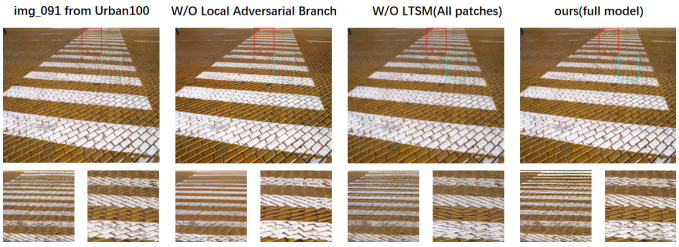

Fig. 5. Urban100 dataset img_091 Reconstruction Comparison, the results show that compared to model trained without the local adversarial branch and trained using all patches in the local branch, the model trained with the LTSM produces more realistic texture details.

such as SRCNN [7], RCAN [9], SRGAN [10], ESRGAN [13], and SwinIR [27]. Additionally, we incorporate the recently proposed Semantic-aware Discriminator (SeD) [34] into ESRGAN and SwinIR, a recent approach designed to enhance texture generation quality by leveraging semantic information. The improved versions of these models are denoted as ESRGAN+ and SwinIR+, respectively. Comparative experiments are conducted on four commonly used benchmark datasets: Set5 [35], Set14 [36], BSD100 [37], and Urban100 [38], with primary evaluation metrics being PSNR (Peak Signal-to-Noise Ratio) and SSIM (Structural Similarity Index).

In Table IV, our model demonstrates best performance across four commonly used datasets at all scales, especially achieves average improvement of 0.15 dB on PSNR compared to SwinIR+ [27][34] at $\times 4$ scale. From the SSIM results, it is evident that our model consistently achieves optimal performance across most datasets except for SSIM on BSD100($\times 4$). Compared to other models, our model shows an average SSIM improvement of 0.053 over SRCNN [7], 0.014 over RCAN [9], 0.047 over SRGAN [10], 0.056 over ESRGAN+ [13][34], and 0.003 over SwinIR+ [27][34]. These findings indicate that our model not only excels in image clarity (PSNR) but also performs exceptionally well in preserving image structure and details (SSIM).

In summary, through comparisons with various existing SR models, our proposed Generative Adversarial Network super-resolution reconstruction method based on local texture adversarial learning and hybrid attention demonstrates outstanding performance in both PSNR and SSIM metrics. This validates its effectiveness and superiority across different types of images.

2) Qualitative comparison: In terms of qualitative comparison, this study selected typical images from different datasets to visually assess the reconstruction results of various models. The specific results are shown in Fig. 6, 7 and 8.

Regarding image details and texture restoration, the proposed model demonstrates significant advantages Compared to other models, it preserves the details and textures of the original images better during reconstruction, the patches highlighted in red boxes represent critical regions for evaluating detail preservation and texture fidelity. For instance, in urban street scene images Img_014 and Img_087 from the Urban100 dataset, the proposed model not only reconstructs building edges and textures clearly but also presents more natural and realistic details. In contrast, other models like SRCNN [7], RCAN [9], and SRGAN [10] may exhibit blurriness or distortion in some details, which the proposed model effectively avoids.

Furthermore, on datasets like Set5 and Set14, the proposed model shows strong robustness and capability in restoring details in natural scenes and facial images. In Baboo from Set14, the proposed model performs a more natural reconstruction effect on facial details such as eyes and beard.

In comparison with existing SR models, the proposed model demonstrates superior performance in both quantitative metrics and qualitative effects. By integrating local texture adversarial learning and hybrid attention mechanisms, the proposed model not only enhances the accuracy of image reconstruction but also achieves a higher level of visual fidelity.

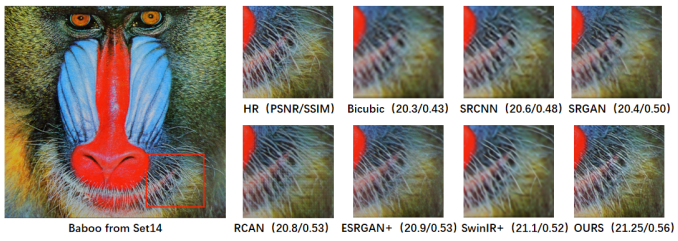

Fig. 6. Baboo from Set14 Reconstruction Comparison, the patches for comparison are marked with red boxes in the original images. PSNR/SSIM is calculated based on the patches to better reflect the performance difference.

V. CONCLUSION

We had proposed a GAN based method for image SR reconstruction, leveraging local texture adversarial and hybrid attention residual block. LTSM is introduced to compute edge intensity in local image regions, this module effectively addresses issues of blurriness and detail loss commonly observed in traditional GAN-generated images. Additionally, a generator equipped with HARB is incorporated to enhance the utilization of input features during generation. This approach ensures better preservation of image structure and details, thereby improving overall image quality in reconstruction. Experimental validation on multiple standard datasets (Set5, Set14, BSD100, and Urban100) demonstrates superior performance in terms of PSNR and SSIM metrics, surpassing various existing super-resolution methods and exhibiting notable advantages in image detail and texture restoration. However it is not without limitations. One key limitation is the computational cost associated with the HARB and LTSM, which may limit its deployment in real-time applications or on devices with constrained resources. Additionally, while the LTSM effectively enhances local texture details, its reliance on patch selection based on edge intensity might overlook non-edge regions with critical texture information, leading to potential gaps in detail preservation in less textured areas.

For future work, we will explore optimizing the computational efficiency of the proposed framework by leveraging lightweight architectures or pruning techniques. Furthermore, incorporating adaptive mechanisms for selecting texture-rich regions, beyond edge intensity, could enhance the model's ability to generalize across diverse image types. Extending the current method to handle multi-frame super-resolution or domain-specific applications, such as medical imaging or satellite imagery, could also provide new directions for further exploration.

Image Restoration of Landscape Design Based on DCGAN Optimization Algorithm

Wenjun Zhang*
School of Architecture and Urban Planning, Henan University of Urban Construction, Pingdingshan 467036, China

***Abstract*—To enhance the quality and effectiveness of image restoration in landscape design, this study optimizes the existing methods for low efficiency and incomplete feature extraction in processing high-resolution and detail rich landscape design images. Firstly, based on the traditional generative adversarial network (GAN), a novel deep convolutional generative adversarial network (DCGAN) model is proposed. Subsequently, the model's ability to extract detailed features was enhanced by integrating dense connected networks (DenseNet) and compressed excitation networks (SENet) into the network architecture. An improved DCGAN is designed for the restoration of landscape design images. According to the results, the optimized model had a restoration precision and repair recall rate of 0.97 in benchmark performance testing, which was significantly better than traditional deep convolutional generative adversarial network models. In practical applications, the model had an average accuracy of over 97% in repairing four different styles of landscape images, with an average repair time as low as 0.06s. From this, it can be seen that the designed model can provide a more efficient technical means for the restoration and digital preservation of landscape design images.**

***Keywords*—Deep convolutional generative adversarial network; image; restoration; landscape architecture; squeeze-and-excitation network; dense convolutional network**

I. Introduction

Influenced by social economy and urbanization, landscape design has gradually become important in urban planning. As a crucial component of urban green infrastructure, landscape architecture not only exerts a crucial function in beautifying the environment and improving ecology, but also has a significant impact on enhancing the quality of life of citizens and the cultural taste of the city [1-2]. However, landscape design images with a long history are often eroded by environmental factors, resulting in image damage and information loss, which affects the research and protection of landscape architecture and challenges its ability of digital preservation and inheritance.

The damaged landscape art images not only affect the research and protection of landscape architecture, but also pose challenges to the digital preservation and inheritance of landscape architecture [3-4]. Generative Adversarial Networks (GANs) have demonstrate strong potential and broad application prospects in image generation and restoration. Traditional image restoration methods mainly rely on manual or rule-based techniques, which often inadequate when dealing with complex scenes and details. In contrast, GAN can effectively capture complex texture and structural features in images through adversarial training mechanisms of generators and discriminators, achieving high-quality image generation and restoration.

However, traditional GAN still faces some specific challenges in landscape image restoration. First of all, in the training process, traditional GAN often has the problem of high training difficulty, and its training process is easily affected by mode collapse and instability, resulting in unstable image quality. Secondly, traditional image restoration techniques are often inadequate in processing complex textures and detailed features, and cannot fully retain the fine features and details in high-resolution landscape design images [5-6]. The main goal of this study is to improve the quality and effectiveness of landscape design image restoration by improving the traditional GAN optimization algorithm, especially in the aspects of feature extraction and restoration efficiency.

Therefore, a deep Convolutional generative adversarial network (DCGAN) model combining DenseNet and SENet is proposed. This new model aims to enhance the ability of the network to extract detailed features, so as to achieve more accurate image recovery in practical applications. The research innovatively introduces Dense Connected Convolutional Networks (DenseNet) and Squeeze-and-Excitation Networks (SENet) as generators, and uses Deep Convolutional Generative Adversarial Networks (DCGAN) as discriminators, ultimately enabling the constructed model to extract more detailed features, reduce computational complexity, and effectively restore the original image. The potential benefit of the research is that the successful implementation of this approach will have a profound impact in several fields. First of all, in urban planning and management, high-quality image restoration can provide more accurate visual basis for decision-making and support more effective land use and environmental design. Secondly, in the field of cultural heritage protection, it can help preserve and restore historical documents and artistic works to ensure the long-term preservation and transmission of cultural heritage. Finally, in the practice of digital preservation, the research results can provide strong technical support for the maintenance of various digital archives and promote the sustainable management and utilization of digital content.

The structure of this paper is divided into six sections. Section II, literature review, summarizes the achievements and shortcomings of domestic image restoration research. Section III introduces the proposed method, including the DCGAN architecture and the integration of DenseNet and SENet, to improve image restoration performance. Section IV presents the experimental results, verifies the performance of the model, and compares the performance of DS-DCGAN with other models. Section V discusses the advantages and potential

applications of DS-DCGAN. Finally, the research contributions were summarized and future research directions were proposed in Section VI.

II. Related Works

GAN is a deep learning approach, which includes a generator and a discriminator, which can generate realistic data through adversarial training between the two. Image restoration adopts computer technology to restore damaged or degraded images, to improve image quality or restore their original state. In image restoration, Liu G et al. designed an image restoration algorithm on the basis of GAN to address the low accuracy of traditional algorithms in restoring large-area damaged images. By extracting multi-scale edge details of the damaged area and constructing a GAN model, the model was trained to generate the best fake image. The results showed that the model could effectively combine contextual and perceptual information, significantly improve image restoration accuracy and image quality, and outperform existing algorithms [7]. In response to the significant impact of equipment and operators on the quality of retinal images, Deng Z et al. explored the retinal image restoration method in real clinical environments. Firstly, a clinical dataset Real Fundus was established, which included 120 pairs images. Secondly, a Transformer-based GAN was proposed to restore the clinical fundus images. The proposed model was helpful for in-depth analysis of clinical fundus images [8]. Yang J et al. proposed a new approach for restoring private facial images on the basis of semantic features and adversarial samples to address the serious threat posed by facial image feature leakage to user information security. Firstly, Segnet network was used for semantic segmentation of facial images, and then GAN was used to generate adversarial samples and perturb the semantic features of facial images. Compared with other advanced technologies, the generated private facial images had stronger median filtering defense capability [9].

In response to the limitations of Wasserstein-GAN in simulating complex distributions such as natural image distributions, Ma H et al. proposed a method to improve Wasserstein-GAN training by introducing pairwise constraints to optimize image restoration tasks. The research results showed that the Wasserstein-GAN model with paired constraints had better consistency and perceptual quality than existing technical methods [10]. Considering that artworks can be damaged over time due to changes in humidity, temperature, and improper storage, Kumar P et al. designed a new virtual restoration strategy for artworks based on GAN. This method adopted an improved U-Net as the generator part. A pre-trained residual network was used to construct the encoder to generate higher quality feature embeddings, improving the quality of image restoration. The research results indicated that this method performed well in performance indicators [11]. Liang M et al. designed a multi-scale self attention GAN to address the common local cross contamination or data loss in the acquisition and processing of pathological digital images. Then this network was applied to restore pathological images of tissue. The research results showed that this network structure could achieve pixel level realistic restoration of tissue pathological images, effectively restoring the detailed features of the images [12].

In summary, although the existing GAN optimization algorithm has made some progress in the field of image restoration, it still has shortcomings in processing high-resolution and detail-rich landscape design images. Therefore, a DCGAN model combining DenseNet and SENet optimization is proposed in this paper, which aims to further improve the quality and effect of image restoration by improving the structure of generator and discriminator. Compared with the current methods, the research method has improved the efficiency of feature extraction and processing. Traditional GAN models often face the problem of insufficient feature extraction when processing complex landscape design images, especially when recovering high-resolution images, fine texture and structural features are easy to ignore. By integrating DenseNet, DS-DCGAN can realize the close connection of features, so that the network can use the feature information from different levels more effectively, and enhance the ability to extract detailed features. At the same time, the introduction of SENet optimizes the channel incentive mechanism and makes the network focus more on important features by adaptively adjusting the weight of the feature map. This channel attention mechanism significantly improves the ability of the generator and discriminator to respond to key features, thereby reducing unnecessary computational overhead while maintaining image quality. Compared with traditional DCGAN, DS-DCGAN has been optimized by deep learning technology to reduce the computational complexity and improve the overall operating efficiency.

III. Landscape Image Restoration based on Improved DCGAN

To improve the restoration effect of landscape images, the DCGAN is first introduced to generate clear landscape images. Secondly, a new generative network is generated by combining DenseNet and SENet, and DCGAN is used as the discriminative network to compensate for the insufficient feature extraction of traditional DCGAN models in repairing landscape images.

A. Design of Landscape Image Restoration Algorithm Based on DCGAN

GAN is a deep learning model proposed in 2014, which introduces two networks, namely a generator and a discriminator, so that these two networks compete with each other during the training process to generate realistic data [13]. The generator is to produce fake data that is close to the true data distribution. It obtains a random noise vector as input and outputs a data point with the same dimension as the training data. The discriminator is to distinguish whether the input data is real or generated by a generator. It can receive data produced by the generator or real data as input and output a probability value to represent the probability that the input data is real. The GAN is displayed in Fig. 1.

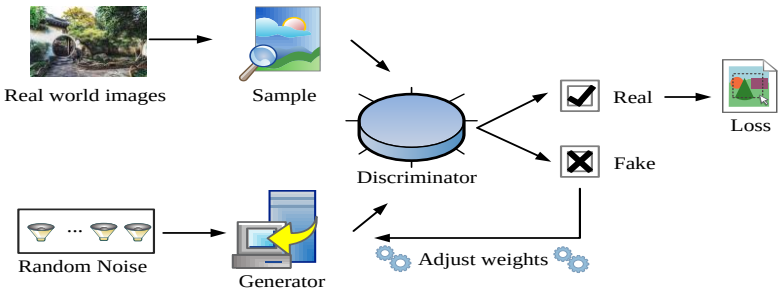

Fig. 1. GAN structure.

In Fig. 1, when training GAN, the generator first receives a random noise vector as input, and then uses this noise to generate a fake image, with the aim of making this image visually indistinguishable from the real image. Next, the discriminator may receive a fake image or a real image generated by the generator, and output a probability value to determine whether the image is real or produced by the generator. Through this adversarial learning, the generator gradually improves its ability to generate high-quality fake images to deceive the discriminator. The discriminator is constantly improving its accuracy in distinguishing between real and fake images. The dynamic confrontation between the two drives the continuous improvement of their performance until the generator can generate images that are almost unrecognizable as fake by the discriminator, while the discriminator accurately identifies the real and generated images as much as possible. The objective loss function of GAN is displayed in Eq. (1) [14-15].

$$\min_G \max_D V(D,G) = E_{x\sim p_{data}}[\log D(x)] + E_{z\sim p_z(z)}[\log(1-D(G(z)))] \quad (1)$$

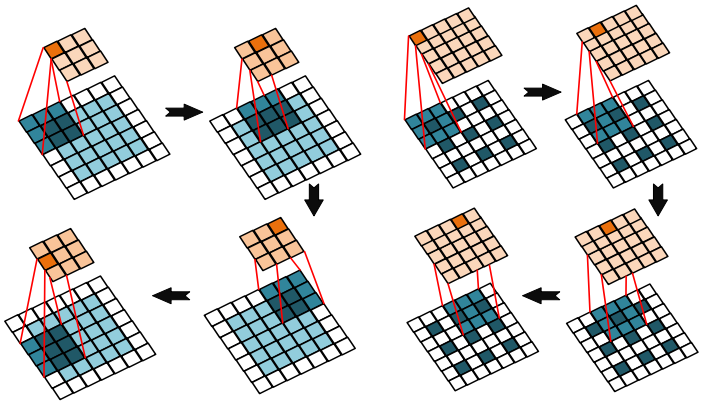
In Eq. (1), G signifies the generator. D signifies the discriminator. z represents noise. x and $G(z)$ signify real samples and produced samples. $D(x)$ and $G(x)$ signify the discriminant function and the generative function, respectively. E represents the expected value. p_{data} and $p_z(z)$ represent the real and the produced distributions. $D(G(z))$ signifies the probability that D will distinguish the data generated by G as real samples. According to Eq. (1), to train GAN, G and D are trained separately. The training process of D is shown in Eq. (2).

$$\max_D V(D,G) = E_{x\sim p_{data}}[\log D(x)] + E_{z\sim p_z(z)}[\log(1-D(G(z)))] \quad (2)$$

In Eq. (2), the meanings of x and z are the same as those in Eq. (1). At this point, if D can recognize x as a true sample, then the value of $\log D(x)$ will be larger. Similarly, if D can identify $G(z)$ as a false sample, then the value of $\log(1-D(G(z)))$ will also be as large as possible. When the values of $\log D(x)$ and $\log(1-D(G(z)))$ are both larger, D remains unchanged and G is trained to confuse D. Similarly, when training G, it is hoped that D in GAN cannot recognize false samples. The training process of G is displayed in Eq. (3).

$$\min_G V(D,G) = E_{z\sim p_z(z)}[\log(1-D(G(z)))] \quad (3)$$

In Eq. (3), the closer the $D(G(z))$ is to 1, the smaller the training value of the entire G. DCGAN is a special type of GAN that combines the advantages of GAN and convolutional neural networks. Convolutional layers are used to construct generators and discriminators, enabling the network to obtain local and global features and generate more refined and realistic images. Firstly, in DCGAN, stride convolution is used in the discriminator to reduce image size, while fractional stride convolution is used in the generator to increase image size. Two convolution methods are shown in Fig. 2.



(a) Stride convolution (b) Fractional stride convolution

Fig. 2. The convolution processes of stride convolution and fractional stride convolution.

Fig. 2(a) and 2(b) show the convolution processes of stride convolution and fractional stride convolution, respectively. In Fig. 2(a), stride convolution reduces the output feature map size by setting the convolutional kernel movement step size. In ordinary convolution operations, the convolution kernel typically slides over the input feature map at stride of 1, resulting in output feature maps of the same size. However, by setting a larger stride value, such as 2 or 3, the convolution kernel will skip multiple pixels each time it slides on the input feature map, effectively reducing its size. This operation not only reduces computational complexity, but also has a down-sampling effect to some extent, allowing subsequent layers to process smaller feature maps, and improving the efficiency of the network. In Fig. 2(b), fractional stride convolution, also known as transpose convolution or deconvolution. This type of convolution is applied to increase the size of the output feature map. Unlike stride convolution, fractional stride convolution inserts zero padding before the convolution operation, allowing the convolution kernel to produce larger output feature maps than the original size when sliding on the input feature map. This operation essentially involves inserting blank spaces between input feature maps, and then performing standard convolution on the expanded image to increase its size. The DCGAN structure combining these two convolution operations is shown in Fig. 3.

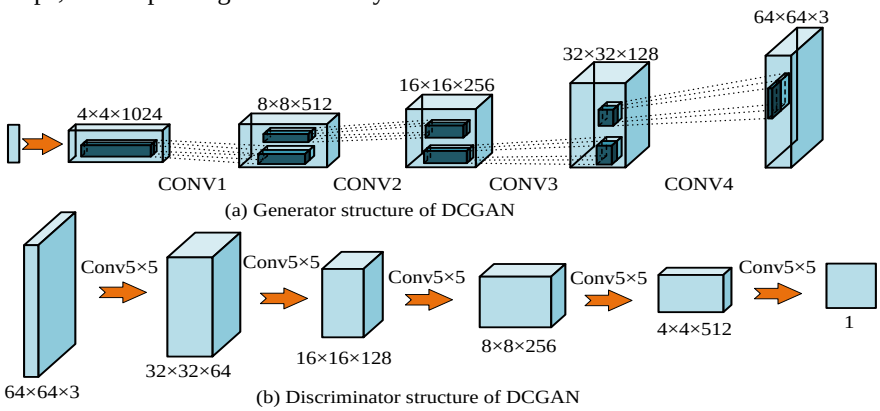


Fig. 3. DCGAN structure diagram.

The DCGAN in Fig. 3 consists of two main parts, namely the generator in Fig. 3(a) and the discriminator in Fig. 3(b). Among them, the former produces fake images. The later distinguishes between real images and generated fake images. The process of using DCGAN for image restoration includes the following key steps. Firstly, the generator takes a random noise vector as input and gradually enlarges the feature map through fractional stride convolutional layers, converting the noise into a fake image. Secondly, the discriminator will receive fake and real images generated by the generator, gradually reduce the size of the feature map through stride convolution layers, extract key features of the image, and output a probability value to represent the possibility that the input image is a real image. In this process, the generator and discriminator are continuously optimized through adversarial training. The generator attempts to generate increasingly realistic images to deceive the discriminator. The discriminator continuously distinguishes between real and fake images. After multiple rounds of iterative training, the generator is able to generate high-quality and realistic images, achieving the image restoration.

B. Construction of an Optimized DCGAN Model Combining DenseNet and SENet

Although DCGAN has better image feature extraction capabilities compared with GAN, there are still some shortcomings in using DCGAN for landscape design image restoration, such as unstable image quality, easy pattern collapse, high training difficulty, and poor feature extraction of some landscape images [16-17]. To address these issues, the DenseNet is combined with SENet to optimize the DCGAN. The structure of DenseNet is shown in Fig. 4.

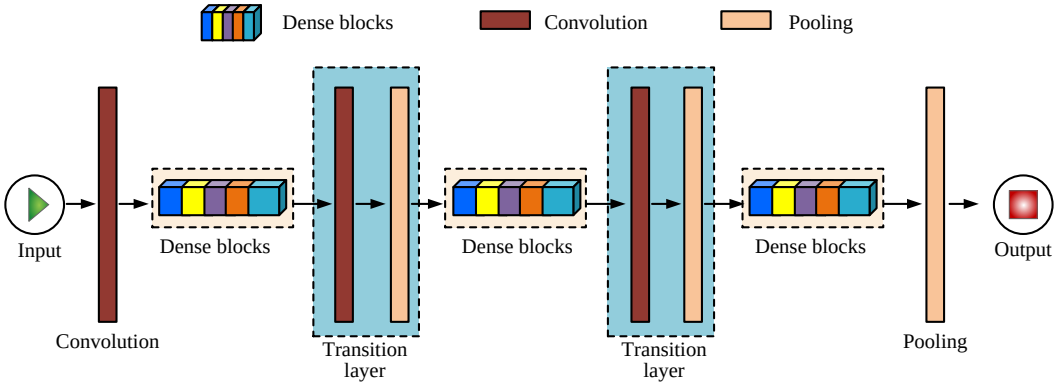

Fig. 4. DenseNet structure diagram.

The DenseNet in Fig. 4 is an innovative CNN structure characterized by the added densely connected modules. DenseNet consists of multiple dense convolutional blocks and transition layers. The layers in each dense convolutional block are directly connected to each other, meaning that the output of each preceding layer is the input of all subsequent layers. This design not only efficiently utilizes feature information, but also alleviates the gradient vanishing, thereby improving network performance. Another significant feature of DenseNet is to implement down-sampling through transition layers. The bottleneck layer in the transition layer can remove redundant information by reducing the number of feature maps, thereby reducing computational complexity and decreasing the parameters. x_0 represents the feature map obtained after convolution processing, which is the input of the dense convolution block to obtain the l-th layer output, as shown in Eq. (4) [18-19].

$$x_l = H_l\left(\left[x_0, x_1, \cdots, x_{l-1}\right]\right) \tag{4}$$

In Eq. (4), $H_l(\cdot)$ represents the transformation function of the l-th layer. $[x_0, x_1, \cdots, x_{l-1}]$ signifies the feature input composed of feature maps from layer 0 to $l-1$. x_l signifies the output of the l-th layer. In addition to using DenseNet to optimize the parameters of DCGAN and reduce the frequency of gradient vanishing, the study also adds SENet module to enhance channel sensitivity and lightweight the DCGAN structure. The SENet is displayed in Fig. 5.

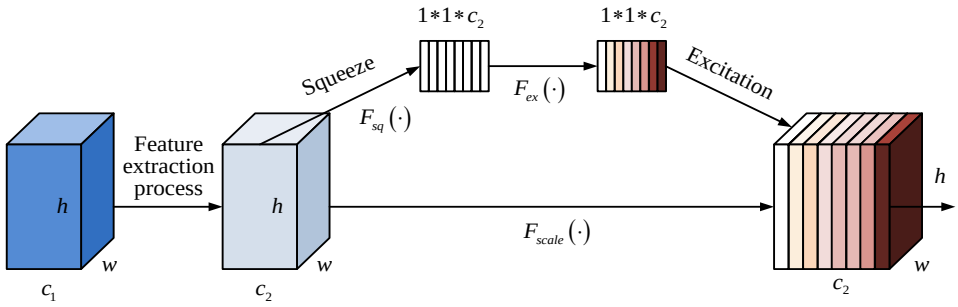

Fig. 5. SENet structure diagram.

In Fig. 5, the key component in the SENet structure is the excitation module, which can perform Squeeze and Excitation operations on the feature maps of the convolutional layer. Firstly, the feature map is compressed into a single value through global average pooling, which represents the global spatial information of the entire feature map. Then, this value is passed through a Fully Connected Layer (FCL) and ReLU function is used to learn the interrelationships between channels. Finally, this value through another FCL, and the Sigmoid is applied to output the weights of each channel. These weights will be used to re-weight the channels of the original feature map. The weights obtained through the incentive module will be multiplied with the corresponding channels to achieve feature re-calibration. After the above processing, the network can adaptively emphasize important features and suppress unimportant features. In the Squeeze operation, the original image feature size is $H*W*C$, where H, W, and C signify the height, width, and channels. Each channel is subjected to a global mean pooling operation to obtain a compressed feature map, which not only has a global receptive field but also has a size of $1*1*C$. The Squeeze operation is shown in Eq. (5).

$$z_c = F_{sq}\left(u_c\right) = \frac{1}{H \times W}\sum_{i=1}^{H}\sum_{j=1}^{W} u_c\left(i, j\right) \tag{5}$$

In Eq. (5), z_c signifies the compressed feature map. u_c represents the feature map extracted by convolution operation. $F_{sq}(\cdot)$ represents the feature compression function. i and j represent the horizontal and vertical axes of the feature map, respectively. The expression for the Excitation operation is shown in Eq. (6).

$$s_c = F_{ex}\left(z, W'\right) = \sigma\left(g\left(z, W'\right)\right) = \sigma\left(W_2 \operatorname{Re} LU\left(W_1 z\right)\right) \tag{6}$$

In Eq. (6), s_c represents the weight coefficient with attention mechanism. $F_{ex}(\cdot)$ represents the characteristic excitation function. z represents the compressed feature map. g represents the gating function. σ represents the reshape function. W', W_1 and W_2 respectively represent the weight coefficients of the attention mechanism, the first FCL, and the second FCL. The weight coefficients obtained through Squeeze and Excitation operations are applied to each channel, as shown in Eq. (7).

$$x_c = F_{scale}\left(u_c, s_c\right) \tag{7}$$

In Eq. (7), $F_{scale}(\cdot)$ represents the feature re-scaling function. x_c represents the weight coefficients applied to each channel. The DCGAN optimized by combining DenseNet and SENet is referred to as DS-DCGAN, and its structure is shown in Fig. 6.

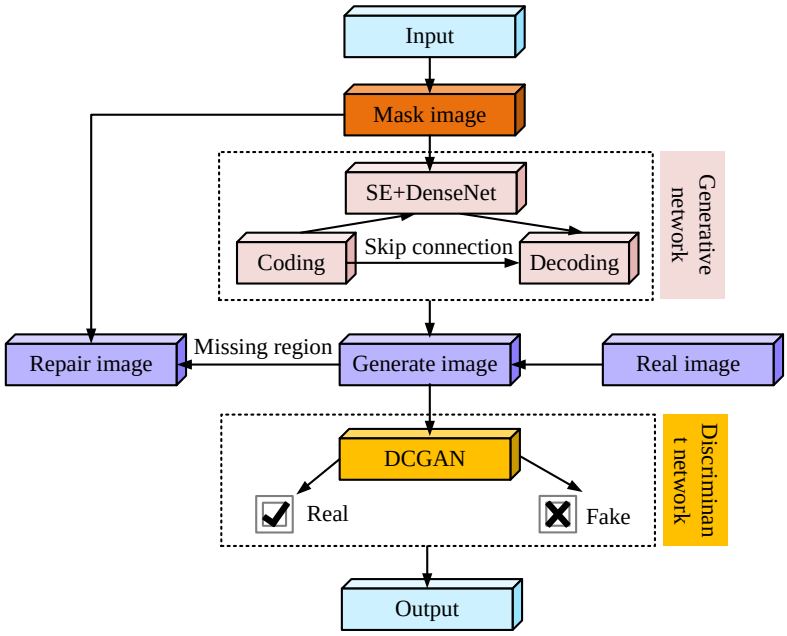

Fig. 6. DS-DCGAN structure.

In Fig. 6, the entire DS-DCGAN structure has the generator and the discriminator. DenseNet organizes the convolutional layers in a densely connected manner, meaning that each layer is directly connected to all the layers above it. In the generator, this dense connection can effectively transmit feature information, reduce information loss, and enable the network to better retain detailed features when generating images. The structure of DenseNet effectively alleviates the common phenomenon of gradient disappearance in deep networks. Since each layer is directly connected to the others, gradients can be passed more smoothly through the layers, ensuring that the generator can quickly learn effective feature representations during training. In the discriminator, by connecting the features of the front layer with the back layer, DenseNet can maximize the use of the features extracted from the front layer and form a stronger feature representation to judge the authenticity of the image. This enhanced feature utilization capability greatly improves the performance of the discriminator, which can more accurately distinguish the real image from the generated image. SENet enables the network to adaptively re-calibrate each channel by introducing a channel attention mechanism. Specifically, SENet acquires a global feature representation for each channel through global average pooling and generates channel weights through two fully connected layers. These weights are used to realign the importance of each channel in the input feature map. In the generator, the introduction of SENet enables the generated images to better highlight important feature channels, thus making the details of the generated images richer and more realistic. In the discriminator, SENet can effectively enhance the perception of key feature channels, making the discriminator pay more attention to the key features that may distinguish between real and generated images. SENet reduces the computational complexity and avoids the processing of meaningless features by cutting out unimportant feature channels. This not only improves computational efficiency, but also helps reduce overfitting and improves the network's ability to generalize on unseen data. In the DS-DCGAN structure, the loss function during training is shown in Eq. (8).

$$Loss_{train} = \lambda_{MSE} L_{MSE} + \lambda_{adv} L_{adv} + \lambda_{TV} L_{TV} \quad (8)$$

In Eq. (8), $Loss_{train}$, L_{MSE}, L_{adv}, and L_{TV} respectively represent the training set loss function, Mean Squared Error (MSE) function, adversarial loss function, and total variation loss function. λ_{MSE}, λ_{adv} and λ_{TV} represent the weights corresponding to the MSE function, adversarial loss function, and total variation loss function, respectively. The L_{MSE} is displayed in Eq. (9).

$$L_{MSE} = \left(x - G\left(M \otimes x\right)\right)^2 \quad (9)$$

In Eq. (9), M represents the binary mask. $\otimes$ represents multiplication between corresponding elements, while the meanings of other parameters remain consistent with those mentioned earlier. The L_{adv} is shown in Eq. (10).

$$L_{adv} = \log\left(D\left(x\right)\right) + \log\left(G\left(M \otimes x\right)\right) \quad (10)$$

In Eq. (10), the meanings of each parameter remain consistent with the previous text. The L_{TV} is shown in Eq. (11).

$$L_{TV} = \sum_{i,j} \left| G_{i+1,j}\left(M \otimes x\right) - G_{i,j}\left(M \otimes x\right) \right| + \left| G_{i,j+1}\left(M \otimes x\right) - G_{i,j}\left(M \otimes x\right) \right| \quad (11)$$

In Eq. (11), i and j still represent the horizontal-axis and longitudinal-axis of the feature map. The test set loss function is shown in Eq. (12).

$$L_{val} = \lambda_{context} L_{context} + \lambda_{prior} L_{prior} \quad (12)$$

In Eq. (12), L_{val}, $L_{context}$, and L_{prior} represent the training set loss function, text loss function, and prior loss function, respectively. $\lambda_{context}$ and λ_{prior} represent the weights of $L_{context}$ and L_{prior}, respectively.

IV. Restoration Effect Testing of Landscape Design Images based on DS-DCGAN

To exhibit the effectiveness of the DS-DCGAN model, the study selects DCGAN, Generative Adversarial Network-variant (GAN-variant), and Conditional GAN (CGAN) as comparison models. The benchmark performance and actual application effects of the four models are compared.

A. DS-DCGAN Model Benchmark Performance Testing

To validate the benchmark performance of the DS-DCGAN, two publicly available datasets for landscape architecture and landscape image restoration are selected for testing. Among them, the Places2 dataset contains over 10 million images of various natural scenes and buildings, widely used for image restoration and generation tasks. The Paris StreetView dataset contains high-resolution images of street view buildings, suitable for evaluating the performance of models in landscape architecture and landscape image restoration. The two datasets are separated into training and testing sets in an 8:2 to comprehensively assess the effectiveness and robustness in different types of image restoration tasks. The loss function value is used as a criterion to determine the stability of the model. The stability of the four models in two datasets is shown in Fig. 7.

Fig. 7(a) and 7(b) show the loss curves of CGAN, DCGAN, GAN-variant, and DS-DCGAN models. According to Fig. 7(a), CGAN, DCGAN, GAN-variant, and DS-DCGAN reached a stable state after 325, 278, 251, and 216 iterations, respectively. Similarly, in Fig. 7(b), CGAN, DCGAN, GAN-variant, and DS-DCGAN also reached a stable state after 296, 268, 223, and 172 iterations, respectively. Based on the two sub-graphs in Fig. 7, DS-DCGAN can iterate to a stable state faster compared with the other three comparison models, indicating its high training efficiency and strong adaptability of the model. The average time consumption of the four models in the decoding and encoding process is compared, as shown in Fig. 8.

Fig. 8(a) and 8(b) show the average encryption time and average decryption time of the four models during the training process, respectively. Based on Fig. 8, the CGAN model during training was 0.63 and 0.70, respectively. Its encryption and decryption process took the longest time, far higher than the DS-DCGAN model. In addition, the GAN-variant model was 0.35, the DCGAN model was 0.46 and 0.48, respectively, and the DS-DCGAN model was 0.21 and 0.19, respectively. Overall, the DS-DCGAN model has the shortest encryption and decryption time and the highest processing efficiency in image processing. The MSE and Mean Absolute Error (MAE) during the training process are displayed in Fig. 9.

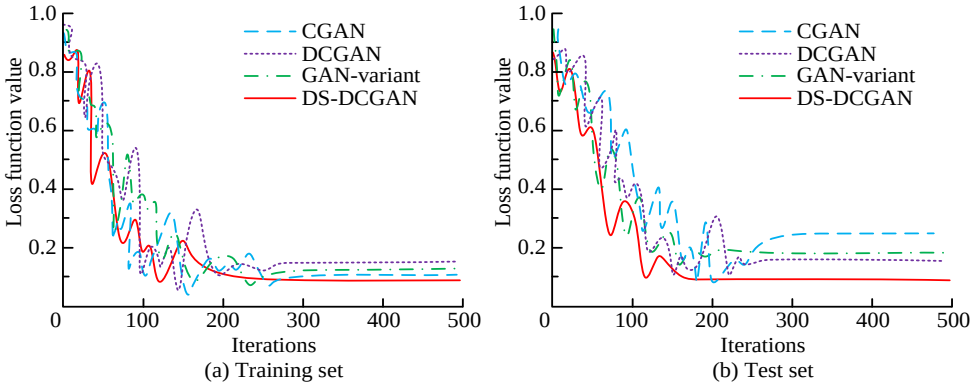

Fig. 7. Loss curve iteration of different models in two datasets.

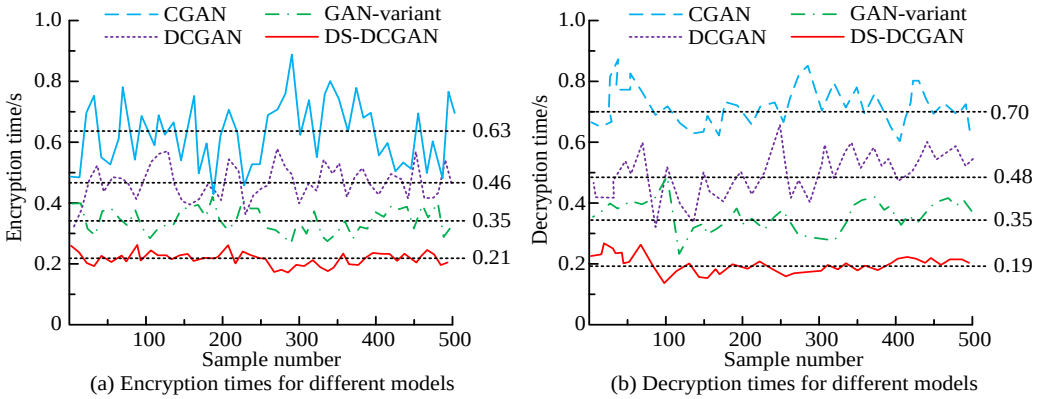

Fig. 8. Average encryption time and decryption time of various models.

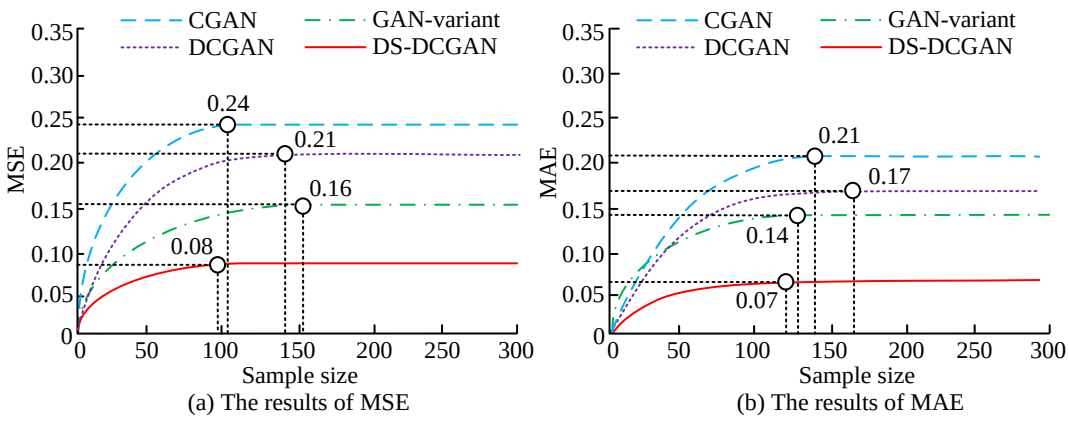
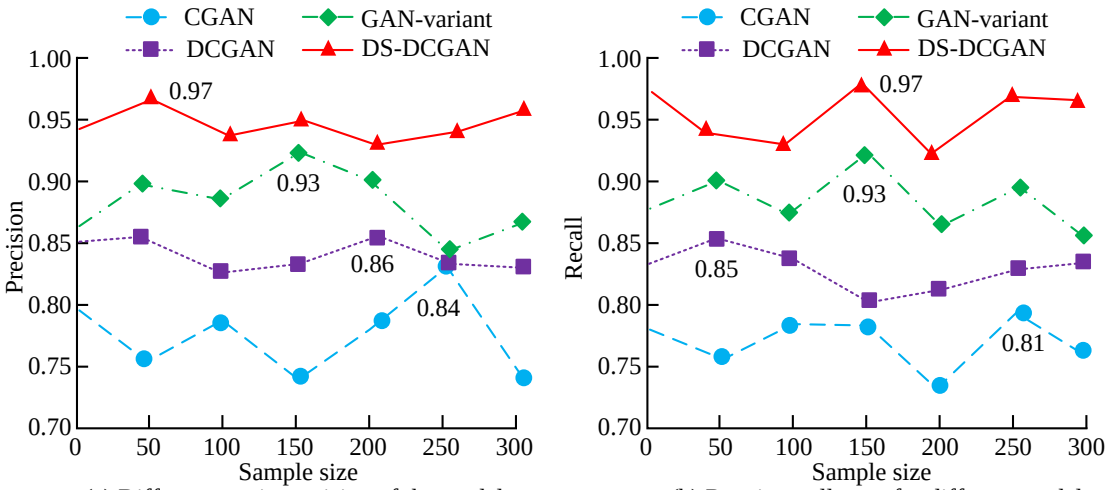


(a) The results of MSE (b) The results of MAE

Fig. 9. Error representation of different models.

Fig. 9(a) and Fig. 9(b) respectively show the MSE and MAE values of the four models. MSE is a common index to measure the difference between the restored image and the real image, and is defined as the average of the square of the difference between the pixel values of the corresponding position of the restored image and the original image. MAE is another measure of the difference between the recovered image and the real image, and it is the average of the absolute values of the difference between the pixel values. According to Fig. 9(a), the MSE values of CGAN, DCGAN, GAN-variant, and DS-DCGAN models after reaching stability were 0.24, 0.21, 0.16, and 0.08, respectively. According to Fig. 9(b), the MAE values of CGAN, DCGAN, GAN-variant, and DS-DCGAN models after reaching stability were 0.21, 0.17, 0.14, and 0.07, respectively. Overall, the DS-DCGAN model performs better in terms of error during training, with lower MSE and MAE values. The repair precision and recall values during the training are compared, as displayed in Fig. 10.



(a) Different repair precision of the model (b) Repair recall rates for different models

Fig. 10. Repair precision and repair recall rate of different models.

Fig. 10(a) and Fig. 10(b) respectively show the repair accuracy and repair recall rate of CGAN, DCGAN, GAN-variant and DS-DCGAN. The repair accuracy is used to evaluate the accuracy of images recovered by the model, and it represents the ratio of the number of pixels successfully recovered to the total number of pixels. The repair recall rate reflects the ability of the model to identify and recover the actual damaged part, and it represents the ratio of the true positives of successful recovery to the actual damaged part. In Fig. 10(a), the maximum repair precision of CGAN, DCGAN, GAN-variant, and DS-DCGAN was 0.84, 0.86, 0.93, and 0.97, respectively. In Fig. 10(b), the maximum repair recall rate of CGAN, DCGAN, GAN-variant, and DS-DCGAN was 0.81, 0.85, 0.93, and 0.97, respectively. From this, the benchmark performance test results of DS-DCGAN are good, which has high repair precision and recall.

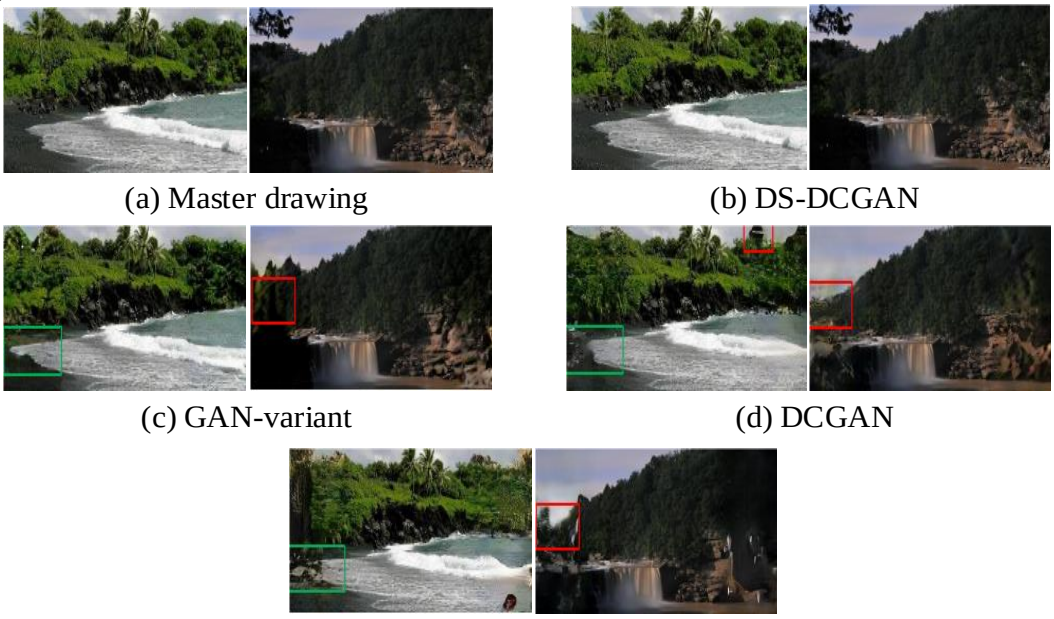
B. *Application Effect Analysis of DS-DCGAN in Landscape Design Image Restoration*

In addition to comparing the benchmark performance of several models, the study also applies four models to practical problems. The application effects in landscape design image restoration are compared. Four different styles of landscape images are selected as the research objects. The restoration time and accuracy of four models for restoring these four real landscape images are obtained, as shown in Table I.

TABLE I. ACTUAL REPAIR EFFECT OF THE MODEL

Image Type	Evaluation index	CGAN	DCGAN	GAN-variant	DS-DCGAN
Image 1	Repair time /s	0.36	0.21	0.14	0.08
	Repair accuracy rate /%	88.23	91.05	95.18	98.15
Image 2	Repair time /s	0.31	0.23	0.18	0.11
	Repair accuracy rate /%	89.94	92.10	96.65	98.57
Image 3	Repair time /s	0.25	0.16	0.09	0.06
	Repair accuracy rate /%	89.69	92.17	95.04	99.03
Image 4	Repair time /s	0.41	0.30	0.24	0.15
	Repair accuracy rate /%	85.74	89.43	93.38	97.96

According to Table I, the repair time for four images using the DS-DCGAN model was controlled within 0.20s, with a minimum of 0.06s required to complete the repair work. At the same time, the accuracy of repairing images 1, 2, 3, and 4 based on the DS-DCGAN model was higher than that of comparison models, reaching 98.15%, 98.57%, 99.03%, and 97.96%, respectively. Among the four models, the CGAN model has the worst performance in practical applications, with a repair time of up to 0.41s and a repair accuracy of only 85.74%. The restoration effects of four models on real landscape images are further compared, as shown in Fig. 11.



(a) Master drawing (b) DS-DCGAN

(c) GAN-variant (d) DCGAN

(e) CGAN

Fig. 11. Actual restoration effects of landscape design images under different models.

Fig. 11 shows the effectiveness of four models in restoring actual landscape design images. Based on Fig. 11, the CGAN, DCGAN, and GAN-variant models all generated features that did not match the original image when repairing images, while DS-DCGAN fully restored the true situation of the actual image without problems such as feature transfer or feature duplication. Overall, DS-DCGAN has the best restoration effect in practical applications. Based on the analysis of experimental results, the performance of the research method is shown in Table II.

TABLE II. PERFORMANCE RESULTS OF DS-DCGAN MODEL

Model	Repair accuracy (%)	Repair recall rate (%)	MSE	MAE	Average repair time (s)
CGAN	84	81	0.24	0.21	0.63
DCGAN	86	85	0.21	0.17	0.46
GAN-variant	93	93	0.16	0.14	0.35
DS-DCGAN	97	97	0.08	0.07	0.19

In Table II, DS-DCGAN's repair accuracy and recall rate are both as high as 97%, demonstrating excellent capabilities in detail recovery and extraction of important data. The high repair accuracy and recall rate indicate that DS-DCGAN is able to

capture critical information in images more comprehensively, thus providing more reliable image recovery results. DS-DCGAN has a MSE and MAE of 0.08 and 0.07, respectively, which are the lowest of all models and significantly reduce errors during image recovery. This shows that DS-DCGAN is able to reconstruct the original image more accurately, retaining more detailed information. The average repair time of DS-DCGAN is 0.19 seconds, which makes DS-DCGAN have good real-time performance in practical applications, especially suitable for scenarios that require fast recovery. The results show that DS-DCGAN provides higher recovery accuracy and speed, and provides effective support for practical applications that need to process high-definition images or large-scale data sets. Using DenseNet and SENet structure optimization, the model not only shows strong ability in processing complex image features, but also reduces the computational complexity after training, which lays a good foundation for the subsequent model iteration and application.

V. Discussion

In the above experimental results, the improved DCGAN model has a good performance and has obvious advantages in the field of image restoration. Therefore, this method also has certain application potential in other fields. In medical imaging, medical imaging technology is highly dependent on image quality. Images are often distorted by noise, motion artifacts, or equipment limitations. By applying the improved DCGAN model, damaged medical images can be effectively restored, enhancing the contrast and detail of the images, thereby helping doctors obtain more accurate diagnoses. DS-DCGAN can be used to process noise reduction and enhance image quality, improving the recognition and classification accuracy of pathology images, which is essential for early diagnosis. In medical image analysis, DS-DCGAN can be used to generate diverse training samples, help train other deep learning models, and promote the accuracy of cancer lesion detection or tissue classification. By generating high-quality composite images, the sample pool can be increased, helping to reduce overfitting and training time for the model. Medical imaging systems usually produce a large number of scanned images. As time goes on, storing and managing these images becomes increasingly important. DS-DCGAN can help digitally preserve expired and damaged medical images, making important historical medical records and records continuously accessible and usable.

In terms of digital heritage protection, many important historical documents, artworks and images of cultural assets face wear and degradation. DS-DCGAN can be used to effectively repair these damaged images, improve their visual effect, and help retain historical information and cultural memory. The improved DCGAN model can be applied in 3D reconstruction to generate 3D assets with a high degree of detail by restoring flat images. In addition, this restoration method can be combined with augmented reality technology to provide visitors with a more vivid experience of cultural heritage. In a virtual museum or exhibition, DS-DCGAN is capable of recreating historical scenes to provide a more immersive and informative presentation.

In other potential areas, such as in film and television post-production, it is often necessary to recover damaged footage or enhance the details of a scene. DS-DCGAN helps production teams quickly fix scenes and generate additional effects, saving processing time and money. In security monitoring, the images captured by cameras are often difficult to provide effective information because of insufficient illumination and blurred motion. DS-DCGAN applications improve the clarity of surveillance images and help analyze and identify potential security threats. In the intelligent traffic management system, DS-DCGAN can optimize traffic monitoring images and recover important road condition information. This can enhance the real-time processing of images and optimize the management and control of traffic flow.

VI. Conclusion

In order to effectively restore landscape design images, a landscape design image restoration model was constructed by combining DenseNet, SENet, and DCGAN. Compared with DCGAN, GAN-variant, and CGAN, the results showed that DS-DCGAN maintained stability after 216 iterations in the training set and 172 iterations in the testing set, with faster iteration speed. In addition, the MSE and MAE of DS-DCGAN were the smallest in stable state, which were 0.08 and 0.07, respectively, indicating that the algorithm had low error. The repair accuracy and recall rate of four algorithms were tested. It was found that the repair precision and recall rate of DS-DCGAN were both as high as 0.97, indicating that this method could better preserve the detailed information during the repair process. In practical applications, the average repair accuracy of this model was as high as 99.03%, and the average repair time was as low as 0.06s. From this, the proposed DS-DCGAN model has good repair performance and application effectiveness. By introducing an improved DCGAN model and combining DenseNet and SENet, a new approach is provided to process and restore landscape design images. This method not only improves the ability of feature extraction, but also significantly improves the accuracy and efficiency of image recovery. The implementation and results of the research will have a profound impact on related fields. Landscape design image restoration can provide more accurate data support for urban planning and management, and help decision makers to better carry out land planning, environmental management and public facilities layout. It provides a new methodology and direction for the field of image restoration, promotes academic accumulation in the field, and promotes the expansion of subsequent research into more complex and diverse image processing tasks. At the same time, due to the complexity of landscape design images and the diversity of their damage types, subsequent research can analyze more types of damaged image restoration. As a result, follow-up studies can add repair analysis for more types of damaged images. At the same time, multiple approaches can be explored to further generalize and adapt the DS-DCGAN model to different types of image restoration tasks. For example, exploring the application of DS-DCGAN to multimodal image restoration, such as combining different types of medical imaging to achieve more comprehensive image restoration; DS-DCGAN is extended to video processing and dynamic scene recovery to improve the image quality under the condition of motion blur and motion

artifact. DS-DCGAN is applied to super-resolution reconstruction tasks, especially scenarios where high-resolution images are recovered from low-resolution images. By exploring these directions in depth, the DS-DCGAN model can not only meet the needs of challenging image restoration, but also show greater value in diverse fields.

Tennis Action Evaluation Model Based on Weighted Counter Clockwise Rotation Angle Similarity Measurement Method

Danni Jiang[1], Ge Liu[2]*
Department of Physical Education, Jinling Institute of Technology, Nanjing, China[1]
Department of Physical Education, Zhongnan University of Economics and Law, Wuhan, China[2]

***Abstract*—In order to intelligently analyze tennis movements and improve evaluation efficiency, a counter clockwise rotation angle of limbs is proposed to solve the direction problem of tennis movements. A dynamic time regularization algorithm is optimized by combining global time weighting and adjacent frame weighting. The results indicated that the proposed counter clockwise rotation angle feature of limbs could effectively represent changes in limb direction and clearly distinguish action postures. The average accuracy of this method in action classification on the Tennis Stroke Dataset was 97.60%. In the action evaluation mode, the average frame rate of the client was between 17.35FPS and 17.49FPS, and the overall average frame rate was about 17.40FPS. The server exhibits higher efficiency in action processing and evaluation, which can process video frames faster. It is more efficient in processing data capabilities and utilizing data resources. This indicates that the performance of the system is relatively consistent in different modes and has stability. The optimized method has a higher generalization ability in recognizing non-tennis movements on different datasets. When dealing with fine movements, the optimized method performs excellently and can better capture subtle differences in the movements. Meanwhile, this enhances the real-time performance of the system, making it suitable for evaluating tennis movements in practical application scenarios. This provides a new technical path for analyzing tennis movements and also serves as a reference for evaluating movements in other sports.**

***Keywords*—Action evaluation; counter clockwise rotation angle; weighting; dynamic time warping; tennis**

I. INTRODUCTION

With the rapid development of artificial intelligence, the combination of computer technology and tennis has become one of the hot topics in the field of sports. As a popular competitive sport, the analysis and evaluation of tennis technique movements are of great significance for athlete training and competition [1]. The Tennis Movement Evaluation System (TME) helps to obtain more accurate match and training data, which can improve athletes' performance and training efficiency, and more scientifically analyze the movement posture during tennis sports [2]. The data representation in tennis videos is in the form of time series. For time series processing, a common task is to compare the similarity between two sequences. Comparing the similarity of time series is more conducive to identifying patterns and trends, which is of great significance for discovering patterns in action data and predicting future behavior. As one of the most important similarity measurement methods in time series analysis, Dynamic Time Warping (DTW) is the process of elongating or shortening unknown variables until they match the length of the reference template. The time axis of unknown data is distorted or bent, so that its feature quantities correspond to the standard pattern. However, traditional action evaluation methods often rely on manual observation and analysis, which have problems such as low efficiency and strong subjectivity [3].

Regarding the evaluation and classification of tennis movements, many researchers have adopted different algorithms and techniques for in-depth optimization, and have achieved certain results. To analyze the performance of the tennis evaluation platform, Wu et al. collected data through wearable devices and selected the Z-score normalized Support Vector Machine (SVM) to classify hitting actions. The accuracy reached 98.4% [4]. Giles et al. proposed a hierarchical clustering method and tennis directional change technique to distinguish tennis movement styles, identify movement features, and analyze temporal movement characteristics such as change speed and directionality. The results showed that this method was feasible [5]. Perri et al. considered the hitting situation in tennis training and used wearable devices and prototype learning to detect different movements to determine exercise load. The results showed that this technology had high accuracy [6]. Wood et al. used Krippendorffs alpha analysis to evaluate the reliability of tennis serve features in 2D videos. This method had high measurement accuracy [7]. Liu et al. extracted different features through the acceleration of the action and the deep mode data. The spatial and temporal convolutional neural network were combined to realize the specific action recognition. The results showed that the accuracy of this method was more than 99% [8]. In order to analyze the trajectory of tennis serve, Hu et al. combined SVM with frame difference technology and median filtering algorithm to locate targets and recognize trajectories. The results showed that the classification accuracy was 97.5% [9]. Perri et al. used wearable GPS devices to record the training serving load for tennis serving information recording. The results showed that this method had good detection performance [10]. Setyawan et al. evaluated the serving movements of athletes of different genders to improve the success rate of serving and evaluate the

differences in tennis serving performance. The results showed that this method was effective [11].

Some scholars have attempted to improve the DTW method in identifying abnormal charging, time series analysis, and image change detection, and have achieved good results. Shuai et al. developed a DTW model with the longest similar substring to identify abnormal charging situations and avoid excessive regularization of DTW for the safety of electric bicycle charging. The average recognition accuracy reached 94% [12]. Deriso et al. proposed a method that combined DTW and iterative refinement techniques to address the trade-off between time regularization characteristics in traditional DTW signal alignment errors. The results showed that this method was feasible [13]. Zhang et al. designed a fast DTW and sequence decomposition method to analyze different components in time series. The time series was decomposed and the similarity between different components was measured. The results showed that this method had high classification accuracy [14]. Xing et al. detected changes in satellite image time series using remote sensing image time series values and DTW to calculate the change amplitude map. The change results were detected in advance. The accuracy was improved by up to 5.10% [15]. Froese et al. proposed two run length encoding time series to improve DTW calculation speed, which shortened the running time and reduced the factors affecting time. The results shows that this method was effective [16]. Kumawat et al. developed a new framework for DTW and adversarial training to enhance the robustness of deep neural networks. Different adversarial examples were created and random alignment paths were implemented. The framework had high efficiency [17]. He et al. proposed Anticor to improve DTW similarity calculation to identify differences between different sequences. The results showed that the algorithm has good practicality [18]. Vorpe et al. introduced non-parametric DTW to capture the leading and trailing relationships between time series for obesity rate prediction. The results showed that this method had good predictive performance [19].

In summary, both the evaluation of tennis movements and the improvement of DTW have shown high accuracy and effectiveness. However, due to the directional information involved in tennis movements and the large computational complexity of DTW, an innovative TME system is developed for this purpose. The feature of Counter Clockwise Rotation Angle (CRA) of limbs is used to quantify and analyze action direction, and global time weighting and adjacent frame weighting are selected to optimize DTW. The research aims to improve computational efficiency and enhance the real-time performance of the system, thereby providing technical support for the field of tennis movement analysis. This study consists of four main parts. Section II is methods and materials. Among them, Part A introduces the physical CRA of tennis actions. The content of Part B is WCRA between adjacent frameworks and global time. Section III is the results of the study. Among them, Part A analyzes the TME system based on WCRA similarity measurement method. Part B introduces the performance analysis of the TME system. Section IV is discussion and conclusion.

II. Methods and Materials

A. Physical CRA of Tennis Actions

Tennis action videos are captured using cameras that can only capture images from one perspective, and these videos are processed and evaluated [20-21]. Considering that tennis courts include both indoor and outdoor environments, factors such as color and lighting affect video images. To cope with environmental impacts, video images need to be preprocessed. This includes adjusting the brightness of the image and performing noise reduction to improve image quality and ensure accuracy in subsequent processing. Monocular cameras can only capture channel information for the red, green, and blue colors of an image, but do not include distance information. Therefore, Two-Dimensional pose estimation is used to identify human skeletal joint points in images, that is, to determine the position information of each joint point. Each joint not only contains positional information, i.e. coordinates, but also semantic information, such as which joint is the shoulder and which is the knee. Simultaneously, the coordinates of joint points are extracted as the basis for subsequent action evaluation [22]. Because tennis movements are dynamic, there may be some joint points obscured in certain frames of the video, which can affect the accuracy of pose estimation. At this point, if the coordinates of the undetected joint point are set as the origin $O(0,0)$, the horizontal and vertical coordinate pair p_i for the i-th joint point is displayed in Eq. (1).

$$p_i(x,y)=\begin{cases} p_i(x,y), & \text{if } p_i \text{ detected} \\ O(0,0), & \text{if } p_i \text{ not detected} \end{cases} \quad (1)$$

Due to significant differences in body shape among individuals, even if two people perform the same action, the overlap rate of their contours may be low, resulting in inaccurate similarity calculation. However, in 2D skeleton nodes, only considering the angle between limbs has certain limitations. Because when the angle between two adjacent limbs formed by three adjacent joints is the same, i.e. $\theta_1=\theta_2$, the actual movement posture is not the same, which cannot accurately describe the movement characteristics [23-24]. The angle and CRA of the tennis movement limbs are shown in Fig. 1.

(a) Action 1 (b) Action 2

Fig. 1. The angle between tennis limbs and CRA.

In the TME system, to overcome the shortcomings of traditional contour overlap rate and simple angle analysis, this study aims to more accurately describe and evaluate human movements by combining directional information of limb angles. The CRA of the right wrist-right elbow-right shoulder in Fig. 1 (a) is denoted as α_1. The CRA of the right wrist-right

elbow-right shoulder in Fig. 1 (b) is denoted as α_2. The difference between angles α_1 and α_2 is obvious and will not be confused, so the CRA is used to more accurately describe the angle and human posture of the angle. The angle value range of CRA is between 0° and 360°. According to the cosine theorem, the angle between two vectors is calculated. Then, the vector product is used to determine their positional relationship [25]. The tennis movements exclude detailed changes in the head. The distribution of joint points and CRA in the limbs is shown in Fig. 2.

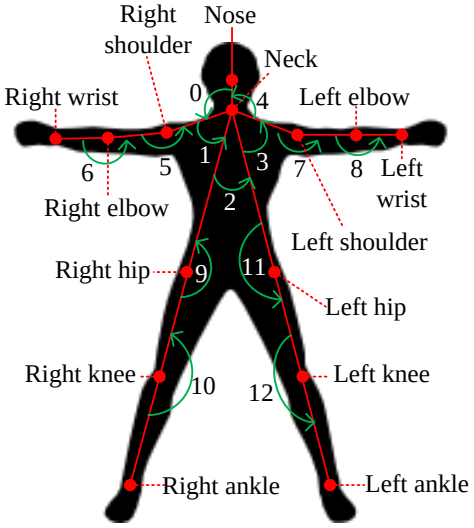

Fig. 2. Schematic diagram of limb joint points and CRA distribution.

In Fig. 2, there are 14 joint points in the limbs. In the template video, OpenPose is used to detect the human joint points of each frame image of two random tennis movements, obtaining 13 limb CRAs. The function of OpenPose is real-time multi person pose estimation and keypoint detection, which can detect the 2D poses of multiple people in images or videos in real time. It is suitable for single person and multi-person scenes and has excellent robustness. The input image or video uses a pre-trained model to identify key points in the human body, including the head, shoulders, elbows, wrists, hips, knees, and other key positions. By identifying and connecting these key points, OpenPose can generate a complete multi-person pose estimation result, thereby recognizing human actions [26-27]. The definition of partial limb CRA is displayed in Table I.

TABLE I. DEFINITION OF LIMB CRA

RA number	Joint number representation	CRA
0	0-1-2	Nose-neck-right shoulder
1	2-1-8	Left shoulder-neck-nose
2	8-1-11	Right Shoulder-neck-right Hip
3	11-1-5	Right Hip-neck-left Hip
4	5-1-0	Left Hip-neck-left Shoulder
5	3-2-1	Right elbow-right shoulder-neck

B. WCRA Between Adjacent Frames and Global Time

In tennis, athletes' movements and scenes change very quickly. Single frame real-time evaluation can quickly adapt to these changes, update evaluation results in a timely manner, and ensure accurate evaluation and feedback in dynamic scenes. Meanwhile, real-time processing of single frame data requires relatively less computation and can effectively utilize computing resources. Compared with processing the entire video stream, single frame evaluation can distribute the computational burden, avoid delays and lags, and ensure the real-time and smooth performance of the system [28]. The single frame evaluation is displayed in Fig. 3.

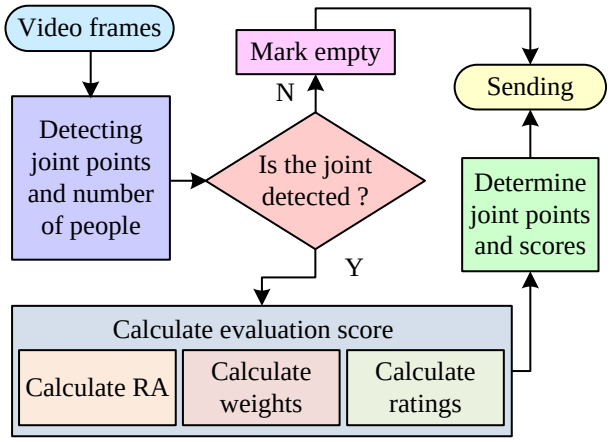

Fig. 3. Flowchart of single frame evaluation.

In Fig. 3, after inputting video frames with a resolution of 656×368, joint points and number of people are detected. If a joint is detected, the evaluation score is calculated from the Rotation Angle (RA), weight, and score to determine the joint points and score. If no joints are detected, it is marked as blank. To facilitate the evaluation of tennis movements in single frame videos, the frame rate of the template video and the input video are set to be the same [29]. The relationship between RA in various limbs of the human body is analyzed to obtain evaluation scores for each frame. The similarity score s_t of t-th frame has a value range of [0, 1], as shown in Eq. (2).

$$s_t = 1 - \frac{\sum_{i=1}^{n} W_i \left| \Delta \alpha_i^t \right|}{C} \tag{2}$$

In Eq. (2), n is the number of RAs. $\Delta \alpha_i^t$ is the difference between the t-th frame input video and the i-th RA of template video. C is the maximum value of RA. When s_t, it indicates that the actions of the template and the input video are completely consistent. When s_t is 0, it indicates that the actions of the template and the input video are completely different. The weight W_i for the i-th RA is expressed as Eq. (3).

$$W_i = aW_i^{\sigma} + bW_i^{\tau} \tag{3}$$

In Eq. (3), a and b are both parameters, with a value of 0.5. W_i^{σ} is the inter frame RA weight of i-th RA input video

actions. W_i^{τ} is the global time RA weight of the template video action for the i -th RA. To analyze TME more comprehensively, the study considers the action situation of the input video. Adjacent Frame Weighting (AFW) focuses on the change details between adjacent frames in the action sequence, which can capture small changes in the action and enhance the matching precision [30-31]. During the DTW process, weight allocation is performed on adjacent frame pairs. AFW considers the changes and interrelationships between adjacent frames, which is suitable for capturing local dynamic changes in sequences. In TME, subtle movement changes can also affect technical evaluation, and AFW can improve the sensitivity of DTW in details. AFW needs to first calculate the cumulative change in limb RA, with a required range between adjacent frames of the current frame, in order to obtain the RA weights between adjacent frames. W_i^{σ} is shown in Eq. (4).

$$W_i^{\sigma} = \begin{cases} \dfrac{\theta_i^{'} + \rho_i^{\sigma}}{\sum_{i=1}^{n} \theta_i^{'} + n\rho_i^{\sigma}} & 0 < \Delta T < t_c \\ 0 & \Delta T \geq t_c \end{cases} \tag{4}$$

In Eq. (4), t_c is the current frame. ΔT is between adjacent frames, and $\Delta T \in (0, t_c)$. $\theta_i^{'}$ signifies the ΔT cumulative change of the i -th RA in the input video from the previous t_c. ρ_i^{σ} is the smoothing term, as shown in Eq. (5).

$$\rho_i^{\sigma} = \sum_{t=t_c-\Delta T}^{t_c} \alpha_i^t \big/ \Delta T + 1 \tag{5}$$

$\theta_i^{'}$ is shown in Eq. (6).

$$\theta_i^{'} = \sum_{t=t_c-\Delta T-1}^{t_c-1} \left| \alpha_i^{t+1} - \alpha_i^t \right| \tag{6}$$

Global Time Weighting (GTW) is used to allocate reasonable weights to the entire action sequence in the time dimension, ensuring that each stage of the entire action process receives appropriate attention. It considers the temporal characteristics of the entire sequence and assigns higher weights to certain key moments or key action points. GTW can balance the importance of different time periods in action sequences, making the DTW algorithm more accurate in matching actions and avoiding certain important time periods from being ignored or underestimated. W_i^{τ} is shown in Eq. (7).

$$W_i^{\tau} = \frac{\theta_i + \rho_i^{\tau}}{\sum_{i=1}^{n} \theta_i + n\rho_i^{\tau}} \tag{7}$$

In Eq. (7), ρ_i^{τ} is the smoothing term, which serves to avoid a weight of 0. If the weight is 0, the corresponding RA information will be ignored, affecting the result. ρ_i^{τ} is shown in Eq. (8).

$$\rho_i^{\tau} = \sum_{t=1}^{T} \alpha_i^t \big/ T \tag{8}$$

In Eq. (8), T signifies the frame number of the template video. θ_i is the degree of change of a specific RA in the time series in the template video. By calculating θ_i, the dynamic variation characteristics of the angle during the action process can be captured. If a certain RA changes dramatically between different frames, θ_i will be larger, indicating that the action point has high dynamism in the entire action sequence and may need to be given higher weight. θ_i is shown in Eq. (9).

$$\theta_i = \sum_{t=1}^{T-1} \left| \alpha_i^{t+1} - \alpha_i^t \right| \tag{9}$$

To better reflect the true s_t, AFW and GTW are applied to the data. The overall evaluation score S for a certain tennis action is shown in Eq. (10).

$$S = \sum_{t=1}^{T} (w_t \cdot s_t), \sum_{t=1}^{T} w_t = 1 \tag{10}$$

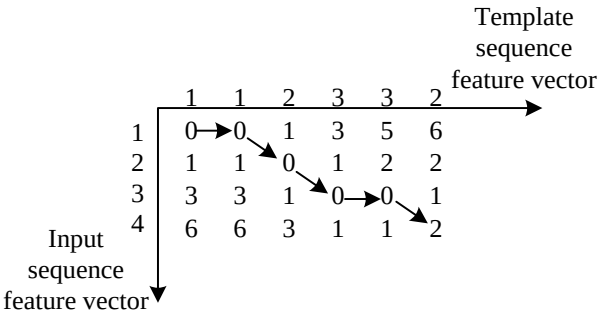
In Eq. (10), w_t is the weighted score, and $w_t \in (0,1)$. AFW focuses more on local changes, emphasizes the dynamic relationship between adjacent frames, and improves the precision and smoothness of matching. GTW focuses more on the temporal characteristics of the entire sequence, emphasizing the matching of critical moments to improve the accuracy and robustness of overall evaluation. Combining these two weighting methods can capture the importance of global key moments in action evaluation while not ignoring the details of local dynamic changes, achieving higher evaluation accuracy and robustness.

C. TME System Based on SDTW

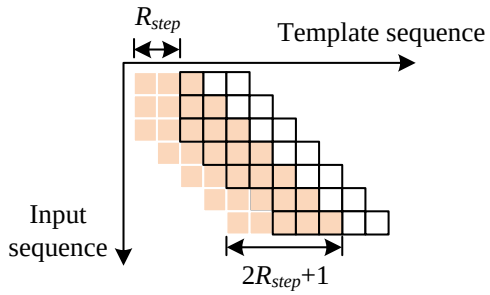
There are multiple similarity or distance functions in time series data in videos. DTW is used to calculate the similarity between two time series. DTW minimizes the cumulative distance between one time series and another by calculating the nonlinear mapping relationship between the two. DTW may not be able to output results in a timely manner, as it requires traversing a large amount of frame data to find the path with the minimum cumulative distance. To solve the real-time of the DTW algorithm, an improved algorithm called Segmented DTW (SDTW) is proposed. The core idea of SDTW is to segment the actions in the template video and perform path search within each segment. This method reduces time complexity and improves computational efficiency by limiting the search range. By segmenting and reducing computational complexity, SDTW can output calculation results in a timely manner at the end of frame processing in action videos, thus meeting real-time requirements. The schematic diagram of path search for DTW and the search area for SDTW with a step size of $R_{step} = 2$ are shown in Fig. 4.

In Fig. 4 (a), a 2D distance matrix D is constructed, with the total frame numbers of the input video and template video being n and m, respectively. The matrix element $d_{(i,j)}$ at the current position (i, j) is displayed in Eq. (11).

$$d_{(i,j)} = d_{\min} + \sqrt{\sum_{k=1}^{n} (\Delta \alpha_k)^2} \tag{11}$$



(a) DTW path search diagram



(b) SDTW's search area

Fig. 4. DTW path search and SDTW search area.

In Eq. (11), $d_{\min}$ signifies the minimum distance value obtained in the previous step. $\Delta\alpha_k$ is the difference between the k-th CRA of the input video and the template video. At the initial position (1,1), $d_{\min}$ is 0. At different positions, $d_{\min}$ is shown in Eq. (12).

$$d_{\min} = \min\left(d_{(i-1,j)}, d_{(i,j-1)}, d_{(i-1,j-1)}\right) \tag{12}$$

In Eq. (12), $(i-1,j)$ and $(i,j-1)$ are the adjacent positions on the upper and left sides of (i,j), respectively. $(i-1,j-1)$ is the upper left corner position of (i,j). DTW first starts from the initial position $(1,1)$ of the time series matrix, gradually accumulates and calculates the distance of each step by moving to the right, down, and right adjacent positions in the matrix, and finds the path in this process to minimize the total accumulated distance. Finally, the DTW algorithm uses this path to find the minimum cumulative distance at the endpoint position (n,m) of the matrix, which represents the minimum similarity distance between two time series. A small distance indicates that the two sequences are more similar in the time dimension, demonstrating that the shapes or patterns of the two sequences are closer. In Fig. 4 (b), when the template video time series is segmented, the step size is set to R_{step}. To better limit the range of path search, the width on both sides of the diagonal is specified to ensure that the search path is concentrated near the diagonal rather than spreading throughout the entire matrix R_{step}. In the case of segmented processing, the total width range of path search is determined by the step size R_{step}, with a maximum width of $2R_{step}+1$ and a minimum width of $R_{step}+1$. This means that the path search range will be limited to the diagonal and its left and right range R_{step}, thereby reducing computation and complexity. The endpoint position of the first segment of SDTW is (n, j_e), and the vertical axis satisfies $j_e \in \left(m+1-R_{step}, m+1+R_{step}\right)$. At this time, the search range of the path is on the diagonal, with a width of $2R_{step}+1$. The computational workload is reduced to avoid global search. Subsequently, by moving R_{step} steps each time, different path searches can be achieved. The average distance $\bar{d}$ for each step is shown in Eq. (13).

$$\bar{d} = \frac{c}{\kappa} \tag{13}$$

In Eq. (13), c and κ are the distance and length of the path. The conversion score s_d is shown in Eq. (14).

$$s_d = \frac{1}{1+h\bar{d}} \tag{14}$$

In Eq. (14), h is the coefficient that adjusts the magnitude of the score decrease, and $h = 0.25\kappa$. As $\bar{d}$ increases, the similarity between two time series decreases. At this time, the result of s_d is closer to 0. Two time series are completely identical, and $s_d = 1$. To evaluate human movements in a single frame video, it is necessary to ensure that the input video and the template video have equal frame rates. Analyzing the relationship between RA in various limbs of the human body can obtain a single frame calculation evaluation score. In practical operation, extracting human joint information is a time-consuming process and may cause delays during network transmission. To alleviate these issues, an offline processing module is added to the TME system. The function of this module is to process the template video in advance, extract and save the joint coordinates of each frame to the local file. Therefore, in the actual real-time evaluation process, the system only needs to read the stored joint information from the local file without recalculating and extracting, greatly reducing the time required for evaluation and improving efficiency. Therefore, the constructed architecture diagram of the TME system is shown in Fig. 5.

In Fig. 5, the client and server of the TME system use Socket to achieve data transmission. The client is connected to the monocular camera through USB, and can display a video interface and collect video data. Meanwhile, customers can preprocess video frame data and then transmit it to the server. The focus of the server is on extracting joint points and evaluating actions. The monocular camera is transmitted to the server via USB connection, and the server receives the data information and transmits the results to the client.

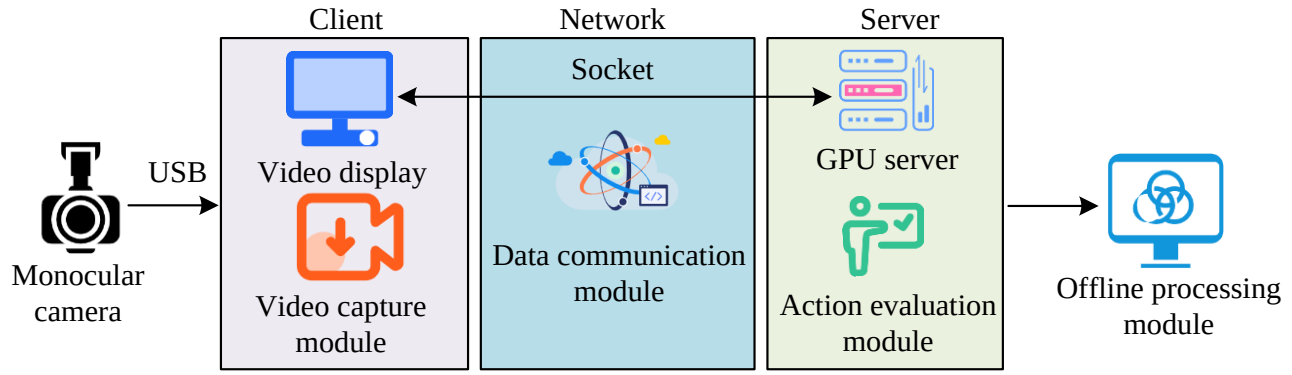


Fig. 5. TME system architecture diagram.

III. Results

A. Analysis of TME System Based on WCRA Similarity Measurement Method

The experimental datasets are the Tennis Videos Dataset and the Tennis Stroke Dataset, with the former containing a large number of tennis matches and training videos, typically used for video analysis, action recognition, and strategy analysis. The latter includes data on various tennis hitting movements, such as smashes, Forehand Strokes (FS), Backhand Strokes (BS), Forehand Cut (FC), and Backhand Cut (BC). The experimental setup is displayed in Table II.

TABLE II. Hardware Equipment and Software Environment for Experimental Setup

Hardware device	Device type	Software environment	Configuration information
GPU server	NVIDIA Tesla P40	Operating system	Ubuntu 14.04.5 LTS
GPU architecture	NVIDIA Pascal	Deep learning framework	Caffe
High definition digital camera	SONY HDR-CX405	GPU parallel computing architecture	CUDA 8.0
Monocular camera	RER-USBFHD01M	Computer vision library	OpenCV 2.4.13

The research indicators include similarity evaluation scores and accuracy. The similarity evaluation score is used to assess the similarity between actions of the same type (such as multiple backhands) and actions of different types (such as backhands and smashes). By calculating and comparing these scores, the similarity between different action types before and after improvement can be analyzed to evaluate the accuracy and effectiveness of the algorithm. Accuracy is used to measure the performance of algorithms in identifying and classifying action types, such as kill actions. By comparing the accuracy and average accuracy of different methods, the effectiveness and reliability of each method can be evaluated under different levels of action performance. To evaluate the impact of different algorithms on real-time performance when processing monocular camera videos using OpenPose. A monocular camera is conFig.d, with a video frame rate of 60FPS and a resolution of 1280×720. The required algorithm environment is set on the server, including OpenPose. Different algorithms are run sequentially and combined with OpenPose to process video streams, recording the actual frame rate per second during the processing. The experiment is conducted 20 times to ensure reliability and statistical significance, with each experiment lasting 10 minutes. In each experiment, the processed video frame rate and changes in frame rate are analyzed, as shown in Fig. 6.

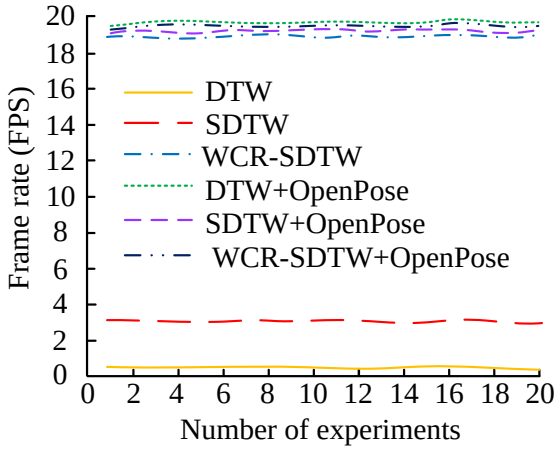

Fig. 6. The frame rate variation of different methods.

In Fig. 6, the average frame rate of DTW without OpenPose processing was the lowest, only 0.5FPS. The average frame rate under the action of WCR and SDTW was19.1FPS, while the average frame rate processed by OpenPose was 19.5FPS, which was time-consuming, but achieved high accuracy. The proposed algorithm, combined with OpenPose, can better maintain the real-time frame rate of the video.

To verify the effectiveness of the designed limb CRA, an analysis is conducted on the changes in CRA values of BS action and smash action, and a comparison between the two was obtained, as shown in Fig. 7.

In Fig. 7 (a), the angle value of CRA 8 fluctuated the most within 30 frames, indicating a more drastic change in the left arm. In Fig. 7 (b), there was a significant fluctuation in the angle value of the right arm CRA 6 during the smash action, ranging from 36° to 260°. Therefore, the proposed limb CRA can effectively represent changes in limb direction, clearly distinguishing between movement and posture situations.

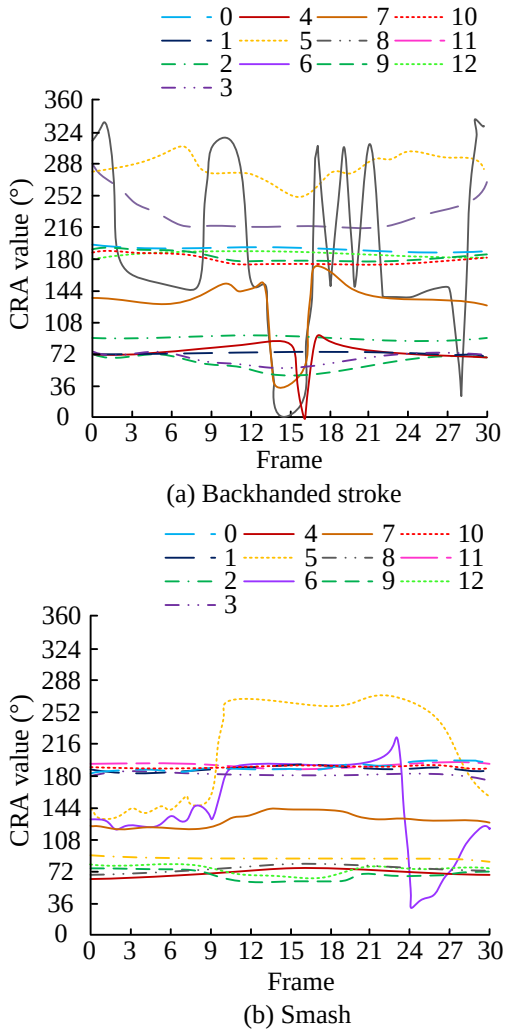

Fig. 7. Comparison of CRA value changes in backhand and smash movements.

To verify the proposed improvement method, the similarity scores between different action types are evaluated to analyze the performance of the improved method. The study randomly selects 250 tennis training videos from the dataset and selects five types of movements: FS, BS, FC, BC, and smash. The similarity scores are analyzed by action type. The similarity scores of same action types and different action types are calculated. The similarity of different action types before and after improvement is compared, as shown in Fig. 8.

In Fig. 8 (a), the similarity scores between actions of the same type and between actions of different types both exceeded 0.75 points. However, according to the similarity score results, the method before improvement was not able to distinguish action similarity scores well. The difference between the maximum and minimum scores for actions of the same type ranged from 0.02 to 0.16 points. In Fig. 8 (b), there was a clear distinction between the five types of actions, with a score difference ranging from 0.27 to 0.49 points. Therefore, the improved method has better discrimination than before.

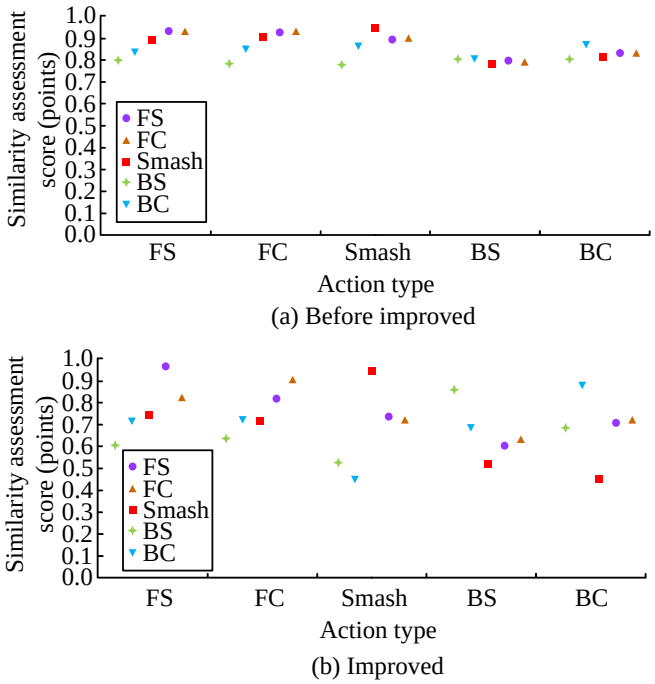

Fig. 8. The similarity score between different action types before and after improvement.

To analyze the accuracy of the improved method, different methods are selected for comparison, including 3D motion capture technology [32], Gaussian Distance-Improved DTW (GD-IDTW) [33], and Joint Angles and Movement Similarity (JA-MS) [34]. The action performance of the dataset is divided into three levels: good, average, and poor. The score for poor action performance ranges from 0.0 to 0.6, the score for average action performance ranges from 0.6 to 0.8, and the score for good action performance ranges from 0.8 to 1.0. The accuracy and average accuracy of different methods of smash actions among the three levels of performance are shown in Fig. 9.

In Fig. 9 (a), the accuracy of the improved method for the smash action was 98.12%, 100.00%, and 100.00% for good, average, and poor performance, respectively. The accuracy of GD-IDTW was relatively close to the improved method, with accuracy rate of 96.97%, 85.77%, and 100.00% for good, average, and poor action performance, respectively. The overall accuracy of the improved method was higher than other methods, because the improved method was significantly better than the GD-IDTW in handling fine actions, which could better capture subtle differences in these actions. In Fig. 9 (b), in the similarity evaluation with good action performance, the improved method had an average accuracy close to GD-IDTW, with 88.15% and 88.01% respectively, showing superior performance. In terms of average action performance, the improved method had an average accuracy of 90.12% in action performance, which was higher than other methods. In the similarity evaluation of poor action performance, the average accuracy of the improved method was 92.55%. The improved method not only enhances computational efficiency, but also improves the accuracy of similarity evaluation.

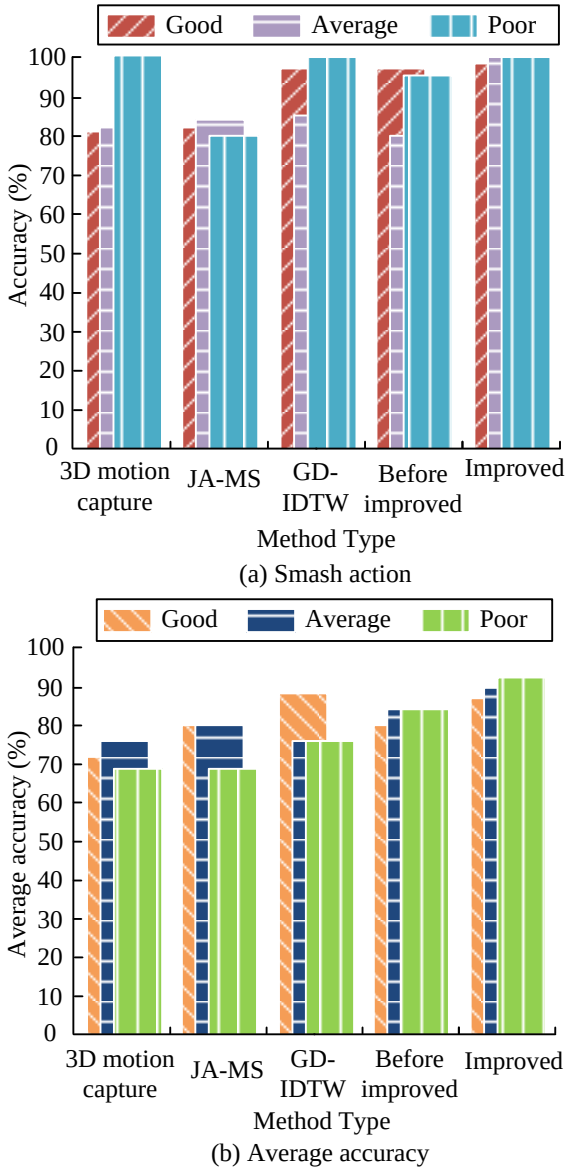

Fig. 9. Comparison of accuracy of different methods.

To verify the accuracy of the improved method for classifying tennis movements, the experiment selects five different types of movements from two datasets, the Tennis Videos Dataset and the Tennis Stroke Dataset, for analysis. The matrix element is the ratio of the number of recognized actions to the number of tested actions. The confusion matrix obtained for the five types of tennis movements is shown in Fig. 10.

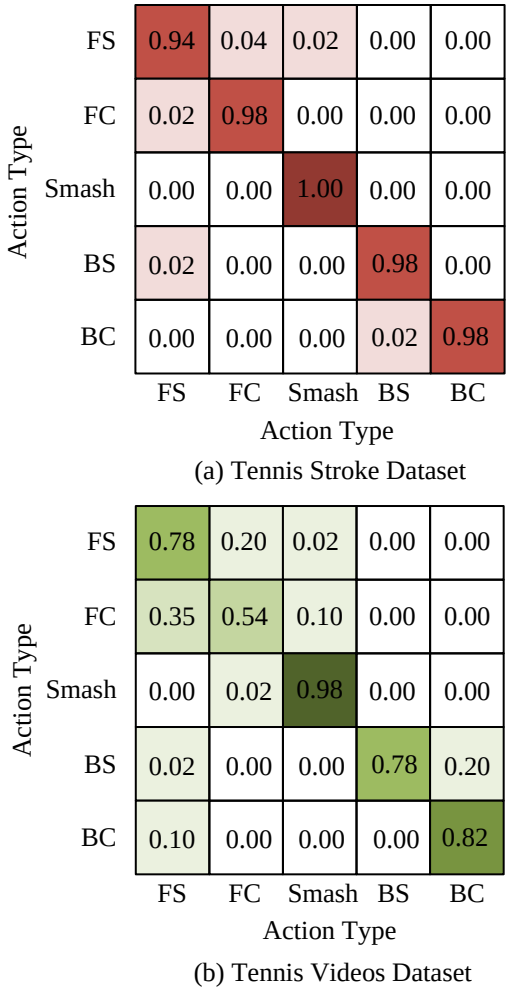

Fig. 10. Comparison of confusion matrices for different datasets.

In Fig. 10 (a), the five columns represent the five recognized action types, and the 5 rows represent the 5 tested action types. The average accuracy of action classification in the Tennis Stroke Dataset was 97.60%. In Fig. 10 (b), there were many classification errors between FS and FC actions in the Tennis Videos Dataset, with an average accuracy of 78.00% for action classification.

To analyze the generalization of the improved method, the study identifies non-tennis movements in two datasets. The number of tests for each type of action is 9, and duplicate videos are filtered out to obtain the recognition accuracy, as displayed in Table III.

TABLE III. RECOGNITION ACCURACY OF NON TENNIS MOVEMENTS

Dataset	Action Type	Bending	Capriole	Running	Walking	High five
Tennis Videos Dataset	Correct number	7	8	7	9	7
	Accuracy	0.78	0.89	0.78	1.00	0.78
Tennis Stroke Dataset	Correct number	6	7	6	8	9
	Accuracy	0.67	0.78	0.67	0.89	1.00

In Table III, for the five movements of bending, Capriole, running, walking, and high five, the average accuracy obtained using the improved method reached 82%. The recognition accuracy of the Tennis Videos Dataset was generally high, with walking movements achieving 100%, and the high five movements of the Tennis Stroke Dataset also achieving 100%. The proposed method has a certain degree of generalization ability in recognizing non-tennis movements on different datasets.

B. Performance Analysis of TME System

Client performance evaluates the real-time performance of video capture and transmission, ensuring that video frames captured by monocular cameras can be transmitted to the server in a timely manner. This includes the frame rate of the camera, data transmission delay, and stability of network transmission. Server performance refers to evaluating the real-time performance of the server in receiving, processing, and analyzing video frames. The server needs to quickly perform algorithm processing and return results after receiving video frames to ensure the overall system response speed. To comprehensively evaluate and optimize the performance of the system, and ensure that the entire TME system can run efficiently and stably in practical applications, real-time testing is conducted on the client and server of the TME system. Five tennis movements are selected for the experiment, and tested five times on both the client and server sides of the system. The average frame rate obtained is presented in Table IV.

In Table IV, the average frame rates of the server in action evaluation and action recognition were 18.52FPS and 18.51FPS, respectively, both higher than those of the client. In the action evaluation mode, the average frame rate of the client was between 17.35FPS and 17.49FPS, and the overall average frame rate was about 17.40FPS. The server exhibited higher efficiency in action processing and evaluation, which could process video frames faster. It is more efficient in processing data capabilities and utilizing data resources. In both modes, there is not much difference in frame rate between the client and server, but the overall trend is consistent. This indicates that the performance of the system is relatively consistent in different modes and has a certain degree of stability.

In the TME system, three individuals are selected for testing. Among the five types of tennis movements, three sets of imitative movements are tested for each movement. The performance levels are good, average, and poor. The similarity evaluation scores for different action types are shown in Fig. 11.

TABLE IV. COMPARISON OF AVERAGE FRAME RATES BETWEEN SERVER AND CLIENT

Mode type	Action Type	FS	FC	Smash	BS	BC	Average frame rate (FPS)
Average frame rate of action evaluation mode (FPS)	Client	17.38	17.35	17.37	17.39	17.49	17.40
	Server	18.50	18.57	18.56	18.43	18.54	18.52
Average frame rate of action recognition mode (FPS)	Client	17.24	17.28	17.38	17.28	17.27	17.29
	Server	18.53	18.51	18.48	18.51	18.49	18.51

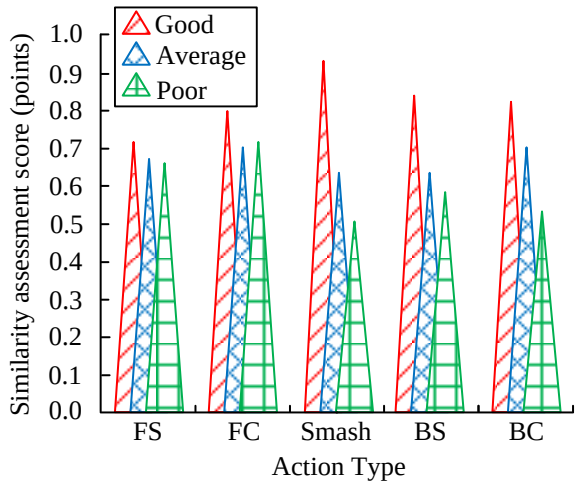

Fig. 11. Similarity evaluation scores for different action types.

In Fig. 11, the similarity evaluation score for the smash action with good performance was the highest, at 0.94, while the similarity evaluation score for this action with poor performance was the lowest, at 0.5. The evaluation scores for smash, BS, and BC actions were relatively high, while the similarity evaluation scores for FS and FC actions were relatively close, resulting in a lower degree of differentiation between the two.

IV. DISCUSSION AND CONCLUSION

There are significant challenges in efficiently and accurately evaluating tennis movements at present. In order to improve computational efficiency and real-time performance of the system, a TME system was developed. The limb CRA was used to quantify and analyze action direction. Then, AFW and GTW weighting were used to optimize DTW. The results showed that the angle value of CRA 8 fluctuated the most within 30 frames, indicating that the changes in the left arm were more severe. The angle value of CRA 6 in the right arm of the smash action fluctuated greatly, ranging from 36° to 260°. The similarity scores between actions of the same type and between actions of different types both exceeded 0.75 points. However, according to the similarity score results, the method before improvement was not able to distinguish action similarity scores well. To address this issue, Zhang et al. focused on evaluating the quality of actions in videos by using distributed autoencoders, likelihood loss sampling scores, and learning uncertainty parameters [35]. The difference between the maximum and minimum scores for actions of the same type ranged from 0.02 to 0.16 points. There was a clear distinction between the five types of actions, with a score difference of 0.27-0.49 points. Therefore, the improved method had better discrimination than before. For the smash action, the accuracy rates of the improved method for good, average, and poor performance were 98.12%, 100.00%, and 100.00%, respectively. The accuracy of GD-IDTW was relatively close

to the improved method, with accuracy rates of 96.97%, 85.77%, and 100.00% for good, average, and poor action performance, respectively. The overall accuracy of the improved method outperformed other methods, because the improved method was significantly better than the GD-IDTW in handling fine actions, which could better capture subtle differences in these actions. In the similarity evaluation of good action performance, the improved method had an average accuracy close to GD-IDTW, with 88.15% and 88.01%, respectively, showing superior performance. As for average action performance, the improved method had an average accuracy of 90.12%, which was higher than other methods. In the similarity evaluation of poor action performance, the average accuracy of the improved method was 92.55%. The improved method not only enhances computational efficiency, but also improves the accuracy of similarity evaluation. This method has a certain positive effect on the Estevam team in obtaining semantic information from videos for recognizing actions [36]. The improved method effectively achieves accurate and real-time action similarity evaluation, which is of great significance for various training and evaluation systems that require real-time feedback. Meanwhile, this innovative method will make significant contributions to the development of sports science research and intelligent sports evaluation systems. However, this study does not consider the impact of lighting environmental factors on the evaluation results. Excessive or insufficient lighting can lead to the loss of details in the image, which in turn affects the accuracy of action recognition and the reliability of similarity evaluation. In the future, experiments can be extended to different lighting environments, including natural light, artificial light sources, and changes in lighting intensity. By testing the performance of the algorithm under various lighting conditions, the robustness of the algorithm in different lighting environments can be identified and optimized.

Internet of Things User Behavior Analysis Model Based on Improved RNN

Keling Bi*
School of Information Engineering, Liaodong University, Dandong 118003, China

***Abstract*—Currently, there are issues with low efficiency and outdated Internet of Things resource allocation. To study real Internet of Things user behavior data, a Bayesian optimization algorithm is used to automatically select hyperparameter combinations and construct an Internet of Things user behavior analysis model based on long short-term memory. The results showed that the prediction accuracy of the model reached 96.8% and 97.53% on the training and validation sets, while in the set 50 maximum iterations, the model achieved 80.78% on the test set. In comparing the performance between the research model and the traditional recurrent network model, it was found that the optimal prediction accuracy of the research model was 80.78%, which was better than the comparison model. The application results of the research model in short-term power load forecasting also indicated that the prediction accuracy of the Internet of Things user behavior analysis model based on the improved recurrent network has reached a good level, far superior to the comparative model. The results have important application value for allocating energy and resources in Internet of Things systems.**

Keywords*—Internet of Things; user behaviors; recurrent neural network; Bayesian optimization; long short-term memory; hyperparameter

I. Introduction

The continuous progress of science and technology has led to an exponential growth trend in the amount of information, and the Internet of Things (IoT) technology has also been further developed. In recent years, the further popularization of 5G technology, the further reduction of hardware costs, and the development of big data technology have led to a significant advancement in the IoT. At this stage, the IoT is no longer merely a network of objects and systems; it has evolved into a comprehensive system that connects all the people, processes, and resources involved, forming a seamless and automated interaction process [1-2]. At the current stage of development, the IoT integrates the interactive factors related to people. The data types and quantities involved in the whole IoT system have greatly increased, and the traditional processing system technology has been unable to meet the actual needs of [3-4]. At this time, artificial intelligence (AI) technologies have emerged as the optimal avenue for industrial advancement within the IoT domain. Furthermore, the integration of AI has become pervasive across various production and operational processes. However, the practical application of AI technology in the IoT often has the problem of poor timing [5-6]. Given this, many scholars have researched the analysis of IoT user behavior, and methods such as mathematics, data mining, and machine learning (ML) have emerged [7-8]. Mathematical methods are characterized by high complexity, limited interpretability, and greater difficulty in achieving results. In contrast, data mining and simple calculation technology are relatively straightforward, yet they often prove ineffective in predicting user behavior. Based on this, the long and short-term memory (LSTM) recurrent neural network (RNN) method in the ML method is used to construct the prediction model. At the same time, to solve the problems of high complexity and optimization difficulty of ML methods, the Bayesian optimization algorithm (BOA) is studied based on the prediction model of LSTM-RNN, which can realize the automatic optimization of the prediction model. This study first hopes to find out the correlation and the implied behavior mode of the user behavior data of the IoT, aiming to provide more temporal data for more accurate, fast, and convenient IoT services. Secondly, the study is expected to construct a user behavior prediction model for the IoT that can adapt to different environmental characteristics. This will provide a basis for user behavior information that can be used to improve the quality of system services in the IoT and further improve the efficiency of resource allocation in the system. Finally, the study validates the model through training in terms of losses, effects, and load forecasting. Through these verification methods, the performance and practical application of the proposed method can be effectively analyzed.

II. Literature Review

In the context of IoT research pertaining to user behavior analysis (UBA), to promote the application of big data in various fields, Hou et al. proposed an IoT unstructured big data analysis online client algorithm built on ML algorithm. The algorithm was used in other big data analysis scenarios and verified to be more efficient than other comparative algorithms [9]. Abdelmoumin et al. conducted research on the performance of IoT-based anomaly-based intelligent intrusion detection system (IDS) ML model. Compared with deep learning-based IDS, anomaly-based ML-based IDS exhibited lower performance and prediction accuracy (PA) in detecting intrusions in IoT [10]. Xu et al. proposed a data-driven intrusion and anomaly detection method using IoT automatic ML to address the current issues of IoT network attacks and intrusions. This algorithm technology not only saved the computational cost of runtime test data, but also solved a multi-class classification problem with an accuracy of 99.7%, with significant advantages over existing algorithms [11]. To solve the optimal pricing and bundling problem of ML-based IoT services, Alsheikh et al. defined data value and service quality from the perspective of ML and proposed an IoT market model. Compared to independent sales, bundling IoT services could maximize the profits of service providers [12]. Woźniak et al.

analyzed the network traffic of various IoT solutions based on deep learning models to address network security issues in network physical systems. The results confirmed that even when the number of evaluated network features decreased, the model was very effective in identifying potential threats, with an accuracy rate of over 99% [13]. Zhao et al. proposed an IoT intrusion detection method based on lightweight deep neural networks. On two real NID datasets, this method had good classification performance, lower model complexity, and smaller model size, making it suitable for IoT traffic classification in both normal and attack scenarios [14].

In studies employing LSTM networks for behavioral prediction, the LSTM network will also be utilized to conduct such studies based on the most abundant user purchase and social behavior data available on the Internet. For example, Sakar et al. used a multi-layer perceptron for feature classification and trained a LSTM-RNN to predict the probability of the user leaving the current site. The purpose was to take corresponding measures to improve the purchase conversion rate of the website [15]. LSTM networks are also used in some prediction studies of action and behavioral trajectories. To estimate the movement intention of people in intelligent manufacturing service of human-robot cooperation, Liu et al. used LSTM network to extract the time pattern of human movement and automatically output the prediction results before the movement. This approach was taken to ensure the efficiency and safety of the system [16]. Huang et al. proposed three properties of asymmetric driving behavior and constructed a vehicle following model based on a LSTM-RNN [17]. Yimin et al proposed a human-centered trajectory tracking control strategy, using a LSTM network to design a model predictive control method considering insertion vehicle driver behavior to track the reference trajectory [18].

In conclusion, many scholars have achieved notable advancements in the enhancement of IoT-UBA performance, economic value, and network security. However, existing IoT-UBA research focuses on predicting whether a certain behavioral action will occur, without considering the usage characteristics of items in IoT and the relationships between users and items. In addition, existing research only considers the sequence relationship between user behavior occurrence, that is, using pre-order behavior to analyze the possible behaviors that may occur in the post-order. This merely indicates the potential for future behavior without specifying the timing of subsequent actions. Consequently, it is unable to enhance the precision, speed, and accessibility of IoT services or provide more detailed temporal data. Based on this, this study innovatively proposes the use of BOA for model hyperparameter selection, improves RNN, and constructs an IoT-UBA model that can adapt to different environmental characteristics. The model can provide more time-series data for more accurate, fast, and convenient IoT services. Furthermore, it can enhance the efficiency of resource allocation within the system.

III. Methods and Materials

This study first conducts relevant data mining and preprocessing based on real IoT user behavior data. Subsequently, the user behavior dataset is employed to train an IoT-UBA model founded upon LSTM-RNN, and BOA is utilized to automatically select model hyper-parameter combinations.

A. Research Data Mining and Preprocessing

The dataset used contains sensor activation data from 00:00:00 to 23:59:59 every second within 30 days in an IoT environment for TWO family members. 86,400s of data are generated every day, with a total of 2,592,000 pieces of data included in the 30 day period. The activation of each sensor represents the use of a certain item, so the activation data of sensors can to some extent represent the behavior of residents in the IoT environment. Table I shows the location, type, and ID of the sensors.

In Table I, the dataset folder "ARAS" contains two folders: "HouseA" and "HouseB", representing two different households. Each household folder contains 30 text files in the format "DAY_x" and one "Readme" text file to explain the basic information of data, sensor information, and activity instructions. Before mining and further processing data, the first is to compress and merge the data. Considering that the IoT-UBA model constructed using RNN is used, this study uses a total of 30 days of monthly data for merging and compression. After conducting a series of pre-experiments, the dataset compressed in units of 20s performs the best in three candidate scenarios: 10s, 20s, and 30s. Therefore, this study will compress the data in units of 20 seconds, meaning that every 20 rows of data will be merged into one row. The merged data in this row will take the maximum activation data of all sensors within 20 seconds, that is, all activated sensors within 20 seconds will be marked as "1". Subsequently, this study formats the data based on the time step determined during the data mining auto-correlation analysis process. The time window processed sequence dataset is shown in Fig. 1.

Dataset $\{x_1, x_2, ..., x_n\}$ is processed into the format shown in Fig. 1 using a time window of length t. The n sequence data are processed into n-t+1 sequence data with a time step of 1. Among them, in the data used, size is to be determined as the hyper-parameter of the model, and the input data dimension is 20 dimensions. The time step is determined by auto-correlation analysis to be 60, which means that the behavior of IoT users in the first 60 time units will have an impact on the current IoT user behavior. The original data consist of 129,600 20 dimensional sensor activation data, with a data format of (129,600*20). After processing through a time window of 60 in length, it has been transformed into a 3D dataset in the shape of (129,541*60*20). Among them, 129,541 is calculated by (129,600-60+1).

TABLE I. ID, TYPE, AND LOCATION OF SENSORS

Sensor ID	Sensor Type	Place
Ph1	Photocell	Wardrobe
Ph2	Photocell	Convertible Couch (Used as bed for Resident 2)
lr1	IR	TV receive
Fol	Force Sensor	Couch
Fo2	Force Sensor	Couch
Di3	Distance	Chan
Di4	Distance	Chair
Ph3	Photocell	Fridge
Ph4	Photocell	Kitchen Drawer
Ph5	Photocell	Wardrobe
Ph6	Photocell	Bathroom Cabinet
Co1	Contact Sensor	House Door
Co2	Contact Sensor	Bathroom Door
Co3	Contact Sensor	Shower Cabinet Door
So1	Sonar Distance	Hall
So2	Sonar Distance	Kitchen
Di1	Distance	Tap
Di2	Distance	Water Closet
Te1	Temperature	Kitchen
Fa3	Force Sensor	Bed

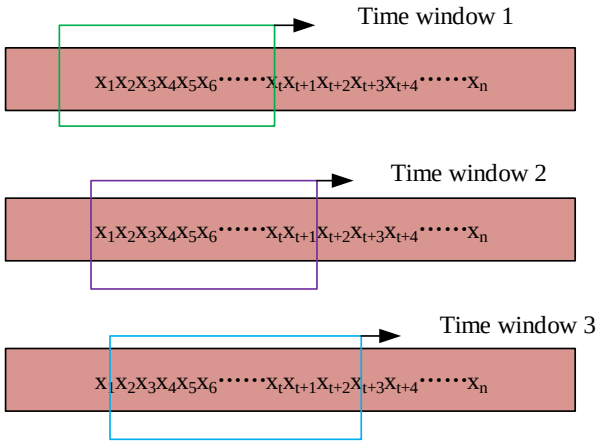

Fig. 1. Time window processed sequential dataset.

The data used in this study is relatively large (greater than 10,000 but less than 100,000), so the data are segmented into a 60% training set, a 20% validation set, and a 20% testing set. After format transformation, 129,541 pieces of data will be divided into the first 77,727, middle 25,907, and last 25,907 pieces according to the time series for model construction. Among them, 77,727 pieces of data are used for the preliminary construction and optimization of the model, and 25,907 pieces of data are used to verify the model's generalization ability during the optimization process. After the model construction is completed, the generalization ability of the final model is tested using the last 25907 pieces of data.

B. Building an IoT-UBA Model Based on Improved RNN

In solving problems related to time series data, complete and continuous strings, images, etc., there is a certain degree of correlation between the front and back data of the dataset involved. That is to say, in model training, the data cannot only enter the neural network unilaterally and independently for parameter training . To build a better IoT-UBA model, it is necessary to fully consider the information carried by the pre-order data in the process of drawing conclusions. Among them, RNN is used to solve sequence related problems. In RNN, the parameter W used for information transmission in hidden states is the same. In the backpropagation gradient descent method used to solve parameters, the chain rule of differentiation will result in the solved gradient containing the multiplication of weights. When the weight value is greater than or less than 1, multiplication will cause the gradient to expand infinitely or approach zero infinitely. The former is called gradient explosion, while the latter is called gradient disappearance. The gradient explosion problem can be solved using gradient truncation, which limits the maximum value of gradients [19-21]. Similarly, if the gradient vanishing problem is to be solved by restricting the minimum value of the gradient, it will result in the obtained weights not reflecting the actual impact of the node well. This study proposes to use LSTM network to solve this problem, and its network structure is shown in Fig. 2.

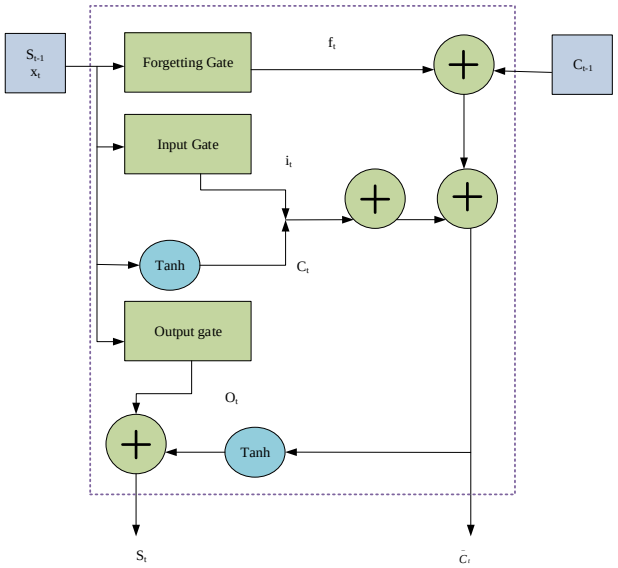

Fig. 2. Internal structure of LSTM unit.

The LSTM unit has three parts: input gate, output gate, and forget gate. The activation function corresponding to the three control gates is the sigmoid function. The output of sigmoid is between 0 and 1. The activation function can be understood as a control valve in the layman's sense, where "0" represents the control valve being closed and the information being completely filtered. "1" represents the control valve closing, and the information is completely retained. By controlling the opening and closing of the valve, important information can be filtered. If the x_t, the previous unit state S_{t-1}, and the long-term state (LTS) C_{t-1} that was memorized in the previous time are input, the unit is entered first and the forget gate is entered next. At this point, a vector f_t composed of numbers is obtained, as shown in Eq. (1).

$$f_t = \sigma\left(W_f \times S_{t-1} + U_f + x_t + b_f\right) \tag{1}$$

In Eq. (1), $f_t \in [0,1]$. W_f, U_f, and b_f represent the weights of the forget gate. The multiplication of f_t and the LTS C_{t-1} from the previous moment determines how much information in C_{t-1} enters C_t, as shown in Eq. (2).

$$K_t = f_t \otimes C_{t-1} \tag{2}$$

In Eq. (2), K_t represents the need to retain the information of the LTS C_t at this moment, and this result will be used as one of the inputs to the input gate. In the input gate, x_t and S_{t-1} are processed by a tanh function to obtain the information $\bar{C}_t$ of the LTS to be added, as shown in Eq. (3).

$$\bar{C}_t = \tanh\left(W_C \times S_t - 1 + U_C + x_t + b_C\right) \tag{3}$$

In Eq. (3), W_C, U_C, and b_C represent the weights of long-term unit states, similar to forgetting gates. x_t and S_{t-1} will also pass through a signoid function to obtain a vector i_t composed of numbers. This vector is multiplied by $\bar{C}_t$ to determine how much information needs to be added to the LTS C_t at this moment, as shown in Eq. (4).

$$i_t = \sigma\left(W_i \times S_{t-1} + U_i + x_t + b_i\right) \tag{4}$$

In Eq. (1), $i_t \in [0,1]$. W_i, U_i, and b_i are the weights of the input gate. By combining the calculation results of the forget and input gates, the LTS C_t is obtained, as shown in Eq. (5).

$$C_t = K_t + i_t \otimes \bar{C}_t \tag{5}$$

In Eq. (5), C_t is only transmitted within the network and will be passed to the next unit as one of the inputs to the next unit. Similarly, passing through the signoid function will generate a numerical vector o_t, as shown in Eq. (6).

$$o_t = \sigma\left(W_o \times S_{t-1} + U_o + x_t + b_o\right) \tag{6}$$

The LTS C_t at this moment is processed by the tanh function and multiplied by o_t to determine how much information in the LTS C_t is output as the unit state S_t at that moment, as shown in Eq. (7).

$$S_t = o_t \otimes \tanh\left(C_t\right) \tag{7}$$

Among them, the unit state S_t on the last time step is the final output of the model. After each batch of data is transmitted into the network, parameters are updated through gradient descent to reduce the loss between actual and predicted values. This study uses binary cross entropy as the loss function M, as shown in Eq. (8).

$$M = -\frac{1}{20}\sum_{I=1}^{20}\left[y_i \log\left(\bar{y}_i\right) + \left(1 - y_i\right)\log\left(1 - \bar{y}_i\right)\right] \tag{8}$$

In Eq. (8), y represents the numerical vector of the true value. $\bar{y}$ represents the numerical vector of the predicted value. In relatively fixed and bounded usage scenarios like IoT, user behavior interacts with relatively fixed objects within a certain range, with limited influencing factors and following certain patterns. To this end, an IoT-UBA model is constructed based on LSTM, as shown in Fig. 3.

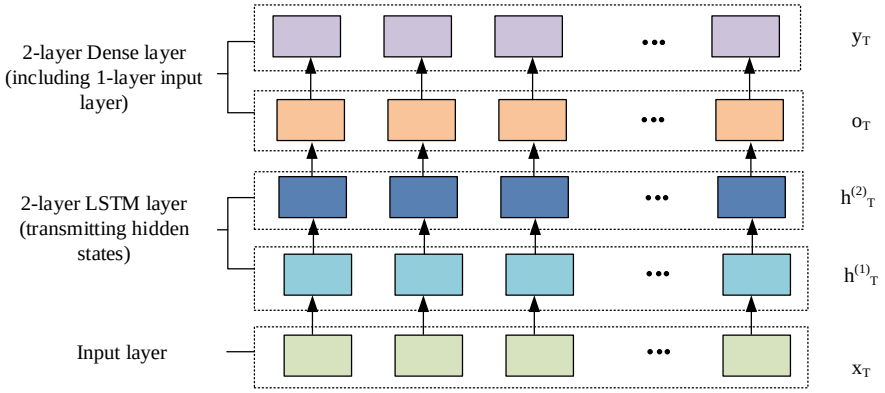

Fig. 3. Schematic diagram of the research model.

This model is a neural network model consisting of two LSTM layers, one Dense layer, and one output layer. On the data of each time step t (t∈[1,T])) with a total of T time steps, the hidden state $h_t^{(1)}$ (t∈[1, T]) of the first layer LSTM layer and the hidden state $h_t^{(2)}$ (t∈[1,T])) of the second layer LSTM layer will be passed to the next LSTM layer at the next time step. Moreover, the hidden state includes LTS C_t^i (i∈[1,2],t∈[1,T]) and short-term state S_t^i (i∈[1,2],t∈[1,T]), thereby achieving the effect of memorizing the hidden information in the preceding data. In addition, this study relies on experience to select hyperparameters that may have a better analytical effect on the model (Table II).

TABLE II. SELECTION OF MODEL HYPERPARAMETERS

Hyper-parameter	Value	Type
Lstm_layer	2	int
Activation_lstm	Tanh	string
Lstm_output_dim	110	int
Dense_layer	2	int
Activation_dense	Softsign	string

Optimizer	Rmsprop	string
Loss	Binary cross entropy	string

C. Optimization of Hyperparameters Based on BOA

After constructing an IoT-UBA model based on LSTM, it is found that having too many hyperparameters can lead to an increase in model complexity and easily lead to overfitting. To solve overfitting problems and improve model generalization ability, ML engineers generally adjust hyper-parameter combinations based on experience to achieve a better level of generalization [22]. However, manual parameter tuning is difficult to fully consider all relevant influencing factors and historical performance. Even though time and manpower are spent manually adjusting parameters and achieved good results, the constructed prediction model only performs well in the IoT-UBA corresponding to specific datasets. The predictive ability of this hyperparameter combination among more IoT users is still unknown [23]. This study proposes using BOA to construct an adaptive hyperparameter selection algorithm, selecting personalized hyperparameter combinations that perform best for different users. The purpose of hyperparameter optimization (HPO) in ML is to find the hyper-parameters of a given ML, which returns the best performance measured on the validation set. Unlike model parameters, hyperparameters need to be set before training. The HPO equation is shown in Eq. (9).

$$\lambda = \arg\min_{\lambda \subseteq x} f(\lambda) \tag{9}$$

In Eq. (9), λ represents the hyperparameter and $f(\lambda)$ represents the minimum objective score evaluated on the validation set, which is also the loss that needs to be optimized for the model. BOA combines the advantages of manual parameter tuning with manual experience and grid search, as well as automatic selection through random search, to track past evaluation results. It forms a probability model by using these results, seeking a combination of hyperparameters in the

probability model that can minimize losses. Before using automatic optimization algorithms to search for the optimal combination of hyperparameters, it is necessary to define the domain space for hyperparameter search. This study constructs a large-scale hyperparameter domain space based on the research model. HPO requires defining the objective of BOA optimization, which is the loss of the objective function. The ultimate goal of selecting hyperparameter combinations in this study is to improve the model's generalization ability. The greater the generalization ability of the model, the better, but the loss of the BOA function can only be the minimum value, so the loss value Q of BIA is shown in Eq. (9).

$$Q = 1 - Pa \quad (9)$$

In Eq. (9), Pa represents the PA of the test set. To learn the "black box" between hyperparameter combinations and optimization objectives, this study uses tree-structured Parzen estimator (TPE) to construct optimization algorithms. The TPE algorithm can construct a probability model for optimization objectives by combining existing hyperparameters and their corresponding loss values. Through this probability model, it is possible to find the hyperparameter combination that minimizes the optimization objective and maximizes the probability. Then, based on the selected hyperparameter combination, the trained model updates the input-output pairs and continues to construct a new probability model. Cycling the above process until the loss value reaches its lowest point, and thus completing the construction of the IoT-UBA model based on improved RNN. The construction process of the model is shown in Fig. 4.

The research model construction in Fig. 4 first involves data mining and preprocessing based on real IoT user behavior data. Then, a prediction model needs to be constructed based on LSTM network, and hyperparameters need to be selected based on experience. Finally, BOA is used to automatically select model hyperparameter combinations.

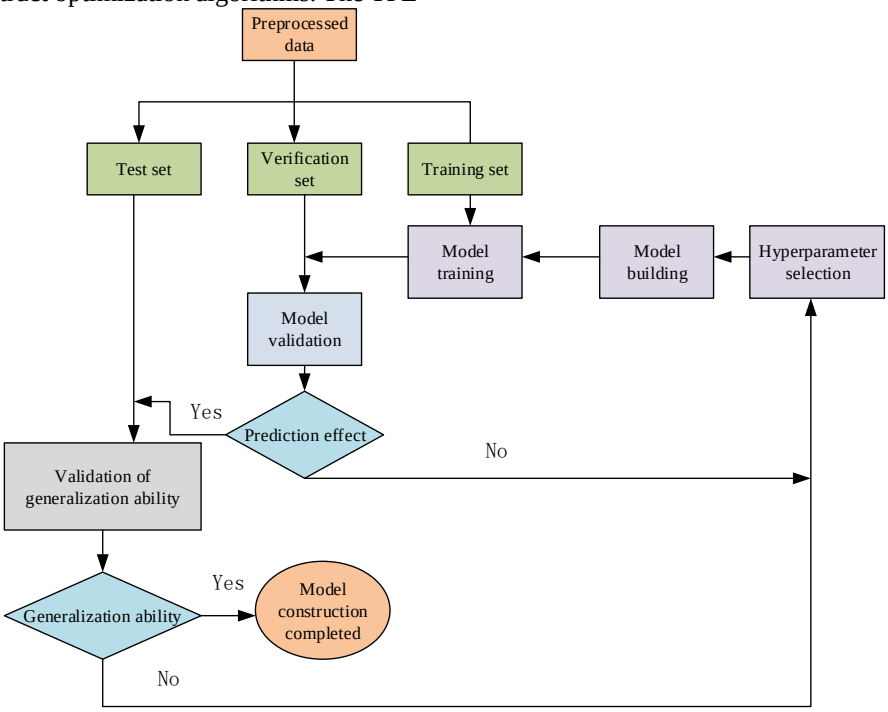

Fig. 4. Model construction process.

IV. RESULTS

A. Training and Validation of Research Models

To test the model effectiveness, this experiment uses the processed training and validation sets for model training and validation and uses the test set to test the model's generalization ability. Table III shows the relevant experimental environments.

This experiment is conducted using XiaoXinPro 14ITL 2021, with a processor environment of 11th GenIntel(R)Core (TM)i5-1135G7@2.40GHz-2.42GHz, a memory capacity of 16.0GB, and the operating system of Windows10. The software used in data mining is SPSS Modeler18.0. The programming environment involved is Python 3.8.3 and the programming IDE used is Anaconda3. Python is used for data preprocessing, model construction, and optimization algorithms. The divided training set and validation set are put into the constructed model. Based on research data and model characteristics, binary classification accuracy is used as a measure of model PA and binary classification cross entropy is adopted as a loss function. The training results of the research model are displayed in Fig. 5.

In Fig. 5, as the training iteration progresses, the loss of the research model on the training and validation sets decreases continuously. At the completion of the last epoch of training, the loss on the training set decreases from the initial 0.1800 to 0.1084, and on the validation set from the initial 0.1362 to 0.0915. The learning ability of the model continues to improve. The PA of the model on both the training and validation sets

surpasses 90%, and as the iteration process continues to rise, the final accuracy reaches 96.8% and 97.53%. The dataset, hyperparameter domain space, and objective function are input into BOA, and the hyperparameter combinations selected for each iteration of BOA, their corresponding training time, and loss values are recorded for tracking optimization history. The optimal combination of hyperparameters for localization prediction is shown in Fig. 6.

TABLE III. EXPERIMENTAL OPERATING ENVIRONMENT

Parameter	Experimental Environment
Tool	XiaoXinPro 14ITL 2021
Processor	11th GenIntel(R)Core (TM)i5-1135G7@2.40GHz-2.42GHz
Memory capacity	16.0GB
Operating system	Windows10
Data mining software	SPSS Modeler18.0
Programming environment	Python3.8.3
Programming IDE	Anaconda3
model building	Python3.8.3

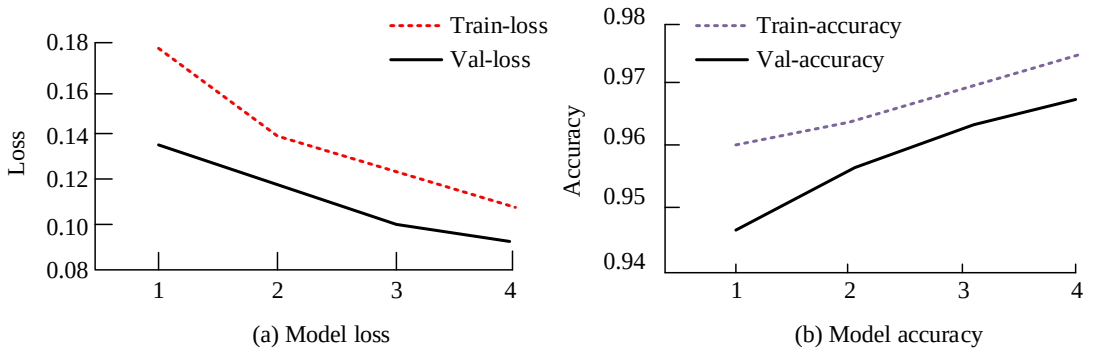

Fig. 5. Model training results.

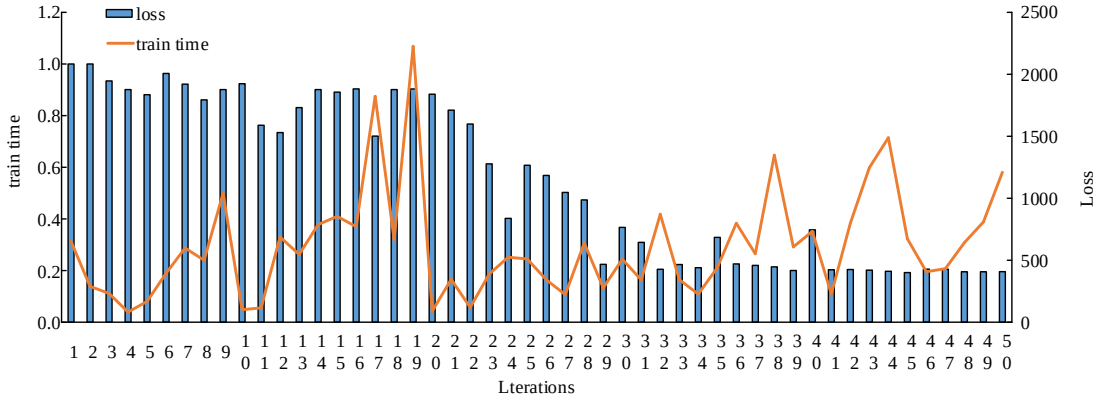

Fig. 6. Iteration loss and training time.

In Fig. 6, the loss shows a significant downward trend with the number of iterations, indicating that when selecting hyperparameter combinations, BOA will choose hyperparameters that are more likely to perform better based on the probability model of the loss with respect to hyperparameters. In the set maximum of 50 iterations, the loss of the objective function reaches its minimum value in the 45th iteration, and the optimal model loss trains under the corresponding hyperparameter combination conditions in this iteration is 0.19. The model's PA on the test set reaches 80.78%, showing that BOA enhances its generalization ability, and searches for a model hyperparameter combination with better prediction ability based on the user behavior characteristics in the IoT environment. To further validate the improved RNN in IoT-UBA, a similar neural network model is constructed using traditional RNN, and BOA is also used to select the optimal hyper-parameter combination. The experimental results are shown in Fig. 7.

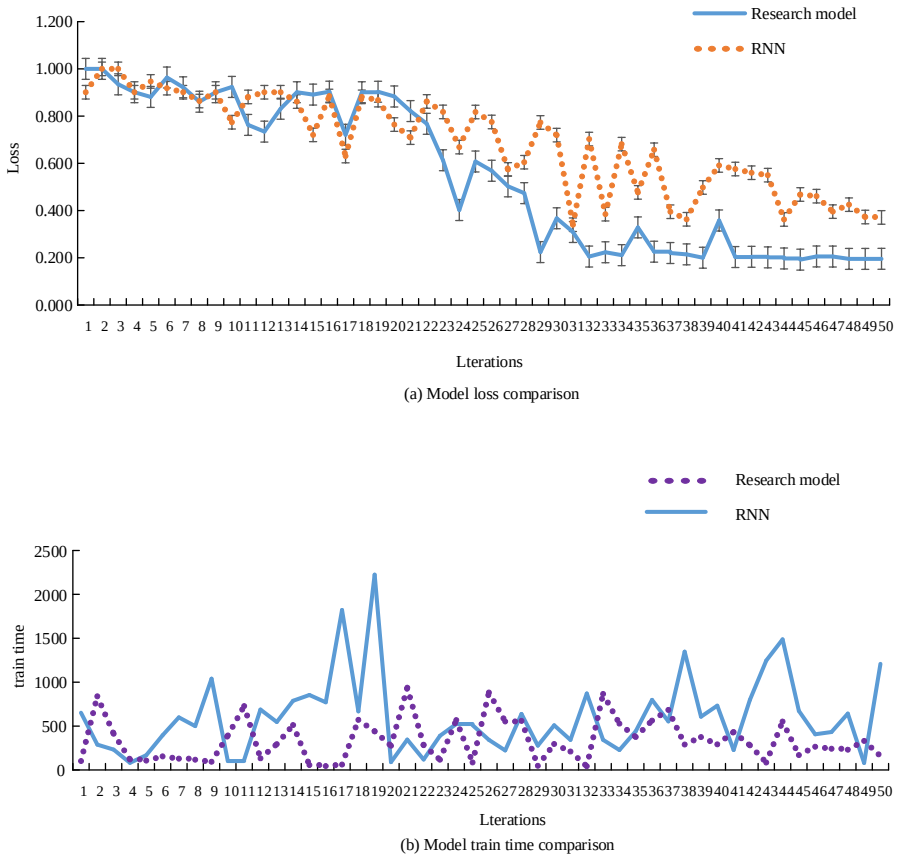

Fig. 7. Comparison of research model and RNN model effects.

Fig. 7 (a) shows the comparison of the loss value changes between the traditional RNN model iteration process and the research model. Both models show a spiral downward trend as the iterations increase. Among them, the minimum loss value of the traditional RNN is 0.34, which means its best PA is only 66.01%, lower than the 80.78% of the research model. Fig. 7 (b) shows the comparison of training time between LSTM and RNN models. The research model reaches the minimum loss value in the 31st iteration, while RNN only selects the optimal hyper-parameter combination in the 45th iteration. The average training time for the research model is 338 seconds, and this value for the RNN model reaches 614 seconds. In terms of iteration times and training time, the research model is significantly better than the RNN model.

B. *Application of Research Models in Short-term Power Load Forecasting*

To test the practicality of the IoT-UBA built on improved RNN, this study selects two benchmark models, auto-regression model (AR) and back propagation neural network (BPNN), to validate the proposed improved RNN model. This study selects three different datasets, namely three load datasets provided by official websites in three foreign regions. The first one is the electricity load data of region A from February 1, 2023 to August 31, 2023, with a sampling rate of 1 hour and a sample size of 5112. The second one is the electricity load data of region B for the whole year of 2023, with a sampling rate of 1 hour and a sample size of 8760. The third one is the electricity load data of region C for the whole year of 2023, with a sampling rate of 1 hour and a sample size of 8760. The power load data of these three regions are processed through data preprocessing and the processed data are divided into datasets. The daily load forecasting results of each model on three different datasets are displayed in Fig. 8.

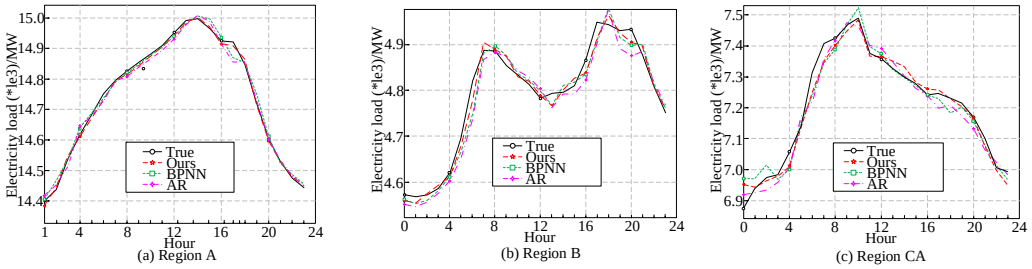

Fig. 8. Daily load forecasting results of each model on three different datasets.

From Fig. 8 (a), in region A, the prediction effect of each model is overall and the load prediction curve in the figure almost coincides with the actual situation. However, Fig. 8 (a) shows that the prediction effect of the research model is better than that of other comparison models. In particular, in the two periods of 13:00 and 17:00, the error rate of the research model is only 0.13% and 0.09%, which is small and has more accurate PA than the comparison model. In the data set of Fig. 8 (b) in region B, in general, at the very beginning, each model has a good prediction effect. However, with the increase of mean absolute percentage error (MAPE), the deviation between the prediction of various models and the reality are increasing, which leads to the decrease of the accuracy of the prediction. Especially in the period of 20:00, each model prediction deviation reaches the largest. The AR model, BPNN model, and acting model of daily load prediction error rates reach 12.13%, 5.72%, and 1.39%, respectively. Among them, the research model error rate is lower than other contrast model. The prediction results and the actual load change trend are the most consistent and the performance effect is better. In region C of Fig. 8 (c), in general, the prediction effect of each model is not good. With the increase of MAPE, the deviation between the prediction of various models and the reality are increasing, leading to a decrease in the accuracy of the prediction. Among them, the period of 2:00 appears the largest prediction error. In the 17:00 period, the AR model reaches the largest error in the prediction. In both 2:00 and 17:00, the prediction effect of the research model is relatively excellent. This indicates that although traditional power system modeling methods can describe the overall trend of the power system, as the complexity of the system increases, the operational efficiency of the power system also decreases, resulting in huge economic losses to the power system. The root mean square error (RMSE) and MAPE of load forecasting for each model within seven days are exhibited in Fig. 9.

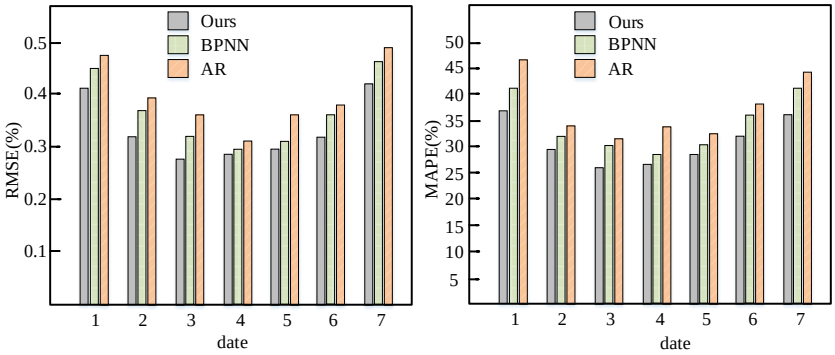

Fig. 9. Comparison of weekly load prediction errors among different models.

In Fig. 9, the weekly load PA of the IoT-UBA is much better than that of BPNN and AR, and BPNN is higher than AR. The comparison between its predicted load value and the actual load value shows that through more accurate prediction of user behavior, the prediction of load value has completed a good level.

V. Discussion

As the IoT technology becomes increasingly pervasive in all aspects of people's daily lives, the collection of user data within IoT systems will become more comprehensive. The data accurately reflect the behavioral patterns and living habits of users. Providing better services and timely responses to users, effectively utilizing this information to predict user behavior and needs, and systematically improving management and service quality are key to enhancing the competitiveness and service level of various industries in the future. The proposed method sets a maximum of 50 iterations. At 45 iterations, the objective function has the smallest loss, and the optimal model has a loss of only 0.19 (test set), with an accuracy of 80.78%. The results of this study are consistent with the predictions of the lightweight dense random neural network proposed by Latif et al. [24] for IoT intrusion detection, and the model performs well. This is because when selecting appropriate inputs for the research model, BOA selects a more promising hyperparameter based on loss estimation. This can search for super parameter combinations with higher predictive performance based on user behavior characteristics in IoT scenarios, thereby enhancing the performance of the model. In this study, the model lost the smallest loss in 31 cycles, the best PA was 80.78%, and the learning time was 338s, which showed better performance. However, the accuracy of the industrial IoT detection method based on graph neural network proposed by Wu et al. [25] can only reached 79.71%. This is because the hyperparameters have been optimized, shortening the iteration and learning time of the model, thereby improving its generalization ability. In summary, the analysis shows that using BOA to select model hyperparameter combinations further improves the generalization ability of the prediction model, enabling the model to construct adaptive prediction models based on the characteristics of different users in different IoT environments.

VI. Conclusion

In response to the current problems in the application of IoT technology, this study utilized BOA to construct an IoT-UBA model based on an improved RNN that can adapt to different environmental characteristics. The results demonstrated that the PA of the research model on both the training and validation sets was greater than 90%, and as the iteration process continued to increase, the final accuracy reached 96.8% and 97.53%. In 50 maximum iterations, the model achieved a PA of 80.78% on the test set. In the comparison of the performance between the research model and RNN, the minimum loss value of traditional RNN was 0.34, which meat its best PA was only 66.01%, lower than the 80.78% of the research model. The research model reached the minimum loss value in the 31st

iteration, while RNN only selected the optimal hyper-parameter combination in the 45th iteration. The average training time for the research model was 338 seconds, and this value for the RNN model reached 614 seconds. In terms of iteration times and training time, the research model was significantly better than the RNN model. The application results of the research model in short-term power load forecasting also indicated that the PA of the IoT-UBA model based on improved RNN has reached a good level, far superior to other comparative models. However, this study is based on a sufficient amount of historical user behavior data. In practical use, the IoT-UBA model will inevitably face the situation of insufficient historical user behavior data at the initial startup of the system. In the future, in-depth research will be conducted in this area.

Network Security Based on Improved Genetic Algorithm and Weighted Error Back-Propagation Algorithm

Junjuan Liang
Henan Polytechnic Institute, Nanyang, 473000, China

***Abstract*—In order to solve the problem of feature selection and local optimal solution in the field of network security, a network security protection model based on improved genetic algorithm and weighted error back-propagation algorithm is proposed. The model combines the dynamic error weight and adaptive learning rate of the weighted error back-propagation algorithm to improve the learning ability of the model in dealing with classification imbalance and dynamic attack mode. In addition, the global search capability of genetic algorithm is utilized to optimize the feature selection process and automatically adjust the hyperparameter settings. The experimental results show that the proposed model has an average accuracy of 96.7%, a recall rate of 93.3% and an F1 value of 0.91 on the CIC-IDS-2017 dataset, which has significant advantages over traditional detection methods. In many experiments, the accuracy of normal data is up to 99.97%, the accuracy of known abnormal behavior data is 99.31%, and the accuracy of unknown abnormal behavior data is 98.13%. These results show that this method has high efficiency and reliability when dealing with complex network traffic, and provides a new idea and method for network security protection research.**

***Keywords*—Genetic algorithm; weighted error back-propagation; multiple strategies; network security**

I. INTRODUCTION

With the speedy prosperity of information technology, network security matters have become more and more notable, and the ways of network attacks have become more complex and diverse. These attacks not only affect the operations of businesses and government agencies, but also pose a significant threat to the privacy and data security of individual users [1]. At the same time, with the rapid growth of network traffic, how to effectively detect and identify potential security threats has become a non-negligible problem that requires urgent handling in the current field of network security. Traditional network security detection methods often rely on matching rules or feature libraries, making it difficult to cope with rapidly evolving attack patterns [2-3].

Thus, a lot of domestic and foreign researchers have promoted in-depth study on network security detection. Wei K et al. focused on optimizing network intrusion detection technology, using a combination of algorithm technology and artificial intelligence to achieve intrusion detection and defense of network security systems. Focusing on the issues of low efficiency and poor detection precision of classical K-means clustering algorithm, an improved K-means clustering algorithm network security detection model was proposed, and experiments were conducted using a dataset. The results indicated that this improvement measure could significantly improve detection efficiency and accuracy [4]. Chen Z optimized traditional network security detection algorithms in response to constantly changing and upgrading network attack techniques. A new network security detection model was constructed using radial basis function neural networks as the main body, optimized through simulated annealing algorithm and hybrid hierarchical genetic algorithm (GA), and relevant experiments were conducted. The results showed that the optimized detection model's predicted values in 15 samples highly approached the true values, which could provide assistance for maintaining network security [5]. Khan M and Ghafoor L explored the special challenges brought by adversarial attacks in the field of network security, and strengthened machine learning-based network security detection systems to address challenges such as the dynamic nature of network environments and the need for real-time decision-making. The experimental results indicated that the research method could provide more powerful and resilient solutions when facing network attacks [6]. Yin L and Zhang D raised a network security detection algorithm grounded on vague reasoning. Firstly, they combined fuzzy reasoning and probability density features to evaluate security data. Then the features of network intrusion data were extracted to achieve safety possibility computation and virus attack detection. The data showed that the raised algorithm had higher calculation precision for network safety possibility, achieved network safety possibility computation and data checking, and enhanced the network's security defense capability [7].

Memon I proposed an authentication key establishment protocol based on IPv6 to protect sensitive information in road network environment. The protocol eliminated duplicate address detection by allowing a moving vehicle to pick up a unique address from a neighboring vehicle or roadside unit, while automatically recycling the address space leaving the vehicle for reallocation. The proposed protocol had the characteristics of anonymous authentication, confidentiality and high efficiency, and the evaluation results showed that the protocol effectively improved the performance of address configuration, and was also very secure in preventing passive and active attacks [8]. Aiming at the growing network demand and massive data traffic management, Farhan N et al. proposed a method based on hybrid clustering to improve the wireless resource management effect of heterogeneous networks [9]. By

analyzing different clustering classifications and existing technologies, they aim to achieve high throughput, low interference and low latency in ultra-dense networks. The results showed that the hybrid clustering technology could effectively improve the wireless resource management in HetNets, increase throughput, and reduce the inter-layer and intra-layer interference, thus enhancing the network performance. Junejo M H et al. addressed the growing security threat in Vehicle ad-hoc networks (VANETs) by proposing cybersecurity solutions that combined machine learning and artificial intelligence techniques to enhance the safety and efficiency of public transportation. In this study, the trust mechanism was compared with cryptography, and its different performance in VANET application and security requirements was analyzed [10]. Although the above methods have high recognition accuracy in the known attack behavior, they may have limitations in the face of new and unknown attack modes. In the actual network environment, the characteristics of network traffic may change with time, and the strategies and techniques of attackers also develop dynamically. Although the feature selection of the current model is optimized based on GA, how to dynamically update and re-select the features to adapt to such changes is still an urgent problem to be solved.

Therefore, a network security protection model based on Weighted Error Back-Propagation (WEBP) and Improved GA (IGA) is proposed in this study. Compared with the existing researches, the main objective of this study is to solve the problem that the efficiency of feature selection is insufficient, resulting in insufficient model learning, and thus affecting the detection accuracy and efficiency. The study is also devoted to solving the problem that the fixed learning rate is difficult to adjust dynamically and cannot adapt to the change of data flow in real time, which is easy to cause the model to fall into the local optimal. Moreover, the study hopes to address the problem that current methods are unable to respond to rapidly evolving attack patterns in a timely and effective manner. The innovation of this model lies in the introduction of a weighted error mechanism, which allows the model to adjust the learning process based on the importance of different samples, thereby improving its adaptability to complex network environments and combining the population search characteristics of GA. Feature selection and hyperparameter optimization are implemented to enhance the global search capacity and robustness of the model. The contribution of the research is to solve the problem of low feature selection efficiency on high-dimensional data, so as to effectively improve model performance and learning efficiency. It provides an effective solution for the field of network security detection, can better deal with the complex network attack mode, and provides a new idea for the practical application of data protection and network firewall.

The research structure mainly includes four parts. The first part constructs the network security detection model based on the WEBP algorithm, analyzes the limitations of the model, and further optimizes it. The second part verifies the performance of the proposed model, and designs experiments to analyze the network security protection capability of the proposed model. The third part is the summary and analysis of the experimental results, and the comparison with the same type of research, emphasizing the advantages of the research method. The last part summarizes the content of the article, and points out the current limitations and future development direction.

II. Methods and Materials

A. Network Security Detection Model Grounded on WEBP Algorithm

WEBP is an improved Back-Propagation Neural Network (BPNN). In traditional back-propagation algorithms, all training samples are assigned the same importance, while the WEBP algorithm allows for adjusting errors during the training process based on the importance or confidence of different samples [11-12]. WEBP essentially introduces error weights in the back-propagation of BPNN to adjust errors. BPNN is a widely studied algorithm in ANN, with the core idea of bidirectional signal transmission [13-14]. Forward transmission refers to the sequential transmission from the input end to the output end. Reverse propagation is when there is a deviation in the results during forward propagation, and the error results are reversed and distributed to each layer structure to correct the weights in the structure [15]. BPNN is usually constructed from three parts: Input Layer (IL), Hidden Layer (HL), and Output Layer (OL). The specific composition model is shown in Fig. 1.

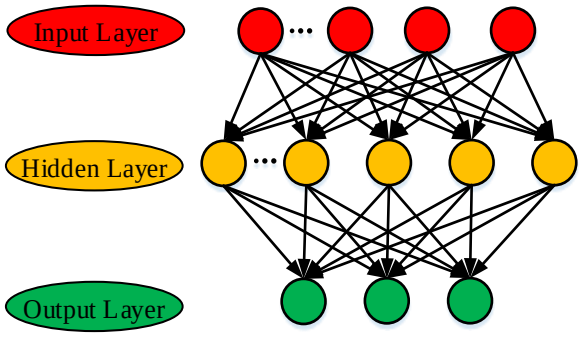

Fig. 1. Example diagram of BPNN structure.

In Fig. 1, after receiving the information data from IL, HL in the BPNN structure will pass the data information to the next layer through a weight function and organize it in the last layer to obtain the final output data. At the same time, BPNN continuously adjusts the weights and thresholds of the structure grounded on the deviation values between the output results and the actual results. The amount of neurons in the IL and OL is defined by the dimensions of the input samples and output results, respectively. However, the selection of neurons in the HL is more sophisticated, and the current intelligence determines it through empirical formulas, as shown in Formula (1).

$$O = \sqrt{n+m} + a \tag{1}$$

1. In Formula (1), 0 represents the HL neuron. n and m represent the number of neurons in the IL and OL separately. a represents a constant, with values ranging from [1,10]. Formula (1) in network security, the strong generalization ability enables the model to handle unseen attack patterns and normal data, effectively identifying potential

threats. In conventional BPNN, using a fixed learning rate makes it difficult to ensure the network has the best learning efficiency in realistic tasks. To solve this issue, research is being conducted on using adaptive learning rates in network structures. Assuming the initial learning rate is $\mu(0)$ and the network fault obtained by the model during the iteration process is denoted as $E(n)$, the change in learning rate is shown in Formula (2).

$$\mu(n)=\begin{cases}\beta\mu(n-1) & E(n)<E(n-1),(1<\beta<1.5)\\ \gamma\mu(n-1) & E(n)>E(n-1),(0.5<\gamma<1)\\ \mu(n-1) & other\end{cases} \quad (2)$$

In Formula (2), β and γ represent constant coefficients, with values of 1.05 and 0.7, respectively. Formula (2) In the dynamic environment of network security, attack patterns and normal traffic are constantly changing, and adaptive learning rates can make the model more flexible in adapting to these changes. In the process of error back-propagation, adaptive adjustment of learning rate can effectively improve convergence speed. Nevertheless, the model continues to disregard the direction of gradient descent throughout the entire process, which renders the model unstable and susceptible to becoming trapped in local optima. The problem of gradient descent direction is solved by introducing error weights, and its description is represented in Formula (3).

$$\Delta w(n)=\alpha\Delta w(n-1)-\mu\frac{\partial E(n)}{\partial w(n)} \quad (3)$$

In Formula (3), α is the momentum term and w represents the weight. Formula (3) can be regarded as a first-order difference formula of $\Delta w(n)$, and its formula is represented in Formula (4).

$$\Delta w(n)=-\mu\sum_{t=0}^{n}\alpha^{n-t}\frac{\partial E(n)}{\partial w(n)} \quad (4)$$

In Formula (4), t represents the time series. The above is the correction of weights, and the specific way to adjust the weights of BPNN is shown in Formula (5).

$$w(n+1)=w(n)-\mu(n)\sum_{t=0}^{N}\alpha^{n-t}\frac{\partial E(n)}{\partial w(n)} \quad (5)$$

Formulas (4) and (5) provide specific methods for weight updating, enabling the model to more accurately correct weights and adapt to new data inputs. In network security protection, it can help detection models quickly adjust to adapt to new threats.

B. Construction of Network Security Protection Model Based on GA-WEBP

Although WEBP improves the performance of BPNN by introducing mechanisms such as weights and adaptive learning rates, the capacity of the model largely relies on the selection and representation of input features. Incorrect or insufficient feature selection may result in the model learning insufficient information, while traditional feature selection methods may be inefficient in processing high-dimensional data. In the field of network security, the feature space is usually large, and anomaly detection is highly sensitive to features. Therefore, the study optimized the model by introducing GA. The logic of GA is represented in Fig. 2.

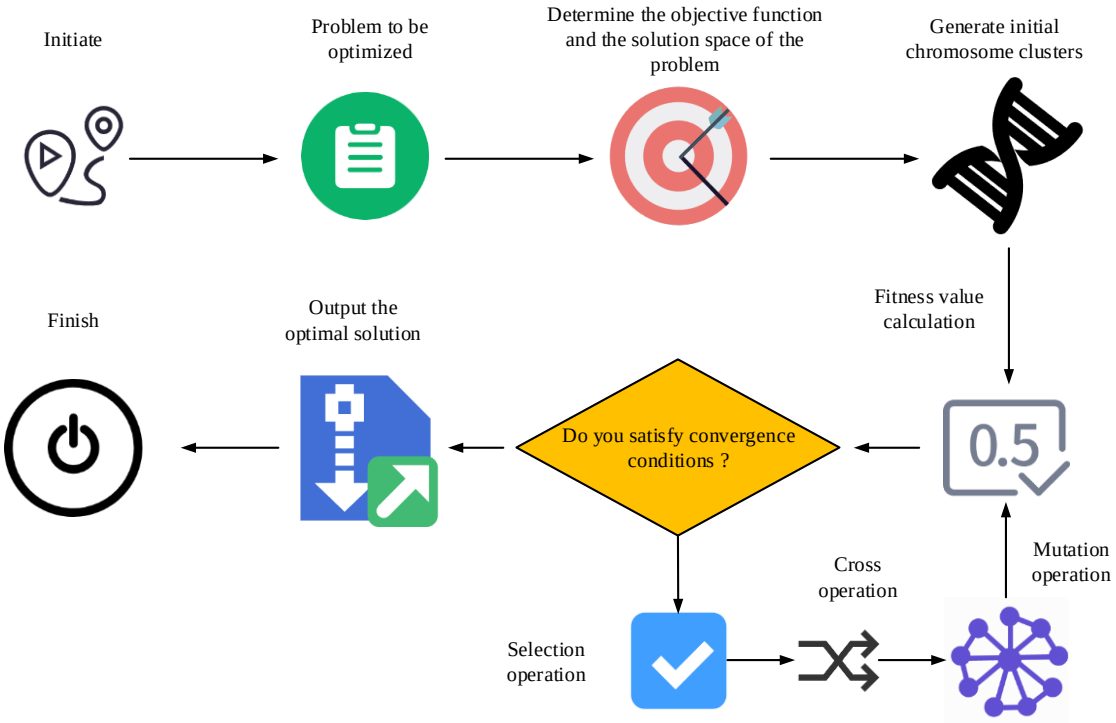

Fig. 2. Schematic diagram of GA process.

In Fig. 2, during the initial stage of GA, the algorithm randomly generates a series of individuals and evaluates each individual based on a predetermined goal, assigning them a fitness value. By comparing these fitness values, individuals who perform well as the new generation are selected. On this basis, screening is conducted to eliminate individuals with poor performance [13-14]. Then, the selected individuals are recombined through crossover and mutation operations to produce the next generation of individuals with excellent traits, gradually approaching the best remedy. Finally, the optimal one is extracted from the last generation population to obtain an approximate optimal solution to the problem. Overall, the process of traditional Gas involves encoding, selection, crossover, and mutation [15-16]. Finally, when the termination conditions are met, that is, when the specified number of iterations or iteration accuracy is reached, as well as the target conditions, the iteration can be stopped. In network security protection, binary encoding is studied as the encoding method for Gas. The second step is the selection operation, which selects high-quality individuals based on their fitness in the environment, in order to use them for generating the next generation. This step is grounded on the law of natural selection, where individuals with greater fitness have a greater possibility of being chosen, while individuals with less fitness have a smaller possibility of being chosen. The study used random sampling as the model selection operation, in which the selection probability of each individual is grounded on their fitness, but the selection process is random. This means that even individuals with lower fitness have the opportunity to be chosen. The possibility of an individual being chosen is shown in Formula (6) [20].

$$F(x_i)=\frac{f(x_i)}{\sum_{i=1}^{Nind} f(x_i)} \tag{6}$$

In Formula (14), $F(x_i)$ points to the fitness of an individual. In network security, fitness usually reflects the effectiveness of an individual under specific security policies or protective measures, such as the ability to detect attacks and reduce false positive rates. $f(x_i)$ points to the possibility of an individual being chosen. In network security applications, this probability determines which individuals (i.e. protection policies or system configurations) can continue to be optimized and evolved, playing a crucial part in improving the comprehensive security of the system. The GA increases the fitness value of individuals by performing crossover operations on different parents in the third step, where the single point crossover structure is shown in Fig. 3.

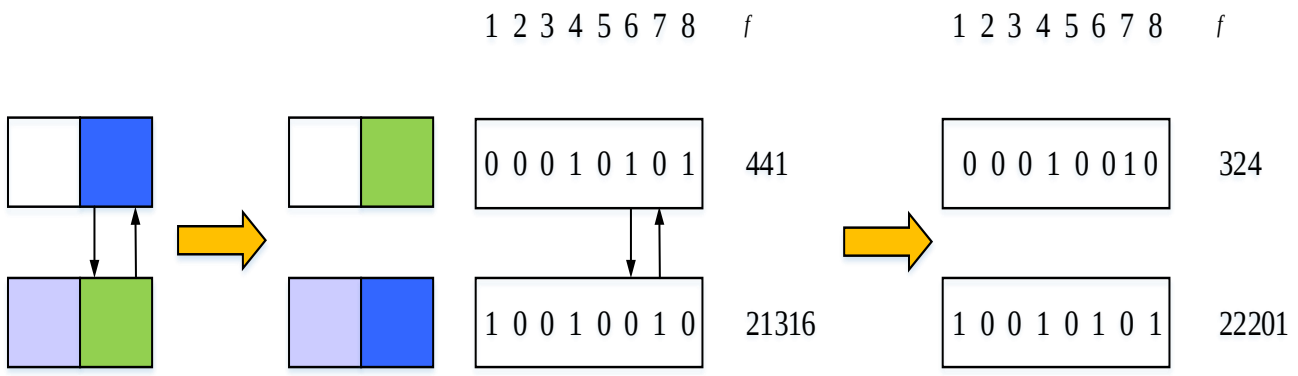

Fig. 3. Single point cross structure.

In Fig. 3, a random crossover point is selected on the chromosome, and the chromosome is divided into front and back parts. Gene exchange is performed in the front or back part of the crossover point to generate new offspring individuals. The mathematical expression for crossover operation is shown in Formula (7) [21].

$$\begin{cases} X_A^{t+1}=\varepsilon X_B^t+(1-\varepsilon)X_A^t \\ X_B^{t+1}=\varepsilon X_A^t+(1-\varepsilon)X_B^t \end{cases} \tag{7}$$

In Formula (7), X_A^t and X_B^t represent the parent individuals performing the crossover operation, and the two parent individuals represent two different protection strategies or configurations. X_A^{t+1} and X_B^{t+1} represent the offspring individuals formed after cross operation, and the newly generated individuals can display different combinations of security policies, helping the network security team find better protection solutions. ε represents the intersection rate. If the intersection rate is high, the algorithm will explore more combinations and may find more effective security protection methods; If it is too low, it may lead to insufficient exploration and inability to adapt to rapidly changing threats. After crossover operation, the GA finally performs mutation operation, as shown in Formula (8).

$$X^{t+1}=X^t-0.5L\Delta \tag{8}$$

In Formula (8), L represents the range of variable values, defining the range within which individuals can vary, ensuring that the mutated individuals remain within the valid parameter space, thereby enhancing the practical applicability of the model. The GA-WEBP network security protection model constructed above, although capable of supporting hyperparameter optimization, may not be able to adapt in a timely manner when facing rapidly changing attack patterns and network traffic. Therefore, research will focus on targeted optimization of Gas from multiple perspectives.

C. Improved Optimization Grounded on GA-WEBP Model

In the optimization of network security protection models based on GA-WEBP, research is conducted from the perspectives of convergence speed, crossover probability, mutation probability, etc. In terms of algorithm convergence speed, the selection of the initial population has a direct correlation. Therefore, the study adopts a real number chromosome as the initial population, and its calculation is represented in Formula (9).

$$X_i = \lceil X_{i\max} - X_{i\min} \times random[0,1] + X_{i\min} \rceil \quad (9)$$

In Formula (9), $\lceil \cdot \rceil$ represents the upward rounding function, X_i represents the value of genes on chromosomes, $X_{i\max}$ and $X_{i\min}$ represent the maximum and minimum values of the values, and $random$ represents any real number within a certain interval range. In network security protection, a good initial population can accelerate the initial exploration of the model, enabling GA to find feasible solutions faster, thereby cutting the amount of subsequent iterations and enhancing algorithm validity. Its expression is shown in Formula (10).

$$\begin{cases} o_c = \begin{cases} \dfrac{s_1(f_{\max} - f_c)}{f_{\max} - f_{avg}} & f_c \geq f_{avg} \\ s_2 & f_c < f_{avg} \end{cases} \\ o_m = \begin{cases} \dfrac{s_3(f_{\max} - f_m)}{f_{\max} - f_{avg}} & f_m \geq f_{avg} \\ s_4 & f_m < f_{avg} \end{cases} \end{cases} \quad (10)$$

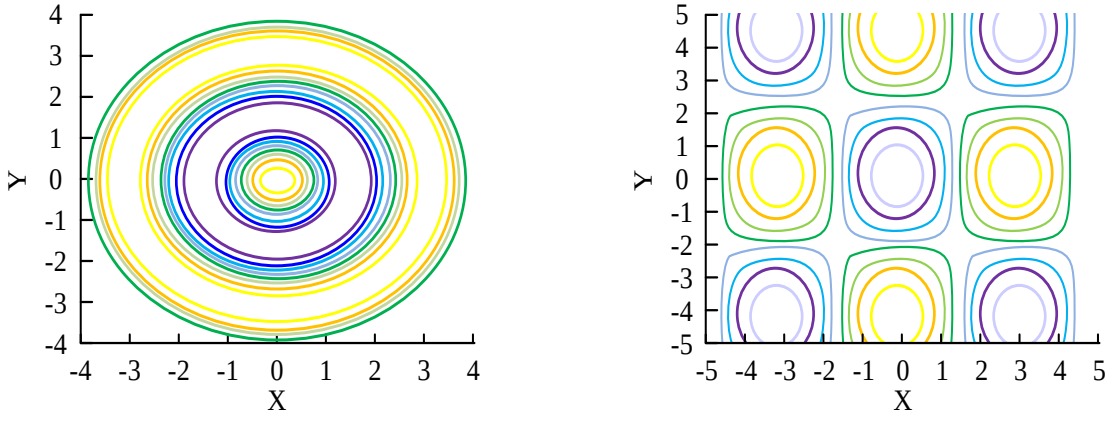
In Formula (10), o_c represents the crossover probability. In network security protection, a higher crossover probability can help discover new attack defense strategies and more effective protection measures. o_m represents the probability of mutation. Enhanced mutation operations can encourage the model to consider non-traditional attack methods and response strategies, thereby improving the adaptability of protection capabilities. s represents the adaptive parameter, and the value of the adaptive parameter is a constant not greater than 1. As the attack and defense strategies continue to evolve, the model can adjust the strategy based on real-time fitness feedback. f represents the fitness value. In Formula (10), the value of the adaptive parameter is greater than the value that should satisfy Formula (11).

$$\begin{cases} s_1 > s_2 \\ s_3 > s_4 \end{cases} \quad (11)$$

In the initial stage of the algorithm, individuals with higher fitness in the population will be retained, but the retained individuals are not the best ones. Therefore, to improve the performance of the algorithm's best remedy, further improvements should be made to crossover and mutation operations. The main purpose of improvement is to ensure that the algorithm can continue to perform crossover and mutation operations even when it has the best individual, as shown in Formula (12).

$$\begin{cases} o_c = \begin{cases} o_{c1} \dfrac{1}{(o_{c1} - o_{c2}) + e^{\frac{f_c - f_{avg}}{f_{\max} - f_{avg}}}} & f_c \geq f_{avg} \\ s_2 o_{c1} & f_c < f_{avg} \end{cases} \\ o_m = \begin{cases} o_{m1} \dfrac{1}{(o_{m1} - o_{m2}) + e^{\frac{f_c - f_{avg}}{f_{\max} - f_{avg}}}} & f_m \geq f_{avg} \\ s_2 o_{m1} & f_m < f_{avg} \end{cases} \end{cases} \quad (12)$$

In Formula (12), the value of $o_{c1} = 0.9$ is adjusted to 0.9, the value range of o_{c2} is [0.5,1], the value of $o_{m1} = 0.1$ is adjusted to 0.1, and the value range of o_{m2} is [0.05,0.1]. For network security protection, continuous crossover and mutation operations can help models adapt to new attack methods and traffic patterns, enhancing their dynamic defense capabilities. The study will use two sets of benchmark functions to testify the solving ability of the improved algorithm, namely the Schaffer function and the Griebank function. The contour plots of the two sets of functions are shown in Fig. 4.



(a) The Schaffer function (b) The Griewank function

Fig. 4. Contour map of two benchmark functions.

Fig. 4 shows the contour plots of the Schaffer function and the Griewank function. Contour plots plot the variation of a function in a given input space by connecting points with the same function values into lines. Through this visualization method, the function value distribution and its fluctuation characteristics in different regions can be intuitively understood. The Schaffer function is often used to test the performance of optimization algorithms because it has multiple local minima and one global minimum, usually near the origin. The contours shown in the figure present a highly concentrated and complex region centered on a smaller function value surrounded by a ring region of larger function values. This distribution shows that the solution of the optimization problem is usually near the origin and the optimization process is complicated. The Griewank function is another classical multi-variable function used to test global optimization algorithms. It is characterized by the existence of a large number of local minima, and the zero point is in a large region. The regular wavy structure in the contour map indicates its various local minima. These local minima are evenly distributed, which indicates the high complexity of the function.

III. Results

A. Performance Testing Based on Improved GA-WEBP Algorithm

The study conducted simulation experiments using MATLAB and analyzed the performance of the IGA through two selected benchmark functions. Firstly, the study analyzed the Schaffer function, which reached its maximum at the origin. Therefore, the study set the parameter values of the GA as follows: the initial population size was 100, the parameter settings satisfied $s_1 = 2s_2 = s_3 = 2s_4 = 1$, and the maximum iteration number of the GA was 100. By improving the GA to solve the Schaffer function, the results are shown in Fig. 5.

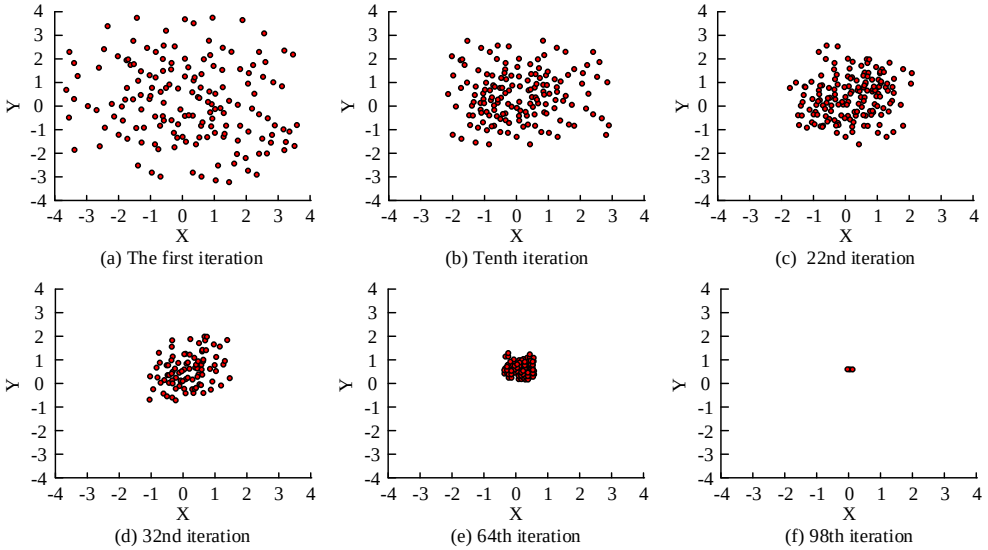


Fig. 5. Partial solution process of Schaffer function.

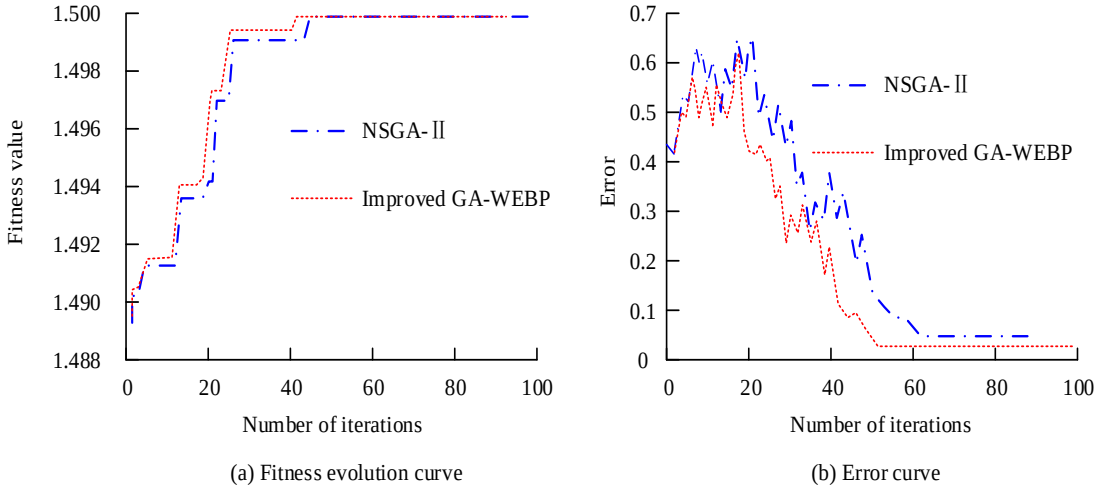
Fig. 5(a)-5(f) show the results of the algorithm's first, tenth, 22nd, 32nd, 64th, and 98th iterations, respectively. The results showed that the IGA gradually converged at the 32nd iteration, and the algorithm basically completed convergence at the 64th iteration. The results showed the ability of the model to explore the search space efficiently. Compared with the traditional algorithm, the improved GA had a faster convergence rate, which was due to the introduction of adaptive mechanism. As a result, the algorithm can effectively filter out the best solution in the early stage. The research used the fitness curve and iteration error curve of Schaffer function as the evaluation index of algorithm performance, and compared with the Non-dominated Sorting GA II (NSGA-II) to verify the effectiveness and progressiveness of the IGA. The results are shown in Fig. 6.

Fig. 6(a) shows the fitness curve results of the Schaffer function, where the NSGA-II algorithm began to converge at the 48th iteration, the proposed algorithm began to converge at the 42nd iteration, and the algorithm had a solution value of 1.5 for the multivariate unimodal function. Fig. 6(b) shows the iterative error curve of the Schaffer function, where the NSGA-II algorithm reached its minimum error at the 60th iteration, with a minimum error of 4.8%; The IGA proposed in the study achieved the minimum error at the 53rd iteration, and the minimum error result was 2.7%. In the Griebank function, there were two extrema in the domain, and the local minima had a regular arrangement. The study set the population size to 100, the adaptive parameters satisfied $s_1 = 2s_2 = s_3 = 2s_4 = 1$, and the maximum number of iterations was 250. The results showed that the research algorithm could achieve efficient feature selection and optimization in high-dimensional and complex optimization environments [19], especially in the field of network security, where it was crucial to quickly adapt to the dynamic changing environment in the face of complex network traffic data. By improving the GA to solve the Griebank function, the results are shown in Fig. 7.



(a) Fitness evolution curve (b) Error curve

Fig. 6. The fitness curve and iteration error curve of Schaffer function.

Fig. 7(a)-7(f) show the results of the first, sixth, 68th, 142nd, 200th, and 250th iterations of the algorithm, respectively. The results showed that the IGA gradually converged at the 68th iteration, and the algorithm basically completed convergence at the 130th iteration. Due to the complexity of Griewank function, the research method showed a good search strategy ability to find the global optimal solution in a large number of local minima, indicating its effectiveness for testing complex optimization problems. The fitness curve and iteration error curve of the Griewank function were studied as evaluation indicators for algorithm performance, and the results are shown in Fig. 8.

Fig. 8 (a) gives the fitness curve results of the Griewank function, where the NSGA-II algorithm began to converge at the 72nd iteration, the proposed algorithm began to converge at the 65th iteration, and the algorithm had a solution value of 2.0 for the multivariate unimodal function. Fig. 8 (b) gives the iterative error curve of the Griebank function, where the NSGA-II algorithm reached its minimum error at the 200th iteration, with a minimum error of 7.7%. The IGA proposed in the study achieved the minimum error at the 164th iteration, and the minimum error result was 5.2%. In the network attack detection, the attack mode was often varied, and the local minimum represented the misjudgment or omission of certain characteristics. The strong anti-interference ability ensured the robustness of the network security detection system, enabled it to effectively identify various attacks in the real environment, and reduced the false positive rate and false negative rate. Based on the analysis of the results in Fig. 7 and Fig. 8, the proposed IGA had good global optimization ability and fast convergence, and its effectiveness had been verified.

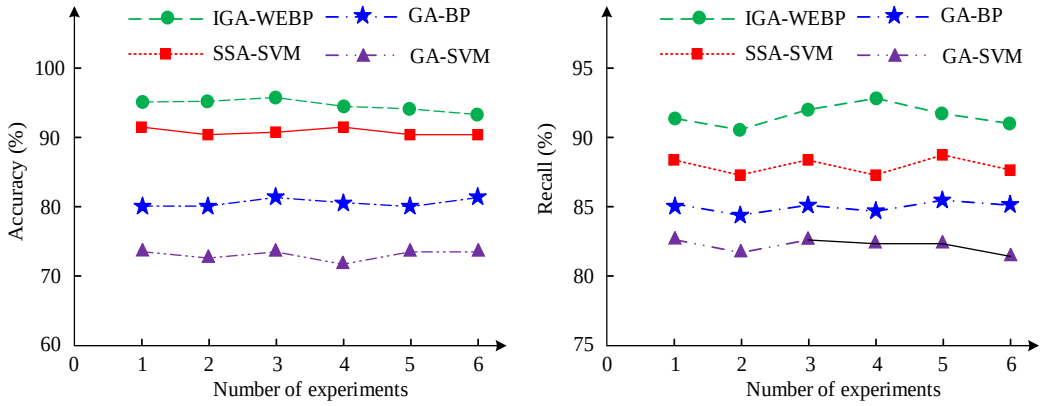
B. *Network Security Protection Analysis Based on Improved GA-WEBP Algorithm*

To testify the effectiveness of the proposed algorithm, it was compared and analyzed with the Genetic Back-Propagation Algorithm (GA-BP), Genetic Support Vector Machine (GA-SVM), and Sparrow Search Support Vector Machine (SSA-SVM) algorithms [17]. The algorithm performance was validated using the CIC-IDS-2017 dataset, and precision, recall, F1 value, PR curve, ROC curve, and mean absolute error were used as comparison indicators for performance comparison. The accuracy and recall results of the four algorithms are represented in Fig. 9.

Fig. 9 (a) shows the accuracy comparison results of four algorithms. According to Fig. 9 (a), the accuracy curves of IGA-WEBP were higher than the other three compared algorithms in all four algorithms, with an average accuracy of 96.7%, which was higher than the 91.4% of SSA-SVM algorithm, 81.0% of GA-BP algorithm, and 74.6% of GA-SVM algorithm. Fig. 9 (b) shows the comparison results of recall rates for four algorithms. According to Fig. 9 (b), the recall curves of IGA-WEBP in all four algorithms were higher than the other three compared algorithms, and its average recall rate was 93.3%, which was higher than the 88.6% of SSA-SVM algorithm, 85.4% of GA-BP algorithm, and 83.0% of GA-SVM algorithm. The above results indicated that, in terms of accuracy and recall, the SSA-SVM algorithm outperformed the three compared algorithms in terms of performance. The good balance of accuracy and recall meant that the model could effectively reduce false alarms in cybersecurity, reduce the burden on security operations teams, and improve response efficiency. This helped to enhance the accuracy of decision-making in practical applications, making network protection measures more targeted. The PR curves and F1 values of the four algorithms are shown in Fig. 10.

Fig. 10 (a) shows the comparison results of PR curves for four algorithms. According to Fig. 10 (a), the space under the PR curve of IGA-WEBP in the four algorithms was 0.89, which was higher than the 0.83 of SSA-SVM algorithm, 0.76 of GA-BP algorithm, and 0.53 of GA-SVM algorithm [18]. Fig. 6(b) shows the comparison results of F1 values for four algorithms. According to Fig. 6(b), the F1 value curves of IGA-WEBP in all four algorithms were higher than the other three compared algorithms, and its average recall rate was 0.91, which was higher than the 0.86 of SSA-SVM algorithm, 0.79 of GA-BP algorithm, and 0.70 of GA-SVM algorithm. The above results indicated that, in terms of accuracy and recall, the ISSA-SVM algorithm outperformed the three compared algorithms in terms of performance. The PR curves and F1 values of the four algorithms are shown in Fig. 11.



(a) Accuracy rate comparison results (b) Recall rate comparison results

Fig. 9. Comparison results of accuracy and recall.

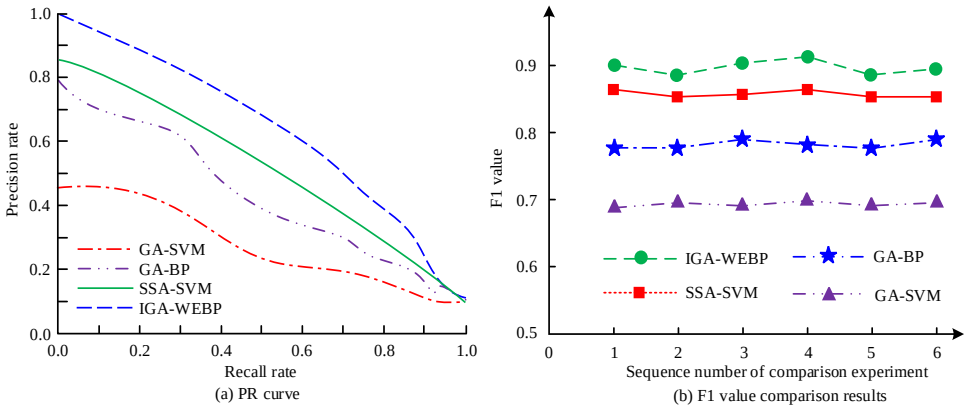


Fig. 10. Comparison results of PR curve and F1 value.

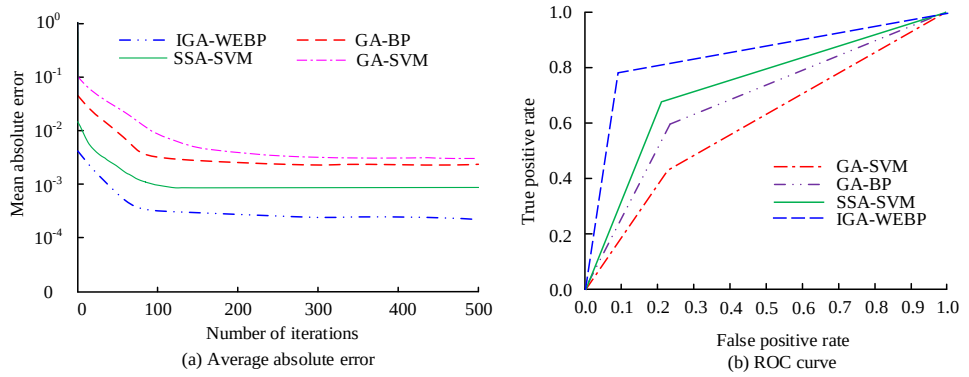

Fig. 11. Mean absolute error and ROC curve.

Fig. 11 (a) shows the comparison results of the average absolute error curves of four algorithms. According to Fig. 11 (a), IGA-WEBP had the lowest average absolute error curve among the four algorithms, and its stable average absolute error was 0.0034. Below 0.0023 for SSA-SVM algorithm, 0.0084 for GA-BP algorithm, and 0.0083 for GA-SVM algorithm. Fig. 11 (b) shows the comparison results of ROC curves for four algorithms. According to Fig. 11 (b), the space under the ROC curve of IGA-WEBP in the four algorithms was 0.88, which was higher than the 0.77 of SSA-SVM algorithm, 0.72 of GA-BP algorithm, and 0.64 of GA-SVM algorithm. The above results indicated that, in terms of average absolute error and ROC curve dimensions, the capacity of the IGA-WEBP algorithm was superior to the three compared algorithms. The results showed that the model had high efficiency in abnormal traffic detection, which indicated that the algorithm could not only handle normal traffic well, but also accurately capture abnormal traffic. The low error rate meant that the system could monitor and analyze the network in a more precise manner, and discover potential threats in time to enhance the security of the network environment. In addition, the actual performance of the network security protection system designed for research was analyzed, and the results are represented in Table I.

TABLE I. VERIFICATION RESULTS OF NETWORK SECURITY PROTECTION PERFORMANCE

Number of experiments	Data type	Input quantity	Correct corresponding quantity	Accuracy of measurement (%)
The first time	Normal data	9000	8974	99.71
	Known abnormal behavior data	3300	3276	99.27
	Unknown abnormal behavior data	560	543	96.96
The Second time	Normal data	11000	10997	99.97
	Known abnormal behavior data	3500	3476	99.31
	Unknown abnormal behavior data	500	486	97.20
The third time	Normal data	10000	9862	98.62
	Known abnormal behavior data	3000	2976	99.20
	Unknown abnormal behavior data	480	471	98.13

Table I shows that the proposed algorithm achieved recognition accuracy of over 95% for normal data, known abnormal behavior data, and unknown abnormal behavior data in each test. In the recognition of normal data, the highest accuracy reached 99.97%; the highest accuracy in identifying known abnormal behavior data was 99.31%; the recognition accuracy of unknown abnormal behavior data reached a maximum of 98.13%. The results indicated that the research method could effectively detect and distinguish normal traffic and potential abnormal behavior when facing different types of data streams, which helped to improve the effectiveness of network security protection in practical applications. These high recognition accuracy data reflected the high sensitivity and adaptability of the algorithm to network traffic changes, and could provide strong support for real-time protection. In network security applications, fast and accurate response capabilities are key to preventing data breaches and system breaches.

IV. Discussion

In the above experiment, when testing the performance of the improved method on two benchmark functions, the minimum error of the improved algorithm in the Schaffer function fitness curve was 2.7%, while NSGA-II was 4.8%; In the fitness curve of the Griebank function, the improved algorithm achieved a minimum error of 5.2% at the 164th iteration, while NSGA-II achieved a minimum error of 7.7% at the 200th iteration. For the analysis of network security protection based on the IGA-WEBP algorithm, the average accuracy of the IGA-WEBP model is 96.7%, the average recall is 93.3%, and the F1 value is 0.91, which is significantly better than the comparison algorithm. The reason why the model proposed by the research has excellent performance is mainly due to its structural advantages. The WEBP used in the IGA-WEBP model dynamically adjusts the weights of each sample. Unlike BPNN which relies solely on error feedback, WEBP allows the model to update based on the importance of the samples during the learning process. This enables samples that are more representative in specific situations to commit a greater effect on the practicing of the model, thereby improving the model's ability to recognize complex attack patterns. The importance of GA lies in its ability to optimize algorithm feature selection and hyperparameter settings through natural selection and genetic operations. Traditional feature selection methods have low efficiency in high-dimensional data processing, while GA can efficiently traverse the search space and find the optimal feature combination. In the same type of research, Unnisa N et al. proposed an intrusion detection system mainly used for detecting threats, and conducted research using various algorithms implemented by machine learning, achieving certain results in network intrusion detection [22]. Kim S et al. conducted a comprehensive review of the security threats faced by cyber physical systems. At the same time, the impact and implementation limitations of typical cyber physical attacks were analyzed, and for each established cyber physical attack, the time response of the physical system using conventional physics-based anomaly detectors was clearly explained [23]. Compared with the model proposed by the research, the methods summarized above exhibit low computational efficiency when the feature space is too large, making them less ideal for time sensitive real-time detection.

V. Conclusion

With the increasing complexity of network attack patterns, the limitations of traditional methods in network security protection have become increasingly apparent. A network security protection model grounded on improved GA-WEBP was proposed to address this issue. This model introduced the dynamic error weight and adaptive learning rate of WEBP, combined with the feature selection and hyperparameter optimization capabilities of GA, to demonstrate the effectiveness of the model in improving network security. Through experiments, the study not only verified the adaptability of the improved GA-WEBP model to dynamic changes in data during feature selection and weight updating, but also demonstrated its ability to effectively reduce false alarm rates and improve detection accuracy in practical applications. Although this research had derived important achievements in improving model performance, there were still some shortcomings. For example, the adaptability of the model to new and unknown attack patterns was still limited, which might affect its security in truly dynamic environments. Therefore, future research can focus on analyzing new feature selection and dimensionality reduction techniques to optimize the performance of the model in real-time environments, in order to further enhance the effectiveness and efficiency of network security protection.

Q-FuzzyNet: A Quantum Inspired QIF-RNN and SA-FPA Optimizer for Intrusion Detection and Mitigation in Intelligent Connected Vehicles

Abdullah Alenizi
Department of Information Technology-College of Computer and Information Sciences,
Majmaah University, Al-Majmaah 11952, Saudi Arabia

***Abstract*—In the evolving landscape of Intelligent Connected Vehicles (ICVs), ensuring cybersecurity is crucial due to the increasing number of cyber threats. Besides, challenges like data breaches, unauthorized access, and hacking attempts are prevalent due to the interconnected nature of ICVs. Several methods have been proposed to secure ICVs; however, accurate intrusion detection remains a challenging task yet to be fully achieved. For this reason, this paper proposes a comprehensive intrusion detection scheme denoted a Q-FuzzyNet, which is specifically tailored to safeguard ICV networks using Deep Learning (DL) approaches. This Q-FuzzyNet approach consists of five phases: (i) Data Collection (ii) Data Pre-processing (iii) Feature extraction (iv) Dimensionality Reduction and (v) Intrusion Detection and Mitigation. Initially, the raw data are gathered from the CICIoV2024 dataset. The collected data are pre-processed via Mean Imputation (MI) for data cleaning. Then, significant features are extracted through higher-order statistical features, Proposed Improved Mutual Information (IMI), Correlation, and Entropy approaches. Subsequently, the dimensionality is reduced via new Improved Linear Discriminant Analysis (ILDA). Ultimately, the data are classified (attacker/Normal) via the Meta-Heuristic Quantum-Inspired Fuzzy-Recursive Neural Network (QIF-RNN) model by combining the Quantum Neural Network (QNN), Recurrent Neural Network (RNN), and Fuzzy logic. The membership function of fuzzy logic is optimized via the new Self Adaptive-Flower Pollination Algorithm (SA-FPA). The identified attackers are mitigated from the network using the Policy Gradient Method. The acquired outcomes from Q-FuzzyNet are validated in terms of Accuracy, Precision, Sensitivity, and F1-score, as well. The highest accuracy of 98.6% has been recorded by the proposed model.**

I. INTRODUCTION

The automotive industry has greatly changed since the gasoline-fueled automobile was first created in the late 19th century [1]. At first, the trade was more interested in straightforward advancements in machines and mass production strategies illustrated by Henry Ford's assembly line [2]. Over time, improvements in safety, fuel economy and design transformed it into better, dependable vehicles. The incorporation of electrification, automation and connectivity into the industry has provided the era of ICVs over the past few years [3]. This change is not just altering how people drive but is also giving rise to new concepts in transportation and mobility [4].

ICVs are developing fast with the help of automation and connectivity, but these are cybersecurity threats as well [5]. ICVs are susceptible to different types of cyber-attacks such as in-vehicle attacks where hackers intrude into the vehicle's systems like the CAN bus to gain control of sensitive operations like brakes and doors [6]. V2X communication systems which are very vital for vehicle safety and efficiency are vulnerable to attacks such as replay, Sybil, and DoS which can compromise the exchange of important information between vehicles and other structures [7]. Besides, viruses and scams are capable of corrupting vehicle software, thus eradicating core functions and granting unauthorized access to information. Another issue is data privacy, which is an issue since people in ICVs are constantly sharing information with each other and personal information such as location data could easily be leaked in the process [8] [9]. Moreover, other parts of a vehicle, like TPMS and smart keys, which are sensor-based, are also vulnerable to the attack, which can result in vehicle tracking or unauthorized access. However, due to the constant development of ICVs, new risks arise and therefore, the need for strong and dynamic security measures [10].

Intelligent connected vehicles (ICVs) rely on advanced technologies that could be at risk of cyber threats, making cybersecurity critical [11]. Critical vehicle systems could be hacked to produce unsafe conditions in the car which would cause accidents if there were no strong cybersecurity measures to protect them. Moreover, strong cybersecurity measures also protect individual privacy by safeguarding their data against breaches and help to build public confidence in ICVs [12] [13]. This is of utmost importance if we are to have large-scale adoption of these driving machines. In addition, cyber security prevents big money loss and protects national interests by securing important transport facilities. Thus, for ICVs to be deployed safely and successfully, cyber safety has to be considered important [13].

Intrusion detection in intelligent connected vehicles involves signature-based, anomaly-based, behaviour-based, hybrid, Machine Learning (ML)-based, network-based, and hardware-based systems. All of these have several merits but also some remarkable demerits. Signature-based IDS works quite effectively against known threats, which mostly suffer

from novel ones and require a frequent signature update [14]. The problems in anomaly-based IDS are high false positives and adaptation. Behavioural-based IDSs are complex, and are not scale; hybrid systems are balanced yet resource-intensive, and hard to integrate. In ML-based IDSs, volumes of data are needed, and it is susceptible to model drift. In general, network-based IDS suffers from difficulties related to encrypted traffic and impacts on performance. Hardware-based IDSs are expensive and challenging to integrate [15]. Traditional Intrusion Detection Systems (IDS) suffer from to evolving attack patterns, limitations in terms of real-time detection, scalability, and ease of adaptation. Most proposed models suffer from excessive false positives, computational intensiveness, and poor feature selection that further degrades performance in dynamic ICV environments. There is a need for efficient intrusion mitigation mechanisms, which are often lacking in such approaches. Most of the existing traditional systems primarily concentrate on detection alone without having many opportunities to respond or mitigate attacks in real-time. Moreover, most of the mitigation techniques are dependent upon the static rule-based approach, which proves to be ineffectual enough for adaptive and evolving threats in the connected vehicle networks. To cope with these challenges, this paper has introduced Q-FuzzyNet, a comprehensive deep learning-based framework specifically designed for intrusion detection and mitigation in ICV networks. The novelty proposal within Q-FuzzyNet comes from the novel integration of Quantum-Inspired Neural Networks (QNN), Fuzzy Logic, and the Self Adaptive-Flower Pollination Algorithm (SA-FPA) in order to optimize membership functions with improved boosting of detection accuracy.

This paper introduced a novel IDS to tackle the previous challenge by attaining enhanced accuracy. The key contributions are:

- To propose a specialized IDS referred to as Q-FuzzyNet tailored for ICVs to enhance network cybersecurity.
- To introduce higher-order statistical features, IMI, correlation, and entropy for significant feature extraction from the CICIoV2024 dataset.
- To use ILDA to reduce data dimensionality while retaining essential information.
- To combine QNN, RNN, and fuzzy logic into a novel QIF-RNN, for efficient.
- To optimize the fuzzy logic membership functions using the SA-FPA to enhance classification performance.
- To utilize the Policy Gradient Method to mitigate the attacker from the ICV network.

This article is structured as a recent literature on IDS in Section II. Section III explains the proposed architecture. Experimentation and results are given in Section IV. Discussion is given in Section V and finally, Section VI concludes the paper.

II. Literature Study

A. Recent Research

In 2022, Cheng et al. [16] presented a new model for detecting automotive intrusion based on the STC features of the in-vehicle communication traffic. This model was based on encoding-detection architecture, in which spatial and temporal relations were encoded at the same time. The model employed the spatial and channel features through an attention-based convolutional network and the temporal features through an attention short-term memory network.

In 2021, Alladi et al. [17] have put forward an AI-driven intrusion detection model for IoV. This architecture also entailed DL Engines (DLEs) that were aimed at detecting and categorizing vehicular traffic into possible cyber threats. To support the dynamism of vehicles and the time-sensitive nature of IoV networks, these DLEs were hosted on MEC servers rather than cloud computing.

In 2022, Yu et al. [18] proposed a federated LSTM neural network-based intrusion detection approach to IVNs in ICVs. This method involved the development of an LSTM neural network model to determine the periodicity of the ID sequence of IVN messages for the prediction of the incoming message IDs. A Network IDS (NIDS) based on ID prediction was then proposed.

In 2021, Pascale et al. [19] developed an IDS that was integrated into the automotive industry, which employed a two-step algorithm to identify potential cyber threats. In the first step, the system first screened the messages in the Controller Area Network (CAN-Bus) using spatial and temporal analysis. When messages were detected as potentially malicious, a Bayesian network was then used to calculate the likelihood that an event was an attack.

In 2022, Ge et al. [20] presented an approach to a distributed longitudinal platooning control of Connected Automated Vehicles (CAVs) that improved robustness and safety under DoS attacks on V2V communications. They came up with a model that was capable of handling such factors as variable mass of the vehicle, delays in the engine and non-linear forces of resistance.

In 2022, Park and Park [21] proposed the PIER method that was used to evaluate cybersecurity threats in CAVs. This method improved on conventional risk analysis by including new factors such as exposure and recovery factors in addition to probability and impact factors. The PIER method was tested with regards to software updates over the air and collision avoidance capabilities and it was shown that it was indeed capable of reducing risk indices.

In 2021, Ahmed et al. [22] developed a solution for DL-based IDS to improve security for CAN in vehicles. Based on the VGG structure, the system is capable of learning multiple network intrusion patterns and recognizing different types of attacks including DoS and fuzzy attacks. The proposed system was tested with the CAN-intrusion dataset to obtain an accuracy of 96% and a low FPR of 0. 6 % accuracy in comparison with more conventional ML approaches.

In 2021, Li et al. [23] presented two model update schemes for ML-based intrusion detection in the IoV. The first scheme, the cloud-assisted update, used a small set of labelled data for new attacks from the IoV cloud. The second scheme which was the local update comes into play when the cloud cannot afford to provide labeled data in time by using pseudo-labels of the pre-classified unlabeled data.

In 2021, Yang et al. [24] proposed a three-layered hierarchical IDS for protecting both the intravehicle and external vehicular networks. This IDS used both the signature-based approach and the anomaly-based approach as a way of detecting both known and unknown attacks. The experimental results show that the proposed system attains a recognition rate of 99. 9% accuracy for known attacks on the CAN-intrusion dataset and 99. The proposed model achieved a CICIDS2017 dataset accuracy of 88%.

In 2023, Alladi et al. [25] presented three DL-based misbehavior classification schemes for intrusion detection in IoV networks. DCLEs were developed for single or multi-step classification on vehicular edge servers using LSTM and Convolutional Neural Networks (CNNs). The schemes include preprocessing vehicular data collected by Road Side Units (RSUs) and forwarding the data to edge servers for classification.

B. Problem Statement

Table I defines the advantages and challenges of recent IDS using various methods. As ICVs become increasingly integrated into modern transportation systems, they are vulnerable to a myriad of cyber threats that can compromise their functionality and safety. The complexity of ICV networks, characterized by dynamic data flows and diverse communication protocols, necessitates robust IDS to identify and mitigate potential attacks in real-time. Traditional IDS methods often struggle to adapt to the evolving nature of threats, making it imperative to develop advanced solutions using ML and DL techniques to enhance detection accuracy and responsiveness. Utilizing ML and DL for IDS provides several advantages, including improved accuracy in detecting anomalies and previously unseen attacks due to their ability to learn from vast amounts of data and recognize complex patterns. These approaches can also adapt to changing environments, making them suitable for the dynamic nature of ICV networks. However, challenges remain, such as the need for high-quality labeled data for training, which is often scarce in cybersecurity contexts. Additionally, the computational requirements of ML/DL models can be significant, potentially leading to delays in real-time detection. Balancing model complexity with efficiency while ensuring robustness against adversarial attacks poses further hurdles that must be addressed in the development of effective IDS for ICVs.

TABLE I. ADVANTAGES AND CHALLENGES OF RECENT IDS USING VARIOUS METHODS

Authors/Year	Methods	Database	Advantages	Challenge	Achievements
Cheng *et al*, 2022	STC features, attention-based convolutional network, attention-short-term memory network	real-world vehicle attack dataset	Encodes spatial and temporal features simultaneously, and achieves strong anomaly classification with spatial-temporal attention features.	Model complexity due to dual-frame approaches, dependent on hyperparameter tuning.	Accuracy = 97% Precision = 93%
Alladi *et al*, 2021	DLEs	IoV Network Traffic Dataset	Uses MEC servers for real-time data processing, suitable for dynamic and time-sensitive IoV networks.	Limited details on specific datasets used, and potential scalability issues with MEC servers.	Accuracy = 95% Precision = 92% Recall = 90%
Yu *et al*, 2022	Federated LSTM neural network	IVN Attack Dataset	Federated learning framework for privacy-preserving model training, LSTM for ID sequence prediction.	Reliance on timely data from the IoV cloud is less effective if cloud data is not available.	Precision = 92% Recall = 91%

III. A Novel IDS Model

A. Proposed Architecture

This paper presents an advanced IDS designed to secure ICV networks through DL techniques. The framework is divided into five key phases: (i) Data Collection, (ii) Data Pre-processing, (iii) Feature Extraction, (iv) Dimensionality Reduction, and (v) Intrusion detection and mitigation. Initially, raw data from the CIC IoV dataset 2024 are pre-processed using MI for data cleaning. Significant features are then extracted using higher-order statistical features, Proposed IMI, Correlation, and Entropy methods. Dimensionality reduction is performed via ILDA. Finally, the intrusion classification is achieved using the Meta-Heuristic QIF-RNN, which integrates QNN, RNN, and Fuzzy Logic. Membership function optimization of fuzzy logic (decision maker) is carried out using the SA-FPA, and the outcome is obtained by fusing QNN, RNN, and optimized fuzzy logic. The identified attackers are mitigated via the Policy Gradient Method. Fig. 1 shows the overview of the proposed model.

B. Data Collection

Raw data are first obtained from the CIC IoV 2024 dataset (https://www.unb.ca/cic/datasets/iov-dataset-2024.html). The topmost CICIoV2024 dataset directory contains four subdirectories pertaining to three different files named as follows:

- Hexadecimal: Data captured in hexadecimal mode (benign, DoS, spoofing-GAS, spoofing-RPM, spoofing-SPEED, and spoofing-STEERING_WHEEL).
- Decimal: Data captured in decimal mode (benign, DoS, spoofing-GAS, spoofing-RPM, spoofing-SPEED, and spoofing-STEERING_WHEEL).
- Binary: Data captured in binary mode (benign, DoS, spoofing-GAS, spoofing-RPM, spoofing-SPEED, and spoofing-STEERING_WHEEL).

C. Data Pre-Processing

It plays a crucial role in enhancing data quality by cleaning and normalizing the raw input, which helps eliminate noise and irrelevant information.

1) MI: It is a simple technique used to handle missing data by replacing missing values with the mean of the available data for a particular feature. This method is commonly used to maintain the dataset's size and ensure continuity in the analysis without distorting the data [26]. Eq. (1) shows the MI procedure. For a feature X, with N observed values, $\hat{X}$ points to the observed value's mean, and X_i signifies non-missing values.

$$\hat{X} = \frac{1}{N}\sum_{i=1}^{N} X_i \quad (1)$$

D. Feature Extraction

Feature extraction includes selecting or transforming relevant features from the CICIoV2024 dataset. It helps in improving the efficiency of the subsequent classification process. From the pre-processed data, features like proposed higher orders statistical features, IMI, Correlation, and Entropy are extracted.

1) Higher-order statistical features: It is used to capture non-linear dependencies and subtle statistical properties in data that are not evident through basic statistical measures like mean or variance. These features are often derived from moments and cumulants, which describe the shape and characteristics of data distributions beyond first and second-order statistics. Table II shows the Higher-order Statistical features and their mathematical expressions [27].

TABLE II. Higher-Order Statistical Features and their Equations

Features	Formula	Description
Skewness V_z	$V_z = \frac{1}{Q}\sum_{l=1}^{q}\left(\frac{a_l-\mu}{\sigma}\right)^3$	Q is total number of values, q is number of values ranging from 1 to Q, a_l be the individual values in the set, μ means the mean value, σ be the standard deviation, $\sum_{l=1}^{q}\left(\frac{a_l-\mu}{\sigma}\right)^3$ be the values deviate from the mean in terms of the cube.
Kurtosis N	$N = \frac{1}{Q}\sum_{l=1}^{q}\left(\frac{a_l-\mu}{\sigma}\right)^4$	$\sum_{l=1}^{q}\left(\frac{a_l-\mu}{\sigma}\right)^4$ be the Sum of the fourth power differences.
Higher-Order Moments M_h	$M_h = \frac{1}{Q}\sum_{l=1}^{q}(a_l-\mu)^h$	h indicates the order of the moment, with $h \geq 3$ representing higher-order moments beyond variance (second-order)

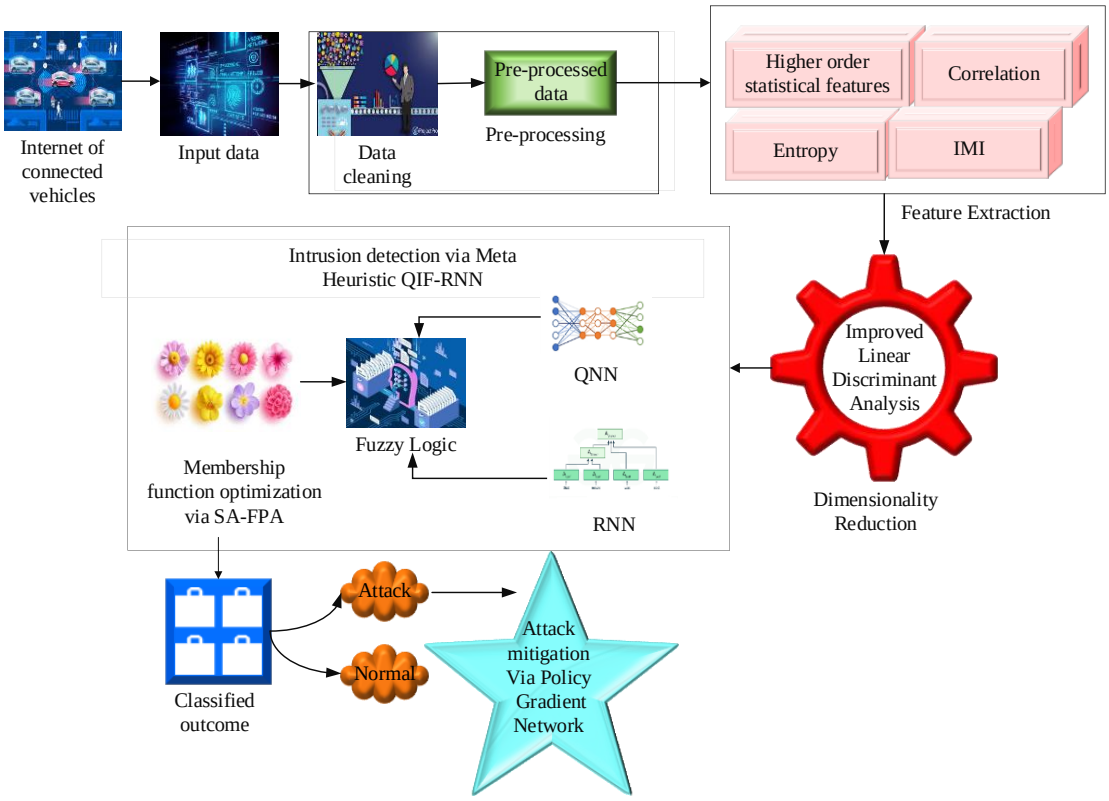

Fig. 1. Overview of the proposed model.

2) Entropy: In the context of an IDS, entropy is used to measure the distribution of different types of network packets, protocols, or system events. A significant deviation in entropy indicates unusual behavior, like a Distributed Denial of Service (DDoS) attack, where packet distributions change unexpectedly. Eq. (2) describes the entropy feature $E(X)$ extraction for IDS, in which $\rho(x_i)$ specifies the probability of occurrence of i^{th} event or value in the dataset, and n refers to total number of unique events or values.

$$E(X) = -\sum_{l=1}^{N} \rho(x_i)\rho(x_i) \quad (2)$$

3) IMI: An intuitive method for measuring the uncertainty of random variables and the information they share is provided by information theory, where two key ideas are mutual information and entropy [28]. A measure of the uncertainty of random variables is the entropy K. Assuming A to be a discrete random variable with alphabet χ and a probability mass function of $s(a) = Su\{A = a\}\, a\epsilon A$, the entropy of A is expressed as shown in Eq. (3).

$$K(A) = -\sum_{a\epsilon A} s(a)log(s(a)) \quad (3)$$

Although two random variables communicate information through a metric known as mutual information, which is shown in Eq. (4).

$$K(B;A) = \sum_{a\epsilon A} \sum_{b\epsilon B} s(b,a)log\frac{s(a,b)}{s(a)s(b)} = K(B) - K(\frac{B}{A}) \quad (4)$$

Where $K(\frac{B}{A})$ is the conditional entropy of B in the case of A is known, and can be represented as in Eq. (5).

$$K(\frac{B}{A}) = -\sum_{a\epsilon A} \sum_{b\epsilon B} s(b,a)log\left(s\left(\frac{b}{a}\right)\right) \quad (5)$$

The IMI and entropy for continuous random variables are defined in Eq. (6) – Eq. (8), respectively.

$$K(B) = -\int_a s(a)\ log\ log\left(s(a)\right) da \quad (6)$$

$$K(\frac{B}{A}) = -\int_{a,b} s(b,a)\ log\ log\left(s\left(\frac{b}{a}\right)\right) da\ db \quad (7)$$

$$K(B;A) = \int_{a,b} s(b,a)\ log\ log\ \frac{s(a,b)}{s(a)s(b)}\ da\ db \quad (8)$$

TABLE III. COMPARATIVE ANALYSIS: PROPOSED AND EXISTING FEATURE EXTRACTION APPROACHES

Metric	IMI	Entropy	Mutual Information
Accuracy	92%	85%	90%
Computational Time	12 seconds	20 seconds	15 seconds
F1-Score	0.88	0.8	0.86
Precision	0.89	0.81	0.87
Recall	0.88	0.79	0.85
Variance Explained	97%	93%	95%

Table III denotes comparative analysis of proposed and existing feature extraction approaches. The accuracy values reflect the fact that IMI substantially enhances the classifier's performance compared to traditional entropy and mutual information measures. The improvement from 85% to 92% shows the capture power of IMI for complex relations between variables. Furthermore, the relative computational time for the IMI measure is relatively low, which is only 12 seconds, while for entropy it took 20 seconds and for mutual information 15 seconds. This efficiency becomes highly valuable in those areas where large datasets are involved, or applications that require prompt outputs.

4) Correlation: A linear relationship among two variables is measured for both its strength and direction using correlation. Correlation is a technique used to determine the relationship between features in the context of feature extraction. A low correlation suggests independence, while a high correlation might point to redundancy.

E. Dimensionality Reduction

From the feature-extracted data, the dimensionality of the extracted features is reduced by utilizing ILDA.

1) ILDA: Statistical methods such as LDA [29] are now commonly employed as ML models for pattern recognition. The method involves projecting data into lower dimensional spaces in order to maximize class separability. Using Fisher's criteria, the optimal strategy for class separation is to maximize the ratio of the average difference to the total number of variables in the projection space for the two groups. The eigenvalue and eigenvector of the ideal projection transformation matrix $T_X^{-1}T_C$, where T_X and T_C are respectively the within-class and between-class scatter matrices, are the outcomes of the maximum ratio. More precisely, ILDA resolves the subsequent optimal problem utilizing Eq. (9).

$$K(x) = \frac{|\tilde{\mu}_1 - \tilde{\mu}_2|^2}{\tilde{T}_1^2 \tilde{T}_2^2} = \frac{x^{U}T_C x}{x^{U}T_C x} \quad (9)$$

where $\tilde{T}_1$ and $\tilde{T}_2$ are respective distribution matrices for classes 1 and 2. Consequently, $K(x)$ represents a measure of the within-class scatter matrix adjusted by a measure of the class mean difference. To determine $K(x)$'s maximum, differentiate and equal to zero and their mathematical expression is shown in Eq. (10) and Eq. (11).

$$\frac{d}{dx}K(u) = \frac{d}{dx}\left(\frac{x^{U}T_C x}{x^{U}T_C x}\right) = 0 \quad (10)$$

$$T_X^{-1}T_C - K(x)x = 0 \quad (11)$$

Resolving the problem of generalized eigenvalues is presented in Eq. (12).

$$T_X^{-1}T_C x = \lambda x \; where \; \lambda = K(x) = Scalar \quad (12)$$

Yield, the mathematical expression of x^* is shown in Eq. (13) and Eq. (14), respectively.

$$x^* = arg\ arg\ Max\ x\ K(x) = arg\ arg\ Max\ x\ \frac{x^{U}T_C x}{x^{U}T_C x} \quad (13)$$

$$x^* = T_X^{-1}(\mu_1 - \mu_2) \quad (14)$$

The mathematical expression of z is presented in Eq. (15).

$$z = x^{U}y, \quad (15)$$

where, y is a variable input, x vector projection, and z is a new feature in projection space used to find the projection space.

TABLE IV. COMPARATIVE ANALYSIS: LDA VS. ILDA

Metric	LDA	ILDA
Accuracy	85% (170/200)	90% (180/200)
Recall	0.8	0.85
F1-Score	0.81	0.86
Precision	0.82	0.88
Variance Explained (%)	95%	96%
Dimensionality Reduced (D)	10 to 2	10 to 2
Computational Time (s)	25	15

A comparison of the ILDA (Incremental Linear Discriminant Analysis) with the classic LDA (Linear Discriminant Analysis) highlights very important advantages of ILDA over a dynamic and evolving dataset, as depicted in Table IV, that the accuracy of ILDA is superior compared to LDA, where there is a great improvement from 85% to 90%. This indicates that ILDA could classify instances more effectively as the dataset grows or changes. It can be noticed from precision and recall values that it has resulted in increased accuracy. ILDA reflected a much greater precision at 0.88 compared with that of LDA, which was only 0.82. The same thing happened with recall: ILDA at 0.85 versus 0.80 with LDA. These improvements, therefore, say ILDA to be more effective in true positive identification, minimizing false positives as well as false negatives.

F. Classification

Using the dimensionality-reduced features, the data is classified via a Meta-Heuristic QIF-RNN. The suggested model is a combination of the QNN, RNN, and Fuzzy logic. The membership function optimization is acquired via the SA-FPA. Then the QNN, RNN, and membership function optimization are fused in the fuzzy logic to acquire an outcome.

1) QNN: A Neural Network (NN) inspired by quantum computing principles that helps in capturing complex relationships within the data, providing more powerful learning capabilities than traditional neural networks [30]. The QNN functions as a quantum circuit by acting on quantum input data through a series of parameter-dependent quantum gates, also known as unitary operators. Typically, a QNN is displayed in Eq. (16).

$$V(\theta) = \prod_{m=1}^{O} W_m V_m(\theta_m) \quad (16)$$

Eq. (16) results from O quantum layers. The product of parametric quantum gates $V_m(\theta_m)$ and non-parametric quantum gates V_m, where θ_m are variational parameters, that make up the l^{th} quantum layer. The parametric quantum gates $V_m(\theta_m)$ in the m^{th} layer is expressed as the generation of T parametric quantum gates and its mathematical expression is shown in Eq.

(17), in which Euler's formula is used to translate each parametric quantum gate $V_{m,k}(\theta_{m,k})$ as shown in Eq. (18).

$$V_m(\theta_m) \equiv T \otimes k = 1\, V_{m,k}(\theta_{m,k}) \quad (17)$$

$$exp\left(-j\theta_{m,k}Q\right) = J\, cos(\theta_{m,k}) - j\, sin(\theta_{m,k})Q \quad (18)$$

where Q is a Pauli operator functioning on qubits from the set $\{Y, Z, A\}$, $J\ is\ a\ 2 \times 2$ identity matrix, and j is the imaginary integer. The measurement result based on the readout qubits' computational basis is the QNN's output. Given that a qubit's measurement result is probabilistic, the measurement findings' expectation value, or E, is the QNN output. The expression of F is shown in Eq. (19).

$$F = \langle \Psi_y | V^{\dagger}(\theta) N V(\theta) | \Psi_y \rangle \quad (19)$$

where $|\Psi_y\rangle$ is represented as the QNN's input quantum state, and N is a linear amalgamation of Pauli operators that act as readout qubit observables. In a hybrid quantum-classical model, the loss M of a training example is computed conventionally on a classical device. An objective function $m(.)$ of the task is used to determine the loss L for the given training sample based on the actual output F and the expected output z. expression of the M is presented in Eq. (20).

$$M = m(F, z) \quad (20)$$

In the model optimization stage, the QNN update its variational parameters via back-propagation and gradient descent, just like a standard NN. It computes the gradient of a variational parameter θ_l in the $l-th$ quantum layer with respect to loss M using the following Eq. (21).

$$\frac{\partial M}{\partial \theta_l} = \frac{\partial M}{\partial F}\frac{\partial F}{\partial \theta_l} \quad (21)$$

$\partial M/\partial F$ is easily obtained using the objective function $m(.)$. $\partial F/\partial \theta_l$ is computed using Eq. (22).

$$\frac{\partial F}{\partial \theta_l} = j\langle \Psi_y | V_{-}^{\dagger}\left[Q_l,\, V_{+}^{\dagger} I V_{+}\right] V_{-} | \Psi_y \rangle \quad (22)$$

where, the Eq. (23) is represented as,

$$V_{+} = \prod_{m=l+1}^{o} W_m V(\theta_l)\ \ and\ V_{-} = \prod_{m=1}^{m=l} W_m V(\theta_l) \quad (23)$$

2) RNN [31]: It serves as a pivotal component, contributing to the model's efficacy in processing sequential data and capturing hierarchical dependencies within the input features. The proposed QIF-RNN excels in identifying complex patterns and relationships within the input features, ultimately enhancing its performance in data classification tasks by utilizing the inherent ability of RNNs to capture dependencies in sequential data. Fig. 2 shows the Structure of the QIF-RNN.

3) Fuzzy logic: It is a mathematical framework that deals with uncertainty and imprecision, where traditional binary logic fails. It helps to capture the vagueness in data, making the system more flexible and robust [32].

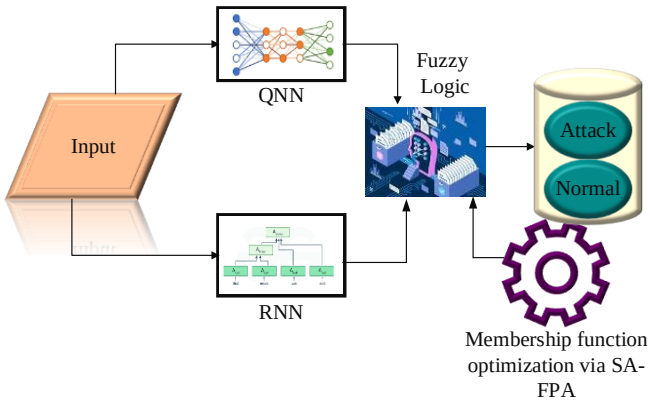

Fig. 2. Architecture of QIF-RNN.

a) Fuzzy sets: Crisp sets that have had their characteristic function changed to the membership function A: X →[0,1] are known as fuzzy sets.

b) Properties of fuzzy sets: Various properties of Fuzzy sets is presented in Table V. Algorithm 1 shows the pseudocode of Fuzzy decision-making.

TABLE V. PROPERTIES OF FUZZY SETS

Operation	Crisp	Fuzzy
Addition	$J + V$	$\tilde{J} + \tilde{V} = [J_1^{(\propto)} + V_1^{(\propto)}, J_3^{(\propto)} + V_3^{(\propto)}]$
Subtraction	$J - V$	$\tilde{J} - \tilde{V} = [J_1^{(\propto)} - V_3^{(\propto)}, J_3^{(\propto)} - V_1^{(\propto)}]$
Multiplication	$J \cdot V$	$\tilde{J} \cdot \tilde{V} = [J_1^{(\propto)} \cdot V_1^{(\propto)}, J_3^{(\propto)} \cdot V_3^{(\propto)}]$
Division	$J \div V$	$\tilde{J} + \tilde{V} = [J_1^{(\propto)} \div V_3^{(\propto)}, J_3^{(\propto)} \div V_1^{(\propto)}], if\ 0 \notin [V_1^{(\propto)}, V_3^{(\propto)}]$

4) Membership function optimization: It is acquired via the SA-FPA.

Algorithm 1: Pseudocode for Fuzzy Decision Making
Using fuzzy decision-making entails the subsequent actions:
Step 1: The identification of variables and the completion of the alternatives is the first phase.
Step 2: The linguistic parameters are transformed from real variables throughout the fuzzification process.
Step 3: The user chooses the variables that must be entered into the knowledge base.
Step 4: A membership function is the expression of a membership function in a mathematical function.
Step 5: Giving the if-then condition rule is the next step. One rule is represented by each variable.
Step 6: Converting the fuzzy value to an output variable is the next step.
Step 7: Practical implementation of the alternative is the final stage of the fuzzy process. If the implementation is successful, the system's performance will improve concerning the process's goal.

a) Proposed SA-FPA: Flowering plants reproduce, and FPA mimics this process [33]. The proposed SA-FPA is used for optimizing the fuzzy membership functions. Membership functions define how each data point belongs to a fuzzy set (e.g., low, medium, high). SA-FPA adapts these membership functions for optimal performance, ensuring that the fuzzy logic system can accurately represent the underlying uncertainties in the data. Algorithm 2 defines the FPA procedure.

Algorithm 2: SA-FPA Procedure
Step 1: The process of biotic pollination is regarded as worldwide, with pollinators carrying out Levy flights.
Step 2: The process of abiotic pollination is seen as a local one.
Step 3: Flower constancy is examined using the hypothesis that the degree of similarities between the flowers in question and the likelihood of reproduction are inversely connected.
Step 4: Whether a pollination technique is local or global is determined by a switching probability p in the interval [0, 1].

A flower m represents a solution vector b_m in FPA. Two distinct search techniques are used by the algorithm: local and global pollination. Utilizing the following Eq. (24), the first and third FPA criteria could be used to numerically express the global pollination procedure.

$$b_m^{x+1} = b_m^x + \gamma \cdot P(\lambda) \cdot (k^* - b_m^x) \quad (24)$$

where $k^*$is the finest flower in the populace of flowers at iteration x, b_m^x represents flower m at iteration x, λ is a constant, γ is a constant scaling aspect to control the step size and $P(\lambda) > 0$ is the Le´vy flight step size, which is drawn from a Le´vy distribution and characterizes the strength of the pollination; $\Gamma(\lambda)$ is the usual gamma function and $w > 0$. The mathematical expression of p is presented in Eq. (25).

$$P \sim \frac{\lambda \Gamma(\lambda) sin sin\left(\frac{\pi\lambda}{2}\right)}{\pi} \cdot \frac{1}{w^{1+\lambda}}, (w > 0), \quad (25)$$

Conversely, the following Eq. (26) represents the local pollination rule (second rule) and floral dependability (third rule), where e is taken from a uniform distribution in [0, 1] and b_n^x and b_o^x are distinct flowers of the same population.

$$b_m^{x+1} = b_m^x + \varepsilon \cdot (b_n^x - b_o^x) \quad (26)$$

As per the fourth rule, a switch probability t in [0, 1] determines the kind of flower pollination (local or global). Reiterating the earlier data. Eq. (27) expresses the fitness estimation of proposed SA-FPA, in which ρ_i refers to prediction error for each fuzzy set, c_i indicates complexity of the membership function, $s(M)$ signifies constraint function ensuring feasible membership function structures, and γ addresses regularization parameter balancing error minimization and function complexity.

$$f_{opt} = \left(\sum_{i=1}^{N} \left(\frac{\rho_i}{c_i}\right) + \gamma s(M) \right) \quad (27)$$

Fig. 3 displays the FPA flowchart, where r is the population size of flowers and h is the number of problem dimensions. Once the QNN and RNN have processed the data, the outputs are fused with the optimized fuzzy logic system. The fusion helps in incorporating both the sequential information (handled by RNN) and the non-binary decision-making capacity (handled by fuzzy logic).

The final classification output O is derived by combining the outputs from QNN, RNN, and the fuzzy system. Let O_{qnn} and O_{rnn} be the outputs from the QNN and RNN, and O_{fuzzy} be the fuzzy logic decision, Eq. (28) states the overall classification output, in which α, β, and γ means for weighting factors to balance the contributions from each component.

$$O = \alpha \cdot O_{qnn} + \beta \cdot O_{rnn} + \gamma \cdot O_{fuzzy} \quad (28)$$

This combined approach allows the QIF-RNN model to utilize the strengths of quantum-inspired learning, sequence prediction, and handling of uncertainty to achieve a highly accurate classification.

G. Attack Mitigation via Policy Gradient Method

The Policy Gradient method is one such technique in reinforcement learning, which achieves those situations where the number of possible actions is high dimensional or continuous is practical for Q-learning. Unlike Q-learning, which emphasizes verdict optimal actions, policy gradient seeks optimal parameters θ for a policy π_θ which would maximize the total reward. The chief aim of the policy gradient is to maximize the expectation of return or collected reward starting from a given initial state. That is, it is apprehended by Eq. (29).

$$J(\pi_\theta) = E_{\tau \sim \pi_\theta}[r(\tau)] = \int \pi_\theta(\tau) r(\tau) d\tau \quad (29)$$

Here, $\pi_\theta(\tau)$ indicates the probability of observant trajectory τ. The method learns the optimal parameter θ by calculating the gradient $\nabla_\theta J(\pi_\theta)$ as per the Eq. (30).

$$\nabla_\theta J(\pi_\theta) = E_{\tau \sim d_{\pi_\theta}}[\sum_{t=1}^{T} r(s_t, a_t) \sum_{t=1}^{T} \nabla_\theta log\ log\ \pi_\theta(s_t, a_t)] \quad (30)$$

In the above equation, d_{π_θ} is the distribution of trajectories produced by policy π_θ . The derivation encompasses the substitution in the Eq. (31).

$$\pi_\theta(\tau) = p(s_1) \prod_{t=1}^{T} \pi_\theta(s_t, a_t) p(s_{t+1} | s_t, a_t) \quad (31)$$

Here, $p(\cdot)$ is independent of the policy parameter θ, and for simplicity, it's not explicitly encompassed in the derivation.

TABLE VI. ATTACK MITIGATION APPROACH: A COMPARATIVE ANALYSIS OF POLICY GRADIENT APPROACH AND Q-LEARNING

Method	Convergence Speed	Average Total Reward	Sample Efficiency	Robustness
Policy Gradient	Fast	High (85)	Moderate	High (10% drop)
Q-Learning	Moderate	Moderate (70)	Low	Low (30% drop)

As indicated in Table VI, we compare the two leading reinforcement learning methods, Policy Gradient and Q-Learning, with a focus solely on attack mitigation. In these dimensions—convergence speed, average total reward, and robustness—the Policy Gradient approach performs better than the Q-Learning method. Hence, this makes policy gradient more viable for dynamic and complex environments.

IV. SIMULATION RESULTS

A. Simulation Setup

The proposed IDS model via suggested QIF-RNN was developed via Python on an Intel core® i5 processor @2.6GHz, 16 GB RAM, 64-bit OS. Here, CICIoV2024 dataset was utilized for detection which is accessible via (https://www.kaggle.com/datasets/hassan06/nslkdd) [Accessed

Date: 24-09-2024]. 70% of the collected data has been used for training and 30% for testing. This assessment considered various metrics like sensitivity, specificity, accuracy, precision, False Positive Rate (FPR), False Negative Rate (FNR), NPV, F1-score, Matthews Correlation Coefficient (MCC), and Recall.

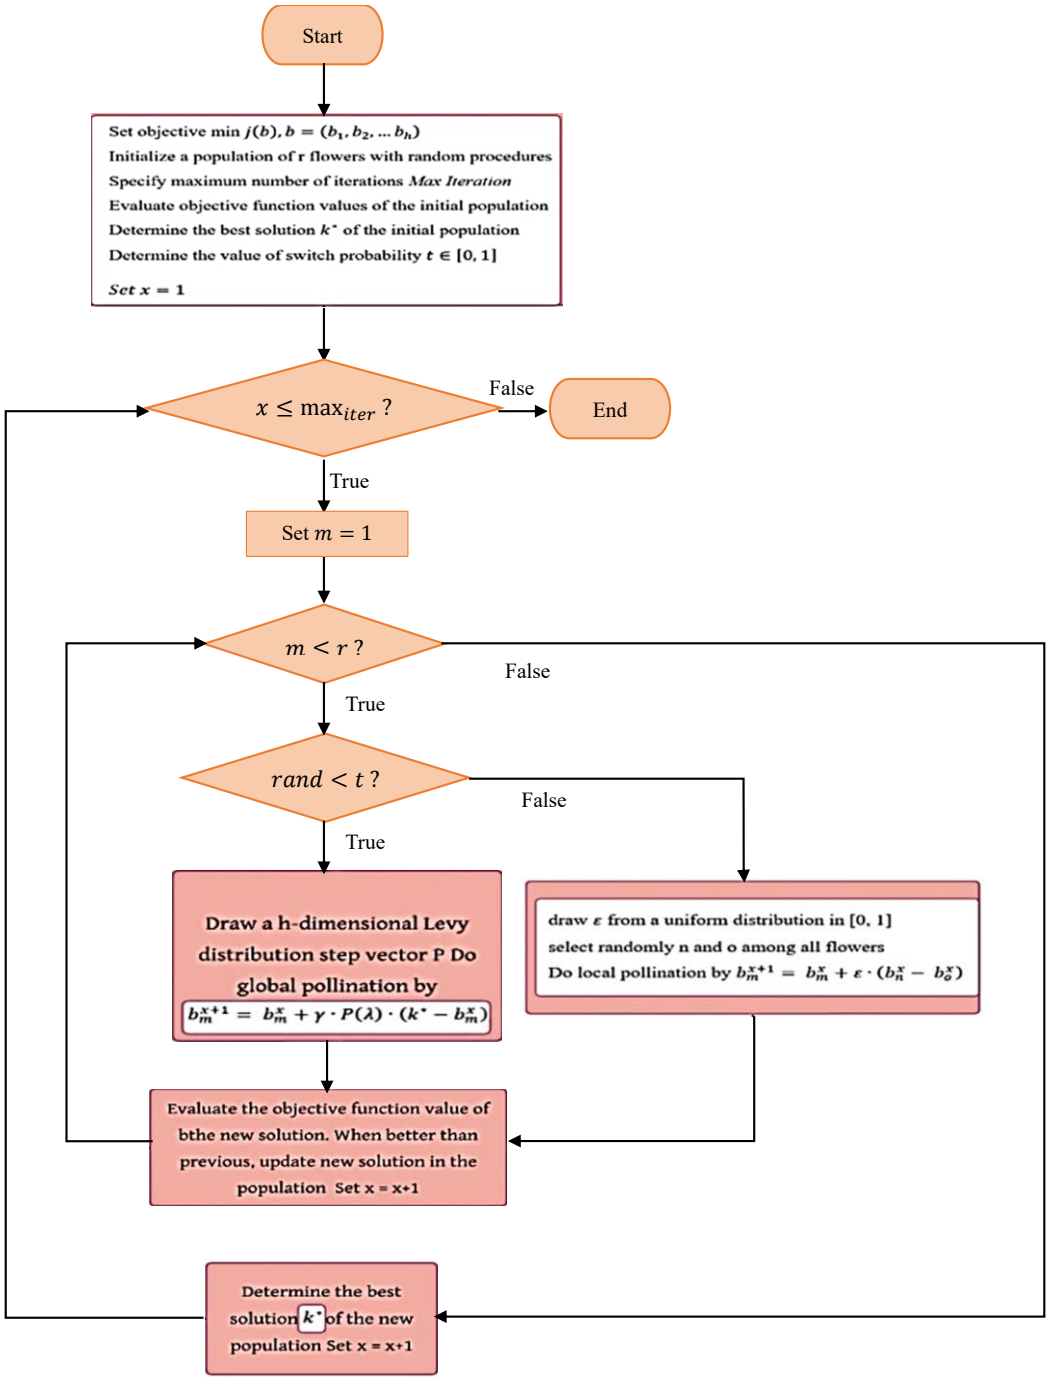

Fig. 3. Flow chart of proposed SA-FPA.

B. *Intrusion Detection Network: Performance Analysis for 70/30 Data Split*

The comprehensive performance analysis demonstrates the superiority of the suggested ensemble framework with quantum learning over the other models already in use, such as Fuzzy RNN (FRNN) [34], RNN, GRU [35], LSTM [35], and Bi-LSTM [36], on a range of critical metrics in Fig. 4. With a sensitivity of 96.8%, the suggested model outperforms FRNN (95.1%), RNN (92.9%), GRU (83.4%), LSTM (77.6%), and Bi-LSTM (77.1%). This indicates the enhanced ability of the suggested model to precisely identify affirmative cases, which is essential for successful intrusion detection. The suggested model outperforms FRNN (98.8%), RNN (98.6%), GRU (93.8%), LSTM (92.4%), and Bi-LSTM (93.3%) in terms of

specificity, achieving a phenomenal 99.6%. The high specificity highlights how well the suggested model can identify negative instances and reduce false positives, which is an important consideration in real-world intrusion detection scenarios. The suggested model's total accuracy is 98.6%, which is higher than that of FRNN (98.6%), RNN (96.2%), GRU (91.9%), LSTM (91.0%), and Bi-LSTM (89.3%). This high accuracy illustrates how the suggested ensemble architecture is resilient in producing accurate and trustworthy classifications for both positive and negative examples. The suggested model's precision, a crucial parameter for assessing the model's capacity to reduce false positives, is reported to be 97%, surpassing that of FRNN (95.5%), RNN (94.3%), GRU (83.6%), LSTM (78.8%), and Bi-LSTM (76.5%). The accuracy with which the suggested model identifies intrusions is demonstrated by its precision.

The suggested model's F1-score, which weighs recall and precision, is stated as 96.4%, indicating that it can successfully strike an equilibrium between accuracy and completeness. This is superior to LSTM (79.7%), Bi-LSTM (77.3%), GRU (83.0%), RNN (94.5%), and FRNN (96.1%). The suggested model consistently outperforms other models in addition to maintaining a high Negative Predictive Value (NPV) of 99.2%. The remarkably low FPR and FNR, which stand at 2.9% and 7%, correspondingly, highlight the potential of the suggested approach to reduce misclassifications. The suggested model's overall Matthews Correlation Coefficient (MCC), which measures how well the model captures genuine correlations in the data, is stated as 94.6%. When compared to FRNN, RNN, GRU, LSTM, and Bi-LSTM, the suggested ensemble architecture consistently performs better across sensitivity, specificity, accuracy, precision, recall, F-measure, NPV, and Matthews Correlation Coefficient. The suggested model is shown by this thorough analysis as a cutting-edge and promising data categorization method, especially for data classification. Table VII shows the Comparative analysis of the suggested framework and existing model performance metrics.

TABLE VII. COMPARATIVE ANALYSIS OF PERFORMANCE METRICS WITH EXISTING MODELS

Metrics	Sensitivity	Specificity	Accuracy	Precision	F1-Score	NPV	FPR	FNR	MCC
Proposed	0.968	0.996	0.986	0.97	0.964	0.992	0.029	0.07	0.946
FRNN	0.951	0.988	0.986	0.955	0.961	0.992	0.036	0.072	0.921

C. Comparative Analysis of Proposed Intrusion Detector Model over SOTA Approaches for Varying Learning Rate

The research proposed a novel Meta-Heuristic QIF-RNN for IDS, structured into five phases: (i) Data Collection, (ii) Pre-processing, (iii) Feature Extraction, (iv) Dimensionality Reduction, and (v) Meta-Heuristic QIF-RNN-based Data Classification.

Table VIII shows the performance of the proposed model in comparison to the prevailing models in terms of Accuracy, Precision, Sensitivity, F-score, Specificity, MCC, FPR, and FNR. The proposed Model gives highest accuracy value of 98.261%, the precision of 98.095%, and F1-score of 97.549%, hence overall better performance due to higher values of correct classification. The Quantum network along with fuzzy and meta-heuristic optimization assisted in enhancing the classification accuracy of the model.

Table IX discusses the contrast of the performance of the proposed model with the existing models on metrics such as Accuracy, Precision, Sensitivity, F-score, Specificity, MCC, FPR, and FNR. The proposed Model reflects better performance on all these metrics with the highest value in accuracy of 99.755% and precision of 99.901%. Its high sensitivity of 98.655% and specificity of 99.075% show its higher classification accuracy in identifying the attacks. The fuzzy logic-based classification has enhanced the detection accuracy of the model. Thus, making it accurate in detecting the attacks.

V. DISCUSSION

The proposed Meta-Heuristic QIF-RNN model for IDS brings several advantages. First, the structured approach involves multiple phases such as data preprocessing steps that ensure only relevant and clean data are used for classification. The use of higher-order statistical features, IMI, correlation, and entropy ensures that the model captures critical attributes of the data. These data helped in detecting intrusions more effectively. Furthermore, the integration of QNN, RNN, and Fuzzy Logic in the classification phase allows the model to handle both sequential and fuzzy data, leading to high classification accuracy of 98.6%. The SA-FPA optimization of the membership function enhances the precision of the decision-making process. Also, the Policy Gradient Method contributes to effective attack mitigation. These features make the model robust in detecting and mitigating cyber threats in ICVs.

Despite these advantages, the model also has limitations. While the use of dimensionality reduction (ILDA) helps minimize the computational load, the complexity introduced by combining multiple components (QNN, RNN, Fuzzy Logic, and SA-FPA) leads to increased computational overhead. This might limit its scalability in real-time environments, particularly when dealing with large-scale and high-speed networks like those in ICVs. Another potential limitation is the static nature of the dataset used (CICIoV2024). It may not represent real-time or evolving attack scenarios. As the research suggests, future improvements could focus on incorporating real-time data streams and advanced optimization techniques to address these limitations.

VI. CONCLUSION

The research proposed a novel Meta-Heuristic QIF-RNN for IDS, structured into five phases: (i) Data Collection, (ii) Pre-processing, (iii) Feature Extraction, (iv) Dimensionality Reduction, and (v) Meta-Heuristic QIF-RNN-based Data Classification. Initially, raw data were collected from the CICIoV2024 dataset, which then underwent preprocessing through a data-cleaning technique. From the pre-processed data, significant features including Higher-Order Statistical Features, IMI, Correlation, and Entropy were extracted. The dimensionality of these extracted features was subsequently reduced using ILDA. Finally, the data were classified using the dimensionality-reduced features in conjunction with the Meta-Heuristic QIF-RNN model, which integrated QNN, RNN, and Fuzzy Logic. The optimization of the membership function was achieved through SA-FPA. The attack mitigation is achieved via the Policy Gradient Method. The proposed model attained 98.6% accuracy and outran existing models. Integrating complex DL algorithms (QNN, and RNN) requires considerable computational time. Future work could focus on enhancing the Meta-Heuristic QIF-RNN model by incorporating real-time data streams for dynamic intrusion detection in ICVs. Additionally, exploring advanced optimization algorithms and integrating ensemble learning techniques improve classification accuracy and robustness. Investigating the model's adaptability to emerging cyber threats and conducting extensive performance evaluations in diverse network environments could further strengthen its applicability. Finally, expanding the feature extraction methods to include DL-based approaches yields richer insights and enhances the model's predictive capabilities.

DATASET ACCESSIBILITY

The dataset used in your study, CICIoV2024, is referenced as accessible through the link to the Kaggle dataset (https://www.kaggle.com/datasets/pushpakattarde/ciciov2024decimalcsv), which is publicly available for download. This ensures reproducibility for anyone looking to replicate the results.

ACKNOWLEDGEMENT

Predicting Learners' Academic Progression Using Subspace Clique Model in Multidimensional Data

Mr. Oyugi Odhiambo James, Prof. Waweru Mwangi, Dr. Kennedy Ogada
Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya

***Abstract*—Subspace clustering examines the traditional clustering techniques that have previously been considered the best approaches to clustering data. This study uses a subspace clustering approach to predict learners' academic progress over time. Using the subspace clustering method, a model was developed that improves the classic Clique by optimizing clustering performance and addresses the clustering challenges posed by inaccuracies due to additional data size and increased dimensionality. The study used an experimental design that included data validation and training to predict students' academic progress. Clustering evaluation metrics including accuracy, precision, and recall measures were identified. The optimized model recorded a better performance index with 98.90% accuracy, 98.50% precision, and 98.50% recall which directly shows the efficiency of the optimized model in predicting learning academic progress through clustering. In this regard, conclusions are drawn for an alternative approach to predictive modeling through cluster analysis, so that educational institutions have a better opportunity to manage learners by ensuring adequate preparation in terms of resources, policies and knowledge. It highlights career guidance for learners based on their academic progress. The result validates the suitability of the model for clustering multidimensional data.**

Keywords*—Subspace clustering; clique model; academic progression; multidimensional data; feature engineering; cross validation and principal component analysis

I. Introduction

A. Introduction

This component describes the background of the study, the objectives and the problems of the study. The literature of the study within the local, regional and international perspectives on the use and application of clique models, the importance and the gaps addressed in this study.

B. Background of Study

Academic progress is important in a learning environment where each learner must be assessed to determine their progress to the next level of learning. Various considerations are taken into account and typically indicators of progress in a learning environment are well established and clearly stated, although this may vary from institution to institution. There are standard learning levels such as certificate, diploma, bachelor's, master's and doctoral. It is also notable that educational institutions need to understand learners' progress to ensure efficient and effective management of learners.

The main objective of this study was to develop a model that predict leaners' academic progression. The improved Subspace Clique model was expected to address the challenges of classical Clique in clustering of data. For instance, the process of finding clusters in multidimensional data space is a complex procedure due to the large number of attributes and tuples involved. In the case of multidimensional data, the density points are at their lowest level. The approach taken by traditional Clique cannot stand due to the inaccuracies and inconsistencies, thus misleading in finding the objective clusters. Because of various scores of attributes involved, clusters are not always found in their actual multidimensional data space [1]. This means that it could be possible to find these clusters in specific subspace of the entire dataset space. The problem of dimensionality is common in data mining, for instance the dimension increases with the increase in the number of attributes in a particular dataset leading to the curse of dimensionality which an optimized Clique can address. In [2], improved Clique algorithm from a hybrid of Clique and K-means, the experiment was conducted on artificially simulated dataset, which revealed that the hybrid was not sensitive to the input parameters used in classical Clique but was silent on the dimensionality challenge and different dataset effect. Ultimately a significant number of attributes are normally dropped before the actual experiments are conducted which may affect the results if not well accounted for [3]. On the other hand, traditional clustering algorithms break when employed in multidimensional data spaces, and that they present many irrelevant attributes that could limit the possibility of clustering. The current subspace clustering methods are mainly used in either numerical or categorical data but not all [4]. The method recommended in this study takes into account the different data types that are subject to proper data preprocessing. In this study, an improved Clique algorithm was proposed, which takes into account students' academic performance in predicting learning progress. This is an area that many researchers have overlooked when conducting behavioral analysis using Clique algorithm.

C. Literature Review

This study is based on the subspace clique clustering technique. The focus of this study was on predicting learners' academic progress using multidimensional data. To achieve this, future forecasts were made based on the available data. Whereas a Cluster is an ordered list of data which have the familiar characteristics [5], Clustering refers to an ill-posed problem which aims to reveal interesting structures in the data or to derive a useful grouping of the observations. However, specifying what is interesting or useful in a formal way is challenging. This complicates the specification of suitable criteria for selecting a clustering method, or a final clustering solution [6] also emphasized this point. He argued that the definition of the true clusters depends on the context and on the

aim of clustering. Therefore, given the data, there is no clear clustering solution, but different aims of clustering imply different solutions, and analysts should in general be aware of the ambiguity inherent in cluster analysis and thus be transparent about their clustering aims when presenting the solutions obtained [7].

CLIQUE is a subspace clustering algorithm that operates on a grid and density basis. By combining the advantages of density-based clustering with the advantages of grid-based clustering, it can find clusters of any shape while still managing large amounts of data [8]. The clustering process starts with a single dimension scaling upwards to higher dimensions. Clique divides the N-dimensional data space into non-overlapping rectangular units from which dense units are identified. A unit is considered highly dense if the sum of the total data points in the unit runs over an input parameter, Clusters are then created from the original data space using the Apriori principle [9]. CLIQUE finds high-quality clusters only in subspaces with the highest dimensionality, making it an efficient method. The threshold density and grid size must be properly adjusted in order to produce meaningful clustering results.

Research on Clique-based Model in Predictive Analysis has been conducted by several scholars, such as [10], One such study focused on forecasting future weights based on a partial order set using the Clique Algorithm for pattern analysis to cluster high-dimensional data [11]. In text mining [12], Customer Segmentation and trend analysis [13], Further, intrusion detection in IoT networks [14]. The study in [15] proposed dimensionality reduction via feature reduction. as well as imaging processing [16]. Student behavioral data [17] among other fields. This study proposed Clique model in predicting leaners academic progression in multidimensional dataset.

Numerous studies have been carried out to forecast the development, effectiveness, and behavior of leaners. For instance, [12] used the vector space model and the clique subspace model to study critical text mining of learners' behavioral patterns in Kenya. The findings demonstrated that even for large data sets, the processing time in Clique is significantly less; however, the researcher noted that grid cell consideration, density threshold, and parameter input requirements are limitations.

Similarly, [18] studied in the USA to find course clusters and course cliques based on the degree of grade correlation between student grades in pairs of courses in one of the universities using subspace clique and network diagrams, where courses are represented as nodes and are connected to courses if they have a high degree of grade correlation. The ability of Clique to cluster academic data is demonstrated by an analysis of the results for course pairs and courses grouped by academic department.

For example, [17] research on student behavior patterns was done in China. In an effort to address the issue, the study suggested an unsupervised clustering framework that combined behavioral data from students with grade point averages to find behavioral patterns, a similar study reflected in study [19]. The suggested framework incorporated the views of statistics and entropy to extract behavior features, which are combined with k-means and density-based spatial clustering of applications with noise (DBSCAN) algorithms to find behavioral patterns. An analysis was conducted to compare the enhanced model with the conventional Clique subspace clustering model. In comparison to the improved model, the results showed that Clique performed a little bit worse. The findings demonstrate that the framework is able to identify both mainstream and anomalous behavioral patterns. Although this was the case, future selection only considered variance and correlation rather than cross validation and principal component analysis, meaning that the data management of clustering was not given much thought.

A similar study by [20] was conducted in Korea on various clustering algorithms with a focus on pattern identification. Clique became one of the algorithms used and tried to study the convergence speed and accuracy of clustering. The study used small data sets that achieved high accuracy with sensitivity to density and hyperparameter tuning. It was not clear how the optimization that resulted in high accuracy was achieved, as the study did not specify the limitations of small datasets and dimensionality management, which has been addressed in this study.

In the United Kingdom, [21] conducted research to design a system for assessing and guiding the mental health of college students. The study examined the applications of clustering data mining algorithms relevant to the researcher's area of interest. The research involved college students and used performance testing to determine the system's accuracy and effectiveness in assessing and managing students' mental health. However, the study acknowledged the pattern recognition ability of the Clique algorithm, although it focused on developing an artificial intelligence-based system for analyzing the mental health of college students. Further suggestions from [22] affirm that the CLIQUE algorithm can perform effective cluster analysis and automatically adapt to different subspaces.

A study by [23] to find nonlinear feature relationship pattern recognition in India. Even in cases where feature relationships are nonlinear, the method enables the discovery of bi-clusters based on feature relationships. The suggested approach used datasets from various domains and did not require the user to provide any parameters. Clustering with the Clique algorithm was used to assess performance. The fact that the new approach outperformed the original Clique, suggests that it needs to be improved. The research in [24] are among the other benchmarked studies with similar findings.

In summary, the studies conducted in Kenya, the United States, the United Kingdom, China, India and Korea using the Clique algorithm clustering technique have not only shown the scope bias but also found serious gaps, which accompany the implementation and use of the Clique algorithm, which require attention. For example, most studies have been conducted to analyze student behavior patterns, but not to direct academic progress and/or performance, which is critical to excelling in an academic learning environment and in managing learners. Other notable challenges would be data preparation before use, data size, methods used for dimensionality reduction, future selection, and consideration of hyperparameters, which in turn affect the accuracy of the clustering method. Other studies that

conducted a comparative analysis between ordinary Clique and other existing models, trying to recommend a model that provides a better performance index for some specific data, which is not necessarily academic in nature did not pay attention to improving the models.

In countering the gaps with studies conducted in Kenya and reflected elsewhere, this study recommends predicting students' academic progress using an improved subspace clique in multidimensional data, which considers model optimization through feature engineering, data standardization, dimensionality reduction and cross-validation.

In other sections, the paper further extends to provide information on study-related work, data acquisition and preprocessing, the design, methods, tools used, and the implementation of the predictive subspace Clique model. The paper concludes by presenting and discussing the results, conducting a comparative analysis, and exploring the significance of the research. Additionally, it draws conclusions and offers recommendations for future work.

II. Related Work

A. Introduction

This section includes a detailed review of the relevant literature and recent studies on implementing the subspace clique model for predicting learners' academic progress in multidimensional data, as well as a summary of results from such applications.

B. Subspace Clique Model

Research on the topic of using Subspace Clique to predict student academic progress and related learning areas, or such behavioral environments is extensive. For example, in a study by [25], blended aerobics learning is analyzed and guided using data mining. Action learning is combined with blended aerobics instruction to promote learning progress. The study proposed a Clique clustering algorithm that meets the following criteria: (1) identify embedded clusters in high-dimensional data subspaces; (2) scale; (3) understand end-user results; and (4) predict cluster descriptions into minimized density expressions to promote understanding [25]. In the modern educational environment, blended learning has enormous growth potential. The study examined the practical value of meta-learning theory in its application to aerobics instruction. The results showed that students have potential meta-learning, can deliberately improve students' meta-learning ability, and it is important to increase students' interest in aerobic skills through appropriate learning strategies [26]. Subjects were tested on basic questions, aerobic technical skills and physical fitness in the experimental data set. A comparative analysis of the semester's academic performance was reviewed following a teaching exam that lasted 15 weeks, equivalent to a full semester at the university. After applying the classic clique model to the dataset and analyzing the results using accuracy, precision, and recall metrics, it was found that the model had an accuracy of 86.5%, a precision of 85.99%, and a recall of 85.9%. Although the accuracy was higher on average, the study's margin of error of 14.5 percent on accuracy was noted and could be associated with certain observations such as the unclear explanation of data management, feature selection, and dimensionality reduction with respect to cross-validation.

In a separate study conducted by [24], investigating clustering algorithms based on grids, the focus was on the appropriate selection of grid cells that contributed to the field, and a novel grid-based algorithm that employs an automated method for calculating the number of grid cells was proposed. The study covered the idea of grid cells in the Clique algorithm and used the Clique model to contrast the outcomes of the upgraded model. A simulated educational dataset was run through a Python script in order to identify learning patterns, which produced results with accuracy of 95.23%, precision 95.0% and a recall of 95.20%. The well-known Clique algorithm was used in the experiment as a benchmark, allowing a quick pinpoint on a few observations; even though the Clique model was efficient at establishing clusters when clustering data. Notably, it required two input parameters, i.e., the threshold for density and the number of intervals. The parameters in this case were difficult to calculate. Based on this study, we can conclude that the model did not function as well as the researcher had hoped.

In a related study, [17] used the clustering approach to analyze student behavior patterns. The study's goal was to assist the institution in setting targeted rules, particularly for unexpected patterns, and in determining more effective ways to provide specialized services and management. To address the issue, the study took into account a clustering technique. The study analyzed the relationships between various behavior patterns and students' grade point averages by conducting experiments on six different types of behavioral data generated by university students (eating behavior, shopping behavior, library entry behavior, and gateway login behavior, respectively). The six attributes were gathered from 9024 university students. Grade point averages served as the foundation for the computation of extrinsic metrics, which quantify the relationship between various behaviors and academic achievement. The characteristics corresponding to each type of behavior were derived from a central tendency perspective. With a comparative performance evaluation against the Clique algorithm, the study proposed a hybrid clustering algorithm that combines the best features of DBSCAN and K-means. Using the Clique algorithm, the results showed an accuracy of 92.0%, precision of 91.83% and recall of 90.12%. This explained the model's ability to group educational data. The researcher added that the improved model performed better than Clique by achieving an accuracy performance of 92.0%, which was only a small improvement. The experimental results show that the proposed method can not only detect abnormal behavior patterns but also identify different behavior patterns more accurately. Based on the clustering results, student departments can take more targeted interventions and specialized services. The study recommended that future work focus on creating meaningful features, creating new distance measures, reducing the dimensionality of feature spaces, and, lastly, investigating behavioral patterns and student labels in order to improve clustering analysis.

In a related study by [18], the researcher in this study computes the correlation of student grades between pairs of courses in a university, based on academic performance, in an

attempt to replicate the course groupings. Courses are represented as nodes in the course network graphs created for the study, and courses are connected if their grade correlation is high. Graph mining and network analysis tools were used in conjunction with the clique algorithm to visualize course networks and detect cliques and clusters within them, where the Pearson correlation was used to determine how similar two courses are to one another. Recall that the Clique concept was used in this study to visualize the results and obtain graphical Cliques. A k-clique is a collection of k nodes that are all connected to one another directly by an edge. In this study, the 0.5 correlation threshold was exceeded by 25% of course pairs and the 0.7 correlation threshold by 5% of pairs when at least 20 common students were examined, these results were evaluated against the metrics of accuracy, precision and recall. Which indicated a uniform performance of 75% for the three metrics. The study found a high correlation between student performance and a number of course pairs. Within the course correlation networks, cliques and modularity classes were recognized as course clusters. Course pairings and course groupings based on academic department were examined. According to the study, there is a significant grouping of courses with strong similarities across scientific disciplines, pre-health courses, and computer science subfields. Notably, the researcher stated that no study that used the concept of course similarity had ever been carried out using the clustering technique in a predictive way.

According to a study by [23] on a free relative density-based clustering method in nonlinear feature relationship patterns. The method proposed in this study allowed finding clusters based on feature relationships, even if the relationships are nonlinear. Since the proposed method did not require any input from the user, it could be applied to datasets from different domains. Fifteen simulated datasets were used for the experiments and eleven different clustering algorithms were used to compare their performance. Among them was the Clique clustering algorithm. For most simulated datasets used to identify behavioral patterns in learning environments, the proposed method appeared to provide better results. After several clustering operations on different simulated datasets, the Clique model showed an average performance of 93.9% accuracy, 94.3% precision and 93.5% recall; this was the best Clique performance in all of the researcher's experiments. The need for research in various dimensions is explained by the fact that the study did not achieve 100% accuracy even after using different data sets.

We can quickly identify a few issues based on the observations made in the various literature in the study for the use of Clique subspace clustering in predicting learners' progress. According to [25] study, Clique was able to perform clustering when used to predict learning progress in Aerobics. However, the algorithm was viewed with disdain due to its ambiguous explanation of data management, feature selection, and dimensionality reduction in relation to cross-validation. In a separate study by [24] Encompassing grid-based clustering algorithms and the use of well-known Clique algorithms in the experiment, it was reiterated that although the Clique model was efficient in forming clusters when clustering data, it required input parameters, a density threshold and the number of intervals required what was difficult to calculate. [17] used the Clique clustering approach to examine patterns of student behavior in a related study. Based on the findings, the study suggested that future research concentrate on developing new distance measures, dimensionality reduction, and behavioral pattern analysis to enhance clustering analysis. Similar to the course groupings created by [18], the researcher in this study used the Clique algorithm to calculate the correlation of student grades between pairs of courses in a university based on academic performance. The researcher noted that no study that used the notion of course similarity had ever employed the clustering technique in a predictive manner. Consequently [23] conducted a study on nonlinear feature relationship patterns. They proposed a free relative density-based clustering method and compared it directly to the Clique algorithm. The research used fifteen different data sets, but it did not establish a clear connection between the research and students' academic progress. However, the literature reveals significant deficiencies in each of the reviewed studies, including shortcomings in input parameters, dimensionality reduction, density threshold, data management, performance metrics and specific areas of application, resulting in inaccuracies in cluster analysis. This study adopts a unique strategy to address these issues and enhance the performance of the Clique algorithm in predicting learners' progress in a multidimensional dataset.

C. Existing Prediction Models

A popular clustering technique for predicting leaner behavior is the K-Means algorithm. This was the main choice made by researchers in a study by [29] titled “Identifying student behavior patterns in higher education using K-Means clustering.” This method is mainly used because it is very simple and gives better, easy-to-understand results. The data set used in the study was obtained from a university database. The dataset includes data derived from student files according to their academic, behavioral and demographic characteristics. Various tuning parameters were used to optimize the model. After several analyses, the results revealed an accuracy rate of 93%, a recall rate of 94%, and a precision rate of 93%. According to the study, universities must recognize student behavior patterns and identify students at risk early on. For example, students may have a positive attitude at the beginning of the semester but perform poorly towards the end, or the opposite. However, by optimizing data preprocessing activities and experimenting in various data sets with different characteristics, the researcher found that K-means clustering should be enhanced to improve the results.

In a study on the BIRCH algorithm (Balanced Iterative Reducing and Clustering Using Hierarchies) to analyze the integration of core competencies in sports and health courses at universities based on data mining techniques by [28]. This study conducted research to examine the state of courses in universities using data mining techniques. The study focused on identifying patterns of information on the essential competencies of university health and physical education courses. Various experiments were conducted to determine the ability of the BIRCH algorithm in predictive analysis. The aftermath experiment outlined the result as follows using the metrics of accuracy (91.1%), recall (91.1%) and precision (91%). The algorithm made credible predictions, but with

limitations in the accuracy and reliability of the results, for instance BIRCH can only process metric attributes. A metric attribute is any attribute whose values can be represented in Euclidean space, i.e. there should be no categorical attributes, which the researcher believed could be addressed by improving the algorithm.

In research conducted by [31], Density-based spatial clustering of applications with noise (DBSCAN) was used in academic performance analysis at higher education institutions with educational data mining in a normally detection manner. Academic data in the form of study findings over a specific time period makes up the data set that was used. It was discovered that the DBSCAN algorithm can identify academic data anomalies with accuracy of up to 91.0%, precision of 90%, and recall of 90% after a series of experiments were carried out to identify data anomalies from academic data. In other words, the variation leaves a gap that can be filled by additional study. Consequently, in order to enhance the effectiveness and dependability of the clustering algorithm, DBSCAN is highly sensitive to the epsilon parameter setting; a low value will result in the clusters being classified as noise. The clusters will merge and become denser simultaneously with the shift to a higher value [30]. One potential issue with DBSCAN could be the global constant parameter needed to determine the neighborhood's radius, since it could have an impact on the accuracy of the findings.

D. Research Gaps

In summary, we can quickly identify the gaps in the literature that led to this study. A number of studies conducted to predict learner behavior or analyze using the Clique model or in comparison with other models have drawbacks, including the initialization of probabilities or the creation of ratios for starting experiments, which become apparent and later affects the accuracy of the results. The choice of data set, whether linear or nonlinear, categorical or numerical, is challenging for some algorithms in such a context. The problem with parameter tuning, which sometimes leads to biased results, has been highlighted in a number of studies. Challenges in reducing dimensionality due to multidimensional data that some of the methods examined in this study could not address. The density threshold limitation for density-based clustering methods, the scope and specific focus of application sometimes does not ensure reliable results, lack of appropriate evaluation metrics caused by inconsistency in metric evaluation for the same algorithm in a similar study area is itself a major gap and finally ambiguity in clustering objectives that affect cluster analysis.

However, in order to predict learners' academic progress using multidimensional data, this study adopted a different strategy and thought about how best to solve these problems. For example, feature engineering is used to process data and is considered effective in feature selection and data labeling. Principal component analysis was used to address data dimensionality, reducing the dimensions to a more manageable set of attributes. The rationale for appropriate parameter tuning and metrics for evaluating results have been addressed in detail in this study to ensure consistency. To confirm the validity of the results, data validation was performed and our work was compared with that of other researchers to ensure new contribution. This study used academic performance data from a university, which represents the main factor in learners' progress and makes the results legitimate and relevant, as opposed to other studies that widely examine general behavioral analysis and not progression. For example, to exploit how unique the application area is from other studies, when a learner completes a course of study and, on the other hand, that learner is good at co-curriculum activities such as sports, the institution, on the assumption that sports is not a subject of study, takes into account academic performance when it comes to the transition to the next academic level, even though sport can have an influence on students' academic performance.

III. Methodology

A. Introduction

The data collection, preprocessing, methodology design, methods and tools for the research are outlined in this section.

B. Data Acquisition and Preprocessing

The study examined the subspace clique algorithm in predicting students' academic progress through interesting pattern analysis. This study retrieved data from a university database consisting of students' average grades over the past five years. In total, the data from 3153 students were examined. The dataset contained the following fields: student number marked D for privacy policy, diploma year 1, diploma year 2, average and grade as indicated in Table I below. A diploma course will probably only take two years. After this, the student is either expected to advance to BSc or not.

TABLE I. Sample Working Data

S/No	diplomaY1	diplomaY2	Average	Grade
D1	69.88	53.42	61.65	Credit
D2	53.33	63.40	58.36	Pass
D3	61.36	67.13	64.24	Credit
D4	60.89	59.90	60.39	Credit
D5	52.09	61.88	56.98	Pass
D6	55.93	53.61	54.77	Pass
D7	72.94	69.72	71.33	Distinction
D8	54.87	52.37	53.62	Pass
D9	61.97	68.13	65.05	Credit
D10	62.82	61.97	62.39	Credit

In the dataset, the grading is divided into the categories “Pass”, “Credit”, “Distention” and “Fail”. Students who achieve “Credit” or above are allowed to progress to BSc, while those who achieve “Pass” and “Fail” are not allowed to progress to BSc. Cleaning the data was done by trying to fill in the missing values, identifying and removing the outliers, which in the end solved the problems of inconsistencies that existed in the data before, this was achieved by Python's Jupyter Notebook. This study employed future engineering in grade assignment, ration creation, and binary label creation to predict student behavior patterns.

C. Design Methodology, Methods and Tools

The study used an experimental research design methodology to validate the use of the Clique subspace clustering model to predict learner's academic progress. Subspace clustering uses a new approach to the traditional clustering technique that aims to find clusters in different subspaces within a dataset (a subspace is a space that is

completely contained in another space or whose points or elements are all in one location in another room). It can also be defined as a vector space that is completely contained in another space. In this context, cluster analysis is about discovering groups or clusters of similar objects. The objects are usually represented as a measurement vector or point in a multidimensional space. The similarities between objects are usually determined by an observable distance measure from different dimensions in a data set. Subspace clustering uses all dimensions selected before clustering performance [27]. The study relied on the following expressed Subspace clique mathematical assumptions;

D. General Subspace Notations

1) Considering data matrix X: $X = \left(x_1, x_2, ..., x_n\right) \in R^{dxn}$ where $x_i \in R^d$ represents a data point in d-dimensional space, and n is the number of data points.

2) A subspace $S_i \subseteq R^d$ is spanned by a subset of the dimensions. For example, if S_i is spanned by dimensions $\left[j_1, j_2, ...j_k\right]$, then: $S_i = Span\left[\ell_{j1}, \ell_{j2}, ..., \ell_{jk}\right]$ where ℓ_j is the unit vector along dimension *j*.

3) The projection of a data ¬oint *x* onto a subspace S_i is given by: $Proj_{S_i}\left(x\right) = p_i\left(x\right)$ where p_i is the projection matrix corresponding to S_i.

4) The goal of subspace clustering is to find a partition of the data points and corresponding subspaces that minimize some form of error. A common objective function is:

$$C_1, C_2, ..., C_k^{min}, s_1, s_2, ...s_k \sum_{i=1}^{k} \sum_{x \in C_i} \left\| x - \Pr oj_{S_i}\left(x\right) \right\|^2$$

where:

- C_i represents the set of data points assigned to the *i*-th cluster.
- S_i represents the subspace corresponding to the *i*-th cluster.

E. CLIQUE (Clustering In QUEst) Algorithm

CLIQUE is a density and grid-based approach of subspace clustering model. It reflects a grid-based approach thus represents the data space through grid and examines the density by counting the number of points in a grid cell. By density-based approach a cluster refers to a maximal set of co-joined dense units in a subspace, a unit therefore is dense if the fraction of total data points contained in the unit exceeds the input model parameter.

Subspace cluster describes a set of neighboring dense cells in an arbitrary subspace, it does unveil some minimal descriptions of the clusters. It systematically recognizes subspaces of high dimensional data space that allow better clustering than original space by concept of a priori algorithm. Mathematically the steps in the Clique algorithm are as follows:

Step 1: Data preparation

1) Let X be a dataset with m rows (also called data size/observation) and n columns (also called number of features)

Step 2: Finding 1-dimensional Dense Units

We define D_1 as the set of 1-dimensional dense units thus a 1-dimensional dense unit is a subset of data points within a feature that satisfies a certain density threshold denoted by τ

2) Let F_i denote the $i-th$ column/feature in the dataset X, for $i = 1, 2, ..., n.$

3) Let u_{ij} denote the $j-th$ in the feature F_i

4) Then, the set D_1 is defined as: $D_1 = \left\{u_{ij} \in F_i : \left\|u_{ij}\right\| > m\tau, \forall i, j\right\}$

Step 3: Candidate Generation for Higer Dimensions

5) Let k be the number of higher dimensions (i.e., $k = 2, 3, ..., n$), C_K be the set of k-dimensional dense units. For $k > 1$, we generate candidate dense units C_k by performing a self-join operation on D_{k-1} where the conditions ensure that the units share ($k-2$) dimensions.

Step 4: Finding Higher dimensional Dense Units

From the candidate dense units C_K,we filter out the units D_k such that ($k-1$) projections of a unit are in D_{k-1}.

Step 5: finding clusters

6) For each feature set $f = \left\{F_1, F_2, ..., F_k\right\}$ containing dense units C_K,we build a graph G where dense units are nodes and connection between dense units (having a common face) are edges. We then find connected components in G to identify clusters.

7) Let ρ_c be the density of combination $c \in C_k$, calculated as:

$$\rho_c = \frac{\text{Number of data points containing all features in c}}{\text{Total number of data points in X}}$$

.

8) The i-th dense unit in the feature set *f* is obtained by the formula:

$$U_i = \arg\max_{c \in C_k}(\rho_c)$$

This formula finds the combination *c* from C_k that maximizes the density.

9) To check whether dense units V and W are connected based on sharing at least one feature can be expressed as follows:

$$\begin{cases} 1, \text{ if } V \cap W \neq \phi \\ 0, \text{ otherwise} \end{cases}$$

10) Let V be the set of vertices in the graph G. The number of connected components in G is obtained by the formula:

$$p = \left| \{ \mathrm{DFS}(v) : v \in V \} \right|$$

where DFS(v) denotes the Depth-First Search traversal algorithm starting from vertex v in V.

F. The Choice for Subspace Clique Algorithm

Because of its distinct benefits in addressing the problems identified in previous research concerning the prediction of learner behavior and academic progress, the Clique Subspace method was selected for this study. Clique is particularly good at handling multidimensional, high-dimensional, and heterogeneous data, which is frequently present in educational datasets that contain a variety of learner information types, including academic performance and extracurricular activities, in contrast to traditional clustering techniques. The following explains why Clique is a good fit in this situation:

- Subspace Clustering for Multidimensionality: Clique is an algorithm for subspace clustering that is specifically tailored to detect clusters within high-dimensional spaces by identifying dense areas in subspaces instead of the entire dimensional space. This capability is particularly important in educational data analysis, where datasets frequently encompass various dimensions such as test scores, participation levels, background information, and extracurricular activities. By concentrating on relevant subspaces, Clique facilitates a natural reduction in dimensionality, effectively tackling the challenges associated with dimensionality reduction in a way that surpasses traditional clustering techniques.
- Density-Based Clustering Advantages: Clique employs a density-based technique that allows for the identification of clusters within subspaces by establishing adjustable density thresholds. This capability facilitates the exclusion of noise and irrelevant information. Such an approach effectively mitigates challenges encountered by other density-based clustering techniques, which often face limitations related to thresholds, resulting in inconsistent clusters when used with multidimensional educational data.
- Robustness to Mixed Data Types: Educational datasets generally comprise both categorical and numerical data. Clique effectively handles mixed data types by partitioning the data into grid cells, which facilitates efficient clustering while minimizing reliance on assumptions regarding the data distribution, whether linear or nonlinear. This characteristic renders Clique especially robust and dependable for analyzing various attributes of learner data.
- Minimization of Bias from Parameter Tuning: Clique stands out from certain clustering techniques that necessitate extensive parameter adjustments, which may lead to bias and inconsistency. Its parameters, specifically density thresholds and grid size, are relatively simple and can be determined either empirically or through domain expertise. This approach mitigates the tuning bias often highlighted in earlier research, thereby promoting stability and replicability in the results.
- Efficient for Large Datasets: The study makes use of extensive academic data, and Clique's grid-based clustering approach which provides a highly computational efficiency, making it well-suited for the large datasets commonly found in educational settings. This effectively resolves the scalability challenges faced by certain other clustering techniques, especially when managing substantial, multidimensional educational datasets.

The purpose of the study was to analyze complex and multidimensional educational data in order to make predictions about learner behavior and academic progression. The traditional clustering techniques have several challenges when applied in this scenario. For example, the K-Means approach requires a predetermined number of clusters, assumes spherical cluster forms, and is sensitive to outliers. On the other hand, BIRCH is only capable of supporting numerical data, it is however, not ideal for the mixed categorical and numerical data that is typically present in educational datasets. In spite of the fact that DBSCAN can recognize clusters of any shape, it is extremely sensitive to the epsilon parameter, which has an effect on the consistency of the clusters.

Importantly, the study considered the following procedures to ensure that the full capability of the experimental design methodology was maximized and the desired outcome was achieved:

a) Data partitioning: The dataset was divided into two separate folds, fold1 and fold2, where fold1 was used for the training dataset and fold2 was used for validation. The training dataset was used to build the Clique model, while the validation dataset was used to perform hyperparameter tuning to optimize the model. The two partitions can be seen in Table II below;

TABLE II. DATA PARTITIONS

Partition	Number of records
Fold 1	1884
Fold 2	1269

b) Benchmark model: The study conducted two different attempts to train the model. The first experiment was used as the main model training, in which the output results of the second experiment were compared.

c) Performance comparison: Precision, accuracy, and recall were used as performance metrics to compare how effective the enhanced Clique model predicted learners' academic progress with the main model.

d) Sensitivity analysis: The study examined the performance of the developed model across a range of datasets and conditions by exploiting variations for the initial state probabilities.

IV. Clique Model for Predicting Learners Academic Progress

A. Introduction

This section explains the basic steps to develop the model, as well as the required parameters and model architecture.

B. Background

Learning is a broad concept that varies depending on the area of application. The common learning environment familiar to many is school, from primary school to secondary school to colleges and universities. In the case of university, students participate in their studies in different categories, from the lowest level (certificate, diploma, bachelor's degree, master) to the highest level (doctoral degree). All of these categories require learners to progress gradually to the highest level after completing the requirements of a particular category. Several factors can determine learners' progress from one category to another, including academic skills, co-curricular activities, government scholarships and many others. The common determinant of a student moving from one category to another is the student's academic performance, usually determined through examination and grading in accordance with the academic policy of the university system. In this study, student performance based on academic grade was considered the primary determinant of progress.

The study examined various grades from students, which are divided into the following categories: A pass is considered to be a performance that is greater than or equal to 50 percent but less than 60 percent; a credit is considered to be an achievement that is greater than or equal to 60 percent but less than 70 percent. A performance of less than 50 percent is considered a failure; an award is given for achievements of 70 percent or more. Each category was assigned an observation that indicates the desired learning progression behavior. Table III below illustrates the state symbols for grade observation.

TABLE III. Grade Observation States

Grade	Observation state	Progress State to BSc
Distinction	Yes	Progress
Credit	Yes	Progress
Pass	No	No Progress
Fail	No	No Progress

For any student who scores a distinction grade automatically qualifies to progress to the BSc Degree, again when a student scores a credit grade the student meets the threshold to proceed to BSc Degrees, on the other hand when a student scores a Pass that student does not qualify to proceed to BSc Degree, consequently when a student gets a Fail that student does not Progress to the Category of learning that is BSc Degree. The mapping can be represented in Fig. 1 below.

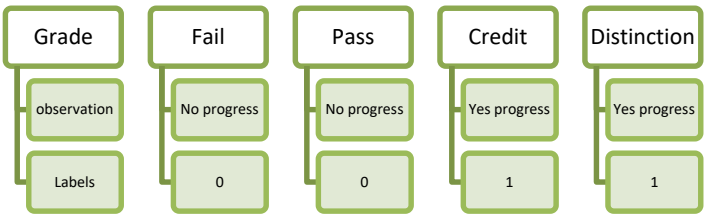

Fig. 1. Observation state mappings.

In this study, the correct assignment of different data categories was carried out, as shown in Fig. 1 above. Grades are assigned to the observed states and indicated by the labels, where “no” means (0) and “yes” means (1). For example, “Fail” means a learner has not made progress and “Credit” means progress. The states “No” and “Yes” are the hidden patterns that need to be discovered through prediction.

C. Predicting Learners Academic Progress

We used a Python script to implement the learner's academic progress in the study. This script is a comprehensive data processing and machine learning pipeline that includes data preparation, feature engineering, dimensionality reduction, clustering, evaluation, and visualization. Below is a detailed step-by-step explanation of how this script works:

- Data preparation is the first step in this process. The very first activity in this phase is to create a dictionary called Data that contains four categories of grades: Credit, Distinction, Fail, and Pass. and the corresponding number of students who answered “no” and “yes” to a particular condition. This data is then converted into a Pandas Data Frame “df” for easier editing and analysis.
- The second step included the task of Feature engineering, feature engineering involves selecting, modifying, and transforming raw data into features suitable for application in machine learning algorithms. Feature engineering was performed in three main stages;

a) Categorical to numerical conversion: The script maps the categorical grades (`Fail`, `Pass`, `Credit`, `Distinction`) to numerical values using a dictionary (`grade mapping`). This is crucial because machine learning models typically work with numerical data.

b) Creating a new feature (`Ratio`): The ratio of "Yes" responses to the total number of students (sum of "No" and "Yes") is calculated. This feature might represent the likelihood or propensity of students to answer "Yes."

c) Label creation: A new binary label, `Label`, is created where 1 indicates that more students answered "Yes" than "No," and 0 indicates the opposite. This served as the ground truth for model evaluation.

- In the third step, the script performed feature selection, where the script selects relevant features (“Grade”, “No”, “Yes”, “Ratio”) from the Data Frame to form the feature matrix “X”. The labels (0 or 1) are stored in the variable “y”.

- In step four we performed data standardization, which involved standardizing the features in "X" using the "Standard Scaler." This ensures that each feature contributes equally to the model and avoids bias due to scale differences.
- In the fifth step, the experiment involved dimensionality reduction using principal component analysis (PCA). This technique reduces the dimensionality of Scaled from 4 to 2 dimensions, which makes the data easier to visualize and also reduces noise. The transformed data is stored in "X_pca".
- In the sixth step, the experiment performed clustering using the clique subspace for cluster analysis and cluster prediction. The script applied clique subspace clustering with 2 clusters ("n_clusters=2") to the PCA-transformed data ("X_pca"). The algorithm attempts to divide the data into two groups based on the input features. To predict clusters, the Clique subspace algorithm assigns each data point to one of the two clusters, and these assignments are stored in y_pred.
- In step seven, cluster label assignment and model evaluation were implemented as follows; since clustering of clique subspaces is unsupervised, the clusters may not correspond directly to the original labels ("y"). The script checks the accuracy of the initial clustering. If it is less than 50%, the cluster labels ("y_pred = 1 – y_pred") are inverted to match the actual labels. During model evaluation, the script calculated key performance metrics including: accuracy (the percentage of correct predictions), precision (the proportion of actual correct positive identifications), and recall (the proportion of actual positive identifications that were correctly identified).
- In the last step the experiment performed results display and visualization. The script adds the predicted cluster labels (`y_pred`) to the Data Frame `df` under the column `Predicted Progression'. It then prints the Data Frame to show the original data along with the predicted progression. Through Visualization a scatter plot of the PCA-reduced data (`X_pca`) is generated, where data points are colored according to their cluster assignments. Horizontal and vertical gridlines are added to the plot to enhance readability. The plot includes labeled axes, a title, and a color bar that indicates cluster labels. This process can be seen in Fig. 2 of the architectural diagram presentation.

Finally, the research examined key points to strengthen its contribution to the existing scientific knowledge base. Key aspects included hyperparameter optimization using density thresholds and input parameters, as well as experimental validation of results through training. Feature engineering was used to create accurate grade assignments, ratios and labels. By standardizing performance metrics, bias reduction and data scalability were achieved. Principal component analysis was used to eliminate noise and prevent overlapping clusters in multidimensional data, allowing clear presentation of study results. However, research highlights a notable strength of the Clique model in predicting learners' academic progress, making it an attractive choice for scholarly contributions. These are presented below:

- This behavioral analysis investigation provided excellent prediction and significantly improved the model analysis by applying the subspace clustering technique and fine-tuning hyperparameters until optimal results were achieved.
- Unlike numerous previous studies, this research adopted a unique strategy by predicting learners' academic progress based on their academic performance, which generally reflects their progress at different stages of academic learning. The scope is more focused and relevant.
- There are various characteristics associated with a situation, such as a student achieving one credit often triggers the transition to a BSc, driven by an invisible urge for advancement. In contrast, a student who receives a passing grade under the policy cannot advance, but there is a compelling reason in this policy that educational institutions should recognize. This unspoken pattern becomes clear through precise mapping in this study.
- A number of multidimensional data sets were used as part of managing multidimensional data for this study. These datasets were manipulated and analyzed using feature engineering techniques and principal component analysis, demonstrating their effectiveness and applicability in cluster analysis. This contributes positively to the existing scientific knowledge.

D. Feature Engineering

This study used feature engineering to ensure appropriate data management, which contributes to the accuracy and reliability of the results. The dataset initially contained multiple columns, which were transformed and used to create new features. Here's a step-by-step breakdown of the feature engineering process:

Step 1. Categorical Conversion (Mapping Grades to Numerical Values):

- Objective: To convert categorical grade information into numerical form, which is necessary for further numerical analysis.
- Implementation: A mapping dictionary (grade_mapping) was created where each grade (e.g., 'Fail', 'Pass', 'Credit', 'Distinction') was assigned a corresponding numerical value (0, 1, 2, 3). The 'Grade' column in the DataFrame was then mapped to these numerical values. Grade_mapping = {'Fail': 0, 'Pass': 1, 'Credit': 2, 'Distinction': 3}.

Step 2. Creation of a New Feature: Ratio of 'Yes' to Total Students:

- Objective: To introduce a new feature that captures the ratio of 'Yes' responses (e.g., passing students) to the total number of students for each grade category.

- Implementation: The ratio was computed by dividing the 'Yes' count by the total number of students ('No' + 'Yes'). This new ratio feature was added as a column ('Ratio') in the DataFrame. df['Ratio'] = df['Yes'] / (df['No'] + df['Yes']).

Step 3. Creation of a Label Column:

- Objective: To generate a binary label indicating whether the number of 'Yes' responses exceeds the number of 'No' responses for each grade category.
- Implementation: A binary label was created using np. where, assigning a value of 1 if 'Yes' responses were greater than 'No' responses, and 0 otherwise. This label was stored in the 'Label' column of the DataFrame. df['Label'] = np. where(df['Yes'] > df['No'], 1, 0).

Step 4. Feature Selection:

- Objective: To select specific columns as features for further analysis.
- Implementation: The script selected the columns 'Grade', 'No', 'Yes', and 'Ratio' as features (X), and the 'Label' column as the target (y). X = df [['Grade', 'No', 'Yes', 'Ratio']] y = df['Label'].

Step 5. Standardization of Features:

- Objective: To standardize the features, ensuring they have a mean of 0 and a standard deviation of 1. This step is crucial for algorithms that are sensitive to the scale of input data, such as PCA and Clique subspace algorithm.
- Implementation: The features in X were standardized using StandardScaler from sklearn. The standardized data was stored in X_scaled. scaler = StandardScaler () X_scaled = scaler.fit_transform(X).

Step 6. Dimensionality Reduction Using PCA (Principal Component Analysis):

- Objective: To reduce the dimensionality of the data, potentially improving the performance of clustering algorithms and enabling visualization in a 2D space.
- Implementation: PCA was applied to the standardized data, reducing it to 2 principal components. The transformed data was stored in X_pca. pca = PCA(n_components=2) X_pca = pca.fit_transform(X_scaled).

Step 7. Clustering Using Clique subspace algorithm:

- Objective: To group the data into clusters based on the transformed features, aiming to identify patterns in the data.
- Implementation: The Clique subspace algorithm was applied to the PCA-transformed data with 2 clusters. The predicted cluster labels were stored in y_pred. Clique subspace algorithm = Clique subspace algorithm (n_clusters=2, random state=42) Clique subspace algorithm. Fit(X_pca) y_pred = Clique subspace algorithm.

Step 8. Manual Label Adjustment:

- Objective: To ensure that the cluster labels align with the actual labels, particularly when the initial clustering might have assigned the labels inversely.
- Implementation: The accuracy of the initial clustering was checked. If the accuracy was below 0.5, the labels were swapped (1 for 0, and 0 for 1). if accuracy score (y, y_pred) < 0.5: y_pred = 1 - y_pred.

Step 9. Evaluation of Clustering Performance:

- Objective: To assess the accuracy of the clustering model.
- Implementation: The accuracy of the clustering compared to the true labels was calculated and printed. accuracy = accuracy score(y, y_pred) print(f"optimized Accuracy: {accuracy * 100:.2f}%").

In summary this systematic feature engineering process effectively transformed the original dataset, enabling the use of advanced clustering techniques to analyze and predict patterns in the data.

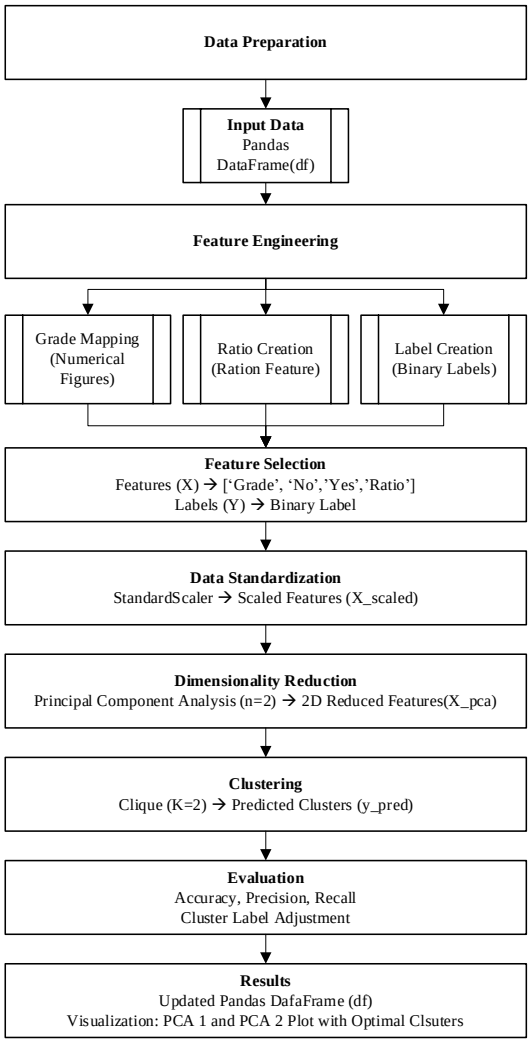

Fig. 2. Clique model for predicting learners' academic progress architectural diagram.

E. Dimensionality Reduction using PCA (Principal Component Analysis)

The experiment involving the use of principal component analysis in this study was conducted in three main phases, namely: feature reduction, clustering using clique, and cluster prediction adjustment.

In the first phase before plotting, the script uses PCA to reduce the dimensionality of the data from four features ("Grade", "No", "Yes" and "Ratio") to two main components. PCA is a linear technique that transforms the data into a new coordinate system in which the axes (principal components) correspond to the directions of maximum variance in the data. By reducing the data to two dimensions, we can visualize it in a 2D graph while retaining as much of the original variability as possible. The PCA(n_components=2) call creates a PCA object that is configured to reduce the data to two dimensions. The "fit transform(X_scaled)" method then applies this transformation to the standardized features ("X_scaled"), resulting in a two-dimensional array ("X_pca"). This array represents the data points in the new coordinate system defined by the first two principal components.

In the second phase, the Clique script applies subspace clustering to the two-dimensional PCA-transformed data. Clique Subspace is an unsupervised machine learning algorithm that divides the data into a certain number of clusters (in this case 2 clusters). The Clique Subspace (n_clusters=2, random state=42)" call initializes the Clique Subspace algorithm to form 2 clusters. The "fit(X_pca)" method is used to fit the model to the PCA transformed data ("X_pca"). The clustering process involves randomly initializing cluster centers (centroids) and iteratively adjusting them by minimizing variance within the cluster until convergence is achieved. After fitting, the model assigns each data point to one of the two clusters and the resulting cluster labels ("y_pred") are saved.

In the third phase of cluster prediction adjustment: Since Clique Subspace randomly assigns cluster labels, the script includes a step to align these predicted labels ("y_pred") with the actual labels ("y"). If the initial precision is below 50%, the script reverses the predicted labels ("y_pred = 1 – y_pred") to optimize the performance metrics (accuracy, precision, and recall). The accuracy of the initial clustering is calculated using the "Accuracy Score (y, y_pred)". If the accuracy is less than 50%, it indicates that the clusters are mislabeled. The script then reassigns the labels by flipping them to ensure that Cluster 1 is more likely to represent the positive class ("Yes" progression). The final step is to visualize the clustering results in a 2D scatterplot. This plot helps understand the distribution and separation of clusters in the transformed feature space. Fig. 3 and Fig. 4 below provide a visual representation of the diagrams.

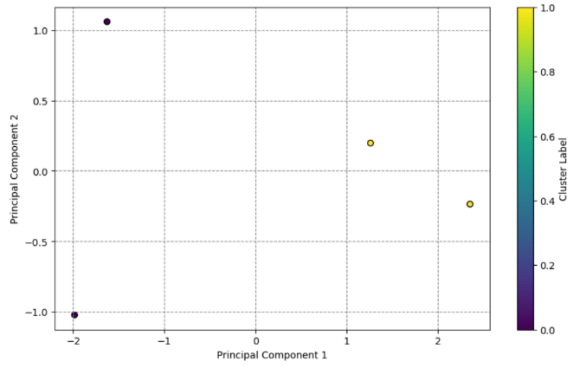

Fig. 3. Training data PCA.

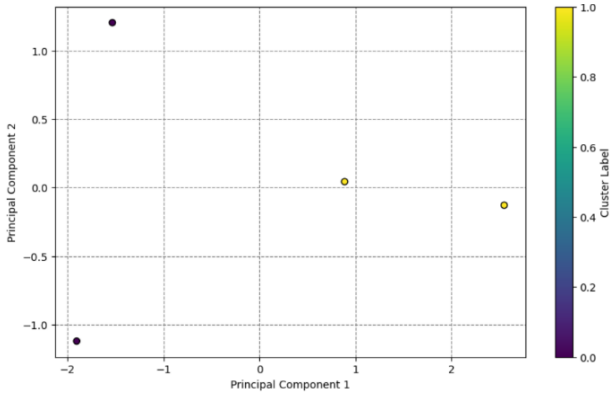

Fig. 4. Validation data PCA.

In summary, the graphs illustrate how well the Clique Subspace algorithm combined with Principal component analysis divides the data into two clusters. The spacing and distribution of points in the graph can provide insights into the natural grouping of data and the effectiveness of the clustering algorithm. Well-separated clusters with minimal overlap indicate that the algorithm has successfully identified different groups within the data. Aligning the principal component analysis axes with the inherent variability of the data ensures that clustering is based on the most informative aspects of the data even after dimensionality is reduced. This detailed process shows how machine learning techniques such as PCA and Clique Subspace are used together to group high-dimensional data and how the results can be scientifically visualized and interpreted.

V. Results

A. Introduction

This part describes the training and validation of the results using the ordinary clique model and the optimized clique model. It provides a comparative analysis of the results at different levels and subsequent discussions and conclusions.

B. Model Training and Validation

The model was trained and validated using the first and second folds of the dataset, respectively. You can see the results in Tables IV and V below.

TABLE IV. MODEL TRAINING RESULTS

Results without Modification						
S/No	Grade	No	YES	Ratio	Labels	Predicted Progression
0	2	156	127	0.449	0	1
1	3	16	269	0.943	1	1
2	0	261	0	0	0	0
3	1	1055	0	0	0	0
Performance Evaluation Metrics						
Precision	75%					
Accuracy	75%					
Recall	75%					
Results with Modification						
S/No	Grade	NO	YES	Ratio	Labels	Predicted progression
0	2	80	203	0.717	1	1
1	3	16	269	0.944	1	1
2	0	261	0	0	0	0
3	1	1055	0	0	0	0
Performance Evaluation Metrics						
Precision	98.50%					
Accuracy	98.90%					
Recall	98.50%					

TABLE V. MODEL VALIDATION RESULTS

S/No	Grade	NO	YES	Ratio	Labels	Predicted Progression
0	2	118	165	0.583	1	1
1	3	9	276	0.968	1	1
2	0	97	0	0	0	0
3	1	604	0	0	0	0
Performance Evaluation Metrics						
Precision	98.50%					
Accuracy	98.90%					
Recall	98.50%					

Training was performed using data fold 1 in Table II of the data partition, which considered the student's academic performance with random initial state probabilities. Training was performed by subjecting the data to two training trials with different hyperparameter tunings and then recording the results. In the first training attempt there was no modification, i.e. no parameter optimization because the implementation used the common and existing Clique algorithm and presented the results. Using the ordinary clique, the model showed an average performance of 75% for precision, 75% for accuracy, and 75% recall.

To confirm the consistency of our working model, we adjusted the dataset and performed some hyperparameter tuning as we observed new prediction patterns. The results showed better patterns with some common predictions from the previous model. We evaluated the performance of the model using the same clustering metrics such as precision, accuracy, and recall. The results with the model modifications showed exemplary performance with a precision value of 98.50%, an accuracy value of 98.90% and a recall value of 98.50%. This performance was consistent with the performance of the validation model. The model built in this study demonstrated efficiency and effectiveness when run on different datasets under different circumstances. During both training and validation, the model showed an accuracy rate of 98.90%. The applicability of the model developed on the entire dataset is consistent with the performance, which is well summarized.

C. Comparison with Related Work

In this study we examined various studies recently undertaken that used the same model and compared the results against our developed Model. The results are presented in Table VI as shown below:

TABLE VI. COMPARISON WITH OTHER STUDIES

Author	Algorithm	Accuracy	Precision	Recall
Oyugi et al. (2024)	Clique Model	98.90%	98.50%	98.50%
[25]	Clique Model	86.5%	85.99%	85.9%
[23]	Clique Model	93.9%	93.5%	94.3%
[15]	Clique Model	93%	93%	93%
[16]	Clique Model	98.6%	98.2%	97.5%
[18]	Clique Model	75%	75%	75%
[17]	Clique Model	92.0%	91.83%	90.12%

From Table VI above, our study is related to other studies, which can be seen from the result of this study. For example, the Clique algorithm was observed to display an overall cluster analysis with above-average performance of at least 75% for all metrics used in the evaluation, namely precision, recall and accuracy. It has also been observed that the accuracy, precision and recall displayed when using clique models are above 90% in most cases with the exception of a few instances reported by [18] in which the findings for all assessed metrics revealed 75%, and similar to [25]. which reported accuracy as 86.5%, precision as 85.99%, and 85.9% recall, this was slightly lower than the performance of clique models generated in other studies. According to our study, our model achieved 98.90% accuracy, 98.50% precision, and 98.50% recall. This was far higher than the value of all other related studies we examined in this study. However, after a careful comparison between our model and the other studies, it is entirely reasonable to conclude

that our model showed excellent performance in predictive cluster analysis. However, this can be attributed to the proper scope, use of future engineering that ensured sufficient and accurate future selection, proper management of the data, proper dimensionality reduction, and scientific cross-validation of the dataset that ultimately resulted in accurate prediction of learner progression.

TABLE VII. COMPARISON WITH OTHER MODELS

Author	Algorithm	Accuracy	Precision	Recall
Oyugi et al.	Clique Model	98.90%	98.50%	98.50%
[29]	K-Means	93%	94%	93%
[28]	BIRCH	91.1%	91.1%	91%
[31]	DBSCAN	91%	90%	90%

As shown in Table VII above, the accuracy rate for K-Means was 93%, for BIRCH was 91.1%, for DBSCAN was 91%, and for the Clique model was 98.90%. According to the other metrics, Clique scored the highest with a precision recall of 98.50 percent, while DBSACN scored the lowest with 90 percent. Clique recorded a maximum recall rate of 98.50 percent, while DBSCAN recorded a minimum recall rate of 90 percent. The above results show that our model performs better than the other models. Based on this study, it is advisable to consider using Clique.

In this study, the subspace Clique model has been analyzed and contrasted with other behavior analysis frameworks and similar methodologies employed in learner prediction research. Furthermore, to assess the challenges identified and the objectives achieved in this investigation, we engage in a thorough analysis and discussion of the pertinent literature. This research aims to enhance decision-making and learner management in educational contexts by predicting learner' academic progress based on their assessment scores. When evaluated against alternative models such as BIRCH, K-Means, and DBSCAN, the Clique subspace model demonstrated commendable performance. However, it is essential to address several issues that emerged from the studies conducted.

In the study of [28] Balanced Iterative Reducing and Clustering using Hierarchies (BIRCH) algorithm for behavior analysis prediction, the researcher observed that BIRCH was particularly effective for clustering large datasets. Nonetheless, it exhibited several limitations, especially in its ability to manage complex data distributions, overlapping clusters and sensitivity to the input parameters. In contrast, the CLIQUE algorithm demonstrated a superior capacity for handling large datasets and accommodating various data distributions, whether categorical or non-categorical, linear or non-linear which formed the features of our academic data. This adaptability positioned the CLIQUE model as a more efficient option for clustering in scenarios involving complex, multidimensional datasets within the scope of this study.

DBSCAN (Density-Based Spatial Clustering of Applications with Noise) is a widely utilized clustering algorithm recognized for its effectiveness in identifying clusters of arbitrary shapes and managing noisy datasets. However, it presents certain limitations, especially when applied to multidimensional data and scenarios involving varying densities [31]. Subspace Clique addresses these shortcomings by concentrating on dense subspaces, effectively managing different density levels, automatically determining critical dimensions, and offering enhanced scalability for predictive clustering.

K-means is an effective and straightforward algorithm designed for low-dimensional, approximately spherical clusters; however, it encounters difficulties when dealing with complex cluster shapes, Multidimensional datasets, and the presence of outliers [29]. The Subspace Clique model offers a solution to these challenges by considering dense subspace clustering techniques. This approach allows for the identification of arbitrary cluster shapes, the management of high-dimensional data, the adaptive determination of cluster structures, and resilience against outliers. Consequently, the subspace CLIQUE model emerges as a more appropriate option for predictive clustering in the context of academic progression as demonstrated in this study results.

Other researchers [16], [15], and [23] who employed the subspace clique method for behavior analysis reported performance levels of 98.6%, 93%, and 93.9% accuracy, respectively. These figures are marginally lower than the accuracy achieved by our model, which stands at 98.90%. Additionally, studies conducted by [25], [18], and [17] yielded accuracies of 86.5%, 75%, and 92%, all of which are again inferior to the performance of the clique model at 98.90%. The discrepancies in accuracy may be attributed to various challenges, including adaptive grid sizing, parameter optimization, and insufficient principal component analysis, all of which could enhance the accuracy of subspace CLIQUE algorithms. In contrast, our model effectively addressed these challenges through the computational efficiency of feature engineering, dimensionality reduction, and cross-validation.

D. Significance of the Research

This study used the subspace clique model to predict learners' academic progress patterns in multidimensional data. The results showed that the model was successfully able to predict learners' progress through clustering and establish hidden patterns that can help in decision making about learners. Student progress is crucial, particularly if they have started at a low level, such as a certificate or diploma in mainstream higher education, and was therefore crucial to this study. Although various studies have looked at the areas of learning in clustering, our study took a different approach and was limited to students' academic progress, which plays a key role in learners' progress as it can reflect the reality of progress in an academic environment Advice on teaching tasks as well as career guidance for the future can be used. It is right that we keep learners under control so that they do not lose track of their progress, as many students drop out of university due to poor performance, which results in them being unable to progress to the next level of learning. The behavioral patterns uncovered in

this study confirm the model's ability to perform predictive and accurate cluster analysis on an educational dataset.

VI. Conclusions and Future Work

The study aimed to predict learners' academic progress using subspace clustering in multidimensional data. However, the study was limited to a grid-based subspace clustering method using the clique model. To achieve this goal, we improve the Clique algorithm through optimization and parameter tuning. These improvements were achieved through future engineering, principal component analysis, data standardization, and cross-validation. The introduction of subspace served to reduce, if not eliminate, noise while performing clustering, which is called the "curse of dimensionality," where the number of dimensions increases as data size increases, resulting in overlapping clusters. Principal component analysis and future engineering helped find a solution to the overlapping clusters. By integrating density-based, grid-based, and subspace clustering, CLIQUE detects clusters embedded in subspaces of high-dimensional data without requiring users to select the subspaces of interest. The algorithm provided an effective and efficient method for pruning the space of dense units to counteract the inherent exponential nature of the problem. However, there was a trade-off for pruning dense units in the sparse coverage subspaces. Although the algorithm was faster, there is an increased chance of missing clusters. Furthermore, while CLIQUE does not require users to select subspaces of interest, its susceptibility to noise and ability to identify relevant attributes depend heavily on the user's choice of unit intervals and sensitivity threshold. The intent of the research was to search the data to reveal learners' progress from one stage to the next, the results clearly demonstrated that it is possible to determine learners' progress in clustering using the subspace clique technique. In summary, subspace clustering is complex but efficient and effective in performing clustering assessment of multidimensional data regardless of its size, and can be used to perform analysis for critical decisions, especially determining learner progression. Subspace clustering can also be used in dimensionality reduction to simplify the complex nature of grid-based bottom-up clustering evaluation methods. Future research can explore different methods and potentially consider a spectral clustering learning approach that leverages clique prediction capabilities to learn more about behavior analysis. Future engineering is recognized as a significant contribution to this study, yet it is sometimes perceived as biased due to its absence of a standardized execution method, consequently, further research is imperative. Given that this study focused on human behavior analysis in educational learning environments, I suggest that future studies be conducted in various settings.

Enhanced TODIM-TOPSIS Framework for Interior Design Quality Evaluation in Public Spaces Under Hesitant Fuzzy Sets

Lu Peng*
Hunan Urban Construction College, Xiangtan, 411100, Hunan, China

***Abstract*—The evaluation of interior landscape design in public spaces involves several aspects, including aesthetics, functionality, sustainability, and user experience. Aesthetic evaluation focuses on the visual appeal and stylistic consistency of the design. Functionality considers the practicality and convenience of the space layout. Sustainability evaluates the environmental friendliness of materials and energy efficiency of the design. Additionally, user experience assessment gathers feedback to gauge comfort and satisfaction. These evaluation criteria help designers optimize spaces to be both attractive and practical while meeting user needs. The interior design quality evaluation in public spaces is multiple-attribute decision-making (MADM) problem. Recently, the TODIM and TOPSIS methods have been applied to address MADM challenges. Hesitant fuzzy sets (HFSs) are used to represent uncertain information in the evaluation of interior landscape design in public spaces. In this study, we developed a hesitant fuzzy TODIM-TOPSIS (HF-TODIM-TOPSIS) approach to tackle Multiple Attribute Decision Making (MADM) issues within the context of HFSs. A numerical case study focused on the interior design quality evaluation in public spaces demonstrates the validity of this approach. The primary contributions of this paper include: (1) Extending the TODIM and TOPSIS approaches to incorporate HFSs; (2) Utilizing information entropy to determine weight values under HFSs; (3) Establishing the HF-TODIM-TOPSIS method for managing MADM in the presence of HFSs; (4) Conducting algorithmic analysis and comparative studies based on a numerical example to assess the practicality and effectiveness of the HF-TODIM-TOPSIS approach.**

Keywords*—Multiple-attribute decision-making (MADM); hesitant fuzzy sets (HFSs); TODIM; TOPSIS; design quality evaluation

I. Introduction

The evaluation of interior landscape design in public spaces involves several key aspects, including aesthetics, functionality, sustainability, and user experience. Aesthetic evaluation focuses on the visual appeal and consistency of style, ensuring overall harmony and beauty. Functionality examines the practicality of layout and convenience of facilities to meet diverse user needs. Sustainability emphasizes the environmental friendliness and energy efficiency of materials, highlighting long-term ecological and economic benefits. Additionally, user experience evaluation gathers feedback to assess comfort and satisfaction. These comprehensive evaluations not only help optimize design but also provide valuable references for future projects, enhancing the overall quality and utility of public spaces. The evaluation of interior landscape design in public spaces has become increasingly important over the past decade as urbanization continues to shape our environments. This literature review synthesizes findings from some significant studies, including some Chinese and some English publications. Li, et al. [1] conducted a pivotal study highlighting the relationship between environmental design and human behavior in public spaces. They advocated for a user-centered approach, emphasizing that aesthetic considerations must align with functional needs to enhance user satisfaction. This work laid the groundwork for understanding how design influences user interactions with public spaces. Kaplan [2] examined the psychological impacts of landscape design, asserting that incorporating natural elements is crucial for fostering emotional well-being in urban environments. This study reinforced the idea that landscapes should do more than just please the eye; they should also promote mental health. Zhao and Chen [3] focused on the aesthetic evaluation of public parks in China. Their research identified key design elements that contribute to user satisfaction, such as visual coherence and cultural relevance. This study was significant in emphasizing the cultural context in landscape design and its effect on user perceptions. Gomez, et al. [4] explored the role of social interaction in public spaces. They proposed that landscape design should facilitate community engagement, suggesting a framework for evaluating designs based on social connectivity and highlighted the social dimension of public spaces, suggesting that design can foster community ties. In the same year, Sun, et al. [5] investigated the effectiveness of biophilic design, concluding that integrating natural elements significantly enhances user satisfaction and well-being in public interiors. Their findings supported the notion that environments rich in nature positively impact users' experiences. Miller [6] further contributed to the discourse by examining sustainable design practices in public spaces. He advocated for eco-friendly materials and practices, providing an evaluation framework for assessing the environmental impact of landscape designs. His work was instrumental in integrating sustainability into the conversation around public space design. In 2017, Zhang and Li [7] discussed the influence of cultural elements on public space design in China. They emphasized the importance of incorporating local heritage into landscape design to enhance community identity, showcasing how cultural context can inform design practices. Haq and Lynch [8] conducted a comparative study on evaluation methods for public space design across different cultures. Their findings underscored the variability in user preferences and highlighted

* Corresponding Author

the need for culturally sensitive evaluation frameworks in landscape design. In 2020, Chen, et al. [9] focused on the integration of technology in evaluating public spaces. Their study introduced a digital evaluation tool aimed at enhancing user feedback, marking a shift toward more interactive and user-driven design evaluations. Fang and Zhao [10] explored the psychological effects of urban green spaces on public health. They proposed a robust evaluation framework that prioritized mental and physical well-being, further emphasizing the health-related aspects of landscape design. The following year, Martin, et al. [11] investigated community participation in the design and evaluation of public spaces. Their findings indicated that involving users in the design process leads to better outcomes and ensures that designs meet community needs. Wang and Liu [12] analyzed climate-responsive design strategies in public spaces, advocating for adaptive landscapes that respond to environmental changes. Their work highlighted the importance of resilience in landscape design, particularly in the face of climate change. In 2023, Zhou, et al. [13] proposed a comprehensive framework that combines qualitative and quantitative methods to assess user experiences in public spaces. Their emphasis on inclusivity and accessibility reflects a growing recognition of diverse user needs in landscape design. Smith and Johnson [14] examined the role of sensory experiences in public space design. They proposed that effective evaluations should consider auditory, visual, and tactile elements, thereby broadening the scope of design evaluations. Lastly, Lu, et al. [15] focused on the integration of smart technologies in public space design evaluation. Their research suggested that smart solutions can enhance user engagement and feedback processes, indicating a future direction for landscape design. The past decade has witnessed significant advancements in the evaluation of interior landscape design in public spaces. Emerging trends emphasize user experience, sustainability, cultural relevance, and the integration of technology. The studies reviewed highlight the necessity of adopting a multidimensional approach to effectively evaluate and enhance public spaces, ultimately contributing to better urban environments.

Multi-attribute decision-making (MADM) is.2000000000000000000000000000000000000111111111111110 a method used to evaluate and select options when multiple conflicting criteria are involved [16-20]. It's widely applied in fields like engineering, economics, and management [21-25]. The decision-making process typically includes defining objectives and evaluation criteria, assigning weights to each criterion, assessing the performance of each option against these criteria, and ultimately selecting the optimal solution based on a comprehensive score [26-29]. Due to the cognitive limitations of decision-makers and the complexities of the decision-making environment [30-34], the process of MADM is often characterized by significant uncertainties, which preclude the accurate representation of evaluation objects using precise numerical values [35-39]. In response, Zadeh [40] proposed the use of fuzzy numbers to address decision-making challenges. However, in specific contexts, a single numerical value fails to adequately capture the nuances of the evaluation object. Consequently, Torra [41] introduced hesitant fuzzy numbers as a means to enhance the understanding of uncertainty within the decision-making process, thereby yielding more precise outcomes [42-48]. This advancement represents a significant breakthrough in MADM research. Interior design quality evaluation in public spaces exemplifies classical MADM. Recently, the TODIM approach [49-52] and the TOPSIS method [53-57] have been applied to address MADM issues. Hesitant fuzzy sets (HFSs) [41] serve as a tool for characterizing uncertain information in this context. To date, few approaches have integrated information entropy [58] with the TODIM-TOPSIS framework under HFSs [41]. Therefore, an integrated hesitant fuzzy TODIM-TOPSIS (HF-TODIM-TOPSIS) approach has been developed to manage Multi-Attribute Group Decision Making (MAGDM). This study presents a numerical example of interior design quality evaluation in public spaces and conducts a comparative analysis to validate the HF-TODIM-TOPSIS approach. The primary research objectives and motivations outlined in this paper are: (1) the extension of the TODIM and TOPSIS methods to HFSs; (2) the application of information entropy to manage weight values within HFSs; (3) the establishment of HF-TODIM-TOPSIS framework for managing MADM under HFSs; and (4) an algorithmic analysis of interior design quality evaluation in public spaces, supported by numerical example to demonstrate the feasibility and effectiveness of HF-TODIM-TOPSIS approach.

The structure of this paper is outlined as follows. Section II discusses the management of HFSs. Section III presents the HF-TODIM-TOPSIS approach applied to HFSs using the entropy method. Section IV provides an illustrative example of evaluating interior landscape design in public spaces, along with a comparative analysis. Concluding remarks are presented in Section V.

II. PRELIMINARIES

The HFSs is constructed.

Definition 1 [41]. The HFSs is demonstrated:

$$V=\left\{\left\langle \theta,u_V\left(\theta\right)\right\rangle \middle| \theta\in\Theta\right\} \tag{1}$$

where $\mu_V\left(\theta\right)\subset\left[0,1\right]$ is possible membership of element $\theta\in\Theta$, $\forall\,\theta\in\Theta$. Then, $v\theta=\left(vu\right)$ is demonstrated as HFN.

Definition 2 [59]. Let $v\theta_1=\left(vu_1\right)$ and $v\theta_2=\left(vu_2\right)$ be two HFNs, the operation is demonstrated:

$$v\theta_1\oplus v\theta_2=\bigcup_{v\gamma_1\in z\theta_1,v\gamma_2\in v\theta_2}\left\{v\gamma_1+v\gamma_2-v\gamma_1v\gamma_2\right\} \tag{2}$$

$$v\theta_1\otimes v\theta_2=\bigcup_{v\gamma_1\in v\theta_1,v\gamma_2\in v\theta_2}\left\{v\gamma_1\cdot v\gamma_2\right\} \tag{3}$$

$$\lambda v\theta_1=\bigcup_{v\gamma_1\in v\theta_1}\left\{1-\left(1-v\gamma_1\right)^{\lambda}\right\},\lambda>0 \tag{4}$$

$$\lambda v\theta_1 = \bigcup_{v\gamma_1 \in v\theta_1} \left\{ \left(v\gamma_1 \right)^{\lambda} \right\}, \lambda > 0 \tag{5}$$

From Definition 2, the operation laws are built [59].

$$(1) v\theta_1 \oplus v\theta_2 = v\theta_2 \oplus v\theta_1, v\theta_1 \otimes v\theta_2 = v\theta_2 \otimes v\theta_1, \left(\left(v\theta_1 \right)^{\lambda_1} \right)^{\lambda_2} = \left(v\theta_1 \right)^{\lambda_1 \lambda_2};$$

$$(2)\ \lambda \left(v\theta_1 \oplus v\theta_2 \right) = \lambda v\theta_1 \oplus \lambda v\theta_2, \left(v\theta_1 \otimes v\theta_2 \right)^{\lambda} = \left(v\theta_1 \right)^{\lambda} \otimes \left(v\theta_2 \right)^{\lambda};$$

$$(3)\ \lambda_1 v\theta_1 \oplus \lambda_2 v\theta_1 = \left(\lambda_1 + \lambda_2 \right) v\theta_1, \left(v\theta_1 \right)^{\lambda_1} \otimes \left(v\theta_1 \right)^{\lambda_2} = \left(v\theta_1 \right)^{\left(\lambda_1 + \lambda_2 \right)}.$$

Definition 3 [59]. Let $v\theta_1 = \left(vu_1 \right)$ and $v\theta_2 = \left(vu_2 \right)$ be HFNs, the score functions of $v\theta_1$ and $v\theta_2$ is demonstrated:

$$SF\left(v\theta_1 \right) = \frac{1}{\# v\theta_1} \sum_{v\gamma_1 \in v\theta_1} v\gamma_1 \tag{6}$$

$$SF\left(v\theta_2 \right) = \frac{1}{\# v\theta_2} \sum_{v\gamma_2 \in v\theta_2} v\gamma_2 \tag{7}$$

where $\# v\theta_1$ and $\# v\theta_2$ are numbers of the elements in $v\theta_1 = \left(vu_1 \right)$ and $v\theta_2 = \left(vu_2 \right)$.

For $v\theta_1 = \left(vu_1 \right)$ and $v\theta_2 = \left(vu_2 \right)$, then

$(1)\ if\ SF\left(v\theta_1 \right) < SF\left(v\theta_2 \right),\ v\theta_1 < v\theta_2;$

$(2)\ if\ SF\left(v\theta_1 \right) = SF\left(v\theta_2 \right), AF\left(v\theta_1 \right) = AF\left(v\theta_2 \right),\ v\theta_1 = v\theta_2.$

Definition 4 [60]. Let $v\theta_1 = \left(vu_1 \right)$ and $v\theta_2 = \left(vu_2 \right)$ be HFNs, the HFN Hamming distance (HFNHD) and HFN Euclidean distance(HFNED) are demonstrated:

$$HFED\left(v\theta_1, v\theta_2 \right) = \frac{1}{\# v\theta} \sum_{k=1}^{\# v\theta} \left| v\gamma_1 \left(\sigma(k) \right) - v\gamma_2 \left(\sigma(k) \right) \right| \tag{8}$$

$$HFED\left(v\theta_1, v\theta_2 \right) = \sqrt{\frac{1}{\# v\theta} \sum_{k=1}^{\# v\theta} \left| v\gamma_1 \left(\sigma(k) \right) - v\gamma_2 \left(\sigma(k) \right) \right|^2} \tag{9}$$

where $v\gamma_1 \left(\sigma(k) \right)$ and $v\gamma_2 \left(\sigma(k) \right)$ are kth largest values in $v\theta_1 = \left(vu_1 \right)$ and $v\theta_2 = \left(vu_2 \right)$ and $\# v\theta = \# v\theta_1 = \# v\theta_2$.

The HFWA and HFWG approach is demonstrated [59].

III. HF-TODIM-TOPSIS Approach for MADM with Entropy

A. HF-MAGDM Issues

The HF-TODIM-TOPSIS approach (Fig. 1) is demonstrated for MADM. Let $VA = \left\{ VA_1, VA_2, \cdots, VA_m \right\}$ be alternatives, and the attributes set $VG = \left\{ VG_1, VG_2, \cdots, VG_n \right\}$ with weight values WV, where $wv_j \in [0,1]$, $\sum_{j=1}^{n} wv_j = 1$. Then, HF-TODIM-TOPSIS approach is demonstrated for MAGDM.

Step 1. Implement the HFN-matrix $VR = \left[v\phi_{ij} \right]_{m \times n} = \left(vu_{ij} \right)_{m \times n}$:

$$VR = \left[v\phi_{ij} \right]_{m \times n} = \begin{array}{c} \\ VA_1 \\ VA_2 \\ \vdots \\ VA_m \end{array} \begin{array}{c} \begin{array}{cccc} VG_1 & VG_2 & \cdots & VG_n \end{array} \\ \begin{bmatrix} v\phi_{11} & v\phi_{12} & \cdots & v\phi_{1n} \\ v\phi_{21} & v\phi_{22} & \cdots & v\phi_{2n} \\ \vdots & \vdots & \vdots & \vdots \\ v\phi_{m1} & v\phi_{m2} & \cdots & v\phi_{mn} \end{bmatrix} \end{array} \tag{8}$$

Step 2. Normalize the $VR = \left[v\phi_{ij} \right]_{m \times n}$ into $VN = \left[n\phi_{ij} \right]_{m \times n} = \left(nvu_{ij} \right)_{m \times n}$.

For benefit attributes:

$$n\phi_{ij} = \left(nvu_{ij} \right) = \left(vu_{ij} \right) \tag{10}$$

For cost attributes:

$$n\phi_{ij} = \left(nvu_{ij} \right) = \left(1 - vu_{ij} \right) \tag{11}$$

B. Implement the Attributes Weight through Entropy

Step 3. Implement the attributes weight through entropy.

The information entropy is employed under different environment[61-65]. Entropy [58] is used to derive weight values. The $HFNM_{ij}$ is demonstrated:

$$HFNM_{ij} = \frac{SF\left(nvu_{ij}\right)+1}{\sum_{i=1}^{m}\left(SF\left(nvu_{ij}\right)+1\right)}, \quad (12)$$

The HFN Shannon entropy $HFNSE = \left(HFNSE_1, HFNSE_2, \cdots, HFNSE_n\right)$ is demonstrated:

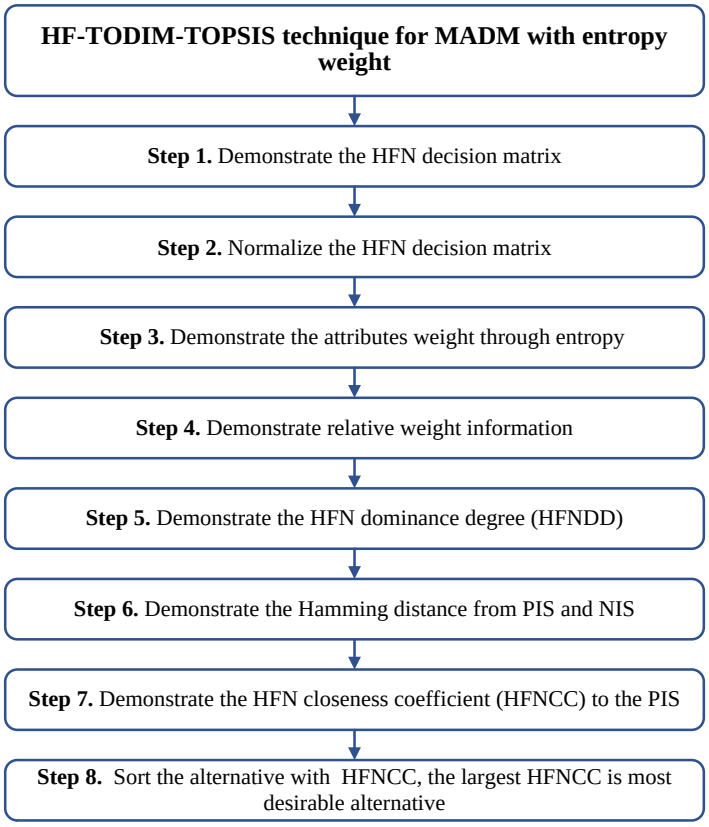

Fig. 1. HF-TODIM-TOPSIS approach for MADM with entropy weight.

$$HFNSE_j = -\frac{1}{\ln m}\sum_{i=1}^{m} HFNM_{ij} \ln HFNM_{ij} \quad (13)$$

and $HFNM_{ij} \ln HFNM_{ij} = 0$ if $HFNM_{ij} = 0$.

The weights $wv = \left(wv_1, wv_2, \cdots, wv_n\right)$ is demonstrated:

$$wv_j = \frac{1 - HFNSE_j}{\sum_{j=1}^{n}\left(1 - HFNSE_j\right)}, \quad j = 1, 2, \cdots, n. \quad (14)$$

C. HF-TODIM-TOPSIS Approach for MADM

The HF-TODIM-TOPSIS approach is demonstrated for MADM.

Step 4. Implement relative weight of VG_j as:

$$rwv_j = wv_j \Big/ \max_j wv_j, \quad (15)$$

Step 5. Illustrate the HFN dominance degree (HFNDD).

(1) The dominance degree $HFNDD_j\left(VA_i, VA_t\right)$ of VA_i over VA_t for VG_j is demonstrated:

$$HFNDD_j\left(VA_i,VA_t\right)=\begin{cases}\dfrac{rwv_j\times\left(\dfrac{HFNHD\left(n\phi_{ij},n\phi_{tj}\right)+HFEND\left(n\phi_{ij},n\phi_{tj}\right)}{2}\right)^{\alpha}}{\sum_{j=1}^{n}rwv_j} & \text{if } SF\left(n\phi_{ij}\right)>SF\left(n\phi_{tj}\right)\\ 0 & \text{if } SF\left(n\phi_{ij}\right)=SF\left(n\phi_{tj}\right)\\ -\dfrac{1}{\theta}\dfrac{\sum_{j=1}^{n}rwv_j\times\left(\dfrac{HFNHD\left(n\phi_{ij},n\phi_{tj}\right)+HFEND\left(n\phi_{ij},n\phi_{tj}\right)}{2}\right)^{\beta}}{rwv_j} & \text{if } SF\left(n\phi_{ij}\right)<SF\left(n\phi_{tj}\right)\end{cases} \tag{16}$$

The values of α,β is determined from study [66].

(2) The $HFNDD_j\left(VA_i\right)\left(j=1,2,\cdots,n\right)$ with respect to VG_j is defined:

$$HFNDD_j\left(VA_i\right)=\left[HFNDD_j\left(VA_i,VA_t\right)\right]_{m\times m}$$

$$=\begin{array}{c}\\VA_1\\VA_2\\\vdots\\VA_m\end{array}\begin{array}{c}\begin{array}{cccc}VA_1 & VA_2 & \cdots & VA_m\end{array}\\\begin{bmatrix}0 & HFNDD_j\left(VA_1,VA_2\right) & \cdots & HFNDD_j\left(VA_1,VA_m\right)\\ HFNDD_j\left(VA_2,VA_1\right) & 0 & \cdots & HFNDD_j\left(VA_2,VA_m\right)\\ \vdots & \vdots & \cdots & \vdots\\ HFNDD_j\left(VA_m,VA_1\right) & HFNDD_j\left(VA_m,VA_2\right) & \cdots & 0\end{bmatrix}\end{array}$$

(3) Implement the overall HFNDD of alternative VA_i over other alternatives for VG_j:

$$HFNDD_j\left(VA_i\right)=\sum_{t=1}^{m}HFNDD_j\left(VA_i,VA_t\right) \tag{12}$$

The overall HFNDD matrix is defined:

$$HFNDD=\left(HFNDD_{ij}\right)_{m\times n}$$

$$=\begin{bmatrix} & VG_1 & VG_2 & \cdots & VG_n\\ VA_1 & \sum_{t=1}^{m}HFNDD_1\left(VA_1,VA_t\right) & \sum_{t=1}^{m}HFNDD_2\left(VA_1,VA_t\right) & \cdots & \sum_{t=1}^{m}HFNDD_n\left(VA_1,VA_t\right)\\ VA_2 & \sum_{t=1}^{m}HFNDD_1\left(VA_1,VA_t\right) & \sum_{t=1}^{m}HFNDD_2\left(VA_1,VA_t\right) & \cdots & \sum_{t=1}^{m}HFNDD_n\left(VA_1,VA_t\right)\\ \vdots & \vdots & \vdots & \vdots & \vdots\\ VA_m & \sum_{t=1}^{m}HFNDD_1\left(VA_m,VA_t\right) & \sum_{t=1}^{m}HFNDD_2\left(VA_m,VA_t\right) & \cdots & \sum_{t=1}^{m}HFNDD_n\left(VA_m,VA_t\right)\end{bmatrix}$$

(4) Implement the positive ideal solution (PIS) and negative ideal solution (NIS):

$$PIS=\left(PIS_1,PIS_1,\cdots,PIS_n\right) \tag{27}$$

$$NIS=\left(NIS_1,NIS_1,\cdots,NIS_n\right) \tag{28}$$

$$PIS_j=\max_{j=1}^{n}HFNDD_{ij},NIS_j=\min_{j=1}^{n}HFNDD_{ij} \tag{29}$$

Step 6. Implement the Euclidean distance from PIS and NIS.

$$ED\left(VA_i,PIS\right)=\sum_{j=1}^{n}\left|HFNDD_{ij}-PIS_j\right| \tag{30}$$

$$ED\left(VA_i,NIS\right)=\sum_{j=1}^{n}\left|HFNDD_{ij}-NIS_j\right| \tag{31}$$

Step 7. Implement the HFN closeness coefficient (HFNCC) from PIS.

$$HFNCC(VA_i, PIS) = \frac{ED(VA_i, NIS)}{ED(VA_i, PIS) + ED(VA_i, PIS)} \quad (32)$$

Step 8. Sort the alternative in line with the HFNCC, the largest HFNCC is the most desirable alternative.

IV. Numerical Example and Comparative Analysis

A. Numerical Example for Interior Design Quality Evaluation in Public Spaces

Evaluating interior landscape design in public spaces is a multifaceted process aimed at enhancing overall quality and user experience. The primary goal is to ensure the design is both aesthetically pleasing and functional while meeting sustainability requirements. Firstly, aesthetic evaluation is crucial. The visual appeal of a design directly affects users' first impressions and long-term feelings. Color coordination, material selection, and spatial layout need to be harmonious to create a pleasant environment. The design should not only align with current aesthetic trends but also possess innovation to inspire interest and curiosity. Secondly, functionality focuses on practicality and convenience. Public spaces must meet various needs, such as socializing, resting, and activities. Therefore, design should consider traffic flow, seating arrangements, and accessibility of facilities. A well-functioning design improves space efficiency, allowing users to engage in activities with ease. Sustainability is an essential element in modern design. Evaluating the environmental friendliness of materials and energy-saving features can reduce negative environmental impacts. Choosing renewable materials and energy-efficient equipment not only lowers long-term operational costs but also enhances ecological value. Designers need to consider lifecycle costs to balance economic and environmental benefits. User experience evaluation is another key aspect. By collecting and analyzing user feedback, designers can gain insights into their true feelings and needs within the space. This user-centered approach helps in making targeted improvements, increasing satisfaction and comfort. Whether through surveys, interviews, or observing behavior, this data provides crucial support for design adjustments. Finally, comprehensive evaluation results offer valuable references for future projects. By summarizing successful experiences and identifying shortcomings, designers can continuously optimize strategies and improve overall project quality. This process of ongoing improvement not only drives design innovation but also enhances the utility of public spaces.

In summary, evaluating interior landscape design in public spaces is a complex yet essential task that involves technical considerations as well as artistic and humanistic care. Through scientific evaluation methods, it is possible to create more attractive, functional, and sustainable public spaces that meet both social and environmental needs. The interior design quality evaluation in public spaces is a MADM issue. Therefore, the interior design quality evaluation in public spaces is presented to demonstrate the approach developed in this essay. Five potential interior landscape design schemes $VA_i\ (i = 1, 2, 3, 4, 5)$ are assessed with four attributes (see Table I):

TABLE I. Four Attributes for Interior Design Quality Evaluation in Public Spaces

Attribute	Description
Aesthetic Value-VG_1	Focuses on the visual appeal of the design, ensuring consistency in color, materials, and style to create a harmonious overall effect.
Functionality-VG_2	Evaluates whether the spatial layout is reasonable and supports various activity needs, as well as the convenience and accessibility of facilities.
Sustainability-VG_3	Examines the environmental characteristics of materials, use of renewable resources, and assesses the energy efficiency and long-term cost benefits.
User Experience-VG_4	Collects and analyzes user feedback to evaluate comfort, satisfaction, and whether the design meets user needs and expectations.

All attributes are beneficial. The five possible interior landscape design schemes $VA_i\ (i = 1, 2, 3, 4, 5)$ are evaluated with HFNs. The HF-TODIM-TOPSIS approach is employed to solve the interior design quality evaluation in public spaces.

Step 1. Illustrate the HFN matrix $VR = \left[v\phi_{ij} \right]_{5\times4}$ (see Table II).

TABLE II. THE $VR = \left[v\phi_{ij} \right]_{5\times4}$

	VG1	VG2
VA_1	{0.1342, 0.5621, 0.8173}	{0.2451, 0.6894, 0.9238}
VA_2	{0.2275, 0.6953, 0.0182}	{0.3184, 0.7439, 0.1347}
VA_3	{0.3526, 0.7195, 0.2834}	{0.4731, 0.8274, 0.3142}
VA_4	{0.4173, 0.8021, 0.3652}	{0.5294, 0.8903, 0.4781}
VA_5	{0.5789, 0.9134, 0.4508}	{0.6891, 0.0257, 0.5723}
	VG3	VG4
VA1	{0.3785, 0.7512, 0.8426}	{0.4923, 0.8034, 0.0159}
VA2	{0.4658, 0.8125, 0.2964}	{0.5709, 0.9142, 0.3471}
VA3	{0.5839, 0.9056, 0.4203}	{0.6912, 0.0328, 0.5784}
VA4	{0.6417, 0.0135, 0.5236}	{0.7542, 0.1267, 0.6895}
VA5	{0.7904, 0.1382, 0.6458}	{0.8916, 0.2493, 0.7341}

Step 2. Normalize the $VR = \left[v\phi_{ij} \right]_{5\times4}$ into $VN = \left[n\phi_{ij} \right]_{5\times4}$ (see able III).

TABLE III. THE $VN = \left[n\phi_{ij} \right]_{5\times4}$

	VG1	VG2
VA_1	{0.1342, 0.5621, 0.8173}	{0.2451, 0.6894, 0.9238}
VA_2	{0.0182, 0.2275, 0.6953}	{0.1347, 0.3184, 0.7439}
VA_3	{0.2834, 0.3526, 0.7195}	{0.3142, 0.4731, 0.8274}
VA_4	{0.3652, 0.4173, 0.8021}	{0.4781, 0.5294, 0.8903}
VA_5	{0.4508, 0.5789, 0.9134}	{0.0257, 0.5723, 0.6891}
	VG3	VG4
VA_1	{0.3785, 0.7512, 0.8426}	{0.0159, 0.4923, 0.8034}
VA_2	{0.2964, 0.4658, 0.8125}	{0.3471, 0.5709, 0.9142}
VA_3	{0.4203, 0.5839, 0.9056}	{0.0328, 0.5784, 0.6912}
VA_4	{0.0135, 0.5236, 0.6417}	{0.1267, 0.6895, 0.7542}
VA_5	{0.1382, 0.6458, 0.7904}	{0.2493, 0.7341, 0.8916}

Step 3. Implement the weight: $wv_1 = 0.2764, wv_2 = 0.1937$ $wv_3 = 0.3429, wv_4 = 0.1870$.

Step 4. Implement the relative weight: $rwv = \{0.8059, 5651, 1.0000, 0.5456\}$

Step 5. Implement the $HFNDD = \left(HFNDD_{ij} \right)_{5\times4}$ (see Table IV):

TABLE IV. THE $HFNDD = \left(HFNDD_{ij} \right)_{5\times4}$

	VG_1	VG_2	VG_3	VG_4
VA_1	0.7143	-0.7965	0.3553	-0.3080
VA_2	-0.2413	0.8392	-1.2242	0.4401
VA_3	-0.3098	0.0711	-0.0800	0.8909
VA_4	0.7102	-0.2481	0.3035	0.3751
VA_5	-0.6798	-0.9131	-0.7609	-0.5322

Step 6. Implement the PIS and NIS (see Table V).

TABLE V. THE PIS AND NIS

	VG_1	VG_2	VG_3	VG_4
PIS	0.7143	0.8392	0.3553	0.8909
NIS	-0.6798	-0.9131	-1.2242	-0.5322

Step 7. Implement the $\left|HFNDD_{ij} - PIS_j\right|$ and $\left|HFNDD_{ij} - NIS_j\right|$ (see Table VI to Table VII).

TABLE VI. THE $\left|HFNDD_{ij} - PIS_j\right|$

	VG_1	VG_2	VG_3	VG_4
VA_1	0.0000	1.6357	0.0000	1.1989
VA_2	0.9556	0.0000	1.5795	0.4508
VA_3	1.0241	0.7681	0.4353	0.0000
VA_4	0.0041	1.0873	0.0518	0.5158
VA_5	1.3941	1.7523	1.1162	1.4231

TABLE VII. THE $\left|HFNDD_{ij} - NIS_j\right|$

	VG_1	VG_2	VG_3	VG_4
VA_1	1.3941	0.1166	1.5795	0.2242
VA_2	0.4385	1.7523	0.0000	0.9723
VA_3	0.3700	0.9842	1.1442	1.4231
VA_4	1.3900	0.6650	1.5277	0.9073
VA_5	0.0000	0.0000	0.4633	0.0000

Step 8. Implement the $HD(VA_i, PIS)$, $HD(VA_i, NIS)$ and $CC(VA_i, PIS)$ (see Table VIII to Table IX).

TABLE VIII. THE $HD(VA_i, PIS)$, $HD(VA_i, NIS)$

	$HD(VA_i, PIS)$	$HD(VA_i, NIS)$
VA_1	2.8346	3.3144
VA_2	2.9859	3.1631
VA_3	2.2275	3.9215
VA_4	1.6590	4.4900
VA_5	5.6857	0.4633

TABLE IX. THE $HFNCC(VA_i, PIS)$ AND ORDER

	$HFNCC(VA_i, PIS)$	Order
VA_1	0.5390	3
VA_2	0.5144	4
VA_3	0.6377	2
VA_4	0.7302	1
VA_5	0.0753	5

Thus, the best interior landscape design scheme is VA_1.

B. Comparative Analysis

Then, the HF-TODIM-TOPSIS approach is compared with HFWA approach[59], HFWG approach [59], HF-MABAC approach [67], HF-CODAS approach [68], HF-EDAS approach [69] and HF-TODIM approach [70]. The comparative results are demonstrated in Table X and Fig. 2.

TABLE X. ORDER FOR DIFFERENT APPROACHES

	Order
HFWA approach [59]	$VA_4 > VA_3 > VA_1 > VA_2 > VA_5$
HFWG approach [59]	$VA_4 > VA_3 > VA_2 > VA_1 > VA_5$
HF-MABAC approach [67]	$VA_4 > VA_3 > VA_1 > VA_2 > VA_5$
HF-CODAS approach [68]	$VA_4 > VA_3 > VA_1 > VA_2 > VA_5$
HF-EDAS approach [69]	$VA_4 > VA_3 > VA_1 > VA_2 > VA_5$
HF-TODIM approach [70]	$VA_4 > VA_3 > VA_1 > VA_2 > VA_5$
HF-TODIM-TOPSIS approach	$VA_4 > VA_3 > VA_1 > VA_2 > VA_5$

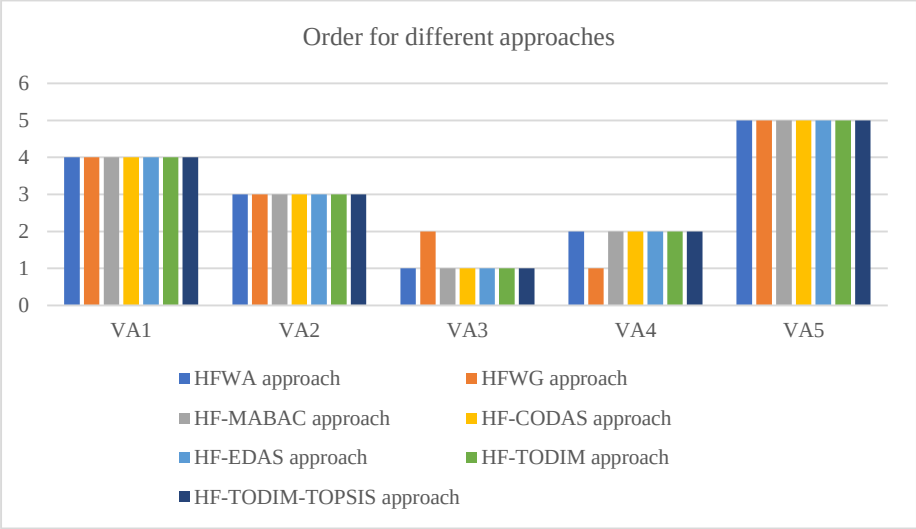

Fig. 2. Order for different approaches.

Through the above analysis, the HF-TODIM-TOPSIS method demonstrates its effectiveness and reliability for multi-attribute decision-making (MADM). The primary advantages of this approach are as follows: (1) the HF-TODIM-TOPSIS method adeptly addresses the uncertainties inherent in real-world MADM scenarios and captures the psychological behaviors of decision-makers during the evaluation of interior landscape design in public spaces; (2) it also explores the dynamics of the TODIM and TOPSIS techniques when integrated into a hybrid model specifically designed for assessing interior landscape design in public spaces. However, a significant limitation of the HF-TODIM-TOPSIS approach is its failure to address issues related to group consensus.

V. Conclusion

The evaluation of interior landscape design in public spaces is highly significant. Firstly, it ensures the beauty and functionality of the space, enhancing the overall user experience. By assessing the visual appeal and practicality of the design, it creates environments that are both pleasant and efficient. Secondly, the evaluation process promotes sustainability by emphasizing the use of eco-friendly materials and energy-efficient designs, reducing environmental impact. Additionally, it focuses on user needs and feedback, ensuring the design meets expectations and improves satisfaction and comfort. This comprehensive evaluation not only provides direction for designers to improve but also offers valuable references for future projects, helping to enhance design quality and innovation, ultimately creating better public spaces for everyone. The interior design quality evaluation in public spaces is MADM. Recently, the TODIM and TOPSIS methods have been employed to address challenges in MADM. HFSs are utilized to represent uncertain information in the evaluation of interior landscape design within public spaces. This study introduces the hesitant fuzzy TODIM-TOPSIS (HF-TODIM-TOPSIS) approach to resolve MADM issues in the context of HFSs. A numerical case study focused on the evaluation of interior landscape design in public spaces demonstrates the validity of this method.

The main conclusions and findings of this study can be summarized as follows:(1) Effectiveness of the HF-TODIM-TOPSIS method: The research demonstrated the effectiveness of the HF-TODIM-TOPSIS method in addressing multi-attribute decision-making problems, such as indoor landscape design in public spaces, through numerical case analysis. This method effectively handles uncertainty in the evaluation process and provides more comprehensive and objective evaluation results. (2) Application value of HFSs: The study indicates that the introduction of HFSs can better capture the hesitation and subjectivity of decision-makers during the evaluation process, making the evaluation results more aligned with actual conditions. (3) Weight determination using information entropy: The study utilized information entropy to determine the weights of different evaluation indicators. Compared to traditional subjective weighting methods, this approach is more objective and reduces interference from human factors. (4) Extension of TODIM and TOPSIS methods: The research extends the traditional TODIM and TOPSIS methods to the HFSs framework, providing new ideas and methods for solving more complex multi-attribute decision-making problems.

In summary, this study proposes a new and more effective multi-attribute decision-making method, HF-TODIM-TOPSIS, and validates its practical value in the evaluation of indoor landscape design in public spaces through case analysis.

ARO-CapsNet: A Novel Method for Evaluating User Experience in Immersive VR Furniture Design

Yin Luo, Jun Liu*, Li Zhang
College of Fine Arts and Design, WenZhou University, WenZhou 325035, ZheJiang, China

***Abstract*—Immersive virtual reality (VR) technology has become an essential tool in enhancing user experience across industries, particularly in furniture design. With the ability to provide realistic, interactive, and immersive environments, it significantly improves user engagement and decision-making in product design. However, existing analysis methods lack precision in evaluating user experience within VR environments. This study aims to develop a more accurate and efficient model for analyzing the application of immersive VR in future furniture design. By integrating the Artificial Rabbit Optimization (ARO) algorithm with Capsule Networks (CapsNet), this research enhances the evaluation of user experience in immersive VR environments. The proposed method uses the ARO algorithm to optimize the parameters of CapsNet, which maps the relationship between the analysis indicators of furniture design and user experience. This model is tested against traditional methods such as CNN and CapsNet alone. The analysis focuses on key factors such as visual elements, interaction, and system performance, with performance metrics like root mean square error (RMSE) and R^2 value used for evaluation. Experimental results show that the ARO-CapsNet model achieves a RMSE of 0.17 and an R^2 value of 0.988, outperforming both CNN and CapsNet in terms of accuracy and efficiency. Additionally, the proposed model improves the immersive VR system's ability to deliver accurate user experience evaluations, making it a superior method for analyzing future furniture design applications. The integration of the ARO algorithm with CapsNet significantly enhances the precision of immersive VR user experience evaluations in furniture design. The ARO-CapsNet model not only improves evaluation accuracy but also increases system efficiency, providing a robust framework for future applications of VR in product design.**

Keywords*—Immersive virtual reality; furniture design; application analysis; artificial rabbit optimisation algorithm

I. Introduction

Due to advancements in science and technology, the production of furniture has consistently risen, leading to heightened rivalry among furniture companies. Additionally, consumer attitudes towards consumption have shifted, resulting in increasingly high expectations for user experience [1]. The technology used for furniture presentation has inherent biases and constraints, resulting in a passive role for the buyer and directly impacting the consumer experience [2]. With the progressive advancement and enhancement of virtual reality technology in recent years, significant achievements have been made. Its interactive capabilities have greatly enhanced the user experience and expanded the scope of research in the domestic furniture virtual display field. This has a significant impact on the development direction of furniture enterprises [3]. Virtual display technology utilizes computer technology to create three-dimensional models of furniture products, which can be accessed and interacted with by users through computers or networks. This technology enables users to have a realistic sensory and emotional experience with furniture products.

The integration of advanced virtual reality technology in furniture design and user experience research enables users to fully immerse themselves in virtual displays, enhancing the depth of information, realism, and overall user experience [4]. This has significant practical applications. At now, immersive virtual reality technology is being used to study several areas of future furniture design, user experience, and application analysis [5]. Svalina et al. [6] examined the use of immersive virtual reality technology to create a virtual exhibition hall. Jafarifiroozabadi et al. [7] developed a virtual reality technology specifically for train driving simulations, which includes realistic acoustic sounds to enhance the user's auditory immersion. Zhang et al. [8] combined virtual reality technology with furniture display design to create a furniture virtual display system that offers users an intuitive and realistic interactive experience. Potseluyko et al. [9] used the LSSVM model to construct an application analysis system for virtual reality technology in future furniture design, using the case of ancient towns in Sichuan and Chongqing for performance analysis. Lastly, Ji et al. [10] proposed a user experience analysis method for future furniture virtual display, utilizing an intelligent optimization algorithm to improve the neural network model. Based on extensive literature study and survey analysis, it can be stated that immersive virtual reality technology and furniture design analysis application has the following features [3]: a. The study on the future furniture virtual display system solely focuses on qualitative analysis and lacks quantitative analysis. The current furniture virtual display system lacks a comprehensive examination of the user experience and performance metrics. Current machine learning algorithms that analyze the use of virtual reality technologies lack adequate accuracy in their evaluation models. The use of intelligent optimization algorithms has led to the creation of a model optimization approach for analyzing the application of virtual reality technology. This approach aims to enhance the accuracy of virtual reality technology analysis [11].

This study presents a way for analyzing and using immersive virtual reality technology in furniture design. The approach is based on intelligent optimization algorithms and deep learning algorithms. The method examines the challenges of using virtual reality in furniture design from a user experience perspective. It identifies key analysis factors and utilizes the efficient optimization capabilities of the artificial rabbit optimization algorithm [12] to optimize the parameters of the capsule network

model [13]. Additionally, it constructs a design application analysis algorithm based on the ARO-CapsNet model. Through comparative analysis validation, the proposed method in this paper demonstrates superior performance.

II. Immersive Virtual Reality in Furniture Design-User Experience

A. Immersive Virtual Reality in Furniture Design-User Experience Application Issues in Analysis

1) Immersive virtual reality: Immersive Virtual Reality (Immersive VR) technology [14] refers to the utilization of three-dimensional input and output devices and software systems to create virtual simulation environments on computers. These environments are designed to be interactive and immersive, providing the user with a multi-channel sensory experience that gives the illusion of being in a virtual environment, as depicted in Fig. 1.

An immersive VR system usually consists of three parts: a reality system, a processing control system, and a motion capture system [15], and its composition is shown in Fig. 2.

Immersive virtual reality technology as a virtual reality technology in the more advanced, more complex a comprehensive technology, its system and table and virtual reality system, AR system and distributed virtual reality system, compared with the following characteristics [15]: 1) immersive; 2) follow the movement; 3) real-time, specific as Fig. 3.

Fig. 1. Effect of immersive virtual reality technology.

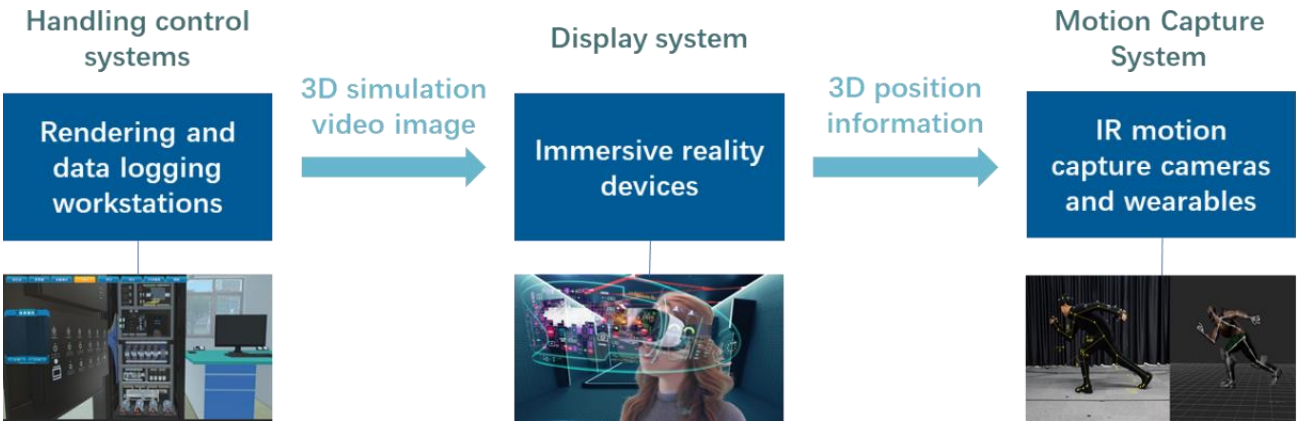

Fig. 2. Immersive virtual reality system composition.

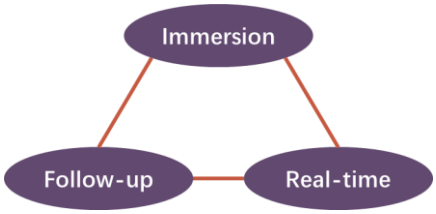

Fig. 3. Characteristics of immersive virtual reality technology.

2) Immersive VR technology in furniture design-user experience: The use of immersive virtual reality (VR) technology in furniture design and user experience is progressively intensifying. This enables consumers to have a comprehensive experience prior to making a purchase by offering an immersive environment, as seen in Fig. 4. The applications of immersive virtual reality (VR) technology in furniture design-user experience encompass various features such as virtual reality roaming, real-time design interaction, home atmosphere simulation, customized experience, cost and resource saving, panoramic home display, integration of virtual and reality, optimization of user experience, remote observation, and multimedia embedding [16].

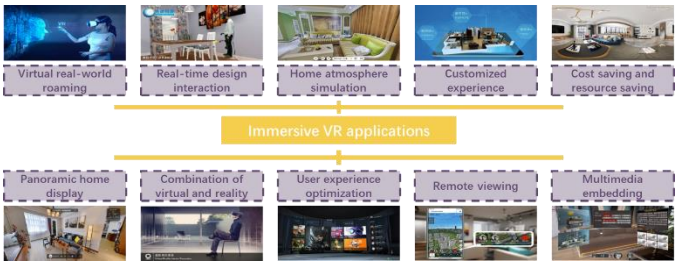

Fig. 4. Analysis of immersive virtual reality technology applications.

B. Extraction and Construction of Indicators for Applied Analysis

1) Immersive VR technology application process: The steps of immersive VR technology application in furniture design-user experience are shown in Fig. 5, and the specific steps include 3D furniture scene design, scene furniture modelling, adjusting lighting, scene roaming, adding detail display, furniture attribute replacement, and system release, etc. [17].

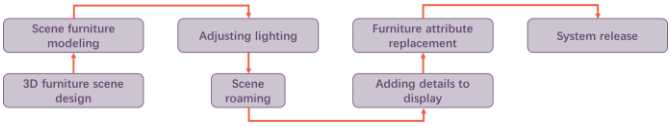

Fig. 5. Steps in the application of immersive virtual reality technology.

2) Application analysis indicator extraction: According to the analysis of the application of immersive VR technology in furniture design-user experience, this paper analyses the visual elements, psychological elements, creating space, colour design, etc., and the construction of the specific indicator set is shown in Fig. 6.

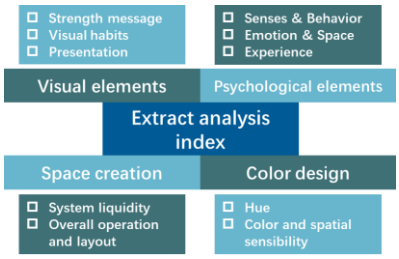

Fig. 6. Extraction and construction of indicators for analysing the application of immersive virtual reality technology.

C. Application Analysis Programme Design

This paper proposes a method for analyzing the application of immersive VR technology in furniture design, specifically focusing on user experience issues. The method is based on intelligent optimization algorithms and deep learning. The detailed design scheme is illustrated in Fig. 7. The immersive VR technology application analysis research technique encompasses several essential technologies, including VR application analysis, application analysis scheme design, application analysis model construction and optimization, and case design analysis.

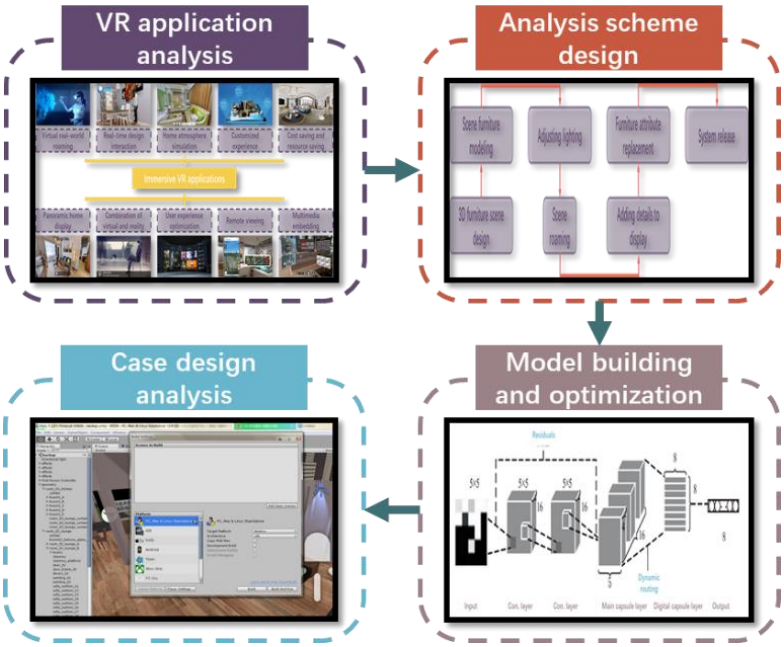

Fig. 7. Immersive virtual reality technology application analysis programme.

III. Application of Virtual Reality Furniture Design

A. ARO Algorithm

Artificial rabbits optimization (ARO) [18] is a nature-inspired swarm intelligence optimisation algorithm. The ARO algorithm is inspired by the survival strategies of rabbits in nature (Fig. 8), including meandering foraging and random hiding. The meandering foraging strategy forces a rabbit to eat grass near other rabbits' nests, which prevents its nest from being discovered by predators. The random hiding strategy allows the rabbit to choose a random burrow among its own to hide in, which reduces the likelihood of being captured by an enemy. In addition, the rabbit's energy contraction causes it to shift from a meandering foraging strategy to a random hiding strategy. The algorithm mathematically models this survival strategy to develop a new optimiser.

Fig. 8. ARO algorithm inspired behaviour.

In the phase of initialising the artificial rabbit population, a certain number of individual rabbits are randomly generated in the space of the defining domain, and each rabbit represents a possible solution in the problem space. And then, the function values of these individuals are calculated based on their locations.

1) Bypass foraging (exploration): When foraging, rabbits will search far away and ignore what is close by. They only eat grass from other areas and not from their own area, a foraging behaviour known as meandering foraging.ARO's meandering foraging behaviour suggests that each searching individual tends to update its position to another randomly selected searching individual in the group with an added perturbation. The specific model is as follows:

$$X_i(t+1)=X_j(t)+R\cdot\left(X_i(t)-X_j(t)\right)+round\left(0.5\cdot\left(0.05+r_1\right)\right)\cdot r_2 \quad (1)$$

$$R=L\cdot c \quad (2)$$

$$L=\left(e-e^{\left(\frac{t-1}{T}\right)^2}\right)\cdot\sin\left(2\pi r_3\right) \quad (3)$$

$$c(k)=\begin{cases}1 & if\ k==g(l)\\ 0 & else\end{cases}\quad k=1,\cdots,d\ and\ l=1,\cdots,\lceil r_3\cdot d\rceil \quad (4)$$

$$g=randperm(d) \quad (5)$$

$$n_1 \sim N(0,1) \quad (6)$$

Where $X_i(t+1)$ denotes the position of the ith rabbit; R denotes the moving step; T is the maximum number of iterations; $\lceil\cdot\rceil$ denotes the ceil function; $randperm$ denotes a random integer from 1 to d; r_1 , r_2 and r_3 are random numbers; n_1 denotes that it obeys a normal distribution. Fig. 9 gives the curve of the step size L with the number of iterations.

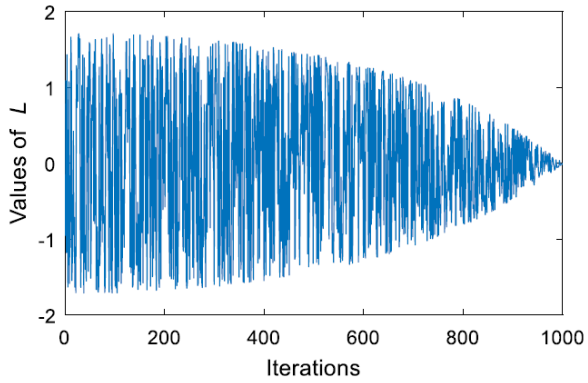

Fig. 9. Curve of step size with number of iterations.

2) Random concealment (exploitation): In order to hide from predators, rabbits usually dig a number of different burrows around their nests. In each iteration of the ARO algorithm, the rabbit always generates a number of burrows around it along each dimension of the search space, and always chooses one randomly from all the burrows to hide, in order to reduce the probability of being predated. The specific model is as follows:

$$X_i(t+1)=X_j(t)+H\cdot g\cdot X_i(t) \quad (7)$$

$$H=\frac{T-t+1}{T}\cdot r_4 \quad (8)$$

$$n_2 \sim N(0,1) \quad (9)$$

$$g(k)=\begin{cases}1 & if\ k==j\\ 0 & else\end{cases}\quad k=1,\cdots,d \quad (10)$$

In order to determine the next behaviour of the rabbit group, its energy factor needs to be calculated, which in turn determines the next behaviour of the individual, i.e. the choice of meandering foraging or random hiding. For the rabbit population, its energy factor at the tth iteration is calculated as shown in Eq. (11):

$$A(t)=4\left(1-\frac{t}{T}\right)\ln\frac{1}{r} \tag{11}$$

where r is a random number. Fig. 10 gives the curve of the energy factor A with the number of iterations, and Fig. 11 gives the schematic diagram of the search mechanism of the energy factor. Fig. 12 gives a schematic diagram of the calculation of the probability of bypass foraging.

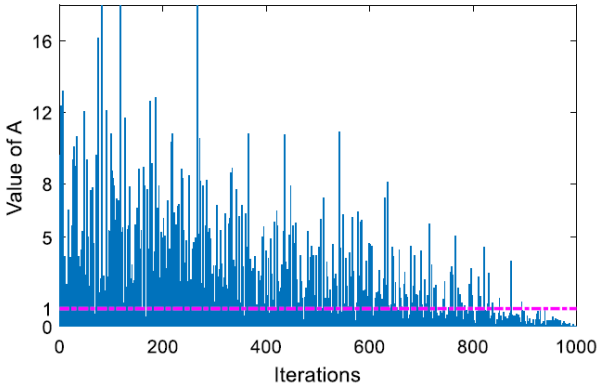

Fig. 10. Curve of energy factor A with number of iterations.

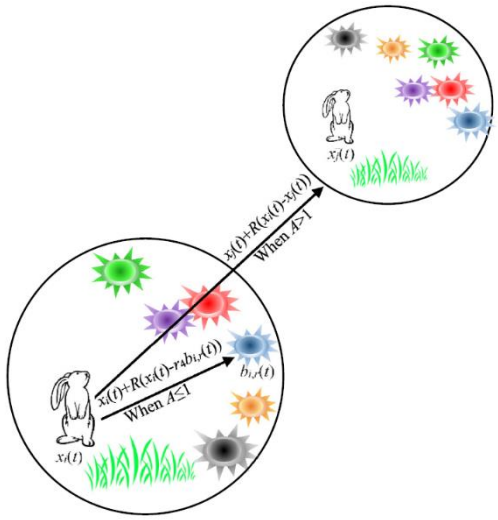

Fig. 11. The curve of step length with a number of iterations.

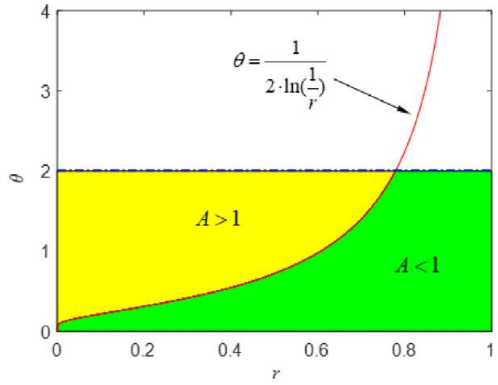

Fig. 12. Calculating the probability of foraging bypasses.

3) ARO process steps: According to the optimization behaviour of the ARO algorithm, the ARO flowchart is shown in Fig. 13, with the following steps: a. set the parameters of the ARO algorithm, including the number of populations, the maximum number of iterations, and other parameters; b. randomly initialize rabbit populations and evaluate the population position to obtain the optimal rabbit position; c. calculate the energy factor A; d. if A<1, update the populations by using a detour foraging strategy, or else use a random hiding strategy to update the population; e. Calculate the updated population position and obtain the optimal rabbit position; f. Determine whether the number of iterations reaches the maximum and output the final optimal solution.

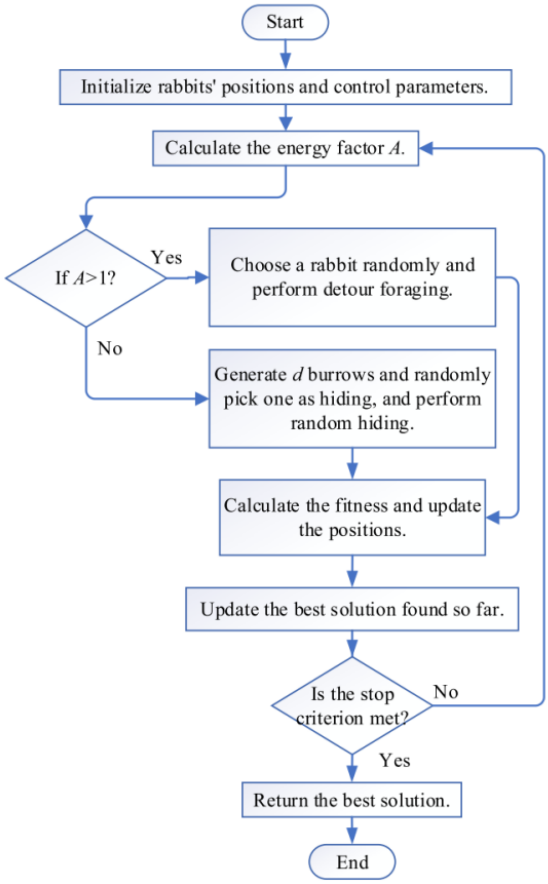

Fig. 13. Flowchart of ARO algorithm.

B. Capsule Network Model

Capsule Networks (CNNs) [19] are a novel deep learning model designed to overcome some of the limitations of traditional Convolutional Neural Networks (CNNs) [20] in processing images, especially in recognising the pose and spatial layout of objects. The core idea of capsule networks is to use so-called "capsules" instead of traditional neurons (as shown in Fig. 14), which are a collection of neurons that collectively represent the instantiated parameters of an object, such as position, size, and orientation. The capsule network learns the relationships between different capsules through a dynamic routing algorithm that allows the network to adaptively focus on relevant features and suppress irrelevant information.

The residual block structure is introduced in the capsule network [21], in order to reduce the number of parameters in the model and improve the robustness of the model. The improved capsule network structure is shown in Fig. 15.

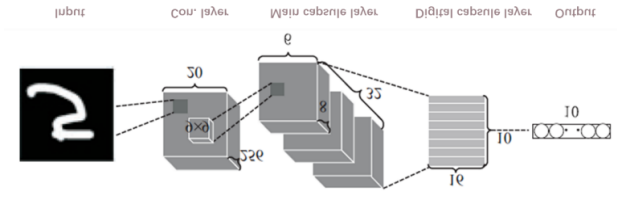

Fig. 14. CapsNet network structure.

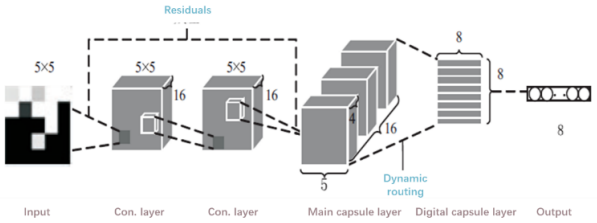

Fig. 15. Improved CapsNet network structure.

The core of a capsule network is a capsule, which is a collection of neurons that together represent a feature vector in the input data, which has the advantage over CNN in that it can better deal with spatial relationships in the data. The core idea of dynamic routing algorithm in capsule network is to adjust the routing weights from the low-level capsule to the high-level capsule through iteration, so that the output vector of the low-level capsule can focus on the high-level capsule associated with it. The iterative process of dynamic routing algorithm in capsule network is described as follows:

$$c_{ij} = \frac{\exp\left(b_{ij}\right)}{\sum_{i} \exp\left(b_{ij}\right)} \tag{12}$$

$$u_{j|i} = W_{i|j} \times u_i \tag{13}$$

$$s_j = \sum_{j} c_{ij} \times u_{j|i} \tag{14}$$

$$v_j = \frac{\left\|s_j\right\|^2}{1+\left\|s_j\right\|^2} \times \frac{s_j}{\left\|s_j\right\|} = squash\left(s_j\right) \tag{15}$$

$$b_{ij} \leftarrow b_{ij} + u_{j|i} v_j \tag{16}$$

where b_{ij} denotes the prior probability that capsule i is connected to capsule j; $W_{i|j}$ is the transformation matrix; u_i is the output vector of low-level capsule i; $u_{j|i}$ is the predicted capsule; s_j is the total input of high-level capsules; and v_j is the output vector of high-level capsule j.

C. ARO-CapsNet Model Application Methodology

1) ARO-CapsNet model: In order to improve the analysis accuracy and design efficiency of the application of immersive VR technology in future furniture design and user experience, this paper adopts the CapsNet model to construct the application analysis model, and at the same time adopts the ARO algorithm to optimise the application analysis model. The ARO-CapsNet model takes the CapsNet network structural parameters as the optimisation variables, and takes RMSE as the fitness value function value, and adopts the ARO algorithm optimisation strategy to optimally find the CapsNet network structure parameters, as shown in Fig.16.

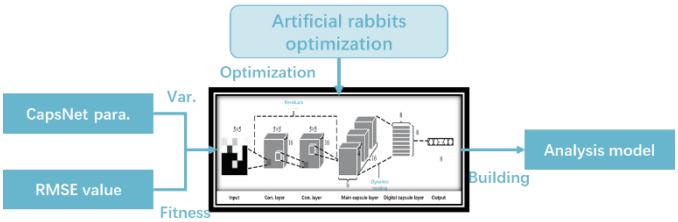

Fig. 16. ARO-CapsNet network model.

2) ARO-CapsNet application process: Based on the ARO-CapsNet model immersive VR technology in the future furniture design and user experience application analysis method by analysing the immersive virtual reality in furniture design-user experience application problems, extracting the application analysis indexes, constructing the index system, using the ARO-CapsNet model to construct the mapping relationship between the application analysis indexes and the assessment value, and obtaining the future furniture design and user experience application analysis model, the specific flow chart is shown in Fig.17.

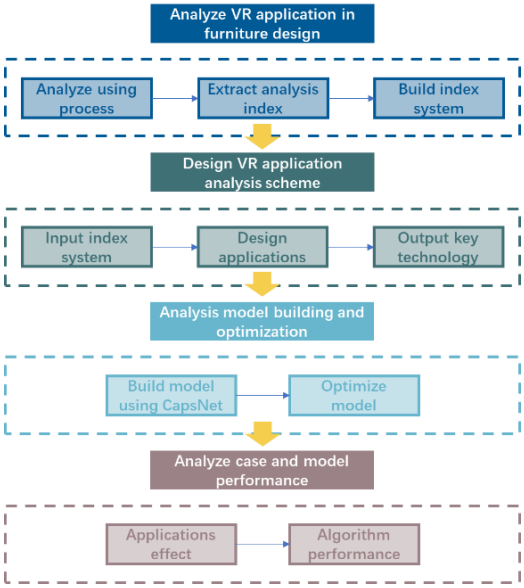

Fig. 17. ARO-CapsNet network model application process.

IV. Experiments and Analysis of Results

A. Experimental Set-up

For the future furniture design problem, this paper adopts Unity3D, 3Dmax and CAD software to develop and design [22], the specific development process is shown in Fig. 18.

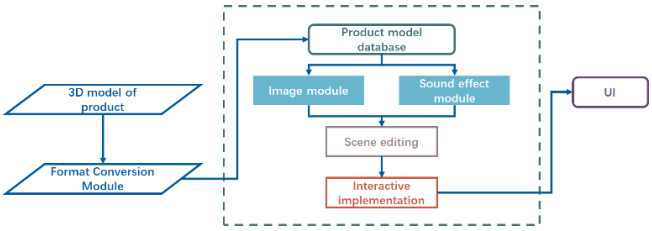

Fig. 18. System development process.

For the immersive VR technology application analysis problem, this paper uses CNN [23], CapsNet [19], ARO-CapsNet model for comparative analysis. The parameters of ARO algorithm are set as follows: the number of populations is 100, and the number of iterations is 1,000; the CNN network is set as follows: the convolutional layer is 100 nodes.

B. Analysis of Results

In order to analyse the application of immersive VR technology in future furniture design, this paper analyses the effect from three aspects: 3D modelling, interaction design and system release [24]. The effect diagram of the showroom is shown in Fig. 19. In Fig. 20, we add the design effect after adding relevant interaction elements. At the same time, the virtual system released on PC, IOS system and Android system is embedded in Fig. 21 to show the effect.

Fig. 19. 3D modelling effect.

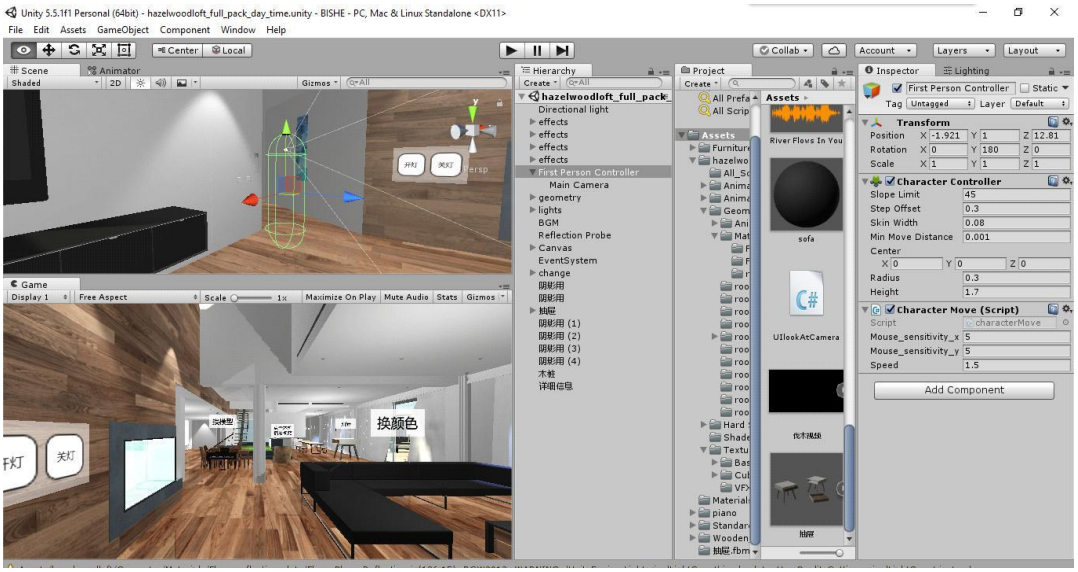

Fig. 20. Interaction design diagram.

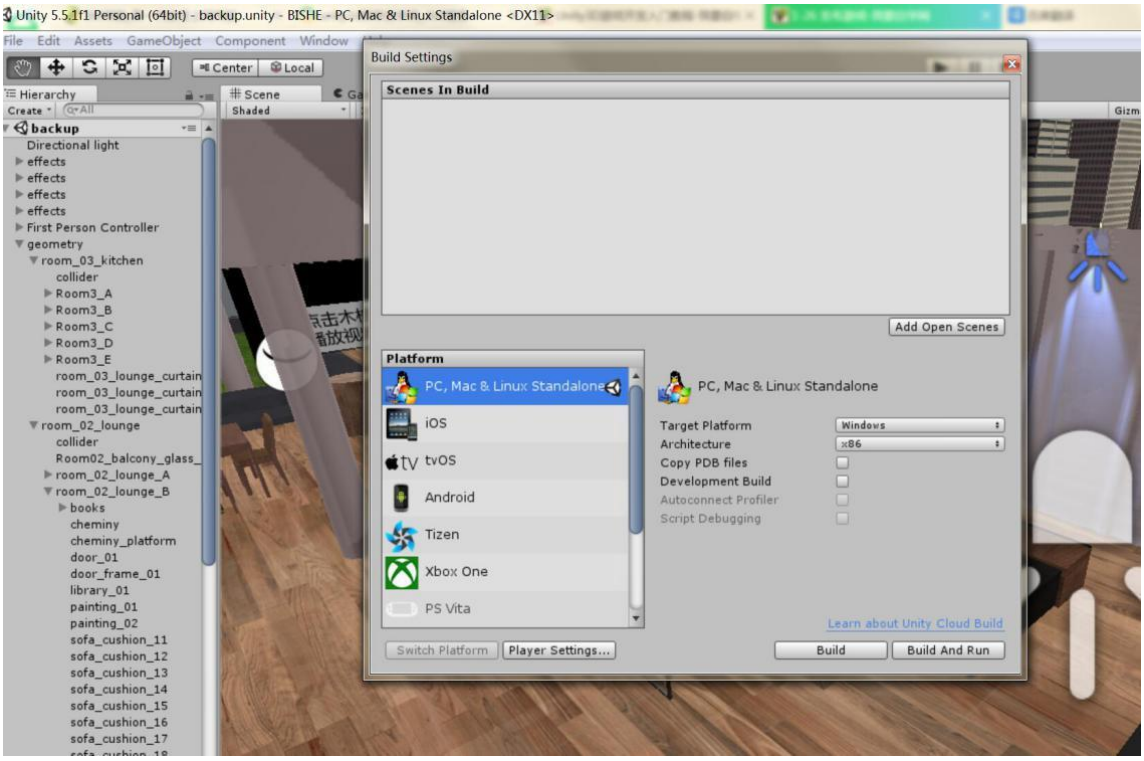

Fig. 21. Schematic system development.

To confirm the efficiency and superiority of the immersive VR future furniture design experience application analysis approach based on the ARO-CapsNet model, we compared and analyzed ARO-CapsNet with CNN and CapsNet. The findings are shown in Fig. 22 and Fig. 23.

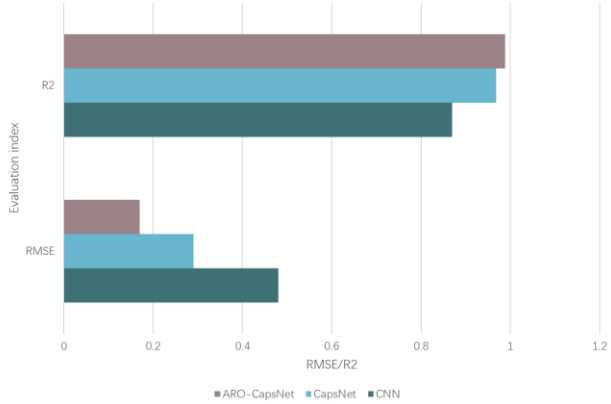

Fig. 22. Comparative analysis of application analytics model performance.

The performance of the application analysis models, namely ARO-CapsNet, CNN, and CapsNet, may be seen in Fig. 22 located in the center of our document. According to the figure. Based on the RMSE and R2 values, it is evident that the ARO-CapsNet model outperforms the other models in predicting application analysis. The RMSE for ARO-CapsNet is 0.17, which is the smallest among all models. Additionally, the R2 value for ARO-CapsNet is 0.988, indicating the highest level of accuracy compared to the other models. Figure The table displays the outcomes of the application analysis for each model in the comparison. Fig. 23 demonstrates that the application analysis technique of immersive VR future furniture design experience, which is based on the ARO-CapsNet model, accurately analyzes the value, bringing it closer to the actual value.

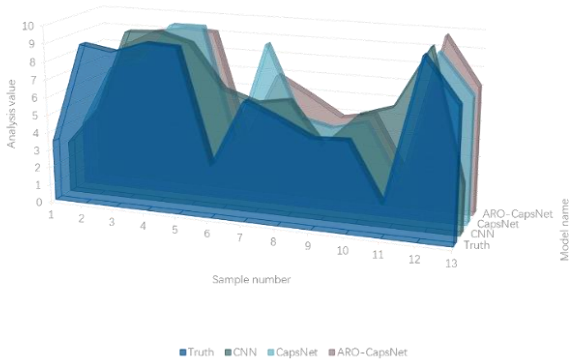

Fig. 23. Application analysis results of each algorithm.

V. CONCLUSION

To address the issues of poor accuracy and low design efficiency in the study of immersive VR technology applications, a novel technique is given. This method utilizes ARO and CapsNet to develop an immersive VR future furniture design experience application analysis method. The technique examines the indications of immersive VR technology application and formulates an application analysis scheme by analyzing the challenges faced in applying immersive virtual reality to furniture design from a user experience perspective.

The ARO algorithm is used to optimize the parameters of CapsNet in the analysis model for immersive VR technology application. Additionally, a new analysis model is developed for the future furniture design experience application in immersive VR, which is based on ARO-CapsNet. By doing experimental analysis and comparing it with other models, the suggested model demonstrates superior performance in application analysis. This further confirms that the model has more flexibility for future furniture design experiences.

***Abstract*—Due to the uncertainty and complexity of the risk factors of the urban railway tunnel project to increase the difficulty of risk analysis, so that the traditional risk assessment methods can not accurately assess the construction risk of the urban railway tunnel project. Aiming at the problems of the existing risk assessment algorithms, the construction risk assessment method of an urban railway tunnel project based on intelligent optimisation algorithm and machine learning algorithm is proposed. Firstly, for the problem of construction risk identification and assessment of municipal railway tunnel project, a tunnel construction risk identification and assessment scheme using a combination of intelligent optimization algorithm and machine learning algorithm is designed, and the principles and functions of each module of the risk assessment system are introduced; then, for the problem of risk assessment construction, a risk assessment algorithm based on the swarm intelligent optimization algorithm to improve the BP neural network is proposed; secondly, relying on the Hangzhou Secondly, relying on Xinfeng Road underground passage close to cross the underground line 9 tunnel and the side through the Hanghai intercity tunnel project in Hangzhou, the effectiveness of the construction risk assessment algorithm is verified from monitoring data and numerical simulation, and the risk control scheme is proposed in turn. The experimental results show that the risk assessment algorithm proposed in this paper effectively solves the problem of construction risk assessment of the urban railway tunnel project, and improves the prediction performance of the risk assessment algorithm, and verifies that the risk control scheme meets the construction safety requirements.**

Keywords*—Municipal railway tunnel construction optimization; scenario risk assessment; machine learning; pigeon flock optimisation algorithm

I. INTRODUCTION

With the rapid development of national economy as well as the improvement of information technology, the pace of urbanisation in China is getting faster and faster, which makes the city scale and population grow dramatically [1], and brings a lot of dilemmas to the urban traffic, including traffic congestion, air pollution, and high energy loss [2]. In order to alleviate this development trend, the development of urban underground space to alleviate the surface eyes, improve urban transport, less urban environmental pollution, and achieve carbon neutrality [3]. In addition to making full use of urban space, underground rail transport has the advantages of fast running speed, large passenger capacity, safety and comfort, punctuality, energy saving and environmental protection, but there are also frequent phenomena of accidents in underground tunnel engineering, such as ground subsidence, sand gushing out, and river water backing up [4].

The risk assessment of the optimisation scheme for urban railway tunnel construction not only provide a more accurate, professional and simplified decision-making basis for the decision-makers of the project, but also help to formulate effective risk countermeasures, and is also conducive to the improvement of the risk management level of urban railway tunnel construction [5]. Therefore, the study of risk assessment algorithms for the construction of urban railway tunnel projects is of great theoretical significance and practical problem-solving significance. Risk assessment algorithm generally includes risk mechanism analysis, risk identification, risk assessment and risk evaluation steps [6]. Risk mechanism is generally analysed from a systematic and professional point of view [7], risk identification is mainly to select and classify the uncertain factors that cause adverse consequences of engineering construction [8], risk assessment is mainly to estimate the identified risks, and risk evaluation is to determine the level of risk through qualitative analysis, quantitative analysis or other methods [9]. The risk assessment research of the tunnel engineering construction optimisation scheme for the city railway mainly includes the tunnel engineering construction risk assessment index system and model construction. The index system research generally adopts SWOT analysis method, flow chart method, cause and effect analysis diagram, work decomposition structure method, accident tree method, etc. [10]. Risk assessment model construction research generally uses fuzzy logic method, grey model, machine learning and other methods [11]. With the development of artificial intelligence technology, risk assessment based on machine learning algorithms has entered the field experts and scholars [12]. Due to the uncertainty, hidden nature and complex structure of the construction risk of the municipal railway tunnel project, which makes the non-linear relationship between the risk assessment indicators and the evaluation level, the machine learning method is not only convenient and effective in constructing the mapping relationship between the risk assessment indicators and the evaluation level, but also improves the efficiency of the risk identification and assessment [13]. Risk assessment methods based on machine learning algorithms for the construction of municipal railway tunnel projects include BP neural networks, support vector machines, decision trees, clustering and other

* Corresponding Author

algorithms [14]. Although the research on construction risk assessment of municipal railway tunnel projects has achieved certain results, research and analysis are still needed in the area of construction risk assessment of cross operation tunnels on top of the pipe. Although the pipe jacking method has been used more often in underground engineering construction, it faces the problem of construction control that threatens the structural safety when the pipe jacking crosses the existing structure [15]. The construction of pipe jacking will cause disturbances such as loading and unloading, changing pore water pressure, and changing stratum compactness to the soil body, destroying the state of stress equilibrium, and in the long term, it will cause deformation of stratum consolidation, which will result in the synergistic deformation of the existing structure and the stratum [16], so it is very meaningful to study the construction risk identification and assessment methods, and the optimal control of the construction risk of the tunnel spanning over the operation of the jacking pipe. Through the domestic and foreign literature research and analysis, there is a certain accumulation of construction risk assessment research for the top tube of urban railway cross operation tunnel, but there are still many problems [17]:

- Less risk research and more construction technology research, and lack of construction overall risk research;
- Lack of reliability of the risk identification process;
- Quantitative analysis of the risk assessment is not in-depth enough;
- Application of the results of the risk assessment is low. The applicability of the results is low.

This paper focuses on the risk assessment of tunnel construction on top of pipe, combines machine learning algorithm and pigeonhole optimisation algorithm, and constructs a risk assessment method based on pigeonhole optimisation algorithm and improved BP neural network. Aiming at the characteristics of the risk assessment problem of tunnel construction above the top tube, a risk assessment scheme for tunnel construction is designed, and the roles of each module of the risk assessment system and its principle are introduced in detail. Combined with the risk assessment scheme and the assessment model construction algorithm, the effectiveness of the risk assessment model is studied and the performance impact of the risk control measures is analysed for the case of the operation tunnel project of Metro Line 9 in the silt stratum of Linping District, Hangzhou City.

II. Design of a Risk Identification and Assessment Programme for Tunnel Construction

A. Programme Design

In order to improve the reliability of the risk identification and assessment method of the construction risk of the pipe jacking up and across the operation tunnel and optimise the feasibility of the risk control scheme, this paper studies the tunnel construction risk identification and assessment scheme using a combination of intelligent optimisation algorithms and machine learning algorithms [18], which is shown in Fig. 1.

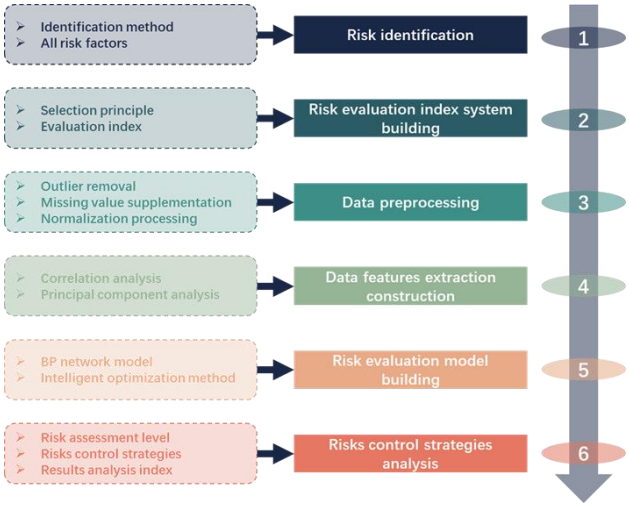

Fig. 1. General scheme of risk assessment for tunnel construction.

From Fig. 1, in the construction risk assessment scheme of the top tube over operation tunnel based on the intelligent optimization algorithm combined with the machine learning algorithm, the mechanism of the analysis of the construction process of the top tube over operation tunnel is analysed, and the sources of risk faced by the construction process are identified by combining with the method of the decomposition structure of the work; in order to further improve the accuracy of the construction risk assessment model of the top tube over operation tunnel, the raw data continue to be pre-processed, and the operations of outliers elimination, missing values supplementation and normalization are carried out. In order to further improve the accuracy of the construction risk assessment model, the raw data are preprocessed, and operations such as outlier removal, missing value supplementation, and normalisation are carried out. In addition, in order to reduce the redundancy of the indicator system and improve the efficiency of the model construction, correlation analysis and dimensionality reduction analysis are carried out for the input indicators; on the basis of the data preprocessing and analysis, the intelligent optimisation algorithm proposed in this paper is combined with the improvement of machine learning algorithm to realise the construction and optimisation of the risk assessment model of the construction of the roof tube above the operating tunnels; According to the risk assessment level and risk probability and control measures, numerical analysis and monitoring analysis are carried out on the proposed deformation control scheme for the construction of roof tube over operation tunnel.

B. Module Analysis

The research on construction risk assessment method of header tube over operation tunnel based on intelligent optimization algorithm and improved machine learning algorithm mainly includes construction risk identification of header tube over operation tunnel, establishment of construction assessment index system of header tube over operation tunnel, processing and analysis of measurement value of header tube over operation tunnel construction risk assessment index, optimization of construction risk assessment model of header tube over operation tunnel and analysis of the results of the risk

control scheme. technical research [19], the specific research composition framework is shown in Fig. 2. In Fig. 2, the construction risk assessment system of top tube over operation tunnel based on intelligent optimization algorithm and improved machine learning algorithm is mainly composed of risk identification, indicator system, risk level, data processing, risk assessment, risk control and other modules in order to accurately and objectively and systematically assess the construction risk of top tube over operation tunnel and deformation control scheme.

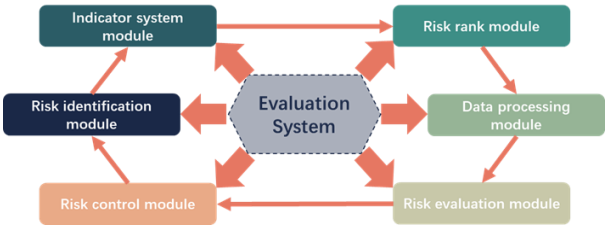

Fig. 2. Risk assessment system building blocks.

1) Risk identification module: The risk identification module identifies and categorises the uncertainties that may cause adverse consequences during the construction of the tunnel, and then screens out the uncertainties that may cause risky accidents. As an important basis for risk management, the risk identification module can determine the impact of different risk factors on the construction of the tunnel above the pipe, and then classify the different risk factors into categories, and the process of line identification is demonstrated in Fig. 3. The inputs of the risk identification module of the construction project of the roof tube over operation tunnel are investigation data analysis, expert consultation, experimental demonstration, and work decomposition structure method, and the outputs are risk code, risk factors, risk events, and risk consequences, and the specific input-output relationship diagram is presented in Fig. 4.

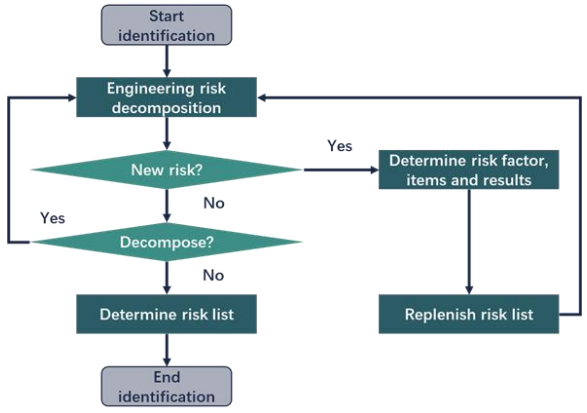

Fig. 3. Risk assessment system building blocks.

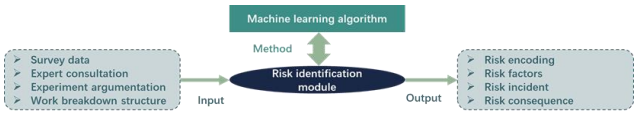

Fig. 4. Risk identification input-output relationship.

2) Indicator system module: When constructing the construction risk assessment index system of the roofed pipe upper span operation tunnel, it is necessary to follow some basic principles, including the principles of systematicity, scientificity, operability, comparability, etc., as shown in Fig. 5.

Fig. 5. Principles for the selection of risk assessment indicators.

On the basis of the identification and classification results of the construction risk of the top tube over operation tunnel, the index system module integrates the field survey and the research of the field research experts, and adopts the methods of quantitative analysis, qualitative analysis, and case study, etc., and constructs the construction risk of the top tube over operation tunnel from the aspects of engineering geological risk A, investigation and design risk B, construction technology risk C, tunnel engineering risk D, management risk E, and environmental factor risk F. Assessment index system, the specific system structure is shown in Fig. 6. As can be seen from Fig. 6, the input of the indicator system module is the selection principle and risk identification results, and the output is the risk assessment indicator system, and the input-output relationship is shown in Fig. 7.

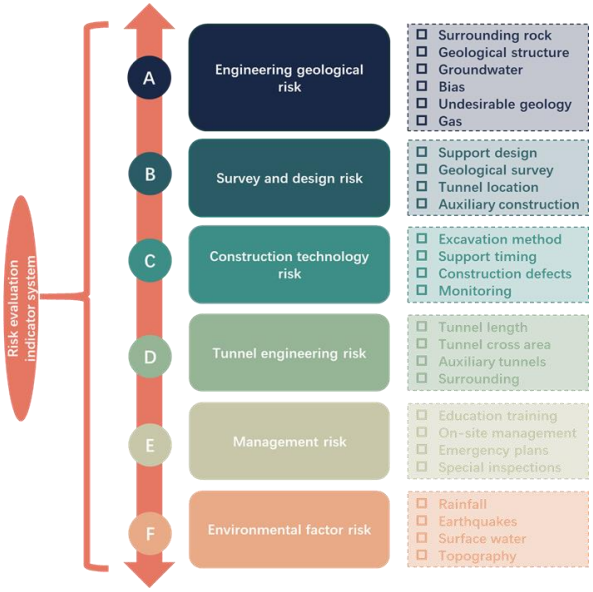

Fig. 6. Risk assessment index system for construction of pipe jacking over operational tunnels.

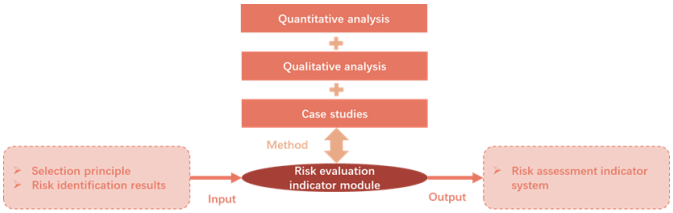

Fig. 7. Principles for the selection of risk assessment indicators.

3) Data processing module: The data processing module includes processes such as outlier removal, missing value supplementation, normalisation, indicator feature correlation analysis, feature dimensionality reduction, etc., as shown in Fig. 8.

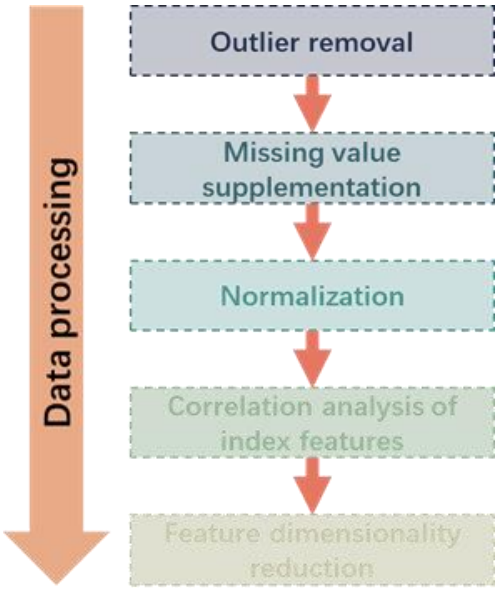

Fig. 8. Data pre-processing flow.

As an important step in data preprocessing, outlier removal removes data points that significantly deviate from other values in the data set. In this paper, we use the outlier processing method based on the 3σ criterion [20], which determines any data point in the data that is outside the range of the mean ± 3 standard deviations as an outlier, and the principle is shown in Fig. 9.

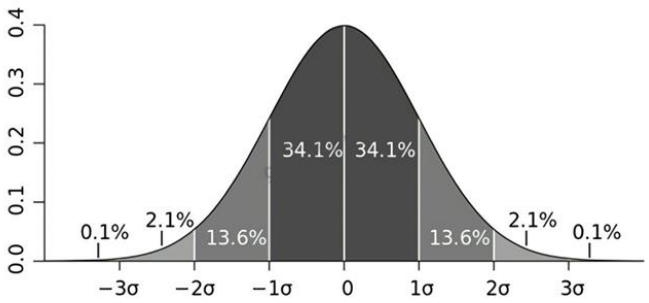

Fig. 9. Outlier rejection algorithm based on 3σ criterion.

In the case of missing data, the missing value supplementation can fill in the data, make the data conform to the pattern, and improve the data quality to improve the performance of the subsequent evaluation model. In this paper, we adopt the proximity filling method, i.e., we use the observations before or after the missing values to fill in the missing values, as shown in Fig. 10.

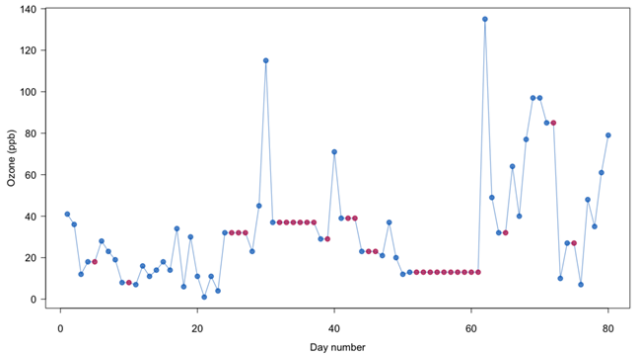

Fig. 10. Algorithm for missing value filling method.

In order to eliminate the variance over the limit brought about by the data magnitude, the normalisation process is to scale the data so that it falls into a small specific interval. For the data characteristics occurring in the construction of the top tube up-span operation tunnel, this paper adopts the *Z*-score normalisation method, i.e., all data are normalised to the range of normal distribution with mean 0 and variance 1, and the calculation formula is as follows Eq. (1):

$$x' = \frac{x - \overline{x}}{\sigma} \tag{1}$$

Where x' denotes the data after normalisation, x is the data before normalisation, $\overline{x}$ is the mean and σ is the standard deviation.

In order to analyse the redundancy of the risk assessment indicators for the construction of the roof-tube up-and-over operational tunnels, Pearson is used in this paper to calculate the correlation coefficients, which are calculated as follows, Eq. (2):

$$\rho(x,y) = \frac{\operatorname{cov}(x,y)}{\sigma(x)\sigma(y)} = \frac{E\left[(x-\mu_x)(y-\mu_y)\right]}{\sigma(x)\sigma(y)} \tag{2}$$

Where $\operatorname{cov}(x,y)$ is the covariance coefficient and $\sigma(x)$ and $\sigma(y)$ are the standard deviations.

In order to reduce the dimensionality of the construction risk assessment indexes of the roof-tube up-and-over operation tunnels and extract the principal components, this paper adopts the Kernel Principal Component Analysis (KPCA) [21] method to extract features and reduce the dimensionality of the input construction risk assessment indexes. The KPCA is an improvement of the Principal Component Analysis (PCA) method, which uses the kernel function to construct complex nonlinear classifiers. The core idea of KPCA is to use the kernel function to map the original data to a high-dimensional feature space, and then perform PCA in that space. The specific principle is shown in Fig. 11.

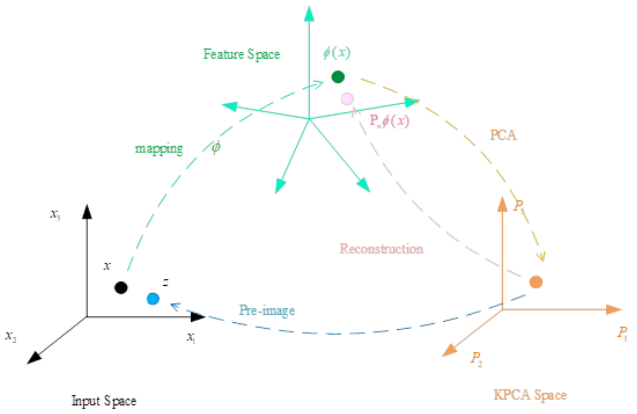

Fig. 11. Principle of KPCA method.

According to the introduction of the principles and mechanisms of the above methodology, the input to the data processing module consists of the original values of the construction risk assessment indicators for the jacked-up cross operational tunnels, and the output is the standardised values of the downgraded assessment indicators.

4) Risk level module: According to the risk assessment index system of the construction risk of pipe jacking up and across the operation tunnel, including engineering geological risk A, investigation and design risk B, construction technology risk C, tunnel engineering risk D, management risk E and environmental factors risk F and other six aspects of the 26 assessment indicators, this paper adopts the AHP to initially determine the weight of the indicators, and the specific process is shown in Fig.12.

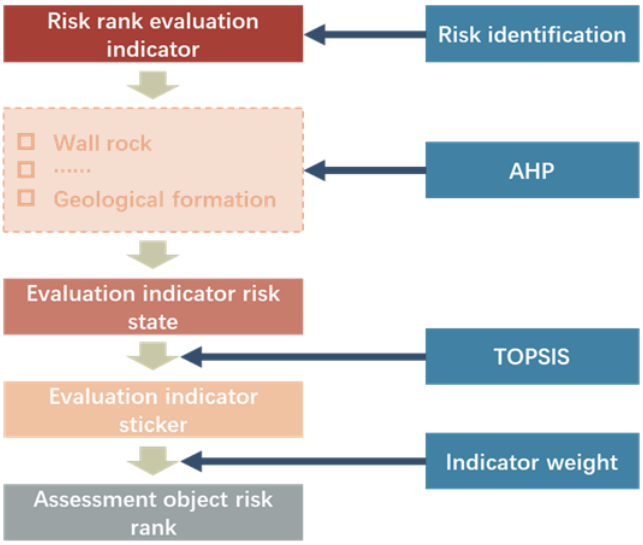

Fig. 12. Flowchart for the initial determination of the overall risk level based on the hierarchical analysis method.

In order to determine the degree of risk impact based on the risk level, so as to determine the risk control strategy, this paper classifies the risk level of the construction of pipe jacking up and across the operation tunnel into five types, which are high risk, higher risk, medium risk, lower risk and low risk, and the scores corresponding to the different risk levels are shown in Table I.

TABLE I. DIFFERENT RISK LEVELS AND CORRESPONDING LEVEL SCORES

Risk level	High	Higher	Moderate	Lower	Low
Score	≥20	15-20	10-15	5-10	0~5

The inputs to the risk level module are the hierarchical analysis method, the indicator system, and the outputs are the classification of the levels and the determination of the level scores.

5) Risk assessment module: According to the risk analysis data of the construction risk of the top tube over the operation tunnel, the machine learning algorithm is used to determine the mapping relationship between the value of the construction risk assessment indexes of the top tube over the operation tunnel and the value of the risk assessment level, so as to construct the risk assessment model of the construction risk of the top tube over the operation tunnel. With the increase of data volume, the machine learning model structure optimisation and parameter optimisation are prone to problems such as premature maturity, falling into local optimum, and slow convergence speed. In order to improve the performance of the machine learning algorithm, an intelligent optimisation algorithm is used to optimise it [22], and the improved paradigm is shown in Fig. 13.

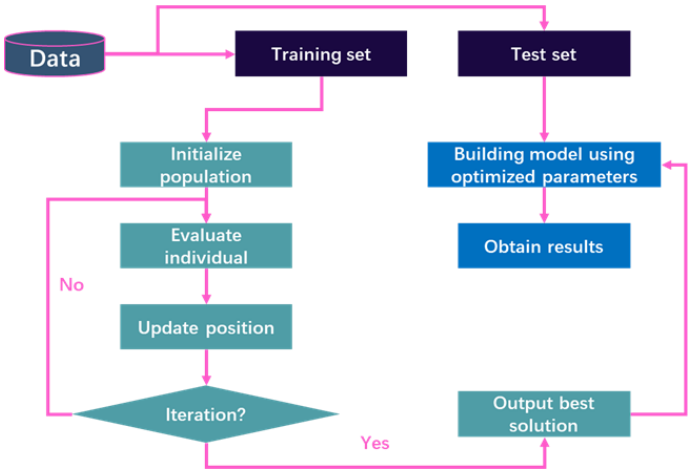

Fig. 13. Machine learning algorithm optimisation.

In Fig. 13, the first step is to determine whether the machine learning algorithm needs to optimise the structural parameters or the control parameters, and the machine learning algorithm chosen in this paper is the BP neural network, so the variables to be optimised are the structural parameters, i.e., the BP neural network weights and biases. According to the initialisation strategy to initialise the BP neural network weights and bias, with the training error as the value of the fitness value function value, the optimisation strategy of the intelligent optimisation algorithm is used, and after iteration, the BP neural network weights and bias with the smallest error are obtained.

The inputs to the risk assessment module are BP neural networks, intelligent optimisation algorithms, risk analysis data for the construction of a roof-tube up and over an operational tunnel, and the outputs are the predicted risk level scores as well as the levels.

6) Risk control module: The risk control module will remove accident risk control measures from engineering geology, construction technology, engineering management and other aspects according to the risk assessment results and risk acceptance criteria. In view of the construction risk problem of pipe jacking up and across operation tunnels, this paper analyses the deformation risk of pipe jacking through operation tunnels, and gives the deformation control method, i.e., the risk control measures are given from the engineering technology level.

III. Improved Machine Learning Algorithms for Risk Assessment Problems

A. Machine Learning Algorithms

Machine learning algorithms are a subfield of artificial intelligence that allow computers to learn from data and improve their performance without the need for explicit programming instructions. These algorithms can be categorised into three types, including supervised learning, unsupervised learning and reinforcement learning, as shown in Fig. 14. Since the problem of risk assessment for the construction of a roofed pipe up and over operational tunnels is a supervised learning problem, machine learning algorithms in the supervised learning category are used in this paper.

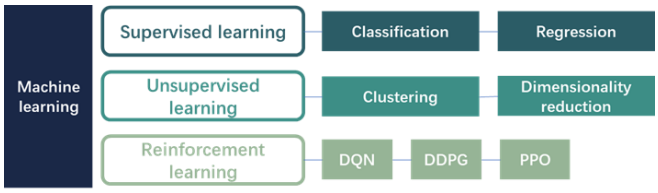

Fig. 14. Machine learning algorithm classification.

Common machine learning algorithms include linear regression, logistic regression, decision trees, random forests, K-nearest neighbours, Bayesian networks, neural networks, support vector machines, and integrated learning [23], as shown in Fig. 15.

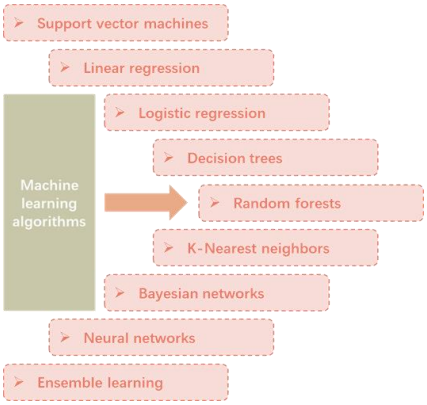

Fig. 15. Types of machine learning algorithms.

B. BP Neural Network

1) Principles and mechanisms: BP neural network [24] consists of three layers: input layer, hidden layer and output layer. W_{mi}, W_{in} The connection weights from the input layer x_m to the hidden layer k_i and the connection weights from the hidden layer k_i to the output layer y_n are represented respectively.

Define the actual output of the network as Eq. (3):

$$\boldsymbol{Y}(s) = (v_N^1, v_N^2, \ldots, v_N^N) \tag{3}$$

Its desired output is Eq. (4):

$$\boldsymbol{d}(s) = (d_1, d_2, \ldots, d_N) \tag{4}$$

a) Positive propagation of the input signal

The output of the m th neuron of layer I can be expressed as Eq. (5):

$$v_M^m(s) = x(s) \tag{5}$$

The inputs u_I^i and outputs v_I^i of the i th neuron of layer H are defined respectively as

$$u_I^i(s) = \sum_{m=1}^{M} w_{mi}(s) v_M^m(s) \tag{6}$$

$$v_I^i(s) = f\left(u_I^i(s)\right) \tag{7}$$

In Eq. (6) and Eq. (7), where $f(\square)$ denotes the H-layer transfer function.

Then the input u_N^n and output v_N^n of the n th neuron of layer O can be expressed as Eq. (8) and Eq. (9):

$$u_N^n(s) = \sum_{n=1}^{N} w_{in}(s) v_I^i(s) \tag{8}$$

$$v_N^n(s) = g\left(u_N^n(s)\right) \tag{9}$$

where $g(\square)$ denotes the output layer transfer function.

Then the overall error of the network can be expressed as Eq. (10):

$$e(s) = \frac{1}{2}\sum_{n=1}^{N} e_n^2(s), e_n(s) = d_n(s) - v_N^n(s) \tag{10}$$

b) Error signal back propagation

When the overall system error is greater than a threshold, the weights need to be adjusted so that the error gradually decreases.

$$w_{in}(s+1) = w_{in}(s) + \Delta w_{in}(s) \tag{11}$$

$$w_{mi}(s+1) = w_{mi}(s) + \Delta w_{mi}(s) \tag{12}$$

In Eq. (11) and Eq. (12), Where, $\Delta w_{in}(s)$ denotes the weight adjustment value of H layer and O layer, and $\Delta w_{mi}(s)$ denotes the weight adjustment value of I and H layers.

2) BP network applications: BP networks are able to mimic the learning and memory mechanisms of the human brain to learn and predict input data.BP networks are widely used in a variety of scenarios [25] due to their ability to learn to train nonlinear mapping laws, including but not limited to:

- BP networks are widely used in the field of pattern recognition;
- BP networks can be used to predict future outcomes or to make optimal decisions, such as in finance for predicting stock prices or developing risk management strategies;
- Train neural networks to control the actions of robots or to optimise production processes to improve efficiency;
- In the field of machine translation, BP networks are used to generate high quality translated texts;
- BP networks also perform very well in the field of speech recognition, such as speech to text and voice command recognition.

3) Problems with BP: Although BP networks have a wide range of applications in many fields, it has some problems and challenges:

- Overfitting the training data leads to performance degradation on the test data;
- The optimisation process may fall into local minima without reaching the global optimal solution;
- In deep networks, gradients may fade away during backpropagation, making it difficult for the network to learn.

C. Pigeon Swarm Optimisation Algorithm

Pigeon-Inspired Optimization (PIO) is a novel population intelligence optimization algorithm [26], which is inspired by the autonomous homing behaviour of domestic pigeons in nature. This algorithm is mainly implemented by map and compass operators and landmark operators to update the position and velocity of pigeon flocks, so as to simulate the homing behaviour of domestic pigeons and find the optimal solution.

4) Algorithmic principles

a) Map and compass calculator: In the flock optimisation algorithm, map and compass operators are used to model the behaviour of domestic pigeons that use the geomagnetic field to determine the approximate direction. The velocity and position of each pigeon is updated based on the previous generation's velocity and current optimal position, as shown in Fig. 16. Specifically, the equations for updating the pigeon's velocity is as follows Eq. (13) and Eq. (14):

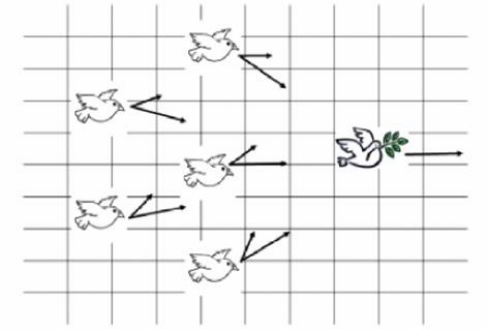

Fig. 16. Map core guide operator.

$$V_i^t = V_i^{t-1} e^{-R \times t} + rand \cdot \left(X_{gbest} - X_i^{t-1} \right) \quad (13)$$

$$X_i^t = X_i^{t-1} + V_i^t \quad (14)$$

Where X_i^t denotes the position information of the i^{th} individual of the flock in the tth iteration, V_i^t denotes the individual velocity information, X_{gbest} denotes the optimal individual position, R denotes the map kernel compass factor, and $rand$ is a random number. When the number of iterations reaches a certain number of iterations, the execution of the map and compass operator stops and enters the landmark operator.

5) Pseudo-code and flowchart: According to the basic principle and optimisation strategy of the pigeon flocking optimisation algorithm, the flowchart of the pigeon flocking optimisation algorithm is shown in Fig. 17 respectively.

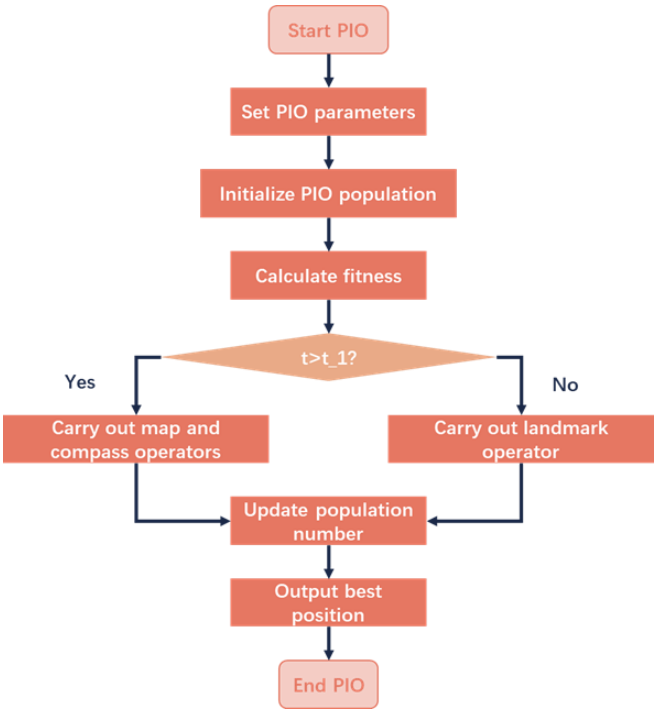

Fig. 17. Flowchart of the PIO algorithm.

D. PIO-BP Neural Network

In this paper, we use real number coding to encode the BP hidden layer weight values and hidden layer bias with the coding dimension of $(m_1 \times l_1 + l_1) + (m_2 \times l_2 + l_2)$, and also use MAE as the adaptation function Eq. (19):

$$MAE = \frac{1}{M}\sum_{i=1}^{M}|\hat{y}_i - y_i| \quad (19)$$

Where, $\hat{y}_i$ denotes the predicted value based on the proposed algorithm, y_i denotes the true value and M is the number of test samples.

The steps of the PIO-BP neural network prediction method (Fig. 18) are as follows:

- PIO algorithm encodes the initial parameters;
- Calculates the value of the fitness function;
- Updates the position and speed of the PIO population by using the map and compass operator and landmark operator;
- Calculates the value of the fitness function and updates the global optimal solution;
- Determines whether or not the termination conditions are satisfied;
- Decodes the PIO algorithm-optimised BP network structure parameters;
- Constructing a tunnel construction risk assessment model based on PIO-BP neural network.

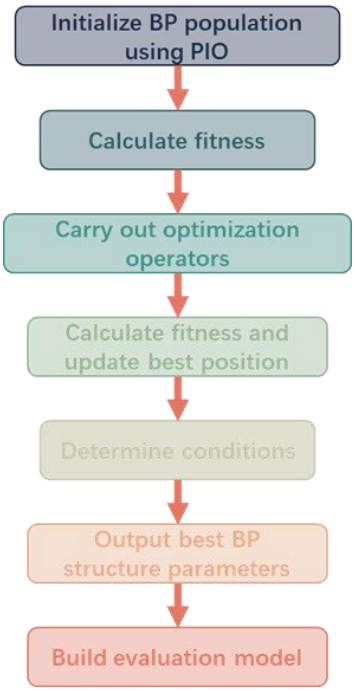

Fig. 18. Tunnel construction risk assessment based on PIO-BP neural network.

- Use either SI (MKS) or CGS as primary units. (SI units are encouraged.) English units may be used as secondary units (in parentheses). An exception would be the use of English units as identifiers in trade, such as “3.5-inch disk drive”.
- Avoid combining SI and CGS units, such as current in amperes and magnetic field in oersteds. This often leads to confusion because equations do not balance dimensionally. If you must use mixed units, clearly state the units for each quantity that you use in an equation.
- Do not mix complete spellings and abbreviations of units: “Wb/m^2” or “webers per square meter”, not “webers/m^2”. Spell out units when they appear in text: “. . . a few henries”, not “. . . a few H”.
- Use a zero before decimal points: “0.25”, not “.25”. Use “cm^3”, not “cc”. (*bullet list*)

IV. Algorithmic Applications

In order to verify the performance of the risk assessment algorithm for the construction engineering of the city railway tunnel project, this paper relies on the construction risk analysis of the tunnel of Xinfeng Road underground passage close to the upper crossing of Metro Line 9 in Hangzhou and the side penetration of Hanghai Intercity Tunnel Project, constructs the risk assessment model, and puts forward the effective risk control measures.

A. Project Description

Xinfeng Road Underpass in Linping District, Hangzhou is located in the north side of the intersection of Xinfeng Road and Wenzheng Street in Linping District, and there are many existing structures within the new construction scope. The channel passes through Xinfeng Road, the main road (roof pipe depth 2.3m), and close to cross (roof pipe and tunnel structure minimum vertical clearance 2.5m) existing operation Hangzhou Metro Line 9, Yuhang high-speed rail station ~ Nanyuan station interval two-line tunnel, and parallel side through (roof pipe and tunnel horizontal clearance 15.6m) existing Hanghai intercity two-line tunnel. The total length of the underpass is 136.5m, which is constructed by pipe jacking method and open cut method, of which the starting shaft and receiving shaft open cut section are 34.9m and 26.6m long respectively, with the depth of the shaft being about 8~9m. The crossing section of the underpass is constructed by pipe jacking method from west to east, with a length of 75m. the standard rectangle pipe jacking section is adopted, with the internal dimensions of 6.0m×3.3m, the wall thickness of the jacking pipe is 0.45m, and the length of the pipe section is 1.5m, and the socket joint is adopted. The length of the pipe section is 1.5m, and the socket joints are adopted.

B. Construction Risk Assessment

For the factors that may lead to excessive deformation of the existing tunnel during the jacking construction process of the pipe jacking section, the main focus is on the silt layer and the close proximity through the existing tunnel in two aspects: (1) the project is located in the silt layer, with high compressibility, high sensitivity and thixotropy, poor engineering properties, and unfavourable control of deformation of the ground layer

disturbed by the construction. At the same time belongs to the low to medium permeability stratum, and this project is adjacent to East Lake, rich groundwater recharge, strata water content is large, jacking process is prone to groundwater gushing, resulting in over-excavation of tunnels and triggering the risk of construction safety; (2) jacking pipe with a vertical clearance of 2.5m through the operating tunnel in the vicinity of the top, jacking process in the front of the strata by the construction of the influence of the stress of the disturbance is serious, resulting in the unloading of the lower part of the front disturbed area as well as the pipe section of the ground below shear disturbance zone During the jacking process, the ground strata in front is severely disturbed by the impact of the application, which causes the unloading disturbance zone in front and the shear disturbance zone in the lower part of the pipe section to be relaxed, and the structure of the operating tunnel in the lower part of the pipe section is uplifted along with the surrounding strata, which has a great impact on the deformation of the existing tunnel before and after jacking. At the same time, the soil cover above the jacking tube is shallow, only 2.3m, and the jacking has a strong influence on the deformation of the ground surface, and the deformation effect of the shallow soil cover will increase the deformation of the tunnel in the unprotected condition.

Aiming at the above key risks, this paper carries out construction risk assessment from engineering geological risk A, investigation and design risk B, construction technology risk C, tunnelling risk D, management risk E and environmental factor risk F. Risk assessment indexes of the six aspects are taken as inputs, and risk level score values are taken as outputs, where the risk index values need to be extracted by downscaling features. According to the risk level score value, the risk level is obtained by combining the correspondence between the risk assessment value and the level grade in the risk level module.

C. Risk Control Programme

The deformation control of pipe jacking through operational tunnels includes deformation monitoring control and factor-specific control. Deformation monitoring and control includes the development of deformation control standards and automated monitoring measures; factor-specific control includes MJS portal-type ground reinforcement measures for the chalky sand stratum close to the underpass and surface hardening measures for shallow overburden.

Standard measures for deformation control were developed as shown in Table II.

TABLE II. DEFORMATION CONTROL STANDARDISATION

Structural safety control indicator control values	metric
Horizontal displacement (mm)	<5
Vertical displacement (mm)	<5
Relative convergence (mm)	<5
Differential settlement at station and zone junction (mm)	<5
Radius of deformation curvature (m)	>15000
relative curvature of deformation	<1/2500
Tube sheet seam opening (mm)	<1
Additional load on outer wall (kPa)	≤10
Crack width (mm)	≤0.1
Contact net guide height (mm)	<20
Roadbed and track displacement (mm)	<5

Aiming at the characteristics of large compressibility, poor engineering properties and large water content of the silt layer, and the large influence of groundwater on the slagging process of the pipe jacking and the stability of the thixotropic mud on the outside of the pipe joints, the all-around high-pressure rotary injection grouting method (MJS) is adopted in the silt layer crossed by the pipe jacking to carry out gated reinforcement in advance in the area of the pipe jacking crossing over the operation tunnel.

V. EXPERIMENTAL ANALYSIS

A. Experimental Set-Up

In order to verify the effectiveness of the risk assessment algorithm for tunnel construction proposed in this paper and the feasibility of taking risk control measures, this paper takes the data of the project of Hangzhou Xinfeng Road underground passage close to crossing the metro line 9 tunnel and side through Hanghai intercity tunnel as the data for analysis, and selects SVM, Decision Tree, and BP as the comparative algorithms of the analysis and assessment algorithms of the PIO-BP neural network, and at the same time analyses the risk control measures from the on-site monitoring and numerical simulation. Two aspects of risk control measures are analysed.

The algorithm setup is shown in Table III. The algorithm used in this paper is PIO-BP neural network and the comparison algorithms are SVM, Decision Tree and BP neural network.

TABLE III. PARAMETER SETTINGS FOR THE COMPARATIVE RISK ASSESSMENT ALGORITHM

Arithmetic	Parameterisation
Support Vector Machine (SVM)	C=100,σ=0.1
Decision Tree	The maximum number of divisions is 4
BP neural network	Hidden layer node is 50, activation function is radial basis function
PIO-BP neural network	Hidden layer nodes are 50, activation function is radial basis function, population size is 50, maximum number of iterations is 100

The experimental simulation environment is Windows 10, the risk assessment algorithm programming language Python 3.7, and the Midas GTS finite element software is used for the risk control measures.

The experimental finite element calculation model for numerical analysis of risk control measures is shown in Fig. 19. *x* is the direction of pipe jacking and *z* is the direction of model elevation. The relevant calculation parameters of each soil layer are shown in Table IV The pipe jacking sheet and tunnel structure, station wall panel structure, enclosure structure and support adopt linear elastic principal structure, and the values of structural parameters are shown in Table V.

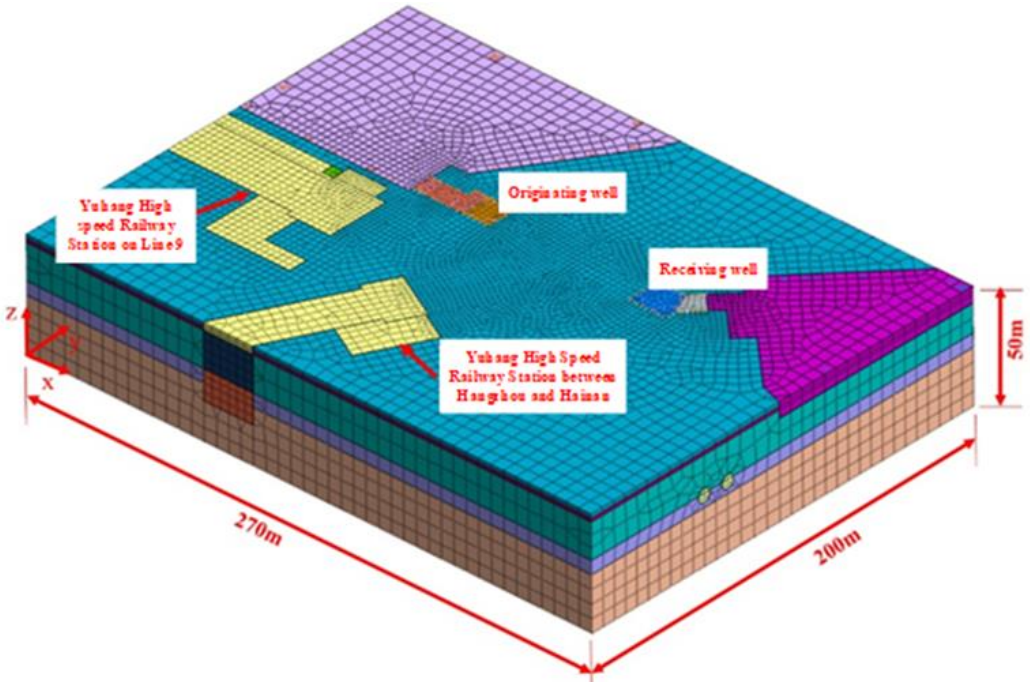

Fig. 19. Schematic diagram of finite element calculation model.

TABLE IV. CALCULATED PARAMETERS FOR SOIL LAYERS

Stratigraphic name	Triaxial loading stiffness E_{50} (MPa)	Triaxial unloading stiffness E_{ur} (MPa)	Consolidator loading stiffness E_{ord} (MPa)	Initial small strain modulus G_0 (MPa)	Modulus stress related power index(m)	Shear strain level $\gamma^{0.7}$
miscellaneous fillings	3.0	15.0	3.0	50.0	0.5	1.0×10^{-4}
clayey silt	7.0	28.0	7.0	112.0	0.5	2.0×10^{-4}
sandy silt	8.5	34.0	8.5	136.0	0.5	2.0×10^{-4}
silt sand	10.0	40.0	10.0	160.0	0.5	2.0×10^{-4}
clays	6.5	27.0	5.4	108.0	0.7	2.0×10^{-4}

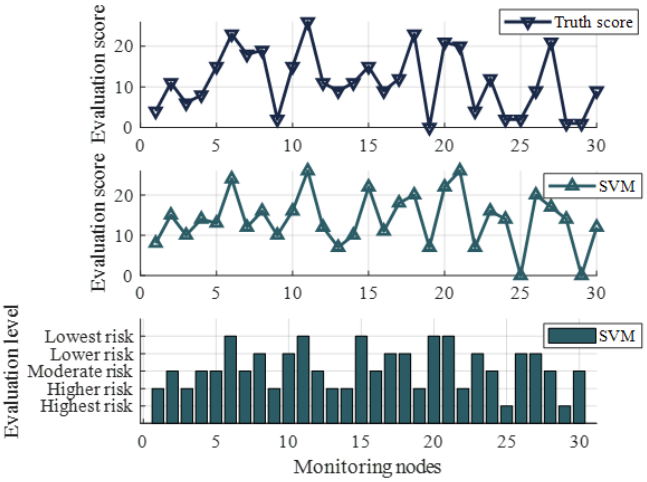
TABLE V. STRUCTURAL CALCULATION PARAMETERS

Typology	Serious $(kN/m)^3$	Modulus of elasticity (Mpa)	Poisson's ratio	Cohesion(kPa)	Angle of internal friction(°)
MJS plus solids	18.0	400	0.2	1000	23
pipe jacking slice	25.0	34500	0.25	-	-
shield	25.0	34500	0.25	-	-
Station wall panels, enclosures and internal supports	24.0	30000	0.2	-	-
steel support	78.0	200000	0.2	-	-

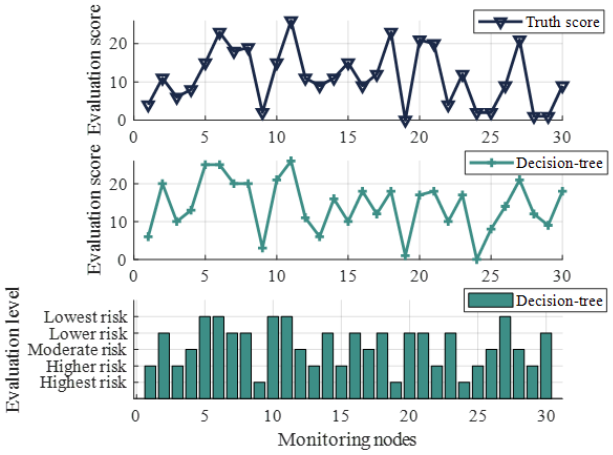
B. Analysis of Evaluation Test Results

In order to verify the effectiveness of the PIO-BP neural network based risk assessment algorithm for tunnel construction, this subsection compares the performance of SVM, Decision-tree, BP, and PIO-BP methods using a test set.

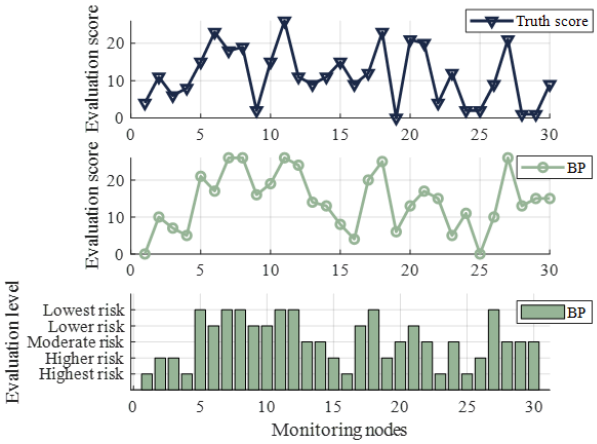
The results of risk assessment of 26 monitoring sections in tunnel construction based on different algorithms are given in Fig. 20. As can be seen from Fig. 20(a) – Fig. 20(d), the accuracy of the risk assessment algorithm of the PIO algorithm optimised BP neural network is better than the other algorithms. The statistical results show that the risk assessment model based on the PIO-BP algorithm is closer to the real value of the test set data than the assessment results of other modelling methods, which demonstrates the high assessment accuracy of the model.



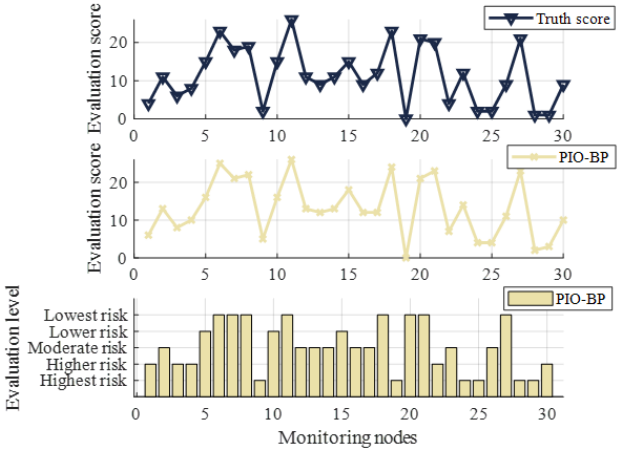
(a) SVM



(b) Decision-tree



(c) BP

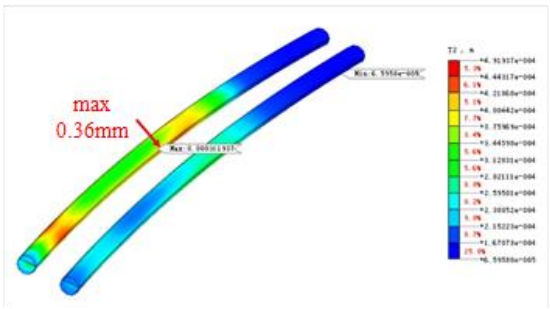


(d) PIO-BP

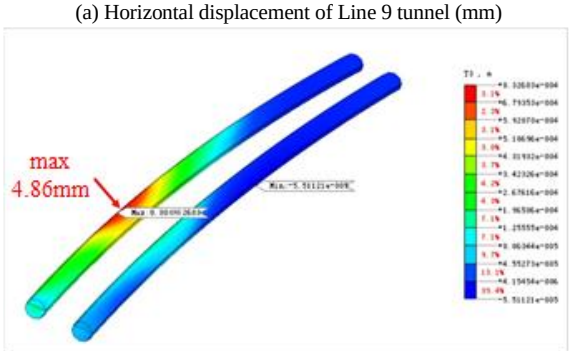
Fig. 20. Test results of different risk assessment model algorithms.

C. Analysis of the Results of the Testing of Risk Control Measures

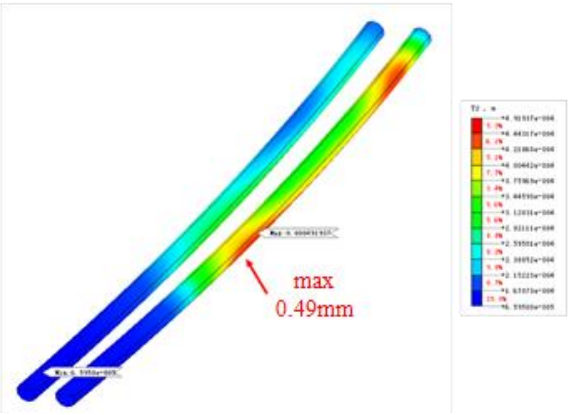
6) Tunnel structural displacement: The software is used to simulate the pipe jacking construction, and the calculation results after the advancement of the pipe jacking in the characteristic working condition are shown in Fig. 21. It can be seen from Fig. 21 that the deformation values of the two operating tunnels satisfy the control requirement of 5mm. The difference settlement at the junction between the tunnel section and the station is small.



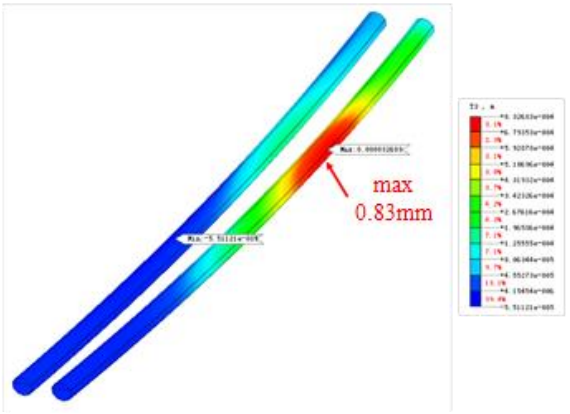
(a) Horizontal displacement of Line 9 tunnel (mm)



(b) Vertical displacement of Line 9 tunnel (mm)



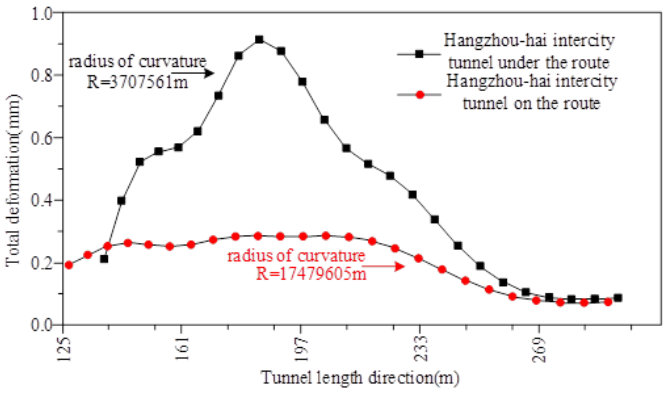
(c) Horizontal displacement of intercity tunnels (mm)



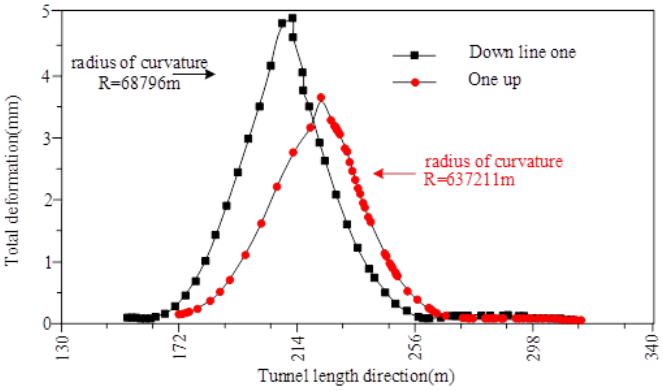
(d) Vertical displacement of intercity tunnels (mm)

Fig. 21. Pipe jacking to complete the upper span construction results.

7) Tunnel structural curvature: According to the maximum deformation results of the two tunnels, the additional radius of curvature of the tunnels caused by the jacking is calculated, and the results are shown in Fig. 22. It can be seen that the additional radius of curvature of the two operation tunnels caused by the jacking construction is much larger than the control requirements of 15,000m, which meets the requirements, and the jacking pipe is directly above the close up penetration of the structural deformation of the operation tunnels is more influential.



(a) Line 9 underground tunnel



(b) Hang Hai Intercity Tunnel

Fig. 22. Additional radius of curvature of operational tunnels.

VI. Conclusion

The research successfully develops a risk assessment algorithm based on a combination of machine learning technology and pigeon-inspired optimization (PIO) algorithm to address the construction risks associated with urban railway tunnel projects. This PIO-BP neural network-based risk assessment model effectively identifies and assesses risks, leading to improved prediction accuracy. The study also provides a corresponding risk control scheme, which has been validated using monitoring data and numerical models, confirming the feasibility of the proposed risk assessment and control measures. The algorithm and approach provide a solid foundation for risk management in complex urban railway tunnel projects.

While acknowledging the contributions of this study, there are three key limitations that cannot be overlooked: Firstly，the risk identification process primarily relies on expert consultations and qualitative analysis, lacking quantitative automation support, which may impact the comprehensiveness and accuracy of risk identification. Then, while machine learning algorithms improve accuracy, the risk assessment indicator system could benefit from deeper quantitative analysis, leveraging big data technologies to enhance the granularity of risk predictions. Finally, the proposed risk assessment model is validated on specific projects but lacks clarity on its adaptability under different geological and environmental conditions, limiting its feasibility for broader applications.

A Data-Driven Deep Machine Learning Approach for Tunnel Deformation Risk Assessment

Fusheng Liu
China Railway Siyuan Survey and Design Group Co., LTD. Hangzhou 310000, Zhejiang, China

Abstract*—The shallow overburden pipe jacking over operation tunnel construction project in chalk stratum has the risk of deformation of the soil layer and the existing tunnel, which increases the difficulty of pipe jacking over construction, and the risk assessment and control become the key technology for the safe and successful completion of the construction. Aiming at the problems of the current deformation risk assessment and control method, such as the assessment system is not comprehensive, systematic and objective enough, the prediction accuracy is not efficient enough, and there is a lack of quantitative analysis, etc., a deformation risk assessment and control method is proposed to combine the heuristic optimization algorithm of human behaviour and deep machine learning algorithm for pipe jacking up to and across operation tunnels on shallow overburden of chalky sand stratum. Firstly, by analyzing the construction process of pipe jacking tunnel, the deformation risk factors of the construction process and the deformation risk control scheme are given; then, a deformation risk assessment and control algorithm with improved deep limit learning machine is proposed by combining human heuristic optimization algorithm; finally, the proposed deformation assessment and control model is applied to the deformation risk assessment and control problem of pipe jacking over operation tunnel on shallow overburden of pulverised sand stratum, and a finite element computational model is used to construct the data. Finally, the proposed deformation assessment and control model is applied to the problem of deformation risk assessment and control in a tunnel with shallow overburden in chalky sand stratum by using finite element computational model to construct the data set, training the deformation risk assessment and control model, and using the monitoring data as the test set to validate the validity of the proposed model algorithm, and solving the problem of the poor prediction accuracy of the control algorithm for deformation risk assessment and control of a tunnel with shallow overburden in a tunnel with shallow overburden in chalky sand stratum.

I. INTRODUCTION

Due to the rapid development of economic technology and science and technology, the urbanisation process in China has been increasing, which has led to many problems in cities, such as traffic congestion, environmental pollution, population increase, and huge energy depletion [1]. In order to alleviate the increasingly serious pressure on urban space, the construction and development of underground space has gradually become an important way for major cities to solve the problems arising from urbanisation [2]. The construction of urban underground space includes the construction of underground tunnels, and its construction methods mainly include shield method and pipe jacking method, two urban tunnel construction methods [3]. The pipe jacking tunnel construction method, as a kind of no-excavation construction technology, achieves the construction of tunnels by setting up work shafts on the ground, and then using pipe jacking machines to push the pipeline or tunnel structure from one work shaft to another work shaft [4]. The pipe jacking tunnel construction technology has the characteristics of reducing damage to the surrounding environment, ensuring construction safety, fast construction speed, controllable quality and strong adaptability [5]. Although there are many advantages in the process of jacking tunnel construction, it is still affected by the geological environment, nearby buildings and other influences, and there is the phenomenon of frequent accidents in underground tunnel engineering, such as ground subsidence, sand and soil gushing out, and river water backing up and other problems [6]. Therefore, it is of great practical significance to study the comprehensive and systematic quantitative risk assessment and control method of tunnel deformation during the construction of pipe jacking tunnels.

Accurate and effective risk assessment methods for deformation of tunnel operating in jacked tube construction not only improve the safety of jacked tube tunnel construction, but also improve the risk management level of tunnel engineering construction [7]. Risk assessment generally includes the steps of risk mechanism analysis, risk identification, risk assessment and risk control [6]. The deformation risk assessment of roof-tube construction and operation tunnel is to analyse and identify the risk factors of roof-span jacking construction in the process of roof-tube top-span operation tunnel construction, use the risk assessment model to construct the complex law relationship between the tunnel deformation risk indexes and the value of the control strategy, and obtain the deformation control strategy of the roof-tube construction and operation tunnel based on the specific deformation situation of the tunnel [7]. Risk assessment algorithm, as one of the key technologies for deformation risk assessment of top tube over spanning operation tunnels, should not only analyse the risk of tunnel changes in the construction process from the perspective of top tube over spanning operation tunnels, but also put forward risk assessment algorithms that can describe the law according to the specificity of the problem. Currently, the research on the top tube over operational tunnels mainly focuses on the deformation of the soil layer around the top tube method and the deformation of the existing tunnel structure, and usually adopts the empirical formula method [8], the theoretical analysis method [9], and the finite element analysis method [10], etc. Literature [8] has shown that the deformation of the soil layer around the top tube method and the deformation of the tunnel structure is the main cause of the risk

of tunnel changes during the construction process; Literature in [9] used random medium method and peck formula method to analyse the difference of surface settlement caused by pipe jacking construction; Literature in [10] for the problem of rectangular pipe jacking construction of large cross-section, the use of finite element software to analyse the disturbance of the soil body, and at the same time put forward the relevant construction control scheme. For the problem of risk assessment model construction, the current more popular assessment algorithms include fuzzy logic method, grey model, machine learning and other methods [11]. Due to the deformation of the top tube over operation tunnel is affected by the uncertainty and complexity of the construction risk, and at the same time, there is a nonlinear relationship between the deformation risk and the control strategy, the deformation risk assessment method of the top tube over operation tunnel based on machine learning algorithms can use the data to quickly construct an accurate model, which is paid special attention to by experts in the field, and has also become one of the directions of the development of the deformation risk intelligent analysis of the top tube construction and operation tunnel [12]. Risk assessment methods based on machine learning algorithms include BP neural networks, support vector machines, decision trees, clustering and other algorithms [13]. Although the research on deformation risk assessment algorithms for roof-tube up-and-over operation tunnels has achieved certain qualitative theoretical results, there are still some problems [14]: 1) the identification of deformation risk of roof-tube up-and-over operation tunnels is not comprehensive and systematic enough; 2) the quantitative research on the deformation control strategy of roof-tube up-and-over operation tunnels is relatively small; and 3) the precision of the deformation risk assessment model needs to be improved.

For groundwater-rich chalk strata, pipe jacking is prone to the risk of over-excavation due to gushing, which affects the stability of the surrounding strata. Compared with general clay and weathered rock strata, there are fewer construction practices in the engineering community for pipe jacking across highly sensitive soils such as chalk strata, and there is a lack of deformation control measures for existing structures that are compatible with such strata [15]. In order to analyse the deformation risk mechanism of pipe jacking across operational tunnels in shallow overburden in chalky sand strata and to quantify the precise deformation risk control measures, machine learning algorithms are used to construct a deformation risk assessment and control model for pipe jacking across operational tunnels in shallow overburden in chalky sand strata.

In order to solve the problems of deformation risk assessment and control method of pipe jacking over operation tunnel, this paper proposes a risk assessment and control method based on hybrid leader optimisation algorithm to improve the depth limit learning machine. In view of the deformation risk problem of shallow overburden pipe jacking over operation tunnel in chalk stratum, the deformation risk mechanism is analysed, and the deformation risk factors and control indexes in the construction process are introduced; in view of the deformation risk assessment and control problem of the tunnel, the hybrid leader optimization algorithm is used to optimize the network of the deep limit learning machine, and the proposed general application is applied to the specific problems. The effectiveness and robustness of the proposed algorithm is verified by analysing the structural numerical simulation data with the case of a close-range up-span underground operation tunnel in chalky sand formation.

The paper's framework begins with an analysis of the deformation mechanisms involved in pipe-jacking tunnel construction within chalky sand strata, focusing on key factors that influence deformation risk and stability control. Following this, it introduces a hybrid machine learning model that combines a Deep Limit Learning Machine (DELM) with a Hybrid Leader-Based Optimization (HLBO) algorithm to enhance prediction accuracy and model robustness. This model is then applied to a case study in Hangzhou, China, where pipe-jacking occurs near existing metro tunnels, with simulations and field measurements used to test accuracy. Comparative experiments validate the model's effectiveness against other methods, presenting detailed parameter evaluations and monitoring data. The paper concludes by discussing the model's contributions to improving deformation risk assessment in tunnel engineering, noting its limitations and proposing areas for further research to increase predictive accuracy and computational efficiency.

II. Analysis of Deformation Risks and Control Options for Pipe Jacking

A. Pipe Jacking Tunnel Construction Process

Pipe jacking tunnelling is a trenchless construction technique, which is mainly used for the construction of urban underground pipelines, subways, pedestrian passages and other projects. This technology achieves tunnel construction by setting up work shafts on the ground and then using pipe jacking machines to push the pipeline or tunnel structure from one work shaft to another, as shown in Fig. 1. Pipe jacking construction technology has the characteristics of reducing damage to the surrounding environment, ensuring construction safety, fast construction speed, controllable quality and strong adaptability.

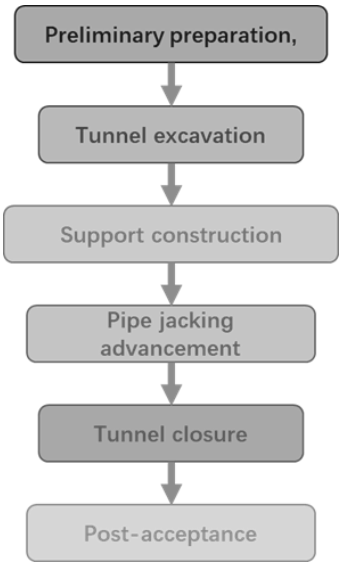

Fig. 1. Construction process of pipe jacking tunnelling.

As shown in Fig. 1, it can be seen that the process of pipe jacking tunnel construction includes pre-preparation, tunnel excavation, support construction, pipe jacking advancement, tunnel closure, and post-acceptance [16].

1) Pre-preparation: Determine the tunnel construction area, carry out geological survey and design, and formulate detailed construction plan, including propulsion path and propulsion machinery selection.

2) Tunnel excavation: traditional tunnel excavation methods, such as blasting or roadheader method, are used to open up a large enough tunnel space for pipe jacking construction.

3) Support construction: choose the appropriate support method according to the geological condition, such as steel frame support, spray anchor support, etc., to ensure the stability and safety of the tunnel.

4) Pipe jacking advancement: choose suitable pipe jacking machinery to carry out the advancement operation, and support the tunnel wall during the advancement process to prevent collapse and instability.

5) Tunnel closure: When the jacking pipe advances to the target position, the pipe closure and connection work is carried out to ensure the sealing and use function of the tunnel.

6) Post-acceptance: acceptance of construction quality, check whether pipe jacking construction meets the requirements to ensure the quality of the project.

B. Project Orientated Risk Analysis of Deformation during the Construction Process

1) Introduction to the project: In order to verify the effectiveness of the deformation risk assessment and control method of the pipe jacking across the operation tunnel, this paper adopts the pipe jacking construction project of Xinfeng Road underground passage in Linping District of Hangzhou City as an analysis sample.

Xinfeng Road Underpass in Linping District, Hangzhou is located in the north side of the intersection of Xinfeng Road and Wenzheng Street in Linping District, and there are many existing structures within the new construction scope. The underpass passes through Xinfeng Road, a main road (header pipe depth 2.3m), and crosses (minimum vertical clearance between header pipe and tunnel structure 2.5m) the existing Hangzhou Metro Line 9 Yuhang High Speed Railway Station to Nanyuan Station double line tunnel, and passes through the existing Hanghai Intercity Double Line Tunnel in parallel (horizontal clearance between header pipe and tunnel 15.6m). The relative position of the underpass and the existing structure is shown in Fig. 2.

The pipe jacking section of the underpass passes through the shield tunnel of Metro Line 9 (inner diameter 5.5m, wall thickness 350mm) and the shield tunnel of Hanghai Intercity (inner diameter 6.0m, wall thickness 350mm).

According to the results of ground investigation, the pipe jacking section is mainly located in ②2 sandy silt and ④ silt stratum, the upper layer is ① miscellaneous fill and ②1 clayey silt stratum, and the layer where the tunnel is located in the lower zone is ④ silt and ⑥ clay stratum, and the physico-mechanical parameter of the soil stratum is shown in Table I.

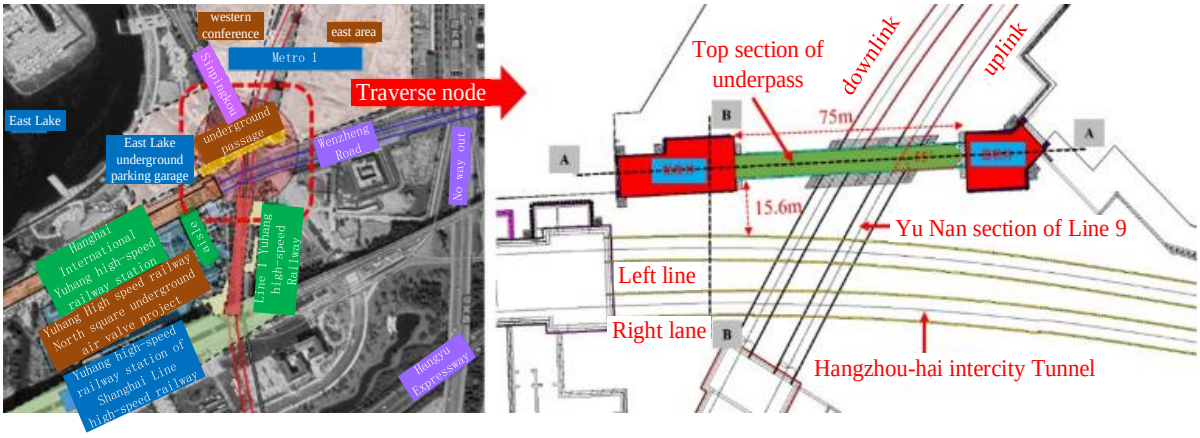

Fig. 2. Relationship between the plan position of the underground passage and the existing structure.

TABLE I. PHYSICAL-MECHANICAL PARAMETERS OF LANDMARKS

Layer number	Stratum	Water content/%	Pore ratio/%	Natural gravity/(kN/m^3)	Cohesion/kPa	Angle of internal friction/°	Horizontal permeability coefficient k/(×10^{-4}cm/s)	Vertical permeability coefficient k /(×10^{-4}cm/s)
①	mixed soil	(30.0)		(19.0)	(7.0)	(15.0)		
②$_1$	clayey silt	25.5	0.731	19.09	5.6	17.6	0.63	0.49
②$_2$	sandy silt	24.6	0.693	19.25	3.0	21.6	7.4	6.1
④	siltstone	24.2	0.677	19.28	3.3	23.4	53.4	37.8
⑥	clays	27.6	0.811	18.88	34.4	14.4		

2) Deformation analysis of pipe jacking construction process: The pipe jacking method of construction generally causes deformation of the ground and the existing tunnel [17].

The deformation of the ground includes ground loss and reconsolidation of disturbed soil. The deformation of stratum mainly refers to the difference between the actual soil volume and the completed tunnel volume during the pipe jacking construction process, and the factors that cause the loss of stratum include soil excavation, pipe section size, tool pipe dragged with soil, pipe jacking correction, pipe section rebound and so on. Re-consolidation of disturbed soil refers to the re-consolidation of disturbed soil after the end of pipe jacking construction, resulting in deformation of the soil layer again, and the main factors include the decrease of void pressure and the disappearance of super pore water pressure.

The deformation of an existing tunnel includes both lateral and vertical deformation [18].

In order to construct an accurate tunnel deformation risk assessment and control model, the tunnel deformation risk factor set is firstly established from two perspectives: ground deformation and existing tunnel deformation, as shown in Fig. 3.

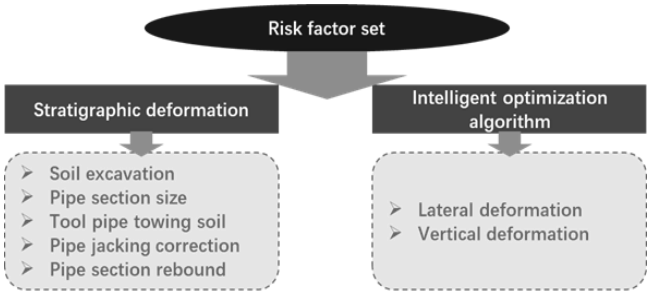

Fig. 3. Tunnel deformation risk factor set.

3) Specific analysis of deformation risk: In this project, there was excessive deformation of the existing tunnel during the jacking construction of the pipe jacking section, mainly focusing on two aspects.

a) Aspects of deformation in chalk strata: Firstly, the project is located in the stratum of silt sand stratum, with high compressibility, high sensitivity and thixotropy, and unfavourable deformation control after stratum construction; secondly, the project is adjacent to the East Lake, with large water content in the stratum, and easy to occurrence of groundwater gushing in the process of jacking.

b) Deformation of existing tunnels: The jacking pipe penetrates the operation tunnel with a vertical clearance of 2.5m, which causes the ground stress relaxation in the unloading disturbance area and the shear disturbance area, and the structure of the operation tunnel near the bottom rises upwards with the surrounding strata; the soil overlay above the jacking pipe is relatively shallow, and the jacking construction has a large impact on the ground surface deformation, as shown in Fig. 4.

C. Deformation Risk Control Programme

In order to analyse the impact of the construction process of the pipe jacking project on the deformation of the operation tunnel, in order to minimise the project risk, the existing tunnel inspection situation is taken into account to determine the structural and surface deformation control scheme of the existing tunnel in the area during the construction process of the pipe jacking project. The existing tunnel structure and surface deformation control program during the construction process of the pipe jacking project is mainly expressed in the form of safety control indicators.

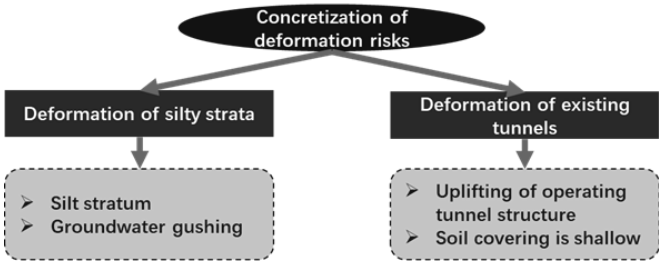

Fig. 4. Schematic diagram for specific analysis of tunnel deformation risk.

The deformation control index of the interval during the construction process of the pipe jacking upper span project is designed from the deformation control of the existing tunnel structure and the surface deformation control in two aspects of the index value [19], in which the deformation control of the existing tunnel structure includes the safety control index and the deformation rate control index [20], as shown in Table. II

TABLE II. SCHEMATIC DIAGRAM OF DEFORMATION CONTROL INDICATORS

Items	Indicators
Existing tunnels	Horizontal displacement of the tunnel
	Vertical displacement of the tunnel
	Tunnel differential settlement
	Tunnel radial convergence
	Rail transverse height difference
	Shield segment joint opening
	Settlement of tunnel structures
	Tunnel structure floats upward
	Horizontal displacement of structure
Surface	Surface uplifting
	Surface subsidence

In view of the shallow soil cover above the jacking tube, 300mm thick reinforced concrete slabs are used for road hardening on the surface above the jacking section of the channel to reinforce the strength of the ground surface, reduce the surface uplift in the jacking process, slow down the effect of shallow soil cover on the deformation of the operation tunnel and act as counterweights above the jacking tube.

III. IMPROVED DEEP LIMIT LEARNING MACHINE MODEL

Deep Extreme Learning Machine is a deep neural network stacked by multiple Extreme Learning Machine self-encoders with fast training speed and good generalisation performance [21]. In order to overcome the problem that the random input weights and biases of deep extreme learning machine affect the

training effect, this paper proposes a deep extreme learning machine model based on hybrid leader optimisation algorithm.

A. Deep Limit Learning Machine

The limit learning machine [22] is denoted as

$$f_{ELM}\left(x_i\right)=\sum_{j=1}^{l}\beta_j g\left(a_j x_i+b_j\right), i=1,2,\cdots,N \quad (1)$$

Where $\beta_j=\left[\beta_{j1},\beta_{j2},\cdots,\beta_{jn}\right]$ denotes the output weights, $a_j=\left[a_{j1},a_{j2},\cdots,a_{jm}\right]$ denotes the input weights, b_j denotes the bias, and $g\left(\cdot\right)$ denotes the activation function.

The ELM output error is

$$\begin{aligned}E&=\sum_{i=1}^{N}\left\|f_{ELM}\left(x_i\right)-y_i\right\|\\&=\left\|\boldsymbol{H}\left(\boldsymbol{a},\boldsymbol{b}\right)\cdot\beta-\boldsymbol{y}\right\|\end{aligned} \quad (2)$$

Where, $\boldsymbol{H}$ denotes the output, β denotes the output weights and $\boldsymbol{y}$ denotes the desired output. In ELM algorithm, by determining $\boldsymbol{a}$ and $\boldsymbol{b}$, $\boldsymbol{H}$ is uniquely determined. The output weights are solved by the formula

$$\boldsymbol{\beta}^{*}=\boldsymbol{H}^{-1}\cdot\boldsymbol{y} \quad (3)$$

where $\boldsymbol{H}^{-1}$ denotes the Moore-Penrose generalised inverse matrix of the matrix $\boldsymbol{H}$.

Deep extreme learning machine (DELM) output weights are

$$\boldsymbol{\beta}^{*}=\boldsymbol{H}^{-1}\left(\frac{1}{C}+\boldsymbol{H}\boldsymbol{H}^{T}\right)^{-1}\cdot\boldsymbol{y} \quad (4)$$

Where, C tables the regular term coefficients.

B. Hybrid Leader Optimisation Algorithm

In intelligent optimisation algorithms, the individuals of the population act as searchers in the problem space, which are candidates for solving the problem, and update the position information through continuous iterative optimisation and comparison to provide a better solution. In this paper, we propose a leader-inspired intelligent optimisation algorithm, Hybrid leader based optimization (HLBO), which uses the best member, a random member, and the corresponding member to update and guide the position information of the population [23].

Like other heuristic algorithms, the population representation of the HLBO algorithm is as follows:

$$X=\begin{bmatrix}X_1\\X_2\\\vdots\\X_N\end{bmatrix}_{N\times m}=\begin{bmatrix}x_{11}&x_{12}&\cdots&x_{1m}\\x_{21}&x_{22}&\cdots&x_{2m}\\\vdots&\vdots&\cdots&\vdots\\x_{N1}&x_{N2}&\cdots&x_{Nm}\end{bmatrix}_{N\times m} \quad (5)$$

At the beginning of the optimisation process, the population, N individuals are randomly initialised with the following initialisation formula:

$$x_{ij}=lb_j+rand\times\left(ub_j-lb_j\right), j=1,2,\cdots,m \quad (6)$$

In HLBO, two search phases are proposed based on leader behaviour: an exploration (global) phase and an exploitation (local) phase.

1) Exploration (global) phase: The exploration phase usually allows the population individuals to precisely search different spaces to reach the original optimal region. Continuous dependence on population-specified individuals can prevent global search and reduce the exploration operation of the algorithm, which results in the population individuals falling into a local optimum. In the HLBO algorithm, a hybrid leadership strategy is used to update the population, and its strategy mainly depends on the current individual, optimal individual, and random individual position information.

The participation factors of current individual, optimal individual, and random individual make the calculation based on individual quality, and the specific formula of individual quality is as follows:

$$q_i=\frac{F_i-F_{worst}}{\sum_{j=1}^{N}\left(F_i-F_{worst}\right)}, i\in\left\{1,2,\cdots,N\right\} \quad (7)$$

The participation factor for each member is calculated as follows:

$$PC_i=\frac{q_i}{q_i+q_{best}+q_k} \quad (8)$$

$$PC_{best}=\frac{q_{best}}{q_i+q_{best}+q_k} \quad (9)$$

$$PC_k=\frac{q_k}{q_i+q_{best}+q_k} \quad (10)$$

Where q_i denotes the individual quality, F_i denotes the fitness value, F_{worst} denotes the fitness value of the worst solution, and PC_i , PC_{best} and PC_k denote the participation factors of the *ith* candidate solution, the optimal solution, and the *kth* candidate solution, respectively.

Based on the calculation of the participation factor, the hybrid leader location information is:

$$HL_i=PC_i\cdot X_i+PC_{best}\cdot X_{best}+PC_k\cdot X_k \quad (11)$$

where HL_i denotes the hybrid leader generated by the *ith* candidate solution and X_k denotes a randomly selected

individual. The *ith* individual position update is based on the guidance of the hybrid leader.

$$x_{ij}^{new,p1}=\begin{cases} x_{ij}+r\left(HL_{ij}+I\,x_{ij}\right) & F_{HL_i}<F_i \\ x_{ij}+r\left(x_{ij}-HL_{ij}\right) & otherwise \end{cases} \quad (12)$$

The HLBO algorithm uses an elite strategy to select individuals as follows:

$$X_i=\begin{cases} X_i^{new,p1} & F_i^{new,p1}<F_i \\ X_i & otherwise \end{cases} \quad (13)$$

Where, $X_i^{new,p1}$ denotes the new position of the *ith* candidate solution, $F_i^{new,p1}$ is the fitness value of $X_i^{new,p1}$, r denotes the random number between $[0,1]$, I is a randomly selected integer from the integer set $\{1,2\}$, and F_{HL_i} denotes the mixed leader fitness value of the *ith* candidate solution.

2) Development (partial) phase: The development phase is a localised search to obtain better solutions in the vicinity of the solution. In the HLBO algorithm, each individual neighbourhood region can allow an individual search to find a better candidate solution. In the development phase, the local search strategy is modelled as follows:

$$x_{ij}^{new,p2}=x_{ij}+(1-2r)\,R\left(1-\frac{t}{T}\right)x_{ij} \quad (14)$$

$$X_i=\begin{cases} X_i^{new,p2} & F_i^{new,p2}<F_i \\ X_i & otherwise \end{cases} \quad (15)$$

Where, $X_i^{new,p2}$ denotes the new position of the local phase of the *ith* candidate solution, $F_i^{new,p2}$ is the fitness value of $X_i^{new,p2}$, R is a constant set to 2, t denotes the current number of iterations, and T is the maximum number of iterations.

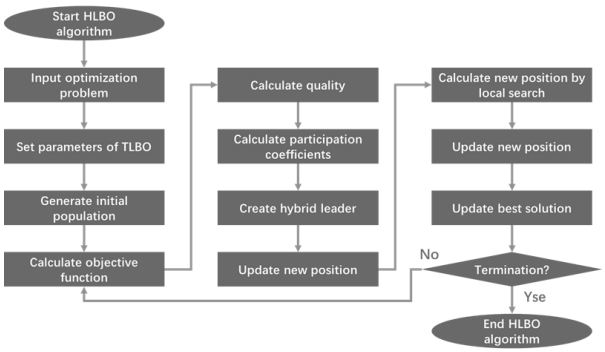

Fig. 5. Flowchart of HLBO algorithm.

3) Process steps: Based on the analysis and description of the above strategies and mechanisms, the flow of the KOA algorithm is shown in Fig. 5.

C. DELM Model based on HLBO Algorithm

1)Coding method: In this paper, the real number coding method is used to encode the hidden layer parameters, which is shown in Fig. 6.

Fig. 6. Encoded DELM parameters.

2) Adaptation function: In this paper, RMSE [24] is used as the adaptation function:

$$RMSE=\sqrt{\left(\sum_{i=1}^{M}\left(\hat{y}_i-y_i\right)^2\right)\Big/M} \quad (16)$$

3) HLBO-DELM methodology: According to the encoding method and fitness function, the flowchart of the deep limit learning machine model step method based on the HLBO algorithm is shown in Fig. 7.

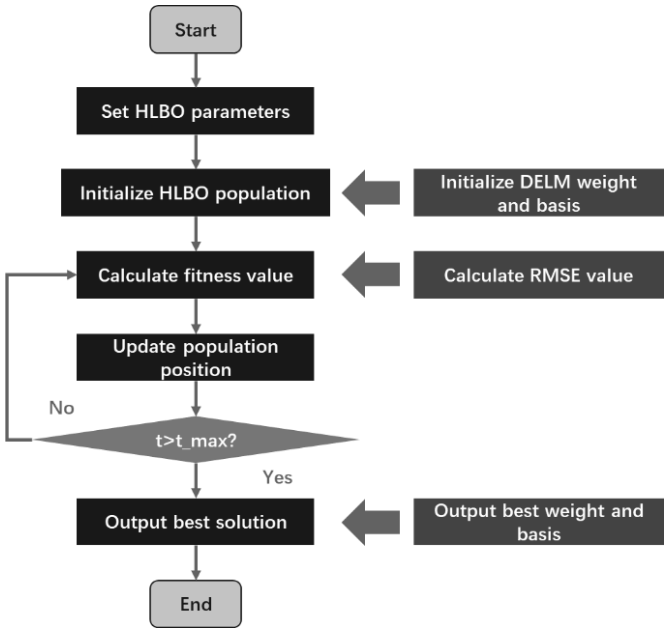

Fig. 7. HLBO-DELM methodology.

D. Application of the HLBO-DELM Model

In order to construct a deformation risk control model for shallow overburden pipe jacking operation tunnels in chalky sand strata, this paper adopts the HLBO-DELM model, by analysing the tunnel deformation risk factors and control indexes, taking the weights and biases of the DELM as the optimisation variables, and taking the RMSE values between the analytical tunnel deformation risk control indexes and the predicted values and the simulated values as the fitness value function, the optimisation strategy of the HLBO algorithm is used to find out the optimal weights and biases of the DELM. The HLBO-DELM model application principle and framework structure are shown in Fig. 8.

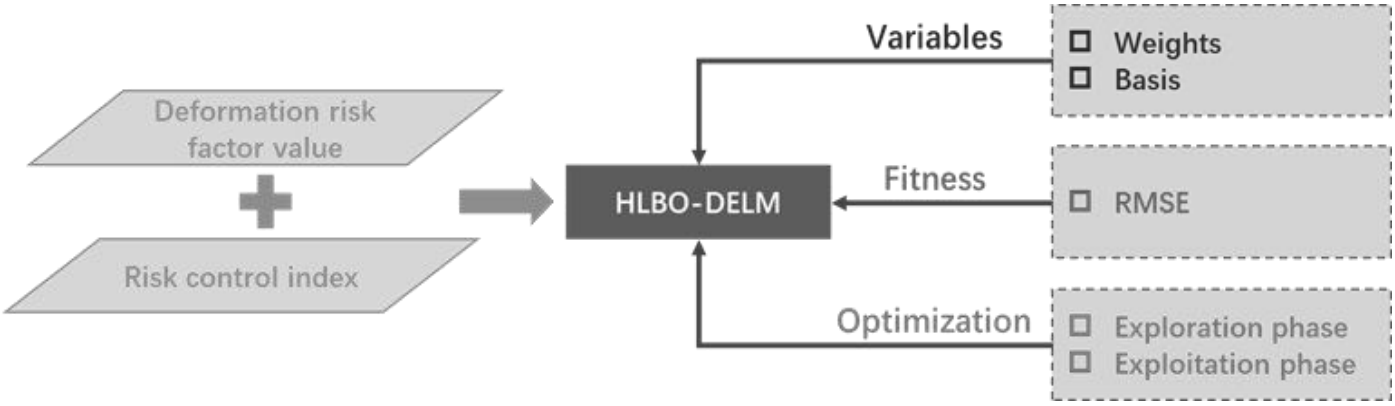

Fig. 8. HLBO-DELM application analysis.

IV. Tunnel Deformation Risk Assessment and Control Process Methodology

Combined with the HLBO-DELM model oriented to the tunnel deformation risk assessment and control problem, this subsection analyses the mapping relationships that need to be constructed in the HLBO-DELM model and gives the tunnel deformation risk assessment and control method flow.

A. Analysis of Model Mapping Relationships

The deformation risk assessment factors of the operation tunnel over shallow cope pipe in chalk stratum are set up from the perspective of ground deformation and existing tunnel deformation, and the deformation control indexes of the operation tunnel over shallow cope pipe in chalk stratum are mainly designed from the control of structural deformation of the existing tunnel and the control of ground surface deformation. The specific construction results are shown in Fig. 9.

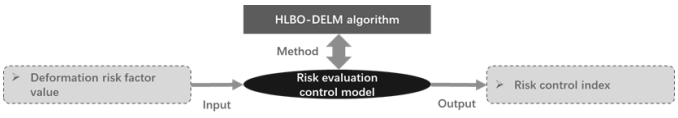

Fig. 9. Schematic diagram of model mapping relationship analysis.

B. Methodological Process

In order to improve the deformation risk assessment and control of the roof-tube up-and-over operation tunnel, this paper investigates the tunnel deformation risk assessment and control method using a combination of intelligent optimisation algorithm and machine learning algorithm, and the specific process is shown in Fig. 10.

As can be seen from Fig. 10, in the construction risk assessment and control scheme of the top tube over operation tunnel, through analysing the deformation risk factors and risk control index set of the top tube over operation tunnel, pre-processing the raw data, combining with HLBO-DELM, constructing the deformation risk assessment and control model of the top tube over operation tunnel, predicting and analysing the amount of deformation control, and improving the precision and accuracy of risk control.

Step 1: Identify and analyse the deformation risk factors of the top tube over the operational tunnel by using expert consultation, experimental demonstration and work breakdown structure method;

Step 2: Analyse and design a set of deformation risk control indicators for the top tube over operational tunnels in terms of both deformation of existing tunnels and deformation of the ground;

Step 3: Construct a sample set of labelled deformation risk factor-risk control indicators;

Step 3: Normalise the original data samples using techniques such as outlier removal, missing value supplementation, normalisation, etc., and perform feature extraction and dimensionality reduction of the input vectors using the Kernel Principal Component Analysis (KPCA) [25] method;

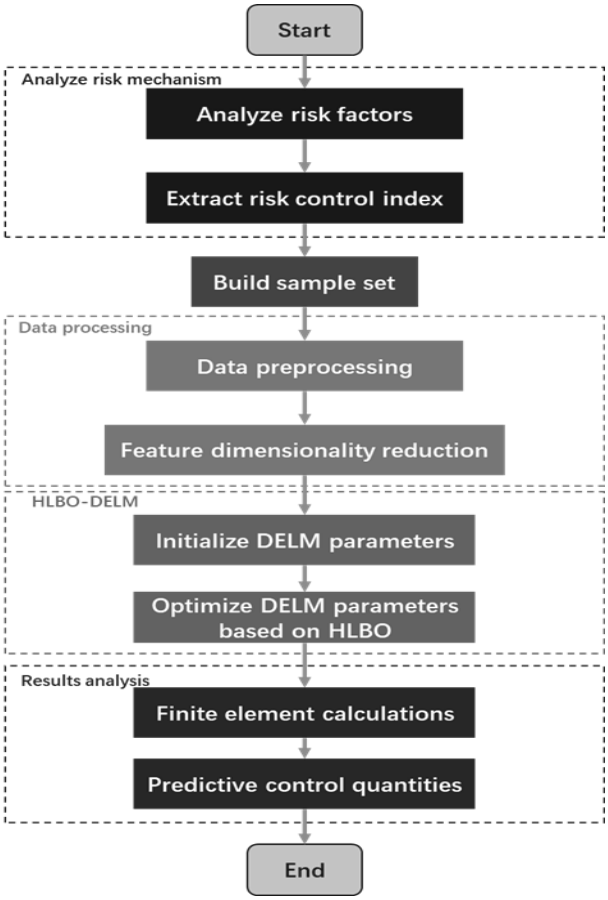

Fig. 10. Flow of tunnel deformation risk assessment and control method.

Step 4: Combine the HLBO-DELM algorithm to construct a deformation risk assessment and control model for the top tube over operation tunnel;

Step 5: Numerical Analysis of Risk Control Measures Experimental Finite Element Computational Models [26] A certain number of samples are constructed and divided into training set, validation set, and testing set;

Step 6: Train the model, analyse the results of the test set, and at the same time collect the project engineering risk factors and input them into the assessment and control model to obtain the deformation risk control index value of the top tube over the operational tunnel.

V. Analysis of Numerical Experiments

A. Experimental Setup

In order to verify the effectiveness and feasibility of the deformation risk assessment and control algorithm of the pipe jacking over operation tunnel proposed in this paper, this paper takes the project of close crossing over Metro Line 9 tunnel and side crossing over Hanghai Intercity Tunnel of Xinfeng Road Underpass in Hangzhou as an analysis sample, and selects DELM, PSO-DELM, GWO-DELM, HHO-DELM, WOA-DELM and HLBO-DELM to compare with the algorithms. algorithms for comparison.

1) Algorithm parameter setting: In Table III, DELM uses Moore-Penrose generalised inverse matrix to solve the optimal structural parameters, PSO-DELM, GWO-DELM, HHO-DELM, WOA-DELM and HLBO-DELM use intelligent optimisation algorithm to solve the optimal structural parameters, the maximum number of iterations of intelligent optimisation algorithm is 100, the number of population counts is 50, and the number of hidden layers is 2.

TABLE III. Comparison Algorithm Parameter Settings

Arithmetic	Parameterisation
DELM	Two hidden layers with 30, 30 nodes in each layer
PSO-DELM	Vmax=30, Vmin=-30, r=0.5
GWO-DELM	GWO algorithm a control parameters using a linear decreasing strategy
HHO-DELM	E0 in the range (-1, 1)
WOA-DELM	The WOA algorithm a decreases from 2 to 0, and the spiral shape parameter is 1.
HLBO-DELM	r denotes a random number between 0 and 1 and I denotes a randomly chosen integer of {1,2}

2) Environmental settings: The experimental simulation environment is Win 10, the risk assessment algorithm programming language Python 3.8, and the structural numerical analyses are performed using Midas GTS finite element software.

B. Analysis of Results

1) Numerical analysis of structures: Using the software for pipe jacking construction simulation, the calculation results after the jacking advancement in the characteristic working condition are shown in Table IV. As can be seen from Table IV, the largest vertical deformation in the deformation of the tunnel structure of Line 9 is the bulge of 4.86mm when completing the construction of the upper span, which occurs in the tunnel tube sheet of the downstream line of Line 9, as shown in Fig. 15. Since the final bulge deformation in this case is due to ground loss and subsequent deformation of the ground, the tunnel bulge deformation will be smaller than the final deformation of 4.86mm when the roof tube is jacked through the tunnel directly above the Line 9 tunnel. The maximum horizontal deformation of the metro tunnel is 0.70mm, while the deformation of the Hanghai Intercity Tunnel is very small compared with that of the metro tunnel, with the maximum horizontal deformation and vertical uplift of 0.49mm and 0.83mm, respectively. according to the results of the calculation, the deformation of the two operating tunnels meets the control requirement of 5mm. The difference settlement at the junction between the tunnel section and the station is small.

2) Parametric analysis: The specific results of the analysis of the number of network hidden layer nodes parameter are shown in Fig. 11 and Fig. 12. From Fig. 11, it can be seen that the number of network hidden layer nodes increases, the accuracy of deformation risk assessment and control increases,

and when the number of network hidden layer nodes increases to 100, the deformation risk assessment and control algorithm RMSE is minimum. From Fig. 12, it can be seen that the number of network hidden layer nodes of DELM increases, and the control time of each algorithm increases; the assessment and control prediction time of the HLBO-DELM model is smaller than that of other models. In summary, the number of hidden layer nodes of DBN network selected in this paper is 100.

3) Example analysis: This subsection compares the performance of the DELM, PSO-DELM, GWO-DELM, HHO-DELM, WOA-DELM and HLBO-DELM methods using the numerical simulation test set.

Firstly, continuous automated monitoring of the Metro Line 9 tunnel was carried out during the implementation of the jacking crossing site and subsequent deformation stabilisation, and the structural deformation of the tunnel after completion of the jacking upper span construction is shown in Fig. 18.

TABLE IV. STRUCTURAL DEFORMATION RESULTS OF OPERATIONAL TUNNELS DURING THE CONSTRUCTION PROCESS

working condition	Line 9 tunnel/mm		Hanghai Intercity Tunnel/mm		Differential settlement at junction/mm	
	horizontal	vertical	horizontal	vertical	Line 9 Interval	Hang Hai District
Shaft Phase 1	0.34	0.22	0.32	0.14	-	-
pipe jacking	0.36	4.86	0.49	0.83	-	-
Shaft Phase 2	0.70	4.64	0.40	0.51	0.02	0.02

Fig. 13 and Fig. 14 give the monitoring results of the roadbed displacement in the tunnel. From Fig. 13 and Fig. 14, it can be seen that the maximum value of vertical displacement in the metro tunnel is 4.0mm, which occurs in the bed measurement point of the downstream line, and the displacement of the downstream line traversed by the jacking tube first is generally larger than that of the upstream line; the maximum value of horizontal displacement is 2.7mm, which occurs in the bed measurement point of the upstream line. The maximum horizontal displacement was 2.7mm, which appeared at the upstream line bed measurement point. The larger values of vertical and horizontal displacements in the upstream and downstream lines were distributed in the area where the jacking pipe traversed, which indicated that the jacking pipe's close spanning construction had a greater impact on the operation tunnel, and the area within 25m directly below the crossing belonged to the strong impact area; the distance from this boundary to 50m had a weaker impact and belonged to the weak impact area; and the area outside of 50m belonged to the non-influence area.

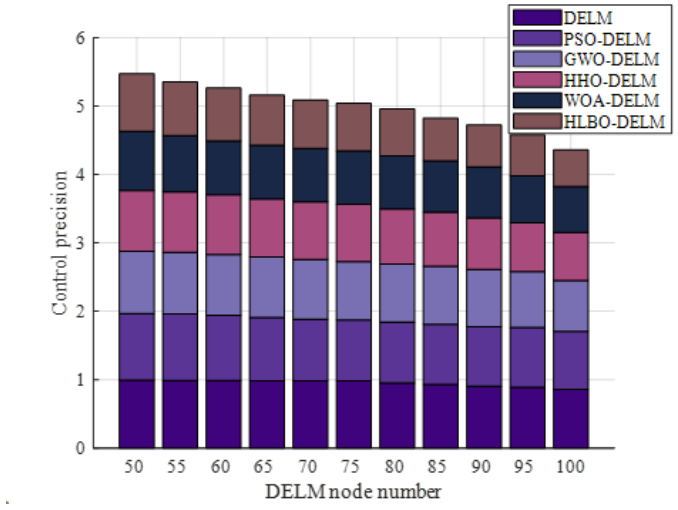

Fig. 11. Effect of different number of hidden layer nodes on the accuracy of control algorithm for deformation risk assessment.

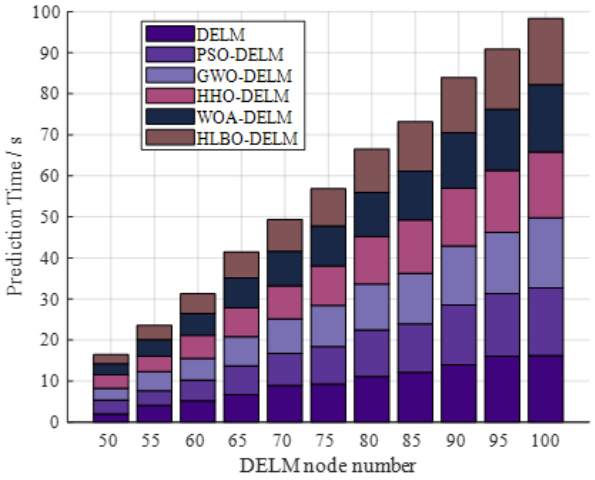

Fig. 12. Effect of different number of hidden layer nodes on control algorithm time for deformation risk assessment.

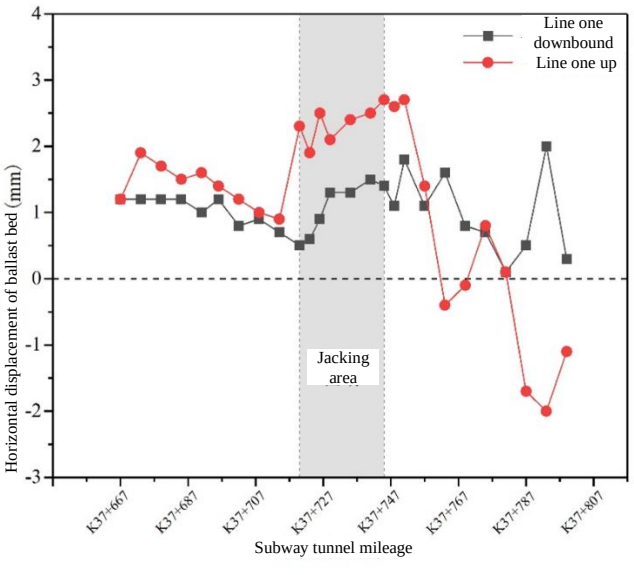

Fig. 14. Horizontal displacement of tunnel bed of Line 9 metro tunnel.

VI. Conclusion and Outlook

As the key technology of deformation risk assessment-control in the construction of roof-tube span, the deformation risk assessment-control algorithm not only reduces the subjectivity and empirical nature of the human-designed control scheme, but also constructs a complex mapping relationship between the risk identification factors and the risk control strategy. In this paper, a deformation risk assessment and control scheme is designed by analyzing the construction process of pipe jacking tunnels and the deformation risk mechanism. Meanwhile, a deformation risk assessment and control algorithm based on TLBO-DELM is proposed for the mapping relationship of the deformation risk assessment and control model, which is applied to the deformation risk and control scheme of pipe jacking up and over operation tunnels with shallow overburden in chalky sand layer, and the effectiveness of the proposed TLBO-DELM model algorithm is analyzed, and the effectiveness of the proposed TLBO-DELM model algorithm is compared with that of the other models. The effectiveness of the proposed TLBO-DELM model algorithm is analysed, and by comparing other model algorithms, it is verified that the deformation risk assessment and control model based on the TLBO-DELM algorithm has a high control prediction accuracy.

While the HLBO-DELM model has shown promise, several limitations remain. Firstly, its generalizability across different geological conditions, such as expansive soils or hard rock layers, requires further validation; performance may vary significantly in these settings. Additionally, the current study relies primarily on simulated data for model training, with limited use of real-world engineering data, which may reduce the model's robustness when applied to diverse tunnel construction projects. The algorithm's computational efficiency and real-time application also pose challenges, particularly in high-dimensional data processing and timely monitoring feedback.

To address these issues, future research should prioritize expanding the dataset by incorporating monitoring data from diverse geological contexts and construction projects, improving the model's adaptability and prediction accuracy. Enhancements in the algorithm's structure—potentially through hybridization with other optimization methods like genetic algorithms or particle swarm optimization—could strengthen its global search capability and computational speed. Moreover, integrating the HLBO-DELM model within a real-time monitoring and alert system would allow for proactive risk detection and control, facilitating automated responses to potential deformation risks in active construction sites.

Scalp Disorder Imaging: How Deep Learning and Explainable Artificial Intelligence are Revolutionizing Diagnosis and Treatment

Vinh Quang Tran[1], Haewon Byeon[2]*
Department of Digital Anti-Aging Healthcare (BK21), Inje University, Gimhae 50834, South Korea[1]
Department of Medical Bigdata, Inje Medical Big Data Research Center, Inje University, Gimhae 50834, South Korea[2]

***Abstract*—Scalp disorders, affecting millions worldwide, significantly impact both physical and mental health. Deep learning has emerged as a promising tool for automated diagnosis, but ensuring model transparency and reliability is crucial. This review explores the integration of explainable AI (XAI) techniques to enhance the interpretability of deep learning models in scalp disorder diagnosis. We analyzed recent studies employing deep learning models to classify scalp disorders from image data and used XAI methods to understand the models' decision-making processes and identify potential biases. While deep learning has shown promising results, challenges such as data quality and model interpretability persist. Future research should focus on expanding the capabilities of deep learning models for real-time detection and severity prediction, while addressing limitations in data diversity and ensuring the generalizability of models across different populations. The integration of XAI techniques is essential for fostering trust in AI-powered scalp disease diagnosis and facilitating their widespread adoption in clinical practice.**

***Keywords*—Scalp disorders; artificial intelligence; explainable artificial intelligence; deep learning; interpretability**

I. Introduction

In recent times, the integration of AI in healthcare has transitioned from theoretical research to practical implementations in clinical settings. This includes areas such as telemedicine, the utilization of robots in surgical settings, and the management of electronic health records. Medical imaging stands out as one of the most recognized applications, constituting 90% of all healthcare data [1]. AI demonstrates promising capabilities in diagnosing and classifying various diseases, particularly in dermatological conditions, where it assists in the identification and categorization of skin issues, including conditions related to the scalp and hair.

Despite these advances, a significant gap in research remains regarding the deployment of deep learning (DL) models in medical imaging, particularly in clinical settings. While current DL models, inspired by neural networks in the human brain, include notable architectures such as Faster R-CNN [2], VGG-net [3], and those based on ImageNet [4] offer impressive accuracy in tasks such as image recognition and classification. their lack of interpretability presents a major challenge, especially in complex areas like dermatology and scalp and hair disorder diagnostics [5]. This issue has spurred growing interest in the role of eXplainable AI (XAI), which aims to make the decision processes of DL models transparent. XAI is not only beneficial for machine learning (ML) researchers but is also vital for clinicians and patients who rely on these models to make informed healthcare decisions. By making AI more interpretable, XAI fosters trust in clinical applications, addressing a crucial need for greater transparency in AI-driven diagnostics.

This review aims to comprehensively examine the progress and challenges in utilizing XAI and DL methodologies for analyzing medical imaging data, specifically for scalp and hair disorder diagnostics. Through an extensive review of existing studies, this paper will highlight the contributions and limitations of various DL models applied to dermatological imaging and evaluate the effectiveness of XAI techniques in enhancing their interpretability and clinical relevance. This examination includes an analysis of how XAI techniques can improve transparency in AI-based diagnostics, particularly for non-expert stakeholders, such as clinicians and patients, who require comprehensible insights into AI-driven assessments.

The significance of this review lies in addressing the critical need for interpretable AI systems in dermatology, with a focus on the largely unexplored domain of scalp and hair disorder imaging. By synthesizing existing findings, this paper aims to provide a reference for developing clinically applicable AI frameworks that enhance both accuracy and interpretability. Ultimately, this review not only consolidates current knowledge but also serves as a foundation for future research aimed at creating trustworthy and effective AI-driven diagnostic tools across dermatological and broader medical applications.

The structure of this paper is organized as follows: Section II details the materials and methods applied in various studies, specifically focusing on the deep learning and XAI techniques employed in scalp and hair disorder diagnostics. Section III presents the results gathered from these studies, offering insights into the effectiveness of each approach. Section IV provides a discussion that highlights both the strengths and limitations of the reviewed studies, analyzing their contributions and identifying potential gaps. Finally, Section V concludes the paper, summarizing key findings and suggesting directions for future research.

II. Materials and Method

A. Artificial Intelligence in Scalp Disorder Diagnosis

Scalp disorders are recognized as dermatological or medical issues associated with the well-being of the scalp and hair, attributed to the abundance of hair follicles and elevated sebum production. These disorders may include dandruff, seborrheic, folliculitis, tinea capitis, psoriasis, are widespread conditions affecting adults globally. Scalp psoriasis, impacting approximately 2% of the Western population [6], and dandruff, with a global prevalence of around 50% [7], contribute significantly to these concerns. These conditions not only affect physical health but also exert a substantial influence on mental well-being, contributing to stress, anxiety, or depression [8], [9]. This impact is particularly noticeable in societies where significant of appearance holds considerable weight, as observed in places like South Korea, where lookism can have implications for health [10].

Therefore, the diagnosis and classification are crucial, as scalp disorders frequently exhibit similar clinical manifestations [11]. The way to diagnosis scalp related-problems could be use various data type, including: medical imaging, clinical notes, and scalp biopsy laboratory test result; however, scalps biopsies can cause risk such as bleeding, pain, and infection meanwhile clinical notes may be subjective and vary in quality, potentially leading to biases or inaccuracies in the diagnostic process among these approaches, scalp imaging stands out as it offers a non-invasive and direct visualization of the scalp. Advanced imaging technologies like dermoscopy (trichoscopy) and optical coherence tomography (OCT), enhance the diagnostic capabilities by providing magnified insights into structural and morphological changes at a microscopic level [12]. For dermatologists, this means enhanced diagnostic capabilities without the associated risks of scalp biopsies. On the patient's side, the non-invasiveness and direct visual feedback contribute to a more comfortable and accessible diagnostic experience. However, a concerning trend is observed, where people frequently seek diagnoses from non-professionals in hair salons rather than consulting dermatologists. This trend has contributed to a worsening state in the overall condition of scalp problems.

In order to overcome these challenges, the advances of AI applications in dermatology have introduced a transformative model shift, revolutionizing how we approach the diagnosis and treatment of scalp hair-related problems. AI, including ML and DL, has become widespread components in any medical analysis workflows and facilitating the path for the real-world diagnostic integration of solutions based on AI [13]. In the context of scalp health, the application of AI holds the promise of not only enhancing precision in identifying and classifying various scalp conditions but also revolutionizing the therapeutic strategies employed, such as providing an opportunity for patients to engage in self-diagnosis [14]. This intersection of AI and dermatology prompts a renewed research interest, particularly in the early detection and diagnosis of scalp hair diseases.

However, complex ML algorithms pose challenges in comprehending their decision-making processes, specifically in complicated tasks such as scalp hair imaging classification. In order to effectively tackle this issue, the implementation of XAI presents a distinctive opportunity, benefiting not only AI experts but also non-experts like medical doctors and patients [15].

B. Advanced Machine Learning in Scalp Imaging

Scalp imaging can be categorized into various modalities, each offering unique insights into different aspects of scalp health. Dermoscopy, or surface microscopy [16], utilizes a handheld device with magnification and lighting to visualize pigmented cutaneous lesions and assess hair follicles, patterns of hair loss, and various scalp conditions. OCT captures high-resolution, cross-sectional images of biological tissues, revealing structural changes in the skin and hair follicles. In Vivo Reflectance Confocal Microscopy (RCM) provides live visualization [17] of cellular structures in the scalp at a high resolution, generated high-quality images of the hair shaft junctions at 1µm spacing, facilitating a comprehensive analysis of the hair structure. In the field of ML and DL, several studies have predominantly utilized portable magnification imaging microscopes [2], [18], [19], [20] or dermoscopy data [21], [22], [23], in comparison to OCT studies [24] and RCM, due to higher costs and challenges in obtaining data. Additionally, limited training programs for RCM [25] contribute to subjective variability in diagnoses.

C. Limitations of Machine Learning in Scalp Disorder Imaging

Since 2014, studies employing ML for scalp imaging classification have evolved, transitioning from unsupervised learning approaches [26], [27] to more complex deep-learning based method [3], [18], [28]. These studies have utilized datasets ranging from small to mid-size, achieving accuracies typically in the mid-80s to low 90s. However, the domain of scalp disorder imaging still faces persistent challenges. Notably in contrast to research studies focused on other skin areas. In these areas, datasets commonly surpass 100,000 images [29], [30]. Moreover, the datasets within scalp disorder imaging exhibit imbalances, further compounded by a deficiency in interpretability and explainability.

As a result, these challenges make it difficult to smoothly apply these technologies in a clinical setting. To address these issues, there is a pressing need to explore new research avenues, particularly in comparison to the advancements made in skin disease classification within the dermatology realm.

D. Advancements in Integrating Deep Learning Models and Explainable AI for Scalp Disorder Imaging

Numerous researchers have dedicated their efforts to advance the deployment of ML models for the classification of scalp hair disorders. The evolution of ML into DL models, including the integration of XAI has been revolutionary. This commitment involves implementing XAI to make it possible to identify and address any potential biases in the model's decision-making process, aiming to increase trust for clinical applications. The following showcases how these advancements can be presented:

1) Convolutional neural network variations model: With the increasing use of DL models in imaging classification tasks,

the foundational technique of Convolutional Neural Networks (CNNs) plays a pivotal role in developing recent models. CNNs consist of various layers, such as convolutional, activation, and pooling layers. The inclusion of one or more Fully-Connected layers (FC) in the network is essential for generating final output predictions. Additionally, dropout layers have been incorporated into the architecture to address the overfitting issue and enhance the model's robustness. The strategic use of dropout layers aids in preventing the network from relying too heavily on specific connections during training, promoting a more generalized and resilient model.

To demonstrate how different models respond to scalp imaging disorder classification tasks, well-known models have been applied. These models can be categorized into two main architectures: one-stage architecture and two-stage architecture. In the two-stage approach, exemplified by Faster R-CNN (Region-based Convolutional Neural Network) [31], the Region Proposal Network (RPN) represents a significant advancement. By sharing convolutional layers with the object detection network, the RPN efficiently generates region proposals directly from the convolutional feature maps, avoiding the need for external proposal generation methods. The RPN evaluates a set of anchor boxes at different scales and aspect ratios, predicting their likelihood of containing an object and refining their coordinates.

On the other hand, one-stage CNNs follow a more streamlined approach, performing simultaneous object detection and localization without a separate region proposal stage. These models directly predict object localization and classification within an image, making them efficient for real-time object detection. However, it's essential to note that they may not always achieve the same level of accuracy as two-stage models in certain situations. One example of one-stage CNNs is the Single Shot MultiBox Detector (SSD) [32].

2) Vision transformers (ViTs): Traditional CNN architectures rely on convolutional layers to extract features from images. These layers progressively learn to identify low-level features like edges and textures, ultimately building towards higher-level features for classification. However, a recent advancement in image classification is the emergence of Vision Transformers (ViTs) [33]. Unlike CNNs, ViTs forego convolutional layers entirely. Instead, they split the image into patches, process them using self-attention mechanisms, and progressively learn relationships between different image regions. This approach allows ViTs to potentially capture long-range dependencies within images that might be missed by CNNs with localized filters. Fig. 1 represents the concept of ViT proposed in Dosovitskiy et al.'s study [33].

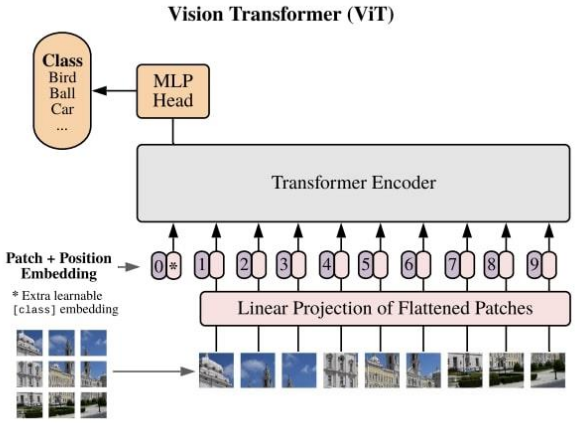

Fig. 1. The concept of vision transformers.

3) Gradient-weighted class activation mapping (Grad-CAM): Ramprasaath and his team [34] introduced a technique aimed at providing visual representations of the decision-making process of deep neural networks, particularly convolutional network. At a high level, the approach involves processing an image as input data and creating a model that is truncated at a specific layer to generate visual representations of the areas in input images that have the most impact on the network's predictions.

Operationally, the method conducts a forward pass of the input image through the network, and the subsequent prediction triggers a backward pass to the sensitivity of the predicted class score to changes in the feature maps. Global Average Pooling (GAP) is then applied to globally average these gradients across each feature map, generating a class-discriminative localization map. This map is utilized as weights to compute a weighted sum of the feature maps, emphasizing regions crucial for the prediction. Following a Rectified Linear Unit (ReLU) activation and up-sampling to match the input image's dimensions, the final heatmap is produced, producing visual maps to show important zones influencing the network's decision.

Nevertheless, Grad-CAM faces limitations in highlighting fine-grained features due to its inability for pixel-level gradient visualization. The down-sampling during convolution and the subsequent need for up-sampling via bilinear interpolation result in a loss of resolution, impacting the accuracy of explanation results. Additionally, inconsistencies between Grad-CAM and the actual model behavior diminish the reliability of its interpretations. These challenges underscore the necessity for improvements in Grad-CAM to enhance precision and alignment with the intricacies of the original model. Fig. 2 represents the concept of Grad-CAM proposed in Ramprasaath et al.'s study [35].

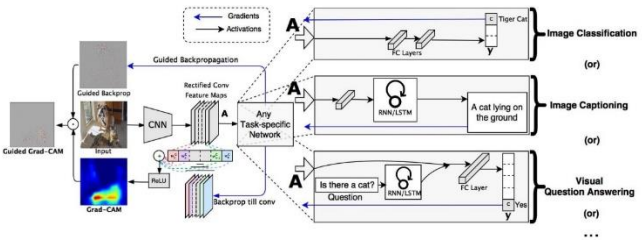

Fig. 2. The overview concept of Grad-CAM by Ramprasaath et al. [34].

4) Locally interpretable model-agnostic explanation (LIME): Local Interpretable Model-agnostic Explanations (LIME) was introduced in 2016 by Ribero et al. [35]. In the pursuit of model-agnostic interpretability, LIME adopts a unique approach by perturbing the input and observing how the predictions change. The essence of LIME lies in approximating the black-box model locally, in the vicinity of the prediction to be explained, by constructing an interpretable model (e.g., a linear model with only a few non-zero coefficients). This is achieved by generating perturbations of the original instance, such as removing words or hiding parts of an image.

The key intuition behind LIME is rooted in the understanding that it is more suitable to approximate a black-box model locally than globally. This involves weighting the perturbed instances based on their similarity to the instance being explained. Consider the scenario of explaining predictions in an image. LIME transforms the image into interpretable components, such as contiguous super-pixels. A collection of manipulated instances is created by switching off certain interpretable components. For each perturbed instance, the model's prediction is obtained. A locally weighted, simple (linear) model is then learned on this dataset, prioritizing instances that possess a greater similarity to the original image. The produced explanation highlights the interpretable components that contribute most heavily to the model's predictions, simultaneously downplaying the prominence of less relevant features. The illustration of the LIME concept is presented in Fig. 3.

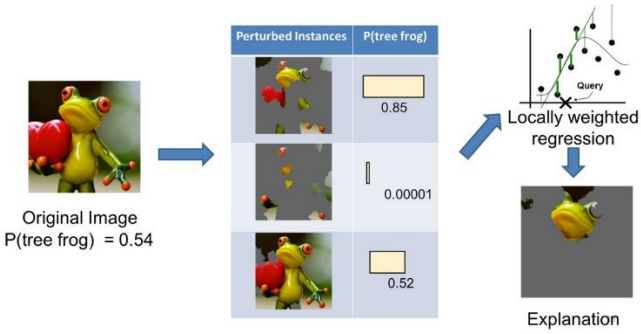

Fig. 3. LIME prediction explained by Ribero et al.

5) Occlusion sensitivity: Occlusion Sensitivity, as introduced by Zeiler and Fergus [36] in their paper on visualization techniques for conventional neural networks, is a method centered around systematically occluding or blocking individual regions of an input image to determine their influence on the model's prediction. The primary concept involves assessing how the probability score of the network changes when specific regions of the image are obscured.

By occluding various portions of the input image and observing corresponding shifts in the model's response, this technique facilitates the exploration of the model's reliance on particular regions or features for accurate predictions. If blocking certain areas significantly influences the model's accuracy, it suggests the importance of the occluded regions in the model's comprehension of the input. However, occlusion sensitivity might be computationally intensive, especially when evaluating multiple occlusions and it may not capture complex non-linear relationships.

6) Attention rollout: Similar to occlusion sensitivity, attention rollout offers a window into the decision-making process of ViT models. However, unlike occlusion sensitivity which physically blocks parts of the image, attention rollout delves deeper into the model's internal computations. Central to the functionality of ViT models are "attention" mechanisms, which enable the model to assign importance scores to various image regions. Attention allows the model to understand the relationships between different parts of an image, assigning importance scores to various regions. Attention rollout builds upon this by iteratively analyzing these attention scores.

Attention rollout starts with the final layer's attention maps, highlighting crucial image regions for the prediction. It then uses these maps to "roll back" through the network, revealing lower-level features (like edges or textures) that ultimately contributed to the final scores. By analyzing these intermediate maps, we gain insights into how the model builds its understanding of the image. Attention rollout offers advantages over occlusion sensitivity: it's computationally efficient and can capture intricate relationships between image regions. However, it doesn't provide a definitive explanation for the model's reasoning process.

III. Results

A. Studies of Scalp Disorder Diagnosis based on XAI and Deep Learning

Although the integration of DL and XAI has found extensive application in various healthcare research domains, its utilization in scalp imaging remains a gap in research. There is a clear necessity for additional research on the implementation of XAI in scalp imaging to advance its capabilities. As outlined in Table I, recent studies demonstrate a comparative analysis with conventional models, emphasizing the potential for enhancement and innovation in the domain of scalp disorder imaging. Table II illustrated Heng et al. research [37] based on two experiments. Tables III and IV display the results of the research conducted by Jeong et al. and Ha et al., respectively.

IV. Discussion

The Shih et al.'s seminal study [26] introduces a pioneering system for automated hair counting in scalp images, addressing challenges such as oily spots, wavy or curly textures, and overlapping hairs through a morphology-based approach, multi-scale line detection, and relaxation labeling. Their

approach leverages a combination of techniques: morphology-based filtering, multi-scale line detection, and relaxation labeling. While evaluated on a limited dataset of 40 images, the system achieves remarkable results with an average precision of 98.0% and recall of 85.6%. Despite the limitations in data size and algorithmic complexity, this study represents a significant pioneering effort in the field of medical image analysis using ML. It paves the way for further advancements in automated hair analysis.

With more focus on telehealth as an application of scalp hair diagnosis, Su et al.'s study [3] introduces a system to automatically identify scalp conditions. The system offers potential benefits like faster diagnosis and utilizes a cloud platform for data collection and analysis, potentially improving accuracy over time. However, some limitations need to be addressed. The system focuses on surface-level conditions like dandruff and doesn't delve into potentially linked medical issues. Additionally, details about the training data used for the DL model are missing. Future work should explore incorporating analysis of potentially linked medical problems, increasing transparency in the system's decision-making process, and integrating with telehealth platforms for wider accessibility.

In a simultaneous effort, Wang et al. utilized a dataset comprising 1000 images, with 880 designated for training and 220 for testing. The scalp images were captured using a 200x magnification camera and categorized into four types of diseases. The researchers also introduced a novel model named ImageNet-VGG-f Bag of Words (BOW), which employ ImageNet-VGG pre-trained model[42] to evaluate its predictive capabilities in comparison to other ML classification algorithms. The achieved accuracy for this model was reported at 89.77%. This accuracy significantly outperforms other ML-based methodologies in the research, such as BOW with support vector machines (SVM) at 80.50% and pyramid histogram of oriented gradients (PHOG) with SVM at 53.0%. These findings underscore the promising potential of integrating hybrid DL approaches in the field of scalp hair imaging diagnosis over conventional ML methods.

Chang et al. introduced ScalpEye [2], a comprehensive system for scalp analysis that represents a significant advancement in scalp imaging. ScalpEye integrates medical imaging with AI analysis, offering a user-friendly mobile app for image capture, a cloud server for model improvement, a centralized platform for system management, and a portable microscope for high-quality image acquisition. The study utilized nearly 2200 scalp images from the COCO dataset, categorized into four common scalp conditions. Three deep learning models were employed for analysis: Faster R-CNN Inception_v2, SSD Inception_v2, and a novel model called Faster R-CNN Inception_ResNet_v2_Atrous. This new model combines Faster R-CNN with Inception_ResNet_v2_Atrous, which utilizes Atrous convolution for a stable receptive field size. This stability allows for better fine-tuning and more accurate predictions. Consequently, the Faster R-CNN Inception_ResNet_v2_Atrous achieved an impressive mean Average Precision (mAP) of 91.75%. While ScalpEye prioritizes both data quality and DL models within a cloud-based telehealth system, a key challenge remains. Annotating large datasets requires significant manpower and expertise. This raises the question of how the system will handle future large-scale datasets.

In Chow et al.'s research [38], the application of the CNN in the last run achieved an impressive accuracy of 96.30%. To gain a more profound insight into the factors that influence the model's classification of hair health, the researchers employed the LIME technique. Upon the analyzing of LIME, several observations were made. For instance, in the case of alopecia areata, a patchy bald condition, the heatmap coincided with the bald patches, although there were some inexplicable identifications in the right corner. The study concluded that despite achieving a remarkable accuracy of 96.30%, the application of LIME highlighted potential biases in the model's decision-making process, suggesting the need for further investigation and refinement. Further studies are crucial to identify and eliminate potential biases that could affect the model's biases and generalizability, potentially through image binarization and randomization techniques.

In the study conducted by Heng et al. [37], two experiments were conducted to assess the performance of dermatological image classification. The first experiment utilized the Dernet dataset, comprising 240 images with categories such as acne keloidalis, alopecia, and others. The second experiment involved a combination of Dermnet and Figaro-1k datasets[43], totaling 485 images, categorized as healthy and unhealthy. Two pre-trained models, Inception-v3[44] and SqueezeNet [45], using the RMSProp optimizer, were employed for these experiments. For the first experiment using Inception-v3, the model achieved an accuracy of 63.9%. In the second experiment, SqueezeNet was utilized, resulting in an impressive accuracy of 100%. However, despite this high accuracy, the integration of three XAI techniques, Grad-CAM, LIME, and occlusion sensitivity, revealed some noteworthy findings. In the second experiment, the classification was influenced by unrelated areas, casting doubt on the reliability of the 100% accuracy. On the other hand, the first experiment suggested that the model's predictions were primarily affected by the forehead area, highlighting the importance of specific regions in making final decisions. However, despite this emphasis, the accuracy achieved was only 63.9%.

TABLE I. SUMMARIZING AI STUDIES IN SCALP DISORDER DIAGNOSIS

Article	Dataset	Model	Results
Shih et al. (2015)[26]	40 scale images	Hair-bundling algorithm	98.0% of precision 85.56% of recall
Su et al (2018)[3]	Not mentioned	VGG-net	90.9% of accuracy
Wang et al. (2018)[4]	1000 images (880 training images/ 220 testing images)	ImageNet-VGG-f model Bag of Words	89.77% of accuracy
Chang et al. (2020)[2]	2198 images	Faster R-CNN based model	91.75% in mAP
Chow et al. (2022)[38]	1079 images (864 training image, 215 validation image)	LIME, CNN	96.63% of accuracy
Heng et al. (2023)[37]	DermNet dataset: 240 images Figaro-1k dataset: 245 images	Integrating Grad-CAM/LIME/Occlusion Sensitivity with multiple DL models	Illustrated in Table II
Jeong et al. (2023)[39]	100,000 images (x60)	EfficientNet-B6	Illustrated in Table IV
Roy et al. (2023)[40]	150 images	CNN	91.1% of accuracy
Ha et al. (2024)[41]	100,000 images (x60)	Attention rollout with ViT-B/16	Illustrated in Table III

TABLE II. HENG ET AL. RESULT [37] BASED ON TWO EXPERIMENTS

Scalp Symptoms	Number of images	Accuracy (%)
Dryness	17,434	91.3
Oiliness	80,416	90.5
Erythema	4,592	89.6
Folliculitis	4,592	87.6
Dandruff	40,482	87.3
Hair loss	25,682	89.0

In Roy et al.'s concurrent research [40], a dataset comprising scalp images from multiple sources was collected, consisting of 150 images depicting three different diseases: alopecia, psoriasis, and folliculitis. The research employed CNN, and after experimenting with 25 different combinations, a neural network architecture with three hidden layers, one input layer, and one output layer was chosen as the final design. The training process used a batch size of 16 for each batch over 50 epochs, and the preprocessed data was divided into a 70-30 train-test split for training and validation purposes. The model was constructed with 256 inputs, a 3x3 square kernel, 3 output units, and a Softmax output layer. The model achieved a training accuracy of 96.2% and a validation accuracy of 91.1%. This approach demonstrates a careful exploration of model architecture variations, leading to the selection of an optimal configuration. The high training and validation accuracies indicate the effectiveness of the chosen model in learning and generalizing from. However, it is essential to consider the potential impact of overfitting and the model's performance on unseen data.

TABLE III. RESULTS OF JEONG ET AL.'S RESEARCH UTILIZING EFFICIENT NET-B6 MODEL

Dataset and Model	DermNet and Inception-V3	Figaro-1k and SqueezeNet
Training accuracy (%)	98.4	100.0
Validation accuracy (%)	63.9	100.0
Validation sensitivity (%)	88.9	100.0

TABLE IV. RESULTS OF HA ET AL.'S RESEARCH UTILIZING THE VIT-B/16 MODEL

Scalp Symptoms	Number of images	Accuracy (%)	F1-Score (%)	Precision (%)	Recall (%)
Dryness	17,434	77.7	76.7	77.0	76.9
Oiliness	80,416	69.0	70.1	69.7	70.6
Erythema	4,592	81.4	81.6	81.5	81.7
Folliculitis	4,592	82.3	82.5	82.3	82.6
Dandruff	40,482	77.1	79.3	79.3	79.3
Hair loss	25,682	82.3	83.1	83.0	83.0

AI-ScalpGrader [39], a DL system designed for scalp diagnosis, offers promise with its detailed classification scheme. Analyzing ten scalp conditions based on seven dermatologist-defined indices, it provides a more comprehensive picture of scalp health compared to limited-scope systems. Additionally, the cloud-based platform facilitates data storage, analysis, and potentially allows remote monitoring of scalp care. However, limitations exist. The system's accuracy, reported to be between 87.3% and 91.3% for various scalp conditions, depends heavily on training data quality and diversity. While a sizeable dataset of 100,000 images is mentioned, details regarding its composition and potential biases such as: F1-score, recall and precision are lacking. Transparency surrounding the verification process is also needed to build trust in the system's reliability. Expanding the training dataset with a wider range of scalp conditions and ethnicities is crucial. Additionally, exploring integration with telehealth platforms could revolutionize access to scalp care services.

One of the latest studies presented in Ha et al.'s research [41] proposes a DL-based intelligent healthcare platform to diagnose six common scalp hair disorders (dryness, oiliness, erythema, folliculitis, dandruff, and hair loss) with the same dataset as Jeon et al.'s study [39]. Distinguishing itself from prior research, this platform not only classifies the presence or absence of a condition but also predicts severity levels ranging from 0 to 3 for each disorder. The study advances the field by encompassing a broader spectrum of scalp conditions, incorporating predictive severity assessment, and integrating XAI techniques for lesion visualization. Moreover, its user-friendly software facilitates convenient self-monitoring at home. However, the authors acknowledge the potential influence of lighting environments on data quality, particularly affecting the classification of oiliness severity. Overall, this study underscores the promising potential of DL and XAI, notably ViT models and attention rollout, in the analysis of scalp health, although further research is imperative to ensure widespread clinical adoption.

In summarize, the pursuit of effective methodologies for scalp imaging and hair disorder diagnosis has led to the establishment of multiple research initiatives. DL techniques have outperformed traditional ML approaches in terms of accuracy, efficiency, and generalizability, showcasing their potential in advancing the field. Nevertheless, the inherent opacity of decision-making processes in DL poses challenges for clinical applications. The integration of XAI techniques, such as LIME, Grad-CAM, SHAP and attention rollout presents promising avenues to address this issue. However, a critical need for further research exists to comprehensively understand how these DL methods interact with wider range of datasets, ensuring their efficacy and reliability in real-world clinical scenarios.

V. Conclusion

In conclusion, our comprehensive review of studies underscores the transformative impact of DL in revolutionizing scalp imaging and advancing the diagnosis of hair disorders, especially with the help of XAI in understanding complex decision-making process. The demonstrated synergy between XAI and DL in handling complex imaging tasks marks a significant advancement. However, the imperative for ongoing research in this domain is encouraged, with the possibility to improve treatments for this global concern. The combination of XAI and DL holds promise not only for professionals but also for non-professionals, offering potential applications in self-diagnosis. Looking forward, the pursuit of further research, particularly in real-time detection, stands to benefit both professionals and individuals, contributing to improved living conditions for those affected by hair scalp diseases. However, several limitations remain. Many studies rely on small, non-representative datasets, limiting generalizability, and the lack of transparency regarding training data raises concerns about potential biases. Additionally, while XAI techniques like LIME, Grad-CAM, and SHAP provide valuable insights into model decision-making, they add computational complexity that may hinder clinical adoption. Some models demonstrate strong performance under controlled conditions but struggle in real-world settings due to variables like lighting and image quality. Moreover, the integration of these systems with telehealth platforms and their ability to predict severity levels across diverse patient populations still require further refinement. Despite these challenges, the combination of DL and XAI offers significant potential for improving the diagnosis and treatment of scalp and hair disorders, but further research is crucial to ensure their efficacy, transparency, and widespread applicability in clinical practice.

***Abstract*—Motion capture technology (MoCap) has emerged as a pivotal innovation, significantly impacting various sectors, including sports. In football training, MoCap is especially crucial for analyzing player movements with precision. Despite its potential, there remains a notable gap in the utilization of MoCap to create motion templates (MTs) that generate extrinsic feedback, particularly in football. This article proposes a comprehensive theoretical framework for evaluating extrinsic feedback in football training through MTs created using MoCap technology and Reverse-Gesture Description Language (R-GDL). The development of this framework involves several key steps: a literature review, acquaintance meetings, interviews, procedural approvals, experimentation, data conversion, MTs creation, and data evaluation. The framework integrates elements such as football players, MoCap systems, raw and processed data, MTs, evaluation processes, and extrinsic feedback models. The main purpose is to harness the full potential of MoCap technology, enhancing the evaluation and improvement of football training activities. By implementing this framework, we aim to revolutionize how football training is analyzed and optimized, providing coaches and players with invaluable insights and feedback.**

***Keywords*—Motion capture; motion templates; football; extrinsic feedback; reverse-gesture description language**

I. Introduction

In the current era of rapid technology revolution, motion capture technology (MoCap) has emerged as an important innovation, profoundly impacting sectors such as sport [1], entertainment [2], healthcare [3] and martial arts [16]. This technology, which digitally records and analyzes movements for comprehensive examination, is distinguished into two types of techniques: marker-based and marker-less systems [3,4,17]. Marker-based systems, which involve attaching physical markers to an individual, excel in capturing movement with exceptional precision, making them invaluable for detailed analyses and the creation of animations, though they may limit natural movement. Conversely, marker-less systems rely on advanced computer vision algorithms to detect the body's natural features without additional equipment, offering a more unobtrusive and adaptable approach [5]. Despite facing challenges in accurately capturing intricate movements, the relentless pace of technological progress is continually improving the accuracy and reliability of both techniques.

The fascination and widespread appeal of football, transcending continents and cultures, significantly highlights its stature as a global sporting phenomenon. This sport, predicated on the principles of teamwork, strategic understanding, and peak physical conditioning, demands a holistic approach to player development, encompassing technical prowess, tactical knowledge, physical fitness, and mental fortitude [6]. Both marker-based and marker-less, play a pivotal role in football, especially in the analysis of player movements, thereby refining training methodologies. Marker-based systems, exemplified by Vicon [7], offer unparalleled precision in tracking athletes' movements within controlled environments, whereas marker-less systems such as OpenPose [8], excel in capturing motion in more organic settings. These technological advancements facilitate a comprehensive examination of player performance, enabling coaches and sports scientists to optimize training activities and enhance strategic execution, underscoring the symbiotic relationship between cutting-edge technology and the evolution of football training practices.

Moreover, a ground-breaking application of MoCap technology in football training is the use of MTs. These templates are engineered through detailed analysis of elite athletes' movements, captured via the MoCap system. They provide a standard for the ideal execution of specific sporting actions, such as kicking and passing, facilitating the accurate replication of optimal movement patterns. This methodology offers a dual advantage: a quantitative benchmark for evaluating performance and a visual aid for enhancing technical proficiency [9]. By setting side by side an athlete's movements with these predefined templates, coaches are empowered to pinpoint inaccuracies and provide bespoke corrective feedback. This tailored approach optimizes training efficiency by aligning with each athlete's unique biomechanical characteristics, thereby fostering a customized coaching paradigm.

Feedback can be classified into two types: extrinsic and intrinsic [10]. The confluence of extrinsic and intrinsic feedback mechanisms plays a quintessential role in football training. Extrinsic feedback, provided by external sources, offers invaluable insights into performance analytics and delineates areas ripe for improvement [18]. This is in harmonious complement to intrinsic feedback, which athletes derive from their own sensory experiences during the performance of an

action. Together, these feedback modalities are indispensable in skill development, highlighting the critical importance of external inputs for learning and refining techniques. This synergy underscores a holistic approach to mastering skills, essential for the attainment of excellence in any sporting discipline.

However, there is a lack of MoCap technology usage to create MTs in sport that produce extrinsic feedback, especially in football. Therefore, the application of MoCap technology within football and additional sports disciplines marks a significant advancement in training methodologies and performance analytics. The integration of both marker-based and marker-less systems, supplemented by innovative solutions such as MTs, enables coaches and trainers to refine training regimens with unprecedented precision, efficiency, and customization. This technological evolution not only enhances the analysis and application of specific athletic movements but also paves the way for ground-breaking research and development within the field of sports science. Consequently, this promises to yield substantial enhancements in athlete performance and the refinement of training methodologies.

The research proposes a theoretical framework of extrinsic feedback in evaluating football training based MTs using MoCap. The next sections discuss the methods in Section III, the proposed framework in Section IV, the expected outcome in Section V and discussion and conclusion in Section VI.

II. Related Works

In MoCap technology, it has become a significant tool in football for analyzing player movement, medical evaluation and training improvement. In existing studies, the researchers have employed various techniques with different MoCap systems in football. For example, Yin et al. utilized a deep learning-assisted motion capture system (DL-MCS) in football training, which evaluates complexity, performance, latency and efficiency. This approach integrates deep learning to support training effectiveness, particularly by evaluating the accuracy of player movement [19]. Similarly, Della Villa et al. implemented a 2D video analysis scoring system to identify football players with a high knee abduction moment, which is a risk factor for ACL injuries. Their approach, which involved a stereophotogrammetric camera system and force platform, aimed to provide accurate health measurement to enhance injury prevention plan [20].

In marker-less MoCap, Bampouras and Thomas validated a Light Detection and Ranging (LiDAR)-based player tracking system for football-specific tasks, focusing on metrics such as velocity and acceleration. This technique evaluates the precision and responsiveness of marker-less system in capturing football player performance during fast-paced actions. By analyzing key performance indicators in real time, this study demonstrated the potential of marker-less MoCap system to provide relevant feedback, but with some limitation in data accuracy that affect the reliability of real-time extrinsic feedback [21].

Aughey et al. compared computer vision system with three-dimensional marker-based MoCap for tracking football players' movement in a stadium environment. Their evaluation, using root mean square deviation (RMSD) to calculate speed and accuracy, demonstrated how advance MoCap technology can capture dynamic football players' movement in large, open spaces, showing the adaptability of MoCap technology to diverse training activity condition. However, while computer vision systems support movement analysis, they still lack the precision needed for extrinsic feedback [22].

These studies highlight that while MoCap technologies have advanced considerably in capturing detailed player motion, the lack of extrinsic feedback remains a significant limitation. The integration of motion templates in MoCap system could bridge this gap, enabling real-time adjustment in training.

III. Method

To create MTs that enable effective extrinsic feedback in football training, benefiting coaches and experts, a systematic approach involving both formal and informal research methodology is essential. The approach to create a new framework was adapted [11], which has proven effective in generating MTs for folk dances but lacking for the dynamic requirements of football training. Incorporation of additional elements into approach is necessary to tailor it specifically to football's unique requirements. By refining this approach, acquisition of critical insights and development of MTs specifically designed for football training become possible. The refined approach, shown in Fig. 1, includes literature study, acquaintance meeting, interview, procedure and approval, experiment, data conversion, motion template creation, and data evaluation.

Fig. 1. New proposed approach for creating MTs in football training using MoCap.

A. Literature Study

Systematic Literature Review (SLR) is one of the methods in academic research, purposely to consolidate all existing evidence. The multifaceted process encompasses the

formulation of a research question guided by specific keywords, the detailed selection of relevant studies, the evaluation of their quality, and the systematic extraction and analysis of data. The objective of SLR is to furnish an impartial, exhaustive overview of the evidence at hand [12] This method not only strengthens the foundation for evidence-based practices but also highlights gaps in current research. By being attached to established reporting guidelines like PRISMA, these reviews ensure transparency and reproducibility [13].

B. Acquaintance Meeting

The primary objective of the meeting is to collect critical information about football and its training. Hence, engaging with the State Football Club, recognized as one of football expertise, which involves the qualified coaching staff, becomes a vital initial step for accruing foundational information prior to progressing with the research. The anticipated outcomes from these introductory sessions include:

- Documentation of football and coaching, encompassing evaluation forms and training guidelines.
- Detailed accounts of the processes involved in football training and coaching.
- Proposal for conducting formal interviews with qualified coaches.

The insights obtained from these preliminary meetings are instrumental for advancing to the next phases of the research.

C. Interview

Conducting interviews serves as an essential method for obtaining comprehensive insights regarding football coaching directly from seasoned professionals. The structure of these discussions varies, encompassing formal interviews with predefined queries, semi-structured interviews with a mix of fixed and open-ended questions, and informal conversations that proceed naturally. To facilitate these discussions, a carefully curated set of questions will be prepared in advance. The frequency of these interviews is determined by the relevance and adequacy of the information collected in meeting specific goals and expectations. Furthermore, it is vital to communicate the purpose of the study to the coaches. This communication not only aids in clarifying the objectives of the research but also invites valuable contributions from the coaches regarding the selection of football training activities for the study.

D. Procedure and Approval

Further research on football training can be conducted by applying for and following the required legal procedures and obtaining the necessary approvals.

1) Letter of purpose for conducting the research: Obtaining approval and support from the appropriate authorities or organizations is important for conducting the research. This letter contains the purpose, needs and importance of research in football training. In addition to explaining the use of current technology which is MoCap that has potential to help improve football training through research.

2) Letter of invitation to interview session: This letter serves as an invitation to certified coaches for a formal interview session. The goal is to collect information related to football training activities that are suitable to, along with suggestions, input, and feedback from the qualified coaches to enhance the research. Essential details such as the names of the coaches, the specific date, time, and location of the interview will be included in the letter. This strategy ensures clarity and facilitates the effective participation of these professionals in the study.

3) Request for nomination of qualified football player: The purpose is to reach out to coaches, seeking their assistance in nominating skilled football players who exhibit diverse qualities, such as being adept with either their left or right leg. Given the coaches' deep familiarity with , their teamsensuring that the selected players are indeed the best fit. This approach leverages the coaches' expertise, ensuring that the chosen athletes truly reflect the required attributes, without any room for doubt or challenge regarding their suitability.

4) Letter of invitation for conducting the fieldwork: An invitation to certified coaches and selected football players to participate in the experiment. The goal is to record and collect the MoCap data of football players' movement doing football training activities that had been assigned by the coaches. Essential details such as the names of the coaches, the specific date, time, and location of the interview will be included in the letter.

5) Request for verification of motion template: The goal is to look for assistance from experts to confirm the MTs created with captured movement data. It is crucial to verify the data's authenticity. The request emphasizes the importance of having several experts available at a designated date, time, and place. This ensures a comprehensive evaluation and verification process.

E. Experiment

The main goal of the experiment is to gather detailed MoCap data of football players as they engage in specific training activities. These activities have been carefully selected based on recommendations from experienced coaches from the previous interview session, ensuring it is relevant to research. The experiment is set to take place in the natural environment of the players, which is outdoors on a football field. To record these movements, the proposed MoCap device is marker-based such as Perception Neuron 3, known for its accuracy and reliability in capturing even the most subtle movements.

Football players will be guided through a series of training activities planned by the coaches. These activities are designed to simulate common football scenarios and challenges, helping to gather a wide range of motion data. As the players perform, coaches will not only supervise but also evaluate their performance using a rubric score assessment form that is validated by the expert. The raw MoCap data collected will then be processed to create MTs. These templates aim to offer detailed data of the movements, serving as a valuable resource for further analysis.

F. Data Conversion

Understanding the need to convert raw data arises from a compatibility issue between the initial format provided by the Perception Neuron 3 MoCap device and the requirements of the Gesture Description Language (GDL) system. Unlike the GDL system, which was originally designed to work with the Xbox Kinect—a marker-less MoCap system. The Perception Neuron 3 relies on a marker-based approach to capture movements. This fundamental difference in technology means that the raw data produced by Perception Neuron 3 contain 59 sections of skeleton joints as shown in Table I [14] while the GDL system contains 25 sections of skeleton joints (Table II) that are available in SKL format. The data from Perception Neuron 3 are available in formats like FBX, BVH, CSV, and MBX, and cannot be directly used in a GDL system without first undergoing a conversion process to suit the SKL format.

TABLE I. SKELETAL JOINT GENERATED FROM PERCEPTION NEURON 3

Section Name	Logotype	Serial Number	Parent Node
Buttocks	Hips	0	Root Node
Right thigh	RightUpLeg	1	0

25	Left Tip

A series of steps outlined (see Fig. 2) are followed to transform the raw data into a format that the GDL system can understand and process. This conversion process results in the production of data in the SKL format, making it compatible for use with the GDL system. The conversion is not just a technical requirement but a bridge that enables the advanced MoCap dataset from Perception Neuron 3 to be utilized effectively in the GDL system environment, thereby enhancing the utility and applicability of MoCap data in various applications.

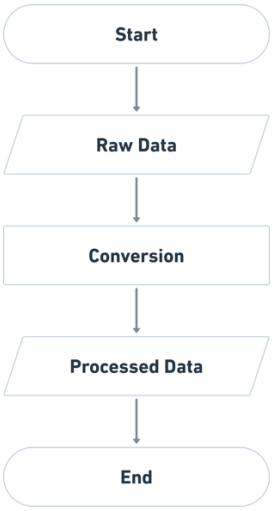

Fig. 2. Data conversion flowchart.

G. Motion Template Creation

R-GDL or Reverse-Gesture Description Language is an extension of the basic concept of GDL, focusing on a machine-learning approach for the recognition of full-body movements. R-GDL's methodology can be considered a form of reverse engineering compared to traditional GDL, as it starts with the outcome (recorded gestures) and works backward to infer the rules that define those gestures. Motion template will be developed by using R-GDL because this method has shown high accuracy in recognizing complex body movements, making it suitable for applications where precise motion detection is required, such as in physical therapy, sports analysis, and advanced human-computer interaction systems [15]. For creating the MTs, features in GDL will be used as shown below:

```
FEATURE angle(ShoulderRight.xyz[0] - ElbowRight.xyz[0],
WristRight.xyz[0] - ElbowRight.xyz[0]) AS RightElbow
 FEATURE angle(ShoulderLeft.xyz[0] - ElbowLeft.xyz[0],
 WristLeft.xyz[0] - ElbowLeft.xyz[0]) AS LeftElbow
 FEATURE angle(ShoulderCenter.xyz[0] - ShoulderRight.xyz[0],
 ElbowRight.xyz[0] - ShoulderRight.xyz[0]) AS RightShoulder
 FEATURE angle(ShoulderCenter.xyz[0] - ShoulderLeft.xyz[0],
 ElbowLeft.xyz[0] - ShoulderLeft.xyz[0]) AS LeftShoulder
 FEATURE angle(HipRight.xyz[0] - KneeRight.xyz[0],
 AnkleRight.xyz[0] - KneeRight.xyz[0]) AS RightKnee
 FEATURE angle(HipLeft.xyz[0] - KneeLeft.xyz[0],
 AnkleLeft.xyz[0] - KneeLeft.xyz[0]) AS LeftKnee
 FEATURE angle(ShoulderRight.xyz[0] - ElbowRight.xyz[0],
 ShoulderLeft.xyz[0] - ElbowLeft.xyz[0]) AS BetweenWrists
 FEATURE angle(KneeLeft.xyz[0] - HipLeft.xyz[0],
 KneeRight.xyz[0] - HipRight.xyz[0]) AS BetweenLeg
```

H. Data Evaluation

GDL are used for the recognition of user actions through the syntactic description of static body poses and movement sequences. It allows for representation of human movements in a way that computer systems can recognize and classify various gestures [15]. By using the GDL system, processed data will be evaluated with a motion template created previously and will produce the output of extrinsic feedback.

IV. PROPOSED FRAMEWORK

In this study, a theoretical framework of extrinsic feedback to evaluate football training has been proposed. Fig. 3 consists of several important models which are the football player, MoCap, raw data, processed data, motion template, evaluation and extrinsic feedback.

Fig. 3 shows the important models in phases of development, testing and evaluation. The development phase consists of football player, MoCap, raw data, processed data and motion template models while the testing phase contains football player, MoCap and raw data models. The evaluation phase consists of comparison and extrinsic feedback models.

A. Football Player

In the development phase of the proposed framework, a certified coach will select skilled and qualified players (Player A). The selection criteria are determined by the coach who also assigns specific football training activities to these players. While in the testing phase, another individual (Player B), who might be new to football or a novice player, participates

alongside Player A in similar training activities. The coach will evaluate their progress using the approved score rubric assessment form.

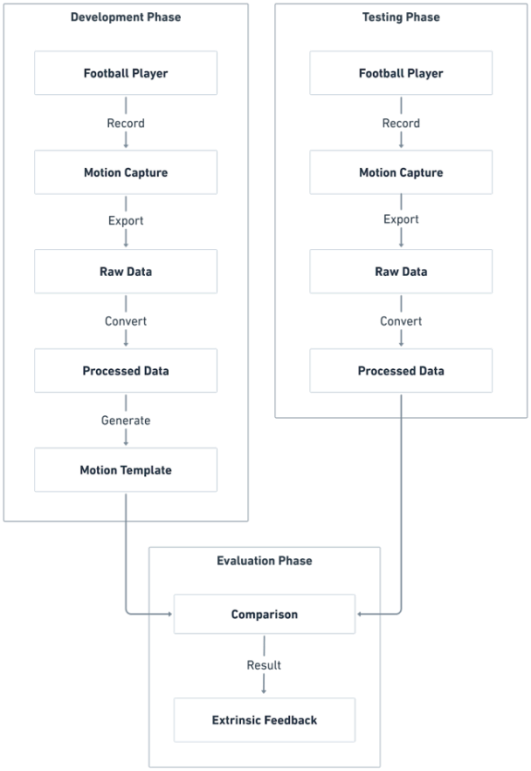

Fig. 3. Proposed framework.

B. Motion Capture

Both development and testing phases, the MoCap device from Perception Neuron with Axis Studio software, will be used on Player A and Player B. Each player will be recorded separately during the same training activities sessions. To ensure the highest quality of data, the actions of each player will be repeated several times per training activities. Specifically for Player A, the data will undergo review by the coach before it can be used as a motion template.

C. Raw Data

The training activities of both players will be digitally captured using the Perception Neuron via Axis Studio, and this data will be accessible in multiple file formats including FBX, BVH, CSV, and MBX that are provided in the software. The FBX and CSV format will be primarily used in the conversion process. This format is preferred because it is widely supported by most of the software, ensuring compatibility and ease of data handling.

D. Processed Data

To produce the processed data from raw data, several procedures in the conversion process (Fig. 2) are needed such as deleting the unused data and rearranging the data. Main purpose of conversion is to have the same attributes of data as the SKL format which is only suitable to use in the GDL system. Both players' data are compulsory to be processed before it can be analyzed.

E. Motion Templates

To create a motion template, the GDL system will be used. This process is exclusively for processed data from player A. As this data has previously received approval from the coach, it will serve as a reference for comparing other data collected from the same training activities by different players or individuals.

F. Comparison

Both motion template data of player A and processed data of player B will be used in the GDL system. To evaluate and get the result of the processed data of player B, the data will be compared to the validated motion template of player A. In the GDL system, it will determine the accuracy and score of the processed data of Player B compared to the motion template of Player A as the result.

The GDL classifier uses rules and features to recognize gestures from MoCap data in the GDL system. It processes MoCap data in several steps. First, it represents a sequence of MoCap data samples taken from ti time to tj, where each sample pta is a vector in R3.d, representing the three-dimensional coordinates (x, y, z) of the body joint.

$$P[ti..tj]=[pti, ...,ptj]$$

This raw data is then transformed into feature space, reducing dimensionality and making it invariant to the camera's position. The transformation is performed by a function *F*.

$$P[ti..tj]F\ ftj$$

The resulting sequence of feature vectors corresponds to the MoCap data samples over time.

$$F[ti..tj]=[fti, ...,ftj]$$

Next, the system evaluates whether specific rules are satisfied at each time step, creating a sequence of rule conclusions rta which can either be true or false.

$$rta \in \{true,false\}r$$

This sequence of rule conclusions over time is represented as

$$R[ti..tj]=[rti, ...,rtj]$$

The transformation function λ considers both the feature vectors and the previous rule conclusions to determine the current rule conclusions.

$$\{F[ti..tj],R[ti..tj-1]\} \rightarrow \lambda\ R[ti..tj]$$

Each time step's data, features, and rule conclusions are stored in a memory stack.

$$sta=\{pta,fta,r'ta\}$$

The entire sequence of MoCap data, feature vectors, and rule conclusions over the given time interval is stored in the GDL memory stack.

$$S[ti..tj]=[sti,...,stj]$$

The classifier uses this stack to apply rules and recognize gestures. When a sequence of rules corresponding to a gesture is satisfied, the gesture is recognized.

G. Extrinsic Feedback

By getting the result of processed data of player B from the GDL system, it can be compared to the previous score rubric assessment form that has the evaluation score from the coach. If the score has high similarity, the expert can verify that the model of motion template of player A can be used to evaluate other players' data because the GDL system produces the same result as the coach evaluation.

V. Expected Outcome

The proposed framework is to improve the way coaches execute and evaluate football training and the player's performance. By integrating MoCap devices, coaches are afforded a clearer picture of player performance. The technology not only assists in detailed analysis but also in decision-making processes and enhances the evaluation of players. Consequently, coaches can refine training methods, ensuring that players are not just practicing harder, but smarter. The immediacy with which feedback is provided to players allows for swift adjustments, fostering an environment of continuous improvement and growth.

Furthermore, MTs are not only an aid in training but a lasting resource that can be accessed, revisited, and utilized repeatedly without degradation or expiration. This aspect guarantees the preservation of data for future use, offering a foundation on which athletes can build and refine their skills over time. Players, therefore, are not just improving in the short term through practice with MoCap devices; they are investing in a resource that supports their long-term development. The reusable nature of these MTs means that both current and future athletes can benefit from a tailored, data-driven approach to skill enhancement, ensuring that the legacy of today's training methods extends far into the future.

VI. Conclusion

A theoretical framework of extrinsic feedback evaluation in football training has been presented in this paper based on MTs. This framework is designed to measure the success of technique execution during football training. To ensure the effectiveness of this study, an initial investigation into the development of MTs in football training, utilizing MoCap, is essential. This includes literature study, acquaintance meeting, procedures and approval, and interview.

In the experiments, the Perception Neuron 3, a marker-based MoCap device, was proposed for utilization due to its accuracy and reliability in capturing data, even for the most subtle movements in sports activities such as football. The data from the device can be used to create MTs, which facilitate the analysis of professional players' data and the preservation of their unique skill movements in digital form. Importantly, this technology is not limited to football but can be explored and applied to other sports activities, enhancing its versatility and value in various athletic disciplines. For futures works, this proposed will be utilized and tested for experimenting the football techniques such as freekick for both left and right footed football players.

Acknowledgment

The author would like to acknowledge the Ministry of Higher Education (MoHE) and Center for Research Excellence and Incubation Management (CREIM), Universiti Sultan Zainal Abidin. This research was supported by the Ministry of Higher Education (MoHE) through Fundamental Research Grant Scheme (Project Code: RR457, Ref. No: FRGS/1/2022/ICT03/UNISZA/02/1). We also want to thank the National Sports Institute of Malaysia and Terengganu Football Club for the shown interest and future collaboration in this study.

An Application of Graph Neural Network Model Design for Residential Building Layout Design

Shiyu Wang[1]*, Ningbo Wang[2]
Zhengzhou Urban Construction Vocational College, Zhengzhou 452370, China[1]
State Grid Xinyuan Henan Tianchi Pumped Storage Co., Ltd., Nanyang 473000, China[2]

Abstract—In the current process of residential building layout design, there are problems such as low design efficiency, excessive manual intervention, and difficulty in meeting personalized needs. To address these issues, a residential building layout design method based on graph neural network model is proposed to improve the intelligence level of residential building layout design. Firstly, the residential building floor plan layout design data are transformed into graph data suitable for graph neural network model processing. Then, deep learning techniques are used to analyse and identify the spatial distribution characteristics of the main functional areas in the space. Finally, the trained graph neural network model is applied to the actual residential building floor plan layout design and compared with the traditional method. The experimental results show that compared with the traditional computer-aided design method, the residential building floor plan layout design and optimisation method improves the completeness of the design scheme by about 2.3%, the rationality by about 3.6%, the readability by about 1.9%, and the effectiveness by about 10.3%. The method improves the efficiency and accuracy of residential building floor plan layout design, helps to shorten the design cycle and reduce the design cost, and helps to promote technological progress and sustainable development in the field of architectural design.

Keywords—Residential building layout plan; deep learning; GNN model; space utilization rate; resident comfort level; quantum particle swarm algorithm; Node2vec algorithm

I. Introduction

With the rapid development of social economy and the acceleration of urbanisation, the demand for residential buildings is increasing, and the floor plan layout design, as an important part of residential building design, directly affects the comfort, functionality and aesthetics of the residence [1]. The traditional floor plan layout design of residential buildings mainly relies on the experience and professional knowledge of designers, which is limited by the personal ability and experience accumulation of designers, and the design efficiency and accuracy are relatively low, and it is difficult to ensure the innovation and uniqueness of the design scheme [2]. In recent years, the development of artificial intelligence technology has provided new possibilities for residential building plan layout design [3]. Among them, the graph neural network (GNN) model, as a kind of neural network that can effectively process graphical data, has achieved remarkable results in the fields of computer vision, natural language processing, and recommender systems [4, 5]. However, in the field of residential building layout design, the application of GNN model is still in its infancy. Most existing research focuses on simple spatial relationship modeling, and there are still shortcomings in comprehensively considering various factors such as complex functional requirements, user preferences, and diverse building codes in residential buildings. In addition, how to build an efficient and accurate GNN architecture that can fully adapt to the special requirements of residential building layout design and achieve automatic generation and optimization of design schemes is still an urgent problem to be solved. The research aims to fill these research gaps by exploring the application of graph neural network models in residential building layout design, constructing more comprehensive and practical design models, and improving the quality and efficiency of residential building layout design, bringing new vitality and innovation to the field of residential building design. The study is divided into four parts: the first part is a summary of related studies; the second part is the design of the GNN model for residential building floor plan layout design, which is validated in the third part; and the fourth part is a summary of the whole study. The innovativeness of the study is mainly reflected in the following aspects The study of applying GNN to residential building floor plan layout design provides a new intelligent method for residential building floor plan layout design. Secondly, the study constructed a GNN model applicable to residential building floor plan layout design and optimised it with a large amount of training data, which improved the design efficiency and accuracy; finally, the GNN model was applied to actual design cases, which achieved significant design results.

II. Related Works

GNN is a neural network that can efficiently process graphical data and automatically learn the structural and relational information in graphical data. Wang et al. proposed a quaternion-based social recommendation knowledge graph neural network, which reduces the parameters during training through the expressibility of quaternion and the weight sharing mechanism of the Hamilton product, and also employs explicit and implicit social relationship integration algorithms to solve the problem of users' social relationship data sparsity problem. Experimental results show that the model can achieve up to 85% recommendation accuracy in study [6]. Huang's group proposes a dynamic spatio-temporal graph neural network model (DSTGNN) to capture the dynamics and dependencies in traffic demand forecasting by constructing a spatial dependency graph. The results show that DSTGNN outperforms existing models in traffic demand prediction on two real datasets [7]. Rusek's group proposes a novel GNN-based network model to understand the complex relationships between topology, routing, and input flows, and to predict key performance indicators. The model was experimentally shown to be accurate up to 88% in predicting

delay distribution, jitter and loss [8]. Lee et al. proposed a new human activity recognition model that combines a pre-trained model and a GNN to effectively overcome the sparsity of radar data. The results showed that the method achieved 96% accuracy in five different human activity classifications [9]. A related study proposes a scalable network slice digital twin based on the GNN model to capture intertwining relationships between slices and monitor end-to-end metrics. Experiments demonstrate that the method accurately reflects network behaviour and predicts latency in various topologies and new environments [10].

Graphic layout design is a design method to achieve an efficient, aesthetically pleasing and comfortable spatial environment by rationally arranging spatial elements. Li et al. proposed an attribute-conditional layout method for solving the problem of design element position and size in graphic layout design while considering element attribute constraints. The method was experimentally demonstrated to be effective in synthesising graphic layouts under different element attribute conditions and supports layout adjustment and original reading order preservation [11]. Murchie's group proposes a graphic design methodology based on the science of communicating vision and provides a high-level overview of terms related to layout, images, fonts, and colours. The method was able to increase graphic design satisfaction by 13% and helped to facilitate research collaboration between scientists and designers [12]. Stephan et al. used a mathematical planning approach to achieve optimal use of urban space by optimising car park layouts. The trade-off between high resolution and computational effort was explored by comparing orthogonal parking mixed integer programs at different resolutions. Experimental results show that the application of the optimised car park design scheme improves the effectiveness by 10% [13]. Boysen's team optimises the layout design of moving walkways through dynamic planning, which effectively improves the total travel time under several relevant extended constraints. The results showed that the method could reduce the total pedestrian travel time by 13% [14]. Wan team members targeted to propose a web page layout aesthetic assessment by automatically predicting the aesthetics of web page layouts based on an improved Adaboost algorithm. Experiments proved the superiority of the model in predicting the aesthetics of web page layouts [15].

In summary, existing research on GNN has achieved significant results in various fields such as social recommendation, transportation demand prediction, network performance indicator prediction, and human activity recognition, demonstrating the powerful ability of GNN to process graphical data structures and relational information. In terms of graphic layout design, although there are various methods such as attribute conditional layout, design based on scientific communication vision, mathematical programming optimization of parking lot layout, dynamic programming of mobile sidewalk layout, and aesthetic evaluation of webpage layout, these studies mostly focus on specific types of layout design or specific optimization objectives. At present, there is a lack of an effective model that deeply applies the powerful graphic data processing capabilities of GNN to residential building layout design, and fails to fully utilize GNN to explore the complex structural and relational information between residential building spatial elements to achieve more comprehensive, intelligent, and universal optimization of residential building layout design. Therefore, the study proposes a GNN model for residential building layout design, aiming to provide intelligent methods for residential building layout design and promote technological progress in the field of architectural design.

III. GNN Model for Residential Building Layout Design

This paper discusses the data acquisition, pre-processing and analysis of residential building floor plan layouts using BIM technology. A layout design method based on GNN and deep learning is proposed to improve space utilisation and occupant comfort. Finally, the quantum particle swarm algorithm is used to optimise the layout design and transform it into a composite model to further enhance the design.

A. Spatial Data Processing of Residential Building Plan Layout

Residential building floor plan layout data acquisition and pre-processing is an important part of the BIM field, which involves the digital modelling of building space and provides basic data for building design, construction and operation [16]. Before carrying out the residential building plan layout, the functional area spatial data need to be collected and processed in order to extract the distribution characteristics of the layout space. The spatial data processing process of residential building plan is shown in Fig. 1.

The data format of spatial layout information mainly includes the location, size, and shape of building floor plans and related functional areas. Specifically, the data will include information such as the coordinates, area, and shape of each functional area. The input of the model is raw spatial data, and the output is processed and analyzed spatial distribution feature information. During the processing, it may be necessary to replace the classification code to adapt to the new data structure and analysis requirements. Finally, the processed data will be verified to ensure its quality [17]. The information entropy of spatial distribution characteristics of the main functional area is shown in Eq. (1).

$$\delta = -\sum_{i=1}^{n}\left(\frac{S_n}{S_0}\right)\ln\left(\frac{S_n}{S_0}\right) \tag{1}$$

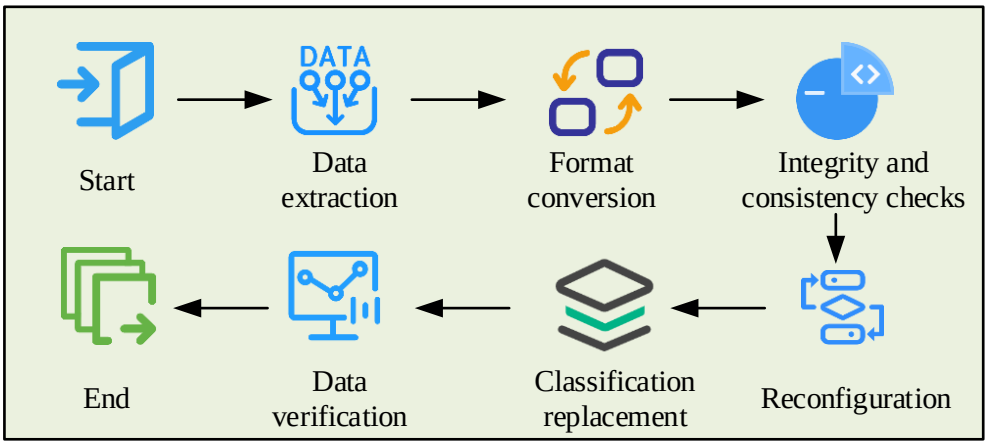

Fig. 1. The data processing process of residential building floor plan space.

In Eq. (2), the measure of spatial functional area land is η and the number of its types is N. The measure of spatial functional area land use can be realised by calculating the equilibrium degree, which takes the value range of [0, 1]. If the equilibrium degree is 0, it means that the use of land in the functional area is unbalanced; if the equilibrium degree is 1, it means that the use of land has reached the ideal equilibrium state. Through this metric, the development of land in the spatial functional area can be better understood and assessed [19]. The morphological characteristics of the main functional zone distribution of the building plan contain shape rate and compactness, and the shape rate of each functional zone is shown in Eq. (3).

$$\lambda = \frac{S_1}{L^2} \tag{3}$$

In Eq. (3), the shape rate of each functional area is λ, the area of the functional area region is S_1, and the length of the region is L. Shape rate is an important indicator to describe the morphological characteristics of the distribution of the main functional area, if the value is small, it means that the area shows obvious belt-like characteristics; if the value is large, it indicates that the distribution of the main functional area in the area is block-like. The compactness of the main functional area is shown in Eq. (4).

$$\mu = \frac{S_1}{S_1^{'}} \tag{4}$$

In Eq. (4), the compactness of each functional area is μ, and the minimum external circle area of functional area is $S_1^{'}$. Subsequently, the study analyses and identifies the spatial distribution characteristics of the main functional zones in the space through the deep neural network technology, and the deep neural network of spatial distribution of the main functional zones in the building plan is shown in Fig. 2.

The spatially relevant feature points of the residential building plan are extracted by deep neural network, and the functional area feature index parameters are calculated as shown in Eq. (5).

$$A = b + \frac{w}{r(s-w)} \tag{5}$$

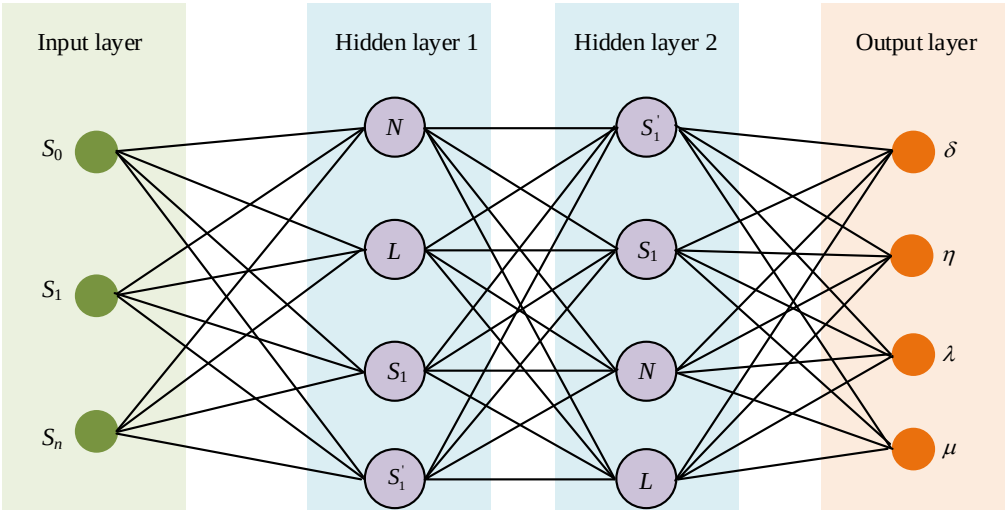

Fig. 2. Deep neural network for spatial distribution of main functional areas in architectural plans.

In Eq. (5), the feature indicator parameter is A, the upper limit value of feature is b, the optimisation coefficient of feature parameter is r, the distribution range is s, and the lower limit value of feature is w. The corresponding feature value index parameters are calculated and the results of the layout feature extraction of the functional area are evaluated. If the result exceeds the preset value range, it indicates that there is an abnormality in the feature extraction and it is necessary to carry out the extraction again. On the contrary, it can be considered that the layout feature extraction results are suitable for layout optimisation design, and the subsequent operations can be continued.

In summary, the study successfully extracted the spatial distribution characteristics of the main functional area by processing and analyzing spatial data using deep neural network technology. Then, using information entropy and spatial functional area land measurement methods, evaluate the development status of land in each functional area. In addition, by calculating the shape ratio and compactness of the main functional area, we have gained a better understanding of the development of the spatial functional area land. The research method not only improves the accuracy of residential building layout design, but also provides effective basis for subsequent layout optimization design.

B. Residential Building Layout Design and Optimisation Methods

Unlike traditional deep learning models, GNN acquires information about graph data by learning the relationships between nodes [20]. The mathematical representation of the graph structure is shown in Eq. (6).

$$G = \langle V, E \rangle \tag{6}$$

In Eq. (6), the graph structure is G, the set of nodes of the graph structure is $V = [v_1, v_2, \ldots, v_i]$, and the set of all edges of the graph structure is $E = [e_{11}, e_{12}, \ldots, e_{ij}]$. The radius subgraph of the nodes is shown in Eq. (7).

$$v_i^{(r)} = (V_i^{(r)}, E_i^{(r)}) \tag{7}$$

In Eq. (7), the subgraph of node v_i within the radius r is $v_i^{(r)}$. The radius subgraph of an edge is shown in Eq. (8).

$$e_{ij}^{(r)} = (V_i^{(r-1)} \bigcup V_j^{(r-1)}, E_i^{(r)} \bigcup E_j^{(r)}) \tag{8}$$

In Eq. (8), the subgraph of edge e_{ij} within radius r is $e_{ij}^{(r)}$. After random initialisation by supervised learning, the node radius subgraphs and edge radius subgraphs are trained by backpropagation. The node embedding representation is updated as shown in Eq. (9).

$$v_i^{(t+1)} = \sigma(v_i^{(t)} + \sum_{j \in N(i)} h_{ij}^{(t)}) \tag{9}$$

In Eq. (9), the node embedding is denoted as $v_i^{(t)}$, the Sigmoid function is σ, and the set of neighbours of the node is $N(i)$. The hidden neighbour vector is $h_{ij}^{(t)}$ and its calculation is shown in Eq. (10).

$$h_{ij}^{(t)} = f\left(W_{neighbor}\left[v_j^{(t)}, e_{ij}^{(t)}\right]^T + b_{neighbor}\right) \tag{10}$$

In Eq. (10), the nonlinear activation function of the neural network is f, the hidden neighbour weight matrix is $W_{neighbor}\left[v_j^{(t)}, e_{ij}^{(t)}\right]^T$, the neighbour offset vector is $b_{neighbor}$, and the edge embedding vector of node $v_i^{(t)}$ and node $v_j^{(t)}$ at time t is $e_{ij}^{(t)}$. The edge embedding vector is updated as shown in Eq. (11).

$$e_{ij}^{(t+1)} = \sigma(e_{ij}^{(t)} + f\left(W_{side}\left(v_i^{(t)}, v_j^{(t)}\right) + b_{side}\right)) \tag{11}$$

In Eq. (11), the edge vector update weight matrix is $W_{side}\left(v_i^{(t)}, v_j^{(t)}\right)$ and the edge embedding vector offset vector is b_{side}. The final output obtained is shown in Eq. (12).

$$y_{build} = \frac{1}{|V|}\sum_{i=1}^{|V|} v_i^{(t)} \tag{12}$$

In Eq. (12), the final output is y_{build} and the number of all nodes is $|V|$. The loss function for residential building prediction is shown in Eq. (13).

$$loss = \sqrt{\frac{1}{m}\sum_{i=1}^{n} W_{reg}(y_i - y_{build})} \tag{13}$$

In Eq. (13), the loss function is $loss$, the regression weight matrix is W_{reg}, the actual score of the samples is y_i, and the number of samples is m. The Node2vec algorithm is an unsupervised machine learning model based on graph embedding, which represents similarity or proximity between nodes by sampling their neighbours in a random wandering manner and mapping the nodes to a high-dimensional space. The Node2vec algorithm borrows from the word2vec algorithm in natural language processing, considering each node in the graph as a word in the text and a sequence of nodes as a sentence in the text. The algorithm mainly solves the problem of how to generate a sequence of nodes starting from an initialised node. The optimisation objective of the Node2vec algorithm is shown in Eq. (14).

$$\max_f \sum_{v \in V} \log \Pr(N_s(u) | f(u)) \tag{14}$$

In Eq. (14), the node mapping function is $f(u)$ and the set of nearest neighbour points of a node is $N_s(u)$. The GNN-based residential building plan layout design model is shown in Fig. 3.

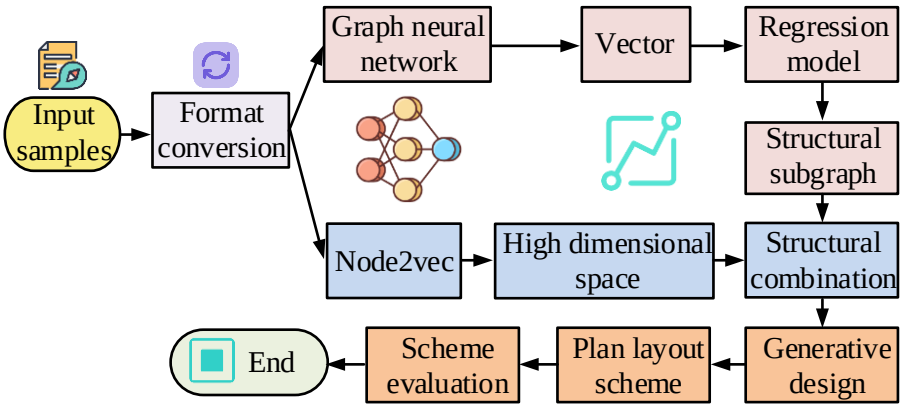

Fig. 3. A residential building layout design model based on GNN.

The residential building floor plan layout design model uses a graph data structure to encode and analyse building floor plans. The graph neural networks involved include Graph Convolutional Neural Networks (GCN) and Graph Attention Networks (GAN). In this model, nodes represent rooms, and node attributes include type, etc.; edges represent connectivity relationships between rooms, such as door connections, open connections, or vertical connections (e.g., stairs, ramps, or lifts). Through supervised learning, the model uses GNN to embed nodes and subgraphs to obtain the corresponding vector representation and the vector representation of the whole graph. Then, the linear regression model assigns weights to the subgraphs to minimise the error between the predicted score and the true score. After training, the subgraphs that have a high impact on the scores are extracted as good design elements. The unsupervised learning part uses the node2vec algorithm to map the sample graph into a high-dimensional space and visualise it to show potential relationships between nodes. This approach provides useful suggestions for subgraph combination, i.e., which nodes should be connected together in the final design. In the structure combination phase, the model identifies the basic modules (subgraphs) and then combines them into a new graph. This process can be achieved by adding new edges and additional nodes. Finally, the validity of the generated design solution is manually evaluated. After obtaining a new diagram that conforms to the design, the model converts the diagram into a residential building plan layout. Overall, the GNN-based residential building floor plan layout design model effectively integrates supervised and unsupervised learning, which helps to generate innovative and design-compliant floor plan layout solutions. The GNN structure used for subgraph construction is shown in Fig. 4.

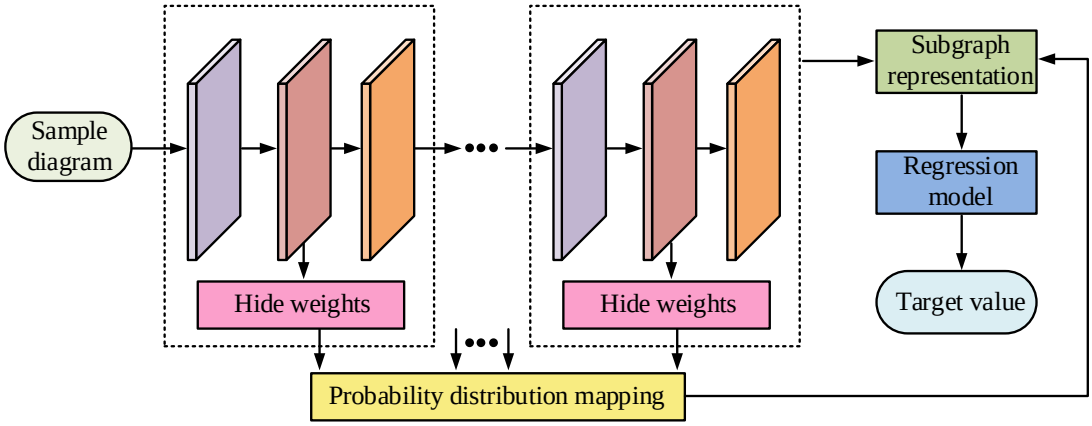

Fig. 4. GNN structure for subgraph construction.

Each layer of the GNN structure used to discover constructed subgraphs consists of neurons that hold real-valued representations of node attributes. In each layer, a convolutional operation processes the node attributes, multiplying the result by the hidden weights and mapping it to a probability distribution via a non-linear function to obtain a potential representation vector. The probability of each layer is related to the objective function score, and subgraph patterns are discovered by accumulating and remembering the neighbourhood contributions of the nodes. The subgraph vector is updated as shown in Eq. (15).

$$x_i^{(t+1)} = x_i^{(t)} + \sum_{j \in N(i)} x_{ij}^{(t)} \quad (15)$$

In Eq. (15), the subplot vector at the time of t is $x_i^{(t)}$ and the subplot vector at the time of $t+1$ after updating is $x_i^{(t+1)}$. The initialisation process of the subplot vector of the residential building plan is shown in Fig. 5.

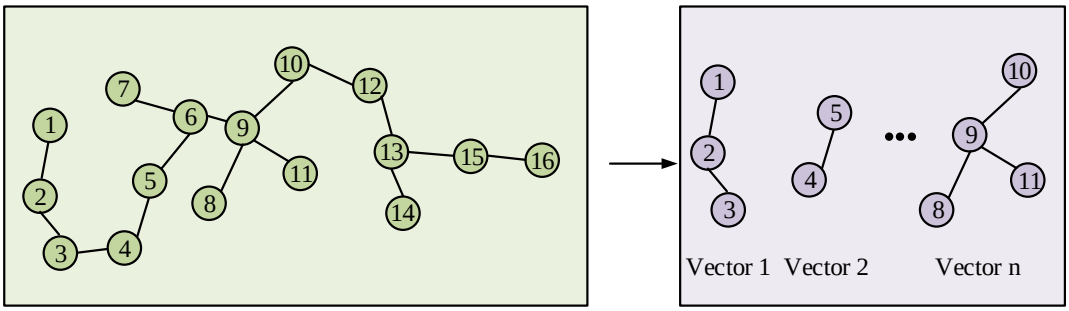

Fig. 5. The initialisation process of subgraph vectors in residential building plans.

The objective of the residential building floor plan layout design optimisation method is to maximise the space utilisation of the residential building while improving the comfort of the occupants, subject to the constraints [21]. The residential building floor plan layout design optimisation method is based on the quantum particle swarm algorithm, which achieves the goal by optimising two factors: the coordination of the layout design and the design cost. The optimisation model transforms the complex layout problem into the form of a composite model, which takes into account a variety of factors such as land type, functional area type, and adjacency. In the solution process, the optimal solution is searched by continuously updating the particle velocity and position, and the preset convergence conditions are satisfied. The final optimal layout design results obtained can be used to guide the actual residential building plan layout design.

IV. Analysis of the Application of Residential Building Layout Design Methods

The content of this chapter focuses on the analysis of data processing, feature extraction and application of design optimisation methods to residential building plan layout images. Firstly, the images in the ScanNet dataset are processed and converted. Then, the frequency and distribution features of different spatial types are analysed. Then, the GNN model performance is evaluated by experimenting different parameters using neural networks and Adam optimiser for training. Finally, the public space layout is optimised by quantum particle swarm algorithm.

A. Analysis of Data Collection and Pre-processing Effects

The experimental environment of the residential building floor plan layout design method includes the following: first, in the software environment, BIM software is used for data acquisition and pre-processing, such as Revit and AutoCAD. This software can help to acquire the relevant information of the building and to organise and process the data. It is also necessary to use deep learning frameworks, such as TensorFlow, PyTorch, etc., for data processing and analysis for model training and prediction. In terms of the hardware environment, we need to use a high-performance computer or server for data processing and model training. Specific configurations include high-speed CPU, high-capacity memory and high-performance graphics card to ensure the efficiency and accuracy of data processing and model training. The programming language uses Python as the main programming language, combined with the corresponding deep learning libraries and APIs of building information modelling software for data processing and model training. The storage device uses high-speed hard discs or solid-state hard discs as the data storage device to improve the data reading and writing speed and model training efficiency. The study selects residential building plan layout images as the raw data for data processing on the ScanNet dataset, and the data conversion processing effect is shown in Fig. 6.

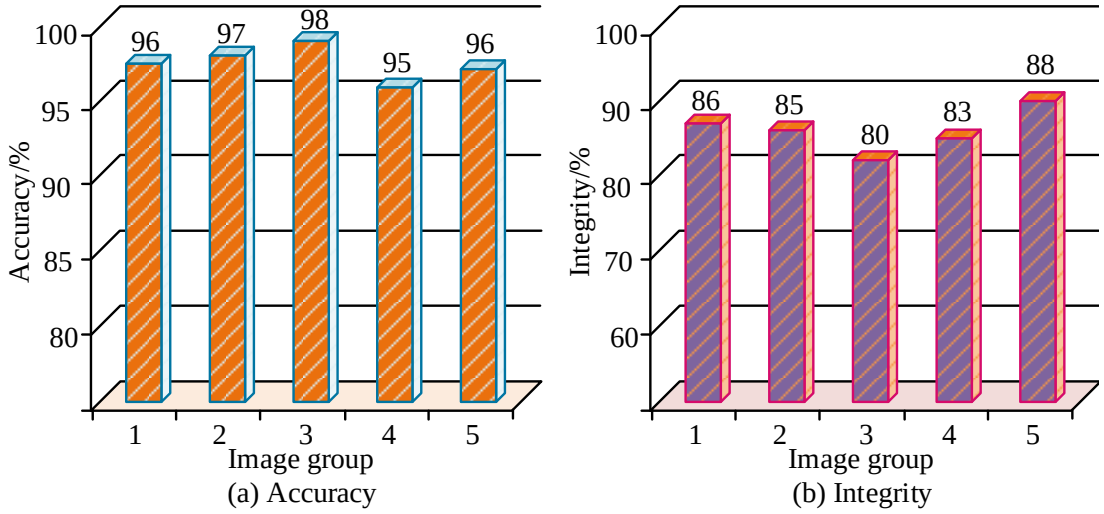

Fig. 6. Data conversion processing effect.

The image grouping in Fig. 6(a) is the random division of the 150 residential building floor plan layout image samples obtained from the ScanNet dataset into five groups of 30 sample images each shows the accuracy of the data conversion, with an average accuracy of up to 96.4%. It indicates that there are very few errors and deviations in the data conversion process, and most of the image samples can maintain a high degree of consistency and accuracy in the conversion process. Fig. 6(b) shows the completeness of data conversion, and the average completeness can reach 84.4%. In the data conversion process, the important information and features of the overall sub-image samples can be retained and reproduced. Comprehensively, the effect of data conversion processing is quite remarkable, with excellent performance in both accuracy and completeness indicators, which lays a solid foundation for further data analysis and processing. The study will contain 24 of the 30 data samples for training and cross-validation, using grid search to adjust the combination of hyperparameters, and the other 6 samples as a test set. The results of feature extraction for residential building plan layout images are shown in Fig. 7.

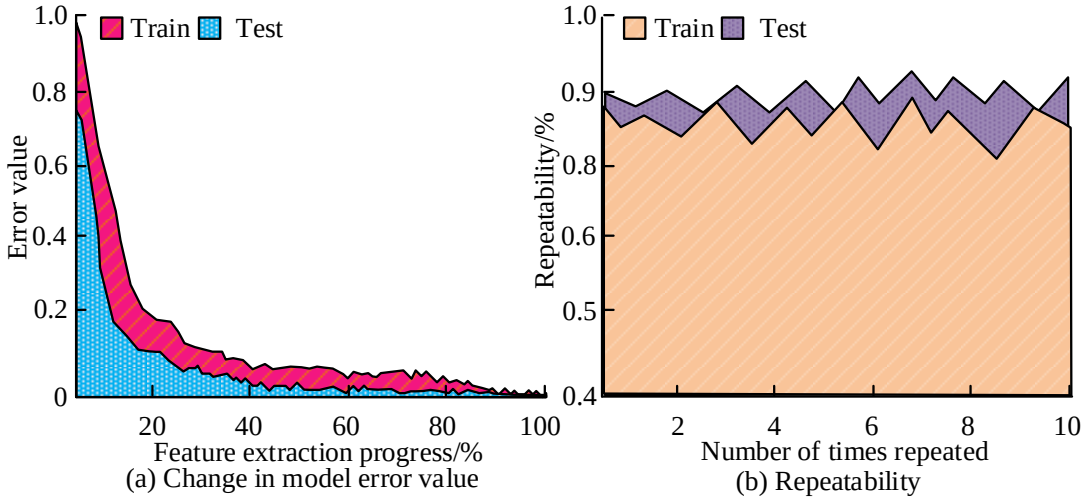

Fig. 7. The effect of feature extraction on residential building layout images.

Fig. 7(a) shows the variation of error values of residential building floor plan layout image feature extraction, and the error values of training and testing tend to be stable in the range of 0-0.01. Fig. 7(b) shows the repeatability test results of residential building floor plan layout image feature extraction, and the repeatability averages of training and testing are 84% and 89%, respectively. The results show that the effect of residential building floor plan layout image feature extraction is more significant, and the accuracy and repeatability are excellent. The results of the sample room type frequency statistics are shown in Fig. 8.

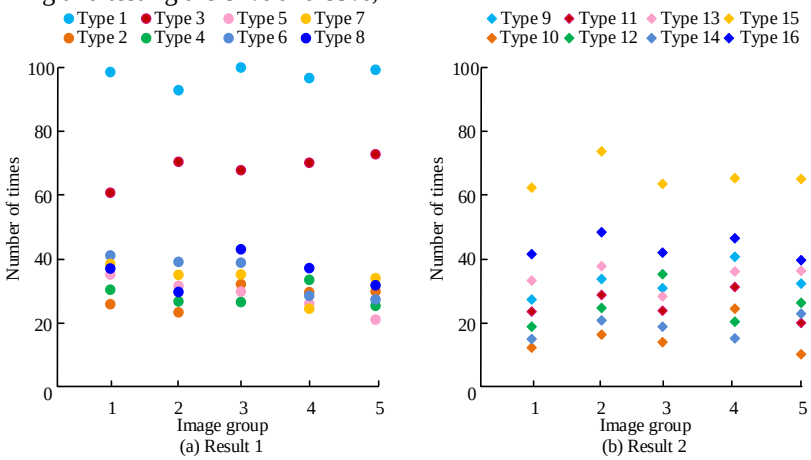

Fig. 8. Sample room type frequency statistics results.

In Fig. 8(a), types 1-8 represent bathroom, bedroom, corridor, kitchen, living room, dining room, parking room and laundry room, respectively. In Fig. 8(b), types 9-16 represent guest rooms, balconies, storage rooms, entrances, studies, master bedrooms, second bedrooms, and bathrooms, respectively. The frequency ranges of different types of spaces are not exactly the same, with bathrooms appearing most frequently, followed by corridors, and to a lesser extent, balconies. With regard to the information entropy of spatial distribution characteristics, the internal spatial distribution of residential buildings presents a high degree of randomness and diversity. In the spatial functional area land metric, functional areas such as bedrooms and living rooms occupy larger areas, while parking rooms and laundry rooms have smaller areas.

Regarding the shape rate of each functional area, kitchen and bathroom show a more regular shape, while bedrooms and living rooms are more irregularly shaped. The main functional areas such as bedrooms and living rooms are more compact, while dining rooms, laundry rooms, etc. are less compact.

B. *Analysis of the Application of Residential Building Layout Design and Optimisation Methods*

When evaluating the application effect of residential building layout design and optimization methods, a comparative evaluation method was used in the experiment to compare the proposed optimization method with computer-aided design (CAD) and poster tools. Nonprofessional and professional users were invited to evaluate the completeness, rationality, readability, and effectiveness of the three design tools. The study uses customised data and parameter settings to train neural networks to solve architectural design problems. Also, the Adam optimiser was used for training and different parameters such as subgraph radius and edge vector dimensions were chosen for the experiments. The effect of different parameters on the GNN model is shown in Fig. 9.

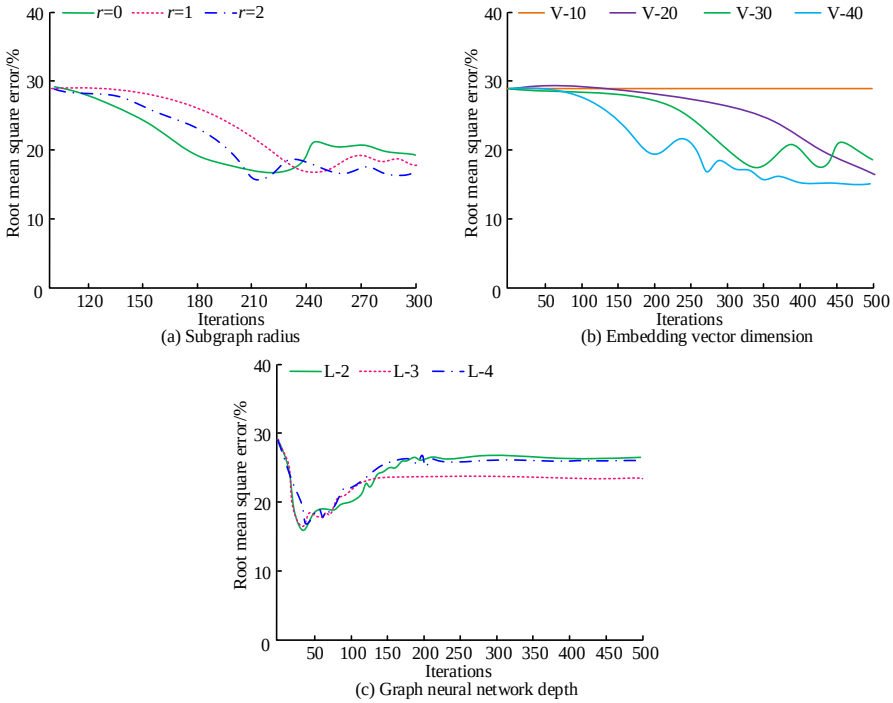

Fig. 9. The impact of different parameters on GNN models.

Fig. 9(a) shows the results of the effect of subgraph radius on the model performance, and it can be seen that the root mean square error of the model can be minimised up to 18.3% when the subgraph radius is 2. Fig. 9(b) shows the results of the effect of vector dimension on the model performance, and it can be seen that the root-mean-square error of the model can be minimised up to 16.9% when the vector dimension is 40. Fig. 9(c) shows the results of the effect of GNN depth on model performance, as can be seen that the model stabilises with a minimum root mean square error of 23.6% at a GNN depth of 3. With the current model setup, a subgraph radius of 2, a vector dimension of 40, and a GNN depth of 3, the smallest root-mean-square error can be obtained, resulting in optimal model performance. The sample room type vector space projection is shown in Fig. 10.

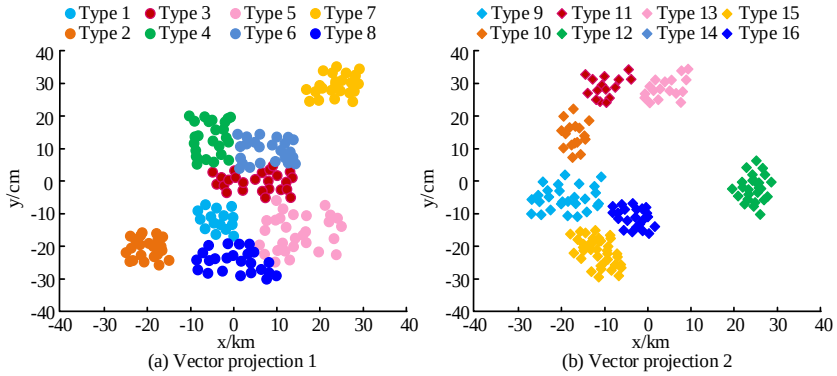

Fig. 10. Sample room type vector space projection.

Fig. 10(a) shows the space vector projections for types 1-8, i.e., bathroom, bedroom, corridor, kitchen, living room, dining room, parking room and laundry room. Fig. 10(b) shows the space vector projections for types 9-16, i.e. guest room, balcony, storage room, entrance, study, master bedroom, second bedroom and bathroom. It can be seen that clusters such as bedrooms and bathrooms are closer to each other, forming a larger category, while kitchens and dining rooms are closer to each other. In addition, clusters such as guest room, bathroom and second bedroom are very close to each other. The optimisation of the residential building floor plan layout design is shown in Fig. 11.

In order to verify the effectiveness of the GNN based residential building layout design and optimization method proposed in the study (marked as Method A), the GCN and GAT models were used as baselines in the experiment, and the intelligent generative method based on genetic algorithm (marked as Method B) and the layout optimization method based on particle swarm optimization (marked as Method C) published in 2023-2024 were compared. The comparison results of different methods are shown in Table I. Table I shows that Method A outperforms the baseline models GCN and GAN in all indicators, and compares Method B with Method C. Compared to the baseline model, the performance of method A has significantly improved, with its root mean square error reduced by nearly half, accuracy increased by about 10%, and F1 value increased by about 6%. Compared with the methods proposed in 2023-2024, Method A leads by about 4% in accuracy and F1 score, demonstrating higher overall performance. This indicates that the GNN based method for residential building layout design and optimization has significant advantages and application potential.

TABLE I. COMPARIING RESULTS OF DIFFERENT METHODS

Method	Root mean square error/%	Accuracy/%	F1 value/%
GCN	20.3%	83.1%	89.3%
GAN	25.1%	80.3%	87.3%
Method A	10.7%	93.2%	95.1%
Method B	13.7%	90.2%	91.3%
Method C	16.1%	89.3%	90.8%

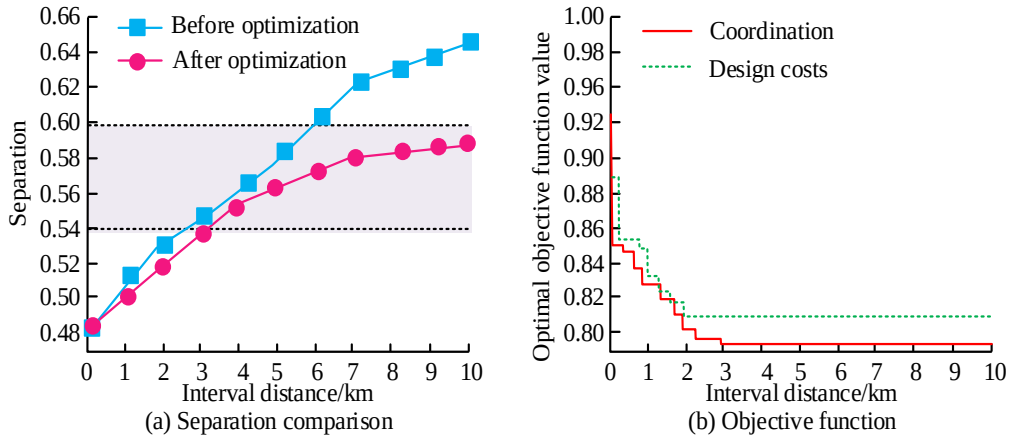

Fig. 11. Optimization of residential building layout design.

Fig. 11(a) shows the results of the comparison of the separation degree of the spatial layout before and after the optimised design. Before the optimal design, the separation degree of each functional area is low, and there are some areas that are not effectively utilised. The separation degree of the functional areas after the optimal design is significantly improved and always within the permitted fluctuation range, which indicates that our proposed design method can effectively optimise the layout of the public space, making the spatial distribution of the functional areas clearer and avoiding the waste of space. Fig. 11(b) shows the results of the objective function solution, which shows a decreasing trend with the increase of the number of iterations. This is because in the quantum particle swarm algorithm, the particles are able to adjust and update all the particle information through quantum mechanics, maintaining the original position and velocity while choosing the appropriate velocity direction based on historical experience. This process of constantly searching and updating position information makes the particles gradually approach the optimal solution, thus optimising the layout of the main functional area of the public space. The evaluation of the application effect of the residential building layout design and optimisation method is shown in Fig. 12.

In Fig. 12, the study compares the proposed method for designing and optimising the floor plan layout of residential buildings with computer-aided design (CAD) and poster tools as a comparison in order to analyse the effectiveness of the application of the proposed method in the study. Fig. 12(a) shows the evaluation results for non-professional users and Fig. 12(b) shows the evaluation results for professional users. Compared with CAD and poster tools, the completeness of the residential building floor plan layout design and optimisation method is improved by about 2.3%, rationality by about 3.6%, readability by about 1.9% and effectiveness by about 10.3%.

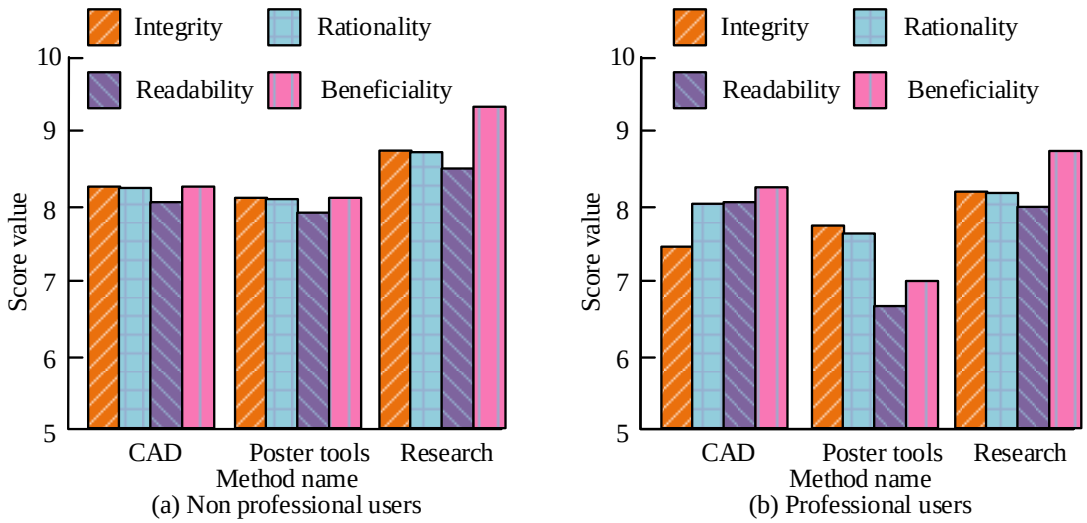

Fig. 12. Evaluation of the application effect of residential building layout design and optimisation methods.

V. Conclusion

In order to improve the space utilisation of residential buildings and the comfort of occupants, the study proposes a GNN-based method for designing and optimising the floor plan layout of residential buildings. The method analyses and identifies the spatial distribution characteristics of the main functional areas in the space through deep learning techniques. The study adopts the quantum particle swarm algorithm to optimise the layout of the public space, and transforms the complex layout problem into the form of a composite model to meet the preset convergence conditions and obtain the optimal layout design results. In the process of data conversion, the average accuracy can reach 96.4% and the average completeness can reach 84.4%, which lays the foundation for further data analysis and processing. The error value of the residential building floor plan layout image feature extraction is within the range of 0-0.01, and the repeatability averages for training and testing are 84% and 89%, respectively. Compared with the most advanced methods, the accuracy and F1 value of the GNN based residential building layout design and optimization method have been improved by about 4%, and its overall performance is better. Compared to CAD and poster tools, the effectiveness of the residential building floor plan layout design and optimisation method was improved by about 10.3%. The results indicate that the GNN-based residential building floor plan layout design and optimisation method has high applicability. This study has made multiple contributions in the field of residential building layout design. Firstly, the innovative application of Graph Neural Networks (GNNs) in residential building layout design provides a new intelligent design approach. Secondly, a GNN model adapted to the layout design of residential buildings was carefully constructed and optimized with a large amount of training data, significantly improving design efficiency and accuracy, effectively addressing the shortcomings of existing research in comprehensively considering multiple factors such as complex functional requirements, user preferences, and building standards of residential buildings. Thirdly, the successful application of the GNN model in practical design cases has improved the completeness, rationality, readability, and efficiency of the design scheme. It has shown outstanding performance in data conversion, image feature extraction, and other aspects. Compared with traditional CAD and poster tools, its efficiency has been significantly improved, effectively promoting technological progress and sustainable development in the field of architectural design. However, the study still has some limitations, such as the limited scope of data collection and the insufficiently fine setting of model parameters. Future research can collect data in a wider range and further optimise the model parameter settings to improve the performance and practicality of the layout design method.

An Intelligent Transport System for Prediction of Urban Traffic Congestion Level

Mohammad Khalid Imam Rahmani[1]*, Shahnawaz Khan[2], Md Ezaz Ahmed[3], Khaurram Jawad[4]*
College of Computing and Informatics, Saudi Electronic University, Riyadh 11673, Saudi Arabia[1, 3, 4]
School of Information & Communications Technology, Bahrain Polytechnic, Isa Town, Bahrain[2]

***Abstract*—Developing a resilient infrastructure is crucial for nation-building by supporting innovations and promoting sustainable growth. The Kingdom of Saudi Arabia is striving to achieve the Sustainable Development Goals (SDGs) set by the United Nations. Industry, Innovation, and Infrastructure (I3) are some of the strategic objectives of the Kingdom's Vision 2030 par with the United Nations' SDGs. The objective is focused to develop trade and transport networks for international, regional, and local connectivity with an investment of billions of dollars to establish a robust transport network and improve the existing one for enhancing road safety to reduce the costs of deaths and serious injuries. For this, a control center for automatic monitoring could be established for 24x7 monitoring of traffic violators; the key project has been named the National Center for Transportation Safety, apart from launching the "Rental Contracts" facility with the Naql portal. Moreover, the growing urban population is causing more vehicles on the roads leading to more traffic congestion which has become severe during peak hours in the major cities causing several other issues such as environmental pollution, high greenhouse gases (GHGs) including CO_2 emissions, health risks to the citizen and residents, poor air quality, higher risks of road safety, more energy consumption, discomfort to the commuters, and wastage of time and other resources. Therefore, in this research, we propose an intelligent transport system (ITS) for predicting traffic congestion levels and assist commuters in taking alternative routes to avoid congestion. An intelligent model for predicting urban traffic congestion levels using XGBoost, Gated Recurrent Unit (GRU), and Long Short-Term Memory (LSTM) algorithms is developed. The comparative performance analysis of the techniques concerning the performance metrics: Mean Squared Error (MSE), Root Mean Square Error (RMSE), Mean Absolute Error (MAE), Mean Absolute Percentage Error (MAPE), Error cost, Outlier sensitivity, and Model Complexity, demonstrate that the LSTM algorithm excels the other two algorithms.**

Keywords*—Sustainable development goals; traffic congestion; traffic prediction; Gated Recurrent Unit; long short-term memory; intelligent transport system

I. INTRODUCTION

Millions of people visit the Kingdom of Saudi Arabia yearly to perform Hajj and Umrah. During the Hajj period, two Holy cities experience the peak of traffic. Due to the large number of expatriates, the other major cities also usually experience the peak. The Kingdom aims to reduce peak hour congestion levels in the major cities as an important element under the SDGs of Vision 2030. So, the priorities in the Kingdom's Vision 2030 include programs for self-driving vehicles [1]. An intelligent transport system for predicting the congestion level and traffic analysis will assist the self-driving vehicle program initiative.

Apart from the proper road design, the main focus of the Transport Ministry in the Kingdom of Saudi Arabia is on road safety mechanisms, like mounting proper traffic and guide signs, adequate water drainage, and highway fencing to avoid accidents due to animal entry [2]. The concerned committees on existing roads and improving safety policies are trying too hard to prevent fatalities due to accidents. The National Road Safety Center (NRSC) is one of the Kingdom's road safety initiatives to reduce traffic fatalities within the National Transformation Program 2020 [3]. The goal is to establish a center of technical excellence and strategic partner for road safety stakeholders to place the Kingdom among the top 20 countries in road safety by 2030 [3]. Therefore, one of the key initiatives of this research project is to apply Artificial Intelligence (AI) technologies to effectively forecast traffic congestion levels during peak traffic load periods to diversify road traffic efficiently.

So, our proposed system will offer effective management of the congestion level, thereby reducing the cost of accidental deaths, serious injuries, and travel time. Consequently, the quality of social life will improve.

Moreover, higher congestion leads to higher energy consumption and creates related challenges such as environmental pollution, high CO_2 emissions, health risks, etc. An ITS capable of predicting the congestion level will help minimize the traffic congestion levels and related challenges [4].

Novelty and Motivation of the Research Work

1) An intelligent transport model development: The research aims to develop an intelligent transport system model for forecasting traffic congestion levels using an amalgamation of ML and deep learning (DL) techniques.

2) Prediction of the traffic congestion levels: We investigate and exploit various learning techniques capable of effectively predicting the traffic congestion levels for developing an intelligent transport system.

3) Better traffic control and management: Controlling and managing traffic congestion during peak hours and in undesirable circumstances e.g., in an accident or any intentional road blockage is in line with the SDGs.

4) Reduction in transportation time: The project's outcomes can be used in the concerned committee settings to

*Corresponding Author.

reduce the overall transport time for the citizens and the residents.

5) Comparative analysis of multiple techniques: A comparative analysis of the proposed model's results with the existing traffic congestion prediction techniques strengthens its validity and viability.

This document is organized as follows. Section II describes the literature review. Section III discusses the Methodology; Section IV outlines the Proposed Work. Section V covers the Experimental Analysis. Section VI concludes the research.

II. Literature Review

The concept of an intelligent transport system is useful for overcoming the crisis of urban traffic congestion levels raised due to the migration of people to urban areas by efficiently predicting traffic congestion levels in urban areas [5-9]. The goal of such a system is to achieve traffic efficiency by minimizing the commuters' travel time, consumption of energy, and requirement of other resources and maximizing road safety and commuters' comfort level. These applications are deployed as strategic and sustainable development plans in techno-savvy countries to bring the concept of intelligent transport systems into reality.

Faster And Safer Travel Through Routing and Advanced Controls (FAST-TRAC) [9] is one of the earliest projects deployed in Oakland County, Michigan. The system receives and shares data and live video of traffic conditions with the Michigan Department of Transportation. It is one of the first suburban adaptive traffic control systems in the USA; also, the first to use video processing for an adaptive traffic control system in the world, and the first to launch a traffic website about real-time traffic information.

Sydney Coordinated Adaptive Traffic System (SCATS) [10] signal system uses eight phase signals to fit into the changing traffic patterns. This traffic control system optimizes traffic flow and implements intelligent algorithms to process real-time data to predict traffic patterns, reduce congestion and travel time, and enhance travel safety. It has reduced travel time by 28%, stops by 25%, fuel consumption by 12%, and emissions by 15%.

Some similar early systems to mention are Driver Information Radio using Experimental Communication Technologies (DIRECT), ADVANTAGE l-75, Suburban Mobility Authority for Regional Transportation (SMART), Cooperative Intersection Collision Avoidance System (CICAS), and Data Use Analysis and Processing (DUAP), etc.

Recent developments for automated and real-time processing of crowding information are the Google Maps transit service [11], Singapore LTA [12], and the Moovit travel app [13]. These systems are not cost-effective.

The paradigm of road safety has shifted from passive to active safety. Effective traffic congestion detection capability and effective analysis of real-time data are the keys to the efficiency of these systems [14].

The concept of intelligent traffic systems is incomplete without extracting useful and distinctive patterns from the collected data for real-time decision-making. A. Drabicki et al. [7] propose a framework for modeling an RTCI (real-time crowding information) system with an agent-based model with PT (public transport) simulations. This system is not validated as a reliable model and ceases to be an evidence-based analytical tool.

L. Li et al. [8] discuss the critical role of trajectory data focusing on traffic flow by revisiting traffic models at three levels (microscopic/mesoscopic/macroscopic). Their research is based on theoretical aspects of the field without practical implementation.

Authors in study [6] deal with the techniques of improved traffic flow and safety and less congestion including evaluating the performance of intelligent transport systems through a survey among the urban truck drivers. They do not implement a model for intelligent transport systems.

Authors in study [15] discuss sustainable traffic management issues focusing on IoT and intelligent information systems. Their research is based on theoretical aspects of the field without practical implementation.

Authors in study [16] propose a deep autoencoder neural networks model for traffic congestion prediction on the SATCS dataset. During the congestion level prediction in their work, there is a loss of information in representing the congestion levels in the proposed network. There is no clarity on information loss and what is the impact of information loss on prediction performance.

K. Zhang et al. [17] propose a data-driven model to predict traffic congestion flow in urban regions using the Convolutional Neural Network (CNN) LSTM network. The model depends on statistical analyses and employs a black box DL model for congestion prediction which lacks interpretable algorithms for traffic modeling.

Authors in study [18] described an intelligent traffic prediction approach using RFs and SVMs. However, they use simulations to validate the outcomes.

Therefore, in this project, we aim to design an effective intelligent model for traffic congestion prediction using an amalgamation of ML- and DL-based approaches which will improve the weaknesses of the previous work. This work will solve the urban traffic congestion of the Kingdom.

III. Methodology

An ITS consists of multiple components such as traffic management systems, electronic toll collection, vehicle-to-infrastructure communications, traffic flow forecasting, traveler information systems, etc. Traffic flow forecasting is an important component of ITS. Accurate traffic flow forecasting can improve an ITS in multiple ways such as improved traffic conditions by route optimization, improved travel efficiency by mitigating congestion, etc. Vehicle traffic flow is influenced by several factors that exhibit complex spatial-temporal dependencies. These complex spatial-temporal dependencies and non-linear relationships in the traffic data, make the forecasting task more challenging. Hence, different techniques of traffic flow forecasting face many challenges. This paper

analyzes many AI techniques for forecasting effective and efficient traffic flow. Several machine-learning techniques have been utilized in forecasting and other complex real-world applications [19-26]. These techniques include LSTM networks for time series, GRU, Nonlinear Autoregressive with exogenous input (NARX), Random Forest (RF), and XGBoost. Each has been evaluated based on its strengths, weaknesses, and suitability for forecasting the inherent spatial-temporal dependencies within traffic data.

A. Random Forest

RF is a machine learning (ML) technique that can be utilized for classification and regression. However, the most common application of this technique is classification. It belongs to the category of ensemble ML approaches. The ensemble approach can be considered as a group of experts working together to find the solution to a problem. Ensemble techniques rely on multiple models (often base learners) working together to generate the final prediction by combining predictions of all the models. RF ensembles multiple decision trees [27, 28] as illustrated in Fig. 1.

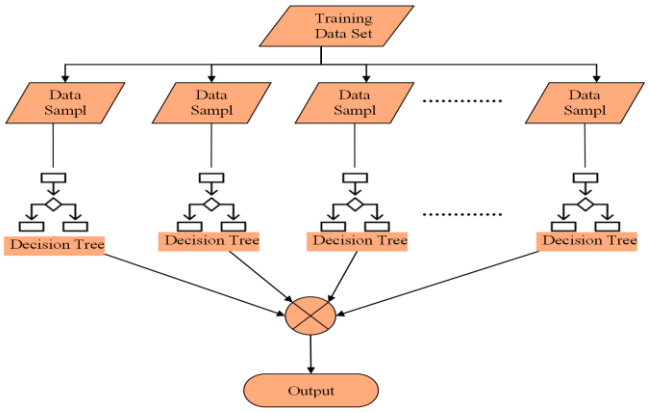

Fig. 1. Random forest.

Therefore, an RF builds an ensemble of multiple decision trees. The predictions of these trees are combined. Each subtree is built on a random subset (with replacement) of training data. This prediction aggregation process is also known as bagging or bootstrap aggregating. At each split in a tree, only a subset of features is considered. This process is known as random feature selection. Due to the randomness, caused by the random feature selection, overfitting is reduced. Each tree gets to vote for the final prediction. In the case of classification, the most likely outcome is the one with the majority of votes, and in the case of regression, the prediction is the averaged predicted value of all the trees [29]. This research predicts the number of vehicles and therefore, the RF regressor model has been utilized for the implementation. The traffic data of the time series has been categorized into four traffic categories for easier interpretation. Therefore, the predicted numbers are converted into high, low, normal, or heavy traffic category. Several research studies have analyzed the effectiveness of RF in forecasting road traffic [29-33]. An analysis by [30] compares the traffic prediction accuracy between the Bayesian network and RF. The study outlines that RF performs better than Bayesian networks in traffic prediction scenarios. Another study [33] analyzes multiple ML models and concludes that RF performs better than the other models.

B. XGBoost

eXtreme Gradient Boosting (XGBoost) is one of the powerful ML techniques for prediction tasks like classification and regression [34]. XGBoost is an ensemble technique. It combines the capabilities of the decision trees and gradient boosting. The decision trees are ensembled sequentially. The prediction errors introduced by the previous tree are corrected by the next tree improving the final prediction. XGBoost incorporates Lasso (L1) and Ridge (L2) regularizations to prevent overfitting. Using regularization also helps in controlling the complexities of the trees. XGBoost allows custom-defined loss functions or uses commonly used loss functions such as MSE and log loss functions. Mean squared is used for regression tasks. As in this research, the model aims to predict the number of vehicles, therefore, the MSE loss function has been used. XGBoost utilizes parallel and distributed computing environments to speed up the training [35]. To improve the speed and optimization, XGBoost uses the computation by pruning the irrelevant branches in the early stage. The pruning process utilizes the sparse learning technique [36]. Several researchers have leveraged the capabilities of XGBoost for traffic predictions [37, 38]. As discussed, it utilizes regularization which helps in preventing overfitting. It can handle complex relationships and non-linearity present in the traffic data points.

C. Neural Network Time Series Nonlinear Autoregressive

Vehicle traffic data can often be subject to high variance and rapid transients. Therefore, time series forecasting models should be able to overcome the non-linearity of these changes. A research study [39] suggests that the following non-linear autoregressive model $\hat{y}(t) = h\big(y(t-1), y(t-2), \dots, y(t-d)\big) + \varepsilon(t)$ can be utilized to model such variance and transient time series data. This model equation has been explained in the next paragraph. The model analyzed past traffic data to predict future traffic volumes for vehicle traffic forecasting. However, as discussed earlier, traffic data is often non-linear, therefore, a non-linear autoregressive neural network has been utilized for traffic volume forecasting. The implemented neural network is a multilayer feedforward network with feedback connections [39, 40]. The general structure of the multilayer nonlinear autoregressive neural network has been illustrated in Fig. 2.

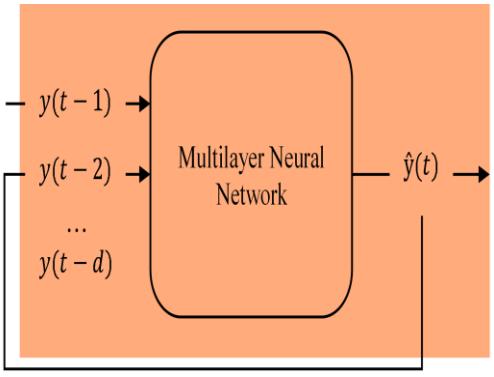

Fig. 2. Structure of the multilayer nonlinear autoregressive neural network.

The mathematical representation of the model can be stated using the following equation:

$$\hat{y}(t) = h\big(y(t-1), y(t-2), \dots, y(t-d)\big) + \varepsilon(t) \quad (1)$$

This equation states that the predicted value can be formulated into a function h of past time-series values. During the training process, weights and bias values are adjusted to approximate the function h. The term $\varepsilon(t)$ represents the error. It is a sequence of random independent variables. The sequence has a mean of zero and a finite variance. The neural network model trains on the past time series data using d feedback delays. The parameter d is the delay and can be tuned by the trial-and-error method for better accuracy. The proposed work has implemented different training algorithms- scaled conjugate gradient, Bayesian regularization (BR), and Levenberg-Marquardt (LM) with the dataset. Due to the features of each algorithm, they may perform differently with the same training data and network architecture. The scaled conjugate gradient algorithm used the gradient calculation method. It made it more memory efficient than the LM and BR training algorithms which utilize Jacobian calculations.

D. Long Short-Term Memory Networks

The LSTM neural network was proposed by Hochreiter and Schmidhuber [41]. These are a category of recurrent neural networks (RNNs) that are types of artificial neural networks. RNNs can identify the patterns in the data sequences or time series.

The vehicle traffic flow data used time series data in this research work. Time series forecasting may lead to sequence dependency issues on the input variable [42]. RNN maintains a memory of the previous inputs through the hidden states to learn from sequential or time-series data. However, RNNs can suffer from the vanishing gradient problem. A vanishing gradient problem where the gradients become very small as they are back-propagated through time. It leads to difficulties in learning long-term dependencies. LSTMs are specifically designed to address this problem. LSTMs utilize memory cells with gates. Gates control the information flow and allow the network to learn long-term temporal patterns. LSTM neural network is composed of multiple cells. The following Fig. 3 illustrates a typical cell of the LSTM neural network at the time t.

The cells of the LSTM network are very similar to those of the RNN neural network and utilize the previous timestep as shown in Fig. 1.

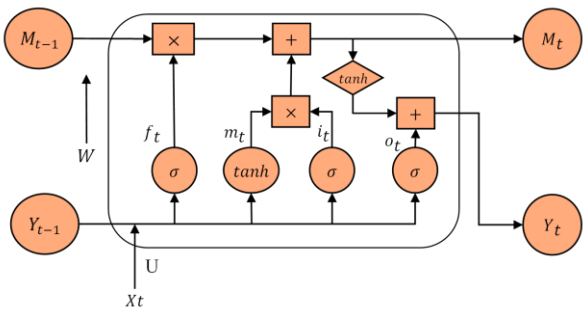

Fig. 3. LSTM neural network cell at the time t.

In LSTM, each cell is composed of an input gate (i_t), an output gate (o_t), a forget gate (f_t) and memory (m_t). The additional component in the LSTM neural network is the memory unit. These cells are the elementary units for the layers of the neural network. The memory of the LSTM neural network comes from the cells of the hidden units. The cell memorizes the values of the unit for an arbitrary period. The forget gate and input gate apply the sigmoid activation function (represented as σ) and the activation function for memory is $tanh$. M_{t-1} represents the memory from the previous cell and M_t represents the memory of the current cell. Similarly, the Y_{t-1} is the output from the previous cell and Y_t represents the output of the current cell. The symbol '×' illustrates the elementwise multiplication and the symbol '+' represents the elementwise addition. X_t is the t^{th} timestep input to the cell. U and W are the weight vectors. The output of these gates is the vectors computed by applying the weights and corresponding activation functions on the input for every timestep. Each cell generates a memory and an output. The memory can either be utilized or forgotten by the next cell depending on the values from the activation function of the forget gate as depicted in Fig. 1.

E. Gated Recurrent Units

The GRUs were introduced by [43], one of the powerful architectures based on RNN. Similar to LSTM, they use a gating mechanism to manage information flow. However, they have simpler architectures with fewer parameters than LSTM, making them faster to train than LSTM [43]. The vanishing gradient issue is where the information from old data sequences does not propagate properly through the network. The GRUs mitigate this issue by capturing long-term dependencies. Research studies [44, 45] have implemented GRUs for traffic prediction with promising results. We discuss the functions of each component of GRUs in the below paragraph.

A GRU unit consists of two main gating mechanisms known as update gate (z_t) and reset gate (r_t). The output hidden state (h_{to}) at time t is determined by the candidate's hidden state (h_t), update gate (z_t) and reset gate (r_t). The update gate is represented mathematically as:

$$z_t = \sigma\,(W_z[h_{t-1},\ x_t] + b_z) \quad (2)$$

The values close to 0 disregard the past state and values close to 1 indicate the higher influence of the past states. The update gate controls the information flow from the previous hidden state (h_{t-1}). The reset gate (r_t) controls the influence of the past states. That is, how much or to what extent, the processing of the current state (x_t) of the network relies on the past hidden states. The reset gate is represented mathematically as:

$$r_t = \sigma\,(W_r[h_{t-1},\ x_t] + b_r) \quad (3)$$

The values close to 1 indicate that the network can utilize the past state and the values close to zero indicate that the network should focus on the current input. The information flow is managed using the activation functions such as sigmoid (σ) or hyperbolic tangent ($tanh$). The candidate's hidden state is calculated using the current input and the selective

information from the previous hidden state. It is represented mathematically as:

$$h_t = tanh\,(W_h[r_t * h_{t-1},\ x_t] + b_h) \quad (4)$$

The output hidden state (h_{to}) is computed by using the previous hidden state, candidate hidden state, and update gate as:

$$h_{to} = (1 - z_t) * h_{t-1} + z_t * h_t \quad (5)$$

In the above equations, W and b are parameter metrics and vectors.

GRUs offer compelling performance with simple architecture which is computationally lighter to train than LSTM.

The predictive ability of the combined method was evaluated by four indices, namely, the MAE, the MSE, the RMSE, and the MAPE:

$$MAE = \frac{1}{n}\sum_{t=1}^{n}|y_t - \hat{y}_t|$$

$$MSE = \frac{1}{n}\sum_{t=1}^{n}(y_t - \hat{y}_t)^2$$

$$RMSE = \sqrt{\frac{1}{n}\sum_{t=1}^{n}(y_t - \hat{y}_t)^2}$$

$$MAPE = \frac{1}{n}\sum_{t=1}^{n}\frac{y_t - \hat{y}_t}{y_t} \times 100\% \quad (6)$$

IV. Proposed Work

Fig. 4 represents the proposed system's general architecture. This project will investigate and exploit several prediction techniques using three algorithms, XGBoost, GRUs, and LSTMs. These methods will be compared based on the performance of prediction accuracy. After evaluating the implemented techniques, the model that performs the best among these alternatives will be selected for forecasting the congestion level and presented as a model for deployment.

A. Dataset Description and Analysis

Actual urban traffic scenarios are complex. Traffic is dynamic over the days of the week and hours of the day. Therefore, proper data analysis depends on the actual traffic scenario. During the weekdays there are very high volumes of traffic usually called rush hours often from 6 am to 8 am and from 4 pm to 6 pm when most people are either going to or coming from work. This period heavily impacts traffic congestion levels. Fridays show unique deviation from anticipated as typical weekday traffic patterns; despite being considered part of weekdays. Congestion is not experienced during normal working hours but there is still increased road usage though not as much as on other days of the week perhaps due to leisure activities and social gatherings. Monday is the only day commuters commute consistently, most likely because it is the first day after taking a weekend off. Therefore, temporal factors should be considered when designing effective management systems since they offer better insights into the potential intensity of bottlenecks at specific times if nothing is done to mitigate them.

The dataset used in the research work is publicly available at Kaggle [46]. Table I summarizes the features of the dataset. The detailed dataset description is available in Table II.

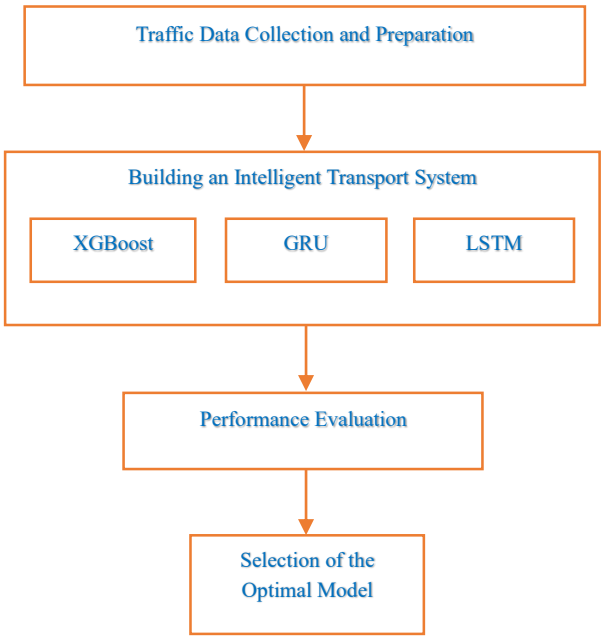

Fig. 4. The proposed ITS architecture.

TABLE I. Dataset Summary

Total Records	5952
No. of Attributes	9
Attributes	Time, Date, Day of the week, CarCount, BikeCount, BusCount, TruckCount, Total, Traffic Situation

TABLE II. Summary of Temporal Traffic Dataset

Day	Period	Traffic Volume	Key Observations
Weekdays	06:00 - 08:00	High	Morning rush hour due to work commutes
	16:00 - 18:00	High	Evening rush hour due to work commutes
Friday	06:00 - 08:00	Lower	Reduced morning congestion compared to other weekdays
	16:00 - 18:00	Moderate	Evening traffic due to social and recreational activities
Weekends	Various	Variable	Much lesser uniformed traffic patterns contrast to weekdays

The quantiles and distributions of the four vehicle types are illustrated in Fig. 5 with box plots and histograms respectively.

The research considers four categories of traffic situations namely low, normal, high, and heavy to analyze the traffic congestion situations. The number of average total transportation for each category of traffic situations has been depicted in Fig. 6.

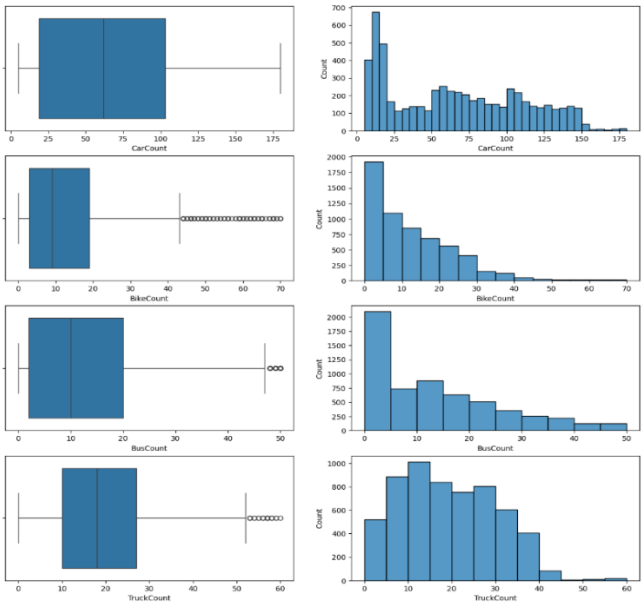

Fig. 5. The box plots and distributions (histograms) of the four vehicle types.

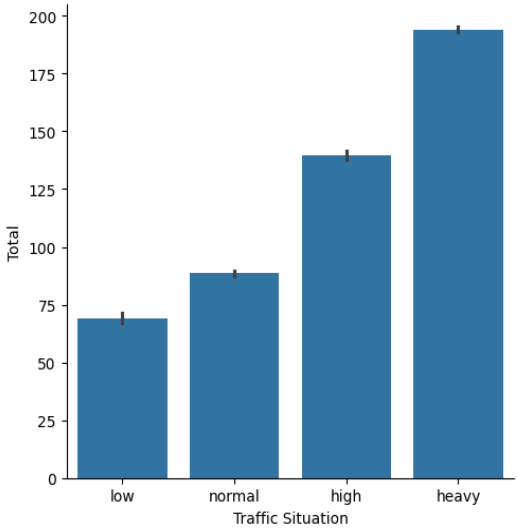

Fig. 6. The number of average total transportation for each category of traffic situations.

A pie chart of total vehicles by traffic situation has been shown in Fig. 7.

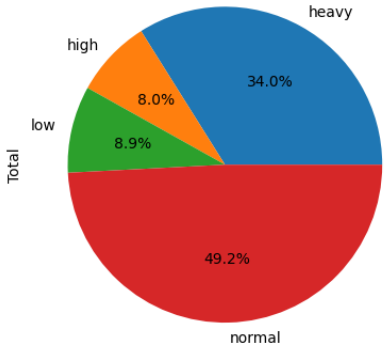

Fig. 7. Total vehicles by traffic situations.

B. Proposed Models

Temporal traffic pattern insights are useful for urban planners and decision-makers to reduce congestion and plan for infrastructural growth and transport system development toward building resilient cities that can withstand natural calamities and shocks such as heavy rains, floods, and earthquakes. Three algorithms are used for predicting future transportation states: XGBoost, GRUs, and LSTMs. The performance metrics used to evaluate the XGBoost model with 100 estimators included MSE, RMSE, MAE, MAPE, Error cost, Outlier sensitivity, Model complexity, etc. We compare the forecast against actual data to visualize our models' performance.

The GRU model, which consisted of a single GRU layer followed by two dense layers, underwent extensive training and evaluation. Performance measures were calculated, and predictions were compared to the real data. However, a type error occurred during the visualization step because the test set and predictions had different formats. This issue was resolved by transforming the forecasts into a NumPy array.

The training, assessment, and presentation procedures for the LSTM model—which consists of one LSTM layer followed by two dense layers—should be mentioned, among other things. It's also important to note that Fig. 8 displays the graphical representation of error distribution for each model, providing insight into the distribution and concentration sections where such errors are in the prediction cluster.

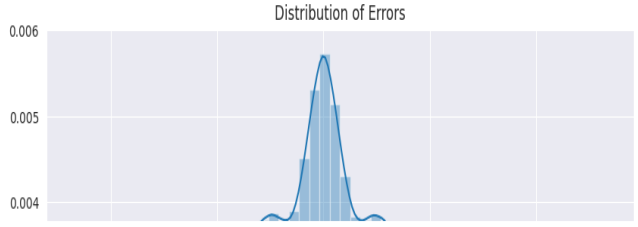

Fig. 8. Error distribution for each model.

V. Analysis of the Experiments

An experimental setup will be established, and its comprehensive experimental analysis will be performed in this section.

We discuss traffic forecast techniques using three models: XGBoost, GRU, and LSTM. To enable the chosen models to use the dataset, we first do considerable pre-processing on it. These procedures include encoding categorical information like the day of the week and traffic conditions and standardizing time to a 24-hour format. The data set is split into train-test sets for model training and evaluation, following the pre-processing. Our investigation begins with the RF model, well known for its ability to handle complex information. It offers insights into its predicted performance through an extensive evaluation process. Specifically, its ensemble learning approach exhibits competitive performance metrics, indicating strong performance in tasks such as traffic prediction where multiple factors influence the final result. The metrics employed by the models are summarized in Table III to give individual and comparative performance evaluations.

TABLE III. COMPARATIVE EVALUATION OF METRICS FOR MODEL PERFORMANCE

Metrics	Performance Values		
	XGBoost	***GRU***	***LSTM***
Mean Squared Error (MSE)	15.6	12.8	10.5
Root Mean Squared Error (RMSE)	3.95	3.58	3.24
Mean Absolute Error (MAE)	2.75	2.45	2.15
Mean Absolute Percentage Error (MAPE)	5.3%	4.7%	3.9%
Error Cost	Moderate	Moderate	Low
Outlier Sensitivity	Low	Moderate	Low
Model Complexity	High	Medium	High

The metrics employed by the XGBoos model are demonstrated in Fig. 9. The MSE for the XGBoos model between the actual and projected values is 15.6. RMSE provides a comprehensible metric of error magnitude and a small deviation from true values because it is the square root of MSE. This relatively low MSE suggests that the model's predictions are reliable. With an MAE of 2.75, the model demonstrates modest prediction errors, indicating its forecasting reliability. These figures are supported by a MAPE of 5.3%, which displays MAPE about actual values, presenting that on average the system's predictions should not deviate significantly (within a range of ±%) from reality. Such an accomplishment reflects an important degree of precision needed in real-world traffic forecasting applications, where it may not always be possible to obtain detailed or reliable historical data on past events to use as the foundation for future projections. In urban traffic management, moderate mistake costs imply manageable effects on flow control strategies intended to reduce congestion within cities; therefore, they can be effortlessly handled using suitable actions taken at strategic points along important paths serving various parts of the city. Mild mistake costs show operational/financial impacts related to incorrect predictions. The RF model's insensitivity to outliers is a crucial feature that makes it perfect for handling traffic data with irregular abnormalities like accidents or abrupt volume increases. This resistance against anomalous values guarantees smooth functioning and accurate predictions are made throughout, even in the face of random data points. Furthermore, the building of numerous decision trees combined is the cause of the high inherent complexity in the RF design. This complexity increases forecasting accuracy and makes it possible to represent intricate relationships within databases, such as those including multiple communicating variables, whose collective impact can either facilitate or obstruct flow depending on what is occurring at any given time. Yet, managing large amounts of input/output data can be challenging and require a higher level of interpretability, requiring more processing power than would typically be necessary under less demanding limitations. These examples show how effective an RF model can be in traffic prediction: Comparatively low MSE and RMSE readings, which indicate accuracy, corroborate its precision; MAE and MAPE exhibit reliability. Moderate error costs show applicability for usage in real-world scenarios where certain errors are expected but don't necessarily result in significant financial losses by striking a balance between accurate forecasts and controllable economic ramifications. When dealing with abnormal data points, XGboost is a good option because of its low sensitivity to outlying observations. This is especially true if the data points are frequently found along major highways with numerous entrances and exits close to one another over short distances, heavy traffic during peak hours, and sharp changes over time due to various factors like accidents, road works, etc.

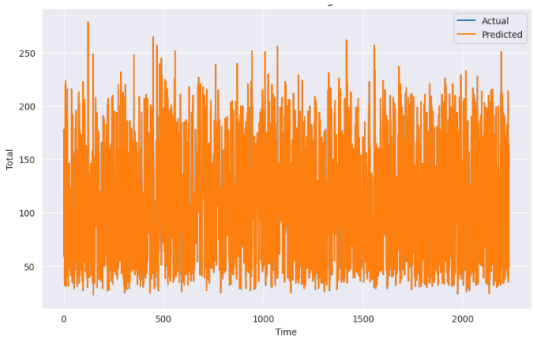

Fig. 9. XGBoost actual vs. predicted values.

The Recurrent Neural Network (RNN) architectures begin with the GRU model. The GRU model is trained and assessed by leveraging its ability to capture sequential dependencies in data. Despite promising results, with significant improvements over traditional ML methods, it does not achieve optimal performance metrics compared to the XGBoost model. Fig. 10 depicts the performance characteristics of the GRU model and provides valuable comparisons with the XGBoost model previously evaluated and shown in Fig. 9. The mean squared variance between the expected and actual values compared to XGBOOST is less than the MSE of 12.8, which indicates that the GRU model can capture temporal correlations in traffic data. The model's RMSE of 3.58, which places it higher in overall predictive performance than the XGBOOST model, further demonstrates its capacity to foresee with a smaller margin of inaccuracy. The MAE of the GRU model is 2.45, a lower value that highlights the model's accuracy in predicting traffic patterns. Furthermore, with a MAPE of 4.7% indicating that it is within 4.7% of the real values, the GRU model performs somewhat better than the XGBOOST model. Despite these promising metrics, the GRU model has moderate error costs, similar to the XGBOOST model, it represents that even though it makes generally accurate predictions, prediction errors can still have adverse operational and economic consequences that must be managed in real-world applications. While handling irregular data points better than many traditional ML models, the GRU model is not as robust as the XGBOOST model due to its moderate sensitivity to outliers. The model's performance in scenarios where anomalies occur frequently, such as traffic accidents or sudden volume increases, may be affected by this moderate sensitivity. In terms of model complexity, the GRU is classified as medium. Due to its gating mechanisms and sequential nature, it is more complex by nature than typical ML models, but not as complex as the ensemble-based XGBOOST model. The medium complexity is a suitable option for capturing temporal trends without unduly straining computational resources as it balances computational needs and predictive capabilities.

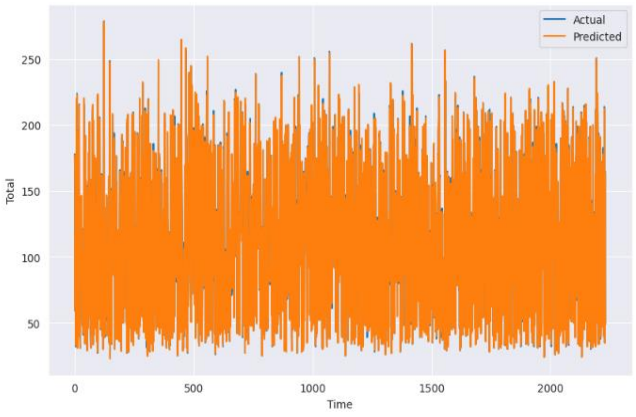

Fig. 10. GRU actual vs. predicted values.

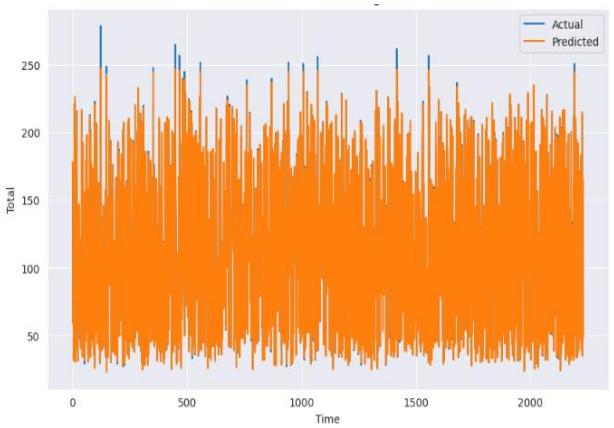

Fig. 11. LSTM actual vs. predicted values.

Next, we introduce the LSTM model known as the best for long-term dependency recognition in sequence data. In this light, traffic prediction tasks are conducted to see how well it can perform. However, there should be some more tests against an XGBOOST model, so we know what works better. Known for its depth and memory cells with specialized functions, the LSTM model has proved effective in traffic prediction. The training phase had several other models whose performance metrics were not as good as those of this one because during evaluation it achieved the lowest test loss among all considered models. This demonstrates that the only algorithm capable of making such complex predictions about traffic patterns would have been the LSTM model, which processes inputs over time and steps into outputs across variable sequence lengths until convergence on some fixed point. What more could you ask for from an LSTM model? Furthermore, the results obtained from examining the plots depicted in Fig. 11 indicate the potential success or failure of a certain predictive capability with other similar ones, such as the two displayed here, where they differ. The difference between the two models' accuracy in predicting all points examined so far throughout our research into each model's strengths and weaknesses is ΔY (Actual – Predicted), which is always within ΔX rather than zero. This indicates that both models perform equally poorly in predicting weak areas closer to either endpoint, possibly in part as none recognize features outside a certain range of values. As an illustration of the lack of consistency between anticipated forecasts made based solely on this type of proof, we can see that, between various points along the x-axis, the most faraway ones are more closely related than the two most adjacent indicated values themselves farther apart, but never precisely identical distance away from each other. This still fails to account for the least squares fits noticed.

The experimental investigation showed that many traffic forecast models ranging from deep DL techniques like GRU and LSTM to conventional ones, like XGBoost, are effective. Each model in traffic congestion prediction has demonstrated pros and cons. However, the LSTM model outperformed the others, achieving the highest accurate rate in traffic trend prediction. These results are critical in transportation planning and management because they offer practical guidance to enhance system efficiency and traffic flow optimization.

VI. Conclusion and Future Work

Our research considers many traffic scenarios to predict traffic congestion levels using an amalgamation of ML- and DL-based algorithms. The research outcomes show that both traditional ML and DL algorithms are effective. Three models, namely XGBOOST, LSTM, and GRU have been implemented on the dataset and are found powerful. The LSTM model is better than others due to its ability to capture long-term relationships between traffic data points and various patterns embedded in them. The concerned committees will utilize the research outcomes for transportation planning and management settings to optimize the flow of vehicles through different traffic routes to maximize the transportation system's efficiency. Citizens will save much of their precious time knowing the congestion level in advance; helping them plan their travel better. Business and industrial sectors can better plan the logistics and manage transport-related requirements. A high congestion level is the root of several environmental bad factors. Proper management of the congestion will improve the environment and will reduce pollution. A high level of congestion can waste commuters' time putting adverse effects on several other economic factors and accounts for high energy consumption. An ITS will assist in mitigating these factors and hence will enhance economic benefits.

The proposed model can be implemented as a mobile application in future work that can collect live data and aid the commuters in suggesting, in advance, the best route to travel based on the traffic congestion level.

While the proposed system considers various traffic scenarios occurring on specific periods of the day of the week, it does not consider other factors like weather and road conditions. We will focus on improving DL models to a hybrid of LSTM with techniques to exploit their strengths in future studies to improve the prediction effectiveness of the traffic congestion levels in ITS.

Moreover, to further increase the effectiveness of the ITS, accessing the real-time traffic data streams through comprehensive integration of vehicles' speed, location, and weather conditions to the ITS can be plenty of achievements like better accuracy in forecasting, scalability, and interoperability.

CONFLICT OF IINTEREST

The authors confirm that there is no conflict of interest to declare for this publication.

ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Scientific Research at Saudi Electronic University for funding this research (9425).

SAM-PIE: SAM-Enabled Photovoltaic-Module Image Enhancement for Fault Inspection and Analysis Using ResNet50 and CNNs

SAM-Enabled Photovoltaic-Module Image Enhancement (SAM-PIE)

Rotimi-Williams Bello*, Pius A. Owolawi, Etienne A. van Wyk, Chunling Du

Tshwane University of Technology, South Africa

***Abstract*—Different models have been developed for segmentation tasks, each with its uniqueness. Recently, the Segment Anything Model (SAM) was added to the pool of these models with expectations of addressing their weaknesses. SAM, although trained on a huge dataset for segmentation of anything, particularly images of natural source, produces suboptimal results when applied to segmentation of photovoltaic module image due to difference in semantic between photovoltaic module and natural images. In spite of the current suboptimal performance of SAM in segmentation of photovoltaic module images, it demonstrates detection and identification of thermal anomalies in photovoltaic module images that majorly contribute to power production loss. The implication of this is that, the task, the model, and the data corresponding to SAM are applicable to photovoltaic module image diagnosis. In this paper, we propose SAM-enabled photovoltaic-module image enhancement (SAM PIE) for fault inspection and analysis using ResNet50 and CNNs. SAM-PIE combines the strength of SAM for enhancement of the fault inspection and analysis procedure, for optimal performance of the proposed method. Experiments were performed on three thermal anomaly image datasets of photovoltaic modules to validate the performance of SAM-PIE for the classification tasks. The results obtained validates the potential capability of SAM-PIE to perform photovoltaic module image classification. The dataset is publicly and freely available for scientific community use at https://doi.org/10.17632/5ssmfpgrpc.1**

I. INTRODUCTION

Recently, there was an emergence of a state-of-the-art foundational model called the Segment Anything Model (SAM) [1] in the field of Computer Vision (CV) for image segmentation tasks. The main components that make the leap possible for the SAM are: (a) Prompts for new segmentation task, (b) SAM's model, and (c) SA-1B dataset. The prompt-able segmentation task was proposed in order to return a valid segmentation mask provided any prompt for segmentation is given. The main task of the prompt is simply to specify the image's object to segment, e.g., spatial or text information can be a prompt for object identification. For an output mask to be valid, there is a requirement that the output under any circumstances (for example, when there is an ambiguity in what object a prompt specifies in an image) should generate sensible mask at the least for one of the objects in the image.

The innovative design of the SAM model satisfies all the constraints imposed on the model architecture due to prompt-able task of segmentation and reality in real-world applications. In particular, prompts flexibility support masks computation in amortized real-time and ambiguity-aware [1-2]. Based on the abovementioned qualities attributed to SAM and its demonstration as a good model trained on a wide-ranging scalable data for flexibility, studies reveal the tendency of it facing challenges in tasks involving domain-specific segmentation solution [3], as noticed in some photovoltaic (PV) module image segmentation scenarios [4-6]. The rise of PV power has given a new dimension to renewable energy as evident in the global renewable energy, and this trend continues in gaining more acceptance as alternative to power generation [7-12].

The PV explosion requires an in-depth knowledge of its widespread, challenges, and prospect for concern individuals [13-15]; and this knowledge is essential for its proper monitoring, management, and maintenance across borders [16-20]. The inspection, detection, identification, and analysis of faults in PV installations have greatly been enhanced by the progress made in CV [21-24]. However, the majority of research on PV installations concentrate on using conventional CV techniques for inspection and analysis of the anomalies in solar cells of PV modules, which performs below expectations [25-27]. Moreover, high-resolution images are extremely required to obtain accurate inspection and analysis of PV modules [28], and the conventional techniques pose challenges regarding this.

Many researchers have attributed the inaccuracy obtained in their segmentation tasks to incapability of SAM when applied to PV image segmentation tasks, confirming the discrepancies in the tasks, model, and datasets. Although SAM shows segmentation efficiency in object-specific tasks, it still has limitations when dealing with fine structures, small disconnected components, weak boundaries and modalities [29-30]. Complex modalities, fine modular structures, small disconnected cell components, and absence of sharp boundaries are the challenges confronting SAM in PV image segmentation [28]. Additionally, the segment anything-1

The authors received funding from the Tshwane University of Technology, South Africa.

billion (SA-1B) of natural images on which SAM was pre-trained couple with the approach to determine boundaries based on discrepancy in intensity [28] is not applicable to PV images due to analysis of solar cells of the PV modules.

Moreover, while SAM can carry out many tasks, it does not have the prompts capability for panoptic and semantic segmentation implementation. Lately, SAM has experienced so much improvement due to many studies commitment to enhancing it due to its disappointing results to suit domain-specific tasks as noticed in PV image analysis. Several of these studies has dedicated their strength to fine-tuning the SAM model to enhance its performance and reliability for PV image analysis. Yang et al. [13] in their quest to meet the demand for the extraction of large-scale PV panel, proposed a novel weakly-supervised method that was based on the SAM model. Knowing the importance of broad data volumes and the knowledge that the extraction process requires the concept of latent PV locations for reduction in scope of the amount processed subsequently, they applied the method to the segmentation of latent PV locations for smooth passage from classification to segmentation. They achieved segmentation results that could stand the test of time.

Although SAM being initialized with a self-supervised technique [28], its efficiencies depend on large-scale supervised training. Rafaeli et al. [2] addressed this issue by proposing segmentation that is prompt-based at varied light conditions and resolutions using SAM 2. Their study revealed the efficiency of SAM 2 over SAM, particularly when prompted by points under lighting conditions that are sub-optimal. SAM's strength is challenged in segmentation of PV images, being a model trained on massive natural images. Although SAM may be prompt-able to efficiently segment PV images, it can still differentiate conspicuous solar cells of PV modules according to changes in image pixels. PV images are images of solar panels with a lot of revealing information only under high thermal image and pixel resolutions [31-32].

Therefore, thermal captured and enhanced images give visual quality to PV images for valuable information on anomalies detection, and analysis beyond what can be obtained from original image. Based on this, the aim of applying the techniques of PV image enhancement (PIE) in this study is to attain efficient and excellent inspection and analysis of PV faults from the available original PV imagery [33]. Therefore, we propose a new SAM-based PIE method (SAM-PIE) with the sole aim of enhancing the inspection and analysis of PV image segmentation models, and giving different perspective to the potential value of SAM in PV image analysis.

Under moderate prompts, the stability scores and masks generated by SAM are essential resource for PV image segmentation and analysis. An important factor that distinguished SAM-PIE from the traditional IE methods is the low-level in which the traditional IE methods frequently work, which is below the high-level requirement for reconstructing and recovering an original image [5], which is what SAM-PIE aims to achieve. This feat by SAM-PIE was attained by increasing semantic structures from SAM. Our proposed image enhancement method, SAM-PIE is easy to adapt to SAM, ensuring its applicability in solving anomalies in solar cells of PV modules by PV experts. In this paper, two classification models, ResNet50 [34] and Convolutional Neural Networks (CNNs), popular for their applications in PV image segmentation tasks were selected for the evaluation of SAM-PIE. One thousand PV module datasets [35], a Mendeley data comprising Hotspots (350 thermal generated images), Cracks (350 thermal generated images) and Shadings (300 thermal generated images) were used in performing the image segmentation experiments.

Research reveals that prior maps generated from effect of adding together the original and SAM's generated images can be employed for network inputs enhancement and thus improving the efficiency and performance of downstream models developed for segmenting PV images. This revelation motivated us to embark upon proposing SAM-PIE by applying the SAM's generated stability scores and masks. The regions of thermal anomalies in the original image can be spotted by the enhanced images, thereby providing the attention maps for the classification models for an enhanced classification of PV images. The techniques in the proposed SAM-PIE enable its effectiveness in inspection and analysis of thermal anomalies in solar cells of PV modules. The work carried out in this paper is a step towards automated inspection and analysis of thermal anomalies in solar cells of PV modules. The unique contributions of the proposed SAM-PIE method are as follows:

- Images of PV modules were originally collected, processed into datasets and publicly and freely available for scientific community use at https://doi.org/10.17632/5ssmfpgrpc.1
- Using drone (DJI Mavic 3 Thermal) for data collection addresses limitations in prior works that focused on collecting static images of PV modules. Moreover, this approach solves data limitations that could negatively influence the performance and accuracy of the proposed SAM-PIE.
- Integration of a novel PIE model into an existing SAM model to generate enhanced images for accurate classification of the thermal anomalies in solar cells of PV modules.

The rest of the paper's contents is as follows: Section II presents the related work. Section III presents the materials and methods. Section IV presents the experiments. Section V presents the results and discussions. Section VI concludes the study.

[23] conducted a survey on ANN for solar PV systems fault diagnosis. Hichri et al. [24] applied genetic-algorithm-based neural network to grid-connected PV systems for fault detection and diagnosis. Zhu et al. [25] proposed an approach based on unsupervised sample clustering and probabilistic neural network model for diagnosing fault for PV arrays. Eskandari et al. [26] proposed an autonomous fault diagnosis method based on weighted ensemble learning for PV systems using genetic algorithm. Wang et al. [27] proposed a support vector machine method for diagnosing PV array fault. Ravi et al. [28] proposed a Sam 2, a SAM model for segmenting anything in images and videos. Bommasani et al. [29] presented a work on the advantages and disadvantages of foundation models. Badr et al. [30] proposed a machine learning classifiers for identifying PV array fault. Lu et al. [31] proposed a CNN and electrical time series graph for diagnosing PV array fault. Liu et al. [32] proposed an approach based on stacked auto-encoder and clustering with IV curves for diagnosing PV array fault. Mellit [33] proposed a method based on thermographic images and deep CNNs as embedded solution for detecting and diagnosing PV module fault. He et al. [34] proposed a deep residual learning method for recognizing images. Bello et al. [35] proposed a PVMD dataset for automated detection and analysis of fault in large PV systems using PV module fault detection.

III. Materials and Methods

A. Data Collection and Description

The main hardware materials employed in this study comprise the hardware components for collecting and processing the data used in performing the experiment in this study. The materials are: (1) DJI Mavic 3 Thermal which is a state-of-the-art drone specifically designed for thermal imaging and inspection tasks, (2) Solar panels, (3) PV modules which include two panels of Jinko JKM200M-72 modules, each producing 200 W, (4) Inverter, (5) Storage battery, (6) DC Load, and (7) Solar charge controller. Table I shows the PVMD Dataset with the number of images in each anomaly category.

Popular PV image classification models, ResNet50 and CNNs were employed in carrying out the experiments of this study with one thousand PV module datasets [35], a Mendeley data comprising Hotspots (350 thermal generated images), Cracks (350 thermal generated images) and Shadings (300 thermal generated images). Afterward, we partitioned the dataset into training dataset (80%) and testing dataset (20%) to ease model evaluation. The images were pre-processed to standard size dimensions, and normalization techniques were applied for dataset consistency.

Additionally, the RGB images which were originally of different dimensions due to unfriendly and unstable environmental conditions were trimmed to size 512x512x3 (3 keeps the color information) and augmented using augmentation techniques such as geometric transformation, color-based transformations, illumination transformation, noise injection, etc., for dataset robustness.

Fig. 1 shows the framework of PV image classification with SAM-enabled PV-module image enhancement (SAM-PIE). The Fig. 1 shows the step-by-step process comparing the PV image classification output with SAM-PIE and without SAM-PIE.

TABLE I. PVMD Dataset with the Number of Images in Each Anomaly Category [35]

Thermal Anomaly of PV Module	Number of images
Hotspots	350
Cracks	350
Shadings	300
Total	**1000**

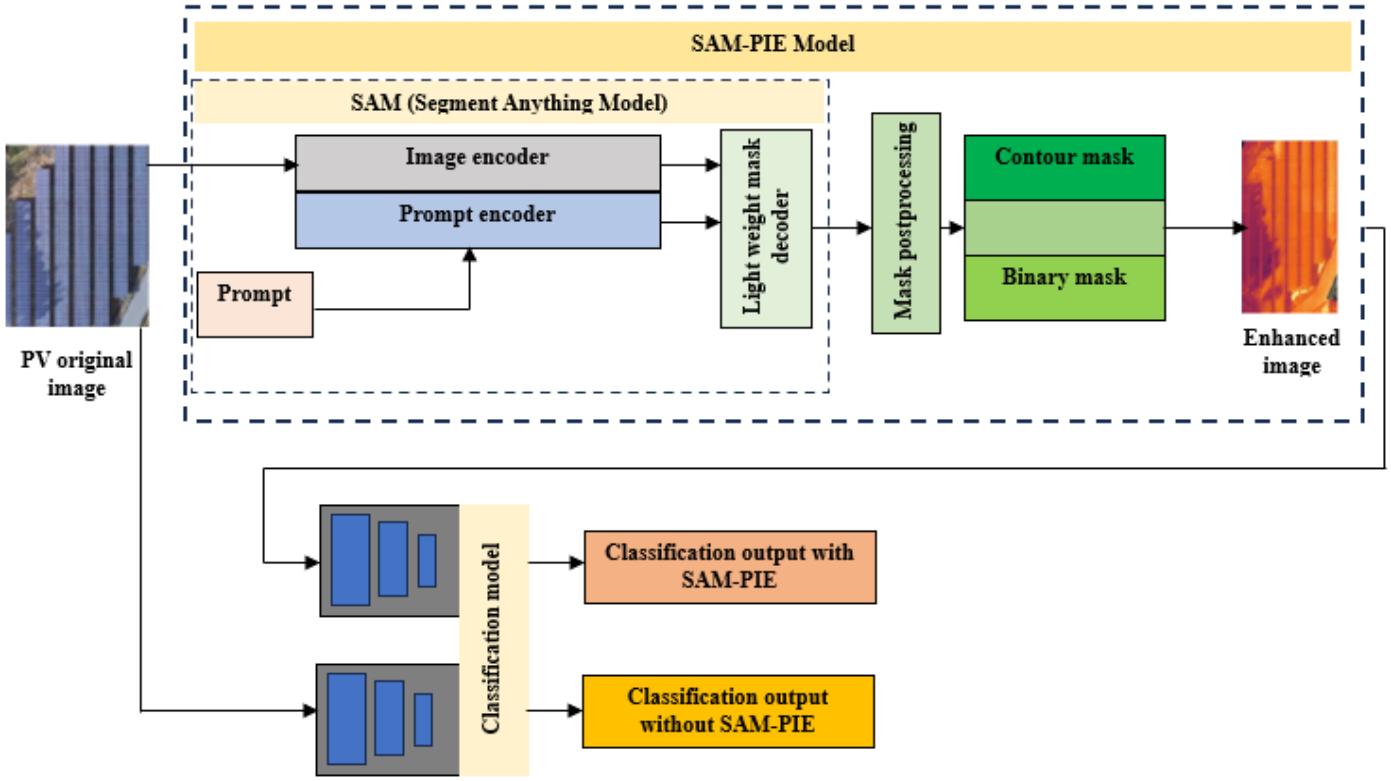

Fig. 1. The proposed framework of PV image classification with SAM-enabled PV-module image enhancement (SAM-PIE).

B. Image Processing Methods

The foundation of this study lies in the utilization of image processing techniques to detect and analyze faults in large PV systems. High-resolution images of PV panels are captured using drones equipped with advanced imaging sensors. These images undergo a series of preprocessing steps, including noise reduction, contrast enhancement, and normalization, to prepare the data for further analysis. The primary method for fault detection is based on the identification of anomalies such as cracks, hotspots, and shadings effects within the images. CV classification models, including ResNet50 and CNNs are employed to highlight these anomalies. Specifically, SAM-PIE method is used to improve the visibility of potential faults.

PV image segmentation method of SAM-PIE is applied to isolate areas of interest, facilitating targeted analysis. Once the segmentation is complete, each segment is analyzed using pattern recognition and classification algorithms to determine the presence and type of fault. The system is designed to operate unsupervised, utilizing machine learning models trained on a diverse dataset of labeled fault types. This approach allows for the automatic classification of detected faults without the need for manual intervention, significantly reducing the time and effort required for maintenance. Fig. 2 shows the hardware components used in developing the system.

C. Video Processing Methods

In addition to image processing, video processing is implemented to provide a comprehensive overview of the PV system's health. Drones equipped with video cameras capture continuous footage of the solar panels, which is then processed frame-by-frame to detect dynamic changes and faults that may not be visible in still images. The video processing workflow begins with the extraction of key frames from the video feed, focusing on frames that show significant changes or potential faults. These key frames are processed using similar techniques used in image processing. However, video processing also allows for the analysis of temporal changes, such as the progression of hotspots or the spread of shadings over time. To enhance the fault detection process, motion detection and tracking algorithms are used to follow up anomalies across multiple frames. This enables the system to monitor the development of faults and assess their impact on the overall performance of the PV system.

The combination of image and video processing ensures a more robust and reliable fault detection mechanism, capable of adapting to varying environmental conditions and operational challenges. As illustrated in Fig. 2, the deployment of a DJI Mavic 3 drone, equipped with a thermal camera, captures the detailed images and videos of a solar PV array. The drone flies over the solar installation, systematically collecting visual data that reveals the thermal characteristics of the PV panels. This data is then transferred to a computer where a specialized application (proposed in this paper) processes the images and videos. The processing involves analyzing the thermal data to detect anomalies such as hotspots, cracks, and shadings issues, which are indicative of faults in the solar panels. This method provides a comprehensive and efficient approach to monitoring and maintaining large PV systems. The drone is equipped with a thermal camera to record the condition of the solar panels.

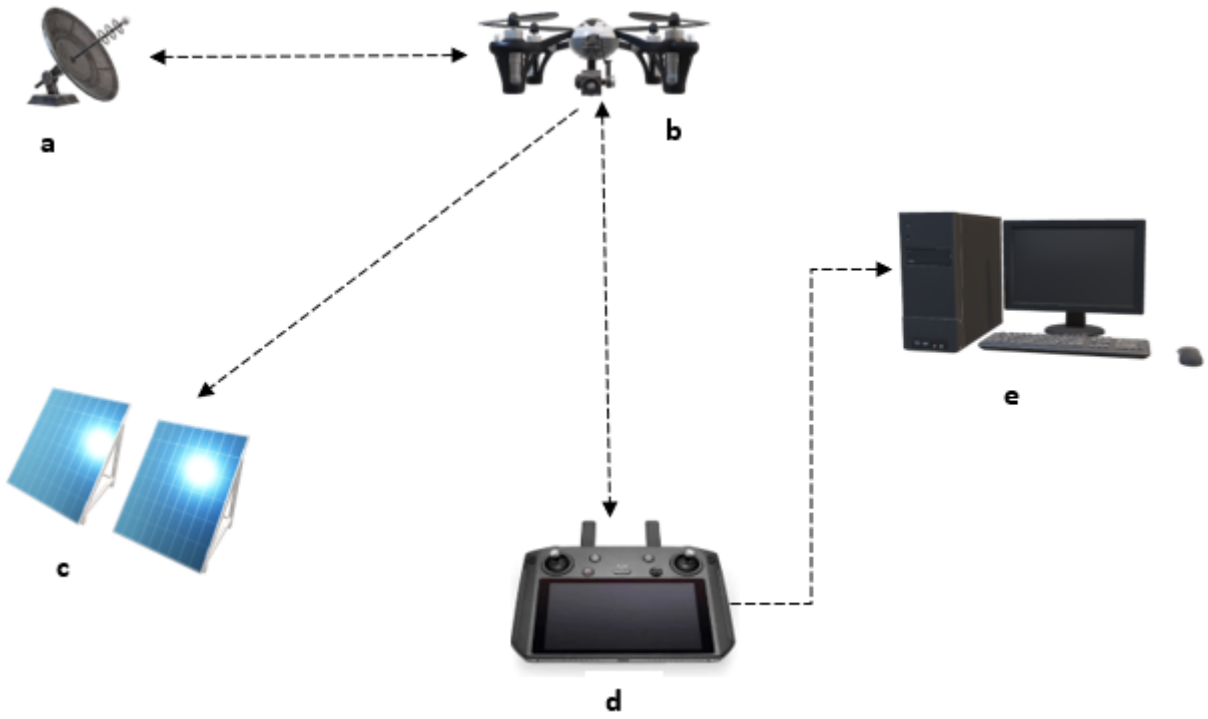

Fig. 2. System description showing the hardware components for (a) Satellite, (b) DJI Mavic 3 Thermal drone, (c) PV, (d) Remote control, (e) Computer system.

The drone captures thermal images and videos of the PV array, collecting comprehensive data on the surface temperature and potential anomalies across the solar panels. After capturing the necessary data, the drone transmits the thermal images and videos to a computer for further processing and analysis. The transferred data undergoes preprocessing, which includes steps like noise reduction and normalization to enhance the quality and clarity of the images and videos, making them suitable for analysis. Machine vision algorithms (proposed in this paper) are applied to the preprocessed data to detect any anomalies, such as hotspots, cracks, or shadings that might indicate faults in the PV panels.

D. Image Enhancement and Classification Models

Applying the pre-trained SAM enables the segmentation masks generation for PV images, and the segmentation masks (including stability scores) can be generated by SAM for the whole regions in a PV image with no antecedent prompts; binary mask and contour mask are also generated, this is followed by a procedure performed to generate enhanced images as evident in Fig. 1 and Fig. 3. Two types of segmentation tasks are involved when segmenting PV images; the foreground (that contains region of object) and the background. Given the following set as the original training dataset $\{(p_1, q_1), (p_2, q_2), (p_3, q_3), \ldots, (p_n, q_n)\}$, where the classification label of the PV image p_i is denoted as $p_i \in \mathbb{R}^{w \times h \times 3}$, $q_1 \in \{0, 1\}$. By the application of SAM-PIE method to each image of PV in the training set, the following set is generated as a new enhanced training dataset: $\{(p_1^{PIE}, q_1), (p_2^{PIE}, q_2), (p_3^{PIE}, q_3), \ldots, (p_n^{PIE}, q_n)\}$, where $p_i^{PIE} \in \mathbb{R}^{w \times h \times 3}$ is the enhanced image p_i of PV. ResNet50 and CNNs (denoted as M) were applied in order to learn from training sets that were not enhanced by SAM-PIE; optimization of the parameters of M is as follows:

$$\sum_{i=1}^{n} loss(M(p_i), q_i) \quad (1)$$

In essence, to minimize the target based on M parameters is the new learning objective:

$$\sum_{i=1}^{n} \alpha loss(M(p_i), q_i) + \theta loss(M(p_i^{PIE}), q_i) \quad (2)$$

Where α and θ put under check the training loss value for original and enhanced images; Eq. (2) would be simplified to Eq. (1) when α=1 and θ=0. However, in this paper, both α and θ take the same number 1, in order to assign equal weight to both original and enhan ced images. Cross-entropy loss was employed for the construction of loss function (expressed in Eq. (1) and Eq. (2)). Eq. (3) is used for testing the model as follows:

$$q = f\left(M(p)\right) \quad (3)$$

where f the sigmoid output activation function.

IV. EXPERIMENTS

A. Implementation Details and Evaluation Metrics

The main software materials employed to process the images and the videos are: (1) Python 3.x on a Windows 11 Home, along with libraries such as Flask, OpenCV, NumPy, Matplotlib, Google Colab and GPU for training the model, (2) CV classification models, including ResNet50 and CNNs. The initial learning rate of 0.01 was set for ResNet50, with batch size fixed at 70; the initial learning rate of 0.001 was set for CNNs, with batch size fixed at 40. The classification experiment was conducted on all the original datasets and the performance compared with the performance of the classification experiment conducted on SAM-PIE enhanced datasets.

In this paper, the performance of the proposed method was evaluated using the evaluation metrics in terms of Precision, Average Precision (AP), and Recall. Precision is denoted by Eq. (4), Recall is denoted by Eq. (5), AP is denoted by Eq. (6), IOU, which stands for Intersection Over Union is denoted by Eq. (7). The analysis stage involves evaluating the detected faults, determining their types, and pinpointing their exact locations on the solar panels. The results of the analysis would be compiled into a comprehensive report. This report not only includes the identified faults and their locations but also suggests potential maintenance actions to address the detected issues.

$$P = \frac{True\ positive}{True\ positive + False\ positive} \quad (4)$$

$$R = \frac{True\ positive}{True\ positive + False\ negative} \quad (5)$$

$$AP = \sum_{n=1}^{N} [R(n) - R(n-1)].maxP(n) \quad (6)$$

Where, N is the number for PR points calculate

$$IOU = \frac{A \cap B}{A\ U\ B} \times 100 \quad (7)$$

Where, f is the sigmoid output activation function.

V. Results and Discussions

A. Results

This study achieved the image enhancement solution for PV thermal Hotspots, PV thermal Shadings, and PV thermal Cracks datasets with the aid of SAM-PIE; this is shown in Fig. 3, which depicts the original images and the enhanced images by SAM-PIE (the processed contour and binary masks resulted in enhanced images).

The performance of the classification experiment conducted on all the original datasets was compared with the performance of the classification experiment conducted on SAM-PIE enhanced datasets. Table II shows the results of the classification task on three datasets, namely Hotspots, Cracks, and Shadings.

The results obtained in this study support SAM performance as a fundamental model that has produced significant achievements in natural image segmentation tasks, even with more better results if well guided for prompt-able segmentation. SAM's performance in segmentation tasks involving PV images is below par with the best due to the dissimilarity between images of solar cells of PV modules and natural images. The performance of SAM's application in PV image segmentation tasks remains a topic of public interest. Fig. 4 shows the graphical results of ResNet50 and CNNs classification models on original Hotspot thermal anomaly dataset and SAM-PIE enhanced Hotspot thermal anomaly dataset. The metrics measure the classification accuracy of the ResNet50 and CNNs classification models on original Hotspot thermal anomaly dataset and SAM-PIE enhanced Hotspot thermal anomaly dataset.

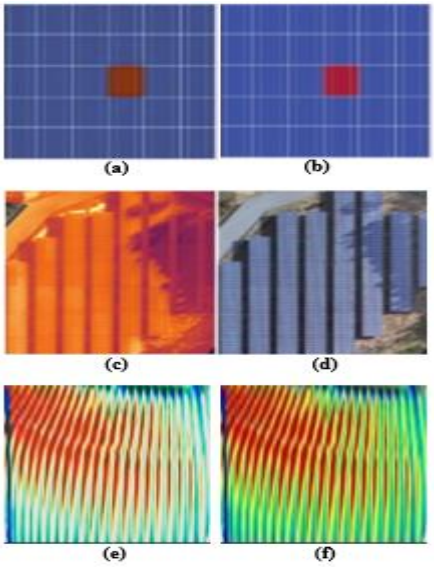

Fig. 3. Image segmentation showing (a) raw image of thermal Hotspot, (b) SAM-PIE enhanced image of thermal Hotspot, (c) raw image of thermal Shading, (d) SAM-PIE enhanced image of thermal Shading, (e) raw image of thermal Crack, (f) SAM-PIE enhanced image of thermal Crack.

TABLE II. The Results of ResNet50 and CNNs Classification Models on Original Three Thermal Anomaly Datasets (Hotspots, Cracks, and Shadings) and SAM-PIE Enhanced Three Thermal Anomaly Datasets (Hotspots, Cracks, and Shadings)

Dataset	Model	AUC	Accuracy	Precision	Recall	F1 score
Hotspot	CNNs	0.906	0.778	0.756	0.900	0.828
	ResNet50	0.958	0.889	0.789	0.915	0.852
	CNNs with SAM-PIE	0.964	0.878	0.766	0.910	0.838
	ResNet50 with SAM-PIE	0.966	0.891	0.847	0.955	0.901
Crack	CNNs	0.899	0.776	0.750	0.888	0.826
	ResNet50	0.950	0.879	0.788	0.910	0.848
	CNNs with SAM-PIE	0.962	0.878	0.764	0.905	0.834
	ResNet50 with SAM-PIE	0.964	0.895	0.795	0.945	0.870
Shading	CNNs	0.850	0.766	0.735	0.824	0.826
	ResNet50	0.940	0.877	0.768	0.915	0.848
	CNNs with SAM-PIE	0.955	0.855	0.765	0.895	0.830
	ResNet50 with SAM-PIE	0.955	0.890	0.785	0.935	0.860

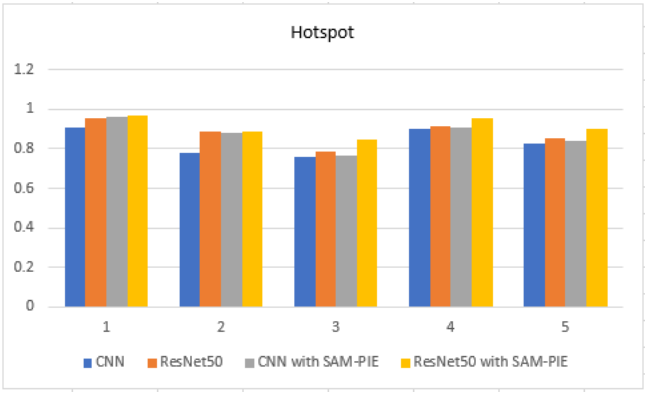

Fig. 4. Graphical results of ResNet50 and CNNs classification models on original Hotspot thermal anomaly dataset and SAM-PIE enhanced Hotspot thermal anomaly dataset.

The solar cells of PV modules are not among the natural images covered in SAM datasets, making it difficult for SAM to be applied to the PV image segmentation task, however, the experimental evidence shows that the performance of SAM, although may not be excellent on solar cells image segmentation, it could perform excellently well on region of thermal anomaly (region of interest) in an image by adjusting the confidence level of the region segmented. In PV fault diagnosis, whether during installation, repair or maintenance, the anomalies occurrence in solar cells of the PV modules are often traced to changes in their morphologies and other components due to environmental factors, making it worthy to apply SAM for the extraction of those regions of interest in this paper. Fig. 5 shows the graphical results of ResNet50 and CNNs classification models on original Crack thermal anomaly dataset and SAM-PIE enhanced Crack thermal anomaly dataset. The metrics measure the classification accuracy of the ResNet50 and CNNs classification models on original Crack thermal anomaly dataset and SAM-PIE enhanced Crack thermal anomaly dataset.

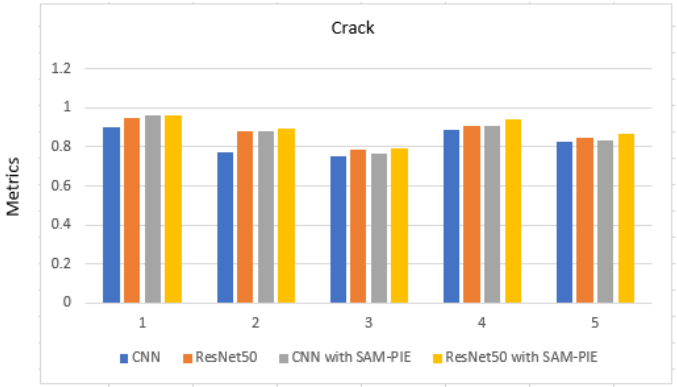

Fig. 5. Graphical results of ResNet50 and CNNs classification models on original Crack thermal anomaly dataset and SAM-PIE enhanced Crack thermal anomaly dataset.

According to Table II, the classification results obtained by ResNet50 and CNNs classification models with SAM-PIE enhanced images in AUC, Accuracy, Precision, Recall, and F1 score were higher than the results obtained by ResNet50 and CNNs classification models without SAM-PIE enhanced images. Moreover, according to Fig. 3, SAM-PIE performed excellently well on image enhancement of raw images of thermal Hotspot, thermal Shading, and thermal Crack as presented in Fig. 3 (a) to Fig. 3 (f).

These results were influenced by the characteristics of individual thermal anomalies. Although SAM-PIE produced promising results, it faced some performance challenges and compromise in enhancing some regions of interest on the image due to unrevealed external information in the image. Fig. 6 shows the graphical results of ResNet50 and CNNs classification models on original Shading thermal anomaly dataset and SAM-PIE enhanced Shading thermal anomaly dataset. The metrics measure the classification accuracy of the ResNet50 and CNNs classification models on original Shading thermal anomaly dataset and SAM-PIE enhanced Shading thermal anomaly dataset.

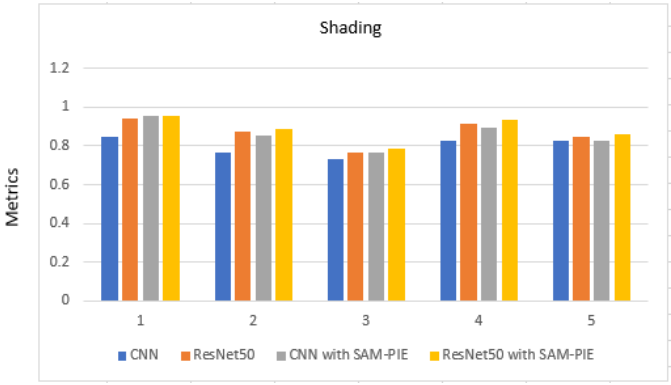

Fig. 6. Graphical results of ResNet50 and CNNs classification models on original Hotspot Graphical results of ResNet50 and CNNs classification models on original Shading thermal anomaly dataset and SAM-PIE enhanced Shading thermal anomaly dataset.

B. Discussions

Table II shows the results of ResNet50 and CNNs classification models on original three thermal anomaly datasets (hotspots, cracks, and shadings) and SAM-PIE enhanced three thermal anomaly datasets (hotspots, cracks, and shadings). These results were compared with similar previous work. The findings from the result obtained in Huang et al. [8] validate the effectiveness of SAM-PIE proposed in this study for diagnosing PV faults. The thermal imaging applied in Cubukcu and Akanalci [9] produced results that also validate the results generated by the drone used in this study to inspect and determine PV power systems faults in real-time. The advanced installation inspection method employed in Tsanakas et al. [10] for PV systems produced results that are on a par with the results produced in Herraiz et al. [11], who applied thermal images analysis through structure based on CNNs for PV plant condition monitoring. However, the performance of the thermal images applied in [10] and [11] was less accurate than the performance obtained in this study for anomaly classification of hotspots, cracks and shadings. The application of the proposed SAM-PIE in this study performed better than the method applied in Cheng et al. [12] for the extraction of solar cell model parameters. The novel SAM-based weakly-supervised method applied in Yang et al. [13], though showed promising results, however, their approach in transiting from classification to segmentation of latent PV locations

segmentation did not extensively cover the thermal anomalies studied in this work. Moreover, the SAM model on which their experiment was based does not have the prompts capability for panoptic and semantic segmentation implementation. The voltage and current observation and evaluation method used in Pei and Hao [14] to detect a fault in PV systems had limitations in its application to hotspots, cracks, and shadings thermal anomalies detection. The results obtained in Georgijevic et al. [15] were on a par with the results obtained in Zhao et al. [16] for detecting fault in PV systems. Their results were in contrast to the results obtained in this study and this is due to the difference in method employed and problem addressed. The problem addressed and the results obtained in Hariharan et al [17] were similar to the problem and results obtained in this study except for the methods. In this study, we addressed and detected full shadings in PV systems, however, partial shading was addressed in [17]. The sensorless line-line and line-ground technique based on MPPT used in Pillai and Rajasekar [18] could not give accurate account of the three anomalies addressed in this study, which are the main challenges faced by PV systems. The method applied in this study are similar to the method employed in Chine et al. [20], Hussain et al. [21], Vieira et al. [22], and Yuan et al. [23] with promising results obtained. The method, CNN and electrical time series graph, used in Lu et al. [31] for diagnosing PV array fault was partially similar to the method used in this study except for the electrical time series graph. However, the classification results of the diagnosed PV array fault were not as accurate as the results obtained in this study. An important factor that distinguished SAM-PIE from the traditional IE methods is the low-level in which the traditional IE methods frequently work, which is below the high-level requirement for reconstructing and recovering an original image [5], which is what SAM-PIE achieved in this study.

VI. Conclusion

SAM-enabled photovoltaic-module image enhancement (SAM-PIE) for fault inspection and analysis using ResNet50 and CNNs has been proposed in this paper. The results from the classification experiments were obtained from three different publicly available thermal anomaly datasets of PV modules, which also validate SAM-PIE efficiency and performance in image enhancement for PV image classification tasks by classification models.

However, SAM-PIE faces some performance challenges and compromise in enhancing some regions of interest on the image due to unrevealed external information in the image. To improve on SAM-PIE limitations for PV image classification, it is part of our future work to employ more practicable tactics such as integrating SAM-PIE into more different PV image classification models or related tasks, for instance.

Understanding Mental Health Content on Social Media and It's Effect Towards Suicidal Ideation

Mohaiminul Islam Bhuiyan, Nur Shazwani Kamarudin*, Nur Hafieza Ismail
Faculty of Computing, Universiti Malaysia Pahang Al-Sultan Abdullah, Pekan, Pahang, Malaysia

***Abstract*—The study "Understanding Mental Health Content on Social Media and Its Effect Towards Suicidal Ideation" aims to detail the recognition of suicidal intent through social media, with a focus on the improvement and part of the machine learning (ML), deep learning (DL), and natural language processing (NLP). This review underscores the critical need for effective strategies to identify and support individuals with suicidal ideation, exploiting technological innovations in ML and DL to further suicide prevention efforts. The study details the application of these technologies in analyzing vast amounts of unstructured social media data to detect linguistic patterns, keywords, phrases, tones, and contextual cues associated with suicidal thoughts. It explores various ML and DL models like SVMs, CNNs, LSTM, neural networks, and their effectiveness in interpreting complex data patterns and emotional nuances within text data. The review discusses the potential of these technologies to serve as a life-saving tool by identifying at-risk individuals through their digital traces. Furthermore, it evaluates the real-world effectiveness, limitations, and ethical considerations of employing these technologies for suicide prevention, stressing the importance of responsible development and usage. The study aims to fill critical knowledge gaps by analyzing recent studies, methodologies, tools, and techniques in this field. It highlights the importance of synthesizing current literature to inform practical tools and suicide prevention efforts, guiding innovation in reliable, ethical systems for early intervention. This research synthesis evaluates the intersection of technology and mental health, advocating for the ethical and responsible application of ML, DL, and NLP to offer life-saving potential worldwide while addressing challenges like generalizability, biases, privacy, and the need for further research to ensure these technologies do not exacerbate existing inequities and harms.**

***Keywords*—Suicidal ideation detection; social media analysis; mental health; text analysis; machine learning**

I. Introduction

As digital technologies permeate and reshape society, social media has emerged as a massive window into the psychological landscape of users. Individual expressions within these platforms can serve as a mirror, presenting critical insights into the mental well-being of the global population. Although revealing various pathologies, a stark reality is reflected that demands urgent attention - suicidal ideation. This affliction continues to take an unconscionable toll, with the World Health Organization (WHO) reporting nearly 800,000 people dying by suicide annually [1]. Shockingly, it is the second leading cause of death for those aged 15-29 years [2]. Many suicides relate to mental health issues like depression, substance abuse, and psychosis. But the causes are complex. Those struggling deserve support [1]. These alarming statistics underscore the human loss and suffering that suicidal behaviors induce worldwide. Clearly, there is a pressing need to earnestly seek more effective strategies for identifying those with suicidal ideation to provide life-saving prediction, prevention and intervention.

Fortunately, advancements in Machine Learning (ML) and Deep Learning (DL) are illuminating a promising path forward, offering technological innovations that could drastically further suicide prevention efforts [3], [4]. The potential of machine learning for suicide prevention is significant, but practical application faces hurdles regarding transparency, ethics, and data quality for which further research is needed [5]. At the core is the ongoing amassment of vast digital traces as we communicate, browse, share, and express ourselves through online conduct. Analyses of resulting "big data" repositories using sophisticated analytical techniques promise to usher impactful progress in decoding and responding to human behaviors and states of mind [6]. Specifically, by applying ML and DL tools to mine social media communications, the recognition of linguistic patterns and semantic complexities associated with suicidal ideation can be realized to an unprecedented degree [7], [8]. Essential human expressions conveyed through unstructured text data can now be computationally elucidated to discern what once remained invisible. This paper aims to comprehensively review the detection of suicidal ideation on social media, focusing on the roles and advancements of machine learning (ML), deep learning (DL), and natural language processing (NLP).

Machine learning, deep learning, and natural language processing are being applied to detect signs of suicidal ideation in social media posts. These technologies can analyze large volumes of unstructured text data to identify linguistic patterns, keywords, phrases, tones, and contextual cues associated with suicidal thoughts. While traditional ML techniques like SVMs and Random Forests can learn predictive rules, they are limited in understanding nuanced semantics and emotions. However, deep learning methods like CNNs and LSTM neural networks, which model complex data patterns, show promise for interpreting broader concepts and context to represent the intricacies of human experience [9], [10], [11]. Though still imperfect, deep learning's ability to comprehend subtext and vulnerability in language offers hope for identifying cries for help and risk factors in a more meaningful way. Advanced NLP and deep learning may enable breakthroughs in computationally decoding the complexities of human expression to uncover suicidal warning signs in text.

*Corresponding Author.

Thus, while challenges and ethical quandaries persist, powerful capacities now exist to extract and analyze massive stores of social expressions for life-saving insights. If properly nurtured under responsible development and usage guidelines, AI and learning systems could gain competencies to serve the public good [12]. Though much progress is still sorely needed, thoughtfully designed mechanisms harnessing big data may move within reach to provide rich awareness of mental states, risk and distress... potentially before tragic outcomes occur [5]. With compassion and diligent effort, the possibility of channeling AI's emerging potential shouldn't be readily dismissed. Perhaps computational tools aimed toward understanding hearts and minds could reveal key markers that humans often miss in order to guide care and resources to those facing darkest moments. Lives awaits saving by transforming big data into wisdom and decisive action [13].

This comprehensive review aims to address critical knowledge gaps by thoroughly analyzing existing research on detecting suicidal ideation through social media using machine learning (ML) and deep learning (DL). It will scrutinize the specific methodologies, tools, and techniques utilized in recent studies, assessing their real-world effectiveness, limitations, and ethical considerations. The review traces the evolution of ML and DL in this application, highlighting advancements that show promise while surfacing areas needing additional exploration and development. Questions around generalizability, biases, and privacy represent just some emerging issues that require elucidation if these technologies are to progress responsibly.

Ultimately, the significance of synthesizing current literature lies not merely in its academic contribution, but also in its potential to meaningfully inform practical tools and suicide prevention efforts. By consolidating empirical insights around the capabilities and development needs of ML and DL for suicide risk detection, this review seeks to guide beneficial innovation of reliable, ethical systems. Such systems could enable early intervention, connecting vulnerable individuals with support and resources.

This research synthesis aims to navigate the intersections of technology and mental health by evaluating recent studies, distilling knowledge, and charting an informed path forward. Applied ethically and responsibly, these emerging analytical methods may offer life-saving potential across populations worldwide. But vigilance around limitations and directing further research is required to ensure applications counter, not exacerbate, existing inequities and harms. This review confronts these multifaceted issues to support deliberate, compassionate translation of scientific discoveries into societal solutions. The primary contributions of this paper are:

- Survey key computational techniques for social media-based screening of suicidal ideation.
- Evaluate the effectiveness of combining sentiment analysis with machine learning on benchmark suicide risk assessment tasks.
- Examine strengths and limitations of social media data sources like Twitter, Reddit, Facebook and various mental health forums.
- Discuss ethical implications including privacy, stigma, and duty of care when analysing social media content.
- Synthesize critical directions and opportunities for impactful research at the intersection of NLP, machine learning, mental health, and suicide prevention.

Advanced analytical methods offer capabilities to decode warnings, risks and signs of suicidal ideation expressed through digital traces. This review article will present a comprehensive analysis of the current state of the art and research trajectory in this critical domain. It will scrutinize in depth the methodologies, tools and techniques being applied to social media data. Key dimensions evaluated will encompass demonstrable performance, advantages, limitations and ethical considerations of using machine learning and AI to detect patterns of mental health distress. The overarching aim is to consolidate current knowledge regarding the promises and perils of computationally surveilling the social landscape with techniques that peer deeply into the collective psyche through the lens of big data... potentially illuminating who requires help and enabling intervention with greater acuity. What is at stake warrants continued exploration to thoughtfully harness such technology for the greatest good.

The remainder of this paper is structured as follows: Section II reviews related work on the detection of suicidal ideation from social media. Section III discusses the evolution of methodologies and details current techniques, including data handling and model applications. Finally, Section IV summarizes insights and outlines future research directions.

II. Previous Works

The detection and analysis of suicidal ideation through social media have gained increasing attention in the field of mental health research. This section provides an overview of the existing literature, outlining the evolution of methodologies and the various approaches used in the detection of suicidal ideation.

In embarking on an analysis of recent studies focused on the detection of suicidal ideation through social media using machine learning (ML), deep learning (DL) and Natural Language Processing (NLP) techniques, we delve into a domain of computational psychiatry that has shown both promising advancements and encountered significant challenges. This analysis will synthesize key findings from various research efforts, evaluating their methodologies, effectiveness, and broader implications within the public health context.

Table I represents a comparison table featuring key details from some of the previous studies on suicidal ideation detection via social media.

The growing prevalence of mental health issues, particularly suicidal ideation, and its manifestation on social media platforms, presents an urgent need for innovative monitoring and intervention strategies. Studies such as those conducted by Samer Muthana et al. [30], Arunima Roy et al. [31], and Swati Jain et al. [32], have explored the utilization of platforms like Twitter, employing techniques ranging from sentiment analysis to complex neural network architectures.

These studies highlight the potential of ML and DL in deciphering the nuanced language of distress and suicidal thoughts expressed in social media posts.

TABLE I. COMPARISON OF STUDIES ON SUICIDAL IDEATION DETECTION

Study Reference	Year	Platform	ML/DL Techniques Used	Dataset Size	Key Features Analyzed	Results (e.g., Accuracy, Precision, Recall)	Limitations
Jorge Parraga-Alva et al. [14]	2019	Various	Unsupervised learning	102 texts	Suicide message categorization	Avg rate: 79% - 87%	-small corpus -lack of multiple categories
Pratyaksh Jain et al. [15]	2022	Reddit	Naïve Bayes, SVM, Logistic Regression	60,000 data points	Depression, Suicidal behavior	Acc: 74.35% - 77.29%, F1: ~0.77	-still room for improve the predictive model
Syed Tanzeel Rabani et al. [16]	2020	Twitter	Random Forest	4,266 tweets	Suicidal ideation	Acc: 98.5%, Precision: 98.7%, Rec: 98.2%	-no direct communication or intervention
Seunghyong Ryu et al. [17]	2019	KNHANES	Random forest	5,773 subjects	Suicide ideation	AUC: 0.947, Acc: 88.9%	-One ML algorithm -SMOTE used to overcome class imbalance problem
Ning Wang et al. [18]	2021	Social media	KNN, SVM, C-Attention network	CLPsych 2021 dataset	Suicide attempts prediction	Best F1 score: 0.737 (6 months prior)	- Traditional ML methods better in some metrics
Samh J. Fodeh et al. [19]	2019	Twitter	LSA, LDA, NMF and Decision Tree and K-means Clustering	12,066 Tweets	Suicide risk factors	Precision: 0.844, Sensitivity: 0.912	-Biased Data Selection -Missing Twitter Metadata -Ignored Ground Truth
Shi Ru Lim et al. [20]	2023	Twitter	SVM, Decision Tree, Naïve bayes	16,158 Tweets	Mental health disorders prediction	Acc: SVM: 99.80% (training), 98.43% (testing)	-Larger dataset needed
Tianlin Zhag et al. [21]	2021	Online	Transformer RNN	659 samples	Suicide notes identification	94.9% recall, 94.9% F1 score, 95% precision	-Explore linguistic -psychological features
Ayaan Haque et al. [22]	2021	Reddit, IMDB large movie dataset	SDCNL, BERT, Sentence-BERT, GUSE	1,895 posts, 50,000 reviews	Depression vs suicidal ideation classification	Strong performance in classification	-Evaluate on other datasets
Yaakov Ophir et al. [23]	2020	Facebook	ANN models (STM, MTM)	83,292 posts of 1002 users	Detect suicide risk	AUC: .697 to .746 (MTM)	-practical detection tools for suicide risk
Tadesse et al. [7]	2019	Reddit	LSTM-CNN, word embedding	Posts from Suicide Watch forum	Suicidal ideation detection	Acc: 93.8% (LSTM-CNN)	-data deficiency -annotation bias
Prasadith Buddhitha et al. [24]	2019	WASSA-2017, CLPsych-2015	Deep Neural Network	-	Depression, PTSD detection	AUC: >90% (multi-channel CNN)	-insufficient unstructured data -lack of intervention
Diniz et al. [25]	2022	Twitter	ML, DL, BerTimbau Large	3788 instances	Suicidal ideation from text	Acc: 0.955, F1: 0.954	-inability to detect typos
Aldhyani et al. [26]	2022	Reddit	CNN-BiLSTM, XGBoost	232074 samples	Textual and LIWC based features from post	Acc: 95% (Textual) Acc: 84.5% (LIWC)	-variations in performance
Renjith et al. [27]	2022	Reddit	LSTM-Attention-CNN	55,680 posts	Suicidal ideation in text	Acc: 90.3%, F1 Score: 92.6%	-
Kholifah et al. [28]	2020	Twitter	LSTM Deep Learning model	-	Level of depression	Acc: 70.89%, Precision: 50.24%, Recall: 70.89%	-accuracy of the classification results can be improved
Cao et al. [29]	2022	Microblog, Reddit	Deep neural networks integrated with knowledge graph	7,329 subjects	Personal factors related to suicidal ideation	Acc: >93%	-Data lacking, noisy abundance

However, this promising avenue is not without its complexities. The critical evaluation of these studies reveals a common challenge – the balance between the technical efficacy of detection algorithms and the ethical implications of privacy and data usage. For instance, while studies like those by Pratyaksh Jain et al. [15] on Reddit and Syed Tanzeel Rabani et al. [16] on Twitter demonstrate high accuracies in detecting suicidal ideation, they also raise questions about the representativeness of their datasets and the ethical management of sensitive personal information.

Moreover, the generalizability of these models across different demographics and social media platforms remains a significant concern. Studies often use datasets that may not adequately represent the broader population, leading to potential biases in prediction models. This limitation is evident in the work of researchers like Jorge Parraga-Alva et al. [14]and Hannah Yao et al. [33], who have tried to categorize and understand the complexity of suicide-related messages across various platforms. Seunghyong Ryu et al. [17] and Tatiana Falcone et al.'s [34] studies offer unique insights into suicide ideation detection in specific contexts. Ryu et al. [17] used data from the Korea National Health & Nutrition Examination Survey to develop predictive models for identifying individuals at risk of suicide, demonstrating the use of machine learning in a clinical or community setting. Falcone et al.'s [34] research on open-source digital conversations among people with epilepsy provides an interesting perspective on how machine learning can uncover specific concerns and struggles related to suicidality in distinct patient groups.

Jianhong Luo et al. [35] and Ning Wang et al. [18] both utilized Twitter data for their research but with different focuses. Luo et al. [35] examined temporal patterns of potential suicidal ideations, using topic modeling to identify latent suicide topics, while Wang et al. [18] developed models for predicting suicide attempts based on social media posts. These studies reveal the complexity and multifaceted nature of suicidal behavior as expressed on social media, and the potential of machine learning in capturing these nuances. John Torous et al. [5] and Gen-Min Lin et al. [36] addressed the integration of technology in suicide prevention and prediction. Torous et al. discussed the potential of tools like text messaging, smartphone apps, and machine learning algorithms in suicide prevention, while Lin et al. focused on predicting suicide ideation in military personnel using various machine learning techniques. These studies illustrate the diverse applications of machine learning and technology in different contexts and populations for suicide prediction and prevention.

Xingyun Liu et al. [37], ML Tlachac et al. [38], and E. Rajesh Kumar et al. [39] explored novel approaches in suicide ideation detection. Liu et al. assessed the feasibility of a proactive suicide prevention approach on social media, while Tlachac et al. investigated the use of smartphone-based communication for passive screening of suicidal ideation. Kumar et al. focused on Twitter data to establish an early warning system for suicidal thoughts detection. These studies highlight innovative applications of machine learning in real-time and proactive detection of suicide risk.

Atika Mbarek et al. [40] and Samh J. Fodeh et al. [19] emphasized the detection of suicidal profiles and factors contributing to suicide risk on Twitter. Mbarek et al. developed a machine learning-based approach for detecting suicidal profiles, while Fodeh et al. used machine learning algorithms to identify factors related to suicide risk. These studies underscore the potential of machine learning in profiling and understanding the underlying factors of suicide risk on social media platforms. Shi Ru Lim et al. [20] and Ibrahim et al.'s [41] studies focused on the prediction of mental health disorders using machine learning techniques. Lim et al. applied various algorithms like SVM and Naive Bayes to predict mental health issues based on Twitter data, while Ibrahim et al. detected PTSD symptoms through Twitter postings. Both studies demonstrate the broader application of machine learning in mental health beyond suicide prevention.

Kamarudin et al.'s [42], [43] two studies expanded the scope of machine learning in understanding mental health challenges through social media data. Their first study employed machine learning and natural language processing to dissect data from virtual communities, while their second study focused on linguistic analysis of online mental health communities. These studies highlight the rich potential of social media data in increasing mental health awareness and informing policy decisions. Kamarudin et al. [44] conducted another study exploring the role of Reddit in providing support to individuals dealing with rape and sexual abuse. Using natural language processing, they analyzed the diversity of topics in responses, including emotional support, relationships, therapy, and legal advice. The findings highlighted the comprehensive nature of support on Reddit, differing from traditional physical-world responses. The study suggests future research involving detailed surveys to understand the perspectives of both support seekers and providers.

Farsheed Haque et al. [45] and Shini Renjith et al. [27] both employed advanced machine learning models for detecting suicidal ideation in social media posts. Haque et al. used Transformer models for text classification, while Renjith et al. developed an ensemble deep learning technique for fast and accurate detection of suicidal ideation. These studies showcase the advancements in machine learning algorithms for suicide ideation detection.

Tianlin Zhang et al. [21], Ayaan Haque et al. [22], and Yaakov Ophir et al. [23] further contributed to the field by developing specialized models and algorithms for suicide and depression classification. Zhang et al. developed a transformer-based deep learning model for identifying suicide notes online, Haque et al. proposed an unsupervised label correction method for classifying depression and suicidal ideation, and Ophir et al. also focused on distinguishing between depression and suicidal ideation using advanced word embedding models. These studies represent the cutting-edge of machine learning applications in mental health.

Michael Mesfin Tadesse et al. [7] and Ramit Sawhney et al. [8] utilized deep learning techniques for detecting suicide ideation in social media. Tadesse et al. developed an LSTM-CNN model for early detection of suicide ideation, while Sawhney et al. compared various deep learning architectures

for suicidal ideation detection. These studies reflect the ongoing evolution and refinement of machine learning techniques in the context of suicide prevention. Prasadith Buddhitha et al. [24] proposed a unique multi-task learning approach with a multi-channel CNN for detecting depression and PTSD. Their approach of incorporating emotional patterns identified by clinical practitioners demonstrates an innovative integration of clinical insights with machine learning.

These studies collectively represent a significant advancement in the use of machine learning and natural language processing techniques to detect, predict, and understand suicide ideation and mental health issues through social media platforms. The diversity in methods, from supervised and unsupervised learning to deep learning and ensemble techniques, highlights the versatility and potential of these technologies in addressing the critical issue of mental health. Moreover, the focus on different populations, languages, and social media platforms underscores the need for tailored approaches that consider the unique aspects of each context and population group. As machine learning continues to evolve, it holds immense promise for enhancing our understanding and prevention of mental health issues, particularly in the realm of suicide prevention. The analysis of these studies also underscores the importance of interdisciplinary collaboration in this field. The integration of insights from psychology, computer science, and ethical considerations is crucial for the development of reliable, effective, and ethically sound detection systems.

This critical analysis aims to provide a comprehensive overview of the current state of research in detecting suicidal ideation through social media. It will highlight the innovations and strengths of recent studies while also addressing the significant challenges and limitations that need to be overcome to harness the full potential of ML and DL in this critical area of public health.

III. Early Styles and Evolution

Initial research in the field of suicidal ideation detection was primarily focused on traditional psychological assessments and face-to-face interactions. However, the emergence of social media as a pervasive communication medium opened new avenue for mental health research. Early studies in this domain utilized basic text analysis techniques, relying on keyword searches and simple statistical methods to identify posts indicative of suicidal thoughts. These methods, though pioneering, were limited in their ability to understand the complexities of human language and context.

A. Advancement in Machine Learning (ML)

The introduction of machine learning algorithms marked a significant advancement in this field. Machine learning, particularly supervised learning techniques, began to be used to identify patterns and features in social media posts that were indicative of suicidal ideation. These approaches involved training models on annotated datasets where posts were labeled as showing signs of suicidal ideation or not. Commonly used machine learning algorithms in this context included Support Vector Machines (SVM), Decision Trees, and Naive Bayes classifiers.

One of the key challenges in applying machine learning was the need for large, annotated datasets. The creation of such datasets involved manually labeling social media posts, a process that was both time-consuming and subject to human error and bias. Despite these challenges, machine learning algorithms proved to be significantly more effective than earlier methods, as they could capture a wider range of linguistic and semantic features.

B. The Role of Natural Language Processing (NLP)

Natural language processing (NLP) emerged as a critical tool in enhancing the effectiveness of machine learning models. NLP techniques allowed for more sophisticated analysis of text data, enabling the extraction of features such as sentiment, thematic elements, and linguistic structures. The use of NLP in conjunction with machine learning algorithms led to more nuanced and accurate detection of suicidal ideation. Techniques such as tokenization, stemming, and lemmatization were employed to preprocess the data, making it more amenable for machine learning models. Sentiment analysis, a subset of NLP, was particularly useful in identifying the emotional tone of posts, which is a crucial aspect in detecting suicidal ideation.

C. The New Frontier of Deep Learning (DL)

The advent of deep learning brought about a paradigm shift in the detection of suicidal ideation on social media. Deep learning models, particularly neural networks, were capable of modeling complex patterns in large datasets. Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs), including their variants like Long Short-Term Memory (LSTM) networks, started being used extensively. These models excelled at understanding the contextual nuances and varied expressions of language, making them particularly effective for this task.

Deep learning models were trained on vast amounts of unstructured social media data, learning to identify subtle patterns and linguistic cues associated with suicidal ideation. These models outperformed traditional machine learning algorithms in many aspects, particularly in their ability to understand the context and semantic meaning of text. The application of deep learning, however, required substantial computational resources and large, well-annotated datasets.

D. Integration of ML, DL and NLP

The integration of machine learning, deep learning, and NLP represents the current state-of-the-art in suicidal ideation detection on social media. This integrated approach leverages the strengths of each of these technologies, offering a more robust and accurate detection mechanism. Machine learning algorithms provide the basis for pattern recognition, deep learning models add an understanding of contextual and semantic nuances, and NLP techniques enable the effective processing and analysis of textual data.

A comprehensive comparison table focusing on suicidal ideation using NLP, Machine Learning, and Deep Learning including various models, their features, performance metrics, and other relevant details is given in Table II:

TABLE II. COMPREHENSIVE COMPARISON TABLE OF NLP, ML, DL MODELS FOR SUICIDAL IDEATION DETECTION

Feature/Model	Traditional ML Models	Deep Learning Models	NLP Techniques
Model Examples	- SVM (Support Vector Machine) - Decision Trees - Random Forest	- CNN (Convolutional Neural Network) - RNN (Recurrent Neural Network) - LSTM (Long Short-Term Memory)	- Sentiment Analysis - Topic Modeling - Word Embeddings
Data Requirements	- Structured data - Limited data size	- Large datasets - Unstructured data	- Large text corpora - Contextual data
Processing Time	- Generally faster - Less computational resources	- Longer due to complexity - High computational resources	- Varies based on technique and data size
Accuracy	- Moderate (depending on the dataset)	- High (especially with large and complex datasets)	- Depends on the complexity of the language and context
Interpretability	- High (easier to understand model decisions)	- Low (often referred to as "black box" models)	- Moderate (varies with techniques)
Suitability for Short Text (e.g., Tweets)	- Less effective due to limited context	- More effective with context preservation techniques	- Effective with appropriate preprocessing
Common Challenges	- Overfitting on small datasets - Limited in capturing complex patterns	- Requires large training datasets - Overfitting risks	- Handling of sarcasm, idioms, and contextual meanings
Preprocessing Needs	- Feature selection - Data cleaning	- Data normalization - Sequence padding (for RNN, LSTM)	- Tokenization - Stop word removal - Lemmatization/Stemming
Application in Suicidal Ideation Detection	- Effective in structured, labeled data - Quick initial assessments	- High accuracy in pattern recognition - Effective in large-scale social media data analysis	- Essential for understanding linguistic nuances - Contextual sentiment analysis

E. Challenges and Ethical Considerations

Despite the advancements in technology, there are significant challenges in this field. The ethical considerations of privacy and consent are paramount. The use of social media data for mental health research raises questions about the privacy of individuals and the potential for misuse of sensitive information. Ensuring that research in this area is conducted with strict ethical guidelines is crucial.

Another challenge is the accuracy and generalizability of these models. Suicidal ideation is a complex and deeply personal phenomenon, and its expression can vary greatly among individuals. Models trained on specific datasets may not generalize well to broader populations. Additionally, the risk of false positives and false negatives in detection is a concern, as it can have serious implications for the individuals involved.

The literature in the field of suicidal ideation detection on social media using machine learning, deep learning, and NLP indicates a rapidly evolving landscape. From basic text analysis to sophisticated deep learning models, the methodologies have advanced significantly. The integration of these technologies offers promising avenues for early detection and intervention in mental health crises. However, the challenges of data privacy, ethical considerations, and the need for accurate, generalizable models remain areas that require ongoing research and attention.

F. Commonly Followed Methods

This section outlines the methodologies and techniques employed in the detection of suicidal ideation on social media, focusing on dataset collection, preprocessing, feature extraction, and the application of machine learning, deep learning, and NLP models.

Following taxonomy represents various approaches and tools used in the studies. Each method or technique is nested within its broader category, illustrating the hierarchical relationship between them:

1) Dataset collection: One of the initial steps in studying suicidal ideation using social media data is the collection of relevant datasets. This process involves selecting social media platforms (such as Twitter, Facebook, Reddit, etc.) and extracting posts that potentially indicate suicidal thoughts or behaviors. The selection criteria for these posts often involve keyword searches, using terms commonly associated with suicidal ideation.

The complexity of dataset collection is amplified by ethical considerations, such as the privacy and consent of social media users. Researchers must navigate these challenges while ensuring that the data is representative and unbiased. Additionally, the dynamic nature of social media, where content is continually created and modified, poses a challenge in creating stable and reliable datasets.

2) Preprocessing: Once the datasets are collected, the next crucial step is preprocessing. This stage involves cleaning and preparing the data for analysis, which is pivotal in NLP and machine learning applications.

3) Some Common Techniques for Suicidal Ideation Detection

a) Lexicon based emotion analysis

i) NRC Affect Intensity Lexicon: The NRC Affect Intensity Lexicon is a lexicon that provides real-valued scores of affect intensity for a large set of English words. It's an extension of the NRC Emotion Lexicon and was developed by Saif M. Mohammad, a senior research officer at the National Research Council Canada [46]. The lexicon aims to quantify the intensity of the affect (emotion) evoked by a word. Each word in the lexicon is associated with an affect intensity score for each of eight basic emotions: anger, fear, anticipation, trust, surprise, sadness, joy, and disgust. The score ranges from 0 (no association with the emotion) to 1 (strong association).

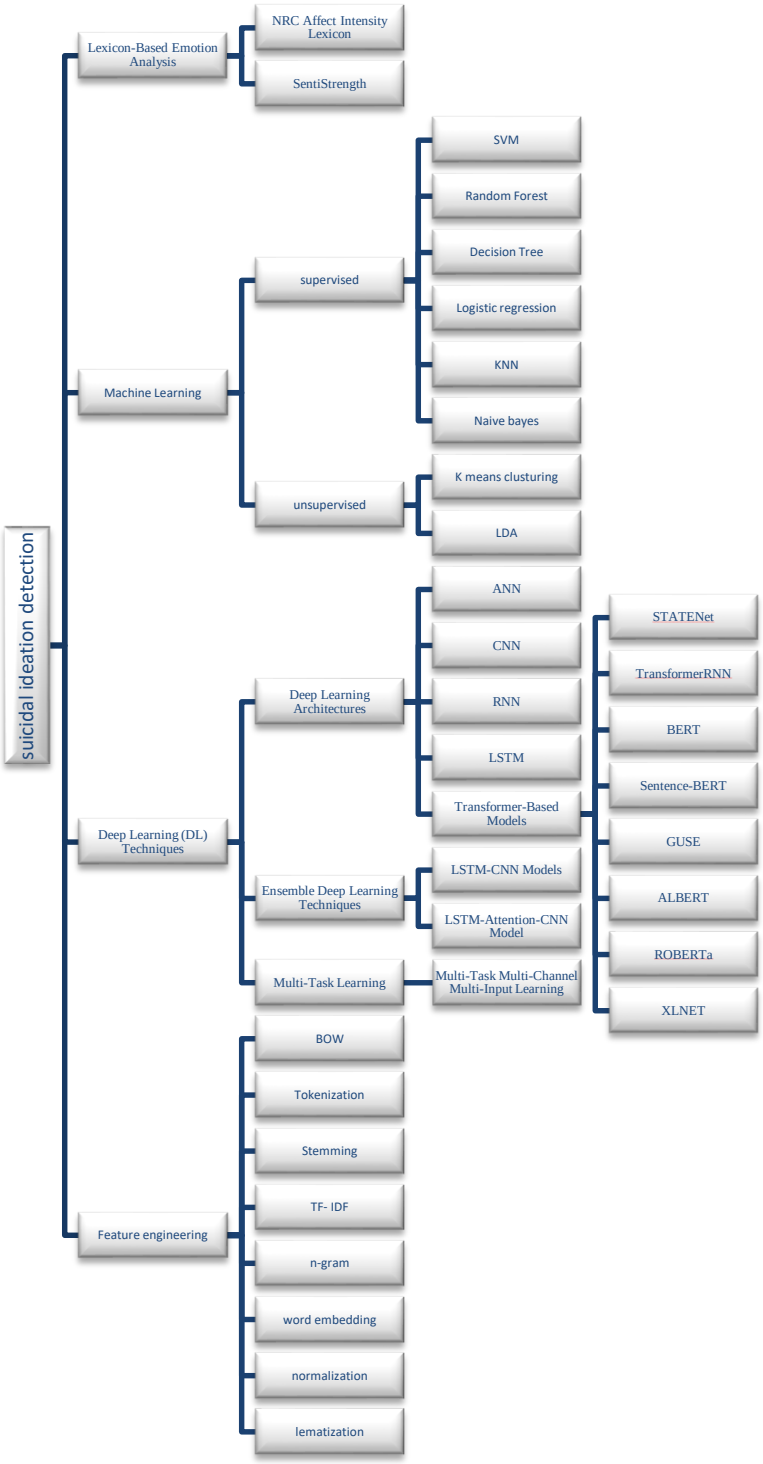

Fig. 1. Hierarchical taxonomy of methodologies for detecting suicidal ideation on social media.

It's widely used in sentiment analysis, social media monitoring, customer feedback analysis, and other areas of natural language processing (NLP) where understanding emotional content is important [47].

ii) SentiStrength: SentiStrength is a sentiment analysis tool designed to decipher the sentiment strength of texts, particularly short informal text found on social media platforms. It is based on a lexicon approach, which means it relies on a dictionary of sentiment-related words, each tagged with sentiment strength scores [48]. SentiStrength can be fine-tuned for specific domains (e.g., software engineering) [49] by adjusting its dictionary to include jargon and terminologies unique to those fields. It can also be adapted to different contexts and languages, recognizing that sentiment expression

varies greatly across cultural and linguistic landscapes. It is used to gauge public sentiment on various topics by analysing social media posts on platforms like Twitter and YouTube. Governments and organizations use it to understand public opinion on policies, products, or events. SentiStrength struggles with posts that contain images [50], as its lexical approach does not account for visual sentiment indicators. Like many sentiment analysis tools, SentiStrength may not accurately interpret sarcasm and irony, which are prevalent in social media text. The rapid evolution of online language can outpace the tool's dictionary updates, potentially leading to inaccurate sentiment scores.

SentiStrength stands out for its ability to decipher sentiment in informal, web-based text, making it a valuable tool for researchers and organizations looking to tap into public sentiment.

The heart of suicidal ideation detection lies in the application of machine learning and deep learning models. These models are trained on preprocessed and feature-extracted data to classify social media posts as indicative of suicidal ideation or not.

b) Supervised machine learning models

i) Support Vector Machines (SVM): Support Vector Machine (SVM) is a robust and versatile supervised machine learning algorithm widely used for classification and regression tasks [51], but primarily known for its applications in classification. The core idea behind SVM is to find the optimal hyperplane that maximizes the margin between different classes in the feature space. For a linear SVM (the simplest form) [52], the decision boundary is a hyperplane, and the goal is to find the hyperplane that leaves the maximum margin from the nearest points of all classes, which are known as support vectors. Mathematically, this can be represented by the equation of the hyperplane:

$$w.x - b = 0 \quad (1)$$

where w is the weight vector perpendicular to the hyperplane, x represents the input features, and b is the bias term. In more complex scenarios, where classes are not linearly separable, SVM uses kernel functions to transform the input space into a higher-dimensional space [53] where a hyperplane can effectively segregate the classes. This is known as the Kernel trick, allowing SVM to perform non-linear classification.

SVM's strength lies in its versatility and efficiency, particularly in high-dimensional spaces. It's relatively memory efficient as it uses a subset of training points in the decision function (the support vectors), making it both powerful and efficient. The optimization of SVM involves finding the right balance between increasing the margin size and minimizing classification error, controlled by a regularization parameter. Support Vector Machine (SVM) is adept at detecting suicidal ideation from social media data, largely due to its proficiency in managing high-dimensional spaces [53]. By employing techniques like TF-IDF for feature extraction, SVM transforms complex and nuanced social media text into a structured format. It then identifies an optimal hyperplane to differentiate between posts that indicate suicidal ideation and those that don't, maximizing the margin between these categories using key data points, known as support vectors. This approach is particularly effective due to the subtle linguistic cues and contextual nuances present in social media content, though its success is contingent on precise data preprocessing and feature selection to capture the complexities of emotional expressions online.

ii) Decision tree: A Decision Tree is a widely used non-parametric supervised learning algorithm used for classification and regression tasks [54]. It models decisions and their possible consequences as a tree-like structure, where each internal node represents a "test" on an attribute, each branch represents the outcome of the test, and each leaf node represents a class label (decision taken after computing all attributes). The paths from root to leaf represent classification rules. In building the decision tree, algorithms like ID3, C4.5, or CART [54]are used to determine how to split the data and construct the tree. These algorithms typically employ measures such as Gini impurity or entropy to choose which feature to split at each step. The Gini impurity for a set is given by:

$$Gini\ Impurity = 1 - \sum_{i=1}^{n} {p_i}^2 \quad (2)$$

Where p_i is the probability of an object being classified to a particular class. Alternatively, entropy, a measure of disorder or impurity, is given by:

$$Entropy = -\sum_{i=1}^{n} p_i \log_2(p_i) \quad (3)$$

In the context of detecting suicidal ideation from social media text data, a Decision Tree algorithm works by learning from the features extracted from the text (such as specific keywords, phrases, sentiment scores, or linguistic patterns) and creating a model that can classify new texts based on these learned patterns [38]. Each node in the tree represents a feature, and the branches represent the decision rules leading to the final classification in the leaf nodes. This approach is particularly suitable for such tasks due to its interpretability; the tree structure allows for easy understanding and tracing of the decision path and reasoning [19]. This transparency is crucial in sensitive applications like mental health monitoring, where understanding the rationale behind a classification (such as why a particular post is flagged as indicative of suicidal ideation) is as important as the classification itself.

iii) Random forest: Random Forest is a machine learning technique for classification, regression, and other tasks that operates by constructing a multitude of decision trees at training time and outputting the mode of the classes or mean prediction of the individual trees [55]. It builds upon the concept of bagging, an approach that improves the stability and accuracy of machine learning algorithms by combining multiple models to 'vote' on the final output [56]. Each tree in a Random Forest makes a class prediction, and the class with the most votes becomes the model's overall prediction. The algorithm injects randomness into the model building process, which not only helps in reducing the variance of the model but also prevents overfitting. This is done by randomly selecting

subsets of the training data set (with replacement) and subsets of the features used for splitting nodes. The decision tree equation typically involves measures like Gini impurity or entropy [57] to find the best split at each node:

$$Gini\ Impurity = 1 - \sum(p_i)^2 \quad (4)$$

$$Entropy = -\sum p_i \log_2(p_i) \quad (5)$$

Where p_i is the proportion of samples that belong to a certain class in a given node.

In the context of suicidal ideation detection from social media text data, Random Forest can be highly effective [7]. It starts with preprocessing and transforming textual data into a numerical format, typically using vectorization methods such as TF-IDF or word embeddings. Each decision tree in the Random Forest then learns from a random subset of these features, creating a diverse set of perspectives for interpreting the data. When new data is inputted, each tree makes a prediction based on its learned patterns, and the final output is decided by a majority vote across all trees. This methodology is particularly suitable for analyzing social media content, as it accommodates the high variability and noise often found in this type of data. The ensemble nature of Random Forest also helps in capturing a wide array of linguistic and contextual indicators associated with suicidal ideation, making it a robust tool for mental health monitoring in digital platforms [16], [17].

iv) Logistic regression: Logistic Regression is a statistical method used for binary classification problems, which models the probability of a binary response based on one or more predictor variables [58]. It operates under the principle that the log odds of the probability of an event occurring versus it not occurring is linearly related to the independent variables [59]. This relationship is expressed through the logistic function:

$$\log\left(\frac{p}{1-p}\right) = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \cdots + \beta_n X_n \quad (6)$$

Here, p is the probability of the dependent event occurring, β_0 is the intercept, β_1 , β_2 , ..., β_n) are the regression coefficients, and X_1, X_2, ..., X_n are the independent variables. The output is then transformed using the logistic function (or sigmoid function), ensuring that the output always lies between 0 and 1, making it interpretable as a probability:

$$p = \frac{1}{1+e^{-(\beta_0+\beta_1 X_1+\beta_2 X_2+\cdots+\beta_n X_n)}} \quad (7)$$

In utilizing Logistic Regression for identifying suicidal ideation within social media text, a nuanced approach is adopted to process and analyze the content [32]. Initially, the textual data undergoes preprocessing to extract meaningful attributes, which might include the frequency of emotive words, the structure of sentences, or the usage of certain language patterns associated with mental health indicators. Logistic Regression then applies its algorithm to these extracted features, determining the likelihood of a post reflecting suicidal thoughts. The output, given as a probability, offers a graded scale of risk assessment rather than a binary classification, providing a more refined analysis. This method stands out for its straightforward interpretability, essential for mental health monitoring, where understanding the reasoning behind a prediction is crucial. However, the model's effectiveness hinges on the relevance and quality of the features selected, necessitating careful curation to avoid biases or misinterpretations [15], [32]. Such an approach allows Logistic Regression to be a potent tool in the sensitive area of mental health surveillance on digital platforms.

v) KNN: K-Nearest Neighbors (KNN) is a simple, yet versatile supervised learning algorithm used for both classification and regression tasks, but it's most utilized for classification [60]. KNN operates on the principle that similar things exist in proximity; in other words, it assumes that similar data points are near to each other. The algorithm doesn't explicitly learn a model; instead, it classifies a new data point based on the majority vote of its 'K' nearest neighbors. The number of neighbors, K, is a critical user-defined parameter, and the distance between data points is calculated using metrics like Euclidean distance, Manhattan distance, or Hamming distance [61]. The Euclidean distance between two points in a plane is given by [62]:

$$d(p,q) = \sqrt{(q_1-p_1)^2 + (q_2-p_2)^2 + \cdots + (q_n-p_n)^2} \quad (8)$$

In suicidal ideation detection from social media text using K-Nearest Neighbors (KNN), the algorithm classifies new posts based on linguistic and emotional similarities with existing posts [18]. After transforming text data into numerical features, KNN identifies the 'K' closest posts in this feature space, determining the new post's category based on the prevalence of categories (indicative of suicidal ideation or not) among these nearest neighbors. This method effectively captures subtle patterns in personal expression [41], with the choice of 'K' and the nature of features used being crucial for accuracy. The model's reliance on direct comparisons with known cases makes it uniquely suited for discerning nuanced expressions of mental states in social media, provided the training data is diverse and representative.

vi) Naïve bayes classifiers: Naïve Bayes is a probabilistic machine learning model based on applying Bayes' Theorem with the assumption of independence among predictors [63]. It's particularly popular for text classification tasks due to its simplicity and effectiveness, even with high-dimensional data. The fundamental equation is Bayes' Theorem [64]:

$$P(A/B) = \frac{P(B/A)P(A)}{P(B)} \quad (9)$$

In this context, A and B represent different events, where $P(A/B)$ is the probability of A given B , $P(B/A)$ is the probability of B given A, $P(A)$ and $P(B)$ are the probabilities of observing A and B independently of each other.

For suicidal ideation detection in social media texts, Naive Bayes works by first transforming text data into a feature vector (often using techniques like bag-of-words or TF-IDF). Each word or phrase in the text contributes independently to the probability that the message reflects suicidal ideation. The model then uses these probabilities, derived from the training data, to predict whether new texts suggest suicidal thoughts [15], [20]. This method's efficiency in handling large volumes of text and its ability to quickly classify new data make it

suitable for real-time monitoring of social media platforms. However, the assumption of independence among words can sometimes oversimplify the linguistic complexities of human communication, particularly in the nuanced context of mental health discussions. Despite this, Naive Bayes remains a popular choice due to its ease of implementation and its proficiency in processing and classifying large datasets efficiently.

c) Unsupervised machine learning models

i) K-Means Clustering: K-Means Clustering is an unsupervised learning algorithm that partitions a dataset into k clusters by minimizing the intra-cluster variance [65]. It does so by iteratively assigning data points to the nearest cluster centroid and updating the centroid to the mean of the points in the cluster. The algorithm's objective is to minimize the sum of squared distances between points and their respective cluster centroids, expressed as:

$$J = \sum_{j=1}^{k} \sum_{i=1}^{n} \left\| x_i^{(j)} - c_j \right\|^2 \quad (10)$$

Here, $\left\| x_i^{(j)} - c_j \right\|^2$ is the Euclidean distance between a data point $x_i^{(j)}$ and the cluster centroid c_j, n is the number of data points in cluster j, and k is the number of clusters.

For suicidal ideation detection in social media text, K-Means can group posts into clusters based on textual similarities, using features like TF-IDF vectors. These clusters can then be analyzed to identify common themes or expressions indicative of suicidal thoughts [19]. This clustering approach helps in organizing large, unlabeled datasets into meaningful categories, facilitating the identification of mental health concerns. However, the effectiveness of K-Means in this context heavily relies on the choice of k and the initial centroid selection, alongside robust preprocessing of the text data.

ii) Latent Dirichlet Allocation (LDA): Latent Dirichlet Allocation (LDA) is a popular unsupervised learning algorithm in natural language processing, primarily used for topic modeling [66]. It assumes that documents are mixtures of topics and that topics are mixtures of words. This generative model allows it to discover hidden thematic structures in large collections of text documents. LDA represents each document as a distribution over topics and each topic as a distribution over words.

For detecting suicidal ideation in social media texts, LDA helps identify topics that may signify mental distress. It processes text data to extract latent topics, potentially flagging those aligned with suicidal thoughts. This method is valuable for exploratory analysis, identifying linguistic patterns related to mental health [19], [43]. However, the effectiveness of LDA depends on accurate text preprocessing and parameter tuning, requiring careful interpretation in the sensitive context of mental health monitoring.

d) Deep learning models

i) Artificial Neural Networks (ANN): Artificial Neural Networks (ANNs) are computational models inspired by the human brain's structure and function, particularly effective in pattern recognition and predictive modeling [67]. An ANN consists of layers of interconnected nodes or neurons, each node in one layer connected to several others in the next layer. The basic operation in a neuron involves weighted input summation and a non-linear activation function [68]. Mathematically, the output y of a neuron can be described by the equation,

$$y = f(\sum_{i=1}^{n} w_i x_i + b) \quad (11)$$

where x_i are the inputs, w_i are the weights, b is the bias, and f is the activation function, like a sigmoid or ReLU function. The network learns to model complex relationships by adjusting these weights and biases based on the input data.

For suicidal ideation detection from social media text, ANNs can be employed to analyze and classify text data [23]. The process involves preprocessing the text (like tokenization, stemming, and vectorization) to transform it into a format suitable for the ANN. The network then processes this data through its layers, learning to identify patterns and linguistic cues that are indicative of suicidal ideation. This might include specific keywords, phrases, or the overall sentiment of the text. The final layer of the network, typically a SoftMax layer, classifies the text based on the learned patterns, indicating whether it likely contains suicidal ideation. The performance of ANNs in this application largely depends on the network's depth and complexity, the quality of the training data, and the model's capacity to capture subtle nuances in the language that may suggest suicidal thoughts or tendencies.

ii) Convolutional Neural Networks (CNN): CNN, or Convolutional Neural Networks, are a class of deep neural networks commonly used in image processing [69] but also effective in text classification [70], particularly for feature extraction [71]. CNNs are particularly effective due to their ability to learn spatial hierarchies of features through the use of convolutional layers. A basic CNN structure includes an input layer, convolutional layers, pooling layers, fully connected layers, and an output layer [72]. The convolutional layers apply a convolution operation to the input, passing the result to the next layer. This can be represented by the equation:

$$Output = Activation(Weights.Input + Bias) \quad (12)$$

where Activation is a non-linear function like ReLU. Pooling layers reduce the spatial size of the convolved features to decrease the computational power required. Finally, fully connected layers combine these features to classify the input into various categories.

For suicidal ideation detection from social media text, CNNs can be utilized to analyze and classify textual data [27]. The process begins with the collection and preprocessing of social media texts, which involves cleaning, normalization, and tokenization to convert text into a form that can be fed into a CNN. CNN then learns to identify patterns and features in the text indicative of suicidal ideation, such as specific keywords, phrases, or linguistic patterns. This involves multiple layers of convolution and pooling to extract and condense the relevant features from the text data. The fully connected layers at the end of the CNN then interpret these features to classify the text,

often outputting a probability score indicating the likelihood of suicidal ideation present in the text. The effectiveness of this approach relies on the quality and diversity of the training data, as well as the complexity and depth of the CNN model used.

iii) Recurrent Neural Networks (RNN): Recurrent Neural Networks (RNNs) are a type of neural network particularly suited for processing sequential data, such as time series or text [73]. Unlike traditional neural networks, RNNs have a unique feature: they maintain a form of memory by using their output as input for the subsequent step. This is achieved through loops within the network [74]. In mathematical terms, the hidden state h_t at time t in a simple RNN is calculated as

$$h_t = activation(W_{hh}h_{t-1} + W_{xh}x_t + b_h) \quad (13)$$

where W_{hh} and W_{xh} are weight matrices, x_t is the input at time t, h_{t-1} is the previous hidden state, and b_h is the bias. The output y_t is then a function of the current hidden state: $y_t = activation(W_{hy}h_t + b_y$ with W_{hy} being the output layer weights and b_y the output bias.

For suicidal ideation detection in social media text, RNNs are particularly effective due to their ability to process and learn from the sequential nature of language. The process starts with preprocessing the text data, including tokenization and possibly embedding the words into a vector space [8]. The RNN then processes this sequential data, with each word (or token) being input sequentially. The RNN's hidden state updates with each word, effectively allowing the network to remember and utilize the context from previous words. This context understanding is crucial for identifying patterns or linguistic cues indicative of suicidal ideation, such as expressions of despair, hopelessness, or direct mentions of self-harm. The final output layer of the RNN can classify the text based on the learned patterns, potentially indicating whether the text suggests suicidal ideation. The performance of RNNs in this application hinges on the depth of the network, the quality of the training data, and the network's ability to capture and utilize long-term dependencies in the text.

iv) Long Short-Term Memory (LSTM) and Bidirectional LSTM (BiLSTM): Long Short-Term Memory (LSTM) networks are an advanced type of Recurrent Neural Network (RNN) designed to better capture long-range dependencies and address the vanishing gradient problem common in standard RNNs [75]. The key to LSTM's effectiveness is its unique cell structure comprising three gates: the input gate i_t, the forget gate f_t, and the output gate o_t. These gates collectively decide what information to retain or discard as the network processes data sequentially. The LSTM cell updates are governed by the following equations:

$$f_t = \sigma\big(W_f.[h_{t-1}, x_t] + b_f\big), (\text{Forget Gate} \quad (14)$$

$$i_t = \sigma(W_i.[h_{t-1}, x_t] + b_i), (\text{Input Gate}) \quad (15)$$

$$\widetilde{C_t} = \tanh(W_c.[h_{t-1}, x_t] + b_c), (Cell\ State\ Candidate) \quad (16)$$

$$C_t = f_t * C_{t-1} + i_t * \widetilde{C_t}, (Cell\ State\ Update) \quad (17)$$

$$o_t = \sigma(W_o.[h_{t-1}, x_t] + b_o), (Output\ Gate) \quad (18)$$

$$h_t = o_t * \tanh(C_t), (Hidden\ State) \quad (19)$$

A Bidirectional LSTM (BiLSTM) extends the standard LSTM by introducing a second layer that processes data in the reverse order [76]. While a regular LSTM processes data from past to future (left to right in a sequence), a BiLSTM also processes data from future to past (right to left), effectively capturing information from both directions. This dual processing makes BiLSTMs particularly effective in applications where the context of the entire sequence is crucial for understanding each part of it.

In the context of suicidal ideation detection from social media text, LSTMs excel due to their ability to capture and remember pertinent information across long text sequences [8], [28], which is crucial in understanding the context and nuances of language. By processing sequential data, LSTMs can identify patterns or phrases indicative of suicidal thoughts, such as expressions of hopelessness or mentions of self-harm. In suicidal ideation detection, a BiLSTM would analyze the text from both directions [45], offering a more comprehensive understanding of the context and sentiment expressed, thus potentially improving the accuracy of detecting signs of suicidal ideation.

v) Transformer models: Transformer-based models have revolutionized natural language processing by offering a more efficient and effective means of handling sequential data compared to traditional RNNs or LSTMs. The core concept of Transformers is the self-attention mechanism, which computes the output of a layer by attending to all positions within the same layer [77]. The basic equation for self-attention can be written as:

$$Attention(Q, K, V) = softmax\left(\frac{QK^T}{\sqrt{d_k}}\right)V \quad (20)$$

where Q, K, and V are queries, keys, and values matrices, respectively, and d_k is the dimensionality of the keys. This mechanism allows the model to weigh the importance of different parts of the input sequence differently, making it highly effective for tasks involving contextual understanding.

Different transformer-based models have emerged, each with unique characteristics [78]:

- STATENet integrates spatial-temporal attention networks for enhanced sequence modeling.
- TransformerRNN combines the transformer architecture with RNNs to capitalize on both methods' strengths.
- BERT (Bidirectional Encoder Representations from Transformers) and its variant Sentence-BERT offer deep bidirectional context understanding by pre-training on large text corpora.
- GUSE (Google Universal Sentence Encoder) is optimized for sentence-level embeddings.
- ALBERT (A Lite BERT) is a more efficient version of BERT with shared parameters across layers.
- RoBERTa (Robustly optimized BERT approach) enhances BERT through robust training methods.

- XLNet combines the best of BERT and autoregressive methods for improved language modeling.

In the context of suicidal ideation detection from social media text, these transformer-based models excel due to their ability to understand and interpret the nuances and context of natural language [22]. By analyzing the text data from social media, these models can capture the subtleties of language that indicate suicidal thoughts or tendencies, such as specific phrases, sentiment, and contextual clues. The self-attention mechanism allows the models to focus on relevant parts of the text, potentially identifying warning signs hidden in normal conversation. This can include detecting direct expressions of suicidal thoughts or more subtle indicators like expressions of hopelessness or isolation. The effectiveness of these models in such applications depends significantly on the quality of the training data and the specific architectural choices made in the model design.

e) Feature engineering

- Bag of Words (BoW): This model treats text as an unordered collection of words, focusing on the frequency of each word but ignoring the order and context [79]. In suicidal ideation detection, BoW can help identify frequently used words in posts that are indicative of distress or suicidal thoughts, such as "helpless" or "worthless."
- Tokenization: This process involves breaking down text into smaller units, typically words or phrases [80]. For suicidal ideation detection, tokenization is the first step in analyzing social media posts, as it helps in isolating individual words or phrases for further examination.
- Stemming: Stemming reduces words to their root form, often by chopping off prefixes or suffixes. For instance, "running" becomes "run" [81]. In suicidal ideation detection, stemming can help in consolidating different forms of a word to a single root, making it easier to analyze and categorize texts.
- TF-IDF (Term Frequency-Inverse Document Frequency): This is a statistical measure used to evaluate the importance of a word in a document, which is part of a corpus. It increases with the number of times a word appears in the document but is offset by the frequency of the word in the corpus [82]. In suicidal ideation detection, TF-IDF can help in identifying unique terms in individual posts that are unusual in general but common in texts expressing suicidal thoughts.
- N-gram: N-grams are continuous sequences of 'n' items from a given sample of text or speech [83], [84]. For suicidal ideation detection, analyzing bigrams (2-grams) or trigrams (3-grams) can reveal specific phrases that are more indicative of suicidal ideation, such as "end my life".
- Word Embedding: This technique involves mapping words or phrases to vectors of real numbers [85], capturing the context and semantic relationships between words. In suicidal ideation detection, word embeddings can provide a deeper understanding of the context and nuances in social media posts, which simple frequency counts cannot.
- Normalization: This process involves transforming text into a more uniform format, such as converting all characters to lowercase, removing punctuation, or converting numbers to words [86]. In detecting suicidal ideation, normalization ensures that the analysis isn't skewed by superficial variations in the text.
- Lemmatization: Similar to stemming, lemmatization also reduces words to their base or dictionary form, but it does so use linguistic knowledge about the word's proper form or lemma [87]. For instance, "better" is lemmatized to "good". In the context of suicidal ideation detection, lemmatization helps in accurately grouping together different forms of a word, leading to more effective analysis.

Each of these techniques contributes to transforming raw text into a structured, analyzable form, aiding in the identification of language patterns associated with suicidal thoughts and behavior.

4) Evaluation matrices: After developing the models, evaluating their performance is crucial. Common evaluation metrics include [88]:

- Accuracy: The ratio of correctly predicted instances to the total instances in the dataset.
- Precision and Recall: Precision measures the proportion of true positive identifications among the positive identifications made by the model, while recall measures the proportion of true positive identifications among the actual positives.
- F1 Score: The harmonic mean of precision and recall, providing a balance between the two metrics.
- AUC-ROC Curve: A performance measurement for classification problems at various thresholds settings.

5) Challenges to address: Despite the advancements in methodologies, there are inherent challenges. One major challenge is the balance between model complexity and interpretability. While deep learning models offer advanced capabilities, they often act as 'black boxes', making it difficult to interpret their decision-making processes.

Moreover, the issue of data imbalance, where instances of suicidal ideation are significantly less than non-suicidal posts, can skew model training and affect the reliability of predictions.

Another challenge is the generalizability of these models. Models trained on specific datasets or demographics might not perform effectively when applied to different datasets or populations. This issue underscores the importance of creating diverse and representative training datasets.

The detection of suicidal ideation on social media using machine learning, deep learning, and NLP involves a complex interplay of various methodologies. From dataset collection

and preprocessing to the application of advanced algorithms and evaluation, each step plays a crucial role in the effectiveness of the detection process. While significant progress has been made, ongoing research is needed to address the challenges of model interpretability, data imbalance, and generalizability.

IV. CONCLUSION

Social media has become a valuable data source for detecting mental health conditions, such as suicidal ideation. This review synthesizes current research utilizing machine learning, deep learning, and NLP techniques to identify warning signs in social media posts. The study highlights the advancement of AI in suicide prevention, showcasing models that leverage deep neural networks and transfer learning to decipher complex linguistic patterns indicative of suicidal thoughts. Key findings demonstrate precision rates of 82-97% and recall rates of 71-94% using models such as SVMs, Random Forests, and neural networks. Despite promising results, model robustness must be improved for real-world application.

Challenges include limited, non-representative datasets that hinder generalizability and may introduce demographic biases. Most models were developed using English data from American users, lacking validation across cultures, languages, and demographics. Achieving a balance between accuracy, complexity, and interpretability remains difficult, with simpler models underperforming and complex models being opaque. Future work should focus on testing across age groups and integrating additional risk indicators, alongside addressing privacy concerns and ensuring ethical data use.

Differentiating genuine suicidal intent from rhetorical expressions is an ongoing challenge, as individuals communicate distress uniquely, influenced by personal and cultural factors. Addressing these nuances requires further qualitative research and interdisciplinary collaboration for better contextual understanding. Early identification through improved technology can facilitate timely intervention, but real-world implementation must consider privacy rights and avoid stigmatization. Clear, ethically aligned protocols are essential for the responsible handling of flagged data.

In conclusion, while significant strides have been made in using machine learning for large-scale screening of suicidal ideation, future research should expand datasets, enhance generalizability, and refine contextual interpretation. Ensuring ethical standards and practical protocols will be vital for maximizing the public health benefits of these technological advances.

Classification of Liver Disease Using Conventional Tree-Based Machine Learning Approaches with Feature Prioritization Using a Heuristic Algorithm

Proloy Kumar Mondal[1], Haewon Byeon[2]*
Department of Electronics and Communication Engineering, Khulna University, Khulna, Bangladesh[1]
Department of Digital Anti-aging Healthcare (BK21), Inje University, Gimhae 50834, South Korea[2]

***Abstract*—Liver disease ranks as one of the leading causes of mortality globally, often going undetected until advanced stages. This study aims to enhance early detection of liver disease by employing machine learning models that utilize key health indicators. Utilizing the Indian Liver Patient Dataset (ILPD) from the UCI repository, we developed a predictive model using the CatBoost algorithm, achieving an initial accuracy of 74%. To improve this, feature selection was performed using the Whale Optimization Algorithm (WOA) and Harris Hawk Optimization (HHO), which increased accuracy to 82% and 85% respectively. The methodology involved preprocessing to correct data imbalances and outlier removal through univariate and bivariate analyses. These optimizations highlight the critical features enhancing the model's predictive capability. The results indicate that integrating metaheuristic algorithms in feature selection significantly improves the accuracy of liver disease prediction models. Future research could explore the integration of additional datasets and machine learning models to further refine predictive capabilities and understand the underlying pathophysiology of liver diseases.**

***Keywords*—Liver disease; classification; prediction; CatBoost algorithm; machine learning; optimization algorithm**

I. Introduction

The liver is an important part of the body that conducts functions such as gall generation, chemical detoxification, and a supply of critical proteins for blood [1]. A huge increase in different liver illnesses has been observed the world in recent years. About two million people are diagnosed with liver disease each year, with one million dying from cirrhosis complications and one million from viral hepatitis and hepatocellular carcinoma. Because cause-specific death data is scarce in many places where liver disease is common, notably in Africa, accurate figures are not always accessible. Furthermore, nearly one-third of the world's countries lack reliable mortality statistics. Even in industrialized nations, it is impossible to distinguish the burden of liver disease according to the cause and stage of the disease [2]. Cirrhosis is the 11th leading cause of death worldwide, while liver cancer is the 16th, an estimated 1.16 million and 788,000 people die each year. They are responsible for 3.5 percent of all deaths worldwide [3]. Liver-related deaths accounted for 3% of all deaths worldwide in 2000. They are ranked 13th (cirrhosis) and 20th (liver cancer). However, the effects can be even greater if acute hepatitis and alcohol use are considered major factors. According to these Fig. 1, the liver disease dies over two million people worldwide each year. Due to worldwide population pressure, India accounts for one-fifth (18.3%) of all cirrhosis fatalities while China's contribution is 11 In Central Asia and the Russian Federation, mortality is increasing. In the UK, mortality is increasing, but in France and Italy, it is decreasing. Males are affected by cirrhosis at a higher rate than females all over the world [2]. Refer to Fig. 1. Liver disease and cancer are among the leading causes of death worldwide.

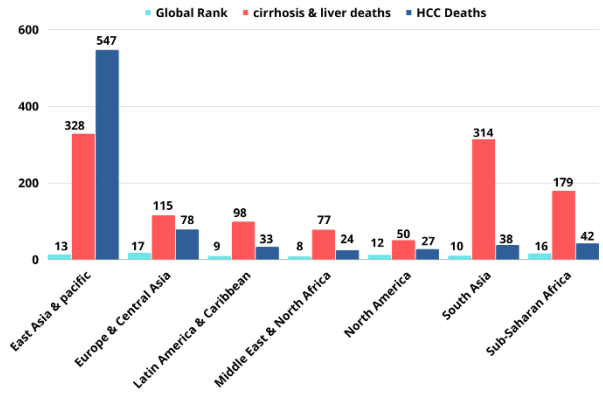

Fig. 1. Global mortality from liver illness and liver cancer.

First, the number of patients with liver disease is increasing every year, however the number of specialist doctors is not increasing. As a result, it has become impossible to diagnose the disease or serve the patient well. It takes a lot of doctors to monitor patients with liver problems which can be very challenging. If we can collect human data in every hospital and every clinic then this process will be much easier for everyone and easy to manage. However, by analyzing the data of these people, we can easily detect the symptoms of the disease if ML is applied. As a result, the number of doctors will be less and the process will be much more comfortable. Artificial Intelligence (AI) includes ML, which allows the system to learn without information. Human inputs and outputs are employed in the training process and prediction accuracy of supervised algorithms, which are used in a variety of classification applications [4]. Fig. 2 shows the five causes of liver failure.

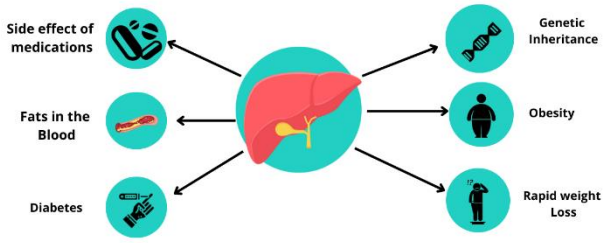

Fig. 2. Five cause of liver failure.

ML is making a significant contribution to healthcare and is expanding day by day. One of the most important problems in healthcare is the growing number of liver patients. The incidence of fatty liver in liver disease is early stage and cirrhosis is the final stage of chronic liver disease which later leads to liver cancer. Many data mining techniques and medical data mining techniques help to present and predict liver disease first and foremost. As a result, the use of this technique greatly reduces the doctor's work.

This paper is organized as follows: Section II provides an overview of related work and highlights the main differences between our work and other existing studies. Section III presents the research methodology, experimental details, configuration and system flowchart. The test results and analysis are discussed in detail in Section IV. Finally, the paper is concluded in Section V.

II. Related Work

Disease prediction has become possible by uncovering hidden features in medical datasets using machine learning algorithms. Different types of datasets, such as blood panels with liver function tests, histologically stained slide images, and the presence of specific molecular markers in blood or tissue samples, have been used to train classifier algorithms to predict liver disease, which provided good accuracy. Machine learning methods described in previous studies have been evaluated for accuracy using a combination of confusion matrix, area under the receiver operating characteristic curve, and k-fold cross-validation. In study [2], the authors studied the prognosis of liver disease and used genetic algorithm combined with XGBoost to predict liver disease and analyzed from the test that the algorithm helped to predict the disease efficiently.

In recent studies, various machine learning algorithms have been applied to improve the diagnosis and prediction of liver-related diseases. In study [3], four machine learning algorithms were tested on ILDP datasets with the Pearson Correlation Coefficient (PCC-FS) optimization technique, resulting in the AdaBoost algorithm achieving a maximum accuracy of 92.19%. Similarly, the study in [4] explored the use of Support Vector Machine (SVM) and Logistic Regression (LR) for diagnosing liver disease, achieving an accuracy of 96%. Additionally, the study in [5] implemented a Random Forest (RF) algorithm to predict liver disease with notable accuracy. Furthermore, the research in [6] focused on the prediction of hepatocellular carcinoma (HCC) using the RF algorithm, achieving an accuracy of 80.86%. These studies collectively highlight the potential of machine learning techniques in enhancing the accuracy of liver disease diagnosis and prediction.

In study [1], the authors in this paper help to identify the patient's liver disease from the data and contribute to the field of medical science so that treatment can be started and the disease can be cured before it becomes severe. To do this they first used the classifier model decision tree (DT) algorithm and achieved the highest accuracy. Then they use seven more classifier algorithms: RF, LR, SVM, K-nearest neighbors (KNN), linear discriminant analysis, AdaBoost, and gradient boosting. Then they used the least absolute shrinkage and selection operator (LASSO) feature selection technique to achieve better accuracy.

Furthermore, recent research has delved into various machine learning techniques to enhance the diagnosis and prediction of liver-related diseases. In study [7], a diagnostic system for chronic liver infections was developed using six classifiers: Logistic Regression (LR), Random Forest (RF), Decision Tree (DT), Support Vector Machine (SVM), K-Nearest Neighbors (KNN), and Naive Bayes (NB), with LR achieving the highest accuracy at 75%. Similarly, the study in [8] utilized LR, SVM, and KNN for liver disease prediction, identifying LR as the most effective. Dhamodharan et al. [9] focused on predicting cirrhosis, liver cancer, and hepatitis, employing Naive Bayes and the FT Tree algorithm, with Naive Bayes providing the highest accuracy. Rosalina et al. [10] used SVM and the Wrapper method for hepatitis prognosis, effectively removing noise features before classification and achieving optimal results by combining these methods. Soliman et al. [11] introduced a hybrid classification system for HCV detection, utilizing Least Squares Support Vector Machine (LS-SVM) and Modified Particle Swarm Optimization (PSO). With Principal Component Analysis (PCA) for feature extraction and a modified PSO for parameter optimization, their method outperformed other systems in accuracy using HCV benchmark data from the UCI repository. Lastly, in study [12], NB and SVM algorithms were applied for liver disease prediction, with SVM achieving the highest accuracy. Collectively, these studies highlight the significant role of machine learning in enhancing the precision and effectiveness of diagnostics for liver diseases.

III. Methodology

This suggested model uses data from machine learning Indian Liver Patient Dataset (ILPD) that has been taken from the UCI Repository to predict the disease in multiple patients with liver disease. To begin, pre-processed data is used to create "clean" data. The feature extraction approach selects the relevant data from all of the dataset's attributes in order to improve accuracy by using only relevant data. After then, the algorithms and data used to classify the objects were examined. CatBoost classifier Algorithm is used to classify the data throughout the analysis process. Performance is evaluated based on the classification findings. We then employed optimization methods, such as the whale Optimization algorithm, in order to improve our results even further. Algorithms are compared on accuracy, sensitivity, precision and f1-scores in order to determine the best performing algorithm for the system's performance. Fig. 3 depicts the system's overall working procedure.

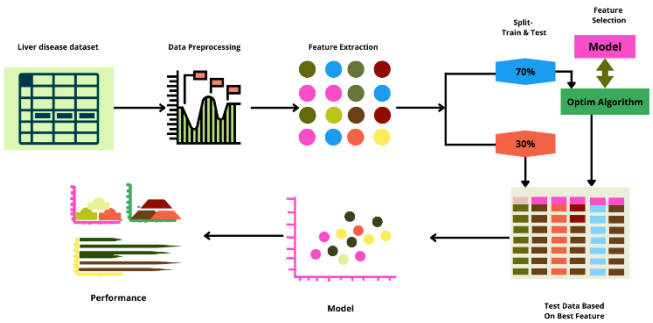

Fig. 3. Working procedure.

1) Dataset description: This dataset was collected from the northeastern Andhra Pradesh of India. In addition, this dataset is publicly available in the UCL machine learning repository [13]. There are 583 patients in the ILPD dataset which 441 are males and 142 are females. Anyone over the age of 89 is reported as having an age of 90. There is also a selector field to determine whether the patient having liver disease or not. Non-LD patients (0) total 167, whereas LD patients (1) total 416. Attribute properties of the dataset include multivariate, integer, and real values. Table I represented the dataset contains a total of 11 specific parameters, out of which we selected 10 parameters for our analysis and 1 was used as the target class. These data are used to train and test the models, and the models' performance is assessed based on their own output. In addition, we have divided the dataset into two parts: 70% for training and 30% for testing. Thus, we have 408 samples in our training set and 175 samples in our validation set. In Fig. 4 the dataset's distribution is displayed.

1	Age	Age of the patient
2	Gender	Gender of the patient
3	TB	Total Bilirubin
4	DB	Direct Bilirubin
5	Alkphos	Alkaline Phosphotase
6	Sgpt	Alamine Aminotransferase
7	Sgot	Asparatate Aminotransferase
8	TP	Total Proteins
9	ALB	Albumin
10	AG Ratio	Albumin and Globulin Ratio

2) Data Preprocessing: As stated in the preceding paragraph, the dataset referred to has flaws and scattered data. Pre-processing has been done so that we can get the most out of this dataset. We manually corrected any incorrect data by going through the dataset and looking for any anomalies. When there are no values to fill in, the median of a feature is used. However, Information is extracted from sources and collected in the form of data or discrete analytical data. Each attribute acts as a variable and each instance has specific attributes. Liver disease is predicted using a dataset, which is created through data collection and pre-processing methods. The dataset helps us diagnose the disease based on its various parameters. 10 features are considered to get accurate results in the dataset of the proposed work. Classification is a process of data mining consisting of problem identification. Best performance-based prediction is provided by observing liver disease characteristics in patients and using machine learning algorithms.

3) Classification and Performance Metrics: Dorogush et al. [14] developed CatBoost in 2018 based on improvements to XGBoost. Yandex released CatBoost, an open-source machine learning algorithm, in 2017, which is still relatively new [15]. The model is built using a training dataset, which consists of a set of objects with known features and labels. The training dataset is also referred to as the "data set". The validation dataset is only used to evaluate the effectiveness of training and contains similarly organized data, but is not used for training. The basis of CatBoost is gradient-boosted decision trees, where a series of decision trees is generated sequentially during training. Each subsequent tree is built with less damage than the previous tree. The initialization parameter determines how many trees will grow. To prevent overfitting, overfitting detectors are used which stop tree growth when activated. We used CatBoost algorithm to classify liver diseases.

4) Features selection: Feature selection is an important process in machine learning, where the most important features (variables or predictors) are selected from the dataset, which play a role in predicting the target variable. This is helpful in reducing dataset dimensions, improving model performance,

and reducing the likelihood of overfitting. In this study, we used two metaheuristic optimization algorithms such as, WOA and HHO. It is well-known swarm-based metaheuristic method for feature selection.

5) Whale optimization algorithm (WOA): WOA is a metaheuristic optimization algorithm that was proposed by Mirjalili and Lewis [16]. The bubble-net hunting method utilized by humpback whales is modelled after and imitated by the algorithm. The entire process can be broken down into three stages: the first stage involves encircling the prey, the second stage involves bubble-net foraging (the exploitation phase), and the third stage involves searching for prey (exploration phase). To better understand these three stages of the WOA strategy we present in Fig. 5. An initial solution candidate is chosen at the beginning of the algorithm, and their fitness is determined with the help of a function. During each cycle of the iterative process, the solution set is either updated through the shrinking encircling mechanism or the spiral updating mechanism (exploitation phase), with the choice of the mechanism being determined by a probability p. In addition, the shrinking encircling mechanism can either update the new solution set so that it is closer to the global best solution or it can use a random search agent. This is determined by a coefficient called A. The equation for the coefficient is presented in the following example:

$$\boldsymbol{A = 2a.r - a} \quad (1)$$

where, a is a random vector in the range [0, 1] and r is a vector that decreases linearly from 2 to 0 over the course of the generation. Because the update that leads to a random agent conducts a worldwide search, the subsequent phase is known as the exploration phase. In Algorithm 1, the pseudo-code for feature selection using WOA is presented.

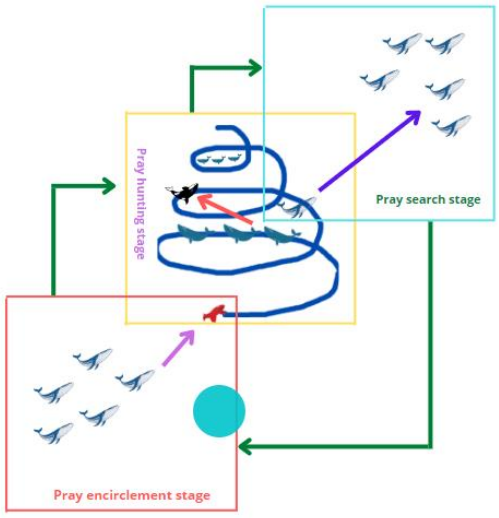

Fig. 5. Whale Optimisation Algorithm.

Algorithm 1: Feature Selection Using WOA

Create the first group of n whales xi (1,2,3……., n)
Set the iteration counter $t_{counter}$ = 0
figure out how fit each whale is.
figure out which whale is the fittest, i.e., Y_{best}
for each whale **do**

Decode feature set from whale position
Calculate the fitness value using CatBoost classifier
end
update X* if a set of the best solutions exists
t = t + 1
end
Save the best feature set

6) Harris hawk optimization algorithm (HHO): Haidari and his colleagues (2019) [17] proposed the use of a new metaheuristic algorithm known as the Harris Hawk Optimization (HHO). HHO imitates the notions of Harris hawks in order to investigate the diverse prey, surprise pounces, and attack techniques used by Harris hawks in the natural world. In HHO, the candidate solutions are symbolized by hawks, and the best solution, which is also referred to as the nearly optimum solution, is referred to as prey. The Harris hawks make use of their keen vision to locate their prey and

then execute a surprise attack in order to successfully capture the target they have located [18].

In most cases, HHO is modeled into two distinct phases: the exploitation phase, and the exploration phase. The HHO algorithm may be used for either exploration or exploitation, and after it has been used for either purpose, the exploration behavior can be altered dependent on the amount of energy that the prey is able to escape with. It is possible to mathematically determine the escape energy of prey using the Eq. (2) to (3):

$$E = 2E_0(t - \frac{t}{T}) \quad (2)$$

$$E_0 = 2r - 1 \quad (3)$$

where t represents the current iteration, T represents the maximum number of iterations, E0 represents the initial energy that is created at random in the range [1,1], and r represents a random value that falls in the range [0, 1]. In Algorithm 2, the pseudo-code for feature selection using HHO is presented.

Algorithm 02: Feature Selection Using HHO algorithm

Inputs: N is the population size, while T is the maximum

Outputs: Rabbit's position and fitness value initialize

While (stopping conditions is not met) **do**

for (each hawk (X_i)) **do**

Update the initial energy E0 and jump strength j

If (|E|≥) **then**

Update the location vector

If (|E|<1) **then**

Update the location vector

else if (r <0.5 and |E|≥0.5) **then**

Update the location vector

else if (r <0.5 and |E|<0.5) **then**

Update the location vector

Return X_{rabbit}

Our feature subset was optimized using the WOA and HHO to minimize the number of features while also increasing prediction accuracy. The feature subsets are selected from the WOA and HHO solution sets. The solution set's value indicates whether or not to choose a feature. The CatBoost algorithm was then used to classify liver disease based on the feature subsets. F1 score true and the predicted class is used as the value of an agent's fitness. The advantage of F1 score is that it helps to provide harmonic mean, accuracy and recall. Because of this, it is harsher on values at the extremes. Overall, an agent's fitness value is referred to as the F1 score (feature subset). The WOA and HHO take the best fitness value as a baseline and update the position in accordance with the methodology used by each. This iteration is repeated until a predetermined end point is achieved.

IV. Results and Analysis

The results of classifier algorithm are detailed in Section A on the experimental evaluation of our proposed CatBoost model. In addition, the relevance of the feature selection with two metaheuristic algorithms mentioned in Section B.

A. Performance Analysis

In the previous section, we discussed the various contents of the dataset. We used a technique and method to classify the class samples in this dataset. In this section, we will present the research findings. Following the described procedure, we set up a classification model where the CatBoost model was used for training the model and the rest of the samples were used for testing. We have split our dataset in the ratio of 70:30. In this paper we have proposed classification algorithms like CatBoost algorithm. However, after finishing data preprocessing steps without applying feature selection techniques, algorithms are used for classification. Our model provided and accuracy of 74%. Besides accuracy, various evaluation criteria such as precision, recall, and f1-score values are compared in Table II.

TABLE II. Classification Report of our Model

Class	Precision	Recall	F1-Score
Non-LD	0.50	0.37	0.42
LD	0.80	0.87	0.84

In Fig. 6 shows a confusion matrix, which is used as a powerful tool for evaluating the performance of classification models in machine learning. This matrix clearly shows how the model classified the data into actual and predicted categories. It divides the results into four different categories, providing important insights into the model's strengths and weaknesses: true positives, true negatives, false positives, and false negatives. In this confusion matrix, the result of a binary classification task, where there are two possible outcomes - "0" and "1". The actual value, or true label, is displayed along the vertical axis and the model predicted value along the horizontal axis. The number in each cell shows how many examples fall into that particular category. In this model, it correctly predicted class "1" in 76 instances (true positives) and correctly assigned class "0" in 11 instances (true negatives). However, the model incorrectly classified class "0" as "1" (false positive) in 19 instances and class "1" as "0" (false negative) in 11 instances. These errors show where the model is having trouble, especially distinguishing between two classes. The confusion matrix gives a clear picture of the prediction performance of the model, which helps us better understand the accuracy, precision, and other evaluation metrics of the model.

Fig. 7 shows a receiver operating characteristic (ROC) curve, which is commonly used to evaluate the performance of binary classification models. This curve depicts the relationship between the true positive rate (TPR) and the false positive rate (FPR) at different threshold settings, giving an understanding of how well the model is able to distinguish between the two classes. The dashed diagonal line represents the performance of a random classifier and serves as a baseline with an AUC of 0.5. The orange curve shows the actual performance of the model, which lies above the diagonal, indicating that the model is giving

better results than the random guess. An AUC value of 0.82 suggests that the model is able to distinguish between positive and negative classes and has an 82% chance of correctly identifying a positive instance.

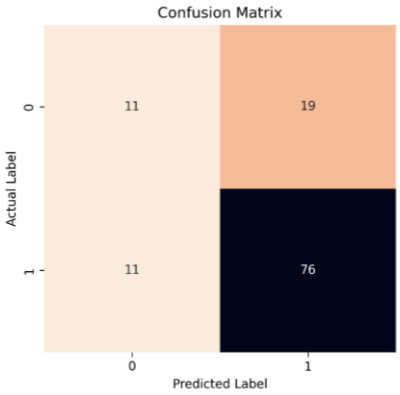

Fig. 6. Confusion matrix.

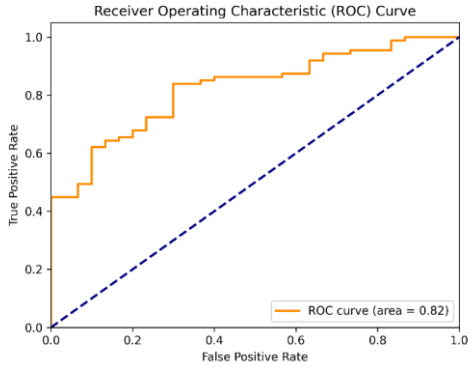

Fig. 7. ROC curves of various classes.

B. Feature Selection Outcome

We applied the FS algorithm to increase the accuracy of the CatBoost classifier and reduce the dimensionality of the features. The FS process was carried out using two metaheuristic algorithms named WOA and HHO. A fitness function is constructed based on the performance evaluation of the CatBoost classifier. Other performance metrics, such as F1 score, precision and recall, are also taken into account. We checked the 'p_r' parameter of WOA and HHO between 0.21, indicating the learning rate potential. A value of 0.25 was identified as optimal for 'p_r', while values were 50 for 'pop_size' and 'epoch' parameters. Various 'p_r' values are shown in Table III, which highlights the set of features returned from the WOA and HHO processes.

TABLE III. BEST FEATURE SOLUTION

Optimization Algorithm	Feature Name	Optimization Algorithm	Feature Name
HHO	Total Bilirubin	WOA	Age
	Direct Bilirubin		Total_Bilirubin
	Alamine Aminotransferase		Alamine Aminotransferase

Table III outlines the best features obtained from two optimization algorithms, HHO and WOA, which have been used to identify the most important features for liver disease detection. Selected parameters for HHO include Total Bilirubin, which is important in evaluating liver function because high bilirubin levels usually indicate liver problems. It also selects Direct Bilirubin and Alanine Aminotransferase, where it is an enzyme that increases in the blood when liver cells are damaged. On the other hand, the WOA algorithm identified Age, Total Bilirubin, and Alanine Aminotransferase as important characteristics that are influential in liver disease. Both algorithms selected Total Bilirubin and Alanine Aminotransferase, indicating their high importance in the diagnosis of liver disease, and proved to be important features for accurate detection.

In Fig. 8, the confusion matrix of the HHO algorithm shows that the model correctly classified 82 cases as true negative (TN) and 96 cases as true positive (TP). However, it misclassified 17 cases as false positive (FP) and 3 cases as false negative (FN). The HHO model achieved 85% accuracy, indicating strong performance in liver disease detection. A particularly low number of false negatives makes the model useful in medical diagnosis, as it indicates that very few cases of true disease are missed.

In Fig. 9, the confusion matrix of the WOA shows that the model correctly classified 13 cases as True Negative (TN) and 84 cases as True Positive (TP). At the same time it misclassified 17 cases as false positive (FP) and 3 cases as false negative (FN). The WOA model achieved 82% accuracy. Although the number of false negatives is low, the model lags slightly behind HHO in detecting true negatives, showing slight weakness in detecting cases without disease.

On the other hand, the previously used CatBoost algorithm achieved only 74% accuracy, which is significantly lower than HHO and WOA. This proves these two optimization algorithms more effective in liver disease detection. Overall, the HHO model shows the best performance in liver disease detection, as it is able to maintain a good balance between high accuracy and true positive and true negative detection.

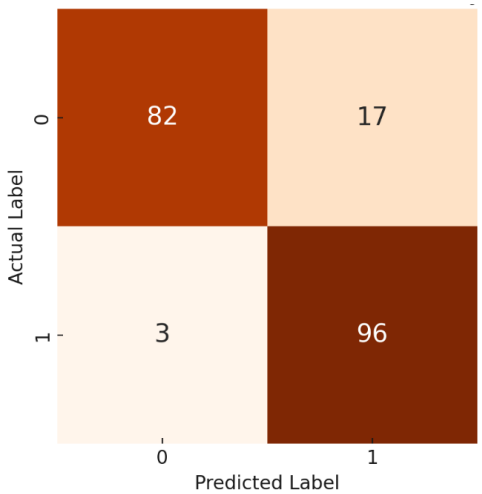

Fig. 8. Confusion matrix for HHO.

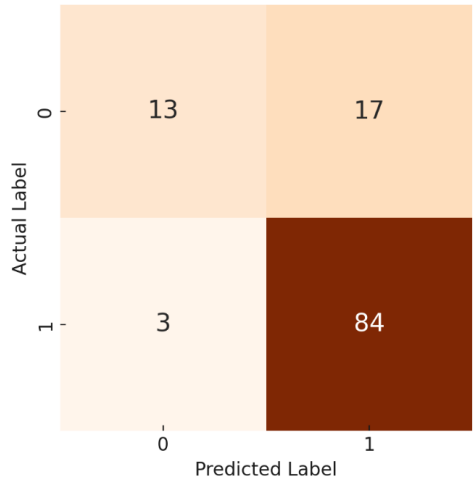

Fig. 9. Confusion matrix for WOA.

V. Conclusion

This study successfully identified key features for liver disease detection using two optimization algorithms: Harris Hawk Optimization (HHO) and Whale Optimization Algorithm (WOA). Both algorithms highlighted Total Bilirubin and Alanine Aminotransferase as critical indicators for diagnosing liver disease. Additionally, Direct Bilirubin and Age were also recognized as significant factors in assessing liver function. Our findings align with existing research while offering new insights that can enhance diagnostic accuracy using clinical data. These results underscore the efficacy and potential of machine learning models combined with optimization algorithms in advancing liver disease diagnosis. This work contributes to the growing evidence that such computational approaches can significantly improve early detection and intervention strategies in healthcare. Future research could explore integrating additional datasets and machine learning techniques to further refine these predictive models and expand their applicability across diverse populations.

***Abstract*—The detection of diabetic retinopathy traditionally requires the expertise of medical professionals, making manual detection both time- and labor-intensive. To address these challenges, numerous studies in recent years have proposed automatic detection methods for diabetic retinopathy. This research focuses on applying deep learning and image processing techniques to overcome the issue of performance degradation in classification models caused by imbalanced diabetic retinopathy datasets. It presents an efficient deep learning model aimed at assisting clinicians and medical teams in diagnosing diabetic retinopathy more effectively. In this study, image processing techniques, including image enhancement, brightness correction, and contrast adjustment, are employed as preprocessing steps for fundus images of diabetic retinopathy. A fusion technique combining color space conversion, contrast limited adaptive histogram equalization, multi-scale retinex with color restoration, and Gamma correction is applied to highlight retinal pathological features. Deep learning models such as ResNet50-V2, DenseNet121, Inception-V3, Xception, MobileNet-V2, and InceptionResNet-V2 were trained on the preprocessed datasets. For the APTOS-2019 dataset, DenseNet121 achieved the highest accuracy at 99% for detecting diabetic retinopathy. On the Messidor-2 dataset, InceptionResNet-V2 demonstrated the best performance, with an accuracy of 96%. The overall aim of this research is to develop a computer-aided diagnosis system for classifying diabetic retinopathy.**

Keywords*—Diabetic retinopathy; deep learning; image processing technologies; imbalanced image dataset; computer aided diagnosis

I. Introduction

Diabetes is a chronic disease and a major public health issue that significantly affects quality of life due to its rising incidence. According to the International Diabetes Federation's Diabetes Atlas, 537 million people worldwide have diabetes, and this number is expected to increase to 629 million by 2045. Most cases occur in low-to-middle-income countries, with more than half undiagnosed. The World Health Organization predicts that diabetes will become the seventh leading cause of death globally.

A common and often unnoticed complication of diabetes is diabetic retinopathy, which progresses slowly but can severely impact patients' quality of life, affecting their families, the economy, and society. The condition necessitates comprehensive care and regular screening. Diabetic retinopathy involves changes to the retina caused by diabetes, as elevated blood sugar levels lead to nerve and blood vessel damage. This results in complications such as retinal swelling, detachment, bleeding, and vision loss [1].

Many countries face shortages in medical resources and ophthalmologists, particularly in rural or remote areas, where patients may not receive timely diagnosis and treatment due to the uneven distribution of healthcare resources. Traditional manual diagnosis by specialists also presents challenges, as it can be time-consuming and early-stage symptoms are often subtle, increasing the risk of misdiagnosis even by a single expert. As a result, monitoring and treating diabetic retinopathy demands considerable time and human resources, while training professional ophthalmologists entails significant costs.

Given these challenges, recent years have seen numerous studies [2–4] proposing automated detection methods to assist medical teams and ophthalmologists in diagnosing diabetic retinopathy more efficiently. Automated diagnostic systems also help address the issue of low screening efficiency in areas with limited medical resources.

Research on automating diabetic retinopathy detection has focused on areas such as medical image enhancement, machine learning, and deep learning-based image recognition. Scholars have reviewed these studies, discussing the advantages and disadvantages of various methods and the factors that may influence recognition results.

The quality of fundus images for diabetic retinopathy is often inconsistent, making image preprocessing a crucial step in many studies. Different research efforts employ appropriate preprocessing techniques based on their specific objectives [5].

This study aims to develop a computer-aided diagnosis system for detecting diabetic retinopathy by addressing the imbalance in data characteristics within the diabetic retinopathy dataset and using categorical focal loss as the loss function instead of categorical cross-entropy loss. The research utilizes the Asia Pacific Tele-Ophthalmology Society-2019 Blindness Detection (APTOS-2019) and Messidor-2 datasets, containing 3,662 and 1,744 images respectively, to train and compare the performance of various convolutional neural network models in diabetic retinopathy classification against other studies. Six convolutional neural network (CNN) models ResNet50-V2, DenseNet121, Inception-V3, Xception, MobileNet-V2, and

InceptionResNet-V2 were used to determine the most suitable model for training with these datasets.

The remaining content research is organized as follows: materials and methodology are presented in Section II. implementation details are shown in Section III. Section IV presents the experimental results, while Section V presents the discussion, and finally, Section VI concluded the paper.

II. Materials and Methodology

This study divides the experimental procedures into four sections: image collection, image preprocessing, deep learning model training, and system performance evaluation. The following subsections detail the processes and methods involved in each step.

The first step is to confirm the dataset accessible under the experimental conditions. Due to concerns regarding medical privacy, diabetic retinopathy datasets often require annotation and grading by ophthalmic experts. To address these issues, a practical approach is to use existing publicly available datasets for experimentation. Public datasets offer several advantages: many previous studies have utilized them to evaluate their systems. By using the same publicly available datasets, researchers can assess the novelty of their approach and compare it with prior work. This also enhances the comparability and credibility of the current study.

The APTOS-2019 and Messidor-2 datasets are foundational resources in artificial intelligence research for the detection and classification of diabetic retinopathy. These datasets contain extensive collections of eye images, each annotated with a specific severity level of diabetic retinopathy, making them instrumental for training and evaluating computer vision models aimed at accurate disease diagnosis.

This research applies a variety of image processing techniques and deep learning models to train a classifier on the diabetic retinopathy dataset, as described in [5]. The classifier is responsible for categorizing images into five distinct stages of diabetic retinopathy: No Diabetic Retinopathy (NDR), Mild Diabetic Retinopathy (MiDR), Moderate Diabetic Retinopathy (MoDR), Severe Diabetic Retinopathy (SDR), and Proliferative Diabetic Retinopathy (PDR). Visual representations of these five stages are provided in Fig. 1.

In addition, the diabetic retinopathy datasets face issues with class imbalance. This imbalance can negatively affect system performance, as certain classes in the dataset may be overrepresented or underrepresented. As a result, the model tends to predict the more frequent classes more easily, while the less frequent classes are harder to predict and are more likely to be misclassified as one of the dominant classes.

In the second step, various image processing techniques were employed, including RGB color space conversion, commission internationale de l'eclairage (CIELAB), contrast-limited adaptive histogram equalization (CLAHE), multi-scale retinex with color restoration (MSRCR), and Gamma correction. These techniques enhance image features to improve the neural network's ability to learn features effectively. Following this, the dataset was split into training, validation, and testing sets, with 80% allocated to training and 20% for testing, as shown in Table I.

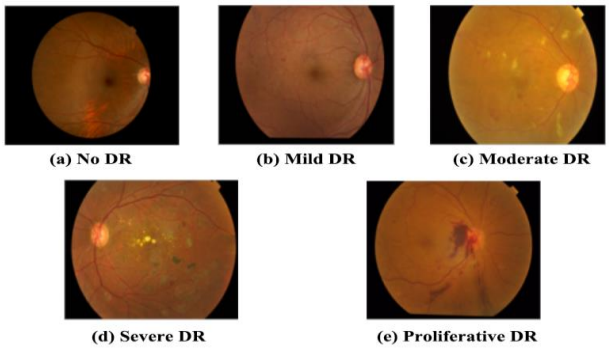

Fig. 1. Classification of the five levels of diabetic retinopathy.

TABLE I. Distribution of Image Quantities Across Disease Categories

Dataset Name	categories					Total
	NDR	MiDR	MoDR	SDR	PDR	
APTOS-2019	1,805	370	999	193	295	3,662
Messidor-2	1,020	264	347	77	36	1,744

After splitting the dataset, the training set undergoes data augmentation techniques, including horizontal flipping, vertical flipping, and pixel value scaling. Before being fed into the convolutional neural network (CNN) models for training, each image is resized to the optimal dimensions required by the model.

Fig. 2 presents a schematic representation of the hybrid image enhancement method used in this investigation, based on findings from previous studies [6–11]. Our proposed technique integrates the CLAHE algorithm with enhancements to the CIELAB color space. Empirical results show that this combined approach produces better results compared to using the hue, saturation, and value (HSV) color space or other color space transformations. In this framework, CLAHE is applied exclusively to the luminance (L) channel of the CIELAB color space. The process of splitting the V channel refers to isolating the Value component from the HSV color space, which allows for further processing or enhancement tasks such as sharpening or brightening.

In medical imaging, particularly in retinal imaging, researchers often convert images to the CIELAB color space to separate luminance (L channel) from color information (a and b channels). Subsequently, CLAHE is applied to enhance the luminance component in CIELAB, preserving the original color information. This approach effectively enhances image details without compromising color fidelity. The synergistic combination of CIELAB and CLAHE provides a robust solution for improving image clarity and quality, particularly when processing high-detail images.

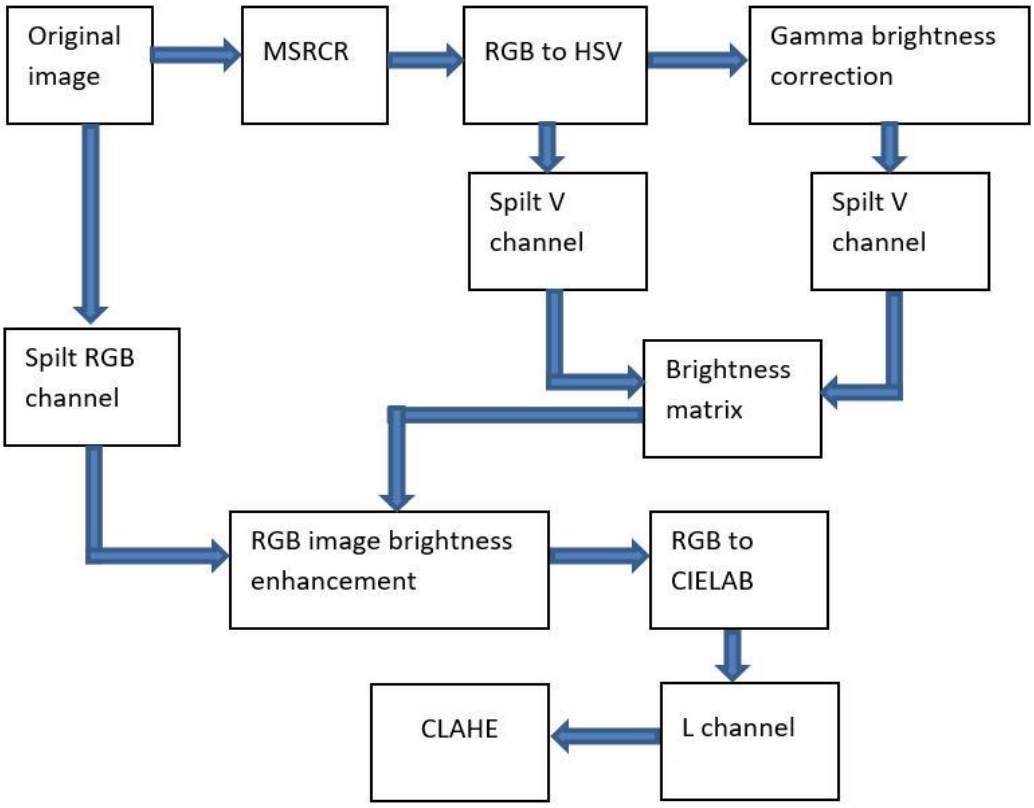

Fig. 2. The schematic of hybrid image enhancement method.

Fig. 3 presents a schematic of alternative image enhancement methods, which are standard preprocessing techniques used in diabetic retinopathy severity grading. The multi-scale retinex with color restoration (MSRCR) transformation is a pivotal aspect of the hybrid image enhancement strategy adopted in this research. MSRCR has been extensively applied in medical image segmentation and classification, including retinal vessel segmentation and arterial-venous classification, as evidenced by studies [12–15].

Data augmentation is a technique that enhances the amount of data by synthesizing new images from an original dataset. This method not only increases the dataset's size but also offers additional advantages, such as more efficient use of computer memory during model training and a regularization effect that helps mitigate overfitting. Common techniques for data augmentation include horizontal and vertical flipping, resizing, cropping, shifting, and scaling pixel values. While these transformations create variations of the original image that may look different to the model, they still allow humans to recognize them as the same image. This principle of generating multiple images from a single original image is the foundation of data augmentation [16].

In the third step, this study employs deep learning models, including ResNet50-V2 and InceptionResNet-V2, which were trained on diabetic retinopathy image datasets processed in the second step. Various CNN models were combined with image enhancement methods to identify the optimal combination and compare the advantages of each. The architecture of the models used in this study is illustrated in Fig. 4. All pretrained deep learning models mentioned serve as base models in this research, utilizing pretrained weights from the ImageNet image database. A custom dense neural network is connected beneath the base model, with each final layer of the CNNs configured to use a SoftMax activation function for five-class classification.

To ensure that model training achieves the expected classification performance, continuous testing and parameter tuning are conducted. Ultimately, other public datasets are used to validate the system's performance and the model's reliability. The evaluation metrics used in this study are described below, sourced from studies related to diabetic retinopathy severity classification [5, 17, 18]. Table II presents the definitions of True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN).

TABLE II. MEANINGS OF TP, TN, FP, FN

Indicator Names:	Descriptions:
True Positive (TP)	True Positive (TP): Predicted positive and predicted correctly.
True Negative (TN)	True Negative (TN): Predicted negative and predicted correctly.
False Positive (FP)	False Positive (FP): Predicted positive but predicted incorrectly.
False Negative (FN)	False Negative (FN): Predicted negative but predicted incorrectly.

Accuracy is used to calculate the proportion of correctly predicted samples by the model among the total number of samples in a classification task. It is calculated as shown in Eq. (1).

$$\text{Accuracy} = （TP+TN）/\text{Total} \quad (1)$$

Precision is the proportion of correctly identified samples of a particular class among all samples predicted to belong to that class by the model. It is calculated as shown in Eq. (2).

$$\text{Precision} = TP/（TP+FP） \quad (2)$$

Sensitivity, also known as the True Positive Rate or Recall, refers to the proportion of true positive samples that are correctly predicted by the model among all actual positive samples. It is calculated as shown in Eq. (3).

$$\text{Sensitivity} = TP/（TP+FN） \quad (3)$$

Specificity, also known as the True Negative Rate, refers to the proportion of true negative samples that are correctly predicted by the model among all actual negative samples. It is calculated as shown in Eq. (4).

$$\text{Specificity} = TN/（FP+TN） \quad (4)$$

Additionally, the diabetic retinopathy datasets exhibit issues with class imbalance. This problem can adversely affect system performance, as certain classes in the dataset may be overrepresented while others are underrepresented. As a result, the more frequent classes are easier to predict, whereas the less frequent classes are harder to predict and more likely to be misclassified by the model as one of the more frequent classes.

III. Implementation Details

A. Experimental Environment

The configuration of the experimental environment in this paper is shown in Table III. The computer hardware used includes an Intel® Core™ i9-9900K CPU 3.60GHz as the central processing unit, an NVIDIA GeForce RTX 2080 Ti 11GB as the graphics processing unit, and 64GB of memory. In terms of software configuration, the operating system is Windows 10 Pro 64-bit. The platform used for programming is Jupyter Notebook 6.4.6, and the programming language used is Python 3.7.11. The deep learning frameworks utilized are TensorFlow-GPU 2.8.0 and Keras 2.8.0.

B. Model Parameter Settings

Each model was trained for a maximum of 100 epochs, with a callback function set to monitor the validation loss for early stopping, saving the model with the best training performance. In addition to early stopping, this study employed ModelCheckpoint to track and save the model weights with the highest validation specificity.

The batch size for all training processes was set to 8. Nadam [16], an adaptive learning rate optimizer, was employed to enhance training stability by adjusting the learning rate based on its variance. The class weight parameters were adjusted according to the proportion of classes from class 0 to class 4 to

balance the training weights for each class. Classes with more examples were assigned lower weights, while classes with fewer examples were assigned higher weights. Instead of using the traditional categorical cross-entropy loss, this study employed categorical focal loss as the loss function.

TABLE III. HARDWARE AND SOFTWARE ENVIRONMENT OF THE EXPERIMENT

experimental environment configuration	specifications
operating system	Windows 10 Professional 64-bit
processor	Intel (R) Core (TM) i9-9900K CPU 3.60GHz
graphic processor	NVIDIA GeForce RTX 2080 Ti 11G
memory	64GB
software development platform	Jupyter Notebook 6.4.6
programming language	Python 3.7.11
deep learning framework	Tensorflow-gpu 2.8.0、Keras 2.8.0

ResNet50-V2 is an improved version of ResNet50 [19], which outperforms both ResNet101 and ResNet50 in terms of system performance on the large-scale ImageNet database. The primary enhancement in ResNet50-V2 involves modifying the propagation formula within the basic building blocks of the Residual Network (ResNet). The architectural differences between the basic units of ResNet50-V1 and ResNet50-V2 are shown in Fig. 5 (with ResNet50-V1 on the left and ResNet50-V2 on the right). In ResNet50-V2, the batch normalization layer and ReLU activation function are moved before the weight layers, resulting in a pre-activation structure. The advantage of this structure is that it accelerates model convergence without changing the model's depth, and placing the batch normalization layer before the ReLU activation function and weight layers enhances the model's regularization effect.

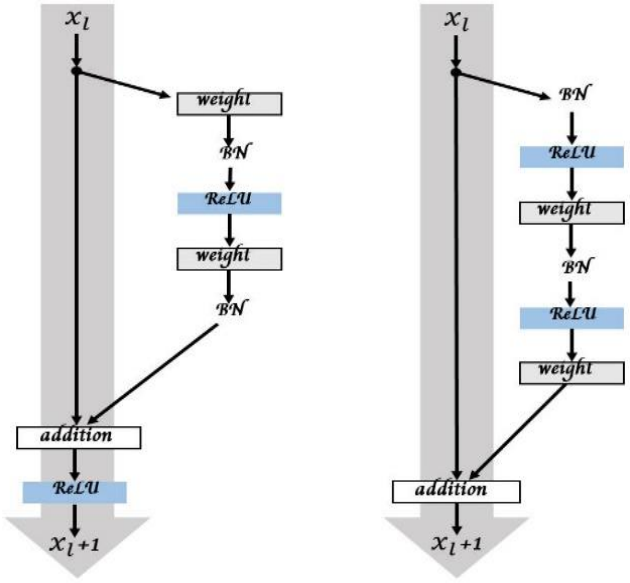

Fig. 5. Architectural differences between basic residual units of ResNet50-V1 and ResNet50-V2.

DenseNet (Densely Connected Convolutional Network) offers several advantages over ResNet, such as reducing network complexity, lowering the number of model parameters, mitigating the gradient vanishing problem, and enhancing feature propagation [20]. Due to its densely connected architecture, DenseNet efficiently improves feature utilization, reduces gradient vanishing, and aids model convergence. Reusing features means there is no need to learn new feature maps, leading to a reduction in the number of model parameters. Fig. 6 illustrates the architecture of a dense block in DenseNet.

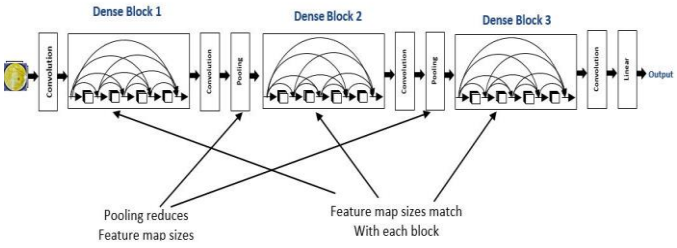

Fig. 6. Schematic diagram of dense block.

Inception-V3 was released in December 2015. The principle of Inception involves connecting convolutional layers of different sizes in parallel. The output from these convolutional layers is then used as input for the next inception block utilizing convolutional layers of varying sizes allows for the creation of better feature maps by extracting diverse feature information. Inception avoids bottleneck issues, which, although reducing the model's parameters, can result in the loss of important features and require slow dimensionality reduction to prevent excessive data loss [21]. Fig. 7 shows a schematic diagram of the inception block, including convolutional layers of different sizes.

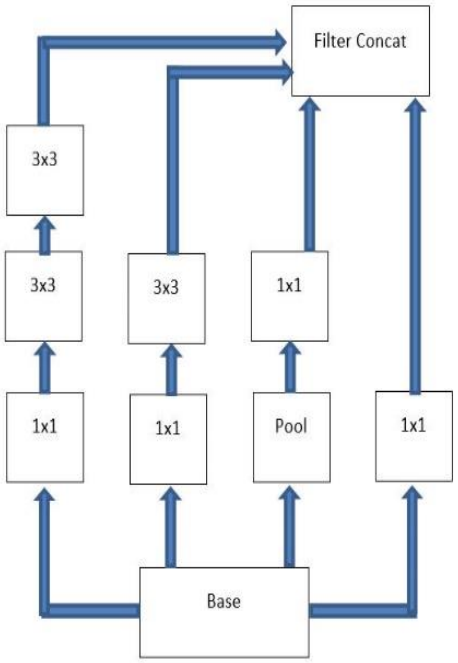

Fig. 7. Schematic diagram of inception block.

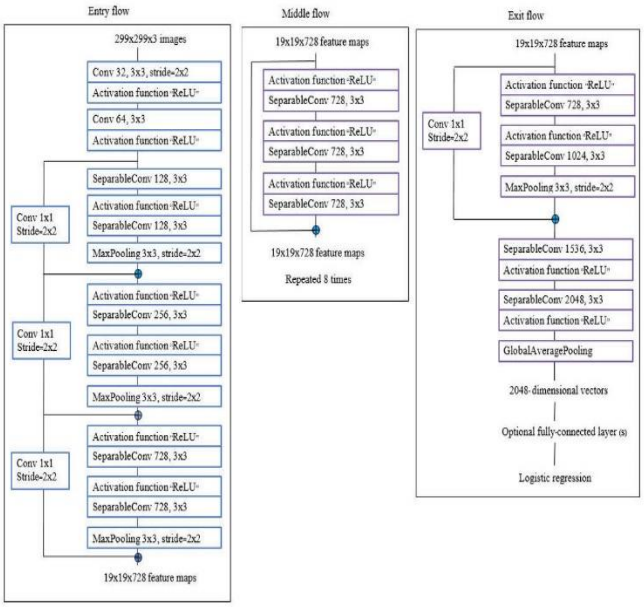

Fig. 8. Xception network architecture diagram.

Xception, short for extreme inception, is a network based on Inception-V3 [22]. It employs a depthwise separable Convolution architecture to replace the inception module structure in the original Inception-V3. depthwise separable convolution maintains the number of parameters of the original Inception-V3 network while reducing model complexity, increasing network width, and improving model accuracy, as illustrated in Fig. 8.

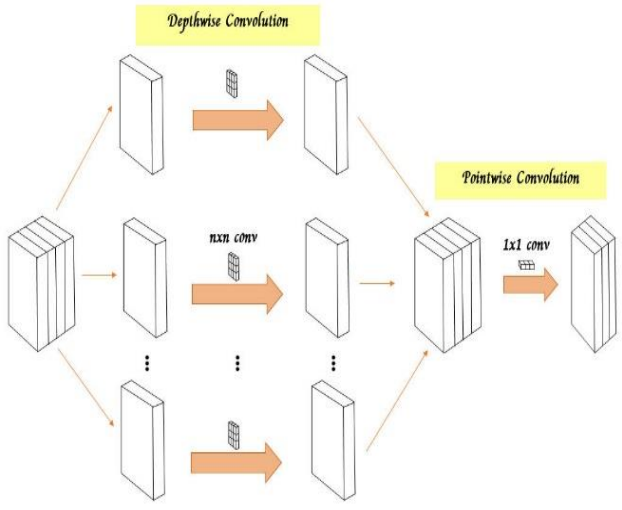

Fig. 9. Convolution operation flowchart of depthwise convolution.

MobileNet is a lightweight CNN model proposed by Google, designed to balance model size and computational speed for use in devices or mobile platforms [23]. MobileNet utilizes a depthwise separable convolution structure, which significantly reduces computational resources while maintaining good accuracy. Although both MobileNet and Xception use depthwise separable convolution, their goals differ: MobileNet focuses on model compression and computational speed, while Xception aims to enhance system performance with a parameter count similar to Inception-V3. The depthwise separable convolution consists of two parts: depthwise convolution and pointwise convolution. Depthwise convolution applies a k×k convolutional layer separately to each input channel, followed by pointwise convolution, which multiplies the output from the previous step using a 1×1 convolutional layer. The combined results provide a feature map, as illustrated in Fig. 9.

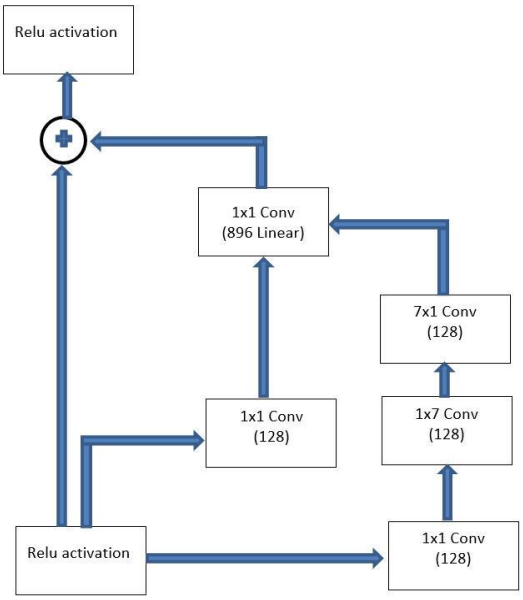

Fig. 10. Architecture diagram of inception block combined with residual connection.

InceptionResNet is a model developed by combining Inception-V3 and ResNet architectures [24]. The developers integrated residual connections into the inception architecture. Experimental results demonstrate that Inception networks with residual connections perform better in terms of system efficiency compared to inception networks without them. Additionally, residual connections significantly accelerate the training speed of the inception network. Fig. 10 illustrates the architectural diagram of an inception block integrated with a residual connection.

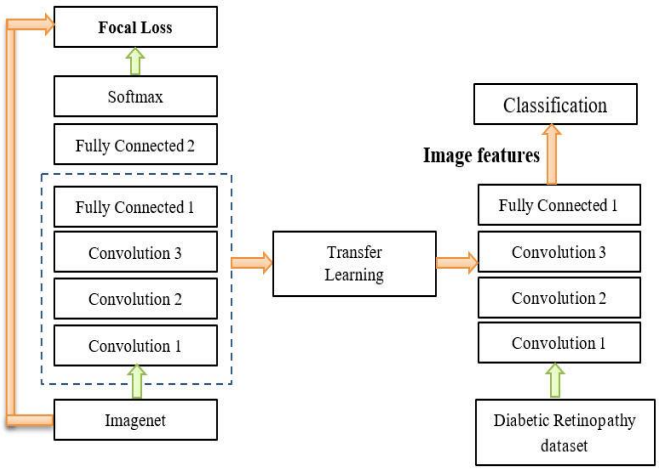

Fig. 11. Transfer learning technique.

Transfer learning involves training a neural network model on a related task and then adapting it to a new, similar problem. This technique leverages the model's pre-trained weights, often learned from large datasets like ImageNet. Transfer learning offers flexibility, enabling the use of pre-trained models as feature extractors or components of entirely new models. It has also been successfully applied in cancer subtype discovery, as illustrated in Fig. 11 [25].

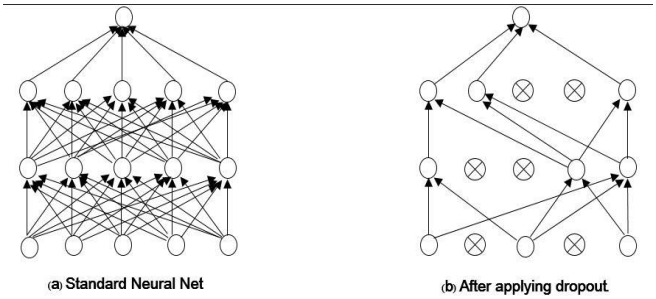

Fig. 12. Dropout technique.

To address overfitting, dropout is employed as a simple regularization technique that randomly deactivates neurons during training. In the context of CNNs, this means that some neurons are temporarily ignored, preventing them from sending signals to other neurons. A dropout rate of 0.5 in fully connected layers indicates that 50% of the neurons are deactivated. Dropout effectively mitigates overfitting by disrupting co-adaptations among neurons, thereby enhancing the model's ability to generalize and reducing its tendency to overfit the training data [25].

C. Categorical Focal Loss

The term α in the focal loss formula serves as a balancing factor that addresses class imbalance. It is calculated as shown in Eq. (5).

$$FL(p_t) = -\alpha(1-p_t)^{\gamma}.log(p_t) \quad (5)$$

Focal loss focuses on difficult examples by adjusting the loss based on the probability of correct classification (p_t). Hard examples, which have low p_t values, exert minimal influence on the modulating factor $(1-p_t)\ \gamma$, while easy examples with high pt values have a diminishing effect [26].

D. Optimizer

Nadam [23] is an optimization algorithm that utilizes past information to efficiently update model weights. It combines the strengths of both Adam and Nesterov momentum, addressing the decaying learning rate issue of Adagrad. This combination leads to faster convergence and reduced parameter instability, enabling more effective model training. Nadam is calculated as shown in Eq. (6).

$$\theta_{t+1} = \theta_t - \frac{\eta}{\sqrt{V_t} + \varepsilon}\left(\beta_1 m_t + \frac{(1-\beta_1)g_t}{1-\beta_1^t}\right) \quad (6)$$

Nadam utilizes a learning rate of 0.002 (η) with an objective function (θ_t) defined by $\varepsilon = 1e^{-08}$ and $\beta_1 = 0.9$. These settings, inspired by [27], leverage v_t, g_t and m_t to enhance the optimizer's efficiency at each time step t.

IV. Experimental Results

Tables IV and V present the system evaluation results of the image enhancement fusion techniques and six deep learning model combinations on the APTOS-2019 and Messidor-2 datasets, respectively.

TABLE IV. System Evaluation Results of Image Enhancement Fusion Techniques and Six Deep Learning Model Combinations used in this Study on the APTOS-2019 Dataset

Models	Accuracy%	Precision%	Sensitivity %	Specificity %
ResNet50-V2	92.4	86.1	99.1	99.5
DenseNet121	93.0	86.7	99.8	99.7
Inception-V3	89.7	85.6	99.7	99.0
Xception	91.9	87.0	99.5	99.6
MobileNet-V2	91.2	83.0	99.7	99.5
Inception ResNet-V2	91.8	82.5	99.1	99.5

DenseNet121 achieved the highest performance on the APTOS-2019 dataset with an accuracy of 93.0%, precision of 86.7%, sensitivity of 99.8%, and specificity of 99.7%. Xception and ResNet50-V2 exhibited slightly lower accuracy compared to DenseNet121. Xception achieved an accuracy of 91.9%, precision of 87.0%, sensitivity of 99.5%, and specificity of 99.6%, while ResNet50-V2 had an accuracy of 92.4%, precision of 86.1%, sensitivity of 99.1%, and specificity of 99.5%. The remaining three models, InceptionV3, MobileNet-V2, and InceptionResNet-V2, showed the following performance: InceptionResNet-V2 achieved an accuracy of 91.8%, precision of 82.5%, sensitivity of 99.1%, and specificity of 99.5%; MobileNet-V2 achieved an accuracy of 91.2%, precision of 83.0%, sensitivity of 99.7%, and specificity of 99.5%; and Inception-V3 achieved an accuracy of 89.7%, precision of 85.6%, sensitivity of 99.7%, and specificity of 99.0%. Overall, the sensitivity and specificity of all six deep learning classification models were greater than 99.0%. In conclusion, the image preprocessing methods used in this study consistently demonstrated good performance across all models with minimal variation, as illustrated in Table IV.

TABLE V. System Evaluation Results of Image Enhancement Fusion Techniques and Six Deep Learning Model Combinations used in this Study on the Messidor-2 Dataset

Models	Accuracy %	Precision %	Sensitivity %	Specificity %
ResNet50-V2	84.0	80.0	99.1	90.6
DenseNet121	85.9	72.9	99.7	94.7
Inception-V3	81.4	57.2	98.9	87.3
Xception	86.9	79.5	99.1	96.2
MobileNet-V2	84.0	64.1	96.9	91.6
Inception ResNet-V2	87.9	75.7	99.4	97.0

InceptionResNet-V2 demonstrated the best performance on the Messidor-2 dataset, achieving an accuracy of 87.9%, precision of 75.7%, sensitivity of 99.4%, and specificity of 97.0%. The second and third best performing models were Xception and DenseNet121, respectively, with slightly lower accuracies. Xception had an accuracy of 86.9%, precision of 79.5%, sensitivity of 99.1%, and specificity of 96.2%. DenseNet121 achieved an accuracy of 85.9%, precision of 72.9%, sensitivity of 99.7%, and specificity of 94.7%. The remaining three models, ranked fourth to sixth, were ResNet50-V2, MobileNet-V2, and Inception-V3, respectively. ResNet50-V2 had an accuracy of 84.0%, precision of 80.0%, sensitivity of 99.1%, and specificity of 90.6%. MobileNet-V2 achieved an accuracy of 84.0%, precision of 64.1%, sensitivity of 96.9%, and specificity of 91.6%. Inception-V3 had the lowest performance with an accuracy of 81.4%, precision of 57.2%, sensitivity of 98.9%, and specificity of 87.3%. Overall, the sensitivity and specificity of all six deep learning classification models were greater than 97.0%. In conclusion, the image preprocessing methods used in this study consistently demonstrated good performance across all models with minimal variation, as illustrated in Table V.

TABLE VI. COMPARISON WITH OTHER STUDIES USING THE APTOS-2019 DATASET

Researches	Accuracy%	Precision %	Sensitivity %	Specificity %
[28]	86.5	85.7	86.1	85.9
[29]	92.0	85.0	99.0	99.0
[30] VGG19	88.1	90.3	79.3	94.0
[30] DenseNet121	89.5	83.8	92.1	87.7
[31]	84.2	-	98.5	98.8
[32]	83.4	69.7	67.7	67.0
This research methodology	**93.2**	**86.8**	**99.5**	**99.6**

Research in [28] utilized the APTOS-2019 Dataset to develop a diabetic retinopathy classification model. The model achieved an accuracy of 86.5%, precision of 85.7%, sensitivity of 86.1%, and specificity of 85.9%. Research [29] reported an accuracy of 92.0%, precision of 85.0%, sensitivity of 99.0%, and specificity of 99.0%. Research in [30] evaluated both VGG19 and DenseNet121 models, with VGG19 achieving an accuracy of 88.1%, precision of 90.3%, sensitivity of 79.3%, and specificity of 94.0, while DenseNet121 attained an accuracy of 89.5%, precision of 83.8%, sensitivity of 92.1%, and specificity of 87.7%, while research [31] showed an accuracy of 84.2%, sensitivity of 98.5%, and specificity of 98.8%. Research [32] reported an accuracy of 83.4%, precision of 69.7%, sensitivity of 67.7%, and specificity of 67.0. The proposed model demonstrated superior performance, achieving an accuracy of 93.2%, precision of 86.8%, sensitivity of 99.5%, and specificity of 99.6%. Overall, the model developed in this experiment demonstrated superior performance in classifying diabetic retinopathy compared to previous studies, as shown in Table VI.

Research in [30] utilized the Messidor-2 dataset to construct a diabetic retinopathy classification model using InceptionResNet-V2 and Inception-V3. The models' performance metrics were as follows: InceptionResNet-V2 achieved an accuracy of 69.2%, precision of 60.2%, sensitivity of 54.9%, and specificity of 75.9%. Inception-V3 obtained an accuracy of 72.8%, precision of 54.3%, sensitivity of 50.2%, and specificity of 80.6%. In contrast, research [33] reported a sensitivity of 81.0% and specificity of 86.1%, while research [29] showed an accuracy of 80.0%, precision of 85.0%, sensitivity of 89.0%, and specificity of 90.0%. Research [34] reported an accuracy of 89.6%, sensitivity of 91.4%, and specificity of 93.2. Comparing these results to the current experiment, which achieved an accuracy of 87.3%, precision of 75.2%, sensitivity of 99.6%, and specificity of 97.8%, it is evident that the current model exhibits high performance compared to other research and closely resembles the results of research [34]. The model in this experiment demonstrated a strong ability to detect positive cases due to its higher sensitivity compared to other studies, as shown in Table VII.

TABLE VII. COMPARISON WITH OTHER STUDIES USING THE MESSIDOR-2 DATASET

Researches	Accuracy%	Precision %	Sensitivity %	Specificity %
[29]	80.0	85.0	89.0	90.0
[30] Inception ResNet-V2	69.2	60.2	54.9	75.9
[30] Inception-V3	72.8	54.3	50.2	80.6
[33]	-	-	81.0	86.1
[34]	89,6	-	91.4	93.2
This research methodology	**87.3**	**75.2**	**99.6**	**97.8**

V. DISCUSSION

In this research, the diabetic retinopathy dataset consists of retinal images with varying resolutions and aspect ratios. The dataset has been adjusted to accommodate different CNN architectures. Additionally, background information or images unrelated to retinal diseases may impact classification accuracy, consistent with findings in prior research [5] [35]. Automated detection of diabetic retinopathy often involves preprocessing original images, including cropping, resizing, and adjusting resolution, to mitigate these issues and improve model training efficiency.

The imbalanced nature of the diabetic retinopathy dataset used to train the classification model resulted in suboptimal performance. To address this issue, categorical focal loss was employed to balance class weights instead of the standard categorical cross-entropy loss, aligning with findings from studies [36–38]. This approach demonstrated improved evaluation metrics. The dataset often suffers from class imbalance, where certain classes are overrepresented or underrepresented. This imbalance can bias the model toward predicting the majority class, making it challenging to accurately classify minority classes.

To enhance feature extraction, this research employed various image preprocessing techniques, including MSRCR, Gamma correction, CIELAB color space conversion, and CLAHE. MSRCR, based on retinex theory, simulates human visual perception by adjusting image brightness and color across multiple scales. Gamma correction controls brightness by

manipulating the gamma value, while CIELAB conversion transforms RGB images into a perceptually uniform color space. CLAHE enhances local contrast by adjusting histograms within image blocks. These techniques provide deeper insights and additional perspectives, contributing to a more comprehensive understanding of the underlying problem. Current research highlights the potential of deep learning techniques for feature extraction in medical image and signal processing.

Feature extraction relates to dimensionality reduction and is a crucial preprocessing step in deep learning, potentially leading to new discoveries. In this study, six models were used to extract features, along with an optimizer, which continuously adjusts model parameters (weights and biases) to improve accuracy. The main goal is to minimize the loss function, enhancing the model's predictive ability. The Nadam optimizer was employed, improving the measurement of the difference between predicted and actual results. The development of these techniques enhances classifier performance and aids in better decision-making for diagnosis. Evaluating large mixed input data requires significant memory and computational power. In this research, transfer learning and dropout techniques were applied to optimize model performance. Feature extraction ultimately helps save processing power and disk space while improving classification, thus enhancing the efficiency of diagnostic support systems. Therefore, developing effective algorithms for feature extraction is essential in building diagnostic support systems. A common method to eliminate irrelevant or redundant data is dimensionality reduction, with feature extraction being a popular approach.

Transfer learning was utilized by fine-tuning the weights of models trained on the APTOS-2019 dataset to adapt them to the Messidor-2 dataset. Although the results were slightly inferior, the best-performing model combination on the Messidor-2 dataset was InceptionResNet-V2, with a sensitivity of 99.4% and specificity of 97.0%. Sensitivity and specificity scores remained stable between 97% and 99%, demonstrating effective differentiation between diabetic retinopathy and normal retina. Compared to other research methods, these results were excellent, showcasing the effectiveness of transfer learning in this study.

VI. Conclusion

In recent years, the application of artificial intelligence-based diabetic retinopathy screening technologies has surged in the medical field. Automated screening methods effectively address the limitations of traditional manual diagnosis, enabling ophthalmologists to make quicker and more accurate assessments. Additionally, these technologies have played a crucial role in overcoming the challenges of inefficient screening in rural areas with limited medical resources, significantly enhancing the chances of early detection and treatment of diabetic retinopathy.

In this experiment, various image processing techniques were combined, including MSRCR, Gamma correction, CIELAB, CLAHE, and image enhancement. These techniques were integrated with six deep learning models and optimization techniques such as Nadam, transfer learning, and dropout. The models were trained and evaluated on the APTOS-2019 and Messidor-2 datasets, consisting of 3,662 and 1,744 images, respectively. These datasets exhibit class imbalance, with five severity levels: NDR, MiDR, MoDR, SDR, and PDR. The experimental results demonstrated that DenseNet121 achieved the highest performance on the APTOS-2019 dataset, with a sensitivity of 99.8% and specificity of 99.7%, outperforming previous studies.

Tables VI and VII present a comparison of the evaluation results between the best model from this research and other studies utilizing the same datasets (APTOS-2019 and Messidor-2). The data in these tables are directly cited from the best results of each study. For the APTOS-2019 dataset, the proposed method demonstrated comparable performance in terms of sensitivity and specificity, achieving values close to 100%. The model excelled across all metrics. In the case of the Messidor-2 dataset, although accuracy was not as optimal, sensitivity and specificity were more stable compared to other studies.

This study employed a fusion technique for image enhancement to improve the feature extraction efficiency of six deep learning models (ResNet50-V2, DenseNet121, Inception-V3, Xception, MobileNetV2, InceptionResNet-V2). The models were trained to classify healthy retinas and four different severities of diabetic retinopathy. Class-weighting techniques, including parameter setting and categorical focal loss, were utilized to enhance the model's accuracy in distinguishing various categories of retinal images, even when certain categories were underrepresented in the dataset.

To address the class imbalance problem and improve feature extraction performance, these models were trained to classify normal retinas and diabetic retinopathy across four different severity levels. categorical focal loss was adopted as the loss function to enhance classification accuracy for different types of retinal images, particularly those with smaller sample sizes. This loss function is specifically designed to address class imbalance issues in classification tasks, especially when the minority class has fewer samples than the majority class. By assigning more weight to samples from the minority class, categorical focal loss enables the model to better classify these underrepresented classes, which is a common challenge in real-world classification problems. This approach significantly contributes to the model's performance on datasets characterized by diabetic retinopathy. However, these methods can impact the model's ability to effectively classify classes with fewer samples. The greater the imbalance in sample proportions between classes, the more pronounced this effect becomes, particularly in improving classification performance for classes with minimal representation. The evaluation scores from this study's best results are compared with those from other research studies.

Acknowledgment

The authors would like to express their sincere gratitude to the anonymous reviewers for their useful comments and suggestions for improving the quality of this paper, and we thank National Pingtung University of Science and Technology Council of the Republic of China, Taiwan for financially supporting this research under Contract No. 111-2410-H-020-007.

Assessing the Usability of M-Health Applications: A Comparison of Usability Testing, Heuristics Evaluation and Cognitive Walkthrough Methods

Obead Alhadreti
Dept. of Computers-Engineering and Computing College, Umm Al-Qura University, Al-Qunfudah, Saudi Arabia

***Abstract*—Mobile health applications have increasingly become an important channel for providing services in the health sector. However, poor usability can be a major barrier for the rapid adoption of mobile services. The purpose of this study is to compare the relative performance of three usability evaluation methods, namely, usability testing, heuristics evaluation, and the cognitive walkthrough methods in determining the usability level of mobile health applications. The study also explores the relationship between the metrics of usability testing and the current level of mobile health applications in Saudi Arabia. An experimental approach has been used in this study, which gathered qualitative and quantitative data. The methods were used to assess two mobile health interfaces and were compared on the number, severity, and types of usability problems identified. Correlation tests were also carried out to examine areas of overlap between usability testing metrics. The heuristic evaluation found significantly greater numbers of usability problems than the other techniques. The usability testing method, however, detects problems of greater severity. There is also a significant correlation between the number of usability issues found and how long it takes to perform tasks in usability tests. Moreover, the level of usability of the Saudi applications tested is below expectation and in need of further improvement. Based on the study results, both usability testing and heuristic evaluation should be employed during the design process of mobile health applications for maximum effectiveness. Additionally, it is recommended that SUS questionnaires should not be the sole method of determining the usability level of mobile health applications.**

Keywords*—Mobile health applications; usability; usability testing; heuristics evaluation; cognitive walkthrough

I. Introduction

Digitalization has come to play a prominent role in delivering health services to individuals and communities. It not only improves patient safety and satisfaction but is instrumental in keeping large-scale health statistics up to date. Hospitals and other healthcare service providers are offering more digitalized services, which has fundamentally altered healthcare systems. Among these services are mobile health (m-health) applications, which are becoming a major avenue of healthcare provision, given that approximately six billion people (around 75% of the world's population) have regular access to mobile phones [1]. As a result, m-health is now a rapidly expanding field of research.

The term, m-health refers in general to the use of mobile devices in the provision of healthcare services [2]. The Global Observatory for e-health defines m-health as "medical and public health practice supported by mobile devices, such as mobile phones, patient monitoring devices, personal digital assistants (PDAs), and other wireless devices" [3]. M-health applications also include processes of data collection [4], service delivery [5], communication between doctors and patients [6] and support for monitoring and adherence in real time [7]. The market for m-health applications is expected to grow in coming years at a significant rate: from USD 99 billion globally in 2021 to USD 332.7 billion by 2025 [8]. The scope for the adoption of m-health applications is further increased by their diversification into such health sectors as nutrition, sports, productivity and behavioral therapy [9].

A crucial requirement for m-health applications is usability. An information system that people cannot use easily represents a threat to the safety of patients, as well as being inefficient and a contributor to staff burn-out and dissatisfaction. An easy-to-use system, on the other hand, is more efficient, enhances emergency care safety and is a real benefit to staff [10]. Usability is generally considered as "the extent to which a system, product or service can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use" [11]. It is clear from this definition that usability (real and perceived) can differ between contexts, target audiences and products, which is especially true in the m-health sector due to its unique characteristics which are as follows. First, unlike general commercial applications, which can use personalized messages to seduce customers into feeling comfortable with the system, it is difficult to establish user satisfaction with m-health applications, which have to give both positive and negative messages about users' health-related behavior. For example, appropriate advice (such as switching off the television and going for a walk instead) may not be what users wish to hear, which has the potential to affect their satisfaction with the system. Second, m-health communication needs to be tailored to individual users' knowledge levels and awareness regarding health, which can vary significantly from one user to the next [10]. Third, these factors are exacerbated when someone has a chronic illness, as this can increase anxiety and stress, which makes the assimilation of information and self-management skills more difficult [11].

The assessment of mobile applications' usability is challenging due to the small screens on which they are viewed and the resolution of their displays, limited input options, restricted processing speeds and power, and connectivity issues [12]. Several methods exist for assessing the usability of mobile applications. The most frequently employed usability evaluation

methods (UEMs) are usability testing (UT), heuristic evaluation (HE), and the cognitive walkthrough (CW) [13]. The UT method is a user-based method that is widely used to measure how easily end–users can use an interface. However, recruiting test participants and performing tests can be an expensive process. HE is a usability inspection method that involves having an expert examines an interface against a set of principles. These principles provide a template to help identify issues a user will likely encounter. One of the limitations of HE is that it tends to detect many low-severity problems. CW is also a reviewer-based method, but the emphasis is on tasks. The idea is to identify users' goals, and how they achieve them in the interface, then experts detect issues users would encounter as they learn to use the system [13]. So far, there has not been any research which compares UT, HE, and CW methods in terms of their performance in measuring m-health application usability. This study, therefore, aims to examine the effectiveness of these UEMs in the context of m-health applications used in Saudi Arabia.

The Saudi healthcare sector is undergoing a digital transformation, including an increasing dependency on m-health applications for expanding access to healthcare, health education, communicating with patients, monitoring their conditions and ensuring conformity to treatments. Various m-health applications have been promoted by the Ministry of Health in Saudi Arabia, such as Sehhaty1. These applications have several purposes, such as booking appointments, remote consultations and delivery of medicines, and they became particularly important in the course of the Covid-19 pandemic, when there was a significant increase in Saudis using m-health applications [14], although this was down to necessity, not their actual interest in using the technology. Indeed, research has shown that it was factors such as stress, fear and depression which led to the rapid adoption of m-health applications, not such reasons as usefulness, ease of use, enjoyability or self-interest [15]. It is therefore crucial to establish whether or not users of m-health applications are satisfied and whether they are continuing to make use of them after the pandemic.

The current study's findings contribute significantly to the research literature on the usability evaluation of m-health apps. This will help usability practitioners to make more informed decisions about which of the examined methods to use and in which context. The findings will also be of value to the governmental and non-government organizations providing healthcare in Saudi Arabia. The rest of this paper is structured as follows. Section II reviews related work. Later sections present the study's methodology, data analysis and its results. The final section sets out the conclusions drawn from the study.

II. Related Work

A number of studies have compared the effectiveness of the UT, HE, and CW evaluation methods across different systems. A study by Tan et al., [16] compared UT and HE and found that HE identified a larger number of problems and more severe issues than UT. However, the study discovered that UT found problems missed by HE. Another study conducted by Hasan et al., [17] indicated that HE identified 72% of problems, UT extracted only 10% and 18% of the problems were found by both techniques. A study by Doubleday et al. [18] revealed that 40% of issues detected were unique to HE, whereas 39% were extracted by the UT method. Jeffries et al, [19] stated that the HE method found approximately three times more issues than UT; but UT found more important problems.

Thankam et al. [20] contrasted the performance of HE with UT to find out which usability issues were revealed by both methods. The comparison was conducted on four dental computer-based patient record interfaces. 50% of the issues were identified by each method. The study recommended that HE can be a useful tool to assess design early in the development process. In a paper by Khajouei et al. [21], the HE and CW evaluation methods were assessed based on the number and severity of the problems extracted and the ISO and Nielsen usability attributes. The number of issues related to the "satisfaction" attribute detected by HE was significantly higher than those identified using CW. However, CW identified a greater number of problems concerning the "learnability" attribute. In addition, Maguire and Isherwood examined the results of UT and HE, and it was found that HE detected approximately five times more problems than UT, thus it could be seen as more effective.

Few studies have explored the user-friendliness level of Saudi m-health applications. AlanziI [8] found that Saudi users were reasonably satisfied. Furthermore, Arafa et al. [22] studied barriers to the use of Saudi m-health applications, along with their personalization and usability, and found that usability scores were low, whereas Shilbayeh and Ismail found an average usability score of 76.8% for the CATA mobile application overall, suggesting general satisfaction [23]. However, most of the research which has been carried out have the significant limitation of having used only subjective data (e.g. from questionnaires), which was not validated against such objective data as expert inspections or task performance in the context of usability testing. It is, therefore, important that this study sheds a light on the usability levels of the m-health applications in use in Saudi Arabia.

The study's research questions are therefore as follows.

- Is there a difference between the performance of UT, HE, and CW methods in evaluating m-health applications?
- Is there a correlation between UT metrics?
- What is the current usability level of m-health applications in the Kingdom of Saudi Arabia?

III. Methodology

A. Study Approach and Variables

This study adopted an experimental approach, using both quantitative and qualitative data collection techniques [24]. The type of evaluation method (UT, HE or CW) formed the independent variable for the study and there were three dependent variables measured: number of usability issues

[1]https://apps.apple.com/sa/app/%D8%B5%D8%AD%D8%AA%D9%8A-sehhaty/id1459266578

detected, problem severity and problem type. Data on participants' task performance and their satisfaction with the usability of the test system was also gathered in the UT sessions to explore how these outcome variables are related to other metrics.

B. Test Objects and Tasks

From a careful assessment of m-health applications used in Saudi Arabia, two were selected as test subjects. It was decided to assess two m-apps instead of one to gain more reliable results pertaining to the UEMs' effectiveness. The two applications were chosen because they had a broad user base, which simplified the participant recruitment process, whilst also making the sample more likely to be representative of actual users. The two applications also had many similarities, which facilitated the formulation of tasks which resembled each other in terms of focus and difficulty. One test subject, App A, was developed by the ministry of health; the other, App B, comes from the private sector. They both have similar features, allowing the booking of GP appointments, the viewing of laboratory reports and health condition monitoring. The names of the applications are anonymized for confidentiality.

An independent usability expert, with extensive health system knowledge, performed a preliminary examination of both applications (and was not involved in later stages of the study). This examination was mainly to ensure that the two test subjects were of sufficient complexity and had sufficient scope for user interaction and the emergence of problems, although the expert did not make any predictions concerning potential problems, nor did she report any.

An analysis of the context of use was then carried out for each application to identify the characteristics of a representative user and select appropriate tasks [25]. Next, each application was examined to reveal typical use cases in order to set the tasks. 15 tasks were then formulated for each application, covering varying degrees of difficulty, as a long list from which the actual tasks set in this study were subsequently selected by the aforementioned independent expert. Equivalence of difficulty between the tasks set for each application was ensured by matching tasks according to the level and depth of their solution within each app. Five tasks were set for each application and their design was done carefully to avoid any bias related to task-related cues or language. These were then piloted by three representative users prior to the main test sessions. Two task examples are given below.

You wish to book an appointment with your general practitioner. What would you do? (App A)

You wish to seek a remote consultation from your doctor. What would you do? (App B)

C. Participants

For the UT evaluation, statistical validity was ensured by recruiting 20 participants [26]. For the HE and CW evaluations, which are done by experts, between three and five evaluators are generally considered sufficient [27], thus four usability experts were recruited for each of the HE and CW tests. 28 participants were therefore included in this study in total. They were recruited by means of convenience and snowball sampling [24].

All of the participants were native Arabic speakers and, for the UT evaluation, averaged 22 years of age (ranging from 18 to 26). All of them had more than five year's daily use of mobile applications and almost 95% had used an m-health application previously, but not the ones under evaluation.

For the HE and CW evaluations, the two evaluator groups were matched with respect to general HCI knowledge and their expertise in relation to user interface design and usability of m-health applications specifically. Of the evaluators, two in each UEM test (four in total) had a PhD related to HCI. The other four had an HCL-related MSc. They all had extensive experience of conducting evaluations by HE and CW, and all had at least seven years' experience of usability evaluation. All of the participants affirmed their informed consent in writing before the study commenced and none were offered, nor received any incentive for their involvement.

D. Experimental Procedure

Due to the risk of a participant being influenced in a second test by their experience in the first [24], a two-week break was inserted between the evaluation sessions. In addition, half of each participant group used App A in the first session and App B in the second, with the other half doing the reverse. The same type of mobile phone was used by all participants (iPhone 15), chosen because of it being the most common type in Saudi Arabia [28].

1) UT evaluation: The setting for the usability testing of both applications in this study was a laboratory. The participants were asked to make themselves familiar with the phone used and then to perform an initial pilot task. After that they were asked to read a sheet of task instructions before setting out to complete the five tasks, which were presented in a different order to each participant to control for any effect on results of task order [26].

The performance measures for the UT condition were 1) the rate of completion of each task, 2) the time each task took to complete and 3) navigational behaviour (such as how many clicks were made and which screens were browsed). After completing all five tasks, the participants were invited to watch a muted recording of their performance and give a retrospective commentary. Participants then completed a System Usability Scale (SUS) [18], which is designed to assess user satisfaction with application usability. Subsequently, all of the test data were reviewed to extract evidence of usability issues.

2) HE evaluation: This study followed the HE procedure as recommended in the work of Nielsen and Molich [29]. 1) a list of ten heuristic principles was distributed to the evaluators as a guideline by which each evaluator then evaluated the user interface, independently. The evaluators all presented a list of the problems they had identified with the system's usability, each with a description, including its frequency, persistence and likely impact on the user, and illustrative screenshots. They were, however, instructed not to share their thought with one another during the session, as one evaluator might miss several problems and each evaluators may identify a broad spectrum of unique problems [24]. The results tend to be more

comprehensive, therefore, when the findings of several evaluators are combined. However, once the independent evaluations were over, the evaluators were asked to collaborate on producing one list of usability issues. That done, each evaluator estimated the severity of every problem detected and classified it by type. They all met finally to determine average severity of the problems identified and the type classifications [29].

3) CW evaluation: In the CW condition, the applications were assessed following Blackmon et al.'s methodology [30]. The evaluators used the five tasks from the UT evaluation and answered the following questions as they did so.

- Will users attempt to achieve the correct result?
- Will users see that a necessary action is available to them?
- Will users connect the desired result with the action necessary to achieve it?
- Are users given confirmation that they have made progress towards the desired result once a necessary action has been carried out?

The overall user goals and the requisite subgoals for each task were determined and the necessary actions were identified in the way illustrated by Blackmon et al. [30]. The evaluators then examined each task systematically, noting 1) the goals users are expected to seek, 2) their subgoals and 3) actions, 4) the responses from the application and 5) potential problems with user interaction. Each evaluator produced a list of problems independently and recorded information about the issue in the same way as for the HE evaluation. Following the completion of each task, the list of usability issues identified was reviewed by the evaluator, adding or correcting items if necessary. The five task-specific lists from each evaluator were gathered and compared communally and a consolidated list of issues was established. As with the HE evaluation, the evaluators determined the types and severity of problems independently, before meeting to agree the average severity of each problem and classify all those listed [30].

E. Analysis of Usability Problems

Usability problems found in the UT evaluation were extracted in a structured manner, as employed in [31] to mitigate biases (i.e. evaluator effect) and enhance data validity and reliability. An inter-coder check on reliability was also conducted, by an independent evaluator, on the UT usability problem analysis. This evaluator coded the usability problems experienced by the first participant in the experiment and discussed them with the researcher, before performing an independent analysis on two videos of the testing, selected at random. The agreement between the problems identified by the test subject and those revealed in the videos was a respectable 78% [32].

Problem severity in all evaluation conditions was classified according to the following scale [24]:

1) A catastrophic problem, which prevents users reaching their goal and has to be remedied.

2) A major problem, which leads to user frustration and difficulty in continuing, which should be remedied.

3) A minor problem, which leads to user frustration and difficulty in continuing, which could be remedied.

4) A cosmetic problem, which leads to minor issues for users and which can be remedied easily.

The problems were also classified in four types, navigation, layout, content and functionality (as in Table I), derived from prior research [31].

TABLE I. PROBLEM TYPE CODING SCHEME

	Type	Problem Definition
1	**Navigation**	Users have difficulty moving between pages or finding the right links for specific functions or information.
2	**Layout**	Users have difficulties in respect of the interface, such as display and visibility problems, inconsistent design and awkward design of structures and forms.
3	**Content**	Users either find unnecessary information or expect information which is not there, or they do not understand the information due to its terminology or style.
4	**Functionality**	Users have difficulties because some functions are missing or otherwise problematic.

IV. RESULTS

A. App A

1) Usability problems identified: A total of *66* problems were identified with App A in the test sessions, 56 with the HE method, 46 with CW and 44 with UT. HE therefore identified a wider range of problems than either UT or CW, significantly more so according to a Kruskal Wallis H test ($p < 0.0001$). The HE evaluators each found an average of 25 problems, while the CW evaluators found an average of 18 problems. In the UT evaluation, 11 individual issues arose in each session. However, HE found 14 unique issues which were not found by the CW and UT approaches. UT identified six issues not found in the other evaluations and CW found four. All of the methods were able to detect 38 of the total problems. This is illustrated in Fig. 1.

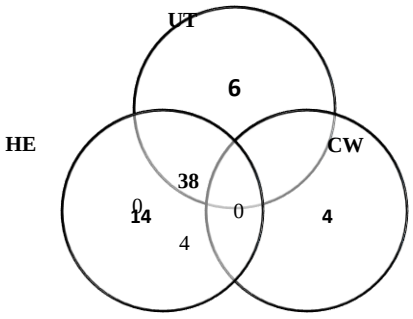

Fig. 1. Venn diagram of the numbers of problems identified by the three evaluation methods (App A).

2) Problem severity: 26 (59%) of the final problems identified in the UT evaluation were of high impact, i.e. either

major or catastrophic). The remaining 41% had low impact, i.e. either minor or cosmetic. However, HE and CW both found 20 (36% and 43% respectively) problems of high impact. In fact, all the problems which were only found by UT method were of high impact, whereas those only found by HE and CW were of low impact (Table II).

3) Problem types: The 66 final problems found on App A were classified as 22 navigational, 19 layout issues, 16 content-related and 9 functional. HE found more layout and content problems, as well as identifying more problems of those types uniquely (Table III).

TABLE II. ISSUE SEVERITY

	UT		HE		CW	
	Unique	**Common**	**Unique**	**Common**	**Unique**	**Common**
Cosmetic	0	4	5	8	2	8
Minor	0	14	9	14	2	14
Major	4	19	0	19	0	19
Catastrophic	2	1	0	1	0	1
Total	6	38	14	42	4	42

TABLE III. PROBLEM TYPES

	UT		HE		CW	
	Unique	**Common**	**Unique**	**Common**	**Unique**	**Common**
Navigation	4	13	3	13	2	13
Layout	1	9	6	11	1	11
Content	1	7	5	9	1	9
Functionality	0	9	0	9	0	9
Total	6	38	14	42	4	42

4) User task performance and satisfaction: Table IV presents the descriptive statistics for task performance and user satisfaction in the UT evaluation. The rate of successful completion indicates that participants encountered difficulties in executing the tasks, as only half were completed, on average. It is clear that the fourth and fifth tasks were found most difficult, being completed only 10% and 8% of the time respectively. The first and second tasks were easier, being completed by 82.1% and 77.4% respectively. This explains why the UT evaluation found more catastrophic usability problems. However, the UT participants evaluated the application's usability highly, giving it an average score of 85, which exceeds the global average SUS score of 68 by a large margin.

TABLE IV. USER TASK PERFORMANCE AND SATISFACTION STATISTICS

	UT	
	Mean	**SD**
Tasks completed	2.50	1.00
Time to complete tasks (m)	33.04	7.35
Number of clicks	170.00	26.63
Number of screens browsed	15.15	4.34
SUS	85.35	10.10

B. App B

1) Usability problems identified: A total of 57 problems were found across the three evaluations for App B. 44 were found by HE, 36 by CW and 32 by UT. Once again, HE found significantly more issues than the other two techniques, which was confirmed by a Kruskal Wallis H test ($p < 0.0001$). The HE evaluators each found 21 problems on average, while those using CW found 16 and each UT session detected nine. The UT and CW methods both failed to spot 15 problems detected by HE, but found five and six, respectively, not found in the other tests. 24 problems were identified by all three evaluation methods (see Fig. 2).

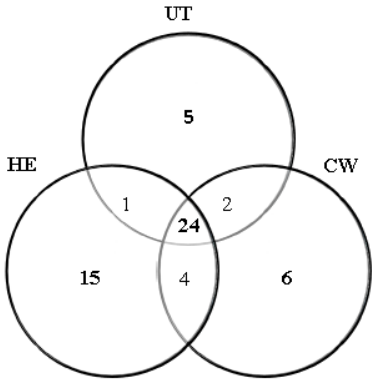

Fig. 2. Venn diagram of the numbers of problems identified by the three evaluation methods (App B).

2) Problem severity: 20 problems identified by the UT method (62%) were of high impact, while 14 (31%) and 15 (41%) of those identified by HE and CW, respectively, were of high impact. The UT method therefore performed better at identifying more severe problems and all of the problems found uniquely by UT were of high impact, whereas all of those found uniquely by HE were of low impact, as shown in Table V.

TABLE V. PROBLEM SEVERITY

	UT		HE		CW	
	Unique	**Common**	**Unique**	**Common**	**Unique**	**Common**
Cosmetic	0	3	3	3	3	2
Minor	0	9	12	12	3	13
Major	4	14	0	13	0	14
Catastrophic	1	1	0	1	0	1
Total	5	27	15	29	6	30

TABLE VI. PROBLEM TYPES

	UT		HE		CW	
	Unique	**Overlap Problems**	**Unique**	**Overlap Problems**	**Unique**	**Overlap Problems**
Navigation	2	8	3	10	0	10
Layout	3	4	6	6	3	5
Content	0	2	5	2	3	2
Functionality	0	13	1	11	0	13
Total	5	27	15	29	6	30

3) Problem types: App B's 57 final problems were classified as 15 navigational, 18 layout-related, 10 content-related and 14 functional (see Table VI). As with App A, HE found more layout and content problems, as well as identifying more problems of all types uniquely.

4) User task performance and satisfaction: Table VII presents the descriptive statistics for task performance and user satisfaction in the UT evaluation. The rate of successful completion indicates that participants encountered difficulties in executing the tasks, as only 3.2 were completed, on average. As with App A, the fourth and fifth tasks were most difficult, having completion rates of 14% and 11% respectively, while the first and second tasks were easier. Participants rated the application with a SUS of 77, which is also above the global average SUS score.

C. Correlation Analysis

Spearman's correlation coefficient was used across the two application case studies to examine any correlations that exist between the measures employed in the study [33]. As can be seen from Table VIII, one correlation that is statistically significant was found, between the time spent by participants on tasks and the number of problems found.

TABLE VII. USER TASK PERFORMANCE AND SATISFACTION STATISTICS

	UT	
	Mean	**SD**
Tasks completed	3.20	1.10
Time to complete tasks (m)	35.16	11.10
Number of clicks	173.30	28.45
Number of screens browsed	17.35	3.88
SUS	77.65	11.74

D. The Applications' Usability Levels

As described above, the usability evaluations revealed 123 problems with the two applications under test. This is a significant number of issues, which corresponds to a low level of usability. 46 of these problems (nearly 38%) were severe issues, having a significant impact on task performance. The majority of problems were navigational and related to the layout of the interface (both 30%), which indicates that users are likely to find it difficult to navigate within the applications. This finding is also supported by the rates of successful task completion. The results therefore clearly show that there needs to an improvement of both of these applications' usability.

TABLE VIII. CORRELATIONS BETWEEN MEASURES IN THE UT METHOD

	Tasks completed	**Time to complete tasks**	**No. of clicks**	**No. of screens browsed**	**SUS**	**No. of problems**
Tasks completed	1	-0.02	0.21	0.1	0.01	0.12
Time to complete tasks	-0.02	1	-0.18	-0.17	-0.25	0.39*
No. of clicks	0.21	-0.18	1	0.08	0	-0.02
No. of screens browsed	0.1	-0.17	0.08	1	0.1	-0.16
SUS	0.01	-0.25	0	0.1	1	0.05
No. of problems	0.12	0.39*	-0.02	-0.16	0.05	1

* The significance level is 0.05

V. DISCUSSION

No prior research has compared the UEMs considered in this study in relation to m-health applications in Saudi Arabia, so it is no possible to draw any comparisons with comparable studies.

A. Is there a Difference between the Performance of UT, HE, and CW Methods in Evaluating M-Health Applications?

In general, the findings of this study are common to both m-health applications studied. HE found the most problems overall and detected more problems than either UT or CW techniques, but UT was able to detect more severe problems. Similar findings emerged from studies of other systems [19,21,34], where HE was found to detect more minor issues than did UT. This is also in line with Farzandipour et al. [35], who found that HE was better at detecting usability issues than the CW technique.

HE's identification of greater numbers of problems can be attributed to the fact that the HE evaluator were able to explore the applications, whereas the CW and UT participants were given specific tasks to do, so that there was a limit to the kind and number of usability problems that they would encounter. It is therefore recommended that the design of m-health applications should utilise both HE and UT methods in order to derive the maximum benefits.

B. Is there a Correlation between UT Metrics?

A strong correlation was found between the time taken to complete tasks and the number of usability problems encountered on these two m-health applications. This result indicates that time taken is a better indicator of the presence of usability problems than other measures.

It was also evident that the SUS does not serve well as a usability metric for m-health applications on its own. This is because it does not predict the presence of usability problems as well as task completion time. Usability practitioners should therefore at least report task completion times in addition to SUS in usability reports. This is in agreement with the findings of recent research into SUS. For instance, Broekhuis et al. [36] also found SUS to be inadequate by itself for e-health system usability evaluations.

SUS's poor predictive power may be due to a number of factors. 1) it is subjective, which means that usability is but one factor influencing the perception of the assessor, along with, for instance, usefulness and enjoyability. 2) SUS is generalised and does not reflect participants' actual performance; greater difficulty and more problems were encountered with App A, yet it received a higher average SUS. 3) SUS does not recognise such inclusivity factors as accessibility (e.g. for people with learning difficulties or visual disabilities) and information overload, even though they affect usability. Future research should include a comprehensive assessment of such factors and their impacts on usability, which is especially important in the context of health-related applications and systems.

C. What is the Current Usability Level of M-Health Applications in the Kingdom of Saudi Arabia?

This study found that the m-health applications targeted do not meet acceptable usability standards and fail to conform to appropriate design principles. According to the UEMs applied, these two applications are very hard to use, due to the large number of usability problems which arise, which was especially clear from the inspection by an independent expert and the task performance data in the UT sessions, even though the applications received good SUS ratings, which, is not a reliable indicator. These findings contradict previous research into user satisfaction with m-health applications in Saudi Arabia [8, 23], which found general satisfaction, perhaps because those studies relied on questionnaire-based, subjective data.

D. Recommendations

On the basis of the results of this study, a number of recommendations is presented below.

1) The varying effects of different UEMs should be considered seriously when evaluating the usability of m-health apps, as the findings suggest that results may differ depending on the method used. Therefore, practitioners should consider the pros and cons of each approach when deciding on an evaluation method.

2) Consider using the UT method when interested in identifying high severity usability problems.

3) Consider using the HE method when seeking to find higher numbers of low severity usability problems—particularly those relating to content and layout.

4) Both UT and HE should be employed during the design process of m- health applications for maximum effectiveness.

5) Usability practitioners should be aware of the fact that participants' satisfaction with the perceived usability of m-health application does not correlate with the number of usability problems that found on the interface. This implies that SUS questionnaires should not be used as a sole metric for determining the usability of the m-health interfaces.

6) There is a need to an improvement of m-health applications' usability in Saudi Arabia. In particular, the navigation and layout aspects of the interface should be given more attention.

7) Web developers are key to ensuring the usability of m-health apps. If there is to be a positive effect, it is important for developers to enhance their awareness of usability standards.

E. Limitations and Future Work

There are, inevitably, some limitations to the present study. First, the UT sessions recorded various task performance parameters, but did not measure behavioural factors, such as attention levels, which other studies have estimated using eye tracking technology [37]. Second, the study was limited to two Saudi m-health applications, which, whilst in common use, may

not reflect the overall usability of m-health applications in Saudi Arabia. Therefore, more research with a broader spectrum of m-health applications across different healthcare domains would be necessary to further assess the generalizability of the results.

VI. Conclusion

This study compared three usability evaluation methods, namely, usability testing, heuristic evaluation, and cognitive walkthrough in terms of their effectiveness in assessing m-health application usability, and to assess the usability of such applications in the Saudi Arabian context. It also explored the relationships between usability metrics. The study finds that heuristic evaluation is able to identify a larger number of usability issues, which is because it takes a broad overview of system design, with predefined principles, rather than focusing on the performance of specific tasks. However, it does appear to identify more minor problems than the usability testing method, which is better at detecting more severe issues. The study also identified a significant relationship between the number of usability problems found and how long participants spend carrying out tasks using m-health applications, which suggests that the existence of usability problems. The findings also show that the two applications tested have low usability levels and need to be improved.

Automated Hydroponic Growth Simulation for Lettuce Using ARIMA and Prophet Models During Rainy Season in Indonesia

Lendy Rahmadi[1]*, Hadiyanto[2], Ridwan Sanjaya[3]
Doctoral Program of Information System, Diponegoro University, Semarang 50241, Indonesia[1, 2]
Department of Information System, Lembah Dempo University, Pagar Alam 31514, South Sumatera, Indonesia[1]
Department of Information System, Soegijapranata Catholic University, Semarang 50234, Indonesia[3]

***Abstract*—Hydroponic farming particularly lettuce cultivation, is gaining popularity in Indonesia due to its economical use of water and space, as well as its short growing season. This study focuses on developing of an Automated Hydroponic Growth Simulation for Lettuce Using ARIMA and Prophet Models during the Rainy Season in Indonesia. We developed a simulation model for lettuce development in the Nutrient Film Technique (NFT) hydroponic system using data collected over four harvest periods during the rainy season in early 2024. Two machine learning models, ARIMA and Prophet, are tested to see which is more effective at forecasting lettuce growth. The Prophet model has the greatest results, with a Mean Absolute Error (MAE) of 1.475 and a Root Mean Square Error (RMSE) of 1.808. Based on this, the Prophet model is utilized to create a web application using Streamlit for real-time growth predictions. Future studies should include more data, particularly from the dry season, to increase model flexibility, as well as investigate the use of other crops and machine learning methods, including hybrid models, to improve forecasts.**

***Keywords*—ARIMA; automated; growth; hydroponic; prophet; simulation**

I. Introduction

Hydroponics is a method of cultivating plants without soil, instead using water and nutrient solutions as the growing medium. This technology has become increasingly popular in Indonesia due to its efficiency in water and space usage, as well as its ability to produce higher-quality crops compared to conventional methods [1]. The trend of using hydroponics in Indonesia has surged in response to growing urban populations and the need for sustainable farming in controlled environments [2]. In Indonesia, hydroponic farming, especially for crops like lettuce, has become a widely adopted technique due to its ability to optimize space and produce yields faster than traditional farming methods. However, hydroponic plant growth is highly dependent on multiple variables. Internal variables such as nutrient concentrations, water temperature, and pH levels directly influence the plant's ability to absorb nutrients. External variables, such as ambient temperature, humidity, and light intensity, further determine the overall growth environment. Managing the interaction between these internal and external factors is complex, as even slight changes in one variable can drastically affect plant health and growth rate [2], [3]. Farmers currently face the challenge of not being able to simulate or predict plant growth. They must wait through the entire growth cycle to observe results, without any predictive system in place. This reliance on post-harvest data leaves room for inefficiencies, and farmers are unable to make informed interventions during the growth phase [4]. As a result, the need for a simulation model that allows real-time prediction and optimization of hydroponic plant growth is critical. Such a system would help farmers simulate future growth patterns, enabling them to make proactive adjustments to environmental variables and optimize the hydroponic system accordingly.

Hydroponics relies heavily on various environmental factors such as temperature, humidity, pH levels, and nutrient concentrations in the water, all of which play crucial roles in determining the growth rate and yield of the crops [5]. To maximize productivity, this study uses the Nutrient Film Technique (NFT) system, where plant roots are continuously submerged in a circulating nutrient solution, ensuring direct access to both nutrients and oxygen [6].

In this study, lettuce (Lactuca sativa) was chosen as the primary subject because it is widely cultivated hydroponically and has a relatively short growth cycle [1]. Data on plant growth was collected daily over four crop cycles, measuring key variables such as temperature, humidity, pH, and nutrient concentrations in the hydroponic solution [7]. Given the complexity of managing these variables, farmers often cannot accurately simulate growth patterns, leading to reliance on reactive measures rather than predictive optimization. This research aims to address that challenge by proposing an automated simulation model, particularly critical during dynamic weather conditions like Indonesia's rainy season. Data collection was carried out using calibrated instruments that were regularly checked for accuracy to ensure precise measurements [8]. This approach provides detailed data on the dynamic interactions of hydroponic variables that influence lettuce growth, offering key insights into how these factors can be optimized to enhance overall yields [9], [10].

Currently, there is no existing model that automatically simulates plant growth in the context of hydroponics, especially during the rainy season. Previous studies, such as those by Sambo et al. (2019) and Ullah et al. (2019), explored the use of IoT to monitor hydroponic variables in real time. However, these studies still rely on manual control without integrating automated plant growth simulations based on actual data. Similarly, Schwartz et al. (2019) addressed automation in

hydroponics, but the model they proposed only accounted for static environmental conditions, not considering seasonal variables like rainfall.

Other studies have utilized predictive models such as ARIMA and Prophet, as seen in the work of Rajendiran & Rethnaraj (2024) and López Mora et al. (2024), which predominantly focus on industrial sectors or weather forecasting, rather than hydroponic farming. The application of these models to predict plant growth in hydroponic environments, especially during the rainy season, remains largely unexplored. Additionally, while there are studies that use ARIMA and Prophet to predict temperature or weather patterns, no research to date has directly compared the performance of these models in the context of lettuce hydroponics in Indonesia.

The research gap is further highlighted by the absence of models capable of integrating automated simulations into a practical web-based application that allows real-time interaction for hydroponic farmers. Such an application would allow farmers to take preemptive measures by simulating growth conditions and understanding the influence of dynamic weather patterns, especially during unpredictable rainy seasons in Indonesia [1], [5]. There is a significant opportunity to develop a web-based solution that facilitates automated plant growth simulations under dynamic seasonal conditions, such as Indonesia's rainy season [1], [2], [5]

This study aims to develop an automated hydroponic simulation model using regression-based ARIMA and Prophet models, focusing on lettuce growth during Indonesia's rainy season. The data used is based on daily observations from January to May 2024. The model is designed to predict environmental variables such as temperature, humidity, and pH to optimize plant growth automatically. Additionally, this study compares the performance of the two predictive models by evaluating their results using the Mean Absolute Error (MAE) and Root Mean Square Error (RMSE) metrics. The findings indicate that the Prophet model outperforms ARIMA in predicting seasonal conditions, particularly during the unstable weather of the rainy season. Finally, the superior Prophet model was implemented into an interactive web application, enabling hydroponic farmers to simulate plant growth automation in real-time. This application aims to improve efficiency and optimize hydroponic production in tropical environments with dynamic weather conditions.

This research introduces a novel approach by developing an automated hydroponic growth simulation model using ARIMA and Prophet, leveraging actual data from Indonesia's rainy season—an area that has rarely been explored in the context of hydroponic farming. This approach allows for more accurate predictions of lettuce growth under dynamic tropical weather conditions. The main contribution of this study is the implementation of the superior Prophet model into an interactive web application, which enables hydroponic farmers to perform real-time automated plant growth simulations, thereby enhancing production efficiency during the rainy season. The research addresses the gap in the literature concerning the lack of automated hydroponic simulation models during the rainy season while offering a practical technology-based solution for hydroponic farmers.

II. Materials and Methods

A. Hydroponics

Hydroponics is a method of cultivating plants without soil, where nutrient-enriched water serves as the primary medium to meet the plants' nutritional needs. Hydroponics involves the use of water as a medium for the cultivation of crops [11]. This method is becoming increasingly popular in Indonesia due to its efficiency in using water and land, as well as its ability to produce higher-quality crops compared to conventional farming methods [1]. One of the most commonly used techniques in hydroponics is the Nutrient Film Technique (NFT), where a thin film of nutrient solution flows around the plant roots, providing direct access to oxygen and nutrients [2].

Key variables in a hydroponic system include temperature, humidity, pH, and nutrient concentration in the solution. The ideal temperature range for plant growth is between 18°C and 25°C, while the optimal pH level is between 5.5 and 6.5. Nutrient concentration is measured by Electrical Conductivity (EC), with the ideal range for lettuce being between 1.2 and 1.8 mS/cm. Additionally, the ideal humidity for hydroponic plants is between 50% and 70% [6]. If these variables are not properly controlled, plants can experience stress, negatively affecting crop yields [5]. Table I summarizes the ideal values for key variables in growing lettuce in a hydroponic system.

TABLE I. Ideal Variables for Growth Phase Lettuce in Hydroponic Systems [8]

Variable	Ideal Range
Temperature	18°C - 25°C
pH	6.0 - 7.0
Humidity	50% - 75%
EC (mS/cm)	1.2 - 1.8
Nutrients (ppm)	800 - 1000 ppm

Modern hydroponic systems often use automated sensors to monitor these variables in real-time, allowing for immediate adjustments if there are drastic changes in environmental conditions, such as during the rainy season. These sensors can detect temperature, pH, humidity, and nutrient levels, sending real-time data to a server for analysis and automatic adjustments [8]. Automated simulations based on seasonal environmental data are essential for maintaining the stability and efficiency of plant growth, especially during unpredictable weather conditions [2].

B. Machine Learning in Hydroponic Agriculture

Machine learning, a branch of artificial intelligence, enables computers to learn from data, recognize patterns, and make decisions or predictions without being explicitly programmed. In various fields, including agriculture, machine learning has become a powerful tool for optimizing processes and improving outcomes by utilizing predictive algorithms. In the agricultural sector, machine learning is widely applied to predict crop yields, manage resources, and monitor environmental conditions

affecting plant growth. The use of machine learning in hydroponic systems helps farmers make faster and more accurate decisions based on real-time data collected from sensors in the field [12].

One common approach in machine learning is supervised learning, where models are trained using labeled data to predict specific outcomes or decisions. In hydroponics, supervised learning is often used to predict variables that influence plant growth, such as temperature, humidity, pH levels, and nutrient concentrations. Algorithms frequently employed in this context include Random Forest, Decision Trees, Support Vector Machines (SVM), and Neural Networks. These algorithms can help farmers manage resources efficiently and increase crop productivity [13]. For example, Random Forest is particularly useful for predicting the non-linear relationships between environmental variables that affect crop yields in hydroponic systems [14].

Machine learning applications in agriculture, particularly hydroponics, also involve models like Long Short-Term Memory (LSTM) and ARIMA, which are designed to handle time-series data. LSTM, a type of neural network, is used to process sequential data and is well-suited for predicting time-related variables such as temperature or humidity in hydroponic systems [15]. On the other hand, ARIMA is used to analyze seasonal data and make long-term predictions based on historical trends. Both models are instrumental in optimizing hydroponic systems by maintaining ideal conditions for plant growth [16].

In IoT (Internet of Things)-based hydroponic systems, sensors collect real-time data that is then processed by machine learning algorithms. This technology allows for automated simulations that adjust key plant growth parameters, such as nutrient supply and temperature control. These models provide predictive recommendations to farmers, enabling them to manage hydroponic systems efficiently without the need for continuous manual intervention [17]. Overall, the integration of machine learning has revolutionized hydroponic management, from monitoring environmental variables to automating production processes [12].

Moreover, machine learning enhances the accuracy of yield predictions by analyzing environmental variables that influence plant growth. For example, regression models can predict plant growth behavior in hydroponic systems based on historical data, allowing farmers to make more informed decisions regarding crop management. With the increasing adoption of machine learning technology in agriculture, these predictive models hold significant potential for improving efficiency and productivity in modern farming environments [12], [18].

C. ARIMA Model

The Autoregressive Integrated Moving Average (ARIMA) model is a widely used statistical method for analyzing and predicting time-series data. It is particularly popular for its ability to process data with seasonal patterns, trends, and stochastic components, which often occur in datasets related to price forecasting, weather, and, in this context, agriculture and hydroponics. ARIMA is highly effective at handling non-stationary data, where the data distribution changes over time—a pattern frequently seen in environmental variables such as temperature, humidity, and nutrient levels in hydroponic systems [19].

The ARIMA model consists of three main components: Autoregressive (AR), Integrated (I), and Moving Average (MA). The AR component predicts future values based on the past values of the variable. The I (Integrated) component is used to transform non-stationary data into stationary data by calculating the differences between consecutive data points. The MA (Moving Average) component predicts future values based on the errors (residuals) of previous predictions (Pindipo et al., 2023). The ARIMA model is commonly written as ARIMA(p, d, q), where p refers to the order of the autoregressive component, d is the degree of differencing to make the data stationary, and q is the order of the moving average component [20].

The general formula for ARIMA can be expressed as follows:

$$Y_t = c + \sum_{i=1}^{p} \phi_i Y_{t-i} + \sum_{j=1}^{q} \theta_j \epsilon_{t-j} + \epsilon_t \quad (1)$$

In this equation, Y_t represents the actual value at time *t*, c is a constant, ϕ_i are the AR coefficients, θ_j are the MA coefficients, and ϵ_t is the residual error at time *t*. The ARIMA model focuses on two key aspects of time-series data: trends and residual errors. In this context, the observed trends in past data are used to predict future values, while the influence of random fluctuations is minimized [21].

The ARIMA process begins by examining whether the data is stationary. If it is not, the model applies differencing to stabilize the data by calculating the differences between consecutive values until the data becomes stationary. Once the data is stationary, the autoregressive (AR) component predicts future values based on past data, while the moving average (MA) component accounts for prediction errors from the AR model [22]. This approach allows ARIMA to handle time-series data with seasonal patterns and complex trends, making it well-suited for predicting environmental variables such as temperature, humidity, and nutrient levels in hydroponic systems [20].

One of the key strengths of the ARIMA model is its ability to handle non-stationary data, which is often a challenge in time-series analysis. However, ARIMA also has limitations, such as its reduced flexibility in managing highly complex or non-linear data, where more advanced models like Long Short-Term Memory (LSTM) networks or Neural Networks tend to perform better. Therefore, in some studies, ARIMA is combined with other models to enhance prediction accuracy [19], [23].

In agriculture and hydroponic systems, ARIMA has been widely applied to predict environmental variables that influence plant growth. For example, Menculini et al. (2021) compared the performance of ARIMA with deep learning models in forecasting food prices, finding that while ARIMA is reliable for short-term predictions, deep learning models are better suited to handling more complex time-series data. In hydroponic systems, ARIMA has been used to predict humidity and temperature levels, which are crucial for maintaining a

stable growing environment. The combination of ARIMA with real-time sensor data allows hydroponic farmers to make faster and more accurate decisions in managing environmental conditions [24].

Additionally, ARIMA is frequently used to forecast temperature and weather patterns, which are key factors in agriculture and hydroponics. For instance, Elseidi et al. (2024) applied ARIMA to predict high-frequency temperature data and combined it with the Prophet model to improve accuracy. Their findings showed that the hybrid ARIMA-Prophet model provided more accurate forecasts than ARIMA alone, particularly in cases where the data exhibited strong seasonal patterns or trends [20].

In another study, Pindiga et al. (2023) compared ARIMA with the Facebook Prophet model in predicting stock indices, which also exhibit seasonal patterns and trends similar to agricultural data. The results indicated that Prophet tends to outperform ARIMA when handling complex seasonal data, but ARIMA remains a strong choice for short-term predictions or simpler datasets [25].

ARIMA's applications in agriculture are not limited to environmental variable predictions. The model has also been used to forecast crop yields based on historical growth data and weather conditions. Kasthuri et al. (2021) used ARIMA in combination with Neural Networks to predict food production yields, offering more accurate crop yield forecasts in scenarios where environmental variables fluctuate significantly. This hybrid approach is becoming increasingly popular in time-series prediction, especially in the agricultural sector, which depends heavily on seasonal data and changing weather conditions [26].

Overall, ARIMA is a powerful and versatile model for time-series data analysis and forecasting. With its ability to process non-stationary data and handle trends and seasonal patterns, ARIMA is well-suited for use in hydroponic farming. However, for more complex or non-linear datasets, hybrid models or deep learning techniques may provide better results. Nonetheless, ARIMA remains one of the most widely used models for time-series forecasting due to its simplicity and reliability in processing relatively straightforward data [19], [21].

D. Prophet Model

The Prophet model is a time-series forecasting tool developed by Facebook (now Meta) designed to handle data with seasonal patterns, trends, and outliers. Prophet is often used for predicting data that exhibits instability in trends, such as sudden changes or irregular seasonal patterns. One of its key strengths is its ability to handle gaps (missing data) and outliers effectively, while still providing accurate predictions even in rapidly changing conditions [22].

Unlike traditional time-series models like ARIMA, Prophet uses an additive approach, where the trend, seasonal, and outlier components are treated separately and then combined to produce the final forecast. The model assumes that time-series data can be broken down into three main components: trend $g(t)$, seasonality $s(t)$, and holiday or event effects $h(t)$, with an additional residual or noise component ϵt. Mathematically, the Prophet model can be described by the following equation [27]:

$$y(t) = g(t) + s(t) + h(t) + \epsilon t \quad (2)$$

Where:

- $y(t)$ is the predicted value at time ttt,
- $g(t)$ is the trend component,
- $s(t)$ is the seasonal component,
- $h(t)$ represents holidays or special events,
- and ϵt is the noise component [28].

Prophet uses piecewise linear regression or logistic growth to capture trends in the data. One of its advantages is the ability to automatically adjust the number of change points in the trend, allowing the model to account for sudden shifts in direction. The seasonal component is defined by a set period, such as yearly, weekly, or monthly, enabling Prophet to capture recurring seasonal patterns more flexibly. The holiday or event component allows for the inclusion of external factors like holidays or recurring seasonal events, which can influence the data [29].

Prophet is highly intuitive to use because it automatically detects and handles missing data within the time-series. The model can also adjust the prediction intervals by giving more confidence to the trend and seasonal components, compared to more traditional time-series models [30]. Additionally, Prophet allows users to customize the prediction intervals, providing flexibility in terms of accuracy and margin of error based on the user's needs [31].

One common application of Prophet is in stock price forecasting and economic data predictions, which require accurate forecasts that can handle fluctuating seasonal trends and trends that are often unstable. For example, Jin et al. (2022) used Prophet to predict Google stock prices, while Angelo & Fadhilrahman (2023) compared the performance of Prophet and ARIMA in forecasting Bitcoin prices. Their findings indicated that Prophet excels in capturing complex seasonal trends and handling data with significant fluctuations [22], [32].

Prophet is also widely used in the energy and weather sectors. For instance, Elseddi et al. (2024) combined Prophet with ARIMA to forecast temperature data, achieving better accuracy than using ARIMA alone. This hybrid approach allows for more comprehensive forecasting by capturing different characteristics of the time-series data [20].

Overall, Prophet is a powerful and flexible model for forecasting complex time-series data, particularly when the data has irregular seasonal patterns. With its additive approach and its flexibility in handling outliers, Prophet offers significant advantages across various sectors, including economics, agriculture, energy, and weather forecasting. Its wide applications range from predicting food prices and crop yields to forecasting energy demand and weather patterns [24].

E. Evaluation Matrix

In evaluating the performance of predictive models, two of the most commonly used metrics are the Mean Absolute Error

(MAE) and the Root Mean Square Error (RMSE). These metrics are essential in assessing how well a model predicts data and provide insight into the level of error between predicted values and actual values.

1) Mean Absolute Error (MAE): The Mean Absolute Error (MAE) measures the average of the absolute differences between predicted values and actual values. MAE gives an overall sense of how much error the model makes on average, without considering whether the error is positive or negative, as all errors are treated equally. The general formula for calculating MAE is:

$$MAE = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}_i| \quad (3)$$

Where:

- y_i is the actual value,
- $\hat{y}_i$ is the predicted value,
- n is the number of data points.

MAE provides an intuitive and easy-to-understand result since it shows the magnitude of errors in the same units as the original data. For example, in a study by Kenyi and Yamamoto (2024), MAE was used to evaluate the performance of the SARIMA-Prophet model in predicting water flow, and the results showed that MAE helped identify the average level of prediction error at each time point [33]. Another study by Angelo and Fadhilrahman (2023) used MAE to compare the performance of ARIMA and Prophet models in predicting Bitcoin prices, demonstrating how MAE can measure the accuracy of time-series predictions in complex datasets [32].

2) Root mean square error (RMSE): Root Mean Square Error (RMSE) is another common metric for evaluating predictive model accuracy. RMSE calculates the square root of the average squared differences between predicted and actual values. Unlike MAE, which focuses on absolute differences, RMSE gives more weight to larger errors because the errors are squared before being averaged. The general formula for RMSE is:

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \quad (4)$$

Where:

- y_i is the actual value,
- $\hat{y}_i$ is the predicted value,
- n is the number of data points.

RMSE is particularly useful when larger errors are more undesirable than smaller ones, as it penalizes large errors more heavily. In a study by Hamiane et al. (2024), RMSE was used to measure the accuracy of hybrid LSTM, ARIMA, and Prophet models in predicting future GDP, showing that RMSE was highly effective in identifying significant differences between predictions and actual data over certain periods. Similarly, Mokhtar et al. (2022) applied RMSE to predict hydroponic yields, revealing that RMSE is more sensitive to outliers than MAE, making it an important evaluation metric when dealing with highly variable data [13], [34].

Using both RMSE and MAE together provides a more comprehensive picture of model performance. While MAE gives a general overview of the average error, RMSE emphasizes larger errors, which can be crucial in applications where minimizing extreme errors is important. Therefore, in many studies, these two metrics are often used together to evaluate time-series predictive models, including in hydroponic farming and energy prediction applications [12].

This combined approach allows for a better understanding of model behavior under various conditions, ensuring that both overall performance and outlier sensitivity are addressed. By evaluating models using MAE and RMSE, researchers can fine-tune predictions to optimize both short-term and long-term outcomes

F. Dataset Preparation Description

In the process of preparing the dataset for machine learning modeling, the first step involved collecting data from the hydroponic system. The dataset includes several critical environmental and growth metrics to ensure that the information fed into the models is relevant and accurate.

TABLE II. INITIAL DATASET SHOWING ENVIRONMENTAL CONDITIONS AND PLANT GROWTH METRICS

	day	hole	time	temperature	humidity	light	pH	Ec	TDS	WaterTemp	LeafCount
0	1	1	09:19:00	26.8	72	17820	7.2	677	340	26.1	3
1	1	2	09:23:00	26.6	72	16490	7.2	677	338	26.1	3
2	1	3	09:27:00	26.4	72	15160	7.2	678	334	26.1	3
3	1	4	09:31:00	26.2	72	13830	7.2	677	338	26.1	3
4	1	5	09:35:00	26.2	72	12500	7.2	673	340	26.1	3

The Table II, summarizes the primary data columns that were included in the dataset. This data was collected at specific time intervals from each plant hole in the hydroponic system.

- Day: Represents the day number during the data collection process, crucial for understanding time-based trends and growth patterns in the plants [12].
- Hole: This refers to the individual plant hole in the hydroponic system. Each hole corresponds to a plant, and this column ensures that the data collected is specific to each plant [35].
- Time: Indicates the exact time the data was recorded. Time tracking is crucial for analyzing daily patterns in plant growth [36].

- Temperature (°C): Records the temperature of the growing environment. Maintaining optimal temperature is vital for plant growth, with prior studies suggesting its significance in hydroponic systems [20].
- Humidity (%): This column records the humidity levels in the environment, an important factor affecting plant water intake and overall health [37].
- Light (lux): Measures the intensity of light, which directly influences photosynthesis and plant growth. The importance of this factor is well-documented in the works of Lontsi Saadio et al. (2022) [14].
- pH: Captures the pH level of the nutrient solution. Balanced pH levels ensure optimal nutrient absorption [8].
- EC (mS/cm): Electrical Conductivity measures the concentration of nutrients in the solution. The correct EC level ensures that plants receive the necessary nutrients for growth [37].
- TDS (ppm): Total Dissolved Solids measure the concentration of dissolved substances, including essential nutrients. This helps monitor nutrient levels in the solution, as supported by Schwartz et al. (2019) [1].
- WaterTemp (°C): This column represents the temperature of the water or nutrient solution, which is crucial for maintaining healthy root systems [36].
- LeafCount: Records the number of leaves on each plant, serving as a metric for plant growth and overall health. Studies show that an increasing leaf count indicates good plant health [34].

This dataset provides comprehensive data necessary for analyzing environmental conditions and their impact on plant growth in a hydroponic system. Each column represents a critical factor in understanding and optimizing plant development, making it a solid foundation for further data processing and modeling.

G. CRISP-DM Methodology

CRISP-DM (Cross Industry Standard Process for Data Mining) is a widely used methodology for structuring data mining projects. Developed in the late 1990s, it provides a systematic and flexible approach applicable across industries, particularly in projects involving complex data analysis. This methodology is commonly applied in various machine learning applications, including hydroponic farming, to guide the entire development process, from the initial stages to deploying a fully functional predictive model [38].

The first phase of CRISP-DM is business understanding, which is crucial for identifying the project's business goals. This phase involves defining the business problems clearly and determining how data mining can provide actionable solutions. In the context of agricultural research, such as yield prediction using environmental data, this stage helps shape the problem and goals, such as optimizing crop yields in hydroponic systems [9].

After establishing the business goals, the next phase is data understanding. This phase focuses on gathering and exploring relevant data to gain an initial insight into the structure and characteristics of the dataset. Data exploration aims to identify patterns, outliers, and relationships between variables. For example, in machine learning studies related to hydroponics, data could include temperature, humidity, and nutrient levels, which would be further analyzed for patterns [4].

The third phase is data preparation, where the collected data is cleaned and prepared for analysis. This involves various steps such as handling missing values, transforming data, and selecting relevant features for the model. The quality of the data is crucial, as cleaner and more relevant data directly impact the model's performance [38].

Once the data is prepared, the next phase is modeling. This is where machine learning algorithms or data mining techniques are applied to the dataset. Depending on the objectives, different algorithms, such as regression or classification, may be used. For agricultural yield prediction, models like Random Forest or Neural Networks are often employed to predict critical variables affecting plant growth. Each model is evaluated to ensure it accurately predicts outcomes according to the predefined goals [9].

Following modeling, the evaluation phase assesses the performance of the model. Here, various evaluation metrics like Mean Absolute Error (MAE) and Root Mean Square Error (RMSE) are used to measure the accuracy and reliability of the model on both training and unseen test data. This ensures that the model is robust and reliable for real-world applications [4].

The final phase of CRISP-DM is deployment, where the evaluated model is integrated into an operational system. At this stage, the model is embedded into broader business processes to provide real-world benefits. For example, in an IoT-based hydroponic system, the developed model can be used by farmers to monitor environmental conditions in real-time and make decisions based on the model's predictions [39].

The usefulness of CRISP-DM lies in its structured and organized approach to managing data mining projects. Each phase can be revisited or refined as needed, ensuring that the desired outcomes are systematically achieved. In the context of machine learning research for hydroponics, CRISP-DM allows for the development of accurate and relevant models that optimize agricultural yields under dynamic environmental conditions [40].

Fig. 1 below illustrates a conceptual framework that combines exploratory data science activities, goal-directed CRISP-DM phases, and core data management activities. The outer circle represents broader exploration activities, while the inner circle shows the structured steps of the CRISP-DM process. At the center are essential data management activities such as data acquisition, simulation, and preparation, which are critical for the success of any data mining project [41].

To effectively address the complexities of managing hydroponic systems in Indonesia’s unique climatic conditions, the CRISP-DM methodology was adopted and adapted to the specific needs of this research. The proposed methodology integrates the structured phases of CRISP-DM, such as data

collection, modeling, and deployment, while incorporating tailored adjustments for hydroponic farming. The figure below illustrates the proposed methodology, which includes detailed steps drawn from the CRISP-DM framework, optimized for the implementation of ARIMA and Prophet models in the context of hydroponic lettuce growth during the rainy season.

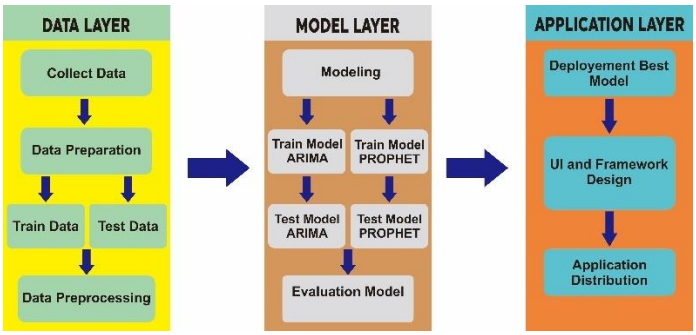

Fig. 1. Proposed methodology based on CRISP-DM framework.

The proposed methodology, as shown in Fig. 1, follows the CRISP-DM framework to provide a systematic approach for predictive modeling in hydroponic farming. ARIMA and Prophet were chosen as the primary models due to their strengths in handling time-series data. ARIMA is effective for stationary data with linear trends but is limited in managing irregular seasonal patterns. Prophet, on the other hand, excels in handling non-stationary data, incorporating flexible seasonalities, and managing missing data, making it more suitable for the dynamic nature of hydroponic systems.

Compared to traditional regression models, which lack temporal dependency analysis, and advanced machine learning methods, which demand larger datasets and computational resources, ARIMA and Prophet offer an optimal balance of accuracy, efficiency, and practicality. This methodology ensures each phase, from data preparation to model deployment, is rigorously executed, creating a scalable framework that can be expanded to other crops or environmental conditions in future research.

The Data Layer represents the initial phases of CRISP-DM, namely Data Understanding and Data Preparation. According to CRISP-DM, understanding and preparing data are foundational to successful modeling. In this research, the data collected includes key environmental parameters such as temperature, humidity, light, pH, Electrical Conductivity (EC), Total Dissolved Solids (TDS), and water temperature— all critical for hydroponic plant growth. The data preparation process involves splitting the dataset into training and test sets, ensuring that both the training data and the test data undergo preprocessing to eliminate noise, handle missing values, and standardize formats.

Data preprocessing is vital because the quality of the input data directly influences the performance of machine learning models. According to Schwartz et al. (2019), high-quality data preparation significantly improves the accuracy of predictive models, especially in controlled environments like hydroponics, where multiple variables can affect plant growth.

The Model Layer corresponds to the Modeling phase in CRISP-DM, where machine learning algorithms are applied to the prepared dataset. This layer includes the training and testing of both ARIMA and Prophet models, which are widely used for time-series forecasting.

1) Training the ARIMA model: The ARIMA model is trained on the dataset to capture time-series patterns that influence plant growth under various environmental conditions. ARIMA has been employed in agriculture for its effectiveness in forecasting time-series data, though it often requires stationary data and is sensitive to outliers.

2) Training the prophet model: Developed by Facebook, Prophet is more flexible than ARIMA and can handle missing data, seasonality, and trends more efficiently. It is particularly effective in capturing the irregular trends often seen in agricultural environments, such as during unpredictable weather patterns like Indonesia's rainy season.

3) Model evaluation: The models are tested on unseen test data, and their performance is evaluated using metrics such as Mean Absolute Error (MAE) and Root Mean Square Error (RMSE). These metrics provide insight into how well each model predicts the key environmental variables that affect lettuce growth. Comparative evaluations ensure that the best model—Prophet in this case—is identified for deployment.

The Application Layer reflects the Deployment phase in CRISP-DM. After evaluating the models, the best-performing model (Prophet) is deployed into a user-friendly web application designed for practical use by hydroponic farmers. This phase involves integrating the trained model into an operational system that can deliver real-time predictions, which allows farmers to make data-driven decisions.

4) UI and framework design: The model is integrated into an intuitive user interface, ensuring that farmers can interact with the application easily. This user interface is designed to simulate plant growth automatically and adjust to real-time data inputs, offering farmers actionable insights into optimizing their hydroponic systems.

5) Application distribution: The final step is distributing the application, making it accessible to users for real-time hydroponic growth simulations. This practical deployment ensures that the model's predictions are embedded into daily decision-making processes, improving efficiency and crop yields in dynamic environments like Indonesia's rainy season

III. Results and Discussion

A. Data Preparation

In this study, data preparation is a crucial step performed before the modeling process. This phase involves data collection and exploratory data analysis (EDA) to ensure that the processed data is of high quality, leading to the development of accurate models. Previous research highlights that data preparation is vital in machine learning and data mining projects, as errors in this stage can significantly reduce model

performance [24]. In this research, data was gathered from a Nutrient Film Technique (NFT) hydroponic system used for growing lettuce (Lactuca sativa) during the rainy season in Indonesia. The system involved monitoring various environmental variables and plant growth [8]. The collected data included temperature, humidity, light intensity, pH, total dissolved solids (TDS), electrical conductivity (EC), water temperature, and the number of leaves. Fig. 2 illustrates the NFT hydroponic system used for data collection, along with the measurement tools employed to capture environmental and plant growth variables.

Fig. 2. Lettuce in the NFT hydroponic system and the calibration equipment.

Fig. 2 shows the lettuce plants grown in the NFT system, where environmental and growth data were collected starting from the first day after planting until harvest on day 40. In the NFT system, plant roots continuously receive nutrients and oxygen through a thin film of flowing solution, enabling optimal plant growth. As noted by Abioye et al. (2022), the NFT system offers advantages in efficient use of nutrients and water in hydroponic crop production [42].

Also shown in the figure are several measurement tools used to collect data on environmental variables, such as a Hygrometer to measure temperature and humidity, and a Lux Meter to measure light intensity. These measurements are crucial for monitoring environmental conditions that affect plant growth. As noted by Sundari et al. (2022), even small changes in light intensity can have a significant impact on the photosynthesis process [43]. Additionally, a pH-TDS-EC meter was used to measure pH, TDS, EC, and water temperature, all of which are key variables in ensuring plants receive sufficient nutrients. Data on the number of leaves, used as a growth variable, was collected through direct observation by counting the number of new leaves each day.

By conducting this thorough data collection process, the study follows a detailed methodology to maximize hydroponic crop yields, particularly during the challenging rainy season [24], [42].

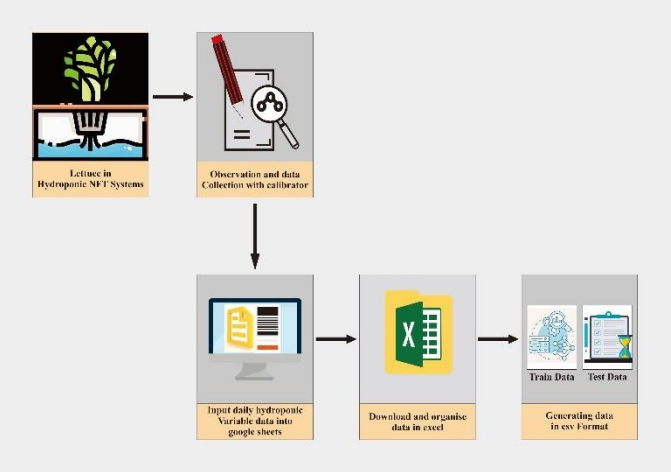

Fig. 3. Stages in the data preparation phase.

The data preparation phase begins after daily data collection from hydroponic variables and lettuce growth in the NFT system. As shown in Fig. 3, data from environmental variables and lettuce growth are manually inputted into Google Sheets each day. This data collection involves the use of various measurement instruments, such as a Hygrometer for temperature and humidity, a Lux Meter for light intensity, and a pH-TDS-EC meter for measuring pH, TDS, and water conductivity (EC), in accordance with standard hydroponic data collection protocols (Sambo et al., 2019).

After collecting data over the 40-day period, from planting to harvest, the data is downloaded from Google Sheets and organized in Excel for further validation and processing, such as formatting adjustments and data cleaning. This step is crucial to ensure there are no outliers or input errors that could impact the predictive model's results (Abioye et al., 2022). The data is then divided into training and testing datasets as required for the machine learning model's training and testing phases (Menculini et al., 2021). In the final stage, the data is saved in CSV format, ready to be used for modeling.

This process enables researchers to maintain data integrity and optimize the quality of the dataset before using it in predictive models. These steps align with methods commonly used in the CRISP-DM (Cross-Industry Standard Process for Data Mining) approach, which emphasizes the importance of proper data preparation to achieve optimal results in machine learning projects (Ayele et al., 2020).

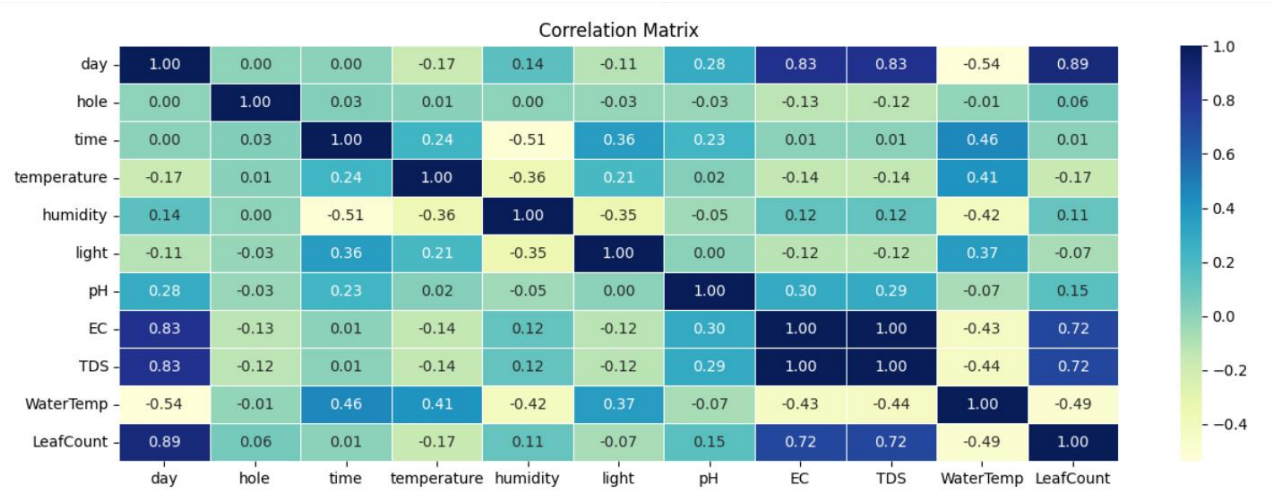

Fig. 4. Correlation matrix.

The correlation matrix is a table that displays the linear relationships between variables in a dataset. Correlation values range from -1 to 1, where a value of 1 indicates a perfect positive correlation, -1 indicates a perfect negative correlation, and 0 indicates no correlation. In data analysis, a correlation matrix helps to understand how variables influence one another and how they might affect the predictive model being developed (Chopra & Khurana, 2023).

From Fig. 4, it is evident that some variables show strong correlations with each other. One of the most prominent examples is the relationship between EC (Electrical Conductivity) and TDS (Total Dissolved Solids), with a correlation value of 1.00. This perfect correlation indicates that EC and TDS are directly related, meaning any change in one variable is always accompanied by the same change in the other. This makes sense in the context of a hydroponic system, where EC measures the concentration of dissolved ions in water, while TDS measures the total amount of dissolved solids. Since EC and TDS essentially measure almost the same aspect of water nutrition, these variables move in tandem.

Additionally, a strong correlation is observed between EC and Leaf Count, with a correlation of 0.72. This suggests that the nutrient concentration (measured by EC) has a significant impact on the number of leaves produced. This aligns with findings from other studies, which highlight that balanced nutrient levels in hydroponics play a crucial role in maximizing plant growth (Sambo et al., 2019).

Another noteworthy correlation is between Day and Leaf Count (0.89), showing that as time progresses (in days), the number of leaves on the plants increases, reflecting a consistent growth process over time. This relationship is important for understanding plant growth patterns, particularly in a hydroponic system, where growth is highly influenced by time and nutrient levels.

However, there are some variables that do not show significant correlations with each other. For instance, Humidity and Water Temperature have a negative correlation (-0.42), indicating that as water temperature increases, humidity tends to decrease. This relationship, however, may not be entirely linear and may require further analysis to understand its impact on plant growth.

Overall, this correlation matrix provides valuable insights into the relationships between variables in the hydroponic system under study. Understanding these relationships will help in building more accurate predictive models by focusing on variables with significant correlations to key outcomes, such as leaf count and nutrient effectiveness in the water.

A correlation matrix is a numerical representation used to describe the linear relationships between two or more variables in a dataset. In the context of machine learning, the correlation matrix is crucial for understanding how variables relate to each other. Strong positive or negative correlations between variables can influence the model's outcomes, as a well-built model should account for inter-variable relationships to avoid redundancy or excessive bias in predictions [18].

In Fig. 5, histograms of key variables in this study such as temperature, humidity, light, pH, EC, TDS, and leaf count are presented to provide an overview of the distribution and variation patterns of each measured variable in the hydroponic system. These histograms help to understand the basic characteristics of the collected data and to identify potential outliers or abnormal distributions.

The temperature distribution ranges from 24°C to 32°C, with the highest frequency between 26°C and 28°C. This pattern indicates that the temperature in the hydroponic environment remains fairly stable within the optimal range for lettuce growth, with extreme temperatures rarely occurring. The humidity distribution shows significant variation, ranging from 40% to 100%, with the highest frequency around 70%, indicating relatively high humidity during most of the measurement period.

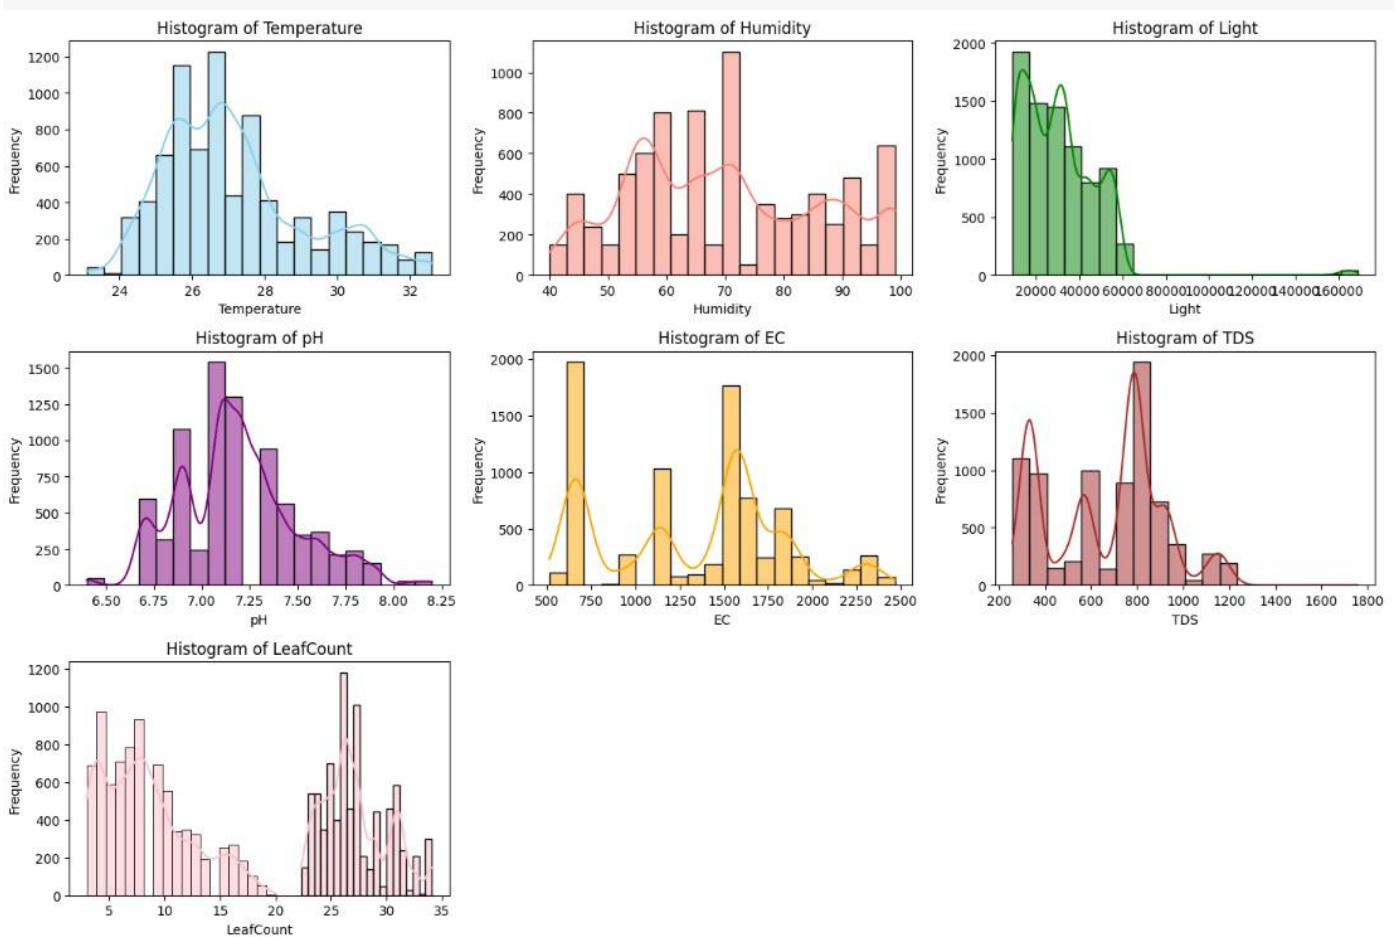

Fig. 5. Histogram of all variables.

The light variable shows a wide range of light intensity values, from 20,000 to over 60,000 lux. The peak distribution occurs between 20,000–30,000 lux, which is considered optimal for photosynthesis in a hydroponic system. The pH distribution also follows a near-normal pattern, with values ranging from 6.5 to 8.0, and the highest frequency around pH 7.2. This suggests that the hydroponic system tends to maintain an optimal acidity level for plant nutrient absorption.

Next, EC (Electrical Conductivity) varies between 500 and 2500 µS/cm, with several peaks reflecting fluctuations in nutrient concentration during the growth cycle. This range is critical to ensure that plants receive sufficient minerals without causing an oversupply. The TDS (Total Dissolved Solids) variable shows a similar pattern, with values ranging from 200 to 1800 ppm, with the highest frequency around 800–1000 ppm. This indicates varying levels of nutrient solubility in the water throughout the observation period.

Finally, the leaf count distribution shows significant variation in the number of leaves, with the highest frequency occurring between 15 and 25 leaves. This variable reflects fairly stable plant growth, while also showing some variation among the plants measured during the hydroponic cycle.

Overall, these histograms provide initial insights into how each variable functions within the hydroponic system and offer important information for the next stage—predictive modeling. The data will be used to build simulations for lettuce growth under Indonesia's rainy season conditions.

Fig. 6 illustrates the changing patterns of various environmental and hydroponic variables over time (in days) as measured throughout the study. In this graph, variables such as EC (Electrical Conductivity), TDS (Total Dissolved Solids), Temperature, Water Temperature, pH, and Light are visualized in relation to days, allowing us to understand the trends and fluctuations of each variable.

It is clear that EC and TDS follow almost identical patterns, with their values gradually increasing over time. This aligns with the findings shown in the correlation matrix, where these two variables have a very high correlation (close to 1), indicating a strong relationship. The increase in EC corresponds with the rising nutrient concentration in the hydroponic solution, which is directly measured by TDS. Over time, the hydroponic system shows a controlled increase in nutrient concentration in the water [8].

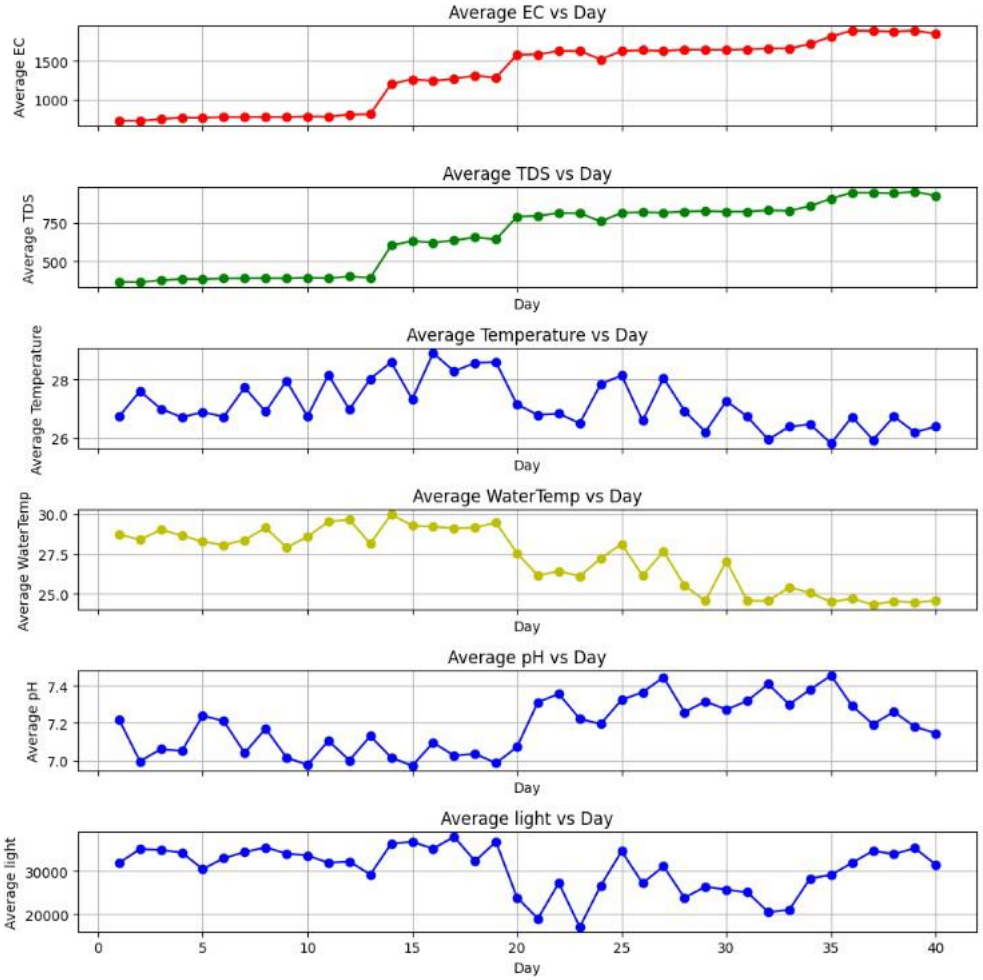

Fig. 6. Visualization of all variables over time.

For the Temperature and Water Temperature variables, the patterns show more irregular fluctuations compared to EC and TDS. Air temperature exhibits more dynamic variation, with several peaks and troughs, though it generally remains within a stable range. This is important because temperature plays a direct role in photosynthesis and plant growth [42]. Water temperature, on the other hand, shows smaller fluctuations, although some sudden drops were recorded on certain days. Maintaining stable water temperature is crucial for keeping the plant roots healthy and ensuring effective nutrient absorption.

The pH graph shows that pH values remain relatively stable with slight fluctuations, tending towards 7.2, which is the optimal pH for lettuce growth in a hydroponic system. This stability is essential to ensure that plants can absorb nutrients effectively [44].

Meanwhile, the Light variable exhibits more regular daily fluctuations. Light intensity greatly influences photosynthesis and plant growth, and the variability in the light pattern may be caused by external factors such as weather changes during the data collection period.

Overall, this visualization provides a clear picture of how each variable contributes to plant growth in the hydroponic system, with EC and TDS being the most closely related variables in influencing nutrient conditions. Understanding these patterns is critical for developing predictive models for future automated simulations of hydroponic plant growth.

B. Data Preprocessing

Data preprocessing is a crucial step in data handling before modeling or further analysis. This phase involves various tasks such as data cleaning, transformation, and formatting adjustments to ensure that the data is optimally prepared for use by modeling algorithms. In the context of machine learning, data preprocessing aims to ensure that the data is clean, free from noise, and ready for modeling purposes, as explained by Kramar and Alchakov (2023) [28]. By undergoing data preprocessing, the data becomes more consistent and structured, ultimately improving the performance of the model being developed. During this phase, several important steps are carried out. For instance, the 'time' column is adjusted by adding digits before and after to ensure that the time format aligns with the standards used in time-series analysis. Additionally, unnecessary columns, such as labels that contain only one type of value, are removed to prevent them from affecting the prediction outcomes.

TABLE III. DATA ADJUSTMENT

	day	hole	time	temperature	humidity	light	pH	Ec	TDS	WaterTemp	LeafCount
0	1	1	09:19:00	26.8	72	17820	7.2	677	340	26.1	3
1	1	2	09:23:00	26.6	72	16490	7.2	677	338	26.1	3
2	1	3	09:27:00	26.4	72	15160	7.2	678	334	26.1	3
3	1	4	09:31:00	26.2	72	13830	7.2	677	338	26.1	3
4	1	5	09:35:00	26.2	72	12500	7.2	673	340	26.1	3

Table III illustrates this data adjustment process, where each column is reviewed and reformatted as needed. For example, the 'time' column had zeros added in front of single-digit hours to follow the standard time format, ensuring that the data could be correctly processed by the model. Furthermore, this process also involves removing irrelevant columns or those containing only one type of label, allowing the data to focus on the variables that influence the forecasting process.

Subsequent processing involves merging the day and time columns to create a new column called datetime. This column serves to provide the appropriate time series format, making it usable in future modeling and prediction processes. This step is crucial because data structured in a time series format allows algorithms like ARIMA and Prophet to recognize patterns and trends that occur over time [28]. The merging of these columns is a key step in data preprocessing, ensuring the data is ready to be used in machine learning modeling.

```
df_model after merge:

Fig. 7. Dataset after preprocessing.

In Fig. 7, the results after the preprocessing stage are shown, where the datetime column has been combined with the main dataset. This new dataset not only includes information about hydroponic variables such as temperature, humidity, light, pH, EC, TDS, and LeafCount, but also includes datetime as a crucial time marker in the time series analysis.

Once the datetime column is added and the dataset updated, the dataset is then saved in csv format. Saving in csv format aims to create a new, more ready-to-use database for the modeling and forecasting process. Data preprocessing like this is essential to ensure that the data is in optimal condition before being input into predictive models, as without this process, the data might be poorly structured or not aligned with the desired format [28].

C. Modeling

In the modeling phase, two time-series models were used: ARIMA and Prophet, each with its own strengths in forecasting time-series data. The ARIMA model operates through three key components: autoregressive (AR), differencing (I), and moving average (MA). To begin with, the stationarity of the data is tested using the Augmented Dickey-Fuller (ADF) test. If the data is found to be non-stationary, differencing is applied to address trends and seasonality, as proposed by Menculini et al. (2021) [24].

Once the data becomes stationary, the parameters p, d, and q are determined to build the ARIMA model. This model is used to predict environmental variables such as EC (Electrical Conductivity) and TDS (Total Dissolved Solids), which are crucial for hydroponic plant growth. On the other hand, Prophet is a flexible model that automatically handles trends and seasonal components, as described by Satrio et al. (2021) [30]. Prophet works by separating data components into trend, seasonality, and residuals, making it well-suited for predicting dynamic weather conditions.

In this study, both models were evaluated using the MAE (Mean Absolute Error) and RMSE (Root Mean Squared Error) metrics. The results showed that Prophet outperformed in handling seasonal trends, especially during Indonesia's rainy season, while ARIMA produced better results for more stationary data [22].

SARIMAX Results

Dep. Variable:	LeafCount	No. Observations:	5282
Model:	ARIMA(1, 1, 1)	Log Likelihood	-10246.137
Date:	Tue, 12 Nov 2024	AIC	20498.274
Time:	11:17:32	BIC	20517.990
Sample:	0 - 5282	HQIC	20505.165
Covariance Type:	opg		

	coef	std err	z	P>|z|	[0.025	0.975]
ar.L1	-0.1913	0.012	-16.310	0.000	-0.214	-0.168
ma.L1	-0.9682	0.003	-314.518	0.000	-0.974	-0.962
sigma2	2.8346	0.051	55.715	0.000	2.735	2.934

Prob(H) (two-sided):	0.00	Kurtosis:	3.68

Fig. 8. SARIMAX results.

SARIMAX (Seasonal AutoRegressive Integrated Moving Average with eXogenous regressors) is a popular method for time series data analysis that takes into account both seasonal and non-seasonal components [45]. In the SARIMAX results shown in Fig. 8, it is clear that the ARIMA (1,1,1) model has been used to predict the variable LeafCount with 5282 observations. According to the reference by Pindiga (2022), SARIMAX is utilized because it can capture fluctuations and seasonal patterns, providing more comprehensive results in time series forecasting [25].

From the SARIMAX results, the AR.L1 coefficient has a value of -0.1913 with a p-value of less than 0.05, indicating that this parameter is significant in the model. The MA.L1 value is also significant, with a coefficient of -0.9682, meaning that the moving average model plays an important role in predicting LeafCount. The sigma2 value (2.8346) represents the variability in the model's residuals, which affects the accuracy of the predictions. Additionally, the AIC (20498.274) and BIC (20517.990) values provide indicators of how well the model fits the data, where lower values suggest a better-fitting model.

Moreover, the Jarque-Bera (JB) statistical test resulted in a value of 242.43 with a p-value of 0.00, indicating that the residual distribution does not follow a normal distribution. This is important in time series model evaluation as it can impact prediction accuracy.

Fig. 9. Preparing data for the prophet model.

Fig. 9 shows the dataset prepared for modeling using Prophet. The dataset includes key columns such as time (ds), the target variable (y), plant hole (hole), and various environmental factors like temperature, humidity, light, pH, EC, TDS, and water temperature (WaterTemp). This data is structured to help predict lettuce leaf growth (LeafCount) based on these factors. Each row in the dataset represents a single point in time, with data collected periodically during the observation period from July 1, 2024, to August 9, 2024. This ensures that the Prophet model can accurately capture any temporal patterns. The data serves as the training set for the Prophet model to predict the target variable, which is the number of lettuce leaves (LeafCount).

D. Evaluation

Evaluation is a crucial stage in the modeling process to assess the performance of the model that has been developed. The goal of evaluation is to determine how well the model predicts the observed data and to ensure that the prediction results are relevant to the research objectives.

To ensure reliable model performance, this study emphasizes the importance of validation measures. We used two key evaluation metrics: Mean Absolute Error (MAE) and Root Mean Squared Error (RMSE). These metrics are essential for assessing prediction accuracy and understanding how well the models perform in forecasting hydroponic growth. MAE shows the average error magnitude, while RMSE highlights larger errors by squaring the differences. Together, they provide a comprehensive view of model accuracy.These two metrics are commonly used in time series modeling because they provide insight into the magnitude of the model's prediction error compared to the actual data (Sushma Niveni, 2022).

MAE measures the average absolute error between the predicted and actual values. It helps in understanding the extent of the prediction error without considering its direction (positive or negative). The smaller the MAE value, the more accurate the model is in making predictions. Meanwhile, RMSE gives more weight to larger errors by squaring them, which is useful for detecting predictions with large deviations from the

actual values. A model with a smaller RMSE is considered better at capturing trends and patterns in the data (Lorenzo Menculini, 2021).

Based on the evaluation of the ARIMA and Prophet models, the following table summarizes the performance comparison of the two models:

TABLE IV. PERFORMANCE COMPARISON OF ARIMA AND PROPHET MODELS BASED ON MAE AND RMSE METRICS

Model	MAE	RMSE
ARIMA	8.17	8.97
Prophet	1.475	1.808

From the evaluation Table IV, it is evident that the Prophet model has much lower MAE and RMSE values compared to ARIMA. The MAE value for Prophet is 1.475, indicating that the average prediction error from this model is much smaller compared to ARIMA, which has an MAE of 8.170. This indicates that Prophet is able to provide more accurate predictions. Additionally, the RMSE value for Prophet, which is 1.808, also shows that this model has fewer large errors, whereas ARIMA, with an RMSE of 8.970, indicates that it tends to make larger errors.

The Prophet model outperformed ARIMA in both MAE and RMSE. Prophet's ability to handle non-stationary data and complex seasonal patterns made it more suitable for hydroponic forecasting compared to ARIMA, which assumes that data is stationary. Prophet can capture non-linear trends and multiple seasonalities, making it more effective for dynamic systems like hydroponics.

Additionally, this study compares Prophet with traditional methods and more complex machine learning models. Traditional models often rely on stationary data, which limits their application in real-world scenarios. Prophet overcomes this limitation, offering flexibility to model changes over time. Compared to machine learning approaches, which require large datasets and high computational resources, Prophet balances accuracy with computational efficiency, making it a practical and accurate tool for hydroponic forecasting.

Overall, Prophet excels in capturing data patterns and generating more consistent and accurate predictions compared to ARIMA.

Fig. 10 shows the evaluation of the Prophet model's performance in predicting the number of lettuce leaves in an NFT hydroponic system, using two key evaluation metrics: Mean Absolute Error (MAE) and Root Mean Square Error (RMSE). In the graph on the left, we can see that the RMSE value obtained is 1.82, while the MAE is 1.49. These two metrics provide an overview of the average error made by the Prophet model in predicting plant growth outcomes. MAE measures the average absolute error, giving a direct view of how far off the model's predictions are from the actual values. Meanwhile, RMSE is more sensitive to larger errors, as it penalizes predictions that are significantly far from the actual values.

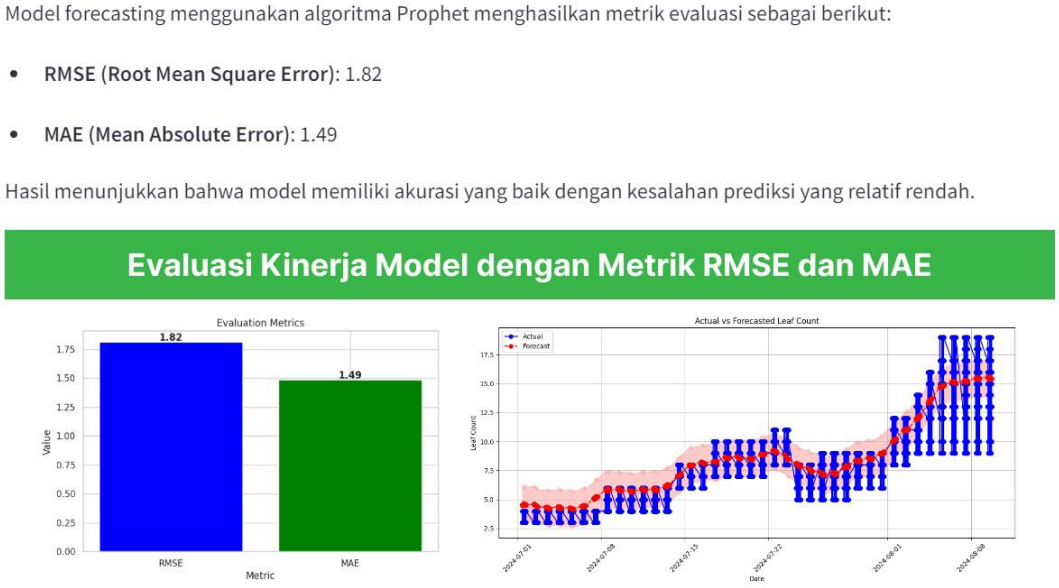

Fig. 10. Model performance evaluation using MAE and RMSE.

The graph on the right in Fig. 10 shows a comparison between the actual values (in blue) and the predicted values generated by the Prophet model (in red) over the measured time period. From this visualization, it can be observed that the Prophet model's predictions closely follow the pattern of leaf growth, especially after the more stable growth period. The range of prediction errors (shaded area) narrows over time, indicating that the model is learning well from historical data and providing more accurate predictions in the later stages.

Overall, this evaluation confirms that Prophet outperforms other models, such as ARIMA, which were also evaluated in this study. As a result, the Prophet model was chosen to move forward to the deployment stage, where it will be used in a web-

based automated growth simulation, helping hydroponic farmers monitor and predict their crop yields more accurately and effectively.

E. Comparison to Existing Study

In the Comparison/Benchmarking section, this study is compared with several similar studies using the ARIMA and Prophet models, based on performance evaluation results measured through MAE and RMSE metrics. The findings of this study, where the Prophet model achieved an MAE of 1.475 and an RMSE of 1.808, are compared to similar studies from academic literature. Through Table V below, we can see the comparison of evaluations using MAE and RMSE from previous research.

TABLE V. COMPARISON OF MAE AND RMSE VALUES

	Purnama, 2023		Elseidi, 2024		Pindiga, 2022		Rahmadi, 2024	
	MAE	***RMSE***	***MAE***	***RMSE***	***MAE***	***RMSE***	***MAE***	***RMSE***
Prophet	2.51	2.89	1.78	2.12	2.65	3.15	1.475	1.808

Purnama's study (2023), which compared ARIMA and Prophet in predicting Bitcoin prices, reported that Prophet performed better with an MAE of 2.51 and an RMSE of 2.89, compared to ARIMA, which had an MAE of 3.12 and an RMSE of 3.58. Although Prophet's results in Purnama's study were better than ARIMA's, they still show a higher error compared to this study, indicating that the application of Prophet in hydroponics provides more accurate predictions than its use for Bitcoin price prediction (Purnama, 2023).
