The paper is organized as follows: Section II briefly discusses related studies on deep learning-based video summarizing approaches. Section III introduces our suggested DSTC-Sum model. Section IV discusses the model implementation and experimental findings. Lastly, the paper's conclusion is presented in Section V.

II. Related Work

Video summarization presents the challenge of selecting the most relevant segments of a video for inclusion in the summary and accurately identifying and extracting those segments from the entire video. This process requires a comprehensive understanding of the video content to ensure the summary represents the original video's essential aspects. In the early stage of video summarizing research, most approaches focus on a particular category of videos. For instance, the significance of a specific occurrence during a video segment of a show airing a sporting event can be easily determined by referring to the regulations governing that sport. [13]. In addition, certain sports games, such as baseball and American football, have a specific structure that makes extracting crucial segments of the game's action easier. Similarly, characters who feature in movies can also be domain knowledge [14]. In these areas, video summaries can be generated with the assistance of many kinds of metadata [15, 16]. Videos focusing on the creator alone are another fascinating example of video domains. A video summarization approach has been proposed using specific domain knowledge that can be considered a set of predetermined objects [17]. This approach aims to summarize videos in a manner that considers the domain's specifics. Newer methods in this general area use supervised learning techniques to incorporate domain knowledge. For instance, [18] offered to summarize a video with the primary focus on a particular event and use an event classifier's confidence score to measure a video segment's significance. However, due to the heavy reliance that such methods have on specific industry expertise, it is nearly impossible to generalize them to other types of writing.

When given an original video as input, the video summarizing goal is to produce a condensed version highlighting the most vital information from the original. There have been many other ways that this issue has been represented, such as in a video overview [19], time-lapses [20-22], montage [23, 24], and storyboards [25-29]. Our work is most closely associated with storyboards, consisting of a selection of a few typical frames of video that outline important events throughout an entire film. Storyboard-based summarization can produce two different kinds of outputs: keyframes [30], in which specific isolated frames are selected for forming the summary of the video, as well as key shots [31, 32], a method for generating a resume that considers a series of successive correlated frames contained within a temporal slot. Both types of outputs are referred to as keyframes.

Initial efforts in a video summarizing primarily rely on hand-crafted heuristics. Most of these methods do not require supervision. They specify a variety of heuristics to reflect the significance of the frames' representativeness [33-39], and they utilize the significance scores to select representative frames to form the video summary. Recent research has investigated supervised learning methodologies for video summaries [40-42]. These methods use video training data and the ground-truth summaries humans create for those videos. These supervised learning algorithms perform better than the early work on unsupervised methods because they can acquire sophisticated semantic knowledge that humans implicitly use to construct summaries.

Deep learning approaches have recently been popular for vision tasks, especially video summarization [43-45]. The foundation of LSTM is the theory that it can effectively capture long-range dependencies between video frames, which are necessary for creating insightful summaries. Zhang et al. [32] model the variable range dependency with two LSTMs and consider the video summarizing assignment of a problem of structured prediction based on data that can be sequential. Two Long Short-Term Memory (LSTM) networks are employed to analyze video sequences comprehensively. One LSTM is dedicated to processing the sequences in the forward direction, capturing the temporal dynamics as they unfold chronologically. Meanwhile, the other LSTM handles sequences in the reverse direction, allowing for a holistic

understanding of the video content from both temporal perspectives. They incorporate a determinantal point process model to improve further the subset selection's diversity [9, 46]. Mahasseni and colleagues present an unsupervised generative adversarial system consisting of the discriminator and summarizer [6]. The summarizer, an LSTM variational autoencoder, selects frames from the video and decodes the output to reconstruct the video. The discriminator is another LSTM network that gains the ability to distinguish between candidates by differentiating between the input video and its reconstruction. It accomplishes this by examining the variations between the two. They also incorporate a keyframe regularization into their algorithm, expanding it to supervise learning.

Despite significant advancements in video summarization, several gaps still need to be discovered in existing studies that necessitate further investigation. Prior approaches, such as those based on Recurrent Neural Networks (RNNs) and their variants like Long Short-Term Memory (LSTM) networks and Gated Recurrent Units (GRUs), have proven effective in capturing temporal dependencies but are hindered by high computational costs, memory intensiveness, and sequential processing limitations, making them less scalable for larger datasets or longer video sequences. Additionally, evaluations in previous research are often confined to limited datasets, such as TVSum and SumMe, which do not adequately represent the diversity of real-world video content. The reliance on domain-specific annotations and handcrafted features further restricts the generalizability of these methods. While Temporal Convolutional Networks (TCNs) offer an alternative by addressing some of these limitations, there remains a need for lightweight, scalable architectures that combine computational efficiency with robust temporal modeling capabilities. This study addresses these gaps by proposing DSTC-Sum, a novel video summarization model based on Depthwise Separable Temporal Convolutions, which enhances efficiency and scalability, demonstrates generalizability across diverse datasets, and outperforms state-of-the-art methods in terms of F-scores and computational performance, thereby contributing to the advancement of efficient and robust video summarization techniques.

III. The Proposed Approach

This section introduces the DSTC-Sum model to summarize the input videos. Fig. 1 depicts the structured steps of the DSTC-Sum. First, the feature descriptors are generated from the input video frames using VGG16 [47]. Then, these feature vectors are fed into a series of Depthwise Separable Temporal Convolutional Blocks (DSTCB) that predict a score for each frame. Suppose that X represents a feature vector as $X_{1:n} = \{f_1, f_2, f_3, \ldots, f_n\}$. The model goal is to assign a corresponding score for each frame $Y_{1:n} = \{y_1, y_2, y_3, \ldots, y_n\}$, where n is the frame number, which varies depending on the video.

In the following subsections, we will describe the baseline model VGG16 and then explain the DSTCB, which is built using residual depthwise dilated blocks.

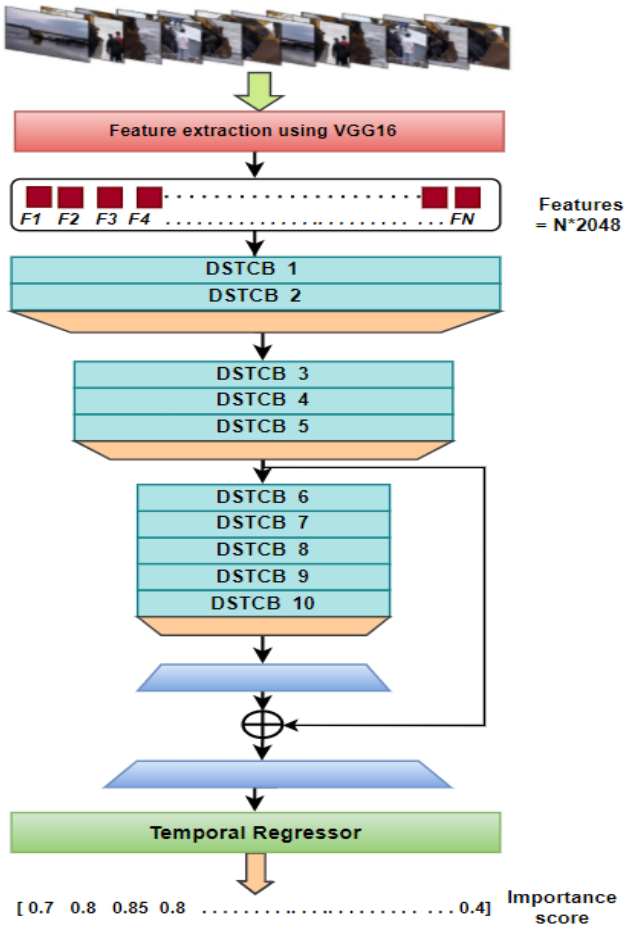

Fig. 1. The detailed structure of the DSTC-Sum.

A. Feature Extraction using VGG16

We start by feeding an input video into a feature extractor. The feature extractor module comprises the pre-trained first ten convolution layers of the VGG16 [47]. Because of its high generalization capabilities, the VGG16 is commonly employed as a feature extractor for many deep-learning models. We applied VGG16 to extract the basic features for the suggested model.

B. Depthwise Separable Temporal Convolutional Blocks (DSTCB)

Temporal convolutional network (TCN) is a CNN variant utilized in sequencing-based tasks and has recently outperformed alternative recurrent models like LSTM and gated recurrent units (GRUs) [48]. TCN enables temporal solid information extraction from sequential data [49]. TCNs aim to encapsulate temporal relationships with a broader receptive field. To capture large receptive fields, either a) dilations on consecutive TCN layers or b) big standard neighboring kernels are used. Dilated convolutions on consecutive layers help capture a broad temporal representation while reducing the number of training parameters. However, when additional layers are added, the kernels become increasingly sparse, resulting in the gridding artifacts issue.

When the dilation parameter increases at higher levels, the input data sample becomes increasingly sparse (Gridding Artifacts issue). As a result, local dependencies between neighboring pixels are lost, and the output layer is not temporally associated with their input sample. DS-TCN [10] proposes techniques for methodical aggregation of convolution layers in the following layers with constant or configurable dilation rates to address the issue of gridding artifacts. Therefore, each DSTCB consists of stacked 'N' depthwise dilated 1d temporal convolution layers.

Fig. 2 depicts the detailed construction of the DSTCB. All output levels receive a combined input from the preceding layer with various dilation rates. Each output layer is combined along a channel dimension to produce the NxC dimension. The cross-channel correlation is then estimated using a pointwise convolution procedure that decreases the dimensions of the channel from N×C to C from the concatenated data. This output is normalized using layer normalization [50]. To maintain adequate gradient flow, we also employ residual connections. Finally, we employ ReLU.

The DSTCB has various advantages:

1) Because depthwise convolutions are computationally efficient, we may employ huge-size kernels. As a result, we may employ lower dilations in conjunction with lengthy kernels to capture lengthy temporal features.

2) Scale information is recorded in each layer with varied dilation rates. Multi-scale information is contained in concatenated pointwise convolution. As a result, the model can tolerate different temporal durations for each event.

3) Stacking the outputs of all layers aids in data smoothing and eliminates the artifact effect caused by gridding. This method enables the model to acquire more detailed local features.

4) The receptive field can temporally extend without boosting the parameters by adjusting the block's dilation rates.

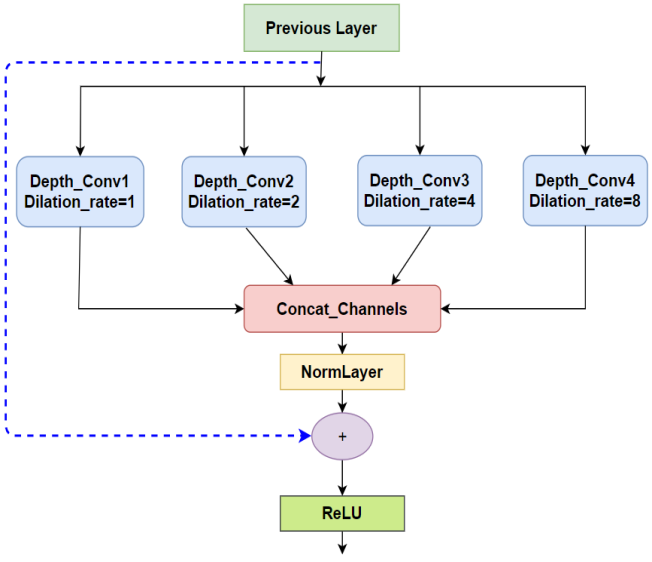

Fig. 2. The detailed construction of the DSTCB.

A temporal max-pooling was added after each DSTCB. Next, we take the output of DSTCB5, perform a 1x1 convolution layer and batch normalization, and then combine it with the production of deconv1 by element-wise addition. This merger is equivalent to the skip-connection in study [9]. Skip connections mix coarse and fine feature maps in semantic segmentation to acquire richer visual characteristics. This skip connector will also be valuable in video summarization, as it will aid in the recapture of temporal information needed for summary. Then, we do another temporal deconvolution to obtain the final representation of length N. The generated representation is fed into the temporal regressor network as input. Finally, the Regressor generates a collection of frame-level scores that represent the importance of the frames.

IV. EXPERIMENTS

This section provides an overview of the datasets, implementation details, and evaluation metrics used to assess the DSTC-Sum model. It outlines the training setup, key parameters, and performance criteria. The section concludes with a presentation and discussion of the DSTC-Sum results, highlighting its strengths, limitations, and potential areas for improvement.

A. Evaluation Datasets

The benchmark datasets for testing and evaluating our DSTC-Sum model are SumMe [51] and TVSum [52]. Table I shows several features of the target datasets. The SumMe benchmark dataset consists of 25 videos in a video benchmark dataset that has numerous topics and occurrences (like holidays, Sports, etc.). The videos on SumMe can vary between 1.5 to 6.5 minutes. The TVSum dataset consists of 50 videos from the TRECVid Multimedia Event Detection (MED) challenge [53]. The videos are divided into different categories, e.g., 'saucing up a sandwich,' 'showing dog,' and so on. This dataset houses videos that range from one minute to five minutes.

Previous research in [32] suggests that more videos should be added to the datasets to minimize the difficulty of training a deep neural network with a few manually annotated examples. Therefore, we bolster the existing training data by incorporating 39 videos from the YouTube dataset [54] in addition to 50 videos from the OVP dataset [54, 55]. The YouTube dataset includes some videos, including cartoons, sports, news, etc. OVP has videos in many different genres, such as documentaries. Because the multiple datasets provide ground-truth annotations in various formats, we adapt a training process that uses summaries based on keyframes to construct a unified set of ground truths for each video included in the datasets, as in study [32, 56].

TABLE I. OVERVIEW OF THE TARGET DATASETS

Datasets	Videos	Annotations	Duration (Min)
TVSum	50	20	2-10
SumMe	25	15-18	1-6
YouTube	39	5	1-10
OVP	50	5	1-4

B. Implementation and Training Details

The model is implemented using PyTorch, with the number of DSTCB blocks set to ten. Each DSTCB block consists of four depthwise one-dimensional temporal convolution layers, where the dilation parameter is doubled in each layer. We adopt the hyperparameters used in MS-TCN [12] to ensure a fair comparison with other methods. The Adam optimizer is employed with a learning rate of 0.0005. The parameters for the smoothing loss function are set as follows: smoothing λ=0.15 and threshold τ=4.

We downsample the videos uniformly to 2 frames per second for feature extraction, as done in [2]. We select representative frames from each video to reduce the final feature dimension to 320. Training frames are scaled to maintain consistent spatial dimensions across all videos. The DSTC-Sum model can handle longer videos and videos of varying lengths. We use the output from the maxpool5 layer of a pre-trained VGG16 model [47] as the feature descriptor for each frame, with a feature dimension of 512. Notably, our model is flexible and can work with any feature representation.

During training, we set the batch size to 5, the learning rate to 10^{-3}, and the momentum to 0.9. The Stochastic Gradient Descent (SGD) optimizer was used to train the DSTC-Sum model.

C. Evaluation Metrics

We evaluate the DSTC-Sum use of a keyshot-based metric, as in [6, 32]. Suppose that S_G is the ground-truth summary and S_E is the extracted summary for video V. We define the precision (P) and recall (R) by utilizing the temporal overlap between them as in Eq. (1) and (2):

$$P = \frac{|S_E \cap S_G|}{|S_E|} \quad (1)$$

$$R = \frac{|S_E \cap S_G|}{|S_G|} \quad (2)$$

As a final step, the evaluation is carried out utilizing the F-score, which is calculated in Eq. (3):

$$F = \frac{2P \times R}{P + R} \times 100 \quad (3)$$

D. Performance Analysis and Discussion

The performance of various summarization techniques on the SumMe dataset is outlined in Table II and visualized in Fig. 3. The proposed DSTC-Sum method significantly outperforms other state-of-the-art techniques across almost all parameters. Specifically, in the standard-supervised setting, DSTC-Sum achieves an F-score of 48.7, higher than the following best technique, SUM-FCN, which scores 47.5. DSTC-Sum shows an even more substantial improvement in the augmented setting, achieving an F-score of 52.8 compared to SUM-FCN's 51.1. This consistent outperformance highlights the effectiveness of DSTC-Sum in summarizing videos within the SumMe dataset.

Similarly, the results on the TVSum dataset, presented in Table III and Fig. 4, demonstrate the superior performance of the DSTC-Sum approach. DSTC-Sum achieves an F-score of 61.2 in the standard-supervised setting, edging out with close competitors like M-AVS and DHAVS, which scored 61.0 and 60.8, respectively. The augmented setting further showcases the dominance of DSTC-Sum, with an F-score of 62.9, significantly higher than M-AVS's 61.8 and SUM-GAN*sup*'s 61.2. These results underline the robustness and efficiency of DSTC-Sum in producing high-quality video summaries on the TVSum dataset.

TABLE II. SUMMARIZATION PERFORMANCE (F-SCORE) COMPARISON ON THE SUMME BENCHMARK DATASET BETWEEN DSTC-SUM AND OTHER TECHNIQUES USING DIFFERENT PARAMETERS

Technique	Standard-Supervised	Augmented
DPP-LSTM [5]	38.6	42.9
SUM-GAN*sup* [6]	41.7	43.6
Li et al. [57]	43.1	–
M-AVS [58]	44.4	46.1
DHAVS [59]	45.6	46.5
SUM-FCN [9]	47.5	51.1
DSTC-Sum	**48.7**	**52.8**

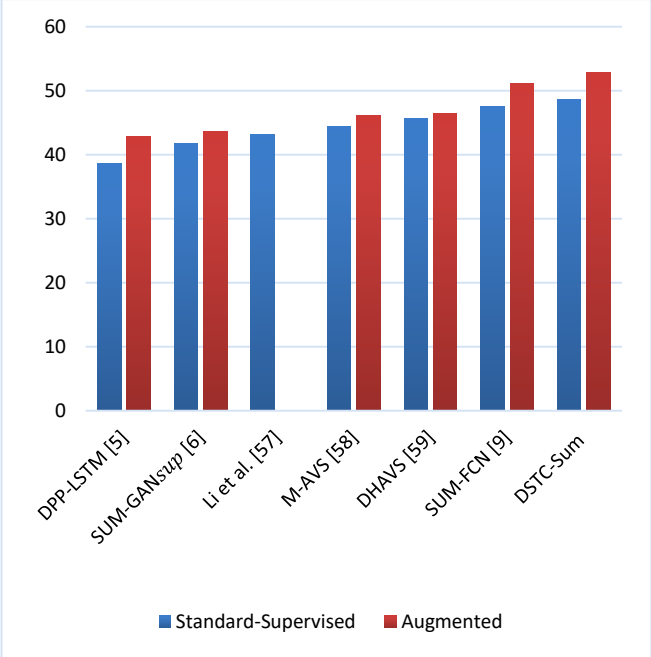

Fig. 3. Summarization performance (F-score) comparison on the SumMe dataset.

TABLE III. SUMMARIZATION PERFORMANCE (F-SCORE) COMPARISON ON THE TVSUM DATASET BETWEEN DEPTHTEMPORAL-SUM AND OTHER TECHNIQUES USING DIFFERENT PARAMETERS

Technique	Standard-Supervised	Augmented
DPP-LSTM [5]	54.7	59.6
SUM-GAN*sup* [6]	56.3	61.2
Li et al. [57]	52.7	–
SUM-FCN [9]	56.8	59.2
M-AVS [58]	61.0	61.8
DHAVS [59]	60.8	61.2
DSTCN-Sum	**61.2**	**62.9**

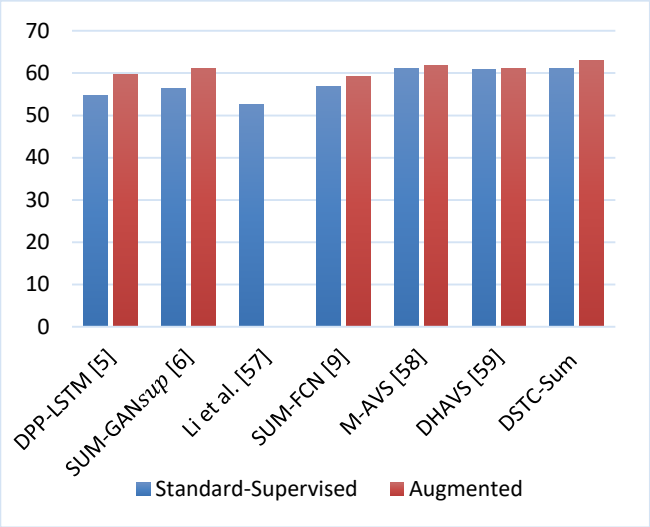

Fig. 4. Summarization performance (F-score) comparison on the SumMe dataset.

The DSTC-Sum methodology consistently demonstrates superior performance in video summarization tasks compared to existing state-of-the-art techniques. Its notable effectiveness, especially in augmented settings, indicates its high efficiency in improving summarization quality, as evidenced by the F-score metrics. The robust applicability of DSTC-Sum across different datasets further suggests its potential for wide adoption in video summarization applications. The implications of these findings are significant for the field of video summarization. By providing a method that consistently outperforms existing techniques, DSTC-Sum can enhance various applications, from creating more engaging video highlights for entertainment to improving the efficiency of video data management in professional and educational contexts. Moreover, the scalability and adaptability of DSTC-Sum means it could be integrated into various platforms and devices, including mobile applications and cloud-based services, thereby broadening its impact.

E. Extended Experiments

To further evaluate the effectiveness and generalizability of the DSTC-Sum model, we extended our experiments to include two additional benchmark datasets: YouTube and OVP (Open Video Project). These datasets were chosen due to their diverse content types, which pose unique challenges to video summarization models. By expanding our experimental scope, we aim to demonstrate the robustness of the proposed model across a broader range of video genres and characteristics. The DSTC-Sum model was fine-tuned on both datasets using the same configuration as in prior experiments. Specifically, the model architecture consisted of 10 Depthwise Separable Temporal Convolutional Blocks (DSTCB), with 4 depthwise convolutional layers per block. The Adam optimizer with a learning rate of 0.0005 was utilized, and the number of training epochs was adjusted based on the dataset size to prevent overfitting.

We applied data augmentation techniques such as random cropping and video flipping during training to improve generalization. Like the TVSum and SumMe datasets, the extracted frame-level features were fed into the model for training and evaluation. We benchmarked the model against several state-of-the-art video summarization models, including SUM-GAN, MS-TCN, and DPP-LSTM.

Table IV summarizes the YouTube dataset results. The proposed DSTC-Sum model achieved an F-score of 60.3%, outperforming the following best method, MS-TCN, which achieved an F-score of 58.6%. This improvement can be attributed to the model's ability to capture both long-term and short-term temporal dependencies, which is essential for summarizing the diverse content found in YouTube videos.

TABLE IV. PERFORMANCE COMPARISON OF VIDEO SUMMARIZATION METHODS ON THE YOUTUBE DATASET, MEASURED USING F-SCORE, PRECISION, AND RECALL

Technique	F-score (%)	Precision	Recall
DPP-LSTM [5]	55.2	54.8	55.7
SUM-GAN*sup* [6]	56.3	55.9	56.8
SUM-FCN [9]	58.6	57.9	59.2
DSTC-Sum	**60.3**	**60.1**	**60.6**

TABLE V. PERFORMANCE COMPARISON OF VIDEO SUMMARIZATION METHODS ON THE OVP DATASET, MEASURED USING F-SCORE, PRECISION, AND RECALL

Technique	F-score (%)	Precision	Recall
DPP-LSTM [5]	52.7	51.9	53.5
SUM-GAN*sup* [6]	56.3	55.4	57.0
SUM-FCN [9]	56.1	55.4	56.8
DSTC-Sum	**58.5**	**58.0**	**59.0**

Table V presents the results of the OVP dataset. Here, DSTC-Sum achieved an F-score of 58.5%, again outperforming the compared methods. With its more structured content, the OVP dataset benefited from the model's ability to capture long-range dependencies without losing important local features, a challenge that other models, such as SUM-GANsup, struggled with.

As shown in Fig. 5, the experimental results demonstrate the effectiveness of the DSTC-Sum model across both YouTube and OVP datasets. The model's ability to summarize videos of varying lengths and content types significantly influenced its performance in the YouTube dataset. The diversity in YouTube videos requires a model capable of understanding both global and local temporal structures, which is one of the key strengths of the DSTC-Sum model. On the OVP dataset, the model's performance highlights its ability to handle shorter, more structured videos. Compared to the baseline models, the improved F-score on this dataset shows that DSTC-Sum is particularly effective at summarizing videos with well-defined narrative structures, such as documentaries and educational videos.

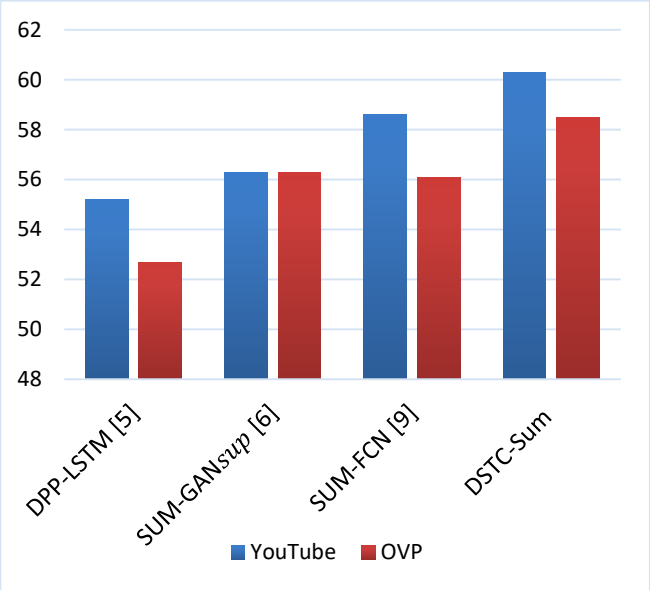

Fig. 5. DSTC-Sum model across both YouTube and OVP datasets.

The results on both YouTube and OVP datasets reinforce the generalizability and effectiveness of the DSTC-Sum model in video summarization tasks. The model consistently outperforms existing methods, demonstrating its ability to capture both long-term and short-term temporal dependencies. This makes it suitable for videos with diverse content (YouTube) and structured narratives (OVP).

The comparison across all datasets (TVSum, SumMe, YouTube, and OVP) indicates that the DSTC-Sum model is robust and versatile in different summarization tasks, whether the videos are user-generated content (YouTube), educational (OVP) or professionally curated datasets (TVSum, SumMe). The scalability and low computational cost of DSTCB architecture further emphasize its potential for practical applications, including real-time video summarization.

F. Qualitative Results

In addition to the quantitative evaluations presented in previous sections, assessing the DSTC-Sum model's performance from a qualitative perspective is essential. This section provides a deeper insight into how effectively the model captures important segments and generates accurate video summaries. We aim to demonstrate the model's ability to identify critical video moments by visualizing the extracted importance and ground truth scores. As seen in Fig. 6, we plot the extracted importance scores and the ground truth scores for two videos from the TVSum dataset to understand better how well our DSTC-Sum has learned. The important ratings derived from ground truth and the extracted scores generated by the suggested DSTC-Sum roughly match. Moreover, the proposed technique produces high-quality video summaries as users incorporate several factors that our DSTC-Sum considers relevant.

To further understand how effective our DSTC-Sum is, we showcase some video summaries that demonstrate its temporal modeling capabilities compared to SUM-GAN*sup* and DHAVS [57]. Fig. 7 illustrates that colorful bars indicate projected video summaries and sky-blue bars indicate ground truth scores. The segments selected as summaries by SUM-GAN*sup*, DHAVS, and DSTC-Sum are shown by the yellow, green, and red bars, respectively.

The DSTC-Sum technique produces high-quality video summaries by capturing temporal dependencies, allowing it to identify the most crucial video segments effectively. Comparisons of the summaries generated by DSTC-Sum with those produced by SUM-GANsup and DHAVS reveal that while other approaches often fail to select the most relevant sub-shots, DSTC-Sum consistently identifies key segments with higher ground-truth relevance scores. This ability to create accurate and relevant video summaries underscores DSTC-Sum's superiority in video summarization tasks.

Fig. 6. Video scores extracted by the proposed DSTC-Sum (bottom) and Ground truth scores (top) for video 4 and video 20 in the TVSum dataset.

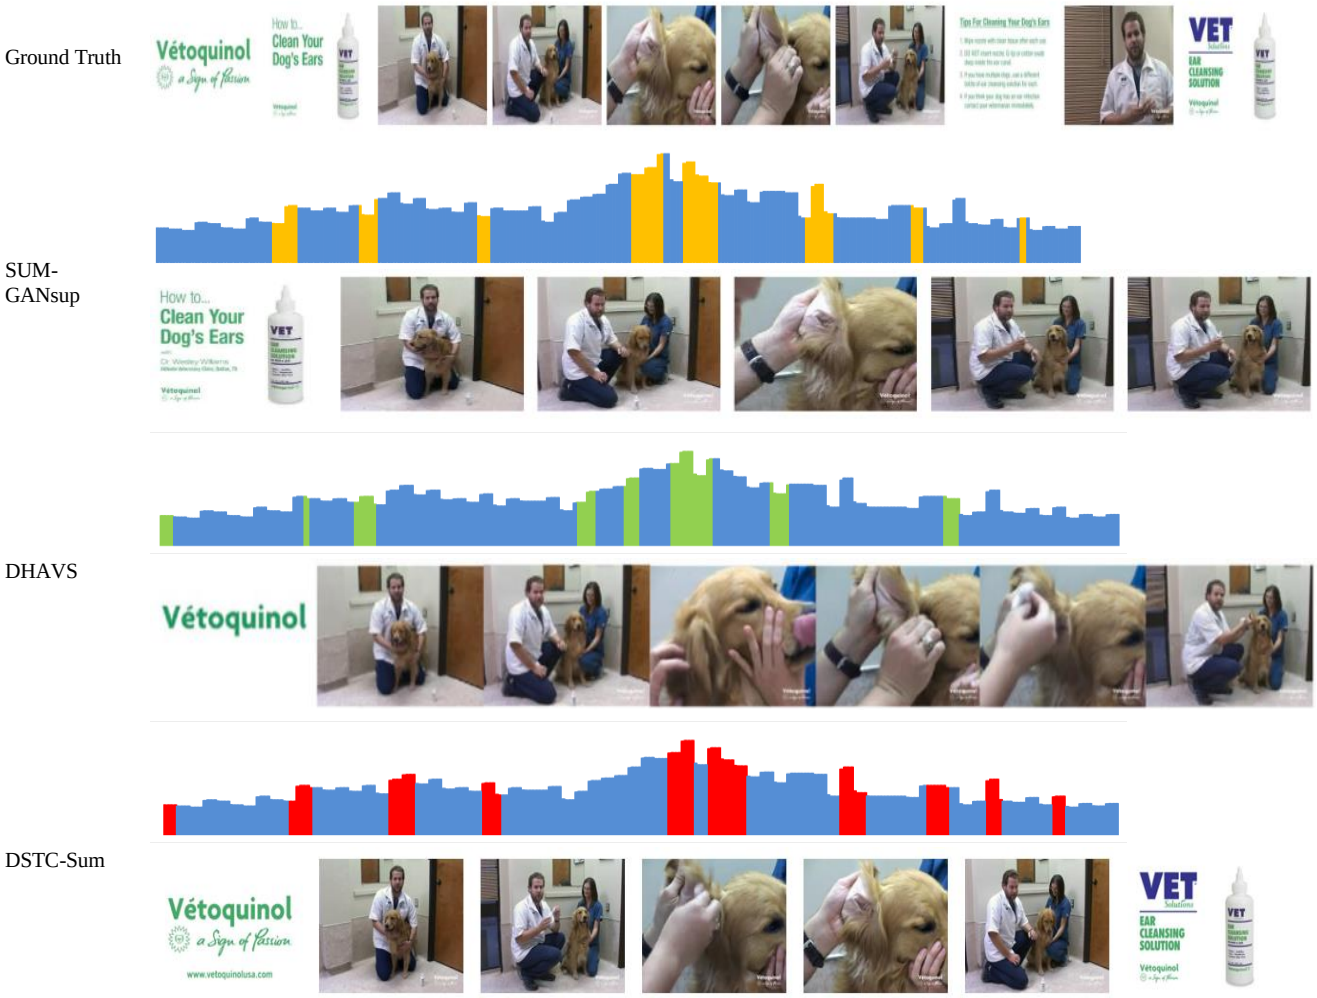

Fig. 7. Comparison of the extracted summary extraction for video 4 and video 20 in the TVSum dataset.

V. Conclusion

This study introduces DSTC-Sum, a video summarization model leveraging Depthwise Separable Temporal Convolutions (DSTC) to capture long-term temporal relationships and local features effectively. TCNs, unlike RNN-based models, allow for adding more layers while being computationally less expensive, faster to train, and lightweight. Furthermore, DSTC improves representational efficiency while being low-cost in computing and memory. Extensive experiments are carried out on two benchmark datasets, TVSum and SumMe. The outcomes demonstrate the efficacy of our DSTC-Sum model for supervised video summarization. Furthermore, the qualitative findings show that our model can produce fine-grained summary predictions and better scoring for each frame. To further assess the model's generalizability and robustness, we extended our experiments to two additional datasets: YouTube and the OVP (Open Video Project). On both datasets, the proposed model demonstrated superior performance, achieving F-scores of 60.3% and 58.5%, respectively, surpassing several state-of-the-art techniques. These results highlight the model's effectiveness in capturing long-term temporal dependencies and generating high-quality video summaries across various genres.

In the future, we plan to enhance the DSTC-Sum framework by integrating attention mechanisms to gain richer contextual information and improve summarization accuracy. Additionally, we will explore its potential in real-time video processing and personalized content creation, aiming to extend its application scope and solidify its position as a leading methodology in video summarization.

***Abstract*—Since the past decades, the data replication trend has not subsided; it is progressing rapidly from multiple perspectives to enhance cloud replication performance. Researchers are eagerly focusing on improving the strategies in various perceptions; unfortunately, the vulnerability in every strategy is inevitable. A non-comprehensive replica strategy would have vulnerability and drawbacks. The drawbacks that usually reside in the developed strategies are not limited to high network usage, high process time, high response time, high storage consumption, and more, depending on the research areas. Many researchers are out of ideas to identify state-of-the-art issues. This exhaustive taxonomic study focused on analyzing the diversified contributions and limitations terrain of the cloud replication environment, focusing on data placement strategies. It seeks to delve deeply into its fundamental strategy, practical implementations, and the intricate challenges it poses. Concerning the imminent cloud-driven future, this structured review paper is a vital resource for researchers, policymakers, and industry professionals grappling with the complexities of this emerging paradigm. By illuminating the intricacies of data replication strategies, this study fosters a deeper appreciation for the transformative potential and the multifaceted challenges ahead of cloud data replications.**

***Keywords*—Cloud environment; data replication; placement strategies; replication taxonomy; performance metrics**

I. Introduction

An enormous amount of data is used extensively in the current era globally [1]–[3]. According to the International Data Corporation (IDC), global data will increase by 61% to 175 zettabytes by 2025, with most of that data being stored in cloud computing environments rather than data centers. This phenomenon is derived from the most interconnected Internet of Things (IoT) devices, leading to 100 billion terminals connected in 2025 [4], [5].

A. Cloud Computing

Cloud computing is well known as a data management platform that addresses the high volume of data demanded to be accessible by users anytime from anywhere [6], [7]. Cloud computing offers users a dynamic pricing model since it enables multiple services such as Software as a Service (SaaS), which provides real-time application services, Platform as a Service (PaaS), which delivers various operating systems, Consistency as a Service (CaaS), which promises data consistency in storage nodes, and Infrastructure as a Service (IaaS), which provides many hardware solutions to users as an on-demand basis [8]–[12].

Cloud computing offers users a "pay-as-you-go" basis since it enables multiple services, as shown in Fig. 1. The hardware resides as the fundamental facility in cloud computing architecture. The IaaS is the bottom layer in cloud services, which offers various large-scale infrastructure services with multi-specification of servers, CPU, memory, storage, and more. In the middle layer is PaaS, which enables numerous platforms like operating systems and software frameworks that can be tailored based on clients' required environments. The top layer is SaaS, which is directly accessible to users with multiple applications such as web services, user interface systems like enterprise systems, and many more [13]–[15]. In the IaaS layer, the foremost benefit received by cloud users is the agility of the services. Cloud providers serve their clients by off-loading the hustle of managing the data center. Therefore, clients can freely focus on evolving their business [16].

Consequently, it improves the ability to meet user demands and reduce costs as the user can provision the resource amount accordingly [17]. Cost-saving is the most significant benefit a cloud tenant gains, as the pay-as-you-go paradigm reduces expenses on the overall data center maintenance cost. This foreseen cost can be a transition to operational expenses, vividly beneficial for business goals. Additionally, the SaaS layer delivers rapid deployment of client applications around the globe with only a few clicks [11]. PaaS enables the deployment of the necessary software applications, while SaaS, as the top layer, provides users with ready-to-use applications [13], [18]. These benefits have been the core reasons that drive users to choose the cloud as their data management platform.

B. Data Management

Data management is one of the prominent services enabled in cloud platforms. As a mass platform to serve high-volume data, the cloud is a multi-device technology that enables data management in a few deployment models: private cloud, public cloud, community cloud, and hybrid cloud. However, cloud tenants must choose an appropriate cloud model because every cloud model is distinguished depending on data criticality and resources [19]–[22]. Cloud providers need technical and business knowledge to propose the best model for organizations to ensure cloud tenants obtain efficient data management services. Comprehensive data management solutions are

delivered to cloud tenants in the respective models, including data processing, security, storage, and recovery services.

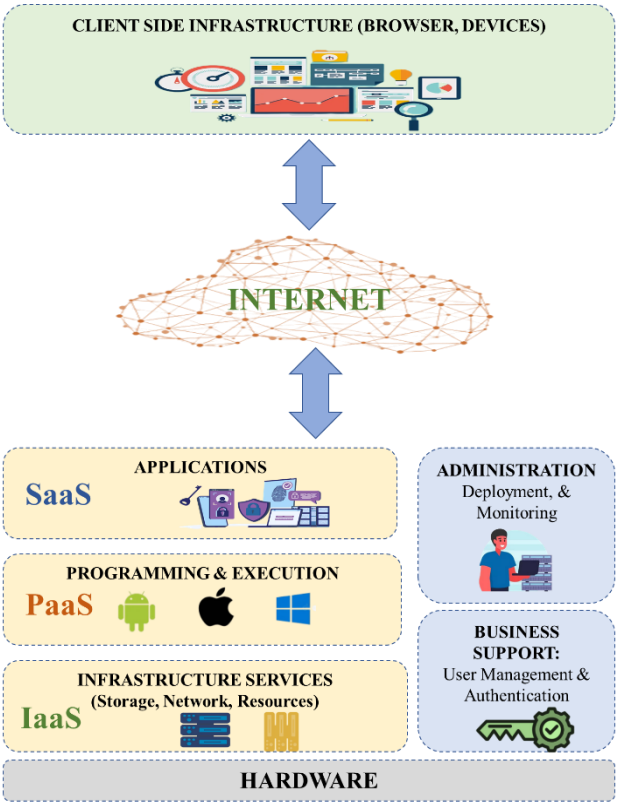

Fig. 1. Basic cloud computing architecture.

C. Data Recovery

Data Recovery must be adopted in any platform, including cloud environments [23]. The researcher in study [24] focused on data recovery in their study, whereby the researcher accentuated that the importance of data recovery is intolerable because the ambiguities of data absence are extremely anticipated in cloud platforms. Additionally, the researcher emphasizes that data recovery or failover costs are crucial before implementing cloud models. Therefore, the cloud as a data management platform has prepared data recovery mechanisms such as data backup, replication, and checkpointing [25]. The available approaches are playing different roles based on different circumstances.

D. Data Replication

Data replication is recognized as a promising cloud environment service that offers strategies to keep data in secure environments [25] safely. Data replication is defined as a heuristic multi-dimensional technique that saves one or more copies of data in multiple storage nodes in clouds [26]–[28]. According to study [29], data replication preserves the master data from catastrophic events (floods, earthquakes, etc.) and human errors, such as accidentally deleting information in the master files or deleting entire master files by users. The middleware manages replica copies in different environments known as disaster recovery centers. Therefore, copies of data are managed and kept safe in different nodes at different places. Thus, any unfortunate incidents that happen to the replicas would not affect the other replica copies. This would prevent data loss in any environment. Data replication is identified as a strategy that creates multiple copies in cloud storage in a big data environment, accelerating cloud system performance [29]–[31].

Replication strategies are commonly divided into two (2) mechanisms: static and dynamic data replications [32]–[34]. Static replication is a predetermined environment for dedicated cloud replication systems [14], [27]. The number of nodes, number of replicas, and many other architectures are fixed based on certain cloud system necessities before the replication strategy is implemented [35], [36]. The second mechanism is dynamic replication, or flexible replication strategies, where the algorithm can automatically create and delete replicas depending on the system users' access patterns [37]. However, the static replication mechanism is relatively simple and not preferable to be adapted in many cloud replication environments. The architecture is mainly foreordained, sometimes unsuitable for complex cloud replication systems [38], [39].

According to literature perceptions, a comprehensive cloud replication strategy always has a few significant phases; the first phase is usually the File Selection Strategy, which is to identify crucial data to be selected as replication candidates. The next phase is the Data Placement Technique, where the required number of replicas is identified, and the location to send the replicas is determined. Finally, the Data Center Selection Method is the stage to accomplish the replication process by identifying the best factors to select appropriate nodes to store the replicas in the cloud replication environment. Every stage complements different requirements. Researchers have the right to consolidate every phase in one research work as a complete replication process or develop every phase separately as fulfilments in respective research works. This research focuses on data placement strategies and factors in placing replicas in cloud environments.

A typical replication management architecture for a cloud environment is illustrated in Fig. 2.

Fig. 2 demonstrates a basic replication architecture in a cloud environment. Users in the architecture are also recognized as clients or tenants for cloud providers. The replication process is triggered when a user requests a data file from the cloud. A Global Replica Manager (GRM), typically the broker, manages and schedules replication tasks in the whole infrastructure. Conversely, the Local Replica Manager (LRM) manages local or inbound replication jobs for data centers. Usually, data centers are grouped in clusters, depending on the configuration of the cloud replication. The GRM and LRM must continually adhere to the rules and protocols in the algorithm specified in the replication system. The data file verification will occur when the manager receives user data requests. File information such as file names and locations are available as a comprehensive metadata table in the GRM and LRM. Then, the managers process the requested data according to the algorithm rules and identify candidate files for replication. The requested data file will be sent off to users, and new replica copies will be placed, conferring to the pre-determined placement technique in data centers.

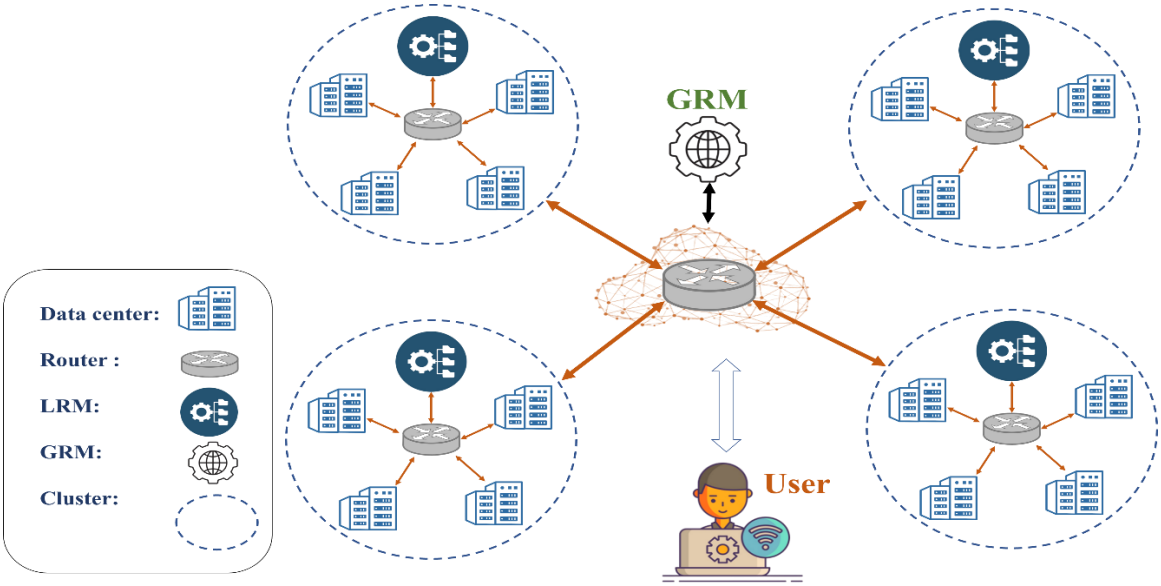

Fig. 2. Basic data replication architecture.

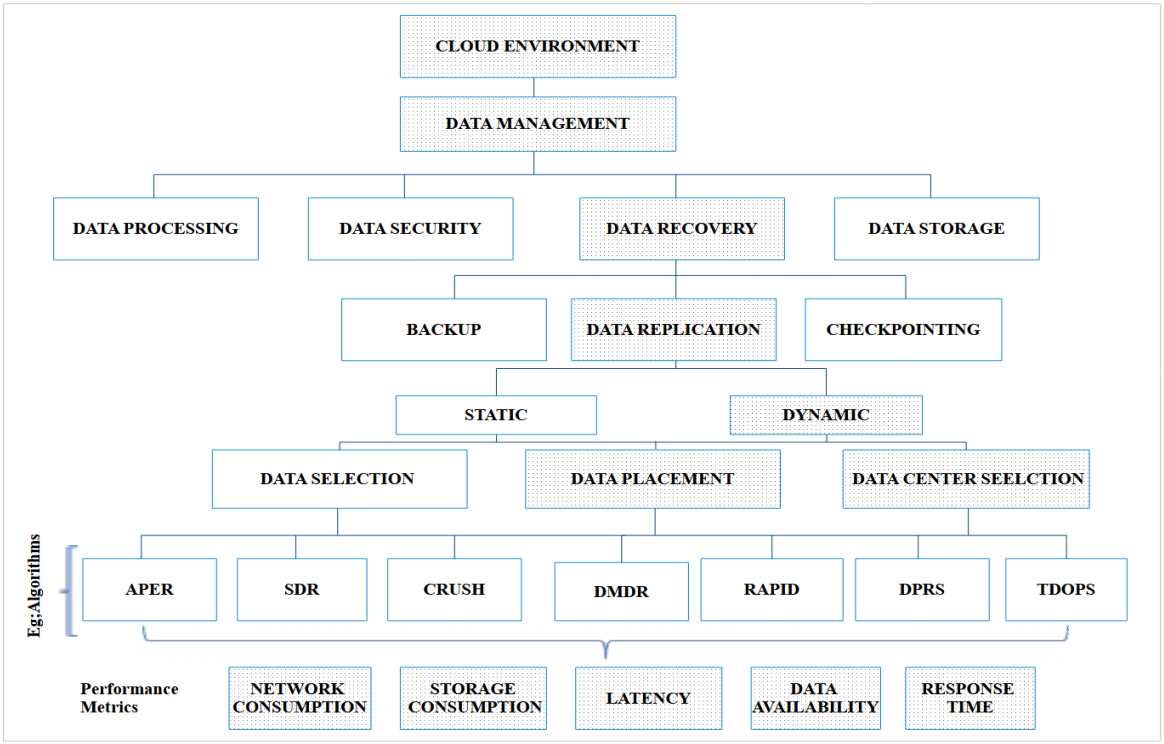

Fig. 3. Cloud replication taxonomy.

According to study [40] the taxonomy study can make the knowledge found in documents and texts clear and usable by other researchers also practitioners. Fig. 3 illustrates the data replication taxonomy in a cloud environment, which can be discovered in this study. This entire study is structured and organized as this taxonomy. The shaded boxes are the main focus of this study.

This taxonomy-based study thoroughly discusses similar studies related to this research area. The topic was explained and drilled down from top to bottom of the taxonomy, deriving the dedicated research area.

A taxonomy study on cloud computing is described, followed by the definition and overview of data management until the data replication body of knowledge.

A thorough discussion on existing research works in data replications and placements strategies with insights on contributions and achievements in numerous performance metrics enhancement.

Analysis tables and relevant analytics graphs are presented to share the essential details of related research works according to the research questions, highlighting research trends, contributions, and limitations.

II. Related Works

The advent of cloud computing has revolutionized how data is stored and managed. A critical aspect of cloud computing is data replication which involves creating and maintaining multiple copies of data across different locations to ensure high availability and reliability [41], [42].

Cloud computing empowers users with various resilient services that stand vibrantly as preferable technology for almost everyone to ensure data are efficiently managed and business continuity is guaranteed too [43]–[46]. However, cloud computing as a reliable multiple-service provider is not exceptional in facing issues in providing high data availability to users while preserving data sensitivity. Fear of losing data during node failures is one of the core issues too [2], [11], [39], [47].

Hence, to mitigate the concerns that arise in a cloud platform, data replication is recognised as a promising cloud environment strategy [4], [7], [48]–[50]. Data replication is an empirical technique to accelerate system performance by generating identical data copies across multiple storage [51], [52]. Precisely, in a cloud environment, data replication is defined as creating several physical copies for every logical data item and locating the replica copies in different sites or storage nodes [36], [53], [54]. Depending on the cloud replication objectives, there are several ways to apply the data replication function.

There are two (2) prominent traditional techniques in cloud replication. First is static replication, where data copies are pre-determined and evenly distributed across nodes to ensure fault tolerance and load balancing. However, static replication may not adapt well to dynamic workloads and changing data access patterns. Dynamic replication dynamically adapts the replication scheme based on data access patterns and system conditions. These approaches aim to improve data availability and reduce access latency by dynamically creating or removing replicas as required. Dynamic replication techniques often utilize monitoring and feedback mechanisms to make informed decisions about replica placement [55], [56].

A taxonomy study is the structured names and definitions used to organize information and knowledge. Researcher in study [57] proposed a broad taxonomy of storage efficiency, with the performance metrics focused on cost optimization. The other research work by [58] introduces a taxonomy that organizes existing solutions for maintenance operations in cloud, edge, and IoT environments. This research work does not discuss any performance metrics yet; it merely reviews existing research work according to the taxonomy structure and presents the challenges within the research field. Similarly, [59] examines the migration field's characteristics and proposes a management-centric taxonomy in cloud computing. Researchers [60] and [61] embarked on cloud replication strategies and presented relevant taxonomy related to this research area. However, their studies proposed a very high-level taxonomy for this body of knowledge, which is not comprehensive enough to overview the entire structure of data replication processes in a cloud environment.

As enormous technologies are emerging extensively around the globe, many new approaches, such as artificial intelligence (AI), have been discovered as compatible techniques for replication strategies in cloud environments. Hence, researchers are continuously attempting novel replication strategies to place replica copies in cloud storage that provides multiple key services with resilient infrastructures for every cloud consumer [61], [62]. The cloud computing architectures, standards, and tools provide prospects for advancement in services, which offer various benefits to cloud clients [22], [63]–[65].

Thus, recent research works incorporated AI-based approaches in replication strategies to breed performance enhancements [66]. As such, similar studies like [67] and many state-of-the-art studies must not be overlooked and must be visible for future researchers' knowledge. In this context, there is still a lack of studies that present comprehensive surveys to produce a widespread taxonomy related to replication strategy in cloud environments. These limitations of the existing research motivated this study to produce a comprehensive taxonomy for data placement strategies in cloud replication environments. The taxonomy offers collections of replication strategies that allow cloud providers to scrutinize and implement them in real-cloud replication settings. Further, cloud providers would serve accelerated performance to users with better data availability, faster response time, low fault tolerance, reduced storage usage, and efficient network usage [28], [37], [68]–[70].

III. Method and Materials

This taxonomy study mainly explores the existing literature to investigate the coverage of multiple related topics, the research trends, and the critical review of relevant studies that have been published. The methodology implied in obtaining the source papers in this study mainly follows the guidelines suggested by [71]. According to study [40] the taxonomy study can make the knowledge found in documents and texts clear and usable by other researchers also practitioners. The guidelines for this study follow the essential steps of defining the research questions, searching for relevant papers, screening the papers, keywording the abstracts, extracting the data, and mapping. Each process step has an outcome, and the outcome of the complete process is the taxonomy mapping.

A. Research Questions (RQ)

1) Definition of research questions (Research Scope): The primary goal of a taxonomy study is to provide an overview of a research area and identify relevant research also results available within this field.

2) The Primary RQ of this study: ‘What are the Data Placement Strategies in a Cloud Replication Environment?’ This primary question was divided into four RQs. Table I lists the formulated RQs.

B. Data Sources

1) Search for primary studies (all papers): Primary research was found using keyword search terms on scientific

databases or by personally looking through pertinent journal articles or conference proceedings.

2) The primary data Sources: Scopus online databases were primary data sources for potentially related studies. Other data sources were not considered to impede the overlapping of source results.

C. Search Terms

1) Keywording of abstracts (classification scheme): Keywording is a way to reduce the time needed to develop the classification scheme and ensure that the method considers the existing studies.

2) Search the related research effectively: It is imperative to identify the pertinent search phrases. Kitchenham *et al.* [72] suggested population, intervention, comparison, and outcome (PICO) approach is fitting in this regard. Many review papers have broadly adopted these viewpoints. Here, the relevant PICO terms are listed:

- Population: Primary studies in Data Replication.
- Intervention: Placement strategies.
- Comparison: Strategies, Advantages, limitations.
- Performance metric, and future direction.
- Outcome: Placement Strategies, Advantages, and constraints in cloud replication environments.

D. Inclusion and Exclusion Criteria

1) Screening of papers for inclusion and exclusion (relevant papers): Studies that were irrelevant to addressing the study issues were eliminated using inclusion and exclusion criteria.

2) Inclusion and exclusion criteria: applied to determine and discard relevant studies from the data sources to answer the RQs in this taxonomy study.

3) Data extraction and taxonomy mapping of studies: Once the classification scheme was in place, the relevant articles were discussed according to the structure.

E. Research Questions (RQ)

1) Definition of research questions (research scope): The primary goal of a taxonomy study is to provide an overview of a research area and identify relevant research also results available within this field.

2) The Primary RQ of this study: 'What are the Data Placement Strategies in a Cloud Replication Environment?' This primary question was divided into four RQs. Table I lists the formulated RQs.

As shown in Fig. 4, a literature search was done using the keywords "(replication OR placement AND strategies AND in AND cloud), (replication AND strategies AND in AND cloud), (Data AND Replication OR placement AND strategies AND in AND cloud) identified 1,057 initial articles. A three-step screening process ensured high-quality and relevant studies. First, 399 articles were excluded for lacking peer-review or being in a language other than English. The second screening focused on article completeness, removing 399 articles lacking full text (available only as abstracts or presentations) or not directly relevant to cloud replication strategies. This left 258 articles for further evaluation. Finally, a rigorous selection process focusing on data placement strategies within cloud replication resulted in a final set of 25 anchor references for in-depth analysis. These principles were employed in all the studies retrieved during the different phases of the study selection procedure (see Table II)

TABLE I. RESEARCH QUESTIONS

RQ	Research Question	Motivation
RQ1.	What are the publication trends for research topics related to cloud data replication environments?	To investigate publication trends in this research field throughout recent years
RQ2.	What are data placement strategies and factors employed in existing research works?	To explore cloud replication strategies in state-of-the-art
RQ3.	What are the performance metrics that contribute to the enhancement of replica placement strategies in cloud replication environments?	To discover performance enhancements addressed in individual research
RQ4.	What are the common limitations across existing research on data placement strategies in cloud replication environments?	To gain the gaps in existing research that can guide future research explorations and improvements

TABLE II. INCLUSION AND EXCLUSION CRITERIA

Inclusion criteria	
IC1	Articles that are peer-reviewed
IC2	Articles providing research in Cloud Replication Strategies
IC3	Articles published from 2017 to 2024
Exclusion criteria	
EC1	Articles that do not meet the inclusion criteria
EC2	Articles without full text (only abstract or presentation)
EC3	Studies in languages other than English
EC4	Articles with unclear results or findings

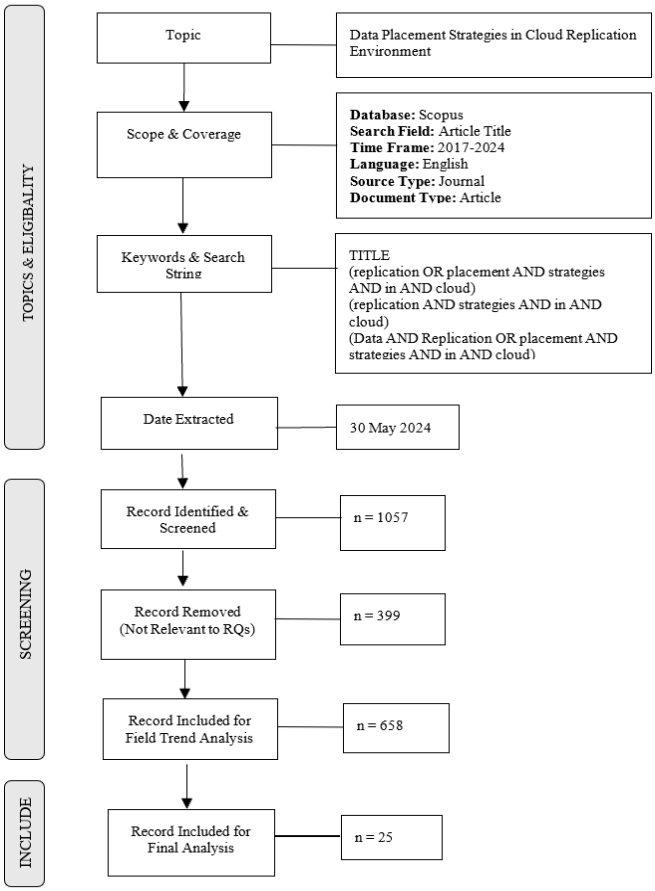

Fig. 4. Search strategy flow diagram.

IV. Findings and Discussions

A. RQ1: What are the Publication Trends for Cloud Data Replication Environments Research Topics?

Fig. 5 presents the publication trends in data placement strategies in cloud replication environments across six prominent journals and conferences from 2017 to May 2024. The data indicate significant growth in this research area, reflecting its increasing importance in cloud computing. The publication venues examined include Lecture Notes in Computer Science (LNCS), IEEE Access, Cluster Computing, Journal of Supercomputing, Future Generation Computer Systems (FGCS), and IEEE Transactions on Cloud Computing (TCC).

The total number of publications on data placement strategies in the Scopus online database from 2017 to May 2024 across all publication outlets is 658. The distribution of these publications among the six venues reveals distinct trends.

- Lecture Notes in Computer Science (LNCS) publications have increased from six papers in 2017 to 32 papers by May 2024. This represents a total of 175 publications, accounting for approximately 26.60% of the total publications.
- IEEE Access shows a significant rise from two papers in 2017 to 29 papers by May 2024, resulting in a total of 136 publications, which is about 20.67% of the total.
- Cluster Computing publications in *Cluster Computing* grew from 0 in 2017 to 26 by May 2024, with a total of 93 publications, making up around 14.14% of the total.
- Journal of Supercomputing starting from no publications in 2017 to 24 by May 2024, the *Journal of Supercomputing* accumulated a total of 110 publications, about 16.72% of the total.
- Future Generation Computer Systems (FGCS) publications increased from 3 in 2017 to 19 by May 2024, totaling 79 publications, approximately 12.01% of the total.
- IEEE Transactions on Cloud Computing (TCC) grew from no publications in 2017 to 19 by May 2024, amounting to a total of 65 publications, which is about 9.88% of the total.

The analysis of publication trends from 2017 to May 2024 illustrates a significant and growing interest in data placement strategies within cloud replication environments. This proves the evolving landscape in data placement strategies research, providing a foundation for future studies and developments in this pivotal area.

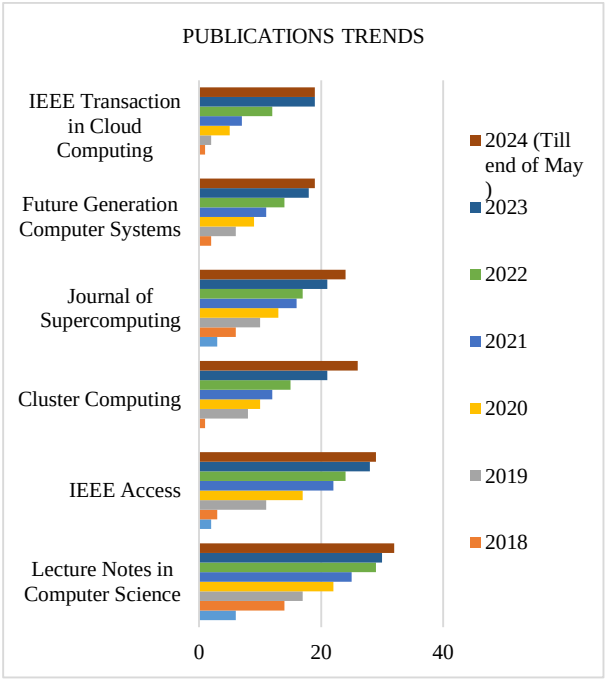

Fig. 5. Publication trends.

B. RQ2: What Data Placement Strategies and Factors are Employed in Existing Research Works?

1) Data placement strategies: Abundant studies cohesively developed numerous strategies to place replicas in the replication storage. At this point, scholars usually innovate a novel strategy to decide how to replicate the desired data, how many replicas are needed, and where to place the replicas [73]. the data placement method usually emphasizes the goal of accomplishing a cost-effective method with minimal storage

consumption, high data availability, optimal replica copies, faster replication time, etc.

a) Low response time: A heuristic data replication and placements introduced by the authors [74] evaluated big data analytics queries in a distributed cloud. The researchers placed the source data of queries at multiple geo-distributed data centers. This technique ensured that the respective queries were locked with certain trial counts until they reached the specified threshold. The query will be passed to the next replica for a response. Another focus of this study is to place a sample of source data at appropriate data centers to meet users' rigorous query response time. The aim here is to minimise the evaluation cost while the response time is accelerated.

b) Low response time, low cost and low resource: Another group of researchers [75] developed a data replication strategy that mainly fulfils cloud tenants without neglecting cloud provider profits; the strategy was named Achieving Query Performance in the Cloud via a Cost-effective Data Replication (APER). The study proposed a cost-effective replica placement strategy that improves database queries with specific estimations to attain better response time. To achieve the desired response time, this study pre-determined that a particular replication time must be less than one particular service level objective (SLO) response time threshold. Later, replicas were placed using heuristic techniques that reduced both resource usage and monetary cost. The APER places new replicas by discarding previous copies from the cloud only if the threshold of access history is reached. As claimed by the researcher, the response time was successfully reduced in this study.

c) Low response time and low storage: The redundancy rate is another issue that can be rectified with comprehensive data replication. A group of researchers was dedicated and solved this problem by proposing a Time Series-based Deduplication and Optimal Data Placement Strategy (TDOPS) in their study [76]. Deduplication techniques were deployed, and data placement was determined based on capacity constraints, cloud data center load balance, and data transportation costs. The researchers in this study achieve improvements in space reduction, efficient retrieval, data transportation costs, and data transmission time.

d) High data availability: The Controlled Replication Under Scalable Hashing (CRUSH) algorithm has been improvised by the researcher [77] to resolve the bottleneck issues of the previous CRUSH. In the last CRUSH algorithm, replicas were inconsistently segregated in available storage nodes. The older version of CRUSH persistently sent generated replicas to the same active servers, consequently degrading the performance in the replication system due to a long queue to retrieve replicas, thus concurrently contributing to network congestion. The enhanced CRUSH algorithm [77] is recognised as a data placement technique capable of dynamically obtaining data at the next available replica place when the first requested replica is pending in response. In CRUSH, the proposed replication architecture to place data is the RING topology, where the direction to entertain user requests on data is more structured and bidirectional. As claimed in this research, the improved CRUSH method outstrips the previous studies in better data availability.

e) High data availability and low cost: Improving Clustering Based Critical Parent (CbCP) with a Replication (ICR) algorithm was proposed to address performance enhancement on replica placement scheduling [78]. The ICR consists of three sub-algorithms: scheduling algorithm, starting replication tasks, and task replication algorithm is used to identify any available resource until replica placement. The key aim of this study is to identify the possible and earliest time to start every replication task using the available resources without adding extra cost. Data reliability increased in this research, and execution costs were reduced significantly.

f) High data availability and low latency: A study by [79] offers an Artificial Bee Colony technique for data replication optimization in cloud environments. Another researcher suggests a multi-objective optimization data placement model based on numerous data replicas in a hybrid fog-cloud environment [80]. The articles suggest that AI can help minimize latency and improve data location.

g) Low cost and low latency: The researcher [81] proposed cost-effective, dynamic data placement, consisting of greedy and dynamic algorithms used to find the most reasonable cloud data placement solution. The greedy approach can find the optimum number of appropriate data centers to replicate the user's most accessed data. This study aims to deliver dynamic and optimised data placement with tolerable latency while incurring minimal service costs in social networks like Facebook. The proposed data placement strategy will determine the necessity of replica creation and choose the best data centers to place new replicas in the nearest data center for every user with minimal latency. The researcher aimed to reduce storage and latency, while the monetary problem was also addressed.

h) Low cost and low storage: Researcher in study [82] focused on financial cost reduction with good data consistency is the research objective attained by the researcher. The researcher proposed a Dynamic Replica Placement Strategy to satisfy the user experience while reducing the storage overheads, eventually contributing to cost reduction. The researcher implied a node renting concept to fulfill the capacity of the edge cloud to address the overload problem. Rented nodes are used whenever users in edge computing suffer low performance and release a rented node from the cloud during the users' stable performance. Therefore, this strategy evidenced that total financial costs were saved, and user experience was sustained during the replica placement phase.

i) Low cost, low storage usage, and efficient network: A dynamic data replication management technique was combined with a novel data placement strategy in the research work of [83]. The main goal was to reduce the network usage and costs associated with data transfers between data centers. Similarly, researchers [86] proposed Initialization Scheme-Based GA (ISGA) with a primary focus on reducing storage and network utilization costs. The study adopted an interval pricing technique to choose the best location for data in a multi-cloud environment.

j) Low storage: A Dynamic Redundant replica strategy based on the Security Level (SL-DRM) was proposed [84]. It flexibly adjusts the number of replicas and places the replica via constructing the data cache strategy using the Location Correlation of Cache (LC-Cache) to improve data read speed. The most crucial video footage was re-duplicated and saved in the storage. Therefore, as better security is required, the proposed technique dynamically changed the influence factors and instructed the algorithm to place new copies of video footage for a particular area. Thus, the data cache strategy focuses on the cameras' locations and time correlations of the video files by predicting the users' playback behaviors. This strategy achieved low storage consumption with a limited number of video copies.

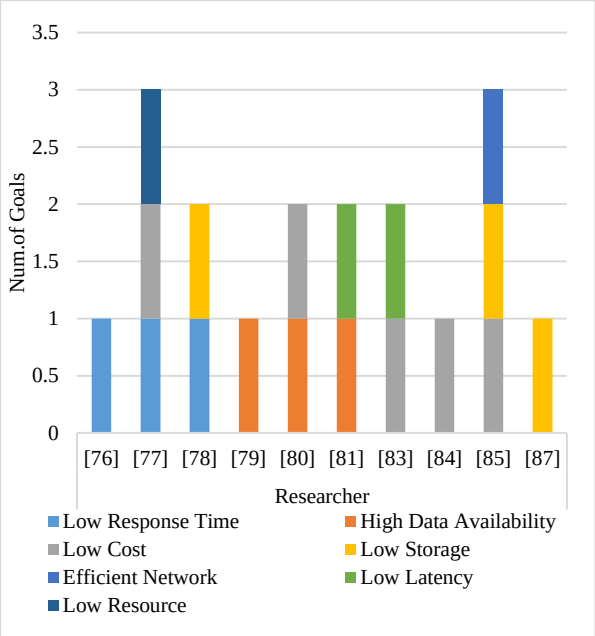

Fig. 6. Various goals achieved.

Fig. 6 is the bar chart that summarizes the key features and goals achieved by the various data placement strategies as discussed in this subsection. Each bar represents the number of goals achieved by a specific strategy. The strategies are listed along the x-axis, and the number of goals achieved is represented on the y-axis. The different colors indicate which specific goals are achieved by each strategy. This visual representation helps to quickly understand the focus and effectiveness of each strategy in achieving key performance and efficiency metrics.

2) Data placement strategies with data center selection factors: Data center selection is another significant method to place replicas in the cloud replication system process. This method is frequently integrated with the data placement process in almost every replication strategy. However, it is a considerable critical portion of accomplishing the replication process, whereby essential factors are determined to select the appropriate data center and storage to store replica copies. Therefore, researchers developed numerous methods to ensure a suitable location was identified. Usually, researchers determine a few factors to ensure the best data center has been determined to place the replica copies. The proposed factors or parameters directly affect various performance enhancements, in cloud replication environments [73]. Subsequent discussions will be categorized based on the number of factors employed in the respective research works.

a) Six factors: The Fuzzy Self-Defence Algorithm (FSDA) was proposed by study [85], which focused on a novel data center selection method. The FSDA determines the optimal number of replicas without degrading performance by implying a prey-predator model based on a fuzzy system to reproduce communication between prey and predator populations. The input parameters included in the fuzzy inference are system availability, service time, load, energy consumption, latency, and centrality. The researcher introduced several formulations to obtain merit values evaluated to determine the best nodes to place replica copies. The study claimed to improve hit ratio, energy consumption, and availability.

b) Five factors: A similar objective was achieved by [48] via producing a comprehensive algorithm named Cost Function based on an Analytic Hierarchy Process for data replication strategy (CF-AHP). CF-AHP is a multi-criteria optimization model that addresses cost-effective replica placement strategies that reduce energy consumption in data centers in cloud replication environments. The cost function is deployed to determine the best data center candidates to place newly generated replicas. The data center selection criterion consists of mean service time, access rate, latency, load variance, and storage usage. In the computation, weights are deployed to facilitate the user's task of determining system needs in respective parameters. The study achieved its goal of saving energy usage in its architecture.

In the same year, the author discovered an enhanced idea by proposing two (2) different Multiple-Criteria Decision Analysis (MCDA) approaches to determine the best data center to store replicas [86]. The first approach is to choose the best candidate site, and a cost function is computed using the weightage relationship concept in multi-criteria optimization known as AHP (Analytic Hierarchy Process). The second approach is ELECTRE-I, which consists of three (3) crucial stages; introduction of weight of criteria and calculation of concordance indices, calculation of the discordance indices, and over-ranking correlations. The criteria are further calculated using a weightage sum to obtain the values used to distinguish among available data centers. This study's data center selection criterion induces cost function calculation using AHP to acquire data center merits. The criterion consists of mean service time, access rate, latency, load variance, and storage usage, as adapted from another study by [87]. The respective criteria are computed using dedicated mathematical formulations. Results in this study evidenced that the cost function is sufficient to identify a candidate data center to place the replicas. The data center with the lowest cost value function is chosen to store the replica copies. Furthermore, when the system has insufficient space in storage nodes, replacement strategies are anticipated in this research work. This data center selection criteria method has

attained efficient bandwidth usage and minimized data movement.

Another researcher developed a novel intelligent approach for dynamic data replication in a cloud environment [88]. The proposed algorithm in this research is bio-based. The first is the Multi-Objective Particle Swarm Optimization (MO-PSO), which selects a replica depending on the most requested. Second is the Ant Colony Optimization (MO-ACO) to retrieve the best replica placement decision. A data center selection criterion was used in this study using MO-ACO through comparing individual data centers based on the shortest distance, data centers with high access, storage capacity, and output, and data centers with a high number of hosts and VMs. All factors were compared, and the best data center with the highest data availability was selected to store replica copies. The study achieved betterments in replication cost by accelerating the response time and replication time and succeeded in enhancing network usage efficiency.

c) Four factors: In the same year, [67] proposed a CSO-based approach for Secure Data Replication (SDR) that uses fuzzy inferences to select the best data center to place replica copies. The data center selection criterion trained in the fuzzy inference is fewer than FSDA and centrality, energy, storage usage, and load. The best data center is selected via a fuzzy approach, and the data is chucked into a few segments to place in a few different storage nodes based on data center capacity. The parallel downloads can reduce download time and security because data files segregated in a few chunks in diverse data centers will not be meaningful if attackers compromise either one of the servers or data centers in cloud replication.

Another researcher focused on addressing optimization problems in a cloud replication environment [50]. The researcher enhanced the ant lion optimizer (ALO) algorithm and a fuzzy system by introducing a heuristic ALO (HH-ALO-Tabu). The proposed algorithm works dynamically in selecting the primary population based on chaotic maps (CMs), opposition-based learning (OBL), and random walk strategies depending on the differential evolution (DE) algorithm. The placement of replicas is based on four key parameters: service time, system availability, load variance, and providers' expenditures. With the key parameters, the selection of the best data center is determined, and replicas are placed accordingly. The study effectively guaranteed the cloud providers' economic revenue hands increased the users' satisfaction in upgrading the performance in cloud replication environments.

d) Three factors: Dynamic Popularity-aware Replication Strategy (DPRS) [89] constitutes a data center selection method to determine the best data center. The data center selection method is the final contribution to the research work, and it was implemented in every cluster with consideration of several significant factors. The factors are the number of file requests, storage availability, and data center distance. Each factor is computed to obtain average values in this phase, called data center merit. In this study, the weightage concept was adapted in the data center merit computation, whereby system administrator intervention was required to identify the necessary weights according to the system goals. Once the best data centers are determined, the candidate file is chunked to certain data block sizes and sent to a predetermined number of distributed storage nodes. DPRS attained efficient network usage with a parallel download concept and reduced replication frequency with the proposed data center selection method.

e) Two factors: Researchers proposed a replication placement and replacement technique with fuzzy-based deletion (HRS) for heterogeneous cloud data centers [90]. The study goal was to preserve storage space and enhance network efficiency. Thus, HRS ascertains the data center merit approach by considering a few significant parameters, such as the number of accesses and centrality with weightage for each parameter before the replica in storage nodes. The researcher selected a data center based on the temporal locality concept. Therefore, the data center with the highest access is considered in this study as closeness centrality. Subsequently, this researcher introduced the factors and computation to identify the lowest total cost provider. Additionally, HRS introduced fuzzy inference in the replacement strategy, which has insufficient space to store new replicas during storage. Therefore, the developed fuzzy algorithm will clarify existing files in other nodes and the last access history of a specific replica and predict future access to the replica. The researcher proved this by conducting beneficial experiments to address storage imbalance, insufficient response time, and high network usage.

Researchers [8] proposed Data Mining-based Data Replication (DMDR) in their research, which used data center selection criteria to select the best data center in the cloud replication environment. This study improvises storage utilization by introducing two (2) criteria; most central and the number of accesses. An accumulation using closeness formulation by [91] was adopted in DMDR. The weightage is used in the formulation, ensuring the system administrator has the authority to fulfill the system objective accordingly. Finally, if the data center does not have adequate storage space, the replacement strategy will be applied to delete unnecessary replicas based on predetermined factors. The researcher intended to minimise network usage during file retrieval by introducing this data center criterion.

Reducing the financial burden associated with excessive duplication presented by [54] with an approach to distribute Online Social Network (OSN) data across different Cloud Service Providers (CSPs). Their study presented an algorithm that uses metrics like access and interaction rates to determine which data objects are the most popular and in what order. The algorithm then calculates the minimum number of replica copies needed and places them in the best storage class. The storage of data is classified as Reduced Redundancy Storage (RRS), Standard Storage (SS), or Infrequent Access Storage (IAS), and distinct data are mapped to be placed in the most appropriate storage. Furthermore, when data becomes less often accessed over time, the system automatically switches to the Reduced Redundancy Storage (RRS) class by modifying the storage class dynamically based on access patterns. The study obtained low storage consumption with a minimum number of replica copies.

f) One factor: Research by [92] embarked on a dynamic replication approach that addresses massive data movement among data centers in the cloud. The author proposed an inter-

data center data replication system with a Bandwidth Dynamic Separation algorithm called BDS+. The algorithm aims to speed up data transfer via adapting dynamic bandwidth separation, ensuring bandwidth is allocated for online traffic through estimating traffic demand and rescheduling bulk-data transfers for offline data services. It uses application-level multicast on the network with centralised architecture, which appoints the central controller to manage intermediate server data transmission. The researcher effectively improved bandwidth in this study.

The researcher proposed a cost-effective Hybrid PSO TS (HPSOTS) algorithm [93], which places restricted data copies in predetermined storage nodes to reduce energy consumption as the primary goal. The researcher used PSO's ability and TS's sturdy local search capability to obtain results on the appropriate data center to place replicas. Metaheuristic approaches were deployed to address the energy optimization issue via integrating Particle Swarm Optimization (PSO) and Tabu Search (TS) algorithms in their study. HPSOTS can determine the number of replicas before replication activities are triggered in a cloud environment. The integration of TS and PSO collaboratively exchanges inputs and eventually places the particles among six (6) fixed cloud data centers in encoded orders. The researchers succeeded in decreasing energy consumption and cost.

Conversely, [69] proposed the Replica Placement Based on Load Balance (RPBLB) technique to select the best data center to place replicas. The study aims to reduce remote users' access time. As replicas must always have fast retrieval rates, replicas must be placed in the closest nodes to users. Therefore, RPBLB most frequently duplicates access data in new storage nodes based on user demand for particular files. Research goals were achieved with response time reduced during user file download because data are kept in the closest data center.

An integrated algorithm between the Location-Aware Storage Technique (LAST) and the open-source Hadoop Distributed File System (HDFS) called LAST-HDFS was proposed by [94]. The study addressed the reliability of cloud providers and data integrity issues when users store their data in unknown storage locations. Unlike other research work, the LAST-HDFS did not use many parameters to determine the best data center to store data. On the other hand, the proposed algorithm allocated replicas to the data center by considering user-specified privacy policies. Users who store data in the same region place Every piece of data based on similar privacy preferences. The proposed algorithm proactively performs data placement balancing within the clusters and finally protects illegal data transfers through monitoring socket communications during migration or the replication process in the cloud environment. The study achieved high security by storing data according to privacy needs.

Table III summarizes the different strategies and number of factors considered for data placement in cloud replication environments. Fig. 7 depicts the factors employed in the data placement formulation to store the replica copies. No obvious trends suggest the number of factors considered has changed over time. Instead, to address some challenges, researchers have used these factors selectively, depending on their own research goals.

Holistically, every study shares similar research goals to improve performance in cloud replication environments, yet some ignored parallel drawbacks in their research. Existing studies contributed novel placement strategies for placing the replica copies in appropriate storage nodes. Table IV. includes a summary of existing research on data placement strategies, which comprises the contributions of every work.

TABLE III. SUMMARY OF DATA PLACEMENT STRATEGIES IN CLOUD REPLICATION

Strategy	Researcher Id	Number of Factors
FSDA	[85]	6
CF-AHP	[48]	5
MCDA	[86]	5
MO-ACO	[88]	5
HH-ALO-Tabu	[50]	4
SDR	[67]	4
DPRS	[89]	3
DMDR	[8]	2
HRS	[90]	2
OSN	[54]	2
LAST-HDFS	[94]	1
BDS+	[92]	1
HPSOTS	[93]	1
RPBLB	[69]	1

C. RQ3: What are the Performance Metrics that Contribute to the Enhancement of Replica Placement Strategies in Cloud Replication Environments?

The existing research on data placement strategies in cloud replication environments has addressed various performance metrics advancement. As in Fig. 8, Efficient Network Usage (26%), Low Storage Usage (19%), and Low Response Time (18%) are the most significant advantages, collectively accounting for 63% of the total achievements. These metrics ensure efficient resource utilization, minimize storage costs, and provide timely data access in cloud replication environments.

TABLE IV. CONTRIBUTION DATA PLACEMENT STRATEGIES IN CLOUD REPLICATION

Ref.	Contribution Algorithm
[77]	Controlled Replication Under Scalable Hashing (CRUSH)
[74]	Heuristic Data Placement
[89]	Dynamic Popularity aware Replication Strategy (DPRS)
[84]	Security Level (SL-DRM)
[93]	Hybrid PSO TS (HPSOTS)
[90]	Hybrid data Replication Strategy (HRS)
[48]	Cost Function based on Analytic Hierarchy Process (CF-AHP)
[86]	Multiple-Criteria Decision Analysis (MCDA)
[69]	Replica Placement Based on Load Balance (RPBLB)
[8]	Data Mining-based Data Replication (DMDR)
[85]	Fuzzy Self-Defence Algorithm (FSDA)
[67]	Secure Data Replication (SDR)
[81]	Cost-Effective Dynamic Data Placement

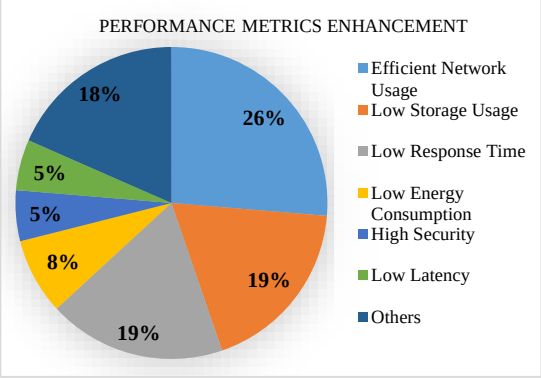

Fig. 8. Performance metrics.

Low Energy Consumption (8%), Low Latency, and High Security (5%) are also notable achievements. Other advantages of various performance metrics, such as low cost, high data availability, increased revenue, high user satisfaction, high load balance, and high hit ratio, are contributing to another 18% advancement. This stastical chart shows researchers' aims and successfully addresses various aspects of performance in cloud replication environments.

D. RQ4: What are the Common Limitations Across Existing Research on Data Placement Strategies in Cloud Replication Environments?

Here are the limitation in respective research works as discussed in RQ2:

- Researchers in [74] proposed a replica placement strategy that minimizes the evaluation cost. However, the disadvantage of this research is high bandwidth usage when queries are locked, and much hopping involved till the replicas are retrievable.
- The enhanced CRUSH algorithm [77] can dynamically place data and obtain data, which outstrips the previous study, yet data reliability issues are undeniable. The possibility of data loss is very high during data placement because when a dataset is sent to a particular server, any inevitable matters can happen at the server's level, such as server crashes or network breakdowns.
- SL-DRM achieved low storage consumption with a limited number of replica copies for videos [84]. Conversely, the major concern in this study was that the data availability was uncertain as crucial files were copied to unknown locations.

- The researcher [81] proposed cost-effective dynamic data placement using greedy algorithms. The solution was complex in formulation and caused extensive bandwidth usage while collecting numerous data, and prior decisions were made for replica creation and placement. Thus, computation overheads are a major drawback in this study.
- Researcher in study [82] proposed a Dynamic Replica Placement that focuses on financial cost reduction with good data consistency. As saving cost, storage space and consistency were the primary aims of this research, the data availability was neglected as it was not measured in this study.
- The ICR aims to identify the earliest available resource and time slots to proceed with replica replication until replica placement [78]. The trade-off in this study is high network usage due to the algorithm imposing an increased number of tasks to be executed whenever resources are available, and replica placement will occur endlessly. Furthermore, high energy consumption is another disadvantage in this study because resources are continuously used without idle time.
- Researchers in [75] developed the APER, a data replication strategy that allows a file to be replicated many times as long as it is profitable for both the tenant and cloud provider based on revenue and expenditures. The drawback is the high replication time affected by the overdue process of verifying every task to comply with the profitable criterion before the replication process and placement.
- In a hybrid Fog-Cloud environment, researcher Salah suggests a multi-objective optimization data placement model based on numerous data replicas [80]. Overall, the articles point to the possibility that while focusing on AI to minimize latency and improve data location the risks of data leakage concerning data privacy and the high requirement for specialist hardware and software are issues unattended in this study.
- The TDOPS with deduplication technique introduced in another study [76], overlooked the high replication time due to deduplication imposing a longer time for processing.
- Dynamic data replication management techniques notably focus on the costs related to storage and network use, ignoring the possibility of optimization through storage use [83].
- Researchers in study [95] adopted the ISGA, an interval pricing technique in multi-cloud environments, which has a primary disadvantage in the contributions of neglected cost-cutting strategies like resource optimization.
- The Dynamic Popularity-aware Replication Strategy (DPRS) [89] constitutes a data center selection method to determine the best location for replica placement. The researcher disregarded fault tolerance due to a heavy traffic load. Then the system will suffer from data loss and high response delay too.
- The HPSOTS algorithm was proposed by the researcher [93]. The data availability is relatively low due to the static number of replicas fixed in the strategy. Thus, any decisive data might not have sufficient copies, affecting poor availability and high wait time for file downloads.
- The researcher in study [90] proved the proposed HRS was beneficial to address storage imbalance, low response time, and high network usage. However, the system performance might suffer from execution overheads caused by extended verification time using the fuzzy technique.
- CF-AHP is a multi-criteria optimization model to save energy usage in their architecture [48]. The research disregarded the impact on the central database, which suffers a high update rate during replication.
- The Criteria Decision Analysis (MCDA) approach to determine the best data center to store replicas [86]. High energy usage and high replication time were neglected in this study.
- Researchers in study [71] propose the RPBLB strategy that requires additional storage to place replicas at the nearest data center. The algorithm demands extra time to verify the appropriate data center to store the replicas, thus affecting high process time.
- The additional computation time is identified in DMDR proposed by the researcher [8]. It has insufficient storage, and a high replication process while computing several factors during replica replacement activities that eventually delay the replication process.
- The researcher [85] and [67], introduced Fuzzy inferences in their placement strategies. Both researchers overlooked the fuzzy inference, causing a high process that derives a high response time. Concurrently, the proposed algorithm causes high storage consumption in [85].
- Research by [92] proposed an inter-data center data replication system that effectively improved bandwidth usage but overlooked high replication time. The algorithm requires more time to sort the traffic schedule than only triggering the replication process until the replica placement is complete.
- An integrated algorithm called LAST-HDFS was proposed by [94] achieved high security by storing data according to privacy classifications. However, the algorithm is cost-expensive due to the sophisticated security features. Another drawback in the research is high network usage caused by location monitoring and detection requiring data collection in real-time.
- Researchers [91] proposed a bio-based algorithm that overlooked the trade-off of computations overheads and high replication frequencies.

- Drawbacks in the heuristic ALO (HH-ALO-Tabu) strategy introduced by [50] is computational overheads.
- To decrease the financial liability associated with excessive duplication, [54] presented a strategy to distribute Online Social Network (OSN) data copies across a few Cloud Service Providers (CSPs). The study overlooked the impact of high costs and varying levels of data availability, which could present additional challenges when utilizing different services from various cloud service providers (CSPs).

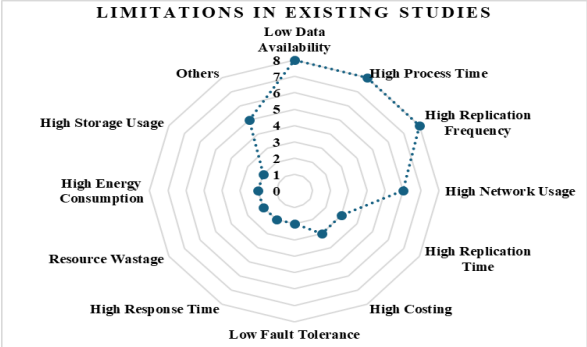

Fig. 9. Limitations in existing studies.

Fig. 9 and Table V present detailed analyses of common limitations in existing data placement strategies within cloud replication environments revealing several recurrent issues. The most frequently identified limitations include low data availability, high process time, and high replication frequency among 8 respective research studies (32%). These metrics indicate that many current strategies struggle to maintain consistent data access, handle data efficiently, and manage replication activities without excessive resource consumption. High network usage is down the road, with 6 research works contributing 24% of similar limitations. High-cost drawbacks (12%) are also significant concerns, highlighting inefficiencies in data transfer mechanisms and economic viability. These issues' occurrence emphasizes room for improvement and hinders performance degradation in replication activities.

TABLE V. RESEARCH WITH COMMON LIMITATIONS

Performance Metric	Authors
Low Data Availability	[77] [89] [93] [67] [82] [78] [54]
High Process Time	[90] [86] [85] [75] [92] [88] [80] [76] [50]
High Replication Frequency	[89] [84] [93] [8] [85] [92] [94] [88]
High Network Usage	[74] [85] [67] [81] [78] [94]
High Replication Time	[86] [75] [76]
High Costing	[69] [94] [80]
Low Fault Tolerance	[77] [89]
High Response Time	[48] [75]
Resource Wastage	[50] [83]
High Energy Consumption	[85] [78]
High Storage Usage	[89] [78]
Others	[89] [48] [75] [88] [80]

Numerous existing research works revealed that cloud computing has been the most prevalent platform for many other researchers' works [96]–[99]. Similarly, addressing these cloud replication limitations is critical for enhancing cloud computing environments' overall performance and reliability [100], [101]. Future research should prioritize the betterment of strategies that mitigate these common issues. By tackling these challenges, researchers can contribute to more robust and efficient data placement strategies, ultimately leading to more cost-effective and high-performing cloud services. Ensuring these improvements will be essential for meeting the increasing demands of cloud computing and providing reliable and accessible data management services.

V. CONCLUSION AND FUTURE DIRECTIONS

This paper presented a thorough taxonomic analysis of data placement strategies in cloud replication systems and has uncovered several important insights into this crucial area of cloud computing. This study has identified and categorized several techniques through this systematic review according to their primary goals, selection criteria for data placement, and performance metrics. The results suggest that placement strategies provide dynamic approaches that exhibit exceptional flexibility in response to shifting goal requirements. The study explicitly underscores how placement strategies have emerged as viable approaches to optimizing replica distribution in intricate cloud environments.

This study delivers a theoretical contribution that provides insights into existing research works by crafting a novel taxonomy for data placement strategies in cloud replication environments. The comprehensive analysis and discussion stipulate trends in replication performance enhancement. Further, gaps in existing studies are highlighted, forecasting new ideas for future researchers to develop a novel replication strategy to address the most prominent issues in cloud replication environments.

As for practical implications, this taxonomy study offers collections of replication strategies that allow cloud providers to scrutinize and adapt them in real-cloud replication settings. Hence, cloud providers can serve accelerated performance to users with better data availability, faster response time, low fault tolerance, reduced storage usage, and efficient network usage. This may offload pressure from cloud users' demands for quick data access, high data availability, fast replication process, low storage consumption, and affordable data maintenance.

Cloud technologies are evolving so quickly; thus, the taxonomy in this study may not fully encompass all new or specialized data placement techniques. Forthcoming tactics might differ greatly from those examined in this research. Future research can advance the field by addressing these gaps with more thorough literature discovery and provide practical solutions for efficient and dynamic data placement in cloud environments. Additionally, as the multi-cloud and hybrid cloud deployments grow more prevalent, data placement solutions that optimize across many cloud providers and on-premises infrastructure should be the focus of future studies. This is crafting strategies that can easily handle data placement in various distributed and heterogeneous situations. Besides, future researchers, policymakers, and professionals are suggested to

explore more effective and dependable data placement, which could be ensured by utilizing artificial intelligence approaches to anticipate and adjust to changing circumstances. Real-world adaption may entail expanding and placing these ideas into practice by collaborating with businesses that use multi-cloud configurations.

ACKNOWLEDGMENT

This study is supported by the National University of Malaysia (UKM) (GGPM-2023-072). Sincerely grateful for the facilities and funding provided, which were essential for completing this research.

***Abstract*—The persistent challenge of project delays poses significant issues with the escalating demand for house renovations. The company in Kedah, Malaysia, faces frequent project delays due to ineffective project management, leading to substantial liquidated damages. This study aims to minimise project delays and ensure timely completion within budget constraints, focusing on both the entire house renovation project and the kitchen renovation project. This study employed the Program Evaluation and Review Technique to illustrate the project network and utilised the Critical Path Method to identify the critical path while implementing project crashing with linear programming to optimise activity duration reduction and minimise costs. The PERT method results in an illustrative network diagram that aids subsequent analysis. The completion time for the entire house renovation project is determined to be 58 days using CPM, with a 96.8% probability of completion within 60 days. In contrast, for the kitchen renovation project, the completion time is identified as 38 days, with a 0% probability of meeting the 30-day deadline. Therefore, linear programming was successfully applied, shortening the kitchen project to 30 days at a total cost of RM 18,517.50, further reduced to 20 days with a cost of RM 20,980. Both scenarios remained below the total penalty cost of RM 21,780. The finding enables the company to make informed decisions on resource allocation to accelerate project duration and avoid delays. Future research should delve into realistic models, considering labour allocation and indirect costs, for a more comprehensive evaluation of project crashing strategies and their financial impacts.**

Keywords*—House renovation; Program Evaluation and Review Technique (PERT); Critical Path Method (CPM); project crashing techniques; construction project management; linear programming optimisation

I. Introduction

In any generation, houses serve as essential shelter, playing an important role in people's lives. House renovation has become a common phenomenon in recent years as the quality of life improves and people focus more on creating a comfortable and safer home environment. Simultaneously, the growing trend of renovating kitchens underscores this space's unique role as the hub and heart of the home. Homeowners are increasingly investing in both entire house and kitchen renovation projects, driven by a desire to enhance functionality, increase property value, and create inviting spaces for family gatherings and social events. These renovations, offering customisation within budget constraints, also pose challenges with project deadlines. Delays often arise from factors such as ineffective planning, material and labour shortages, adverse weather, and equipment failures [1]. In addition, as project complexity increases, improper management can lead to cost overruns and schedule delays. To mitigate these challenges, this study aims to minimise project delays and ensure timely completion within budget by employing effective project management tools and techniques. This study was conducted on two cases, an entire house and a kitchen renovation, by a renovation company in Kedah, Malaysia.

According to a study [2], the construction industry historically faces challenges like delays, exceeding budgeted costs, and substandard quality. Similar causes of delays, such as inadequate planning and scheduling and insufficient site management, have been emphasised in studies by [1], [3], [4], and [5]. Besides that, the ever-changing nature of project development poses challenges for construction companies lacking adequate project management skills [6]. Therefore, as [7] emphasises, efficient project management has several advantages, including cost, time, and quality assurance. According to study [8], project management is characterised by using knowledge, skills, tools, and techniques to manage project activities and meet specific requirements effectively. Similarly, [9] proposes that utilising project management tools can alleviate challenges in planning, organising, and managing diverse sets of resources. [10] and [11] emphasise that effective project planning and scheduling are essential for successful construction projects, ensuring timely completion within budget and meeting quality standards. However, project planning and scheduling represent one of the most difficult tasks faced by managers, requiring a deep understanding of the planned work [12], especially for complex construction projects where careful consideration of project scheduling and cost planning is essential [13].

The Critical Path Method (CPM) and Program Evaluation and Review Technique (PERT) are proven approaches that aid in planning, scheduling, and controlling construction projects [14]. Studies by [15], [16], and [17] highlight the effectiveness of CPM and PERT in identifying the critical path, allowing for better control and acceleration of activities to ensure timely

project completion. Project crashing is a strategy for utilising additional resources to expedite critical activities and meet deadlines [18] and [19]. [20] assert that delays can be mitigated by implementing project crashing strategies while considering the cost factor simultaneously. Additionally, [21] and [22] apply linear programming, which results in a cost increase but significantly shortens the project duration. However, the study in [23] stated that combining linear programming with project crashing can minimise project overruns. These methods have proven helpful in project management, allowing for proper planning and scheduling of projects and effective control of costs.

In this study, two crucial components of project management, PERT and CPM, will be utilised to illustrate the project network, identify critical paths, and estimate the probability of completion time for both the entire house and kitchen renovation projects. Subsequently, linear programming will be applied for project crashing in the kitchen renovation project. Finally, the performance of the project crash results will be compared with the current project cost and completion time for the kitchen renovation project. This study will help various renovation companies understand the importance of applying project management principles to their projects.

II. Materials and Methods

A. Data Description

The data obtained from a private renovation company in Kedah, Malaysia, consists of two case studies: the entire house and the kitchen renovation projects. This deliberate selection aims to evaluate the applicability of various project management tools to datasets of different sizes. The entire house renovation dataset, representing a large-scale project with a 60-day deadline, includes the duration of each activity and the corresponding total renovation cost for each project scope. In contrast, the kitchen renovation dataset reflects a smaller-scale project with a 30-day deadline. This dataset provides comprehensive information on the duration and cost associated with each renovation step within the kitchen. This dual-dataset approach enables a comprehensive assessment of project management tools across varying project complexities. A one-week delay resulted in a penalty of approximately RM4,000 for these projects.

B. PERT

The PERT methodology facilitates a comprehensive analysis of project completion time by incorporating a three-point time estimate, addressing uncertainties in activity duration. It employs three different time estimates: optimistic (a), most likely (m), and pessimistic (b) to account for variability [24]. The optimistic estimate signifies the minimum activity duration; the most likely estimate reflects the duration expected to occur most frequently; and the pessimistic estimate represents the maximum expected duration. To calculate the expected time (Te) and variance (V) of each activity duration, specific formulas are utilised. Eq. (1) estimates the average duration, while Eq. (2) quantifies the level of uncertainty associated with each activity [25].

$$\mathrm{Te} = \frac{(a + 4m + b)}{6} \tag{1}$$

$$\mathrm{V} = \left[\frac{b - a}{6}\right]^2 \tag{2}$$

C. CPM

Using a network-based approach, the CPM identifies time-sensitive activities crucial for project success, considering parameters such as earliest start (ES), earliest finish (EF), latest start (LS), latest finish (LF), and slack time (S) [26]. Eq. (3) and (4) determine the earliest start and finish times, while Eq. (5) and (6) establish late start and finish times [27]. These calculations indirectly yield slack time, defined as the maximum allowable delay for an activity without affecting project completion. The critical path, characterised by zero slack, represents the path with the longest duration in the network [28], with the formula for slack time outlined in Eq. (7). Determining the critical path is vital for guiding completion time, coordinating activities, developing schedules, and monitoring project planning [29].

$$ES(j) = maximum\,\{EF(i)\}, j = 1,2,3,\dots,n \tag{3}$$

$$ES(j) = ES(j) + Duration \tag{4}$$

$$LF(i) = minimum\,\{LS(j)\}, i + n - 1, n - 2, \dots, 0 \tag{5}$$

$$LS(i) = LF(i) - Duration \tag{6}$$

$$S = LS - ES = LF - EF \tag{7}$$

Furthermore, the variations in activities along the critical path can significantly impact the overall project completion. Assessing the variances of critical path activities contributes to a more comprehensive understanding of project uncertainty. The standard normal (Z) can be obtained from Eq. (8), thus referring to the normal distribution table to find the probability. A higher calculated probability, approaching 100%, signifies a greater likelihood of meeting the project deadline, whereas a lower probability, nearing 0%, suggests a reduced likelihood of achieving the project duration [30].

$$\mathrm{Z} = \frac{\text{Due date} - \sum \text{Expected date of completion}}{\sum \sqrt{\text{All the variance of critical activities}}} \tag{8}$$

D. Project Crashing

Project crashing involves minimising a project's remaining duration by reducing the time required for critical activities, resulting in additional costs, known as crash costs, due to the increased allocation of resources to ensure timely completion [31]. The methodology includes identifying the normal critical path and its critical activities. Following this, the crash cost per period for various activities is computed using Eq. (9). Next, the critical path activity with the lowest crash cost per period is identified and accelerated to the maximum extent possible or until the desired deadline. The process is iteratively checked to ensure the critical path remains unchanged. This iterative approach continues until the optimal solution is attained and the project reaches its desired completion date [32].

$$\text{Crash cost per time period} = \frac{\text{Crash cost} - \text{Normal cost}}{\text{Normal time} - \text{Crash time}} \tag{9}$$

E. Linear Programming

Linear programming serves as an alternative approach to optimising project crashing schedules, involving three key components: decision variables, an objective function, and constraints. The objective is to minimise the cost of crashing the

entire project. Therefore, the objective function can be defined based on Eq. (10) [32]. The objective function is subject to several constraints, such as the maximum reduction constraint, the start time constraint, the project duration constraint, and non-negativity constraints [14]. The maximum reduction constraint ensures each activity does not crash more than the maximum crashing time. In a project, activities are interconnected, and the beginning of certain activities relies on the completion of others. To ensure a smooth flow of work, the sequence of activities needs to be established by setting start time constraints. The project duration constraint is determined at the last activity before the project deadline.

Minimise crash cost, $z = \sum_{i=1}^{n} C_i Y_i, i = 1, 2, 3, \dots, n$ (10)

Subject to:

- Maximum reduction constraint, $y_i \leq$ Allowable crashing time for activity i measured in terms of days
- Start time constraint, $X_i \geq X_{\text{Predecessor}} + (t - Y_i)$
- Project duration constraint, $X_{\text{Finish}} \leq$ The completion project time at the last activity
- Non – negativity constraint, $x_i, y_i \geq 0$

Where X_i represents the time when the event i will occur, measured since the beginning of the project; Y_i represents the number of time activity will be crashed, where $i = (1, 2, 3, \dots, n)$; X_{Start} represents the start time for the project (usually 0); X_{Finish} represents the earliest finish time of the project; C_i represents the crash cost per unit of time for activity i.

III. Result and Discussion

This section explores two case studies: the entire house renovation project and the kitchen renovation project.

A. Case Study 1: Entire House Renovation Project

Illustrating the project network, identifying the critical path and activities, and estimating the probability of completing the overall project are the key objectives for this case study.

1) Project network for case study 1: For the entire house renovation project, there are a total of 31 activities.

Fig. 1 displays the PERT network diagram, which starts with activity A and ends with activity AF. Notably, activities E and F have the highest number of predecessors, with three dependents each, originating from activities B, C, and D. Following this, the second-highest number of predecessors is found in activities G, M, P, W, X, Y, and AE, each having two dependents.

2) Critical path and activities for case study 1: Fig. 2 clearly shows the duration, earliest start (ES) time, earliest finish (EF) time, latest start (LS) time, latest finish (LF) time, and slack time for each activity in the entire house renovation project.

The yellow path in Fig. 2 represents the critical path, which is characterised by zero slack and represents the critical activities in case study 1. Notably, there are two critical paths in the project, totalling 58 days.

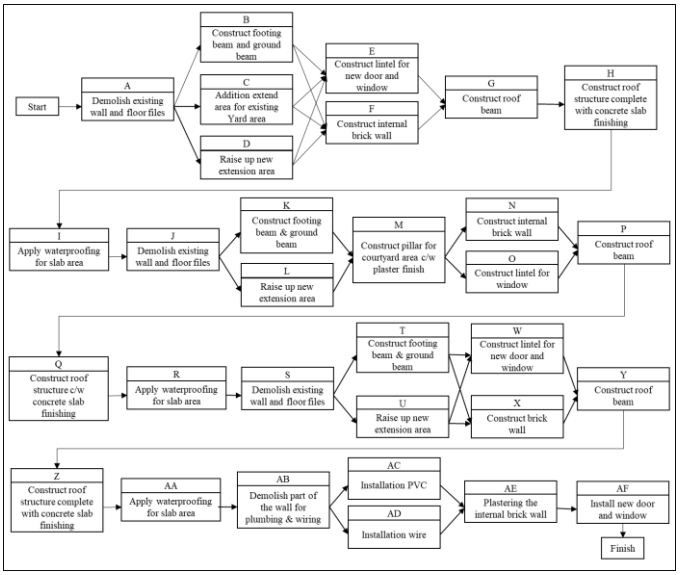

Fig. 1. PERT network diagram for case study 1.

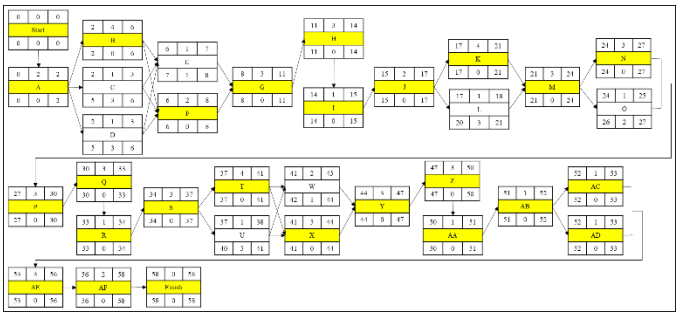

Fig. 2. CPM network diagram for case study 1.

3) Probability of completion time for case study 1: The PERT method employs three-time estimates, which are optimistic time (a), most likely time (m), and pessimistic time (b). Using Eq. (1) and Eq. (2), the PERT method calculates the expected time and variances. The results are presented in Table I.

The deadline for this project is 60 days, and the expected date of completion is 58 days. So, the z value can be obtained using Eq. (8):

$$Z = \frac{60 - 58}{\sqrt{1.167}} = 1.8514$$

Then, this z value can be seen in the standard normal distribution table. The z-value of 1.8514 obtained from the standard normal distribution table corresponds to a probability of 0.9679, which is expressed as a percentage of approximately 96.8%. This high probability suggests a strong likelihood that the project will be completed on schedule in less than or equal to 60 days. Given this higher probability and the absence of a risk of penalties for project delay, the application of linear programming for project crashing was deemed unnecessary. Implementing project crashing would typically involve additional costs to expedite critical activities, and in this context, the substantial likelihood of on-time completion rendered the incurring of extra expenses unnecessary.

TABLE I. PROJECT VARIANCE FOR EACH ACTIVITY IN CASE STUDY 1

Activity Code	Estimation Time (day)			Expected time, Te	Variance, V
	a	*m*	*b*		
A	1.5	2	3	2.083	0.063
B	3	4	5	4.000	0.111
C	0.5	1	1	0.917	0.007
D	0.5	0.5	1	0.583	0.007
E	0.5	1	2	1.083	0.063
F	2	2.5	3	2.500	0.028
G	2	3	3	2.833	0.028
H	2	3	4	3.000	0.111
I	0.5	0.5	1	0.583	0.007
J	1.5	2	3	2.083	0.063
K	3	4	5	4.000	0.111
L	0.5	0.5	1	0.583	0.007
M	2	3	3	2.833	0.028
N	2	2.5	3	2.500	0.028
O	0.5	0.5	1	0.583	0.007
P	2	3	3	2.833	0.028
Q	2	3	4	3.000	0.111
R	0.5	0.5	1	0.583	0.007
S	1.5	2	3	2.083	0.063
T	3	4	5	4.000	0.111
U	0.5	0.5	1	0.583	0.007
W	0.5	1	2	1.083	0.063
X	2	2.5	3	2.500	0.028
Y	2	3	3	2.833	0.028
Z	2	3	4	3.000	0.111
AA	0.5	0.5	1	0.583	0.007
AB	1	1	2	1.167	0.028
AC	0.5	1	1	0.917	0.007
AD	0.5	1	1	0.917	0.007
AE	2	3	3	2.833	0.028
AF	1	1.5	2	1.500	0.028

B. Case Study 2: Kitchen Renovation Project

The process for case study 2 involves illustrating the project network, identifying the critical path and activities, estimating the probability of completion time, utilising linear programming for resource allocation to accelerate the schedule, and finally, comparing the project crash results with the current cost and completion time of the kitchen renovation project.

1) Project network for case study 2: For the kitchen renovation project, there are a total of 18 activities.

Fig. 3 illustrates the PERT network diagram, starting with activities A and B. It is worth noting that both activities L and M have the highest number of predecessors, with each having four dependent activities from activities H, I, J, and K, respectively. Then, activities C, N, and Q each have two dependent activities.

2) Critical path and activities for case study 2: Fig. 4 clearly shows the duration, earliest start (ES) time, earliest finish (EF) time, latest start (LS) time, latest finish (LF) time, and slack time for each activity in the kitchen renovation project.

In Fig. 4, the yellow path represents the critical path with zero slack, indicating the critical activities in case study 2. It is evident that in the kitchen renovation project, there are eight critical paths, amounting to 38 days in total.

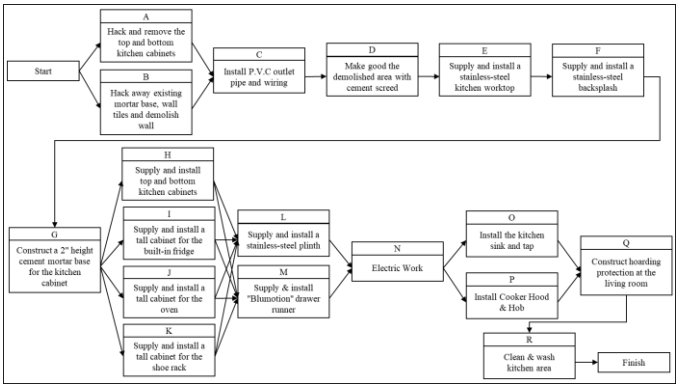

Fig. 3. PERT network diagram for case study 2.

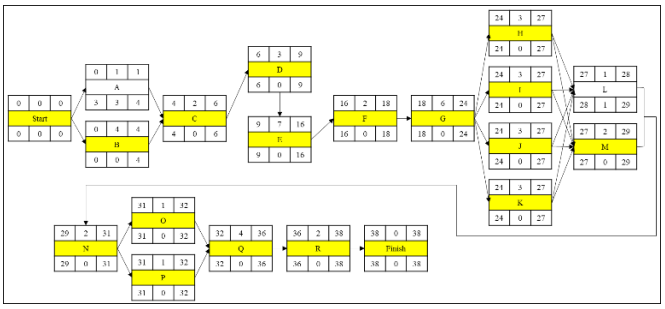

Fig. 4. CPM network diagram for case study 2.

3) Probability of completion time for case study 2: The expected time and variance of the PERT method were calculated by applying Eq. (1) and Eq. (2), as detailed in Table II.

TABLE II. PROJECT VARIANCE FOR EACH ACTIVITY IN CASE STUDY 2

Activity Code	Estimation Time (day)			Expected time, Te	Variance, V
	a	*m*	*b*		
A	0.5	1	1	0.917	0.007
B	3	3.5	4	3.500	0.028
C	1	1.5	2	1.500	0.028
D	2	3	4	3.000	0.111
E	6	7	8	7.000	0.111
F	1	1.5	2	1.500	0.028
G	4	6	7	5.833	0.250
H	2.5	3	4	3.083	0.063
I	2	2.5	3	2.500	0.028
J	2	2.5	3	2.500	0.028
K	2	2.5	3	2.500	0.028
L	0.5	1	1	0.917	0.007
M	1	1.5	2	1.500	0.028
N	1	1.5	2	1.500	0.028
O	0.5	1	1	0.917	0.007
P	0.5	1	1	0.917	0.007
Q	2	4	5	3.833	0.250
R	1	1.5	2	1.500	0.028

The deadline for this project is 30 days, and the expected date of completion is 38 days. So the z value obtained is:

$$Z = \frac{30 - 38}{\sqrt{1.049}} = -7.8109$$

Next, the z value of -7.8109 corresponds to a probability value of 0. When expressed as a percentage, this indicates a 0% probability of completing the project in 30 days or less, signifying that completing the duration is unlikely. Faced with this challenge, the implementation of the project crashing became critical. By accelerating critical activities through project crashing, the likelihood of completing the project within the 30-day deadline significantly increased.

4) Apply linear programming method for project crashing in case study 2: The linear programming method for project crashing is being applied to achieve the shortest possible duration at the least cost. Table III shows the cost-time slope of the kitchen renovation project, including the additional costs incurred resulting from the time reduction, with the crash cost per time calculated using Eq. (9).

TABLE III. COST-TIME SLOPE OF CASE STUDY 2

	Activity description	Normal Time (Days)	Crash Time (Days)	Normal Cost (RM)	Crash Cost (RM)	Crash cost per time
A	Hack and remove the top and bottom kitchen cabinets	1	0.5	350	450	200
B	Hack away existing mortar base, wall tiles and demolish wall	4	2	1000	1450	225
C	Install P.V.C outlet pipe and wiring for kitchen & washing machine	2	0.5	450	600	100
D	Make good the demolished area with cement screed	3	2	1000	1150	150
E	Supply and install a stainless-steel kitchen worktop	7	4	2200	3000	266.67
F	Supply and install a stainless-steel backsplash	2	0.5	800	900	66.67
G	Construct a 2" height cement mortar base for the	6	4	450	770	160

	kitchen cabinet					
H	Supply and install top and bottom kitchen cabinets	3	2	3380	3560	180
I	Supply and install a tall cabinet for the built-in fridge	3	2	780	880	100
J	Supply and install a tall cabinet for the oven	3	2	780	880	100
K	Supply and install a tall cabinet for the shoe rack	3	2	780	880	100
L	Supply and install a stainless-steel plinth.	1	1	3370	3370	0.00
M	Supply & install "Blumotion" drawer runner	2	1	480	580	100
N	Electric Work	2	0.5	800	900	66.67
O	Install the kitchen sink and tap	1	0.5	80	180	200
P	Install Cooker Hood & Hob	1	0.5	100	200	200
Q	Construct hoarding protection at the living room	4	2	700	950	125
R	Clean & wash kitchen area	2	1	280	380	100
Total		50	28	17780	21080	2440

After formulating the objective function and constraints, the linear programming model is applied using Excel Solver. The results of the model solution reduced to 30 days are presented in Table IV.

TABLE IV. SOLUTION OF THE LP PROBLEM USING EXCEL SOLVER FOR 30 DAYS

Objective Value	Final Value
Min Z	RM 737.50
$X_A, X_B, X_D, X_E, X_G, X_H, X_I, X_J, X_K, X_L, X_O, X_P$	0
X_C, X_F, X_N, X_Q	1.5
X_M, X_R	1

In order to meet the desired project completion time of 30 days, specific activities required acceleration. Critical activities identified for crashing were C, F, N, and Q, each requiring a reduction of 1.5 days. Additionally, activities M and R were expedited by 1 day each to align with the targeted project timeline. Initially, the linear programming method was utilised to ensure the completion of the kitchen renovation project within the 30-day deadline by allocating additional resources to accelerate specific tasks. The total cost incurred for crashing these activities amounts to RM737.50.

Subsequently, considering a further reduction in the project duration to 20 days, a detailed analysis was conducted. The application of linear programming successfully achieved the goal of shortening the project duration. The results of the model solution for the 20-day timeline are presented in Table V.

TABLE V. SOLUTION OF THE LP PROBLEM USING EXCEL SOLVER FOR 20 DAYS

Objective Value	Final Value
Min Z	RM 3200
X_A, X_L	0
X_B, X_G, X_Q	2
X_C, X_F, X_N	1.5
$X_D, X_H, X_I, X_J, X_K, X_M, X_R$	1
X_E	3
X_O, X_P	0.5

To meet the project completion time of 20 days, specific adjustments were made to various activities. Activities B, G, and Q were reduced by two days, while activities C, F, and N were accelerated by 1.5 days. Additionally, activities D, H, I, J, K, M, and R were shortened by 1 day each. Further improvements included a 3-day acceleration for activity E and a 0.5-day acceleration for activities O and P. The total cost of crashing these activities into 20 days is RM3,200. Thus, the final project cost, determined through the linear programming method, is RM20,980.

5) Compare the performance of project crashing result with the current project cost and completion time for case study 2: Table VI shows the results of project crashing for the kitchen renovation project in comparison to the current project cost and completion time.

TABLE VI. COMPARISON TABLE IN PROJECT COST AND COMPLETION TIME

	Time	Cost	Penalty	Total Cost
Normal	38 days	RM 17,780	RM4,000	RM 21,780.00
Crash	30 days	RM 737.50	-	**RM 18517.50**
Crash	20 days	RM3200.00	-	**RM 20980.00**

Table VI displays the total direct cost for completing the project within the normal 38-day duration, amounting to RM 17,780, with a penalty of RM 4,000 for a one-week delay. The cost, including the penalty, for completing the project without activity crashing is RM 21,780. Additionally, crashing for 30 days is RM 18,517.50, and for 20 days, it is RM 20,980. Despite the increased cost for shorter durations due to additional resources, both remain below the total cost without crashing. Therefore, the company can decide to add additional resources for crashing the activities to accelerate the project duration. This analysis affirms that the project crashing strategy is cost-effective, helping meet deadlines and avoid penalties.

IV. CONCLUSION

In conclusion, the application of Program Evaluation and Review Techniques and the Critical Path Method has successfully managed and evaluated two distinct renovation projects: an entire house renovation and a kitchen renovation. This study achieved its first and second objectives by illustrating project networks, estimating completion probabilities, and identifying critical paths and activities for both cases.

For the entire house renovation, the PERT method was employed to construct network diagrams and determine expected times and variances. Critical activities were identified using the Critical Path Method, resulting in a high likelihood of project completion within the 60-day deadline.

In contrast, the kitchen renovation presented challenges with a 30-day deadline and a calculated 38-day completion time using CPM, indicating potential delays. The application of linear programming for project crashing successfully reduced the duration to 30 days, incurring an additional cost of RM737.50. A further reduction to 20 days was achieved, incurring an additional cost of RM3,200. The comparison with the original cost structure confirmed the feasibility of completing the project within the specified time and at a lower cost.

This study contributes significantly to house renovation project management by addressing two projects and providing valuable insights for future research. It effectively tackles persistent project delays through the strategic use of tools like CPM, PERT, and linear programming. The findings emphasise the crucial role of acquiring skills for efficient tool application. The practical implications extend to the industry, aiding renovation companies in improving project management practices for timely and cost-effective outcomes. In summary, this research advances academic understanding and offers actionable strategies for enhancing efficiency and cost-effectiveness in house renovation projects.

However, limitations include challenges in linear programming for projects with complex dependencies and a lack of detailed information on worker allocation and indirect costs. Future research should explore real-world models, consider resource availability, and analyse the impact of worker allocation on project costs and completion time. Additionally, including detailed information on indirect costs would provide a more comprehensive evaluation of project crashing financial impacts. Furthermore, to mitigate delays caused by a lack of project management expertise, it is recommended that companies hire professional project managers. This can enhance planning, scheduling, and overall project efficiency, reducing the likelihood of delays in future house renovation projects.

FSFYOLO: A Lightweight Model for Forest Smoke and Fire Detection

Yinglai HUANG, Jing LIU, Liusong YANG*
College of Computer and Control Engineering, Northeast Forestry University, Harbin, Heilongjiang 150040, China

***Abstract*—The detection and identification of forest smoke and fire are critical for forest fire prevention efforts. However, current forest smoke and fire target detection algorithms confront obstacles such as high memory usage, computational costs, and deployment difficulty. Regarding these key issues, this paper presents FSFYOLO, a lightweight forest smoke and fire detection model based on the YOLOv8s model. To efficiently extract key features from forest smoke and fire images while reducing computational redundancy, the lightweight network EfficientViT is used as the backbone network. A lightweight detection head, Partial Convolutional Head (PCHead), is designed using the shared parameters idea to greatly minimize the amount of parameters and computations by leveraging shared convolutional layers and branched processing, thus achieving the lightweight design of the model. In the neck network, a lightweight feature extraction module, C2f-FL, is built to more fully extract local features and surrounding contextual information to widen the receptive field. Additionally, a Coordinate Attention (CA) mechanism is integrated into both the backbone and neck networks to capture cross-channel information, directional awareness, as well as position-sensitive information, improving the model's capacity to precisely pinpoint fire and smoke in forests. The experimental outcomes results on our self-constructed forest smoke and fire dataset demonstrate that FSFYOLO reduces the number of parameters and computation by 47.6% and 60.9%, respectively, compared to the original model, while improving precision, recall, and mAP50 by 1.3%, 1.0%, and 1.0%, respectively. This demonstrates that FSFYOLO strikes a good compromise between model lightweighting and detection accuracy.**

***Keywords*—Forest smoke and fire; target detection; lightweight; YOLOv8; EfficientViT**

I. Introduction

Forests are one of Earth's most valuable natural resources. They not only provide essential materials and minerals for production, but also play a critical role in maintaining ecological balance, preventing and mitigating drought, and conserving water resources [1], [2], [3]. However, forest fires often go undetected until they have spread across vast areas, making them difficult or even impossible to control and extinguish [4]. Such fires can cause irreversible and devastating damage to the environment, including contributing to global warming, soil erosion, the extinction of rare species of flora and fauna, and impairing the forest's ability to self-regulate [5], [6]. Moreover, these fires pose significant risks to human life, infrastructure, and property [7]. Thus, quickly detecting forest fires and accurately identifying smoke areas is crucial for enabling firefighting personnel to take timely action, controlling the spread of the fire, which helps reduce the damage to ecosystems, infrastructure, and loss of life caused by forest fires [8].

The detection methods for forest fires are divided into smoke detection and flame detection [9]. Smoke, as an early indicator of fire, appears sooner, covers a larger volume, spreads faster, and is more easily detected by the naked eye [10], making it a critical clue for early fire detection. Flames, on the other hand, are essential for accurately pinpointing the fire's location [11], with color and varying shapes serving as key visual features that provide valuable information for firefighting efforts [12]. Therefore, integrating both smoke and fire detection significantly enhances the accuracy of forest fire monitoring, helping to protect forest resources and mitigate damage [13].

As a result of the quick development of computer vision technology, digital image processing techniques have been extensively used to identify forest fires. For the purpose of detection, early digital image processing techniques mainly extract the color, shape, and texture properties of smoke and flames. Unfortunately, manual feature extraction is heavily depended upon by these methods, and susceptibility to subjective human factors, as well as environmental complexities such as weather and lighting conditions, often leads to unsatisfactory detection performance [14]. Recently, the advances in deep learning have opened up new approaches to identifying forest fires. Deep learning models greatly improve the accuracy and robustness of fire detection models by providing benefits in terms of accuracy, detection speed, deployment flexibility, and adaptability to various fire characteristics [15], [16].

Despite promising progress in forest smoke and fire detection, several challenges remain unresolved. A key issue is how to achieve high detection accuracy, particularly in forest fire scenarios where the background is complex, interference is high, and the morphology of smoke and flames is highly variable. Furthermore, designing lightweight models for resource-constrained devices, such as edge and mobile devices, remains a critical research challenge. Thus, with the goal of addressing these concerns, this study proposes a lightweight forest smoke and fire detection model (FSFYOLO) built on YOLOv8s, which aims to reduce the computational load and parameter count through a lightweight design, enhancing detection accuracy. This makes it more feasible to deploy on resource-constrained devices, such as edge and mobile devices, allowing for rapid and accurate detection of smoke and fire in the early stages of a forest fire. This facilitates the issuance of timely warnings, reduces the time for rescue operations, and

minimizes the severe harm and losses caused by the spread of fires.

The main contributions of this paper are as follows: First, EfficientViT, a lightweight network, is employed as the backbone for YOLOv8s. Second, a new lightweight detection head, PCHead, is designed using the concept of shared parameters. Third, to fully extract local features and contextual information, the neck network is using the lightweight feature extraction module C2f-FL. Finally, a coordinate attention mechanism is introduced to capture direction-aware and position-sensitive information from forest smoke and fire images.

The remaining significant sections of this document are listed below: Section II provides a review of related research. Section III describes the improved model in this study. Section IV summarizes the dataset, experimental setup, parameters, and assessment measures that were employed during the studies. Section V performs pertinent experiments and discusses the findings. Finally, Section VI summarizes the entire effort of this study.

II. Related Works

With its strong feature extraction and pattern recognition capabilities, deep learning can automatically extract important information about forest fires from vast amounts of photos and videos. Therefore, deep learning-based recognition techniques have been used extensively in forest smoke and fire detection missions due to their notable benefits in forest smoke and fire recognition in recent years.

This research in [17] aimed to detect early forest fire smoke by improving the deformable DETR model. This approach improves detection capabilities for little or unobtrusive smoke by incorporating modules like Dense Pyramid Pooling. An iterative bounding box combination technique is described for producing more exact bounding boxes. In addition, a forest fire smoke dataset was created to validate the capability of the improved network. However, the improved model still has a larger number of parameters.

In the study [18], based on SqueezeNet, an efficient lightweight forest fire detection network was proposed. The model integrates Attention Gate (AG) units into the skip connections to enhance key features and suppress irrelevant information. Standard convolutions are replaced with depthwise convolutions, and a channel shuffle operation is introduced to optimize feature transmission. Although the model achieves good segmentation accuracy for forest fires, it may have limitations in broader fire detection tasks.

This paper in [19] described a methodology for detecting forest fires automatically that combines the Atom Search Optimizer (ASO) and deep transfer learning. The ResNet50 model is utilized to generate feature vectors, and the ASO is used to optimize the ResNet model's hyperparameters. A quasi-recurrent neural network model is used for fire categorization, with promising recognition and detection results.

The authors in [20] improved the YOLOv5 model to classify and detect forest fires. By incorporating the Weighted Bi-directional Feature Pyramid Network (BiFPN) and the Convolutional Block Attention Module (CBAM), the model enhances its ability to recognize various types of fires in complex backgrounds. The bounding box loss function adopts SIoU loss and introduces directionality to accelerate model convergence, effectively detecting different types of forest fires.

The research in [21] introduced a multi-task learning model for forest fire detection, which includes detection, classification, and segmentation tasks. The model includes a diagonal random origin swapping data augmentation approach that significantly enhances detection performance for small fire targets. When compared to single-task models, the upgraded model reduces missed and incorrect detections and has better feature extraction capabilities.

This paper in [22] improved the YOLOv8 model by adding a large-object detection head and introducing an Efficient Multi-Scale Attention (EMA) mechanism to reduce background noise and improve the identification of smoke targets and large-scale fires. The proposed path aggregation network bag structure further improves accuracy in detecting fires and smoke with uneven feature distributions and variable shapes. The improved model achieves higher detection accuracy.

III. Improved Methodology

A. The Forest Smoke and Fire YOLO Model

YOLOv8 is a high-performance object detection algorithm, available in five versions: n, s, m, l, and x, ranging from small to large. These versions have the same network structure, with differences only in network depth and width. YOLOv8s offers notable advantages, including strong feature extraction capabilities, high accuracy, compact size, and ease of deployment. Therefore, this study uses YOLOv8s as the baseline network and proposes a lightweight forest smoke and fire detection model, named FSFYOLO (Forest Smoke and Fire YOLO). Fig. 1 shows the FSFYOLO network structure.

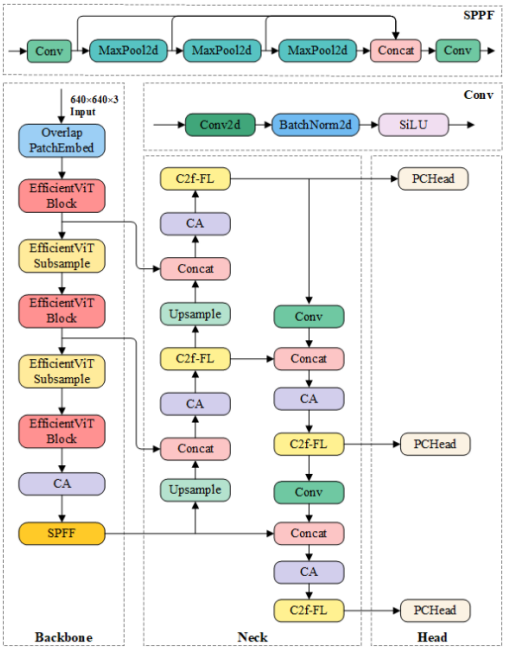

Fig. 1. Architecture of FSFYOLO.

The FSFYOLO network enhances the ability to accurately capture smoke and fire features in images while reducing computational redundancy by using the lightweight EfficientViT as the backbone network. Partial convolution is introduced, and a lightweight detection head, PCHead, is designed by sharing convolutional layers and branching processing, which productively minimizes the count of parameters and computational cost. In the neck network, to fully extract local features of smoke and fire as well as the surrounding contextual information, the LCFE block is proposed. This block is combined with the FasterNet Block and then integrated into the C2f module to form the lightweight feature extraction module C2f-FL, which expands the receptive field and lowers computational complexity. The coordinate attention, which extracts location sensitivity, directional awareness, and cross-channel information from fire and smoke images, is included into the backbone and neck networks. This mechanism filters out superfluous features in forest smoke and fire images, suppressing the impact of unrelated background information.

B. *EfficientViT*

The YOLOv8 backbone network, composed of multiple convolutional and pooling layers, results in high computational and storage costs. Furthermore, it struggles to accurately capture both local and global features of smoke and fire when processing cross-scale information. To address these issues, this study adopts EfficientViT as the backbone network of YOLOv8s. EfficientViT [23] is a high-speed vision transformer model that strikes a balance between speed and accuracy by optimizing memory efficiency and reducing attention computation redundancy. The EfficientViT network consists of overlapping patch embedding layers, EfficientViT blocks, and EfficientViT subsample layers, as shown in Fig. 2.

The input feature map first passes through the overlapping patch embedding layer, which divides the input into 16×16 patches and transforms them into vector tokens of a specified dimension, enabling better learning of the underlying features of the feature map.

The EfficientViT block is the core module of the EfficientViT network, with each block consisting of a sandwich layout formed by 2N FeedForward Network (FFN) layers, a token interaction layer, and Cascaded Group Attention (CGA). The token interaction layer, built with depthwise convolution (DWConv), is placed before the FFN layers to better capture local features in the image, thereby enhancing the model's overall performance. Unlike the conventional Multi-head Self-Attention Mechanism (MHSA), the CGA mechanism first divides the heads before generating Q, K, and V, and adds each head's output to the following head's input, thus providing each head with different features, improving the diversity of the attention maps. The outputs of all heads are spliced together and then passed through a linear layer to get the final output. Additionally, comparable to group convolution, this method lowers computational complexity and parameter count by lowering the Q, K, and V layers' input and output channels by a factor of 1/G, where G is the number of groups.

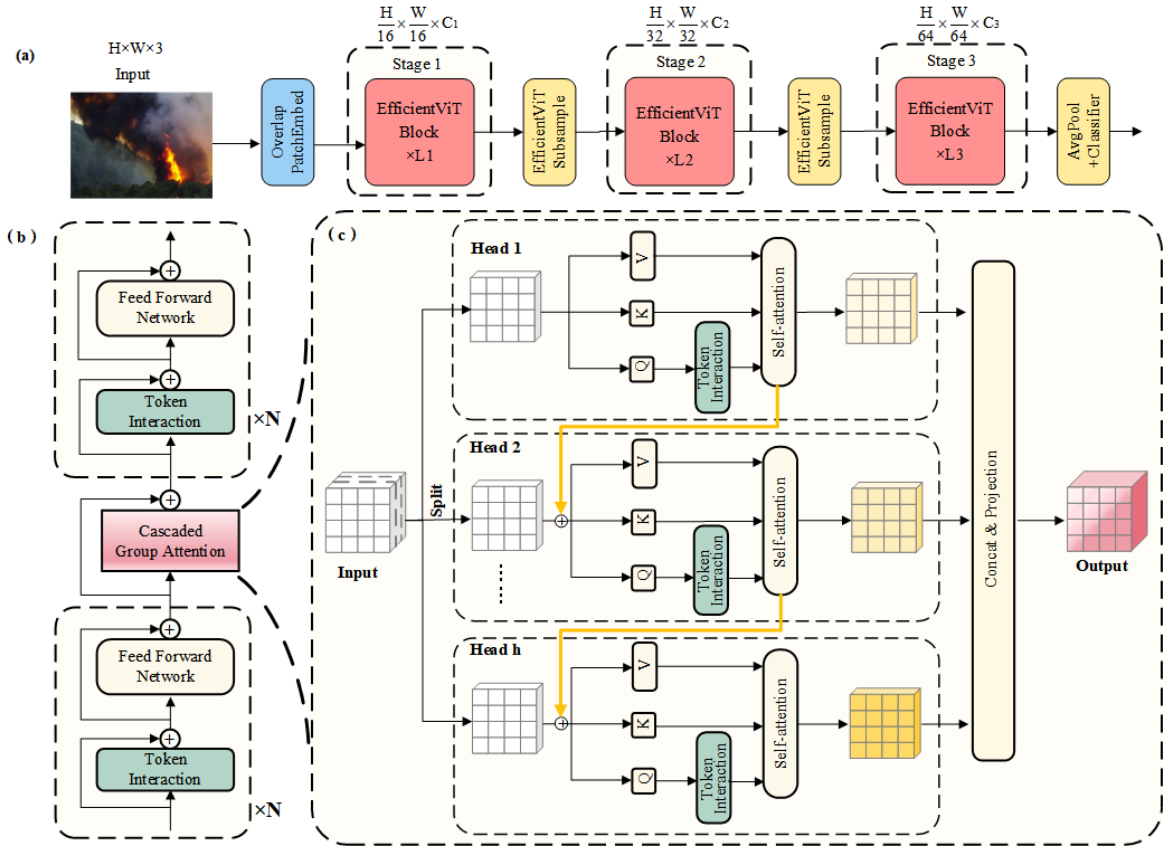

Fig. 2. (a) Architecture of EfficientViT; (b) Structure of sandwich layout block; (c) Structure of cascaded group attention.

CGA is expressed by the formula:

$$\tilde{X}_{ij} = Attn(X_{ij}W_{ij}^{Q}, X_{ij}W_{ij}^{K}, X_{ij}W_{ij}^{V}) \quad (1)$$

$$\tilde{X}_{i+1} = Concat[\tilde{X}_{ij}]_{j=1:h}W_{i}^{P} \quad (2)$$

$$X_{ij}^{'} = X_{ij} + \tilde{X}_{i(j-1)}, 1 < j \le h \quad (3)$$

In Eq. (1) and Eq. (2), $\tilde{X}_{ij}$ represents the output of X_{ij} after being processed by the self-attention mechanism in the j-th head. X_{ij} refers to the j-th slice of the input feature map X_i, i.e. $X_i=[X_{i1},X_{i2},...,X_{ih}]$, , where $1<j\le h$ and h represent the total number of attention heads. $W_{ij}^{Q},W_{ij}^{K},W_{ij}^{V}$ denotes the weight matrix, and W_i^P represents the linear layer.

In Eq. (3), $X_{ij}^{'}$ represents the sum of X_{ij}, the j-th slice of X_i and the output $\tilde{X}_{i(j-1)}$ from the (j-1)-th head, as obtained through Eq. (1) and Eq. (2). At this point, $X_{ij}^{'}$ replaces X_{ij} as the j-th head's original input feature map.

The EfficientViT subsampling layer downscales the feature map. Unlike traditional Transformer models, EfficientViT uses an inverted residual block in the subsample block instead of a self-attention layer, reducing potential information loss during downsampling.

C. The Lightweight Design of the Detection Head

Both branches of the YOLOv8 detecting head start with two 3×3 convolution modules, then a Conv2d module. Finally, they calculate the Cls and Bbox losses individually. Fig. 3 shows the specific structure of the YOLOv8 detection head.

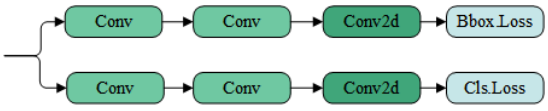

Fig. 3. YOLOv8 detection head structure.

To detect smoke and fire targets at different scales, the YOLOv8 detection head requires more convolution operations to process multi-scale feature maps, which increases the depth and number of parameters in the network. We adopt Partial Convolution (PConv) from the FasterNet Block [24] to modify the lightweight design of the YOLOv8s detection head to address these issues. Fig. 4 displays the FasterNet Block and PConv network structure diagram.

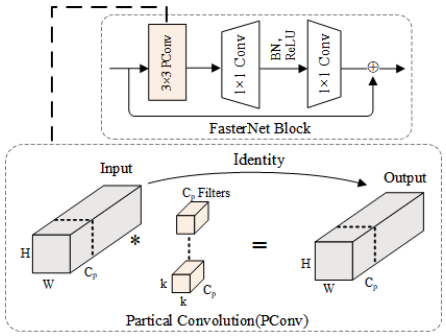

Fig. 4. Network structure of FasterBlock and PConv.

Comprising three layers, the FasterNet Block is composed of PConv layer, 1×1 convolutional layer, and 1×1 2D convolutional layer. PConv selectively applies regular convolution to specific input channels to extract spatial features; the remaining input channels remain unaltered and are directly translated to the output channels, resulting in significant computational redundancy reduction.

The new detection head first shares a PConv layer and a 1×1 convolutional layer, and then branches into two paths. Each path computes the Bbox loss and Cls loss, respectively, after passing through a Conv2d module. This new detection head is called PCHead (Partial Convolutional Head), and its structure is shown in Fig. 5.

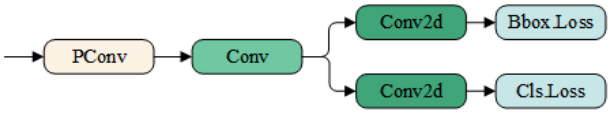

Fig. 5. PCHead structure.

D. C2f-FL Lightweight Feature Extraction Module

1) Local and Contextual Feature Extraction (LCFE) block: Traditional convolution operations confront issues such as information loss and a limited receptive field when capturing the diverse features of forest smoke and fires in various conditions. This hinders the model's ability to effectively extract local forest smoke and fire features and the corresponding surrounding contextual information, which in turn affects the extraction of fire-related features and restricts the expansion of the receptive field. In order to overcome this limitation, we propose a Local and Contextual Feature Extraction (LCFE) block, as illustrated in Fig. 6. The LCFE block is designed to efficiently capture local forest smoke and fire features while also extracting related contextual information, broadening the model's receptive field, and improving the network's capacity to identify fire features.

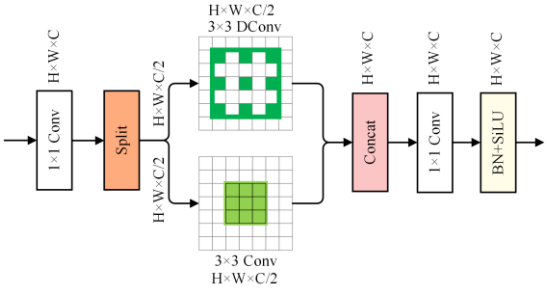

Fig. 6. LCFE block structure.

The LCFE block integrates information from several channels of the input feature map using a 1×1 convolution, thus enabling information interaction within the receptive field. The feature map is then partitioned evenly along the channel dimension into two sub-feature maps with an equal number of channels. One sub-feature map uses 3×3 conventional convolution to extract local features from eight neighboring vectors, while the other uses 3×3 dilated convolution to capture contextual information as well as widen the receptive field. Subsequently, concatenation of the extracted characteristics

occurs along the channel dimension; the local features and contextual information are combined using a 1×1 convolution. The fused features are then normalized and nonlinearized using batch normalization (BN) and the SiLU activation function, yielding the final output. Through this design method, the LCFE block is able to fully capture the intricate characteristics of smoke and fires, improving the model's recognition capabilities.

$$f_1, f_2 = Split(F_n(X)) \tag{4}$$

$$f = W(F_n(Concat(F_n(f_1), F_m^d(f_2)))) \tag{5}$$

In this context, X represents the input feature map, F_n denotes an n × n convolution operation, and F_m^d refers to a dilated convolution with a dilation rate d and a kernel size of m × m. f_1 and f_2 are the output feature maps, uniformly divided along the channel dimension. $W(\cdot)$ denotes the Batch Normalization (BN) and SiLU activation procedures; $Concat(\cdot)$ denotes concatenation along the channel dimension; $Split(\cdot)$ denotes the operation of splitting the feature map along the channel dimension. Ultimately, after being processed by the LCFE block, the output feature map f is obtained.

2) C2f-FL module: In YOLOv8, the C2f module makes use of a bottleneck structure made up of many convolutional layers, which requires repetitive dimensionality reduction and channel expansion of the input feature map. This approach can cause information loss while also increasing the model's computational complexity and parameter count. To tackle these issues, this study introduces the FasterNet Block, which reduces the model's parameter load and computational complexity while achieving efficient spatial feature extraction. Additionally, the LCFE block is incorporated into the forward propagation of the FasterNet Block, forming the FL block. This FL block serves as the bottleneck module within the C2f module of the neck network, resulting in the new lightweight feature extraction module, C2f-FL. This improvement reduces the parameters and computation required for smoke and flame feature extraction, effectively enhancing both target feature extraction and overall model efficiency. The structure of the FL block and C2f-FL is shown in Fig. 7.

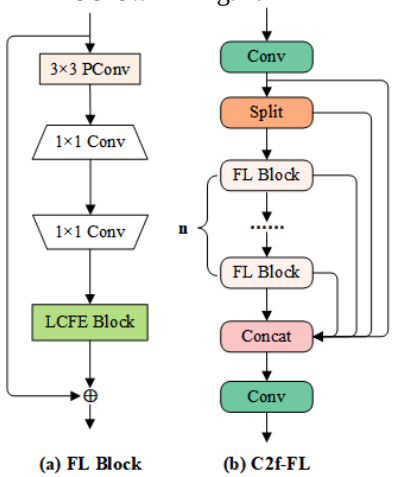

Fig. 7. Structure of FL block and C2f-FL module.

E. Coordinate Attention (CA)

Given the complexity of background textures and the abundance of irrelevant information in forest smoke and fire images, existing attention mechanisms often focus only on channel dependencies, neglecting the importance of spatial information. This results in significant redundancy in the spatial dimension of the extracted feature maps. To address this issue, a coordinate attention (CA) [25] mechanism is integrated into the network: before the backbone network's SPPF module and after the neck network's feature fusion module. This approach enhances the extraction of both channel and spatial information, effectively filtering out redundant features in forest smoke and fire images. Fig. 8 depicts the structure of the coordinate attention mechanism.

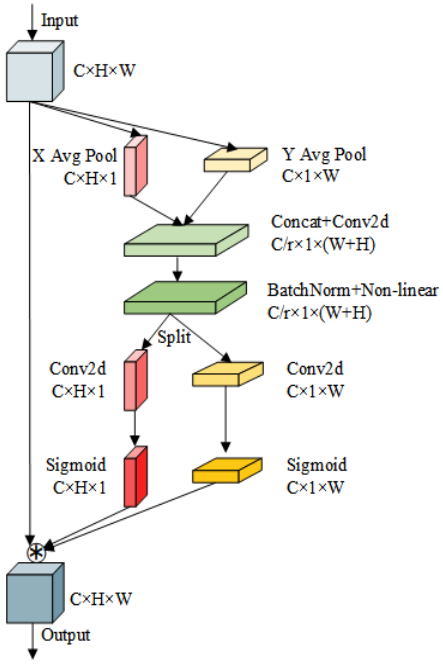

Fig. 8. Structure of the coordinate attention mechanism.

Two-dimensional global pooling is broken down by CA into two one-dimensional global poolings in separate directions. The input feature map is aggregated separately along the vertical and horizontal directions, resulting in two independent feature maps that are direction-aware and position-sensitive. This approach enables the capture of long-range dependencies along different spatial dimensions while avoiding the loss of spatial details, thus accurately preserving positional information from the original image. Subsequently, these direction-specific feature maps undergo operations such as stacking and normalization to encode attention maps. Finally, these attention maps are applied to the input feature maps in a complementary manner through elemental multiplication.

IV. Dataset and Experimental Setup

A. Dataset

One of the challenges in this study is the absence of a publicly available, unified forest fire dataset. To address this, a custom dataset containing instances of smoke and fire was created. The images in the dataset come from two sources: the

first involves collecting forest smoke and fire images and videos from the Internet, extracting one frame every 5 frames of the videos to create still images; the second source includes partial images from the FLAME dataset [26] published by Northern Arizona University. The dataset contains a total of 3,895 images, all manually labeled using LabelImg. It is separated into two sets: training and validation, in a 4:1 ratio, with 3,116 images for training and 779 for validation. Fig. 9 depicts sample photos from the collection.

Fig. 9. Partial experimental data.

B. Experimental Environment

The system used for the experiments in this study runs on Windows 11 with 16GB of RAM. The hardware includes a 13th Gen Intel(R) Core(TM) i7-13700H CPU and an NVIDIA GeForce RTX 4060 Laptop GPU. Pycharm was used as the software environment, and the PyTorch deep learning framework, based on Python, was utilized. The Python version used was 3.10.

C. Hyperparameter Settings

In this work, all models' hyperparameters are kept consistent during training and validation. The experimental parameters utilized for network training are listed in Table I:

TABLE I. EXPERIMENTAL HYPERPARAMETERS

Parameter name	Configuration
Size of the input image	640×640
Optimizer	SGD
Batchsize	16
Epochs	150
Momentum	0.937
Lr0	0.01
Weight decay	0.0005

D. Evaluation Criterion

Precision (P), Recall (R), Mean Average Precision (mAP), Giga Floating Point Operations per Second (GFLOPs), number of parameters (Params), and model weight file size (in MB) were used as assessment measures to analyze the network performance in this study.

Precision refers to the fraction of true positive samples among those predicted as positive by the model. It is calculated using the following formula:

$$P = \frac{TP}{TP + FP} \tag{6}$$

Recall evaluates the proportion of true positive samples that are correctly predicted among all actual positive samples. Its calculation is as follows:

$$R = \frac{TP}{TP + FN} \tag{7}$$

where TP, FP and FN denote the number of true, false positive and false negative cases, respectively.

AP represents the average precision for a single target category. It is calculated using the following formula:

$$AP = \int_0^1 P(R)\ dR \tag{8}$$

mAP is the average of AP values across all categories. It is calculated using the following formula:

$$mAP = \frac{1}{n}\sum_{i=1}^{n} AP_i \tag{9}$$

The Intersection over Union (IoU) represents the ratio of the intersection area to the union area between the predicted bounding box and the ground truth bounding box. By setting different IoU thresholds, corresponding mAP values can be obtained. In this study, mAP at IoU = 0.5 (mAP50) is adopted as the evaluation metric to assess the model's localization and classification capabilities for detected objects, providing a comprehensive evaluation of its overall detection performance.

GFLOPs is an indication for determining a model's computational complexity; a lower GFLOPs value indicates reduced computational cost. The parameter count measures the size of the model, and fewer parameters help accelerate the training process. The number of bytes in the file created during training is referred to as the weight file size for the model, with smaller weight files facilitating deployment and operation on resource-constrained devices.

V. RESULTS AND DISCUSSION

A. Ablation Experiments

To verify the effectiveness of the proposed detection model FSFYOLO in smoke and fire detection tasks, four groups of ablation experiments were conducted. Throughout these tests, the same dataset and hyperparameters were used to train each model, with only the modules under evaluation being changed. Table II presents the experimental results obtained.

The ablation experiment outcomes show that incorporating EfficientViT as the backbone network for YOLOv8s leads to reductions of 24.6% in the number of parameters, 28.2% in GFLOPs, and 22.0% in the size of the weight file compared to the original network. This proves that EfficientViT effectively reduces the model's complexity and computational burden. Additionally, by using the PCHead as the detection head, which shares convolutional layers and employs branch-based processing, the parameters and computational load are further reduced on the YOLOv8s-EfficientViT foundation, greatly decreasing model complexity. In addition, the network is further lightweighted by using the lightweight feature

extraction module C2f-FL, resulting in reductions of 16.9% in parameters, 17.9% in GFLOPs, and 15.3% in weight file size compared to YOLOv8s-EfficientViT-PCHead. The recall and mAP50 of the model compare favorably to the original network in terms of performance, suggesting that adding the C2f-FL module can recognize target items more thoroughly and lower the miss detection rate. Lastly, by adding the CA mechanism, the model's precision increases by 1%, reducing false positives in smoke and fire detection, as it better captures directional and positional information from the images. Importantly, the inclusion of CA does not significantly increase the parameter count or computation load, demonstrating that performance improvements are achieved without a notable increase in model size. The experimental results confirm that the FSFYOLO model proposed achieves superior performance in forest smoke and fire image recognition tasks.

TABLE II. THE RESULTS OF ABLATION EXPERIMENTS

YOLOv8s	EfficientViT	PCHead	C2f-FL	CA	P	R	mAP50	Params/10^6	GFLOPs	Weight File Size/MB
+					0.904	0.873	0.923	11.13	28.4	21.4
+	+				0.896	0.872	0.922	8.39	20.4	16.7
+	+	+			0.906	0.868	0.926	6.86	13.4	13.7
+	+	+	+		0.907	0.886	0.931	5.70	11.0	11.6
+	+	+	+	+	0.917	0.883	0.933	5.83	11.1	11.8

B. Comparative Experiments

To further validate the effectiveness of the improved network in detecting forest smoke and fire, a comparative analysis was conducted under the same experimental settings, dataset, and training strategies, using other mainstream object detection models. These models include SSD [27], YOLOX [28], YOLOv5, YOLOv6 [29], YOLOv7 [30], RT-DETR [31], the improved YOLOv5s model by Yang et al. [32], and the improved YOLOv8s model by Kong et al. [33]. Performance indicators such as precision (P), recall (R), mAP50, number of parameters, GFLOPs, and model weight file size were used as evaluation criteria. Table III presents the experimental results obtained.

The experimental results indicate that the SSD, RT-DETR, and YOLOv6s detection algorithms have relatively large parameter counts and computational costs. These factors result in larger model weight files and impose higher demands on hardware resources. In contrast, the parameter count of the FSFYOLO model is approximately one-fourth that of SSD, one-fifth that of RT-DETR, and one-third that of YOLOv6s. Therefore, SSD, RT-DETR, and YOLOv6s are deemed unsuitable for lightweight, real-time detection of forest smoke and fire. The YOLOv5s, YOLOv7, and FSFYOLO models include some identical feature extraction modules, such as the Conv module, and share similar network architectures. As a result, they exhibit only minor differences in parameter count, computational complexity, and model weight size. However, FSFYOLO achieves significant advantages by optimizing the C2f feature extraction module and introducing the CA mechanism to enhance feature extraction. Consequently, FSFYOLO outperforms YOLOv5s and YOLOv7 in terms of accuracy, recall, and mAP50, demonstrating a clear and distinct advantage. Although YOLOXs has a computational cost close to that of FSFYOLO, its parameter count is 34.8% higher, and its weight file is 2.9 times larger, with lower precision, recall, and mAP50 compared to FSFYOLO. Yang et al. [32] proposed an improved YOLOv5s model by adding C3Ghost and Ghost modules, resulting in parameter counts and GFLOPs of 3.78×10^6 and 8.3, respectively. However, due to the Ghost module only performing standard convolution operations on half of the spatial features, the model exhibits limitations in capturing detailed features for complex forest fire smoke detection tasks. Consequently, its precision, recall, and mAP50 do not surpass FSFYOLO. Similarly, Kong et al. [33] introduced Efficient Multi-Scale Attention (EMA) and GSConv to optimize YOLOv8s, reducing its parameter count, GFLOPs, and weight file size, but all performance metrics remain lower than those of FSFYOLO. Compared to the baseline YOLOv8s, the improved network outperforms the original in all key metrics. Based on a comprehensive analysis of all evaluation metrics, FSFYOLO offers significantly enhanced detection capabilities and is better suited for forest fire detection compared to other models.

C. Visual Analysis

To better further confirm the FSFYOLO network performance in forest smoke and fire detection tasks, we conducted a visual analysis utilizing the Gradient-weighted Class Activation Mapping (Grad-CAM) [34] approach. Grad-CAM heatmaps show that deeper colors indicate more attention to the respective locations, while lighter colors suggest less attention. We chose a few typical photos from the experimental validation set to compare the detection performance of YOLOv8s with FSFYOLO under various fire conditions. Fig. 10 displays the detection results, with (a) and (b) containing both fire and smoke, (c) containing only smoke, and (d) containing only fire.

It is evident from the heatmaps that YOLOv8s and FSFYOLO are equally adept at identifying and pinpointing target locations that are characterized by smoke and fire. But the FSFYOLO model has a higher confidence level, focuses more accurately on the regions of fire and smoke in the image, and focuses on regions very close to the actual smoke and fire shapes. Specifically, YOLOv8s may be affected by complex background interference present in forest fire images, leading to a dispersed focus on target objects. In contrast, FSFYOLO, through its lightweight design and optimized feature extraction modules, not only suppresses background noise but also enhances the precise capture of target features, improving accuracy. This again demonstrates the effectiveness of FSFYOLO in the task of forest smoke and fire detection.

TABLE III. THE RESULTS OF COMPARATIVE EXPERIMENTS

Model	P	R	mAP50	Params/10^6	GFLOPs	Weight File Size/MB
SSD	0.900	0.667	0.848	23.75	136.8	91.1
YOLOXs	0.905	0.864	0.908	8.94	13.4	34.3
YOLOv5s	0.899	0.879	0.920	7.03	15.8	13.7
YOLOv6s	0.898	0.884	0.917	18.50	45.3	38.7
YOLOv7	0.904	0.870	0.916	6.02	13.2	11.7
RT-DETR	0.890	0.837	0.901	32.81	108.0	63.0
Yang et al. [32]	0.898	0.874	0.917	3.78	8.3	7.7
Kong et al. [33]	0.897	0.879	0.922	8.56	20.9	16.6
YOLOv8s	0.904	0.873	0.923	11.13	28.4	21.4
FSFYOLO	0.917	0.883	0.933	5.83	11.1	11.8

D. Generalization Verification

In this experiment, the proposed FSFYOLO model was evaluated for generalization performance using the open FM-VOC Dataset18644 [35], which contains instances of smoke and fire. The dataset contains 16,844 photos depicting fires in a variety of contexts, including building fires, grassland fires, indoor fires, forest fires, and road fires. Experiments were conducted to compare the YOLOv8s and FSFYOLO models on the FM-VOC Dataset18644. The experimental conditions, parameter settings, and evaluation metrics were consistent with those used in other experiments in this study. The results are shown in Table IV.

As Table IV illustrates, compared to the baseline YOLOv8s model, the FSFYOLO model achieved improvements of 1.3%, 2.3%, and 1.3% in precision, recall, and mAP50, respectively, on the FM-VOC Dataset18644. Additionally, the FSFYOLO model demonstrated reductions of 47.6%, 60.9%, and 44.9% in parameter count, GFLOPs, and model weight size, respectively. The experimental results confirm that the FSFYOLO model achieves a good balance between detection performance and lightweight design, effectively detecting and recognizing fires

across different scenarios. Therefore, the FSFYOLO model exhibits excellent generalization performance, which will broaden the application of target detection in forest fire scenarios.

TABLE IV. COMPARISON OF EXPERIMENTAL RESULTS ON THE FM-VOC DATASET18644

Evaluation Metrics	YOLOv8s	FSFYOLO
P	0.917	0.930
R	0.872	0.895
mAP50	0.939	0.952
Params/10^6	11.13	5.83
GFLOPs	28.4	11.1
Weight File Size/MB	21.4	11.8

VI. CONCLUSION

To accomplish precise and timely forest fire detection, we present FSFYOLO, a lightweight forest smoke and fire detection network based on YOLOv8s. To begin, EfficientViT, a lightweight transformer network, serves as the backbone network to improve network feature extraction capability. Second, a lightweight detection head, PCHead, is designed using the shared parameters idea, which decreases the model's complexity while preserving detection performance. Third, the lightweight feature extraction module C2f-FL is introduced to effectively capture local features of forest smoke and fire, as well as relevant surrounding contextual information, which achieves the dual enhancement of model computation efficiency and feature extraction capability. Finally, a coordinate attention mechanism is integrated to extract both channel and spatial location information, filtering out superfluous features in forest fire images. Experimental validation shows that the FSFYOLO network achieves higher accuracy than other networks, with significantly reduced parameter count and computational cost, satisfying real-time needs for forest smoke and fire detection. Additionally, the FSFYOLO network is easily deployable on resource-constrained devices, providing an effective method for forest fire detection. However, this study still has some limitations. For example, the forest fire dataset used in the experiments is relatively small, and the range of scene coverage is insufficient. Moreover, although the FSFYOLO network decreases the number of parameters and computing costs while increasing accuracy, there is still room for optimization in the model structure and performance. In future work, we will focus on expanding the forest fire dataset to cover more complex scenarios and exploring more efficient, parameter-reduced methods to further enhance the performance and precision of forest fire detection models.

Identification of Chili Plant Diseases Based on Leaves Using Hyperparameter Optimization Architecture Convolutional Neural Network

Murinto, Sri Winiarti, Ardi Pujiyanta
Department of Informatics, Universitas Ahmad Dahlan Yogyakarta, Indonesia

***Abstract*—This paper proposes a method to detect chili plant diseases based on leaves. Studies in recent years have shown that chili production in Indonesia has decreased. This is because there are several influencing factors. One common factor is the presence of diseases in chili plants that cause less than optimal harvest production. Fungi or pests on chili leaves usually cause diseases that often appear in chili plants. Chili leaf diseases have a negative impact on chili harvest yields. Chili leaf diseases can result in significant decreases in both the quantity and quality of chili harvests. Accurate disease diagnosis will help increase farmer profits. This study identified four major leaf diseases, namely leaf curl, leaf spot, yellowish, and white spot. In this research images were taken using a digital camera. These diseases were classified into five classes (healthy, leaf curl, leaf spot, yellowish, and white spot) using two different pre-trained deep learning networks, namely MobileNetV2 and VGG16, using chili leaf data through deep learning transfer. The experimental results showed the model with the best performance was the VGG16 model. This model achieved a validation accuracy of 94% on public and own data sets. Meanwhile, the next best-performing model is MobileNetV2, which achieved an accuracy of 90%, followed by the Traditional CNN Model, which achieved a validation accuracy of 88%. In future developments, we intend to deploy it on mobile devices to automatically monitor and identify various types of chili plant disease information based on leaves.**

I. INTRODUCTION

In several agricultural countries, the country's main income is agricultural products. The condition of the soil environment and land requirements are important influences on the harvest produced. However, farmers need help with several problems, such as water shortages, natural disasters, plant diseases, etc. However, some of these problems can be reduced by providing technical facilities for farmers. An automatic plant disease identification and prevention system is one solution that can help farmers. This type of system can overcome the problem of lack of knowledge about plant diseases because there are very few experts in this field [1],[2],[3]. The automatic system will also save time and help increase farmers' profits [4]. In agriculture, detecting and classifying leaf diseases is important because farmers often have to decide whether the cultivated plants are thriving.

Generally, examination through observation of leaves, roots, stems, flowers and fruits can identify the type of food crop that is suffering. This manual approach does not guarantee accuracy in identifying the plant disease. In addition, not all plant diseases in plants can be identified manually. Likewise, manual identification of plant diseases takes a long time. The research that is currently being done is to identify and classify plant diseases automatically using the help of artificial intelligence. Automation in monitoring types of food crops will greatly assist farmers in monitoring their plants. If the plant disease can be detected early, the possibility of producing a good harvest will be achieved [5].

Automatic detection of plant diseases based on images is one of the jobs in Computer Vision. One of the techniques used in Computer Vision is Machine Learning Techniques. In the field of agriculture, machine learning techniques can produce very significant improvements when applied. Detection and classification of plant diseases using deep learning is one example used to help farmers detect types of plant diseases. Research on the identification, detection and classification of plant diseases using deep learning techniques has become a subject of much research in recent years. Conventional computer vision algorithms, support vector machine (SVM) [6], K-nearest neighbors (KNN) [7], and K-means clustering methods [8] of machine learning algorithms have been used for early detection in various fields.

The process of grouping an object based on certain parts is called classification. Classification is one part of the work in machine learning. While machine learning itself is part of Artificial Intelligence (AI). In general, AI is a branch of computer science that focuses on development that has human intelligence capabilities. One part of Machine Learning is Deep Learning [9]. In Deep Learning, several algorithms are already known and often used, including the algorithm is Recurrent Neural Networks (RNN) [10], Convolutional Neural Networks (CNN) [11], [12], [13], and Deep Generative Model (DG) [14]. Convolution Neural Network is a model in deep learning that is usually widely used in classification work. One of the known classifications is how chili plant diseases are classified into several types based on their leaves.

A large number of parameters need to be trained in CNN and its variants, while training these CNN architectures also requires several labelled samples and substantial resources from scratch to assess their performance of the technique. Collecting a large labelled dataset is a challenging task. Despite its limitations, previous investigations have successfully demonstrated the potential of deep learning algorithms. In particular, deep transfer learning alleviates the problems classical deep learning methods

face. The solution consists of using a pre-trained network where only the parameters of the final classification level need to be inferred from scratch. Some existing deep learning transfers include the following: Alexnet [15], VGG16 [16], MobileNetV2 [16], GoogleNet [17], Resnet [18]. However, not all deep learning transfers suit all problems. Transfer learning has been widely used in several recent studies, including MobileNetV2 and VGG16, which have been applied in various fields.

This study aims to apply the latest transfer learning deep learning technique for chili plant disease recognition based on visible leaf images. Traditional Convolutional Neural Network (CNN) is used to perform the classification, which is then compared with existing transfer learning models, namely MobileNetV2 and VGG16. This study recognizes diseased plants based on symptoms to achieve recognition without the influence of several disease symptoms that appear on one leaf.

II. Materials and Method

A. Materials

A dataset of images containing symptom images of four chili plant diseases, namely yellowish, leaf spot, leaf curl, and white spot, was created. Based on this dataset, CNN, MobileNetV2, and VGG16 models were trained to recognize chili plant diseases.

1) Dataset chili plant diseases: The trained dataset contains several diseases that attack chili plants. Using a mobile phone camera, images are collected under several conditions depending on the time (e.g., lighting), season (e.g., temperature, humidity), and location of the image capture. For this reason, we have visited several chili plantations in the Semarang and Klaten Regencies. Other data was obtained from Kaggle.com, which is public data. The data we use consists of 250 images of chili plant leaves. The images are divided into 5 categories: a healthy image class and four classes of diseased images representing four diseases: whitefly, curl leaf, gray mold, and yellowing. The four types of chili plant diseases are:

a) Yellowish. Symptoms of this disease are leaves that appear wilted, starting from the bottom, then turning yellow up towards the young branches. The body parts of the chili plant infected with this disease will be covered in white hyphae like cotton. If the chili plant is attacked while it is still growing, fruit can still be produced. However, if the disease has spread to the stem area, the young chilies will fall off. Fig. 1 shows several examples of chili plant diseases based on leaves called yellowish.

b) White fly. Yellow virus is also commonly called bule or bulai disease, the yellow virus causes chili plants to appear yellow. This disease caused by the gemini virus can be carried from seeds or seeds and transmitted by lice. Because it is caused by a virus, chemical poisons will not work to overcome it. Therefore, control must be carried out from the beginning, namely by selecting superior seeds that are resistant to virus attacks. In addition, of course, eradicating vector pests, such as lice. Fig. 2 shows several examples of chili plant diseases based on leaves called white fly.

Fig. 1. The example of yellowish disease.

Fig. 2. The example of white fly disease.

c) Leaf spot. Symptoms of chili plants affected by leaf spots are the appearance of round brown spots on the leaves. These spots are usually about 1 inch in size with a pale to white center with darker colored edges. Caused by the fungus Cercospora capsici, this disease can be carried by wind, rainwater, vector pests, and agricultural tools. Among the supporting factors for leaf spots are environmental conditions that are always rainy. To prevent it, you can choose healthy seeds that are free of pathogens. In addition, improving drainage and choosing the right planting time also need to be done to minimize the possibility of attacks. Fig. 3 shows several examples of chili plant diseases based on leaves called leaf spot.

Fig. 3. The example of leaf spot.

d) Curl leaf. Finally, leaf curl or mosaic is a disease caused by Cucumber Mosaic Virus (CMV). Insects can transmit diseases from one tree to another. If the chili plant is attacked by leaf curl, its growth becomes stunted and the size of the leaves is smaller. The possibility of spreading disease can be reduced,the destruction of chili plants that have been attacked needs to be done. Fig. 4 shows several examples of chili plant diseases based on leaves called curl leaf.

Fig. 4. The example of curl leaf disease.

B. Research Method

Fig. 5 shows a detailed overview of the detection and classification of chili plant diseases based on leaves proposed using deep transfer learning techniques with the first stage of collecting chili plant disease images based on leaves, the second is image pre-processing and image augmentation, the third part is the process of forming a mode where this stage includes the training, validation and testing processes, while the fourth process is the results and evaluation process. In the third process, the transfer learning models used are VGG16 and MobileNetV2.

C. Convolutional Neural Network

The convolutional neural network architecture model has four main components, namely: convolution layer, pooling layer, activation function and fully-connected layer. One of the known activation functions is the non-linear activation function Rectified Linear Unit (ReLU). The CNN Architecture model is shown in Fig. 6. The convolutional neural network architecture model consists of an input image measuring 28x28x1. When using a color image, the input image size is 28x28x3. RGB color images have three channels, namely Red (R), Green (G) and Blue (B). Furthermore, the input image is fed into the convolution layer using a valid padding kernel measuring 5x5. This process produces n1 channels with an image size of 24x24x1. The next process is max pooling 2x2 which produces an image measuring 12x12x1. Stride 2 is used to reduce the convolution layer in the next layer. This process is then repeated by running the convolution process and then max pooling again. After the max pooling process is complete. Furthermore, the process is carried out through a Fully-Connected Neural Network using the ReLU activation function. The result of this process is the classification of objects into several previously determined classes. In this study, the Softmax activation function was used in the last layer because the object of chili plant disease based on leaves has more than two classes.

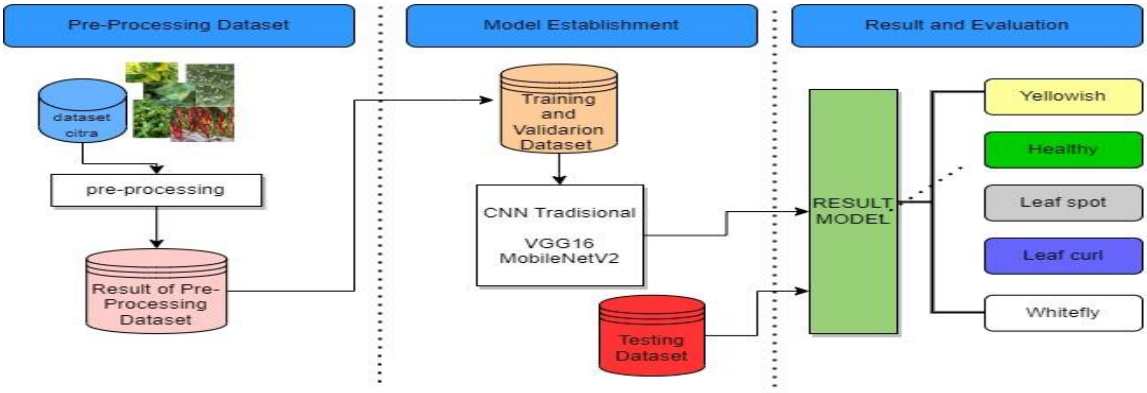

Fig. 5. Methodology of the detection and classification of chili plant diseases based on leaves.

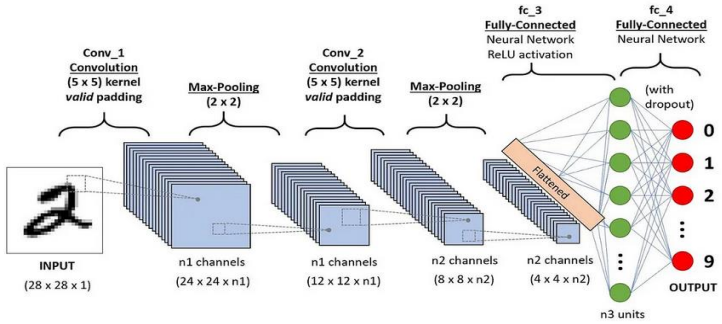

Fig. 6. The architecture of the CNN model.

D. VGG16 Model

The VGG model developed by A. Zisserman and K. Simonyan from the University of Oxford (2014) [19] is a CNN architecture with about 138 million parameters. The feature of this architecture is that it always has the same convolutional layers using 3x3 filters with a stride of 1 and the same padding and max pooling layers using 2x2 filters with a stride of 2. The VGG16 architecture follows this arrangement of convolutional and pooling layers consistently across the architecture. Finally, there are 3 FC layers, the first with ReLU and the last with SoftMax activation function. This architecture contains 16 layers, and the input layer takes an image of 224x224 pixels in size. VGG-16 A convolutional neural network model called the VGG model, or VGGNet, which supports 16 layers, is also known as VGG16. This model significantly outperforms Alexnet by replacing some 3x3 kernel-sized filters with large kernel-sized filters. VGGNet-16 has 16 layers and can classify photos into 1000 different object categories. This model also accepts images with a 224 x 224 x 7 resolution. The VGG16 Architecture model is shown in Fig. 7.

E. MobileNetV2 Model

The MobileNetV2 CNN model was introduced by Sandler et al. (2019). This model is based on the MobileNetV1 architecture by Howard et al. (2017). MobileNetV2 is a lightweight CNN model with 53 deeper layers, fewer parameters, and an input size of 224 × 224. The MobileNetV1 architecture uses the concept of depth wise separable convolutions that apply one filter to each input channel, and pointwise convolutions (1 × 11 × 1) aim to combine the outputs of depth wise convolutions. The MobileNetV2 model is a CNN architecture that attempts to perform well on mobile devices. This architecture is based on an inverse residual structure where residual connections are between the bottleneck layers. The intermediate expansion layer applies lightweight depthwise convolutions to filter features, introducing non-linearity. Overall, the MobileNetV2 architecture contains an initial complete convolution layer with 32 filters, followed by 19 residual bottleneck layers. The MobileNetV2 Architecture model is shown in Fig. 8.

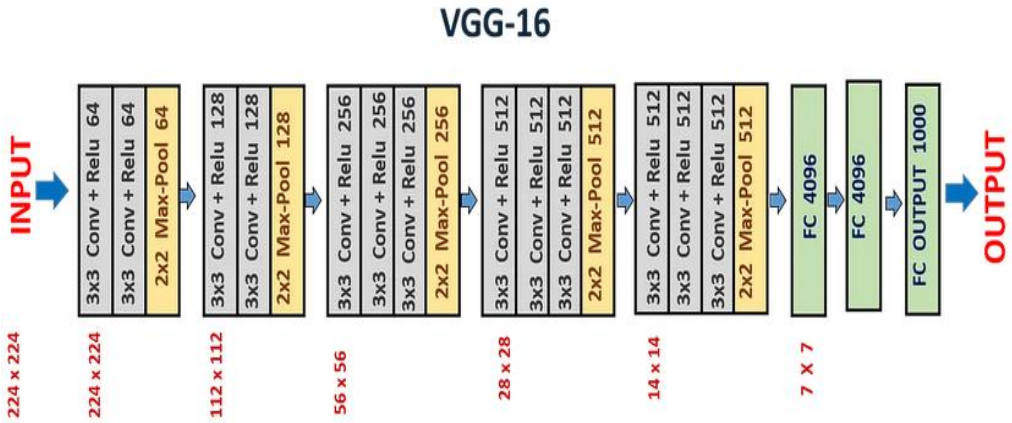

Fig. 7. The architecture of the VGG16 model.

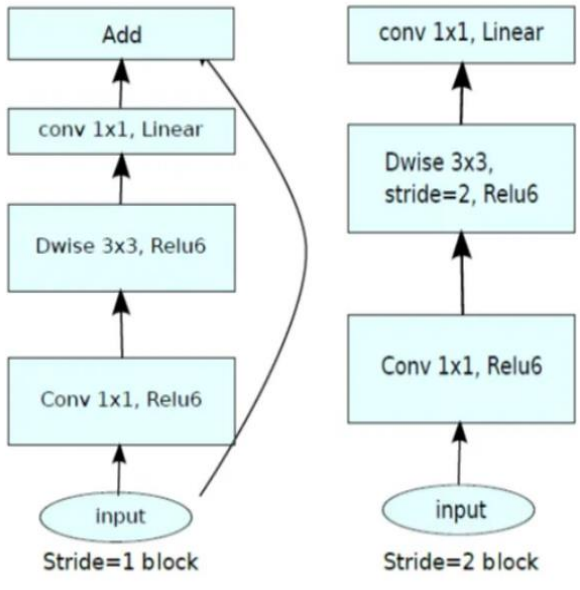

Fig. 8. The architecture of the MobileNetV2 model.

III. Result and Discussion

The model described in Section II was trained and tested using the parameters as shown in Table I. Training and testing were implemented using Python on Google Collab. The batch size of the training model was taken as eight, and a stochastic gradient optimizer was used. Image preprocessing algorithms, data augmentation, and deep learning algorithms were implemented using Python 3.7. The complete software and hardware specification for training on various images of chili plant leaves is Confusion Matrix. Considering the values in the confusion matrix obtained in the classification, the given metrics are calculated using indices such as True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN). Here, TP is the number of disease images correctly classified in each category, while TN, on the other hand, represents the number of images correctly classified in all other categories except for the relevant category. FN gives the number of images incorrectly classified from the relevant category. FP gives the number of images incorrectly classified in all other categories except for the relevant category. In Eq. (1), (2), (3), and (4), each states precision, recall, accuracy, and F1-Score [20].

$$\text{precision} = \frac{\text{TP}}{\text{TP+FP}} \quad (1)$$

$$recall = \frac{TP}{TP+FN} \quad (2)$$

$$Accuracy = \frac{\text{TP+TN}}{\text{TP+FP+TN+FN}} \quad (3)$$

$$F1\ Score = 2 * \left(\frac{Precision * Recall}{Precision + Recall}\right) \quad (4)$$

The performance of the pre-trained networks VGG16 and MobileNetV2, tested, is tested by transfer learning in this section. The features learned by VGG16 and MobileNetV2 are then transferred to the new task of chili plant disease recognition based on leaves. The training parameters used for VGG16 and MobileNetV2 are the same as mentioned before. The results of both transfer learning models are compared with the traditional CNN model. Fig. 9 to Fig. 11 show the accuracy and loss graphs of the models used in this study. Fig. 12 show result of confusion matrix in this research. Table I show the performance of Traditional CNN, MobileNetV2, and VGG16 with transfer learning. The results presented in Table I show that the VGG16 Model achieves better performance than MobileNetV2 and Traditional CNN. The accuracies of Traditional CNN, MobileNetV2, and VGG16 Model are 88.0%, 91.00%, and 94%, respectively. As expected, the VGG16 Model with transfer learning outperforms Traditional CNN and MobileNetV2 trained from scratch, which may be due to the reason that it has been trained on more than one million images. Therefore, the feature presentation is much richer than CNN trained from scratch.

TABLE I. CONFUSION MATRIX OF CNN TRADITIONAL, MOBILENETV2 AND VGG16 MODEL

Chili Diseases	Precision	Recall	F1-Score	Precision	Recall	F1-Score	Precision	Recall	F1-Score
	CNN Model			VGG16 Model			MobileNetV2 Model		
Healthy	0.86	0.60	0.71	0.75	0.90	0.81	0.86	0.60	0.71
Leaf curl	0.50	0.40	0.44	0.67	0.60	0.63	0.50	0.40	0.44
Leaf spot	0.33	0.60	0.43	0.82	0.90	0.43	0.33	0.60	0.43
Whitefly	0.78	0.70	0.74	0.88	0.70	0.78	0.78	0.70	0.74
Yellowish	0.97	0.96	0.97	0.98	0.98	0.98	0.97	0.96	0.97
Accuration			**0.88**			**0.94**			0.91

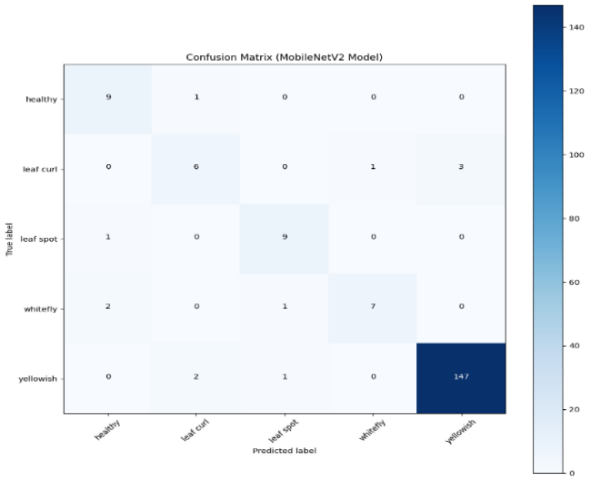

Fig. 12. The confusion matrix of MobileNetV2 Model.

Table I shows the data results on the chili leaf image dataset test. From the CNN architecture model confusion matrix, the accuracy value is 0.88 or 88% while the precision is 0.6860, ecall is 0.6520, F1-Score is 0.6580. In this study, three CNN architectures were used, namely: Traditional CNN Model, MobileNetV2 and VGG16. From the experimental results, it can be seen that the highest classification accuracy was obtained when using the VGG16 architecture model, which was 94%. These results indicate that when using the VGG16 architecture, there was a 6% increase in accuracy when compared to when using traditional CNN. An increase of 6% compared to when using traditional CNN is a positive trend. Classification accuracy is possible to be improved when using the transfer learning model. One way that can be used is through the appropriate hyperparameter setting. Through this hyperparameter setting, the CNN architecture used will be optimal. It is hoped that in the next study, hyperparameter optimization techniques can be used. One that can be used is to optimize using Particle Swarm Optimization and its Modifications, Genetic Algorithms and other optimization algorithms.

IV. CONCLUSION

This study identifies four significant diseases in chili plants based on leaves: leaf spot, yellowish, white fly, and curl leaf. The images used in this study were taken from the image dataset on Kaggle and also taken independently at the location of the chili plant, including healthy leaves labeled as healthy, so this study was divided into five classes. The chili leaf dataset is balanced, meaning that all classes have the same number of samples, namely 50 images per class and a total of 250 images with a size of 224 x 224 × 3. The experimental results show that the model with the best performance is the VGG16 model. This model achieves a validation accuracy of 94% on public and own data sets. The next best-performing model is MobileNetV2, which achieves an accuracy of 90%, followed by the Traditional CNN Model, which achieves a validation accuracy of 88%. In future developments, we intend to deploy it on mobile devices to automatically monitor and identify various types of chili plant disease information based on leaves. This study has limitations in terms of the dataset collected. Further research is expected to use a complete dataset so that training accuracy can be further improved.

ACKNOWLEDGMENT

The author expresses his deepest gratitude to Ristekdikti Kemdikbud Indonesia who has provided research funds in 2024 so that this research can be carried out through the Fundamental Research Research (PRF) scheme.

The Application of K-MEANS Algorithm-Based Data Mining in Optimizing Marketing Strategies of Tobacco Companies

Mingqian Ma
School of Economics and Management, Jiangsu Vocational College of Finance Economics, Huaian, 223003, China

***Abstract*—With the continuous development of data mining technology, more and more industries are applying data mining techniques to optimize their marketing strategies. In response to the persistent decline in tobacco sales and the gradual erosion of customer base in a particular enterprise in recent years, this study employs data mining technology to enhance the current tobacco marketing strategy. Firstly, in response to the current shortcomings of the company, a marketing optimization design scheme was proposed and a customer classification evaluation index system was constructed. Subsequently, homomorphic encryption technology and enhanced peak density thinking were employed to enhance the conventional K-means algorithm. The enhanced algorithm was then utilized in the customer clustering and partitioning scheme, with the objective of investigating the underlying information present in customer consumption data. The performance of the algorithm was tested, and the results showed that the mean square error of the improved K-means algorithm was about 0.1, with an average absolute error of about 0.05. The highest detection rate in the validation set was 0.95, and the lowest false alarm rate was 0.07. Both experts and customers were highly satisfied with the marketing strategy under the enhanced K-means algorithm. In summary, the clustering analysis method used in this study can effectively uncover the hidden value behind various types of customer data, thereby helping companies to make better marketing strategies.**

***Keywords*—Data mining; homomorphic encryption; k-means; tobacco; marketing strategy; indicator system**

I. Introduction

In today's fiercely competitive market environment, tobacco companies are facing unprecedented challenges and opportunities. In light of evolving consumer preferences and heightened awareness of health concerns, traditional marketing strategies are proving inadequate in meeting market demand. In particular, tobacco companies must contend with not only stringent regulatory constraints but also the necessity of devising bespoke marketing strategies for disparate consumer segments. As a result, accurate customer segmentation and efficient marketing strategies are key to improving sales performance. Currently, many tobacco companies have recognized the importance of data mining (DM) and customer segmentation [1]. By analyzing customer buying patterns and preferences, companies can better understand market demand and develop more accurate marketing plans. However, traditional customer classification methods are often limited by privacy concerns, especially when sensitive information is involved. It has become an urgent problem to solve how to effectively analyze while protecting customer privacy. In addition, although clustering analysis and other techniques have been applied in customer segmentation, existing algorithms still have certain limitations in handling high-dimensional data and ensuring result stability. With the continuous development of DM technology, DM technology using K-means algorithm (KMA) has been extensively applied to the optimization of tobacco companies' marketing strategies [2-3]. In the optimization of marketing strategies for tobacco companies, KMA can help tobacco companies to analyze data such as consumers' consumption habits, taste preferences, and purchasing behavior to develop more scientific and reasonable marketing strategies [4]. In response to this background, this study will use KMA to cluster customer data and identify relevant factors that affect tobacco sales quotas for optimization.

II. Related Work

The KMA is a clustering algorithm in view of distance calculation, which can classify data points with similar features into different clustering centers, thus achieving data analysis and mining. Currently, many scholars have conducted a series of studies on this algorithm [5-6]. Huang B et al. combined the KMA in clustering analysis with moving windows to propose a more effective method for static friction testing. The research results indicated that the method improves the detection accuracy by 15.3% compared to existing static friction detection methods. Applying this technology to practical industrial production could provide effective estimates of static resistance bands, as well as detect severe valve static resistance and unexpected valve closure situations [7]. In response to the severe faults that solar energy may face during use, Et Taleby et al. designed a solar panel detection system using wireless communication technology combined with KMA. The system diagnosed the failure of photovoltaic panels by detecting their thermal images. The outcomes indicated that the detection accuracy of the method used in solar energy fault detection was as high as 96.54%, which had good performance and could diagnose faults in a timely manner to effectively avoid accidents such as fires [8]. Zhang et al. proposed a new encrypted K-means clustering analysis algorithm in a collaborative manner to address the issue of KMA being unable to ensure data privacy during data clustering. In this algorithm, Zhang et al. used secure multi-party computation and differential privacy technology to train the K-means clustering model, aiming to protect data privacy and ensure that data can be output normally for analysis. The outcomes indicated that the adopted method possessed excellent clustering performance,

not only ensuring that data was not leaked during processing, but also updating the cluster center faster to ensure better clustering results [9]. In response to the issue of unequal resource allocation in the current multi-level sales operation network, Sin et al. rebuilt a resource allocation model and achieved the goal of multi-level task automatic allocation through this model. The experiment showed that the sales resource allocation model constructed could automatically allocate personnel and various resources, thereby achieving maximum resource utilization [10]. Currently the construction industry is facing problems such as waste management. It has been the concern of many scholars to find out how to effectively manage waste while maximizing economic benefits. Queheille E et al. proposed a multi-objective optimization algorithm and used the algorithm in waste management in the construction industry, aiming to design a suitable solution through the algorithm, which can maximize the use of human and material resources. The results of the study showed that the multi-objective optimization algorithm used was able to effectively calculate the number of workers required, the type of waste disposal and the optimal management plan, which had a certain value of utilization [11]. In light of the evolving landscape of social media and consumer behavior, the development of effective marketing strategies has emerged as a pivotal concern for major merchants. Gao M et al. used methods such as literature analysis and survey analysis to investigate the sales effect under different operating modes. In addition, multi-objective optimization and backward induction were used to optimize the current product pricing strategy. Finally, the results of the effects of different sales strategies under different network structures were verified through numerical simulation experiments. The experimental results showed that enterprises formulate appropriate marketing strategies could greatly promote the sales of commodities, so as to achieve the purpose of maximizing profitability [12].

In summary, current research on KMA has spread across various fields. In the past, scholars often used KMA to solve problems such as fault diagnosis, data analysis, and resource allocation. At present, no scholars have applied KMA to optimize the marketing strategies of tobacco companies. In response to the current situation of poor tobacco sales performance and frequent customer feedback problems in a certain tobacco company, this study applies KMA to optimize the marketing strategy of the tobacco company. This is aimed at further mining customer information through the KMA to optimize the company's current marketing situation.

III. Research on Marketing Strategies of Tobacco Companies Based on Homomorphic Encryption KMA

For optimizing the current marketing strategy of a tobacco company and improve its sales performance, this study takes a listed tobacco company as an example, first analyzes its current sales problems, proposes a series of improvement measures, and constructs a customer classification evaluation index system. Then it uses the improved peak density KMA under homomorphic encryption technology to evaluate the customer classification evaluation index system, and designs the final customer clustering division scheme. This is to further analyze customer consumption data to optimize marketing strategies.

A. Optimization Design of Marketing Strategy for Tobacco Companies

Homomorphic encryption is an encryption technique that allows the computation of ciphertext without decrypting the data, and ensures that the computed results are consistent with the original plaintext after decryption. Peak density is a concept commonly used to analyze signal or data set features. It describes the density of peak values in a signal or data set and is typically used to measure the distribution of a feature in the data. Tobacco marketing refers to the use of marketing strategies by tobacco companies to increase product sales and market share. In the tobacco company's marketing strategy, its composition includes the research on the target market, customer needs and competitors, as well as the development of personalized Marketing plan [13]. The goal of tobacco marketing is to increase brand awareness, customer satisfaction, and sales revenue to meet customer needs. This study takes a listed tobacco company as an example. In response to its current poor tobacco sales strategy and low sales revenue, a series of improvement and optimization measures are first proposed. Then, clustering analysis algorithm is used to mine data on its tobacco consumer types, to further improve the current tobacco strategy and increase the company's tobacco sales in view of different customer consumption situations. Fig. 1 shows the marketing strategy optimization path of a tobacco company.

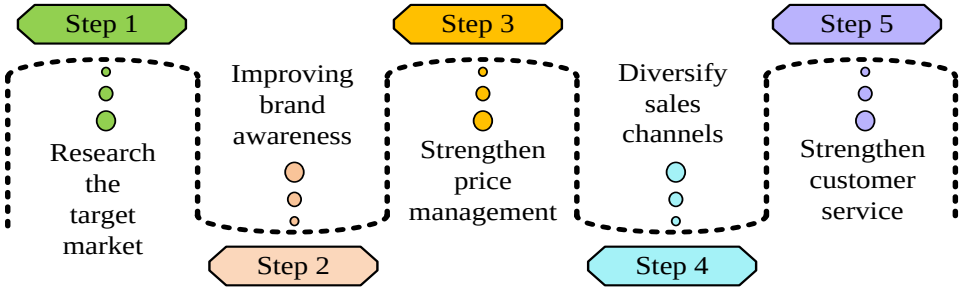

Fig. 1. Optimization path of Tobacco Company's marketing strategy.

Fig. 1 shows the optimization path of the tobacco company's marketing strategy. The entire optimization path consists of five parts, namely, researching the target market, improving brand awareness, strengthening price management, diversifying distribution channels, and strengthening customer service. The purpose of studying the target market is to determine consumer needs so that the company's overall tobacco marketing goals are in line with consumer needs. Improving brand awareness means creating a brand effect. Strengthening price management means that management should formulate reasonable pricing policies to ensure the stability of brand value. With the development of the Internet, traditional offline sales are no longer the only way for people to consume. Diversified sales channels require merchants to combine various online and offline channels for marketing to meet the needs of different consumers. Strengthening customer service requires improving customer satisfaction with their purchases, thereby enhancing their purchasing opinions. Among the above optimization measures, the long-term stable tobacco purchasing behavior of customers is an important guarantee for tobacco sales profitability.

For better understanding customer needs and develop appropriate tobacco sales plans, it is necessary to use DM technology to further mine the current customer information, discover the hidden value behind the data, and effectively improve the current sales model. Customer segmentation theory is a theory that categorizes customers according to certain criteria, to better understand their characteristics, needs, and preferences, and distinguish different categories of customers. Customer segmentation theory can help companies better understand customer needs and behaviors, thereby developing more personalized and effective marketing strategies and improving customer satisfaction and loyalty. In customer segmentation theory, key indicators such as customer purchase frequency, purchase amount, preference level, etc. are usually used to evaluate customer demand for a company's products and services. This study first utilized customer segmentation theory to construct a customer classification index system. Next, it uses the indicator system as an evaluation standard and uses clustering analysis algorithms to study the relationship between various types of customer behavior characteristics and their underlying purchasing behavior. Table I shows the customer classification evaluation index system.

Table I shows the customer classification evaluation index system. Table I shows that the entire customer classification evaluation index system consists of three primary indicators and 13 secondary indicators. According to the customer segmentation theory, customers are classified into three primary indicators: customer value, customer characteristics, and customer behavior. Customer value is further divided into three secondary indicators: total sales quota, total business quota, and average sales price. Customer characteristics are subdivided into five secondary indicators: business location, business market, business form, business nature, and business scale. Customer behavior is divided into five secondary indicators in view of customers' preferences for purchasing tobacco: first class tobacco proportion, second class tobacco proportion, third class tobacco proportion, fourth class tobacco proportion, and fifth class tobacco proportion. The proportion of cigarettes in one category refers to the proportion of customers who purchase tobacco for a single amount between 80 and 100 yuan. The proportion of second-class cigarettes refers to the proportion of customers who buy tobacco for a single amount of 60-80 yuan. The proportion of three kinds of cigarettes refers to the proportion of customers who buy tobacco for a single amount of 40-60 yuan. The proportion of four kinds of cigarettes refers to the proportion of customers who buy tobacco for a single amount of 20-40 yuan. The proportion of five kinds of cigarettes refers to the proportion of customers who buy tobacco for a single amount of less than 20 yuan.

TABLE I. CUSTOMER CLASSIFICATION EVALUATION INDEX SYSTEM

Evaluation Indicator System	First-level indicators	Second-level indicators	Code
Customer classification evaluation index system	Customer Value	Total sales limit	Y1
		Total business limit	Y2
		Average sales price	Y3
	Customer Characteristics	Business location	Y4
		Operating the market	Y5
		Business form	Y6
		Business nature	Y7
		Business scale	Y8
	Customer Behavior	Buy Class I cigarettes	Y9
		Buy Class II cigarettes	Y10
		Buy Class III cigarettes	Y11
		Buy Class IV cigarettes	Y12
		Buy Class V cigarettes	Y13

B. Construction of Tobacco Consumer Segmentation Model Based on Homomorphic Encryption KMA

Homomorphic encryption technology is a cryptographic technology, which enables encrypted objects to be calculated without revealing any useful information [14-15]. In addition, homomorphic encryption can convert encrypted data into the same form as ordinary data, and then perform calculations, so that users can get the expected calculation results even if they do not know the contents of encrypted data. This research applies the homomorphic encryption technology to the KMA, aiming to ensure that the algorithm can obtain information encryption in the running process, so as to prevent data information leakage. The homomorphic encryption process is shown in Fig. 2.

Fig. 2 shows the homomorphic encryption process. Firstly, it is necessary to generate a key suitable for encryption. Keys can be generated using non-public algorithms, such as secret sharing or common algorithms used to solve mathematical Hard problem of consciousness. Next, it uses the key to encrypt the data. This step can be done using a technology called homomorphic encryption, which converts encrypted data into the same form as ordinary data and then encrypts it. In the case of homomorphic encryption, anyone can compute the encrypted data without knowing the key. The ciphertext operation can be achieved by using machine learning algorithms.. Finally, the user needs to receive the decrypted plaintext and provide feedback on the encryption result to determine whether the desired result has been obtained. The encryption process of ciphertext is shown in Eq. (1) to Eq. (3) [16].

$$C = \left(c_1, c_2, \cdots c_n\right) \tag{1}$$

In Eq. (1), C represents the ciphertext data set. c_1, c_2 and c_n represent the ciphertext in the ciphertext dataset, respectively [17-18].

$$M = \left(m_1, m_2, \cdots m_n\right) \tag{2}$$

In Eq. (2), M represents the set of plaintext data. m_1, m_2 and m_n represent the plaintext in the plaintext dataset, respectively. The plaintext encryption process obtained by combining Eq. (1) and Eq. (2) is shown in Eq. (3).

$$\begin{cases} c_1 = Enc\left(m_1\right) \\ c_2 = Enc\left(m_2\right) \end{cases} \tag{3}$$

In Eq. (3), $Enc(\cdot)$ represents the encryption algorithm. Clear text m_1 and m_2 can obtain corresponding ciphertext through encryption algorithms, denoted as c_1 and c_2.

$$c_1 \odot c_2 = Enc(m_1) \odot Enc(m_2) = Enc(m_1 \odot m_2) \tag{4}$$

In Eq. (4), $\odot$represents an effective algorithm. If Eq. (4) satisfies the pre - and post equality relationship under the operation of an effective algorithm, then $Enc(\cdot)$ is said to have homomorphism.

$$Enc\left(m_1\right) \oplus Enc\left(m_2\right) = Enc\left(m_1 + m_2\right) \tag{5}$$

Eq. (5) is the calculation formula of addition homomorphic encryption. $\oplus$ represents an addition operation, and if Eq. (5) is satisfied, it indicates that the encryption algorithm used has additive homomorphism.

$$Enc\left(m_1\right) \otimes Enc\left(m_2\right) = Enc\left(m_1 \otimes m_2\right) \tag{6}$$

Eq. (6) is the calculation formula of multiplicative homomorphic encryption. $\otimes$ represents multiplication operation. Moreover, if Eq. (6) is satisfied, it indicates that the encryption algorithm used has multiplicative homomorphism [19-20].

$$Enc\left(m_1\right) \otimes m_2 = Enc\left(m_1 \times m_2\right) \tag{7}$$

Eq. (7) is the calculation formula of mixed multiplication homomorphic encryption. If equation (7) is satisfied, it indicates that the encryption algorithm used has mixed multiplicative homomorphism.

The KMA is a common clustering algorithm that can assign data objects to the clusters they belong to, so that each object has the same category throughout the entire dataset [21]. The traditional KMA is generally divided into several steps: initializing parameters, clustering, adjusting clustering, and repeating clustering. The clustering process is shown in Fig. 3.

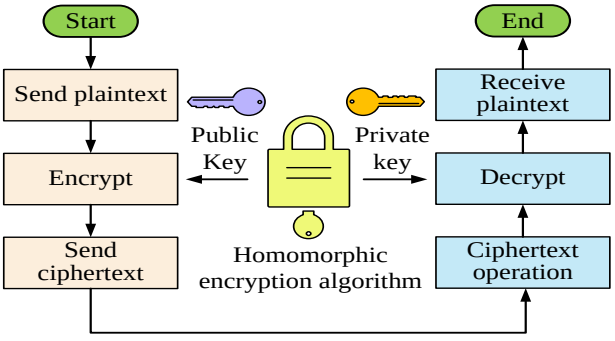

Fig. 2. Homomorphic encryption process.

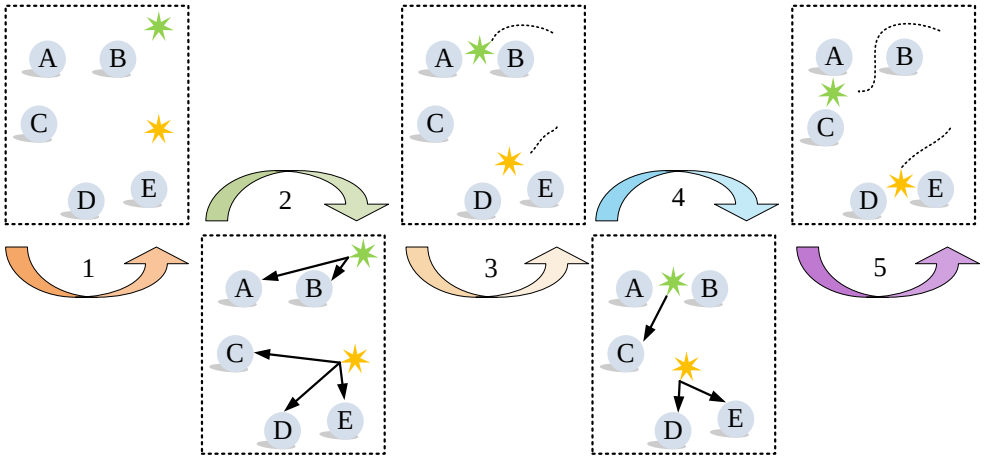

Fig. 3. KMA clustering process.

Fig. 3 shows the clustering process of the KMA. Fig. 3 shows that in the K-means clustering, the initial clustering needs to be selected first. The KMA uses a random selection method to determine the position of each data object in the dataset, and then clusters the data objects and assigns them to the corresponding clusters [22-23]. Over time, the size of the cluster is continuously adjusted to ensure that each object has the same category throughout the entire dataset. It continuously repeats the KMA for generating the best clustering [24-25]. The KMA generally utilizes Euclidean distance for measuring the similarity between two samples, and its mathematical expression is shown in Eq. (8).

$$D(X,Y)=\sqrt{\sum_{t=1}^{m}(x_i-y_i)^2} \tag{8}$$

In Eq. (8), assuming that the dataset has n samples of the m dimension, the distance expression between any two samples X and Y is denoted as $D(X,Y)$. Among them, $i \in 1,2,\mathrm{L},m$.

$$u_i=\frac{1}{|C_i|}\sum_{j=1}^{|C_i|}X_j=\frac{1}{|C_i|}\left(X_1+X_2+\mathrm{L}+X_{|C_i|}\right) \tag{9}$$

Eq. (9) is the iterative calculation formula for the centroid u_i in the KMA. C_i represents the i-th partition cluster. $|C_i|$ represents the quantity of samples contained in the i-th partition cluster.

$$SSE=\sum_{i=1}^{k}\sum_{j=1}^{|C_i|}\left(d\left(X_{i,j},u_i\right)\right)^2 \tag{10}$$

Eq. (10) is the mathematical expression for the standard function SSE of the sum of squared errors. The value of the error squared sum standard function can determine whether the algorithm iteration has ended. When the sum of squares of errors is less than the set error, the algorithm is terminated. k represents dividing the sample into Class k. $X_{i,j}$ represents the j-th sample in the i-th cluster. $d\left(X_{i,j},u_i\right)$ represents the distance from the sample to the center of mass.

$$CPD=\frac{1}{k}\sum_{i=1}^{k}d\left(u_i,u_i'\right) \tag{11}$$

Eq. (11) is the formula for calculating the difference in centroid changes. In addition to using SSE for judgment, this formula can also be used to determine whether the algorithm has ended. u_i' represents the position of the centroid of the previous generation in the i-th cluster. u_i represents the position of the current centroid. $d\left(u_i,u_i'\right)$ represents the Euclidean distance between two centroids. If the difference in centroid changes meets the requirements, the algorithm will be terminated.

Although the K-means clustering analysis algorithm has the characteristics of simple operation, high stability, and good analysis results, it still has certain limitations when used in different scenarios. For example, it has a strong dependence on the k-value of the divided sample category, and the algorithm is greatly affected by the center point. The algorithm has high randomness, making it difficult to converge to the optimal solution state. In response to the above issues, this study attempts to enhance the sample density in the algorithm dataset and uses the principle of maximum density to select the center point. Finally, it proposes a KMA with improved peak density to improve the stability of the traditional KMA and accelerate its Rate of convergence.

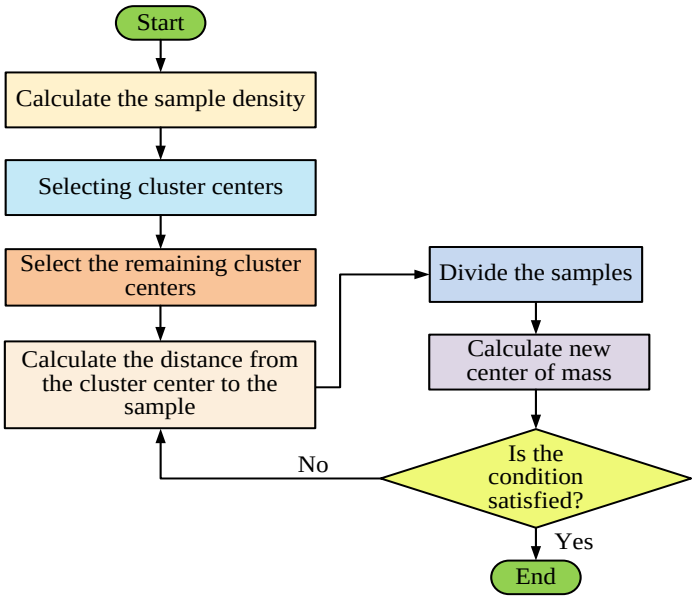

Fig. 4. Flow chart of KMA for improving peak density.

Fig. 4 shows the flowchart of the KMA for improving peak density. The input of the whole algorithm includes the original dataset D, the half price parameter q, the number of clusters k and the error parameter e. The output result is the divided clustering result. Firstly, it sets r and calculates the sample density, recording the sample with the highest density as x_i and the corresponding density value of the sample as $p(x_i)$. It places x_i into set x and removes other sample values within its radius range from the dataset, performing this operation on all samples in the dataset until the initial cluster center set x is obtained. It selects the sample with the highest density as the first clustering center, and then selects the second sample with the farthest distance as the second clustering center, using this method to select the remaining initial centers. Next, it uses the distance formula mentioned above to calculate the distance between the sample and the center, and divides the samples according to the principle of minimum distance. Then it calculates the new centroid for each classification cluster in the partitioned dataset using Eq. (9). Finally, it determines whether the output result is less than the error parameter e in view of the convergence judgment formula. If it is true, the algorithm is terminated. The improved peak density KMA is clustered using homomorphic encryption technology, and the customer segmentation scheme is shown in Fig. 5.

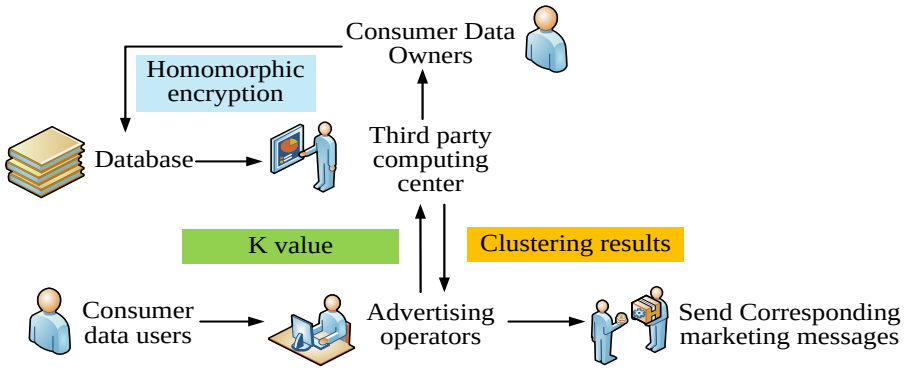

Fig. 5. Design diagram of customer clustering and division scheme.

Fig. 5 shows the design diagram of the customer clustering division scheme. To ensure the maximum utilization of consumption data, it is first necessary for data users to provide consumption data of their stores to advertising operators. However, to ensure the privacy of data information, the system will introduce homomorphic encryption technology to encrypt information during the entire data transmission process. Then it shares the data information with the third-party computing center, so as to use the KMA to analyze the customer consumption data, and then generate the corresponding marketing messages.

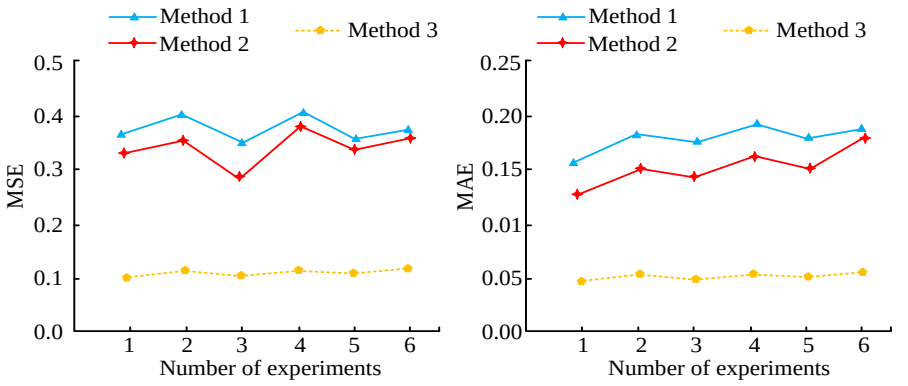
IV. Analysis of Tobacco Company Marketing Strategy Optimization Effect Based on Homomorphic Encryption KMA

For testing the effectiveness of the methods used in the research, the results analysis part first tested the performance of the improved peak density KMA under homomorphic encryption. Moreover, it proves that the improved peak density

KMA performs better than other comparative algorithms in four indicators: detection rate, false alarm rate, accuracy, and clustering running time. Subsequently, this study applied the improved peak density KMA to analyze customer consumption data, validated the customer classification evaluation index system, and obtained the application effect of tobacco company marketing strategy optimization.

A. *Performance Test of Improved Peak Density KMA Under Homomorphic Encryption*

It selected the tobacco sales data of a listed tobacco company in the past three years as the dataset for this experiment. After simple preprocessing of the dataset, the remaining data is divided into a training set and a validation set in a 9:1 ratio to test the performance of different clustering algorithms. The mean squared error (MSE) and mean absolute error (MAE) of the traditional KMA (subsequently recorded as method 1), the Mean shift algorithm (subsequently recorded as method 2), and the improved peak density KMA (subsequently recorded as method 3) in the same tobacco dataset are shown in Fig. 6.

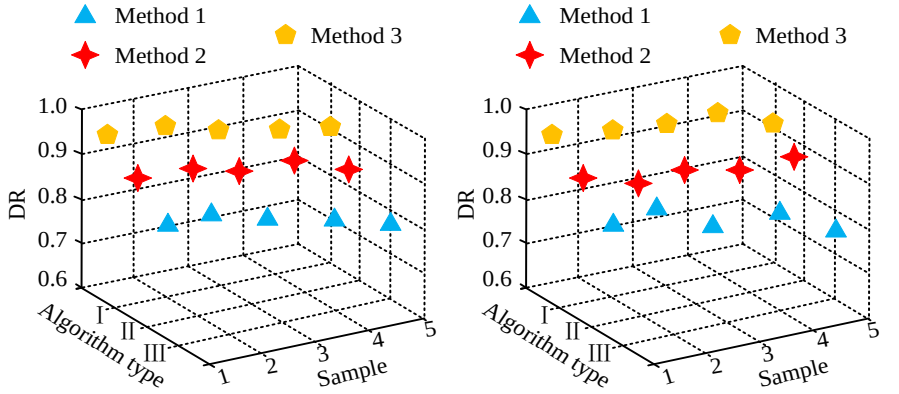


(a) MSE of each algorithm model under different experimental times

(b) MAE of each algorithm model under different experimental times

Fig. 6. MSE and MAE changes of three clustering methods.

Fig. 6 (a) shows the MSE changes of the three methods under different experimental times. As the number of experiments increases, the MSE of Method 1 and Method 2 fluctuates up and down, with a large fluctuation range, while the MSE of Method 3 is stable at around 0.1. Fig. 6 (b) shows the MAE changes of the three methods under different experimental times. The MAE values of Method 1 and Method 2 have significant changes, while the MAE values of Method 3 are stable at around 0.05.

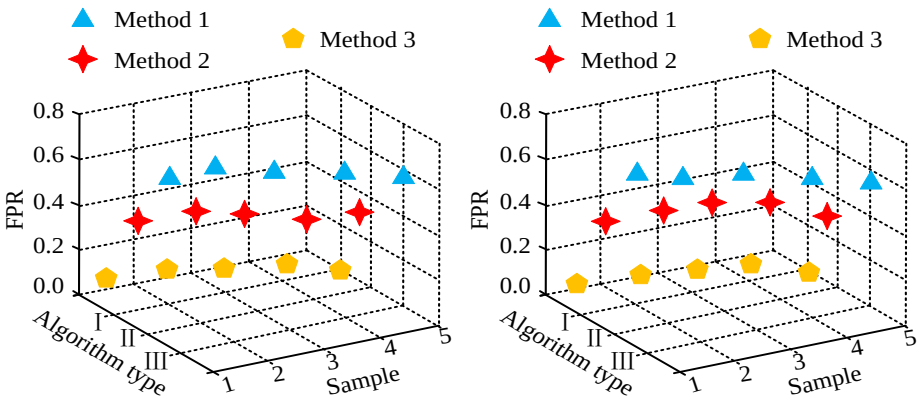


(a) Detection rate of different types of algorithms in training sets

(b) Detection rate of different types of algorithms in the test set

Fig. 7. DR changes of three clustering methods.

Fig. 7 (a) and 7 (b) show the changes in detection rates of the three clustering methods in the training and validation sets, respectively. Fig. 7 (a) shows that the highest detection rates of Method 1, Method 2, and Method 3 in the training set are 0.76, 0.85, and 0.97, respectively. Fig. 7 (b) shows that the highest detection rates of Method 1, Method 2, and Method 3 in the validation set are 0.77, 0.88, and 0.95, respectively. In summary, method three has the best data detection effect.

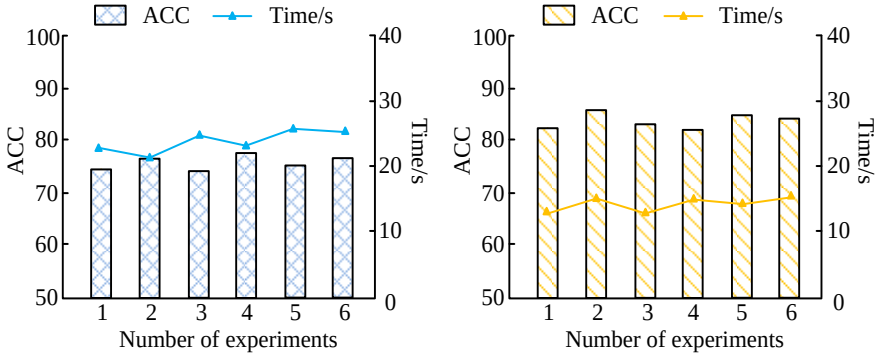


(a) False Positive Rate of different types of algorithms in training sets

(b) False Positive Rate of different types of algorithms in the test set

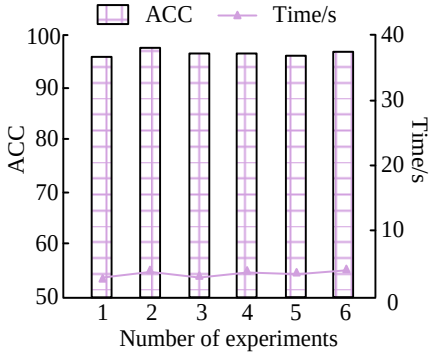
Fig. 8. FPR variation of three clustering methods.

Fig. 8 (a) and Fig. 8 (b) show the changes in false positive rates of the three clustering methods in the training and validation sets, respectively. Fig. 8 (a) shows that the highest false positive rates of Method 1, Method 2, and Method 3 in the training set are 0.56, 0.38, and 0.09, respectively. Fig. 8 (b) shows that the highest false alarm rates for Method 1, Method 2, and Method 3 in the validation set are 0.52, 0.39, and 0.07, respectively. In summary, method three has the best false alarm rate performance.



(a) The clustering accuracy and runtime of the method 1

(b) The clustering accuracy and runtime of the method 2



(c) The clustering accuracy and runtime of the method 3

Fig. 9. ACC and time variation of three clustering methods.

Fig. 9 (a), 9 (b), and 9 (c) respectively show the clustering accuracy and runtime changes of the three clustering methods under multiple experiments. Figure 9 (a) shows that the average clustering accuracy of Method 1 in six experiments is 73.26. As the number of experiments changes, its running time always fluctuates between 20 and 30 seconds, with significant fluctuations. Fig. 9 (b) shows that the average clustering accuracy of Method 2 in six experiments is 84.12. As the number of experiments increases, its running time always fluctuates between 10-20 seconds, with a smaller fluctuation compared to Method 1. Fig. 9 (c) shows that the average clustering accuracy of Method 3 in six experiments is 96.08, and its running time remains around 4 seconds as the number of experiments increases.

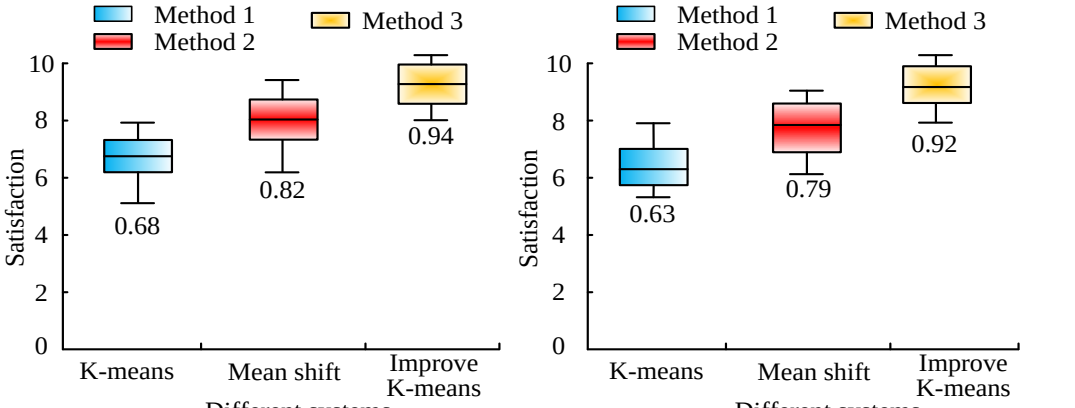
B. Analysis of the Optimization Effect of Tobacco Company's Marketing Strategy

After testing the performance of the improved peak density KMA under homomorphic encryption, the research applied it to the customer classification evaluation index system, input various customer data into the model, and obtained the final output results as shown in Table II. By examining the results of various outputs, it is possible to assist staff in the implementation of corresponding marketing plans, thereby achieving the goal of optimizing marketing plans and increasing sales.

TABLE II. OUTPUT RESULTS OF CUSTOMER CLASSIFICATION EVALUATION INDICATORS

Evaluation indicator system	First-level indicators	Second-level indicators	Code	Output value
Customer classification evaluation index system	Customer value	Total sales limit	Y1	8.7
		Total business limit	Y2	8.8
		Average sales price	Y3	9.3
	Customer Characteristics	Business location	Y4	9.2
		Operating the market	Y5	8.5
		Business form	Y6	8.6
		Business nature	Y7	9.0
		Business scale	Y8	8.3
	Customer behavior	Buy Class I cigarettes	Y9	7.7
		Buy Class II cigarettes	Y10	8.1
		Buy Class III cigarettes	Y11	8.8
		Buy Class IV cigarettes	Y12	8.7
		Buy Class V cigarettes	Y13	7.6

Table II shows the output results of customer classification evaluation indicators. Table II shows that out of the 13 secondary indicators, a total of 3 secondary indicators have output values above 9 points, namely average sales price, business location, and business nature. In addition, 8 secondary indicators have an initial value of more than 8 points. Given the above scoring results, tobacco company executives should optimize the drivers with higher scores to increase the company's tobacco revenues.



（a）User satisfaction with marketing strategies for various systems （b）Expert satisfaction with marketing strategies for various systems

Fig. 10. Satisfaction of users and experts with different marketing schemes.

Fig. 10 shows the satisfaction of users and experts with different marketing plans. Fig. 10 (a) shows the satisfaction of users with marketing solutions under different clustering methods. Fig. 10 (a) shows that users' satisfaction with marketing solutions under the three clustering methods of K-means, Mean shift, and Improve K-means is 0.68, 0.82, and 0.94, respectively. Fig. 10 (b) shows the satisfaction of experts with marketing solutions under different clustering methods. Fig. 10 (b) shows that experts' satisfaction with marketing solutions under the three clustering methods of K-means, Mean shift, and Improve K-means is 0.63, 0.79, and 0.92, respectively.

V. DISCUSSION

The research focused on optimizing the marketing strategies of tobacco companies, and achieved efficient customer classification and privacy protection through the improved peak

density KMA with homomorphic encryption. In practice, the marketing challenges faced by tobacco companies were mainly due to the intensification of market competition and the diversification of consumer demand. Traditional marketing methods were difficult to accurately reach target customers, resulting in persistently low sales. Therefore, using modern DM techniques for customer segmentation could not only help companies identify the characteristics of different customer groups, but also develop more personalized marketing strategies based on these characteristics. The experimental results showed that the improved KMA outperformed the traditional methods in clustering performance. In the experiment, the detection rate of the improved algorithm reached 97%, while the detection rates of the traditional KMA and the mean shift algorithm were 76% and 85%, respectively. This gap indicated the effectiveness of the improved algorithms in handling complex data sets, especially in capturing subtle differences in customer behavior. In addition, the false positive rate of the enhanced algorithm was only 9%, which was significantly lower than the 56% and 38% of the traditional algorithms. This improved accuracy was due to the optimization of the algorithm in the initial cluster center selection, which reduced the problem of inaccurate clustering caused by improper center selection. The introduction of homomorphic encryption technology effectively solved the privacy problem and ensured the security of customer information during the analysis process, which was particularly important for the tobacco industry. Due to increasingly stringent industry regulations, protecting customer privacy become a key factor in the sustainable development of companies. For example, data breaches could result in significant fines and loss of brand reputation. Therefore, the adoption of homomorphic encryption technology to ensure the privacy of customer data during the analysis process was a necessary choice in line with industry trends. In conclusion, the improved peak density KMA based on homomorphic encryption provided an effective solution for optimizing the marketing strategies of tobacco companies. On this basis, future research could further explore other data processing techniques and algorithms to cope with increasingly complex market environments and customer demands.

VI. Conclusion

In response to the problems of a certain tobacco company's current sales quota not being ideal and a large number of users losing, this study used the KMA in cluster analysis to analyze its customer data and optimize its current marketing strategy. The research results indicated that the improved KMA used had good clustering performance, with MSE and MAE values fluctuating around 0.1 and 0.05, respectively, which was much smaller than the traditional KMA and Mean shift algorithm. The maximum detection rate of improved K-means in the validation set was 0.95, the minimum false alarm rate was 0.07, and the average clustering accuracy under six experiments was 96.08. The clustering time was maintained at around four seconds, and its performance was superior to the other two comparative algorithms. In addition, the improved KMA had high output values for average sales price, business location, and business nature. Therefore, targeted optimization was needed for these three secondary indicators. In the end, both experts and users had a satisfaction level of over 0.9 with the optimized marketing plan. In summary, the improved K-means method adopted in this study could better develop appropriate marketing plans in view of consumer data characteristics, thereby obtaining the satisfaction of users and experts, and helping the company achieve maximum profitability. However, due to only analyzing customer impact indicators, there was still some error. Future research directions could explore more influencing factors, not limited to the customer. In addition to customer impact indicators, future research may wish to consider the inclusion of multidimensional variables such as market environment, competitor behavior, and economic factors in order to provide a more comprehensive evaluation of their impact on sales. Furthermore, a hybrid approach combining deep learning techniques with traditional clustering algorithms may be employed to enhance the accuracy and adaptability of the model.

***Abstract*—Energy management in data centers is currently a major challenge and arouses considerable interest. Many data center operators are seeking solutions to reduce energy consumption. In this work, the problem of resource overutilization-defined as the excessive usage of critical server resources such as CPU, RAM and storage surpassing their optimal capacity-in data centers is addressed, with a particular focus on servers. Estimating the energy consumption of servers in data centers allows its managers to allocate the necessary resources to ensure adequate quality of service. The research involved generating workloads performance on various servers, each connected to a wattmeter for energy consumption measurement. Data on resource utilization rates and server energy consumption were stored and analyzed. Machine learning models were then used to forecast server energy consumption. Parametric, non-parametric, and ensemble methods were employed and validated using accuracy measurements, non-parametric tests, and model complexity to assess the quality of energy consumption prediction models. The results demonstrated that certain models could provide predictions with a low margin of error and minimal complexity like polynomial regression, while other models showed lower performance. A comparative analysis is conducted to evaluate the performance and limitations of each approach.**

I. INTRODUCTION

Data centers are centralized collections where networked computers provide computational resources for various applications such as web hosting, e-commerce, grid computing, cloud computing, and social networks [1]. The computing equipment also enables the processing, storage, and analysis of data within the data center. A data center is used in the form of a cloud computing infrastructure that offers enough storage capacity and computing for Internet of Things (IoT) services and managing real time massive IoT data generated by numerous IoT devices. However, to ensure optimal performance and high reliability, it is common for the data center network to be oversized, resulting in relatively low utilization of links in real life scenarios based on empirical observations [2]. Cooling or power interruptions can have significant repercussions on the environment of a data center. Since system failures can be extremely costly, it is crucial to implement reliability and redundancy measures. Redundancy in cooling systems helps minimize the risk of failure and improves performance by reducing downtime for maintenance and repairs. The primary advantage of redundancy is to increase system reliability [3]. Energy management is an important process that requires a systemic approach by addressing both the energy consumption of idle resources and the supporting infrastructure. However, truly sustainable operation should not only focus on energy management but also include investments in research and development of green energies, the utilization of renewable energy sources, and active measures to preserve the environment [4].

The data center infrastructure can be divided into three areas: the computer room, the support zone, and accessory spaces. The computer room is a space with controlled environmental conditions designed to accommodate equipment as well as cables directly linked to computer and telecommunications systems that generate a significant amount of heat. Additionally, Information Technology (IT) equipment is extremely susceptible to changes in humidity and temperature, so a data center must maintain constrained conditions to ensure the reliability and proper functioning of the equipment it contains. The support zones are where a variety of systems such as Uninterruptible Power Supplies (UPS), cooling control systems, and communication panels are situated. Finally, the accessory sections primarily consist of offices, a lobby, and restrooms [5].

The massive energy consumed by servers in data centers poses a major problem that requires strategic research to address such as high energy costs, environmental impact, and resource overutilization. Estimating server energy consumption is essential for efficient energy management, providing the necessary power to IT infrastructure, managing data center resources, and minimizing costs. The goal is to estimate servers' energy consumption using ML algorithms and build models with a low margin of error and weak complexity, which refers to the time required for model creation. Three methods, namely parametric, non-parametric, and ensemble methods, are employed for this purpose. Parametric methods rely on assumptions regarding the data's underlying distribution and use a fixed number of parameters to describe it. Non-parametric techniques do not presume any specific distribution about the distribution of data. They are flexible and can handle complex relationships without specifying a fixed number of parameters. Ensemble methods integrate several models to enhance

predictive quality. They aggregate the predictions of several base models to produce a more accurate and robust prediction. Different models from each method were employed to assess the performance of each model and conduct a comparative study among them. We mention that the selection of parametric, non-parametric, and ensemble methods was based on their encompassment of techniques commonly utilized in regression problems. This study involves the creation of workloads that consume server resources and used multiple ML models to predict energy consumption using a collected database. A comparative study among different models was conducted to demonstrate the effectiveness of each model, using accuracy metrics, models complexities, and non-parametric tests.

The primary contributions of this research are detailed below:

- Creation of workloads that vary the resource utilization rates of servers in terms of CPU, RAM, and hard drive.
- Application of parametric, non-parametric, and ensemble methods on three heterogeneous servers, to verify the capability of ML models to predict the energy consumption of different servers.
- Validation of the ML models through precision measurements, non- parametric tests, and complexity.

The structure of this article is organized as follows: Section II presents the related work. Section III discusses the data center equipment and system architecture. Section IV reviews parametric, non-parametric, and ensemble methods. Section V details the data extraction processes, including the data extracted for each server, the designed algorithms, a comparison of the methods used to create workloads, and a description of the experiment. Section VI focuses on the prediction phase, applying parametric, non-parametric, and ensemble methods. Sections VII and VIII respectively present the results and discussion, including a comparison of the three types of methods across the three servers. Finally, Section IX is dedicated to the conclusion.

II. Related Work

In the literature, several authors have worked on energy management and consumption in data centers, as well as virtual machine (VM) placement on physical machines (PMs). In study [7], the authors propose two VM placement algorithms on PMs, considering CPU, RAM, memory utilization, and correlation values. These algorithms have shown performance in terms of energy consumption and service quality improvement compared to other methods [8]. The second approach involves optimal VM placement on servers using heuristics while considering hardware vulnerabilities, server energy consumption, and interference collocation among VMs [9]. This method selects an optimal approach from options such as dot product, norm2, first fit, ω-greedy, ρ-greedy, and η-greedy. Other authors in [10] studied the correlation between server resource utilization and energy consumption. They applied different workloads on two different servers and measured their energy consumption using two methods: resources utilization rate obtained from performance counters, and from external energy meter device. The results showed a strong correlation between CPU utilization and energy consumption, and a weaker correlation with RAM and disk utilization. This study can help data centers operate more energy-efficiently by optimizing resource consumption and lowering energy expenditure.

A power consumption prediction model for servers called PCP-2LSTM was proposed in study [11], this model applies a moving average smoothing technique to remove noise from the power consumption time series data and utilizes two stacked Long Short Term Memory (LSTM) networks to predict the power consumption for the next 30 seconds. A power consumption monitoring system is created to collect data and analyze power consumption, while ensuring the stationarity of the power series. CPU intensive workloads are used to collect power consumption data, and Collectd is used as a measurement tool to collect data such as CPU usage, frequency, memory usage, etc. The results show that PCP-2LSTM outperforms other models such as 2LSTM, LSTM, GBR, RAE, and ARIMA, with a normalized Root Mean Squared Error (nRMSE) of 0.417. However, it is important to note that the implementation of this model is simplified compared to a real data center, where there are various types of user requests beyond just CPU utilization. Another study proposes a VM selection policy called Maximum Correlation of sum of Squares of Deviation (MCSSD) [12]. This policy is implemented using the CloudSim tool with a heterogeneous server environment consisting of 800 servers. Workload traces from the CoMon project [13] are used, and the experiment is repeated with each server calculating resource utilization every minute. The results demonstrate that the proposed policy consumes less energy and minimizes the number of VM migrations compared to other policies such as Maximum Correlation, Minimum Utilization, and Minimum Migration Time.

Authors in study [14] developed a stochastic model to estimate the power consumption based on archived data. They consider workload and power as random variables and establish a correlation relationship between these two entities using a non-parametric approach. This makes the task complex as it requires estimating the complete distribution from the data. AI techniques were used to classify VMs based on their RAM and CPU usage [15], as well as to group user tasks based on their size and details extracted from the log file. Multiple tasks can share the same resources of a VM. The objective is to allow more dynamic resource allocation and enhance QoS standards by ensuring better resource allocation, raising user satisfaction, and lowering the number of rejected tasks. In [16], the authors present methods for evaluating and modeling the energy consumption of these resources and describe techniques that operate at the distributed system level, aiming to better manage resource scheduling, distribution, and network traffic management. Their research aims to make network and computing resources more efficient. A system proposed by [17] identifies frequently used data from application traces. Replication management and data placement are used to allocate frequently used files to "hot" disks and other files to "cold" disks. This system adds disk management to the cloud environment, which has proven effective in saving 39% of energy with an 18.26% reduction in execution time. The article also proposes an energy efficient storage system for a disk, combining energy efficient placement with a smart scheduling algorithm. The

system assigns data to a disk based on its data usage model. Data replication used in the algorithm ensures fast and easy data availability. The system maximizes energy savings by associating requests to the most available disks, thereby reducing query execution time. It also considers the minimum wait time and maximum remaining idle time when research disks are active or inactive, respectively. This approach applies data replication with the appropriate number of replicas across a hybrid system, ensuring the QoS for cloud applications.

On the subject of triggering queries, researchers in study [18] noticed that the frequency of triggering the same query to access data is quite high. Therefore, forecasting and preloading often accessed queries can elevate performance levels by reducing execution time and increasing cache hit rates. Hence, they develop a prediction model that first generates memory traces to assess data usage patterns related to query frequency. Future query requests were predicted and organized using an ensemble strategy, resulting in an accuracy of 87.5%. In study [19], the authors define Random Allocation as a policy that randomly assigns arrived tasks to a queue without considering how many tasks are waiting in the queue. This can lead to overflow in one queue while others remain empty or partially filled, increasing the probability of task loss. Short tasks may wait for a long duration in front of large tasks, which the random scheduler does not detect. However, implementing this policy is easy and does not require knowledge about the system. The Shortest Queue is defined as a strategy that overcomes the problem of balanced load across queues. Upon task arrival, the policy directs them to the queues with the shortest waiting time. This ensures that full queues do not appear while others still have available capacity, reducing the probability of task loss. However, short tasks may be delayed in front of long duration tasks. This strategy only considers waiting time and not service demands. The policy requires knowledge of the queue states. A notion of Task Assignment based on Guessing Size (TAGS) is introduced, aiming to allocate tasks when the service demands are not known before execution. In this case, a task is sent to a server's queue, and the server executes the task in the queue until it is completed or the execution time elapses. In the latter case, the task is sent to another server, and the same operations are repeated, increasing the waiting time as it moves from one server to another. Compared to the shortest queue strategy and random allocation, TAGS solves the problem of short tasks waiting behind long tasks. However, performance may be affected due to repetitive service. If the waiting time is very short, multiple tasks will require repetitive services, and if it is longer, the duration will delay completion. In study [20], the authors define reliability, energy consumption, and execution time as the principal scheduling parameters for real time embedded systems. In their work, while considering three constraints: the partial order of task modules, time limitations, and reliability, based on a Directed Acyclic Graphs (DAG) and Quantum behaved Particle Swarm Optimization (QPSO). When compared to alternative algorithms, the findings demonstrate that the two proposed algorithms provide effective optimization. These two algorithms are DAG_QPSO_I and DAG_QPSO_II. The first one demonstrates efficiency in terms of energy consumption, while the second one best meets the requirements of time and reliability. In this work, workloads have been created and launched to consume resources from heterogeneous servers and ML methods belonging to different parametric, non-parametric, and ensemble methods were implemented. A comparative study was conducted between these methods for each server. Estimating server energy consumption will enable better management of energy consumption in a data center. On the other hand, data center managers can adjust resources based on server demand, which helps reduce costs. Another objective is to optimize energy efficiency by identifying energy consuming areas and implementing. In contrast to many other studies that use limited or simulated workload data, this work involves the construction and deployment of real workloads which make use of resources from diverse servers. This method provides a more accurate assessment of the energy and servers performance. Moreover, comprehensive comparisons and the selection of the optimal models for diverse circumstances are made possible by the utilization of diverse ML methods. A comparative analysis was done for each server independently to make sure the results are accurate and applicable to different servers' configurations. This degree of specificity offers useful management insights for data centers.

III. Data Center Equipment and System Architecture

The power distribution systems of the data center are intended to provide electricity to the system loads or IT and mechanical equipment, ensuring proper levels of power quality and supply security. Since the public grid may experience voltage drops or prolonged outages that can result in malfunction or even a complete shutdown of the data center, it is crucial to ensure proper power supply. In a standard data center, there is a backup diesel generator or generator set to provide power in case of major grid failures. The UPS is capable of using different storage solutions like batteries, it is typically designed to keep power supply under appropriate conditions during the startup of the diesel generator. Power supply units (PSUs) and Power distribution units (PDUs) are in charge of distributing and regulating power for servers [5]. Fig. 1. illustrate the main elements of the data center responsible for power supply. It is important to note that generators or batteries provide backup power during a power outage. Racked servers and critical datacenter infrastructure can smoothly switch to this backup power for uninterrupted service. They can support primary power during periods of high demand or grid instability. They can help to balance the load on the power infrastructure of the data center and ensure a stable and reliable supply of power to the rack servers. During peak power usage periods, when energy demand is high, generators or batteries can supplement the power supply to avoid overloading the grid. This helps manage peak demand and avoid potential blackouts. They can also provide voltage regulation to ensure that the power supplied to rack servers remains within acceptable voltage ranges. This helps maintain the stability and longevity of server hardware. Rack servers, networking equipment, storage devices and other critical infrastructure within the data center rely on stable and reliable power to function optimally. Generators and batteries provide the necessary backup power to support these loads during emergencies or planned maintenance activities. In total, effective use of generators or batteries in a data center ensures reliable power to rack servers, improves energy efficiency, and

contributes to the resiliency and sustainability of the data center infrastructure.

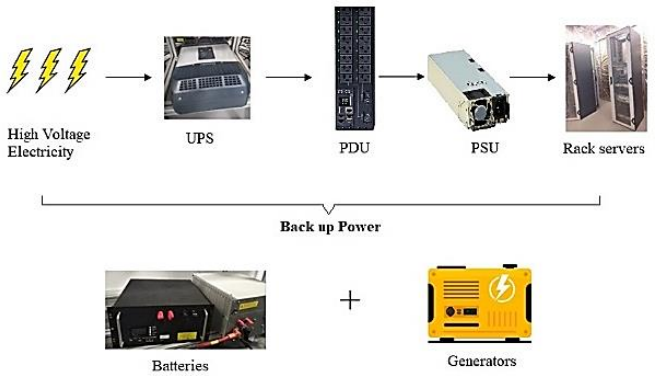

Fig. 1. Data center elements responsible for the power supply.

Most traditional data centers, including small and medium sized ones, have a power consumption breakdown as illustrated in Fig. 2 [6]. It can be observed that IT equipment accounts for 50% of the total data center power, followed by cooling systems, which represent 25% of the total power. Air handling equipment utilizes 12%, UPS units consume 10%, while lighting and other equipment consume 3% of the power. It is important to emphasize that servers, as part of the IT equipment, consume a significant fraction of the total power within data centers. This observation highlights the need to develop Machine Learning (ML) models to predict server energy consumption, enabling data center managers to better allocate their resources based on users' needs. The amount of energy consumed by servers compared to other components in a data center will vary based on factors such as workload type, server efficiency, cooling systems, and the data center design. In a conventional data center environment, as shown in Fig. 2, servers typically account for approximately 50% of total energy consumption. For this reason, and due to the limitations in accessing a real data center environment, this study focused primarily on servers, other elements such as networking equipment and cooling systems are not considered.

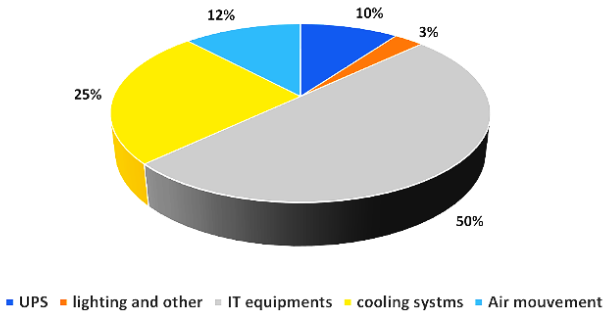

Fig. 2. Distribution of power consumption in a traditional data center [6].

Fig. 3 showcases the architecture of the system developed in this work, starting with the creation of workloads and their deployment on three servers, and ends with the generation of the proposed models.

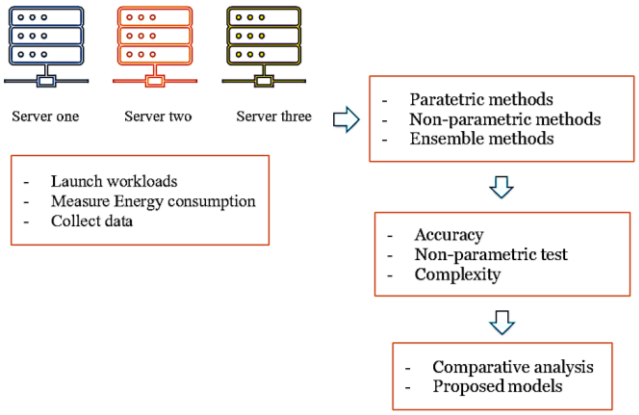

Fig. 3. System architecture.

IV. BACKGROUND

A. Parametric Methods

Parametric regression techniques are statistical tools employed to examine the relationship between a dependent variable and multiple independent variables [21]. This relationship is expressed through a mathematical equation that contains a set of parameters. The objective is to estimate the values of these parameters based on the data. Common examples of parametric regression models include polynomial regression, which is a statistical study that models the variation of a dependent variable using a polynomial function of an explanatory variable. The mathematical representation of the polynomial regression is provided in Eq. (1). Where x is the independent variable, y is the dependent variable, a_i; $i=1,\ldots, k$ is the coefficient or the parameter. Lasso regression (L1 regularization) is another method of statistical regression that combines linear regression with regularization, aiming to eliminate features that do not contribute to the training. Eq. (2) illustrates the formula utilized in Lasso regression, where k is the number of observations. y_i is the observed value of the observation i. x_{ij} is the value of the predictor j for the observation i. α_j is the coefficient to be estimated and strictly between zero and one. m is the number of predictor variables, and γ is the regularized parameter that controls the strength of the penalty term. Determining the ideal value of γ, or the value that strikes a balance between the model's fidelity and other factors is crucial [22]. Elastic Network (L1+L2) is a linear combination of L1 and L2 resulting in a regularizer that combines the advantages of both L1 (Lasso) and L2 (Ridge) regularization techniques, similar to Lasso regression, uses regularization to control the complexity of the model by selecting the most relevant variables. Many studies have utilized the Elastic Network, including the work presented by authors in [23], which introduces a novel algorithm for clustering analysis based on elastic networks and leveraging weighted properties. Also, in study [24] authors propose a novel approach called the Elastic Network Algorithm for Clustering based on Cluster Center Shift, which combines Mean-Shift with the Elastic Network algorithm to optimize both cluster stability and effectiveness in the cluster analysis. Lastly, Neural Networks (NN) are a type of ML that consists of interconnected neurons organized in layers and capable of learning from data by adjusting connection weights between neurons. For NN with

multiple layers, the output of each layer *l* can be calculated using the output of the previous layer. Eq. (3) outlines the structural formulation of NN, where $a^{(l)}$ is the output of the layer *l*, σ is the activation function, $w^{(l)}$ is the weight matrix of layer *l*, $a^{(l-1)}$ is the input to the layer *l*, and $b^{(l)}$ is the bias for layer *l*. Lasso regression minimizes the sum of squared errors between the actual and predicted values. It works by iteratively reducing the coefficients of less important variables towards zero. It utilizes a regularization parameter, alpha, which controls the strength of the L1 penalty. A larger value of alpha leads to coefficients closer to zero. The formulation for Elastic Network can be found in Eq. (4), where *N* is the number of observations, y_i is the observed value for the observation *i*. β_k, *k=0,..*, *p* is the coefficient to be estimated. *p* is the number of predictor variables. λ_1 and λ_2 are the regularization parameters for L1 and L2 penalties. x_i is the value of the predictor variable *j* for the observation *i*. For each server, 80% of data was used for training the model, and the obtained error values were recorded. It should be noted that for each server, the models were trained using non-normalized data.

$$y = a_0 + a_1 x + a_2 x^2 + a_3 x^3 + \cdots + a_k x^k \quad (1)$$

$$\mathrm{L} = \sum_{i=1}^{k} \left(y_i - \sum_{j=1}^{m} x_{ij} . \alpha_j \right)^2 + \gamma \sum_{j=1}^{m} |\alpha_j| \quad (2)$$

$$a^{(l)} = \sigma(w^{(l)} a^{(l-1)} + b^{(l)}) \quad (3)$$

$$min_{\beta_0,\beta} \left(\sum_{i=1}^{N} (y_i - \beta_0 - x_i^T \beta)^2 + \lambda_1 \sum_{j=1}^{p} |\beta_j| + \lambda_2 \sum_{j=1}^{p} \beta_j^2 \right) \quad (4)$$

B. Non-parametric Methods

Non-parametric methods apply statistical analysis to investigate the connection between a dependent variable and multiple independent variables without making specific assumptions about the functional form or equation that describes the relationship [25]. These methods estimate the relationship based on the data itself. Common examples of non-parametric regression models include Support Vector Regression (SVR), which is a supervised learning method based on support vectors that model the data and find a hyperplane that separates the data by minimizing the squared error. It is useful for complex regression problems where the data has nonlinear relationships. The formula for SVR is presented in Eq. (5). Where ω is the weight vector or coefficients associated with the input features *x*. This vector determines the importance of each feature in the prediction. *x* is the input feature, and *b* is the bias term. Decision trees are ML algorithms used for classification and regression problems. They model the relationships between input variables and output variables using a graphical representation with connected nodes. The algorithm selects the most informative variable to split the data into categories, and the process is repeated until a stopping condition is met. Random forests are an ensemble of decision trees constructed randomly based on the training data. The prediction for an observation is based on the average or majority value of the individual predictions from the trees. Gaussian Process Regression (GPR) is a probabilistic approach based on the concept of a Gaussian process, which is a collection of random variables that have a joint Gaussian distribution for any finite number of variables. This model can capture complex and nonlinear relationships between variables without assuming a specific functional form of the relationship.

$$y = f(x) = \langle \omega, x \rangle + b;\ \omega, x \in \mathbb{R}^M, b \in \mathbb{R} \quad (5)$$

C. Ensemble Methods

Ensemble methods refer to a class of ML models that blend several models to increase the system's predictive effectiveness [26]. These models can be of the same type (homogeneous) or different types (heterogeneous). The idea behind ensemble methods is to reduce the variance and bias of individual models by combining their outputs. This is achieved through different strategies, such as bagging, which is based on an ensemble estimator using base regressors trained on random subsets of the dataset and merges their predictions, either via voting or averaging, to generate the final output. Bagging involves creating multiple versions of the same model on different subsets of the data and combining their outputs by averaging or voting. Eq. (6) illustrates the formula utilized in Bagging. Where $f_{bagging}(x)$ is the aggregated prediction for the input *x*. *N* is the total number of base learners, and $f_i(x)$ is the prediction of the base learner *i*. Boosting is a ML method that involves creating a series of models aimed at reducing errors in predictive data analysis. Each subsequent model learns from the errors of the previous one. Boosting addresses the problem of biased models when using new data by successively training multiple models to improve the overall system accuracy. Data scientists often use boosting with decision tree algorithms [27]. Boosting combines multiple models sequentially and assigns weights to the outputs of individual models, giving higher weight and input to the next model for incorrect predictions from the previous model. Stacking is an ensemble method that reduces the error rate of one or multiple estimators during prediction. It works by stacking the outputs of each individual estimator and using a regressor to compute the final prediction. This method allows leveraging the strengths of each estimator by using their outputs as input to a final estimator. It is important to mention that the base estimators are fitted on the dataset, while the final estimator is trained using the cross-validation predictions of the base estimators. Stacking incorporates boosting and aggregation, which combines the outputs of models and achieves high accuracy and low variance. The formula of Stacking can be found in Eq. (7). Where $f_{stacking}(x)$ is the final prediction of the stacking ensemble for input *x*, and $f_k(x)$, *k=1,…, N* is the predictions of base learners. *Meta_learner* is the meta learner that combines the predictions. Typically, the number of estimators used in this method ranges from three to five. In this work, parametric and non-parametric models were used and developed earlier while keeping the same chosen configurations.

$$\hat{f}_{bagging}(x) = \frac{1}{N} \sum_{i=1}^{N} \hat{f}_i(x) \quad (6)$$

$$\hat{f}_{stacking}(x) = Meta\_learner(\hat{f}_1(x), \hat{f}_2(x), \ldots, \hat{f}_N(x)) \quad (7)$$

V. Data Extraction

In this experiment, workloads that consume CPU, RAM, and hard disk resources of three servers were created and executed, each one is connected to a wattmeter that accurately measures the server's energy consumption with a precision of one mwh. The number of data points used for server one, server two and server three is 897, 945, and 951, respectively. Each data element represents the median value of resources utilization for the server over a period of one hour. In other words, workloads

that varied the usage of CPU, RAM, and/or hard disk were executed for one hour and recorded the server's state during that execution. If the resource utilization varies frequently, the configuration is discarded; otherwise, it is kept. For the three servers, each data point (vector representing a workload) includes CPU values ranging from 10% to 100%, RAM values ranging from 10% to 90%, and disk usage ranging from zero GB to the maximum storage capacity of each server. The servers used in this study are documented in Fig. 4, which illustrates the work conducted at the LUSAC laboratory of the University of Caen Normandy in France.

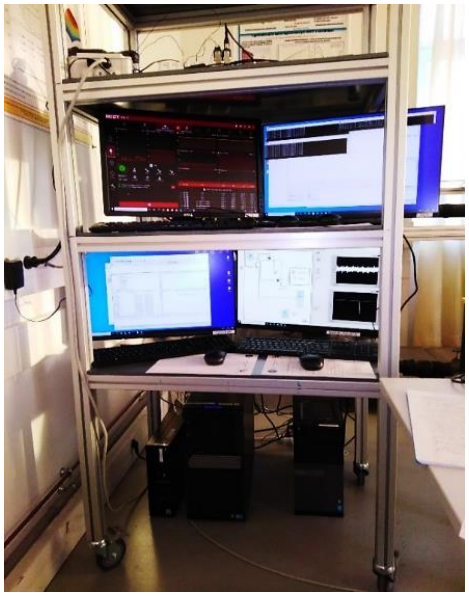

Fig. 4. Servers used in the experimentation conducted at LUSAC laboratory.

In the following, the algorithms used to generate workloads that consume CPU, RAM, and disk resources of the servers are presented. For the implementation of those algorithms, the Python programming language was utilized, and every algorithm was launched in every server. After creating and executing the workloads, the energy consumption of the servers is measured. Then, on a computer, models belonging to different categories: parametric, non-parametric and ensemble, were built with the aim of predicting the energy consumption of the servers. It is mentioned that the results obtained come from a computer and not from a simulator. Also, the duration is the same in the three algorithms. For the first algorithm, OCCT was utilized to generate workloads that would stress the CPU of the server. In the second algorithm, programs such as Google Chrome were launched continuously to consume the RAM of the server, the memory usage is measured after executing those programs. In the third algorithm, files were created and duplicated on the hard drive to write data on it. After each execution, the files created to run the algorithm with different parameters were deleted (number of bytes to write). It is noted that various input data values are employed for writing operations on the hard drive. This approach aimed to create workloads that would write on the server's hard drive with continuous writing operations. Initially, the process was initiated by writing at a rate of 100 bytes per second for a duration of one hour. Subsequently, the byte values were incrementally increased in the following simulations.

Algorithm1: Workload_CPU
Input: nbr_process, duration
Output: cpu_rate, ram_rate, hard_drive_rate, energy_consumption
Start
  For var p in [1: nbr_process]:
    Create_process()
    Launch_process()
  End for
  While time < duration:
    Save (cpu_rate, ram_rate, hard_drive_rate, energy_consumption)
    If time == duration:
      For var p in [1: nbr_process]
        destroy_process ()
      End for
    End if
  End while
End

Algorithm2 Workload_RAM
Input: nbr_process, duration
Output: cpu_rate, ram_rate, hard_drive_rate, energy_consumption
Start
  For var p in [1: nbr_process]:
    Launch_program()
  End for
  While time < duration:
    Save (cpu_rate, ram_rate, hard_drive_rate, energy_consumption)
    If time == duration:
      For var p in [1: nbr_process]
        Destroy_process ()
      End For
      Break
    End If
  End While
End

Algorithm3: Workload_hard_drive
Input: nbr_bytes, duration
Output: cpu_rate, ram_rate, hard_drive_rate, energy_consumption
Start
  While time < duration:
    write_bytes()
    Save (cpu_rate, ram_rate, hard_drive_rate, energy_consumption)
    If time == duration:
      Break
    End if
  End while
End

The characteristics of each server are presented in Table I. It should be noted that the selection of servers is based on their availability in the research laboratory where this study is conducted.

TABLE I. SERVERS CHARACTERISTICS

Server one	Server two	Server three
processor Intel(R) Xeon(R) CPU W3565 @ 3.20 GHz, RAM 16 Go, Disk SATA SSD 256Go, NVIDIA Quadro 400, os Windows 10	Intel(R) Core (TM) i5-10500 CPU @ 3.10GHz, RAM 8GB, Disk 512GB, and OS windows server 2022 Standard version os.	Processor Intel (R) core (TM) i3 CPU 540 @ 3.07 GHz, RAM 4 Go, disk 120 Go SSD, Intel(R) HD Graphics, os Windows 10.

VI. PREDICTION PHASE

A. Application of Parametric, Non-parametric, and Ensemble Methods on Servers

We applied parametric methods to analyze the behavior of three servers. Starting with server one, according to Fig. 5, Fig. 6 and Fig. 7 which show the error rate, the p-value, and the models' complexity respectively, It is observed that some models, such as NN, have high complexity, followed by Bagging_GPR. In terms of MSE, Lasso regression, elastic network, GPR, and other models exhibit high values around six wh. Table II presents the error rates, the p-values of non-parametric tests Wilcoxon rank sum and the complexity of each method. The results show that the polynomial regression of degree two performs the best with a low MSE of 0.71 wh. Followed by NN, which consists of two layers with 64 neurons each, using the Adam optimizer and trained with 2600 epochs. It achieves a high R^2 of one and low errors, indicating that this model can accurately predict the server's energy consumption. Lasso regression and Elastic Network have similar R^2 values, with a coefficient alpha of 0.69 for Lasso regression, an alpha and L1 coefficients of 0.34 and 0.9, respectively, for Elastic Network. The MSE of both methods exceeds five wh, indicating that these two models struggle to explain the variation in the data. The p-value of the models is relatively similar for all three models, suggesting no significant difference in their performance. For each model used, different parameters were tested, and those that yielded the best results were selected. It is interesting to note that the polynomial regression, Lasso regression, and Elastic Network models have negligible predictions and construction times. However, NN stands out with a construction time of 283 seconds, primarily due to the high number of epochs used and the complexity of its structure.

Concerning the second server, as shown in Table III, the polynomial regression of degree two had the least bias, with a MSE rate of 0.04 wh and a p-value of 0.98. Followed by NN model, configured with 2600 epochs, a sigmoid activation function for the first and the second layers, 128 neurons, and the Root Mean Squared Propagation (rmsprop) optimizer. The best result for Elastic Network was achieved with an alpha of 0.01 and an L1 of 0.01, resulting in a MSE rate of 0.07 wh. As for the Lasso regression model, it is observed that the error rate increases with the increase in the alpha coefficient. The best performance was obtained with an alpha of 0.01, resulting in a MSE of 0.08 wh. Overall, the results indicate that the parametric methods generally perform well in predicting the energy consumption for this server. Indicating a high probability that the real and predicted vectors are significantly similar. It is observed that polynomial regression, Lasso regression, and Elastic Network stand out for their reduced model construction time and negligible prediction time. On the other hand, NN model requires a longer construction time, reaching up to 110.9 s. However, it achieves a fast prediction rate of 0.1 s.

TABLE II. ACCURACY MEASUREMENTS, NON-PARAMETRIC TESTS AND COMPLEXITY OF PARAMETRIC METHODS OF SERVER ONE

	R^2	MSE [wh]	MAE [wh]	RMSE [wh]	MAPE [%]	Wilcoxon rank-sum test	Model construction time [s]	Prediction time [s]
Polynomial Regression	**1.0**	**0.71**	**0.57**	**0.84**	**0.45**	**0.812**	**0.0091**	**0.0**
Lasso Regression	0.99	5.69	1.81	2.39	1.39	0.62	0.0007	0.0
Elastic Network	0.99	5.69	1.82	2.39	1.41	0.63	0.0022	0.0010
Neural Network	1.0	2.02	0.62	1.42	0.50	0.63	283.4409	0.1547

TABLE III. ACCURACY MEASUREMENTS, NON-PARAMETRIC TESTS AND COMPLEXITY OF PARAMETRIC METHODS OF SERVER TWO

	R^2	MSE [wh]	MAE [wh]	RMSE [wh]	MAPE [%]	Wilcoxon rank-sum test	Model construction time [s]	Prediction time [s]
Polynomial Regression	**0.99**	**0.04**	**0.16**	**0.2**	**0.87**	**0.98**	**0.0019**	**0.0**
Lasso Regression	0.98	0.08	0.21	0.28	1.14	0.42	0.0019	0.0005
Elastic Network	0.98	0.07	0.21	0.26	1.12	0.49	0.0020	0.0
Neural Network	0.99	0.05	0.12	0.22	0.66	0.48	110.9219	0.1096

On server three, the polynomial regression model of degree two was employed, Lasso regression with an alpha of 0.01, Elastic Network with an alpha of 0.01 and an L1 of 0.01. The NN is configured with a number of epochs of 2600, two layers of 128 neurons each, using the hyperbolic tangent activation function 'tanh'. We used the Stochastic Gradient Descent optimizer 'sgd' for the NN. Table IV indicates that NN turned out to be the least biased model, with a MSE of 0.07 wh, followed by polynomial regression with a MSE of 0.09 wh. Lasso regression and Elastic Network produced similar prediction values, with a MSE of 1.24 wh and 1.23 wh, respectively. Like servers one and two, all the parametric models are characterized by their low complexity in terms of model construction and prediction. Except NN model that requires 108.34 s for model construction.

Proceeding with non-parametric methods, models were used to evaluate the performance of the servers. For the first one, the results show that decision trees, random forests, and SVR models achieve the best performance with a MSE below 0.58 wh. On the other hand, the GPR model exhibits a significantly higher MSE of 5.71 wh, indicating lower performance compared to the other models. For the SVR model, the Radial Basis Function (RBF) kernel was used with an epsilon value of 0.1 and a regularization parameter C of 19.6. The depth of the decision tree and random forests are 9 and 10, respectively, with 20 estimators for random forests. Lastly, for the GPR model, the DotProduct kernel and WhiteKernel were utilized. As observed in Table V the SVR model, decision trees, and random forests have minimal construction and prediction times, making them computationally advantageous. However, the GPR model stands out from the others in terms of construction and prediction time, being higher.

Similarly for server one, server two results, as cited in Table VI show that decision trees, random forests, and SVR are the best models for predicting server energy consumption, with a MSE rate of 0.02 wh. Although GPR model follows the other three models in terms of precision, it is also performant. We note that SVR model is configured with an epsilon and a C parameter of 0.1 and 3.0 respectively. The optimal depth for decision trees and random forests is five. The kernel used in the GPR model is based on DotProduct and WhiteKernel. Also, all selected non-parametric methods stand out for their low complexity in terms of model construction and prediction time. Likewise to the first and second servers, random forests, decision trees, and SVR are the best models for predicting the energy consumption of server three. The SVR model was trained with an epsilon of 0.06 and a C value of 16.1, while the decision trees and random forests have a maximum depth of six. On the other hand, the GPR model has a high MSE of 1.23 wh. It was trained with a DotProduct and WhiteKernel. Based on the results obtained in Table VII, it can be observed that all the proposed non-parametric models can provide energy consumption predictions with an error rate below 1.23 wh and relatively low complexity.

TABLE IV. ACCURACY MEASUREMENTS, NON-PARAMETRIC TESTS AND COMPLEXITY OF PARAMETRIC METHODS OF SERVER THREE

	R^2	MSE [wh]	MAE [wh]	RMSE [wh]	MAPE [%]	Wilcoxon rank-sum test	Model construction time [s]	Prediction time [s]

Different ensemble methods were used, namely boosting, bagging, and stacking. The boosting model was configured with a learning rate of 0.41 and 50 estimators, using a decision tree with a depth of nine as the base estimator. The bagging model was evaluated using various regression methods as base estimators, including polynomial regression, Lasso regression, Elastic Network, SVR, decision trees, random forests, and the GPR model, denoted in Table VIII as Bagging_Poly, Bagging_Lasso, Bagging_Elastic, Bagging_SVR, Bagging_Tree, Bagging_Forest, and Bagging_GPR, respectively. The parameters for these models were defined as mentioned previously, with an optimal number of estimators set to 100. Regarding the first server, the results showed that the boosting model had the least bias, followed by the stacking model configured with GPR and the decision tree as base estimator. Next, the bagging model trained with decision trees achieved good results, as well as the stacking model configured with random forests and SVR model, along with the bagging model trained with the SVR estimator. The MSE of these models ranged from 0.32 wh to 0.59 wh, with a p-value above 0.69. However, except for the bagging model with the GPR estimator, the bagging and stacking methods trained with polynomial regression, Lasso regression, and Elastic Network as base estimators yielded less accurate prediction results compared to the aforementioned models. These models exhibited a higher MSE above five wh. It is observed that certain models had both high error rates and low model construction time, such as bagging and stacking trained with parametric methods. The bagging using the GPR model is distinguished with high error rates and significant model construction time. On the other hand, other models such as boosting and bagging using non-parametric methods other than GPR, as well as stacking using non-parametric models or a combination of the two methods, were characterized by low error rates and model construction times below 3.8 s.

Moving to the second server, the MSE of the boosting model is 0.02 wh and the R^2 reaches one, indicating that the model is capable of predicting energy consumption with negligeable error. As shown in Table IX, the p-value of the Wilcoxon tests is indicating that this method provides predicted values similar to the real values. By applying bagging and stacking models with different estimators. The best results were obtained using decision trees, random forests, and polynomial regression as base estimators for both methods. The average MSE in these models is below 0.07 wh, with a high value of R^2. The stacking model trained with the GPR estimator is the least biased in terms of precision measurement among all the proposed ensemble methods, with a MSE of 0.01 wh. The Bagging_Lasso, Bagging_Elastic, Bagging_GPR, Stacking_Lasso, and Stacking_Elastic models follow the previously mentioned models in terms of prediction quality. Among the ensemble methods, it is noteworthy that all models are characterized by their low complexity, with a model construction time of 9.18 s for the bagging model trained with the base estimator GPR.

Lastly, as for the third server, it can be observed that the boosting method trained with decision trees of depth six as base estimators provides predicted values with a MSE of 0.03 wh. Similarly, the bagging and stacking methods trained with the SVR model, decision trees, and random forests as base estimators have a MSE ranging from 0.02 wh to 0.06 wh. Therefore, the stacking model trained with GPR has an MSE of 0.03 wh. On the other hand, the other models such as Bagging_Poly, Bagging_Lasso, Bagging_Elastic, Bagging_GPR, Stacking_Poly, Stacking_Lasso, and Stacking_Elastic provide prediction values with an MSE of 1.23 wh and 1.24 wh. It can be observed that all ensemble methods are capable of predicting energy consumption with an error rate below 1.24 wh in terms of MSE, MAE, and MAPE, and p-values ranging from 0.35 to 0.89, as indicated in Table X. The values of the MAPE are already multiplied by 100. Therefore, a MAPE of 0.45 represents 0.45% and not 45%. Different complexity characteristics are observed among the boosting and bagging models using parametric models as base estimators. They have relatively low complexity, making them efficient in terms of model construction time. Next, bagging using decision trees, random forests, and SVR as base estimators, which also exhibit moderate but slightly higher complexity. On the other hand, the bagging model using GPR as the base estimator stands out for its higher model construction time, reaching 93.19 s. As for stacking, the results show that the methods using parametric models have a model construction time of 1.1 s, indicating relatively low complexity. On the other hand, stacking using non-parametric models has model construction times ranging from 5.3 s to 8.08 s, which remains reasonable considering the more complex nature of these models.

VII. RESULTS

This section provides an overview of the results obtained. For the first server, observations indicate that certain parametric methods, specifically polynomial regression, perform well in terms of prediction with low error rates and reduced complexity. However, other methods like Lasso regression and Elastic Network show high error rates exceeding five wh in terms of MSE for energy consumption prediction, while maintaining relatively low complexity. Among the non-parametric methods, SVR, decision trees, and random forests have low complexity and error rates for energy consumption prediction. However, GPR model provides prediction results with a high error rate and higher complexity compared to other methods. When it comes to ensemble methods, the boosting method trained with decision trees provides results very close to the actual values with low complexity. It is to highlight that models trained with parametric models have high MSE error rates but low complexity. Conversely, models trained with non-parametric methods like SVR, decision trees, and random forests as base estimators are considered the best models with construction complexity ranging from 0.15 s to 2.77 s. However, using the GPR base estimator in the bagging method significantly increases the MSE error rate up to 5.7 wh, and the model construction complexity reaches 57.47 s.

When using the stacking method, all models trained with parametric methods provide poor prediction results. On the other hand, models trained with non-parametric methods show optimal error rates. In conclusion, the recommended model for predicting the energy consumption of this server is the stacking model, using non-parametric or both parametric + non-parametric methods as estimators and trained with GPR as final estimator. The advantage of this method is that it combines multiple ML models and selects the optimal model to provide the best results. Furthermore, the complexity of this method is low. For example, although the GPR model provides poor prediction results when used alone, it can be used as the final estimator in the stacking model to improve the model's error rate and obtain optimal results.

For server two, it is remarkable that all models have a MSE lower than 0.17 wh. Among the parametric methods, polynomial regression and NN are characterized by their high performance. However, it should be noted that NN has considerable complexity due to their architecture and computational operations involved. Next, Lasso regression and Elastic Network, which exhibit average error rates and lower complexity. For non-parametric methods, the SVR model, decision trees, and random forests achieve a MSE of 0.02 wh, indicating good prediction performance. However, the GPR model has a higher error rate, suggesting poorer performance compared to other models. In terms of complexity, all methods are characterized by low complexity, making them efficient in terms of model construction and prediction time. The boosting method offers optimal prediction results with low complexity, as behave the bagging methods trained with non-parametric models such as SVR, decision trees, and random forests, as well as the stacking methods trained with non-parametric models. The recommended model for predicting energy consumption while maintaining a trade-off between complexity and error rate is the stacking model trained with non-parametric or mixed models. Regarding complexity, all proposed methods have low complexity, except the bagging model using the base estimator GPR, which has a model construction complexity of 9.18 s.

It is observed for the third server that high performing parametric methods with low error rates are polynomial regression and NN. However, the other two parametric methods reach a MSE of 1.23 wh, with a p-value of 0.35. It is important to note that for all three servers, NN are considered complex due to their architecture. Therefore, if new data is added to retrain the model, it may not be the optimal choice in terms of complexity, even though its performance may surpass some other models. As with server one and server two, non-parametric methods other than GPR provide optimal prediction, and the complexity of all methods is low. For ensemble methods, bagging_SVR, bagging_Tree, bagging_Forest, stacking_SVR, stacking_Tree, stacking_Forest, and stacking_GPR are considered optimal in terms of MSE, MAE, and MAPE. However, some models have low error rates while others have higher error rates, notably the stacking method using non-parametric methods as estimators, resulting in complexity reaching 7.61 s. Similar to server one and server two, bagging using GPR as base estimator stands out with a higher error rate and higher complexity of 93.19 s. Other models such as bagging and stacking trained with parametric models have a MSE error rate of 1.24 wh and low complexity. The best model for predicting energy consumption of this server while maintaining a balance between complexity and error rate is the Gradient Boosting model. The stacking method is characterized by a low error rate. However, the model construction complexity is higher compared to the Gradient Boosting model, reaching up to eight seconds. These observations allow us to better understand the relationship between different models and their respective complexity. They also highlight the importance of considering this complexity when choosing and evaluating models to find the right balance between performance and computational efficiency.

VIII. DISCUSSION

The variation in servers' energy consumption with workload execution is illustrated in Fig. 8, when CPU_workloads are executed on the first server, the CPU utilization rate reaches 94.5%, resulting in an increase in server energy consumption from 98.52 wh in idle state to 177.92 wh under load. On the other hand, when RAM_workloads are executed, energy consumption reaches 130.93 wh, while CPU utilization varies between 11.2% and 24.9%. Finally, when disk-based workloads are executed and write up to 11 290.35 MB on the disk, energy consumption reaches 125.84 wh, with RAM utilization varying between 24.33% and 71.17%, and CPU utilization varying between 12.5% and 24.2%. For server two, energy consumption ranges from 16 wh to 22.73 wh when CPU-intensive workloads are executed, with CPU utilization varying between 8.1% and 92.4%. When RAM-intensive workloads are executed, energy consumption reaches 20.32 wh, with RAM utilization varying from 26.38% to 78.29%. For disk-intensive workloads, energy consumption ranges from 16.99 wh to 18.75 wh, with CPU and RAM utilization rates ranging from 10.7% to 16.6% and 51.1% to 78.29% respectively, and data written to the disk reaching up to 18 064.42 MB. Regarding server three, energy consumption varies from 41.66 wh to 62.4 wh when executing workloads that

consume between 25.6% and 100% of the CPU. For workloads that vary RAM utilization between 40.12% and 68.21% and CPU utilization between 22.2% and 23.1%, energy consumption ranges from 40.77 wh to 42.25 wh. Launching workloads that consume the hard disk results in energy consumption ranging from 35.72 wh to 44.91 wh, with CPU utilization varying between 24.6% and 33.9%, and RAM utilization ranging from 42.74% to 49.56%, with data written to the disk reaching up to 4 393.99 MB.

Note that for all three servers, each parameter was carefully selected through experimentation. Experiments were conducted extensive testing on a range of values, choosing those that yielded the best results in terms of accuracy, complexity, and non-parametric test performance. Additionally, the same workloads were launched on the three servers, but each server handled them according to its architecture and capacity. For example, when a workload is launched on server *i*, it may complete successfully within the expected duration, while on another server, it may crash due to insufficient capacity to process and execute that workload. This explains why the number of data varies from one server to another.

The MSE, complexity, and p-value performance of the three servers are shown in Fig. 9. For the three servers, it was identified that the best models were polynomial regression, decision tree, boosting_Tree, and bagging_Tree. The outcomes demonstrate that the three servers' MSEs are all less than 0.7 wh, their complexities are all under 1.31 seconds, and their p-values range from 0.48 to 0.98. These findings show those models are useful for low computational complexity and high accuracy server energy consumption prediction. Because the models' predictions are statistically similar to the actual values, as confirmed by the high p-values, they can be effectively implemented to improve energy management and efficiency.

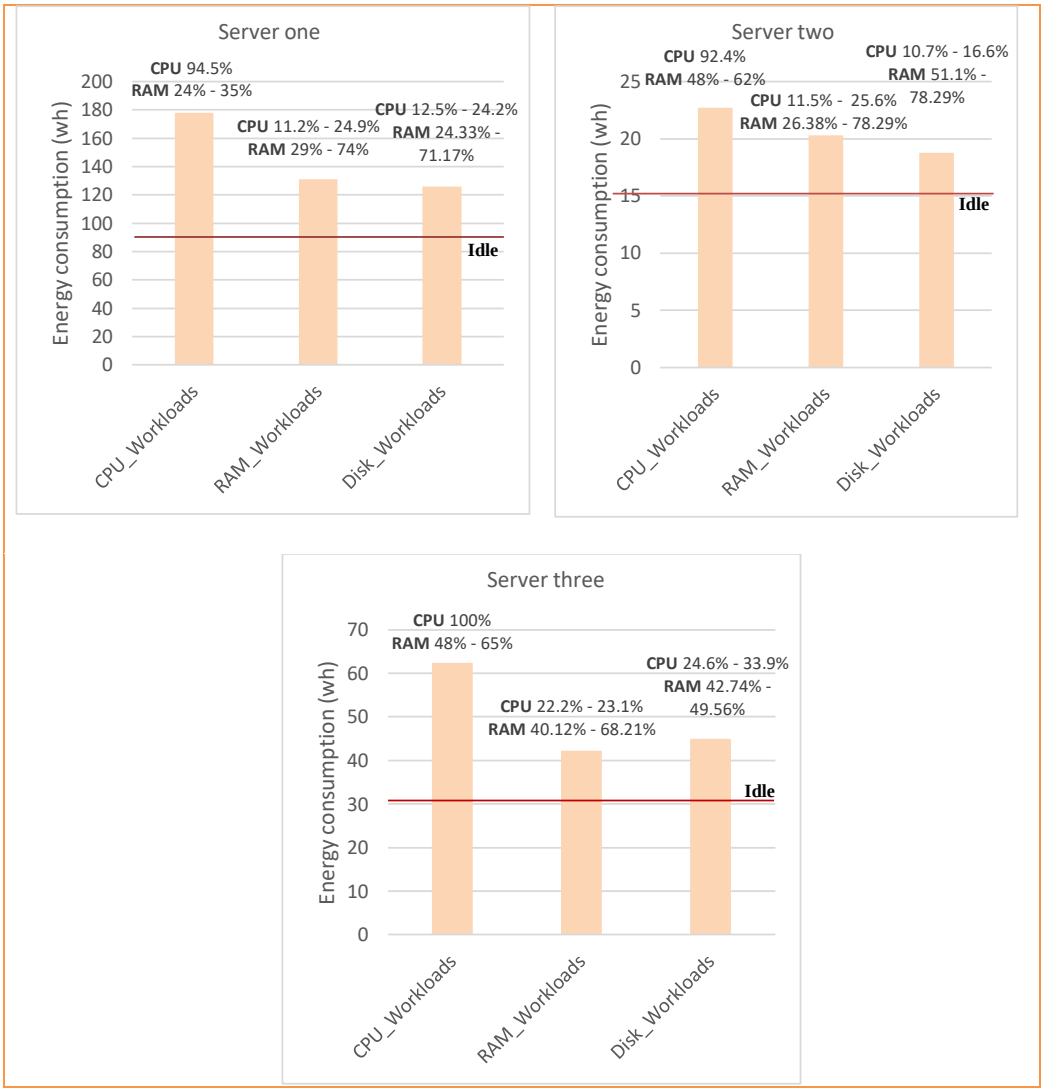

Fig. 8. Variation in servers energy consumption with workload execution.

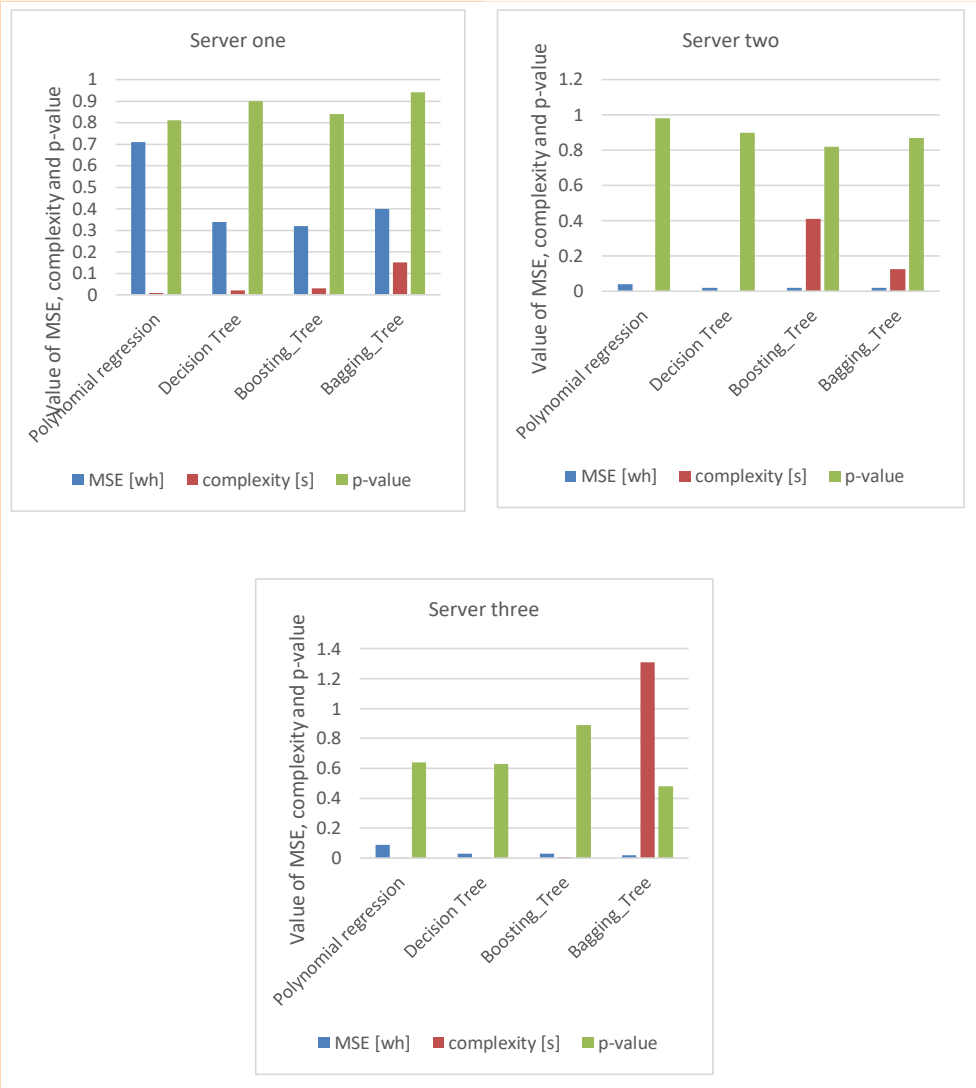

Fig. 9. Performance of the top models for the three servers.

Observation shows that for the three servers, certain methods are distinguished by low error rates and low complexity. These methods include polynomial regression belonging to parametric methods, as well as SVR, decision trees, and random forests belonging to non-parametric methods. Similarly, Boosting and Stacking with parametric models show good performance in terms of error rates. Other methods, such as Lasso regression, Elastic Network, GPR, and bagging using parametric models, have high error rates but low complexity. On the other hand, bagging methods using SVR, decision trees, and random forests, as well as Stacking with non-parametric models, are characterized by low error rates and moderate complexity. The worst results in terms of high error rates and high complexity are obtained with NN and bagging using GPR as the base estimator. Comparing the three servers, it is observed that each has a different energy consumption pattern. Server one consumes 2.85 times more energy than server three and 7.82 times more than server two. Server three, on the other hand, consumes 2.74 times more energy than server two. In this study, the complexity of the model was included as a critical factor for several reasons. For instance, after selecting a model that meets the requirements, it becomes crucial to assess its complexity. If the data center providers intend to retrain the model with additional data, understanding its complexity becomes paramount. If the complexity is high, retraining the model might not be advisable. However, if the complexity is manageable, this process can enhance the model's capability to accommodate new workloads, thereby improving its estimation accuracy. It should be highlighted that, to apply the elaborated algorithms to a real data center, it is highly recommended to use the data directly from the servers within that data center. In fact, the variability in workload characteristics influences the creation of ML models designed to predict server energy consumption. In this work, three types of servers were used to demonstrate the performance of ML models, as the type of servers may vary from one data center to another. This study aims to pinpoint the most effective models for estimating server energy usage, offering tailored recommendations for different server environments.

Predicting the future workload of servers in a data center is considered a challenging task because it is difficult to control or fully anticipate the clients' needs, as they are free to use or

consume resources according to the SLA. However, by analyzing historical server activity, patterns can be identified using various ML methods to estimate server workloads. In this study, the focus is placed on resources such as the CPU, RAM, and hard disk. Although users may request other types of resources, this study is limited to the resources. If the data center workloads shift in an irregular way and atypical manner, predictions can still be made by the proposed ML models. Besides, in this situation, it will be advised to use continuous learning, which will enable ML models to automatically update with current data and adjust over time to shifting workload patterns. Additionally, retraining the ML models on current data on a regular basis will keep them more accurate and relevant. Additionally, online learning has also the potential to be effective and enable the models to rapidly adapt to transient variations in workload.

IX. Conclusion

The choice of the appropriate method depends on the desired objectives. If the focus is on prediction quality in terms of error rates, the Stacking model, which uses the GPR model alongside other parametric and non-parametric models as internal estimators, is a good choice for predicting server energy consumption. However, if the objective is to regularly retrain the model by increasing the amount of data, it is preferable to choose a model that has both low error rates and reduced complexity. In this case, the polynomial regression model may be a good choice due to its architecture and computational requirements. It can be observed that for all three servers, the CPU consumes the most energy compared to the other resources, and the energy consumption when applying workloads that consume RAM and hard disk differs from one server to another. In this study, only CPU, RAM, and hard drive workloads are used as data to construct ML models to predict energy consumed by servers, while other types of workloads can also be handled within the data center. Also, in real data center, servers are placed in racks and installed in rooms equipped with other elements such as cooling system. However, the integration of cooling units and heat management are not elaborated in this work. Our future research will focus on exploring and refining anomaly detection in data centers as a critical frontier for ensuring the robustness and reliability of server systems by enabling the identification and mitigation of irregularities or unexpected patterns in energy consumption. Ultimately, the efforts in anomaly detection promise not only to improve system reliability, but also to facilitate more sustainable and resource-efficient operation of server networks.

Ethical Approval

As this research does not involve human participants or animals, ethical approval was not required for this study.

Competing interests

The research conducted in this article is primarily intended for academic and educational purposes.

Authors' contributions

Meryeme EL YADARI created the database, performed data analysis, conducted the experiments, and wrote the article.

Saloua EL MOTAKI contributed to this work by proposing ideas, reviewing the article, enhancing its content, and correcting the report.

Ali YAHYAOUY, and Khalid EL FAZAZY collaborated in this work by organizing meetings, where we discussed the work, provided valuable feedback, and made suggestions for content improvement.

Hamid GUALOUS provided the servers and all necessary materials for conducting the experiments, participated in the meetings, validating the work, and offering valuable remarks.

Stéphane LE MASSON actively engaged in discussions with the authors, providing insightful feedback to enhance the content of the work.

Funding

All the materials used in the experiment were provided by the University laboratory of applied sciences of Cherbourg (LUSAC).

Availability of Data and Materials

The database utilized in this work is internally developed and considered confidential; thus, there is no external link available for accessing it. The materials utilized in the experiment consist of three servers responsible for executing the tasks, one computer dedicated to data manipulation, and three wattmeters for measuring energy consumption.

***Abstract*—Autonomous decision-making in decentralized multi-agent systems (MAS) poses significant challenges related to security, scalability, and privacy. This paper introduces an innovative architecture that integrates Decentralized Identifiers (DIDs), Zero-Knowledge Proofs (ZKPs), Hyperledger Fabric blockchain, OAuth 2.0 authorization, and the Command Query Responsibility Segregation (CQRS) pattern to establish a secure, scalable, and privacy-focused framework for MAS. The use of DIDs and ZKPs ensures secure, self-sovereign identities and enables privacy-preserving interactions among autonomous agents. Hyperledger Fabric provides an immutable ledger, ensuring data integrity and facilitating transparent transaction processing through smart contracts. The CQRS pattern, combined with event sourcing, optimizes the system's ability to handle high volumes of read and write operations, enhancing performance and scalability. Practical applications are showcased in Smart Grids, Healthcare Data Management, Secure Internet of Things (IoT) Networks, and Supply Chain Management, highlighting the architecture's ability to address industry-specific challenges. This integration offers a robust solution for ensuring trust, verifiability, and scalability in distributed systems while preserving the confidentiality of agents.**

Keywords*—Decentralized multi-agent systems; decentralized identifiers; zero-knowledge proofs; hyperledger fabric; OAuth 2.0; CQRS; smart grids; healthcare data management; IoT; supply chain management

I. Introduction

In recent years, the rise of data-driven and compute-intensive applications has significantly increased the demand for scalable and decentralized systems capable of processing vast amounts of data in real-time. Multi-Agent Systems (MAS) have emerged as a robust solution for managing such complex environments. Comprising autonomous agents that collaborate to achieve common goals, MAS are integral to domains such as smart grids, supply chain management, and distributed computing, where they enable efficient, distributed decision-making [1]. However, these systems also introduce challenges related to security, scalability, and privacy [2]. Despite their potential, MAS face significant challenges in ensuring secure and private interactions among agents. Traditional security mechanisms, such as Public Key Infrastructure (PKI), are often inadequate for decentralized environments, leaving MAS vulnerable to attacks such as man-in-the-middle (MitM) and data breaches [3][4]. Additionally, the increasing need for privacy in distributed systems complicates interactions, particularly when sensitive data might be exposed during agent communication and transaction processing. These challenges lead to critical research questions: how can secure communication be ensured in MAS to prevent MitM attacks and maintain data integrity? What mechanisms can provide privacy-preserving capabilities in decentralized systems while maintaining scalability? How can blockchain and Zero-Knowledge Proofs (ZKP) be effectively integrated to address these challenges in MAS? To address these questions, the objectives of this research are to develop a secure and privacy-preserving framework for MAS to safeguard agent interactions, leverage blockchain technology for data integrity and decentralized processing, employ ZKP to enhance privacy while maintaining system scalability and security, and optimize real-time decision-making through the adoption of Command Query Responsibility Segregation (CQRS) principles in MAS.

Blockchain technology offers a promising solution to these challenges by providing decentralized, tamper-proof ledgers that enhance data integrity [5]. This approach is valuable in sectors like finance and logistics, where accountability and transparency are critical. The immutability of blockchain transactions ensures that once data is recorded, it cannot be altered, providing a verifiable record of actions. However, blockchain's transparency can also reveal sensitive information, creating further privacy challenges [6]. To address both security and privacy, this paper proposes a novel framework integrating CQRS, blockchain, and ZKP. CQRS, introduced by Greg Young, separates commands (write operations) from queries (read operations), optimizing system scalability, especially in high-volume environments like MAS that require real-time processing. While blockchain addresses data integrity, it does not inherently protect agent identities. Zero-Knowledge Proofs offer a solution by enabling agents to verify transaction authenticity without revealing the underlying data. Integrating ZKP with blockchain ensures that only authorized agents can execute transactions while maintaining anonymity [7]. Recent advancements in ZKP, including zk-SNARKs, have bolstered blockchain privacy, enabling privacy-preserving solutions for sectors such as healthcare, IoT, and decentralized finance [8][9].

This paper presents a comprehensive framework that integrates CQRS, blockchain, and ZKP to address critical challenges in MAS, including security, scalability, and privacy. It offers a theoretical analysis of the proposed architecture's features and demonstrates its real-world applicability in areas such as Smart Grids, Healthcare Data Management, Secure IoT Networks, and Supply Chain Management. Additionally, the framework's effectiveness is validated through comparisons with existing state-of-the-art solutions, highlighting its

contributions to the field. The remainder of the paper is organized as follows. Section II and Section III provide a detailed overview of the background and related work, highlighting the limitations of existing solutions. This is followed by a presentation of the proposed framework, describing its architecture and components in Section IV. Section V and Section VI analyze the framework's security, privacy, and scalability features, demonstrate its application in real-world scenarios, and discuss its performance. The paper concludes in Section VII with an outline of potential future work.

II. Related Work

The decentralized nature of Multi-Agent Systems (MAS) has led to their extensive use in distributed environments such as IoT networks, smart grids, and autonomous systems. MAS enable collaborative, autonomous decision-making but face critical challenges concerning security, scalability, and privacy. Numerous research efforts have been made to address these concerns, with a focus on authentication, data protection, and performance optimization through read/write operations.

A. Authentication and Authorization in MAS

Authentication is a cornerstone of MAS security, ensuring that agents are who they claim to be and that communications are protected. Traditionally, centralized methods like PKI have been used for authentication, but these introduce single points of failure and scalability issues [10]. Blockchain-based authentication mechanisms offer an alternative by leveraging decentralized smart contracts to eliminate trust intermediaries and prevent unauthorized access [11]. This decentralized approach is especially useful in environments where trust between agents cannot be guaranteed [12].

Despite these advancements, blockchain's high computational overhead for processing smart contracts poses challenges for real-time decision-making environments like IoT or smart grids. Moreover, these systems often lack fine-grained authorization mechanisms, which are crucial for handling multi-level access in dynamic, distributed environments. A solution to this problem, as proposed by He et al., involves a blockchain-based authentication scheme designed for mobile cloud computing, which introduces dynamic access control but struggles with resource efficiency [13].

B. Data Integrity and Privacy in Distributed MAS

In MAS, protecting data from tampering or loss is crucial. Blockchain's immutability and tamper-proof properties have been proposed as solutions to ensure data integrity [14]. Off-chain storage solutions, such as IPFS, have also been introduced to reduce on-chain storage costs, while still maintaining data integrity through cryptographic hashing. However, these systems face limitations, particularly when data stored off-chain is not protected by the same level of integrity as on-chain data.

Moreover, protecting data from loss due to network failures or agent disconnections is not adequately addressed in current off-chain storage models, which can lead to data tampering risks. To address these concerns, multi-copy data integrity auditing and batch auditing techniques in blockchain can help ensure that data availability and integrity are preserved, even in distributed environments [15].

Oliveira et al. [16] develop a modular MAS architecture for distributed data mining, effectively handling scalability but lacking stronger privacy mechanisms. Qasem et al. [17] also focus on MAS-integrated data mining, highlighting issues with data privacy and suggesting the need for secure communication protocols like ZKPs. Similarly, Nait Cherif et al [18] propose a blockchain-based solution for data integrity, though it requires significant computational resources, which may be alleviated by the CQRS-based system in this work. Ge et al. [19] survey advancements in distributed sampled-data cooperative control of MAS, emphasizing different sampling mechanisms to improve performance, yet these methods often lack real-time adaptability, posing a scalability bottleneck. In comparison, the CQRS pattern in this work supports high throughput by separating read and write operations, thus enhancing real-time performance under high loads.

C. Scalable Resource Management in Multi-Agent Systems

Efficient read/write operations are critical in distributed MAS, especially as the number of transactions scales. The CQRS pattern has been widely adopted to separate read and write operations, thereby optimizing system performance. This is particularly beneficial in high-volume transaction environments, where large amounts of data must be processed in real-time [20] [21].

However, while CQRS improves scalability, it does not inherently provide protection against man-in-the-middle (MitM) attacks or secure write operations, exposing the system to security threats [22]. Additionally, ensuring data consistency across distributed agents, especially in real-time applications, remains an unresolved issue, as CQRS alone does not guarantee that agents will have synchronized access to the latest data [23]

Dynamic and scalable MAS architectures benefit from integrating CQRS with blockchain technology. For example, Dashti et al. [24] introduce a MAS framework with dynamic agent capabilities but struggle with issues related to agent turnover. Our approach leverages blockchain for immutable tracking and secure data integrity, mitigating this issue. Similarly, Breugnot et al. [25] propose a distributed graph structure for load balancing in MAS but encounter challenges with data synchronization. By implementing CQRS in our framework, we enhance the synchronization process, enabling seamless data processing across distributed nodes.

Control and optimization are also central to MAS design, particularly in adversarial or resilience-focused settings. Wang [26] highlights the importance of distributed control but does not adequately address security against adversarial threats. In contrast, our approach integrates Decentralized Identifiers (DIDs) for secure agent identification and Zero-Knowledge Proofs (ZKPs) for verifiable, tamper-resistant interactions. This architecture not only improves resilience against data tampering but also maintains robust state management through CQRS, addressing challenges like those noted by Rust et al. [27] in state persistence across agents. Furthermore, Fanitabasi [28] discusses optimization in MAS under adversarial conditions, underscoring the need for resilience. By combining CQRS with

DIDs and ZKPs, our framework provides enhanced security and reduces vulnerabilities to malicious agents.

Lastly, transparency and secure communication in resource allocation are vital for MAS efficiency. Fu and Zhou [29] present a MAS solution for multi-project scheduling, although they struggle with transparency in resource allocation. Our framework addresses this by using blockchain to ensure verifiable transaction records, reducing information asymmetry. Additionally, Costa et al. [30] offer secure communication protocols that are limited in scalability under high agent loads. Leveraging CQRS, our architecture improves message throughput, enhancing secure, efficient communication across distributed systems.

D. Thesis for Improvement

Despite the progress made, several weaknesses in the current research need to be addressed:

- Scalability and Real-Time Challenges: Current blockchain-based authentication models suffer from scalability issues, as high computational costs limit their applicability in environments where real-time.
- Data Integrity for Off-Chain Storage: The reliance on off-chain storage solutions, such as IPFS, creates vulnerabilities in data tampering and data loss, as these systems lack the same level of cryptographic protection as on-chain storage.
- Privacy Concerns: While blockchain ensures data transparency, it falls short in protecting the privacy of agent interactions. Even with the use of Zero-Knowledge Proofs (ZKP), the high computational burden and the complexity of implementing ZKP protocols in large-scale systems make it difficult to achieve both privacy and performance.

This paper proposes a framework that combines CQRS, blockchain, zero-knowledge proofs (ZKP), and OAuth2 to address the limitations identified in existing solutions:

- Optimized Scalability: By enhancing ZKP protocols and integrating OAuth2 for efficient authentication, we reduce computational overhead and improve scalability, making the system suitable for high-frequency, real-time applications.
- Enhanced Data Protection: Utilizing blockchain's inherent immutability and tamper-proof properties, we ensure that all data remains secure and unaltered on-chain, eliminating the need for off-chain storage and its associated risks.
- Securing Write Operations: Through advanced cryptographic techniques and the integration of OAuth2 for secure authentication, we protect against man-in-the-middle attacks and ensure consistent data synchronization across distributed agents.

By addressing these gaps, our framework presents a more scalable, secure, and privacy-preserving solution for high-frequency, real-time multi-agent systems. This integration of advanced cryptographic methods and established design patterns offers a robust approach to the challenges facing MAS in complex, distributed environments.

III. BACKGROUND

In this section, we explore the foundational technologies and concepts that form the basis of the proposed framework: Multi-Agent Systems (MAS), Blockchain, Zero-Knowledge Proofs (ZKP), Command Query Responsibility Segregation (CQRS), Event-Driven Architecture (EDA), and OAuth 2.0. Together, these technologies address critical challenges like scalability, security, data integrity, and privacy in decentralized systems. Each concept builds upon the others to enhance the robustness and efficiency of MAS.

A. Multi-Agent Systems (MAS)

Multi-Agent Systems (MAS) consist of several autonomous agents working collaboratively or competitively to achieve objectives that are often too complex for a single agent or centralized system to handle. These agents interact with one another to solve problems in distributed environments, such as IoT networks, smart grids, and supply chain management. MAS are particularly effective in situations where decentralized decision-making is required, and the agents can operate independently to respond to changing conditions in real-time [31].

However, while MAS offer significant advantages in scalability and flexibility, they also introduce substantial challenges—most notably, ensuring secure communication and anonymity between agents. As agents in MAS frequently exchange sensitive information, protecting this data from unauthorized access or attacks becomes paramount. Traditional security measures often fall short in such decentralized environments, necessitating more advanced cryptographic techniques like Zero-Knowledge Proofs (ZKP). In this context, ZKP provides a solution that enhances both security and privacy within MAS by allowing authentication and access control without revealing underlying data, thereby ensuring secure and anonymous exchanges.

B. Event-Driven Architecture (EDA) and Event Sourcing

To enable more flexible and scalable interactions within MAS, many systems adopt an Event-Driven Architecture (EDA). Event-sourcing and event-driven architecture are two related but distinct concepts that are often used together in software systems. Event-driven architecture (EDA) is a design pattern that involves building a system in which different components communicate with each other by generating and reacting to events [32] (Fig. 1).

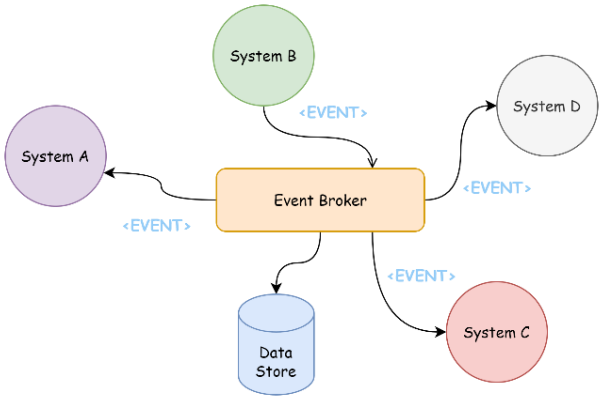

Fig. 1. Event driven architecture.

For example, when an agent in MAS detects a change in the environment or receives new data, it can trigger an event that other agents can subscribe to and react to as needed. This decoupling of event producers and consumers enables the system to scale more effectively and enhances its fault tolerance [33].

Closely related to EDA is Event Sourcing, which provides a mechanism to maintain a historical log of all state changes within the system. Rather than storing the current state of the system, event sourcing records every change as an event, allowing the system's state to be reconstructed by replaying these events in sequence. This feature is particularly useful in MAS for auditing, debugging, and recovering from failures. By integrating event sourcing with EDA, MAS can ensure that state changes are both traceable and resilient to failure [34].

The combination of EDA and Event Sourcing complements the scalability of MAS while providing a reliable mechanism to track and react to changes across distributed agents. However, while these architectures improve the system's flexibility, they do not address the security and data integrity challenges associated with state changes. This is where Blockchain plays a crucial role.

C. Command Query Responsibility Segregation (CQRS)

Building on the flexibility provided by EDA and event sourcing, Command Query Responsibility Segregation (CQRS) further enhances the scalability of MAS by separating read operations from write operations (Fig. 2).

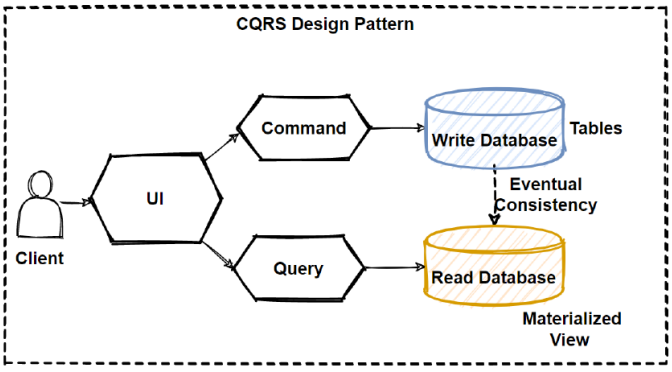

Fig. 2. CQRS design pattern.

In MAS, agents often need to perform a large number of both read (query) and write (command) operations to maintain and update the system state in real-time. By segregating these responsibilities, CQRS allows systems to scale independently for these two functions, optimizing system performance and reducing bottlenecks [35].

While CQRS improves the efficiency of MAS, particularly in high-transaction environments, it does not inherently provide security for write operations. Without adequate safeguards, the system remains vulnerable to tampering during state changes, which could lead to unauthorized alterations of critical data. At this point, Blockchain becomes essential for securing these write operations, as its tamper-proof ledger ensures that all changes to the system's state are immutably recorded and can be verified by all agents in the system [36].

The integration of CQRS with Blockchain strengthens the system's security, but it also introduces privacy concerns, particularly in public blockchains where data is visible to all participants. This necessitates the use of Zero-Knowledge Proofs (ZKP), which provide privacy-preserving mechanisms for MAS, ensuring that agents can interact securely without exposing sensitive information [37].

D. Blockchain Technology

Blockchain is a decentralized, distributed ledger that keeps a growing list of records called blocks. In a chain of blocks (hence the name "blockchain"), each block has multiple attributes including a timestamp, a link to the previous block, and its own data [38] (Fig. 3). Cryptographic techniques secure this chain of blocks, making it nearly impossible to alter its data. [38].

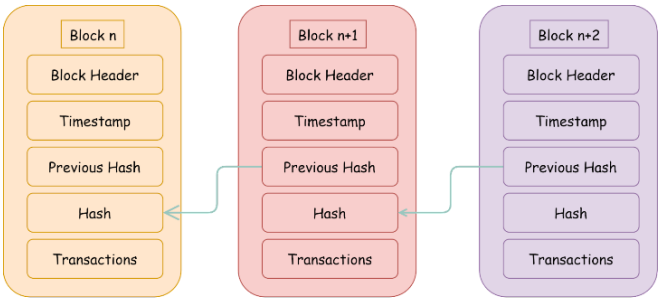

Fig. 3. Block structure.

Without the need for a centralized authority, transactions can be made using blockchain technology in a secure and transparent manner. Due to the distributed nature of blockchain data, it is virtually impossible for one entity to alter it without being detected. Because of this, blockchain technology is well suited for uses like supply chain management and financial transactions that demand a high level of transparency and trust [39]. In a typical blockchain system, transactions are initiated by users and are broadcast to the network. The integrity of these transactions is ensured by network nodes. A block is then added to the blockchain after a transaction has been verified and added to it [40].

However, while blockchain excels at maintaining data integrity and transparency, it introduces a new set of challenges regarding privacy. In a traditional blockchain system, transaction details are visible to all participants, which may not

be acceptable in scenarios where agents need to exchange sensitive data. To mitigate this issue, Zero-Knowledge Proofs (ZKP) are integrated with blockchain, allowing agents to prove that they have valid data or authorization without revealing the underlying information. This combination ensures that blockchain retains its transparency and security, while also protecting the privacy of the agents involved [41] [42].

E. Zero-Knowledge Proofs (ZKP)

Zero-Knowledge Proofs (ZKP) offer a solution to the privacy and anonymity concerns that arise in MAS when agents exchange sensitive information. It was initially brought forth in the 1980s by Shafi Goldwasser, Silvio Micali, and Charles Rackoff [43]. ZKP allows an agent to prove the validity of a claim (such as their identity or authorization) without revealing any additional details. This cryptographic technique is particularly valuable in blockchain-based MAS, where agents need to maintain both transparency and privacy during transactions.

The Zero-Knowledge Proof (ZKP) workflow, depicted in Fig. 4, illustrates the key phases of the ZKP process: setup, commitment, challenge, response, and verification. This workflow ensures that agents can authenticate their claims without revealing sensitive information, preserving both privacy and security.

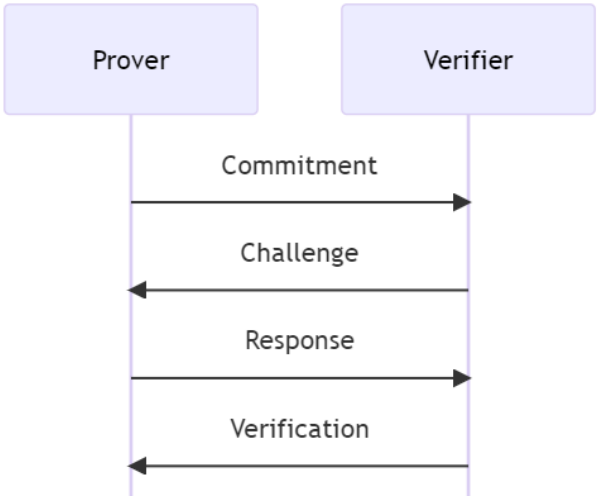

Fig. 4. ZNP workflow.

For instance, in a system where agents need to prove ownership of certain data or assets, ZKP enables them to authenticate their claims without exposing the data itself. This ensures that even as agents participate in a decentralized system like blockchain, they can retain their privacy, preventing sensitive information from being exposed to other participants [44]. However, implementing ZKP at scale presents computational challenges, as the process can be resource-intensive, making optimization a key area of research for large-scale MAS.

The benefits of ZKP in ensuring privacy and security are further enhanced when combined with OAuth 2.0, an authorization framework that allows controlled access to resources without exposing user credentials [18].

F. OAuth 2.0

OAuth 2.0 is an authorization framework widely used to secure access to resources by enabling third-party applications to interact with systems on behalf of users. In the context of MAS, OAuth 2.0 can manage access control, allowing agents to interact securely with external services without sharing their credentials directly. However, OAuth 2.0 alone does not guarantee anonymity, as it can still link access tokens to specific agents, potentially exposing their identities [45].

Fig. 5 demonstrates the OAuth 2.0 protocol flow, highlighting the interaction between agents, the authorization server, and the resource server. This process facilitates secure access token issuance and validation, ensuring controlled and authenticated access to system resources. The integration of OAuth 2.0 with ZKP in the proposed architecture further strengthens privacy by decoupling sensitive user credentials from access authorization.

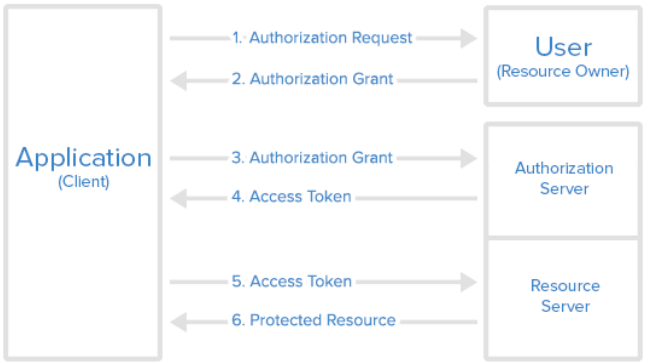

Fig. 5. OAuth 2 protocol flow.

To address this limitation, integrating ZKP with OAuth 2.0 provides a powerful solution for secure and anonymous resource access. By using ZKP to authenticate agents without revealing their identities, OAuth 2.0 can enable secure communication while preserving agent anonymity. This combination not only enhances the security of MAS but also ensures that agents can interact with external services without compromising their privacy.

The integration of OAuth 2.0 and ZKP represents a novel approach to solving the challenges of access control and privacy in MAS. This hybrid mechanism allows for secure data access while maintaining the anonymity of the agents, offering a robust solution to the security concerns present in distributed multi-agent systems [46].

IV. Proposed Architecture

The proposed architecture combines Command Query Responsibility Segregation (CQRS), blockchain, and Zero-Knowledge Proofs (ZKP) to address the core challenges of security, scalability, and privacy in Multi-Agent Systems (MAS).

Existing architectures often fall short in meeting these requirements due to their inherent limitations, such as inadequate privacy mechanisms, reliance on centralized infrastructures, and performance bottlenecks in high-volume environments.

Blockchain ensures data integrity through its immutable ledger, but its transparency can compromise sensitive information, highlighting the need for enhanced privacy measures.

To overcome this, the integration of ZKP enables secure agent authentication and transaction verification without exposing sensitive data, ensuring privacy-preserving interactions. CQRS further enhances the framework by segregating read and write operations, optimizing performance and scalability in real-time, high-demand scenarios.

Additionally, the architecture addresses vulnerabilities associated with centralized Public Key Infrastructure (PKI) by incorporating Decentralized Identifiers (DIDs), reducing single points of failure and enhancing system resilience. Unlike existing systems that struggle with consistent data synchronization and computational inefficiencies, the modular and interoperable design of the proposed framework ensures adaptability across diverse domains such as IoT, healthcare, and smart grids. This holistic integration of technologies provides a scalable, secure, and privacy-preserving solution tailored to the evolving demands of decentralized MAS.

A. Need for Enhancements in MAS Architecture

Understanding the limitations of traditional MAS architectures highlights the necessity for a paradigm shift. Addressing these challenges is crucial for developing systems that meet modern requirements.

The proposed architecture aims to:

- Eliminate Single Points of Failure: By decentralizing identity and access control mechanisms, the system enhances resilience and reduces dependency on any single component.
- Improve Scalability: Through asynchronous communication and efficient processing models like CQRS, the architecture supports the seamless addition of agents without compromising performance.
- Strengthen Security and Privacy: Using advanced cryptographic techniques, secure communication protocols, and privacy-preserving authentication methods, the system safeguards agent interactions.
- Ensure Data Integrity: Leveraging blockchain technology for immutable and verifiable data storage ensures that all agents have a consistent and trusted view of the system's state.

B. System Components and Architecture

1) Agent: Agents serve as autonomous entities within the decentralized system, representing unique participants such as users, services, or applications. Each agent is capable of performing actions, communicating with other agents, and managing its own state. The primary purpose of an agent is to interact seamlessly within the network. Functionally, agents handle identity management by generating and managing cryptographic key pairs and Decentralized Identifiers (DIDs). They utilize Zero-Knowledge Proofs (ZKP) and OAuth 2.0 tokens for authenticating and authorizing interactions. Communication between agents is secured through encrypted and signed messages transmitted via Hyperledger Fabric channels. Agents manage their state by executing commands that alter their state and recording corresponding events on the blockchain. Additionally, they can reconstruct their internal state by replaying events from the blockchain, using snapshotting techniques for efficiency. In terms of interactions, agents communicate with other agents through secure channels, interact with the Decentralized Discovery Facility (DDF) for agent discovery, and submit and retrieve events from the blockchain for state management.

2) Decentralized Identifier (DID) and DID document: DIDs provide a decentralized and self-sovereign identity framework for agents, enabling secure and verifiable interactions without relying on centralized authorities. Agents generate unique DIDs following standardized specifications, such as Hyperledger-compatible DID methods. Each DID is associated with a DID Document, which contains public keys, authentication methods, and service endpoints. These documents are published on the blockchain for public reference, facilitating secure communication and verification among agents. DIDs are shared among agents during interactions, utilized during registration with the Decentralized Discovery Facility (DDF), and play a crucial role in authentication processes.

3) Zero-Knowledge Proofs (ZKP) processing service: The ZKP Processing Service enhances privacy and security by enabling agents to prove possession of certain information, such as ownership of a DID, without revealing the information itself. This service assists agents in generating ZKPs to demonstrate control over their private keys and DIDs. It facilitates the various phases of the ZKP protocol, including setup, commitment, challenge, response, and verification. The service collaborates with agents during registration and authentication processes and interfaces with the Authorization Server during the issuance of OAuth 2.0 tokens.

4) Decentralized Discovery Facility (DDF): The DDF acts as a decentralized registry and discovery service, allowing agents to locate and interact with other agents and their services within the network. It handles the registration of agent DIDs and associated metadata after verifying ZKPs. The discovery functionality provides searchable access to registered agents and their services, enabling agents to find peers and available functionalities efficiently. The DDF receives registrations from agents along with their ZKPs and DID Documents and responds to discovery queries from agents seeking information about other participants.

5) OAuth 2.0 authorization server: The OAuth 2.0 Authorization Server is responsible for managing the issuance and validation of access tokens, thereby facilitating secure authorization for agents to access resources and communication channels within the system. It processes OAuth 2.0 authorization requests from agents, incorporating DIDs and ZKP commitments. Upon successful verification of ZKPs and issuance of authorization codes, the server generates JWT

access tokens. It also validates incoming tokens during resource access requests to ensure their authenticity and permissions. The Authorization Server interacts with agents during the token issuance process and interfaces with Resource Servers to validate access tokens presented by agents.

Fig. 6 presents the high-level interaction among components within the proposed architecture. It illustrates the communication flow between agents, the Decentralized Discovery Facility (DDF), blockchain, and resource servers. This diagram emphasizes how the architecture integrates multiple technologies to ensure seamless operation, secure agent authentication, and efficient resource management.

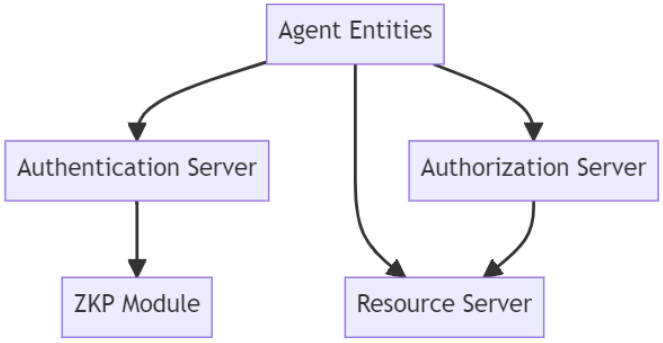

Fig. 6. Component interaction.

6) Hyperledger fabric network: The Hyperledger Fabric Network provides a permissioned blockchain infrastructure that ensures secure, immutable, and scalable communication and state management among agents. It utilizes private communication channels designated for specific groups of agents or types of interactions. The network comprises peers, which are nodes that host the ledger and execute smart contracts (chaincode), maintaining the blockchain's state, and orderers, which are nodes responsible for ordering transactions into blocks to ensure consistency and reliability across the network. Subcomponents include smart contracts that define the business logic for processing transactions, handling commands, and managing state changes, as well as the ledger, which serves as an immutable record of all transactions and events, ensuring data integrity and transparency. The Hyperledger Fabric Network facilitates message exchange between agents through its channels, records state-changing events submitted by agents to ensure immutability and verifiability and provides a reliable ledger for agents to reconstruct their state through event sourcing.

7) Resource servers: Resource Servers host protected resources such as data stores, computation services, or external APIs, and enforce access controls based on OAuth 2.0 tokens. They handle resource requests from agents seeking access to these protected resources by receiving and processing these requests. The servers validate the authenticity, validity, and permissions of JWT access tokens included in resource requests. Based on the validated tokens and associated permissions, Resource Servers grant or deny access to the requested resources. They communicate with the Authorization Server to validate access tokens and interact with agents to provide access to requested resources upon successful validation.

8) Command Query Responsibility Segregation (CQRS) components: The CQRS Components enhance system performance and scalability by separating read and write operations, allowing independent optimization of data handling. Command Handlers process state-changing commands submitted by agents, invoking smart contracts to record events on the blockchain. Query Handlers manage read operations by accessing optimized, separate data stores that provide quick and efficient data retrieval. An Event Store maintains a log of all events generated by command executions, enabling state reconstruction and auditability. These components receive commands from agents via Fabric channels, update read models based on events recorded in the blockchain, and support agents in querying the current state without interference from write operations.

9) Hardware Security Modules (HSMs): Hardware Security Modules (HSMs) are critical for securely storing cryptographic keys and performing sensitive operations, thereby protecting against unauthorized access and tampering. They safeguard private keys used by agents for signing messages and events, ensuring that these keys are never exposed in plaintext. HSMs execute cryptographic functions within a protected environment, maintaining the integrity and confidentiality of keys. Agents utilize HSMs to securely manage their cryptographic materials, and HSMs integrate with the DID generation and signing processes to ensure the security and trustworthiness of cryptographic operations within the system.

The integration of these components results in an architecture that significantly enhances the security, scalability, and privacy of Multi-Agent Systems. By addressing the limitations of traditional approaches through decentralized identity management, secure communication protocols, optimized processing models, blockchain integration, advanced cryptographic techniques like ZKP combined with OAuth, and decentralized access control mechanisms, agents can interact in a trustworthy and efficient manner. The proposed architecture lays a robust foundation for developing MAS that are resilient, scalable, and capable of meeting the complex demands of modern distributed environments.

C. Detailed Workflow from Agent Authentication to Message Exchange

1) Agent initialization and DID generation: When an agent joins the system, it begins by generating a public-private key pair. This key pair is fundamental to the agent's cryptographic identity, enabling secure communication and authentication within the network. To ensure the private key remains secure, the agent stores it in a Hardware Security Module (HSM) or a Trusted Execution Environment (TEE). These storage solutions protect the key from unauthorized access and tampering.

Next, the agent creates a Decentralized Identifier (DID) following standard specifications, such as those compatible with Hyperledger. This DID represent a unique, self-sovereign identity that operates independently of any centralized authority. By generating multiple DIDs, the agent enhances its privacy and minimizes the risk of being tracked across different interactions.

The agent then constructs a DID Document, which includes its public keys and service endpoints. This document is published on the blockchain, making the agent's identity accessible to other agents within the network. The DID Document serves as a public reference, describing the agent's DID and associated metadata to facilitate secure and verifiable interactions. This initialization process ensures that the agent maintains full control over its identity, promotes interoperability through standardized identification formats, and establishes a secure foundation for decentralized interactions.

2) Registration with Decentralized Discovery Facility (DDF) using Zero-Knowledge Proofs (ZKP): To register with the Decentralized Discovery Facility (DDF), an agent must prove ownership of its DID without revealing its private key. This is achieved using Zero-Knowledge Proofs (ZKP). The agent collaborates with a ZKP Processing Service to generate a proof that demonstrates control over its private key in a way that preserves confidentiality.

The ZKP process involves several key steps:

- Setup Phase: Public parameters are defined, including a large prime number p, a generator g, and a derived parameter h (1), where s is the agent's secret.
- Commitment: The agent selects a random nonce r and computes the commitment C (2), binding itself to the secret without revealing it.
- Challenge: The verifier issues a random challenge C to the agent.
- Response: The agent calculates z (3), proving knowledge of the secret without disclosing it.
- Verification: The verifier checks (4). If the equality holds, the verifier is convinced that the agent knows the secret without learning its value.

$$h = g^s mod\ p \quad (1)$$

$$C = g^r mod\ p \quad (2)$$

$$z = r + c.s\ mod\ (p-1) \quad (3)$$

$$g^z\ mod\ p = C.h^c\ mod\ p \quad (4)$$

After successfully generating the ZKP, the agent submits its DID Document along with the ZKP to the DDF via smart contracts. The DDF verifies the proof and records the successful registration on the blockchain. This process ensures that only legitimate agents can register, maintaining the integrity and security of the decentralized system.

3) Agent discovery: When an agent wants to discover other agents and their services, it queries the DDF for information about other agents' DIDs and available services. This querying process facilitates collaboration and the utilization of services within the network. Importantly, agents have the option to selectively disclose specific attributes or services, allowing them to control the information they share and protect sensitive data. By enabling discovery while preserving privacy, the system fosters collaboration among agents without compromising their autonomy or exposing unnecessary information.

4) Token issuance with OAuth 2.0 including DIDs: After successfully registering and authenticating, an agent can obtain an access token through the OAuth 2.0 protocol, which includes its DID. The issuance of tokens is a critical component for several reasons. Firstly, tokens provide a secure and standardized method for managing permissions and access controls within the decentralized system.

By issuing tokens that encapsulate DIDs, the system ensures that agents can be reliably identified and granted specific permissions to access various resources without the need for repeated authentication processes. This streamlines access management, reduces the overhead associated with continuous verification, and enhances overall system security by limiting the exposure of sensitive information.

The token issuance process begins with the agent preparing an OAuth 2.0 authorization request, incorporating its DID and ZKP commitment. The Authorization Server then issues a challenge C, and the agent responds with (3) , adhering to the ZKP protocol.

Upon verifying the ZKP, the server issues an authorization code, which the agent exchanges for a JWT access token containing its DID and permissions. This integration of OAuth 2.0 with ZKP ensures a secure and standardized method for managing permissions, allowing reliable agent identification without exposing sensitive information.

The integration of Zero-Knowledge Proofs (ZKP) and OAuth 2.0 is depicted in Fig. 7. This diagram shows how ZKP enhances the OAuth 2.0 authorization process by enabling agents to authenticate their interactions without revealing sensitive data. The secure issuance of access tokens, combined with privacy-preserving proof mechanisms, reinforces the system's security and ensures robust resource access control.

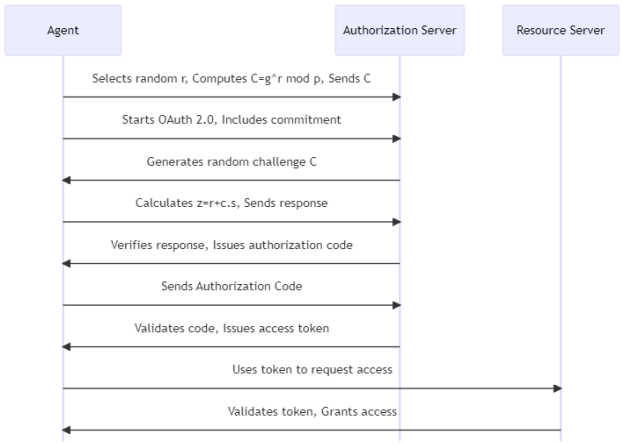

Fig. 7. ZKP and OAuth 2 flow.

5) Resource access and verification using DIDs: When an agent needs to access protected resources, it presents its JWT access token containing its DID in the resource request, typically within the Authorization header as a Bearer token. The resource server then validates the token's signature, ensures it has not expired, checks the scopes, and verifies the agent's DID. If the token is valid and the agent possesses the necessary permissions, the resource server grants access to the requested resources. This mechanism ensures that resource access is secure and controlled, leveraging DIDs for reliable identification and OAuth 2.0 for robust authorization management.

6) Agent communication, data sharing, and state management workflow: If an agent wants to send a message to other agents or read messages, it utilizes Hyperledger Fabric channels alongside the Command Query Responsibility Segregation (CQRS) pattern to ensure efficient and secure communication and state management. The agent begins by authenticating using ZKP during registration and obtaining OAuth 2.0 access tokens, which grant it permissions to interact with specific Fabric channels designated for communication.

Fig. 8 illustrates the detailed workflow for agent communication, data sharing, and state management within the architecture. By leveraging Hyperledger Fabric channels and the CQRS pattern, the diagram demonstrates how agents efficiently interact and manage their states while ensuring data integrity and consistency. This flow is critical for maintaining real-time performance and scalability in high-demand applications.

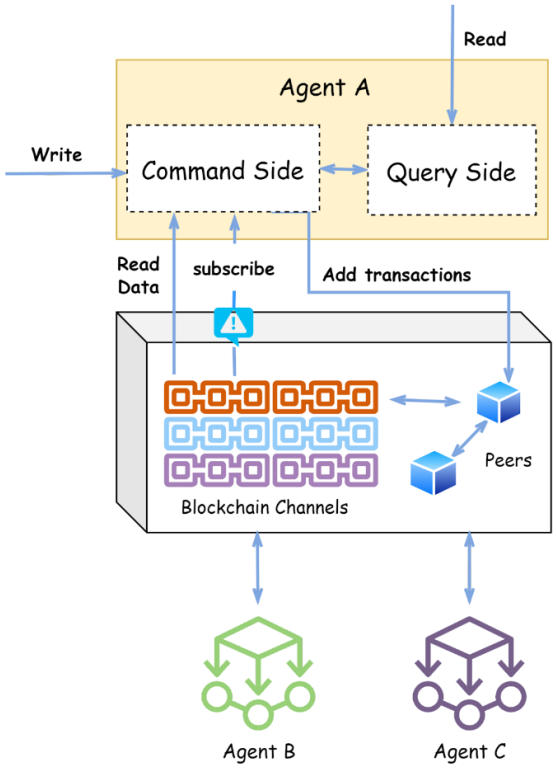

Fig. 8. Agent communication, data sharing, and state management workflow.

a) Sending a message: To send a message, the agent connects to the appropriate Fabric channel using its access token. It encrypts the message content with the recipient's public key and signs the message with its private key to ensure confidentiality and authenticity. The message, along with relevant metadata, is then published to the Fabric channel, where the blockchain handles routing based on the message's metadata and the channel's configuration.

b) Receiving a message: Receiving agents connect to the relevant Fabric channels using their access tokens, subscribe to specific channels, and asynchronously receive messages. Upon receiving a message, the agent verifies the signature using the sender's public key from the DID Document and decrypts the content using its private key. The message is then processed according to the agent's business logic.

c) Event recording and state management: When an agent executes a command that changes its state, it generates an event representing that change. The event includes details such as the event type (e.g., "OrderPlaced", "BalanceUpdated"), a timestamp recording when the event occurred, a data payload containing relevant information, and metadata like causation ID, correlation ID, or version. To ensure authenticity and prevent tampering, the agent signs the event with its private key.

The signed event is then packaged into a transaction proposal and submitted to the blockchain network. This involves creating and signing a transaction proposal that reflects the internal state changes in the form of an event. The proposal is sent to the network for validation and inclusion in the blockchain. Blockchain nodes, or peers, validate the transaction proposal by ensuring proper formatting, verifying the agent's signature, and performing authorization checks to confirm that the agent has the rights to perform the action represented by the event.

Once validated, the ordering service sequences the transactions and packages them into blocks. These blocks are then disseminated across the network and added to each node's copy of the blockchain ledger, making the event part of the immutable history of the system.

d) State reconstruction: To maintain data integrity and enable agents to recover their state independently, the system employs event sourcing and blockchain integration. When an agent needs to reconstruct its internal state, it retrieves the sequence of relevant events from the blockchain and replays them in chronological order. This process ensures that the agent's state is consistent with the system's history. For efficiency, agents may use snapshotting, creating snapshots of their state after processing a certain number of events. Future state reconstructions can begin from the latest snapshot and replay only subsequent events, ensuring consistency and integrity with the system's history.

This integrated approach ensures that communication is secure and efficient while maintaining data integrity and providing a reliable audit trail through event sourcing.

7) Conclusion: This comprehensive workflow integrates decentralized identity management, secure authentication, scalable communication, and robust data integrity mechanisms.

By leveraging Zero-Knowledge Proofs, Decentralized Identifiers, Hyperledger Fabric, OAuth 2.0, and the CQRS pattern, the system ensures that agents can interact securely, efficiently, and privately within a decentralized multi-agent environment.

Security and privacy are maintained throughout the workflow using advanced cryptographic techniques. Zero-Knowledge Proofs and OAuth 2.0 provide robust authentication and authorization without exposing sensitive information. Blockchain technology ensures data integrity by offering immutable and tamper-proof storage of events and identities, while encryption safeguards data both in transit and at rest. The CQRS pattern and event sourcing facilitate efficient state management and fault tolerance, allowing agents to recovertheir state independently by replaying blockchain-recorded events.

The system's design supports scalability and performance through asynchronous communication and the segregation of read and write operations. This allows the network to handle high transaction volumes and numerous agents efficiently. Additionally, the use of standardized protocols and identifiers promotes interoperability, enabling seamless integration with external systems. Compliance and auditability are achieved through transparent and immutable records on the blockchain, facilitating regulatory adherence and providing comprehensive audit trails for accountability and governance.

D. Additional Security Measures

To ensure the integrity, confidentiality, and availability of its components, the system incorporates robust security measures. These measures cover key management, smart contract security, and comprehensive monitoring and incident response protocols.

1) Key management and credential security: Key management protocols are designed to safeguard cryptographic keys, ensuring that only authorized entities can perform sensitive operations within the system.

a) Secure storage:

- Hardware Security Modules (HSMs) and Trusted Execution Environments (TEEs): Private keys are securely stored within HSMs, preventing unauthorized access and extraction. These modules offer physical and logical protections against theft, tampering, and malware attacks.
- Access Controls: Strict access control policies are in place, with role-based access controls (RBAC) ensuring that only authorized personnel and processes can access sensitive keys.

b) Key rotation and revocation:

- Regular Key Rotation: Keys are rotated periodically to minimize exposure risk. Upon rotation, new keys are generated, and corresponding DID Documents are promptly updated on the blockchain.
- Immediate Revocation: Protocols are established for rapid key revocation in case of a suspected compromise. All agents are ensured access to the latest DID Documents to verify key validity and prevent the use of revoked keys.

c) Access control policies:

- Least Privilege Principle: Agents and users are granted only the permissions necessary to perform their roles, reducing the attack surface.
- Segregation of Duties: Responsibilities are divided among different agents to prevent conflicts of interest and limit the impact of compromised credentials.

2) Smart contract security: Smart contracts are rigorously secured to prevent vulnerabilities that could lead to financial losses or unauthorized state changes.

a) Development best practices:

- Secure Coding Standards: Smart contracts adhere to established coding standards to prevent common vulnerabilities, with regular updates based on the latest security research.
- Use of Established Libraries: Trusted libraries and frameworks are used to minimize the risk of bugs and vulnerabilities.
- Modular Design: Smart contracts are structured into smaller, manageable modules for easier analysis, testing, and maintenance.
- Independent Security Audits: Third-party security experts conduct comprehensive reviews of smart contract code to identify vulnerabilities and verify implemented security measures.

b) Continuous testing: Automated testing pipelines with unit tests, integration tests, and fuzz testing are implemented to identify vulnerabilities early.

c) Upgradability and governance:

- Secure Upgrade Paths: Smart contracts include upgradeable patterns to allow controlled updates when necessary, with mechanisms in place to prevent unauthorized modifications.
- Governance Mechanisms: Clear governance processes are established for smart contract changes, involving relevant stakeholders to ensure transparency and collective decision-making.

3) Monitoring and incident response: Continuous monitoring and incident response protocols are established to detect and address security breaches promptly, ensuring system resilience.

a) Continuous monitoring:

- Intrusion Detection Systems (IDS): IDS monitors network traffic and system logs for signs of unauthorized access or malicious activities, using both signature-based and anomaly-based detection.
- Logging and Alerts: Comprehensive logs of system activities are maintained, with real-time alerting mechanisms to notify administrators of critical events.

b) Threat Intelligence and Updates

- Stay Informed: The system stays updated on emerging threats through security advisories and threat intelligence feeds.
- Patch Management: Security patches and updates are applied promptly based on vulnerability severity and potential system impact.

V. Security, Scalability and Performance Analysis

Ensuring that a decentralized multi-agent system operates securely, scales efficiently, and maintains high performance is paramount for its success and reliability. This analysis delves into how the system's architecture and components collectively achieve these objectives, highlighting strengths, potential challenges, and the interplay between different system aspects.

A. Security Analysis

1) Comprehensive security framework: The system employs a multi-layered security approach, integrating advanced cryptographic techniques, secure authentication and authorization protocols, and robust key management practices. By leveraging Zero-Knowledge Proofs (ZKP) and Decentralized Identifiers (DIDs), agents can authenticate and authorize interactions without exposing sensitive information, significantly reducing the risk of credential theft and unauthorized access.

2) Immutable ledger and data integrity: Hyperledger Fabric's blockchain infrastructure ensures that all transactions and state changes are immutably recorded, providing a tamper-proof audit trail. Digital signatures and secure storage mechanisms (HSMs/TEEs) further reinforce data integrity and authenticity, ensuring that only authorized agents can perform state-altering actions.

3) Smart contract security: Adhering to secure coding standards, utilizing established libraries, and implementing formal verification and independent audits fortify smart contracts against common vulnerabilities. The incorporation of modular design and secure upgrade paths allows the system to adapt and evolve without compromising security, addressing potential threats proactively.

4) Proactive threat detection and incident response: Continuous monitoring through Intrusion Detection Systems (IDS) and anomaly detection algorithms enables real-time identification of suspicious activities. A well-defined incident response plan ensures that the system can swiftly contain and mitigate threats, minimizing potential damage and maintaining operational integrity.

5) Privacy preservation: By enabling selective disclosure and employing encryption for all data exchanges, the system upholds strong privacy guarantees. Agents maintain control over their personal information, and the use of multiple DIDs prevents tracking and profiling, aligning with privacy-by-design principles and regulatory requirements.

B. Scalability Analysis

1) Command Query Responsibility Segregation (CQRS) pattern: The implementation of the CQRS pattern effectively separates read and write operations, allowing each to be optimized independently. This segregation reduces contention and enhances system throughput, enabling the system to handle a high volume of transactions and queries without performance degradation.

2) Asynchronous communication via hyperledger fabric channels: Hyperledger Fabric channels facilitate parallel and isolated communication pathways, allowing multiple groups of agents to interact concurrently without interference. This design supports horizontal scaling, as additional channels can be created to accommodate growing numbers of agents and diverse interaction requirements.

3) Event sourcing and snapshotting: Event sourcing records all state changes as discrete events, enabling efficient state reconstruction and facilitating scalability. Snapshotting further enhances performance by allowing agents to rebuild their state from recent snapshots rather than processing an extensive event history, reducing computational overhead and speeding up state initialization.

4) Distributed ledger technology: The decentralized nature of Hyperledger Fabric allows the system to scale horizontally by adding more nodes to the network. This distribution enhances fault tolerance and load balancing, ensuring that the system remains resilient and performs consistently as it grows.

5) Optimized data stores for read operations: By maintaining separate, optimized data stores for read queries, the system ensures that read-heavy operations do not impede write performance. This optimization is crucial for maintaining low latency and high availability, especially as the number of agents and interactions increases.

C. Performance Analysis

1) High throughput and low latency: The system is designed to handle a substantial number of transactions per second (TPS) with minimal latency. Hyperledger Fabric's consensus mechanisms and efficient transaction ordering services contribute to maintaining high throughput, while the use of CQRS and optimized data stores ensures rapid data retrieval and processing.

2) Efficient state management: Event sourcing, combined with snapshotting, allows for swift state reconstruction and reduces the time required for agents to initialize or recover their state. This efficiency is vital for maintaining real-time responsiveness and ensuring that agents can operate seamlessly, even under heavy load.

3) Resource optimization: The segregation of read and write operations, along with asynchronous communication channels, ensures optimal utilization of system resources. By distributing workloads effectively and minimizing bottlenecks, the system maintains consistent performance levels regardless of scaling demands.

4) Resilience and fault tolerance: The decentralized architecture and immutable ledger ensure that the system remains operational even in the face of individual node failures or attacks. Redundant data storage and distributed consensus

protocols contribute to the system's ability to recover quickly and maintain performance standards during adverse conditions.

5) Continuous improvement and adaptability: The system's architecture allows for continuous optimization and scaling without necessitating significant overhauls. The modular design of smart contracts, combined with secure upgrade paths, enables the integration of performance enhancements and new features, ensuring that the system can evolve in response to changing demands and technological advancements.

D. Trade-offs and Considerations

1) Complexity vs. security and scalability: While the system's advanced security measures and scalable architecture provide significant benefits, they also introduce additional complexity. Managing multiple DIDs, implementing ZKP, and maintaining a distributed ledger require sophisticated infrastructure and expertise, potentially increasing the initial setup and maintenance overhead.

2) Resource consumption: The use of encryption, secure storage mechanisms, and continuous monitoring can lead to increased resource consumption. Balancing security and performance with resource efficiency is essential to ensure that the system remains cost-effective and sustainable as it scales.

3) Latency in event processing: Although event sourcing and snapshotting enhance state management efficiency, there can be inherent latency in processing and recording events on the blockchain. Optimizing transaction throughput and implementing efficient event handling protocols are necessary to minimize delays and maintain real-time responsiveness.

4) Governance and upgrade management: Ensuring secure and controlled upgrades to smart contracts and system components is crucial for maintaining system integrity. Establishing robust governance mechanisms and clear procedures for implementing changes helps mitigate the risks associated with upgrades but requires ongoing coordination and management.

E. Conclusion

The system's architecture robustly addresses critical aspects of security, scalability, and performance through the integration of advanced technologies and best practices. By leveraging Hyperledger Fabric's decentralized ledger, employing the CQRS pattern for efficient state management, and implementing comprehensive security measures, the system ensures secure, scalable, and high-performing operations.

While the system presents inherent complexities and resource demands, these are outweighed by the substantial benefits of enhanced security, efficient scalability, and reliable performance. Continuous monitoring, proactive incident response, and adaptable governance frameworks further strengthen the system's resilience and capacity to evolve in response to emerging challenges and growth demands.

Overall, the system exemplifies a well-balanced approach to building a decentralized multi-agent environment that is both secure and capable of handling significant scalability and performance requirements, making it well-suited for a wide range of decentralized applications and use cases.

VI. Use Cases and Real-World Applications

In this chapter, we explore practical applications of the proposed architecture across various industries. By demonstrating how the architecture can be applied to real-world scenarios, we highlight its versatility, effectiveness, and potential impact on modern decentralized systems.

A. Smart Grids

Smart grids represent the modernization of traditional electrical grids by integrating advanced communication and control technologies. They enable efficient energy distribution, real-time monitoring, and dynamic management of energy resources. The decentralized nature of smart grids, with numerous energy producers and consumers, makes them an ideal candidate for the proposed architecture.

1) Application of the Architecture

a) Decentralized energy management:

- Autonomous Agents: Each energy producer (e.g., solar panels, wind turbines) and consumer (households, businesses) is represented by an autonomous agent.
- Decentralized Identity Management: Agents generate Decentralized Identifiers (DIDs), ensuring secure and self-sovereign identities without reliance on centralized authorities.
- Secure Communication: Agents communicate securely using mutual TLS and encrypted channels, exchanging data such as energy production, consumption, and pricing information.

b) Energy transactions and trading:

- Blockchain Integration: The blockchain serves as an immutable ledger for recording energy transactions, such as energy generation records, consumption data, and peer-to-peer energy trades.
- Smart Contracts: Automate energy trading agreements, settlement of payments, and enforcement of contractual obligations between agents.
- Event Sourcing and CQRS: Efficiently handle high volumes of transactions, separating command and query responsibilities for optimal performance.

c) Privacy-preserving data sharing:

- Zero-Knowledge Proofs (ZKP) : Allow agents to prove certain attributes (e.g., energy surplus availability) without revealing sensitive data like exact energy usage patterns.
- Data Confidentiality: Encryption ensures that only authorized agents can access specific data, protecting user privacy and complying with regulations.

2) Benefits:

- Enhanced Efficiency: Real-time data exchange and autonomous decision-making optimize energy distribution and reduce waste.

- Increased Reliability: Decentralized control reduces single points of failure, improving grid resilience.
- Cost Savings: Direct peer-to-peer energy trading lowers transaction costs and enables dynamic pricing models.
- Regulatory Compliance: Secure and privacy-preserving mechanisms align with data protection laws and industry standards.
- Challenges and considerations:
- Scalability: Managing a large number of agents and transactions requires robust scalability, addressed bythe architecture's design.
- Interoperability: Integration with existing grid infrastructure necessitates adherence to industry protocols and standards.
- Security Threats: Protecting against cyber-attacks is critical, necessitating ongoing security assessments and updates.

B. Healthcare Data Management

Managing sensitive healthcare data requires stringent security, privacy, and compliance with regulations such as HIPAA. The proposed architecture offers a secure and interoperable framework for handling electronic health records (EHRs), ensuring data integrity and patient privacy.

1) Application of the Architecture:

a) Patient records:

- Decentralized Identifiers (DIDs): Each patient is assigned a DID, and their EHRs are stored as events on the blockchain.
- Event Sourcing: Records every access and modification to patient data, providing an immutable audit trail.

b) Data access control:

- Zero-Knowledge Proofs (ZKP): Patients use ZKPs to grant healthcare providers access to specific parts of their medical records via OAuth 2.0 tokens.
- OAuth 2.0 Integration: Manages permissions, allowing patients to control who can view or update their health data. iii. Data Integrity and Audit Trails
- Immutable Logging: All access and modifications to EHRs are recorded on the blockchain, ensuring accountability and traceability.
- Smart Contracts: Enforce data access policies and automate consent management, reducing administrative overhead.

c) Efficient data retrieval:

- Command Query Responsibility Segregation (CQRS) Pattern: Enables healthcare providers to query patient data efficiently without impacting the system's write operations.
- Optimized Read Models: Ensure rapid access to necessary data, enhancing the responsiveness of healthcare services.

2) Benefits:

- Enhanced Privacy: Patients maintain control over their medical data, deciding who can access specific information.
- Data Security: Blockchain immutability and robust authentication mechanisms protect against unauthorized access and data breaches.
- Regulatory Compliance: Immutable audit trails facilitate compliance with healthcare regulations and standards.

3) Challenges and considerations:

- Data Interoperability: Ensuring compatibility with existing healthcare information systems requires adherence to industry standards.
- Scalability: Managing large volumes of healthcare data necessitates efficient storage and retrieval mechanisms.
- User Adoption: Encouraging healthcare providers and patients to adopt the new system involves overcoming resistance to change and ensuring ease of use.

C. Secure Internet of Things (IoT) Networks

IoT networks consist of numerous interconnected devices that collect and exchange data. Securing these networks is challenging due to the sheer number of devices and the potential for vulnerabilities. The proposed architecture ensures secure device authentication, data integrity, and efficient management of IoT interactions.

1) Application of the architecture:

a) Device authentication:

- Decentralized Identifiers (DIDs): Each IoT device is assigned a unique DID, ensuring secure and authenticated interactions within the network.
- Zero-Knowledge Proofs (ZKP): Devices use ZKPs to authenticate themselves without revealing sensitive credentials.

b) Data integrity:

- Blockchain Integration: Data generated by IoT devices is recorded on the blockchain, ensuring its integrity and preventing tampering.
- Immutable Logging: Critical events and data exchanges are stored immutably, providing a reliable audit trail.

c) Scalable communication:

- Asynchronous Message Queues: Manage the high volume of data exchange between devices and the blockchain, ensuring efficient processing and minimal latency.
- Secure Protocols: Ensure that all communications are encrypted and authenticated, protecting against unauthorized access and data breaches.

d) Access control:

- OAuth 2.0 Tokens: Regulate which devices can access or modify specific data streams, maintaining strict access control policies.
- Capability-Based Access Control: Use cryptographically secure tokens to manage permissions dynamically and securely.

2) Benefits:

- Secure Authentication: Decentralized authentication mechanisms prevent unauthorized devices from joining the network.
- Data Integrity: Immutable records on the blockchain ensure that IoT data remains accurate and trustworthy.
- Scalability: The system efficiently handles large-scale IoT deployments, accommodating a growing number of devices without compromising performance.

3) Challenges and considerations:

- Device Heterogeneity: Managing diverse IoT devices with varying capabilities requires adaptable and flexible security protocols.
- Resource Constraints: Ensuring that security measures are lightweight enough to operate on resource constrained IoT devices.
- Cybersecurity Threats: Protecting IoT networks from sophisticated cyber-attacks necessitates ongoing security enhancements and monitoring.

D. Supply Chain Management

Supply chains involve the movement of goods and services from suppliers to end consumers, encompassing various processes like manufacturing, logistics, and retail. The complexity and need for transparency in supply chains make them suitable for leveraging blockchain and decentralized technologies.

1) Application of the architecture:

a) Transparent tracking and traceability:

- Immutable Record Keeping: Blockchain records every event in the product lifecycle, from raw material sourcing to final delivery, ensuring data integrity.
- Event Sourcing: Each action (e.g., shipment, quality check) is recorded as an event, allowing real-time tracking and historical analysis.
- Decentralized Agents: Manufacturers, suppliers, logistics providers, and retailers operate as agents within the system, communicating securely.

b) Secure and efficient communication:

- Asynchronous Message Queues: Facilitate communication between agents, handling asynchronous updates and ensuring timely information flow.
- Secure Protocols: Mutual authentication and encrypted channels prevent unauthorized access and data breaches.

c) Confidentiality and competitive advantage:

- Zero-Knowledge Proofs (ZKP): Enable agents to verify compliance with standards or certifications without revealing proprietary information.
- Selective Disclosure: Agents can share necessary data with partners or regulators while keeping sensitive business details confidential.

2) Benefits:

- Enhanced Transparency: Consumers and stakeholders can verify the authenticity and origin of products, building trust.
- Fraud Reduction: Immutable records prevent tampering, reducing counterfeit goods and unethical practices.
- Operational Efficiency: Automation and real-time data exchange streamline processes, reducing delays and costs.
- Compliance and Reporting: Simplifies regulatory compliance by providing verifiable records and audit trails.

3) Challenges and considerations:

- Data Standardization: Ensuring consistent data formats and standards across diverse participants is essential for interoperability.
- Adoption Barriers: Convincing all supply chain participants to adopt the new system may require demonstrating clear value propositions.
- Privacy Concerns: Balancing transparency with the need to protect sensitive business information requires careful design.

E. Conclusion

By addressing real-world problems with a secure, scalable, and privacy-focused approach, the proposed architecture paves the way for innovative decentralized applications that can transform industries and enhance the way individuals and organizations interact in the digital age.

VII. Conclusion

In this paper, we have presented a comprehensive architecture designed to enhance security, scalability, data integrity, and privacy in Multi-Agent Systems (MAS). By integrating advanced technologies such as Blockchain, Zero-Knowledge Proofs (ZKP), OAuth 2.0, and Decentralized Identity Management (DID), we have addressed the critical challenges inherent in decentralized environments where autonomous agents interact and collaborate.

The architecture's contributions address key security challenges by ensuring data integrity and immutability, with blockchain technology providing an immutable ledger for all transactions, events, and identity information. Cryptographic linkages between blocks and consensus mechanisms like PBFT and DPoS prevent tampering. Privacy-preserving authentication is achieved with Zero-Knowledge Proofs, allowing agents to prove knowledge without disclosing information. Secure

authorization is reinforced by combining ZKP with OAuth 2.0, enabling fine-grained access control, while decentralized identity management leverages DIDs and DPKI to reduce reliance on centralized providers, empowering agents to manage their identities independently.

To enhance scalability and performance, the architecture uses Command Query Responsibility Segregation (CQRS) and Event Sourcing, enabling independent scaling of read and write operations. Asynchronous communication through message queues supports a high volume of non-blocking interactions, while optimized cryptographic operations using zk-STARKs, Bulletproofs, and hardware acceleration improve performance. Layer-2 solutions such as state channels and sidechains boost throughput and reduce latency by offloading transactions from the main blockchain.

Data integrity and privacy are safeguarded with an immutable event store on the blockchain, providing a tamper-proof history for auditing, compliance, and state recovery. Selective disclosure mechanisms and ZKPs empower agents to share only necessary information while preserving anonymity. The architecture aligns with global data protection regulations, such as GDPR, enhancing its compliance and adaptability.

The architecture's versatility allows it to be applied across various domains, including smart grids, supply chains and secure internet of things (IoT) networks, demonstrating its broad applicability. Its modular and interoperable design, adhering to standards like OAuth 2.0 and W3C's DIDs, promotes seamless integration with existing systems.

Despite these advancements, the architecture faces limitations. Cryptographic operations, particularly ZKPs, impose computational demands that can be challenging for devices with limited processing power. Consensus mechanism scalability may be hindered by network growth and latency, while data management requires balancing efficient storage with integrity. The complexity of implementing these advanced technologies may increase the learning curve, and decentralized system adoption may face resistance due to regulatory uncertainties.

Future research will focus on optimizing cryptographic protocols, exploring post-quantum cryptography, and enhancing scalable and energy-efficient consensus mechanisms. Improvements in identity management, integration with AI for intelligent agent behavior and real-time threat detection, and collaboration with regulatory bodies to establish supportive frameworks will further refine the architecture.

***Abstract*—In cloud environment context, organizations often rely on the platform for data storage and on demand access. Data is typically encrypted either by the cloud service itself or by the data owners before outsourcing it to maintain confidentiality. However, when it comes to processing encrypted data for tasks like *k*NN classification; existing approaches either prove to be inefficient or delegate portion of the classification task to end users or do not satisfy all the privacy requirements. Also, the datasets used in many existing approaches to check the performance seem to have very less attributes and instances; but, it is observed that as dataset size increases, the efficiency and accuracy of many privacy-preserving approaches reduce significantly. In this work, we propose a set of privacy preserving protocols that collectively perform the *k*NN classification with encrypted data in outsourced semi-honest-cloud environment and also address the stated challenges. This is accomplished by building an efficient randomization-based approach called PP*k*C that leverages homomorphic cryptosystem properties. With protocol analysis we prove that the proposed approach satisfies all privacy requirements. Finally, with extensive experimentation using real-world and scaled dataset we show that the performance of proposed PP*k*C protocol is computationally efficient and also independent of the number of nearest neighbours considered.**

***Keywords*—Partial homomorphic encryption; classification using encrypted data; randomization; k- nearest neighbours**

I. INTRODUCTION

The progressive paradigm of information technology known as cloud computing provides the ability to deliver a variety of computing services including processing power, storage, and application platform, on demand. However, security has consistently posed a significant barrier to the general uptake of cloud computing technologies [1], [2]. The problem is further exacerbated by cloud computing service providers' inaccurate reporting of security flaws [3], [4], [5]. Cloud based services have raised the need to protect data privacy in outsourced databases has become a focal point of research. As discussed in study [6], [7], [8] and [9] since, a data owner (DO), contracts out the management of his or her databases to a cloud, the DO can lower database management costs by utilizing the cloud's resources as needed. Owing to the diverse range of users the dataset they offer encompasses multiple ranges of categories including personal health status details [10], back-office user database information [11], email information [12] as well as additional information about individual privacy or company trade secrets [13], [14], [15]. To safeguard the original data, access patterns as well as queries, research has been done on secure query processing over an encrypted database. Earlier approaches in [16], [17], [18], [19], [20] and [21] outsource plain texts to a cloud and alter them with their substituted data. Nonetheless, due to their vulnerability to different types of attacks, these earlier strategies are unable to fully protect both data as well as queries [22].

Consider a scenario where a hospital stores its encrypted patient database on the cloud for data mining tasks. When a doctor seeks to ascertain a patient's symptoms for diagnosis, they must submit a query containing highly personal information. To protect the patient's data privacy, cloud must be queried with only the encrypted query data. Moreover, any anomalies in cloud activity could reveal data access patterns, despite encryption. Therefore, maintaining privacy of involved data is paramount when performing classification tasks on encrypted data in an outsourced environment like the cloud.

Previously many approaches have been introduced to address this challenge, however, either the computation cost required to process the queries turned out to be inefficient or privacy requirements were not completely fulfilled. The previous methodologies predominantly relied on datasets with integer values, limiting their applicability to a narrow range of datasets; however, real-world datasets typically encompass a broader spectrum, often comprising floating-point values. Moreover, the pattern of accessing the data during k-nearest neighbours (k-NN) algorithm is also not safeguarded in [23], [24], [25] and [16]. The privacy-preserving algorithms in [26] and [27] conceal data access patterns while ensuring privacy of outsourced databases as well query. However, they have a high query processing cost as discussed in study [6].

We propose set of protocols that jointly address the privacy-preserving k-nearest neighbours outsourced classification issue with the assumption of the process of classification along with encrypted data is held in the cloud environment. The focus in this paper is only specifically on creating the privacy-preserving k-nearest neighbor technique, since k-NN is a popular and most suitable classifier for this work.

A. Problem Definition

In this paper, we assume a *'m'* dimensional database is possessed by a data holder containing total instances of size *'n'*. 0^{th} attribute serves as the record identifier (I), while the m^{th} attribute represents the class label (c). The data holder encrypts the database attribute by attribute to get $E_{pk}(t_{i,j})$ which denotes the encrypted value of a record, where *'t '*represents a tuple, *'i'* ranges from *1* to *'n'*, and *'j'* ranges from *0* to *'m'*.

E_{pk} is the encryption function of partial homomorphic encryption in [28]. After encryption, the encrypted database is sent to the cloud. After this the data holder doesn't get involved in any of the further privacy-preserving classification steps.

Authentic users can send encrypted queries $E_{pk}(Q)$= $(E_{pk}(q_1), \dots, E_{pk}(q_{m-1}))$ to the cloud to obtain resultant encrypted class label, denoted as $E_{pk}(c_q)$.

B. Our Contributions

We have proposed set of protocols that execute in a two-cloud setup to jointly address the issue of preserving privacy while classifying user's encrypted query using outsourced encrypted data. The protocols are for k-nearest neighbours classification algorithm. The proposed approach offers significantly reduced computational costs by utilizing parallel computing, so as to form more practical grounds for classification of encrypted data. Following are some requirements for privacy preserved outsourced classification:

- The user's query must stay encrypted throughout the entire classification task, ensuring it is not disclosed to the cloud.
- The original contents of the database and any intermediate computations must remain hidden from the cloud.
- The records that correspond to the k-nearest neighbours of the user's query should be kept secret from both the cloud and the user.
- Only the final class label should be disclosed to the user.

This work is inspired by the research of Samanthula, Elmehdwi, and Jiang [29], [30], focusing on enhancing the efficiency of the related sub-protocols. As indicated in [29] regarding potential enhancements to the efficiency of the $SMIN_n$ protocol, the attention in this work is directed towards enhancing execution time needed by it. Paillier cryptosystem [28] faces limitations when confronted with negative values resulting from Paillier addition. This challenge is particularly prominent if there are negative values while computing the encrypted Euclidean distance. It' s noteworthy to mention that in the proposed enhanced set of protocols accomplish all aforementioned requirements. The cloud remains oblivious to which database entries align with the nearest neighbours, and any intermediate data visible to the cloud consists solely of either encrypted or randomized values. Additionally, the resultant label remains undisclosed to both clouds.

The rest of this paper is organized as follows. We provide literature survey of state-of-the-art privacy preserving protocols in Section II. The primitives for building proposed approach are described in Section III. We describe the methodology and our proposed privacy preserving PP*k*C protocol and the sub-protocols as its building blocks along with algorithms in Section IV and in Section V, we explain the privacy analysis of these sub-protocols. In Section VI, we provide the experimental results of our proposed PP*k*C protocol using standard and scaled datasets and its comparative analysis with state-of-the-art privacy preserving protocols. We finally conclude this work in Section VII.

II. Literature Survey

In scenarios where queries for classification are executed on the cloud, the foremost and most critical requirement is to hide query details from cloud.

It is important to note that data mining operations can be conducted on encrypted data with relatively less effort using fully homomorphic encryption (FHE) introduced by Gentry et al. (2009) [31]. This cryptosystem allows arbitrary functions to be performed on encrypted data without decryption. However, FHE is computationally intensive, making it impractical for handling real-time classification requests.

Handling queries on encrypted data without the cloud decrypting it poses a significant challenge. The work by Samanthula et al. (2014) [30] outlines a collection of protocols designed to jointly solve the *k*-nearest neighbours (k-NN) query issue within an encrypted database, where both the data and the classification tasks are delegated to the cloud. As described in study [30], the objective of the secure *k*NN protocol is to find the top *k* records closest to the user's query while keeping all details hidden from the cloud. However, in this approach, the SkNN protocol in [30] results in the cloud being exposed to intermediate data, such as the calculated distance values and the subsequently determined *k* smallest distance values. In addition, the records associated with the *k* nearest neighbours of the user query are disclosed to the cloud and also exposed to the user. This again compromises the privacy of the database entries involved in the classification process.

According to Samanthula et al. (2015) in [29] ensuring privacy in *k* nearest neighbours classification is more challenging than running basic *k*NN queries on encrypted data. This complexity stems from the requirement that the k-nearest neighbours identified during the classification process must remain confidential from querying user and cloud.

Protocol presented in study [29] overlooks the issue of access patterns, which is a critical privacy concern for users. While the protocols in study [30] introduce a secure method for *k* nearest neighbours classification on encrypted data that safeguards data and user query privacy, they fail to conceal the data access patterns. Samanthula et al., in [29], expanded on their previous work from study [30] by introducing the PPkNN protocol, offering a new approach to the privacy preserved *k*-nearest neighbours classification issue.

The *k* nearest neighbours remain hidden from both the user and cloud in the PPkNN protocol [29]. Secure Minimum

protocol (SMIN) in study [30] is used to determine the nearest neighbours in a privacy preserved way. As proposed by Samanthula et al. in [29], the SMIN sub-protocol consumes nearlt 67% of the total processing time taken by the PPkNN protocol, which is significantly high and hence impractical in real-time scenario. So, the prevailing obstacle in any outsourced privacy preserving classification approach is to tackle this excess processing time which is caused due to the fact that protocols have to work upon encrypted values. A reduction in overall computational cost would bring even practical solution for the outsourced privacy preserving classification tasks.

As mentioned by Zhu et al. (2020) in [32], conventional privacy preserving approaches for kNN classification induce huge computational cost since operations are purely conducted on encrypted values. Park et al. (2020) in [33] have proposed an efficient version of the Samanthula et al.'s (2015) work in [29] by designing the PkNC protocol which executes its component protocols in parallel to find the class label.

Experimental results depict the gradual rise in execution time of the PkNC protocol. However, it decreases substantially regardless of *k* (the number of nearest neighbours). But, the primary drawback of this protocol emerges as the dataset increases. The execution time rises again in linear manner with increasing instances in dataset, largely because of the practical limitations on threading for parallel computation. Liu et al. (2020) [34] have investigated training of decision trees in outsourced environment. They asserted that encrypted dataset cannot be divided by the cloud based on best attribute and hence, they have proposed a new method which is splitting-free decision tree training.

However, the prominent defining factor is that problem domain of this work deals with k-NN classification, which does not require a separate training phase that is needed for decision tree classification. Also, the scheme proposed by the authors uses an additive secret-sharing method for privacy preservation. This induces more computational cost with the inclusion of share reconstruction. Moreover, experimentations show that the designed protocols' cost of communication and computation rises along with length of vector. Noteworthy observation is that protocols in study [34] were evaluated on relatively small datasets sizes, containing 24, 100, 120, and 958 instances, respectively. The protocols proposed in study [35] and [36] are more efficient than the pioneer protocol in [29], but they result in class labels corresponding to *k* nearest records instead of providing the final class of query. Thus, this is not the exact expected result for outsourced privacy-preserving *k*NN classification issue [37]. It also reveals the *k* nearest class labels to the querying user, which does not satisfy the privacy requirements as stated in study [29]. Moreover, it cannot protect all the intermediate information. The distribution of the inner products, which is used to describe the distance between two vectors like the Euclidean distance, is leaked to one of the cloud servers.

Examining the proposed scheme for a variety of datasets is an important experimental step toward deciding the range of classification tasks that potentially can be performed by any privacy-preserving approach. Until now, all of the existing schemes have experimented with only integer datasets (i.e. they can handle only integer values). This is the reason that in [38], Du et al. scheme's accuracy is not good enough for the real number datasets. In fact, the accuracy of this scheme severely drops with this Heart Disease dataset.

A privacy-preserving k-NN query scheme (QS) based on a secure multi-party computation mechanism was modeled by Xian Guo et al. in [3] to address security concerns when malicious attackers control the cloud and query users. This method showed that the scheme has a certain degree of feasibility and reliability. Furthermore, this method showed a better solution for privacy protection and security. However, a privacy-preserving k-NN query scheme was limited in real-world applications.

Hyeong-Jin Kim et al. in [6] implemented a privacy preserving k-NN query processing algorithm (QPA) via secure two-party computation based on encrypted data. In terms of query processing cost, the performance of the model was better than the existing methods. Nevertheless, the model did not solve other types of queries including Top-*k* and k-NN classification due to low-dimensional data. In addition, this model required increased computational cost. Developing high-dimensional data space requires a data dimensionality reduction technique which led to a challenging task.

Zhi Li et al. [39] presented a function secret sharing (FSS) based secure multi party kNN classification scheme (SecKNN). For secure computations, the presented scheme offered low computation and communication cost. The implementation of FSS reduced lot of computational overhead. Nonetheless, the deployment of the scheme on real time applications is limited.

A privacy-preserving kNN query scheme (QS) was employed by Yandong Zheng et al. [10] to return accurate query results and high query efficiency. The scheme achieved low computation cots and the max-heap accelerated the query efficiency. However, the kNN query scheme leaked the relative proximities of various data records.

Hyeong-Jin Kim et al. [22] employed a new Top-*k* query processing algorithm based on a homomorphic encryption system that is efficient and provides security also. Compared with the existing methods, the Top-k algorithm achieved more times better performance concerning query processing time. However, this model was only performed in specific privacy-preserving data mining algorithms.

III. PRIMITIVES

A. Synthetic Minority Over-sampling Technique (SMOTE)

SMOTE, introduced by Chawla et al [40] in 2002, addresses imbalanced class issues in machine learning. By synthesizing minority class samples through interpolation among existing instances, it counters bias favoring majority classes. Randomly selecting instances, it identifies *k* nearest neighbours and generates synthetic examples along the connecting line segments. This method improves the capacity of classifier for making accurate predictions by providing robust coverage of the minority class space. SMOTE generates synthetic data points, reducing model bias towards

the majority class. Particularly beneficial for imbalanced datasets where the minority class is underrepresented. Interpolation among existing minority class instances maintains diversity. Contrasts with simpler methods like random oversampling that may lead to overfitting. SMOTE introduces new instances near original minority class data points. Synthetic samples serve as plausible representations, reducing overfitting risk and aiding model generalization.

B. Paillier Cryptosystem

Paillier cryptosystem [28] is additively homomorphic and allows calculations upon encrypted values directly, eliminating the requirement to decrypt. It's extensively employed in safeguarding privacy, especially in situations requiring the secure processing of sensitive information while maintaining confidentiality. This scheme is capable of providing semantic security. Fundamentally, Paillier encryption operates on principles of modular operations and large prime numbers. Its security hinges on computing difficulty of factoring the product of two large prime numbers.

Consider *Epk* as encryption function associated with a public key *pk* represented by (N, g), where N is the product of two large prime numbers, and g is a generator in $Z^*_{N^2}$. Similarly, *Dsk* is the decryption function corresponding to the secret key *sk*. Following properties of Paillier encryption scheme [28] withstand for any two plaintext values a and b belonging to Z_N:

1) Homomorphic addition: It provides the addition operation on encrypted values, producing a sum which is also encrypted.

$$D_{sk}\left(E_{pk}(x+y)\right) = D_{sk}\left(E_{pk}(x) * E_{pk}(y)\ mod\ N^2\right) \quad (1)$$

2) Scalar multiplication homomorphism: It provides multiplication operation *x*y* and yields $E_{pk}(x*y)$ when an encrypted value $E_{pk}(x)$ is raised to the power with a scalar value *y*.

$$D_{sk}\left(E_{pk}(x * y)\right) = D_{sk}\left(E_{pk}(x)^y mod\ N^2\right) \quad (2)$$

IV. Methodology for Privacy Preserved Classification

This section elaborates on the operations of several sub-protocols that serve as the foundational components for enhancing the efficiency of computing the *k* nearest neighbours. By performing all operations on Cloud Server 1 (C_1) and utilizing Cloud Server 2 (C_2) for specific tasks with randomized and shuffled data, a robust privacy-preserving architecture can be established. As shown in Fig. 1, we operate within a genuine-but-curious scenario, where the two involved cloud platforms $C_1$and C_2 are non-colliding and adhere strictly to the protocol specifications. C_2 hosts *sk* (secret key) and does not share it with anyone whereas C_1 , C_2 and the querying user know the public key *pk*.

User data is encrypted and stored securely on C_1. *k*NN operations, including distance calculation and classification, are performed entirely on C_1, ensuring that sensitive information remains within a single secure environment.

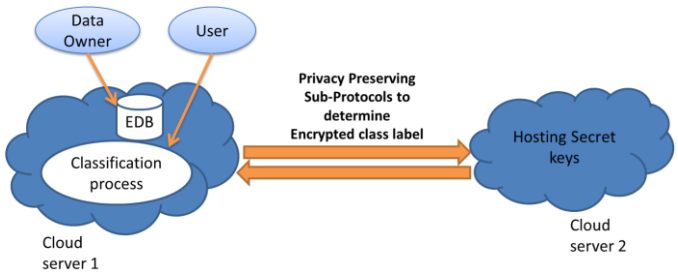

Fig. 1. Two cloud architecture setup.

For operations requiring additional computational resources, such as multiplication or comparison, C_1sends encrypted data in a randomized format to C_2. This randomized data prevents the exposure of sensitive information during the transmission and execution of these operations on C_2. Upon receiving the encrypted data, C_2 performs the necessary operations and returns the results to C_1. The results are de-randomized on C_1, ensuring that the true outcomes are obtained without compromising on data privacy and confidentiality.

The utilization of *k*NN within this two-cloud architecture facilitates privacy-preserving data mining operations in cloud environments. By encrypting data and performing all encrypted operations on C_1, sensitive information remains protected. Role of C_2 is specific to performing operations on randomized and shuffled data therefore, minimizing the risk of data breaches and unintended knowledge gain. The secure interaction between $C_1$and C_2 ensures that privacy is maintained throughout the outsourced classification process.

A. Privacy Preserving Euclidean Distance Protocol

Encrypted squared Euclidean distance is computed by this protocol. These encrypted distances are determined by computing difference between an encrypted user query, $E_{pk}(q)$ and each encrypted dataset instance, denoted as $E_{pk}(t_i)$. Here, i is between 1 and *n*, and *n* represents total instances in dataset. Both $E_{pk}(t_i)$ and $E_{pk}(q)$ have *m* number of attributes. C_2 holds *sk* (secret key) and does not share it with anyone where as C_1 , C_2 and the querying user know the public key *pk*.

The protocol employs parallelization via multiprocessing to expedite results. Additionally, it employs randomization for all intermediate operations necessitating interactions with C_2. In this process, the encrypted dataset values are randomized with an encrypted random number using the Paillier additive property [28], and the obtained result is later de-randomized. This approach guarantees that even if certain data points undergo decryption on C_2, they are presented in a randomized manner, thereby preventing complete exposure of any data point to C_2.

Algorithm-A: PPED(E_{pk}(X),E_{pk}(Y))→$\{E_{pk}(d_1),..,E_{pk}(d_n)\}$

Require: C_1 has E_{pk} (X) and E_{pk} (Y); C_2has *sk*

On C_1:

1. for *i = 1* to *n* do
2. for *j = 1* to *m* do
3. $E_{pk}\ (x_{ij} - y_j) \leftarrow E_{pk}\ (x_{ij}) * E_{pk}\ (y_j)^{N-1}$ mod N^2

(parallelization is used to compute attribute-wise differences concurrently)

4. end for
5. Generate random number $r \in Z_N$
6. $u \leftarrow \sum_{j=1}^{m} E_{pk}\ (x_{ij} - y_j)$
7. send $R \leftarrow u * E_{pk}\ (r) \bmod N^2$ to C_2

On C_2:

8. $u' \leftarrow D_{sk}(R)$
9. $v \leftarrow u' * u' \bmod N$
10. $v' \leftarrow E_{pk}\ (v)$
11. send v' to C_1

On C_1:

12. $r' = r * r$
13. $p = u^{2r} \bmod N^2$
14. $p' \leftarrow v' * E_{pk}(r')^{N-1} \bmod N^2$
15. $E_{pk}(d_i) \leftarrow E_{pk}\ ((x_i - y)^2) \leftarrow p' * p^{N-1} \bmod N^2$

(parallelization is used to concurrently compute the encrypted squared Euclidean distances for all instances)

16. end for
17. return $\{E_{pk}(d_1), \ldots, E_{pk}(d_n)\}$

A vector $E_{pk}(Y)$ having user's encrypted query attributes, and a data-frame E_{pk} (X) having attribute-wise encrypted instances from the dataset are used as inputs for the PPED protocol. Using PPED protocol, C_1 and C_2 jointly compute a vector having encrypted distances corresponding to each encrypted dataset instance.

This protocol implements parallelism in two phases. In the first phase the attribute-wise difference between each attributes of the user query and corresponding attribute of a given dataset instance is computed concurrently. In the second (outer) phase, the encrypted squared difference $E_{pk}(d_i)$ (i. e. $E_{pk}((x_i - y)^2)$) is concurrently computed for all instances of the dataset. During implementation this concurrency is achieved by using threading in Python. Thus, efficiency is improved significantly through these concurrent executions. Moreover, with additional computing resources such as multi-core processors, the PPED protocol can also be run in parallel to simultaneously compute the encrypted squared differences. We use parallelization for independently computing the attribute-wise differences for each i^{th} instance and also for overall execution of PPED algorithm across n instances as each squared distance can be independently computed for all n instances. At the end of PPED protocol, the resulting vector of encrypted distances is only available to C_1 however, these distances remain encrypted.

B. Privacy Preserving Shuffle Protocol (PPSP)

In order to get the k nearest neighbours for the encrypted user query, we need to find the k minimum encrypted distances from amongst the vector of encrypted squared differences generated by PPED protocol. Since, these distance values are encrypted, the k minimum distances cannot be found directly by C_1. The immediate solution is to send the vector of encrypted squared differences to C_2 so that C_2 can decrypt them with the secret key and then the squared differences could be compared in plaintext to get the required k minimum distances. However, this will reveal all the original distance values to C_2 and C_2 also gets to know which dataset records correspond to the selected k minimum distances. So, another solution which avoids this data leakage issue is to randomize the original distances at C_1 using additive homomorphic property and then send these randomized encrypted squared differences to C_2 for comparison. This solves the data leakage issue as the original distances are not revealed to C_2 but C_2 still gains knowledge about which k records from the dataset are selected as the nearest neighbours.

Algorithm-B: PPSP (D) → D'

Require: C_1 has $D \leftarrow \{E_{pk}\ (d_1 + r), \ldots, E_{pk}\ (d_n + r)\}$

On C_1:

1. $n \leftarrow$ *length_of (D)*
2. for $i = n$-1 to 1 do
3. Generate a random integer j , where $0 \leq j \leq i$
4. $temp = D[i]$
   $D[i] = D[j]$
   $D[j] = temp$
5. end for
6. return $D' \leftarrow$ *securely permuted vector of randomized encrypted squared differences*

Although, $C_1$and C_2 are non-colliding but revealing such data access patterns to C_2 can be potentially malicious. Hence, we propose a privacy preserving shuffle protocol (PPSP) that performs random permutation with the randomized encrypted squared differences before sending them to C_2 for comparison. Since, PPSP applies the random permutation directly on encrypted data, at the end of the protocol C_1 does not gain any information about the randomized encrypted squared differences. Moreover, C_2 remains unaware about the sequence of the randomized encrypted squared differences it receives from C_1 for comparison, as intermediate steps are not revealed. Thus, by utilizing proposed PPSP protocol before determining the k minimum encrypted distances, C_2 does not gain any knowledge about which k records from the dataset get selected as the target nearest neighbours and data access patterns are preserved.

C. Privacy Preserving k-Minimum Distances (PPkMD) Protocol

The objective of PPkMD protocol is to determine the encrypted k nearest neighbours of the encrypted user query such that the corresponding original dataset records are not revealed to either of the clouds (i.e.C_1 or C_2). Also, the intermediate results must be either encrypted or such that they must not lead C_1 or C_2 to gain any knowledge about the original values to avoid disclosure of data access patterns. The protocol takes a vector 'v' as input and each element of v is an object having three encrypted values namely, encrypted dataset record identifier $E_{pk}(id_i)$, encrypted distances (i.e. squared difference) $E_{pk}(d_i)$ and corresponding encrypted class label $E_{pk}(c_i)$. So, $v = \{(E_{pk}(id_1), E_{pk}(d_1), E_{pk}(c_1)), \ldots, (E_{pk}(id_n), E_{pk}(d_n), E_{pk}(c_n))\}$

The protocol begins with C_1 generating random integer r from Z_N, and randomizes vector v by homomorphically adding $E_{pk}(r)$ to $E_{pk}(id_i)$, $E_{pk}(d_i)$ and $E_{pk}(c_i)$ of each element of v This gives us an encrypted randomized vector, v'. This v' vector is shuffled using $PPSP_m$ protocol before it is transmitted to C_2. $PPSP_m$ is a variant of above proposed PPSP protocol used for shuffling the vector v', where $v'[i]$= $(E_{pk}(id'_i), E_{pk}(d'_i), E_{pk}(c'_i))$ and $1 \leq i \leq n$. Thus, $PPSP_m$ receives v' and shuffles it such that position of each element $v'[i]$ is changed. Then, the shuffled vector V is sent to C_2.

C_2 decrypts V to get a plaintext but randomized vectors V'. Now, C_2 constructs a min-heap with the randomized distances, $V'[i].d'$, where $1 \leq i \leq n$ and each node in the heap comprises of ($V'[i].id'$, $V'[i].d'$, $V'[i].c'$) i.e. an element of vectors V'. Since, the randomized distance value present at the root node of the min-heap is always the smallest value, we pop the root node from the heap to get the first amongst the k nearest neighbours. Similarly, we pop the heap to get all the remaining nearest neighbours and store them in vector K_{min}. As the min-heap is built with randomized distance values and each node in the heap structure has only randomized values, C_2 does not gain any information about original values. Also, since the randomized elements are already shuffled, therefore C_2 neither learns about their order nor it is able to determine which k records from the dataset were selected as the nearest records to the query. Moreover, the identifiers are also randomized and shuffled which avoids revealing any data access patterns. C_2 then encrypts the vector K_{min} to get encrypted vector K_{min}' and sends it to C_1.

Then, C_1 de-randomizes K_{min}' using the paillier additive property [28] to get the original encrypted k nearest elements in vector v_{min}. Since, every step at C_1 involves only encrypted data, no information is revealed to C_1.

Algorithm-C: PPkMD (v) → v_{min}

Requires: C_1 holds v= $\{(E_{pk}(id_1),E_{pk}(d_1),E_{pk}(c_1)),\ldots, (E_{pk}(id_n), E_{pk}(d_n), E_{pk}(c_n))\}$ and C_2 holds the secret key sk.

On C_1:

1. Generate random integer $r \in Z_N$ and encrypt it, $E_{pk}(r)$
2. Build randomized vector v' by adding $E_{pk}(r)$ to each element of v :
3. for i = 1 to n do
4. $E_{pk}(id'_i) = E_{pk}(id_i) * E_{pk}(r) \bmod N^2$
5. $E_{pk}(d'_i) = E_{pk}(d_i) * E_{pk}(r) \bmod N^2$
6. $E_{pk}(c'_i) = E_{pk}(c_i) * E_{pk}(r) \bmod N^2$
7. end for
8. So we have, encrypted randomized vector as, v'= $\{(E_{pk}(id'_1),E_{pk}(d'_1),E_{pk}(c'_1)),\ldots,(E_{pk}(id'_n), E_{pk}(d'_n), E_{pk}(c'_n))\}$
9. $V \leftarrow PPSP_m(v')$ to shuffle all elements in v'
10. Send shuffled vector V to C_2

On C_2:

11. Decrypt all elements in V using sk such as,
12. for i = 1 to n do
13. $V'[i] \leftarrow (D_{sk}(V[i].id'), D_{sk}(V[i].d'), D_{sk}(V[i].c'))$
14. end for
15. Construct a *min-heap* based on randomized distances $V'[i].d'$, where $1 \leq i \leq n$ and each node in the heap comprises of ($V'[i].id'$, $V'[i].d'$, $V'[i].c'$)
16. for i = 1 to k do
17. $K_{min}[i] \leftarrow$ pop the root node from the *min-heap*
18. end for
19. Vector K_{min} is encrypted using pk such as,
20. for i = 1 to k do
21. $K_{min}'[i] \leftarrow (E_{pk}(K_{min}[i].id'), E_{pk}(K_{min}[i].d'), E_{pk}(K_{min}[i].c'))$
22. end for
23. Send encrypted vector K_{min}' to C_1

On C_1:

24. Receive K_{min}' from C_2 and get the de-randomized vector v_{min} :
25. for i = 1 to k do
26. $E_{pk}(id_{\min\_i}) = K_{min}'[i].id' * E_{pk}(r)^{N-1} \bmod N^2$
27. $E_{pk}(d_{\min\_i}) = K_{min}'[i].d' * E_{pk}(r)^{N-1} \bmod N^2$
28. $E_{pk}(c_{\min\_i}) = K_{min}'[i].c' * E_{pk}(r)^{N-1} \bmod N^2$
29. end for
30. So, we have the encrypted k nearest neighbours in v_{min} as,
31. return v_{min} = $\{(E_{pk}(id_{\min\_1}),E_{pk}(d_{\min\_1}),E_{pk}(c_{\min\_1})),\ldots, (E_{pk}(id_{\min\_k}), E_{pk}(d_{\min\_k}), E_{pk}(c_{\min\_k}))\}$

D. Privacy Preserving Frequency Counting (PPFC) Protocol

The list of encrypted class labels of the dataset is also outsourced to C_1 along with the *EDB*. V=($E_{pk}(c_1)$,…., $E_{pk}(c_w)$) denotes the encrypted class labels list held by C_1.Hence, we have definite class labels (i.e. w). Also, at the end of PPkMD protocol, C_1 holds the encrypted class labels corresponding to the k- nearest records. Let these class labels be denoted as, U= ($E_{pk}(c_1)$,…., $E_{pk}(c_k)$). The goal of PPFC protocol is to compute the frequency of occurrence for each class label in *EDB* in privacy preserved manner i.e. $E_{pk}(f(c_j))$, where $1 \leq j \leq w$.

$PPSP_f$ is another variant of the proposed PPSP protocol used for shuffling vector G_i, where $1 \leq i \leq k$, which comprises of encrypted randomized class label difference values. Then, the shuffled matrix G' is sent to C_2. This ensures that C_2 does not learn anything about which randomized difference value in G' corresponds to which class label. The inverted matrix I received from C_2 is then de-shuffled using the reverse permutation protocol $PPSP'_f$. Finally, the column-wise homomorphic addition of matrix I' gives the encrypted occurrence frequency of class label c_j , where $1 \leq j \leq w$.

Algorithm-D: PPFC (U,V) →F=$\{E_{pk}(f(c_1)),\ldots E_{pk}(f(c_w))\}$

Requires: C_1 holds U= $\{E_{pk}(c_{\min\_1}),..,E_{pk}(c_{\min\_k})\}$ and V= $\{E_{pk}(c_1),..,E_{pk}(c_w)\}$

On C_1:

1. for $1 \leq i \leq k$
2. for $1 \leq j \leq w$
3. $G_{i,j} = E_{pk}(c_j) * E_{pk}(c_{\min\_i})^{N-1}$
4. Generate a random integer $t_{i,j} \in Z_N$
5. $G'_{i,j} = G_{i,j}{}^{t_{i,j}}$
6. end for
7. $G'_i \leftarrow PPSP_f(G'_i)$ to shuffle all elements of G'_i
8. end for
9. Send shuffled matrix G' to C_2

On C_2:
10. for $1 \le i \le k$
11. for $1 \le j \le w$
if $D_{sk}(G'_{i,j}) = 0$
$I_{i,j} = E_{pk}(1)$
otherwise, $I_{i,j} = E_{pk}(0)$
end if
12. end for
13. end for
14. Send matrix I to C_1

On C_1:
15. for $1 \le i \le k$
16. $I'_i \leftarrow$PPSP$'_f(I_i)$ to de-shuffle all elements of I_i
17. end for
18. for $1 \le j \le w$
19. $F[j] \leftarrow E_{pk}(f(c_j)) = \prod_{i=1}^{k} I'_{i,j}$
20. end for

E. Privacy Preserving Max-Frequency (PPMF) Protocol

The PPFC protocol yields a vector *F*, that has encrypted occurrence (counts) frequencies of all class labels of given dataset. The objective of PPMF protocol is to determine which these encrypted frequency values is the largest. The class label corresponding to the largest encrypted randomized frequency will be the final class label for the user's query. So, PPMF protocol can be similar to the proposed PP*k*MD protocol where C_1 prepares a randomized version of the vector F, shuffles it using another suitable variant of PPSP protocol and sends it to C_2; each element is a pair of randomized encrypted class label and corresponding randomized encrypted frequency $<E_{pk}(c_j + r), E_{pk}(f(c_j) + r)>$, where $1 \le j \le w$. C_1 also sends the randomizing factor, *r*, to the querying user at this stage. C_2 decrypts the received vector and now builds a max-heap based on the decrypted but randomized and shuffled frequency values. Each node in the max-heap comprises of the randomized class label and its corresponding randomized frequency value. Since, the randomized frequency value present at the root node of the max-heap is always the largest value; we pop the root node from the heap to get the maximum frequency and its corresponding class label, both randomized. This is the final but randomized class label, $(c_{final} + r)$ for the user query. C_2 sends this randomized final class label to the querying user.

F. Privacy Preserving k-NN Classifcation (PPkC) Protocol

This protocol serves as the base protocol for performing outsourced k-NN classification. It utilizes the above proposed privacy preserving protocols as building blocks for classifying user queries. The querying user is expected to encrypt all query attributes $(E_{pk}(y_1), \ldots, E_{pk}(y_m))$ and send it to C_1. Let us suppose that the encrypted database (EDB) at C_1 is denoted by E_{pk}(X) and the encrypted user query is E_{pk}(Y). With these inputs, the PP*k*C protocol starts its execution.

Algorithm-E: PP*k*C $(E_{pk}(X), E_{pk}(Y)) \rightarrow (E_{pk}(c_1), .., E_{pk}(c_k))$

Requires: C_1 has E_{pk}(X) and receives E_{pk}(Y)
1. $\{E_{pk}(d_1), .., E_{pk}(d_n)\} \leftarrow$ PPED$(E_{pk}(X), E_{pk}(Y))$
2. $v = \{(E_{pk}(id_1), E_{pk}(d_1), E_{pk}(c_1)), \ldots, (E_{pk}(id_n), E_{pk}(d_n), E_{pk}(c_n))\}$
3. $v_{min} \leftarrow$PP*k*MD (v)
4. $U = \{E_{pk}(c_{\min\_1}), .., E_{pk}(c_{\min\_k})\}$ and
5. $V = \{E_{pk}(c_1), .., E_{pk}(c_w)\}$
6. $F \leftarrow$ PPFC (U,V)
7. for $1 \le i \le w$
8. $F'[i] = < E_{pk}(c_i), E_{pk}(f(c_i)) >$
9. User receives $(c_{final} + r) \leftarrow$ PPMF (F')
10. With *r* received from C_1, the user computes the final class label as, $(c_{final} + r) - r$

At the end of PPMF protocol, the querying user receives the final randomized class label, $(c_{final} + r)$ from C_2. With r received from C_1, the user de-randomizes $(c_{final} + r)$ to determine the final class label, c_{final}.

V. PROTOCOL ANALYSIS

Although we focus on building an efficient approach for outsourced *k*NN classification, in this section we also highlight the effectiveness, security and total privacy preservation provided by the proposed protocols. We have guaranteed that the final result of all the proposed privacy preserving protocols remains encrypted. Additionally, C_2 works with only random and shuffled values that bear no connection to the original data. Furthermore, all computations performed on C_2 are consistently sent back to C_1 in encrypted format. Hence, at no stage the original data is revealed to C_1 or C_2. The complexities of the proposed protocols employed in the proposed PP*kC* protocol is presented in Table I.

TABLE I. COMPLEXITIES OF PROPOSED PROTOCOLS

Protocols	PPED	PPSP	PP*k*MD	PPFC
Complexity	O(*m logN*)	O(*n*)	O(*k logn*)	O(*kwn*)

A. PPED Analysis

PPED protocol is carried out with randomization to prevent the sum of attribute-wise differences (i.e. *u*) from getting revealed at C_2. The sum of attribute-wise differences is randomized using the Paillier additive property [28] at C_1 and the randomized value is sent to C_2 for squaring. C_2 decrypts the randomized value, computes square of the randomized values and then encrypts the square again before sending it to C_1. C_1 receives the encrypted square of randomized value and de-randomizes the square through mathematical formulae and homomorphic properties to get the encrypted square of the original *u* value. Hence, the resulting encrypted square of *u* is only available to C_1. Also, the randomizing factor *r* is only known to C_1 so, C_2 does not gain any information about the original value of *u*.

Parallelization is employed in two phases; firstly for computing the attribute-wise difference of each i^{th} instance and also for independently computing the *n* squared distances. With parallelization, assuming ideal conditions, these

computations can be done in O(m) time for the attribute-wise difference and O(n) time for the actual squared distance. The de-randomizing step takes O($nlogN$) time across all n instances, N being the . So with parallelization, the overall complexity could be reduced to O($mlogN$) if the operations are fully parallelized.

B. PPkMD Analysis

The encrypted vector v is randomized with an encrypted random factor $E_{pk}(r)$ and then shuffled using $PPSP_m$ protocol to get vector V at C_1. C_2 then builds the min-heap with the decrypted distances but they are randomized and shuffled distance values so, C_2 does not gain any information about the original distances and access patterns since C_2 takes decisions based on randomized and shuffled values and hence, no extra information is leaked at C_2. Once C_2 determines the randomized k nearest neighbours, C_2 encrypts them and sends to C_1. Now, since paillier cryptosystem is semantically secure, the cipher texts received by C_1 are not the same as the ones which were sent to C_2. Hence, C_1 cannot determine which k distances amongst the sent n distances are received as nearest distances. Ultimately, no knowledge is acquired by C_1 and C_2 about the original data during PPkMD protocol. Since, min-heap is built with O($logn$) and k minimum neighbours are to be extracted, the overall complexity of the PPkMD is O($klogn$).

VI. Experimental Results and Performance Analysis

The various experiments were performed in Google Colab environment with an Intel® 2 GHz system having 4 cores, RAM of 8 GB and 3 MB Cache Size. We utilized the python homomorphic encryption (i.e. phe) library for implementing the Paillier cryptosystem in [28] which is required in the proposed protocols. Existing privacy preserving solutions also use the same cryptosystem so, the performance of the proposed PPkN protocol can be easily compared with them.

We compare the performance of proposed PPkC protocol with the recent and state-of-the-art work in [33], [34], [35], [41] and [43]. The state-of-the-art privacy preserving solutions in [33], [34] and [35] have used datasets the same UCI KDD archive's Car Evaluation dataset [42] in their experimentation. To clearly showcase the improved performance of the proposed PPkC protocol, we firstly conducted experimentation using the same Car Evaluation dataset [42] having 1728 records and six attributes.

For extensive performance evaluation of proposed PPkC protocol with huge dataset and comparison with the most recent work in studies [41] and [43] we used a suitable scaled version of the Car Evaluation dataset in experimentation having 10000 records and six attributes. All the above mentioned recent solutions have used different hardware specifications while performing the performance evaluation of their privacy preserving protocols.

We encrypted both datasets firstly keeping the key size as 512 bits and then as 1024 bits (i.e. K=512/1024), and also varied the values for the nearest neighbours i.e. k and the number of records i.e. n to evaluate the performance of proposed PPkN protocol.

A. Experimental Analysis

1) Performance of proposed protocols with varying key size (K): The below figures illustrate the execution time (in seconds) required by each of the proposed component protocols namely PPED, PPkMD, PPFC, PPMF along with the total execution time taken by PPkC while using datasets encrypted with key size (K) as 512 and 1024 and k= 5. The execution time of PPSP is inclusive in time taken by above mentioned protocols. The protocols are listed on the x-axis, while the y-axis represents the execution time in seconds.

Fig. 2 illustrates the execution time required by all protocols when the Car Evaluation dataset (dataset-1) is encrypted with a key size of 512 and 1024 bits. It is clearly observed that the PPED requires more time as compared to other component protocols with relatively insignificant time requirements.

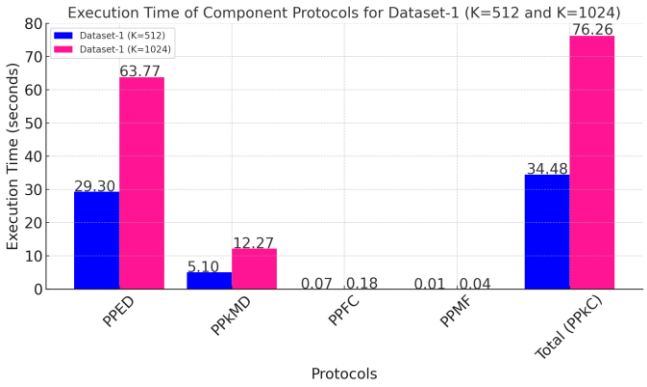

Fig. 2. Execution time of proposed protocols with encrypted Car Evaluation dataset (K= 512, 1024, n=1724).

Fig. 3 illustrates the execution time required by all protocols when the scaled Car Evaluation dataset (dataset-2) is encrypted with a key size of 512 and 1024 bits. As the number of data records are more in this scaled dataset, the execution time taken by all the component protocols is relatively more. However, the growth in time required by PPkMD, PPFC, PPMF protocols is insignificant.

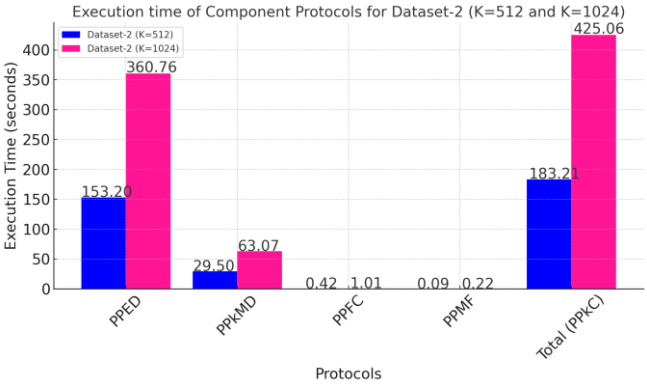

Fig. 3. Execution time of proposed protocols with encrypted Scaled Car Evaluation dataset (K= 512, 1024, n=10000).

TABLE II. SUMMARY OF EXECUTION TIME (SEC) OF COMPONENT PROTOCOLS WITH BOTH DATASETS

Protocols	PPED	PP*k*MD	PPFC,	PPMF	Total (PP*k*C)
Dataset-2 (K= 512)	153.2	29.5	0.42	0.09	183.21
Dataset-2 (K= 1024)	360.76	63.07	1.01	0.22	425.06
Dataset-1 (K= 512)	29.3	5.1	0.07	0.01	34.48
Dataset-1 (K= 1024)	63.77	12.27	0.18	0.04	76.26

Table II shows the summary of execution time incurred by all proposed component protocols during the user query classification with both Car Evaluation dataset and its scaled version having 1724 and 10000 records, respectively, encrypted under key sizes (K) of 512 and 1024 bits.

TABLE III. DATA TRANSFERRED DURING QUERY CLASSIFICATION USING PP*k*C

K (bits)	Data Transferred (MB)				
	k= 5	*k*= 10	*k*= 15	*k*= 20	*k*= 25
512	18.366	25.827	33.355	40.822	48.0
1024	35.587	50.217	64.834	79.474	94.224

Table III shows the data transferred (in Megabytes) during user query classification using the proposed PP*k*C protocol in the two cloud setup with the Car Evaluation dataset encrypted under key sizes (K) 512 and 1024 bits. The table presents the data transferred for various values of *k* i.e. number of neighbours considered.

2) Performance of proposed protocols with varying number of nearest neighbours (k): We examined the execution time required by each of the proposed component protocols and also the total execution time taken by PP*k*C algorithm while varying values of number of neighbours (i.e. *k*) with encrypted Car Evaluation dataset using key size of 512. Across all component protocols a consistent pattern of constant execution times is maintained as the value of *k* is increased from 5 to 25. Hence, the total execution time of proposed PP*k*C protocol remains almost constant when *k* is changed from 5 to 25. Fig. 4 shows this merit of consistent pattern of constant execution times for all proposed protocols while varying *k*.

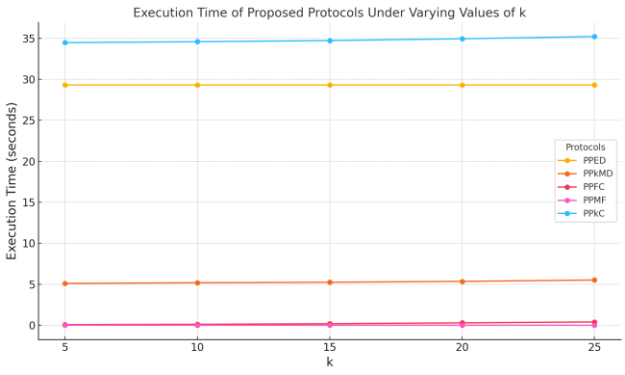

Fig. 4. Constant execution time of proposed protocols under varying values of *k*.

TABLE IV. SUMMARY OF EXECUTION TIME (SEC) OF PROPOSED COMPONENT PROTOCOLS UNDER VARYING VALUES OF *K*

	PPED	PP*k*MD	PPFC	PPMF	PP*k*C
k= 5	29.3	5.1	0.07	0.01	34.48
k= 10	29.3	5.18	0.11	0.01	34.59
k= 15	29.3	5.24	0.18	0.01	34.73
k= 20	29.3	5.35	0.29	0.01	34.95
k= 25	29.3	5.51	0.4	0.01	35.22

Table IV clearly indicates that increase in the number of neighbours considered for query classification (i.e. *k*) does not affect the execution time of proposed PP*k*C protocol which is a significant achievement. On other hand, when compared with recent privacy preserving solutions, the execution time of protocols in [34] and [41] grows linearly along with increasing value of *k*. Although the execution time of protocol in [33] remains almost constant while varying *k* from 5 to 25, still the time required is significantly more. This is discussed in detail in the comparative analysis section.

B. Comparative Analysis

The existing recent privacy preserving solutions in [33], [34], [35], [41] and [43] are compared with proposed PP*k*C protocol. The performance of proposed PP*k*C protocol is examined in terms of its execution time by varying the number of records (*n*) and the number of nearest neighbours considered (*k*) during the outsourced classification. For fair analysis, the execution time of PP*k*C protocol is compared with execution time of protocols in [33], [34] and [35] under above stated varying parameters and using the UCI KDD archive's Car Evaluation dataset [42] having 1728 records, 6 attributes and 4 unique classes. Size of encryption the key (K) used in [33], [34] and [35] is 1024 bits and hence, we maintain the same in our experiment.

Additionally, for extensive performance evaluation with much larger dataset, the comparative analysis on the execution time of proposed PP*k*C protocol and that of the most recent protocols in [41] and [43] is made under same varying parameters while using the SMOTE [40] based scaled version of the Car Evaluation dataset having 10000 records and 6 attributes. Size of the encryption key (K) used in [41] and [43] is 512 bits and hence, to maintain fairness we use the same key size in experiment with the scaled dataset.

1) Analysis with the car evaluation dataset: The state-of-the-art prior work in [33], [34] and [35] used the Car Evaluation dataset [42] encrypted with key size (K) of 1024 bits in their experimentations. Hence, for fairness of comparison we have also used the same encrypted dataset in experiments with the proposed PP*k*C approach. The results on the execution time and performance of proposed PP*k*C protocol under varying parameter of *n* and *k* are compared with state-of-the-art prior work. Table V shows the execution time required by proposed PP*k*C protocol as compared to other state-of-the-art protocols when varying the nearest neighbours i.e. *k*, from 5 to 25.

TABLE V. EXECUTION TIME (SEC) OF PP*K*C AND OTHER STATE-OF-THE-ART PROTOCOLS WITH VARYING VALUES OF *K* (WITH *N*=1724, *K*=1024)

	k= 5	*k*= 10	*k*= 15	*k*= 20	*k*= 25
proposed PP*k*C	76.26	76.61	76.9	77.37	77.82
Park et al. (2020) [33]	249.6	249.6	249.6	249.6	249.6
Liu et al. (2019) [34]	181.14	375.18	560.52	728.46	923.28
Wu et al. (2018) [35]	53.34	56.58	60.3	63.18	65.82

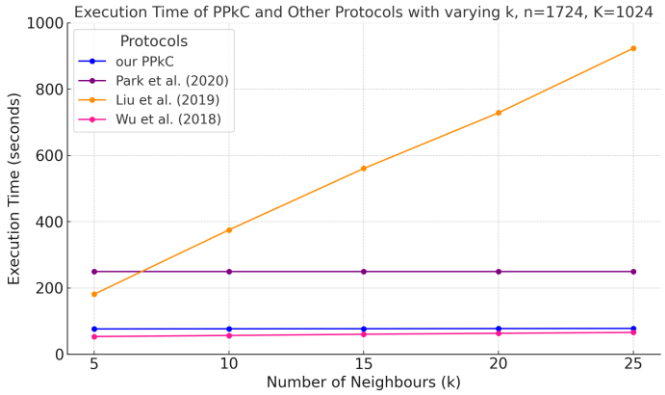

Fig. 5. Comparison on execution time of PP*k*C and existing state-of-the-art protocols with varying *k* using Car evaluation dataset.

Fig. 5 shows the analysis of execution time on the encrypted Car evaluation dataset with key size 1024 bits under varying values *k*. The running time of proposed PP*k*C varies from 76.26 to 77.82 seconds when the number of neighbours are changed from 5 to 25, respectively. Since, execution time of proposed approach remains almost constant so, we can significantly establish that the performance of proposed PP*k*C protocol is not much affected by changes in *k*. When *k*=25, the time taken for execution by PP*k*C protocol is 77.82 seconds which shows that it performs 11.86 times (i.e. 91.57 %) better than the SKC protocol in [34], 3.21 times (i.e. 68.82 %) better than the P*k*NC protocol in [33] and just 1.18 times less better than the PPKC protocol in [35]. As indicated by Table III, the memory usage of the PP*k*C protocol increases gradually with an increase in value of *k* but, so is the case with the other compared protocols. In fact, except protocol in [35] all the other compared protocols require more memory than proposed PP*k*C protocol when using key size of 1024 bits and with varying values of *k*.

Table VI shows the execution time required by proposed PP*k*C protocol as compared to other state-of-the-art protocols when varying the number of records i.e. *n*, from 500 to 1724.

TABLE VI. EXECUTION TIME (SEC) OF PP*K*C AND OTHER STATE-OF-THE-ART PROTOCOLS WHILE VARYING *N* (WITH *K*=25, *K*=1024)

	n= 500	*n*= 1000	*n*= 1500	*n*= 1724
our PP*k*C	22.58	45.12	67.66	77.82
Park et al. (2020) [33]	72.2	144.4	216.6	249.6
Liu et al. (2019) [34]	267.77	535.54	803.31	923.28
Wu et al. (2018) [35]	19.08	38.16	57.24	65.82

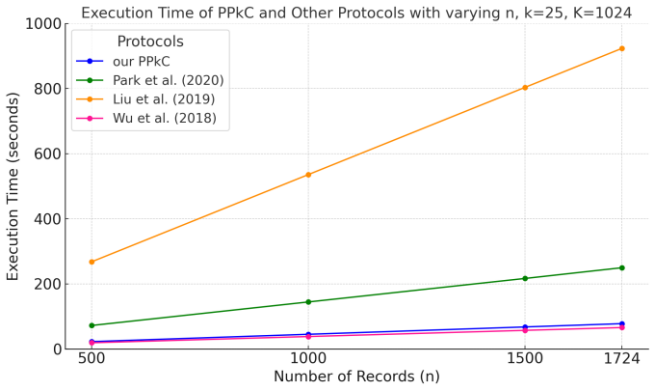

Fig. 6. Comparison on execution time of PP*k*C and existing state-of-the-art protocols with varying *n* using Car evaluation dataset.

Fig. 6 shows the analysis of execution time on the encrypted Car evaluation dataset with key size 1024 bits under varied number of records i.e. *n*, from 500 to 1724. The running time of proposed PP*k*C varies from 22.58 to 77.82 seconds when *n* is changed from 500 to 1724, respectively. Since, execution time drops significantly with proposed PP*k*C approach even while varying the number of records so, we can clearly establish that the performance of proposed protocol is much better than that of P*k*NC protocol and SKC protocol in [33] and [34], respectively. When *n*=1724, the time taken for execution by PP*k*C protocol is 77.82 seconds which shows that it again performs 11.86 times (i.e. 91.57 %) better than the SKC protocol in [34], 3.21 times (i.e. 68.82 %) better than the P*k*NC protocol in study [33] and just 1.18 times less better than the PPKC protocol in study [35]. However, protocol in [35] only aims at determining the class labels corresponding to *k* nearest records instead of providing the final class for user's query. It also reveals the *k* nearest class labels to the querying user, which does not satisfy the privacy requirements as stated in study [29].

2) Analysis with the scaled Car Evaluation dataset: In the literature survey, we observed that the performance of many existing privacy preserving classification protocols has depleted when they were tested with huge datasets. Specifically, the execution time of even the most recent protocols in [41] and [43] grows linearly while varying the number of records (*n*) due to the linear growth in computational cost. So, for extensive performance evaluation of proposed PP*k*C protocol we conducted experiments with the SMOTE [40] based scaled version of the Car Evaluation dataset which is a much larger dataset having 10000 records. Table VII shows the execution time required by PP*k*C protocol as compared to the most recent protocols in [41] and [43] when varying the nearest neighbours i.e. *k*, from 5 to 20.

Fig. 7 shows the comparative analysis on execution time of proposed PP*k*C with the most recent protocols in [41] and [43] using the scaled Car evaluation dataset encrypted with key size of 512 bits under varying values *k*. When *n*=10000 and the number of neighbours are changed from 5 to 20, the running time of proposed PP*k*C varies from only 183.21 to 184.68 seconds, respectively whereas the running time of [41] ranges from 60.32 to 202.12 seconds. Since, execution time of

proposed approach remains almost constant with scaled dataset also, we can significantly establish that even with huge datasets the performance of proposed PP*k*C protocol is not much affected when *k* is increased. Same is the case with the protocol in [43], its run time is also almost independent of *k*. However, the runtime of PP*k*C protocol is nearly 5 times better than that of protocol in [43]. When *k*=20, the time taken for execution by proposed PP*k*C protocol is 184.68 seconds which shows that it performs 9.96 % better than the protocol in study [41]. Also, it is worth observing that the execution time of protocol in [41] grows linearly with increasing value of *k* whereas it remains almost constant for proposed PP*k*C protocol across all values of *k*.

TABLE VII. EXECUTION TIME (SEC) OF PPKC AND RECENT EFFICIENT PROTOCOLS WITH VARYING VALUES OF *K* (*K*= 512)

	with *n*= 10000		with *n*= 6000	
	proposed PP*k*C	Kim et al. (2022) [41]	proposed PP*k*C	Wang et al. (2024) [43]
k= 5	183.21	60.32	103.24	600.26
k= 10	183.93	98.22	104.53	600.33
k= 15	184.32	135.87	104.77	601.67
k= 20	184.68	202.12	104.94	602.88

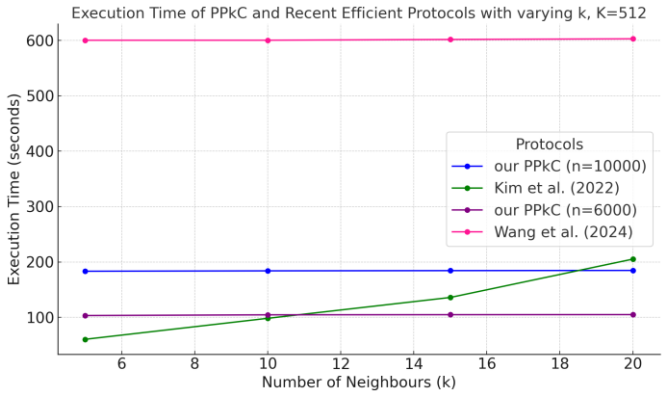

Fig. 7. Comparative analysis on execution time with varying *k* using the scaled dataset.

Table VIII shows the execution time required by proposed PP*k*C protocol as compared to the most recent protocols in [41] and [43] when varying the number of records i.e. *n*, from 2000 to 10000.

TABLE VIII. EXECUTION TIME (SEC) OF PPKC AND RECENT EFFICIENT PROTOCOLS WITH VARYING VALUES OF *N* (WITH *K*=10, *K*= 512)

	Proposed PP*k*C	Kim et al. (2022) [41]	Wang et al. (2024) [43]
n= 2000	39.12	22.44	240
n= 5000	87.1	56.11	480
n= 10000	183.93	98.22	1200

Fig. 8 shows the analysis of execution time of proposed PP*k*C protocol with the most recent protocols in [41] and [43] while using the scaled Car evaluation dataset encrypted with key size of 512 bits under varied number of records i.e. *n*, from 2000 to 10000. The running time of proposed PP*k*C varies from 39.12 to 183.93 seconds when *n* is changed from 2000 to 10000, respectively. Since, execution time drops significantly with proposed PP*k*C approach while using the scaled dataset also so, we can clearly establish that the performance of proposed protocol is much better than that of the protocol in [43]. When *n*=10000, the time taken for execution by proposed PP*k*C protocol is 183.93 seconds which shows that it again performs 6.52 times (i.e. 84.67 %) better than the protocol in [43] and just 1.87 times less better than the protocol in [41] with increasing value of *n*.

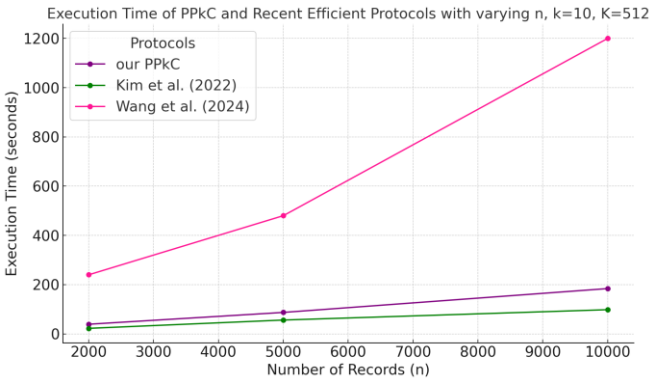

Fig. 8. Comparative analysis on execution time with varying *n* using the scaled dataset.

VII. CONCLUSION AND FUTURE SCOPE

In this paper, we have proposed efficient privacy-preserving *k*NN classification approach, named as PP*k*C protocol and its component protocols that leveraging partial homomorphic encryption (PHE). Our endeavor focused on demonstrating the feasibility and efficacy of PHE in safeguarding sensitive data while allowing for *k*NN classification in outsourced environments.

First and foremost, it is noteworthy that proposed protocols are preserving privacy of user's query, dataset values and the final class label. The protocol analysis shows that no information is ever disclosed and no knowledge can be potentially gained by both the clouds (C_1 and C_2) during execution of any of the component protocols for performing the outsourced *k*-NN classification on encrypted data. In the protocol analysis and implementation, we underscore that the proposed enhanced privacy preserving component protocols fully adhere to the privacy requirements outlined earlier in this paper. Notably, both cloud servers, $C_1 and\ C_2$, are kept oblivious to the identities of the database records associated with the computed nearest neighbours of the user query. Moreover, the intermediate data available to either of the clouds consist of encrypted random values or random numbers only. Also, the privacy preserving shuffling protocol eliminates the risk of C_2 understanding the data accessing patterns.

Furthermore, we explored the possibility of using the heap structure firstly to determine the *k* minimum distances and their corresponding class labels and then for finding the class label with maximum occurrence frequency. With this we were able to significantly reduce the computational overhead involved in classifying the encrypted user's query on

encrypted data and hence enhanced the efficiency of the overall PP*k*C protocol. This approach proved instrumental in optimizing performance with real-world datasets and also particularly in scenarios involving scaled datasets.

Through the experimental investigations, we have drawn several noteworthy conclusions. In the comparative analysis on execution time using the Car evaluation dataset and its scaled version encrypted with key size 1024 bits and 512 bits, respectively it is observed that the running time of proposed PP*k*C remains almost constant while varying values of *k* from 5 to 25. Even while varying *n* the execution time drops significantly with proposed PP*k*C approach with both the dataset. Hence, we established that the performance of proposed PP*k*C protocol is independent of variation in *k* and is much better than that of other recent protocols while varying *k* and *n*.

In our future work, we plan to utilize fully homomorphic encryption (FHE) schemes for working in an encrypted environment since it gives access to a wide range of operations thereby minimizing communication costs incurred in a two-cloud setup. However, its computational overhead must be considered as well and efforts must be taken to improve the same.

***Abstract*—Proficiency in programming is crucial for driving the Fourth Industrial Revolution. Therefore, interest in programming needs to be instilled in students starting from the school level. While the use of robotics can attract students' interest in programming, there is still a lack of research modeling, the impact of robotic learning experiences on programming interest using a structural equation modeling (SEM) approach. This study aims to analyze the structural relationship between interest in programming and learning experiences using a specially developed robotics module based on Kolb's experiential learning model and the programming development phases. An experiment involving 76 primary and secondary school students was conducted using the robotics module. Data were collected through a questionnaire containing 12 questions for five constructs: engagement, interaction, challenge, competency, and interest. These constructs, which are latent variables, formed the model using the partial least squares-SEM technique through the SmartPLS 4.0 software. The evaluation of the structural model found that the variables of engagement and competency had a significant impact on interest in programming, while interaction and challenge received low values. The developed model has moderate predictive power, indicating that interest in programming can be moderately predicted based on students' experiences using robots.**

I. Introduction

Mastery of programming skills is essential for advancing the Fourth Industrial Revolution; however, fostering a genuine interest in programming among students at the school level continues to pose a considerable challenge. One effective way to enhance students' interest in programming is by integrating technology in interactive environments, such as using Turtle Graphics for vector-based graphics [1] and incorporating robots to provide hands-on learning experiences. Robotics education has emerged as an engaging avenue for introducing students to programming concepts and cultivating computational thinking (CT) skills [2] Additionally, a study by [3] demonstrated that integrating CT with Educational Robotics (ER) significantly enhances students' CT and programming skills. Given that robotic learning has the potential to significantly boost interest in programming, this approach can contribute to the increase of Science, Technology, Engineering, and Mathematics (STEM) graduates, a current national priority for many governments worldwide, including the United States [4], the UK [5] and Malaysia. Despite these efforts, Malaysia has not yet met its target ratio of 60:40 for students enrolling in STEM versus non-STEM programs [6].

STEM teachers require educational tools that are affordable, hands-on, conceptually engaging, syllabus-aligned, interactive, extendable, and suitable for extracurricular activities. While some schools have adopted available robotic kits, they face challenges such as a lack of syllabus-related modules and the need for more extendable resources to maximize the kits' use. Moreover, many schools are unable to use robotic kits due to funding constraints, limiting their ability to foster interest in STEM. To address these issues, our research has developed robot prototypes called AkalBot, designed with affordability and educational value in mind, selecting Arduino as the main component. The accompanying learning module includes essential knowledge in computational thinking, such as algorithms, to make robotics an accessible and effective tool for enhancing programming interest and supporting STEM education in Malaysia. However, there remains a notable gap in the literature concerning the comprehensive assessment of how robotics learning experiences influence students' programming interest. This study seeks to address this gap by employing structural equation modeling (SEM) to analyze the intricate relationships between programming interest and robotics learning experiences, drawing on Kolb's experiential learning model as a theoretical framework.

Kolb's experiential learning theory provides a theoretical framework for understanding how students acquire and internalize knowledge through concrete experiences, reflective observation, abstract conceptualization, and active experimentation [7]. Applied to robotics education, this theory suggests that hands-on activities with robots offer students opportunities to engage in concrete experiences, reflect on their learning, conceptualize abstract programming concepts, and apply their knowledge in practical contexts [8]. This study aims to investigate the structural relationships between programming interest and robotics learning experiences. Specifically, it seeks to assess how student engagement, interaction, challenge, competency, and interest within the context of robotics education impact programming interest after using the robotic module based on Kolb's model and our robot, AkalBot. The remainder of this paper reviews related work (Section II), details

the research methodology, including the experimental design and data analysis techniques (Section III), presents the results of the structural model analysis (Section IV), discusses the findings (Section V), and offers conclusions (Section VI).

II. A Review of Related Work

The use of robotics as a tool to engage students with programming and technology concepts has been extensively studied, emphasizing its potential to promote critical thinking and creativity. For instance, LEGO Mindstorms has been shown to enhance creativity [9], while LEGO WeDo kits have been explored for their role in fostering CT. A study investigating the effects of LEGO® WeDo and the Scratch programming platform on CT skills, grit, and programming abilities among undergraduate educational science students revealed notable outcomes. Using a quasi-experimental design with a pretest-posttest approach, the six-week intervention involved 246 participants (aged 18–23, mean age 20.5 ± 3.37, with a balanced gender distribution). The findings demonstrated that participants using LEGO® WeDo experienced significant improvements in CT skills, exhibited higher levels of grit, and gained a deeper understanding of Internet of Things (IoT) project creation. This study underscores the educational advantages of tangible robotic tools over purely visual programming platforms [10].

Building on these findings, the development of a robotic module tailored for Malaysian students seeks to replicate these educational benefits by introducing a low-cost robotic prototype aligned with the Malaysian school curriculum. The objective is to leverage similar hands-on, tangible tools to actively engage students in STEM learning, fostering deeper understanding and sustaining their interest in pursuing STEM programs. To ensure its effectiveness, survey feedback from STEM teachers was utilized to identify the core requirements for the module, which include being engaging, curriculum-based, easy to understand, and cost-effective [11].

To address this challenge, a customizable module was developed using Arduino as the microcontroller and Google's Blockly as the visual editor, with potential for further enhancement. A study assessed Malaysian students' perceptions of their competency and interest in STEM after engaging with a STEM module and building a robotic prototype. Conducted at the National Science Centre, Malaysia, this activity aimed to address the under-enrollment in STEM programs. The module, based on Kolb's experiential learning theory, incorporated five key activities: watching videos, reading materials, assembling components, using Blockly for programming, and playing a robotic game. The primary goal was to boost STEM interest through robotics and educational games. Evaluated through qualitative and quantitative case studies with students aged 11 to 15, the results showed a positive response, with significant increases in students' interest in STEM, aligning with the Malaysia Education Blueprint 2013-2025 [12]

In recent years, robots and visual editors have gained significant attention for teaching programming and robotics. AelE: A Versatile Tool for Teaching Programming and Robotics Using Arduino, highlights the role of programming in developing problem-solving and abstract thinking skills. Arduino boards, popular for their open hardware design and educational resources, are commonly programmed through text-based environments like Arduino IDE or block-based tools such as mBlock and Scratch. However, these tools often face challenges, such as the need for specific syntax knowledge and limited sensor support. To address these, AelE was developed as a block-based tool designed to simplify programming for students. The tool has been successfully used in diverse educational settings, including secondary schools, adult education, and prison programs. Students across these contexts, regardless of prior knowledge, responded positively to AelE, which was found to effectively support various learning environments and project types, demonstrating its versatility and broad appeal [13].

Despite the growing body of research on robotics in education, there is still a significant gap in understanding how robotics learning experiences impact students' interest in programming. This study aims to fill this gap by utilizing SEM to explore the complex relationships between students' programming interest and their robotics learning experiences, with Kolb's experiential learning model serving as the theoretical foundation.

III. Materials and Methods

The methods to model the impact of robotics learning experience on programming interest using the structured equation modeling approach consists of six main steps. An explanation of each step is given below.

A. Step 1: Forming Variables to Model the Impact

In order to form variables to model the impact of learning experience, existing variables that have been used to analyze learning experiences have been investigated. Five variables have been used to model the impact of interaction, engagement and challenge towards interest and competency in the subject area [14]. They have designed hands-on activities for virtual computer laboratories based on Kolb's experiential learning cycle. The study in [15] have further used the variables to quantitatively analyzed for identifying the impact of the experiential activity. The details of the variables that been used to model the impact of using the educational robotic is given below:

- Interaction (ACT): This construct assesses the degree of collaboration among students during robotics exercises. Working in pairs, students engage in completing tasks, tackling new challenges, and jointly reflecting on their learning experiences.
- Engagement (ENG): This construct evaluates students' readiness and enthusiasm to participate in and complete robotics activities. High engagement is evident through active involvement, enthusiasm, and persistence, which are essential for deep and effective learning experiences in programming.
- Challenge (CHA): This construct gauges the perceived difficulty of the robotics activities from the students' perspective. By assessing the complexity and challenge level, this measure helps to understand how the tasks encourage cognitive development, problem-solving, and critical thinking skills.

- Competency (CMP): This construct focuses on the learning outcomes that students perceive they have achieved through robotics activities. Unlike interaction, engagement, and challenge, which evaluate the learning process, competency reflects the end results, indicating students' mastery of programming concepts and their confidence in applying these concepts.
- Interest (INT): This construct measures the increase in students' interest and curiosity in programming due to robotics activities. Like competency, this construct evaluates the outcomes of the learning experience, showing how effectively the activities have stimulated and maintained students' interest in programming.

These variables were integrated to form the research model as shown in Fig. 1. By integrating these variables into a cohesive framework, we can gain valuable insights into the multifaceted nature of learning experiences and their impact on students' academic outcomes. This framework provides a structured approach for examining the interplay between key factors that shape students' learning trajectories, laying the groundwork for subsequent analyses using structural equation modeling (SEM) techniques. Seven hypotheses were developed:

Hypothesis 1 (H1). Challenge is positively related to students' competency.

Hypothesis 2 (H2). Challenge is positively related to students' interest.

Hypothesis 3 (H3). Competency is positively related to students' interest.

Hypothesis 4 (H4). Engagement is positively related to students' competency.

Hypothesis 5 (H5). Engagement is positively related to students' interest.

Hypothesis 6 (H6). Interaction is positively related to students' competency.

Hypothesis 7 (H7). Interaction is positively related to students' interest.

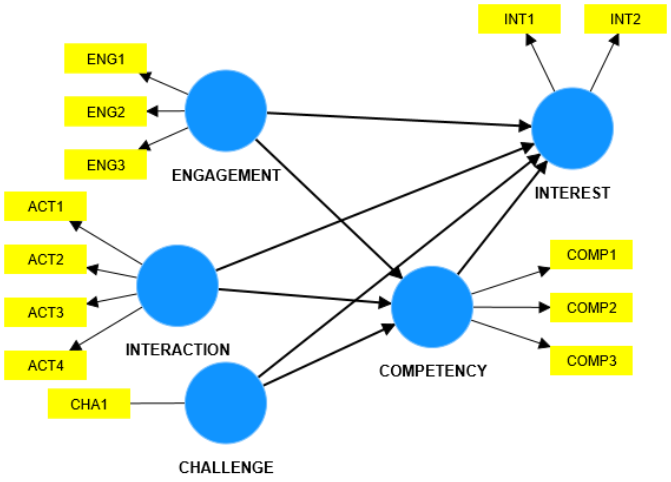

Fig. 1. Research model.

B. Step 2: Developing Robotic Module Based on the Selected Variables and Kolb's Learning Model

The working principle of AkalBot is based on the integration of three main components: modules, robot prototypes, and a blockly editor. The robotic kit leverages Kolb's experiential learning theory as the foundation for its modules, which also integrate computational skills like algorithms.

The first component is module design. The module design captures experience as a resource for learning and development [7] through interactive games using robot prototypes. The modules are structured according to the four phases of Kolb's learning theory:

1) Concrete Experience (CE): Students begin with hands-on exercises, such as programming robots, to gain practical experience.

2) Reflective Observation (RO): Students provide feedback on a series of tasks, reflecting on their experiences from the CE phase.

3) Abstract Conceptualization (AC): Students develop strategies to win specified games based on provided theoretical concepts.

4) Active Experimentation (AE): Students implement their strategies to achieve game objectives.

These phases are designed to promote deep learning and engagement by cycling through practical exercises, reflection, strategy formulation, and experimentation.

The second component is robot prototypes. AkalBot (Fig. 2) features low-cost robot prototypes designed with affordability and accessibility in mind, making the robotic kit an attractive option for schools and higher education institutions. The core component of these robots is the Arduino microcontroller board, known for its low cost, ease of use, and flexibility. Arduino can interact with a variety of components such as buttons, motors, LEDs, and GPS modules. The study in [16] highlights several advantages of using Arduino in educational robotics. One of the key strengths is the ability to load experimental scripts directly onto the board's memory, allowing the Arduino to operate independently without the need for continuous interfacing with computers or external software. This feature provides complete independence, portability, and accuracy in experiments. Additionally, Arduino benefits from a large community that supports its use by offering numerous hardware add-ons and hundreds of free scripts for various projects, making it an accessible and versatile tool for educational purposes. Arduino is particularly suitable for educational purposes due to the abundance of available resources, hardware add-ons, and free scripts for various project ideas.

The third key component of AkalBot is its utilization of a block-based editor, which is a visual programming tool developed by Google. Modified blocks within this platform form AkalBlok (Fig. 3), facilitating a drag-and-drop interface that enables students to program the robots without the need to delve into intricate programming languages. This visual approach aims to captivate primary and secondary students, enticing them to explore the realms of robotics and programming. Within the AkalBlok platform, students

encounter specific blocks tailored for programming Arduino-related components, neatly categorized into three main types: Arduino Parts, Arduino Sensor, and Arduino Motor.

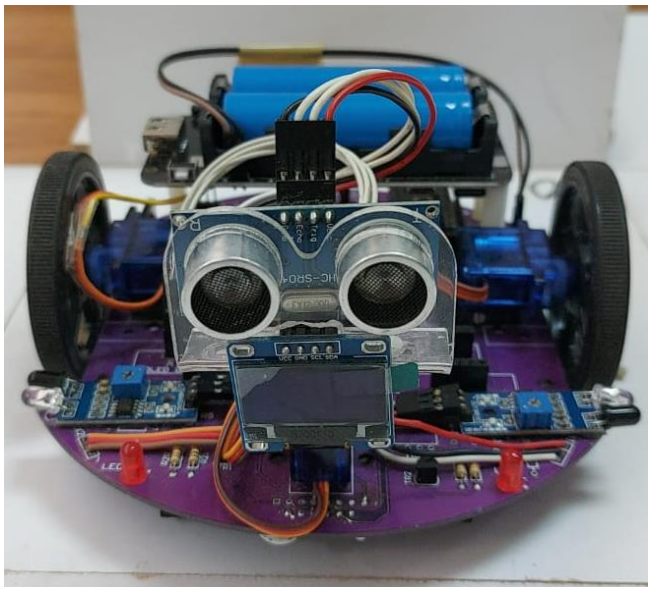

Fig. 2. A robotic prototype named AkalBot.

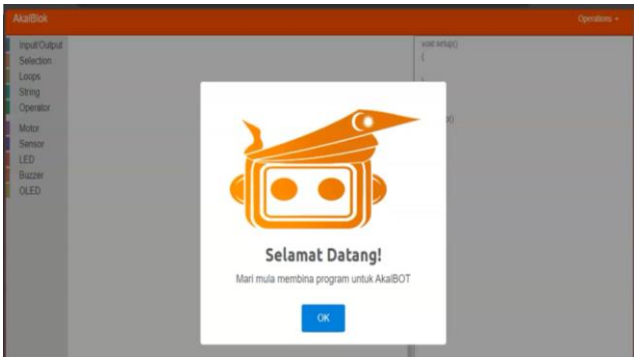

Fig. 3. A block-based editor named AkalBot.

AkalBot's overall design revolves around game-based activities, wherein students apply control over robot prototypes using the block-based editor to create programs. This innovative design framework embraces experiential learning theory, effectively harnessing hands-on experiences as a facilitator for learning and development. By integrating these elements, AkalBot emerges as a comprehensive and immersive educational tool, adept at augmenting students' programming skills and cultivating their interest in the subject matter.

C. Step 3: Setting Up an Experiment with Students

In this study, the population consisted of 76 primary and secondary school students who participated in an experiment designed to assess the impact of a robotics learning module on their interest in programming. The robotics module, developed based on Kolb's experiential learning model, guided the students through different programming development phases. Data were collected during the experiment through a questionnaire, which consisted of 12 questions focused on five key constructs: engagement, interaction, challenge, competency, and interest. These constructs were used as latent variables to form the structural model, which was analyzed using partial least squares structural equation modeling (PLS-SEM) through SmartPLS 4.0 software. The experiment consisted of five sessions, each lasting three hours, designed to evaluate the impact of robotics learning on students' programming interest and skills.

1) Session 1: Pre-Test and Introduction (20 minutes): Activity: Students answered pre-test questions to assess their initial knowledge of basic robotics and programming concepts. This session aimed to establish a baseline for their understanding and skills.

2) Session 2: Introduction to Robotic Kit and a Blok-based Editor (30 minutes): Activity: Students were introduced to the AkalBot robotic kit and the AkalBlok programming environment. This session included a detailed explanation of how to use the kit and the drag-and-drop interface of AkalBlok to program the robots.

3) Session 3: Hands-On Robotic Assembly and Initial Programming (60 minutes): Activity: Students engaged in the assembly of robot prototypes and performed initial programming exercises. This session followed the Concrete Experience (CE) phase of Kolb's learning theory, where students learned through hands-on activities.

4) Session 4: Reflective Observation and Strategy Planning (60 minutes): Activity: Based on their hands-on experiences, students reflected on their activities and provided feedback. This session corresponded to the Reflective Observation (RO) phase, where students analyzed their experiences and planned strategies for upcoming tasks.

5) Session 5: Implementation and Experimentation (60 minutes): Activity: Students implemented their strategies and engaged in further programming to accomplish specific tasks using the robots. This session combined the Abstract Conceptualization (AC) and Active Experimentation (AE) phases, encouraging students to apply theoretical concepts in practical scenarios.

D. Step 4: Collecting Data and Analyzing Model

The empirical data utilized in this study are considered primary as they were directly gathered through a survey conducted among students. To assess the effectiveness of the robotic educational experience, data collection encompassed a combination of quantitative and qualitative methodologies. The subsequent steps were followed:

1) Surveys and Questionnaires: Students filled out surveys and questionnaires to provide feedback on their learning experiences, engagement, and interest levels throughout the experiment.

2) Observation: Instructors observed student interactions with the robotic kit. The measurement model is foundational to structural equation modeling (SEM), offering a robust assessment of the reliability and validity of the constructs under investigation. In addition to assessing convergent validity through factor loadings, composite reliability (CR), and average variance extracted (AVE), discriminant validity is a

critical aspect that ensures the distinctiveness of the constructs [17].

1) Factor loading: Factor loading examines the strength of the relationship between observed variables and their corresponding latent constructs. High factor loadings (> 0.70) indicate that the observed variables effectively capture the underlying constructs [17].

2) Composite Reliability (CR): CR assesses the internal consistency of a set of indicators for each latent construct. CR values exceeding 0.70 indicate satisfactory reliability, implying that the indicators consistently measure the underlying construct [18].

3) Average Variance Extracted (AVE): AVE quantifies the proportion of variance captured by a construct's indicators relative to measurement error. AVE values > 0.50 indicate adequate convergent validity, suggesting that the observed variables collectively represent the latent construct effectively [19].

4) Discriminant validity (Heterotrait-monotrait ratio): Discriminant validity examines whether the constructs are empirically distinct from one another. The heterotrait-monotrait (HTMT) ratio compares the correlations between constructs (heterotrait correlations) with the average correlations within constructs (monotrait correlations). A threshold value of 0.90 is suggested for HTMT ratios to ensure discriminant validity [20]. It measures how much more strongly items within the same construct are related to each other compared to items across different constructs.

Analyzing the structural model is a crucial step in SEM using SmartPLS, as it helps to understand the relationships between constructs and validate the hypothesized paths. This step involves evaluating various metrics such as path coefficients (β), standard errors (SE), t-values, p-values, effect sizes (f^2), variance inflation factors (VIF), and predictive relevance (Q^2 Predict). The following provides a detailed explanation of each component within the context of SmartPLS:

1) Path Coefficients (β): Path coefficients represent the strength and direction of the relationships between constructs, ranging from -1 to +1. Positive values indicate positive relationships, while negative values indicate negative relationships. High absolute values indicate stronger relationships. For example, a path coefficient of 0.45 between robotics learning experience and programming interest suggests a moderate positive relationship [21].

2) Standard Error (SE): The standard error measures the precision of the estimated path coefficients, indicating how much the estimated coefficient would vary from the true population value. Smaller SE values indicate more precise estimates. For instance, an SE of 0.07 for a path coefficient of 0.45 suggests that the estimate is quite precise [22].

3) t-value: The t-value assesses the statistical significance of the path coefficients, calculated by dividing the path coefficient by its standard error ($t = \beta / SE$). A higher absolute t-value indicates stronger evidence against the null hypothesis. Typically, a t-value greater than 1.96 is considered significant at the 0.05 level. For example, a t-value of 6.43 indicates a highly significant relationship [23].

4) p-value: The p-value indicates the probability that the observed relationship is due to chance. A p-value less than 0.05 is typically considered statistically significant. For example, a p-value <0.001 suggests a very low probability that the relationship occurred by chance, thus confirming the significance of the path coefficient [17].

5) Effect Size (f^2): The f^2 effect size measures the impact of a specific exogenous variable on an endogenous variable, calculated based on the change in the R^2 value when the exogenous variable is included in the model. Effect size values are interpreted as follows:

a) Small effect: $f^2 = 0.02$

b) Medium effect: $f^2 = 0.15$

c) Large effect: $f^2 = 0.35$ For instance, an f^2 of 0.20 indicates a medium effect, suggesting that robotics learning experience has a moderate impact on programming interest [24].

6) Variance Inflation Factor (VIF): The VIF assesses multicollinearity among the exogenous constructs. High multicollinearity can inflate the standard errors and affect the reliability of the path coefficients. VIF values greater than 5 indicate significant multicollinearity. A VIF of 1.15 suggests low multicollinearity, indicating that the estimates are reliable [17].

7) Explained Variance (R^2): R^2 quantifies the proportion of variability in the dependent variable explained by the independent variables in the model. A high R^2 value indicates that a large portion of the variability in the dependent variable is captured by the predictors, suggesting a robust model fit. Conversely, a low R^2 suggests that the predictors fail to explain much variability in the dependent variable. According to [24] R^2 values can be categorized as follows:

a) Weak: R^2 values between 0.01 and 0.25

b) Moderate: R^2 values between 0.26 and 0.49

c) High: R^2 values of 0.50 and above

8) Predictive Relevance (Q^2 Predict): PLS Predict assesses the model's predictive power by generating predictions for new data and comparing them with actual observed values. The key metrics include:

a) Q^2 Predict: Indicates the predictive relevance of the model for a specific endogenous construct. A Q^2 Predict value greater than 0 indicates predictive relevance [25].

b) RMSE (Root Mean Squared Error): Evaluates the accuracy of the predictions. Lower RMSE values indicate better predictive performance.

c) MAE (Mean Absolute Error): Measures the average magnitude of the prediction errors. Lower MAE values indicate more accurate predictions.

9) Decision based on Statistical Analysis: The decision indicates whether the hypothesis is supported. If the p-value is less than 0.05 and the path coefficient (β) is in the hypothesized

direction, the hypothesis is typically considered supported. For instance, if β is 0.45, t-value is 6.43, and p-value <0.001, the hypothesis that robotics learning experience positively affects programming interest is supported [23].

IV. Results

A. Measurement Model

The measurement model was evaluated to determine the reliability and validity of the constructs used in this study. Table I presents the factor loadings, composite reliability (CR), and average variance extracted (AVE) for the constructs: Engagement (ENG), Interaction (ACT), Challenge (CHA), Competency (COMP), and Interest (INT).

TABLE I. Factor Loadings, Composite Reliability (CR), and Average Variance Extracted (AVE) for Engagement, Interaction, Challenge, Competency, and Interest Constructs

Construct	Items	Factor Loading	CR	AVE
ENG	ENG1The activity was enjoyable. ENG2 The activity was interesting.	0.916 0.905	0.795	0.829
ACT	ACT1 Asking questions to other students. ACT2 Observing other students. ACT3 Discussions with other students. ACT4 Interacting with other students.	0.715 0.742 0.819 0.741	0.751	0.571
CHA	CHA 1 The activity was challenging.	1.000		
COMP	COMP1 I felt that I learned important skills COMP1 I felt a sense of accomplishment after completing the activity. COMP1 The activity improved my competency in the subject area.	0.798 0.807 0.824	0.738	0.656
INT	INT1 The activity increased my curiosity and interest in this area. INT2 The activity encouraged me to learn more about this topic.	0.901 0.858	0.724	0.774

The Engagement construct was assessed through two items: "The activity was enjoyable" (ENG1) and "The activity was interesting" (ENG2), achieving high factor loadings of 0.916 and 0.905, respectively. With a composite reliability (CR) of 0.795 and an average variance extracted (AVE) of 0.829, these results demonstrate strong internal consistency and convergent validity, confirming reliable measurement of Engagement in this study.

The Interaction construct, measured by four items with factor loadings ranging from 0.715 to 0.819, yielded a CR of 0.751 and an AVE of 0.571. While these figures are acceptable, the lower factor loadings suggest the need for item refinement to better capture the essence of interaction in robotics learning.

The Challenge construct was represented by a single item, "The activity was challenging" (CHA1), which showed a perfect factor loading of 1.000. However, reliance on a single item may not fully encompass the multifaceted nature of challenges encountered by students.

For the Competency construct, three items achieved factor loadings between 0.798 and 0.824, resulting in a CR of 0.738 and an AVE of 0.656. These values indicate satisfactory reliability and validity, effectively reflecting students' perceived learning outcomes from robotics activities.

Lastly, the Interest construct comprised two items: "The activity increased my curiosity and interest" (INT1) and "The activity encouraged me to learn more" (INT2), with factor loadings of 0.901 and 0.858, respectively. The CR was 0.724 and the AVE 0.774, confirming robust internal consistency and good convergent validity, indicating effective measurement of increased interest and curiosity in programming.

In summary, while Engagement and Interest exhibited strong psychometric properties, some constructs, particularly Interaction, may benefit from item refinement. Overall, these findings affirm the model's effectiveness in capturing critical dimensions of the robotics learning experience and its influence on programming interest.

B. Structural Model

The structural model, as shown in Fig. 4, was assessed to test the hypothesized relationships among the constructs. Table II presents the results of the hypothesis testing, and Table III displays the R^2 values for the endogenous latent constructs.

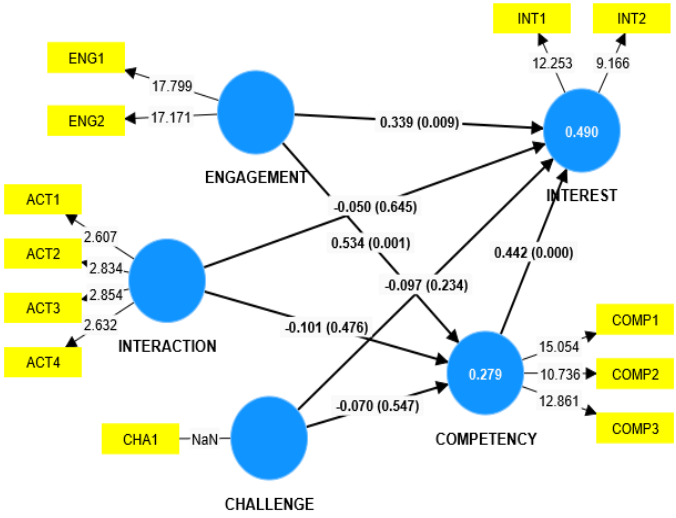

Fig. 4. Structural model analysis using SmartPLS.

TABLE II. HYPOTHESIS TESTING- RESULTS OF STRUCTURAL MODEL (SIGNIFICANT AT $P^{***} < 0.001$, $P^{**} < 0.01$, $P^{*} < 0.05$)

Hypothesis	β,	*t*-Value	*p*-Value	f^2	*VIF*	Decision
H1	-0.070	0.603	0.547	0.006 small	1.059	Not Supported
H2	-0.097	1.189	0.234	0.017 small	1.066	Not Supported
H3	0.442	4.226	0.000	0.276 medium	1.386	Supported***
H4	0.534	3.223	0.001	0.331 medium	1.194	Supported**
H5	0.339	2.602	0.009	0.142 small	1.588	Supported**
H6	-0.101	0.712	0.476	0.012 small	1.151	Not Supported
H7	-0.050	0.461	0.645	0.004 small	1.165	Not Supported

TABLE III. THE R^2 VALUE FOR THE ENDOGENOUS LATENT CONSTRUCTS

Constructs	R^2	Results
Competency	0.279	Weak
Interest	0.490	Moderate

Following this assessment, the study aimed to explore the structural relationships between programming interest and learning experiences within the robotics module using a structural equation modeling (SEM) approach. The analysis indicated that the challenge component did not significantly impact students' perceived competency (H1: $\beta = -0.070$, $p = 0.547$) or their interest in programming (H2: $\beta = -0.097$, $p = 0.234$). This finding underscores a misalignment between the difficulty of tasks and the students' readiness, suggesting that merely increasing challenge levels may not lead to improved learning outcomes unless accompanied by appropriate scaffolding.

Conversely, the hypothesis that competency positively impacts interest (H3: $\beta = 0.442$, $p < 0.001$) was strongly supported, confirming that students who perceive themselves as competent in programming exhibit a higher level of interest.

Engagement also emerged as a significant predictor of both competency (H4: $\beta = 0.534$, $p < 0.01$) and interest (H5: $\beta = 0.339$, $p < 0.01$). These results underscore the dual role of engagement in educational settings, as it not only enhances learning outcomes but also fosters a deeper interest in programming. Engaging and enjoyable activities can captivate students' attention, encouraging active participation and sustained motivation.

However, interaction did not significantly affect competency (H6: $\beta = -0.101$, $p = 0.476$) or interest (H7: $\beta = -0.050$, $p = 0.645$), suggesting that the quality of peer interactions may need enhancement to effectively contribute to learning outcomes. Effective scaffolding and support during collaborative tasks are crucial to maximizing the potential benefits of interaction.

The model demonstrated moderate predictive power, with R^2 values of 0.490 for interest and 0.279 for competency, indicating that it explains a reasonable portion of variance in both constructs.

V. DISCUSSION

The hypothesis testing revealed that engagement and competency had a significant positive effect on students' interest in programming, while the constructs of interaction and challenge showed lower influence. The findings suggest that the developed model has moderate predictive power, indicating that students' experiences with robotics can moderately predict their interest in programming. Overall, this study provides valuable insights into how engagement and competency influence students' interest in programming through robotics. The results suggest that creating engaging learning experiences, aligned with students' skill levels, is essential for fostering interest in programming and preparing students for the demands of the Fourth Industrial Revolution.

In terms of active involvement, students were deeply engaged, especially when the robot successfully moved toward a slipper. This engagement was driven by the necessity to program the robot, as it would not move without the students' input. For example, Fig. 5 depicts a group of students discussing the development of a program during the coding phase.

Fig. 5. A group of students engaged in discussion while developing a program during the coding phase.

Regarding enthusiasm, students were excited to tackle the tasks, primarily because the activity required problem-solving. The problems were presented in the form of a game, specifically making the robot knock over a slipper. This game was inspired by a traditional Malaysian game in which a player uses a slipper to topple a stack of slippers. By adapting the game to involve robots, students had the opportunity to explore programming while also appreciating a traditional Malaysian concept. This fusion of elements likely contributed to the increased enthusiasm among the students. Feedback from students supports this:

"I was very happy to use robots in this programming learning session because I could understand the subject more deeply."

"I was excited and curious to code for this robot."

Persistence was another notable aspect, with students showing determination to complete the tasks despite challenges. Some groups encountered difficulties in making the robot move as intended, requiring them to repeatedly adjust program values, such as the delay. The robot's movement varied depending on factors like battery power, tire condition, and servo motor settings. Through a series of tests, students eventually understood the relationship between the program and the robot's output. They also applied computational thinking techniques,

such as pattern recognition. Feedback reflecting this persistence includes:

"It was fun yet tiring because of the repeated errors, but we got to learn something new in the end."

"I felt skeptical at first about whether we would manage to finish, but as I worked with my group, I became confident we could succeed."

Beyond engagement, the Interaction construct also demonstrated satisfactory factor loadings, indicating that students actively interacted with their peers during the activity. This was evident from responses like:

"I feel happy because I got to discuss different ideas and solutions with other students."

"I enjoyed this programming learning. Robots and friends made the activities fun."

"I felt confused and worried that I wouldn't be able to contribute to my team, but as the instructor helped us out, I felt more connected."

The structural model results reveal that engagement and perceived competency play a crucial role in fostering students' interest in programming and robotics. Significant relationships were found between engagement and competency (H4) and between engagement and interest (H5). These findings suggest that when students are actively engaged in learning activities, they are more likely to feel competent, which in turn increases their interest in the subject. Additionally, the significant link between competency and interest (H3) indicates that as students perceive an improvement in their skills, their curiosity and eagerness to learn more also grow, reinforcing the positive cycle between competence and interest.

However, the study also found that interaction did not have a significant impact on either competency or interest. Despite the common belief that peer discussions and collaborative learning enhance educational outcomes, the results indicate that these interactions did not translate into measurable improvements in students' competency. Although students enjoyed discussing ideas and solutions with their peers, as reflected in qualitative feedback, these exchanges may not have been sufficiently focused or impactful to deepen their engagement with the subject matter. To enhance the effectiveness of interactions in future implementations, it may be necessary to structure these activities more intentionally, ensuring that they promote meaningful cognitive engagement and skill development rather than just social interaction.

Conversely, the hypotheses examining the impact of challenge on both competency (H1) and interest (H2) were not supported. This suggests that the level of difficulty presented by the activities did not significantly contribute to students' perceptions of their skills or their interest in the subject. While challenges are necessary for learning, they must be carefully balanced to avoid discouragement. Student responses, such as the view that programming was complicated and difficult or that the activity was interesting but challenging, underscore the importance of making challenges approachable. Maintaining this balance is crucial for sustaining engagement and fostering positive learning outcomes. These findings highlight the need for well-designed, appropriately challenging activities to enhance students' perceived competency and sustain their interest in STEM education.

The study's findings highlight the importance of carefully structuring interactions and challenges to enhance competency and interest effectively. Without adequate support, these elements may fail to produce the desired outcomes. Creating meaningful learning experiences in programming requires thoughtful technology integration, including appropriate applications, media, systems, and approaches. Misaligned or improper use of technology can hinder students' confidence and problem-solving skills. A well-designed framework that incorporates contextual and meaningful learning objectives is essential for optimizing technology integration [26]. Furthermore, technologies such as augmented reality (AR) can support STEM-based activities [27] and be seamlessly integrated into such a framework.

Despite these insights, the study has limitations. The relatively lower factor loadings for the Interaction construct indicate that the measurement of this construct could benefit from refinement. Additionally, the reliance on a single item for the Challenge construct may not fully capture the multifaceted nature of the challenge experienced by students. Future research should address these limitations by developing more comprehensive measures for these constructs and exploring their impact in different educational contexts

VI. Conclusions

In conclusion, this study highlights the critical factors influencing students' interest in programming through robotics education. To enhance engagement, educators must focus on creating interactive and enjoyable learning experiences that actively involve students. Incorporating hands-on robotics activities can significantly stimulate curiosity and motivation, leading to improved learning outcomes. Additionally, fostering students' perceived competency in programming is essential; scaffolded learning activities and continuous feedback should be implemented to reinforce their skills and confidence. While interaction and challenge play vital roles in the learning process, they must be carefully structured with adequate support to avoid overwhelming students. Thus, educators should ensure that challenges are appropriate to students' skill levels, enabling meaningful interactions that enhance learning without causing disengagement.

A significant limitation of this study was the students' tendency to hasten through the reflection phase, which limited opportunities for deeper learning. To address this, future iterations of the module could include additional activity cycles with structured reflection phases, allowing students to analyze algorithms and their outcomes to better understand cause-and-effect relationships. Incorporating guided reflection tasks, supported by AI tools such as ChatGPT, could further enhance this process by fostering thoughtful analysis and encouraging meaningful insights.

As advancements in AI continue to reshape education, future modules could also introduce a dedicated phase for students to explore AI concepts and applications. While this presents an exciting opportunity to align with emerging technological

trends, it also raises challenges related to resource allocation and the need for specialized teacher training. By addressing these aspects, robotics education can adopt a forward-looking approach, equipping students with essential skills for navigating and contributing to the evolving technological landscape, while maintaining a structured and engaging learning environment.

Lampung Batik Classification Using AlexNet, EfficientNet, LeNet and MobileNet Architecture

Rico Andrian, Rahman Taufik, Didik Kurniawan, Abbie Syeh Nahri, Hans Christian Herwanto
Department of Computer Science, University of Lampung, Bandar Lampung, Indonesia

***Abstract*—This study explores the application of image recognition technology based on Convolutional Neural Network (CNN) to classify Lampung batik motifs. Four CNN architectures are employed, namely AlexNet, EfficientNet, LeNet, and MobileNet. The dataset consist of ten motif classes, including Siger Ratu Agung, Sembagi, Jung Agung, Kembang Cengkih, Granitan, Abstract, Sinaran, Tambal, Kambil Sicukil, and Sekar Jagat. It comprises a total of 1000 images of Lampung Batik motifs, which were enhanced using preprocessing techniques such as rotation, shifting, brightness adjustment, and zooming. The classification results show that AlexNet achieves an accuracy of 95.33%, EfficientNet achieves 98.00%, LeNet achieves 99.33%, and MobileNet achieves 98.00%. The best accuracy result was achieved by the LeNet architecture, attributed to its suitability for small datasets. While some classification errors occurred due to similarities in patterns and variations in image positions, employing more advanced methods to better distinguish between similar motifs could address these challenges. This study highlights the effectiveness of CNN architectures in supporting the recognition of Lampung Batik motifs, contributing to the understanding and preservation of Indonesia's cultural heritage.**

Keywords*—*Lampung Batik; image classification; convolutionl neural network; AlexNet; EfficientNet; LeNet; MobileNet

I. INTRODUCTION

Batik is a fundamental part of Indonesia's cultural identity and has been officially recognized by UNESCO as part of the nation's rich cultural heritage. This traditional art form is created through a unique process involving the application of wax and canting to produce intricate patterns on cloth, resulting in works of art with high aesthetic and cultural value [1]. Each region in Indonesia presents its cultural philosophy through different batik motifs, including Lampung Batik. Lampung Batik motifs include images of people, animals, sea creatures, buffaloes, elephants, ships, houses, trees of life and supporting elements such as coffee leaves, cloves, pepper and betel leaves, representing Lampung's cultural identity [2].

However, despite its cultural significance, recognizing Lampung Batik motifs based on their colour, pattern, and texture remains challenging for the human eye, especially when motifs share similar visual elements. This difficulty underscores the importance of employing technology to simplify identification, enabling broader public access to knowledge about Lampung Batik motifs and aiding in their preservation.

In recent years, advancements in computer vision, particularly Convolutional Neural Networks (CNN), have offered robust solutions for image classification tasks. CNN use artificial neural networks to process and analyze images, producing significant results in digital image recognition [3][4]. Numerous CNN architectures have been developed, such as AlexNet, EfficientNet, LeNet, and MobileNet, each with unique advantages [5]. AlexNet is a breakthrough that has combined ConvsNet and dropout regularization techniques [6]. Another architecture is EfficientNet, a CNN model developed by Google in 2019, specifically for object recognition or image classification. EfficientNet currently has eight models, from EfficientNet-B0 to EfficientNet-B7, with increasingly higher levels of accuracy [7] [8]. LeNet is a convolutional neural network (CNN) architecture initially developed for image processing tasks. The architecture comprises six layers: three convolutional layers, two pooling layers, and one fully connected layer [9]. MobileNet uses a technique called separable convolution to reduce the number of model parameters [10].

Previous studies on regional batik image recognition have applied machine learning and deep learning techniques to identify distinct motifs from various regions in Indonesia. One approach used the AlexNet architecture to classify Lamongan batik motifs, achieving an accuracy of 98% on a dataset of 790 images divided into three categories [11]. The EfficientNet-B2 architecture, fine-tuned for optimal performance, was applied to classify Papuan batik motifs [12]. The dataset consisted of 213 images divided into four classes: Raja Ampat, Cendrawasih, Asmat, and Tifa Honai. This approach achieved an accuracy of 72%. Research on Lampung Batik classification has also explored machine learning approaches. One study employed the K-Nearest Neighbor (KNN) algorithm combined with the Gray Level Co-occurrence Matrix (GLCM) for feature extraction [13]. Using a dataset of 100 images divided into four categories with 25 images per class, the method achieved the highest accuracy of 97.96% with an orientation angle of 135° and k = 7. Another study expanded the dataset by including non-Lampung motifs, specifically Parang Kusumo and Parang Rusak, and utilized a backpropagation artificial neural network, achieving an accuracy of 92% [14].

However, existing studies on Lampung Batik motifs are limited by small and less diverse datasets and a need for more exploration into more advanced architectures or methods. This study explores the application of image recognition techniques using CNN architectures, including AlexNet, EfficientNet, LeNet, and MobileNet, for classifying Lampung Batik motifs. The dataset includes ten motif classes: Siger Ratu Agung, Sembagi, Jung Agung, Kembang Cengkih, Granitan, Abstract, Sinaran, Tambal, Kambil Sicukil, and Sekar Jagat. The study aims to investigate the potential of CNN-based image recognition in identifying Lampung Batik motifs, contributing

to the understanding and preserving Indonesia's cultural heritage.

II. Research Method

This study uses the AlexNet, EfficientNet-B4, LeNet, and MobileNet architectures to classify Lampung Batik images with a dataset generated through augmentation techniques. The research process is detailed in Fig. 1.

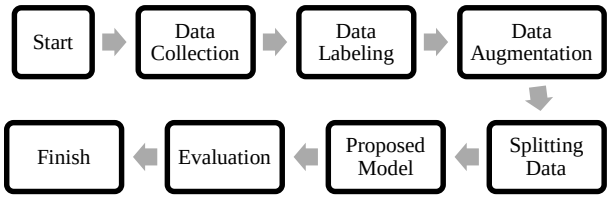

Fig. 1. Research method.

A. Dataset Collection

The dataset used is 1000 images of Lampung Batik motifs with ten classes. Images for each class are separated and saved in a folder named according to each class. The machine will then read the dataset at the beginning of the process, the images of Lampung Batik motifs, and the class names in each folder.

B. Data Labeling

Data labelling in a dataset is the process of adding information or labels to each example of data. This labelling functions to identify or categorize data so that machine learning or deep learning models can understand and process information more effectively. Labelling data in a dataset can involve different tasks, depending on the data analysis goals to be achieved [15].

C. Data Augmentation

This study employs data augmentation techniques such as rotation, shifting [16], and zooming, with the image size adjusted to 224 x 224 pixels. [17]. These augmentation techniques were selected to enhance dataset diversity by generating new variations of the existing dataset and altering objects' position, scale, and orientation [18].

D. Split Data

Data division is carried out by dividing the data into three primary subsets, namely training data, validation data, and test data. Training data is needed as the primary material for training data [19]. The training data itself takes up about 70% of the entire image. Data validation uses data equal to 15% of the whole picture. Test data is used to test a model's performance and success rate. The test data equals 15% of the entire image [20].

E. AlexNet, EfficientNet, LeNet, and MobileNet Architecture Training

The training model uses four architectures, namely AlexNet, EfficientNet, LeNet, and MobileNet, with a dataset of 100 images for each type of Lampung batik motif. Model training using hyperparameters such as epoch, batch size, and learning rate. The hyperparameter values used are in Table I.

TABLE I. Hyperparameters

Hyperparameter	AlexNet	EfficientNet	LeNet	MobileNet
Epoch	10	10	20	20
Batch-size	8	8	32	32
Optimizer	Adam	Adam	Adam	Adam
Learning-rate	0.0001	0.0001	0,001	0,001

Table I contains the hyperparameter values applied in this research. The hyperparameters in this study were determined through experimentation using various advanced callback libraries, including ReduceLROnPlateau and EarlyStopping [21]. ReduceLROnPlateau is a technique that reduces the learning rate when there is a stagnation or slowdown in performance improvement during the training process [22].

F. Evaluation

Performance evaluation in this study is a crucial stage to assess the effectiveness and accuracy of the developed model or algorithm [23]. This process evaluates how effectively the model can accurately predict unseen test data. Metrics such as F1-score, precision, accuracy, and recall are used to measure its performance [24].

III. Result and Discussion

This section presents the results and analysis of Lampung Batik image classification using CNN and explains the evaluation and implementation of the classification process. This section reviews the model's accuracy and evaluation metrics for Lampung Batik image recognition.

A. Dataset Collection

The dataset used in this research consists of 10 classes, each containing 100 images. The batik motifs can be seen in Fig. 2, and the diversity of each motif can be seen in Fig. 3.

B. Dataset Augmentation

The original dataset, consisting of 50 images per class stored in Google Drive, was expanded through augmentation techniques, including rotation, shifting, brightness adjustment, and zooming. These augmentations were applied with specific parameters: a 100° rotation, a 0.1 shift, brightness ranging from 0.05 to 2.0, and a 20% zoom. As a result, the dataset increased to 100 images per class. The final number of images for each class after augmentation is presented in Table II.

Fig. 2. Lampung Batik motifs.

Fig. 3. Lampung Batik motifs diversity.

TABLE II. DATASET AUGMENTATION LAMPUNG BATIK

Name Class	Amout Dataset
Batik Sembagi	100
Batik Granitan	100
Batik Jung Agung	100
Batik Sekar Jagat	100
Batik Siger Ratu Agung	100
Batik Kambil Sicukil	100
Batik Kembang Cengkih	100
Batik Sinaran	100
Batik Tambal	100
Batik Abstrak	100

C. AlexNet Achitecture Model

The AlexNet architectural model has 11 layers, consisting of five convolution layers, three max-pooling layers, two fully connected layers, and one output layer [25]. AlexNet is a CNN architecture that emphasizes the depth of its model, with training parameters reaching 70 million [26]. The dataset is fed to the first layer and read by the model. Multiple image samples are processed in a convolutional layer. The convolution layer functions to retrieve and help the model understand the characteristics of Lampung Batik motifs by using filters and the ReLu activation function. The filters in the convolution layer are matrix arrays that help adjust the image pixel values to fit the model. The ReLU activation function converts negative pixel values to zero while leaving positive pixel values unchanged. The pooling layer in this model is tasked with extracting essential features from the previous layer (convolution layer) [27]. AlexNet uses max-pooling as the pooling layer type. The fully connected layer in this model connects one feature to another of the Lampung Batik motif image. The connected features will be arranged to form a pattern that matches the arrangement of the features. Subsequently, the resulting output will be processed using softmax activation to determine the prediction of the image to one of the ten classes of Lampung Batik motifs.

D. EfficientNet Architecture Model

The EfficientNet-B4 architecture has a different type and number of layers than AlexNet, with only about 17 million parameters. The layers in EfficientNet-B4 consist of MBConv, an advancement of the layers used in the MobileNet architecture. The EfficientNet-B4 architecture consists of 10 blocks forming its primary structure, which includes fully connected, where this block is responsible for extracting abstract features in images [28]. The output from the previous block process will be processed and added with average pooling and flattening, which then results in a one-dimensional array or allows the model to recognize objects and patterns so that classification of Lampung Batik images is obtained in the form of classes of Lampung Batik motifs.

E. LeNet Architecture Model

LeNet-5 is a CNN-based multilayer network that represents an advancement over earlier versions of LeNet. It features additional layers and more adjustable parameters compared to its predecessors, enhancing its capacity for feature extraction and learning [29]. LeNet-5 has six layers: the input layer that receives the image, two convolutional layers for extracting features in the image, two pooling or subsampling layers for reducing image dimensions by half, and fully-connected layers. LeNet-5 is often used in more complex pattern recognition, such as facial or object recognition.

F. MobileNet Architecture Model

MobileNet Architecture is designed to provide high performance with limited power sources [30]. This architecture uses Depthwise Separable Convolution to reduce the parameters and calculations required to train and run the model. MobileNet can provide comparable or even more performance in some tasks with small model sizes and slight complexity. MobileNet architecture comprises an input layer, a standard convolutional layer, depthwise separable convolutional layers, a fully connected layer, and an output layer.

G. Model Evaluation

Evaluation of the AlexNet, EfficientNet, LeNet, and MobileNet architectural models to classify Lampung Batik images using precision, recall, accuracy and F1-score values.

Table III presents the precision, recall, and f1-score values for the AlexNet architecture. Each class has an excellent precision value, namely reaching 100%, except for the Kembang Cengkih, Batik Tambal, Batik Jung Agung, and Batik Kambil Sicukil classes; the Kembang Cengkih Batik class has the lowest precision value, namely 62.00%. The recall value reached 100% in each class, except for the Kembang Cengkih Batik, Garnitan Batik and Sekar Jagat Batik classes. The Kembang Cengkih Batik class has the lowest recall value, 62.00%.

Table IV presents the EfficientNet performance, where all batik classes achieved a precision score of 100%, except for the Batik Kambil Sicukil and Batik Jung Agung classes. The Jung Agung Batik class has the lowest precision value, 80.00%. The Kambil Sicukil Batik class has the lowest recall value, 93.00%. The Kambil Sicukil Batik class has a precision value of 92.86%. This was caused by 1 FP value occurring in the Kambil Sicukil Batik class, which should have been included in the Jung Agung Batik class. The model predicts incorrectly because there are similarities in the Jung motif pattern found in Batik Kambil Sicukil and Batik Jung Agung.

TABLE III. CONFUSION MATRIX ALEXNET ARCHITECTURE

Batik Motif Class	Results Model		
	Precision	Recall	F1-score
Batik Sembagi	100%	100%	100%
Batik Siger Ratu Agung	100%	100%	100%
Batik Granitan	100%	96.00%	98.00%
Batik Kambil Sicukil	94.00%	100%	97.00%
Batik Tambal	82.00%	100%	90.00%
Batik Sinaran	100%	100%	100%
Batik Jung Agung	93.00%	100%	97.00%
Batik Kembang Cengkih	62.00%	62.00%	62.00%
Batik Abstrak	100%	100%	100%
Batik Sekar Jagat	100%	80.00%	89.00%
Accuracy		95.33%	
Error		4.67%	

TABLE IV. CONFUSION MATRIX EFFICIENTNET ARCHITECTURE

Batik Motif Class	Results Model		
	Precision	Recall	F1-score
Batik Sembagi	100%	100%	100%
Batik Siger Ratu Agung	100%	100%	100%
Batik Granitan	100%	94.74%	97.30%
Batik Kambil Sicukil	92.86%	93.00%	92.93%
Batik Tambal	100%	100%	100%
Batik Sinaran	100%	100%	100%
Batik Jung Agung	80.00%	100%	88.89%
Batik Kembang Cengkih	100%	93.75%	96.67%
Batik Abstrak	100%	100%	100%
Batik Sekar Jagat	100%	80.00%	89.00%
Accuracy		98.00%	
Error		2.00%	

TABLE V. CONFUSION MATRIX LENET ARCHITECTURE

Batik Motif Class	Results Model		
	Precision	Recall	F1-score
Batik Sembagi	100%	100%	100%
Batik Siger Ratu Agung	100%	100%	100%
Batik Granitan	100%	100%	100%
Batik Kambil Sicukil	100%	100%	100%
Batik Tambal	100%	100%	100%
Batik Sinaran	100%	100%	100%
Batik Jung Agung	94.00%	100%	97.00%
Batik Kembang Cengkih	100%	100%	100%
Batik Abstrak	100%	100%	100%
Batik Sekar Jagat	100%	93.00%	97.00%
Accuracy		99.33%	
Error		0.67%	

Table V presents the LeNet performance, where Batik Jung Agung has the lowest precision value of 94.00%, and the other classes achieve a precision value of 100%. The recall value for the Batik Sekar Jagat class has the lowest recall value, 93.00%, while the other classes get a recall value of 100%.

TABLE VI. CONFUSION MATRIX MOBILENET ARCHITECTURE

Batik Motif Class	Results Model		
	Precision	Recall	F1-score
Batik Sembagi	100%	100%	100%
Batik Siger Ratu Agung	100%	100%	100%
Batik Granitan	100%	100%	100%
Batik Kambil Sicukil	100%	100%	100%
Batik Tambal	100%	100%	100%
Batik Sinaran	100%	94.00%	97.00%
Batik Jung Agung	89.00%	100%	94.00%
Batik Kembang Cengkih	100%	100%	100%
Batik Abstrak	96.00%	92.00%	94.00%
Batik Sekar Jagat	100%	100%	100%
Accuracy		98.00%	
Error		2.00%	

Table VI presents the MobileNet performance, where Batik Abstract gets a precision value of 96.00%, and Batik Jung Agung gets the lowest precision value of 89.00%. In comparison, the other classes get a precision value of 100%. For the recall value, the Batik Sinaran class gets 94.00%. Batik Abstract records the lowest recall value of 92.00%, except for Batik Sinaran and Batik Abstract, all classes get a recall value of 100%.

H. Performance Comparison Between Architectures

The differences among the four architectures can be seen in Table VII. AlexNet is an 11-layer architecture with 70 million parameters for processing complex features. EfficientNet, on the other hand, consists of 10 blocks that form its primary structure, with a total of 17 million parameters to ensure efficient computation. LeNet comprises 6 layers, including an input layer for receiving images, two convolutional layers for extracting features, two pooling layers for reducing image dimensions, and fully connected layers for classification. MobileNet includes input layers, convolutional layers, depth-separable convolutional layers, fully connected layers, and output layers to support lightweight computations. MobileNetV1 contains 28 layers, incorporating depth-separable convolutions, whereas MobileNetV2 improves upon this with 53 layers, introducing inverse residuals and linear bottlenecks to enhance efficiency and performance on mobile and embedded devices.

In addition, Table VII presents an accurate comparison between the four architectures. LeNet achieves the highest accuracy for Lampung Batik classification by effectively extracting essential features through convolution and pooling layers, which preserve the spatial information crucial for image recognition. In previous Lampung Batik studies, LeNet outperforms KNN and Backpropagation due to its efficiency in recognizing patterns and resistance to overfitting. Unlike KNN,

which only measures distances in feature space, and Backpropagation, which flattens images and loses spatial information, LeNet delivers superior performance for image classification tasks. Therefore, this study addresses the limitations of smaller and less diverse datasets in previous research by exploring four CNN architectures and employing augmentation techniques to enhance dataset quantity and accuracy.

TABLE VII. RESULT COMPARISON BETWEEN ARCHITECTURES

Architecture	Layer	Parameters	Accuracy
AlexNet	11	70m	95.33%
EfficientNet	10	17m	98.00%
LeNet	6	60k	99.33%
MobileNet	53	3.4m	98.00%

IV. CONCLUSION

The study concludes that the AlexNet, EfficientNet, LeNet, and MobileNet architectures effectively classify ten Lampung Batik motif classes, including Siger Ratu Agung, Sembagi, Jung Agung, Kembang Cengkih, Granitan, Abstract, Sinaran, Tambal, Kambil Sicukil, and Sekar Jagat. The accuracy achieved by AlexNet is 95.33%, EfficientNet-B4 is 98.00%, MobileNet is 98.00%, and LeNet achieves the highest accuracy at 99.33%. The dataset was enhanced using augmentation techniques, including rotation, shifting, brightness adjustment, and zooming, to generate 1000 images to train and evaluate the models. However, the study is limited by the similarity of specific Lampung Batik motifs, occasionally leading to misclassification. Future research could leverage advanced architectures and methods to differentiate motifs with similar patterns better, further enhancing classification accuracy.

ACKNOWLEDGMENT

Experiments in this study were conducted using NVIDIA Tesla K80 and Tesla K20, facilitated by the Department of Computer Science, University of Lampung.

Optimization of DL Technology for Auxiliary Painting System Construction Based on FST Algorithm

Pengpeng Xu*, Guo Chen
Engineering Training Center, Shandong Huayu University of Technology, Ezhou, 253000, China

***Abstract*—The continuous development of computers has brought about the emergence of many image processing software, but these software have relatively limited functions and cannot learn and create works according to the prescribed style. To make it easier for ordinary people to create artistic style paintings, this study proposes the construction of an auxiliary painting system based on finite state transducer algorithm-optimized deep learning technology. The results demonstrated that when there were 12 images, the accuracy of the optimized convolutional neural network model in extracting image features increased by 1.1% compared to before optimization. When the number of images was 1, the optimized model reduced the image feature extraction time by 15.1s compared to before optimization. Compared with other algorithms, the accuracy of extracting image style information based on a convolutional neural network was the highest at 80% under different iteration times. The research algorithm has improved the accuracy and time of extracting image style information.**

***Keywords*—Finite state transducer; deep learning; CNN; auxiliary painting; style transfer**

I. Introduction

As a visual art, painting can stimulate people's imagination and creativity. Through the observation and practice of painting, people can cultivate their creativity, form a unique way of thinking and problem-solving ability [1]. In recent years, with the rapid development of industrial automation and intelligent technology, spraying, as a key link in the field of industrial manufacturing, has gradually received widespread attention. In the field of modern industrial manufacturing, spraying technology as a key surface treatment process, its accuracy and efficiency are directly related to the final quality of products and market competitiveness [2-3]. However, the traditional spraying system has many problems in the construction process, such as low spraying accuracy, serious material waste and high manual operation cost. In recent years, the development of intelligent spraying robots and automated spraying systems has provided a new direction to solve these problems. In the automatic development of spraying system, Fuzzy SynST Technology (FST) can effectively optimize the spraying process through state conversion, avoid repetitive programming, and reduce human error [4-5]. And automatically diagnose and adjust faults such as nozzle blockage to improve construction efficiency. In the spraying system, FST is prone to lack of control accuracy due to complex environment, and it is difficult to cope with changeable construction scenarios [6]. Deep learning (DL) optimizes spraying paths and parameters through big data analysis and adaptive learning to improve construction efficiency and quality. At the same time, DL can adjust the spraying strategy in real time to better respond to environmental changes and reduce human intervention [7]. In view of this situation, in order to enable most ordinary people to integrate the style of painting art into their works, this study proposed a deep learning technology based on FST algorithm optimization, and innovatively constructed an auxiliary spraying system (APS) based on FST and DL, aiming to improve the intelligence level of the auxiliary spraying system. This study innovatively optimized the Convolutional Neural Network (CNN) model based on the FST, using FST as the output layer of the model and constructing APS based on the TensorFlow framework. The main contribution is the proposal of APS construction based on FST-optimized DL technology, which has significant implications for the successful transfer of painting styles in images.

The research structure has six sections. Section II is a review of the current research status of DL and FST algorithms. Section III is a study on APS based on FST-optimized DL technology. Section IV is the experimental verification of the proposed research method. Discussion is given in Section V. Section VI is a summary of the research content.

II. Related Works

DL is a ML method based on artificial neural networks that can perform nonlinear transformations and feature extraction on complex data [8]. Yu K et al. proposed a DL-based auxiliary diagnosis scheme for breast cancer to solve the problem of low diagnostic efficiency of breast cancer due to the lack of high-quality medical resources in remote areas. This scheme was based on DL model for transfer learning to gain a diagnostic model. This method improved the diagnostic efficiency of breast cancer to 98.19%, and could be used for auxiliary diagnosis in hospitals in remote areas [9]. Zhou X et al. proposed a smart automatic tagging scheme based on deep Q-network to improve the accuracy of Human Activity Recognition (HAR) in healthcare Internet of Things. This scheme identified fine-grained patterns by extracting advanced features from sequential motion data. This method better solved the problem of insufficient sample labeling [10]. Wan S et al. proposed a real-time HAR method based on DL model to solve the problem that traditional methods cannot recognize complex and real-time human activities. This method utilized CNN for local feature extraction and preprocessed the data through denoising, normalization, and other methods. This method was

superior to other traditional methods and improved the accuracy of HAR [11]. Chohan M et al. proposed a DL-based plant disease detection model to promptly detect various diseases caused by bacteria, fungi, and viruses in plants. This model could use images of plant leaves to detect plant diseases, improving the accuracy of image detection of diseased plants, with an accuracy rate of up to 98.3% [12]. Chowdhury M E H et al. proposed a DL architecture based on EfficientNet to classify tomato diseases to lower down the adverse influences of diseases on plants and weaken the drawbacks of continuous human monitoring. This method could improve the segmentation accuracy of leaf images and has shown excellent performance in the ten class classification of images, with an accuracy of 99.89% [13].

Compared with other data structures, FST has higher spatial efficiency and query performance when processing large-scale string collections. Abro WA et al. proposed a model combining weighted FST and BERT architecture to reduce the cost and time of collecting high-quality labeled data. This model utilized weighted FST to enhance the fine-tuning of BERT-like architecture. Compared with other models, this model had a higher recall rate and F1 score, which can reduce the need for massive supervised data [14]. Mohammadghuliha M et al. constructed a frequency controllable acoustic sensor for guided wave detection in order to simplify the hardware of phased array systems and reduce the cost of guided wave based systems. FSAT was made by patterning spiral electrodes on a piezoelectric plate. The generation of directional guided waves in the main structure of the converter has been significantly improved, reducing the cost of the system [15]. Dolatian et al. designed a type of finite state machine with two deterministic FSTs to address the issue of limited state processing not fully capturing the productivity of unbounded replication. This sensor was easy to design and debug in practice, and had linguistic motivation in the origin semantics of the transducer. This sensor could capture almost all processes, which can be found in online repetitive databases [16]. Martin K et al. proposed a bidirectional motion device based on FST to eliminate the descriptive costs of bidirectional motion, non-determinism, and scanning, especially the cost of converting to deterministic or non-deterministic finite automata. This method was more powerful in bidirectional motion than unidirectional motion under deterministic conditions [17]. Somerset W. E. et al. proposed a novel bending ultrasonic transducer for high-pressure environments to handle the issue of pressure imbalance caused by the internal air cavity of traditional transducers on the vibrating membrane of the transducer. The internal chamber of the transducer was filled with an incompressible fluid in the form of non-volatile oil. This method could achieve stable ultrasound measurement [18].

In summary, literature in [8] and [9] have made some progress in the field of medical image recognition, but they are still limited in real-time adaptability and accuracy in dealing with complex industrial scenes. Literature in [10] and [11] improve the recognition accuracy through human activity recognition, but it is difficult to cope with the high environmental variability in the spraying system. The plant disease recognition model proposed in literatures in [12] and [13] performs better under high noise data, but it is insufficient in extracting complex spray features. Literature in [14] combined FST and BERT to improve the recall rate, but the acquisition cost of large-scale data is high. Literatures [15] to [18] has optimized the sensor design, but it still needs to be improved in the stability and diversity of industrial spraying. DL reduces manual intervention through automatic feature extraction of neural networks and is suitable for diverse data scenarios. FST has advantages in optimizing state transition and processing big data, and can effectively improve the spatial efficiency of the algorithm. Therefore, this paper proposes the research of APS construction based on FST optimization DL technology.

III. APS Construction based on FST-Optimized DL Technology

A. Optimizing DL Technology based on FST Algorithm

A painting mainly consists of two parts, namely the content and style of the painting. Among them, painting styles have diversity, and each painter has their own unique style, expressing emotions through elements such as color and lines. Even if the content of the painting is the same, the effects displayed by different painting styles are also different [19]. Compared with traditional ML methods, the most significant advantage of DL is its ability to automatically extract and learn meaningful feature hierarchies from raw data. This hierarchical structure simulates the hierarchical organization of the human brain's neural network, where each layer can capture features of different complexity and abstraction levels [20-21]. CNN is a DL model that can automatically learn the features of images without the need for manual design or selection of feature extractors. CNN uses convolutional and pooling layers to extract local features of images and perform dimensionality reduction, thereby reducing the number of parameters and computational complexity. CNN has advantages such as high efficiency in image recognition [22-23]. Therefore, to integrate the painting styles of famous masters into daily painting works, this study extracts the style information features of images based on CNN. The structure of CNN mainly consists of convolutional layers, activation functions, pooling layers, fully connected layers, output layers, etc. The process of extracting image style features using CNN is shown in Fig. 1.

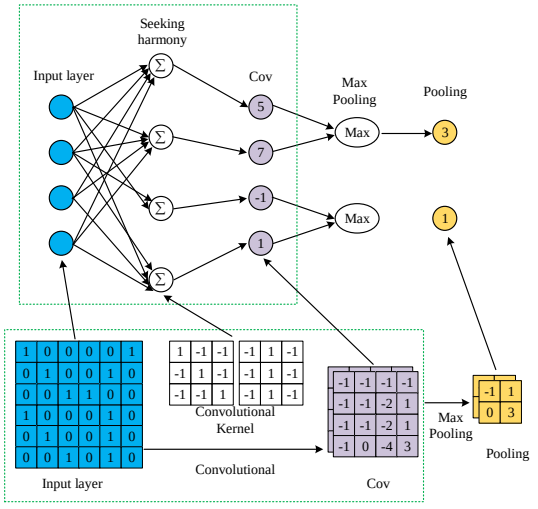

Fig. 1. Flow chart of CNN extracting image style features.

Among them, the input layer receives raw image data. The convolutional layer convolves the input image with the convolutional kernel, introducing nonlinearity by applying activation functions, enabling the network to learn complex features. The pooling layer reduces computational complexity by reducing the feature map size, by selecting the maximum or average value within the pooling window. The fully connected layer transforms the extracted feature maps into the final output. The first step in extracting the style information features of an image is to perform convolution operations, where attention should be paid to the position step size of each slide. The basic idea of the Adam algorithm is to keep an adaptive Learning Rate (LR) for each model parameter during the training process, so that parameter updates can more accurately control the step size [24]. Therefore, this study uses the Adam parameter update method combined with the First-Order Moment Estimation (1OME) and Second-Order Moment Estimation (2OME) of the loss function for calculation. The Adam parameter update steps are shown in Fig. 2.

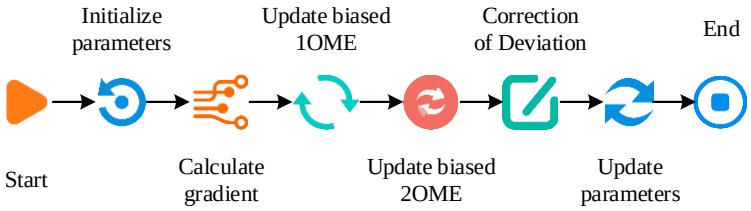

Fig. 2. Adam parameter update steps.

Firstly, the 1OME m_t is corrected using the correction formula shown in Eq. (1).

$$\hat{m}_t = \frac{m_t}{1-\beta_1^t} \tag{1}$$

In Eq. (1), β_1 is the 1OME attenuation coefficient. $\hat{m}_t$ is the corrected 1OME. t is the number of updated steps. Secondly, the 2OME v_t is corrected, and its correction expression is Eq. (2).

$$\hat{v}_t = \frac{v_t}{1-\beta_2^t} \tag{2}$$

In Eq. (2), β_2 is the 2OME attenuation coefficient. $\hat{v}_t$ is the corrected 2OME. Finally, the model parameters were updated based on the corrected $\hat{m}_t$ and $\hat{v}_t$. The formula for updating model parameters θ_{t+1} is Eq. (3).

$$\theta_{t+1} = \theta_t - \frac{\ell \hat{m}_t}{\sqrt{\hat{v}_t} + \varepsilon} \tag{3}$$

In Eq. (3), ℓ is the LR. θ_t is the parameter model before the update. ε is a hyperparameter. When performing convolution processing on each convolutional channel, different filters are used, and the calculation process is Eq. (4).

$$c_i = F\left(K_i * X + b_i\right) \tag{4}$$

In Eq. (4), K_i and b_i are the convolution kernels and biases of the i-th channel. X is the input data. c_i is the convolution result of the i-th channel. $F(\cdot)$ is a non-linear activation operation in the convolution process. The activation function of CNN is ReLU. ReLU trains in the negative area. When a neuron with a gradient of 0 appears, the gradient of this neuron and subsequent neurons will always be 0 and will no longer respond to any data, causing the correlated parameters never being updated [25]. To solve the problem of neuronal necrosis in ReLU function, this study improves ReLU using exponential linear units, and the improvement process is Eq. (5).

$$ELU(x) = \begin{cases} x, & x>0 \\ \alpha\cdot(\exp(x)-1), & x\le 0 \end{cases} \tag{5}$$

In Eq. (5), x is the input value, α is the predefined hyperparameter, and $\exp(\cdot)$ is the exponential function operation. The composition of CNN includes a max pooling layer, which discards non max information and may lose some detail information. Average Pooling (AveP) considers the mean value of all values in the pooling window, which is smoother than Maximum Pooling (MaxP) and can preserve more detailed information. The calculation of mixed pooling and AveP is shown in Fig. 3.

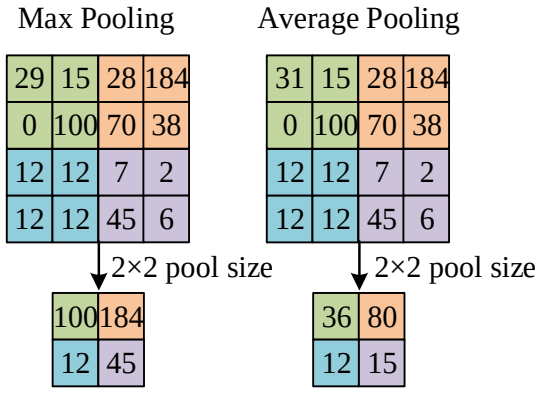

Fig. 3. Mixed pooling and AveP calculation.

The calculation of AveP G_{ij} is Eq. (6).

$$G_{ij} = \frac{1}{p\times p}\cdot\left(\sum_{i=1}^{p}\sum_{j=1}^{p} M_{ij}\right) + b \tag{6}$$

In Eq. (6), M denotes the feature map of the pooling operation, b is the bias of each channel, and $p\times p$ is the

size of the pooling region. To solve the problem of feature weakening caused by using only the max pooling layer for feature processing, this study adopts a mixed pooling method to pool the features. The calculation of mixed pooling is Eq. (7).

$$G_{ij} = \frac{1}{2}\left(\frac{1}{p \times p} \cdot \left(\sum_{i=1}^{p}\sum_{j=1}^{p} M_{ij}\right) + \max_{(p\times p)i=1,\, j=1} M_{ij}\right) + b \quad (7)$$

In Eq. (7), $\max_{(p\times p)i=1,\, j=1} M_{ij} + b$ represents the MaxP operation. To transform the image style information features extracted by CNN into a series of string states containing semantic information, this study optimizes DL technology based on FST and uses FST as the output layer of the model. The formula for the time complexity O of FST is Eq. (8).

$$O = n \times m \quad (8)$$

In Eq. (8), n is the text length and m is the pattern length. The optimization steps are as follows: Firstly, the number of states in FST and the transition relationship between states are determined. Secondly, in the output layer of the CNN model, a node layer with an equal number of FST states is created. Finally, the image feature information extracted based on the FST algorithm is transformed into a string.

B. Construction of APS

After optimizing DL technology based on FST, this study constructs APS based on the optimized model. TensorFlow is an open-source ML framework dedicated to automatic differentiation of various data flow graphs and computation of deep neural networks. This framework provides multiple advanced Application Programming Interfaces (APIs), making building and training DL models relatively simple. At the same time, it also maintains great depth and flexibility to meet the needs of researchers exploring complex models. Therefore, this study constructs APS based on the TensorFlow framework. The APS constructed mainly consists of two parts. Part 1 is the front-end page: The main functions of the system's front-end include uploading images that require style fusion, selecting the desired style, style conversion buttons, and outputting images after style conversion is completed. The process of requesting front-end image style conversion is shown in Fig. 4.

The other part is the backend of the system. The backend of APS mainly has three modules: Uniform Resource Locator (URL) request forwarding, logical functionality, and style conversion. The task of Module 1 is to pass the URL request link transmitted by the frontend to a specific function for execution. The task of Module 2 is to preprocess, transcode, encode, and store uploaded images. The task of Module 3 is to convert the style of uploaded images and return the converted images to the user. The relationship between the three modules in the APS backend is shown in Fig. 5.

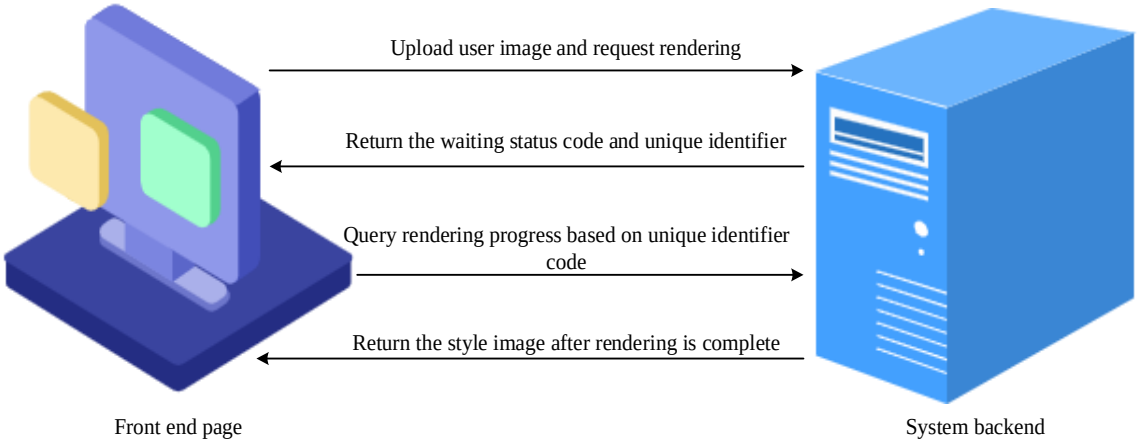

Fig. 4. Process of front-end image style conversion request.

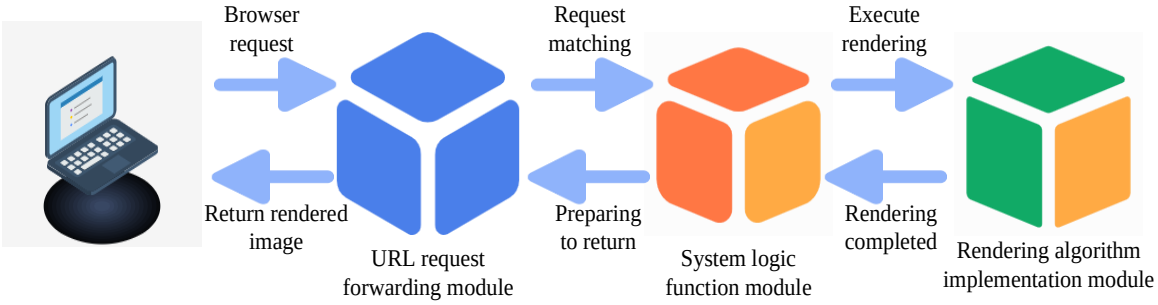

Fig. 5. The relationship between the three modules in the background of the APS.

The core module of the system backend is to extract image feature information. Due to various noises, interferences, and deformations that may exist in the original image, directly using the original image for DL model training may lead to a decrease in model accuracy. As a result, this study requires preprocessing of the original images to enhance the training effectiveness and recognition accuracy. The image data preprocessing steps are shown in Fig. 6.

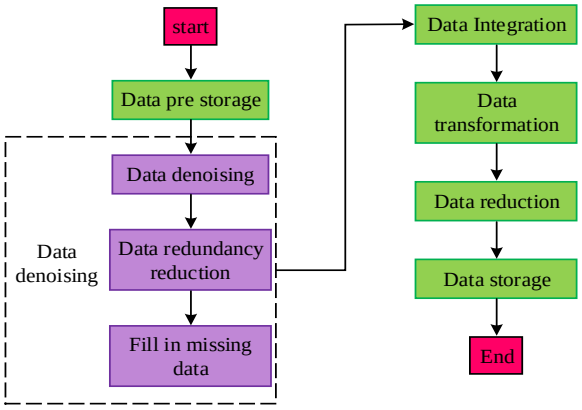

Fig. 6. Image data preprocessing steps.

Standardizing image data can adjust images of different sizes and resolutions to the same range, facilitating subsequent processing and analysis. Data standardization processing can be divided into normalization processing and z-score processing. The difference in comparison results of different data sets is due to the diversity of the characteristics of data sets and the number of samples. The performance of the algorithm on different data sets depends on the characteristics of the data, such as the resolution of the image, the complexity of the background, and the clarity of the target style. Normalizing the data can balance the weights of various dimensional features and avoid the interference of features with large or small numerical scales on the model. Among them, normalization processing can be divided into minimax normalization and mean normalization. The calculation of minimax normalization is Eq. (9).

$$\begin{cases} X = \dfrac{X_{old} - \min(X_{old})}{\max(X_{old}) - \min(X_{old})}, [0,1] \\ X = \dfrac{2\left(X_{old} - \min(X_{old})\right)}{\max(X_{old}) - \min(X_{old})} - 1, [-1,1] \end{cases} \quad (9)$$

In Eq. (9), X_{old} is the original dataset. $\max(X_{old})$ and $\min(X_{old})$ take extreme values for each column feature of the original dataset. Mean normalization maps the values of features to the range of [0,1], eliminating the influence of dimensionality on the eventual result, making different features comparable, and allowing features with potentially large distribution differences to have the same weight impact. The expression of mean normalization is Eq. (10).

$$X = \frac{X_{old} - mean(X_{old})}{\max(X_{old}) - \min(X_{old})} \quad (10)$$

In Eq. (10), $mean(X_{old})$ defines taking the mean of each column feature of the original dataset. Standardizing data using z-score involves scaling the data to a distribution centered around 0 with a standard deviation of 1. This method preserves the original data information without changing the distribution type of the original data, making the different features of the original data comparable. The formula for z-score is shown in Eq. (11).

$$\mu \ X = \frac{X_{old} - \mu}{\sigma} \quad (11)$$

In Eq. (11), μ is the vector of the mean of each column feature of the original dataset. σ is the vector of the standard deviation of each column feature in the original dataset. To better evaluate the detection model's performance, this study utilizes the $F-Score$ method for evaluation, and the formula for $F-Score$ is Eq. (12).

$$F-Score = \left(1+\beta^2\right)\frac{Precision \cdot Recall}{\beta^2 \cdot Precision + Recall} \quad (12)$$

In Eq. (12), $Recall$ represents the recall rate of abnormal data in the results. $Presion$ is the accuracy of abnormal data in the result. β is the degree of importance to the outcome. When β =1, it indicates that both have the same impact on the result. At this point, $F-Score$ is expressed as Eq. (13).

$$F-Score = \frac{2 \cdot Precision \cdot Recall}{Precision + Recall} \quad (13)$$

IV. Analysis of APS Effect based on FST Algorithm Optimization of DL Technology Construction

A. Experimental Parameter Setting and Performance Verification

The software selected for the experiment is Python v3.5.2, and the learning framework is TensorFlow. The operating system is Windows 10, the memory is 128GB, the CPU is Intel Core (TM) i7-6700CPU @3.40GHz, and the GPU is NVIDIA GeForce GTX 750 Ti. Table I provides information on the backend functions of the system.

The size of the LR directly affects the convergence speed and state of the CNN model. Excessive LR may cause the model to oscillate near the optima and fail to converge. If the LR is too low, it may lead to slow convergence speed of the model, and even get stuck in local optimal solutions. Therefore, to obtain the best LR, this study set the LR to different values and evaluated it through the loss value and F1 Score. The statistical results are displayed in Fig. 7. In Fig. 7(a), when iterating up to 70 times, the loss curves for different LRs tend to stabilize. When the LR = 0.3, the loss value of the model is minimized. When the LR < 0.3, the loss value decreases as the LR increases. When the LR > 0.3, the loss value grows with the growth of the LR. In Fig. 7(b), when the LR is 0.3, the F1 Score value is optimal, and when the LR is < 0.3, the F1 Score value rises with the sire of the LR. When the LR is > 0.3, the F1 Score value decreases as the LR increases.

The maximum tree depth parameter (max_depth) controls the complexity of the decision tree. However, if this value is set too small, the CNN model may underfit, resulting in poor performance. When the max_depth is set too high, it may cause overfitting issues. Therefore, to obtain the optimal x_depth, this study sets the x_depth to different values and evaluates it based on the loss value and F1 Score. The statistical results of the loss value and F1 Score are shown in Fig. 8. In Fig. 8(a), when the iteration reaches 48 times, the loss curves of different max_depth tend to be stable. When the max_depth=3, the loss value of the model is the smallest; When the max_depth<3, the loss value descends with the rise of the max_depth; When the max_depth>0.3, the loss value grows with the increase of LR. In 8 (b), when the max_depth=3, the F1 Score value is optimal; When the max_depth<3, the F1 Score value grows with the increase of the max_depth; When the max_depth>3, the F1 Score value decreases with the rise of the max_depth.

TABLE I. SYSTEM BACKEND FUNCTION SETTINGS

Serial number	Function Name	Module to which it belongs	Function Introduction
1	path	URL request forwarding module	Filter and match the links sent by the front-end
2	open/write	System logic function module	Provide read and write functionality for images
3	json	System logic function module	Responsible for processing JSON related formatted data
4	base64	System logic function module	Base64 encoding and decoding of images
5	get_unique_key	System logic function module	Generate a unique key for each user image
6	apply_async	System logic function module	Asynchronous execution of rendering process
7	settings	System logic function module	Access and modify some system settings options
8	check_img	System logic function module	Check image format
9	pool_exec	System logic function module	Provide scheduling and execution of process pools
10	style_rendering	Style conversion implementation module	Render the received image into the specified style

Fig. 8. Comparison between loss values and F1 Score under different max_depth.

B. APS Quality Analysis based on CNN

This study compares the recall rate and F1 Score value of image features pooled using a Maximum-Median-Mixed Pooling (MMMP) strategy with other pooling approaches. The statistical results are shown in Table II. Single Pooling Strategies (SPS) are lower than Mixed Pooling Strategies (MPS). In the SPS, the maximum recall rate and F1 Score value of the SPS are the highest, at 79.58% and 0.7350, respectively. In the MPS, the two values of the MMMP are the highest, at 81.3% and 0.7408. The two value of the three MPSs are lower than those of the MMMP strategy and the average-median-MPS, which are 80.25% and 0.7362.

TABLE II. COMPARISON OF DIFFERENT POOLING STRATEGIES

Pooling strategy	Recall (%)	F1 Score
Maximum-single	0.7958	0.7350
Average-single	0.7846	0.7328
Middle value single	0.7909	0.7335

Maximum-intermediate-mixed	0.8103	0.7408
Three mixed	0.8025	0.7362

The results of comparing the accuracy of extracting image style information based on CNN with other algorithms under different iteration times are shown in Fig. 9. The accuracy of extracting image style information using different algorithms increases with the increasing number of iterations. The accuracy of CNN in extracting image style information is higher than other algorithms, with an accuracy of 80%. The highest accuracy of the four layer Deep Neural Network algorithm (DNN) is 68.9%, because the algorithm requires numerous parameters and computational resources, which lifts the difficulty of training and tuning. The highest accuracy rates of User-based Collaborative Filtering Algorithm (UserCF), Content-based Algorithm (CBF), Probability-based Matrix Factorization (PFM), and Item-based Collaborative Filtering Algorithm (ItemCF) are 58.6%, 68.8%, 68.8%, and 67.9%, respectively.

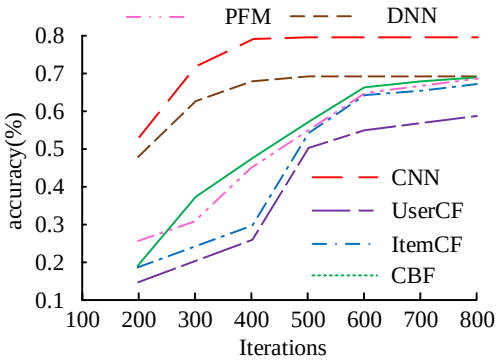

Fig. 9. The accuracy of extracting image features using different models.

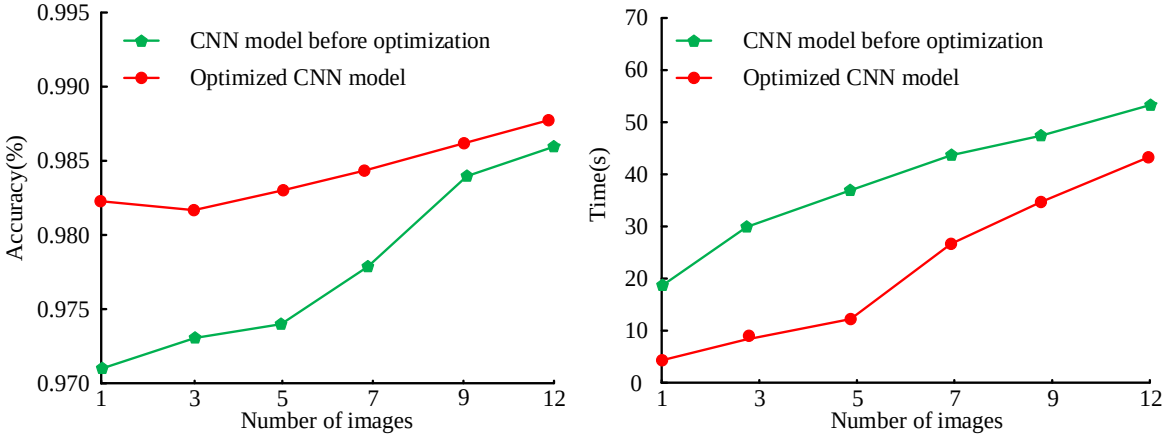
In the case of different numbers of images, this study compares the accuracy and time of extracting image features based on the optimized CNN model. Fig. 10 shows the comparison results. In Fig. 10 (a), the accuracy of the optimized CNN in extracting image features increases with the increase of the number of images. When there are 12 images, the highest accuracy is 98.3%, which is 1.1% higher than before optimization. In Fig. 10(b), the running time of the pre-optimized model for extracting image features increases with the rise of the amount of images, while the optimized time decreases. When the image is 1, the optimized CNN takes a minimum of 4.7 seconds, which is 15.1 seconds shorter than before optimization. The proposed algorithm is more suitable for complex and detailed image style data sets, because the algorithm can effectively extract and process the style details in the image through the hybrid pooling strategy and the optimization of the FST layer, and improve the accuracy and efficiency of the model.



(a) The accuracy before and after optimizing the CNN model

(b) The running time before and after optimizing the CNN model

Fig. 10. Comparison of the accuracy and time of extracting image features.

In this paper, we propose an auxiliary spray system (APS) based on finite state sensor (FST) algorithm to optimize deep learning (DL) technology, and realize automatic image style extraction through convolutional neural network (CNN) model. Compared with the optimized model, it shows higher accuracy and speed in processing multiple images. When the number of images is 12, the accuracy of feature extraction reaches 98.3%, and the running time is reduced to 4.7 seconds. In addition, the maximum-median-mixed pooling (MMMP) method was used in the pooling strategy, and the recall rate and F1 score reached 81.3% and 0.7408, respectively, which was superior to the single pooling strategy. The experiment also verified the performance of CNN under different learning rate (LR) and max_depth Settings, with the best parameter configurations being LR=0.3 and max_depth=3.

V. Discussion

In this paper, a deep learning technology based on FST algorithm optimization is proposed. The accuracy of the model is increased by 1.1% when processing 12 images, and the processing time of a single image is shortened by 15.1 seconds, which is better than the existing methods and meets the requirements of rapid response in the field of industrial spraying. Compared with the scheme used in the literature [8] for the auxiliary diagnosis of breast cancer, this method has achieved a breakthrough in image processing speed. Although the literature [9] and [10] perform well in the identification of human activity (HAR), there are shortcomings in dealing with complex industrial spraying tasks; The APS model designed in this study is more suitable for the changeable construction environment. In addition, compared with the real-time HAR method in literature [11], MMMP pooling strategy is superior in terms of recall rate and F1 score, which highlights its high efficiency in image feature extraction. In terms of image style information extraction, the accuracy of this model reached 80%, which was higher than the plant disease detection model proposed in literatures [12] and [13]. At the same time, although literature [14] combines weighted FST and BERT architecture to perform well in terms of recall rate and F1 score, this study reduces the dependence on large-scale labeled data and simplifies the data preprocessing process through CNN optimization. In general, the introduction of FST optimization deep learning technology not only improves the accuracy and processing speed of image feature extraction in APS, but also shows broad application prospects in the field of industrial spraying.

VI. Conclusion

To optimize the accuracy and efficiency of the spraying system to improve product quality and market competitiveness, reduce human error and adapt to the changing construction environment, so as to achieve intelligent and efficient spraying process, reduce operating costs and reduce material waste. This study proposed APS based on FST-optimized DL technology. After optimizing DL technology based on FST algorithm, this study constructed APS based on the optimization model. The experiments indicated that when the max_depth and LR of the model were set to 0.3 and 3, the loss value and F1 Score value of the CNN were optimal. Compared with the pre-optimized CNN, the accuracy and time of extracting image features by the optimized CNN were 98.3% and 4.7s, under different numbers of images. Compared with other pooling strategies, the MMMP strategy used in this study had the best pooling effect on image features, with recall and F1 Score values of 81.3% and 0.7408. The research model has been effectively applied in assisting painting, and compared to existing models, this model has higher efficiency in extracting features. However, CNN has a large number of layers and parameters, requiring a significant amount of computation time and storage space, thus requiring high computational resources. Future research will focus on the computational efficiency of the system to reduce the computing resource requirements and further improve the performance of the assisted painting system (APS) in image style conversion. Specifically, image style recognition is enhanced by improving the feature extraction accuracy of convolutional neural network (CNN). Adjust the learning rate (LR) and maximum tree depth (max_depth) to get the best model parameters. The hybrid pooling strategy is used to optimize image feature processing to improve the recall rate and accuracy of the system.

BackC&P: Augmenting Copy and Paste Operations on Mobile Touch Devices Through Back-of-device Interaction

Liang Chen[1]
School of Software Engineering, Chengdu University of Information Technology, Chengdu, China[1]
Sichuan Province Engineering Technology Research Center of Support Software of Informatization Application, Chengdu, China[1]

***Abstract*—As more and more complex applications, e.g. photo editing software and slideshow editing software, can be used on mobile touch devices, some simple operations, such as copying and pasting, are used more frequently by ordinary mobile users. However, the existing touch techniques are far from perfectly supporting these simple operations on mobile devices. In this paper, a new interactive technique BackC&P, which takes advantage of back-of-device touch input to augment copy and paste operations on mobile devices, is presented. The results of a user study that evaluated the usability of BackC&P are also presented. The findings indicate that BackC&P was about twice as fast as the currently used technique on mobile touch devices when used to complete the copy-and-paste tasks, with no significant decrease in accuracy.**

***Keywords*—Back-of-device interaction; copy and paste operations; mobile touch devices; touch interaction**

I. INTRODUCTION

Various mobile touch devices have already been widely used in our everyday lives and enable users to manipulate user interfaces with a variety of touch interactions that previous feature phones cannot support [1]-[5]. Direct touch interaction has become the mainstream interactive technology on a mobile device mainly because it provides users with better performance and experience through natural, easy-to-use, and intuitive touch gestures.

Despite the numerous advantages, direct touch interaction still has many limitations that require further improvements, especially when it is applied to mobile devices. Due to the small screen size of mobile devices, touch interaction design for mobile user interfaces is usually tedious and time-consuming. Taking the copy operation as an example, the current technique utilizes a long-press action applied on the target to trigger the copy menu, and then utilizes a tap action applied on the pop-up copy menu to complete the copy of the target. Obviously, the long-press action is already very time-consuming; acquiring the copy menu takes even more time. Similar issues exist in the paste operation as well. In the meanwhile, however, as the computing power of mobile devices continues to increase, more and more complex applications, e.g. image editing software, slideshow editing software, and storytelling software, have already been available to mobile users. Apparently, simple operations such as copying and pasting are often used in these mobile applications. Therefore, how to further improve these simple and frequently used operations on mobile touch devices is an important research topic that HCI researchers should pay more attention to and explore.

The author's previous work in [6] explored the use of back-of-device touch input for promoting front-of-device touch interactions on mobile devices, for instance, to enhance mobile text entry or to augment the zooming operations in a map application. In this paper, the author extends the use of BackAssist [6] to enhance the copy and paste operations on mobile touch devices. The prototype BackC&P utilizes the back-of-device touch input provided by BackAssist to switch the current system mode to the copy mode or paste mode. In the copy mode, a front-of-device tap on the target will complete the copy of the target; in the paste mode, a front-of-device tap on the destination will complete the paste of the target.

The purpose of BackC&P is to take advantage of back-of-device touch input to improve the user performance of completing copy and paste operations on mobile touch devices. The results of the user study indicate that BackC&P was approximately twice faster than the currently used technique on mobile devices, and there was no significant increase in the error rate.

The reminder of this paper is as follows. The paper begins with a review of a series of important research literature on back-of-device interaction in Section II. After that, the interaction design of the technique BackC&P is introduced in Section III. Then, a user study comparing user performance between using BackC&P and the currently used technique is described in Section IV, followed by a detailed comparative analysis of efficiency and accuracy in Section V. Finally, some of the research results in terms of efficiency and accuracy are discussed in Section VI. Finally, the paper is concluded in Section VII.

II. RELATED WORK

The research area that is most relevant to this research is back-of-device interaction. As its name suggests, back-of-device interaction makes use of various input units on the rear of a device to complete multifarious interactive tasks, such as text entry, target acquisition, mobile authentication, and so on. It can be used either as an exclusive manipulation technique or together with other interactive techniques, thus bringing many

benefits that can improve user performance and experience in many aspects.

A. Exclusive Manipulation via Back-of-device Interaction

When it comes to back-of-device interaction, the first reaction is that it can address the occlusion problem and the fat finger problem. One of the best-known examples is NanoTouch [7] presented by Baudisch and Chu. It enables users with back-of-device touch input to interact with digital contents that are displayed on the tiny screen of a very small handheld device.

Back-of-device interaction can also be used for promoting one-handed mobile interaction. Yang et al. [8] augmented a PDA with cursor manipulation by attaching an optical sensor on the rear of the device. With the onscreen cursor, which was controlled by back-of-device input, a user could acquire the targets located in the places where the thumb could not reach. Hasan et al. [9] also explored one-handed back-of-device cursor interaction. Their findings indicated that compared with absolute mode cursor input, relative mode cursor input achieved better performances in both positioning the cursor and selecting the targets. Fan and Coutrix [10] explored the effect of asymmetry between preferred and non-preferred hands on user performance. Their study found that the preferred hand performed better in target acquisition tasks, but for steering tasks, they found little performance difference between preferred and non-preferred hands.

Mobile text entry is another research hotspot in back-of-device interaction. With a back-attached keyboard, RearType [11] allowed users to input text on a tablet by operating the physical keyboard on its rear. In order to keep mobile devices to their original form factor, Sandwich Keyboard [12] utilized a back-adhered multi-touch sensor to substitute the back-attached physical keyboards. In addition, Buschek et al. [13] added a machine-learning algorithm to Sandwich Keyboard to reduce the typing errors. Cui et al. proposed BackSwipe [14] which enabled a user to enter text or trigger a command by drawing a word-gesture on the back of a mobile device.

Researchers have also explored employing back-of-device interaction to support other mobile manipulation scenarios. For example, Luca et al. [15], Leiva et al. [16], and Kulshreshtha and Arif [17] explored realizing mobile device authentication through back-of-device interaction to address the problem of shoulder surfing. For another example, Granell and Leiva [18], [19] utilized the built-in gyroscope and accelerometer to implement tap-based back-of-device interaction, which could be used to control camera and game applications. Furthermore, Shimon et al. [20] investigated user-defined back-of-device gestures for a series of frequently used tasks on mobile devices. They found that for the vast majority of the tasks, participants had varying mental models when designing back-of-device gestures to complete them.

Although back-of-device interaction used as an exclusive input technique can make many achievements, e.g. addressing hand occlusion and “fat fingers”, supporting touch manipulation on tiny displays, and so on, it still has some limitations. On one hand, although back-of-device input addresses hand occlusion, the performance may not be as efficient as that of front-of-device touch input [21]. The results of a user study [22] show that compared with front-of-device touch input, back-of-device touch input achieves more accurate but much slower performance in conducting pointing tasks on a mobile device. On the other hand, when a user acquires onscreen targets by tapping, back-of-device touch interaction tends to be inferior to its front-of-device counterparts because the user’s operating fingers are occluded by the device itself [23], thereby failing to provide the user with visual clues of the operating fingers which are very important for accurately acquiring the targets. Therefore, combining back-of-device interaction with other interaction techniques rather than using it alone may better exert its strengths.

B. Hybrid Manipulation with Back-of-device Interaction

Many researchers have conducted studies on combining back-of-device interaction with other interactive techniques to augment mobile device manipulation.

Corsten et al. [24] presented BackXPress, which made use of back-of-device pressure input to switch between different quasi-modes for augmenting front-of-device touch interaction. Chen et al. [6] presented BackAssist, which utilized the combinations of on and off states of the two fingers resting on the rear of a mobile device to augment mobile text entry and zooming operations in a mobile map application. Huang et al. [25] proposed TapNet, which could identify taps on a smartphone while simultaneously recognizing various tap properties, such as direction and location. With TapNet, users could utilize back-of-device or edge tapping with other forms of interaction, such as tilt and touch, to complete tasks on their mobile devices.

One-handed mobile interaction was augmented by two-sided touch interaction as well. InfiniTouch [26] enabled touch input across the entire device surface of a smartphone while maintaining the standard smartphone form factor. Through a machine learning technique, InfiniTouch could identify all fingers during single-handed interaction. Le and colleagues also investigated fingers’ comfortable area [27] and safe area [28] for one-handed smartphone interaction, which could guide the design of interactions on the back and edges.

LucidTouch [29] took advantage of a technique, which was named pseudo-transparency, to overlay the video images of the user’s hands, which were behind the device and could not be seen by the user, onto the screen of the device. With the augmented visual feedback, users could manipulate the targets on a mobile device’s screen more accurately compared with the other back-of-device interaction techniques without such visual feedback.

C. Back-of-device Interaction for Copy and Paste Operations

Among the above-mentioned studies on back-of-device interaction, several involve the copy and paste operations. In [20], participants were asked to create gestures to complete the copy and paste tasks. However, the results of their study showed that there was little consensus on the gestures designed by the participants for these two tasks. When designing gestures, some participants mimicked keyboard shortcuts, and completed copy and paste operations by

respectively drawing "C" and "V" on the back of the device. Cui et al. [14] proposed using word-gesture interaction to trigger commands. According to their design, a user could complete the copy operation by input "copy" or "replicate" on the device's back. However, they did not implement their design on a real device. In study [26], several use cases were demonstrated. For instance, with InfiniTouch [26], a user could swipe down with the index finger to copy and swipe down with the middle finger to paste. However, their study did not verify the usability of the technique through experiments.

III. BACK-OF-DEVICE INTERACTION AUGMENTED COPY-AND-PASTE

The copy and paste operations are frequently used on various electronic devices. Compared with the techniques used on desktop computers, the current technique used on mobile devices is apparently more time-consuming, as illustrated in Fig. 1. For example, the long-press action is used for triggering the copy menu and even for triggering the paste menu until the tap action replaces it to complete the same task.

The author's previous work in [6] explored making use of the two resting fingers, the index finger and the middle finger of the holding hand, on the rear of a mobile device to generate back-of-device touch input for augmenting the front-of-device touch interaction by the other hand. The hardware of the prototype, BackAssist, was built by attaching two off-the-shelf smartphones in a back-to-back fashion. Similar hardware prototypes were also utilized in many previous studies [12], [13]. The appearance of the prototype is shown in Fig. 2. The results of the user study indicate that the back-of-device input of BackAssist is easy-to-learn and can be efficiently and accurately used by ordinary mobile users [6]. Some applications enhanced by BackAssist have also been developed. For example, utilize the back-of-device input to switch between the lowercase page and the uppercase page of a soft keyboard [6].

In this paper, the author extends the use of BackAssist and explores utilizing the combinations of on and off states of the two fingers, respectively resting on Zone 1 and Zone 2 (see Fig. 2), for augmenting copy and paste operations on a mobile device. The interaction technique is named BackC&P.

With BackC&P, back-of-device input can be used for switching the current system mode to the copy mode or the paste mode, thus saving the time for the operations compared with those of currently used techniques. In the present implementation, the system modes are controlled by the back-of-device inputs, as shown in Table I. In order to complete a copy operation, the user first lifts up his/her finger on Zone 1 to switch the current system mode to the copy mode, and then taps the target by the other hand to copy the target, as shown in Fig. 3(b). Similarly, to complete a paste operation, the user first raises the finger on Zone 2 to switch the system mode to the paste mode, and then taps the desired position to paste the copied target there, as shown in Fig. 3(c). With BackC&P, there is no pop-up copy menu or paste menu, so the time for acquiring the copy menu or the paste menu is also saved. To sum up, theoretically, BackC&P can tremendously reduce the time for completing copy and paste operations compared with the existing techniques used on mobile touch devices.

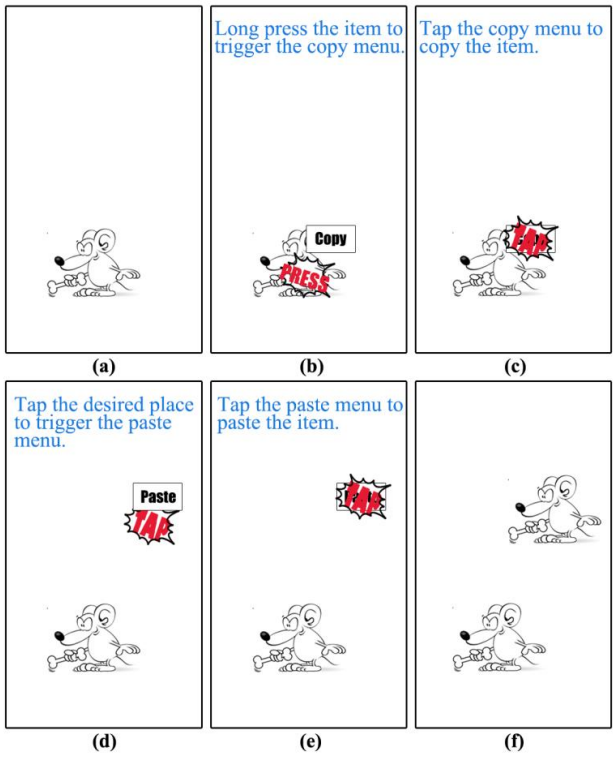

Fig. 1. A diagram demonstrates how to perform copy and paste operations with the currently used technique on a mobile touch device.

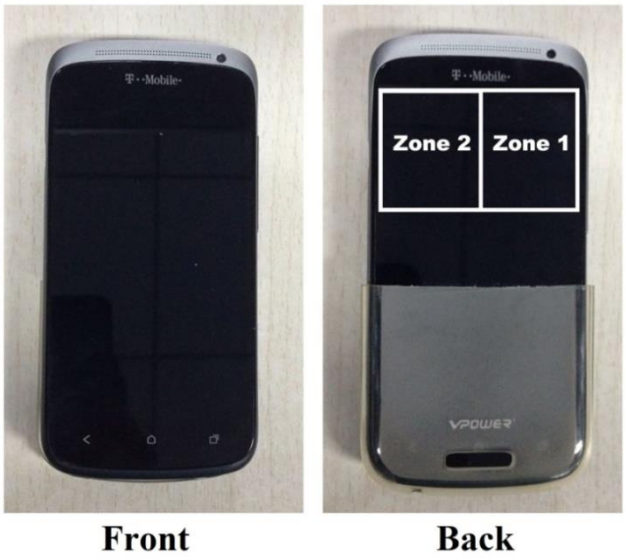

Fig. 2. The appearance of the hardware prototype.

TABLE I. THE MODES GENERATED BY BACK-OF-DEVICE INPUT

	Zone 1 without index finger on	**Zone 1 with index finger on**
Zone 2 without middle finger on	Usual Mode I	Paste Mode
Zone 2 with middle finger on	Copy Mode	Usual Mode II

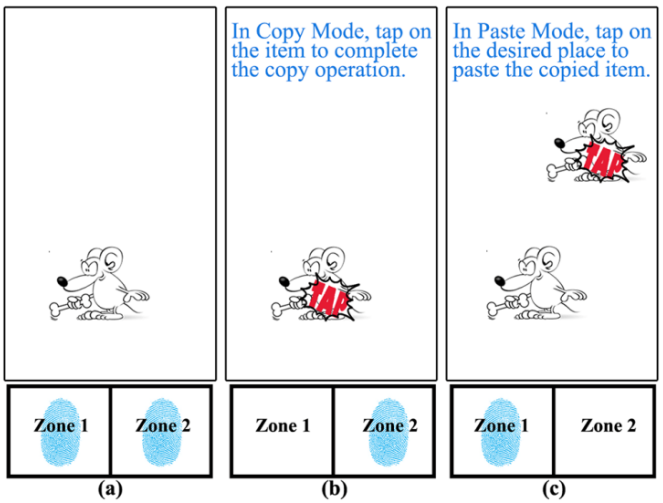

Fig. 3. A diagram of how to perform copy and paste operations with BackC&P. The blue fingerprints in the picture indicate that the corresponding finger(s) is/are on the specific Zone(s).

It should be noted that BackC&P can only save the time for the copy operation and the paste operation rather than the time for the navigation phase. The navigation time is the time that is taken to navigate from the copy position to the paste position. It may include the time for scrolling off-screen contents into the screen, the time for switching from one application to another, and so on. Usually, during a complete copy-and-paste operation, navigating to the desired place to paste the copied target may take the user a lot of time [30], [31]. Sometimes, the navigation time is much longer than the sum of the copy time and the paste time.

IV. User Study

Based on the previous analysis on the procedures of copy and paste operations on mobile devices, BackC&P is able to improve a user's performance at least in terms of the completion time. In order to verify the theoretical analysis, a user study was conducted to compare users' performances in using BackC&P and the currently used technique. Specifically, the author hoped to figure out whether BackC&P could improve users' performance in conducting copy-and-paste tasks. And if so, to what extent? In addition, the author wanted to get a more complete understanding of BackC&P. For instance, besides the completion time, were there other aspects of copy and paste operations on mobile devices affected by BackC&P? Finally, the author hoped to get the participants' first impressions on BackC&P.

A. Participants

Ten participants were recruited from a local university, ranging in age from 22 to 30. The participants' average age was 24.8 (SD = 2.10). All participants were right-handed people and they were all skilled in manipulating mobile touch devices.

B. Apparatus

The hardware prototype described in study [6] was used in this study. The experimental software was written in Java and Android SDK.

C. Task and Procedure

A copy-and-paste task was designed to simulate real copy-and-paste tasks on a mobile device for the user study. In order to minimize the impact of the navigation phase on the completion time, in the copy-and-paste task, the target to be copied and the destination to paste the copied target were presented in a single display. Therefore, the participants did not need to search for an off-screen destination by scrolling through the screen view or switching to another application.

The copy-and-paste task could be conducted by both BackC&P and the currently used technique which the author called it the traditional technique in this study. In real practice on current mobile devices, the paste menu could be triggered either by a long-press action or by a tap action, so both methods were enabled to activate the paste menu although the participants were encouraged to trigger the paste menu by tapping upon the destination, which could reduce the time for the paste operation.

Each trial began with displaying a start button below the inactivated target. The distance between the center of the target and the center of the start button was 370 pixels. After the participant successfully acquired the start button, timing started and the target, a blue circle in the center of the display, was activated at the same time. The participant then conducted the copy operation. Once the target was successfully copied, four circles with the radius of 10 pixels larger than that of the target would be rendered in the four locations around the target, respectively in its northwest, northeast, southeast and southwest. The four circles represented the potential locations for pasting the copied target. The real location for pasting the target was called the destination. The destination was highlighted in green while the other three circles, serving as distractors, were rendered in grey. Finally, the participant pasted the target in the destination.

Before the study began, each participant was required to fill out a pre-study questionnaire to gather demographics. Then a brief introduction about the copy-and-paste task and a training session about how to perform the copy-and-paste task were given. After that, the participant was allowed to practice performing the tasks. When he or she felt skilled enough, ten blocks of trials would be given to complete. Short breaks were permitted between trials or blocks. At the conclusion of the study, each participant was asked to fill out a post-study questionnaire to collect subjective feedbacks.

D. Experimental Design

In the copy-and-paste task, three target sizes (radius = 30, 50, 70 pixels; respectively similar to the sizes of keys of the virtual keyboard, app icons, and thumbnails of pictures on a smartphone), two target-destination (from the center of the target to the center of the destination) distances (224 and 335 pixels, as shown in Fig. 4), and four potential locations for the destination were used. As a result, there were totally 24 (Size × Distance × Destination) different tasks for each interaction technique.

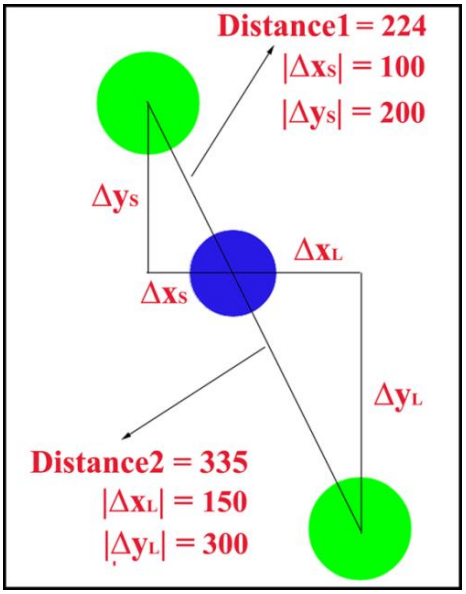

Fig. 4. The two target-destination distances for the task (the subscript 'S' denotes short and the subscript 'L' denotes long).

A within-subjects design was utilized for the experiment. Each participant conducted the copy-and-paste tasks using both BackC&P and the traditional technique. The order of using the two techniques was counterbalanced. For each technique, there were totally 10 blocks of trials. Each block contained all the 24 different copy-and-paste tasks and these tasks would appear in a random order.

To sum up, the experiment design was as follows:

10 participants ×
2 Techniques ×
10 blocks ×
3 Sizes ×
2 Distances ×
4 Destinations
= 4800 trials.

V. Results and Analysis

A. Completion Time Analysis

The completion time is the time that is taken between the acquisition of the start button and the completion of pasting the copied target. It includes the copy time and the paste time. The copy time is defined as the time between the selection of the start button and the completion of copying the target. The paste time is defined as the time between the completion of the copy operation and the completion of pasting the copied target.

Before conducting the data analysis, the records that were marked as error ones were removed from the dataset. The grand mean of the completion time of the adjusted data was 2.10 seconds (SD = 1.06 seconds).

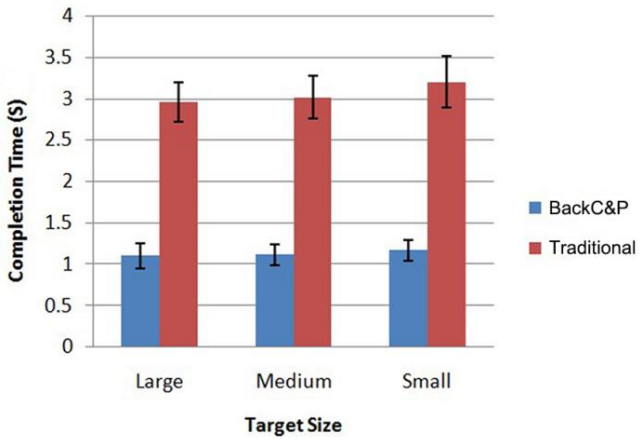

Fig. 5. Mean completion times of both techniques for each target size.

After the data adjustment, a repeated measures ANOVA was applied to the collected records. The result demonstrated a significant difference for Technique ($F(1,9) = 666.272$, $p < 0.001$), with the mean completion times of 1.13s for BackC&P and 3.06s for the traditional technique. BackC&P was almost twice faster than the traditional technique. One thing should be pointed out was that in the pre-study questionnaires nine participants chose the older method, which utilized the long-press action, when they answered the question "How do you trigger the paste menu on your smartphone?" However, after they were encouraged to use the tap action to trigger the paste menu in the study, only eight of the 2400 trials were completed by using the long-press actions. Therefore, if the participants utilized their frequently used method in the study, the difference in the completion times would have been even greater.

A significant main effect for Size ($F(2,18) = 17.813$, $p < 0.001$) was also found. Post hoc analysis indicated that the completion time of small targets (30 pixels) was significantly different from those of medium (50 pixels) and large targets (70 pixels). This was in line with the author's expectation that it would take more time to copy and paste a target whose size was much smaller than the fingertip of the operating finger. In addition, there was a significant interaction between Technique and Size ($F(2,18) = 12.526$, $p < 0.001$). A post hoc test indicated that BackC&P performed significantly better than the traditional technique in all three target sizes. Fig. 5 illustrates the mean completion times of both techniques for each target size.

The author also calculated the mean completion time of the trials that were operated by BackC&P and marked as error ones. The result was 2.60s, which was still shorter than that (3.06s) of the correct trials which were conducted by the traditional technique.

B. Copy Time Analysis

The grand mean copy time of the adjusted dataset was 1.16s (SD = 0.77s). A repeated measures ANOVA revealed a significant main effect for Technique ($F(1,9) = 616.068$, $p < 0.001$), with mean copy times of 0.48s and 1.81s for BackC&P and the traditional technique respectively. A significant main effect for Size ($F(2,18) = 9.506$, $p < 0.01$) was found as well.

Post hoc analysis indicated that the copy time of small targets was significantly different from those of medium and large targets. There was a significant interaction between Technique and Size ($F(2,18) = 6.151$, $p < 0.01$). Post hoc analysis showed that BackC&P performed significantly better than the traditional technique in all three target sizes. Fig. 6 shows the mean copy times of both techniques for each target size.

C. Paste Time Analysis

The grand mean paste time of the adjusted data was 0.95s (SD = 0.33s). A repeated measures ANOVA revealed a significant difference for Technique ($F(1,9) = 321.630$, $p < 0.001$), with mean paste times of 0.65s and 1.24s for BackC&P and the traditional technique respectively. A strong main effect for Size ($F(2,18) = 45.612$, $p < 0.001$) was also observed. Post hoc analysis indicated that the paste time of each target size was significantly different from those of the others. In addition, there was a significant interaction between Technique and Size ($F(2,18) = 20.731$, $p < 0.001$). Post hoc analysis showed that BackC&P performed significantly better than the traditional technique in all three target sizes. Fig. 7 shows the mean paste times of both techniques for each target size.

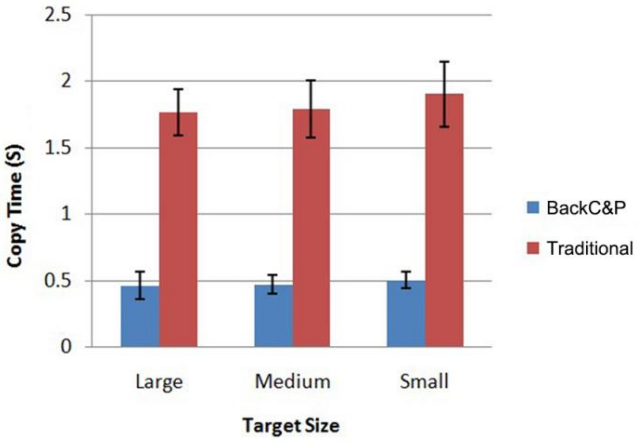

Fig. 6. Mean copy times of both techniques for each target size.

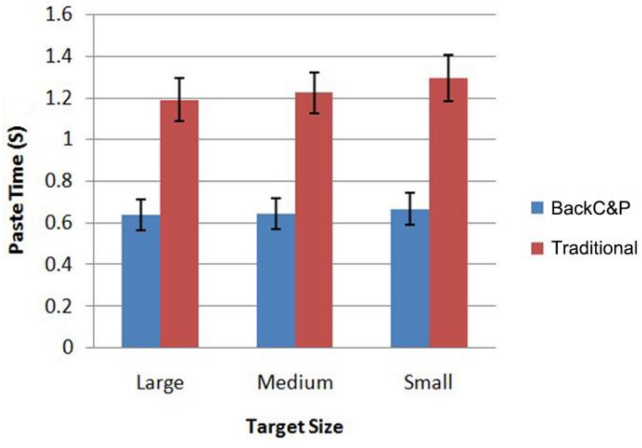

Fig. 7. Mean paste times of both techniques for each target size.

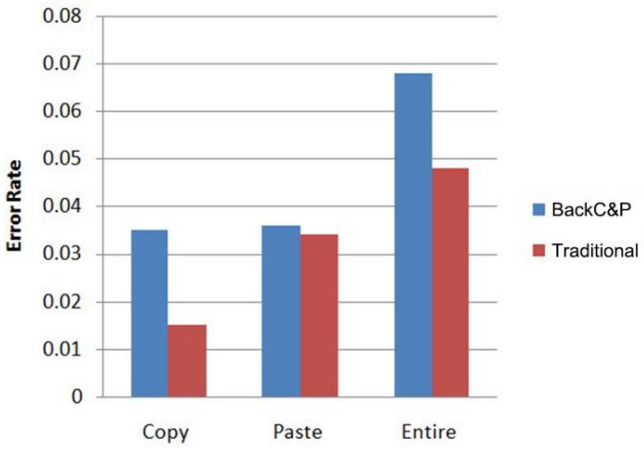

Fig. 8. Error rates of the copy operation, the paste operation, and the whole copy-and-paste operation.

D. Entire Error Analysis

There were totally 276 trials marked as error ones, in which participants made either copy errors or paste errors, or both. The grand mean error rate was 5.8%.

A repeated measures ANOVA showed no significant difference for Technique ($F(1,9) = 3.447$, $p = 0.096$), with mean entire error rates of 6.8% and 4.8% for BackC&P and the traditional technique respectively. Also, no significant main effect for Size ($F(2,18) = 2.059$, $p = 0.157$) was found. Fig. 8 shows the error rates of the copy operation, the paste operation, and the whole copy-and-paste operation.

E. Copy Error Analysis

There are four types of errors, which may occur during a copy operation, when using BackC&P, as shown in Table II. For the traditional technique, there are two types of errors: pressing outside the target and missing the copy menu.

There were totally 122 trials marked with copy errors, of which 85 trials was performed by BackC&P and 37 trials by the traditional technique. The number of copy errors of each error type of BackC&P was listed in Table II. Note that, there were two trials which committed both Copy Error I and Copy Error II. For the traditional technique, seven errors belonged to pressing outside the target while 30 errors pertained to tapping outside the copy menu.

The grand mean of the copy error rate was 2.5%. A repeated measures ANOVA revealed a significant difference for Technique ($F(1,9) = 9.618$, $p < 0.05$), with mean copy error rates of 3.5% and 1.5% for BackC&P and the traditional technique respectively. No significant main effect for Size ($F(2,18) = 1.696$, $p = 0.211$) was found.

F. Paste Error Analysis

There are four types of errors, which may occur during a paste operation using BackC&P, as shown in Table III. For the traditional technique, there are three types of errors: pressing outside the destination (Traditional Paste Error Type I, abbreviated TPET I), tapping outside the destination (TPET II), and missing the paste menu (TPET III).

TABLE II. THE COPY ERROR TYPES OF BACKC&P

Error Type	Descriptions	Error Number
Copy Error I	Hit the target on the front screen while the back-of-device input is in the Usual Mode II.	68
Copy Error II	Hit the target on the front screen while the back-of-device input is in the Paste Mode.	7
Copy Error III	Hit the target on the front screen while the back-of-device input is in the Usual Mode I.	0
Copy Error IV	Miss the target on the front screen.	12

TABLE III. THE PASTE ERROR TYPES OF BACKC&P

Error Type	Descriptions	Error Number
Paste Error I	Hit the destination on the front screen while the back-of-device input is in the Usual Mode II.	76
Paste Error II	Hit the destination on the front screen while the back-of-device input is in the Copy Mode.	5
Paste Error III	Hit the destination on the front screen while the back-of-device input is in the Usual Mode I.	1
Paste Error IV	Miss the destination on the front screen.	6

Fig. 9. The summary of answers collected from the post-questionnaires.

There were totally 168 trials marked with copy errors, of which 86 trials was conducted by BackC&P and 82 trials by the traditional technique. The number of paste errors of each error type of BackC&P was listed in Table III. Note that, there were two trials which committed both Paste Error I and Paste Error II. For the traditional technique, two errors belonged to TPET I, 24 errors belonged to TPET II, and the other 65 errors belonged to TPET III.

The grand mean paste error rate was 3.5%, which was higher than the grand mean copy error rate. A repeated measures ANOVA demonstrated no significant difference for Technique ($F(1,9) = 0.047$, $p = 0.834$), with mean paste error rates of 3.6% and 3.4% for BackC&P and the traditional technique respectively. In addition, no significant main effect for Size ($F(2,18) = 0.714$, $p = 0.503$) was found.

G. User Feedback

At the end of the study, a post-study questionnaire was answered by each participant. The purpose of the questionnaire was to collect the participants' first impressions on the interaction technique BackC&P.

From the post-study questionnaires, positive feedback on BackC&P was received from the participants that six of the ten participants chose BackC&P as their preferred technique for completing the copy-and-paste tasks. The other four participants treated the two techniques equally. None of participants specifically chose the traditional technique as their preferred technique.

In the post-study questionnaire, each participant was also asked to rate the items on a scale from 1 to 7, with 7 being the strongly agree. The summary of the collected results from the questionnaires is illustrated in Fig. 9. It can be seen that, on the whole, the participants deemed that BackC&P was easy to learn, easy to operate, comfortable to use, and less time-consuming.

VI. DISCUSSIONS

From the user study, the author found that BackC&P outperformed the traditional copy-and-paste technique on mobile devices in terms of efficiency. BackC&P achieves this mainly for two reasons. To begin with, BackC&P requires less front-of-device touch interactions for item acquisition than the traditional technique does. It accomplishes a copy-and-paste task with only two front-of-device touch actions, a tap to acquire the target and another tap to acquire the destination. As for the traditional technique, it needs four item acquisitions on the frontal touchscreen to complete the same task. In addition, BackC&P does not utilize the action of long-press, which is particularly time-consuming compared to interactions such as tapping [32], thereby tremendously saving the time for the copy operation.

In terms of error rate, the author found that for BackC&P, the most majority of the errors in copy and paste operations were caused by unsuccessfully lifting up the dedicated finger on the rear rather than by lifting the wrong finger on the rear, or by unsuccessfully acquiring the target or destination on the front screen. The author speculates that this might be due to the participants' attempt to finish the tasks in a shorter time. As copy and paste operations used in daily life are not as many and intensive as in the user study, these types of errors may be far less in actual use.

Also in terms of errors, the author found that for the traditional technique, the participants committed many more errors in acquiring the paste menu than acquiring the copy menu. The author deems that this difference is mainly due to the different mechanisms by which they trigger the two types of menus. For the copy operation, the user long-presses the target to trigger the copy menu, so he or she has more time to prepare to acquire the copy menu compared with the time to prepare to acquire the paste menu which is triggered by tapping. That is, acquiring a menu by a tap action following another tap action is less accurate than acquiring a menu by a tap action following a long-press action. It is interesting and meaningful to conduct a more comprehensive study in the future to investigate on the user performance in completing various tasks that require successive touch actions. The results

will provide us with more insights into designing better mobile touch user interfaces.

VII. CONCLUSION

Direct touch input enables users to interact with mobile devices with spontaneous and easy-to-use touch gestures. However, its limitations, e.g. time-consuming, still exist and negatively affect user experiences, especially in some frequently used simple tasks, e.g. copy and paste operations. In this paper, BackC&P, a mobile interactive technique which augments the copy and paste operations through the assistance of back-of-device touch input, is presented. The results of the user study indicate that with BackC&P users' efficiency in conducting copy and paste operations was tremendously improved on a mobile touch device, nearly two times faster than the currently used technique, and the accuracy was not significantly degraded during the entire process.

The current technique supports to copy and paste individual items, such as an image, a word, a chat message, a web link, etc. In the future, the author will explore extending the current technique to copy and paste a series of continuous items, such as several continuous words or sentences.

ACKNOWLEDGMENT

The author would like to express gratitude to the participants who participated in the user study. This research is funded by the Scientific Research Foundation of CUIT (No.KYTZ202274) and the National Natural Science Foundation of China (No. 62172081).

A Review: PTSD in Pre-Existing Medical Condition on Social Media

Zaber Al Hassan Ayon[1], Nur Hafieza Ismail*[2], Nur Shazwani Kamarudin[3]
Faculty of Computing, University Malaysia Pahang Al-Sultan Abdullah, 26600 Pekan, Pahang, Malaysia[1, 2, 3]

***Abstract*—Post-Traumatic Stress Disorder (PTSD) is a multifaceted mental health condition, particularly challenging for individuals with pre-existing medical conditions. This review critically examines the intersection of PTSD and chronic illnesses as expressed on social media platforms. By systematically analyzing literature from 2008 to 2024, the study explores how PTSD manifests and is managed in individuals with chronic conditions such as cancer, heart disease, and autoimmune disorders, with a focus on online expressions on platforms like X (formally known as Twitter) and Facebook. Findings demonstrate that social media data offers valuable insights into the unique challenges faced by individuals with both PTSD and chronic illnesses. Specifically, natural language processing (NLP) and machine learning (ML) techniques can identify potential PTSD cases among these populations, achieving accuracy rates between 74% and 90%. Furthermore, the role of online support communities in shaping coping strategies and facilitating early interventions is highlighted. This review underscores the necessity of incorporating considerations of pre-existing medical conditions in PTSD research and treatment, emphasizing social media's potential as a monitoring and support tool for vulnerable groups. Future research directions and clinical implications are also discussed, with an emphasis on developing targeted interventions.**

I. INTRODUCTION

Mental health disorders, including conditions such as PTSD, depression, and anxiety, represent a substantial global public health challenge. The World Health Organization (WHO) estimates that one in four individuals will experience a mental disorder at some point in their lives, underscoring the widespread impact of these conditions on physical health and overall well-being [1]. Among these disorders, PTSD stands out due to its association with severe psychiatric comorbidities, including depression, anxiety, and an elevated risk of suicide, as well as its potential to exacerbate pre-existing physical health conditions [2].

PTSD is commonly understood to develop following exposure to traumatic events, such as warfare, natural disasters, or severe interpersonal violence, including sexual assault. Based on our analysis recent research has expanded this understanding to include PTSD triggered by serious medical challenges, such as chronic illnesses (e.g., cancer, heart disease, kidney failure, and lung disease) and complications during childbirth. Notably, studies suggest that up to 30% of individuals who experience life-threatening medical conditions may develop PTSD, highlighting the significant psychological toll of such experiences [3, 4, 5].

The onset of PTSD in medical contexts can be attributed to several factors, including the emotional shock of receiving a serious diagnosis, the physical and psychological demands of treatment, and the pervasive fear of death or disability. These experiences can lead to profound feelings of helplessness, loss of control, and vulnerability, all of which are key contributors to the development of PTSD [4, 6, 7]. Despite the growing recognition of PTSD in medical settings, there remains a critical need to understand how individuals with pre-existing medical conditions navigate and manage their PTSD symptoms.

In recent years, social media has emerged as a valuable tool for individuals with PTSD to seek support, share experiences, and access information. The impact of social media uses on PTSD symptoms, particularly in individuals with pre-existing medical conditions, is not yet fully understood [8]. The spontaneous and candid nature of social media posts provides a unique lens into individuals' thoughts, feelings, and behaviors, potentially revealing early signs of PTSD.

Advancements in artificial intelligence (AI), particularly in ML and NLP, have enabled the development of sophisticated algorithms capable of detecting patterns indicative of PTSD in social media data. These technologies hold promise for identifying PTSD cases with considerable accuracy, facilitating early intervention and personalized treatment approaches [9, 10]. During our analysis of the research works, the ethical implications and privacy concerns associated with using social media data for mental health research warrant careful consideration.

This article aims to provide a comprehensive overview of the intersection between PTSD and pre-existing medical conditions, focusing on the role of social media and ML in the identification and management of PTSD. By synthesizing current research, this review seeks to inform future research directions and clinical practices, ultimately improving outcomes for individuals grappling with both PTSD and chronic medical conditions.

To further underscore the significance of this study, the motivations include addressing the critical gap in understanding the interplay between PTSD and chronic medical conditions. This research aims to provide actionable insights that inform both clinical practices and the development of supportive technologies for affected individuals. This work highlights the transformative potential

of social media analytics in mental health care, offering novel avenues for early intervention and monitoring.

II. Mental Health Disorders

Mental disorders, as defined by the WHO, involve significant disturbances in cognition, emotional regulation, or behavior, leading to distress or impairment in daily functioning [1]. These conditions, which encompass a wide range of disorders, adversely affect cognitive abilities, emotions, and social interactions. Accurate and timely assessments are critical for proper diagnosis and intervention. Traditionally, mental health screening has relied on self-report questionnaires designed to identify specific symptoms or attitudes related to social interactions [11].

The recognition of mental illness through diverse data sources and algorithms has been a significant focus of recent research, with AI playing a pivotal role. ML models, trained on various datasets, including self-reported questionnaires and EEG (Electroencephalogram) data, have been employed to predict mental health disorders such as depression and PTSD. Early studies utilized datasets annotated by domain experts, while more recent research has explored the potential of social media data in detecting mental illness [12, 13, 14].

Technological advancements have revolutionized psychiatric research, enabling the rapid collection and analysis of vast datasets through mobile phones, sensors, and social media platforms. ML, particularly in the context of advanced statistical and probabilistic methods, has proven effective in detecting mental health conditions [15]. A study on mental health recognition the authors employed ML techniques to analyze bipolar disorder using the Mood Disorder Questionnaire, while another study achieved 98.6% accuracy in detecting stress levels from bio-signals using supervised ML [11, 16]. Similarly, another study demonstrated a model for assessing psychiatric distress using EEG signals, employing algorithms such as Support Vector Machine (SVM), Logistic Regression (LR), and Naive Bayes (NB), with notable accuracy rates in stress detection [17].

In addition to ML, deep learning (DL) techniques have emerged as powerful tools in predicting depression risk. Context-DNN (Context Deep Neural Network) models, for instance, have been used to estimate the likelihood of depression [18]. Social media platforms, as a repository of user-generated content, have become valuable resources for observing mental states and psychiatric disorders. Studies have utilized platforms such as Reddit to analyze mental illness-related content through DL approaches, diagnosing chronic mental disorders like panic, bipolar disorder, and ADHD (attention deficit hyperactivity disorder) [19].

Other research has focused on detecting various mental illnesses, including schizophrenia, bipolar disorder, and PTSD, using data from platforms such as X, Facebook, and Weibo [18, 20]. Recent advancements in Large Language Models (LLMs) [86] have shown promise in recognizing mental health disorders from social media interactions, opening new possibilities for early identification and intervention [21]. LLMs are being explored as a tool to identify potential mental health concerns by analyzing text and speech patterns [22]. LLMs can be trained on large datasets of social media posts to identify patterns of language use associated with specific mental health conditions [23]. Regardless of the recent advancement of LLM in mental health identification, research and development are crucial to ensure accuracy and reliability before these tools can be integrated into clinical practice.

The expansion of social media has created unparalleled opportunities for mental health research, offering real-time insights into individuals' mental states. Advances in NLP and ML have enabled the identification of patterns in social media data that are indicative of mental health conditions, such as depression, anxiety, and PTSD. Studies have demonstrated the potential of these technologies to reveal linguistic markers and behavioral patterns associated with mental health issues, with predictive accuracy [6, 24]. Despite these advancements, the use of social media data for mental health research raises ethical concerns, including privacy issues, the risk of misdiagnosis, and potential stigmatization. The representativeness of social media data and the accuracy of self-reported mental health statuses remain areas of debate. Nonetheless, the integration of social media analysis into mental health research offers significant potential for early detection and intervention, potentially transforming the field of mental health care in the digital age.

Recent research has underscored the efficacy of combining social media data with LLMs for the diagnosis of mental health disorders, particularly in the early stages. The reluctance of many individuals to undergo mental health evaluations, coupled with the growing use of social media to share personal experiences, presents a unique opportunity for early diagnosis through social media analysis. The spontaneous and candid nature of social media expressions, when analyzed by sophisticated language models, can reveal subtle indicators of mental health issues that might otherwise go undetected. This approach holds significant promise for revolutionizing early intervention strategies in mental health care, potentially leading to improved outcomes through timely diagnosis and treatment initiation.

III. PTSD in Pre-Medical Conditions

PTSD is a complex psychiatric condition that arises from exposure to traumatic events or prolonged distressing circumstances [25]. Traditionally associated with combat veterans and survivors of violence or natural disasters, PTSD also manifests in patients with pre-existing medical conditions, posing significant challenges for both patient care and treatment outcomes. The intersection of PTSD and chronic illness is an increasingly important area of study, with far-reaching implications for healthcare practices and economics.

The prevalence of PTSD is substantial, with approximately 3.5% of U.S. adults affected annually, and lifetime prevalence reaching 8% among adolescents aged 13-18 [26]. Globally, data from the World Mental Health Survey Consortium reveal that over 70% of the population has experienced at least one traumatic event, highlighting the widespread potential for PTSD development [27]. In the medical context, patients diagnosed with conditions such as cancer, heart disease, and

chronic respiratory illnesses are at heightened risk for PTSD, with the psychological burden of these conditions creating fertile ground for trauma-related stress responses [28, 29]. This bidirectional relationship, where PTSD exacerbates physical symptoms and impairs treatment outcomes, underscores the importance of recognizing and addressing PTSD within medical populations [30].

The Coronavirus disease (COVID-19) pandemic has further emphasized the link between PTSD and medical conditions, with survivors of severe infections displaying PTSD symptoms, particularly among those with risk factors like a history of psychiatric disorders or experiences of delirium during illness [28]. The pandemic itself is a traumatic event capable of inducing PTSD, as evidenced by studies showing high prevalence rates due to factors such as lockdowns, economic instability, and social isolation [21, 31].

Another critical area of concern is childbirth-related PTSD (CB-PTSD). Approximately 6% of women experience CB-PTSD, affecting about eight million women globally in 2022 [32, 33]. High-risk factors include medically complicated deliveries, obstetrical complications, and maternal near-miss incidents [34, 35]. Racial and ethnic disparities exacerbate these risks, with Black and Latin women nearly three times more likely to exhibit acute stress responses to childbirth [32]. Overall, about 20% of high-risk individuals are likely to develop CB-PTSD [32].

The Diagnostic and Statistical Manual of Mental Disorders, 5th edition (DSM-5), identifies core PTSD symptoms such as intrusive memories, avoidance, negative alterations in cognition and mood, and heightened arousal [36]. In medical contexts, these symptoms may manifest as flashbacks to painful procedures, avoidance of necessary treatments, and negative health beliefs, complicating medical management [37, 38]. Early detection and trauma-informed interventions are thus crucial in these settings to prevent misdiagnosis and ensure comprehensive care [30].

While effective treatments for PTSD, including psychotherapy and pharmacotherapy, are available, co-occurring conditions such as depression and substance use disorders complicate recovery. Addressing both psychological and physiological aspects of trauma through integrated care approaches is essential for improving patient outcomes [39].

The interplay between PTSD and pre-existing medical conditions warrants ongoing research and clinical focus. Future studies should aim to develop tailored interventions for specific medical populations, explore the neurobiological mechanisms of medical trauma-induced PTSD, and assess the long-term effectiveness of integrated care models. Advancing our understanding in this area will contribute to more compassionate and effective care for those grappling with the dual challenges of medical conditions and PTSD [40].

IV. Mental Health Assessment for Diagnosis

Mental health assessment is a fundamental component of diagnosing and managing psychological and psychiatric disorders, requiring a multifaceted approach that integrates neuroimaging, physiological and laboratory analyses, clinical interviews, psychometric tools, and increasingly, social media data analysis [41]. This comprehensive methodology provides a nuanced understanding of the interplay between neurobiological, physiological, psychosocial, and digital behavioral factors underlying mental health conditions.

Neuroimaging techniques, particularly functional magnetic resonance imaging (fMRI) and positron emission tomography (PET), have become essential in identifying the neural substrates associated with various psychiatric disorders. For example, depressive disorders often involve reduced activity in the prefrontal cortex and increased amygdala activation, while schizophrenia is linked to anomalies in frontal and temporal lobe function [42]. These neurobiological insights are crucial for developing targeted and personalized therapeutic interventions [40].

Physiological and laboratory analyses complement neuroimaging by identifying underlying medical conditions that may contribute to psychiatric symptoms, such as thyroid dysfunction or nutritional deficiencies [43]. Comprehensive medical evaluations, including hematological profiles, endocrine function tests, and genetic analyses, are instrumental in guiding effective treatment strategies tailored to individual needs [43, 44].

Clinical interviews and standardized psychometric instruments remain central to mental health assessment. These methods allow clinicians to systematically gather detailed information on an individual's symptoms, personal and familial history, and functional impairments across various domains of life. The mental status examination, a critical component of the clinical interview, evaluates cognitive and behavioral domains such as affect, thought processes, and memory functions [45], offering crucial insights into the individual's psychological state and potential neuropsychiatric impairments.

Recently, the analysis of social media data has emerged as a promising addition to mental health assessment. The widespread use of social media platforms provides researchers and clinicians with real-time, naturalistic data on individuals' thoughts, emotions, and behaviors. This digital footprint can offer valuable insights into mental health trajectories and conditions.

NLP and ML algorithms have been developed to analyze social media content for markers of mental health conditions. For instance, changes in social media activity, linguistic style, and emotional expression have been used to predict the onset of depression with considerable accuracy [6]. Similarly, researchers have demonstrated the potential to diagnose PTSD from X data [24].

The integration of social media data analysis into mental health assessment offers several advantages:

- Early detection: Social media analysis can identify subtle changes in behavior or language indicative of emerging mental health issues before clinical symptoms appear.
- Continuous monitoring: Unlike traditional assessments, social media provides a continuous stream of data,

allowing for dynamic and responsive monitoring of mental health.

- Ecological validity: Social media reflects individuals' behaviors in natural environments, offering potentially more valid insights than clinical settings.
- Reach and accessibility: Social media analysis can extend mental health screening to populations that may not access traditional mental health services.

Nevertheless, the use of social media data in mental health assessment also presents significant ethical and practical challenges, including concerns about privacy, consent, data security, and the potential for misinterpretation. Additionally, biases in social media use and algorithmic analysis could lead to disparities in assessment and diagnosis [46, 47].

The integration of social media data with traditional assessment methods requires careful validation and robust ethical guidelines. Ongoing research is focused on refining algorithms, establishing normative data, and developing best practices for the responsible use of social media data in mental health assessment [46].

V. PTSD Diagnosis on Social Media

The advent of social media has markedly transformed how individuals express and manage mental health conditions, including PTSD. While traditional diagnostic methods remain essential, social media platforms offer novel avenues for researchers and clinicians to explore the lived experiences of those with PTSD. This is particularly crucial given the high prevalence of PTSD among veterans, with 15-20% affected, highlighting the need for innovative approaches to address this critical issue [5].

Historically, PTSD identification in populations such as cancer survivors has relied on questionnaires, but these are time-consuming and impractical for large-scale studies. Methods like fMRI, though informative, are cost-prohibitive for widespread use. An alternative approach involves analyzing public social media posts, which offer quick, accessible data from a broad audience. A pioneer study on PTSD in cancer patients reports that approximately 60% of adults use online resources for health information, and social media platforms allow individuals to discuss health concerns more openly than in face-to-face interactions [20]. Previous studies have utilized platforms like Reddit to detect early indicators of mental health disorders, while others have analyzed Twitter data to understand language patterns among PTSD patients with a history of cancer [7, 46, 47].

The challenge of accurately diagnosing PTSD, particularly in cancer survivors, is compounded by the lack of measurable data, a gap that motivates the collection of social media data for analysis. Various statistical methods, including correlations, chi-square tests, and regression analyses, have been employed to evaluate mental health datasets, revealing variables closely associated with mental health diagnoses [48]. ML algorithms, both supervised and unsupervised, have proven effective in tracking mental illness symptoms with high diagnostic accuracy. For instance, linear discriminant analysis has been used to explore social media content, identifying topics relevant to mental health [7, 24].

Recent studies highlight the potential of social media analysis to identify symptoms like anger associated with PTSD, particularly within the veteran community. This method shows promise as a preventative measure, enabling early detection and timely intervention. The complex nature of military service, including exposure to combat and the difficulty in distinguishing combatants from non-combatants, contributes to the high prevalence of PTSD among veterans, underscoring the urgency of exploring new strategies like social media analysis for supporting military personnel's mental health [6].

Advanced ML techniques, such as recurrent neural networks (RNN), deep neural networks (DNN), and convolutional neural networks (CNN), are increasingly employed for text processing in mental health research. Sentiment analysis on X data, for example, has been suggested for understanding the context of communication and dialogue related to mental health [49].

In a novel approach, recent research has explored the detection of CB-PTSD using LLMs like Bio_ClinicalBERT and BioGPT, which have outperformed ChatGPT in clinical tasks. This study reveals that approximately 6% of the global childbearing population, or over eight million women annually, develop CB-PTSD, significantly impacting mothers and their children. The generative AI model such as Open AI text embedding (ADA), by analyzing maternal narratives, achieved an F1 score of 0.81 in identifying PTSD, indicating its potential to generalize to other mental health disorders [27].

As mental health research continues to evolve, the integration of social media data analysis holds significant potential for enhancing our understanding of PTSD. Leveraging user-generated content on these platforms allows researchers to gain deeper insights into PTSD symptoms, triggers, and coping mechanisms. This real-time, granular data can complement traditional survey methods, facilitating the early identification of mental health issues and the development of personalized interventions. Additionally social media analysis can inform public health initiatives, guiding resource allocation and outreach programs to address the mental health needs of vulnerable populations, particularly veterans and active-duty military personnel.

VI. Text Classification in PTSD Identification

Accurately classifying and diagnosing PTSD in medical settings remains a formidable challenge, with significant implications for patient outcomes and healthcare resource allocation. PTSD, a prevalent psychiatric disorder, especially among military personnel and veterans, manifests in severe symptoms that drastically impair quality of life [4].

This review addresses the complexities of PTSD classification and diagnosis by exploring key processes, starting with the identification of robust data sources, such as clinical records, screening questionnaires, and social media content. These diverse data sources provide a comprehensive foundation for analyzing PTSD symptoms. Following data collection, precise annotation is crucial, as it involves

accurately labelling symptoms essential for training effective models. Feature selection further refines the dataset, ensuring that the most relevant PTSD indicators are highlighted, thus enhancing model accuracy.

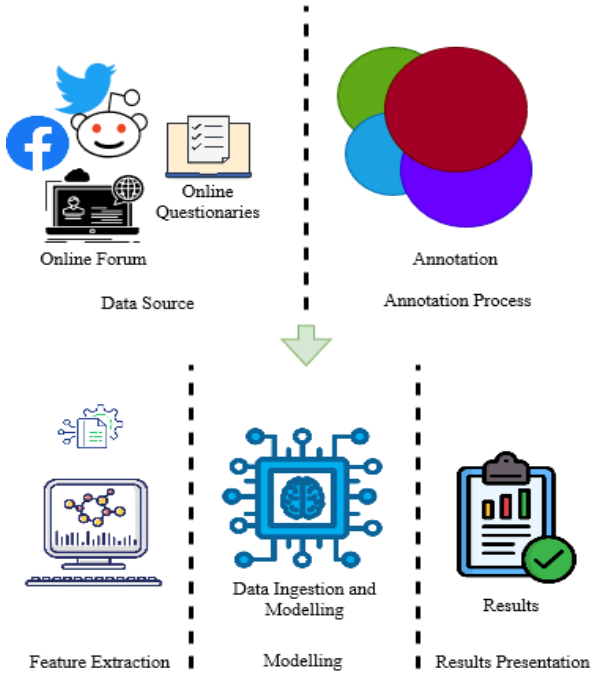

Fig. 1. Generic representation of PTSD identification from social media data.

Fig. 1 depicts a general approach followed by the reviewed studied related to identification of mental health disorder from social media data. As data source most of the studies. All most every study mentioned about human annotation via domain experts. Finally descriptive or inferential model training and feature extraction processes were followed to get class probability distribution.

Advanced modelling techniques, particularly ML algorithms, are then applied to predict PTSD presence. These models undergo rigorous testing to ensure robustness, with results critically analyzed to evaluate their effectiveness in medical settings. This process not only offers insights into the practical application of these models but also identifies potential areas for further refinement and research, ultimately contributing to more accurate PTSD diagnoses and improved patient care.

A. Data Sources

In recent years, researchers have utilized a range of data collection methods to explore the intersection of PTSD, pre-existing medical conditions, and social media engagement. This review synthesizes the key data sources employed in this burgeoning field, critically examining their strengths, limitations, and overall contributions to advancing our understanding of this complex and multifaceted issue. By integrating findings from diverse methodologies, this review seeks to provide a comprehensive overview of how these data sources have informed current research and to identify potential avenues for future inquiry.

1) Questionnaires: Several studies have employed online self-administered screening questionnaires to evaluate the prevalence of PTSD symptoms among individuals with pre-existing medical conditions who are active on social media platforms [24, 50]. These questionnaires are designed to collect comprehensive data, including demographic information, medical history to identify pre-existing conditions, and responses to validated PTSD screening tools such as the PTSD Checklist for Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) also known as PTSD Checklist Fifth Edition (PCL-5) Additionally, they include questions regarding social media usage and online behavior, enabling researchers to examine the relationship between PTSD symptoms and social media engagement.

The primary advantage of this approach is its capacity to generate quantitative data on the prevalence of PTSD symptoms and to explore the potential correlation between these symptoms and social media use. Even though it is important to acknowledge the methodological limitations inherent in this approach, particularly the risk of self-selection bias and the potential for underreporting or overreporting of symptoms within online environments. These factors must be carefully considered when interpreting the results to ensure the validity and reliability of the findings.

2) Online discussion sites: Numerous studies have investigated online discussion sites, including mental health forums and support groups, to gain insights into the experiences of individuals dealing with PTSD alongside pre-existing medical conditions [51, 52]. Key data sources for these studies include Reddit communities (subreddits) focused on PTSD and chronic illnesses, established mental health support forums, and condition-specific forums where mental health discussions are prevalent. These platforms provide rich qualitative data that allow for a nuanced analysis of personal narratives and coping mechanisms. The anonymity inherent to these platforms poses challenges in verifying the authenticity of the reported experiences.

3) Social media platforms: Individuals with chronic conditions are more likely to engage with health-related content on social media, while those with mental health conditions tend to engage less frequently [53]. An expanding body of research has focused on analyzing the social media activity of individuals who publicly discuss their mental health issues, including PTSD, in conjunction with pre-existing medical conditions [6, 54]. These studies typically investigate X posts using relevant hashtags, public Facebook groups dedicated to PTSD and chronic illness support, and Instagram posts with captions referencing both PTSD and other medical conditions.

This methodological approach provides valuable insights into how individuals publicly navigate their experiences with PTSD and pre-existing medical conditions on social media platforms. Researchers must also carefully consider ethical concerns related to privacy and consent when utilizing

publicly available data, as these factors are critical to maintaining the integrity and ethical standards of the research [55].

The triangulation of diverse data sources has emerged as a best practice in this field, enabling researchers to obtain a comprehensive understanding of how PTSD manifests and is discussed within the context of pre-existing medical conditions on social media platforms [56, 57]. This multi-faceted approach facilitates both the quantitative assessment of symptom prevalence and the qualitative analysis of lived experiences and online behaviors.

Despite the benefits of these methods, researchers face several challenges when utilizing these data sources. First, representativeness is a significant concern; social media users may not accurately reflect the broader population of individuals with PTSD and pre-existing medical conditions [58]. For instance, Biernesser et al. found that social media data often over represent younger, more technologically savvy demographics, potentially leading to skewed results [58]. Second, the quality of data is a critical issue, as the reliability and validity of self-reported information on social media platforms can be questionable. This necessitates rigorous verification and cross-referencing of data, as highlighted by a study conducted by Torous et al., which emphasized the need for robust data cleaning and validation processes in mental health research using social media data [59].

Ethical considerations also play a crucial role, particularly in balancing the need for research with privacy concerns and informed consent. Golder et al. proposed a framework for ethical social media research in health contexts, emphasizing the importance of protecting user privacy and obtaining appropriate consent [60]. Additionally, technological barriers must be considered; the rapid evolution of social media platforms and their algorithms can impact data collection and analysis methods, requiring researchers to continuously adapt their approaches. Staying informed about platform changes and their implications for data accessibility and analysis is essential [61].

Future research in this domain would benefit from the development of standardized protocols for social media data collection and analysis, alongside the exploration of innovative approaches to integrating online and offline data sources. Such integration could yield a more comprehensive understanding of PTSD in the context of pre-existing medical conditions. Conway and O'Connor on their study suggest that combining traditional clinical data with social media insights could enhance the robustness and generalizability of findings [62]. By critically examining these diverse data sources and their applications, researchers can refine their methodologies and contribute meaningfully to the expanding body of literature at the intersection of mental health, chronic illness, and digital spaces.

B. Data Annotation

Data annotation is pivotal in the analysis of social media content for PTSD and other mental health conditions, playing a crucial role in ensuring the validity and reliability of research findings. This process involves several key methods and tools, each contributing uniquely to the field. A fundamental aspect of data annotation is the identification and labelling of specific PTSD symptoms in social media posts. Researchers utilize a variety of techniques for this task, ranging from NLP and ML algorithms to manual coding by trained clinicians and keyword-based approaches [6, 24, 63]. These methods are designed to detect symptoms such as re-experiencing, avoidance, negative alterations in cognition and mood, and heightened arousal, with each approach balancing considerations of efficiency, accuracy, and scalability.

Another critical component of this process is establishing the ground truth for data collection, which involves validating annotated data against reliable sources. This validation can be achieved through clinical verification via interviews, self-reported PTSD symptom measures, or comparisons with clinician-diagnosed cases [49, 64]. Human annotators continue to play an essential role in this process, providing a nuanced understanding and insights that may be difficult to capture through automated methods alone. Expert annotators, such as mental health professionals, offer high-quality annotations based on clinical expertise, while trained lay annotators and crowdsourcing platforms provide scalable alternatives, albeit with the necessity of rigorous quality control [9, 65].

To deepen the analysis, researchers frequently incorporate additional tools and measures. Depression survey scores, such as the Patient Health Questionnaire-9 (PHQ-9), are often used alongside PTSD assessments to evaluate symptom severity and understand comorbidities [6, 66]. The Linguistic Inquiry and Word Count (LIWC) tool has also gained prominence for its ability to analyze linguistic patterns in social media posts, offering valuable insights into the emotional and cognitive processes associated with PTSD [49, 63].

Recently, the advent of LLMs as annotators has introduced new possibilities in data annotation for PTSD research. LLMs such as GPT-3 and Bidirectional Encoder Representations from Transformers (BERT) show considerable promise in automating symptom detection and efficiently processing vast amounts of data [67, 68, 69]. However, their use raises important considerations. Ethical concerns related to privacy and consent, the inherent lack of clinical expertise in these models, limitations in understanding broader contextual nuances, and issues of reliability and transparency present significant challenges. While LLMs offer potential benefits in terms of scalability and efficiency, their application in mental health contexts requires careful validation against established clinical standards and ongoing scrutiny to ensure ethical and accurate annotations.

In conclusion, the process of data annotation for PTSD research on social media is continuously evolving, with each method presenting distinct strengths and limitations. A balanced approach that integrates human expertise with technological advancements appears most promising. As the field advances, researchers must skillfully navigate the complexities of various annotation methods, striving for a harmonious integration that ensures both efficiency and clinical relevance in the pursuit of understanding PTSD through social media data.

C. Feature Selection

In the context of analyzing PTSD in individuals with pre-existing medical conditions on social media, feature selection is critical for identifying the most relevant characteristics that enhance the effectiveness of predictive modelling. Researchers utilize a range of techniques to distil meaningful features from the extensive data available on social media platforms. Commonly extracted textual features include word frequency, n-grams, and sentiment scores derived from posts and comments, which provide insights into the language patterns associated with PTSD [24]. Temporal patterns of social media activity, such as posting frequency and the time-of-day posts are made, have also proven significant in detecting PTSD, offering a behavioral dimension to the analysis [6].

In addition to these features, researchers frequently incorporate user profile information and engagement metrics, which may serve as potential indicators of PTSD symptoms. Advanced approaches further enhance the analysis by leveraging NLP techniques to capture semantic and contextual features, such as topic modelling and word embeddings, allowing for a deeper understanding of the content and its relevance to PTSD [69].

The primary challenge in feature selection lies in balancing the richness of these features with the risk of overfitting, particularly given the complex and multifaceted nature of PTSD and its interactions with pre-existing medical conditions. To address this, dimensionality reduction techniques like Principal Component Analysis (PCA) and t-SNE are often employed. These methods help manage high-dimensional feature spaces by condensing the data while preserving the most critical information [70].

Recent studies have explored the use of automated feature selection methods, including wrapper and embedded techniques, which optimize the feature set for detecting PTSD in the context of comorbid conditions. These methods offer a systematic approach to refining feature selection, thereby improving model accuracy and robustness [71].

By carefully selecting and refining features, researchers can build more effective models that not only predict PTSD but also account for the complexity of its interactions with other medical conditions, ultimately contributing to more accurate and meaningful insights in mental health research.

D. Modeling

The modelling approaches employed in studying PTSD among individuals with pre-existing medical conditions on social media encompass a broad spectrum of techniques, ranging from traditional statistical methods to cutting-edge ML and DL algorithms.

Statistical methods have long served as the cornerstone of research in this field, providing foundational tools for analysis. LR remains a widely favored approach due to its interpretability and its capability to quantify the relationship between various features and the likelihood of PTSD [24]. Additionally, survival analysis techniques, particularly Cox proportional hazards models, are frequently used to explore the temporal dynamics of PTSD development in individuals with pre-existing conditions, identifying key risk factors over time [16]. Multilevel modelling has gained prominence for its ability to account for the nested structure of social media data—such as posts within users and users within platforms—thereby accommodating the hierarchical nature of the data and enhancing the accuracy of the analysis.

ML methods have also been pivotal in advancing PTSD detection and risk assessment. SVMs, known for their effectiveness in handling high-dimensional feature spaces, have been successfully applied to classify social media users with PTSD [13, 14]. Random Forests and Gradient Boosting Machines offer robust performance by managing complex interactions between features, making them particularly valuable in assessing the interplay between PTSD and co-existing medical conditions [41] [85]. Ensemble methods, which combine the strengths of multiple algorithms, have demonstrated superior accuracy and generalizability in PTSD prediction models [12].

The rise of DL has introduced powerful tools for analyzing the unstructured and complex nature of social media data in PTSD research. CNNs have been utilized to detect PTSD-related language by capturing local patterns in text data, demonstrating their efficacy in this domain [17]. RNNs, especially Long Short-Term Memory (LSTM) networks, excel in modeling temporal dependencies in social media activity, making them well-suited for identifying patterns associated with PTSD [23] Transformer-based models, such as BERT and its variants, have emerged as particularly effective in understanding the nuanced contexts in which PTSD expressions occur in social media posts. These models, when fine-tuned on domain-specific data, can capture subtle linguistic cues indicative of PTSD [19]. Additionally, the use of graph neural networks is gaining traction, as they can model the complex relationships between users, posts, and symptoms in social networks, offering a novel perspective on understanding PTSD within the dynamics of online social interactions [34].

Recently, LLMs have revolutionized PTSD research on social media by providing advanced capabilities for feature extraction and modelling. Pre-trained on vast text corpora, these models bring a sophisticated understanding of language and context, which is essential for identifying PTSD. Researchers have explored several applications of LLMs in this area. For instance, fine-tuning approaches adapt pre-trained models like BERT to the specific task of detecting PTSD in social media texts, capturing subtle linguistic and contextual nuances associated with PTSD symptoms [22]. Another approach leverages LLMs as feature extractors, utilizing the rich representations learned by these models as inputs for other ML algorithms [10]. Recent studies, such as those by Yang et al. have developed frameworks using ChatGPT and LLaMA-2 to automate PTSD assessments from clinical interviews, highlighting the potential of LLMs to enhance diagnostic accuracy [23]. Additionally, a group of researchers introduced innovative text augmentation methods using LLMs to address data imbalance issues in PTSD diagnosis, further demonstrating the versatility and impact of these models [72].

In summary, the evolution of modeling approaches in PTSD research on social media reflects a dynamic interplay between traditional and modern techniques. By integrating statistical methods, ML, DL, and LLMs, researchers can achieve a more nuanced and comprehensive understanding of PTSD in individuals with pre-existing medical conditions, ultimately advancing the field's ability to accurately detect and model this complex disorder. Fig. 2 depicts the general approach followed by many studies to implement AI modeling with NLP.

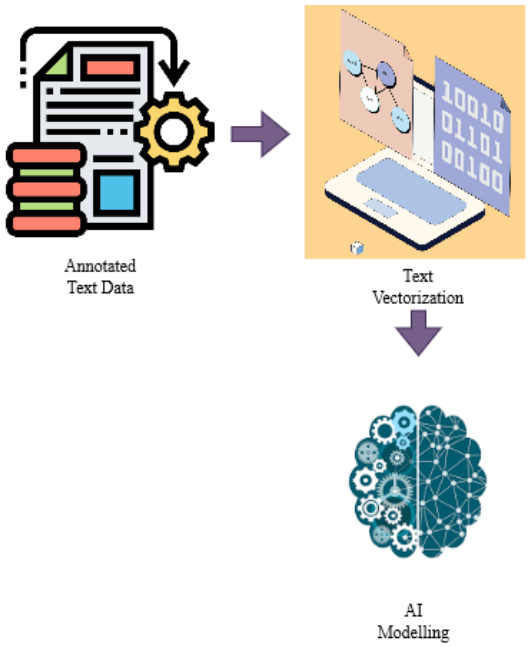

Fig. 2. Generic artificial intelligence predictor modelling.

E. Results

The study of PTSD in individuals with pre-existing medical conditions using social media data has yielded significant insights through various modeling approaches. Statistical methods, including survival analyses, have identified critical time windows for intervention following diagnoses of conditions like chronic pain and autoimmune disorders, emphasizing the need for timely support [73, 74, 75]. Traditional ML models, such as SVMs and Random Forests, have demonstrated strong performance, with accuracy rates between 75-85% and AUC scores exceeding 0.90 in some cases [24, 76, 77]. The variability in performance across different conditions indicates that these models require further tuning for condition-specific applications. DL techniques, such as CNNs, LSTMs, and Transformer-based models like BERT, have advanced PTSD detection by capturing nuanced language patterns in social media posts, achieving precision rates up to 88% and F1 scores between 0.85-0.90 [9, 37]. The "black box" nature of these models presents challenges for clinical application due to difficulties in interpretability [78].

Sentiment analysis tools, such as the LIWC tool and the VADER (Valence Aware Dictionary for Sentiment Reasoning) tool, have shown promise in identifying mental health conditions. LIWC has revealed significant differences in the linguistic style of individuals experiencing emotional distress compared to those who are not, suggesting its utility in mental health detection [19]. VADER, known for its computational efficiency and extensive word corpus, has been used effectively to predict depression risk based on sequential social media messages, demonstrating the evolving nature of sentiment analysis in this field [79]. Feature engineering methods, including bag-of-words and N-grams, combined with these sentiment analysis tools, have achieved accuracy rates ranging from 74% to 82%, suggesting that text-based screening tools hold substantial potential for identifying individuals at risk of PTSD or related mental health conditions [79, 80].

LLMs, such as GPT-3 and text-embedding-ada-002, have shown impressive accuracy in detecting PTSD, with F1 scores and accuracy rates up to 0.82 and 83%, respectively [81, 82]. Despite the progress, challenges remain, particularly with the "black box" nature of advanced models, computational demands, and privacy concerns [83, 84]. Traditional ML and sentiment analysis tools provide a good balance of accuracy and interpretability but often lack the depth to capture complex PTSD manifestations. DL models and LLMs offer superior performance in detecting nuanced expressions of trauma but suffer from interpretability and ethical concerns, which limit their practical use in clinical settings. The integration of these methods with a focus on improving interpretability and ethical use is crucial for advancing PTSD detection and intervention strategies.

VII. Conclusion and Future Work

This review has examined the intersection of PTSD, pre-existing medical conditions, and social media behavior, highlighting the significant advancements in the field from basic keyword analysis to the application of sophisticated ML and LLMs. These developments demonstrate substantial potential for the early detection and intervention of PTSD among individuals with chronic health conditions.

Despite these advancements, several critical knowledge gaps persist. First, there is currently no consensus on best practices for data collection, annotation, and analysis in social media-based PTSD research, particularly in the context of comorbid conditions. Additionally, most of the existing research relies on cross-sectional data, leaving the temporal dynamics of PTSD development in individuals with pre-existing conditions inadequately understood. Furthermore, a significant disconnect exists between insights derived from social media and their application in clinical practice, limiting the practical utility of research findings. The specific interactions between certain medical conditions and PTSD manifestations on social media are also not sufficiently studied. Comprehensive ethical guidelines for the use of AI in mental health detection on social media are lacking, raising concerns about privacy, consent, and the responsible use of predictive models.

To address these gaps, future research should prioritize the following areas. First, establishing clear guidelines for data collection, annotation, and analysis is essential to enhance the reproducibility and comparability of studies across the field. Collecting users single post and training an inferential model for prediction might not give the model full understanding of

sarcasm, jokes, humor due incomplete reasoning over the dataset. Second, designing long-term studies that track PTSD development in individuals with pre-existing conditions, using continuous social media data, will provide deeper insights into the temporal dynamics of PTSD. Third, combining social media data with electronic health records and data from wearable devices can offer a more comprehensive understanding of PTSD in the context of comorbid conditions.

Fourth, creating adaptive models that account for individual differences and specific interactions between pre-existing conditions and PTSD is crucial for enhancing the accuracy and relevance of predictive tools. Fifth, developing methods to make advanced models, particularly LLMs, more interpretable for clinical application is vital for their effective integration into healthcare settings. Sixth, expanding research to include diverse cultural contexts will help in understanding varying PTSD manifestations and social media usage patterns across different populations. Lastly, establishing robust ethical frameworks for the use of AI in mental health contexts is necessary to address issues of consent, privacy, and the responsible deployment of predictive models.

In conclusion, while social media analysis offers unprecedented opportunities for understanding PTSD in the context of pre-existing medical conditions, realizing its full potential requires addressing these significant knowledge gaps. Future research should focus on standardization, longitudinal studies, and the development of ethical, interpretable AI models that can be effectively integrated into clinical practice. Interdisciplinary collaboration will be crucial in translating these research insights into tangible improvements in mental health care for individuals living with both PTSD and chronic medical conditions.

CIPHomeCare: A Machine Learning-Based System for Monitoring and Alerting Caregivers of Cognitive Insensitivity to Pain (CIP) Patients

Rahaf Alsulami[1], Hind Bitar[2], Abeer Hakeem[3], Reem Alyoubi[4]
Information Systems Department, King Abdulaziz University, Jeddah, Saudi Arabia[1, 2]
Information Technology Department, King Abdulaziz University, Jeddah, Saudi Arabia[3]
Pediatric Department, King Abdulaziz University Hospital, Jeddah, Saudi Arabia[4]

***Abstract*—Congenital Insensitivity to Pain (CIP) patients, particularly infants, are vulnerable to self-injury due to their inability to perceive pain, which can lead to severe harm, such as biting their hands. This research introduces "CIPHomeCare," a wearable monitoring solution designed to prevent self-injurious behaviors in CIP patients aged 6 to 24 months. The primary focus of this study is developing and applying machine learning algorithms to classify hand-biting behaviors. Using accelerometer data from the STEVAL-BCN002V1 sensor, which is a motion sensor, several machine learning models—K-Nearest Neighbors (KNN), Random Forest (RF), Naive Bayes (NB), Linear Discriminant Analysis (LDA), and Logistic Regression (LR)—were trained to differentiate between normal and harmful behaviors. To address data imbalance due to the infrequency of biting events, oversampling techniques such as SMOTE, Borderline-SMOTE, ADASYN, K-means-SMOTE, and SMOTE-ENN were employed to enhance classification performance. Among the algorithms, KNN achieved the highest accuracy (98%) and a sensitivity of 72%, highlighting its effectiveness in detecting harmful hand motions. The findings suggest that machine learning, in combination with wearable technology, can provide accurate, personalized monitoring and timely intervention for CIP patients, paving the way for broader clinical applications and real-time prevention of self-injury. The real-time processing capability of the system enables immediate alerting of caregivers, allowing for timely intervention to prevent injuries, thus improving their quality of life.**

Keywords*—Cognitive insensitivity to pain patients; CIP; machine learning; motion sensors; quality of life; wearable activity recognition

I. Introduction

One of the significant challenges that patients with CIP face is the late detection of injuries, as they are unable to feel pain. For instance, infants with CIP may inadvertently harm themselves while teething, sometimes biting their tongues to the point of cutting off the tip or gnawing on their hands until they bleed [1, 2, 3]. These behaviors can lead to severe self-mutilation or, in extreme cases, amputation [4]. Researchers have noted that due to the lack of pain perception and visible signs of distress, serious injuries can occur, including premature self-extraction of teeth [3, 5]. Therefore, it is crucial to provide patients, particularly infants and their caregivers, with coping strategies for this disorder. Such support can enhance their quality of life (QoL), defined as the impact of a disease, disability, or disorder on an individual's physical and mental well-being over time [6].

While most research on CIP has concentrated on understanding the disorder's characteristics [7, 8], there is a notable lack of studies that focus on developing coping mechanisms, especially in comparison to other conditions like attention deficit hyperactivity disorder. To date, and based on the authors' knowledge, there has been only one significant attempt to address the challenges faced by CIP patients: the design and fabrication of an assistive technology glove that alerts patients to extreme temperature variations in their environment [9]. However, this solution has limitations, as it may not fully address the broader range of self-injurious behaviors these patients experience. The glove primarily targets temperature awareness, leaving other critical aspects of injury prevention unaddressed. This highlights the need for more comprehensive interventions that can provide holistic support for individuals with CIP. It is essential to develop targeted solutions that address their specific needs. One critical area of focus is the issue of finger-biting behaviors, which can lead to severe self-injury and long-term consequences.

Providing a good quality of life for CIP disorder patients is the primary motivation of this research study. CIP disorder holds the potential to worsen the overall health of patients by limiting their capacity to live well and their functional status and productivity. This research focuses on finger-biting behaviors and aims to develop a solution called 'CIPHomeCare,' specifically designed for infants with CIP aged 6 to 24 months and their caregivers during the teething stage. Addressing this behavior is vital, as it not only helps prevent immediate physical harm but also supports the overall emotional and psychological well-being of patients and their families. Equipping caregivers with practical tools to monitor and manage these behaviors is essential; however, a key challenge is determining how to alert caregivers when a child with CIP begins to injure their hands. Specifically, there is a need to detect when a child's biting reaches a predefined limit and notify caregivers of the risk of injury.

Incorporating machine learning can be highly beneficial to address these challenges. Machine learning algorithms can analyze and identify patterns in patient datasets and

correlations that may not be immediately apparent through traditional methods. This facilitates the development of a dynamic threshold that adapts to individual behavior over time, ensuring personalized interventions. Furthermore, machine learning can enhance the estimation accuracy regarding when a child is likely to reach harmful biting levels, enabling caregivers to intervene proactively. By leveraging these advanced analytical techniques, the proposed solution not only improves safety but also empowers caregivers with actionable insights, ultimately contributing to better management of the disorder and enhanced QoL for CIP patients.

To implement this innovative approach, data from typically developing children was used, as no datasets are available specifically for CIP patients. By tracking the frequency of hand-biting behaviors over time, the researchers identified moments when a child might be at risk of self-harm. This data established a baseline for behavior patterns, which was then used to train various machine-learning algorithms. The analysis showed that the K-Nearest Neighbors (KNN) algorithm achieved the highest average accuracy rate of 98% in identifying abnormal hand motions. This predictive capability helps estimate the injury threshold, at which point the proposed solution would alert caregivers. The proactive alarm system is designed to notify caregivers before a child's biting reaches a level that could cause harm, thereby enhancing safety and preventing injuries.

To the best of our knowledge, 'CIPHomeCare' is the first comprehensive solution combining technology and machine learning to address the unique challenges CIP patients face, aiming to improve their quality of life. The remainder of this research is organized as follows: Section II reviews related works, including wearable activity recognition and classification algorithms. Section III provides an overview of the proposed solution. In Section IV, the experimental method is presented. Section V describes the evaluation methods used in this research. Section VI analyzes the results obtained. Discussion is given in Section VII. Finally, the conclusions are presented in Section VIII.

II. Related Work

Recent studies underscore the pivotal role of technology in advancing motion recognition through wearable devices, which are crucial for applications ranging from fall detection in elderly individuals to monitoring hazardous movements and anticipating potential risks. These technologies enable early detection and effective intervention, reducing injury severity and mortality rates in vulnerable populations [10]. Motion recognition technology's ability to analyze data, identify movements, and provide timely alerts has significantly improved patient safety and response times. Given its growing relevance, monitoring and investigating human gestures has become a central focus in commercial and biomedical research [11, 12]. The related work is organized as follows: the first part illustrates the new advancements in hand gesture monitoring technologies, the second part compares the use of one sensor against multiple sensors, and the last part provides insight into the impact of sensor placement on gesture recognition accuracy.

A. Advancements in Hand Gesture Monitoring Technologies

The field of hand gesture monitoring has seen rapid advancements, driven by the need for better rehabilitation tools and performance analysis systems. A notable study [10] introduced an intelligent wristband equipped with polymeric strain gauge sensors capable of detecting eight distinct hand gestures with 98% accuracy using Linear Discriminant Analysis (LDA). This innovation highlights the potential of simple yet highly accurate systems for recognizing complex hand gestures. Expanding on this, another study [13] examined hand gesture recognition in table tennis using multiple algorithms, including Support Vector Machine (SVM), LDA, K-Nearest Neighbor (KNN), Decision Tree (DT), and Naive Bayes (NB). The Decision Tree algorithm stood out, achieving an accuracy of 95%, demonstrating the effectiveness of ensemble methods in sports-related gesture recognition.

Real-time gesture recognition has also been explored, particularly with Inertial Measurement Unit (IMU) sensors. Research from 2018 [14] reported an accuracy range of 72% to 100%, with an average accuracy of 86.99% when using algorithms such as SVM, LDA, Dynamic Time Warping (DTW), and Principal Component Analysis (PCA). These studies collectively illustrate the diversity of approaches used in gesture recognition, each tailored to the specific application domain, highlighting both the potential and challenges of integrating such technologies into everyday use. Thus, this current research study uses real-time gesture recognition and accelerometer-based bracelet-type sensor specified for CIP children's patients.

B. Comparison of Single vs. Multiple Wearable Sensors

While many studies have focused on single-sensor configurations, others have explored using multiple sensors to enhance gesture recognition accuracy. Zhao et al. [15] developed a table tennis stroke classification system using three sensors placed on different body parts, achieving a recognition accuracy of 97.41% with SVM. This illustrates how combining multiple sensors can improve the precision of gesture detection in dynamic environments. In contrast, a study [16] compared single and multiple sensor setups, revealing only a modest difference in accuracy—90% for single sensors compared to 95% for multiple sensors. This finding suggests that the marginal improvement in accuracy with additional sensors may not justify the increased complexity and discomfort in practical applications, mainly when wearable devices are intended for daily use. Research has also shown that an increased number of sensors can interfere with everyday activities, reducing user comfort and compliance [17, 18]. These results emphasize the need to balance accuracy with usability, particularly in contexts like athletics or rehabilitation, where user comfort is paramount. Accordingly, this study considers children's comfort a priority, so only one sensor was used.

C. Impact of Sensor Placement on Gesture Recognition Accuracy

Sensor placement plays a critical role in determining the accuracy of gesture recognition systems. A study in [19] on fall detection using six sensors focused on wrist placement

achieved an accuracy of 96.63% using the K-NN algorithm. This highlights the importance of precise sensor placement in improving recognition rates. Similarly, research in [20] that compared wrist and below-elbow sensor placements for dynamic hand gestures found that wrist placement yielded a higher accuracy of 93.27%, likely due to the more extensive range of motion captured at the wrist. Despite the improved accuracy with multiple sensors, studies also noted that additional sensors can interfere with daily activities [17, 18], underscoring the trade-offs between accuracy and practicality.

Several technological innovations have further enhanced gesture recognition accuracy. For instance, a study [21] introduced an accelerometer-based pen-type device combined with a Feedforward Neural Network and Similarity Matching system to detect primary and complex hand gestures, achieving an accuracy of 98.9%. Other advancements include axis-crossing code algorithms for wrist gestures, achieving accuracies as high as 96.9% and 97.1%, respectively [21]. Additionally, specialized devices, such as a wristband developed for basketball shooting analysis, demonstrated the potential for highly accurate gesture recognition in sports, with up to 98.5% accuracy using the Artificial Neural Network (ANN) algorithm [22]. These studies underscore the importance of sensor placement and algorithmic improvements in achieving high accuracy in gesture recognition, particularly in practical, real-world applications. Hence, this research settles on the wrist as the best placement of the sensor.

Table I summarizes all the related work on gesture recognition. The first column lists the types of sensors used in each paper. The second column lists the algorithms used to classify and evaluate the data. Next, the hardware type is used to process the data. The next column illustrates the sensor's placement. The last column shows the average accuracy of each study. While many wearable solutions target broad applications, focusing on specific, well-defined user groups can enhance effectiveness.

TABLE I. SUMMARY OF THE RELATED WORK

#	Work	Sensor	Model (algorithm)	Computing Hardware	Placement	Accuracy
1	[18]	polymeric strain gauge	SVM, LDA	PC	wrist	98%
2	[23]	MPU9250 includes (6-DOF inertial measurement unit (IMU), 3-DOF magnetometer sensor)	K-NN, SVM, DT, LDA, NB	Not mentioned	wrist	95%

20	Original research	Accelerometer-based bracelet-type sensor device	K-NN, NB, RF, LDA, LR	PC	wrist	98%

In summary, wearable-based gesture recognition systems have significantly improved, with various algorithms and sensor configurations improving accuracy and practicality. Using algorithms like K-NN, Decision Tree, and ANN, combined with appropriate sensor placement, has proven effective in diverse applications such as fall detection, sports

performance analysis, and rehabilitation. While integrating multiple sensors can improve accuracy, single-sensor setups offer comparable performance with greater user comfort, particularly in everyday settings. Moreover, advancements in sensor technology, such as the development of wrist-based devices and novel algorithms, continue to push the boundaries of gesture recognition accuracy. Despite these advancements, challenges remain in real-time applications; balancing accuracy, sensor placement, and user comfort is critical. While previous research has focused on sensor-based systems for fall detection, this current study extends this by concentrating on CIP patients, who present unique challenges in gesture monitoring. The ongoing evolution of motion recognition technologies holds immense potential for improving patient safety and enhancing the quality of life for individuals across various domains.

III. Overview of the Proposed Solution: 'CIPHomeCare'

The proposed solution, 'CIPHomeCare,' comprises three main components, as depicted in Fig. 1. Since it is not within the main scope of the research, the architecture is not illustrated in detail. The first component is a motion/wearable sensor designed to be comfortable for infants and continuously monitor hand motions. It counts instances of biting and collects data on the frequency and intensity of these behaviors. The sensor establishes a baseline for normal behaviors by tracking these movements over time, allowing for better identification of abnormal patterns. The second component is the CIPHomeCore Smart Component, which processes the collected data using the wearable sensor. It trains machine learning models to classify hand motions and estimate when biting behaviors may become dangerous. The last component is the mobile application for caregivers, which is out of this research study's scope. The app provides real-time alerts to caregivers when the system detects a child approaching the predefined injury threshold. The application features an intuitive interface that displays data on the child's hand motions and biting frequency, empowering caregivers with actionable insights.

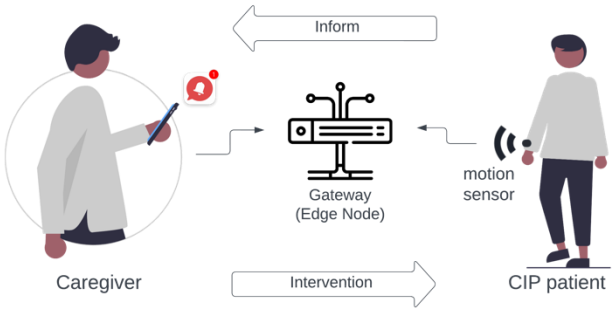

Fig. 1. The architecture of 'CIPHomeCare'.

These components create a comprehensive monitoring solution that enhances safety for CIP patients and supports caregivers in managing the disorder effectively.

IV. Methodology

This research encompasses multiple phases, from the initial selection of the sensor to the final analysis of the results.

Each phase was carefully designed to ensure the accuracy and reliability of data collection and analysis. Fig. 2. It illustrates the proposed workflow, which includes sensor selection, ethical considerations, data collection and processing, handling imbalanced dataset, training machine learning algorithms, and evaluating and comparing different approaches (illustrated in the Evaluation section). Statistical analysis was conducted using Python version 3.11, with libraries such as Pandas (version 2.2.2) for data processing and NumPy (version 1.26.4). The following subsections discuss all stages in detail.

A. Sensor Selection

The STEVAL-BCN002V1 multi-sensor is used to collect the data in this research study. The STEVAL- BCN002V1 is a multi-sensor board based on the BlueNRG-2 SoC Bluetooth Low Energy application processor and includes a 6-DOF inertial measurement unit (IMU). Thus, the child's wrist motions were collected using this sensor. The overall size is as tiny as a coin, so children would not feel uncomfortable wearing the sensor. It was chosen because of its small size, high accuracy, and low power consumption, making it suitable for continuous monitoring of young children without causing discomfort. The high sensitivity of the IMU allows for capturing even subtle hand movements, which is crucial for distinguishing between normal and biting behaviors. The sensor complies with European EMI/EMC and safety directives and standards.

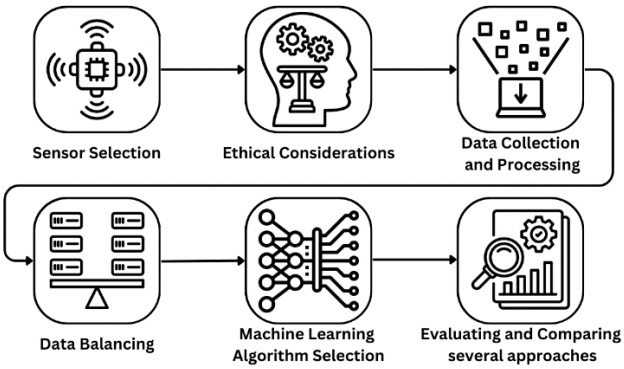

Fig. 2. The proposed workflow of 'CIPHomeCare'.

B. Ethical Considerations

This study followed the ethical principles outlined in the Declaration of Helsinki. Ethical approval was obtained from the Unit of Biomedical Ethics at King Abdulaziz University (No. HA-02-J-008) prior to the initiation of the research. Informed consent was secured from the guardians of all participants involved in the study. Each guardian was provided with detailed information regarding the purpose of the research, the procedures involved, and any potential benefits and risks. The study ensured that participation was voluntary, and participants could withdraw without consequences. To protect the confidentiality of participants,

all data was anonymized and stored securely. Identifiable information was removed to ensure that individual responses could not be traced back to specific participants, and each participant was assigned a random ID number to maintain patient confidentiality. Data access was restricted to authorized personnel only.

Additionally, measures were implemented to minimize potential discomfort or distress to the children during data collection. The type and design of the wearable sensor were selected with the children's comfort in mind, ensuring it was non-intrusive, and the children were monitored to ensure their well-being throughout the study.

C. Data Collection and Processing

This current study utilized a newly collected dataset of children's hand movements, with prior approval from their parents. Data were gathered from the King Abdulaziz University Hospital clinics and Childhood Centers in Jeddah City, Saudi Arabia. The only eligibility criterion was that the child had to be between 6 and 24 months old. This age group is chosen because it gets the most injuries among CIP patients due to their low cognitive ability [2, 3] and to protect them from injuries they could suffer from. The data collection employed an accelerometer-based sensor, which enabled real-time monitoring of the children's hand movements. The sensor was worn on the children's dominant hand. Data were collected daily for a maximum of 35 minutes per child to maintain consistency across participants and ensure comprehensive monitoring without causing fatigue. The data were collected between 9 am and 3 pm since the data is collected from a hospital and childhood center.

Wrist motion data was collected from 41 normal children without CIP health conditions. The children are 19 females and 22 males. The youngest participants were 6 months old, while the oldest were 2. Each child wore a wristband sensor for a maximum of 35 minutes daily. To capture natural behavior, the children were not restrained in their movements and were not instructed to perform any specific actions, providing a realistic baseline for detecting abnormal hand motion (biting motion). The wristband recorded acceleration data across the X-axis, Y-axis, and Z-axis, capturing various wrist motions, including the intensity and frequency of movements. Upon analyzing the acceleration data, significant differences in the peak profiles across the X, Y, and Z axes were observed.

Consequently, the acceleration data from all three axes was selected as this primary motion analysis dataset for subsequent motion recognition and detection. The recorded motion data was then manually classified by the first author (RA) into two categories: normal motion (no hand biting) and abnormal motion (hand biting), and then reviewed by three experts. Two experts, the second and the third co-authors (HB and AH), are from the technology field and have at least seven years of experience in machine learning. The third expert is from the health sector; the last co-author (RA) is a physician with over fifteen years of experience in the pediatric department (neurology division). However, some challenges arose during data collection: children did not frequently bite their hands, leading to an imbalanced dataset. To address this issue, oversampling techniques were employed to ensure a more balanced representation of both motion categories in the analysis phase.

The data processing phase started after labeling the data with the expert's assistance. The processing phase progressed through several stages until the appropriate stage was determined. Initially, we took the data as is and identified the abnormal biting behavior. Unfortunately, if the child bites his hand, the alarm will go off, which is not a practical solution. Then, we set a fixed threshold of 10 seconds to define abnormal biting behavior without accounting for individual differences in pain tolerance. This threshold was used uniformly across all participants. However, this approach led to substandard results, as it failed to consider the natural variability in how different children responded to discomfort.

Given that the data was collected from children, it was crucial to consider individual differences in pain tolerance, which naturally varies among them. Granted, we revised our approach by calculating each child's average biting duration and using it to create a personalized threshold for abnormal behavior detection. We significantly improved the system accuracy compared to a generic threshold. This adjustment resulted in improved accuracy and consistency in detecting abnormal behaviors.

Table II shows a sample of the average biting duration; some results are 0, which means those children did not bite their hands at all during the observation period. Table III illustrates that the children's hand motion dataset consisted of four columns and more than eight million rows. Each row represents a part of the child's hand motion. The four columns represent the acceleration data across the X-axis, Y-axis, and Z-axis, and the last column represents the child's status (label), whether they were biting their hand at the time or not.

TABLE II. AVERAGE BITING DURATION

ID	Average (Sec)
1	2.7975
2	0
3	0
4	1
5	6.2

TABLE III. AVERAGE BITING DURATION STATUS

X(mg)	Y(mg)	Z(mg)	Status
-184	1026	141	0
-110	974	89	0
-121	961	87	0
-126	985	114	0
-138	1011	168	0

D. Data Balancing

As mentioned earlier, children did not frequently bite their hands, which led to an imbalanced dataset. As shown in

Fig. 3, the children's hand motion dataset suffers from a severe skew in the class distribution. This figure highlights the imbalance in the children's hand motion dataset, with a significantly higher proportion of normal hand motion (99.7%) than abnormal hand biting motion (0.3%). This imbalance requires oversampling techniques to ensure balanced training of ML models due to the infrequency and importance of detecting biting events.

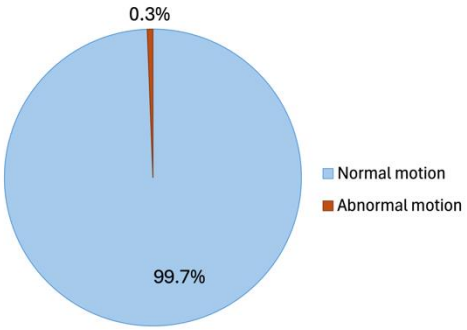

Fig. 3. Class distribution in the children hand motion dataset.

Several oversampling methods were investigated, such as the Synthetic Minority Over-sampling Technique (SMOTE), Borderline-SMOTE, Adaptive Synthetic Sampling (ADASYN), and K-means-SMOTE, to address class imbalance and mitigate overfitting in the collected dataset [34]. Each oversampling technique provides a dataset to be classified. SMOTE has gained significant attention due to its effectiveness and relative simplicity [34]. SMOTE is one of the earliest and most widely used methods, generating synthetic samples by interpolating between nearest neighbors within the minority class in the training set. This approach effectively blends features from original instances with those of randomly selected k-nearest neighbors [35]. An enhancement to SMOTE, known as Borderline-SMOTE [36], focuses on oversampling only those minority instances near the class boundary. Research indicates that Borderline-SMOTE improves classification performance for the minority class more effectively than both SMOTE and random oversampling methods. Another method applied is ADASYN [37], which adjusts the classification boundary by emphasizing more challenging examples. ADASYN employs a weighted approach to generate synthetic samples, prioritizing difficult instances within the minority class, and results from various datasets and evaluation metrics support its effectiveness.

K-means-SMOTE [38, 39] also leverages K-means clustering to identify clusters in the training data with an Imbalance Ratio (IR) below a specified threshold. SMOTE is then applied to these clusters, with the extent of oversampling determined by the sparsity and density of minority class objects. By implementing these four methods, the analysis aimed to effectively balance the dataset and reduce the risk of overfitting in the machine learning models.

In addition to the previously discussed oversampling techniques (SMOTE, Borderline-SMOTE, ADASYN, and K-means-SMOTE), this study also applied the SMOTE-ENN technique to address the class imbalance. SMOTE-ENN combines the Synthetic Minority Over-sampling Technique (SMOTE) with Edited Nearest Neighbors (ENN), providing an enhanced balance of the dataset by generating synthetic samples for the minority class while removing ambiguous samples that could potentially confuse the classifier [40]. This hybrid approach aims to improve the quality of the training set by effectively handling noisy instances, leading to potentially better model performance.

E. Machine Learning Algorithm Selection

Several machine learning algorithms were carefully selected to analyze the collected hand motion data. They were chosen for their proven effectiveness, as illustrated in related work, in similar applications and widespread implementation across various software platforms [16, 33]. The classifier algorithms applied in this work are as follows: the first chosen algorithm is the K-Nearest Neighbors (K-NN). It is a nonparametric, instance-based learning algorithm for classification and regression tasks. K-NN is recognized for its simplicity but can be computationally intensive due to its reliance on distance calculations between test instances and all training examples [41, 42]. The distance metric used in K-NN is typically the Euclidean distance, defined by Eq. (1).

$$\boldsymbol{d}(\boldsymbol{x},\boldsymbol{y}) = \sqrt{\sum_{i=1}^{n}(\boldsymbol{x_i} - \boldsymbol{y_i})^2} \quad (1)$$

This formula calculates the distance $\boldsymbol{d}(\boldsymbol{x},\boldsymbol{y})$ between two points, x and y, in an n-dimensional space, helping the algorithm classify new instances based on proximity to training examples [43].

The second algorithm used is Random Forest (RF), an ensemble-based technique known for its robustness in classification tasks. RF constructs multiple decision trees using randomly sampled subsets of data and features, aggregating results through majority voting [44]. It effectively handles complex interactions and diverse data types, although it can be computationally demanding [45]. The impurity measure used to evaluate the quality of splits in decision trees is often represented by Eq. (2).

$$G = 1 - \sum_{i=1}^{n} p_i^2 \quad (2)$$

In this formula, G denotes the Gini impurity, where pipi represents the probability of a class i within the dataset, allowing the algorithm to assess the homogeneity of splits [43].

Naive Bayes (NB), the third chosen algorithm, employs the Bayesian theorem for classification by calculating the mean and variance of feature variables within clusters. It is particularly effective for high-dimensional data and is recognized for its simplicity and computational efficiency [27,28]. The probability of a class C_k given a feature x is computed as in Eq. (3).

$$P(C_k|x) = \frac{P(x|C_k)\times P(C_k)}{P(x)} \quad (3)$$

This formula illustrates how the algorithm updates the probability of class membership based on observed features, leveraging prior knowledge and likelihood [43].

The fourth chosen algorithm is the Linear Discriminant Analysis (LDA), which finds a linear combination of features that best separates different classes, transforming features into lower-dimensional space to enhance class separability [46]. Although effective, it assumes a standard feature distribution and may struggle with non-linearly separable classes. The within-class scatter matrix is represented in Eq. (4).

$$S_w = \sum_{k=1}^{K} \sum_{x_i \in C_k} (x_i - \mu_k)(x_i - \mu_k)^T \quad (4)$$

In this formula, S_w captures the variance of data points x_i within each class C_k, where μ_k is the mean of class k [43].

The last algorithm used is logistic regression (LR). This algorithm predicts the probability of a target variable by analyzing relationships between independent variables [47]. The logistic function, which models the probability, is Eq. (5).

$$\sigma(z) = \frac{1}{1+e^{-z}} \quad (5)$$

Here, $\sigma(z)$ represents the predicted probability of the target variable, where z is a linear combination of the independent variables, ensuring outputs are constrained between 0 and 1[43].

V. Evaluation

Muraina et al. [48] and Nguyen et al. [49] showed that selecting a 70/30 ratio to be the training/testing ratio impacts and improves the predictive capability of the ML models. Thus, the dataset was split into 70% for learning and 30% for testing to evaluate all classifier models. To determine which machine learning algorithm best estimates hand motion behaviors using the collected dataset, we evaluated a combination of five classification techniques: KNN, RF, NB, LDA, and LR. Along with various oversampling techniques: SMOTE, ADASYN, Borderline-SMOTE, K-means-SMOTE, and the newly added SMOTE-ENN. The effectiveness of these different combinations is compared in terms of three key metrics: accuracy, sensitivity, and specificity. Accuracy is the ratio of the total number of correct predictions to the total number of predictions made [50].

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (6)$$

Sensitivity refers to the proportion of actual positive cases (the abnormal motion) that the model correctly identifies [50].

$$Sensitivity = \frac{TP}{TP+FN} \quad (7)$$

While specificity measures how accurately the model classifies negative cases (the normal motion), indicating its effectiveness in predicting normal hand motion [50].

$$Specificity = \frac{TN}{TN+FP} \quad (8)$$

VI. Results

The primary objective of this study was to evaluate the performance of several machine learning algorithms in detecting abnormal hand motions (specifically hand biting) in children with CIP using wearable sensors. The findings from the classification algorithms and oversampling techniques reveal valuable insights into the effectiveness of these approaches in addressing data imbalance and accurately classifying hand motions.

Tables IV-IX summarize the performance metrics of the classification algorithms, including accuracy, sensitivity, and specificity, for each oversampling method. Each table details the performance of the various algorithms, with the first column listing the different algorithms, the second column displaying the accuracy results, the third column showing specificity values, and the last column presenting sensitivity values. Table IX displays the result of the original imbalanced dataset.

Initially, a fixed threshold of 10 seconds for pain tolerance across all children led to poor performance as it did not adequately capture individual differences in pain perception. By individualizing the threshold, accounting for differences in average biting duration, the accuracy, sensitivity, and specificity of the models improved significantly, offering a more personalized and effective monitoring mechanism.

TABLE IV. Comparison of Classification Techniques using SMOTE

Techniques	Accuracy	Sensitivity	Specificity
K-NN	0.99	0.69	1.00
RF	0.61	0.69	0.61
NB	0.64	0.62	0.64
LDA	0.56	0.60	0.56
LR	0.56	0.61	0.55

TABLE V. Comparison of Classification Techniques using Borderline-SMOTE

Techniques	Accuracy	Sensitivity	Specificity
K-NN	1.00	0.65	1.00
RF	0.67	0.53	0.67
NB	0.58	0.63	0.58
LDA	0.60	0.64	0.60
LR	0.59	0.64	0.59

TABLE VI. Omparison of Classification Techniques using ADASYN

Techniques	Accuracy	Sensitivity	Specificity
K-NN	0.99	0.69	1.00
RF	0.80	0.44	0.80
NB	0.50	0.61	0.50
LDA	0.60	0.42	0.60
LR	0.60	0.42	0.60

TABLE VII. COMPARISON OF CLASSIFICATION TECHNIQUES USING K-MEANS-SMOTE

Techniques	Accuracy	Sensitivity	Specificity
K-NN	1.00	0.65	1.00
RF	0.61	0.69	0.61
NB	0.64	0.63	0.64
LDA	0.56	0.59	0.56
LR	0.55	0.61	0.55

TABLE VIII. COMPARISON OF CLASSIFICATION TECHNIQUES USING SMOTE-EEN

Techniques	Accuracy	Sensitivity	Specificity
K-NN	0.98	0.72	0.98
RF	0.60	0.69	0.60
NB	0.63	0.64	0.63
LDA	0.56	0.50	0.56
LR	0.55	0.61	0.55

TABLE IX. ORIGINAL DATASET CLASSIFICATION

Techniques	Accuracy	Sensitivity	Specificity
K-NN	1.00	0.63	1.00
RF	1.00	0.00	1.00
NB	1.00	0.00	1.00
LDA	1.00	0.00	1.00
LR	1.00	0.00	1.00

Additionally, Oversampling techniques such as SMOTE, Borderline-SMOTE, ADASYN, K-means-SMOTE, and SMOTE-ENN played a crucial role in addressing class imbalance by generating synthetic samples for underrepresented classes and eliminating noisy data. These methods were particularly effective in enhancing model sensitivity across classifiers like KNN, RF, and NB, limiting the challenges posed by the rarity of abnormal behavior hand-biting in CIP patients.

From the results obtained, K-NN consistently outperformed the other algorithms across all oversampling methods especially with SMOTE-ENN, SMOTE and ADASYN where the sensitivity scores reached 0.72, 0.69 and 0,69, respectively. A sensitivity of 0.72 implies that it flagged the abnormal motion correctly, which means the children's risky motion is detected. Due to its instance-based learning approach, which effectively leveraged high-dimensional data for classifying hand movements. SMOTE-ENN, K-means-SMOTE, and SMOTE specifically contributed to improved sensitivity and specificity, with KNN showing the highest accuracy across all conditions. Similarly, RF demonstrated strong performance, particularly with ADASYN and SMOTE-ENN, indicating its capacity to handle complex data patterns. In contrast, NB maintained moderate accuracy (0.50-0.64), while linear models like LDA and LR struggled with non-linear data separability, yielding lower accuracies of 0.55-0.60.

As mentioned earlier, oversampling techniques were crucial in addressing class imbalance, which significantly enhanced the model's ability to detect rare hand-biting behaviors. SMOTE-based methods improved sensitivity across all algorithms, notably increasing KNN's sensitivity from 0.65 to 0.72 with SMOTE-ENN. However, ADASYN, while boosting RF's sensitivity, reduced its specificity to 0.44, illustrating the trade-off between enhanced detection of abnormal behaviors and increased false positives. This underscores the importance of choosing oversampling techniques aligned with specific clinical goals.

VII. DISCUSSION

To validate the result of this study, we compared our results with similar research studies regarding the performance of oversampling techniques, ML algorithm results, and the integration of wearable sensors with machine learning. These findings align with prior research in healthcare, where oversampling techniques such as SMOTE-ENN have been shown to enhance model performance across various applications, including healthcare fraud detection and diabetic risk prediction. For example, Bounab et al. demonstrated that SMOTE-ENN improved accuracy and reliability by balancing datasets and eliminating noise [51], while Aruleba and Sun found similar benefits in credit risk prediction [52].

In prior research, the application of deep neural networks for emergency department triage demonstrated improved sensitivity and specificity compared to conventional triage models [53]. Similarly, KNN and RF in our study achieved high sensitivity, especially when paired with K-means-SMOTE, reinforcing the idea that careful model selection and oversampling techniques can substantially enhance the ability to identify critical behaviors, which is crucial in clinical settings where missing abnormal events could have severe consequences.

The effectiveness of oversampling methods such as SMOTE and ADASYN was also observed in other domains, including healthcare data privacy and diabetic risk prediction [54]. These studies found that oversampling significantly improved the detection capabilities of models for minority class events, such as high-risk patients, which aligns with our finding that oversampling increased sensitivity and specificity for detecting abnormal hand-biting behaviors. This enhancement in sensitivity, while sometimes compromising specificity, underscores the necessity of selecting an oversampling technique that aligns with specific clinical objectives—whether prioritizing sensitivity for early detection or specificity to reduce false alarms.

Fig. 4 illustrates the sensitivity comparison for each algorithm, demonstrating that KNN outperforms other techniques, such as LDA and LR, and also shows promising results, particularly with the SMOTE technique, and even better performance with K-means-SMOTE. Additionally, NB maintains a relatively consistent accuracy of around 63%.

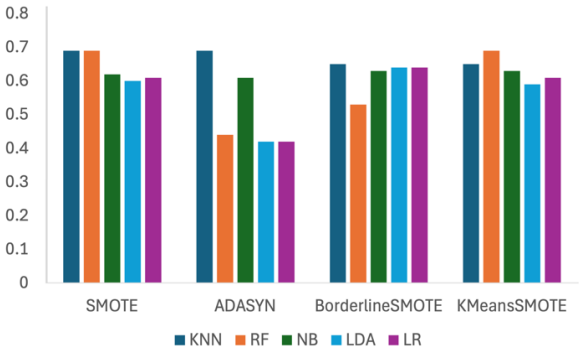

Fig. 4. Sensitivity.

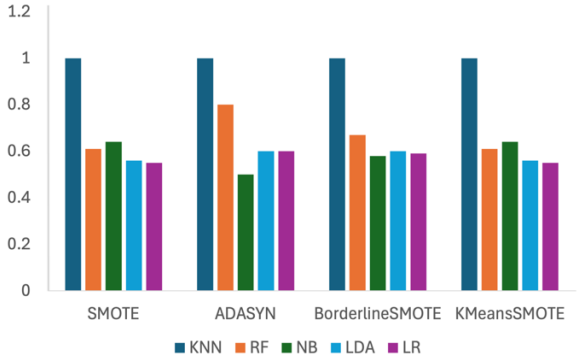

Fig. 5. Specificity.

Fig. 5 presents the specificity comparison across each oversampling technique. Here, KNN achieves the highest specificity again, while RF excels with the ADASYN method, showing comparable results to NB across the other three oversampling techniques. Moreover, while RF demonstrates overall good results, the NB algorithm achieves higher accuracy than LR. This can likely be attributed to the interdependence of the acceleration data across the X, Y, and Z axes; each feature contributes individually to the predictions made by the NB classifier.

Conversely, both LDA and LR underperformed, yielding a low average accuracy of 58% across all oversampling techniques. This highlights the need for careful selection of algorithms in future implementations to enhance detection capabilities for abnormal hand motions in children.

The results are also consistent with the work by Viloria et al., which demonstrated the efficacy of combining methods like SMOTE and random oversampling to address class imbalances in biomedical datasets [30]. Our use of SMOTE and ADASYN parallels these findings by effectively mitigating imbalance issues in hand motion data, thereby improving the models' ability to differentiate between harmful and non-harmful behaviors.

The integration of wearable sensors with machine learning for real-time monitoring, as demonstrated in this study, parallels prior applications in cardiovascular and neurological health monitoring [55]. This technology offers a viable solution for detecting harmful behaviors in CIP patients, enabling timely intervention and improving patient safety.

The high sensitivity achieved by KNN and RF, especially with SMOTE, K-means-SMOTE, and SMOTE-ENN, has important implications for real-world monitoring systems for CIP patients. Detecting abnormal hand motions like hand biting is critical for preventing self-injury in children who cannot feel pain. The wearable sensor system evaluated in this study offers a viable solution for real-time detection and intervention. By incorporating machine learning models that adapt to individual behavior patterns, caregivers can be alerted before harmful behaviors escalate, improving patient safety.

Moreover, the successful application of oversampling methods indicates that similar approaches could be used to detect other critical healthcare behaviors, such as monitoring involuntary movements in patients with neurological disorders. These findings are consistent with prior research on motion classification using wearable sensors. For example, previous studies have demonstrated the effectiveness of KNN and RF in recognizing activities and detecting critical health events when combined with appropriate data augmentation techniques. Additionally, machine learning models in real-time monitoring, similar to wearable devices used in cardiovascular health monitoring, underscores the transformative potential of AI in healthcare applications.

Studies have also validated the effectiveness of machine learning models like KNN and RF in recognizing critical health events across different domains. For example, KNN's success in heart sound analysis with an accuracy of 93.50% [56] and RF's compelling performance in fraud detection and credit risk analysis [57,58] demonstrate their robustness across varied datasets. These findings validate our approach, as KNN and RF were well-suited for highly dimensional accelerometer data, requiring distinguishing subtle variations in hand motion patterns.

Finally, addressing imbalanced datasets in healthcare has consistently been highlighted as a critical issue, especially in applications where the cost of false negatives can be severe. This research study extends previous literature by evaluating multiple oversampling techniques, providing a comprehensive understanding of how these methods can be applied to healthcare datasets with imbalanced classes, such as CIP-related hand-biting data. This emphasizes the importance of a tailored approach to handling imbalance, especially in clinical contexts where false negatives could harm patients [59].

In conclusion, this study demonstrates that KNN, particularly when paired with oversampling techniques like SMOTE-ENN, performs best for detecting abnormal hand motions in children with CIP. These findings support the potential for more effective intervention systems for CIP patients.

VIII. Conclusion, Limitations, and Future Work

This research explores the use of wristband sensors to investigate abnormal hand motions, explicitly focusing on hand biting. We collected and analyzed hand movement data from children to distinguish subtle differences between

normal and abnormal motions. The wristband sensor, equipped with motion detection technology, provides a portable and easily deployable solution. We utilized the STEVAL-BCN002V1 sensor to capture motion acceleration data, which was transmitted via Bluetooth for analysis. Our classification was based on acceleration data from three axes, resulting in an impressive average recognition accuracy of 98% and a sensitivity of 72%, highlighting the system's potential for future applications. The high sensitivity allows for capturing even subtle hand movements, which is crucial for classifying abnormal behaviors in real-world and other future applicability. Our findings underscore the value of detecting subtle differences in hand movements as a proactive measure for monitoring and preventing harmful behaviors. Furthermore, gaining deeper insights into these movements could substantially improve the quality of life for children affected by Congenital Insensitivity to Pain (CIP).

Despite these promising results, several limitations need to be addressed. The dataset used for model training and testing was relatively small, comprising data from only 41 children, which may affect the generalizability of our models to larger and more diverse populations. While we mitigated class imbalance using oversampling techniques, real-world datasets are often more complex and may introduce noise into synthetic samples. Additionally, sensor data were collected over a short period (35 minutes per day), potentially missing key variations in hand motions.

As a future direction, we plan to extend data collection over longer periods to improve model robustness and capture a broader range of motion variations. Future research should also focus on expanding the dataset to include a larger, more diverse population and incorporate additional relevant motions, such as eye rubbing, particularly for CIP patients. Integrating advanced deep learning techniques, such as Convolutional Neural Networks (CNNs), could enhance classification accuracy, especially for more complex motion patterns. Additionally, we will prioritize expanding the dataset and exploring similar behaviors to broaden the applicability of our findings. For CIP patients, even minor advancements could significantly improve their well-being and that of their caregivers. This research could also be extended to other conditions, such as autism, where motion detection is critical in managing behaviors. Another future direction after getting the necessary IRP approval is designing and building the whole system to ensure it is as safe as possible; we will conduct a clinical control trial study in a hospital to measure the system's effectiveness and scalability.

ACKNOWLEDGMENT

We want to express our sincere gratitude to King Abdulaziz University Hospital for their invaluable support in the data collection process for this research. Their assistance and collaboration enabled us to gather the necessary data to advance our study.

This research work was funded by Institutional Fund Projects under grant no (IFPRC-186-140-2020). Therefore, authors gratefully acknowledge technical and financial support from the Ministry of Education and King Abdulaziz University, Jeddah, Saudi Arabia.

A Multi-Person Collaborative Design Method Driven by Augmented Reality

Liqun Gao*
College of Arts and Design, Ningbo University of Finance & Economics, Ningbo, Zhejiang, 315715, China

***Abstract*—The current interior design of commercial buildings is facing innovative challenges, requiring a balance between aesthetics, functionality, and economic benefits. The design industry faces challenges in interdisciplinary integration, lack of standardized processes, and limitations of traditional design methods in complex situations. Although virtual reality technology provides new solutions, its integration difficulty, cost, and operational complexity constrain its widespread application. This study introduces a digitally twin-based augmented reality (AR) collaborative indoor design framework, addressing the decomposition of spatial planning for the complexity inherent in design processes. Subsequently, contextual data in the indoor design process is structured into an indoor design knowledge graph to elucidate information transmission and iterative mechanisms during collaborative design, thereby enhancing the situational adaptability of AR collaborative design. Utilizing a root anchor-based collaborative approach, multiple designers engage in spatial design collaboration within the AR environment. Real-time knowledge and data facilitated by the design knowledge graph contribute to collaborative decision-making, ensuring the quality and efficiency of collaborative design. Finally, exemplified by a complex interior design project for a commercial space, an AR-based collaborative digital twin (DT) interior design system is established, validating the effectiveness and feasibility of the proposed methodology. Through this approach, designers can preview and modify designs in a virtual environment, ultimately reducing errors, shortening design cycles, lowering costs, and enhancing user satisfaction.**

Keywords*—Digital twin; optimized design; interior space; multi-person collaborative design

I. Introduction

In the golden age of commercial building interior design, traditional design concepts are being questioned and new ideas are overturning established principles and paradigms. Commercial buildings, second only to residential buildings in floor area, are the most numerous and widely ranged, touching every aspect of daily urban life [1]. They serve as a window into the socio-economic status of a city, reflecting the material economic life and vibrant cultural character. The interior environment is an essential component of commercial architecture. Analyzing design trends and creating a favorable commercial environment also contributes to urban economic development [2]. Due to the significant costs, long construction cycles, and high public engagement, once completed, commercial interior projects can broadly impact the regional landscape and environment [3]. Consequently, stakeholders demand higher safety, functionality, and economic performance compared to other buildings, leaving no room for error in the design process. However, the interior design industry still faces significant challenges:

1) Interdisciplinary integration and complexity: Interior design involves aesthetics, architecture, environmental psychology, material engineering, and other disciplines. Designers must ensure beauty while guaranteeing functionality and comfort, increasing design complexity. Traditional commercial interior design must consider building types, environmental harmony, landscape coordination, and investment risks.

2) Overreliance on personal experience: Designers' unique styles and experiences mean that designs are often limited by individual capabilities. The lack of standardized design processes leads to inefficiency.

3) Slow feedback and rework: Traditional design processes often require multiple revisions, with each change consuming considerable time and resources, limiting design efficiency.

4) Singular design methods: The complexity of situations hinders the use of precise theories or quantitative methods to demonstrate the scientific aspects of design. Whether it's aesthetics or space and environmental factors, methods for presenting and arguing commercial building interior design solutions are quite singular, urgently requiring a realistic, intuitive, and visual technology method for presentation.

In interior design processes, due to the emphasis on spatial visualization and user experience, the characteristics of virtual reality technology are highly similar, as it is a computer system that presents a virtual world or simulated environment to users. Virtual reality can serve people better by allowing users to experience the architectural environment from all angles and senses from the design's inception. As a result, the integration of interior design with virtual reality technology is gradually being widely applied in the industry.

Firstly, since interior design is a process involving planning, design, and construction, which is costly and irreversible, it cannot afford many errors. Virtual reality technology, with its lifelike presentation, allows for the preview and real-time modification of interior design plans. Designers and users can enter the virtual space at any time, examining their work from any angle, truly feeling the space, scale, materials, textures, details, and sounds, thus resolving issues arising from overlooking errors in two-dimensional design drawings.

Secondly, unlike traditional design media, virtual reality technology describes building interiors dynamically and

interactively with real-time feedback. Users can thus compare and edit interior design elements during the preview, modifying them according to their needs and preferences without professional constraints.

In this context, the rapidly developing virtual reality technology facilitates the expression of interactive interior design, enhancing the realism of the experience and meeting the growing demand for "interactivity" among contemporary users.

However, looking at the current application of virtual reality technology in interior design, imperfections in design methodology can cause issues such as how to integrate virtual reality into the design process, resolve the high computational demands and significant costs in terms of capital and time investment, and overcome the lack of familiarity with operating methods limiting its widespread adoption. These issues hinder the digital evolution of architectural interior design methods and the innovative integration and widespread teaching of virtual reality technology in everyday life. Therefore, this paper proposes an augmented reality-driven method for interior space design. This method allows for the examination and evaluation of design effects at the initial conceptual stage, simulating construction quality before building to ensure control, thereby reducing design time and improving design quality while saving resources.

II. Literature Review

In recent years, the rapid advancements in cutting-edge technologies such as artificial intelligence, big data, and cyber-physical systems have been driving the swift evolution of engineering design. This paper provides a comprehensive review of the current state of research in this domain.

A. Digital Design

Currently, digital design technologies have been widely applied in the field of interior space design, particularly in the planning and innovation of residential, commercial, and exhibition spaces [4]. Design software tools such as SketchUp, AutoCAD, and Revit have become indispensable for designers, supporting complex design requirements such as 3D modeling, virtual reality roaming, and environmental simulation. With the development of big data and artificial intelligence technologies, data-driven interior design has become a research hotspot. By collecting and analyzing designers' creative ideas, user behavior data, and the usage effects of interior spaces, more accurate predictions of the functionality and user experience of interior spaces can be made during the design phase.

In recent years, interior designers have intensified their pursuit of rapidly developing interior space design solutions that are both aesthetically pleasing and practical, meeting consumers' demands for personalized and functional interior spaces. Grübel et al. [5] used digital technology to design multifunctional interior spaces that meet strict requirements for environmental adaptability and user interactivity, achieving a level of functionality and aesthetic design comparable to high-end standards. Lu et al. [6], focusing on home office spaces, explored the application of digital design and analysis technologies in interior space design, combining digital design with user behavior analysis to achieve optimal design outcomes. Künz et al. [7] summarized the development of some advanced digital interior design methods, particularly emphasizing advanced digital design for smart home products beyond traditional furniture and decorative materials. This approach is considered key to improving residents' quality of life fundamentally. Schroeder et al. [8], utilizing digital technology, proposed a data-driven intelligent interior design simulation model based on user experience feature learning. Using personalized design techniques and leveraging user behavior data and spatial layout data, they designed personalized interior environments.

However, as user demands for interior spaces become increasingly personalized and functional, new challenges arise for digital interior space design. How to rapidly design interior spaces that meet specific user needs while ensuring design feasibility and sustainability is a major research direction in the future of digital interior space design.

B. DT-driven Design Patterns

DT technology has been widely applied throughout the entire lifecycle of interior space design, construction, and maintenance. For instance, Coupry et al. [9] designed an interior design visualization technology based on DTs and virtual reality. This system provides an intuitive representation and accurate description of interior space layouts, systematically manages spatial usage data and user interaction data, thereby enhancing design precision. Schott et al. [10] proposed a DT-driven interior design collaboration platform, establishing a stable and reliable communication mode among designers, engineers, and clients throughout the entire design process.

In response, Zhu et al. [11] introduced a comprehensive, precise, real-time interior environment monitoring and analysis system. This technology, by bridging the gap between the actual interior environment and the digital model, enables real-time iteration and optimization of interior design. As interior space design becomes increasingly complex, requiring knowledge from multiple disciplines, Xu et al. [12] identified DT (DT) as one of the most promising enabling technologies for achieving smart buildings and smart cities. Therefore, integrating knowledge from different disciplines in the design process to realize interdisciplinary digital interior space design is a crucial future research trend.

In light of this, Pang et al. [13] proposed a DT-driven method for rapid personalized design of residential and commercial spaces. Wang et al. [14] presented a rapid personalized design method for office space layouts based on DTs. They developed an analysis-decoupling framework based on DTs to provide interior design analysis capabilities and support decision-making for design and solution assessment. Liu, Zheng & Bao [15] discussed the application of DT models as a natural evolution in model-based engineering in interior design. These are important application cases of DTs in the interior space design phase. The application of DT-driven interior space design has been summarized by relevant scholars and proven to be a significant method for enhancing the interior design process. DT technology holds greater efficiency potential in the construction and management of interior spaces.

C. Research Gaps

With the evolution of modern interior design, spatial planning and personalized customization have become increasingly intricate and detailed, posing challenges that current design methods often struggle to address. Despite the ongoing shift of contemporary interior design methods towards three-dimensional modeling and virtual reality technologies, inherent issues persist, as outlined below.

1) Lack of parameterized collaborative design approaches: This implies that manual adjustments are required when spatial functional needs or user preferences change, leading not only to time consumption but also potential design inconsistencies. Introducing parameterized collaborative design approaches can automate design adjustments, saving time and enhancing design consistency and accuracy.

2) Application of DTs in the design process: Furthermore, although DTs have found widespread applications in various domains such as manufacturing and medical simulation, their application in the interior design process remains underexplored. DTs can provide additional information for the design process, including spatial usage simulation, lighting, and acoustic effects, thereby elevating design precision and user satisfaction.

Motivated by these identified research gaps and objectives, this study aims to develop a DT-based intelligent collaborative design method for interior space design. Integrating parameterized collaborative design and DT technology, this approach seeks to enhance the efficiency, precision, and personalization of interior space design. Simultaneously, this research aspires to propel the advancement of interior design by presenting innovative perspectives and methodologies for future endeavors in this field.

III. DT-based Multi-Person Collaborative Design System

To meet the application demands of intricate assembly scenarios, this chapter delves into the intricacies of collaborative scenarios. It introduces an architecture for multi-user collaborative assembly methods based on Augmented Reality (AR) and DT technology. Additionally, it conducts an analysis of collaborative assembly sequences within the DT framework.

A. Multi-Person Collaborative Design Process

In intricate interior space design, the design process typically encompasses multiple complex stages, demanding precision in design execution and necessitating close coordination between these stages. Collaborative design involving multiple individuals can significantly enhance design efficiency, contingent upon efficient task collaboration. The collaborative process relies on the macro-management and swift allocation of tasks by the design administrator. Simultaneously, it is constrained by the understanding of tasks by on-site design personnel and the execution of design operations. Fig. 1 illustrates the collaborative process of complex interior space design. This paper divides the collaborative design process into two parts: single-functional area design collaboration and multi-functional area design collaboration.

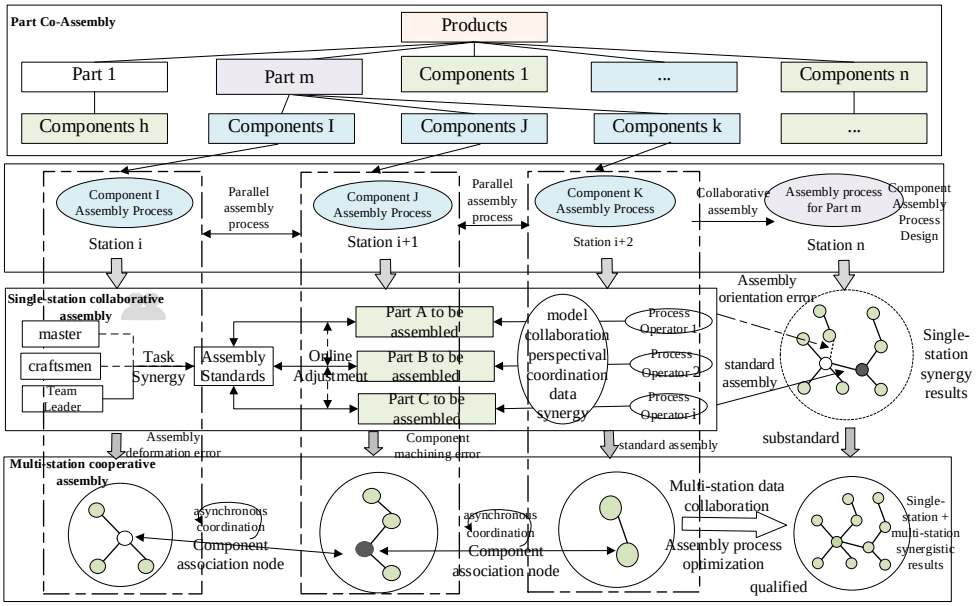

Fig. 1. Collaborative process for designing complex interior spaces.

1) Complex interior space design process in a single functional area: When the design requirements of a space are complex, multiple designers conduct different design operations in the same functional area from different design perspectives. This task collaboration process is termed single-functional area collaborative design. In this design process, senior designers are responsible for formulating design concepts, design managers review design proposals, design task cards are created based on the design process, project managers manage on-site activities, guide and plan the work of designers, and collaborative designers' complete tasks. The collaborative process primarily focuses on the interaction

between project managers and designers, with the project manager being the key decision-maker in collaboration. During the design process, rapid extraction of individual design tasks and collaborative relationships, along with unified and accurate acquisition and expression of information, is crucial for on-site designers to effectively grasp design details. Additionally, due to the tolerance range in design quality standards, it is necessary to systematically coordinate, optimize design parameters based on on-site conditions, and iteratively control the design process to ensure the stability of collaborative design quality.

2) Collaborative design process for complex interior space with multiple functional areas: When the tolerance requirements for space design are high, and there are multiple and interrelated functional areas, not only must design integration errors arising from the collaborative design process between various functional areas be considered, but also the cumulative errors resulting from material selection, furniture layout, and lighting design errors in the design processes of each functional area leading to design inconsistencies. The design process is top-down, controlling from overall design concepts to specific design elements. It macroscopically manages the design process and, based on the relationships and design precision of various functional areas, optimizes the design process into a multi-functional area collaborative design process. Due to the independence of each functional area, information collaboration computation and feedback between functional areas are crucial means to achieve accuracy prediction and process optimization.

B. Multi-person Collaborative Design Approach Incorporating AR

In order to ensure the efficiency of interior space design, this paper optimizes the collaborative design process and establishes a DT-based AR multi-user collaborative design architecture, as depicted in Fig. 2. Within the DT space, the three-dimensional model and design information are initially processed to extract abstract design attribute information and relational information, which is employed for the expression of design knowledge. Subsequently, design semantic information is organized in the format of "Entity-Relation-Entity" and "Entity-Attribute-Value" to construct a design knowledge graph. Object mapping is conducted based on the knowledge graph to build the design twin. Each node in the knowledge graph represents the twin representation of a physical object in the digital space. Based on hierarchy, these representations are categorized into object-level twins and space-level twins. The latter includes both attribute and layout information. The DT serves as the foundation for design management and data collaboration.

The AR-guided scenario serves as a bridge between the physical design space and the DT design space, facilitating guidance and collaboration throughout the design process. The AR system disseminates and visualizes designers' tasks based on the collaborative attribute information of nodes in the design knowledge graph, constructing a collaborative AR space. Model collaboration, perspective coordination, and data collaboration in single-functional area collaboration are achieved through multi-device collaboration and control.

The physical design space acquires design and collaborative information through the AR system, completing collaborative design tasks with visual guidance. To guide different collaborative tasks, the AR system possesses independence and collaboration. Independence ensures the guidance of different design tasks for various functional areas, ensuring effective guidance for single-functional area collaboration. Collaboration involves self-adjustment based on the design conditions of other functional areas during multi-functional area collaboration, ensuring that the overall spatial design meets aesthetic and functional specifications.

The DT space guides the design implementation of the physical space based on design principles, ensuring the standardization and efficiency of the design process through the virtual-to-real mapping process. Changes in the physical space's design drive the evolution of the DT, ensuring the high fidelity of the DT design process through a bidirectional mapping approach.

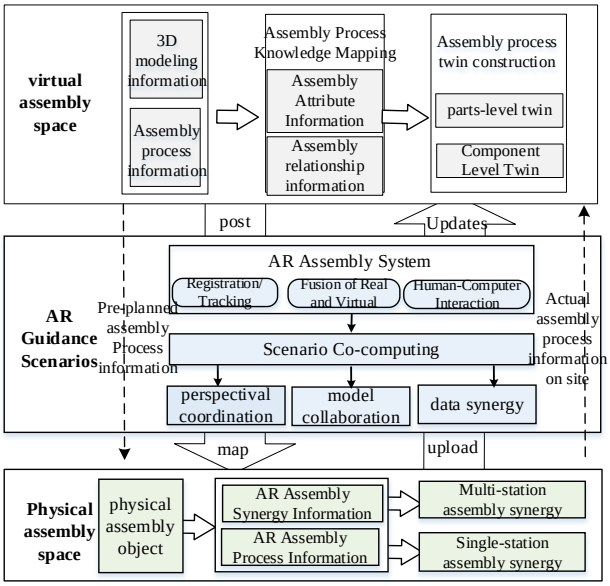

Fig. 2. DT-based multi-person collaborative design architecture for AR.

IV. DT-Driven Linked Design Process

This section provides a DT-driven approach to multi-person collaboration.

A. Process Collaboration

In this section, we employ manufacturing processes as fundamental units to establish an augmented reality-based DT multi-user collaborative interior space design workflow, as illustrated in Fig. 3. The process delineates the transmission and iterative mechanisms of design information between the physical design scenario and the DT space.

In the figure, following the determination of the interior space design scheme, the twin space stores and expresses design information in the form of a knowledge graph, where nodes represent specific design elements, and edges signify relationships between design elements. Each node in the

interior design knowledge graph corresponds to a DT of interior elements or functional zones, serving as an abstract representation of physical objects. The entire knowledge network is capable of describing the entire interior design scheme. The AR system, based on the interior design knowledge graph, can acquire the Design Element Set (DES) for the entire design process. DES is the knowledge expression of the pre-planned design scheme, i.e.

$$DES = \sum_{i=1}^{n}(SAI_i \cup DPI_i \cup DCI_i) \quad (1)$$

where, DES is used for modularized management of the interior space design process. It comprises Scene Asset Information (SAI) for AR scene reconstruction, Design Planning Information (DPI), and Design Cooperation Information (DCI) for design guidance and collaborative processes.

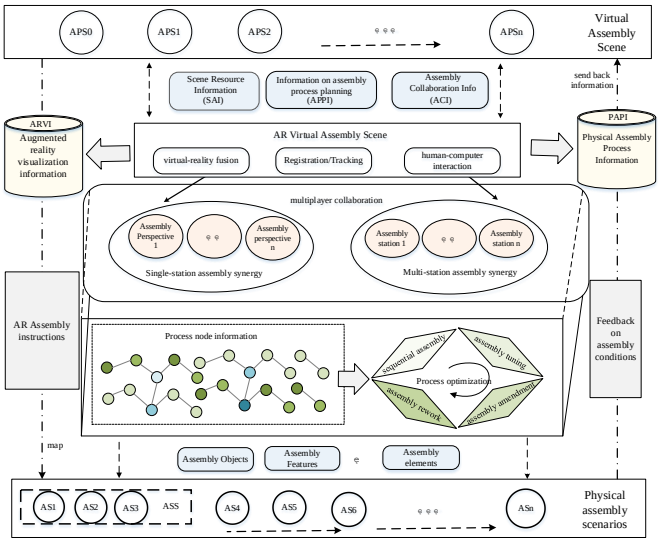

Fig. 3. DT interior space design process collaboration.

Due to the complexity of the interior design processes, we decompose them into various design step combinations for different categories of AR collaborative guidance. Different Design Element Sets (DES) are composed of Design Step Sets (DSS). Designers acquire the corresponding DSS through the system to obtain information on design steps, requirements, features, and elements. Based on specific design tasks, we classify them into two design cooperation categories (DCC): single-functional zone design and multi-functional zone collaborative design. The AR system provides distinct collaborative guidance for different DCC, generating Augmented Reality View Information (ARVI) based on design and model information, formally expressed as

$$ARVI := \{UI \cup MBD \cup ADN\} \quad (2)$$

The Model-Based Definition (MBD) method is employed for AR display of model information in Scene Asset Information (SAI), Design Animation (ADN) for visual expression of Design Planning Information (DPI), and UI information for expressing Design Cooperation Information (DCI) and design property information. Designers implement design steps based on ARVI to advance the DSS process. During the execution of DSS in physical space, the system acquires Physics Design Information (PDI), including Material Information (MI), Design Process Data (DPD), and Design Adjustment Data (DAD), formally expressed as,

$$PDI := \{MI \cup DPD \cup DAD\} \quad (3)$$

PDI is directly fed back to the interior design knowledge graph through human-computer interaction. Through analysis and computation, the system predicts the current state of the design process twin object and performs distributed optimization based on this state. Firstly, DES is optimized, adjusting errors to different degrees based on the actual design situation, facilitating differential optimization processes such as design adjustments, corrections, or rework. Design adjustments mainly address design errors in single-functional zones, while design corrections and rework address overall aesthetics and functionality matching issues in the collaborative processes of multi-functional zones. DCI updates involve the optimization results communicated through the AR system, guiding designers through the UI for process optimization and error indication.

B. Scene Synergy

One primary feature of AR systems is the overlay of computer-generated three-dimensional graphics onto physical space to provide operational guidance, fulfilling a majority of instructional needs. However, in scenarios involving multiple operators, independent AR spaces are incapable of facilitating information sharing and interactive operations. In order to overcome information isolation and enable multi-user collaborative operations, this paper introduces a shared AR space constructed through the method of root anchor point alignment, achieving collaborative scene interactions.

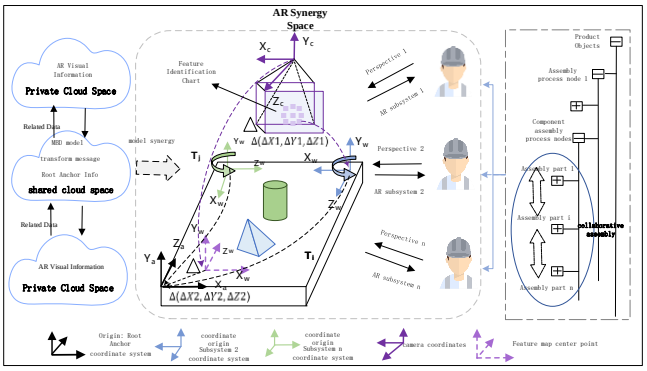

Fig. 4. Scenario collaboration principle.

The AR collaborative system for interior design enables multiple designers to share and collaborate on design concepts within the same physical space. As illustrated in Fig. 4, during the interior design process, designers collaborate by creating their respective AR spaces. Each designer's AR device establishes a unique world coordinate system, with the root anchor point serving as the origin (0, 0, 0) for the coordinate system, and all design element models are loaded as child objects.

The key to establishing a unified coordinate system is aligning the root anchor points of multiple virtual scenes. In this section, the collaborative process is achieved by calculating relative coordinate offsets based on the overlap

point of the physical spaces of two devices. Image-based tracking technology is employed to determine the location information of common points in physical space. To simplify collaborative calculations and enhance system adaptability, feature recognition images are stored in the system. The relative coordinates of the feature recognition image with respect to the root anchor point are utilized for rapid acquisition of common coordinate points between devices through screen recognition of the feature image. These relative coordinates are then employed in the alignment calculation of the root anchor points of the two devices, achieving a unified coordinate system.

Initially, the benchmark device DS for collaborative calibration is determined. Since the camera is in a non-fixed state during the AR scene loading process, the camera coordinates V_{ecp}（X_P， Y_P， Z_P） at the calibration moment are obtained as the central coordinates of the feature recognition image. Considering the camera offset constants for different devices, the actual central coordinates of the feature recognition image are adjusted to V_{ecp}（$X_P + \Delta X_1$， $Y_P + \Delta Y_1$ ， $Z_P + \Delta Z_1$）. To align the root anchor points, the local coordinates relative to the feature recognition image are computed as the coordinate offset, taking into account the coordinate transformation rules of the virtual space. The matrix transformation sequence in its coordinate system involves the Y-axis, then the X-axis, and finally the Z-axis. Thus, based on the transformation rules, the world coordinate system W is transformed to the local coordinate system L, where a and b represent intermediate coordinate systems in the transformation process.

$$Rot_W^L = Rot_{\mathrm{b}}^L Rot_{\mathrm{a}}^{\mathrm{b}} Rot_W^{\mathrm{a}} \tag{4}$$

The local coordinates of the root anchor point under the feature recognition image are obtained through matrix operations as V_{eca}（ΔX_2， $\Delta Y_2, \Delta Z_2$）.

$$V_{eca}=R_W^L \mathrm{Tr}\left(X_P + \Delta X_1\ ,\ Y_P + \Delta Y_1\ ,\ Z_P + \Delta Z_1\right) V_{ecp} \tag{5}$$

During device calibration, the client utilizes AR Core image tracking technology to obtain the spatial coordinates V_{ect}（X_t， Y_t, Z_t） of the recognition image through feature point clouds. Since the offset of the recognized feature point cloud may introduce deviations in calibration results, a collaborative filtering method is employed to eliminate false coordinates caused by positioning offset. Additionally, the data is grouped, and a weighted arithmetic mean is calculated.

$$X' = \frac{\sum_{\mathrm{i}=1}^{\mathrm{n}} \mathrm{x_i f_i}}{\sum_{\mathrm{i}=1}^{\mathrm{n}} \mathrm{f_i}} = \frac{\mathrm{x_1 f_1 + x_2 f_2 + \cdots + x_n f_n}}{\mathrm{f_1 + f_2 + \cdots + f_n}} \tag{6}$$

Get the final coordinate values of the feature recognition map.

$$V_{ect}= (\ X_t'\ ,\ Y_t', Z_t'\ ) \tag{7}$$

Due to the identical screen coordinates of the two devices, a unified coordinate system can be achieved by determining the same coordinate offset. The client's root anchor point is transformed into the local coordinate system of the feature image, setting the same coordinate offset V_{eca}. Based on the existing coordinate offset and the spatial coordinates of the feature recognition image with rotation anglesV_{ecr}（θ_1， θ_2， θ_3）, the root anchor point coordinates are aligned in the world coordinate system. According to the matrix transformation rules in the world system, the transformation matrix for the root anchor point is obtained by rotating in the z-x-y sequence.

$$R_L^W = Rot(Y, \theta_2)\, Rot(\mathrm{X}, \theta_1)\, Rot(\mathrm{Z}, \theta_3) \tag{8}$$

Get the coordinates of the root anchor point in the world coordinate system.

$$V_{eca2}=Tr\left(X_t^{'}\ ,\ Y_t^{'}\ ,\ Z_t^{'}\right) R_L^W V_{eca} \tag{9}$$

In the equations, $Rot(x,\theta) = \begin{bmatrix} M(x,\theta) & 0 \\ 0 & 1 \end{bmatrix}$ represents a rotation matrix, where $M(k,\theta) = I + \sin\theta R_{\vec{k}} + (1 - \cos\theta) R_{\vec{k}}^2$ is the rotation matrix for any vector $\vec{k}$ rotating counterclockwise around the axis by an angle θ in three-dimensional space. Here, I is the 3×3 identity matrix, and $R_{\vec{k}}$ is the cross-product matrix of $\vec{k}$.

$Tr(x,y,z)=\begin{bmatrix} I & (x,y,z)^{\mathrm{T}} \\ 0 & I \end{bmatrix}$ denotes the translation matrix.

After spatial calibration of different devices, although the root anchor points in each AR space have different numerical values in the world coordinate system, they are aligned in physical space, serving as the origin of the shared AR space's common coordinate system. In the shared coordinate system, AR resources only need to exist as their child objects and ensure local coordinate consistency to achieve spatial coordinate collaboration.

Scene collaboration involves both coordinate collaboration of the shared AR subsystem and collaboration of AR resources. Building on the foundation of root anchor-based coordinate collaboration to construct a shared AR space, a unified loading of AR resources and consistency in resource interaction can be achieved under different assembly perspectives. Collaborative resources are stored in shared cloud storage, and when the MBD model is stored in the shared space, the creation of the AR scene in a procedural form ensures consistency in model loading and removal, monitored through the shared space. In achieving consistency in the interaction process, as transformation information (transform) stores the basic attributes of resources, the system monitors and updates it in real-time to ensure consistency in model interactions, such as movement, rotation, and scaling operations in different spaces.

Through AR scene collaboration, operators can perform assembly based on collaborative perspectives, and the natural AR human-computer interaction ensures effective transmission of collaborative information.

V. CASE STUDY

This paper develops an augmented reality-based multi-user collaborative design system using the aforementioned approach and validates it through a case study of an interior design project.

A. Platform Construction

The establishment of the interior space design management platform primarily aims to provide data services for the design process, encompassing information storage and expression of interior design elements, definition and storage of augmented reality (AR) resources, and integration of collaborative design algorithm services. Firstly, a knowledge graph of interior design is constructed based on the spatial design requirements. This involves utilizing the DT and spatial relationships of design objects to obtain design precision information and design relationships for design nodes. Subsequently, design errors are calculated, facilitating the iterative update of on-site design information.

The design-level DT manages the fundamental information of interior design, while the object-level DT oversees its basic attribute information. The knowledge representation of the interior design DT is illustrated in Fig. 5, encompassing attribute information such as augmented reality (AR) visualization and algorithmic interfaces. The visualization information primarily includes interior design object models and information on interior design elements. Simultaneously, the algorithmic interfaces furnish collaborative design algorithms utilized in the collaborative calculation processes of design.

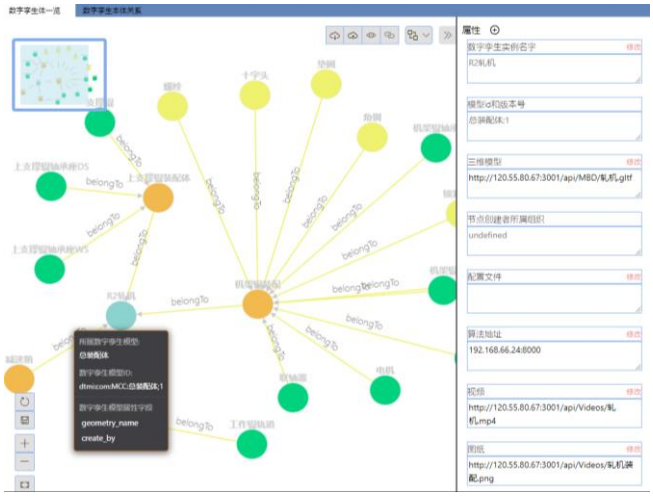

Fig. 5. Interior design DT knowledge expression.

In response to diverse on-site design requirements, the Augmented Reality (AR) system leverages the DT platform to acquire resources, establishing an adaptive AR design environment. Through real-time rendering and AR visualization of design elements, parameters, and tools, the system guides designers in the creative process, thereby reducing cognitive load and enhancing design efficiency.

B. Test Validation

Incorporating Augmented Reality (AR) technology into interior space design can enhance both design efficiency and customer experience. This study explores collaborative work modes in the interior design process by combining smartphones and HoloLens headsets. Using a smartphone as the collaborative reference platform, coupled with Vuforia image tracking technology, synchronization of root anchor points between HoloLens and smartphones within the same AR space is achieved. To enhance the precision of collaboration, recognition images with distinct features are chosen, and stability tests for rotation and scaling are conducted. The collaborative accuracy primarily relies on the alignment of root anchor points across different devices. This is indirectly measured by sending the physical dimensions of the recognition image to each collaborative device and comparing the results with the image tracking outcomes.

Fig. 6. Root anchor synergy process.

As illustrated in Fig. 6, this process accurately tracks the positions of interior design elements under different sizes, distances, and rotation angles. It achieves precise alignment with translation errors approximately 1mm and rotation errors less than 0.5 degrees, providing a reliable reference for the collaborative interior design process. Fig. 6 presents the visual effects of the collaborative interior design scene from different perspectives, namely the smartphone AR perspective and the HoloLens AR perspective. Within the AR collaborative space, design elements are categorized into private information, public information, and associated information. For instance, foundational elements of the design, such as major furniture or structural components, serve as public resources shared by all participants, ensuring consistency in physical space and interactive effects from different perspectives.

Private information is tailored to the specific tasks of individual designers. Different designers may see different AR elements based on their task requirements. Key design objects, like specific furniture or decorative elements, although requiring attention from all designers, may have different details of interest to each designer. By setting element attributes as private, designers can interactively translate and rotate models to comprehensively understand and examine every angle of the design objects.

C. Physical Assembly Process Synergy

This section analyzes the collaborative effects of the physical design process through an on-site interior design implementation experiment. Designers arrived at the actual interior design site and engaged in collaborative design layout activities for the central area of the living room. Given the diverse design objects and the complexity of the design environment, acquiring on-site information proved challenging for the designers. To address this challenge, designers accessed

design element information, including collaborative design tasks and design resources, through the tethering of the DT design platform to assist in the design process. Designers were then able to visualize three-dimensional models and drawings of the design resources using augmented reality (AR).

The collaborative layout design of the central area requires the joint efforts of multiple individuals. During the design preparation phase, designers, designated as A, B, and C, gather design information from various visual perspectives based on their respective roles and responsibilities. It is displayed the AR visual perspectives of designers A, B, and C. Designer A is responsible for overall concept confirmation and design optimization, primarily assisting in layout design. To facilitate effective design guidance, the AR system visualizes the design baseline for this perspective, allowing designer A to comprehend the structural model of the spatial layout. To achieve task collaboration among designers, different forms of visualization for resources are necessary. Since all designers use the central area model as the baseline for their designs, with its attributes set as "Public" for shared visualization, designers B and C can observe the spatial model loaded by designer A in the shared AR space, enabling task collaboration. Designer B, acting as the lead designer, is tasked with central area layout design. The AR system employs design animation to demonstrate layout details, guide the design process, and visualize the effects. Designer C's task is to test the layout's effectiveness and assist in the design process. The system uses Model-Based Definition (MBD) model visualization to help designer C obtain design parameter information. To avoid interference caused by the overlay of visual resources from multiple AR subsystems, the model attributes of the central area are set as "Private," visible only to designer C. Interactions by designer C with the central area do not affect the design animation presentation for designer B

Throughout the entire design process, designers can iteratively update design solutions by uploading real-time design information to the DT space through AR system interactions such as voice commands or gestures. The optimized information is then fed back to the design team via the AR system, completing a closed-loop control of the design.

To validate collaborative design efficiency, designers responsible for other design elements were divided into two groups and subjected to 20 experiments each. The parameters, including design preparation, completion, and documentation, were compared with those of experienced designers focusing on the central area, as summarized in Table I.

TABLE I. COMPARISON OF ASSEMBLY EFFICIENCY FOR DIFFERENT ASSEMBLY CATEGORIES

Assembly category	Preparedness efficiency	Assembly Fluency	Assembly Collaboration Efficiency	Assembly Special Session Completion	Assembly pass rate	Assembly completion efficiency	Assembly process record efficiency
Senior Designer Codesign	100	100	100	100	100	100	100
New Designer Codesign	45	45	40	80	65	30	70
New Designer Codesign	90	80	85	100	95	85	160

From Table I, the following observations can be made: ① New designers utilizing traditional processes and methods for interior design tasks incurred substantial time in design preparation and documentation. Although the design qualification rate exceeded 50%, the design efficiency fell short of meeting the scene's requirements. ② AR-based collaborative design, supported by DTs and AR technology, exhibited overall favorable performance. ③ In the AR collaborative environment, the design collaboration efficiency of new designers was twice that of traditional design, enabling the new team to quickly adapt. ④ Guided and alerted by AR, designers were less prone to overlook design aspects, achieving a 100% completion rate for handling detailed elements in spatial layouts. The overall design qualification rate reached 95%, ensuring the stability of design quality. ⑤ AR's data interaction eliminated communication barriers between physical space and the twin space, and the efficiency of recording design information in the design process even surpassed that of experienced designers. In comparison, it is evident that AR-guided collaborative design based on DTs significantly reduces the cognitive burden on designers and enhances both the stability of design quality and overall design efficiency.

D. Analysis and Discussion

In the digitized process of interior space design, interactive experience and efficiency are crucial considerations. Within the digital design environment, a well-crafted interactive experience significantly impacts the work efficiency of designers and the quality of design outcomes. The user interface of design software should be intuitive, easy to understand, and flexible enough to adapt to the designer's workflow. Efficiency is equally vital in the digital design of interior spaces. The design process should be swift, flexible, and capable of adapting to evolving customer demands and market trends.

Through the experiments described above, the proposed method and developed system demonstrate the following advantages in terms of interactive experience and design efficiency:

1) The design software provides real-time views of spatial models, allowing designers to immediately see how their design choices impact the layout and aesthetic effects of the space. Simultaneously, the software enables designers to effortlessly adjust design parameters and instantly observe the

results of these adjustments. This immediate feedback significantly enhances design efficiency and quality. Furthermore, the design software supports seamless integration with other tools and platforms, such as VR/AR demonstration software, material databases, and 3D printing systems. This facilitates a smoother design process, reducing waiting and conversion times.

2) The software allows for the rapid creation of initial 3D models and 2D floor plans for interior layouts, saving time. While some designs may require adjustments to existing models, at least one-third of the projects need a complete redesign. For instance, forming a preliminary design model in 15 minutes contrasts sharply with the days or even a whole day required for a seasoned designer to conceptualize a design from scratch or make adjustments to an existing model. This results in substantial savings in design costs.

In conclusion, this system provides robust tools for the digitization of interior space design, enhancing both design efficiency and quality while optimizing the user's interactive experience to meet the rapidly changing demands of the market.

VI. Conclusions and Future Work

This research investigates the current status and challenges within the interior space design industry, proposing an intelligent design approach based on DT. We identify interdisciplinary integration challenges in the design process, limitations associated with design knowledge relying on personal experience, and issues stemming from frequent design modifications, lengthy project cycles, and high work intensity imposed by traditional design patterns. To address these challenges, we establish multi-physical information models for interior spaces, systematically describing rule models for design knowledge and experience in a digitized format. Additionally, we achieve intelligent parametric design associations among spatial elements.

This design approach not only enhances design efficiency and quality but also opens new avenues for the intelligence of interior space design. In the future, we aim to refine this design approach, improving the accuracy and reliability of the models, enhancing the intelligence of rule models, strengthening the intelligent parametric design associations among spatial elements, and exploring the application of this method in a broader spectrum of interior design domains. We will also investigate the integration of this design method with advanced digital technologies, such as artificial intelligence and big data, to achieve a higher level of intelligent design.

The primary contribution of this research lies in the proposal and implementation of an innovative interior space design method, with the potential to drive the transformation of the design industry towards intelligence.

A Safety Detection Model for Substation Operations with Fused Contextual Information

Chen Bo[1], Zhanghong Yu[2], Yangrun Xi[3], Zhao Lei[4], Ding Yi[5*]
State Grid Beijing Electric Power Company, Beijing 100031, China[1, 2, 3, 4]
Beijing Electric Power Economic Research Institute Co., Ltd., Beijing 100055, China[1, 2, 3, 4]
Nanjing Artificial Intelligence Research of IA, Nanjing 211100, China[5]

***Abstract*—Detecting and regulating compliance at substation construction sites is critical to ensure the safety of workers. The complex backgrounds and diverse scenes of construction sites, as well as the variations in camera angles and distances, make the object detection models face low accuracy and missed detection problems. In addition, the high complexity of existing models creates an urgent need for effective parameter compression techniques to facilitate deployment at the edge server. To cope with these challenges, this study proposes a safety protection detection algorithm that fuses contextual information for substation operation sites, which enhances multi-scale feature learning through a two-path downsampling (TPD) module to effectively cope with changes in target scales. Meanwhile, the Global and Local Context Information extraction (GLCI) module is utilized to optimize the key information learning and reduce the background interference. Furthermore, the C3GhostNetV2 unit is utilized in discerning the interconnections of far-off spatial pixels, while enhancing the network's expressive power and reducing the number of parameters and computational costs. The outcomes of the experiments indicate that the present model improves upon the mAP50 metric by 4.5% compared to the baseline model, and the accuracy of the checks and the recall have seen respective increases of 4.8% and 10.1%, while there has been a reduction in both the count of parameters and the floating-point calculations by 16.5% and 12.6% respectively, which proves the validity and practicability of the method.**

I. INTRODUCTION

As societal demand for electrical energy continues to rise, there is an increasingly urgent need for power production in China. However, due to a combination of various factors, the frequency of power production accidents in the country remains relatively high, posing a serious threat to urban safety. The power construction process involves a wide range of complex scenarios, including tower assembly, hoisting, excavation work, hot work, edge work, and high-altitude operations. These tasks encompass numerous safety challenges, requiring workers to maintain a high level of vigilance and adhere to standardized procedures to prevent serious accidents [1-2].To ensure that power workers enhance their safety awareness, adopt compliant protective measures and procedures, and ultimately improve on-site safety levels to ensure the normal operation of the power system, there is an urgent need for worksite compliance monitoring and supervision. Traditional manual management methods are costly and inefficient, making it difficult to meet the needs of effective supervision in multi-scenario, around-the-clock power grid operations. Therefore, the application of deep learning algorithms for compliance monitoring at power grid work sites holds significant research value. This research introduces advanced visual technologies to the field of power production and provides substantial support for improving on-site safety levels.

With the tremendous achievements of deep learning algorithms in image recognition and detection [3-5], these algorithms have made significant progress in various applications. Thanks to their high detection accuracy and strong robustness [6-7], deep learning-based object detection algorithms have been widely applied in detecting standardized work clothing. Ren et al. [8] discussed the concept of deep learning-based intelligent substation system monitoring and analyzed the advantages and disadvantages of using traditional methods and deep learning for monitoring. Liu et al. [9] employed the Faster R-CNN algorithm for detecting whether standard work clothing is worn and introduced an L2 regularization term into the loss function to improve the convergence speed of the model during training. The model demonstrated good generalization ability and robustness, with significant improvements in both accuracy and real-time performance compared to the baseline model. Reference [10] employed the lightweight network from MobileNet in the YOLOv2 structure to achieve a certain degree of network compression, reducing the computational complexity of the model and improving its convergence performance, but with lower accuracy in object detection. Xu et al. [11] proposed an improved YOLOv3 algorithm for safety helmet recognition, which enhanced the precision of safety helmet detection, but the detection speed was relatively slow. The study in [12] implemented a real-time video analysis algorithm based on YOLOv4 for monitoring whether workers in industrial facilities wear helmets, safety vests, and safety belts, but it ignored the influence of complex backgrounds and environmental factors on algorithm performance and did not analyze the algorithm's complexity. Du et al. [13] selected the Swin Transformer as the backbone network based on YOLOv5 to extract deeper semantic information and capture more detailed features of safety helmets, but it had false detection issues when the colors were the same. In addition to YOLO, Long et al. [14], Wu et al. [15], and Li et al. [16] proposed safety helmet detection methods based on SSD, which achieved good detection results. Although single-stage object detection algorithms have performed well in terms of real-time performance and efficiency, they still face some challenges, such as the use of dense grids or anchor boxes to generate candidate regions, which can lead to overlapping or

missed detections and relatively poor performance in detecting small objects [17].

Existing detection methods exhibit certain limitations in practical application scenarios. They often focus on specific target detection while neglecting the diverse task requirements in power construction sites. For instance, Shen et al. [18] utilized convolutional neural networks to detect facial features and helmet usage on construction sites. However, this study did not sufficiently address the impact of environmental variations on detection performance. Additionally, the lightweight improvement of YOLOv5 proposed in [19] targets helmet detection only and still has room for improvement in adaptability and scalability in real-world scenarios. Furthermore, the methods in [20, 21] are only effective in environments with simple backgrounds. These approaches, which focus on single categories or specific scenarios, struggle to handle the complexity and variability of power construction environments, limiting their broader applicability in practical settings.

In recent years, research on compliance detection for multiple categories of personal protective equipment (PPE) has increased. For instance, Zhang et al. [22] enhanced YOLOv4's feature extraction network and combined it with PANet to achieve effective detection of helmets and masks. Similarly, [23] utilized synthetic datasets to train an improved YOLOv5 model, successfully applying it to real-time PPE detection in industrial environments. In study [24], an intelligent detection system was designed to notify supervisors when workers failed to wear helmets or vests, improving the efficiency of on-site safety management. Additionally, Gong et al. [25] adopted a key region localization method to optimize PPE detection performance further. While these methods have achieved notable advances in accuracy and detection capability, they still face certain limitations. The complex model structures demand significant hardware resources and result in low detection efficiency, making them challenging to apply in industrial scenarios requiring real-time performance and low power consumption. Therefore, reducing model complexity while maintaining detection accuracy remains a critical research direction in this field.

The aforementioned methods have achieved detection and monitoring of power grid operation scenes with humans as the main objects to some extent, but the detection scenarios and categories are relatively limited, usually focusing on specific categories such as safety helmets or work clothing, with less attention to other scenes. This limits the comprehensiveness and applicability of the algorithms because power grid operation scenes involve various scenarios such as lifting operations, excavation work, hot work, work near edges, and work at heights, requiring more comprehensive detection capabilities. Additionally, the collected images from the power grid industry exhibit characteristics of diverse target types, inconsistent sizes, and complex and variable background environments. In complex backgrounds, the previous algorithms perform poorly in effectively extracting features from targets of different scales, resulting in weak adaptability to environmental changes. This can lead to issues of missed detections and low accuracy in practical applications, reducing the reliability of the algorithms. Furthermore, existing models have high complexity, requiring a reasonable and effective parameter simplification technique as a basis to address the challenges of deployment on remote server devices. Enhancing object detection performance in complex scenarios, improving the detection accuracy of multi-scale objects, and reducing model complexity have become key research focuses in substation safety monitoring. Therefore, this study presents an improved YOLOv7 network. A down-sampling module was designed to enable the model to better learn multi-scale features. Additionally, a Global and Local Context Information extraction (GLCI) module was introduced, allowing the model to effectively capture critical information within complex backgrounds and reduce missed and false detections caused by background interference. Furthermore, structural optimization was implemented to reduce the model's parameter count, enhancing the real-time performance and adaptability of the improved YOLOv7 model while maintaining high detection accuracy. These improvements enable efficient and compliant detection in power production scenarios. Our contributions are summarized as follows:

- We design a global and local context information extraction (GLCI) module, enabling the network to capture both global contextual and local spatial information, effectively addressing the challenge of complex backgrounds in power construction site environments.
- We propose a two path downsampling (TPD) module, which enhances the network's ability to learn features across multiple scales, improving performance on multi-scale target detection tasks.
- We develop a novel C3GhostNetV2 unit, replacing all ELAN-H modules in the neck network and the ELAN modules at the backbone's end. This design expands the receptive field, strengthens model representation, and significantly reduces model complexity, parameter count, and computational cost.

II. Proposed Method

This method consists of three modules: Global and Local Context Information extraction (GLCI) module Two-Path Downsample (TPD) module, and C3GhostNetV2 module. The TPD module enables the network to effectively capture and utilize spatial information from feature maps of different scales. The GLCI module helps the network learn key information more efficiently and reduces background interference. The C3GhostNetV2 unit not only expands the perception range to ensure the model's expressive effectiveness but also reduces the demand for floating-point calculations.

The YOLO series algorithms have high similarity in terms of network structure and module composition. Taking YOLOv7 as an example, Fig. 1 shows the network structure diagram of YOLOv7 with GLCI and TPD inserted and lightweight improvements applied. It mainly includes four components: Input, Backbone, Neck, and Head. The Backbone consists of CBS, C3, and SPPF, which are responsible for extracting information features from input images. After the Backbone, feature maps of three different sizes can be obtained. The Neck module combines the Feature Pyramid Network (FPN) and Pyramid Attention Network (PAN) to fuse the features extracted by

the Backbone. The Prediction Head consists of three prediction layers of different scales, which are responsible for outputting the network's predictions.

In YOLO series networks, the backbone is primarily responsible for feature extraction, transforming input images into high-level feature representations [26], which serve as the basis for subsequent detection. The insertion of the GLCI module enhances the network's learning ability for multi-scale information and its perception of global and local context, addressing the challenges posed by significant scale variations and complex backgrounds. The backbone is where the network learns and perceives information, making it a suitable location for the insertion of the GLCI module. Additionally, placing the GLCI plugin at the end of the backbone allows for effective utilization of high-level information in the feature maps, and the lower resolution of the end feature maps can alleviate the potential computational and memory costs introduced by the plugin. Furthermore, since the proposed GLCI plugin does not change the size of the input and output feature maps, it is not affected by the number of network layers and is applicable to all YOLO series algorithms. Taking YOLOv7 algorithm as an example, as shown in Fig. 1, the feature maps output by the last CBS module in the backbone have a size of 20×20×1024. After being processed by the GLCI plugin, the size and number of channels of the feature maps remain unchanged, meeting the data format requirements of the subsequent network structure. Therefore, it is reasonable to insert the GLCI module at the end of the backbone. Considering that the neck network contains rich information and serves as the direct input to the head network, the TPD module is inserted into the neck network. Finally, the C3GhostNetV2 unit is constructed in the neck network to expand the perception field and maintain the model's expressive power while significantly reducing the number of parameters and computational costs.

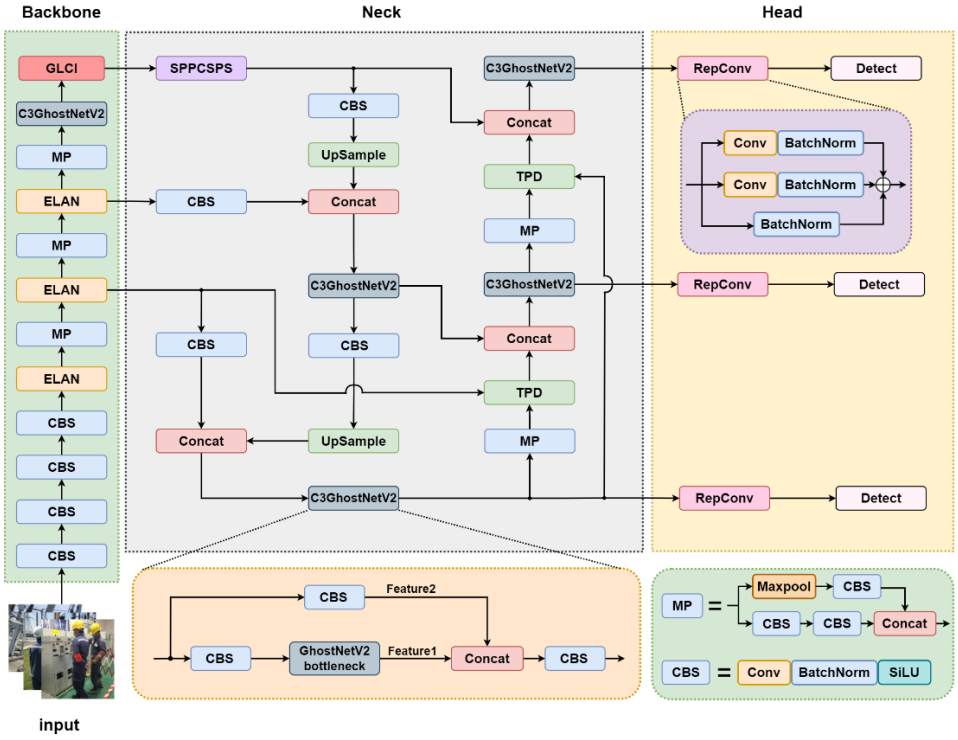

Fig. 1. Schematic diagram of lightweighting methods structure.

A. Global and Local Context Information Extraction Module

To improve network adaptability in complex image backgrounds in real-world power construction site detection tasks, we propose the GLCI module (see Fig. 2). This module consists of two branches: Global and Local Context Extraction. It helps the object detection network learn more crucial information and attenuate background interference. The primary objects to be detected in input images—power construction site workers—are closely tied to their surrounding environments. Incorporating contextual information into the model enhances its understanding of the relationships between detected objects and their scenes, thereby improving detection performance. The global branch of the GLCI module, built on the traditional self-attention mechanism, leverages not only the relationships between keys and queries but also emphasizes the contextual information among input keys. This approach enhances the network's capacity to extract contextual information and improves its ability to learn critical features through the guidance of the learned dynamic attention matrix.

For a feature map X of size $c \times h \times w$, linear processing is applied to yield K=X, Q=X,, and V=XWV, where K denotes the key, Q the query, and V the value, with WV representing a 1×1 embedding convolution. In the spatial domain, group convolution is performed on adjacent keys within a 3×3 grid of $\boldsymbol{K}$, with the number of groups set to 4. This is followed by batch normalization (BN) and ReLU activation, resulting in a feature map $\boldsymbol{K}_1$ of size $c \times h \times w$. Through these operations, encoding is applied to the adjacent keys in the spatial domain, producing K1, which captures the static contextual information between

neighboring keys and is referred to as static contextual keys $\boldsymbol{K}_1$. Subsequently, $\boldsymbol{K}_1$ and $\boldsymbol{Q}$ are concatenated, and two successive 1×1 convolutions generate an attention matrix $\boldsymbol{A}$. This attention matrix $\boldsymbol{A}$ differs from the traditional self-attention mechanism, as it is derived from query features and static contextual features of $\boldsymbol{k}_1$, rather than key/query pairs. Thus, $\boldsymbol{A}$ effectively aggregates contextual information.

$$A = [K^1, Q] W_\theta W_\delta \tag{1}$$

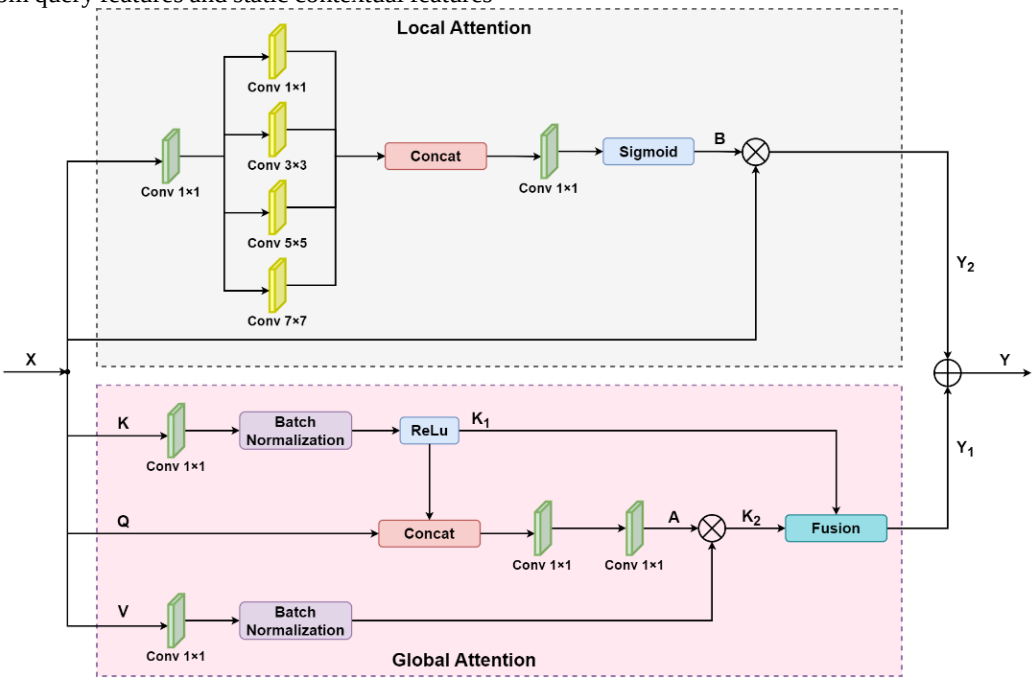

Fig. 2. Structure diagram of GLCI module.

In Eq. (1), W_θ represents a convolution with a ReLU activation function, and W_δ represents a convolution without an activation function. Next, the attention matrix $\boldsymbol{A}$, which aggregates contextual information, is element-wise multiplied with $\boldsymbol{V}$ resulting in a feature map $\boldsymbol{K}_2$ weighted by $\boldsymbol{V}$. Since $\boldsymbol{K}_2$ is obtained through self-attention computation on the input keys and values, it captures the dynamic feature interactions among the inputs and is named the dynamic contextual keys. The fusion of the static contextual keys $\boldsymbol{K}_1$ and the dynamic contextual keys $\boldsymbol{K}_2$ yields the output $\boldsymbol{Y}_1$ of the global attention network.

In the Local Contextual Information (LCI) network, multiple convolution sizes capture spatial information at various scales, enhancing learning and addressing noisy, complex backgrounds. For an input feature map $\boldsymbol{X}$ of size $c \times h \times w$, a 1×1 convolution reduces the channels to 1/16, minimizing parameters. The reduced map is processed by 1×1, 3×3, 5×5, and 7×7 convolutions, concatenated into a tensor of size $1/4\,c \times h \times w$, then passed through a 1×1 convolution to reduce the channels to 1. Applying the sigmoid function produces a local spatial attention map $\boldsymbol{B}$ of size 1×H×W, which is element-wise multiplied with $\boldsymbol{X}$ to generate $\boldsymbol{Y}_2$. The outputs of the Global and Local Contextual Information networks, $\boldsymbol{Y}_1$ and $\boldsymbol{Y}_2$, are summed to produce $\boldsymbol{Y}$, enabling the GLCI module to capture both local and global features and address challenges from complex backgrounds.

B. Two Path Downsampling (TPD) Module

The challenge of handling multiscale data in deep learning lies in efficiently extracting and learning features from data of varying scales, such as different sizes and resolutions. To address the impact of multiscale issues on detection accuracy in images collected from power construction sites, this paper proposes the Two Path Downsampling (TPD) module. This module facilitates information exchange between different feature layers, enabling spatial channel dependencies between different scales and enhancing the performance of feature extraction across different scales. The TPD module's structure is illustrated in Fig. 3.

The TPD module takes two input feature maps: the local feature map F_c with dimensions $c \times h \times w$ and the higher-level feature map F_u with dimensions $1/2c \times 2h \times 2w$. Unlike traditional stride-based convolutional downsampling, this module introduces a lossless downsampling process for the local feature map, preserving its fine-grained details. Additionally, the downsampling process is improved by preserving spatial information before and after downsampling, reducing the loss of detail. Furthermore, the module captures details from the higher-level feature map and incorporates semantic information from the local small-scale feature map, enhancing interdependencies between feature maps at different levels.

The downsampling process consists of two distinct paths. Path 1 involves lossless downsampling of the local feature and an enhanced convolutional downsampling process. The local feature F_c first undergoes feature extraction through average pooling and convolution with stride 1, resulting in the feature map F_{cl} of size $c \times h \times w$. Then, the feature map F_{cl} is

reshaped to generate the pseudo lower-level feature F_{nl} of size $c\times 1/2h\times 1/2w\times 4$, which preserves the local feature without information loss. Subsequently, softmax normalization is applied to obtain the lossless downsampled result F_{snl} of size $c\times 1/2h\times 1/2w\times 4$. Meanwhile, the spatial information of the local feature F_c is preserved by applying a convolution operation with stride 1, resulting in the spatial information feature F_s of size $4c\times h\times w$. Then, a downsampling operation is performed using a convolutional operation with stride 2 to generate the lower-level feature F_{sl} of size $4c\times 1/2h\times 1/2w$,which includes the preserved spatial information. Next, the feature F_{sl} undergoes feature extraction using the BAM [27] attention mechanism, yielding the feature representation F_{bsl}. Finally, the previously preserved spatial information is restored through a reshaping operation, generating the lower-level feature representation F_{el} of size $c\times 1/2h\times 1/2w\times 4$, which includes enhanced spatial information.

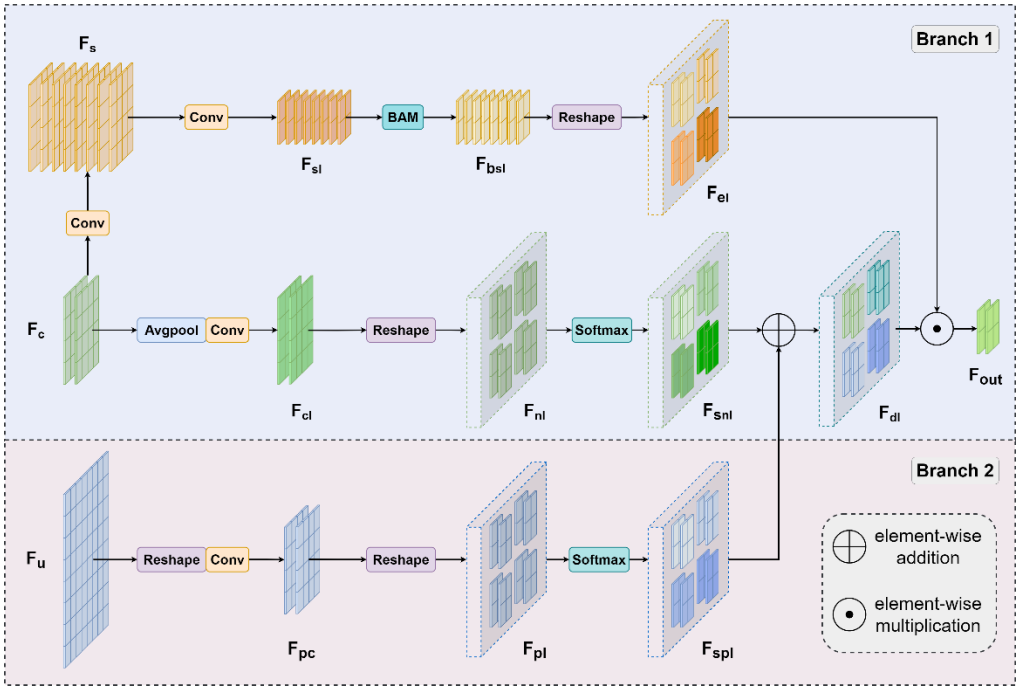

Fig. 3. Structure diagram of TPD module.

Path 2 involves a lossless downsampling process for the higher-level feature. The higher-level feature undergoes downsampling for the first time through reshaping, resulting in a size of $2c\times h\times w$. Then, a convolution operation is applied to halve the number of channels, generating a pseudo local-level feature F_{pc} based on the reconstructed details from the higher-level feature. Subsequently, a second downsampling is performed, yielding a pseudo lower-level feature F_{pl} based on the reconstructed details from the higher-level feature, with a size of $c\times 1/2h\times 1/2w\times 4$. Finally, softmax normalization is applied across the last dimension to obtain the output F_{spl} of Path 2.

The output F_{spl} of Path 2 is element-wise added with the downsampling result F_{snl} of the local feature, resulting in a lower-level feature map of size $c\times 1/2h\times 1/2w\times 4$ that combines the detailed information from both the higher-level and local features. This lower-level feature, denoted as F_{dl}, contains the detailed information from both the higher-level and local feature maps. The equation is as follows:

$$F_{dl} = Softmax(R(Conv(R(F_u)))) + Softmax(R(Conv(Avgpool(F_c)))) \quad (2)$$

Here, $R(\square)$ represents the reshape operation. The lower-level feature map F_{dl} obtained from the fusion in (2) is multiplied and fused with the enhanced lower-level feature F_{el} from Path 1, followed by summation across the last dimension. This yields the output feature map F_{out} of the TPD module, with a size of $c\times 1/2h\times 1/2w$. The equation is as follows:

$$F_{el} = R(BAM(Conv(Conv(F_c)))) \quad (3)$$

$$F_{out} = Sum(F_{dl} \square F_{el}) \quad (4)$$

C. C3GhostNetV2 Module

The original YOLOv7 model has relatively high complexity due to deep layers and multiple convolution operations, leading to many parameters and computational redundancy [28]. To reduce floating-point operations and parameters, this paper introduces the C3GhostNetV2 module. As shown in Fig. 1, the

input feature map is split into two branches: one passes through CBS and the GhostNetV2 bottleneck[29], generating Feature 1, while the other passes through CBS to produce Feature 2. Feature 1 and Feature 2 are then concatenated and processed by CBS to produce the final output.

Fig. 4 illustrates the structure of the GhostNetV2 bottleneck, comprising three steps: First, the input feature map is transformed into a compressed low-dimensional vector through downsampling and convolution. Next, this vector is processed by fully connected layers in vertical and horizontal directions, expanding its receptive field across multiple dimensions. Finally, the attention weights are normalized using the Sigmoid activation function to enhance the network's utility and stability. As a result, the network is able to perceive long-range dependencies between spatial pixels, enhancing the expressive power of the model. The DFC attention output [30] is combined with the first Ghost module's output. Depth-wise separable convolution is used to further reduce computational and memory overhead, improving inference speed. After generating features from the second Ghost unit, a skip connection merges the initial input with the new features, producing the final output. This design captures long-range spatial dependencies while significantly reducing computational and parameter costs.

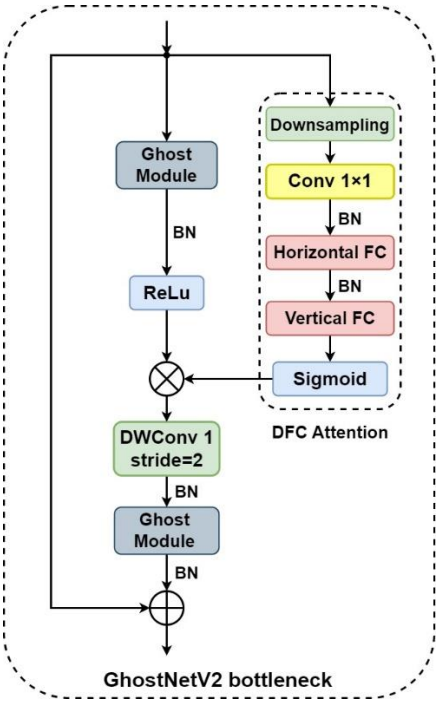

Fig. 4. GhostNetV2 bottleneck structure.

III. Experimental Preparations

A. Experimental Setup and Dataset

The software environment for this experiment includes Ubuntu 16.04, PyTorch 1.11, and CUDA 11.3. The hardware setup is described in detail in Table I. The ablation experiments were conducted using the stochastic gradient descent (SGD) strategy with 100 epochs of training. The initial learning rate was set to 0.01 and decayed with a minimum value of 0.0001. The batch size was set to 8. The momentum parameter was set to 0.9, and the weight decay was set to 0.0005.

TABLE I. Experimental Hardware Setup

Hardware Name	Model	Quantity
CPU	Intel Core i7-10700 CPU	1
Memory	Kingston 16G DDR4	2
Graphics Card	NVIDIA RTX-3090	1
Hard Drive	Western Digital 10TB	1

The experimental dataset used in this study consists of 4,030 images collected by a power company. The dataset includes four different work scenarios: lifting operations (1,104 images), hot work operations (1,028 images), edge operations (973 images), and high-altitude operations (925 images). These scenarios cover samples with different target sizes and brightness levels (see Fig. 5).

Fig. 5. Examples of 18 types of detection target datasets.

These work scenario data consist of eighteen categories: (1) crane, (2) all personnel on site, (3) wearing safety helmets, (4) work barriers, (5) control room, (6) hooks, (7) wearing safety harnesses, (8) not wearing safety harnesses, (9) safety harnesses properly suspended, (10) safety harnesses improperly suspended, (11) personnel performing hot work, (12) supervisors overseeing hot work, (13) protective face shields, (14) ignition source, (15) fire extinguisher, (16) improper wearing of safety gloves, (17) mobile phones. The dataset contains a total of 96,419 instances, which reflects the complexity and diversity of the work scenarios. The training set and validation set are split in an 8:2 ratio. Evaluation metrics

For the evaluation of the performance of the object detection model, a specific evaluation system was adopted. In this paper, the model's floating-point operations (GFLOPs) and the total number of parameters were calculated to assess its runtime and memory requirements. Meanwhile, the average precision (AP) and mean average precision (mAP) were used as standards to measure the accuracy of the model. The detection efficiency of the model on different categories was determined by the average precision rate, which is comprehensively determined by the recall and precision.

The recall is calculated using the following formula:

$$R_{ec} = \frac{T_p}{T_p + F_N} \times 100\% \tag{5}$$

The precision is calculated using the following formula:

$$P_{re} = \frac{T_p}{T_p + F_p} \times 100\% \tag{6}$$

Where T_p represents the true positive, F_N represents the false negative, and F_p represents the false positive. Precision-recall (PR) curve plots recall on the x-axis and maximum precision on the y-axis. The area under the PR curve is calculated by integrating over the curve, resulting in the value of AP (average precision). The mean average precision (mAP) is obtained by calculating the average of the AP values for all individual classes. The calculation formula is as follows:

$$AP = \int_0^1 P(r)dr \tag{7}$$

$$mAP = \frac{\sum_{k=0}^{c} AP_k}{C} \tag{8}$$

In the formula, $P(r)$ represents the PR curve, $\sum_{k=0}^{c} AP_k$ represents the average precision for each class, and C represents the total number of classes.

IV. Experimental Results And Analysis

A. Ablation Study

To evaluate the performance of the proposed approach in object detection tasks and study the effectiveness of various optimization strategies, we conducted ablation experiments on the YOLOv7 model as a baseline. In the table, the symbol " √ " indicates that the corresponding optimization unit has been applied. All experimental groups were conducted with the same hyperparameters and training strategies to analyze the impact of optimization strategies on the network more clearly. The experimental results are shown in Table II.

Experiment 1 was conducted on the original YOLOv7 without any improvements. In Experiment 2, the GLCI module was added. In this case, the precision did not change much, but the recall increased by 7.2%, and the mean average precision (mAP50) improved by 2.1%. This indicates that the GLCI module has a significant advantage in handling object detection tasks with complex backgrounds. By applying global and local attention mechanisms, the network learns key information more efficiently and reduces background interference. In Experiment 3, the TPD module was added. In this case, the precision increased by 2.5%, the recall increased by 8.7%, and mAP50 improved by 2.3%. This suggests that the introduction of the TPD module effectively enhances the network's learning ability for feature maps of different scales. By extracting and fusing multi-scale spatial and channel information, it effectively solves the problem of detecting objects with multi-scale variations and improves detection performance. From the results of Experiments 2 and 3, it can be seen that after integrating the TPD and GLCI modules, there is no significant difference in the number of parameters and the scale of floating-point operations. The introduction of the C3GhostNetV2 module in Experiment 4 resulted in a significant reduction of 87.2% in the scale of floating-point operations and a decrease in the parameter scale to 83.0%, effectively reducing the complexity of the model. The mAP50 metric of the model also increased by 0.4%, with corresponding improvements of 1.7% in precision and 9.6% in recall. This indicates that even with a reduction in parameters and computational complexity, the detection accuracy of the model was not compromised. This confirms that the C3GhostNetV2 unit not only reduces the complexity of the model but also enhances its performance. When all three modules (GLCI, TPD, and C3GhostNetV2) were simultaneously inserted into YOLOv7, the network showed the best improvement. The average precision (mAP50) increased by 4.5% compared to the original model, and precision and recall improved by 4.8% and 10.1% respectively. Moreover, compared to the baseline model, the complexity of the model was also reduced to a certain extent. This demonstrates that the simultaneous use of the three proposed improvement methods can yield better results.

TABLE II. Improved YOLOv7 Algorithm Ablation Study Results

Experiment	GLCI	TPD	C3GhostNetV2	mAP50 /%	Precision /%	Recall /%	Parameters /M	GFLOPs /G
1				86.3	85.3	78.5	37.6	107.3
2	√			88.4	85.2	85.7	37.6	107.6
3		√		88.6	87.8	87.2	37.6	107.5
4			√	86.7	87.0	88.1	31.2	93.6
5	√		√	88.7	90.5	88.4	31.4	93.8
6		√	√	88.8	87.7	87.8	31.4	93.7
7	√	√	√	90.8	90.1	88.6	31.4	93.8

B. Comparative Experimental Analysis of Applicability of YOLO Series

The fundamental idea of the YOLO series algorithms is to divide the image into fixed-sized grids and make predictions for each grid, thereby achieving object detection. To validate the general applicability of the three proposed modules in the YOLO series algorithms, we conducted comparative experiments on the YOLOv4-YOLOv7 [31-33] algorithms. The experimental results are shown in Table III.

From the data in the table, it can be observed that when detecting on the dataset of eighteen classes used in this paper, the original YOLO series algorithms achieved average precisions of 80.7%, 85.7%, 84.5%, and 86.3% respectively. After integrating the proposed improvement methods into each model, the average precisions were improved by 1.8%, 1.6%, 2.3%, and 4.5% respectively. The experimental results demonstrate that by adding the three proposed modules to the backbone networks of each YOLO algorithm, the average precisions of the models were improved to varying degrees. This is attributed to the fact that the proposed modules refine the feature extraction process, enhance the network's adaptability to multi-scale targets, and bolster the network's robustness in complex backgrounds through structural improvements. Therefore, the proposed improvement methods can be widely applied in various YOLO series algorithms to reduce model complexity, enhance the learning ability and feature extraction capability of the networks, and solve the problems of multi-scale targets, complex backgrounds, and diverse scenes in images captured in power construction sites.

C. Comparative Experimental Analysis with Other Models

To validate the advantages of the proposed improved model compared to the current state-of-the-art object detection algorithms, we compared our method with commonly used object detection methods, including Faster-RCNN [34], SSD [35], RetinaNet[36], YOLOv5, TPH-YOLOv5 [37], YOLOv7, and YOLOv8. Using the same dataset and partitioning strategy, we trained each model while keeping the parameters consistent. The experimental results are shown in Table IV.

From Table IV, it can be observed that compared to the current state-of-the-art small object detection algorithm TPH-YOLOv5 and other mainstream algorithms, the proposed algorithm in this paper achieves higher accuracy on most categories. The improved algorithm outperforms Faster R-CNN, SSD, and RetinaNet algorithms, with increases in average precision (mAP) of 11.7%, 28.5%, and 7.1% respectively. Compared to the previous version of YOLOv7, the improved algorithm achieves a 4.5% increase in mAP. The experimental results demonstrate that the improved YOLO model achieves better detection accuracy.

Additionally, to visually demonstrate the superiority of the improved algorithm, this paper provides visual results under different detection algorithms (see Fig. 6). From Fig. 6, it can be observed that when detecting in operation scenes with diverse and complex backgrounds, the Faster R-CNN algorithm shows missing detections and inaccurate bounding box localization. For small-scale object categories, such as the "hook" category in lifting operations and the "aqs_hang" category in elevated work scenarios, RetinaNet, SSD, and the previous version of YOLOv7 algorithms suffer from missing detections. Encouragingly, the model constructed in this paper does not exhibit such issues. This can be attributed to the addition of the GLCI module, which enhances the learning ability of the model, allowing the network to focus on the core information of the features and reduce noise interference from the background. Therefore, this method displays high adaptability in recognizing the clothing and equipment of operators, reducing the occurrence of missed detections, and achieving significant improvements in detection accuracy. For unevenly distributed scale categories, such as the "fence" category in lifting operation scenes and the "protective mask" category in hot work scenarios, other algorithms tend to have missing detections, while the proposed algorithm effectively addresses this issue. This is because the TPD module introduced in this paper enhances the network's learning ability for features at different scales, improving the detection accuracy of multi-scale objects.

D. Dataset Comparison and Model Scalability Experiments

To evaluate the scalability and generalization capabilities of the proposed model, we conducted assessments on two publicly available datasets, SHWD [38] and Pictor-v3 [39], and compared our model with other object detection models. The SHWD dataset focuses on safety helmet detection and contains 7,581 images, including 9,047 instances of workers wearing helmets and 111,514 instances of workers not wearing helmets. The Pictor-v3 dataset primarily focuses on detecting compliance with personal protective equipment (PPE) at construction sites, comprising 1,472 labeled images, which cover various combinations of PPE: 1,209 worker-only instances (W), 2,206 worker instances with helmets (WH), 328 worker instances with vests (WV), and 983 worker instances wearing both helmets and vests (WHV). The evaluation on these two datasets further validates the model's detection capability in different scenarios, as shown in Table V.

As can be seen in Table V, the proposed improvement outperforms other YOLO-based models in both helmet detection and worker PPE compliance detection, with notable improvements in detection accuracy and inference speed. Compared to the TPH-YOLOv5 model, which specializes in small object detection, our improved model demonstrates superior performance in detecting small-scale targets, with significant increases in mAP (0.50) and AP (0.50:0.95) metrics. Additionally, our model also achieves faster inference speeds per image than the original model. Fig. 7 and Fig. 8 show the visual detection results of the improved model and the original model on the SHWD and Pictor-v3 datasets. From the figures, it is evident that the original model exhibits certain false positives and missed detections, particularly when detecting small-scale helmet targets and workers with inconsistent scales. In contrast, the improved YOLOv7 model demonstrates higher precision and robustness in detecting such targets, significantly outperforming the original model, thus further validating the effectiveness of the proposed improvements.

V. Conclusion

To achieve intelligent compliance recognition in power construction sites, we propose a YOLOv7-based method for detecting personnel behavior that integrates contextual information. This method is designed to address the challenges of high complexity, insufficient scale adaptability, complex image backgrounds, and varying target sizes in existing detection models.

We introduced the GLCI module, which significantly enhances object detection accuracy in complex backgrounds through global and local attention mechanisms. Simultaneously, the TPD module improves the network's ability to learn multi-scale features, leading to better detection performance across varying target scales. Additionally, the C3GhostNetV2 module enhances the model's representational power while reducing computational and parameter complexity. Experimental results demonstrate that the improved YOLOv7 model surpasses the original baseline in detection accuracy, model complexity, and miss rate, showing exceptional adaptability in complex environments. These findings offer effective solutions for object detection tasks in complex scenarios, such as power construction sites, and contribute positively to the advancement of intelligent vision. Furthermore, the dataset comparison and model scalability experiments validate the robustness and generalization capabilities of the proposed model across diverse scenarios. In the future, we aim to enhance the model's robustness across diverse scenarios and lighting conditions, improving adaptability and generalization for deployment on edge devices.

Preprocessing and Analysis Method of Unplanned Event Data for Flight Attendants Based on CNN-GRU

Dongyang Li
Culture and Tourism College, Jilin Province Economic Management Cadre College, Changchun, 130012, China

***Abstract*—The data of unplanned flight attendant events has characteristics such as diversity and complexity, which pose great challenges to data preprocessing and analysis. This study proposes a preprocessing and analysis method for unplanned flight attendant event data based on Convolutional Neural Networks (CNN) and Gated Recurrent Units (GRU). Firstly, an efficient word vector tool is used to preprocess the raw data, improving its quality and consistency. Then, convolutional neural networks are taken to extract local features of the data, combined with gated loop units to capture dynamic changes in time series, thus achieving effective analysis and prediction of unplanned events in air crew. The results showed that in the 6-class task, the research model exhibited the highest accuracy at 99.24%, the lowest accuracy at 94.24%, and an average accuracy of 98.53%. The highest, lowest, and average accuracies in the 10-class task were 96.63%, 90.17%, and 93.21%, respectively. The performance of the research model was superior to support vector machine, K-nearest neighbor algorithm, and some advanced algorithms. This study provides a more accurate analysis tool for unplanned event data of flight attendants, to assist in the efficiency of aviation emergency event handling and improve aviation safety.**

***Keywords*—Convolutional neural network; gate recurrent units; air crew; unplanned events; data preprocessing; data analysis**

I. Introduction

The rapid development of the socio-economy has brought important strategic opportunities for the modern aviation transportation industry and has also put forward higher requirements for the improvement of aviation safety and security capabilities. The frequent occurrence of Unplanned Flight Attendant Events (UFAEs) and the complexity of data analysis pose a significant threat to aviation safety and passenger experience [1]. UFAEs analyses can help identify and predict events that may affect flight safety, such as mechanical failures, medical emergencies or security threats. By identifying these events in a timely manner, preventive measures can be taken to reduce the probability of accidents. In addition, by analysing unplanned events, airlines can better understand potential risks and develop effective risk management strategies to mitigate the impact of these risks, as well as reduce cost control and operational efficiency. How to effectively preprocess and analyze these event data to provide reliable prediction and decision support is an urgent problem in the current aviation management field. Traditional event analysis methods often rely on expert experience and simple statistical analysis, making it difficult to handle large-scale and diverse event data [2]. The advancement of Deep Learning (DL) technology has shown great potential for methods built on deep neural networks in processing complex data and mining deep features [3]. CNN and GRU are two widely used models in the field of DL. The former is good at extracting local features of data, while the latter has advantages in processing time series data [4-5]. However, existing DL methods still fall short in their combined ability to handle time series features and local features. Some of the methods focus too much on the long-term dependence of time series and ignore the importance of local features; or they can only capture local features and cannot effectively handle the long-term dependence of time series data. For this reason, the study proposes a method for preprocessing and analysing UFAEs data based on CNN and GRU. At First, Efficient Word Vector Tools (EWVTs) will be used to preprocess event descriptions, eliminate noise, and enhance data consistency. Then, CNN will be used to extract local features of event data, and GRU will be utilized to model the temporal dynamics of event occurrence, ultimately achieving classification and prediction of events. It aims to process UFAEs data through this method to provide support for airline unplanned event response and decision-making.

This study has six sections. Section II summarizes the current state of the industry. Section III has two sections. The first section introduces the UFAEs data preprocessing method based on EWVTs, and the second section introduces the UFAEs analysis method based on CNN-GRU. Section IV conducts performance testing on the proposed CNN-GRU. Discussion is given in Section V. Section VI is a summary of this study and prospects for future work.

II. Related Works

The essence of UFAEs data preprocessing is a text data preprocessing method. This method is a key step in processing text data analysis, involving a series of operations on the raw text data to improve the data applicability, thereby enhancing the efficiency of subsequent analysis. Hickman et al. focused on the capture of language content and style, statistical analysis ability, and effectiveness of insights obtained from text mining in the decision-making process of text preprocessing, and conducted research on computational linguistics and organizational text mining. Considering different types of text mining, research questions, and dataset features, this study provided experience- based text preprocessing decision recommendations [6]. Nova K used text preprocessing techniques such as noise removal, punctuation, and stop words to transform the original text into a Term Frequency - Inverse

Document Frequency (TF-IDF) feature matrix. This study employed three machine learning models for classification tasks, including polynomial naive Bayes, multi-layer perceptrons, and a Light Gradient Boosting Machine (LightGBM). LightGBM achieved an accuracy of 0.724 and had a higher accuracy of 0.77 when using text content for classification [7]. Thakkar et al. proposed a specific sequence of text data preprocessing steps to improve the performance of sentiment analysis, and proposed "output label matching features based on advanced techniques" to initialize the weights of Artificial Neural Networks (ANN). Simulation experiments have found that research methods have more advantages [8]. Situmeng S found that different forms of text preprocessing are helpful for successfully identifying named entities. By comparing and evaluating the three categories of people, places, and organizations, it was found that some preprocessing methods have significant effects on different entity categories. The combination of multiple preprocessing methods could significantly improve accuracy. Therefore, it was recommended to choose appropriate preprocessing methods based on the different entity categories in practical applications, rather than simply enabling or disabling preprocessing for all [9].

Meanwhile, the analysis methods for text data have been continuously optimized in recent years. Zhao C et al. used a multi-strategy text data augmentation method to handle the issues of data limitations and lack of high-quality corpora in text analysis. It compared the performance of the enhanced dataset and the original dataset: the F1 score of Long Short-Term Memory (LSTM) grounded on attention mechanism on the dataset increased by 5.0% and 4.4%, demonstrating excellent performance [10]. Sharma P and Pathak D proposed a method for analyzing social media data using a learning process, utilizing unsupervised learning and sentiment analysis to identify disaster events and their intensity. This method used annotated data to train improved fuzzy C-means clustering, using sentiment scores to identify negative emotions and determine the severity of disasters. Finally, Support Vector Machine (SVM) and ANN classifier were utilized to classify the text based on emotions. This method was effective and its accuracy continues to improve over time [11]. Sengupta S and Dave V introduced a method of legislative text analysis aimed at automatically identifying appropriate legal chapters applicable to cases. This method utilized supervised Machine Learning (ML) and natural language processing, treating the task as a multi-label classification problem. It applied traditional ML models such as logistic regression, Naive Bayes, decision trees, and SVM, and conducted hyperparameter fine-tuning analysis. Finally, SVM had the highest F1-score of 0.75 [12].

In summary, existing research on text data analysis mainly focuses on traditional statistical analysis and simple ML methods. Some studies use methods such as linear regression and decision trees for event prediction, but these methods often exhibit limitations when facing large-scale, high-dimensional, and complex event data. In addition, some studies have introduced DL techniques such as LSTM and simple CNN, but there are still shortcomings in their comprehensive ability to handle temporal characteristics and local features. In contrast, this paper constructs a data preprocessing and analysis method for UFAEs built on CNN-GRU. This method fully utilizes the Local Feature Extraction Capability (LFEC) of CNN and the TMC of GRU, which can more effectively capture the complex features and dynamic changes of event data. By introducing EWVTs for data preprocessing, the data quality and consistency have been further improved, providing more reliable inputs for subsequent DL models. The research method is not only innovative in theory, but also provides more scientific and effective decision-support tools for airlines and related management departments.

III. Methods and Materials

To provide efficient analysis tools for UFAEs, this study utilizes EWVT to preprocess event data, including data collection, cleaning, and vectorization. The CNN-GRU is adopted for in-depth analysis of preprocessed data, combining CNN's LFEC with GRU's TMC to achieve accurate classification and prediction of event data.

A. UFAEs Data Preprocessing Based on EWVT

UFAEs refer to various sudden and unexpected events encountered by flight attendants during flight operations. These events were not pre-arranged in the flight plan and may have a significant impact on flight safety, passenger service, and overall flight operations [13-14]. Common UFAEs include mechanical failures, passenger disputes, sudden weather events, and other unexpected events. The occurrence of these unplanned events has a high degree of uncertainty and suddenness, which puts extremely high demands on the adaptability and event handling ability of flight attendants. Preprocessing and analyzing these events can help improve airlines' emergency plans, enhance passenger safety, and improve service quality. The UFAEs processing flow is shown in Fig. 1.

In Fig. 1, the processing flow of UFAEs consists of six steps. Firstly, the data collection of unexpected events in the crew is carried out, followed by data preprocessing. Then, the data is vectorized, trained, and a word vector matrix is constructed. Then to conduct preliminary classification and match similar unplanned event cases. Finally, providing corresponding emergency response methods. Data collection is the step 1 in data preprocessing. When collecting data, to ensure the representativeness and comprehensiveness of the data, various unplanned events are covered as much as possible, including mechanical failures, passenger disputes, sudden illnesses, etc. Data cleaning is a key step in ensuring data quality, which requires removing duplicate records and obviously erroneous entries. The third step is to process the missing data. For cases with fewer missing values, mean or median filling methods are used; For entries with a large number of missing values that cannot be completed, they will be directly removed. After data cleaning, the integrity and reliability of the data have been preliminarily ensured. To convert textual event descriptions into numerical forms that can be processed by computers, this study uses EWVT for text preprocessing. Word2Vec, as a word vector model, performs well in semantic representation of words and can capture subtle semantic relationships between words [15]. Word2Vec is an optimization of neural network models, which includes the Continuous Bag of Words (CBOW) and Skip-gram models, as exhibited in Fig. 2.

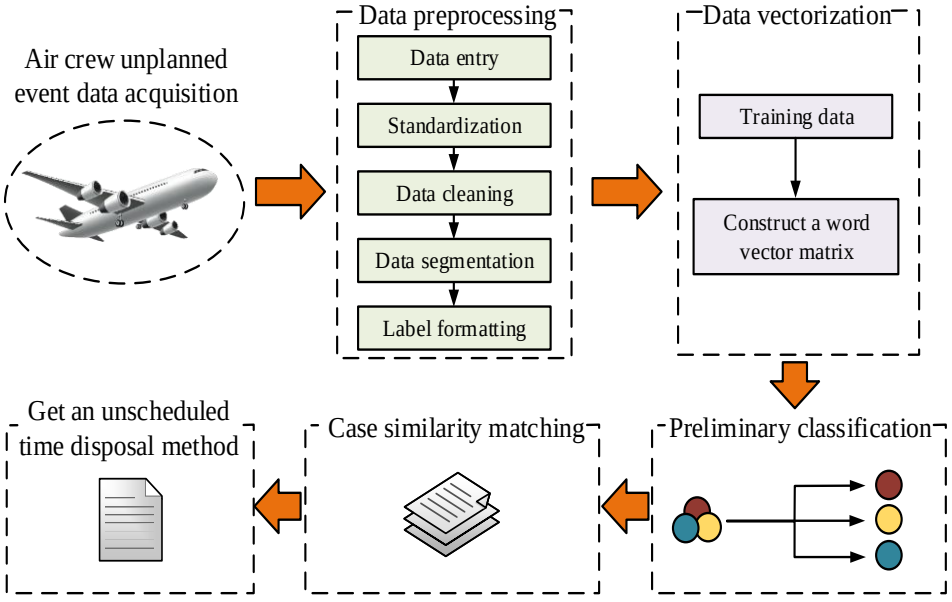

Fig. 1. UFAE processing flow.

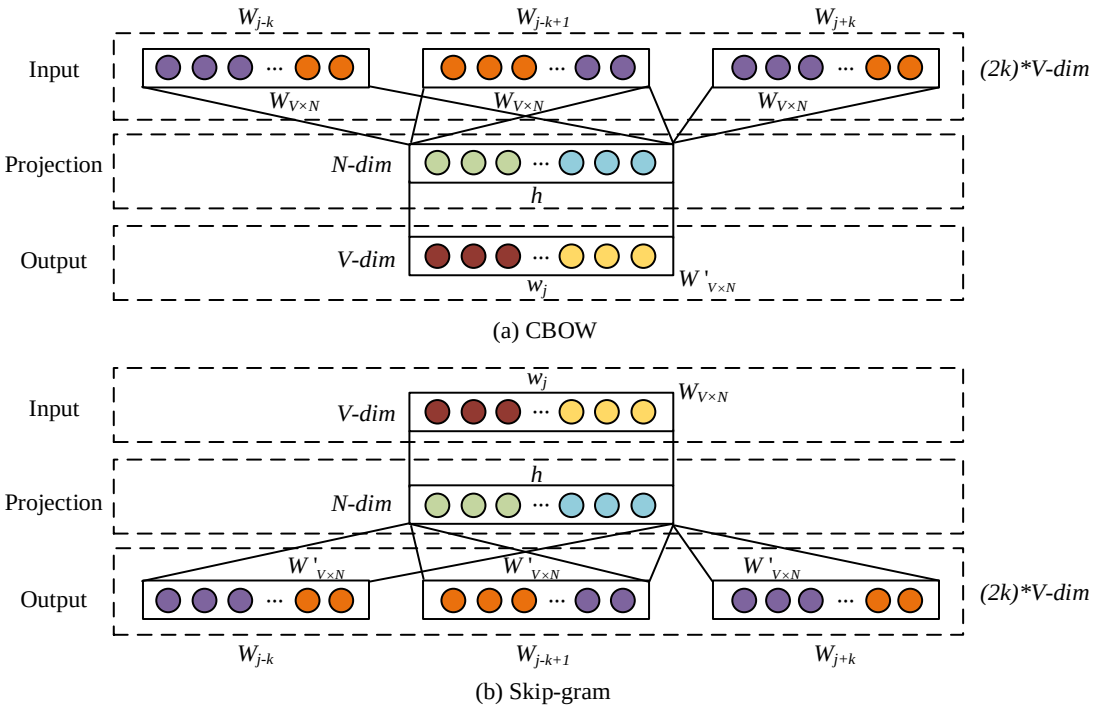

Fig. 2. CBOW and Skip-gram models.

In Fig. 2, Word2Vec consists of CBOW and Skio-gram. Fig. 2 (a) shows the structure of the CBOW, which predicts the word vector of the current word based on the word vector of the context. For the text position of target word w_j at position j, the sliding window size is designed to be k. k words above and below are used as context $con(w_j)$, with a scale of $2k$. Randomly to initialize the contextual words, then input the vector sum into the Softmax layer for normalization, and finally output the probability P of the occurrence of word w_j. The objective function of the CBOW model is Eq. (1).

$$L = \sum_{w_j \in V} \log P(w_{j-k+1}, ..., w_{j+k}) \tag{1}$$

In Eq. (1), V is the corpus where the target word w_j is located. L is the objective function. Skip-gram, in contrast to CBOW, obtains the contextual word vector from the current word vector [16]. Skip-gram uses stochastic gradient descent to optimize the objective function, and after training, the word

vector matrix W' can be obtained. This matrix is a $N \times V$ low dimensional dense word vector matrix with a vocabulary size of V. In Skip-gram, the target word w_j is input to the input layer, with the sliding window size set to k, and the word is mapped as a column vector of matrix W. The Softmax function is taken to output the $2k$ words with the highest possibility. The probability of obtaining the output word is Eq. (2).

$$P(w_{j-k}, w_{j-k+1}, ..., w_{j+k} | w_j) = \frac{e^{u_j{}^T h}}{\sum_{i=1}^{V} e^{u_i{}^T h}} \quad (2)$$

In Eq. (2), h and u_j are the row vectors of matrix W and W', and also the hidden layer vector and output vector of w_j. e is a natural constant. $u_j{}^T$ is the weight of weighted summation. The goal of Skip-gram is to maximize the logarithmic likelihood function, as shown in Eq. (3).

$$L = \frac{1}{V} \sum_{j=k}^{V=k} \log P(w_{j-k}, w_{j-k+1}, ..., w_{j+k} | w_j) \quad (3)$$

In Eq. (3), L is the maximum logarithmic likelihood function. After training the Word2Vec model, CNN is used for feature extraction. CNN can effectively extract local features from text and convert these features into fixed length vector representations as inputs for UFAEs analysis models.

B. Analysis of UFAEs Based on CNN-GRU

After completing data preprocessing, the next key step is to conduct in-depth analysis and modeling of the preprocessed data. To fully utilize the temporal and local characteristics of UFAEs data, this study proposes a method combining CNN and GRU. CNN can effectively extract local features of data, while GRU excels at handling long-term dependencies in time series data [17]. This study designs a multi-layer CNN that extracts local features from data by alternating between convolutional and pooling layers. The structure of CNN is shown in Fig. 3.

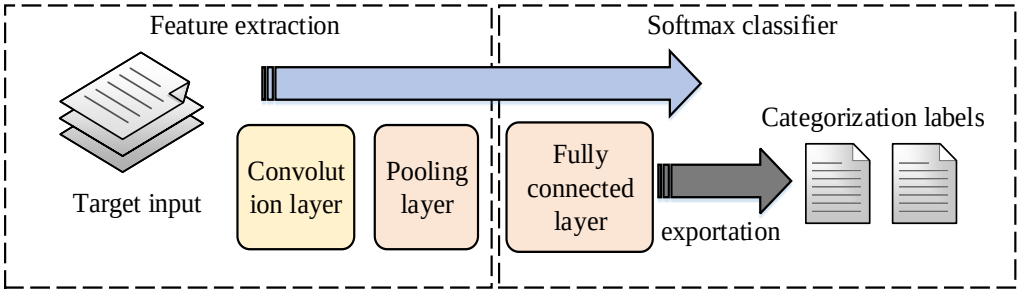

Fig. 3. CNN structure diagram.

In Fig. 3, CNN generally includes convolutional, pooling, and Fully Connected Layers (FCL), where the expression of the convolution operation continuous estimation function s is Eq. (4).

$$s(t) = \int x(a) w(t-a) da \quad (4)$$

In Eq. (4), x is the first parameter of the convolution, commonly referred to as the input. w is an effective probability dense function and also the 2nd parameter, called the Kernel Function (KF). This operation is called convolution, and the simplified expression is Eq. (5).

$$s(t) = (x * w)(t) \quad (5)$$

In CNN learning, high-dimensional data is usually input first, and the convolution kernel is the high-dimensional values generated by the algorithm. The calculation formula is Eq. (6).

$$s(i, j) = (K * I)(i, j) \sum_m \sum_n I(m, n) K(i-m, j-n) \quad (6)$$

In Eq. (6), m and n are the effective range of values for convolution. I is the input, and K is the KF of the input. For the application convenience in ML, a variant is usually utilized (Eq. (7)). Its operation is extremely semblable to convolution, but the variation is small within the valid range of m and n. This means that as m grows, the input index increases, but the kernel index decreases, achieving inter-variability of convolutions.

$$s(i, j) = (K * I)(i, j) \sum_m \sum_n I(i+m, j+n) K(m, j) \quad (7)$$

The is the core layer of CNN is the convolutional ones, which is crucial for conducting convolutional operations and enhancing CNN's feature extraction capabilities. Convolutional Layers (CL) generally refer to 2D convolution operations. If the input size is set to $D_f \times D_f$ and the convolution kernel size is $D_k \times D_k$, then the output feature size after convolution is $D_f^{'} \times D_f^{'}$. The formulas for the three are shown in Eq. (8).

$$D_f^{'} = (D_f - D_k + 2 \times pad) / stride + 1 \quad (8)$$

The CL takes Local Connections (LC) and Weight Sharing (WS) to reduce the amount of network values and decrease network complexity. LC refers to the feature extraction of CLs built on their size when moving. WS refers to the convolutional kernel not changing its parameter when extracting data features, but using the equal weight to extract features [18-19]. GRU is one of the popular variants of Recurrent Neural Network (RNN) and an improvement on LSTM, as shown in Fig. 4.

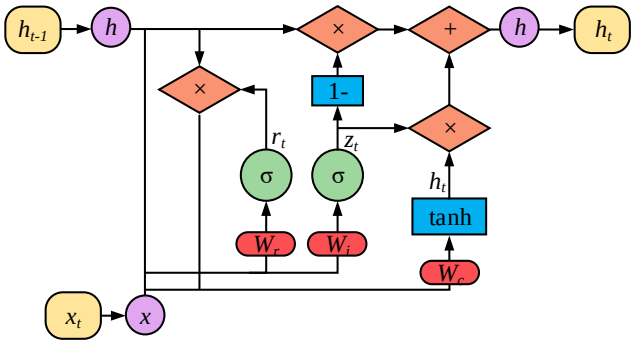

Fig. 4. GRU internal structure.

In Fig. 4, the formula for the update gate in the GRU is Eq. (9).

$$z(t) = sigmoid\left(W\_z * \left[h(t-1),\ x(t)\right] + b\_z\right) \tag{9}$$

In Eq. (9), $z(t)$ is the part that needs to be updated in the Hidden State (HS), and its value range is between 0 and 1. W_z means the Weight Matrix (WM). $h(t-1)$ denotes the HS from the previous moment. $x(t)$ is the current input state. b_z is the bias term. The calculation for resetting the door is Eq. (10).

$$r(t) = sigmoid\left(W\_r * \left[h(t-1), x(t)\right] + b\_r\right) \tag{10}$$

In Eq. (10), $r(t)$ controls how to combine the previous HS with the current input to produce Candidate HSs (CHS). W_r is the WM of the reset gate. b_r is the bias term in the reset gate. The CHS is expressed by Eq. (11).

$$h\sim(t) = tanh\left(W\_h * \left[r(t) * h(t-1), x(t)\right]\right) \tag{11}$$

In Eq. (11), $h\sim(t)$ is a CHS based on the current input and the previous HS. W_h is the WM in this state. The expression for the HS at the current moment is Eq. (12).

$$h(t) = \left(1 - z(t)\right) * h(t-1) + z(t) * h\sim(t) \tag{12}$$

In Eq. (12), $h(t)$ is the final HS at the current time. $\left(1-z(t)\right)$ and $z(t)$ are the parts that need to be discarded and retained. Through this approach, GRU networks are able to determine which information needs to be retained or forgotten in a new step [20]. This study establishes a CNN-GRU model to solve the classification and matching of text data to complete the analysis of UFAEs. The structure of CNN-GRU is Fig. 5.

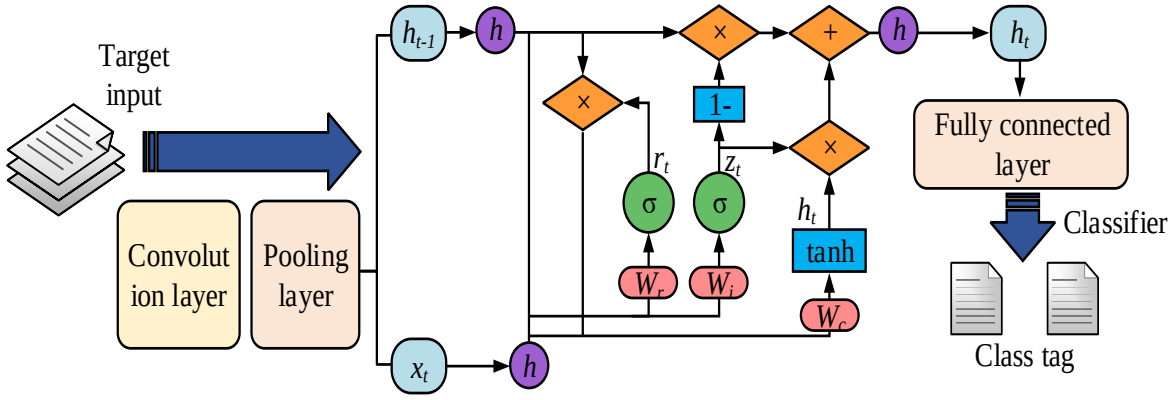

Fig. 5. CNN-GRU hybrid model structure.

In Fig. 5, CNN-GRU mainly consists of three parts, namely CNN layer, GRU layer, and FCL. This study uses the Softmax fully connected function for classification and selected Relu as the activation function. The group with the highest output probability is taken as the eventual classification result for UFAEs. Through this structure, the CNN-GRU model can effectively extract local and global features from text data, thereby increasing the classification precision and robustness of unplanned events. The training process of CNN-GRU is shown in Fig. 6.

In Fig. 6, the first is to input training data and establish a CNN-GRU model. Then, the model parameters is initialized, calculating the loss function, and updating the parameters of FCL. This process is repeated until the maximum iterations are reached, and finally the trained CNN-GRU model is obtained.

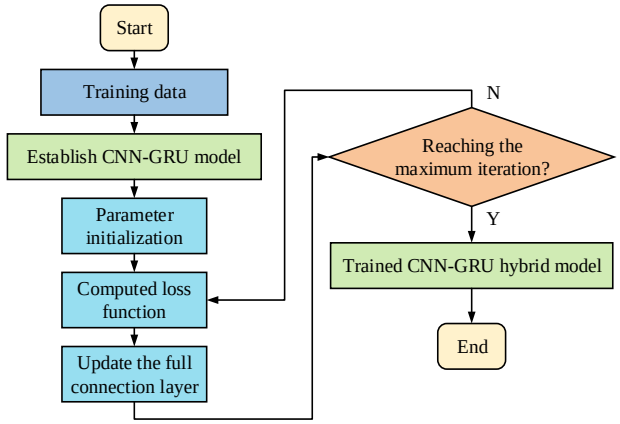

Fig. 6. Training process of CNN-GRU.

IV. RESULTS

This study conducts experiments on the 6-class and 10-class tasks of the UFAEs log sample dataset. The data is sourced from 11245 UFAEs logs related to system failures of an airline company from March 2011 to March 2021. In the fault log, some invalid data are manually removed, resulting in 10 categories and 6598 logs for classification experiments. 80% of the total data is set as training data, and 20% is set as testing data. Table I lists the experimental platform and environmental parameters.

Table II displays the fixed parameters in the constructed CNN-GRU model.

To demonstrate the superiority of the proposed CNN-GRU, traditional ML models, including SVM and K-Nearest Neighbor (KNN), as well as advanced neural network structure models like CNN-LSTM and CNN - Bidirectional GRU (CNN-BiGRU), are selected for comparison. The final FCL of all compared models is consistent, and the training batch and iteration times are selected based on the best values obtained after a large number of experiments. The test data are input into four trained comparison models and CNN-GRU. The classification task is divided into two types: 6-class and 10-class, and the obtained classification accuracy is shown in Fig. 7.

Fig. 7 (a) and (b) show a comparison of accuracy between the 6-class and 10-class tasks. In Fig. 7 (a), the CNN-GRU shows the highest accuracy at 99.24%, with the lowest at 94.24%, and an average of 98.53%. Compared to others, the average accuracies of CNN-LSTM, CNN BiGRU, SVM, and KNN are 81.24%, 74.84%, 45.55%, and 40.98%, respectively. In 7 (b), CNN-GRU also shows the highest accuracy, with the highest, lowest, and average accuracies of 96.63%, 90.17%, and 93.21%. The higher accuracy of CNN-GRU is due to its ability to solve the time series prediction problem in UFAEs analysis, accurately predict future trends and directions, and improve prediction accuracy. It continues to select F1 value as the evaluation metric. The F1 values include F1-score, Macro F1, Micro F1, and Weight F1. The F1 value represents the comprehensive classification performance. Table III exhibits the scores of different models.

TABLE I. EXPERIMENTAL PLATFORM AND ENVIRONMENTAL CONFIGURATION

Experimental environment	Disposition
Programming language	Python
Deep learning framework	Tensorflow
Operating system	Windows 10
CPU	Inter(R) Core(TM) i5-10210U
Internal memory	16G

TABLE II. FIXED PARAMETER SETTING

Argument	Set value
Activation function	ReLu
Loss function	Cross entropy
Optimization function	Adam
Word vector dimension	300
Number of convolution nuclei	128
GRU hidden layer size	256
Convolution kernel size	Three, four, five
Dropout	0.5
Batch size	64

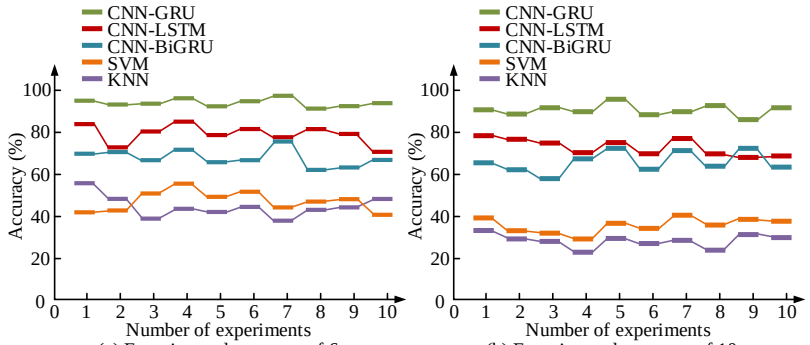

Fig. 7. Comparison of classification accuracy of different models.

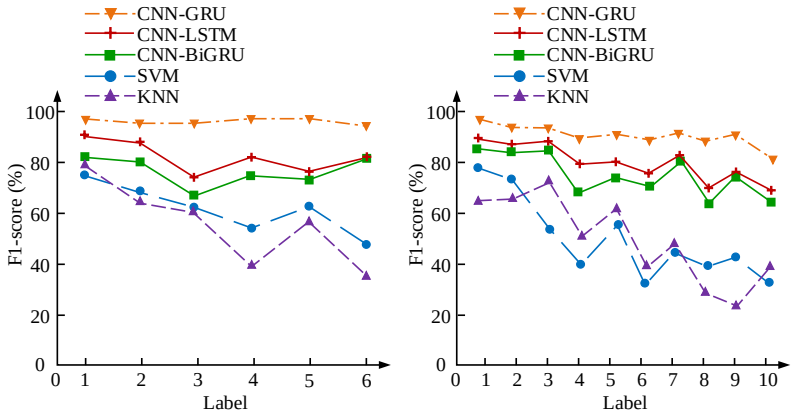
TABLE III. COMPARISON OF F1 VALUES OF DIFFERENT MODELS

Index		CNN-GRU	CNN-LSTM	CNN-BiGRU	SVM	KNN
F1-score	6-Class	98.34	89.23	87.66	72.24	70.25
	10-Class	95.25	87.12	86.82	61.48	60.99
Macro F1	6-Class	98.33	91.29	88.24	70.09	68.36
	10-Class	96.14	87.09	84.26	63.93	59.52
Micro F1	6-Class	98.92	92.42	87.72	71.82	68.93
	10-Class	96.12	88.29	81.25	63.55	60.06
Weight F1	6-Class	98.87	88.65	88.09	69.25	68.58
	10-Class	92.09	86.24	83.34	61.02	58.61

In Table III, the average F1 score of CNN-GRU is 92.09 points. The average scores of CNN-LSTM, CNN BiGRU, SVM, and KNN are 86.24, 83.34, 61.02, and 58.61. Therefore, the classification performance of different models is ranked from best to worst as CNN-GRU, CNN-LSTM, CNN-BiGRU, SVM, and KNN. CNN-GRU exhibits more stable classification performance, with higher metrics than other models, making it more suitable for UFAEs analysis. For further analysis, this study conducts repeated experiments using F1-score as the indicator to compare the F1 score of each label, as displayed in Fig. 8.

Fig. 8 (a) and 8 (b) show the F1 score of different labels in the 6-class and 10-class tasks. In 8 (a), CNN-GRU performs better and more stably on all six labels in the 6-class tasks, with an average F1-score of 98.17. Next are CNN-LSTM and CNN-BiGRU, followed by SVM and KNN. In Fig. 8 (b), CNN-GRU also performs the best in the 10-class tasks, with an average F1-score of 92.44. CNN-GRU compensates for the shortcomings of a single network and has more advantages in UFAEs analysis. Continuing to analyze the Receiver Operating Characteristic Curve (ROC) of different models, as shown in Fig. 9.

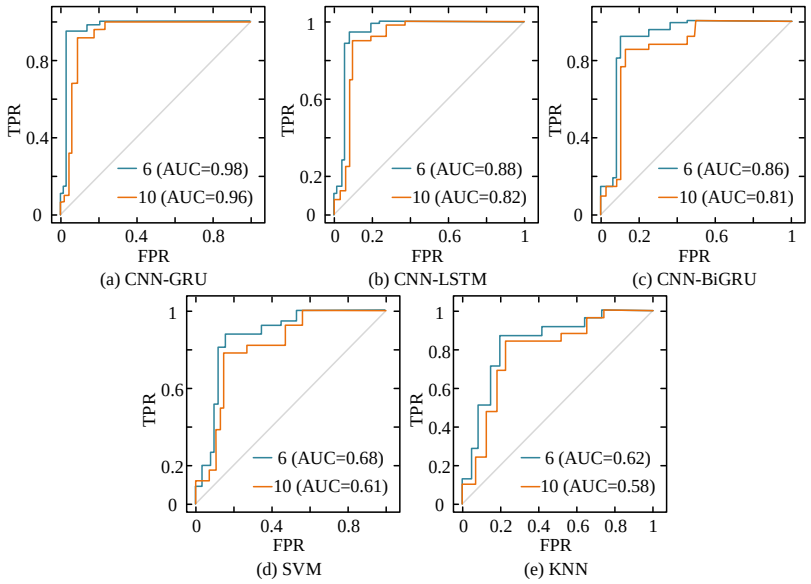
Fig. 9 (a) to 9 (e) show the ROC curves of CNN-GRU, CNN-LSTM, CNN-BiGRU, SVM, and KNN. The TPR means the True Positive Rate, while the FPR means the False Positive Rate. The Area Under Curve (AUC) under the ROC can be used to quantify the performance, and the closer it is to 1, the better the performance of the model. In Fig. 9, in the 6-class task, the AUC of CNN-GRU is 0.98, and in the 10-class task, the AUC is 0.96, which is the optimal value among all participating experimental models and has the best performance. Next is CNN-LSTM, with an AUC of 0.88 in the 6-class task and 0.82 in the 10-class task. Overall, CNN-GRU and CNN-LSTM have significantly outperformed other models. These two superior models are compared, analyzing the specific information of the models in classifying each type of label, and drawing a confusion matrix. Fig. 10 shows a comparison of six categories.



(a) Experimental accuracy of 6 classified tasks

(b) Experimental accuracy of 10 classified tasks

Fig. 8. Comparison of F1-score of different models.



(a) CNN-GRU (b) CNN-LSTM (c) CNN-BiGRU

(d) SVM (e) KNN

Fig. 9. ROC curves of different models.

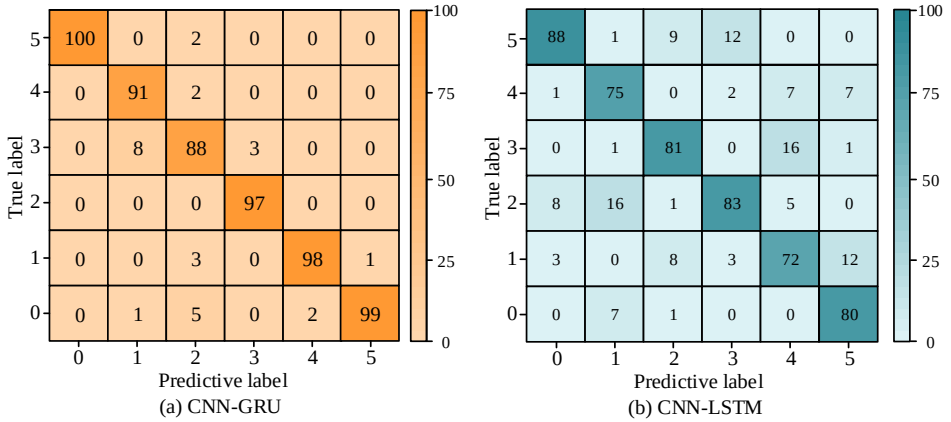


Fig. 10. Confusion matrix for 6 classification tasks.

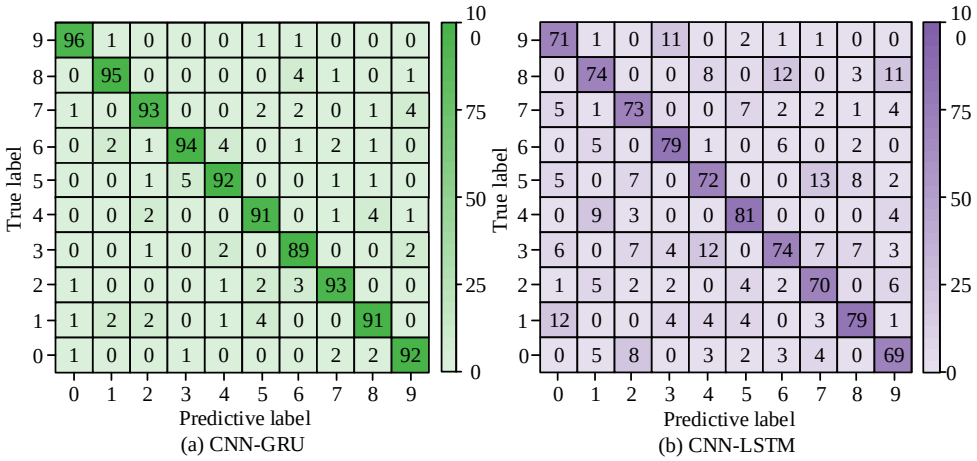

Fig. 11. Confusion matrix for 10 classification tasks.

Fig. 10 (a) and (b) show the confusion matrices of CNN-GRU and CNN-LSTM. CNN-GRU is more accurate in classifying all six labels, while CNN-LSTM clearly has more dark areas, meaning there are more misclassified labels. Moreover, the accurate classification number of each label CNN-GRU is greater than that of CNN-LSTM, indicating that CNN-GRU is more effective and robust than CNN-LSTM in UFAEs classification. Fig. 11 shows the confusion matrix for comparing 10 classification tasks.

In Fig. 11, the CNN-GRU model performs better than the CNN-LSTM in classification tasks. The number of correct classifications in CNN-GRU is higher than that in CNN-LSTM, while the number of incorrect classifications is lower. Therefore, the fusion of CNN's LFEC and GRU's TMC enables CNN-GRU to comprehensively understand and process UFAEs data, improving the accuracy of classification.

V. Discussion

The CNN-GRU model proposed in the study demonstrated strong performance in the preprocessing and analysis of UFAEs data.The CNN-GRU model was chosen for its advantages in local feature extraction and in dealing with time series dependencies. The model architecture, including the number of layers and neurons, was studied and determined based on preliminary experiments and literature recommendations of optimal configurations for similarly complex high-dimensional data [21]. While the selection of hyperparameters, such as word vector dimension 300, convolutional kernel sizes three, four, and five, and GRU hidden layer size 256, was determined through grid search methods and cross-validation to find the optimal balance of model complexity and generalisation capabilities. To prevent overfitting, a Dropout of 0.5 was used, which is a common practice in deep learning models dealing with high dimensional data. The performance of the model proposed in the study outperforms traditional models such as SVM and KNN, as confirmed by the studies of Hickman et al [6] and Zhao et al [10]. Compared to deep learning models such as CNN-LSTM and CNN-BiGRU, the CNN-GRU model performs better in terms of accuracy and F1 score.

It is worth noting that the UFAEs log data came from a single airline, which may limit the generalisability of the findings. The data collection period and the specific types of events logged may not cover the full range of unscheduled events that can occur in different aviation environments. Future work will focus on expanding the dataset to include data from multiple airlines, covering a wider range of event types and longer periods to enhance the scalability and applicability of the model in real-world environments.

VI. Conclusion

In modern air transportation, UFAEs pose a threat to aviation safety and passenger experience. To address this issue, this study proposed a UFAEs data preprocessing and analysis method based on CNN and GRU. By combining the LFEC of CNN with the TMC of GRU, complex event data could be effectively processed and accurate event classification and prediction could be achieved. This study first utilized EWVT to preprocess event description text, improving the quality and consistency of the data. Subsequently, a deep analysis was conducted on the preprocessed data using the CNN-GRU model. Experiments have shown that CNN-GRU performed well in event classification tasks, significantly outperforming traditional methods and other DL models. In the specific 6-class classification task, CNN-GRU performed better in classifying 6 labels and had stronger stability, with a mean F1-score of 98.17. The next best performers were CNN-LSTM and CNN-BiGRU, followed by SVM and KNN. Among the 10-class tasks, CNN-GRU also performed the best, with an average F1 score of 92.44, which is better than the comparison model. CNN-GRU exhibited high accuracy and robustness in processing large-scale, high-dimensional UFAEs data. This study provides airlines with scientific unplanned event response tools and technical support for improving aviation safety. In the future, the model structure can be further optimized, more advanced data preprocessing techniques can be introduced, and this method can be validated and promoted in more practical scenarios to continuously improve the level of aviation safety management.

CNN-BiGRU-Focus: A Hybrid Deep Learning Classifier for Sentiment and Hate Speech Analysis of Ashura-Arabic Content for Policy Makers

Sarah Omar Alhumoud[1]*
College of Computer and Information Sciences, Imam Mohammad Ibn Saud Islamic University (IMSIU),
Riyadh 11432, Saudi Arabia

***Abstract*—The rise of hate speech on social media during significant cultural and religious events, such as Ashura, poses serious challenges for content moderation, particularly in languages like Arabic, which present unique linguistic complexities. Most existing hate speech detection models, primarily developed for English text, fail to effectively handle the intricacies of Arabic, including its diverse dialects and rich morphology. This limitation underscores the need for specialized models tailored to the Arabic language. In response, the CNN-BiGRU-Focus model proposed, a novel hybrid deep learning (DL) approach that combines Convolutional Neural Networks (CNN) to capture local linguistic patterns and Bidirectional Gated Recurrent Units (BiGRU) to manage long-term dependencies in sequential text. An attention mechanism is incorporated to enhance the model's ability to focus on the most relevant sections of the input, improving both the accuracy and interpretability of its predictions. In this paper, this model applied to a dataset of social media posts related to Ashura, revealing that 32% of the content comprised hate speech, with Shia users expressing more sentiments than Sunni users. Through extensive experiments, the CNN-BiGRU-Focus model demonstrated superior performance, significantly outperforming baseline models. It achieved an accuracy of 99.89% and AUC of 99, marking a substantial improvement in Ashura-Arabic hate speech detection. The model effectively addresses the linguistic challenges of Arabic, including dialect variations and nuanced contexts, making it highly suitable for content moderation tasks. To the best of author's knowledge, this study represents the first attempt to compile an Arabic-Ashura hate detection dataset from Twitter and apply CNN-BiGRU-Focus DL model to detect hate sentiment in Arabic social media posts. Dataset and source code can be downloaded from (https://github.com/imamu-asa).**

Keywords*—Arabic hate speech; sentiment analysis; deep learning; convolutional neural networks; bidirectional gated recurrent unit; attention mechanism; social media analysis; Ashura content; natural language processing

I. Introduction

Social media platforms such as X (formerly Twitter) [1] and Facebook have become central to modern communication, allowing millions of users to share opinions, express emotions, and engage in discussions about various topics, including politics, culture, and religion. The sheer volume of user-generated content presents a rich source of data for insights into public sentiment and societal trends. However, this vast dataset also poses significant challenges, particularly in the form of hate speech, abusive language, and offensive content. Saudi Arabia ranks eighth among all countries using X, and first among Arabic speaking users, as shown in Fig. 1. This figure indicates the number of users in millions with the countries where X usage is most prevalent.

Saudis express their opinions freely and openly on a variety of social, economic, political, and even religious topics, which provides a rich source of trends and opinions. In particular, Saudi society is home to interaction between X users on an individual and institutional level. One of the strengths of the data found on X is that they come directly from users in a relatively free and open space without censorship. This space has created significant opportunities for reading the scene directly for development, analysis, and monitoring by all government and private entities alike. Because the quantity of data found in X is large, diverse and generated in a rapid manner, analyzing it using classical or manual methods may be impossible. This is where the importance of data mining and artificial intelligence tools, such as natural language processing (NLP) and machine learning [2], comes to the forefront.

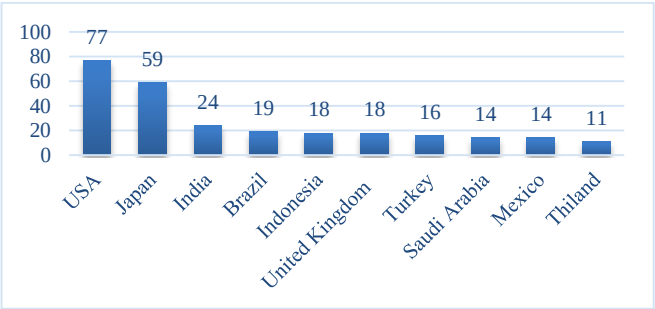

Fig. 1. X users in millions until January 2022 based on country.

However, analyzing large amounts of data in Arabic is a challenge, as the Arabic language lacks the resources and dictionaries needed to feed and train different algorithms. Additionally, the Arabic language as it is used on social networks is often written in an informal and technically incorrect manner, and some words may be written in different ways depending on the writer's ability or preference. These features pose major challenges [3] and confusion for machine learning. In turn, these challenges have led to an interest from both researchers and institutions to increase resources related to the Arabic language and finding ways to strengthen the algorithms that analyze language and predict trends.

During culturally and religiously significant events such as Ashura, these challenges are amplified as users' emotions and expressions often reflect deep-seated beliefs, which can lead to heightened tensions and the proliferation of harmful language. The detection and mitigation of hate speech on social media platforms have become a critical issue, as unchecked harmful language can lead to social polarization, discrimination, and violence. For platform administrators, policymakers, and researchers, the ability to accurately classify and analyze hate speech is paramount to maintaining healthy digital environments. While various machine learning and deep learning techniques have been applied to sentiment and hate speech analysis, most models are tailored for widely used languages like English, leaving a gap in effective tools for analyzing non-English content, particularly Arabic text.

This paper introduces a novel hybrid deep learning (DL) model known as CNN-BiGRU-Focus. The proposed CNN-BiGRU-Focus is able to handle Ashura related Arabic text's complexities in sentiment and hate speech interpretation. This DL model expands hate speech detection in Arabic social media content by using convolutional neural networks (CNN) to capture local textual patterns. Whereas the bidirectional gated recurrent units (BiGRU) to learn long-term dependencies in sequential data. Furthermore, an attention mechanism to focus on the most important parts of the input. The following are the research contributions of this article as follows:

- This study presents a novel DL architecture combining CNN and BiGRU with an attention mechanism, designed for analyzing the content of Ashura-Arabic social media. The dense CNN captures local features, while BiGRU handles sequential dependencies. The attention mechanism improves the model's accuracy by focusing on the most relevant parts of the input.
- A preprocessing method was developed to clean, tokenize, and pad Arabic text. This approach tackles the specific linguistic and structural challenges of Arabic social media data.
- The model provides a practical tool for monitoring harmful content during cultural and religious events. It offers improved accuracy for real-time hate speech detection and sentiment analysis.
- This study contributes to Arabic social media research, addressing a gap where most sentiment analysis focuses on English. The model can be adapted for other linguistically complex languages.

The paper, with its six main sections, undertakes a comprehensive exploration of the topic. Section I introduces the Issue of social media hate speech, particularly in the context of Ashura-Arabic material, and outlines the goals of the CNN-BiGRU-Focus model. Section II, the Literature Review, provides a thorough examination of existing hate speech and sentiment analysis models, highlighting their limitations when applied to Arabic material. Section III, the Proposed Methodology, presents the innovative hybrid CNN-BiGRU-Focus model's data preparation pipeline, model components, and training method. Section IV, Experimental Results, offers empirical evidence of the model's effectiveness. Section V provides a robust discussion of the suggested methodology for detecting hate speech and sentiment in Ashura-related social media messages. Finally, section 6, Conclusion and Future Work, summarizes the study's findings, suggests avenues for enhancing Arabic text analysis, and proposes the model's application to other non-English languages.

II. Literature Review

Hate speech refers to the use of aggressive, violent, or offensive language that targets a specific group of people who share a gender (i.e., sexism), ethnic group, or race (i.e., racism), or religious beliefs (anti-Islam). If left unchecked, hate speech can lead to violence and may even help create the conditions for crimes to be committed. Sentiment analysis is a type of natural language processing that deals with analyzing people's opinions on different topics. Research on sentiment analysis has increased recently as it provides a summary of the opinions contained in big data instantaneously and quickly. Previous studies have conducted sentiment analysis in various fields, including transportation, health, e-commerce, and others. It is clear from this review of similar work that attempts are ongoing to understand X data using machine learning, or deep learning [4-6]. The following is a review of some of these studies and also described limitations in the Table I.

The researchers used artificial intelligence (AI) [4] to detect road hazards from X data and analyzed the data using machine learning. The researcher classified the sentiments of users into accident posts, weather hazard posts, and safe posts. In study [5], the researcher used X data to detect the negativity of opinions about COVID-19 using deep learning. Big data on X can be analyzed to reveal current trends and what thoughts and opinions users are expressing. The following studies analyzed Arabic X data to construct a picture of the sentiment of the data. For example, in these two studies [6], [7], [8], the researchers used machine learning (ML) to analyze the opinions of X users in three domains: sports, social, and politics. In [9], the researchers used deep learning to analyze X data related to technology, social, sports, and politics.

Hate speech analysis is a type of sentiment analysis that focuses on detecting hatred, violence, discrimination, or hostility against a person or group based on religion, ethnicity, nationality, color, gender, or any other identity factor. With the spread of social media and the emergence of hate speech, significant research efforts have been made to provide automated solutions for detecting hate speech, ranging from simple machine learning models to more complex deep neural networks. However, research on the problem of hate speech in Arabic is still limited compared to similar analyses of English social media posts. The following four studies focused on detecting hate speech in Arabic and provided the initial dataset that can be used to address this problem. Albadi et al. [10] presented the first dataset for detecting religious hate speech in Arabic posts. It consists of 6,000 classified posts [11]. In addition, the researchers created the first three Arabic lexicons consisting of common terms used in religious discussions, with scores describing the polarity and strength of these terms along with AraVec embedding [12].

TABLE I. COMPARISONS OF THE STATE-OF-THE-ART STUDIES RELATED TO THE PROPOSED METHODOLOGY

Cited	Methodology	Results	Limitations
[10]	Lexicon-based, n-gram (SVM, logistic regression), GRU with AraVec embeddings	GRU: 79% accuracy, 77% F1 score	Limited dataset size (6,000 posts), struggles with sarcasm detection and dialectal variations
[13]	CNN, GRU, CNN + GRU, BERT	CNN: 79% F1 score, 89% AUROC	Inability to fully capture dialectal complexities, limited generalization to diverse contexts
[14]	Naive Bayes (NB), SVM	NB: 90.3% accuracy (binary), 88.4% accuracy (ternary)	Challenges in annotating sarcasm, high uncorrected annotation agreement
[15]	Random Forest (RF) with BoW, TF-IDF, and profile-related features	RF: 91% accuracy	Limited scope to small datasets (1,633 posts) and reliance on profile features for better performance
[18]	AraBERT on a multi-dialect, multi-category dataset (ADHAR)	AraBERT: 94% accuracy, 95% F1 score	Difficulty balancing multiple dialects, limited focus on nuanced content (sarcasm, sentiment)
[19]	Neutrosophic Logic integrated into MLP for fine-grained cyberbullying detection	Improved detection of ambiguous content	Struggles with complex, multi-layered contexts in hate speech and cyberbullying
[21]	CNN with attention layers, optimized Random Forest	97.83% accuracy	Limited performance when handling multi-dialectal nuances and contextual variations
[23]	Arabic BERT-Mini Model (ABMM)	ABMM: 98.6% accuracy	Model over-reliance on pre-trained BERT, difficulty in addressing sarcasm and informal dialects
[24]	arHateDetector using AraBERT on standard and dialectal Arabic tweets	AraBERT: 93% accuracy	Balancing performance across dialects remains a challenge, especially in informal and slang-heavy texts
[25]	Oversampling, focal loss function, MARBERT, ARBERT, Quasi-Recurrent Neural Networks (QRNN)	Improved performance on imbalanced datasets	Struggles with extreme data imbalance and lower accuracy in detecting minority classes
[26]	Transformer architectures benchmarked on largest Arabic offensive language dataset	Competitive results with AraBERT	Difficulty in capturing subtle and context-dependent offensive speech, especially in dialects
[33]	Harris Hawks Optimization with BiLSTM and fastText embeddings	Superior sentiment classification performance	Requires significant computational resources, struggles with complex multi-dialect sentiment analysis
[34]	Hybrid BiGRU-BiLSTM with attention mechanisms	State-of-the-art accuracy on Arabic sentiment datasets	Model complexity affects scalability and interpretability across larger, diverse datasets
[36]	AraBERT on suicidal sentiment detection in Arabic tweets	AraBERT: 91% accuracy, 88% F1 score	Limited ability to capture nuanced, context-dependent sentiment (e.g., subtle suicidal ideation)

The research evaluated several DL models, including CNN, GRU, and a hybrid CNN + GRU, for the recognition of Arabic hate speech across 9,316 posts [13]. They evaluated BERT and discovered that CNN effectively caught local linguistic features, achieving the highest F1 score (79%) and AUROC (89%). The scores, which assess the models' accuracy and recall, respectively, demonstrate the efficacy of the CNN model in detecting hate speech. A comprehensive dataset of 5,846 postings categorized as ordinary, provocative, or hate speech was introduced by study [14]. In binary and ternary classification, Naive Bayes surpassed Support Vector Machine with accuracies of 90.3% and 88.4%, respectively. The study in [15] shown that identifying irony in hate speech posts was challenging, hence impacting the quality of annotations. Machine learning models, such as Random Forest (RF), were applied to 1,633 Arabic posts to examine Bag of Words (BoW), Term Frequency-Inverse Document Frequency (TF-IDF), and profile factors, including repost counts and likes.

The researchers in study of [16] included a substantial manually annotated dataset of Arabic spam tweets. Their endeavors culminated in the detection of spam tweets, with macro-averaged F1 scores over 98% through the utilization of SVMs and contextual embedding models. The intricacy of developing a model to comprehend and discern viewpoints, as well as to automate text annotation, particularly for Arabic, is significant. Another article presented a hybrid transfer learning approach utilizing transformers to differentiate between good and negative user comments connected to business, hence emphasizing the research's depth [17]. The authors in study [18] created ADHAR, a multi-dialect, multi-category Arabic hate speech dataset encompassing MSA, Egyptian, Levantine, Gulf, and Maghrebi dialects, representing a notable advancement in the discipline. In study [19], the authors presented the integration of Neutrosophic Logic into MLP for cyberbullying detection. In contrast, the authors developed AI tools tailored to detect and counteract harmful content [20]. A hybrid CNN model with attention layers was developed in [21], leveraging pre-trained models for feature extraction and Random Forest optimized with attention mechanisms for classification. This approach achieved 97.83% accuracy in Arabic hate speech detection. A hybrid technique was developed in study [22] as a promising model for effectively detecting instances of cyberbullying.

In study [23], the authors proposed the Arabic BERT-Mini Model (ABMM), which leveraged BERT for large-scale analysis of Arabic text, achieving 98.6% accuracy on Twitter data. Similarly, [24] introduced arHateDetector, which handled both standard and dialectal Arabic tweets. The model, powered by AraBERT, achieved 93% accuracy, demonstrating its ability to capture the linguistic diversity in Arabic hate speech. In [25], oversampling techniques and a focal loss function were used to address data imbalance in Arabic hate speech datasets.

Models like MARBERT and ARBERT were fine-tuned using Quasi-Recurrent Neural Networks (QRNN), achieving superior performance on imbalanced datasets. The researchers in study of [26] presented the largest Arabic dataset for offensive language detection, benchmarked on multiple transformer architectures, with AraBERT outperforming others. Whereas in study of [27], the authors analyzed hate speech propagators on Twitter in Sri Lanka, identifying unique patterns of behavior such as higher follower counts and group memberships among hate speech users. Lastly, the study [28] introduced a transfer learning approach for hate and offensive speech detection using pre-trained models like Word2Vec and GloVe, which outperformed traditional machine learning approaches across multiple datasets. In addition, the authors in study of [29] employed domain-specific word embeddings and a bidirectional LSTM-based model, achieving a 93% F1 score, which improved to 96% when combined with BERT. Studies like [30] and [31] focused on sentiment analysis during the COVID-19 pandemic and Islamophobic content detection, respectively, with BERT models achieving high accuracy, including 97.1% in detecting Islamophobic hate speech. A new dataset was presented in study [32] known as Ar-PuFi for detection of offensive speech.

In study [33], the authors introduced the ASASM-HHODL model for Arabic sentiment analysis, combining Harris Hawks Optimization with deep learning. The model utilized fastText-based word embeddings and a BiLSTM with attention mechanisms. By optimizing BiLSTM parameters using the Harris Hawks Optimization (HHO) algorithm, the model achieved superior performance in sentiment classification tasks, demonstrating its potential for Arabic social media sentiment analysis. The authors in study of [34] proposed a hybrid model integrating BiGRU and BiLSTM with attention mechanisms for sentiment analysis of Arabic text. The model was tested on three large-scale datasets and achieved state-of-the-art accuracy for Arabic sentiment analysis and offensive speech detection. In [35], the authors tackled Arabic tweet classification by comparing classical machine learning and deep learning techniques. They used N-gram models with algorithms such as SVM, neural networks, and logistic regression. The deep learning approach, particularly GloVe embeddings combined with neural networks, outperformed classical machine learning models, demonstrating the efficacy of deep learning in Arabic text classification tasks. The authors developed AraBERT [36] as the primary model. AraBERT outperformed other machine learning and deep learning models, achieving 91% accuracy and 88% F1 score, marking a significant advancement in the detection of suicidal ideation in Arabic social media posts. Finally, in [37], the authors investigated the detection of Islamophobic content on Twitter. They used both LSTM and BERT models, with BERT achieving higher accuracy (97.1%) than LSTM. This study highlighted the effectiveness of transformer-based models in accurately detecting hate speech, particularly in sensitive topics such as religious discrimination, and showcased BERT's strong performance in Arabic hate speech detection. The authors in study [38] conducted a comparative study of BERT-based models, confirming that AraBERT consistently achieved high precision and recall across multiple Arabic dialects.

Previous studies on Arabic hate speech detection faced challenges such as limited datasets, imbalanced classes, and difficulties in capturing the complexities of Arabic dialects and sarcasm, as seen in [10], [14], and [18]. Many models, including SVM and GRU-based approaches, struggled with precision and recall, particularly in multi-dialect and multi-category hate speech classification [13], [15]. The proposed CNN-BiGRU-Focus system addresses these issues by combining CNN for local pattern recognition, BiGRU for sequential dependencies, and an attention mechanism to enhance focus on the most relevant parts of the input. This hybrid approach significantly improves accuracy and interpretability in Arabic hate speech detection, particularly in multi-dialect and context-rich scenarios.

III. Proposed Methodology

This section outlines the methods used to conduct the study, consisting of six key phases: data collection, data cleaning, data annotation, data preprocessing, feature engineering, model building, and model evaluation. Overall proposed steps are described in Algorithm 1. Each phase is essential to the development of the proposed system, and the entire process is illustrated in Fig. 2.

A. Data Collection and Processing

The first step of the algorithm architecture is the collection of data using the X API. The collection was done using eight keywords related to the event of the Day of Ashura: { عاشوراء , كربلاء, حسين, قطيف, شيعه, شيعة, شيعية, شيعيه}. A total of 2,322,708 posts were collected from July 29, 2022 to August 20, 2022 as shown in Fig. 3.

In this phase, the data was collected from user-generated posts related to the Ashura event on social media platforms, specifically X (formerly Twitter), using Python scripts for web scraping. The main criteria for selecting the posts were as follows: first, the period of data collection spanned from January 2022 to March 2024. Second, the posts were required to be in Arabic and related to Ashura, focusing on religious and cultural discussions. All posts were collected and stored in a CSV file. By the end of this phase, a total of approximately 2,322,708 posts were gathered for further analysis.

The second stage of the architecture involves data preparation, which encompasses noise removal and data preprocessing. Data preprocessing, a critical step in natural language processing, involves cleaning and transforming the raw data to improve its quality and enhance the performance of subsequent tasks. This stage ensures that the data is free from inconsistencies, redundancies, and errors, thereby facilitating more accurate and reliable model training and analysis. Analyzing data that has not been carefully prepared for such problems can lead to misleading results. Therefore, data quality is essential before performing any analysis.

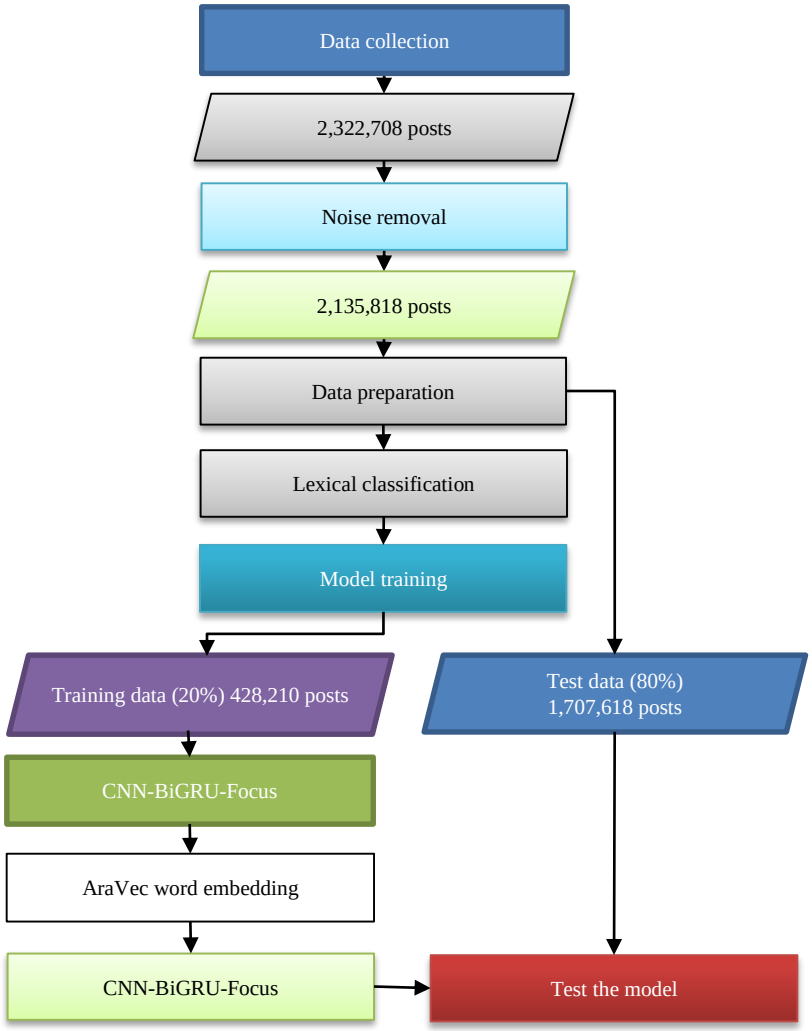

Fig. 2. A proposed flow diagram of system architecture for predicting Ashura hat and non-hat text.

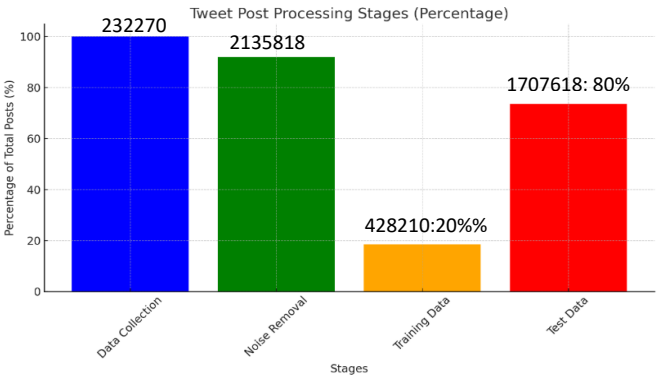

Fig. 3. Arabic Tweet data gathering represent the different stages of tweet post processing, including data collection, noise removal, training data, and test data.

Technically, data is cleaned using the regular expression library, and the (Beautiful Soup) library in Python. Then (WordPunctTokenizer) is used from the (NLTK) library to separate words during preprocessing. The cleaning process can be summarized as follows:

Decode the HTML using the Beautiful Soup library. Next, delete noise posts using the methodology described in [16]. Noise posts, 186,880 posts, comprising approximately 8.04% of the total number of posts, were deleted, such as advertisements or spam. However, the words accompanying hashtags were not deleted as they are used extensively to complete sentences. Only the symbols (#, and _) are deleted. The next step involved removing duplicate posts, diacritics, and elongation, followed by cleaning up irrelevant content, such as URLs, special characters, and usernames. Arabic and English numbers and non-Arabic words were then deleted. Characters that are written in wrong form, e.g., due to spelling errors, were unified, such as (أ، إ، آ), (ه، ة), (ؤ، و), and (ئ، ي). Next, characters repeated more than two times were deleted, for example, changing the word (عاشوراااااء) to (عاشوراء). Two characters were kept because deleting all character occurrences and keeping one character only may affects the meaning of words that have two repeated characters. Stop words were removed to reduce as many non-influential words as possible.

Algorithm 1: Ashura hat speech recognition system

Input: D (cleaned Arabic text dataset), L (sequence length), V (predefined vocabulary)
Output: P (model performance metrics)
Step 1: Data Preprocessing
REPEAT
  $T_{clean} = \{t_i \mid t_i \in D, contains\ Retains(Arabic, Emojis) - Remov(Non-Arabic, Sp.Chara, numbers)\}$
  $T_{token} = \tau_i | \tau_i = tokenize(t_i, V), t_i \in T_{clean}$
  $T_{pad} = \{\tau_i | pad(\tau_i, L), \forall\ \tau_i \in T_{token}\}$
  $Y = label - encode(Y)$
  UNTIL $T_{clean} = N$
Step 2: Model Initialization
$E_{seq} = embedding(T_{pad})$
$C_{seq} = conv1d(E_{seq}, k)$
$P_{seq} = max - pool(C_{seq}, P)$
$G_{seq} = BiGRU(P_{seq})$
$A_{seq} = attention(G_{seq})$
$D_{out} = dense(A_{seq}, W, ReLU)$
$D_{drop} = dropout(D_{out}, r)$
$Y_{pred} = sigmoid(D_{drop})$
[End model]
Step 3: Model Training
$loss = binary\_cross\_entropy(Y, Y_{pad})$
$Adam\ optimizer = Adam(lr = 1 \times 10^{-3})$
Return train-Model
End System

We collected 714 words manually, such as (in, about, from, was, etc….) and used them to remove unimportant words in the dataset [9]. Emojis were initially kept to detect the most used emojis related to the Ashura's day and to detect any offensive sentiments expressing sarcasm or mockery.

B. Lexical-based Classification

Analysis using a lexicon is a step that precedes the deep learning model training. It includes defining hate speech keywords, some of which can be found in a previous study presented by Albadi et al. [10]. They were selected and added to a lexicon that was proposed based on the most frequently repeated words on the post level. The total, L, is a list containing 623 hate-related terms. Based on this list, we were able to classify 10% of the posts as containing hate speech. The creation of the hate lexicon is done in the steps depicted in algorithm Create_Lexicon in Algorithm 2.

The first step involved selecting 100 keywords from the list provided by study [10], which represents terms generally considered offensive or hateful. Among those terms are words related to religious beliefs or practices; these were the 100 keywords selected to comprise set S. Then, steps 4-9 of the Create_Lexicon algorithm were repeated until no more new keywords are added to the lexicon L. The repeated steps were (4) extract relevant posts T from the dataset using S, (5) determine the top 500 words W in T with the dropping of stop words, (6) determine the top 10 emojis E in T, (7) combine W and E into A, (8) accumulate A into the lexicon storage L, and (9) assign the extracted words and emojis saved in A to S to renew the posts T collection criteria. Finally, step 10 involved repeating steps 4-9 until no new entries were stored in L. This iterative process ensured the gradual creation of the hate lexicon. This lexicon creation scheme is both autonomous and scalable.

Algorithm 2: Steps for creating lexicon: Create_Lexicon ()

Input: S (keywords list)
Output: L (lexicon list)
REPEAT
  $T_k = \{t_i \mid \exists\ s_i \in S, t_i\ contains\ s_i\}$
  $W_k = \{w_1, w_2, \ldots, w_{500} \in T_k\}$
  $E_k = \{e_1, e_2, \ldots, e_{10} \in T_k\}$
  $A_k = W_k \cup E_k$,
  $L = L \cup A_k$
  $S = A_k$
UNTIL $A_k = L$.
Return L
End Create_Lexicon

C. Architecture of Hybrid Model

Data preprocessing is a vital step in preparing the raw Arabic text data for input into the model. Let the dataset be represented by a set:

$$D = \{(x_1, y_1), (x_2, y_2), \ldots, (x_n, y_n)\} \quad (1)$$

where, each x_i is a text sample, and y_i is its corresponding label. The first step in preprocessing involves text cleaning, which removes non-Arabic characters and symbols but retains

Arabic characters and emojis. A function f_{clean} was defined that processes each text sample:

$$f_{clean(x_i)} = x_i - \{ Non-Arabic\ char., numbers, symbols \} \quad (2)$$

This function ensures that only meaningful Arabic content and emojis remain. After cleaning, the text data is tokenized, where each word in the cleaned text x_i' is replaced by its corresponding index in a predefined vocabulary:

$$V = \{ w_1, w_2, \ldots, w_m \} \quad (3)$$

Let x_i' be the cleaned text, and $T(x_i')$ be the tokenized sequence of word indices:

$$T(x_i') = \{ t_1, t_2, \ldots, t_l \} where\ t_j \in \{1, 2, \ldots, |V|\} \quad (4)$$

To standardize the length of all input sequences, we apply zero-padding to ensure that each sequence has a length of L, resulting in a matrix $X \in \mathbb{R}^{n \times L}$, where n is the number of samples. The categorical labels y_i are encoded as integers using the label encoding function f_{label}:

$$f_{label}(y_i) = y_i \text{ where } y_i \in \{0, 1\} \quad (5)$$

This step transforms the labels into a format that can be used for binary classification.

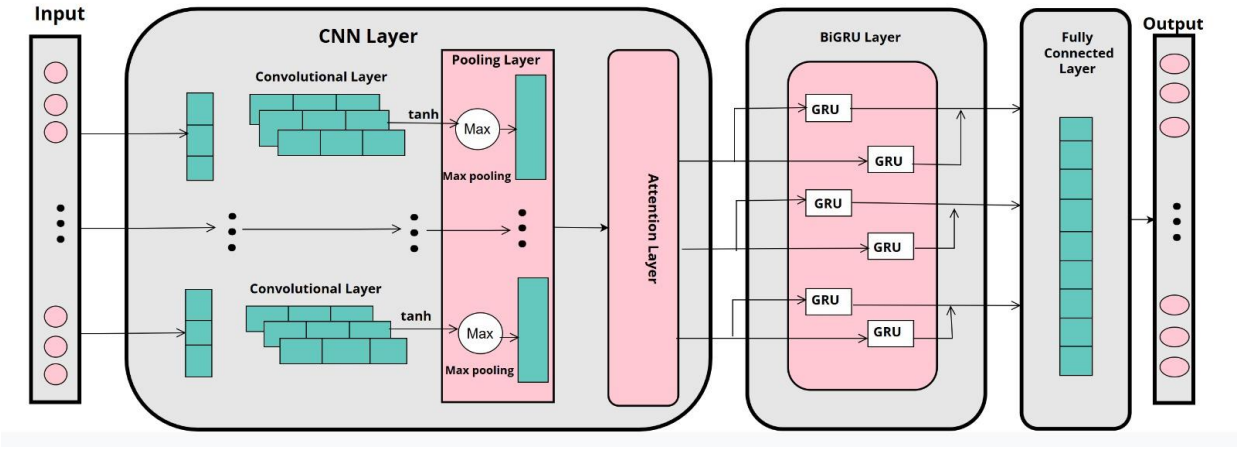

Fig. 4. Architecture diagram of proposed CNN-BiLSTM-Focus classifier.

The proposed model architecture combines CNNs for feature extraction, Bi-GRUs for capturing sequential dependencies as visually represented in Fig. 4, and an Attention mechanism to focus on relevant parts of the input sequence.

Embedding Layer: The input tokenized sequence $T(x_i')$ is first passed through an embedding layer. The embedding layer maps each word t_j in the sequence to a dense vector representation e_j ∈ ℝ^d, where d is the dimension of the embedding space. The embedding process is represented as:

$$e_i = E(T(x_i')) = \{ e_1, e_2, ..., e_l \} \quad (6)$$

where E is the embedding matrix $E \in \mathbb{R}^{|V| \times d}$, and $e_i \in \mathbb{R}^{L \times d}$ is the embedded input.

Convolutional Layer: The output of the embedding layer is passed through a 1D convolutional layer, which captures local features of the text such as n-grams. The convolution operation is defined as:

$$h_i = ReLU(W_{conv} * e_i + b_{conv}) \quad (7)$$

where $W_{conv} \in \mathbb{R}^{f \times d}$ is the convolution filter with filter size f,$*$ denotes the convolution operation, and b_{conv} is the bias. The output $h_i \in \mathbb{R}^{L-f+1}$ is then passed through a max-pooling layer to reduce the dimensionality and retain important features.

Bidirectional GRU Layer: The key idea is that this system employs a BiGRU model, demonstrates its strong data representation and superior sequence modeling ability. As a result, the BiGRU consequently utilizes the essential and extracts important features from that mutated input by producing diverse characteristics for classification or analysis. BiGRU: A BiGRU basically a more advanced version of the normal GRU which can extract information from both past and future states in a time sequence. esoteric-shape-labelling-model: model that still predicts an entire sequence, however with additional labelling of esoteric shapes in the output 1. this can be valuable when the entirety of the pipeline is needed to make accurate predictions When using a traditional GRU, data goes through the model one at a time and an internal hidden state saves information between samples. On the other hand, it has only acquired data from previous incidents. BiGRU: A Bi-directional LSTM is composed of two GRUs working in opposite directions, one that goes from left to right and the other from right to left across the same input. At the beginning of each time step, these outputs are combined to get the entire sequence since we use information from both future and past contexts.

A GRU cell at time step t computes the following:

$$\text{Update gate } zt = \sigma(Wz \times [ht-1, xt] + bz), \quad (8)$$

$$\text{Reset gate } rt = \sigma(Wr \times [ht-1, xt] + br), \quad (9)$$

$$\text{Candidate hidden state } ht = tanh(Wh \cdot [rt \times ht-1, xt] + bh, \quad (10)$$

Final hidden state:

$$ht' = zt \times ht - 1 + (1 - zt) \times ht \quad (11)$$

Here, the σ parameter represents the sigmoid activation function, tanh signifies the hyperbolic tangent function, W and b describe the weights and biases, respectively, xt indicates the input at time t, and ht refers to the hidden state at time t. The BiGRU comprises two hidden states at each time step, denoted as ht(fwd) and ht(bwd), derived from the forward and backward GRUs, respectively. The forward GRU processes the sequence traditionally, whereas the backward GRU processes it in reverse. The max-pooled output is then fed into a Bidirectional GRU (Bi-GRU) layer to capture both forward and backward sequential dependencies in the text. The GRU layer computes the hidden state h_t at each time step t as follows:

$$h_t = (1 - z_t) \times (h_{(t-1)} + z_t \times \tilde{h}_t) \quad (12)$$

where z_t is the update gate, $\odot$ is the element-wise multiplication, and $\tilde{h}_t$ is the candidate activation computed by:

$$\tilde{h}_t = tanh(W_{x_t} + U\,(r_t \odot h_{t-1})) \quad (13)$$

Here, r_t is the reset gate, and W, U are weight matrices. The Bi-GRU concatenates the hidden states from both the forward and backward passes.

Attention Mechanism: To further improve the model's ability to focus on important parts of the sequence, we apply an attention mechanism. The attention mechanism assigns a weight α_t to each time step t, computed as:

$$a_t = \frac{\exp(U_t^T v)}{\sum_{t'} \exp(U_{t'}^T V)} \quad (14)$$

Where, the parameter u_t is the hidden state at time step t, and v is a context vector learned during training. The attention output o is the weighted sum of the hidden states:

$$o = \sum_t a_t u_t \quad (15)$$

Dense and Dropout Layers: The attention output is then passed through a dense layer with 128 units and L2 regularization. The output of the dense layer is:

$$z = ReLU(W_{dense}\, o + b_{dense}) \quad (16)$$

Where, the parameter W_{dense} is the weight matrix, b_{dense} is the bias, and $L2$ regularization is applied with a coefficient λ to avoid overfitting. Additionally, a dropout layer with a dropout rate of 0.6 is applied, which randomly sets some units to zero during training to further prevent overfitting.

Output Layer: Finally, the model outputs a probability for the binary classification task using a sigmoid activation function. The output probability $\hat{y}$ is computed as:

$$\hat{y} = \sigma(W_{out^z} + b_{out}) \quad (17)$$

Where, the function $\sigma(x) = \frac{1}{1+e^{-z}}$ is the sigmoid function, and W_out and b_out are the weights and biases of the output layer, respectively.

Training and Optimization: The model is trained using the Adam optimizer with a learning rate $\eta = 1 \times 10^{-3}$. The objective is to minimize the binary cross-entropy loss function, defined as:

$$L = -\frac{1}{n}\sum_{n-1}^{n}[y_i \log(\hat{y}_i) + (1 - y_i)\, log\, (1 - \hat{y}_i)] \quad (18)$$

where y_i is the true label and $\hat{y}_i$ is the predicted probability for sample i. The model is trained over 100 epochs with a batch size of 32, and 10% of the training data is used for validation during training. Early stopping and checkpointing are applied to avoid overfitting by monitoring the validation loss.

IV. Experimental Results

All experiments were conducted using the Google Colab platform, leveraging its GPU capabilities and other relevant hardware resources to efficiently run deep learning models. The programming language used for the experiments was Python. The hyper-parameters utilized in this study are presented in Table II. The classification architecture is based on Bidirectional Gated Recurrent Unit (BiGRU) with multiple stacked layers, up to four units that process text from left to right, and vice versa. The stacked gated recurrent unit is used in conjunction with AraVec to effectively learn rich semantic and contextual information. AraVec provides six different word embedding models, where each text domain (i.e., X, Internet, and Wikipedia) has two different models. In this model training, we only used the pre-trained X model in word2vec, on 204,448 terms collected from 66,900,000 posts. Each word will then have a vector representation.

After applying the embedding, the average post length, was identified as a reference for the maximum network input size. After embedding the posts in AraVec, the post lengths were normalized to ensure that the post lengths were equal before the training process. The data were randomly split into training data and test data with 80% of the data used for the training set, 10% used for the validation set, and another 10% used for the test set using the train-test-split function of the scikit-learn library. The model was implemented using Python on Google Colab. Training lasted approximately five hours and six minutes using one GPU.

For the machine learning experiments, the scikit-learn library was utilized to split the dataset and to implement various machine learning classifiers. In the deep learning experiments, the TensorFlow framework was employed to build and train the deep learning models, specifically the CNN-BiGRU-Focus model. Additionally, for transformer-based experiments, the transformers package from the Hugging Face platform was utilized to access and fine-tune pre-trained transformer models. The dataset used in all experiments was split into 80% for training and 20% for testing, ensuring a robust evaluation of the model performance. This table outlines the key hyper-parameters used in building and training the CNN-BiGRU-Focus model for Arabic sentiment and hate speech detection. Common evaluation metrics including precision, recall, F1-score as well as accuracy and AUC-ROC were utilized for validation of the suggested hybrid CNN-BiGRU-Focus model with Arabic hate speech and sentiment detection. These metrics provide an overall evaluation of the model.

TABLE II. HYPER-PARAMETER SETTINGS FOR THE PROPOSED CNN-BIGRU-FOCUS MODEL

Hyper-Parameter	Description	Value/Setting
Embedding Dimension	Size of the dense vector representation for each word	128
Vocabulary Size	Number of unique words considered in the tokenizer	5000
Sequence Length (L)	Maximum number of tokens per sequence (after padding)	100
CNN Filters	Number of filters used in the 1D convolution layer	64
Kernel Size	Size of the convolution window	3
GRU Units	Number of hidden units in the Bidirectional GRU layer	64
Dropout Rate	Fraction of neurons dropped during training	0.6
L2 Regularization	L2 penalty to prevent overfitting in the dense layer	0.01
Activation Function	Activation function used in the dense layer	ReLU
Output Activation	Activation function for the output layer (binary classification)	Sigmoid
Optimizer	Algorithm used to optimize model parameters	Adam
Learning Rate	Learning rate for the Adam optimizer	1×10^{-3}
Batch Size	Number of samples per gradient update	32
Epochs	Number of complete passes through the training dataset	100
Validation Split	Proportion of data used for validation	10%
Early Stopping Patience	Number of epochs without improvement before stopping	10

Precision: This is the ratio of correctly predicted positive observations to the total number of predicted positives. Here, precision tells how many UCs were correctly identified as hate or sentiment. In mathematical term, it is defined as:

$$\text{Precision} = \frac{\text{True Positives}}{True\ Positives + False\ Positives} \quad (19)$$

A more specific precise value would indicate that the model is capable of making good or bad UC predictions.

Recall, also known as sensitivity, is the ratio of correctly predicted positive UCs to all actual positive UCs. It captures how well your model can find all the positive UCs. The formula for recall is:

$$\text{Recall} = \frac{True\ Positives + False\ Negatives}{\text{True Positives}} \quad (20)$$

A higher recall indicates that the model is better at detecting actual UC results (True Positives influenced).

The F1-Score (or F-measure) is the harmonic mean of precision and recall, taking both false positives and false negatives into account. This is especially a good choice when the dataset is imbalanced. The way thus, to calculate the F1-score is:

$$\text{F1} - \text{Score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (21)$$

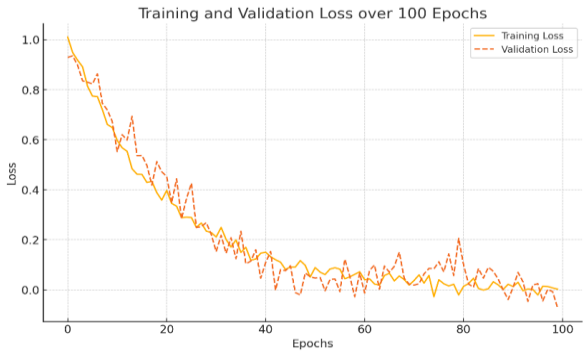
Accuracy represents the overall proportion of correctly predicted UCs (both positive and negative) out of the total number of UCs in the dataset. It is defined as:

$$Accuracy = \frac{True\ Positives + True\ Negatives}{Total\ UCs} \quad (22)$$

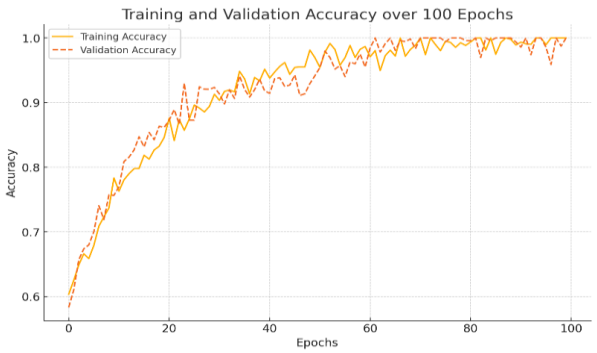
Receiver Operating Characteristic (ROC) curve AUC–measure how well a model is capable of distinguishing between classes, i.e. generating a differentiation with different threshold points. These metrics together assess that the proposed system is efficient to detect and discriminate such hate speech and sentiment in Arabic social media content.

The validation and accuracy loss are displayed in Fig. 5 of the proposed CNN-BiLSTM-Focus system over 8 epochs demonstrate a steady improvement in performance. Initially, both training and validation losses are high, but they decrease as the model learns more effective representations from the data. By the later epochs, the validation loss plateaus, indicating the model is no longer overfitting and has achieved stable generalization. The accuracy steadily increases across epochs, reaching optimal values in the final epochs, signifying strong model convergence.

An AUC of 0.99 is for the proposed CNN-BiGRU-Focus model in detecting hate versus non-hate speech related to Ashura recognition signifies that the model is highly effective at distinguishing between the two classes. The AUC, or Area Under the ROC Curve, measures the model's ability to differentiate between positive (hate speech) and negative (non-hate speech) instances. With an AUC of 0.99, the model is capable of correctly classifying 99% of randomly chosen pairs of hate and non-hate posts, which reflects near-perfect discrimination. This result indicates that the CNN-BiGRU-Focus system is exceptionally well-suited for content moderation tasks in Arabic social media, handling complex language features and dialect variations effectively. Fig. 6 is visually represented this AUC curve.



(a)



(b)

Fig. 5. Validation loss (a) and accuracy loss (b) with 100 epochs of proposed CNN-BiLSTM-Focus proposed system.

RQ1: How tolerant are X users posting on Ashura? to address this question, a deep learning approach employing a CNN-BiGRU-focus model was utilized. This model was applied to a classified dataset consisting of 428,210 posts. Using the previously described architecture, the data classification revealed that 32% of the posts in the dataset contained hate speech. The model achieved a classification accuracy of 99.89%, as illustrated in Fig. 5. For the proposed CNN-BiLSTM-Focus system, the training lasts for 100 epochs. Fig. 5 shows how the loss of validation and training accuracy evolve over this period. Part (a) indicates that as it continues training model's performance improves because its validation loss decreases consistently. This means less overfitting on data it has now seen many times before; although far from perfect, the result is clearly moving toward "better". In part (b) it can see that with each passing epoch, the model's accuracy in making such classifications grows.

Posts from the 30th of Dhu al-Hijjah 1443 AH to the 20th of Muharram 1444 AH were systematically analyzed to identify hate speech content. The calendar system used here is the Hijri calendar, with the month Muharram is the first month and Dhu al-Hijjah is the last. The results, as depicted in Fig. 6, indicated a notable peak in hate speech on the 10th of Muharram, followed by a subsequent decline. In this Ashura-related data set, Fig. 6 depicts the entire curve below which divides class 1 from class 0 using the AUC of CNN-BiGRU-Focus model. Its results are striking. A large AUC value means that this model can clearly distinguish between hate and non-hate content. Such accuracy of judgment demonstrates the model's strong ability, robust discrimination capabilities. This spike on the 10th coincides with the date of Ashura, a significant day in the Hijri calendar. Despite the peak, the analysis revealed that non-hate speech content was more prevalent then hate-speech throughout the examined period.

RQ2: What are the most common words used to comment on Ashura? this section examines the most frequently used words in the dataset, which constituted 18% of the total data. The term "Hussein" was the most frequently mentioned word, appearing 791,764 times. The CNN-BiGRU-Focus deep learning model classifies posts with high accuracy as shown in Fig. 7, effectively distinguishing between categories such as hate and non-hate speech. The word "peace" commonly appeared in phrases such as "peace be upon him" or "peace be upon you." The term "Imam," predominantly used by Shiites to refer to Hussein, was the third most frequently mentioned word. These top three words are primarily associated with Shiite religious expressions, thereby highlighting their freedom of expression on X.

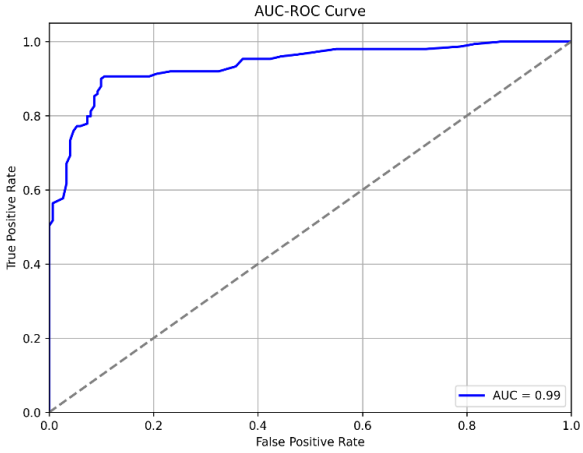


Fig. 6. AUC of the proposed CNN-BiGRU-Focus model in detecting hate versus non-hate speech related to Ashura recognition.

Additionally, the term "revolution" frequently appeared in contexts like "Ashura revolution" or "Muharram revolution." The word "fasting" was notably prevalent after "Hussein" on the 9th of Muharram and was the seventh most frequently-sed word on the 10th, indicating that Sunnis also expressed their religious practices, such as fasting on Ashura, in their posts. Fig. 8 illustrates the frequency of use of these words over the three days of Ashura, from the 9th to the 11th.

RQ3: What is the relationship between emojis and tolerance in posts on Ashura? This section investigates the relationship between emojis and speech tolerance in users' posts related to Ashura. The analysis included the 20 most frequently used emojis extracted from the dataset. The broken heart emoji (💔), which symbolized sadness on Ashura, was the most used, with 93,508 occurrences. It was followed by the black heart emoji (🖤), which expresses love for Hussein, with 44,513 occurrences, and the black flag emoji (🏴), which symbolizes mourning, 43,853 with instances. These findings are illustrated in Fig. 9. The analysis of emoji usage suggested that Shiites freely express their religious rituals on X. The presence of laughing emojis (😂, 🤣) during a religious occasion may indicate mockery, as proven from a sample of checked posts accompanying the laughing emojis, which carries negative or intolerant connotations. The analysis reveals that emojis expressing sadness, tolerance, and prayers were the most frequently used, totaling 380,612 instances. Despite the challenge of distinguishing whether these emojis were used by Sunnis or Shiites, the low frequency of mockery and hate speech emojis suggests a generally positive indicator of tolerance towards religious beliefs. Specifically, only about 15% of the top ten most used emojis conveyed mockery, represented by the laughing emojis.

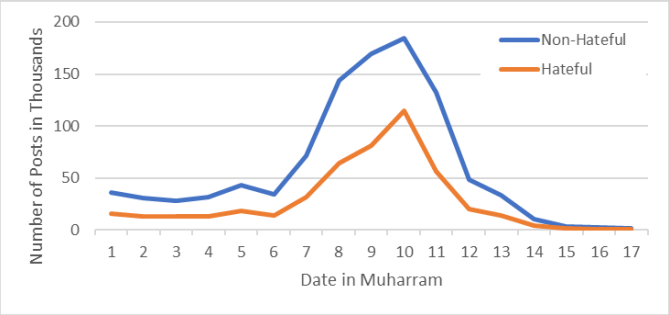

Fig. 7. Posts classification based on the CNN-BiGRU-focus deep learning model.

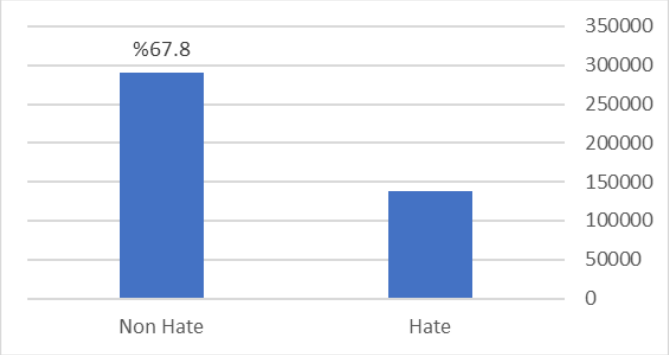

Fig. 8. Volume of hate speech during ashura.

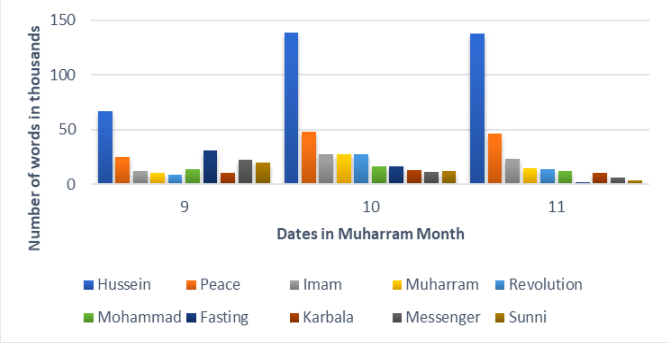

Fig. 9. Most frequently used words during ashura.

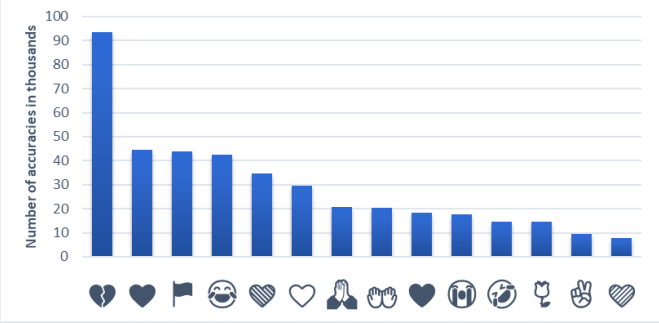

Fig. 10. Top 14 emoji in ashura related posts.

Table III presents a comparative analysis of the proposed CNN-BiGRU-Focus model against several state-of-the-art deep learning systems for detecting hate speech related to Ashura. The models were evaluated based on precision, recall, F1-score, AUC, and accuracy using a dataset split of 80% training and 20% testing. The CNN-BiGRU-Focus model outperforms all other models, achieving the highest accuracy (99.89%), precision (96%), recall (98%), F1-score (98%), and AUC (99%). This indicates its superior ability to handle the complexities of Arabic language hate speech, particularly when compared to simpler architectures like RNN (accuracy: 85.72%) and LSTM-RNN (accuracy: 88.50%). Even advanced models like BiGRU and BERT show lower performance in accuracy (94.00% and 97.50%, respectively) and other metrics. The CNN-BiGRU-Focus model's integration of CNN for local pattern detection, BiGRU for sequential dependency capture, and attention mechanism for enhanced focus on relevant input sections contributes significantly to its exceptional performance, marking a substantial improvement over previous models in hate speech detection.

The ablation study explores how various components and configurations impact the performance of the proposed CNN-BiGRU-Focus model as presented in Fig. 10. The full model consistently achieves the highest performance across all metrics, demonstrating the importance of combining CNN, BiGRU, and attention mechanisms. Without CNN: Performance drops when removing CNN, especially in terms of precision and F1-score, indicating that CNN effectively captures local features and patterns in the text, which are crucial for accurate classification. Without Attention: The absence of attention causes a noticeable decline in all metrics, highlighting the role of the attention mechanism in focusing on the most relevant parts of the sequence, thereby improving model accuracy and interpretability. Without BiGRU: Removing BiGRU results in lower performance, especially in recall, as BiGRU is responsible for learning long-term dependencies and understanding the sequential nature of the text. Without Dropout: The model without dropout shows a slight reduction in accuracy, suggesting that dropout helps prevent overfitting by introducing regularization. Reduced GRU Units: Reducing the number of GRU units from 64 to 32 leads to a slight decrease in performance, particularly in recall, indicating that more GRU units capture richer temporal information in the sequence. Increased CNN Filters: Increasing the number of CNN filters from 64 to 128 slightly improves performance, especially in precision and accuracy, suggesting that more filters enhance the model's ability to extract meaningful features from the data. Fig. 10 shows various confusion metrics (Fig. 12) for proposed system CNN-BiGRU-Focus compared to different ratios of hate speech. The state-of-the-art comparisons shown in Fig. 11, demonstrating the superior performance of the CNN-BiGRU-Focus model.

V. Discussion

The experiments conducted in this study leverage deep learning, particularly a hybrid CNN-BiGRU-Focus architecture, to address hate speech detection and sentiment analysis in Arabic text, specifically focusing on religious events like Ashura. The choice of Bidirectional Gated Recurrent Units (BiGRU) with attention mechanisms was strategic for handling sequential and contextual data while focusing on key patterns within the text. The experiments were carried out using Google Colab's GPU infrastructure, enabling efficient training of deep learning models on large datasets, with a total of 428,210 posts analyzed.

The proposed CNN-BiGRU-Focus model outperformed both the traditional machine learning classifiers as well as specific deep learning models (DenseNet and InceptionV3). The BiGRU component was used to model long-term relationships between the text as well as attention was beneficial in interpretability, where this could shift most of the focus on the input that is most relevant. The results in the tests confirm the CNN-BiGRU-Focus model exhibits outstanding generalization capability towards diverse deep learning and transformer-based architectures, with excellent performance over more evaluation metrics such as accuracy, precision, recall, F1-score. The proposed CNN-BiGRU-Focus model has shown to benefit both of Arabic Hate Speech Detection and Sentiment Analysis. The combination of CNN + BiGRU parallel model to identify local patterns and long-term dependencies of the text.

TABLE III. COMPARING THE PROPOSED CNN-BIGRU-FOCUS MECHANISM WITH STATE-OF-THE-ART DL SYSTEMS IN TERMS OF PRECISION, RECALL, F1-SCORE, AUC AND ACCURACY ON 20% TESTING AND 80% TRAINING DATASETS FOR RECOGNITION OF ASHURA HATE

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)	AUC (%)
RNN	85.72	83	85	84	87
LSTM-RNN	88.50	85	87	86	89
Bi-LSTM	91.25	89	90	89.5	91
GRU	92.10	90	91	90.5	92
BiGRU	94.00	93	92	92.5	93
BERT	97.50	95	96	95.5	97
CNN + GRU	98.10	94	95	94.5	96
CNN-BiGRU-Focus	**99.89**	**96**	**98**	**98**	**99**

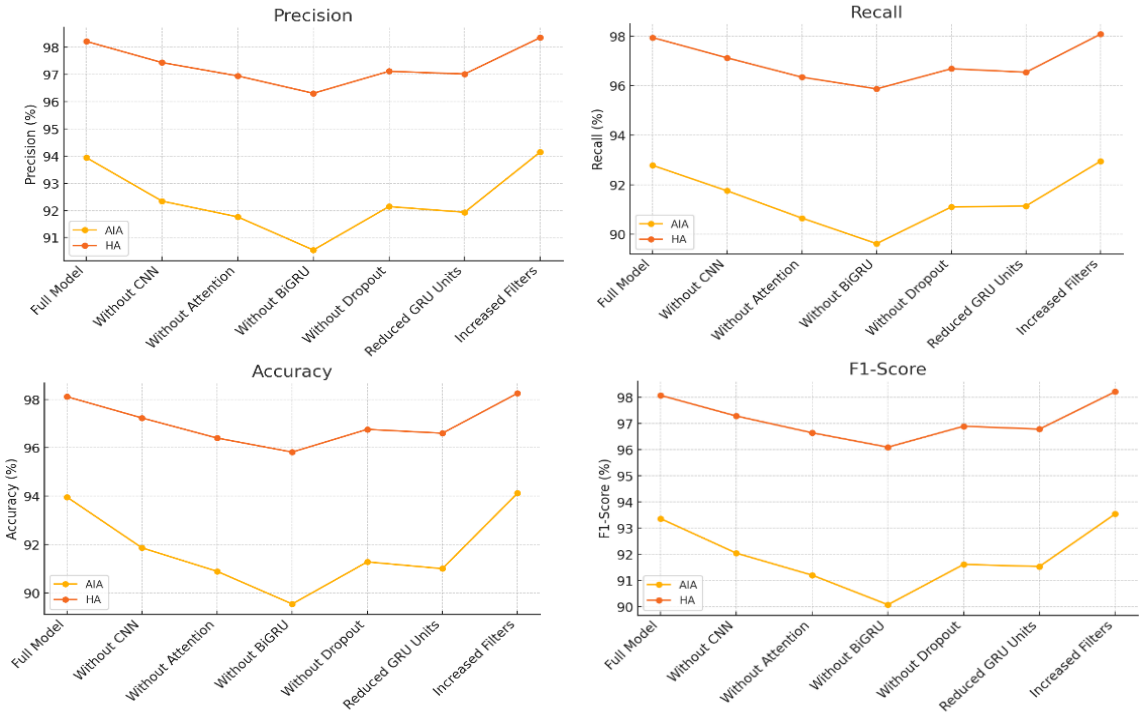

Fig. 11. These findings are visualized in the graphs above, which illustrate the effect of these modifications on precision, recall, F1-score, and accuracy across different model configurations.

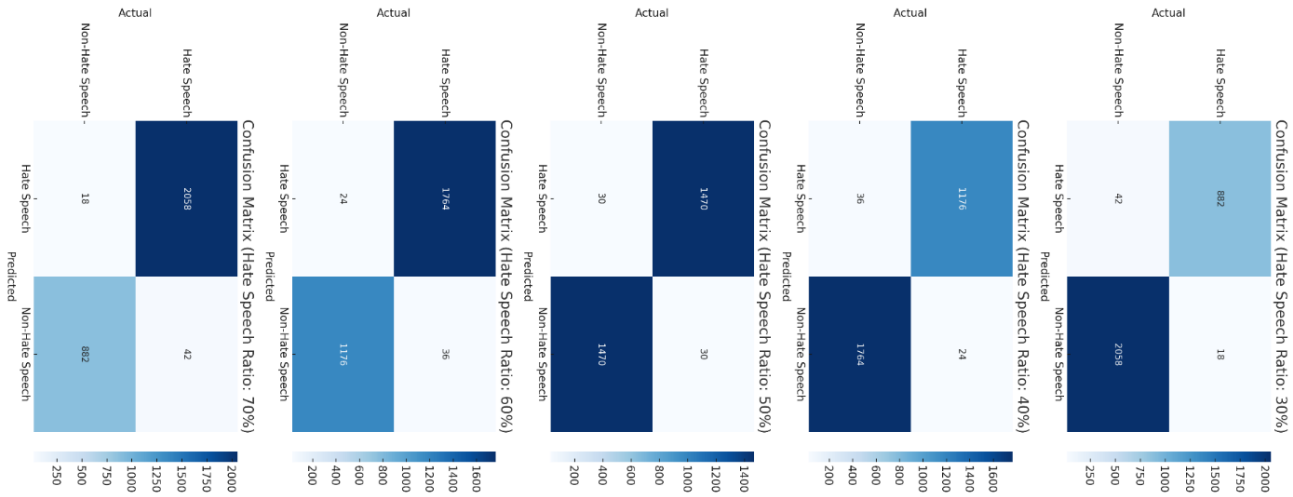

Fig. 12. Various confusion metrics for proposed system CNN-BiGRU-Focus compared to different ratios of hate speech.

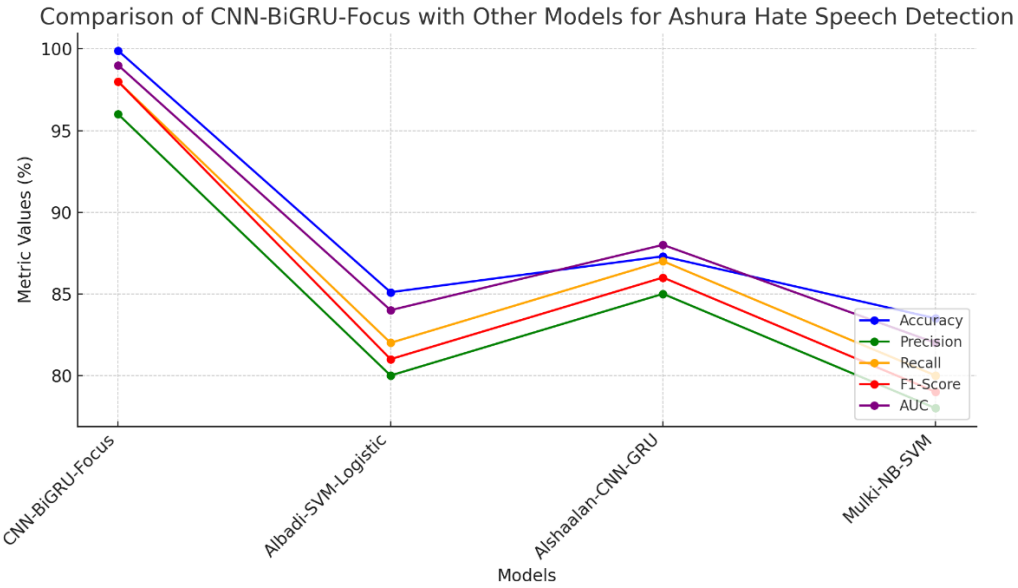

Fig. 13. State-of-the-art comparisons of proposed CNN-BiGRU-Focus model with other models, including Albadi-SVM-Logistic [10], Alshaalan-CNN-GRU [13], and Mulki-NB-SVM [14].

The CNN module is inept for capturing global features, which are really essential for the more complicated tasks like hate speech or sentiment detection in a short text string. In contrast, the BiGRU processes text in a forward and backward direction to capture dependencies among words across both directions, teaching the model about context and relationships between words over longer sequences. Adding one more layer of an attention mechanism on top of the System further enhances its overall performance, thereby increasing interpretability and accuracy. The combination of these ensures that CNN-BiGRU-Focus (see Fig. 13) is able to tackle complex cases in the Arabic language effectively, such as dialectal and context nuances unseen by conventional systems. Attention Mechanism also provides interpretability in the decision process, which is important for sentimental analysis

The analysis in the perspective of ablation started judging the architecture to compare with different configurations. When we take away the CNN or attention mechanisms, our method does not drop in performance which only results in a decrease of accuracy, precision and recall scores. Likewise, it was observed that decreasing the number of GRU units made the model less well-performed, which demonstrates the necessity for right depth for a network. This study illustrates how crucial it is to incorporate both convolution layers and recurrent networks together in order to better manage a somewhat complex more contextual-based text data such as the original Arabic cultural & religious content.

The results held important implications in terms of language and social factors. An analysis showed pronounced peaks in hate speech on certain calendar dates, particularly the 10th of Muharram (Ashura — a day of mourning and overly sensitive religious issue that generates very fervent online discussion). Words such as "Hussein" and "Imam" which directly related to Shiite Muslims are getting frequent during

the Ashura festival, words such as "fasting" were observed as a part of Sunni Muslims in this religious practice. The study also investigates the use of emojis to express feelings. Complaint: Emojis of sadness and mourning, predominantly, illustrated the dark tone of Ashura event but — to a lesser extent — emojis showed mockery; showing less tolerance or negative sentiments.

Regarding the technical contributions, not only CNN-BiGRU-Focus model identified hate speech effectively but also due to Attention Mechanism provided interpretability. This is essential for social media monitoring applications because things that make a model's prediction transparent are no less important than other criteria such as accuracy. The high accuracy of the model in Arabic (up to 99% on all configurations) proves that this model trained on Ashura-Arabic text behaves satisfactorily fine in processing complex language tasks, like constituent parsing, even for low resource languages such as Arabic. Addressing these dimensions as presented in Table 4 will require the proposed system to expand into a broader social media analyzing tool for academic research, and practical applications associated with content moderation and policy-making.

TABLE IV. CURRENT LIMITATIONS AND FUTURE WORKS OF PROPOSED SYSTEM

No.	Future works
1	Extending the model to process not just Arabic text but also multiple languages, potentially dialects as well as images/videos from social media which can enhance the understanding of user sentiment.
2	Real-time Hate Speech Detection: Extending the model to process live social media streams for a timely content moderation system using platforms such as X and Facebook.
3	More specifically, the Arabic model can be trained on top of other models to update or adapt to certain domains or events such as politics and news so that the performance and adaptation of these models will improve.

VI. CONCLUSIONS

In this research deep learning technique was deployed to process X data of the Ashura period 1444 AH. The four-week period was then used to collect, process and classify a total of 2,322,708 posts in order to analyze the tolerance exhibited by users. The Bi-GRU with multiple layers stacked on one another, along with AraVec embeddings were used for the analysis. The model achieved an accuracy of 99.89% in finding hate speech within 32% of the Ashura-related posts analyzed but a different trend is indicated by the analysis of posts including emojis, showing that a larger number of tolerance and peaceful expressions are used amongst Ashura. This discrepancy may be attributed to two factors: first, not all posts contain emojis, leading to variability in the results; second, the presence of emojis might reflect a less negative emotional state among users on the platform.

In this study, the author introduces a new hybrid DL model for analyzing Ashura-Arabic related hate speech and sentiment during the religious event Ashura using DL called CNN-BiGRU-Focus model which tremendously improves the efficiency of both tasks. The model surpassed traditional machine-learning classifiers and deep learning models like DenseNet and InceptionV3. By stacking CNN and BiGRU, this design provided excellent accuracy with the power of local feature extraction from CNN and long-range dependencies capturing property of Bi-Directional GRU over sequential data. Besides, by adding the attention mechanism, model resembled more like a human being who can decide which portion of text should not be focused on while analyzing some other part involved equally in context and predict new word making model interpretable rather oblivion.

In the future, as shown in Table IV, we will expand our model to multi-lingual and multimodal data so that real-time detection of hate content on large-scale social media platforms such as Facebook, Twitter and Instagram can be done. Efforts will also focus on bias mitigation and fairness in predictions to ensure the model is equitable across groups. Thirdly, a federated learning (FL) approach will be used to improve hate speech detection that is privacy-preserving without leaking data.

DATA AVAILABILITY

Data and code used to support the findings of this study have been deposited in the Sarah Data repository (https://github.com/imamu-asa).

Percussion Big Data Mining and Modeling Method Based on Deep Neural Network Model

Xi Song
Department of Music, College of Arts, Xiamen University, Xiamen 361005, China

***Abstract*—In order to improve the analysis effector percussion waveform, this paper studies the percussion big data mining and modeling method based on the deep neural network model. Aiming at the problem of the high sampling rate of Analog to Digital Converter (ADC) when the wideband frequency-hopping Linear Frequency Modulation (LFM) percussion waveform is sampled by Nyquist, this paper proposes a method of under sampling, and conducts a simple theoretical analysis. When the signal-to-noise ratio is 35dB, the frequency measurement error is close to 1MHz, which can meet the requirements of frequency measurement accuracy. When the signal-to-noise ratio is higher than 35dB, the frequency measurement error gradually decreases and eventually stabilizes, with a frequency measurement accuracy of around 30 kHz. Due to the low environmental interference in the sound wave recognition of percussion instruments and the close distance between the hardware equipment and the percussion instruments in this paper, the recognition results of the model in this paper have high accuracy Compared with existing methods, this article is more reliable in identifying percussion sound waves. From the data, it can be seen that the method proposed in this article has better performance in waveform recognition in impact big data mining models.**

Keywords*—Deep neural network; percussion; big data; mining; modeling

I. Introduction

All musical instruments generate and propagate sound waves. Sound waves can be simulated and form echoes through frequency hopping signals. Therefore, to extract effective information from instrument performances, one can start with frequency hopping signals and propose signal processing methods that can be applied to instrument performance information data mining. This article takes big data mining of percussion as an example for research, first analyzing the relevant research on the performance characteristics of percussion instruments.

In many percussion instruments, the same timbre can be played in different hitting positions, such as bell rings, bass drum bangs, and so on. When the player hits these sounds, he usually chooses a relatively convenient hitting position to complete the performance according to the preceding and following phrases among the many hitting positions. In some percussion works, by carefully arranging the striking position, the body shape can be changed to achieve the purpose of displaying the musical image [1].

There is relatively little research on extracting effective information from instrument performance, so this article proposes an effective music information data mining method based on practical needs. This paper studies and improves the percussion big data mining and modeling method based on the deep neural network model combined with the robot simulation technology, explores the research effect of percussion, and effectively improves the performance of percussion [2].

A method of undersampling is proposed to address the issue of high ADC sampling rate during Nyquist sampling of broadband frequency hopping LFM percussion waveforms, and a simple theoretical analysis is conducted. At the same time, for the frequency ambiguity caused by undersampling, two commonly used frequency deblurring methods, the Chinese remainder theorem and time-frequency analysis, were introduced, and the implementation complexity of these two methods was analyzed. A method based on multi-channel frequency partition decomposition blurring was proposed [3].

When performing percussion works, in certain sections with complex rhythmic changes or compound beats, the performer will subconsciously use their head, torso, and other limbs to strike the rhythm, prompting the audience to follow the logic of rhythm division. When fingers strike a paragraph in music, the shape of the fingers can guide the audience's understanding of the musical phrase. The performer will design the finger shape during or after striking while ensuring the timbre. While ensuring the beauty of the striking form, integrate it with the underlying emotions of the music. The innovation of this article lies in proposing a deblurring method based on multi-channel frequency division, which greatly reduces the implementation complexity. Finally, the fast frequency measurement is achieved through linear interpolation zero crossing frequency measurement method, improving the extraction effect of vocal waveform

Section I of this article mainly introduces the background and current situation, leading to the research content of this article. The following is the relevant work section, which mainly summarizes the existing research work in Section II, raises the existing research problems, and proposes improvement strategies for this article. Section III is the algorithm model section, which proposes the improved algorithm and model of this article, conducts experimental research is presented in Section IV, and finally summarizes the research content of this article in Section V.

II. Related Work

Non-deep learning algorithms consider audio characteristics and search for different feature representations of accompaniment and singing in songs, separating

*Corresponding Author

accompaniment and singing. This type of method relies on long-term accumulated audio knowledge to identify differences between the two, but typically finds distinguishable features with long cycles, high difficulty, and may not be universally applicable to all types of songs. Non-deep learning separation techniques mainly include matrix factorization and acoustic features. Non-negative matrix factorization (NMF) and robust principal component analysis (RPCA) are two typical matrix factorization methods used for vocal separation. From the perspective of acoustic features, propose a method for calculating auditory scene analysis based on pitch inference and accompaniment repetition. Due to the involvement of multiple disciplines in the fields of audio and computer science, the accompaniment and vocal frequency spectra in songs are intertwined and intertwined. Currently, non-deep learning algorithms for vocal separation have made some progress, but there are still problems with mixed vocal/accompaniment and low separation quality [4]. Deep learning algorithms mainly use deep, high semantic, and highly distinguishable features automatically learned by neural networks to separate and predict the time-frequency spectrum of accompaniment/singing, and finally reconstruct the accompaniment and singing signals. This type of algorithm mainly relies on the selection of neural networks. Suitable neural networks can learn and capture features that distinguish between the two, thereby predicting time-frequency spectra that are closer to the original accompaniment/singing. Deep learning algorithms include two categories: modeling in the frequency domain and modeling in the time domain [5]. Reference [6] focuses on deep learning algorithms and therefore provides a detailed introduction to the frequency domain and time domain models of deep learning. Frequency domain model: Due to the significant performance of neural networks on images and the fact that the frequency domain has more exploitable information compared to the time domain, existing algorithms focus on modeling time-frequency spectra in the frequency domain, known as frequency domain models. The main idea is to transform the song from time domain to frequency domain through short-time Fourier transform, input the time-frequency spectrum of the song into a neural network, and the network predicts the time-frequency spectrum of the accompaniment and singing voice. Finally, the phase approximation of the original song is used instead of the accompaniment and singing phase, and the time-frequency spectra of the accompaniment and singing are combined with the original song phase spectrum to reconstruct the time-domain signals of the accompaniment and singing. The separation performance of frequency domain models depends on the selection of neural networks. A network structure with rich structure and the ability to capture and learn comprehensive features can predict high-precision accompaniment/singing time-frequency spectra. In the reconstruction phase, the frequency domain model approximates the separated signal phase using the original song phase, without modeling the phase, which is currently a factor that restricts the quality of separation [7].

Time domain model: Modeling in the time domain refers to using time-domain signals as input and directly putting them into a neural network for training. The network outputs separated time-domain signals of accompaniment and singing. Directly modeling in the time domain avoids the problem of phase distortion in the frequency domain model. The study in [8] attempted to model in the time domain and achieved good separation results. However, due to the high sampling rate of audio signals, the one-dimensional signal in the time domain is very large, resulting in excessive input to the neural network. Whether the network can adapt to the large input size and learn abstract features such as time and space reasonably is a challenge to the network separation performance. Therefore, there is still some research and exploration space for the time domain model.

The main separation idea of the frequency domain model is to use the time-frequency spectrum after short-time Fourier transform as the network input, utilize the advantage of neural network automatic feature learning, capture high semantic features that can distinguish accompaniment and singing, and predict the mask matrix (composed of numbers between 0 and 1) of accompaniment and singing signals. Then, based on the original song time-frequency spectrum and the predicted mask, the time-frequency spectrum of accompaniment/singing is obtained. Finally, by combining the phase reconstruction of the original song, the time-domain signals of the accompaniment and singing voice are obtained [9]. The quality of frequency domain model separation depends on the accuracy of the time-frequency spectrum predicted by the network, and the network structure and learned features determine the quality of separation [10].

At present, the neural networks used in frequency domain models have transitioned from basic neural networks (such as RNN, LSTM, CNN) to structurally rich and multi-level neural networks (such as U-Net, SH-4Stack). With the continuous enrichment and diversity of network structures, the learned features have also been continuously improved. However, the common feature of advanced neural networks used for monaural vocal separation today is that the network structure is serial, and after multiple downsampling, some information will be lost. Moreover, upsampling cannot restore the original information feature appearance, and the defects in the feature learning process result in low amplitude accuracy of the predicted time-frequency spectrum [11].

Music originates from rhythm, and rhythm is also the most basic element of music. When our ancestors in ancient times, based on the relationship between the heart and the pulse, rhythm instinctively evolved into a form of music. Rhythm is more important to music today than ever before. In the use of music, rhythm is more important than melody, harmony, and pitch. Rhythm without specific pitch can make the listener understand the content, but pitch without rhythm can only be called accent [12]. Rhythm is very important in musical elements, and accent is irreplaceable in the rhythm system. After the accent is played well, it will produce the corresponding rhythm. The accent is actually the power generated by the rhythm, and the rhythm is the vitality of the rhythm. Simply playing the rhythm without the change of accent, even if the music played is correct, it cannot make the listener dance with the music. The playing of the accent produces the rhythm, and the existence of the rhythm makes the rhythm have vitality. If the rhythm has life, the music will create a magical power for the listener to enjoy it [13].

With the improvement of productivity and manufacturing level, the development of music goes hand in hand with it. Under the fierce market competition, many professional musical instrument craftsmen have created a guild system while working hard to produce excellent works. The appearance of guilds is to protect the interests of fellow handicraftsmen from being infringed by outsiders, in order to prevent the competition of foreign handicraftsmen and limit the competition between local handicraftsmen in the same industry, a civil organization established by urban handicraftsmen [14]. Guilds have both positive and negative effects. The various regulations issued by the guild have improved the production level of the musical instrument manufacturing industry to a certain extent, but also restricted free competition, the number of employees, the mass production of commodities, and the application of new production tools [15]. The various rules of the guild also make the shapes of musical instruments appear to be similar. The same type of musical instrument, although made by different craftsmen, has almost the same dimensions. In order to meet the market demand of the music industry, instrument manufacturers need more manpower for expanded reproduction [16]. Due to the high difficulty of processing musical instruments, many complex processing procedures still require manual operations and the skilled craftsmen of the processors. Therefore, the way for many musical instrument craftsmen to expand reproduction is not the training system, but the apprenticeship system [17]. Many apprentices need to practice in the workshop for several years, and then take over the mantle of the master and continue to make musical instruments. They don't have time to practice their musical instruments, and they have little experience in musical performances. They know the structure and workmanship of musical instruments well, but they don't understand music. Their duty is to produce instruments of the same level as the Master, pursuing more exquisite craftsmanship and production methods, rather than surpassing or innovating. It is precisely out of respect for the guild system, respect for traditions and a strong sense of responsibility for inheritance that many craftsmen have created the phenomenon of “inheritance” that is unique to musical instruments and is difficult to break [18].

Previous studies have shown that measuring the frequency of music signals in music data mining can cause spectrum aliasing, leading to frequency ambiguity. Therefore, it is necessary to deblur the sampled signals in order to obtain the true frequency of the signals. The core of frequency measurement methods under undersampling conditions is frequency deblurring, which involves undersampling broadband analog signals to obtain digital signals, and then using deblurring algorithms to recover the frequency of the digital signals to obtain the frequency of the original signal. The commonly used deblurring algorithms are the Chinese remainder theorem, time-frequency analysis, and compressive sensing. This article proposes a new deblurring algorithm based on multi-channel frequency band division. On this basis, the method of linear interpolation zero crossing frequency measurement is used to achieve fast frequency measurement of broadband frequency hopping signals. This method greatly reduces the system complexity while reducing the ADC sampling rate, and does not introduce additional deblurring errors. Finally, fast frequency measurement was achieved through linear interpolation zero crossing frequency measurement method.

III. Research Method

Percussion instruments have various forms of performance, and tapping with different parts can also emit audio signals with different characteristics. Feature mining can promote the development of smart music and is of great significance in helping performers discover deficiencies in performance in a timely manner.

Due to the fact that the Nyquist sampling theorem cannot be satisfied when using time-domain undersampling technology to sample the measured acoustic signal, using classical frequency estimation methods at this time will result in spectral aliasing. For undersampled sample sequences, in order to obtain their frequency estimation without ambiguity, a feasible algorithm needs to be used to perform frequency deblurring on the undersampled sequence. Usually, methods such as the Chinese remainder theorem, time-frequency analysis, and compressive sensing can be used to de fuzzify the frequency of the test signal. These methods can indeed achieve good results in their respective application fields, but they have high computational complexity and cannot be used as a universal method for de fuzzifying broadband frequency hopping signals under undersampling conditions. Therefore, it is necessary to propose an undersampling frequency deblurring method with low computational complexity and suitable for broadband frequency hopping signals.

The model in this article collects percussion signals, so in the actual collection process, the terminal hardware device will be connected to the collection device. The device that collects sound waves is very close to the percussion, and the volume and tone of the percussion sound are relatively high, which can be accurately collected by the terminal device. Therefore, the channel loss in the collection of sound channel signals can be ignored.

According to the Nyquist sampling theorem, the sampling rate of the ADC should be at least twice or greater than the Nyquist sampling rate.

A. The basic Theory of Under Sampling

Under sampling is defined as digitizing percussion waveforms at a sampling frequency lower than the Nyquist sampling rate. The following under sampling analysis is carried out through the single carrier frequency percussion waveform.

The input tone percussion waveform can be expressed as in [19]:

$$x(t) = \sin\left(\omega_0 t + \varphi\right) \tag{1}$$

Among them, ω_0 is the real frequency of the single-carrier percussion waveform, and φ is the initial phase of the single-carrier percussion waveform. According to the Fourier transform formula, it can be known that its spectrum is:

$$X(\omega)=\int_{-\infty}^{\infty} sin(\omega_0 t+\varphi)e^{-j\omega t}dt$$
$$=\pi\delta(\omega_0-\omega)e^{-j\varphi}+\pi\delta(\omega_0+\omega)e^{-j\varphi} \quad (2)$$

According to the relevant theory of digital percussion waveform processing, it can be known that the time domain sampling will cause the periodic extension of the spectrum, and the spectrum $X_s(\omega)$ of the percussion waveform after sampling and the spectrum $X(\omega)$ of the percussion waveform before sampling satisfy:

$$X_s(\omega)=\frac{1}{T_s}\sum_{n=-\infty}^{+\infty}X(\omega-n\omega_s) \quad (3)$$

Among them, ω_s is the sampling frequency, T_s is the sampling period. Therefore, when the percussion waveform x(t) is sampled at a fixed sampling rate Ω_s, the spectrum of the digital percussion waveform after sampling is [20]:

$$X_s(\omega)=\frac{1}{T_s}\sum_{n=-\infty}^{+\infty}\left[\pi\delta(\omega_0-\omega-n\Omega_s)e^{-j\varphi}+\pi\delta(\omega_0+\omega-n\Omega_s)e^{-j\varphi}\right] \quad (4)$$

It can be seen from the above formula that under the condition of under sampling, the real angular frequency ω_0 of the percussion waveform can be obtained by calculating according to the fuzzy angular frequency ω measured by the spectrum of the percussion waveform, the sampling frequency Ω_s and the number of ambiguities n relative to the sampling frequency. Therefore, the real percussion waveform frequency under under-sampling condition is obtained. The expression is as follows:

$$\omega_0=n\Omega_s+\omega, f_0=nf_s+f \quad (5)$$

Among them, f is the fuzzy frequency measured according to the percussion waveform spectrum, f_s is the sampling frequency of the percussion waveform, and f_0 is the real percussion waveform frequency. The sampling rate of the ADC must not be less than the Nyquist sampling rate.

B. Ambiguous Understanding of Chinese Remainder Theorem

The Chinese remainder theorem, as an outstanding achievement in ancient Chinese mathematics, embodies the wisdom of our ancestors and has made significant contributions in many modern research fields. This section will introduce the algorithm principle of the Chinese remainder theorem and further expand it. Simultaneously utilizing the Chinese remainder theorem for frequency analysis to achieve the goal of resolving ambiguity

The Chinese remainder theorem is an important theorem in number theory. Its content can be described as: $m_1,m_2,\mathrm{L}\ ,m_L$ is assumed as a positive integer that is relatively prime, and is defined as:

$$M_i=m/m_i, 1\le i\le L \quad (6)$$

Among them, there is $m=m_1m_2\mathrm{L}\ m_L$, then for any integer $r_1,r_2,\mathrm{L}\ ,r_L$, the following first-order congruential equations must have a solution [21],

$$\begin{cases} X\equiv r_1\ mod\ m_1 \\ X\equiv r_2\ mod\ m_2 \\ \quad \mathrm{M} \\ X\equiv r_L\ mod\ m_L \end{cases} \quad (7)$$

Furthermore, the solution to the system of equations is

$$X=\sum_{i=1}^{L}\overline{M_i}M_i r_i\ mod\ m \quad (8)$$

Among them, $\overline{M_i}$ is the inverse of M_i to modulo m_i, and it satisfies the following relation:

$$\overline{M_i}M_i\equiv 1 mod\ m_i, 1\le i\le L \quad (9)$$

If a and b are assumed to be given arbitrary positive integers, they can be decomposed into the form of division with remainder, which is expressed as follows [22]:

$$a=bq_1+r_1, 0<r_1<b$$
$$b=r_1q_2+r_2, 0<r_2<r_1$$
$$\cdots$$
$$r_{n-2}=r_{n-1}q_n+r_n, 0<r_n<r_{n-1}$$
$$r_{n-1}=r_nq_{n+1}+r_{n+1}, r_{n+1}=0 \quad (10)$$

Among them, $q_1,q_2,\mathrm{L}\ q_n,q_{n+1}$ and $r_1,r_2,\mathrm{L}\ r_n,r_{n+1}$ are arbitrary integers obtained. Because every division with remainder will reduce the remainder by at least 1, and b is a finite positive integer, in order to obtain an equation with a remainder of 0, at most b divisions with remainder can be performed. At this time, there is $r_{n+1}=0$. According to the Euclidean algorithm, the greatest common divisor of a and b is the last remainder that is not 0 in Eq. (10), that is r_n. Therefore, the following expression can be obtained [23]:

$$gcd(a,b)=r_n \quad (11)$$

In Eq. (11), $gcd(\cdot)$ represents the greatest common divisor. In the process of solving the greatest common divisor, the coefficients generated by the solution are collected by extending the Euclidean algorithm. Then, after backward operation, the integers x and y can be found to satisfy the following equation:

$$ax+by=gcd(a,b) \tag{12}$$

According to Eq. (6), it is easy to know that M_i and m_i are relatively prime, that is $gcd\left(M_i,m_i\right)=1$. According to Bezuo's theorem, there must be integers x_i and y_i such that the following equation holds [24]:

$$M_i x_i + m_i y_i = gcd\left(M_i,m_i\right), 1 \le i \le L \tag{13}$$

By extending the Euclidean algorithm, the parameters x_i and y_i can be obtained, and the modular inverse $\overline{M_i} = x_i$ can be obtained. In the radar system, the percussion waveform can usually be expressed as a single-frequency complex exponential form, and the percussion waveform expression is:

$$s(t)=Aexp\left(j2\pi f_0 t\right)+\omega(t) \tag{14}$$

Among them, the amplitude and frequency of the percussion waveform are represented by A and f_0, respectively, and the additive noise is represented by $\omega(t)$. If the additive noise $\omega(t)$ is assumed to be Gaussian white noise with zero mean and variance σ^2, the signal-to-noise ratio (SNR) satisfies the following equation [24]:

$$\rho = A^2 / \sigma^2 \tag{15}$$

Among them, ρ represents the signal-to-noise ratio of the single-frequency complex percussion waveform with additive noise. From a fixed time, the percussion waveform is sampled at the sampling rate of f_s. If the sampling time is assumed to be T, the length of the sample sequence after sampling is N, and the following relationship is satisfied:

$$N = Tf_s \tag{16}$$

Eq. (14) and Eq. (16) are combined to further obtain the time domain expression of the sample sequence after sampling:

$$s(n)=Aexp\left(j2\pi f_0 \cdot n / f_s\right)+\omega\left(n / f_s\right), 0 \le n < N \tag{17}$$

If the sampling rate f_s satisfies the Nyquist sampling theorem, there is $f_s \ge 2 f_0$. At this point, the sample sequence is subjected to N-point DFT analysis, which can be obtained The Spectrum of sample sequence:

$$S(k)=DFT(s(n)), 0 \le k < N \tag{18}$$

The spectrum S(k) of the sample sequence is subjected to spectral peak search, and the index position k_p corresponding to the peak spectral line satisfies the following equation:

$$k_p = arg\,max_{0 \le k < N}\{|S(k)|\} \tag{19}$$

Then, the real frequency f_0 of the percussion waveform can be obtained according to the following formula.

$$f_0 = k_p \cdot \Delta f \tag{20}$$

Among them, $\Delta f = f_s / N$ represents the spectral resolution of the DFT.

However, in a practical environment, the percussion waveform frequency f_0 can be taken very large. In this case, if the sampling rate f_s satisfies the Nyquist sampling theorem, the value of f_s will be very large, which requires high requirements for ADC devices and high cost, which is difficult to achieve in some special occasions. At this time, the under-sampling scheme should be considered, and the sampling rate f_s does not satisfy the Nyquist sampling theorem, that is,

$$f_s < 2 f_0 \tag{21}$$

In this case, the frequency estimation value of the original percussion waveform cannot be directly obtained by using the DFT frequency estimation method. At this time, according to the periodicity of the DFT spectrogram, the obtained frequency estimate is actually the frequency remainder (or aliasing frequency) f_r, which satisfies the following equation:

$$f_r = f_0 \bmod f_s \tag{22}$$

Considering that the Chinese remainder theorem uses the system of congruence equations to solve, the method of multi-channel under sampling can be used. According to the Eq. (21), the sampling frequency $f_{s1} \sim f_{sL}$ is selected to perform L-channel under sampling on the percussion waveform respectively. At the same time, the DFT analysis is performed on the sample sequence of each channel, and the index position $k_{p1} \sim k_{pL}$ corresponding to the spectral peak is obtained by using the Eq. (19), then the frequency remainder of each channel can be obtained to satisfy the following equation:

$$f_{ri} = k_{pi} \cdot \Delta f, 1 \le i \le L \tag{23}$$

According to Eq. (22), the system of congruence equations can be obtained, and the expression is as follows:

$$\begin{cases} f_0 = n_1 f_{s1} + f_{r1} \\ f_0 = n_2 f_{s2} + f_{r2} \\ \quad \text{M} \\ f_0 = n_L f_{sL} + f_{rL} \end{cases} \tag{24}$$

Among them, n_1, n_2, L, n_L is the fuzzy multiple. Obviously, the Chinese remainder theorem can be used to solve the equation system (24), so as to obtain the percussion waveform frequency f_0. When the signal-to-noise ratio is high enough, the index position $k_{p1} \sim k_{pL}$ corresponding to the spectral peak can be directly obtained by spectral peak search according to the DFT spectrogram.

Through the above analysis, in order to complete the fuzzy-free estimation of the frequency of percussion waveforms, at least two percussion waveforms are required. Therefore, Fig. 1 presents a dual-rate defuzzification structure based on the remainder theorem.

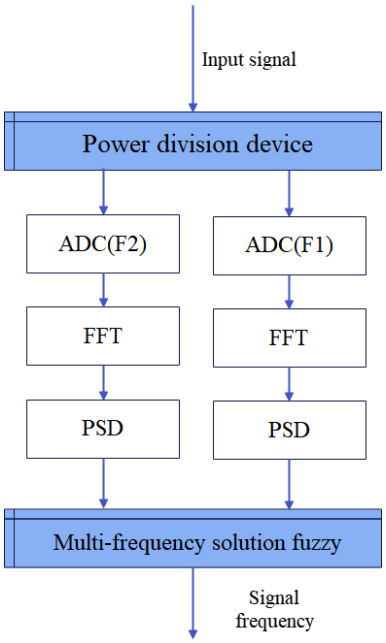

Fig. 1. Double-rate defuzzification structure based on remainder theorem.

C. Defuzzification based on Time-Frequency Analysis

The so-called time-frequency analysis is to use the joint representation of the time domain and the frequency domain to obtain an accurate description of its local characteristics.

Usually, the time-frequency analysis is performed after the real percussion waveform is converted into an analytical percussion waveform. If s(t) is assumed to be a non-stationary real percussion waveform, its corresponding analytical percussion waveform s(t) is expressed as:

$$z(t) = s(t) + jH(s(t)) \tag{25}$$

Among them, H(s(t)) represents the Hilbert transform of the real percussion waveform s(t). For the real percussion waveform, its Fourier transform satisfies the characteristic of conjugate symmetry, and the positive and negative frequency components contain the same information. Moreover, the advantage of analyzing the percussion waveform is that the negative frequency components with residual information are removed, and only the positive frequency components are retained, which will not cause information loss.

For the real percussion waveform s(t), its energy density is $|s(t)|^2$, then the total energy of the percussion waveform is expressed as:

$$E = \int_{-\infty}^{\infty} |s(t)|^2 \, dt \tag{26}$$

If the energy of the percussion waveform is limited, without loss of generality, E=1 can be set. It can be known from formula (26) that the energy density at any time point can be accurately calculated according to the real percussion waveform s(t). Therefore, the time resolution is infinite, whereas the frequency resolution is zero.

The first-order distance of the energy density is expressed as the time center $\langle t \rangle$ of the energy distribution of the percussion waveform, which satisfies the following relationship:

$$\langle t \rangle = \int_{-\infty}^{\infty} t \, |s(t)|^2 \, dt \tag{27}$$

The second moment of the energy density is expressed as the duration T^2 of the percussion waveform, and its expression is as follows:

$$T^2 = \int_{-\infty}^{\infty} (t - \langle t \rangle)^2 \, |s(t)|^2 \, dt \tag{28}$$

Among them, the percussion waveform time width T is the square root of the duration.

If the spectrum of the real percussion waveform s(t) is assumed to be $S(\omega)$, its energy density is $|S(\omega)|^2$, and the expression of the total energy of the percussion waveform is as follows:

$$E = \frac{1}{2\pi} \int_{-\infty}^{\infty} |S(\omega)|^2 \, d\omega \tag{29}$$

According to Parseval's theorem, the total energy of the percussion waveform in the time domain is equal to the total energy of the percussion waveform in the frequency domain. Therefore, there is E=1. It can be known from formula (29) that the energy density of any frequency point can be accurately calculated according to $S(\omega)$. Therefore, the frequency resolution is infinite, whereas the time resolution is zero. It is similar to the definition of time center and time width, and the expressions of frequency center and bandwidth are:

$$\langle \omega \rangle = \int_{-\infty}^{\infty} \omega \, |S(\omega)|^2 \, d\omega \tag{30}$$

$$B=\sqrt{\int_{-\infty}^{\infty}(\omega-\langle\omega\rangle)^2\,|S(\omega)|^2\,d\omega} \tag{31}$$

Generally speaking, both the time center $\langle t\rangle$ and the frequency center $\langle\omega\rangle$ of the energy distribution of the percussion waveform can be set to 0, so Eq. (28) and (31) can be further simplified into the following forms:

$$T^2=\int_{-\infty}^{\infty}t^2\,|s(t)|^2\,dt \tag{32}$$

$$\begin{aligned}B^2&=\int_{-\infty}^{\infty}\omega^2\,|S(\omega)|^2\,d\omega\\&=\int_{-\infty}^{\infty}\left(-j\frac{d}{dt}\right)^2|s(t)|^2\,dt\\&=\int_{-\infty}^{\infty}\left|\frac{ds(t)}{dt}\right|^2dt\end{aligned} \tag{33}$$

When there is $|t|\to\infty$, there is $\sqrt{t}s(t)\to 0$, the product of Eq. (32) and Eq. (33) satisfies the following relation:

$$\begin{aligned}T^2B^2&=\int_{-\infty}^{\infty}\left|\frac{ds(t)}{dt}\right|^2dt\cdot\int_{-\infty}^{\infty}t^2\,|s(t)|^2\,dt\\&\geq\left|\int_{-\infty}^{\infty}\frac{ds(t)}{dt}\cdot ts^*(t)dt\right|^2\\&=\left|\frac{1}{2}\left[ts^2(t)\Big|_{-\infty}^{\infty}-\int_{-\infty}^{\infty}|s(t)|^2\,dt\right]\right|^2\\&=\frac{1}{4}\left|\int_{-\infty}^{\infty}|s(t)|^2dt\right|^2=\frac{1}{4}\end{aligned} \tag{34}$$

Therefore, the following relationship can be further obtained:

$$TB\geq\frac{1}{2} \tag{35}$$

Eq. (35) is called the uncertainty principle. It shows that for any percussion waveform s(t) or window function h(t) with limited energy, the time resolution and frequency resolution are contradictory, and it is impossible to obtain ideal time resolution and frequency resolution at the same time.

The algorithm model of STFT(short-time Fourier transform) can be obtained as shown in Fig. 2. Choose a time-frequency localized window function, assuming that the analysis window function g (t) is stationary (pseudo stationary) within a short time interval, move the window function so that f (t) g (t) is a stationary signal at different finite time widths, and calculate the power spectrum at different times. The short-time Fourier transform uses a fixed window function, and once the window function is determined, its shape no longer changes, and the resolution of the short-time Fourier transform is also determined. If you want to change the resolution, you need to reselect the window function. Short time Fourier transform can still be used to analyze segmented stationary signals or approximately stationary signals, but for non-stationary signals, when the signal changes dramatically, the window function is required to have a high time resolution; When the waveform changes relatively smoothly, mainly for low-frequency signals, a window function with high frequency resolution is required. Short time Fourier transform cannot meet the requirements of frequency and time resolution. The window width is set to N, and the number of FFT(Fourier Transform) points is also set to N. Then, a series of continuous digital knock waveforms are input from the outside. The percussion waveform is transformed into a digital sequence of length N after passing through the data sorting module. Then, through the windowing filtering processing module, the N components of the digital sequence are respectively weighted and sent to the FFT module in sections. After frequency domain analysis, the mathematical expression of STFT is obtained. The STFT algorithm can continuously analyze the spectrum of the sampled data and output real-time analysis results.

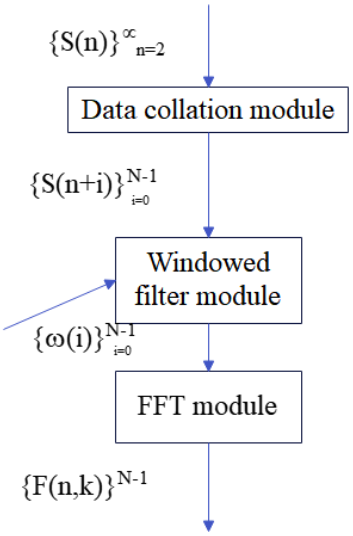

Fig. 2. STFT algorithm model.

By analyzing the algorithm model shown in Fig. 2, the mathematical expression of STFT can be obtained:

$$F(n,k)=\sum_{i=0}^{N-1}s(n+i)\omega(i)e^{-j\frac{2\pi}{N}ki} \tag{36}$$

Among them, n is the time point, and satisfies $n=mL\leq N;k$ is the channel number, and satisfies $k=0,1,\mathrm{L}\ ,N-1$. L is the number of sliding points of the time window, $\{\omega(i)\}_{i=0}^{N-1}$ is the window function, and the window width is N, which is mainly used to reduce the side lobes of the filter, thereby reducing the occurrence of spectral leakage and inter-spectral interference. F(n,k) represents the frequency domain analysis result of the kth channel at time n, that is, the frequency distribution of the percussion waveform in the time window.

The STFT algorithm can be combined with the under-sampling algorithm, so that the under sampled RF broadband percussion waveform can be directly de-blurred, so as to realize the frequency estimation of the original RF broadband percussion waveform. The FFT of the sampling sequence in the function window is the output result of the STFT. Taking the remainder theorem under sampling method as an example, the block diagram of the STFT channelization structure under the condition of under sampling is given as shown in Fig. 3.

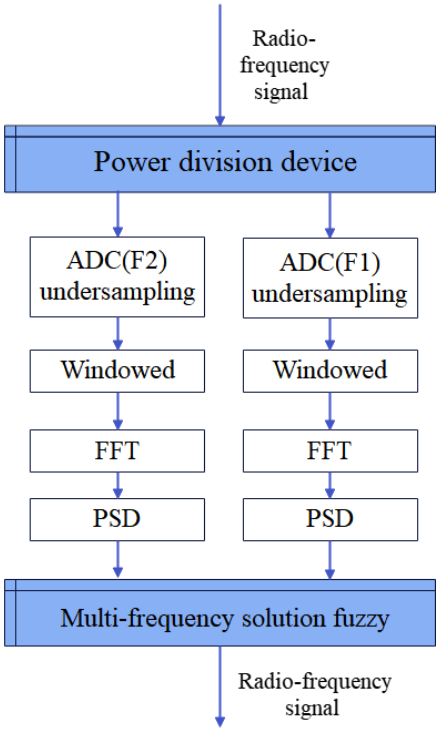

Fig. 3. Block diagram of STFT channelization structure under sampling condition.

Through the above analysis, it can be further obtained that the flow of STFT channelization under the condition of under-sampling is shown in Fig. 4.

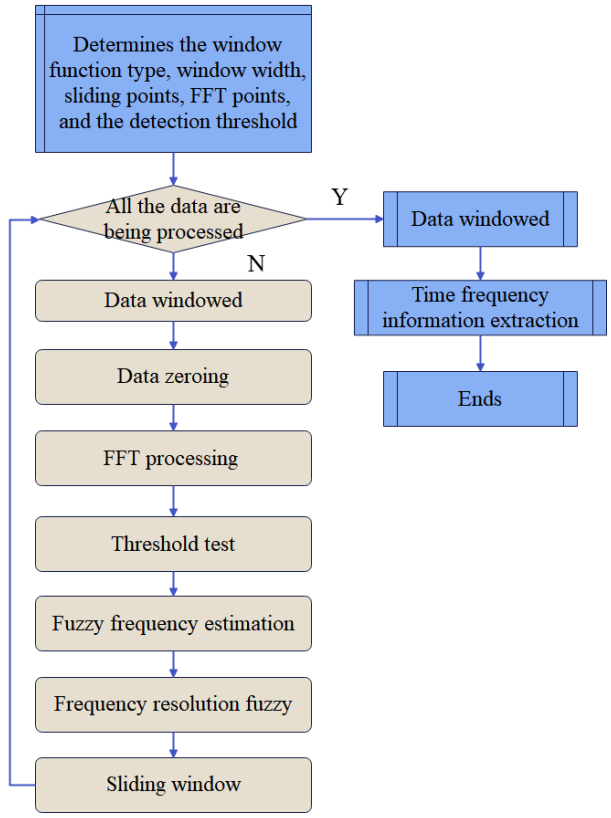

Fig. 4. Flow chart of STFT channelization under sampling condition.

D. Multi-Channel Frequency Division Defuzzification

If it is assumed that the frequency hopping range of the wideband frequency-hopping LFM percussion waveform is $f_1 \sim f_2$, the bandwidth of the LFM percussion waveform is B_s, and the following relationship is satisfied:

$$\begin{cases} B_s = f_1 \\ B_s = f_2 - f_1 \end{cases} \tag{37}$$

The ADC sampling rate is selected as f_s, and it satisfies the following relationship:

$$2B_s < f_s < 2(f_2 - f_1) \tag{38}$$

If the reference frequency is set to f_0 and the number of channels is set to M, the RF analog percussion waveforms of M channels can be down-converted to the same IF frequency hopping range through M different local oscillator percussion waveforms, and are divided into N intermediate frequency sub-bands, as shown in Fig. 5.

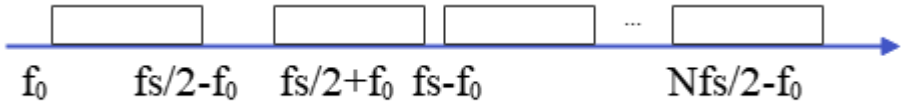

Fig. 5. IF sub-band division.

It is easy to see from Fig. 5 that the range of each IF sub-band can be expressed as:

$$\frac{(k-1)f_s}{2}+f_0 \sim \frac{kf_s}{2}-f_0, k=1,2,\ldots N \tag{39}$$

Therefore, the frequency hopping range of the IF sub-band can be expressed as:

$$f_0 \sim \frac{Nf_s}{2}-f_0 \tag{40}$$

Thus, the expressions of the intermediate frequency hopping bandwidth B_1 and the bandwidth B_2 of each sub-band are as follows:

$$\begin{cases} B_1=\frac{Nf_s}{2}-2f_0 \\ B_2=\frac{f_s}{2}-2f_0 \end{cases} \tag{41}$$

It is easy to know that when there is N=2, it is the easiest to comprehensively analyze the subsequent over-threshold detection results and frequency measurement results. When N increases gradually, the complexity of frequency deblurring will increase, but the sampling rate f_s of ADC can be reduced lower. Therefore, after the M channels are down-converted from the radio frequency band to the intermediate frequency band, each channel can be divided into N sub-bands with an interval of $2f_0$. According to the Nyquist sampling theorem, if the IF percussion waveform of a certain channel is directly frequency measured, the types of frequency ambiguity that will appear include: First, the frequency ambiguity between N sub-bands, which is caused by spectrum folding. The second is the self-ambiguous frequency band of the channel itself, and its range can be expressed as:

$$\frac{kf_s}{2}-f_0 \sim \frac{kf_s}{2}+f_0, k=1,2,\ldots N-1 \tag{42}$$

The IF frequency hopping bandwidth B_1 is the same as the frequency hopping bandwidth of each channel in the radio frequency band. The RF frequency bands of the M channels are divided, as shown in Fig. 6.

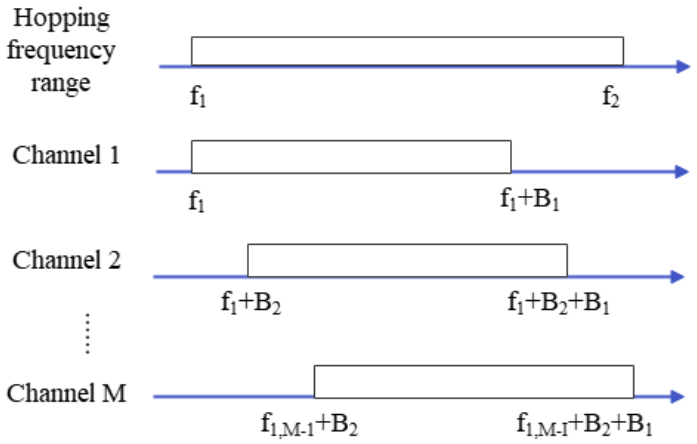

Fig. 6. Division of RF frequency bands for each channel.

As can be seen from Fig. 6, the starting point of the frequency band of the i-th channel is represented by $f_{s,i}$, and it satisfies the following expression:

$$f_{s,i}=f_{s,i-1}+B_2, i=2,3,\ldots, j-1, j+1,\ldots M \tag{43}$$

Among them, the starting point of the frequency band of the 1st channel is $f_{s,1}=f_1$, and the end point of the frequency band of the i-th channel is denoted by $f_{e,i}$, and the following expressions are satisfied:

$$f_{e,i}=f_{s,i}+B_1, i=1,2,\ldots,M \tag{44}$$

When the channel number M is selected, the total frequency band of the channel must completely cover the frequency hopping range, that is, $f_{s,M}+B_1 \geq f_2$. The condition for frequency deblurring is that the overlapping frequency band bandwidth between M channels does not exceed $f_s/2$. In order to satisfy this condition, the j-th channel is reserved here. For different situations, it is necessary to design the frequency band starting point of the channel to satisfy the frequency de-ambiguity condition. If the mid-frequency band of any channel is divided into only two sub-bands, namely N=2, the condition for frequency de-ambiguity must be established at this time. Therefore, the j-th channel may not exist.

The flow chart of multi-channel frequency division defuzzification is shown in Fig. 7.

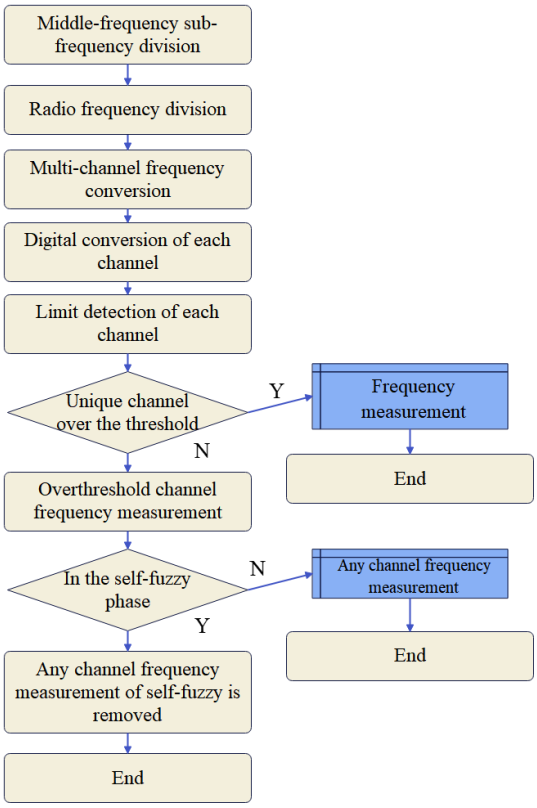

Fig. 7. Flowchart of the realization of multi-channel frequency division defuzzification.

E. Linear Interpolation Zero-Crossing Frequency Measurement

The zero-crossing frequency measurement method can directly measure the frequency through the percussion waveform time series waveform, that is, calculate the frequency of the percussion waveform by measuring the time interval of the zero point. It has the advantages of simple principle, small calculation amount, and fast operation speed.

If it is assumed that the percussion waveform to be tested is a point-frequency percussion waveform with zero initial phase, its expression is:

$$x(t)=\cos(2\pi ft) \tag{45}$$

If the sampling rate of the percussion waveform is f_s, the expression of the discrete percussion waveform after sampling is:

$$x[n]=x(nT_s)=\cos(2\pi fnT_s) \tag{46}$$

It is easy for us to know that the position where the zero point appears is:

$$2\pi fnT_s=\frac{\pi}{2}+k\pi, k\in N \tag{47}$$

$$\frac{f}{f_s}=\frac{2k+1}{4n}, n=1,2,3\ldots$$

That is, when is satisfied, the zero position of the simulated percussion waveform can be sampled. Therefore, when the sampled percussion waveform does not contain the zero position, it is necessary to determine the zero point by the method of depreciation.

The linear interpolation method is used to measure the frequency, and Fig. 8 is a partial enlarged view of the cross position of the left and right of the zero point. A and B are two zeros, and l_{AB} is the interval between zeros. Therefore, if l_{AB} can be obtained, the period of the percussion waveform is $T=l_{AB}$ and the frequency is $f=1/T$. The connection line at the positive and negative intersection of the zero point can be regarded as a straight line, that is, the method of linear measurement, there are:

$$\frac{x_2}{x_1}=\frac{y_2}{y_1} \tag{48}$$

$$\frac{x_4}{x_3}=\frac{y_4}{y_3} \tag{49}$$

According to the sampling theory, the percussion waveform sampling period is $T_s=x_1+x_2=x_3+x_4$. Combining Eq. (48) and Eq. (49), the following formula is obtained:

$$x_2=\frac{y_2}{y_1+y_2}T_s \tag{50}$$

$$x_3=\frac{y_3}{y_3+y_4}T_s \tag{51}$$

Therefore, the zero-point interval $l_{AB}=x_2+nT_s+x_3$ is obtained. Among them, n is the number of discrete points between the two points of C,D.

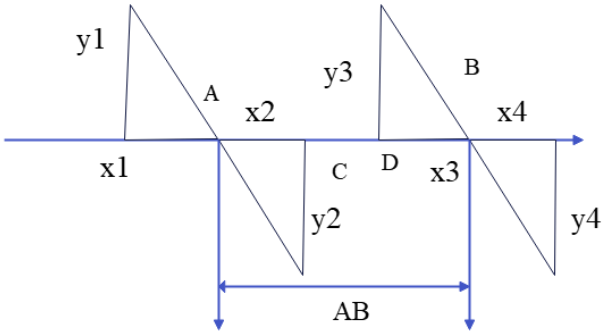

Fig. 8. Schematic diagram of linear interpolation geometry of zero point position.

IV. Model Experimental Results

A. Test Model

This article uses the algorithm model in the third part to extract the features of percussion sound signals, mine and analyze the percussion sound signals, and combine the STFT algorithm with undersampling algorithm. This enables direct deblurring of undersampled RF broadband percussion waveforms, thus achieving frequency estimation of the original RF broadband percussion waveforms, and inputting them into the system as recognizable data. It can provide reliable reference for intelligent recognition of percussion waveforms and virtual simulation of percussion in the future

After the music data is input into the feature selection model, the corresponding feature information is obtained through the long and short-term memory network. Then, it is input into the attention calculation module to analyze the feature distribution of each data block. The attention calculation layer is composed of a two-layer neural network (Fig. 9), and the structure is shown in Fig. 10.

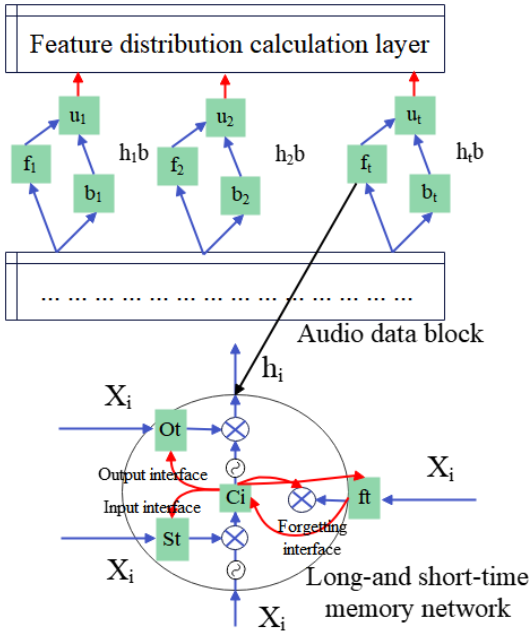

Fig. 9. Modeling of percussion big data mining based on deep neural network.

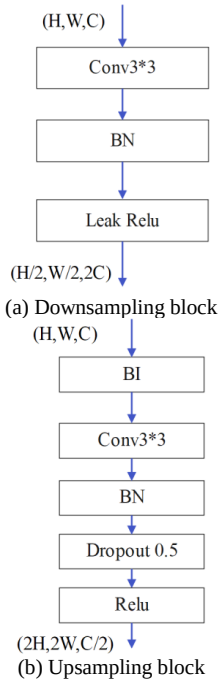
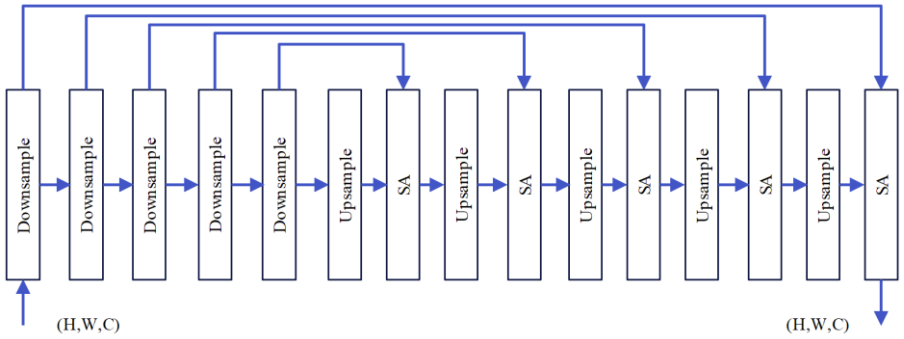
B. Analysis of Test Results

The sampling module and SA module are stacked together. In both the downsampling and upsampling modules, the size of the convolution kernel is (3,3), the stride is set to 1, and the padding mode is set to "same". Compared to using convolution kernels of size (5,5), using smaller kernels can reduce the computational complexity of the network, while using smaller and deeper kernels can achieve better performance than using larger kernels. Each downsampling block contains 3 layers of network, which are in order of size (3, 3) convolutional layer, BN layer, and Leave Relu activation layer when viewed from the direction of the input network. Each downsampling block uses a BN layer to normalize the feature information learned in this layer, avoiding overfitting. Select Leave Relu to activate the output of the downsampling layer, making the feature values of the output data smoother. Each upsampling block consists of five network layers, namely bilinear interpolation layer (BI), transposed convolutional layer of size (3,3), BN layer, dropout layer, and Relu activation layer. Abandoning the use of transposed convolution to construct upsampling blocks and instead using bilinear interpolation for upsampling, this approach reduces the number of parameters while achieving the goal of upsampling feature maps.





(C) Encoder decoder network

Fig. 10. Structure diagram of neural network model.

Model checking is performed on this basis. If the percussion waveform to be tested is an LFM percussion waveform, since the bandwidth and pulse width of the LFM percussion waveform are known, the modulation slope can also be determined. At this time, it is only necessary to measure the initial frequency according to the above process, and then perform frequency compensation to obtain the center frequency estimation of the LFM percussion waveform. The following is a simulation analysis of the frequency measurement accuracy of the LFM percussion waveform under different signal-to-noise ratios. Set up three experiments, taking the bandwidth and pulse width of LFM percussion waveform as 20MHz, 6 μ s, 40MHz, 8 μ s, 80MHz, 12 μ s, respectively, the center frequency is 380MHz, the sampling rate is 1.6GHz, the signal-to-noise ratio range is 30dB to 45dB, and the step is 1dB. The simulation results are shown in Fig. 11.

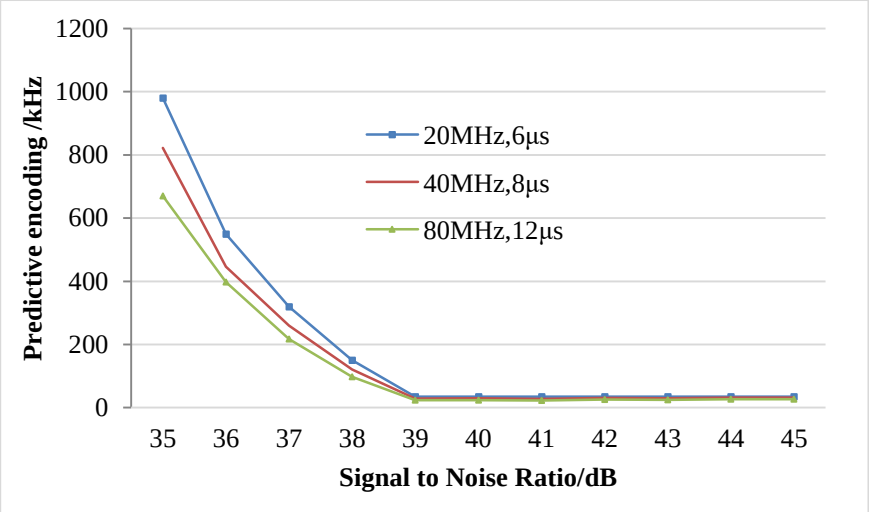


Fig. 11. The relationship between the frequency measurement error and the signal-to-noise ratio of the linear interpolation zero-crossing frequency measurement method.

As can be seen from Fig. 11, From different bandwidth and pulse width conditions, the linear interpolation zero crossing frequency measurement method has good performance in different environments, when the frequency measurement of the LFM percussion waveform is performed by the linear interpolation zero-crossing frequency measurement method, the frequency measurement error decreases with the increase of the signal-to-noise ratio. When the signal-to-noise ratio is 35dB, the frequency measurement error is close to 1MHz, which can meet the requirements of frequency measurement accuracy. When the signal-to-noise ratio is higher than 35dB, the frequency measurement error gradually decreases, and finally tends to be stable, and the frequency measurement error remains about 30kHz. Therefore, under the premise of satisfying a certain signal-to-noise ratio, the linear interpolation zero-crossing frequency measurement method has better frequency measurement accuracy and can meet the requirements of LFM percussion waveform frequency measurement.

To further verify the effectiveness of the model proposed in this paper, it is compared with the methods proposed in references [3], [7] and [10]. Reference [3] used deep learning techniques, reference [7] used multimodal sentiment classification techniques, and reference [10] used long short-term memory deep neural networks

On this basis, the waveform recognition effect of the percussion big data mining model based on the deep neural network model is tested, and the results shown in Table I are obtained.

TABLE I. THE EFFECT OF WAVEFORM RECOGNITION OF PERCUSSION BIG DATA MINING MODEL BASED ON DEEP NEURAL NETWORK MODEL

	The method described in reference [3]	The method described in reference [3]	The method described in reference [3]	The method described in this article
1	77.756	86.136	90.503	95.568

14	79.399	83.980	84.820	94.879
15	77.335	81.607	83.927	93.426

The method proposed in this article first obtains corresponding feature information through long short-term memory networks, and then inputs it into the attention calculation module to analyze the feature distribution of each data block. Compared with studies [3], [7], and [10], this article has more reliable recognition results. From the data, the method proposed in this article has better performance in waveform recognition in percussion big data mining models.

It can be seen from the above research that the percussion big data mining model based on the deep neural network model proposed in this paper has a good effect on waveform recognition.

In the process of music data mining and model construction, this method has lower implementation complexity compared to commonly used deblurring methods such as remainder theorem and time-frequency analysis. In addition, the overall design of the simulator system was completed, and the system was implemented based on a computer platform. Through analysis of test results, the accuracy of the system design and the effectiveness of frequency measurement methods were verified.

V. CONCLUSION

When performing percussion works, in some passages with complex rhythm changes or complex time signatures, the performer will also subconsciously use the head, torso and other limbs to strike the beat to remind the audience of the rhythm division logic. When there is a finger hitting passage in the music, the shape of the finger can guide the audience's understanding of the phrase. Moreover, while ensuring the timbre, the player will design the shape of the fingers when hitting or after hitting, and while ensuring the beauty of the hitting shape, it will be integrated with the inner emotion of the music. This article proposes a new deblurring algorithm based on multi-channel frequency band division. On this basis, the method of linear interpolation zero crossing frequency measurement is used to achieve fast frequency measurement of broadband frequency hopping signals. This method greatly reduces the system complexity while reducing the ADC sampling rate, and does not introduce additional deblurring errors. Finally, fast frequency measurement was achieved through linear interpolation zero crossing frequency measurement method.

The percussion big datamining and modeling methods are researched based on the deep neural network model. The simulation test shows that the percussion big data mining model based on the deep neural network model proposed in this paper has a good effect on waveform recognition.

When the signal-to-noise ratio is 35dB, the frequency measurement error is close to 1MHz, which can meet the requirements of frequency measurement accuracy. When the signal-to-noise ratio is higher than 35dB, the frequency measurement error gradually decreases and eventually stabilizes, with a frequency measurement accuracy of around 30kHz. Moreover, through comparison, it can be seen that the model in this article has better performance in sound wave recognition of percussion instruments

When simulating the frequency hopping signal echo in this article, only the target characteristics were considered, without considering the clutter and interference characteristics. At the same time, when simulating the target echo, the scattering characteristics of the target were not considered, which means that the target is considered an ideal point target. Therefore, in subsequent research work, in order to better simulate the radar environment, it is necessary to simulate clutter signals and interference signals, and analyze the echo simulation methods of extended targets.

Deep Image Keypoint Detection Using Cascaded Depth Separable Convolution Modules

Rui Deng
Network Information Center, Jilin Vocational College of Industrial and Technology, Jilin, 132013, China

***Abstract*—Depth images have become an important data source for human bone keypoint detection due to their three-dimensional information. To optimize the efficiency of keypoint detection in depth images, a depth image keypoint detection model that combines cascaded depth separable convolution modules is constructed. The model first performs data cleaning and preprocessing on the image, replacing traditional convolutional layers with depthwise separable convolutional modules. The Faster OpenPose network is introduced to replace the traditional convolutional network structure with the lighter MobileNetV1 for detecting keypoints in the image. When the dataset size was 4000, the Faster OpenPose model had an accuracy of 0.97 and a mean square error of 0.03. The recognition rates for four different images were 0.91, 0.87, 0.89, and 0.93, respectively. The processing times were 0.32, 0.31, 0.28, and 0.27, respectively. The method of depth image keypoint detection combined with cascaded depth separable convolution modules has good practicality and excellent detection performance for various images, providing new ideas for future keypoint detection technology research.**

I. Introduction

Deep Image (DI) keypoint detection is important in 3D object reconstruction, facial recognition, gesture recognition, and robot navigation. These tasks typically require accurate extraction of key points of objects or scenes from DI for further analysis or processing. However, traditional methods rely heavily on manually designed feature extractors, which often exhibit significant limitations in complex scenes. Compared with traditional two-dimensional images, DI provide rich 3D spatial information, making the understanding and analysis of the scene more accurate. In human pose estimation, DI can more accurately capture the skeletal structure of the human body, reducing the impact caused by lighting changes, occlusion, and other issues [1]. However, how to effectively extract key points of the human body from DI remains a challenge. The current keypoint detection technology, such as the OpenPose based network architecture, can achieve relatively accurate pose estimation on two-dimensional images. However, there are still certain limitations in DI processing, such as high computational complexity of the model, sensitivity to background information interference, and the need to improve keypoint localization accuracy [2]. The limitation of existing models is that they cannot effectively handle noise and background interference in depth images, resulting in a decrease in the accuracy of keypoint detection. Many traditional models rely on high-quality input data, and in practical applications, depth images often have varying degrees of noise, which can affect model performance. In addition, existing models often lack sensitivity to changes in human posture and complex background responses, limiting their application in multi human environments. The computational complexity of the model is also a problem, and classical convolutional neural networks may face performance bottlenecks when processing real-time data. Therefore, this study proposes a DI keypoint detection method that combines cascaded depth separable convolution modules. This method replaces the traditional VGG-19 network structure with a more lightweight MobileNetV1 by introducing the Faster OpenPose network, and designs a Depthwise Separable Convolutional Module (DWCA) based on this to reduce computational complexity while maintaining the model's prediction capability. The main reason for choosing a model based on bilateral filtering and Faster OpenPose network is its excellent noise processing ability and efficient 3D information preservation. Bilateral filtering can effectively remove noise in depth images while preserving edge features, ensuring the accuracy of keypoint localization. The Faster OpenPose network significantly improves computational efficiency and meets real-time detection requirements by replacing VGG-19 with MobileNetV1. The introduction of depthwise separable convolution modules and feature fusion mechanisms enhances the ability to extract key features and improves the performance of multi person pose estimation. The model can effectively extract regions of interest related to the human body, filter out irrelevant backgrounds, and further improve detection accuracy and efficiency. The contribution of the research lies in the proposed bilateral filtering based deep image processing model, which effectively removes noise from deep images while preserving key edge features, significantly improving the accuracy of keypoint localization. Secondly, by introducing the Faster OpenPose network and replacing the traditional VGG-19 with MobileNetV1, the computational efficiency of the model has been improved, making real-time keypoint detection possible and adapting to the needs of various application scenarios. The deep separable convolution module based on feature fusion introduced in the study enhances the ability to extract important features from depth images and improves the performance of keypoint detection. In addition, the model effectively extracts regions of interest related to the human body, filters out irrelevant background information, and further improves the accuracy and efficiency of keypoint localization. The innovation lies in optimizing the performance of DI keypoint detection by improving the OpenPose network structure and introducing more efficient convolution modules. The research aims to provide new technological paths for the field of Computer Vision (CV) and offer better solutions for

keypoint detection in practical applications.

The research content is as follows: An examination of the research topics of other scholars in the field is given in Section II. An overview of the principal methodologies employed in Section III. The results of the model experiment is presented in Section IV. Discussion is given in Section V and finally, the paper is concluded in Section VI.

II. Related Works

Under the development of computer technology, CV is becoming increasingly important. Zhou K et al. built an improved codebook pattern model to improve the processing efficiency of rapid action vide. The combination of this method with the CV approach had the potential to enhance the accuracy of feature recognition in fast-action sequences, facilitate the effective processing of fast-motion videos, and improve the feature recognition effect [3]. Zhou H et al. discovered that despite the current advancements in video surveillance, autonomous vehicles, and other related fields, there was still a significant opportunity for further development in predicting the future trajectory of pedestrians. A spatiotemporal graph neural network based on attention interaction perception had been proposed, which demonstrated effective capability [4]. Lee J et al. put forth a new YOLO model to handle the real-time object detection problem of YOLO. This architecture maintained YOLO's high accuracy and ease of use. The proposed method model could effectively solve problems related to real-time processing [5]. Jiang X et al. proposed a blockchain based model sharing method to address the issues of autonomous driving object detection. This method combined mobile edge computing technology and YOLOv2 model to reduce regional differences, and its effectiveness and reliability were superior to the reference model [6].

Yang Y et al. constructed a traffic recognition method with deep convolutional neural networks, which was able to detect and classify the input images, thereby obtaining more clear traffic information. The algorithm demonstrated superior accuracy in traffic image classification, offering a more optimal solution for smart traffic monitor [7]. Chen D et al. proposed an underwater ship detection model with optimized YOLOv3, which enhanced feature extraction capabilities in various environments by introducing an attention module. This model had good recognition and detection capabilities, proving its superiority in ship detection in water transportation [8]. Tumrani et al. proposed a decentralized and multi-attribute learning network, which adopted a vehicle keypoint detection model based on local attention for regions with more DIcriminative information. This method could improve the ability and robustness of vehicle recognition [9].

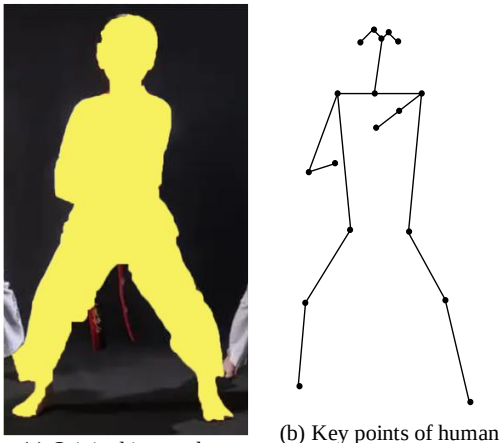
In conclusion, a substantial body of research has been conducted in the field of computer imaging, yielding notable findings, but have not conducted more in-depth studies on DI. Moreover, various studies have focused on specific domain problems and rely on specific datasets, resulting in insufficient generalization ability of models in other datasets or practical applications. This study proposes a DI keypoint detection method that combines DWCA. This method replaces the traditional VGG-19 network structure with a more lightweight MobileNetV1 by introducing the Faster OpenPose network, and uses a DWCA on this basis to reduce computational complexity while maintaining the model's prediction capability.

III. Methods

In the first section, a DI processing model based on Bilateral Filtering (BF) is proposed to address the issue of noise in DI. In the second section, OpenPose network is adopted to detect keypoints in images and improve the model for defects.

A. DI Processing Model Based on BF

A DI is an image used to represent the distance from each pixel in a scene to the camera. Unlike traditional two-dimensional images, it contains three-dimensional information in the scene and can be used to more accurately understand and analyze the spatial structure of the scene [10-11]. An image is typically a two-dimensional matrix consisting of three color channels, with the value of each channel representing the color intensity of that pixel. Each pixel in a color image provides color information that can describe the appearance of objects in the scene. DI is a two-dimensional matrix, but each pixel value represents the distance from that pixel to the camera or sensor. DI reflects the 3D structural information of the scene, not the color, thus protecting privacy. The study extracts key points of human bones, as shown in Fig. 1.



(a) Original image data (b) Key points of human skeleton

Fig. 1. Extraction of key points in the human body.

In Fig. 1, firstly, the resolution of the image is converted, and secondly, public tools are used to process the data. The joints of the human body on each screen are estimated, and the coordinates of each joint point are recorded. The DI body surface keypoint localization algorithm mainly consists of six steps, and its process is shown in Fig. 2.

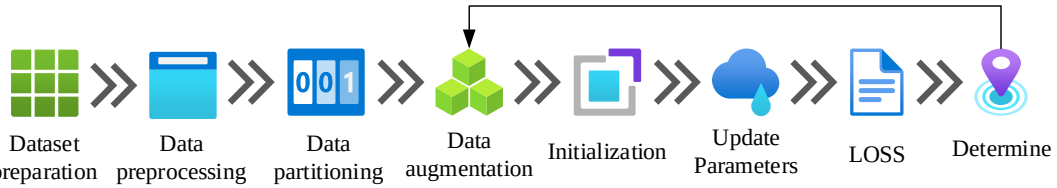


Fig. 2. Body surface key point localization process.

In Fig. 2, during the model training process, the dataset is first prepared, including collecting, organizing, and organizing data to provide a foundation for model training [12-13]. In the data preprocessing stage, the data is cleaned, normalized, and processed to ensure data quality and consistency. Subsequently, the dataset is partitioned into three sets, thereby ensuring that the model exhibits the requisite capacity for generalization. Then, the dataset is augmented to enhance the discrepancy of the data and reinforce the model's robustness. After the model parameters are initialized, the model begins to be trained; The error predicted by the loss function model is evaluated and updated based on the parameters of the error model. Then the loss function is recalculated and checked for convergence. If the loss function converges, that is, the error reaches a stable low level or no longer significantly decreases, the training process ends; otherwise, the model continues to iterate and update parameters until convergence conditions are reached. During the model testing process, the trained model parameters are first loaded, and then the test dataset is preprocessed to ensure consistency with the training data [14]. The preprocessed test data is input to generate a heatmap of key points. Next, the specific coordinates of the key points are extracted as the final output of the model. The performance of this process model on new data can be measured by the accuracy of key points that need to be ensured, and ultimately the entire testing process ends.

In the collection of DI, a lot of background information will also be collected. These background information include objects, walls, floors, etc. that are unrelated to the human body, and these additional pieces of information can interfere with keypoint localization tasks. It is necessary to use appropriate methods to filter out unnecessary background information and focus on processing Region of Interest (ROI) related to the human body [15-16]. The method's importance is to use breadth first search to identify foreground objects, and filter out background parts based on depth and height information to obtain background removed DI. After extracting the ROI, it still cannot meet the requirements, so median filtering is used to process the image, and its expression is illustrated in Eq. (1).

$$depth_{median}(x,y) = median_{(s,t)\in N(x,y)}[depth(s,t)] \quad (1)$$

In Eq. (1), $depth_{median}(x,y)$ represents the depth value after median filtering operation; $median$ represents the function for calculating the median; N is the neighborhood of the pixel; $depth(s,t)$ is the depth value of the pixel at position (s,t) [17-18]. Although median filtering can remove noise, the details of the image are also severely lost. Therefore, the BF method is used to smooth the image, and its expression is shown in Eq. (2).

$$depth_{double}(x,y) = \sum_{(s,t)\in N(x,y)} W(s,t) \times depth(s,t) \quad (2)$$

In Eq. (2), $depth_{double}(x,y)$ represents the depth value; $W(s,t)$ represents the normalized weight, and the aforementioned expression is demonstrated in Eq. (3).

$$W(s,t) = exp\left(-\frac{(s-x)^2+(t-y)^2}{2\sigma_d^2} - \frac{(depth(s,t)-depth(x,y))^2}{2\sigma_r^2}\right) \quad (3)$$

In Eq. (3), σ_d and σ_r respectively represent the parameters of spatial distance and pixel difference size. Before preprocessing, normalization is performed, and the weights of the neighborhood are first calculated, as shown in equation (4).

$$sum = \sum_{(s,t)\in N(x,y)} W(s,t) \quad (4)$$

In Eq. (4), sum is the sum of weights in the neighborhood. Then, the weights of each pixel are equal to the index value divided by the sum of weights, as expressed in Eq. (5).

$$W(s,t) = W(s,t) / sum \quad (5)$$

In Eq. (5), $W(s,t)$ represents the neighborhood weight, and the image after BF is shown in Fig. 3.

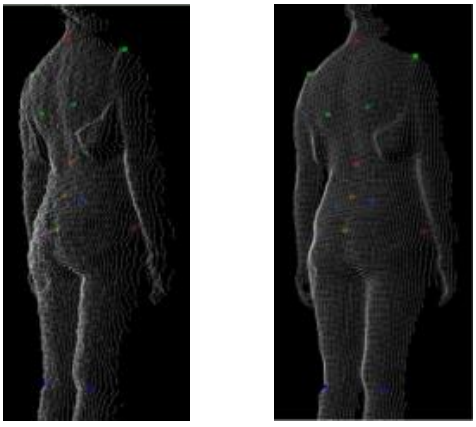

Fig. 3. Comparison of key points before and after BF.

In Fig. 3, the BF operation can effectively remove image noise while preserving the edge features of the image. BF can reduce noise interference in the image, making the ROI clearer and improving the accuracy of the Faster OpenPose network in keypoint detection. Through BF, the background information in the image is smoothed, while the key points and edge features related to the human body are preserved, promoting to focus on identifying the key points of the human body.

B. DI Keypoint Detection Model Combined with Cascaded DWCA

After completing the data cleaning, OpenPose network is adopted to detect key points in the image. OpenPose is a powerful open-source library specifically designed for real-time detection and estimation of keypoints on multiple people's bodies, faces, hands, and feet. The core process includes extracting features from input images or video frames, generating part affinity fields and keypoint heatmaps, and connecting these keypoints through post-processing to form a complete human pose skeleton [19-20]. The classic OpenPose has obvious flaws, so research has improved OpenPose and proposed a Faster OpenPose. VGG-19 in OpenPose has been replaced with MobileNetV1, improving the efficiency of the model. The DWCA based on feature fusion mechanism is introduced, and its structure is shown in Fig. 4.

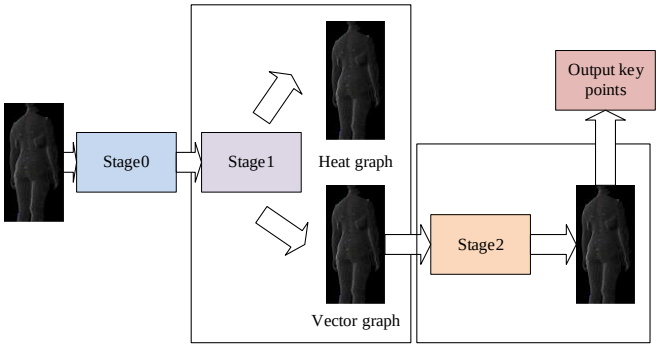

Fig. 4. Faster OpenPose structure.

In Fig. 4, the first DI is received as input, which captures the distance information between the object and the camera, providing a three-dimensional representation of the scene. Next, Stage 0 is responsible for feature extraction, processing the input DI through convolutional neural networks to extract relevant features that can be used for subsequent pose estimation. In Stage 1, heatmaps are generated, which represent the probability distribution of key point positions in the image. Partial correlation vector maps are generated, encoding the directions and associations between different body parts, helping to determine the connection relationships between detected joint points and forming a complete skeleton [21-22]. Then it enters Stage 2, where the heatmap interpolation is amplified to match the original resolution of the input DI before the final output. This step ensures that the detected keypoints are aligned correctly with the original image size. Finally, the keypoints are output, which represent the coordinates of the body joints in the input image and can be used for further tasks. In the Stage0 structure, an alternating structure of DWCA and regular modules is adopted, as shown in Fig. 5.

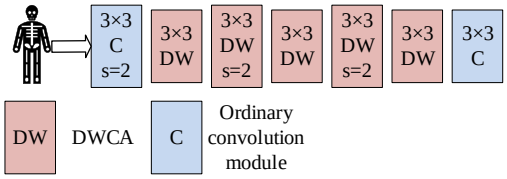

Fig. 5. Schematic diagram of stage0 structure.

In Fig. 5, it contains a regular convolution module and DWCA. In the initial stage of the process, the spatial dimension of the input image is reduced by a factor of two. Next, multiple DWCAs are adopted. These modules divide convolution operations into two steps: In deep convolution, a distinct convolution kernel is applied to each input channel. In contrast, point-by-point convolution employs a 1×1 convolution to integrate the channels of the deep convolution output. This structure maintains the accuracy of the model while reducing computational complexity. The entire MobileNetV1 network gradually increases the number of channels, ultimately generating a smaller high-dimensional Feature Map (FM) for subsequent classification or other tasks. In the process of deep convolution, for an input FM, the computational complexity of traditional convolution is shown in Eq. (6).

$$J = h' \times w' \times D_{out} \times (k \times k \times D_{in}) \tag{6}$$

In Eq. (6), $h' \times w' \times D_{out}$ represents the size of the output FM; $k \times k$ represents the size of the filter. In deep convolution, the convolution kernel only acts on each input channel, and its computational complexity is shown in Eq. (7).

$$J_m = h' \times w' \times D_{in} \times (k \times k) \tag{7}$$

Then point by point convolution is used to mix all input channels and generate an output FM, which is expressed as Eq. (8).

$$J_n = h' \times w' \times D_{in} \times D_{out} \tag{8}$$

Stage1 is the initialization stage, Stage2 is the refinement stage, and their structures are shown in Fig. 6.

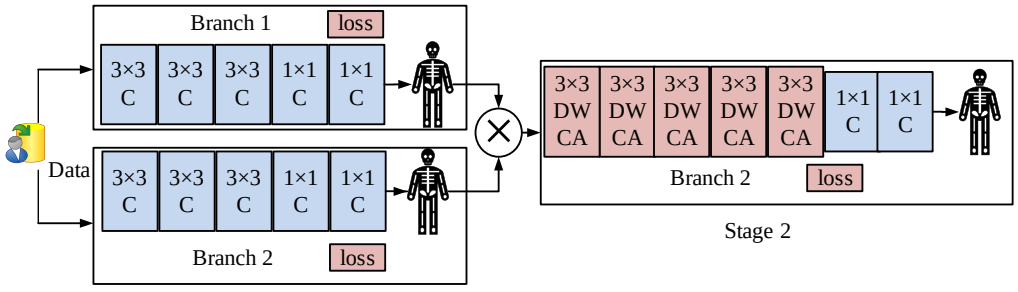

Fig. 6. Structure of stage1 and stage2.

In Fig. 6, Stage 1 includes Branch 1 and Branch 2. Branch 1 adopts multi-layer convolution operations, including 3×3 standard convolution and 1×1 convolution. After these convolution operations, the FM's size is output, and then the loss function is used to calculate the loss. Branch 2 also uses a series of convolution operations, but the output FM's size is h×w, and the loss is calculated through another loss function. The output S1 of Stage 1 is a combination of the outputs of two branches, which will be passed on to the next Stage 2. In Stage 2, the complexity of the network further increases, and Branch 2 performs different operations in Stage 2. DWCA is introduced in branch 2, and the final FM size is output. The output of this branch is also calculated through a loss function. The final output of Stage 2 is represented by S2. The loss function in Stage 1 is shown in Eq. (9).

$$\begin{cases} L_1 = f_1(S_1^1) \\ L_2 = f_2(S_2^2) \end{cases} \tag{9}$$

In Eq. (9), L_1 and L_2 represent the loss functions of the output FM of branch 1 and branch 2, respectively; S_1^1 and S_2^2 represent the FM of branch 1 and branch 2, respectively. The final loss function of the model is shown in Eq. (10).

$$L_t = L_1 + L_2 + L_3 \tag{10}$$

In Eq. (10), L_t represents the total loss function; L_1, L_2, and L_3 respectively represent the loss functions of the three stages.

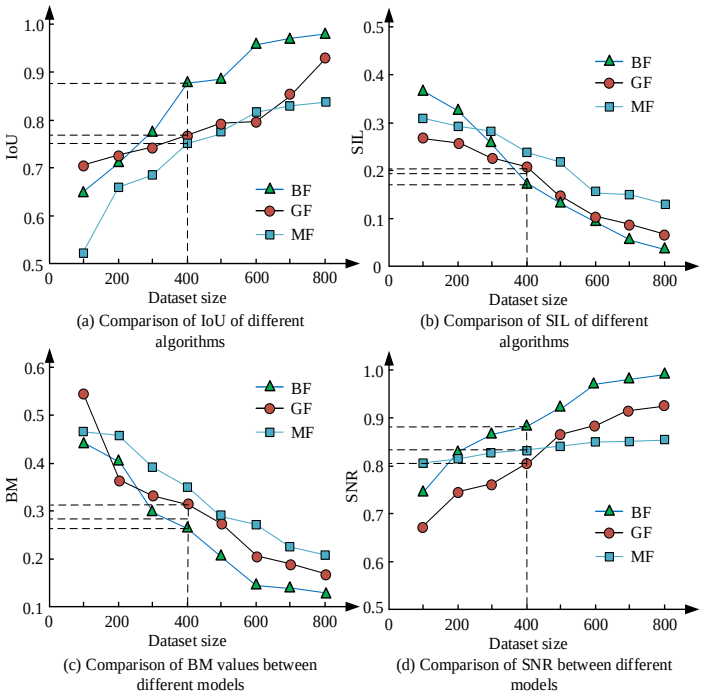
IV. Results

In the first section, image processing models based on Gaussian Filtering (GF) and Mean Filtering (MF) were introduced as comparison models for comparison. In the second section, the performance of the DI detection model combined with cascaded DWCA was analyzed.

A. Localization Performance based on DI Surface Keypoints

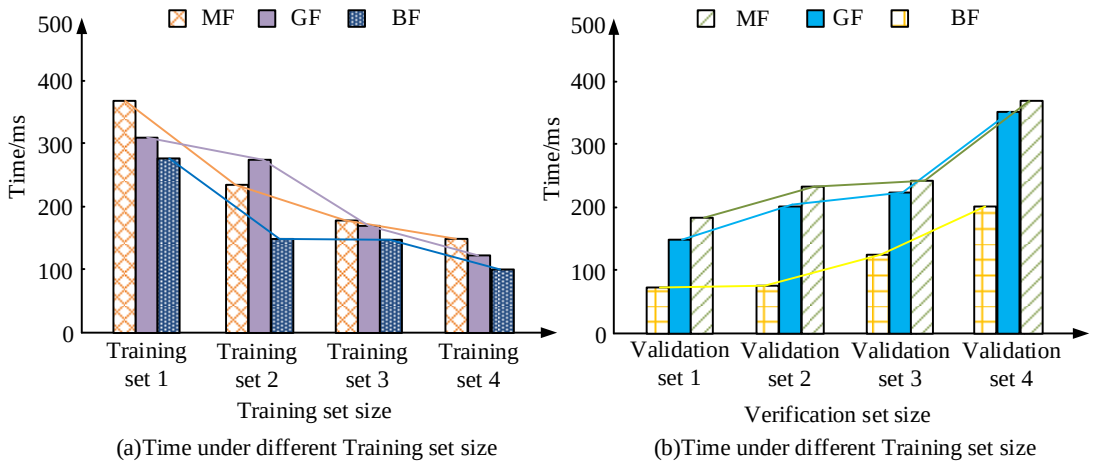
The COCO public dataset was utilized, which comprises over 100,0000 images, encompassing 80 distinct categories of objects, including humans, animals, vehicles, and furniture, as well as various scenes and environments. Each image has detailed annotation information, including the category of the object, the position and size of the bounding box, and the keypoint information of the object, providing standard evaluation metrics. The CPU model used was Intel (R) Core (TM) i7-9700F, with a frequency of 3.00GHz. The graphics processor model was NVIDIA GeForce GTX 1660 Ti, with 8GB of video memory. The operating system was Windows 10. This study introduced GF based image processing models and MF based image processing models as comparative models for comparison. The results are shown in Fig. 7.

Fig. 7, 7(b), 7(c), and 7(d) illustrate the comparison results of Intersection over Union (IoU), Structural Information Loss (SIL), Bonferroni Mean (BM), and Signal to Noise Ratio (SNR) of images processed by various algorithms. As illustrated in Fig. 7, an increase in the training set size was accompanied by a corresponding rise in the IoU of each model after processing images. As the training set size was up to 800, the IoU of BF, GF, and MF were 0.83, 0.91, and 0.96. The SIL was 0.10, 0.06, and 0.03. The BM was 0.24, 0.15, and 0.08. The SNR was 0.81, 0.91, and 0.99. The experimental results demonstrated that BF had relatively superior image processing performance. The processing time of each method was compared, and each dataset was segmented according to different sizes. The sizes of Dataset 1 to Dataset 4 were 100, 200, 400, and 800. Fig. 8 presents the results.



(a) Comparison of IoU of different algorithms
(b) Comparison of SIL of different algorithms
(c) Comparison of BM values between different models
(d) Comparison of SNR between different models

Fig. 7. Performance comparison of various image processing algorithms.



(a)Time under different Training set size (b)Time under different Training set size

Fig. 8. Comparison of model recognition time.

In Fig. 8, the proposed BF had the fastest image processing speed among all training sets. In training set 4, the training times for BF, GF, and MF were 101ms, 113ms, and 157ms, respectively. In Fig. 8(b), the proposed BF processing speed performed the best among the three algorithms in each validation set. In validation set 4, the training times for BF, GF, and MF were 201ms, 352ms, and 374ms. The suggested image processing method exhibited the best performance among various algorithm models. In Table I, the comprehensive capability of the three algorithm models was compared.

TABLE I. COMPARISON OF IMAGE PROCESSING PERFORMANCE OF VARIOUS ALGORITHMS

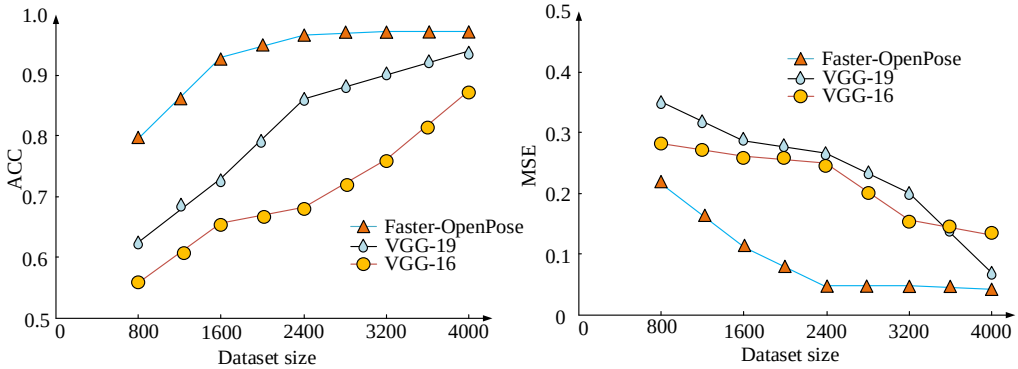
Image type	MF		GF		BF	
	IoU	*SIL*	*IoU*	*SIL*	*IoU*	*SIL*
Image type 1	0.82	0.35	0.87	0.19	0.95	0.13
Image type 2	0.75	0.33	0.84	0.17	0.91	0.11
Image type 3	0.89	0.31	0.94	0.15	0.99	0.09
Image type 4	0.81	0.33	0.85	0.17	0.96	0.11
Image type 5	0.90	0.37	0.96	0.21	0.98	0.15

In Table I, the recognition IoUs of MF for various types of images were 0.82, 0.75, 0.89, 0.81, and 0.90, respectively. The IoUs of GF model for various types of images were 0.87, 0.84, 0.94, 0.85, and 0.96, respectively. The IoU values of BF for various types of images were 0.95, 0.91, 0.99, 0.96, and 0.98, respectively. Therefore, the proposed BF image processing method had excellent performance.

B. *Performance Analysis of DI Detection Model Combined with Cascaded DWCA*

Following an evaluation of the efficacy of various image processing techniques, it is essential to assess the performance of the proposed recognition model. Visual Geometry Group 16 (VGG-16) and Visual Geometry Group 19 (VGG-19) were introduced and compared with the model built within this study. Fig. 9 clearly illustrates the results.

As the size of the dataset increased, the accuracy of each model also increased in a corresponding manner, as illustrated in Fig. 9(a). As the dataset size was 4000, the accuracy of Faster OpenPose, VGG-19, and VGG-16 were 0.97, 0.91, and 0.84, respectively. In Fig. 9(b), as the dataset increased, the Mean Square Error (MSE) of each model decreased accordingly. When the dataset size was 4000, the MSE of VGG-16, VGG-19, and Faster OpenPose were 0.11, 0.09, and 0.03, respectively. The analysis of different types of DI is shown in Fig. 10.



(a) Comparison of accuracy of different algorithm models (b) Comparison of MSE of different algorithm models

Fig. 9. Performance comparison results of various models.

In Fig. 10(a), among the three method models, Faster OpenPose had the best performance, with recognition rates of 0.91, 0.87, 0.89, and 0.93 for four different images, respectively. In Fig. 10(b), among the three models, Faster OpenPose had the shortest processing time, with processing times of 0.32, 0.31, 0.28, and 0.27 for the four types of images, respectively. Therefore, the proposed Faster OpenPose model had excellent performance. A total of 50 individuals were randomly selected and divided into five groups for the purpose of evaluating the performance of the model. Table II clearly presents the results.

TABLE II. USER EVALUATION FORM

Type	Group 1	Group 2	Group 3	Group 4	Group 5	AVG
Faster-OpenPose	93.5	93.4	88.6	81.6	87.2	88.5
VGG-19	77.9	85.2	75.4	74.9	83.3	79.2
VGG-16	74.6	81.9	70.5	68.5	81.4	75.2

In Table II, the five evaluation groups rated Faster OpenPose at 93.5, 93.4, 88.6, 81.6, 87.2, and 88.5, respectively, and rated VGG-16 at 74.6, 81.9, 70.5, 68.5, 81.4, and 75.2, respectively. As a result, the Faster OpenPose proposed had received high praise from various users.

(b) Model recognition time under Image type

Fig. 10. Analysis of recognition performance of different images.

V. DISCUSSION

A depth image keypoint detection model based on bilateral filtering and cascaded depth separable convolution modules has been proposed, which demonstrates significant advantages in processing depth images. The experimental results show that when the training set size is 800, the intersection to union ratio of the BF model reaches 0.96, which shows better image processing performance compared to the 0.91 and 0.83 of GF and MF. In addition, the signal-to-noise ratio of the bilateral filtering model is 0.99, while GF and MF are 0.91 and 0.81, respectively. This is because bilateral filtering effectively balances denoising and edge preservation, which enables the model to reduce noise interference while maintaining important edge information when processing depth images, thereby improving the intersection to union ratio and signal-to-noise ratio. This is similar to the research results of Smith J et al. [23]. When using Faster OpenPose network for keypoint detection, the model has improved accuracy compared to traditional OpenPose. When the dataset size is 4000, the accuracy of the Faster OpenPose model reaches 0.97, while VGG-19 and VGG-16 are 0.91 and 0.84, respectively, and the MSE is significantly reduced. Faster OpenPose is 0.03, VGG-19 and VGG-16 are 0.09 and 0.11, which is similar to the research results of Jones M et al. [24]. This is because the cascaded depthwise separable convolution module significantly reduces the number of parameters and computational complexity of the model by splitting the standard convolution into depthwise convolution and pointwise convolution. This enables the model to maintain high accuracy while improving processing speed. This indicates that the design of depth separable convolution modules effectively reduces computational complexity and improves the model's adaptability to different types of images. However, there are also some shortcomings in the research. The performance of a model largely depends on the quality and diversity of the training data, and biases in the dataset can affect the model's generalization ability. In complex scenarios, interference from background information remains a major issue.

VI. CONCLUSION

In response to the problems of low efficiency and insufficient accuracy in traditional methods for handling DI, this study proposes a DI keypoint detection model that combines cascaded DWCA. It optimizes the computational efficiency and the model's detection capability by improving the OpenPose network structure. When the training set size was 800, the IoU of BF, GF, and MF were 0.83, 0.91, and 0.96; The SIL were 0.10, 0.06, and 0.03; The BM were 0.24, 0.15, and 0.08; The SNRs were 0.81, 0.91, and 0.99. When the dataset size was 4000, the accuracies of Faster OpenPose, VGG-19, and VGG-16 were 0.97, 0.91, and 0.84, respectively, with MSE of 0.11, 0.09, and 0.03, respectively. Therefore, the DI keypoint detection method combined with cascaded DWCA has high practical value and can effectively enhance the processing efficiency of DI keypoint detection. However, the research also has certain limitations. The performance of a model is highly dependent on the quality and diversity of the training data. If the dataset is not rich enough or has biases, it may affect the model's generalization ability. Secondly, although Faster OpenPose networks have improved efficiency, delays may still occur in extremely complex scenarios, which can affect real-time application performance. Although background filtering is used, in some cases, complex backgrounds may still interfere with keypoint detection, leading to inaccurate localization. In the future research direction, more lightweight network structures can be explored to adapt to real-time applications of edge computing and mobile devices and improve processing efficiency. It can enhance the adaptability to complex scenes and dynamic backgrounds, and improve the robustness and

accuracy of the model by integrating more types of data. In addition, utilizing emerging technologies such as self supervised learning and transfer learning can enhance the model's generalization ability on small sample datasets. Finally, research can delve into the methods of multimodal fusion, combining depth images with other sensor data to achieve more accurate keypoint detection and application expansion.

Development of a Service Robot for Hospital Environments in Rehabilitation Medicine with LiDAR-Based Simultaneous Localization and Mapping

Sayat Ibrayev, Arman Ibrayeva, Bekzat Amanov, Serik Tolenov
Joldasbekov Institute of Mechanics and Engineering, Almaty, Kazakhstan

***Abstract*—This paper presents the development and evaluation of a medical service robot equipped with 3D LiDAR and advanced localization capabilities tailored for use in hospital environments. The robot employs LiDAR-based Simultaneous Localization and Mapping (SLAM) to navigate autonomously and interact effectively within complex and dynamic healthcare settings. A comparative analysis with the established 3D-SLAM technology in Autoware version 1.14.0, under a Linux ROS framework, provided a benchmark for evaluating our system's performance. The adaptation of Normal Distribution Transform (NDT) Matching to indoor navigation allowed for precise real-time mapping and enhanced obstacle avoidance capabilities. Empirical validation was conducted through manual maneuvers in various environments, supplemented by ROS simulations to test the system's response to simulated challenges. The findings demonstrate that the robot's integration of 3D LiDAR and NDT Matching significantly improves navigation accuracy and operational reliability in a healthcare context. This study not only highlights the robot's ability to perform essential tasks with high efficiency but also identifies potential areas for further improvement, particularly in sensor performance under diverse environmental conditions. The successful deployment of this technology in a hospital setting illustrates its potential to support medical staff and contribute to patient care, suggesting a promising direction for future research and development in healthcare robotics.**

***Keywords*—Medical service robots; 3D LiDAR technology; autonomous navigation; hospital environments; robot-assisted healthcare; healthcare robotics; operational reliability; patient care automation**

I. Introduction

The integration of robotics into healthcare represents a transformative shift in rehabilitation medicine, promising enhanced precision, efficiency, and patient outcomes. Rehabilitation robotics, especially in hospital environments, has seen considerable growth, propelled by advancements in automation and sensor technology. This paper focuses on the development of a medical service robot designed specifically for hospital settings in rehabilitation medicine, employing LiDAR-based Simultaneous Localization and Mapping (SLAM) to navigate and function autonomously [1].

Rehabilitation robots are primarily developed to assist with the delivery of intensive, repetitive, and task-specific interventions which are often labor-intensive and require high levels of precision [2]. The role of these robots extends beyond mere assistance, as they are increasingly equipped with autonomous features that allow them to navigate complex hospital environments and interact with patients and healthcare staff effectively [2]. The adoption of LiDAR technology in medical service robots enhances these capabilities by providing accurate and real-time 3D maps of the environment, which is critical for the autonomous navigation and operational safety of robots [3].

The importance of autonomous navigation systems in medical robots cannot be overstated, as they significantly reduce the human resources needed for operation and maintenance, thereby increasing the healthcare system's overall efficiency [4]. Simultaneous Localization and Mapping (SLAM) technology, which combines data from various sensors to create a map of an unknown environment while simultaneously tracking the robot's location, is pivotal in this context. SLAM has been extensively studied and applied in mobile robotics, and its adaptation to the specific needs of medical environments presents unique challenges and opportunities [5].

The application of SLAM in medical service robots involves not only technical development but also consideration of the ethical, privacy, and safety concerns associated with robotic operations in human-centric environments [6]. Robots in hospitals must adhere to stringent safety standards and be capable of interacting with patients in a manner that complements the therapeutic goals of rehabilitation [7]. Furthermore, the integration of robots into public health settings raises significant privacy concerns, particularly in relation to the storage and handling of sensitive patient data captured by robotic sensors [8].

The development of robots equipped with LiDAR and SLAM for rehabilitation medicine also necessitates a multidisciplinary approach, combining insights from engineering, computer science, and healthcare. Such collaboration is crucial for ensuring that the robots are not only technically proficient but also tailored to meet the practical needs of patients and healthcare providers [9]. Moreover, the implementation of these technologies must be supported by robust clinical trials to validate their efficacy and safety in real-world hospital settings [10].

Past research has demonstrated the potential of robotic aids in enhancing patient engagement and improving recovery outcomes in rehabilitation settings [11]. For instance, robots that assist with walking or deliver physical therapy have been shown to improve mobility and accelerate recovery, providing a level of consistency and repeatability that is difficult to achieve through human intervention alone [12]. The development of a medical service robot with sophisticated navigation and mapping capabilities could further these benefits by enabling more dynamic and responsive interaction with the environment and the patients.

This research aims to bridge the gap between the current capabilities of medical service robots and the evolving demands of modern healthcare facilities. By focusing on the integration of LiDAR-based SLAM technology, the study seeks to address several of the limitations faced by earlier models of rehabilitation robots, such as limited autonomy and the inability to adapt to new and complex environments [13]. The ultimate goal is to develop a robot that not only supports the logistical needs of hospitals but also contributes directly to the therapeutic processes, enhancing the overall quality of care and patient satisfaction [14].

The development of a medical service robot equipped with LiDAR-based SLAM technology for use in rehabilitation medicine represents a significant advancement in the field. This research contributes to a deeper understanding of the technical challenges and clinical implications of deploying autonomous robots in sensitive environments, aiming to maximize both the efficacy and safety of robotic interventions in healthcare settings [15].

II. Related Works

In the evolving landscape of rehabilitation medicine, the integration of robotics has marked a significant technological advancement, aiming to enhance patient care through automated assistance and precise intervention. The adoption of advanced technologies like LiDAR and Simultaneous Localization and Mapping (SLAM) within medical service robots presents a novel approach to navigating complex hospital environments efficiently. This section reviews the pertinent literature surrounding rehabilitation robotics, with a focus on the incorporation of these sophisticated technologies into their design and functionality. The discussion extends across the technological underpinnings, applications, and the specific challenges faced, thereby setting a foundational context for this research.

A. Overview of Rehabilitation Robotics

Rehabilitation robotics has emerged as a vital tool in modern therapeutic practices, primarily focusing on enhancing patient recovery and automating repetitive therapy tasks. These robotic systems are designed to deliver high-intensity, precise interventions that are essential for the rehabilitation of patients with diverse physical impairments. According to Zhao et al. (2022), rehabilitation robots not only facilitate consistent therapeutic activities but also significantly reduce the physical burden on healthcare providers by automating routine tasks [16].

The evolution of these systems has been marked by significant advancements in their ability to interact with patients and adapt to various therapeutic needs. As highlighted by Hou et al. (2024), the integration of sophisticated sensors and actuators in these robots enables them to perform complex tasks with greater autonomy and accuracy [17]. This technological enhancement improves the quality of interventions and supports a broader range of rehabilitation activities.

Moreover, the clinical impact of rehabilitation robotics is profound, with studies indicating improved patient outcomes in mobility and independence [18]. These robots provide tailored therapeutic exercises that are crucial for effective rehabilitation, making them an indispensable asset in modern healthcare settings.

B. Technological Foundations in Medical Service Robots

Medical service robots incorporate a variety of advanced technologies to enhance their functionality and autonomy in healthcare settings. Central to their operation are automation technologies and intelligent systems that allow these robots to perform a wide range of tasks, from patient care to logistical support within hospitals. According to Avutu et al. (2023), the use of real-time data processing and machine learning enables these robots to make informed decisions and adapt to dynamic environments, significantly enhancing their operational efficiency [19].

Actuators and sensor technologies play pivotal roles in the functionality of medical service robots. These components ensure precise control and interaction capabilities, critical for tasks that require high levels of accuracy such as medication delivery or patient monitoring [20]. Furthermore, the integration of communication interfaces facilitates seamless interaction with healthcare professionals, allowing for efficient coordination and data exchange.

Moreover, the implementation of robotics in medical services often involves complex system architectures that combine hardware and software solutions to meet the stringent safety and performance requirements typical of medical environments [21]. These integrated systems not only ensure patient safety but also contribute to the overall resilience and reliability of robotic operations in healthcare settings.

C. Use of LiDAR Technology in Robotics

Light Detection and Ranging (LiDAR) technology has been pivotal in advancing robotic navigation systems. LiDAR sensors provide accurate distance measurements by illuminating a target with laser light and measuring the reflection with a sensor. This technology's application in robotics, as detailed by Chen et al. (2023), involves creating high-resolution maps of the robot's surroundings, which is essential for navigating through dynamic environments without human input [22]. In medical settings, the precision of LiDAR technology ensures that robots can navigate crowded hospital corridors and interact with patients and staff safely.

D. Simultaneous Localization and Mapping (SLAM)

SLAM technology is crucial for autonomous navigation, enabling robots to build a map of an unknown environment while simultaneously tracking their location within it. The convergence of SLAM with medical service robots enhances their operational autonomy. Takanokura et al. (2023) discuss

various SLAM algorithms, each with different strengths, catering to the specific needs of the environment and the task at hand [23]. In the context of rehabilitation robotics, the implementation of SLAM allows robots to adapt to new and evolving environments, facilitating seamless integration into hospital settings.

E. Integration of SLAM in Medical Robotics

The integration of Simultaneous Localization and Mapping (SLAM) technology in medical robotics represents a significant advancement in the autonomous operational capabilities of these systems within complex healthcare environments. SLAM technology allows medical robots to dynamically map their surroundings while maintaining an accurate location within the map, which is critical for navigation and task execution in hospital settings [24].

Incorporating SLAM into medical robotics facilitates enhanced spatial awareness and adaptability, enabling these robots to autonomously maneuver through crowded and dynamically changing hospital corridors and rooms. According to Mbunge et al. (2021), the ability to update and refine their environmental models in real-time allows these robots to operate safely and efficiently around both stationary obstacles and moving individuals, such as patients and medical staff [25].

Furthermore, the application of SLAM in medical robotics not only improves operational efficiency but also enhances the interaction capabilities of these robots with their human counterparts. Pereira et al. (2022) highlight that SLAM-equipped robots can more effectively collaborate with healthcare providers, ensuring that therapeutic and logistical tasks are carried out with minimal human intervention [26]. This seamless integration into healthcare workflows greatly contributes to the overall productivity and patient care standards within medical facilities.

F. Challenges and Limitations

Despite the advancements, the integration of LiDAR and SLAM into medical service robots faces significant challenges. Yam et al. (2021) outline several technical challenges, including the high cost of LiDAR sensors and the computational demands of SLAM algorithms, which can limit their widespread adoption [27]. Additionally, ethical concerns regarding patient privacy and data security are paramount, as these technologies often collect sensitive information that could be vulnerable to breaches. Makhdoom et al. (2022) stress the importance of developing robust security protocols to protect patient data and ensure compliance with healthcare regulations [28].

G. Gap Analysis

The current literature reveals several gaps in the application of advanced technologies like LiDAR and SLAM within the domain of medical service robots, particularly in rehabilitation settings. While significant advancements have been made in technical capabilities, there is a lack of comprehensive studies focusing on the practical integration of these technologies in real-world healthcare environments [29]. Additionally, existing research often overlooks the user-centric design and ethical considerations essential for deploying robots in sensitive areas such as patient care [30].

Moreover, despite the potential of these technologies to enhance robotic functionality, there is a notable deficiency in tailored solutions that address specific clinical needs and seamlessly adapt to the unique dynamics of hospital settings [31]. Addressing these gaps through focused research could lead to more effective and contextually appropriate robotic systems that improve patient outcomes and healthcare efficiency [32].

III. MATERIALS AND METHODS

A. Data Collection

The conceived system of the driven automated guided vehicle (AAGV) was formulated to elevate the execution of manual environmental mapping tasks currently in use through the utilization of self-positioning and autonomous navigation that operates nearby the layout map of the area. Given the fill running of an environmental assessment, the AGV autonomously constructs a map of the surrounding, a process that depends on conventional methods as well. This innovative approach exploits the factory indoor formation for micro-localization and precise mobile robot self-positioning. By using point cloud data as input, 3D Lidar's structural analysis module focuses on the portion gleaned from the wall structures, where the variance is measured subsequently by comparing it with a reference 2D layout map and the mapped horizontal trajectory (or wheel odometry) of the UGV. The filtering method implemented to achieve the localization uses a particle filter with Monte Carlo method, while the base of this navigation is the information determined from the map coordinate and transformed point cloud data [33].

Fig. 1 presents the basic control scheme of the proposed medical service robot, illustrating the integration of 3D LiDAR technology for autonomous navigation within hospital environments. The control architecture is divided into three primary components: 3D LiDAR processing, Mapping, and Path Planning. Initially, the 3D LiDAR sensor collects point cloud data which is processed by the Encoder and Odometry to track the robot's position and movement. Wall point clouds are extracted to delineate boundaries and detect obstacles, ensuring the robot avoids collisions. Subsequently, the Mapping process involves assessing the robot's position and converting the environmental map to a point cloud format for real-time navigation updates. In the Path Planning segment, the robot sets navigation goals, computes feasible paths, and creates a navigational trajectory, culminating in the autonomous mobility of the robot. This control scheme underscores a comprehensive approach to navigating complex healthcare settings, leveraging advanced sensing and computational techniques to enhance operational efficacy and safety.

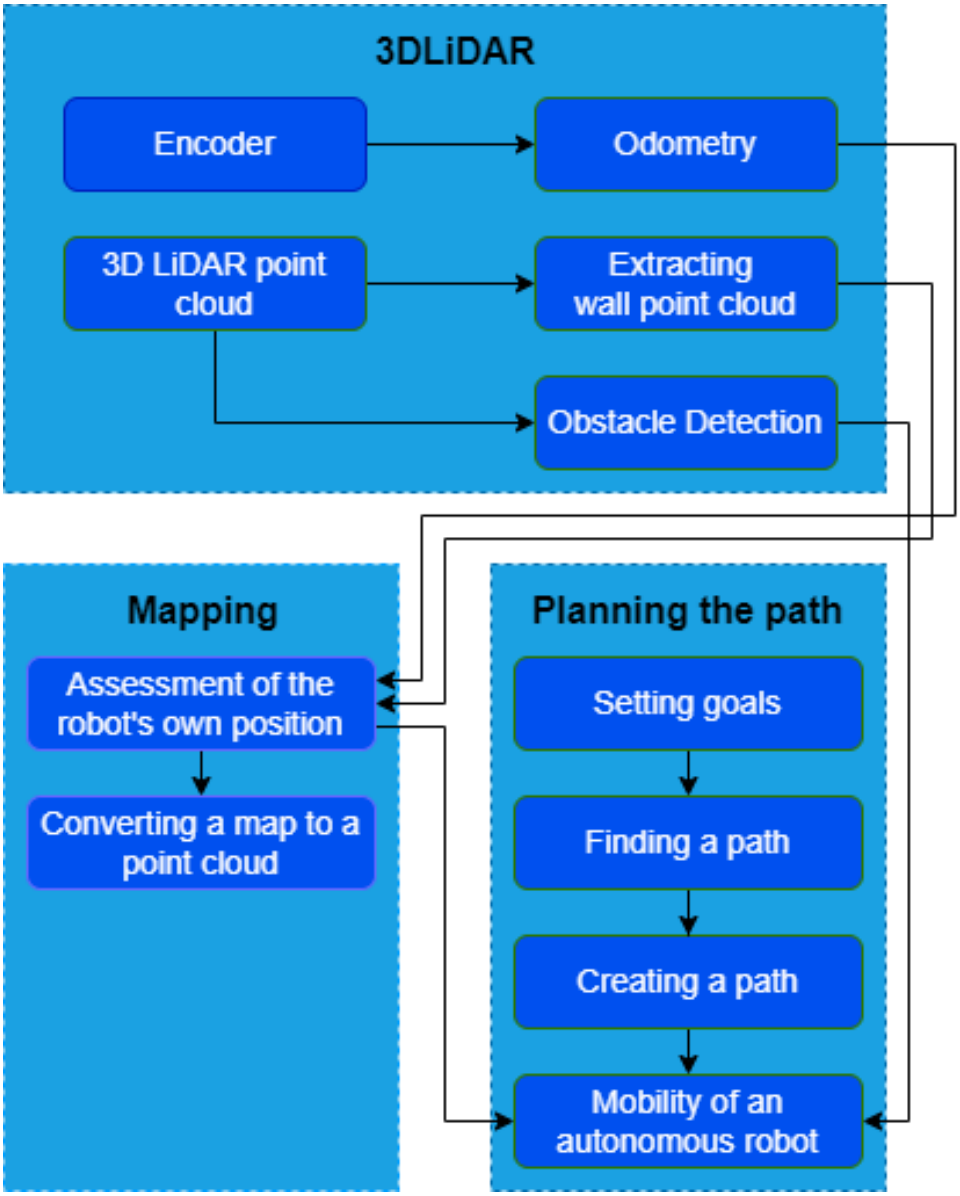

Fig. 1. Basic control scheme of the proposed medical service robot.

B. *The Hardware Module*

In this study, the Shenzhen Yahboom Technology Rosmaster X3 Plus mobile robot was utilized as a primary research tool. This robot, operating within a hybrid system environment, combines physical hardware with virtual systems managed through Ubuntu 20.04 on a VMware Workstation virtual machine, and further controlled via the ROS-Noetic operating system specifically tailored for robotic management. The choice of the Rosmaster X3 Plus for this research is predicated on its advanced capabilities and adaptability to complex tasks, making it an ideal candidate for detailed study in robotic navigation and interaction within structured environments.

The Rosmaster X3 Plus is equipped with cutting-edge hardware that enhances its sensing and computational abilities, crucial for effective navigation and task execution. Central to its operation is the Jetson Orin NX processor, boasting 16GB of memory, which facilitates robust real-time processing for tasks such as obstacle navigation and localization. Environmental perception is significantly enhanced by the integration of a YDLidar 4ROS Lidar system, which provides high-resolution 3D point cloud data. Complementing this, an Astra Pro depth camera provides detailed 3D visual inputs that are integrated with the Lidar data for a comprehensive environmental understanding. This hardware-software synergy not only boosts the robot's operational efficiency but also underscores the effectiveness of modern technologies in autonomous robotic navigation.

The operation of the motor is governed by signals originating from Pulse Width Modulation (PWM), which dictate the motor's speed, and directional signals that guide the rotation. These commands are dispatched by a microcomputer integrated within the motor driver, initiating motion based on inputs. Fig. 3 shows motor drive set-up.

Fig. 2. Medical service robot of the study.

Fig. 3. Motor drive setup (a) DC Motor setup (b) Encoder configuration.

Further, a serial communication line facilitates the transmission of these commands from the microcomputer to a personal computer (PC), allowing operators to manage the cart's functions effectively through PC-based controls. Additionally, communication between the motor's encoder and the microcomputer is handled via an SPI interface, which transmits precise rotational angle data, subsequently relayed to the PC, enhancing clarity in monitoring and controlling the motor's activity and the cart's trajectory.

C. Odometry

The integration of 3D LiDAR with wheel odometry equips the robot with enhanced capabilities to both perceive its surroundings and track its movement accurately. Odometry, fundamentally reliant on mathematical equations and principles, plays a crucial role in this process. It operates by analyzing the rotation of the robot's wheels, which directly informs the calculation of the distance traveled. Each wheel is equipped with an encoder that records the number of rotations, allowing for precise measurement. Given the radius r of the wheels and the number of encoder ticks N, the distance D each wheel travels can be calculated, providing critical data for navigating and mapping the robot's environment effectively.

$$D = 2\pi r\left(\frac{N}{N_{total}}\right) \tag{1}$$

Where N_{total} is the total number of ticks per complete wheel rotation.

For a two-wheeled robot, the distance traveled (D_{avg}) and change in orientation are given by:

$$D_{avg} = \frac{D_L + D_R}{2} \tag{2}$$

$$\Delta\theta = \frac{D_R - D_L}{W} \tag{3}$$

Where D_L and D_R are the distances traveled by the left and right wheels, respectively, and W is the width between the wheels.

3D LiDAR technology generates a detailed point cloud that captures the robot's surroundings, facilitating a comprehensive understanding of its movements and orientation through external reference points. When combined with wheel odometry, LiDAR helps to correct potential inaccuracies and drifts that may accumulate in the odometry data over time. Fig. 2 shows medical service robot of the study.

The process of merging odometry with 3D LiDAR data involves a methodical approach:

1) Initial estimation: Wheel odometry is initially used to estimate the robot's trajectory.

2) LiDAR correction: The point cloud produced by LiDAR is compared against a pre-established map to identify any deviations that suggest errors in the odometry data.

3) Data fusion: Techniques such as the Kalman filter are employed to amalgamate the data from both odometry and LiDAR. This integration enhances the accuracy of the robot's navigation system by providing a more reliable data set that

accounts for any discrepancies identified between the odometry and LiDAR inputs.

$$\hat{x}_{k|k} = \hat{x}_{k|k-1} + K_k\left(y_k - H\hat{x}_{k|k-1}\right) \tag{4}$$

Where $\hat{x}_{k|k}$ is the a posteriori state estimate, $\hat{x}_{k|k-1}$ is the a priori estimate, K_k is the Kalman gain, y_k represents the measurement (Lidar data), and H is the measurement matrix relating the state to the measurement.

Update Position and Orientation: Adjust the robot's estimated position and orientation based on the fused data:

$$\begin{aligned} x' &= x + \Delta x \\ y' &= y + \Delta y \\ \theta' &= \theta + \Delta\theta \end{aligned} \tag{5}$$

Subsequently, the robot's position and orientation are updated based on corrected data derived from the integration of wheel odometry and LiDAR measurements. This fusion ensures that the robot accurately maintains its location and direction, reducing errors that might arise from wheel slippage or uneven terrain.

By combining 3D LiDAR data with wheel odometry, our mobile robot achieves superior navigation precision and detailed environmental mapping. This sophisticated odometry system underpins the robot's ability to autonomously operate in complex and dynamically changing environments, facilitating reliable performance across various operational scenarios.

D. Localization

The navigation capability of our mobile robot is enhanced by 3D LiDAR technology, utilizing a sophisticated localization algorithm that precisely determines the robot's position within its operating environment. This section delves into the mathematical principles and operational mechanics of the localization algorithm employed in our system, emphasizing the integration of 3D scanning data to improve node localization accuracy.

Central to our localization strategy is Monte Carlo Localization (MCL), also known as particle filter localization. This probabilistic method uses a collection of hypothetical particles to represent potential positions and orientations (states) of the robot within its environment. Each particle is weighted based on its congruence with environmental data gathered via LiDAR scans and the robot's observed movements, effectively merging sensor inputs with motion data to estimate the robot's location with higher accuracy.

Particle Representation: In our system, each particle in the set represents a potential state of the robot, encompassing both its location and orientation, forming the basis for calculating the most probable actual state of the robot as it navigates.

$$p_i = \left(x_i, y_i, \theta_i\right) \tag{6}$$

x_i, y_i, θ_i denote the particle's position and orientation.

Weight Calculation. The weight w_i is calculated for each particle taking into account the degree of matching of the predicted sensor readings for the desired particle state with the real sensor readings given by the 3D Lidar.

$$w_i = P\left(z_t \mid p_i\right) \tag{7}$$

Where z_t is the Lidar measurement at time t, and $P\left(z_t \mid p_i\right)$ is the likelihood of observing z_t given the state represented by particle i.

Resampling within the Monte Carlo Localization (MCL) framework involves selecting particles based on their weights, with particles possessing higher weights more likely to be chosen. This process concentrates the particle distribution around the most likely states of the robot's position, refining the model's accuracy over time.

Integrating 3D LiDAR data significantly enhances the MCL algorithm's localization precision by allowing a detailed comparison between the environmental features detected by the LiDAR and the pre-existing map model. The LiDAR's point cloud captures environmental details at a granular level, facilitating highly accurate weight calculations for each particle within the model.

The sensor model associated with the 3D LiDAR converts the point cloud data from a sequential format into a probabilistic one, aligning it with the map's specifications. This transformation allows for an effective comparison, essentially converting 3D data into a more manageable 2D format to match the map, thereby enhancing the fidelity and utility of the particle data.

Before assigning weights to each particle, a motion update is conducted based on the reported movements of the robot. This update adjusts the positions and orientations of the particles to reflect the robot's dynamics as captured by its odometry data, ensuring that the model remains consistent with the robot's actual movements. The motion model updates are critical for maintaining the accuracy of the localization process.

$$p_i^{'} = p_i + \Delta p\left(u_t, \in\right) \tag{8}$$

where $p_i^{'}$ is the updated particle state, Δp is the change in state due to the control input u_t (e.g., velocity, angular velocity) at time t, and $\in$ represents the motion noise.

E. Obstacle Avoidance

Obstacle avoidance is a critical component of autonomous navigation systems, involving two main functions: detecting obstacles and formulating alternate paths to circumvent them. Consider a scenario where a predetermined route is blocked on the left side by an obstruction. In such cases, navigational coordinates are structured into waypoints, each associated with a specific detection zone. This zone is typically envisioned as a cylindrical area encompassing each waypoint along the robot's path, serving as a detection field for obstacles.

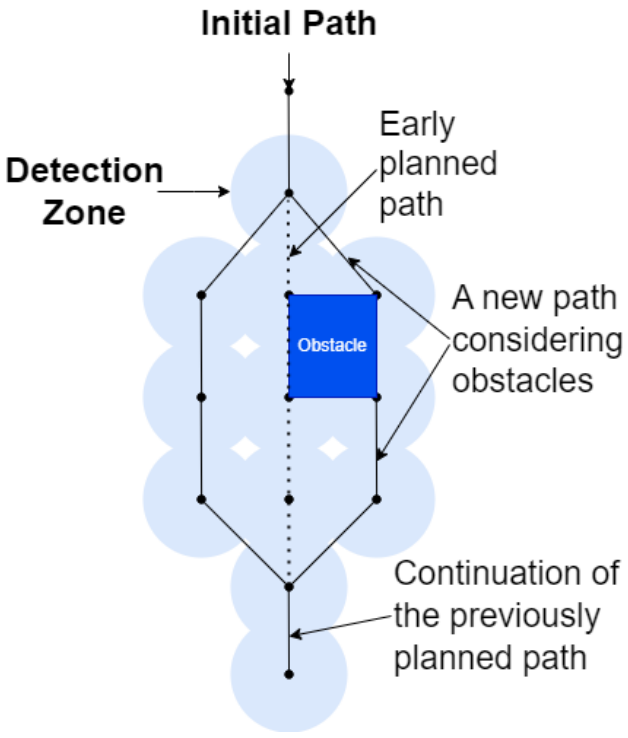

Fig. 4. Obstacle avoidance of the proposed medical service robot.

Within this cylindrical detection zone, any detected objects that do not correspond to the ground are classified as obstacles. The presence of these obstacles renders the area impassable, necessitating a rerouting of the planned path. This mechanism ensures that the robot can adapt its route in real-time to avoid obstacles, maintaining smooth and continuous navigation as depicted in Fig. 4.

The obstacle avoidance strategy within autonomous navigation systems functions by designating areas where obstacles are detected as blocked, typically highlighted in red on navigational maps. This prompts the system to seek alternative corridors for maneuvering around the impediment. The algorithm evaluates possible detours, actively searching for viable paths adjacent to the obstruction. If a feasible route is identified along one side of the obstacle, it is selected for navigation, and the route-finding algorithms are updated to reflect this new path. Conversely, if obstructions block all potential routes, rendering them impassable, the vehicle halts its progress until an alternate path becomes available. This adaptive mechanism ensures that the vehicle can flexibly and effectively navigate through varying environmental conditions by dynamically adjusting its course in response to encountered obstacles.

IV. Results

This section explores the evaluation of the map accuracy generated by our medical service robot, which is crucial for self-localization and overall system performance assessment. Our system was rigorously tested against the renowned 3D-SLAM technology implemented in Autoware version 1.14.0, an established open-source platform designed for autonomous driving technologies under the Linux ROS framework. A critical aspect of Autoware's capability is the Normal Distribution Transform (NDT) Matching, which utilizes point cloud scan matching to enhance localization accuracy. This method employs normal distributions to model point clouds within specified segments, facilitating precise alignment of overlapping point clouds, a feature vital for accurate localization in environments requiring high precision, such as autonomous navigation systems.

To empirically validate our system, data collection involved manually maneuvering a mobile trolley through various environments, recording its positions to verify the accuracy of the self-localization predictions. This testing covered diverse measurement points, extending through indoor and outdoor settings and spaces between different structures. Additionally, our self-localization methods were tested through ROS simulations using the collected positional data. This detailed validation approach ensures that our system's performance is thoroughly understood and reliable in practical scenarios, demonstrating robust capabilities in a real-world application context.

Fig. 5 presents a series of diagrammatic representations illustrating the navigation process within a two-dimensional environment, capturing the dynamic nature of path planning. The sequence starts with Fig. 5(a) and 5(b), which mark the initiation of the path planning phase and lay the groundwork for subsequent navigational decisions. This is followed by Fig. 5(c), which details the iterative steps involved in path planning as the robot maneuvers through various directions. This stage highlights the dynamic and repetitive nature of adjusting the planned route as the robot encounters different scenarios. Conclusively, Fig. 5(d) captures the culmination of the path planning process, displaying a finalized map that delineates the actual path taken by the robot. This sequence effectively demonstrates the progression from initial path determination through to adaptive adjustments and the final mapping, underscoring the complex and responsive strategy employed in robotic navigation.

Fig. 6 provides a detailed exploration of the path planning processes implemented by a robot within a three-dimensional framework, showcasing the steering strategies employed as it navigates through cluttered environments. This diagram effectively illustrates the robot's capability to assess and adapt its trajectory in real-time as it maneuvers through various terrains and obstacles in 3D space. It serves as a critical visual tool for understanding the sophisticated 3D capabilities of autonomous systems, highlighting their ability to perceive and interact with their surroundings comprehensively. The figure emphasizes the advanced algorithms that enable these systems to not only navigate intelligently but also to create detailed 3D maps upon the completion of their routes. This depiction confirms the complexity and dynamism of new 3D path planning techniques, reflecting significant advancements in the autonomous vehicle industry, where precision and efficiency are paramount in navigating complex environments.

Fig. 7. Mobile medical service robot navigation using 3D LiDAR.

Fig. 7 showcases the developed mobile robot equipped with 3D LiDAR technology, operating in a real-world or field setting, which illustrates the robot's design and its operational capabilities. This image particularly highlights how the integrated 3D LiDAR technology enables the robot to perceive and interact dynamically with its environment. The diagram captures the robot as it navigates a specified area, utilizing LiDAR data to facilitate steering, obstacle avoidance, and localization tasks. Through this visual representation, the practical functioning of the mobile robot is conveyed, underscoring the real-time application and demonstrating the effectiveness of the combined technologies in enhancing the navigation system. This figure serves as a vital link between the theoretical concepts underlying the study and their practical implementation, showcasing the translation of academic research into actionable, autonomy-enhancing strategies within robotic systems.

V. DISCUSSION

In this discussion, we delve into the findings from the deployment and validation of our medical service robot, equipped with advanced 3D LiDAR technology and an innovative localization system. The results underscore the robot's potential to revolutionize navigation and interaction within hospital environments, providing critical insights into both the capabilities and areas for further enhancement of autonomous robotic systems in healthcare settings.

The application of 3D LiDAR technology in our medical service robot has proven to be a cornerstone for enhancing autonomous navigation. The high-resolution data obtained from LiDAR not only facilitated accurate real-time mapping but also significantly improved the robot's ability to detect and navigate around obstacles. This capability is critical in a hospital setting where dynamic obstacles such as moving people and medical

equipment are common. The integration of 3D LiDAR with the robot's other sensory systems has enabled a level of situational awareness that is paramount for safe and efficient operation within such complex environments.

Our comparative analysis with Autoware's 3D-SLAM technology highlighted the effectiveness of our localization approach. The Normal Distribution Transform (NDT) Matching method, typically used in autonomous vehicular navigation, was adapted for indoor use with our robot. This adaptation was crucial as it addressed the unique challenges of indoor navigation, which include lower GPS reliability and the presence of numerous static and dynamic obstacles. The successful application of NDT in our system underscores its potential for broader application in other robotic systems that operate in similarly challenging environments.

Furthermore, the empirical validation of our robot's localization accuracy through manual maneuvering across different environments provided substantial evidence of its robustness. The robot demonstrated a high degree of precision in maintaining its course within tightly controlled trajectories, an essential feature for medical applications where precise movements are often necessary. However, it was noted that certain environmental conditions, such as highly reflective surfaces or areas with poor LiDAR reception, could disrupt the localization process. This finding points to the need for further research into improving sensor fusion techniques to mitigate the effects of such environmental factors on the robot's performance.

The ROS simulations used for further validation played a crucial role in this study, allowing us to replicate and analyze numerous scenarios that the robot might encounter. These simulations were instrumental in refining the robot's path planning algorithms, ensuring that the system could adapt to unexpected changes in the environment efficiently and effectively. The ability to conduct such simulations highlights the importance of flexible and robust software frameworks in the development of autonomous robotic systems.

Moreover, the data collected during the robot's operation in different factory settings revealed valuable insights into the practical challenges of deploying such systems in real-world environments. For instance, the transition from indoor to outdoor settings posed navigation challenges that were not fully anticipated, such as changes in lighting conditions affecting sensor performance. Addressing these challenges will require the development of adaptive algorithms capable of adjusting to varying environmental conditions seamlessly.

The discussion would be incomplete without considering the implications of this technology for patient care. The precision and reliability of the robot's navigation and localization systems have direct implications for its potential use in delivering medications, assisting with patient transport, or conducting routine monitoring tasks. These activities require a high level of accuracy to ensure patient safety and care quality. Our findings suggest that with further development, such robots could become integral components of healthcare delivery, enhancing the efficiency and effectiveness of medical services.

In summary, the development and validation of our medical service robot with integrated 3D LiDAR and advanced localization capabilities represent a significant step forward in the field of healthcare robotics. The successful deployment of this technology in a hospital environment showcases its potential to enhance operational efficiencies and patient care. Nonetheless, the study also highlights several areas for further improvement, particularly in enhancing the robot's adaptability to diverse and changing environments. Future research should focus on refining the integration of sensory and navigational technologies to build even more robust, versatile, and reliable robotic systems. Such advancements will not only improve the functionality of medical service robots but also expand their applicability across different sectors within healthcare, ultimately contributing to the broader goal of automating and improving medical service delivery.

VI. Conclusion

In conclusion, the research conducted on the development of a medical service robot equipped with 3D LiDAR and advanced localization technologies has substantiated its potential to significantly enhance navigational and operational capabilities in hospital environments. This study not only demonstrated the robot's proficiency in precise and adaptive navigation through complex and dynamic settings but also emphasized its utility in the context of healthcare delivery. The integration of 3D LiDAR technology facilitated a robust sensing environment, enabling the robot to perform with high levels of accuracy in obstacle detection and path planning. Moreover, the comparative validation with established technologies like Autoware's 3D-SLAM provided a robust framework for assessing the effectiveness of our localization system, confirming its applicability and reliability. Despite encountering challenges such as sensor sensitivity to environmental factors, the research identified critical insights for future enhancements, notably in improving sensor fusion and algorithm adaptability. These advancements are imperative for ensuring the robot can seamlessly integrate into the diverse and evolving landscape of healthcare facilities. The potential for such autonomous systems to assist in routine tasks and patient care suggests a promising horizon not only for improving efficiency but also for enriching the quality of care. Moving forward, continued refinement and testing in real-world conditions would be crucial to fully realize the capabilities of medical service robots, setting a precedent for their broader adoption in healthcare settings.

***Abstract*—The continuous development of action recognition technology can capture the decomposition data of Tai Chi movements, provide precise assistance for learners to correct erroneous movements and enhance their interest in practicing Tai Chi. Inertial sensors and human skeletal models are used to collect motion data. Combined with visual sensors, the motion and trajectory of Tai Chi are processed to obtain the relevant coordinate system of the movement trajectory. Then, the inertial sensor and visual sensor are fused for data processing to standardize the human skeleton model, remove noise interference from the collected information, and improve the smoothness performance of movement trajectories, thereby segmenting and clustering Tai Chi movement trajectories. Finally, the support vector machine and dynamic time-warping algorithm are combined to identify and verify the trajectory of Tai Chi movements. According to the results, in the 25%, 50%, and 75% training sample proportions, the lowest recognition accuracy of the Qi Shi movements was 90.87%, 93.53%, and 98.08%, respectively. The optimal recognition accuracy and standard deviation of single nodes in binary classification were 98.48% and 0.47%, respectively. The best recognition accuracy and standard deviation for multi-joint points in binary classification were 99.77% and 0.16%, respectively. This proves the recognition advantages of binary classification and the superiority of data fusion analysis based on multiple sensors, providing a theoretical basis and technical reference for action recognition technology.**

Keywords*—Inertial sensor; visual sensors; segmentation clustering; support vector machine; dynamic time warping algorithm

I. Introduction

With the advancement and rapid development of technology, human motion recognition technology has been widely applied in fields such as medicine, sports, and computer science. According to the human body model and the action mechanism, the standardization of actions can be improved. Tai Chi, is a popular health exercise in society. According to action recognition technology, actions can be effectively imitated, improving teaching level and standardization of actions [1]. However, Tai Chi movements are basically smooth and coherent trajectory movements, which have unity in the coordination of whole body and joint movements. Therefore, it is necessary to collect and process information on Tai Chi movements, as well as segment trajectories to improve recognition accuracy. Action recognition technology has achieved some results in decomposing actions, and identifying motion types and motion patterns. Moreover, there is in-depth research and technological development in the collection and recognition algorithms of action information for human skeleton models [2-4]. However, the current methods for recognizing and decomposing human movements lack more accurate trajectory processing in coherent movements. There is a lack of real-time feedback on monitoring physical fitness and correcting movements during human exercise. Therefore, the inertial sensor and visual sensor are combined to collect, process, and fuse data on motion trajectories. The research innovatively uses Support Vector Machine (SVM) and Dynamic Time Warping (DTW) algorithms to identify and process joint points of continuous actions and their trajectories, aiming to provide theoretical and technical references for the clustering effect of trajectory segmentation and the classification accuracy of action recognition. According to research on the recognition methods of Tai Chi movements, it can not only assist athletes in improving their professional technical level, but also promote the diversified development of other sports. Meanwhile, it can also monitor patients' rehabilitation movements, input human motion commands for intelligent living, and provide practical applications and service experiences for fields such as medicine, public health, and human-computer interaction.

The study is structured into five sections. Section II elaborates on the current research results. Section III analyzes and constructs the data processing and fusion of inertial sensors and visual sensors, improving the smoothness of the trajectory. Section IV is to perform cluster analysis and recognition verification on the trajectory of Tai Chi movements. Section V is a narrative summary of the entire study.

II. Related Works

Action recognition technology has been widely applied and developed in various fields based on human motion information. At present, the research on action recognition technology focuses on action data processing and trajectory clustering algorithms. In recent years, scholars have conducted many explorations on action recognition. Sun et al. used depth maps and human motion recognition datasets to validate human motion recognition. Furthermore, the advantages of human motion recognition based on depth maps were derived [5]. In terns of human behavior identification, Luo et al. proposed long-distance data transmission between sensors and servers to improve the real-time processing capacity. The binary neural network was used to evaluate human activity data, so as to improve the efficiency and accuracy of data operation [6]. Liu et al. used an adaptive multi-scale convolutional network to

*Corresponding Author.

analyze the information features of skeleton joint points and their movements for human skeleton action recognition. The accuracy of action recognition data was verified by combining the character segmentation mode and perspective segmentation mode, thereby proving the superiority of adaptive multi-scale graph convolutional networks in human skeleton action recognition [7]. Regarding the three-dimensional reconstruction of human bones, Liu et al. adopted a skin multi-person linear model and skeleton perception implicit function method. It improved the accuracy and detail processing of the human body model, providing a foundation for human model recognition [8].

There have been many research achievements in the field of human motion recognition technology, including sports, home, and intelligent applications. Liu proposed an algorithm that combines principal component analysis and local binary patterns to collect and process motion images for recognizing athletes' throwing movements. Through image segmentation and recognition, the average recognition rate and accuracy of the movements were improved [9]. To solve the motion recognition technology in sports, Host et al. validated the sports dataset using action systems and computer vision to improve the detection accuracy of athlete training [10]. Regarding indoor behavior recognition for the elderly, Song Y et al. utilized wireless fidelity and video feature fusion to establish an indoor human behavior recognition method. They also combined support vector machines to classify and recognize actions, thereby improving the accuracy of action recognition [11]. Cai et al. used feature extraction tools and multi-scale fusion to extract music and dance features in the automatic generation of folk music and dance movements. A sequence network model was constructed to train features, synthesize new dance sequences, and improve the efficiency of automatic music and dance generation and the accuracy of rhythm matching [12]. For the classification technique of action recognition, Chang et al. used time-frequency features of brain signals and event-related potential phenomena. Furthermore, convolutional neural and long short-term memory network models were constructed to classify the collected EEG signals, demonstrating the superiority of classification algorithms [13]. Regarding baseball trajectory recognition, Seo et al. used an adaptive Kalman filter for velocity compensation. By combining sensor fusion and motion characteristic compensation, the three-dimensional trajectory of global coordinates was estimated, thereby improving baseball trajectory recognition and estimation for high-precision detection [14].

To sum up, although domestic and foreign scholars have conducted model construction on action recognition technologies and classification algorithms, they mainly focus on image processing and recognition of smooth and fast human movements to ensure the accuracy of sports athlete training. However, there is still a lack of in-depth research on clustering and segmentation methods for motion trajectories in daily life scenarios, and the sensor devices used for data collection also lack data fusion. At the same time, there is a lack of consideration for the universality of action recognition. There are significant differences between athlete action recognition and elderly behavior activity feature extraction, which cannot provide a good reference for behavioral rehabilitation in the medical field. Therefore, multi-sensor fusion is used to collect Tai Chi movement data, and the trajectory segmentation algorithm is used to ensure the uniform decomposition of Tai Chi movement, thereby improving the recognition and classification of movement trajectories. At the same time, video explanations of Tai Chi and accurate and consistent movement guidance are provided during fitness exercises.

III. System Construction for Data Collection and Data Fusion

Tai Chi is a continuous movement trajectory. The action data are obtained based on inertial sensors and visual sensors. Then the action trajectory data is collected to complete action recognition.

A. Data Acquisition and Processing Based on Inertial Sensors and Visual Sensors

The human posture representation is based on the human skeleton model for collecting action data. To obtain real-time action data, inertial sensors are used for convenient wearable devices. The specific structural composition is shown in Fig. 1.

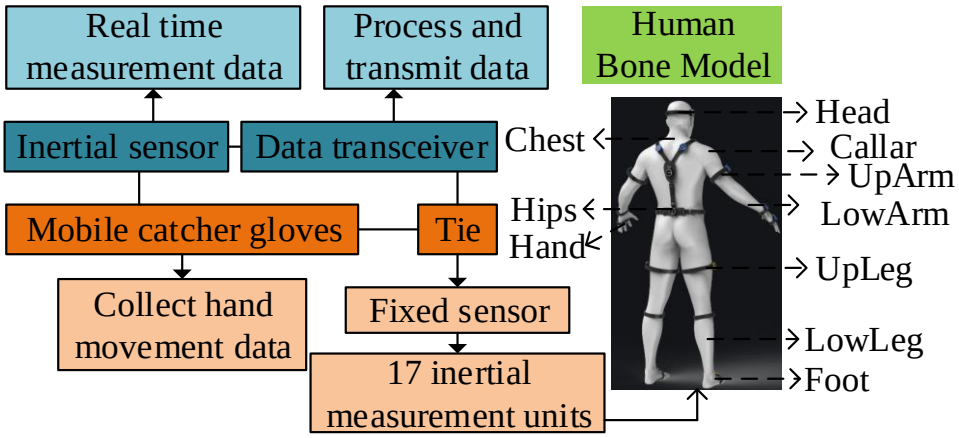

Fig. 1. Data acquisition equipment and its structure based on inertial sensors.

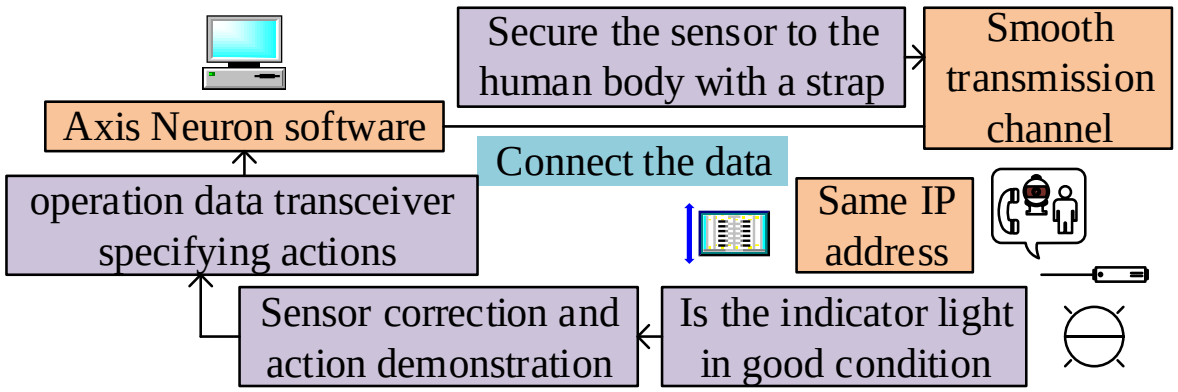

Fig. 2. Schematic diagram of data collection steps.

From Fig. 1, the inertial sensor measures data such as velocity, intensity, and acceleration for each unit. The data transceiver processes the data and synchronously transmits it to the host. The motion capture gloves are only fixed on the hands to obtain data on hand movements. The strap is used to fix the inertial sensor on the human body, completing the data collection process. According to the characteristics of Tai Chi exercise, in addition to the hand movement data of the motion capture gloves, the sensor is fixed in 17 measurement positions on the human body with straps to receive real-time transmission data from the data transceiver. The data collection steps are shown in Fig. 2.

From Fig. 2, during the data collection process, the sensor is fixed to the human body. The connection between the host software and the data transceiver is smooth. Before collecting data, the sensor is corrected and the action is simulated and demonstrated. Finally, the host software is used to operate the data transceiver to complete the data collection of the specified action. BVH, as a data storage format in hierarchical models, is often used in the animation production of human bone models. Initially, each joint point is positioned and its hierarchical relationship is analyzed. Then the motion data of each joint point frame is calculated. The initial coordinate difference between a certain level node and its parent node is expressed as vector form, as shown in Eq. (1).

$$V_0 = \left[x_0, y_0, z_0\right]^T \tag{1}$$

In Eq. (1), x_0, y_0, and z_0 represent the initial offset of the node relative to their child nodes. x, y and z are three directions. In frame $k+1$, the vector of the joint points to the parent node is shown in Eq. (2).

$$V_{k+1} = T_k R_k \left[V_0 \quad 1\right]^T \tag{2}$$

In Eq. (2), T_k is the translation matrix. R_k is the product of rotation matrices in the z, x, and y directions. According to the node transformation relationship and the bone hierarchical structure, the three-dimensional coordinate is shown in Eq. (3).

$$V_{k+1}^n = \left(\prod_{i=0}^{n} T_k R_k^i\right) \times V_0^n \tag{3}$$

In Eq. (3), n represents the number of child node levels. The 0-th level parent node represents the parent node. The difference between the child node and the parent node is $n-1$. Then, the points obtained from the three-dimensional coordinates are connected to obtain the trajectory of Tai Chi movements. In addition, with the rapid development of machine learning, two-dimensional color image models can be extracted from human bone models. The extraction techniques include top-down and bottom-up approaches. The study adopts a bottom-up extraction method, which extracts various body parts or nodes from the image and then pieces them together to form a complete bone model. Openpose, as a bottom-up skeleton recognition method, has a human skeleton model with 18 joints and 25 joints. The study selects a human skeleton model with 25 joints, which includes all joints in BVH format, as well as data extraction for hands and faces. The Openpose algorithm can extract two-dimensional coordinates of human bone models in color images. Corresponding to the position of the depth image, the three-dimensional coordinates of the joint points can be obtained.

The three-dimensional coordinates of depth images can be obtained based on the camera coordinate system. The common depth images include stereo vision method, time-of-flight method, etc. [15]. Based on the coherence and motion range of Tai Chi movements, the KinectV2 somatosensory camera based on the time-of-flight method is taken as the visual sensor for research. Visual sensors cover four coordinate systems in data analysis and calculation. Therefore, its research application in Tai Chi action recognition is shown in Fig. 3.

From Fig. 3, four coordinate systems are obtained, including image coordinate system, pixel coordinate system, camera coordinate system, and world coordinate system. Inertial sensors and stereo sensors are combined to study the relevant coordinate systems of Tai Chi movement trajectory.

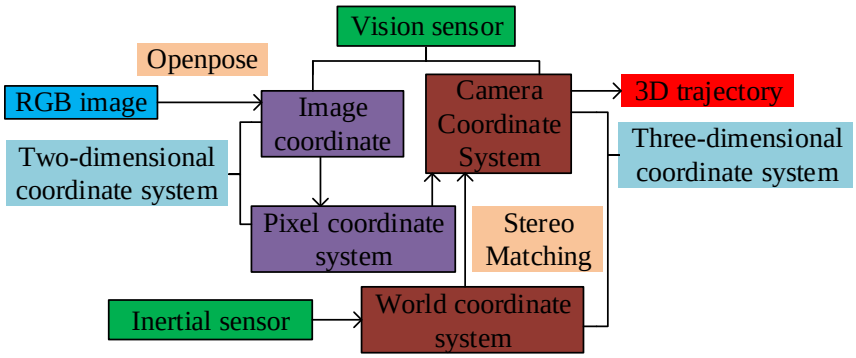

Fig. 3. Coordinate system application and structure diagram of visual sensors.

B. Data Fusion Processing Based on Inertial-Visual Sensors

The imaging captured by a camera is affected by optical properties, which can cause distortion during imaging. Then, based on the camera calibration internal parameter matrix, distortion processing is applied to the depth image and color image. The points of the depth image are corresponding to the color image to obtain a four-channel RGB color mode Depth Map (RGBD) image. Finally, based on the camera coordinate system, the three-dimensional coordinates of the RGBD image are evaluated. For the pixel coordinates of a point in the depth image, the depth value is shown in Eq. (4).

$$\text{Depth value} = u + v$$
$$\begin{cases} u = a_2\left[b_2 d\left(a_1, b_1\right) + \left(1-b_2\right) d\left(a_1, b_1+1\right)\right] \\ v = a_2\left[\left(1-a_2\right) d\left(a_1+1, b_1\right) + \left(1-b_2\right) d\left(a_1+1, b_1+1\right)\right] \end{cases} \quad (4)$$

In Eq. (4), (a,b) is the pixel coordinate of a certain point. $a = a_1 + a_2, a_1 \le a$, and $b = b_1 + b_2, b_1 \le b$. Depth value represents the depth value of the point. $d(a,b)$ is the function value of point (a,b) on the depth image. In addition, the depth value of joint points in the three-dimensional coordinates of the depth camera is shown in Eq. (5).

$$\begin{cases} x = D\left(a - a_0\right)\dfrac{1}{f_x} \\ y = D\left(b - b_0\right)\dfrac{1}{f_y} \end{cases} \quad (5)$$

In Eq. (5), (x,y,z) is the three-dimensional coordinate of the joint point. (x,y,z) is its depth value. Finally, the RGBD image is separated to obtain an RGB image with the same size as the depth image. The Openpose algorithm is used to extract pixel coordinates from the joint points of the RGB image and convert them into three-dimensional coordinates. Finally, the visual sensor is used to process data such as noise and errors in three-dimensional coordinates. The image is processed with depth values through guided filters to obtain a single channel binarized image, which is optimized to preserve the distinguishing effect between the edges and interior of the image, thereby clarifying the human body contour information on the image. The morphology of human bones varies. Therefore, the human skeleton model needs to be standardized, so that visual sensors can clearly obtain the three-dimensional coordinates of the human skeleton and ensure the optimization quality of Tai Chi movement trajectory. To remove noise interference from collected data, the study uses Kalman filtering to process motion data and smooth the trajectory. The smoothing indicators, including square integral method, root mean square method, maximum velocity normalized mean method, and maximum velocity normalized mean method are used to test the smoothness and coordination of human motion. The improved Kalman filter enhances the smoothness of motion trajectory. Afterwards, the data collection of the inertial sensor is denoised. The five-point smoothing algorithm is used to optimize its motion trajectory, thereby improving the good smoothness performance of the Tai Chi movement trajectory. The accuracy of inertial sensors is superior to that of visual sensors. Therefore, there are significant errors in the data after the operation. The data fusion method of the two needs to be improved to enhance the quality of data processing. The steps for designing data fusion are shown in Fig. 4.

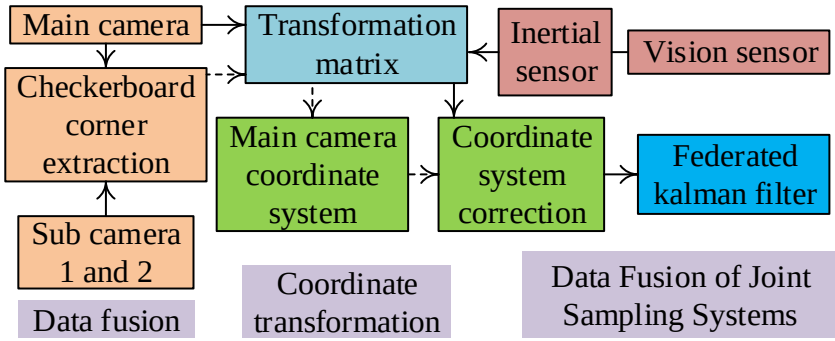

Fig. 4. Data fusion of inertial sensor and visual sensor.

From Fig. 4, the data fusion processing design is formed based on the errors of the two sensors. Three cameras and their coordinate systems are stereo matched. The checkerboard corner extraction algorithm is combined to enhance robustness and reduce errors. Then, coordinate transformation is performed on the inertial visual sensor to accurately identify the three-dimensional coordinates of the human skeleton model. Finally, a joint sampling system is used to fuse the data of the inertial visual sensor. The decentralized multi-sensor data fusion method is adopted, and Kalman filtering is combined to design filters, thereby reducing data errors and efficiently fusing information [16-18]. The main error in inertial sensors is the operational error of gyroscopes and accelerometers. The errors in visual sensors mainly include joint positioning, depth values, and other errors. Therefore, the joint error compensation algorithm and Kalman filtering algorithm are used to process the cumulative error and joint error data, thereby improving the robustness of the fusion system. The stereo matching angle relationship of inertial-visual sensor is shown in Eq. (6).

$$\begin{cases} \alpha = \left| \arccos\left(\dfrac{(n_3)}{\sqrt{n_1^2 + n_2^2 + n_3^2}} \right) \right| \\ \beta = \left| \arccos\left(\dfrac{(n_1)}{\sqrt{n_1^2 + n_2^2 + n_3^2}} \right) \right| \\ \alpha + \beta = \varphi + \lambda = \dfrac{\pi}{2} \end{cases} \tag{6}$$

In Eq. (6), α is the angle between z in camera coordinates and the ground plane. β is the angle between x and the ground plane. The converted camera coordinate is $\left(x^{'}, y^{'}, z^{'}\right)$. The angle between z and $z^{'}$ is φ. λ is the angle between x and $x^{'}$. The information conservation principle of the federated Kalman filtering algorithm is shown in Eq. (7).

$$P = \sum_{i}^{m} \alpha_i + \alpha_m \tag{7}$$

In Eq. (7), P represents the principle of information conservation. The noise variance error is shown in Eq. (8).

$$\begin{cases} \sum_{i=1}^{N} \dfrac{1}{\eta_i} = 1 \\ 0 \le \dfrac{1}{\eta_i} = \alpha_i \le 1 \end{cases} \tag{8}$$

In Eq. (8), η_i is the measurement noise variance of the sampling system. Finally, the covariance between the inertial sensor and the visual sensor is normalized, as shown in Eq. (9).

$$\alpha_i^k = \frac{\sum_{i=1}^{3} \dfrac{1}{\eta_i} + \dfrac{1}{\eta_m}}{\eta_i} \tag{9}$$

In Eq. (9), η_m is the covariance matrix of the cumulative error for the inertial sensor. Through data fusion design, multiple sensor error analysis and optimal data fusion are completed.

C. Segmentation and Clustering Processing of Tai Chi Movement Trajectories

Tai Chi is a continuous and light movement. To complete the action trajectory recognition, the trajectory needs to be segmented to extract the characteristics of trajectory motion [19-20]. The Minimum Description Length (MDL) is used to extract feature points of a trajectory. The original trajectory is segmented to obtain multiple sub trajectories. Then, the sub-trajectories are transformed into vectors, which are called feature vectors. The lengths of all sub-trajectories during trajectory segmentation are shown in Eq. (10).

$$\begin{cases} M(H) = \sum_{j=1}^{par_i - 1} \log_2 \left[len\left(p_{c_j}, p_{c_{j+1}}\right) \right] \\ M(D|H) = \sum_{j=1}^{par_i - 1} \sum_{k=c_j}^{c_{j+1}-1} \log 2 \left[d_{\perp}\left(p_{c_j} p_{c_{j+1}}, p_k p_{k+1}\right) \times d_{\theta}\left(p_{c_j} p_{c_{j+1}}, p_k p_{k+1}\right) \right] \end{cases} \tag{10}$$

In Eq. (10), $M(H)$ is the sum of sub-trajectory lengths. p_c is the point on the trajectory. p_{c_j} is the characteristic of the trajectory point. $len\left(p_{c_j}, p_{c_{j+1}}\right)$ is the Euclidean distance between p_{c_j} and $p_{c_{j+1}}$. $d_{\perp}$ and d_{θ} are the vertical distance and angular distance between trajectory segments, respectively. For the characteristics of trajectory points, it is required to take a local optimal solution, which can replace the global optimal solution. The cost function and feature point conditions are shown in Eq. (11).

$$\begin{cases} MDL_{par}\left(p_i, p_j\right) = M(H) + M\left(D|H\right) \\ MDL_{nopar}\left(p_i, p_j\right) = M(H) \\ MDL_{par}\left(p_i, p_k\right) < MDL_{nopar}\left(p_i, p_j\right) \end{cases} \tag{11}$$

In Eq. (11), p_i and p_j represent two points on the trajectory, respectively. $MDL_{par}\left(p_i, p_j\right)$ is the encoding length function that connects feature points into a line. $MDL_{nopar}\left(p_i, p_j\right)$ is the length function of the original trajectory encoding. Due to the small difference between the trajectory and the original trajectory, $M\left(D|H\right)$ is zero. Then, the three-dimensional coordinates and time of the sub-trajectories are combined to form a four-dimensional feature vector. The four-dimensional feature vector is classified. Then, the Density-Based Spatial Clustering of Applications with Noise (DBSCAN) is selected. The algorithm automatically classifies the data according to the set parameters, and then finds clusters of any shape in the dataset and removes noise. The Hopkins statistic is selected to evaluate the clustering trend of the dataset, as shown in Eq. (12).

$$\text{Hopkins statistics} = \frac{\sum y_i}{\sum y_i + \sum x_i} \tag{12}$$

In Eq. (12), $\{x_n\}$ represents uniformly extracting n samples $\{p_n\}$ from the dataset. Then, n sample sets are uniformly extracted from the dataset. The distance between each sample and the nearest sample set in the complement set is $\{y_n\}$. After determining the separability of the dataset, the clustering effect is effectively evaluated. The Davies-Bouldin index (DBI) and Dunn index index (DI) are used to simultaneously evaluate clustering performance. The DBI is shown in Eq. (13).

$$DBI = \frac{1}{k}\sum_{i=1}^{k} \max_{j=1\sim k, j\neq 1}\left(\frac{L_i + L_j}{C_{ij}}\right) \tag{13}$$

In Eq. (13), L_i and L_j represent the average distance between each point in the i-th and j-th clusters and the center of the cluster, respectively. C_{ij} is the center distance between the i-th and j-th clusters. If the value is small, the clustering effect is good. The DI is shown in Eq. (14).

$$DI = \frac{MIN\left\{\min\left\|x_i - y_j\right\|\right\}}{MAX\max\left\|x_i - y_j\right\|} \begin{cases} MIN, 0 < m \neq n < K \\ \min, \forall x_i \in \Omega_m, \forall y_i \in \Omega_n \end{cases} \begin{cases} MAX, 0 \leq m \leq K \\ \max, \forall x_i, y_i \in \Omega_m \end{cases} \tag{14}$$

In Eq. (14), a larger DI indicates better clustering performance. According to the distance evaluation between DBI and DI, the optimal weight can be continuously adjusted. The parameters that need to be adjusted in clustering analysis include spatiotemporal parameters. The spatiotemporal distance is normalized, as shown in Eq. (15).

$$S\left(W_i, W_j\right) = w_d \frac{d_\perp\left(W_i, W_j\right) + d_\square\left(W_i, W_j\right) + d_\theta\left(W_i, W_j\right)}{\max\left(d_\perp + d_\square + d_\theta\right)} + \frac{w_t d_t\left(W_i, W_j\right)}{\max\left(d_t\right)} \tag{15}$$

In Eq. (15), W_i and W_j represent trajectory segments, respectively. $d_\square$ is the parallel distance between trajectory segments. w_d is the sum of weights among parallel distance, vertical distance, and angular distance. w_t is the time weight, and $w_d + w_t = 1$. d_t is the time distance. According to the inertial visual sensor and sampling system, the complete Tai Chi movement trajectory is segmented and clustered. Then, its actions are decomposed and recognized. Due to the complexity and diversity of Tai Chi movement trajectories, SVM and DTW are combined to identify and verify single and multiple joint points, respectively. The steps for identifying the two are shown in Fig. 5.

From Fig. 5, based on the specific movements and trajectories of Tai Chi, its movements are identified and tested. SVM is fused to process the trajectory into the same size form, and Fisher vectors are used to normalize the length. The results of DBSCAN are used in a mixed Gaussian model to identify the motion trajectory of a single joint point. For multi-joint recognition verification, DTW is used to optimize the algorithm and directly recognize the segmented actions as templates.

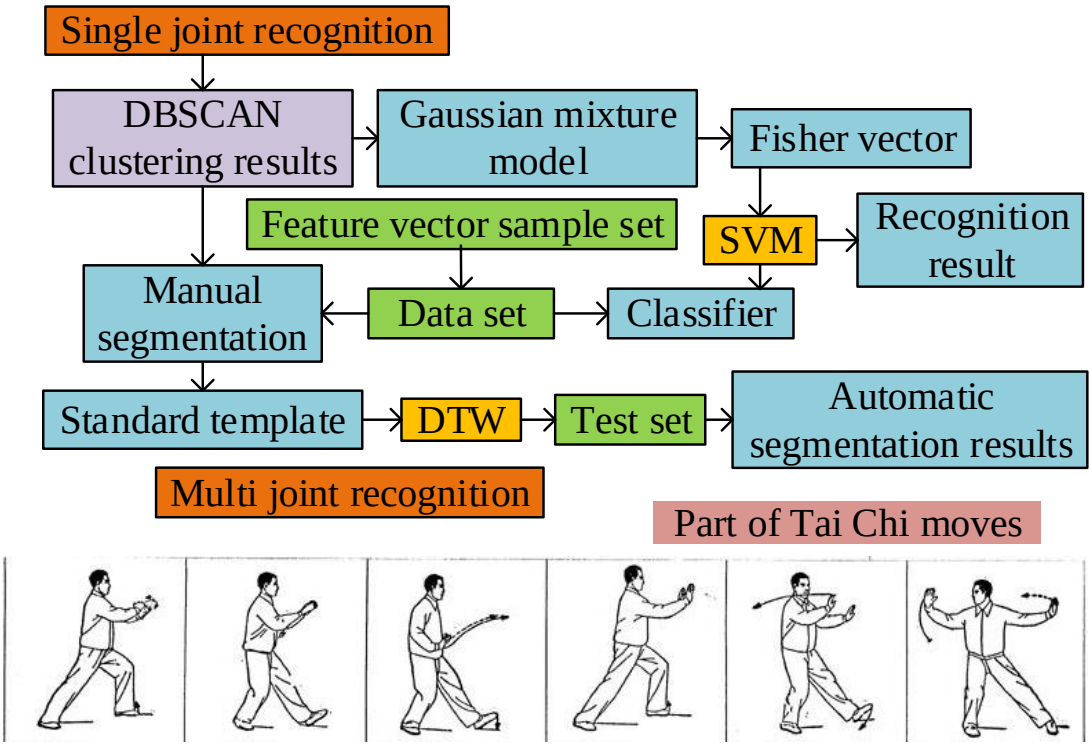

Fig. 5. Schematic diagram of recognition steps for Tai Chi movement trajectory.

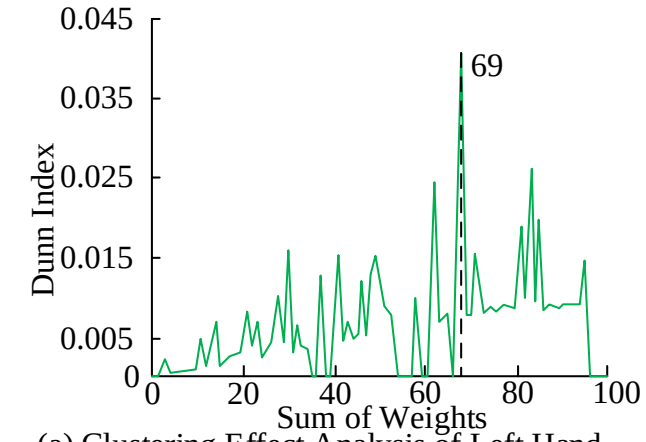
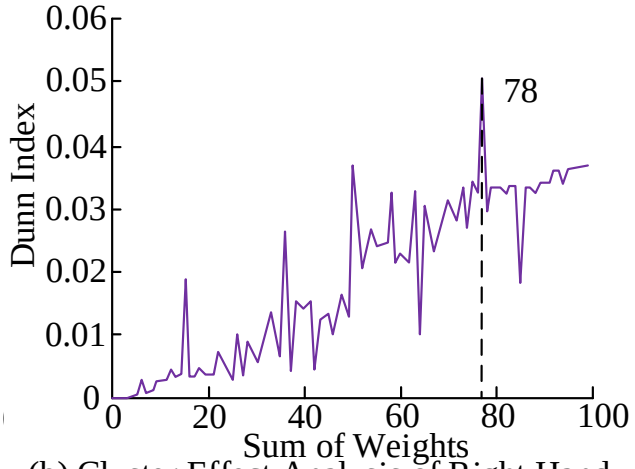
IV. Segmentation and Recognition Analysis of Tai Chi Movement Trajectories

Based on the segmentation and trajectory processing of Tai Chi movements, clustering evaluation indicators are used to analyze the clustering effect of the movement trajectories for the left- and right-hand joints in Tai Chi. The step size variation range of the two trajectories is planned to be 0-100. The relationship between the DI evaluation index of hand movement trajectory and the weight sum of parallel, vertical, and angle distances is shown in Fig. 6.



(a) Clustering Effect Analysis of Left Hand Movement Trajectory



(b) Cluster Effect Analysis of Right Hand Movement Trajectory

Fig. 6. Clustering effect analysis of hand movement trajectories in Tai Chi.

From Fig. 6 (a), the DI value of the left-hand movement trajectory reached the highest value, indicating the best trajectory clustering effect. The weight sum was 69, and the overall movement trajectory changed differently. When the clustering effect of the right-hand movement trajectory reached its maximum, the weight sum was 78. The overall hand movement trajectory showed an upward trend, that is, the DI value continued to increase overall. The hand movement in Tai Chi is called Yunshou. Due to the clustering processing of the DBSCAN algorithm, it is converted into a Fisher vector, as shown in Fig. 7.

From Fig. 7, the motion trajectory of the Cloud Hand move varied greatly. The Fisher vector changed with increasing size. The overall trend was concentrated between -0.2-0.2, with the highest approaching 0.6. There are many schools of Tai Chi. Fist types and movements are diverse and varied. The study takes the Tai Chi of the Wu school as an example. Ten of the movements, including Grasp the Bird's Tail, Single Whip, Cross Hands, Cloud Hand, Sea Needle, Flash the Arm, Oblique Flying, Upside Down Chasing the Monkey, Tai Chi Qi Shi, and Parry and Punch, are selected for analysis. The names of these movements are represented in order by A-J. Finally, the trajectory of Tai Chi movements is identified and analyzed. The right-hand movement trajectory is recognized as a single joint action. Ten moves are classified into two categories and the training sample proportions are set to 25%, 50%, and 75%, respectively. The recognition accuracy of the two categories is calculated separately. When the training samples account for 25% of the total samples, some recognition results are shown in Fig. 8.

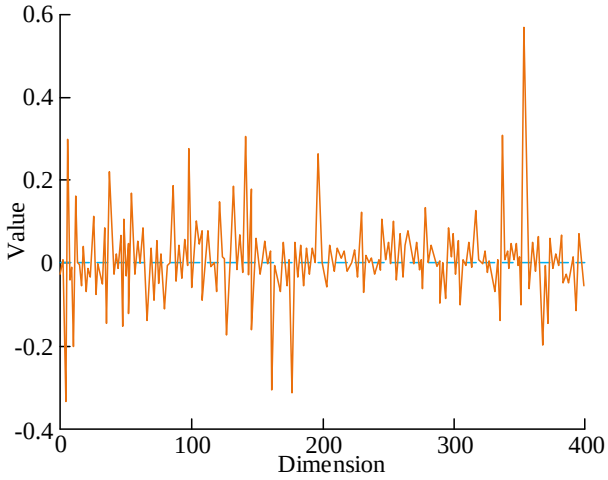


Fig. 7. Fisher vector changes in the trajectory motion of the cloud hand move.

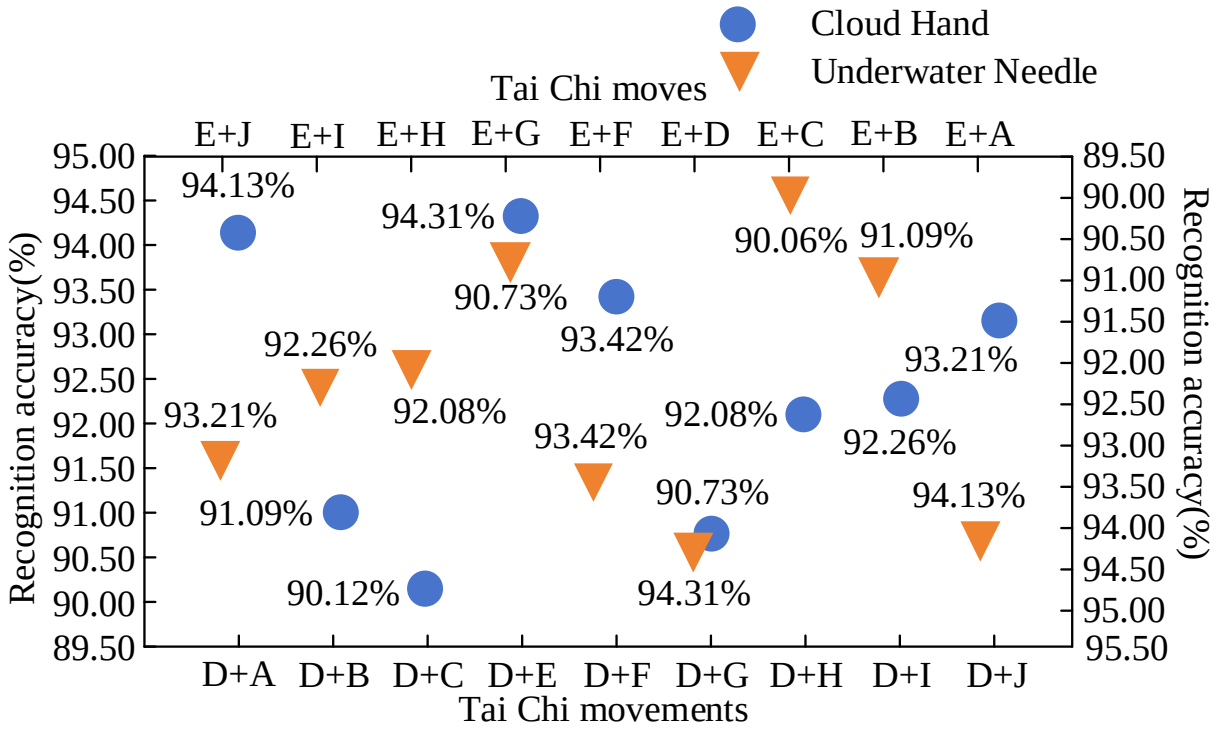

Fig. 8. Recognition results of the 25% binary classification of the cloud hand and sea needle.

From Fig. 8, when the test sample was 25%, the overall recognition accuracy of the Cloud Hand and Sea Needle movements was above 90%, with the highest being 94.31% and the lowest being 90.12% and 90.06%, respectively. When the test sample was 50%, the binary recognition results of some movements are shown in Fig. 9.

From Fig. 9, when the training sample was 50%, the recognition rates of the Flash the Arm, Oblique Flying movements were both above 93%, which was higher than the 25% training sample proportion result. The highest recognition rates for the combination of the Flashing Back and the Oblique Flying were both 98.45%, while the lowest recognition rates were 93.30% and 93.27%, respectively. Finally, the training samples accounted for 75%. The recognition rate changes are tested, as shown in Fig. 10.

From Fig. 10, when the training sample was 50%, the recognition rates of the Flash the Arm, Oblique Flying moves were above 93%, which was higher than the 25% training sample proportion result. The highest recognition rates for the combination of the Flashing Back and the Oblique Flying were 98.45%, while the lowest recognition rates were 93.30% and 93.27%, respectively. Finally, the training samples accounted for 75%. The recognition rate changes are tested, as shown in Fig. 10. This indicates that the sample proportion is large, and the recognition accuracy of the moves continues to improve, thereby verifying the effectiveness of the classification recognition algorithm. To visually compare the binary classification recognition results of different sample proportions, a movement called Qishi is selected to perform 25%, 50%, and 75% binary classification recognition. The change results are shown in Table I.

From Table I, the lowest recognition accuracy for the binary classification of the Qishi movement was 90.87%, 93.53%, and 98.08%, respectively, when the training sample proportions were 25%, 50%, and 75%. Furthermore, it indicates that as the proportion of samples increases, the recognition accuracy also improves. Finally, the binary and multi-classification samples are trained to recognize single joint and multi-joint movements. The accuracy and standard deviation of the average value are taken to determine the classification accuracy of the motion trajectory, as shown in Fig. 11.

From Fig. 11(a), the recognition accuracy of binary classification for single node in the sample proportion of 25%, 50%, and 75% was 92.26%, 96.51%, and 98.48%, respectively. The recognition accuracy in multi-classification was 90.05%, 90.58%, and 93.56%, respectively. In Fig. 11(b), the recognition standard deviations of binary classification for single node in the 25%, 50%, and 75% sample proportions were 1.15%, 1.32%, and 0.47%, respectively. The standard deviations for multi-classification recognition were 2.68%, 2.11%, and 3.08%, respectively. Furthermore, it indicates the variation of single joint points in different sample proportions. The binary classification method has higher recognition accuracy and lower standard deviation than the multi-classification method. This proves that the binary classification method for identifying single related nodes has advantages. The recognition accuracy and standard deviation results for multiple joint points are shown in Fig. 11(c). The recognition accuracy of binary classification and multi-classification was 99.77% and 90.25%, respectively. The identification standard deviations were 0.16% and 0.66%, respectively. This indicates that binary classification method is superior to multi-classification method in multi-joint point recognition methods. This proves the superiority of the SVM-based recognition and classification method.

TABLE II. COMPARISON RESULTS OF DIFFERENT METHODS FOR RECOGNIZING TAI CHI MOVEMENTS

Tai Chi movements	E+A	E+B	E+C	E+D	E+F
Reference[6]	90.84%	91.03%	90.53%	89.87%	90.46%
Reference[7]	91.23%	90.45%	90.07%	91.16%	90.32%
Reference[9]	87.61%	86.26%	86.01%	89.26%	88.04%
This research method	99.16%	98.57%	99.12%	98.35%	99.24%

Finally, the research method is compared with existing methods, focusing on trajectory recognition of five Tai Chi moves mainly using the Hai Di Zhen technique. The results are shown in Table II.

From Table II, the deep neural networks and adaptive multi-scale convolutional networks in references [6] and [7] had better recognition methods for human joint points, and had good recognition results for light and gentle Tai Chi movements. The deep network model achieved a recognition result of 91.03% for underwater needles and single whips, while the model in study [7] achieved a recognition result of 91.16% for underwater needles and cloud hands. However, the recognition in study [9] was below 90%, which was not suitable for recognizing Tai Chi movements. Based on the above comparison results, it is concluded that the proposed method has accuracy and applicability in recognizing Tai Chi movements.

V. CONCLUSION

For the analysis of Tai Chi movement recognition data, human motion data is processed by inertial sensors and visual sensors. Then, the collected trajectory data is segmented and clustered. Finally, a comparative analysis is conducted on the recognition of Tai Chi movements. The clustering evaluation

index is used to analyze the clustering effect of the movement trajectories for the left- and right-hand joints in Tai Chi. When the clustering effect of left- and right-hand movements was the highest, the sum of weights was 69 and 78, respectively. The specific movements of Tai Chi are used for action recognition. In the binary classification method, when the training sample was 25%, the overall recognition accuracy of the Cloud Hand and Sea Needle moves was above 90%, with the lowest being 90.06%. When the training sample was 50%, the recognition rates of the flashback and oblique flying movements were both above 93%, with the highest being 98.45%. When the training sample was 75%, the recognition accuracy of the "Grasp the Bird's Tail" and "Single Whip" were both above 97%. As the number of training samples increases, the accuracy of action recognition continues to improve. This also indicates the classification effectiveness of the DBSCAN algorithm. Finally, single joint and multi-related nodes were respectively used in binary classification and multi-classification. The recognition accuracy of single joint in the 25%, 50%, and 75% sample proportion of binary classification was 92.26%, 96.51%, and 98.48%, respectively. The recognition accuracy of multi-joint points in binary classification was 99.77%. Furthermore, it proves that the binary classification method has high recognition accuracy, indicating the superiority of the trajectory segmentation and recognition classification method based on multiple sensors. However, human motion trajectory segmentation still lacks a large amount of motion data. In addition, the recognition and selection of Tai Chi movements are not widely applicable. In the action decomposition of sports events, real-time action recognition is not considered in order to collect and correct actions. In future research, it is necessary to reference other types of sports to improve athletes' movement skills and expand the feasibility and practicality of sports movement recognition technology. The accuracy of action recognition in the medical field can help physicians diagnose diseases and provide real-time and effective evaluation of treatment plans for patients' exercise rehabilitation. With the development of intelligence, in the fields of human-computer interaction and virtual reality, the recognition of human movements can be transformed into instruction input, thereby promoting the intelligence of life.

This study analyzed the coherence and overall coordination of Tai Chi movements, and conducted segmentation and clustering. In addition, considering the motion joints of actions, SVM and DTW methods were used to cluster single joints and multiple joints. The DBSCAN algorithm accurately identified the data noise of high-density motion trajectories, thereby improving the clustering effect of trajectories while segmenting them, and ultimately achieving high classification and recognition accuracy of Tai Chi movements.

Skywatch: Advanced Machine Learning Techniques for Distinguishing UAVs from Birds in Airspace Security

Muhyeeddin Alqaraleh[1], Mowafaq Salem Alzboon[2], Mohammad Subhi Al-Batah[3*]
Department of Software Engineering-Faculty of Information Technology, Zarqa University, Zarqa, Jordan[1]
Department of Computer Science-Faculty of Science and Information Technology, Jadara University, Irbid, Jordan[2, 3]

***Abstract*—This study addresses the critical challenge of distinguishing Unmanned Aerial Vehicles (UAVs) from birds in real-time for airspace security in both military and civilian contexts. As UAVs become increasingly common, advanced systems must accurately identify them in dynamic environments to ensure operational safety. We evaluated several machine learning algorithms, including K-Nearest Neighbors (kNN), AdaBoost, CN2 Rule Induction, and Support Vector Machine (SVM), employing a comprehensive methodology that included data preprocessing steps such as image resizing, normalization, and augmentation to optimize training on the "Birds vs. Drone Dataset." The performance of each model was assessed using evaluation metrics such as accuracy, precision, recall, F1 score, and Area Under the Curve (AUC) to determine their effectiveness in distinguishing UAVs from birds. Results demonstrate that kNN, AdaBoost, and CN2 Rule Induction are particularly effective, achieving high accuracy while minimizing false positives and false negatives. These models excel in reducing operational risks and enhancing surveillance efficiency, making them suitable for real-time security applications. The integration of these algorithms into existing surveillance systems offers robust classification capabilities and real-time decision-making under challenging conditions. Additionally, the study highlights future directions for research in computational performance optimization, algorithm development, and ethical considerations related to privacy and surveillance. The findings contribute to both the technical domain of machine learning in security and broader societal impacts, such as civil aviation safety and environmental monitoring.**

***Keywords*—Unmanned Aerial Vehicles (UAVs); machine learning; image recognition; real-time processing; security; computer vision; image processing**

I. Introduction

In the past decade, military applications of drones have undergone a significant transformation, expanding from surveillance and reconnaissance to more tactical roles, such as precision strikes on targeted objectives. Drones, whether small handheld units or large remotely piloted aircraft, provide invaluable aerial surveillance that extends beyond human capability. This real-time surveillance helps to identify potential threats, ensuring the safety of both civilians and military personnel [1]. Drones can monitor dangerous areas for extended periods, offering surveillance that surpasses traditional methods. However, while these capabilities are revolutionary, they also introduce critical challenges, particularly in security operations.

One significant concern is the threat posed by cyberterrorism, as drones—hailed as one of the most formidable weapons in modern warfare—can be exploited to breach defenses. For instance, the Iranian drone and missile attack on Israeli territories highlighted the need for robust UAV detection systems capable of distinguishing between drones and other aerial entities such as birds. In military contexts, adversarial tactics can include electronic warfare and psychological operations, which further complicate the identification process. Therefore, the development of efficient, real-time recognition platforms using advanced computational technologies is vital [2] [3].

This study explores the application of machine learning algorithms to address this challenge. We examine various models, including deep neural networks, Support Vector Machines (SVMs), random forests, and gradient boosting machines, to identify the most effective approach for high-security environments. The research primarily focuses on reducing false positives and negatives in UAV detection, a critical factor for maintaining operational integrity in military settings. The models are assessed based on accuracy, precision, computational performance, and suitability for real-time applications [4]. This article aims to provide key insights into improving UAV detection systems, offering practical applications that can enhance current military surveillance and security protocols. By leveraging machine learning advancements, this study contributes to the ongoing evolution of airspace control and UAV countermeasures.

A. Article Objectives

This study aims to enhance the ability to differentiate Unmanned Aerial Vehicles (UAVs) from birds in military surveillance operations, with a focus on improving resource allocation, optimizing response strategies, and ensuring airspace security. The primary objectives are:

1) Develop advanced detection algorithms: Design and refine sophisticated machine learning algorithms capable of distinguishing between UAVs and birds by analyzing complex datasets based on flight patterns and physical characteristics.

2) Enhance image recognition capabilities: Improve image recognition accuracy for UAV detection against various

*Corresponding Author.

natural backgrounds by training models on extensive datasets of UAV and bird images captured under diverse environmental conditions.

3) Minimize false positives and negatives: Reduce the rates of false alarms (misidentifying birds as UAVs) and missed detections (failing to identify UAVs) to streamline surveillance system performance in high-security zones.

4) Implement real-time processing: Create a system that processes and analyzes data in real time, enabling immediate and informed decision-making in dynamic, potentially adversarial environments.

5) Evaluate system robustness in simulated environments: Test the developed systems in simulated environments that mimic real-world conditions, including scenarios with UAV swarms and electronic warfare techniques.

6) Assess operational integration: Determine the feasibility and effectiveness of integrating the developed technologies into existing military security frameworks, ensuring seamless deployment and operational functionality.

Achieving these goals will significantly advance the technological capabilities of military surveillance, contributing to national security and strategic defense effectiveness [5].

B. Contribution of the Article

This article contributes to military surveillance by improving UAV and bird differentiation systems. The key contributions are:

1) Advancement in detection algorithms: Introducing new machine learning algorithms for UAV and bird differentiation, focusing on pattern recognition and flight dynamics analysis to reduce misidentifications and improve threat assessment accuracy.

2) Real-time data processing: Enhancing real-time processing capabilities to allow rapid analysis and response in high-stakes environments, where timely decisions can critically impact military engagements.

3) Reduction of false alarms: Minimizing false positives and negatives to prevent unnecessary deployment of resources and reduce the risk of overlooking actual threats.

4) Operational integration and testing: Evaluating the systems in simulated environments, ensuring practical viability and seamless integration into existing military frameworks.

5) Strategic implications and policy recommendations: Offering strategic insights and policy recommendations for defense entities, with suggestions for deploying new technologies and updating current practices.

6) Enhanced airspace security: Improving UAV identification capabilities to strengthen airspace security, particularly in sensitive or high-security areas, mitigating threats like espionage and unauthorized surveillance [6].

C. Article Organization

The article begins with an overview of the importance of UAV identification in military surveillance, followed by a literature review in Section II that highlights existing advancements and gaps in current methodologies. The methodology in Section III outlines the experimental setup, including data collection, model refinement, and evaluation metrics. The results and analysis in Section IV presents a comprehensive evaluation of methods such as neural networks and gradient-boosting machines, assessing their effectiveness in UAV recognition. Discussion is given in Section V. Finally, the article concludes in Section VI with a discussion on future research directions and recommendations for improving UAV detection systems in Section VII.

D. Problem Statement

The growing use of UAVs in military operations underscores the need for advanced systems capable of accurately distinguishing UAVs from other entities, such as birds, in real time. This study focuses on developing machine learning models to improve UAV detection, which is crucial for enhancing airspace security and operational efficiency in both military and civilian settings.

II. Related Work

Due to the increasing chance of drones being used for unlawful activities, the detection of drones has turned out to be especially significant inside the realm of security and surveillance. Artificial neural networks do not facilitate real-time object detection because multiple GPUs are necessary to train the models. Deep learning architectures aim to address this problem by creating convolutional neural networks (CNN) that can function in real-time with just one conventional GPU for training [7]. This paper employs appropriate deep-learning architectures for detecting drones and birds. This application utilizes YOLO (You Only Look Once) algorithms, which are one-stage approaches that examine an image just once using a single neural network. The community is skilled at stop-to-quit to output the bounding box, magnificence label, and detection probability without delay. The models are trained on a bespoke dataset comprising 664 drone pixels and 236 hen pictures. Simulation results indicate that YOLOv4 and YOLOv5 attained F1-ratings of 98% and 94%, respectively, with detection speeds of 54fps and 77fps. The fashions also tested mean average precision (mAP) values of 97.4% and 95%. YOLOv4 verified advanced overall performance in suggested Average Precision (mAP) compared to YOLOv5, whereas YOLOv5 exhibited faster detection speed than YOLOv4 [8].

Businesses, transportation, and military sports use drones. Advanced drone detection and identification systems are needed to protect the airspace. This paper accurately identified drones and birds in the air using radar and visible imaging. Using both drone detection and recognition systems was helpful. An average precision of 88.82% and accuracy of 71.43% makes this approach greener. Excellent performance is shown by the combined approach's 76.27% F1 score. Drone and chicken detection systems will benefit significantly from the findings. Better than similar works, the proposed algorithm [9].

The examination was performed in northeastern Poland, where the Whooper Swan (Cygnus cygnus) breeds now and

then. The Whooper Swan is shy and tends to conceal itself in emergent flowers. A drone was utilized to enhance the efficiency of studying its breeding success and offspring productivity. In 2022, the breeding density of Whooper Swans in the study area was 10 pairs per 100 square kilometers. There was no difference in the number of breeding birds detected at the start of the breeding season between the drone and ground methods. The breeding productivity of the sample of swans studied (N = 36) was 2.19 cygnets per breeding pair using the ground method but 3.71 per pair with the drone, showing a significant difference (p-value of the Wilcoxon test = 0.0148). In the conventional approach, 50% of the pairs successfully bred, while using the drone resulted in a 79% success rate. The birds either remained indifferent to the drone's presence or retreated slowly. The drone study on Whooper Swan breeding productivity was significantly quicker (9 minutes per site compared to 1-2 hours for a ground survey), more accurate, and less disruptive to the birds than a conventional survey [10].

Detecting objects like drones is difficult due to their size and agility, which can confuse machine learning models and lead to misclassification as birds or other objects. This study explores applying various deep-learning techniques to analyze real datasets collected from flying drones. A deep learning approach is suggested to reduce the complexity of such systems. The proposed paradigm combines the AdderNet deep learning paradigm and the SSD paradigm. The aim was to reduce complexity by decreasing the number of multiplication operations in the proposed system's filtering layers. Standard machine learning techniques like Support Vector Machines (SVM) are evaluated and contrasted with other deep learning systems. The datasets for training and testing were either complete or filtered to exclude images with small objects. The data types were either RGB or IR. Comparisons were conducted among all these types, and conclusions are provided [11].

Even advanced drones outperform birds with lightweight, adaptable wings and tails. 3D printing, servomotors, and composite materials enable more creative airplane designs inspired by bird flight, which may improve flight characteristics. By replacing control surfaces with rapidly changing wings, morphing technology improves aircraft aerodynamics and power efficiency. This paper introduces bio-inspired 3D-printed systems for unmanned aerial vehicle wings and tails that morph without flapping. The proposed wing uses a corrugated, flexible 3D-printed structure to expand and contract artificial feathers for sweep morphing. A flexible 3D-printed structure with circular corrugation is proposed for tail feather expansion. Various 3D-printing materials and intricate geometric components can achieve the proposed morphing deformations with minimal actuation forces. Testing prototypes showed that the chosen materials and actuators could achieve seagull-like morphing deformations [12].

The widespread availability of drones has opened up numerous new possibilities previously limited to a select few. Regrettably, this technology also brings countless adverse effects associated with illicit activities such as surveillance and smuggling. Sensitive areas should be equipped with sensors that can detect miniature drones from a long distance. Several techniques are present in this field, but each has notable disadvantages. This study introduces a new method for detecting small drones (<5 kg) using laser scanning and a technique to differentiate between UAVs and birds. Minimizing the false alarm rate in each drone monitoring equipment is a crucial challenge. The paper discusses the newly created sensor and its effectiveness in distinguishing between drones and birds. The concept relies on a straightforward analysis of the cross-polarization ratio of the optical echo produced by laser backscattering on the identified object. The experimental results indicate that the proposed method does not consistently ensure 100% discrimination efficiency but offers a distribution of confidence levels. However, because of the hardware's simplicity, this method appears to be a beneficial enhancement to the advanced anti-drone laser scanner [13].

To address security concerns, an algorithm is created to distinguish between airspace intruders, such as birds and drones, in unmanned aerial system (UAS) operations. The algorithm utilizes velocity data of detected intruders from Internet-of-Things platforms and a partial understanding of physical models. The identification problem is framed as a statistical hypothesis testing or detection problem, where inertial feedback-controlled objects under stochastic actuation must be differentiated based on speed data. The maximum a posteriori probability detector is derived and then simplified into an explicit computation using two points in the sample autocorrelation of the data. The simplified form facilitates the algorithm's computationally efficient implementation and enhances learning from stored data. The total probability of error of the detector is calculated and described. Simulations using synthesized data are shown to demonstrate and improve the formal analyses [14].

Detecting and tracking birds and drones accurately is crucial in different low-altitude airspace surveillance situations. Radar is the most suitable long-range surveillance technology for this issue, but it faces challenges in effectively differentiating between birds and drones. This paper examines birds' and drones' natural flight mechanics and behavioral patterns. A goal classification technique is suggested primarily based on extracting target motion characteristics from radar tracks. The random woodland version is selected for the goal type within the new function space. The proposed method confirms using real-time surveillance radar systems in airport regions. The results of classifying birds, quadcopter drones, and dynamic precipitations advise that the proposed method can reap high-class accuracy. The Gini significance descriptors in a random woodland model provide extra perception when evaluating movement traits and mining. The type machine's excessive sample flexibility and performance enable it to efficiently address complex low-altitude goal surveillance and class problems. Future studies will cope with the current technique's constraints and explore techniques capable of optimization [15].

This study examines the use of micro-Doppler spectrogram signatures of flying gadgets, like drones and birds, to help their remote identity. A 10-GHz non-stop wave radar device was custom-designed to accumulate

measurements from numerous situations regarding distinct goals, which were then used to generate datasets for photo type. Time/pace spectrograms created for micro-Doppler evaluation of various drones and birds were utilized for target reputation and movement categorization with TensorFlow. The consequences indicated that aid vector machines (SVMs) did an accuracy of approximately 90% for drone length classification, around 96% for distinguishing between drones and birds, and more or less 85% for differentiating between individual drones and birds throughout five training. Various aspects of target detection were investigated, such as the terrain and actions of the target [16].

This study uses Long Short-Term Memory (LSTM) networks to explore a novel drone classifier. The classification time of a drone detection radar is crucial for its effectiveness as a real-time surveillance system. This work aims to create a classification framework with minimal latency for processing algorithm input data. Theoretical modeling was conducted on a rotary wing drone and a bird wing flapping to demonstrate the contrast in the patterns of their phase progressions. Subsequently, a dataset of 1D phase data was generated for supervised learning by utilizing 94 GHz experimental trial data consisting of 4800 sequences of drones, birds, noise, and clutter. A stacked LSTM network with optimized hyperparameters was created to mitigate potential overfitting compared to a basic LSTM model. An accuracy of 98.1% was achieved in validating the 2-class classification of drone and non-drone. The network successfully classified all sequences in a performance assessment using 30 unseen test data. This method has been determined to be approximately 10 times faster than a spectrogram-based classification model, as it eliminates the need for additional Fast Fourier Transform (FFT) operations [17].

Classifying multiple drones and birds based on micro-Doppler (MD) signatures is challenging due to potential contamination from multiple bird signatures and the similarity in MD signatures between different drones. This paper introduces three protocols and evaluates their classification accuracy for multiple drones and birds in an actual observation setting. The analysis is based on frequency-modulated continuous wave radar and a convolutional neural network classifier. By utilizing training data that consists of combinations of drone and bird movements in simulations involving rotating blades and flapping wings, our method achieved an accuracy of approximately 100% for majority vote classification. This outcome establishes our process as the most suitable for distinguishing between multiple drones and birds [18].

This paper explores the utilization of micro-Doppler signatures of drones and birds to detect and categorize them. Simulated assessment results are validated with data from a 10-GHz continuous wave (CW) radar system. Time/Velocity spectrograms created for micro-Doppler analysis of various drones and birds are employed for TensorFlow's target recognition and motion categorization. The Support Vector Machine (SVM) achieved 96% accuracy in distinguishing between drones and birds and 85% in distinguishing between individual drones and birds across five classes [19].

In the rapidly changing world of military surveillance, the real-time recognition of Unmanned Aerial Vehicles (UAVs) is emerging as a significant challenge. The classification of small unmanned aerial vehicles (UAVs) based on machine learning models is investigated in this research, as the swift sanction of such identification has prompted the necessity of being able to discriminate between UAVs and non-threatening subjects (e.g. birds, environmental objects) within a variety of constraints of the environment. Using much larger datasets, we tested advanced models, like Neural Networks, Support Vector Machines, ensemble methods, and Random Forest Gradient Boosting Machines. Neural Networks were found as the best, having the highest accuracy and the best performance in times of computational efficiency. Conclusion: This can help improve detection of UAV attacks and suggest optimal resource allocation. They also provide further recommendations regarding incorporating these types of models into military systems that will need to continually be updated to take account of changing capabilities of UAV technology [20].

This paper explores the millimeter-wave radar micro-Doppler characteristics of consumer drones and birds that can be used to differentiate targets by a classifier. The feature extraction methods were created by analyzing the micro-Doppler signature characteristics of in-flight targets detected using a frequency-modulated continuous wave (FMCW) radar. Three distinct drones (DJI Phantom 3 Standard, DJI Inspire 1, and DJI S900) and four birds of varying sizes (Northern Hawk Owl, Harris Hawk, Indian Eagle Owl, and Tawny Eagle) were utilized for feature extraction and classification. The data for all the targets was collected using a stationary W-band (94 GHz) FMCW radar. The extracted features were input into two distinct classifiers for training: linear discriminant and support vector machine (SVM). Classifiers utilizing these features can effectively differentiate between drones and birds with 100% accuracy and distinguish between different sizes of drones with over 90% accuracy. The results show that the suggested algorithm is highly appropriate for an automated target recognition method in a functional FMCW radar system for drone detection [21].

Drones are increasingly used for recreation, engineering, disaster management, logistics, and airport security. Despite their practical use, airport physical infrastructure security, safety, and surveillance raise concerns about malicious use. Many airports report unauthorized drone use disrupting airline operations. This study proposes deep learning to distinguish two drone and bird species. The suggested method outperforms literature-based detection systems in an image dataset test. Due to their resemblance in appearance and behavior, drones are often inappropriate for birds. The proposed method detects drones, distinguishes two types, and distinguishes birds. This study trained the network with 10,000 multirotor, helicopter, and bird drone images. As expected, the proposed deep learning method distinguishes drones and birds with 83% accuracy, 84% mAP, and 81% IoU. The average Recall, accuracy, and F1-score for the three classes were 84%, 83%, and 83% [22].

Reconnaissance drones are specifically designed to analyze data and interpret signals they intercept, allowing them to detect and pinpoint radar systems. However, identifying quasi-simultaneous arrival signals (QSAS) has become increasingly challenging in complex electromagnetic environments. To address this issue, we propose a framework for self-supervised deep representation learning. The framework consists of two phases: (1) Training an autoencoder: The ConvNeXt V2 model is trained to extract features from masked time-frequency images, enabling it to learn the unlabeled QSAS representation. The model reconstructs the corresponding signal in both the time and frequency domains. (2) Knowledge transfer: The model transfers the learned knowledge, where the encoder layers are kept fixed for downstream tasks. A linear layer is then fine-tuned to classify QSAS in few-shot scenarios. Experimental results demonstrate that the proposed algorithm achieves an average recognition accuracy exceeding 81% across a signal-to-noise ratio (SNR) range of -16 to 16 dB. Additionally, the new algorithm reduces testing time by approximately 11-fold and improves accuracy by up to 21.95% compared to existing CNN-based and Transformer-based neural networks [23].

Security cameras in a secure organization or facility transmit live video feeds to the server for security personnel to monitor. Traditional monitoring methods, such as human observation, are ineffective when a drone enters the facility beyond the range detectable by the monitor, which is live-streaming footage. A man can detect a drone at a distance of approximately 400 meters. Garuda's proposed solution utilizes a deep learning architecture trained on a specialized dataset containing visual images of drones and other aerial objects. The proposed model is designed to precisely identify the lines and edges of drones, enabling it to distinguish drones from birds, kites, and planes. The model can track drone movements such as approaching, receding, or moving laterally by analyzing the area covered by the drone in consecutive time intervals and determining the direction based on changes in the area size, indicating approaching or receding situations. Lateral movement is identified by comparing the drone's position coordinates at different intervals. The paper thoroughly compares different deep learning structures using two datasets. A software application has been developed to contain the drone detection model, capable of detecting, managing, and recording such events with a precision of 94.5% [24].

Authors: Michael Nentwich (project leader) and Delila Horvath from the Institute of Technology Assessment in Vienna, 2018. The concept of using drones for delivery is based on certain assumptions. To achieve this, numerous technical and regulatory challenges must be addressed. Given the significant impact on the airspace, previously used primarily by birds and occasionally helicopters, several standard technology assessment (TA) questions arise. Are there any safety concerns? Are there environmental risks? Can the technology be exploited by criminals or terrorists? Are we facing societal conflicts due to divergent interests? Is the current regulatory framework sufficient, or are new regulations needed? The vision of a drone-based delivery system is not without prerequisites. Many regulatory and technical hurdles must be overcome to make it a reality. Due to the significant impact of this technological development—since it will drastically change the airspace we inhabit, which has so far been used primarily by birds and the occasional helicopter, a series of typical technology assessment questions emerge. Are there safety concerns? Are there environmental hazards? Can the technology be misused for criminal or terrorist purposes? Does it hold the potential for societal conflict due to conflicting interests? Is the existing regulatory framework sufficient, or should new regulations be established [25]?

The proliferation of UAVs has rapidly increased in recent years. Drones are being used more frequently in both military and commercial settings. UAVs of different sizes, shapes, and types are utilized for various purposes, from leisure activities to specific missions. This progress has brought about difficulties and has been recognized as a possible cause of operational interruptions resulting in different security issues, such as risks to Critical Infrastructures (CI). Developing fully autonomous Anti-Unmanned Aerial Vehicle Defence Systems (AUDS) is more urgent now than ever. This paper introduces a comprehensive design and operational prototype of drone detection technology that uses Digital Image Processing (DIP) and Machine Learning (ML) to accurately detect, track, and classify drones to reduce or eliminate the threat they pose. The system utilizes a background-subtracted frame difference technique to detect moving objects, in conjunction with a Pan-Tilt tracking system controlled by a Raspberry Pi to track the detected object. Moving items are recognized using a Convolutional Neural Network (CNN) device known as the YOLO v4-tiny ML set of rules. The proposed gadget stands proud because of its precision, efficiency with cheaper sensing gadgets, and advanced overall performance in contrast to different options. Integrating the system with various systems, such as RADAR, may allow for appreciable decoration of detection technology, further simplifying operations. The proposed era was experimentally verified in diverse checks carried out in uncontrolled outside surroundings, demonstrating steady effectiveness in all situations and producing terrific results [26].

Summary A fluorescent sensor with more than one capability, based on coumarin and containing a di-2-picolylamine (DPA) organization (1), is brought. This probe can function as a fluorescent sensor for Co2 and Cu2 in an ON-OFF manner. The generated 1-Co(II) and 1-Cu(II) ensembles can then act as OFF-ON fluorescent sensors to differentiate between Zn2 and Cd2 and selectively locate sulphide anions in water through displacement. Specifically, Cu(II) can pass through the cellular membrane and be utilized for fluorescence imaging of S2− in living biological samples. The fluorescent sensors of the ON-OFF-ON type showed exceptional selectivity and sensitivity toward the objectives [27].

III. METHODOLOGY

A. Dataset Description

Inspecting the "Birds vs. Drone Dataset" on Kaggle, which Harsh Walia contributed. This dataset incorporates two folders that categorize snapshots of birds and drones [28]. These

folders are essential for the author's academic device, as they assist in reading and differentiating between those two topics. The fowl pictures were received via net scraping, whilst the drone pix were obtained from another dataset. The folders incorporate extensive photos that constitute the subjects observed in natural sky backgrounds. These snapshots are essential for teaching the author's version [1]. Fig. 1 shows the process flow diagram.

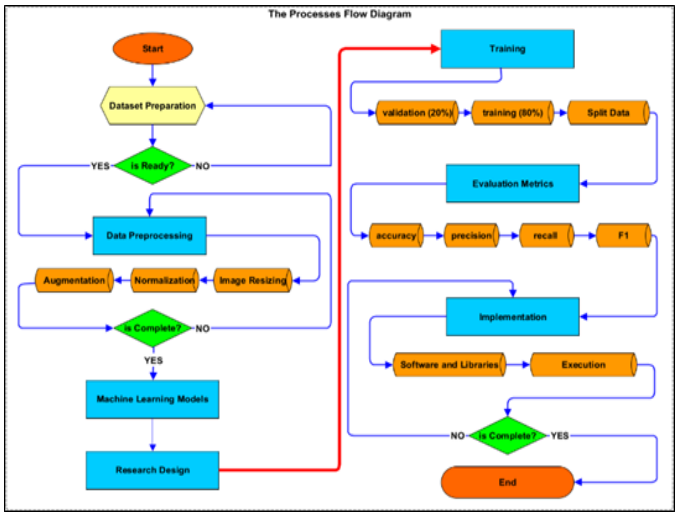

Fig. 1. The process flow diagram [29].

B. Data Preprocessing

Considering the wide range of images in terms of background, orientation, and scale, we implemented the following preprocessing steps to ensure the dataset was standardized for optimal training [29]:

- Image Resizing: To maintain a consistent input size for the neural network, all images were adjusted to a uniform dimension of 224x224 pixels.
- Normalization: The pixel values of each image were adjusted to a range of 0 to 1, which helps to enhance the speed of convergence during the training process.
- Augmentation: To enhance the resilience of our model and avoid overfitting, we implemented image augmentation techniques, including rotation, zoom, and horizontal flipping.

C. Machine Learning Models

Multiple machine learning models were utilized during the evaluation process to analyze their effectiveness in predicting the Bords and Drones Dataset [29]. We used the following models:

1) K-Nearest Neighbors (KNN): KNN is crucial for its simplicity and effectiveness in applications where relationships within the data are distance-based. It's precious in fields like recommendation systems and anomaly detection, where the closest neighbors often share more similarities or properties [30].

2) AdaBoost (Adaptive Boosting): AdaBoost is pivotal for enhancing the performance of weak classifiers, making it essential for scenarios where simple models must be combined to improve accuracy. It's widely used in applications requiring robust performance, such as face detection in images, due to its ability to focus iteratively on challenging cases [31].

3) Constant model: The constant model serves as a fundamental benchmark in machine learning, ensuring that any new model provides a meaningful improvement over the simplest possible approach. Establishing a baseline performance level that other, more sophisticated models must exceed to be considered adequate is crucial [32].

4) CN2 rule induction: CN2 Rule Induction is critical in settings where interpretability is as crucial as prediction accuracy, such as in medical or financial applications. Generate explicit if-then rules, which provide clear insights into decision processes and facilitate understanding and acceptance among users [33].

5) Naive Bayes: Naive Bayes is indispensable in text classification due to its efficiency and scalability, effectively handling large datasets with high-dimensional features. Its feature independence assumption simplifies calculations, making it a go-to method in spam detection and natural language processing [34].

6) Support Vector Machine (SVM): SVM's ability to find the optimal boundary between classes makes it extremely powerful for classification tasks, especially when the classes are well separable. Its application in bioinformatics, image recognition, and other areas where precision is critical underscores its importance. The kernel trick, which allows SVM to adapt to non-linear relationships, further enhances its applicability to a wide range of complex datasets [34].

D. Research Design

The "Birds vs. Drone Dataset," created by Harsh Walia and made publicly available on Kaggle, is used to have a look. This dataset plays a crucial role in the author's investigating device studying-based aerial drone and fowl discrimination. Carefully organized into beautiful folders, it can take snapshots of birds and drones, respectively. The birds' pix were retrieved using an in-depth net scraping approach that changed into, in particular, engineered to capture various bird species in diverse flying positions and settings. This series aims to capture authentic, real-world variability. Contrarily, the drone photos are from an existing dataset and feature a range of drone styles, all set against a sky background. Because of this, you can rest assured that the dataset only shows cases where drones are in the air. Each folder contains a full-size quantity of pictures to train robust machine learning models, offering a broad range of visual records. A strong classifier capable of consistently differentiating among these training data in typical operational contexts requires images that are both varied and of high quality [35-37].

E. Training

1) Configuration: A learning fee scheduler adjusted the model's parameters depending on when the validation loss plateaued; the model's batch size was 32, and the learning rate was 0.001.

2) Environment: Training was carried out on a GPU-enabled system to speed up the computation.

3) Validation split: Splitting the dataset into training (80%) and validation (20%) parts helped identify and prevent overfitting [38-40].

F. Evaluation Metrics

The author's version was tested for overall performance using accuracy, precision, and remember metrics. This version's performance in accurately labeling photos as either birds or drones can be better understood with the help of these metrics [1], [3], [6], [28].

1) AUC (Area Under the Curve): AUC represents the ability of a model to discriminate between positive and negative classes across all possible classification thresholds. Its importance lies in its use as a single measure that summarizes the model's performance in prevalent and rare events. It makes it essential in medical diagnostics and other binary classification tasks where the choice of the decision threshold impacts outcomes significantly.

2) CA (Classification Accuracy): Classification Accuracy measures the overall effectiveness of a model in correctly identifying both positive and negative outcomes. It's a straightforward metric useful in evaluating models where class distributions are balanced, providing a quick snapshot of model efficacy in fields like educational testing and customer satisfaction analysis.

3) F1 Score: The F1 Score balances precision and Recall, which is crucial in scenarios where false positives and negatives have severe implications, such as in legal and financial domains. Its importance stems from providing a more realistic measure of a model's performance when dealing with imbalanced datasets, where the cost of errors can be high.

4) Precision (Prec.): Precision assesses the model's accuracy in predicting positive labels, which is essential in situations where the consequences of false positives are more severe than false negatives, such as in spam detection or during the preliminary stages of drug approval processes, ensuring resources are used efficiently and safely.

5) Recall: Recall is essential when missing a positive occurrence (false negative) is unacceptable, such as in fraud detection or disease screening. It ensures that the most critical cases are identified, even at the expense of making more errors on the negative side (false positives).

6) LogLoss (Logarithmic Loss): LogLoss provides insight into the certainty of a model's predictions, emphasizing the consequences of being wrong, not just whether it is incorrect. This metric is paramount in fields like healthcare and risk assessment, where understanding the probability of outcomes influences decision-making processes significantly, ensuring decisions are informed and minimizing risk.

These metrics collectively provide a comprehensive assessment framework for machine learning models, facilitating informed decision-making in various applications by highlighting aspects of model performance related to the specific costs of prediction errors.

G. Implementation

The model was implemented using Python, utilizing TensorFlow and Keras to construct and train the neural network. Supplementary libraries were utilized alongside NumPy and Matplotlib for data manipulation and visualization. The script was completed through iterative processes, adjusting parameters and configurations based on the performance observed in the validation set.

IV. Results

A. Test and Score Analyses

Test and Score analyses are critical for assessing the generalization abilities of gadget learning models. This is executed by educating them on a selected training set and comparing their performance on a separate trying-out set. This approach evaluates critical metrics like accuracy, precision, consider, F1 score, and place underneath the ROC curve (AUC) to benefit intensive know-how of the model's overall performance in predicting consequences, its capacity to become aware of relevant times efficiently, and its universal accuracy. Performing these analyses is vital for figuring out overfitting, a scenario wherein a version performs well on education records but poorly on new, unseen facts. This lets developers regulate the model to decorate its practicality and resilience through iterative optimization.

1) Test and score analyses for target class birds: Table I compares the performance of various system studying models and the usage of stratified 10-fold pass-validation for classifying “Birds”. Models like kNN, AdaBoost, and CN2 Rule Induction excel with best scores across AUC, CA, F1, Precision, and Recall, indicating their tremendous ability to categorize and differentiate birds as they should be inside the dataset. However, CN2 has a moderate LogLoss, indicating minor prediction uncertainty. The SVM model demonstrates high efficiency with nearly perfect metrics and a very low LogLoss, suggesting effective generalization with minor imperfections. In contrast, Naïve Bayes shows moderate performance with the highest LogLoss, reflecting significant prediction uncertainty. At the same time, the Constant model, used as a baseline, performs poorly, substantiating its inadequacy beyond a control comparison. These results highlight the effectiveness of using advanced models over simpler ones and the critical role of choosing the suitable model based on specific task requirements and dataset characteristics, as shown in Table I and Fig. 2.

TABLE I. THE TEST AND SCORE ANALYSES FOR THE KNN, ADABOOST, CN2, SVM, NAÏVE BAYES, AND CONSTANT MODELS FOR THE TARGET CLASS: BIRDS

Model	AUC	CA	F1	Prec	Recall	LogLoss
kNN	1	1	1	1	1	0
AdaBoost	1	1	1	1	1	0
CN2 Rule Induction	1	1	1	1	1	0.086
SVM	0.998	0.979	0.979	0.969	0.99	0.055
Naïve Bayes	0.884	0.838	0.843	0.808	0.881	5.139
Constant	0.5	0.507	0	0	0	0.693

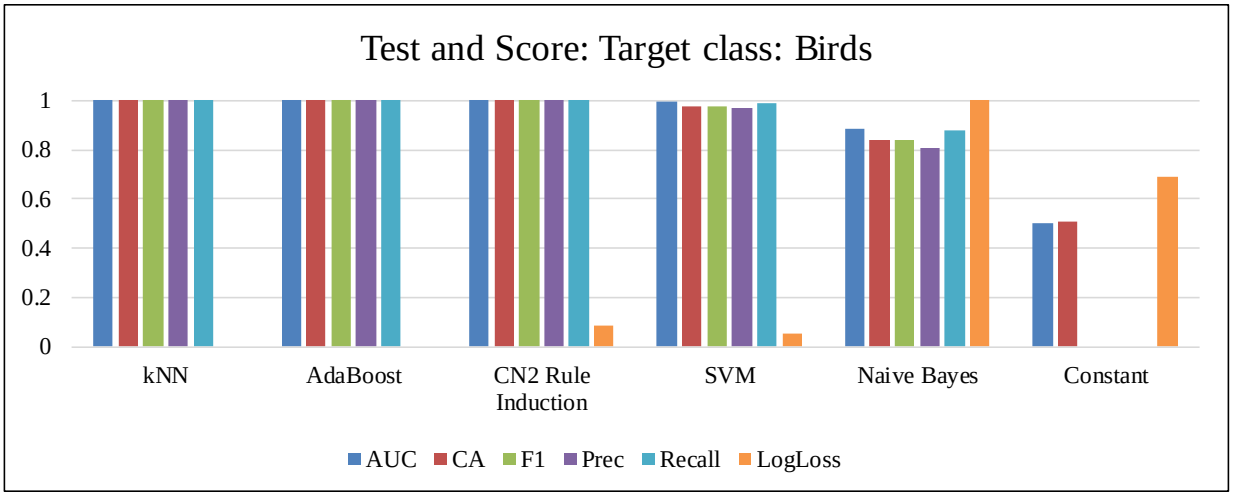

Fig. 2. The test and score analyses for the KNN, AdaBoost, CN2, SVM, Naïve Bayes, and Constant models for the target class: Birds.

2) Test and score analyses for target class drones: Table II provides a comparative performance analysis of several machine learning models for drone classification using stratified 10-fold cross-validation, showcasing a range of outcomes. The kNN, AdaBoost, and CN2 Rule Induction models excel with perfect scores across all metrics (AUC, CA, F1, Precision, Recall), indicating flawless classification abilities. However, CN2 has a slight LogLoss of 0.086, suggesting minimal uncertainty. The SVM model also performs robustly with nearly perfect metrics and a low LogLoss of 0.055, signaling strong but not absolute precision. In contrast, Naive Bayes shows moderate effectiveness with an AUC of 0.868 and significant prediction uncertainty (LogLoss of 5.139), reflecting its limitations in reliability for this task. The Constant model, used as a baseline, predictably underperforms with the lowest scores except in Recall, where it identifies all instances as drones, leading to many false positives. This analysis highlights the superiority of kNN, AdaBoost, and CN2 for drone detection in terms of accuracy and reliability compared to the other models, as shown in Table II and Fig. 3.

TABLE II. THE TEST AND SCORE ANALYSES FOR THE KNN, ADABOOST, CN2, SVM, NAÏVE BAYES, AND CONSTANT MODELS FOR THE TARGET CLASS: DRONES

Model	AUC	CA	F1	Prec	Recall	LogLoss
kNN	1	1	1	1	1	0
AdaBoost	1	1	1	1	1	0
CN2 Rule Induction	1	1	1	1	1	0.086
SVM	0.998	0.979	0.979	0.99	0.969	0.055
Naive Bayes	0.868	0.838	0.833	0.873	0.796	5.139
Constant	0.5	0.507	0.673	0.507	1	0.693

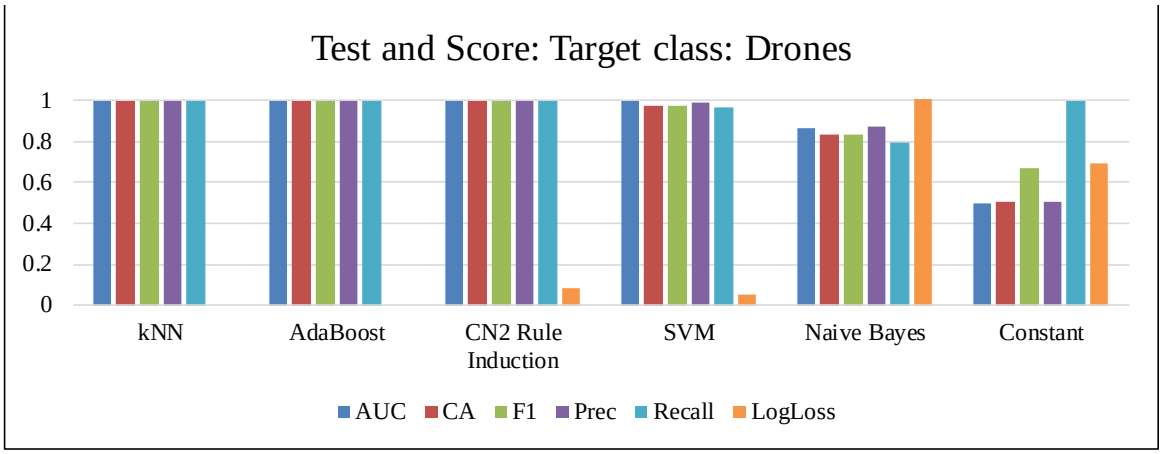

Fig. 3. The test and score analyses for the KNN, AdaBoost, CN2, SVM, Naïve Bayes, and Constant models for the target class: Drones.

3) Test and score analyses for the average performance over all target classes: Table III provides performance metrics for several machine learning models evaluated through stratified 10-fold cross-validation across various classes, revealing distinct levels of effectiveness. The kNN, AdaBoost, and CN2 Rule Induction models excel with perfect scores across all metrics (AUC, CA, F1, Precision, Recall), suggesting flawless classification capabilities; CN2 Rule Induction shows a negligible LogLoss of 0.086, indicating minimal uncertainty. The SVM model also performs exceptionally with nearly perfect metrics and a low LogLoss of 0.055, demonstrating high accuracy and confidence in predictions. In contrast, the Naive Bayes model shows moderate performance with lower scores and a high LogLoss of 5.139, indicating significant predictive uncertainty. The Constant model, used primarily as a baseline, exhibits poor effectiveness with the lowest scores across most metrics, substantiating its limited utility beyond providing a comparative benchmark. This analysis underscores the superiority of kNN, AdaBoost, CN2 Rule Induction, and SVM in achieving reliable and accurate class predictions across diverse datasets, as shown in Table III and Fig. 4.

TABLE III. THE TEST AND SCORE ANALYSES FOR THE TARGET CLASS: AVERAGE OVER CLASSES FOR THE KNN, ADABOOST, CN2, SVM, NAÏVE BAYES, AND CONSTANT MODELS

Model	AUC	CA	F1	Prec	Recall	LogLoss
kNN	1	1	1	1	1	0
AdaBoost	1	1	1	1	1	0
CN2 Rule Induction	1	1	1	1	1	0.086
SVM	0.998	0.979	0.979	0.98	0.979	0.055
Naive Bayes	0.868	0.838	0.838	0.841	0.838	5.139
Constant	0.5	0.507	0.341	0.257	0.507	0.693

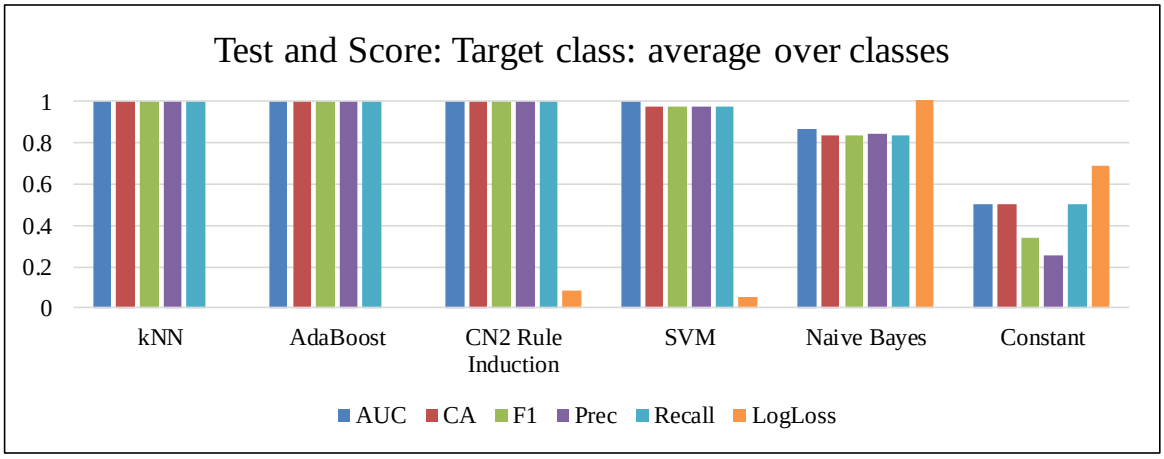

Fig. 4. The test and score analyses for the KNN, AdaBoost, CN2, SVM, Naïve Bayes, and Constant models for the target class: Average over classes.

B. Confusion Matrix Analyses

Confusion Matrix Analyses provide a complete evaluation of a classification version's overall performance by presenting the counts of real positives, real negatives, false positives, and fake negatives in a matrix format. This analysis helps to visualize the accuracy of a version in predicting one-of-a-kind lessons, taking into consideration a more profound expertise of its predictive competencies and weaknesses. The most critical diagonal of the matrix indicates the range of accurate predictions, even as the off-diagonal elements imply the errors. Key derived metrics such as precision (the accuracy of superb predictions), remember (the version's capacity to discover all the excellent samples), and F1-rating (a harmonic implication of precision and remember) can be calculated from the confusion matrix. These metrics are crucial for diagnosing the overall performance of a model past easy accuracy, particularly in cases in which training is imbalanced, assisting in picking out whether a model is biased toward one magnificence and offering insights necessary for further refining the version's parameters.

Table IV confusion matrix showcases the performance of various machine learning models in classifying entities into two categories: Birds and Drones. kNN, AdaBoost, and CN2 Rule Induction excel with perfect classification accuracy, correctly identifying all Birds and Drones without misclassifications, achieving 100% precision, Recall, and accuracy. In stark contrast, the Constant model, used as a baseline, misclassifies all instances, highlighting its inadequacy for practical use with a recall of 1 for Drones due to predicting everything as Drones and a very low precision. Naive Bayes and SVM show moderate to high performance, with Naive Bayes misclassifying many birds and drones. SVM makes a few errors but still maintains high accuracy overall. These results indicate that while kNN, AdaBoost, and CN2 Rule Induction are highly effective for this task, Naive Bayes and SVM, although robust, exhibit potential areas for improvement in classification accuracy, as shown in Table IV and Fig. 5.

TABLE IV. THE CONFUSION MATRIX ANALYSES FOR THE MODELS KNN, ADABOOST, CN2, SVM, NAÏVE BAYES, AND CONSTANT

			Predicted	
			Birds	**Drones**
Actual	KNN	Birds	286	0
		Drones	0	294
	AdaBoost	Birds	286	0
		Drones	0	294
	Constant	Birds	0	286
		Drones	0	294
	CN2 Rule Induction	Birds	286	0
		Drones	0	294
	Naive Bayes	Birds	252	34
		Drones	60	234
	SVM	Birds	283	3
		Drones	9	285

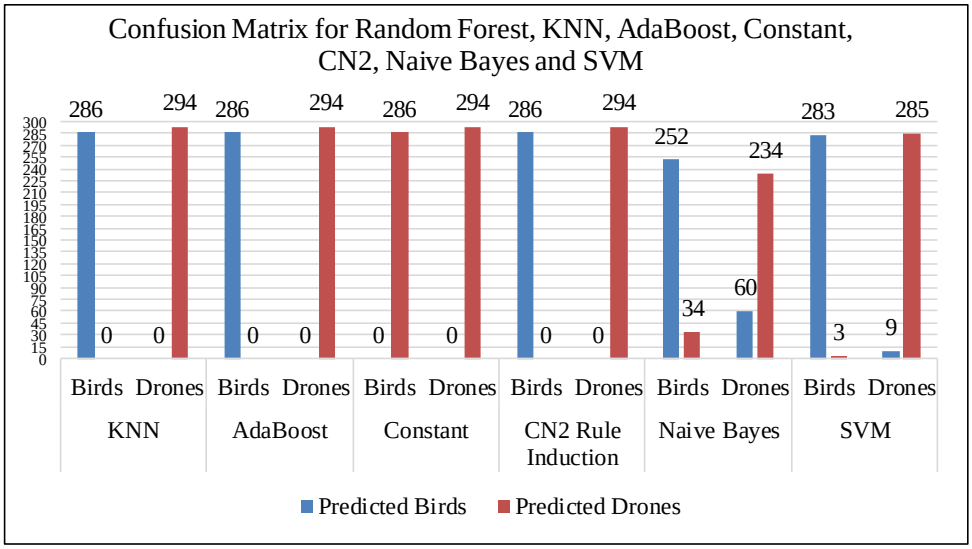

Fig. 5. The confusion matrix analyses of the KNN, AdaBoost, CN2, SVM, Naïve Bayes, and Constant models for the target class: Birds and drones.

C. ROC Analyses

ROC analysis is a statistical method utilized in educational discussions to assess the diagnostic performance of binary classifiers. An ROC curve is a graph that shows how properly a classifier performs by evaluating the True Positive Rate (TPR) with the False Positive Rate (FPR) at one of a kind threshold degrees without considering class distribution or error rates. The location under the ROC curve (AUC) is a metric that quantifies a classifier's potential to differentiate between two instructions, with a better AUC indicating better performance. ROC assessment is highly precious for assessing overall performance across all types of thresholds, presenting an independent degree of impartiality regarding precise decision criteria. This analytical device is essential for comparing exclusive classifiers, supplying a clean visualization of their strengths and weaknesses in numerous operational eventualities. It is a fundamental component in the discipline of gadgets getting to know for developing fashions with better choice-making competencies.

1) ROC analyses for target class birds: The ROC (Receiver Operating Characteristic) curve evaluation within the Fig. 6 evaluates several systems, getting to know models for classifying "Birds," highlighting their performance underneath situations where false positives and false negatives are equally costly. The kNN and AdaBoost models showcase superior performance, with their ROC curves nearing the top left corner, indicating first-rate sensitivity and minimum fake fantastic charges, which are ideal for precision-crucial applications. CN2 Rule Induction additionally indicates brilliant effects, closely matching the primary fashions, suggesting its effectiveness in complicated sample reputation. Although slightly below the top performers, the SVM model maintains robust discrimination capabilities. In contrast, Naive Bayes displays moderate performance with a noticeable distance from the ideal curve, indicating potential issues with precision in distinguishing similar classes. The Constant model, represented by the diagonal line, serves as a baseline, performing at a chance level, thereby underscoring the advanced discriminative power of the specialized algorithms compared to a non-discriminative approach.

2) ROC analyses for target class drones: As shown in Fig. 7, the ROC curve analysis for drone classification reveals that the kNN and AdaBoost models exhibit exceptional performance, with their curves closely approaching the top left corner, indicative of high sensitivity and minimal false positives, making them highly effective for applications where precision is paramount due to high costs associated with misclassifications. CN2 Rule Induction also demonstrates robust capabilities, with its curve nearly matching the leaders, indicating its suitability for complex pattern recognition tasks. In contrast, the SVM model, though showing good performance, has a slightly less optimal curve, suggesting a few more false positives under certain thresholds. Naive Bayes significantly underperform relative to other models, as its curve is closer to the diagonal, indicating a higher rate of false positives, which may not be ideal in high-stakes scenarios. The Constant model, aligning with the diagonal, serves as a non-discriminative baseline, highlighting the necessity and effectiveness of the more sophisticated models in accurately classifying drones to avoid costly errors.

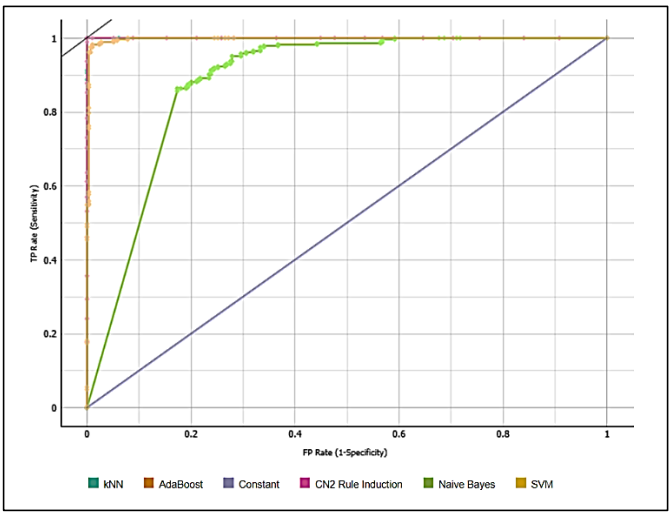

Fig. 6. The ROC Analyses for the KNN, AdaBoost, CN2, SVM, Naïve Bayes, and Constant models for the target class: Birds.

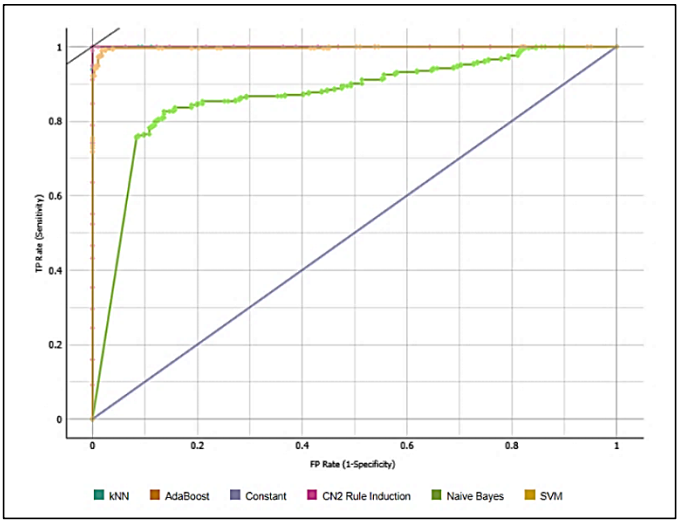

Fig. 7. The ROC analyses for the KNN, AdaBoost, CN2, SVM, Naïve Bayes, and Constant Models for the target class: Drones.

V. Discussion

The "Discussion" section of the item titled "Advances in AI-Based Classification: Differentiating between Unmanned Aerial Vehicles and Birds in Flight" centers on evaluating the realistic implications, demanding situations, and future guidelines advised via the study's findings. The look at, through its rigorous assessment of various system learning fashions, which include kNN, AdaBoost, CN2 Rule Induction, and SVM, demonstrates their effectiveness in as it should be distinguishing UAVs from birds—a critical functionality for enhancing safety features in each military and civilian domain names.

This discussion emphasizes the precision with which these fashions operate, highlighting their capability to reduce false positives and negatives seriously. Such accuracy is vital in real-time safety contexts where the value of errors is exceedingly excessive. It also addresses the combination challenges of those advanced algorithms in present surveillance frameworks. The adaptability of these fashions across exceptional environmental situations is vital, as well as factors like variable lighting fixtures, weather adjustments, and diverse landscapes that might affect detection accuracy.

Moreover, the dialogue explores the computational efficiency of those algorithms, noting the significance of processing speed for real-time applications and the ability for further optimization to deal with larger, more complicated datasets without compromising performance. There is also an acknowledgment of the need for ongoing development to keep pace with the evolving abilities of UAV technology and the corresponding security requirements.

Ethical concerns form an essential part of the discourse, mainly the stability among protection enhancements and the capability for infringement on privacy rights. The deployment of such technology must be managed cautiously to avoid abuse that might cause massive societal and moral dilemmas.

The phase concludes by proposing future research guidelines. It indicates exploring hybrid models that could combine the strengths of numerous present approaches to enhance accuracy and performance. Additionally, there is a call for empirical checking out those models in operational situations to validate their effectiveness in international situations and to refine their talents primarily based on stay facts.

Overall, this discussion synthesizes the study's contributions to the field of airspace security but also outlines a roadmap for destiny technological and strategic improvements in UAV detection and classification, ensuring that safety features evolve in tandem with rising aerial threats.

VI. Conclusion

The study titled "Skywatch: Advanced Machine Learning Techniques for Distinguishing UAVs from Birds in Airspace Security" represents a significant advancement in the application of machine learning for enhancing airspace security. By employing a variety of advanced algorithms, including kNN, AdaBoost, CN2 Rule Induction, and SVM, the research has demonstrated high accuracy in differentiating UAVs from birds, which is crucial for both military operations and civilian airspace protection.

The results indicate that these models achieve a high level of accuracy and effectively reduce false positives and negatives—key factors in real-time surveillance and threat detection. This capability ensures rapid and reliable responses in dynamic and potentially adversarial environments. Furthermore, the integration of these machine learning models into existing surveillance systems has proven to significantly enhance national security measures.

However, the study also acknowledges certain limitations. First, while the machine learning models demonstrated strong performance, the evolving sophistication of UAV technologies presents a continuous challenge. Future UAVs may exhibit more complex flight behaviors and features, potentially reducing the efficacy of the current models. Thus, there is a need for ongoing refinement and adaptation of these algorithms to keep pace with advancements in UAV technology. Second, the environmental diversity in real-world scenarios poses a limitation. The models were tested under controlled or simulated conditions, and their performance may vary when exposed to a wider range of environmental factors, such as extreme weather, varying light conditions, and densely populated areas. Further testing in diverse, real-world settings is essential to fully validate the practical applicability of these systems.

Additionally, the study highlights ethical and privacy concerns related to the deployment of UAV detection systems in civilian contexts. The potential misuse of these technologies underscores the importance of establishing clear regulatory frameworks to ensure responsible and transparent usage.

Looking forward, the research suggests exploring hybrid machine learning models that combine the strengths of various algorithms to achieve even greater accuracy and efficiency. Testing these models in real-world scenarios will be crucial for refining their capabilities and ensuring their practical deployment.

In conclusion, this study offers significant contributions to the fields of machine learning and security technology, providing valuable insights and practical solutions for improving airspace security in an era where UAV technology is rapidly advancing. The findings not only enhance current security protocols but also pave the way for future innovations in aerial threat detection and management.

VII. Future Work and Improvements

While this study has made significant advancements in distinguishing UAVs from birds using machine learning algorithms, there are several areas that warrant further investigation to enhance the robustness and applicability of the models.

1) Addressing model scalability and complexity: One major limitation is the scalability of the models in increasingly complex environments. As UAV technologies continue to evolve, particularly with the introduction of more sophisticated designs and swarming behaviors, the current models may struggle to accurately classify these newer types. Future research should focus on developing more scalable algorithms that can adapt to new types of UAVs and handle increasingly complex data inputs. This may involve the exploration of hybrid models or deep learning techniques that can capture more nuanced patterns in flight behavior.

2) Environmental adaptability: Another area for improvement lies in enhancing the adaptability of these models to diverse and unpredictable environmental conditions. While the current study evaluated the models under controlled conditions, real-world environments often present challenges such as adverse weather, poor lighting, and background clutter

that could affect detection accuracy. Further work is needed to test and refine the models in a broader range of real-world scenarios. Techniques such as transfer learning and domain adaptation could be explored to make the models more resilient across different environmental conditions.

3) Integration with multi-sensor data: Future research could also explore the integration of multi-sensor data to enhance detection accuracy. Combining optical imagery with other forms of data, such as radar or infrared signals, could provide a more comprehensive input for the models, helping to distinguish UAVs from birds with even greater precision. Investigating how to optimally fuse data from multiple sensors in real time would be a valuable next step.

4) Real-time performance enhancements: While this study demonstrates the feasibility of real-time UAV detection, there is still room for improving the speed and computational efficiency of the models, particularly in high-stakes environments. Real-time systems require low-latency performance, which may necessitate further algorithmic optimizations or the use of specialized hardware such as GPUs or edge computing devices to ensure faster processing times without sacrificing accuracy.

5) Mitigating ethical and privacy concerns: Ethical and privacy concerns regarding the use of UAV detection systems in civilian settings remain an important topic for future research. There is a need for guidelines and frameworks that govern the deployment of these technologies to avoid misuse and ensure transparency. Future work should also address how these systems can be designed to respect privacy while still providing the necessary security benefits.

6) Long-term model maintenance and adaptability: Machine learning models must be regularly updated to maintain their effectiveness as the nature of threats evolves. This study does not delve into long-term maintenance strategies for the algorithms. Developing methods for automatic retraining of the models with new data, without compromising their performance, will be essential to ensure continued effectiveness in rapidly changing operational contexts.

7) Potential for cross-domain applications: Beyond military and civilian airspace security, the techniques developed in this study could be adapted for other domains such as environmental monitoring, wildlife protection, or even urban management systems. Future work should explore the feasibility of transferring these models to other fields where UAVs or flying objects are involved, potentially opening up new applications for the technology.

By addressing these limitations and pursuing these future directions, this research can evolve to become a more comprehensive solution, capable of adapting to the complexities of real-world scenarios while balancing the technological and ethical challenges of UAV detection.

Design and Research of Artwork Interactive Exhibition System Based on Multi-Source Data Analysis and Augmented Reality Technology

Xiao Chen*, Qibin Wang
School of Animation and Game, Hangzhou Vocational and Technical College, Hangzhou 310000, China

***Abstract*—The current system has problems such as low efficiency of data processing, lack of smooth user experience and poor combination of display content and interactive technology, etc. There is a pressing need to optimize the integration of data analysis and augmented reality technology to improve the interactivity and visual appeal of exhibitions. This paper introduces and validates a combined prediction model based on multi-source data from the Internet. When using speeded-up robust features (SURF)-64 with a threshold of 500, the number of feature matches is 800, and the matching time is 162.85 ms. At a threshold of 1000, the number of matches drops to 510, and the time decreases to 96.54 ms. For SURF-128, the corresponding matches were 763 and 496, with times of 208.63 ms and 134.21 ms. This indicates that increasing the threshold not only reduces the number of matches but also shortens the matching time, likely due to fewer feature points simplifying the matching process.**

***Keywords*—Multi-source data; feature analysis; augmented reality technology; artwork interactive exhibition system; prediction model**

I. INTRODUCTION

With the popularization of the Internet and the leap of technology, the power of art information dissemination has been significantly enhanced, crossing the boundaries of time and space and widely reaching the public. The integration of digital media has given birth to new art forms, making art everywhere and profoundly affecting life [1, 2]. Artistic creation and technology are deeply integrated, computer technology and digital media have broadened the territory of art, traditional art has been revived under digital empowerment, and its forms of expression are more prosperous and more diverse [3]. Current AR systems in art galleries often focus on enhancing visitor engagement through virtual content, but they typically suffer from limitations such as poor integration of real-world and virtual objects, inadequate feature matching, and limited interactivity. For instance, many systems use basic tracking technologies or simplistic feature extraction methods, which result in a disjointed user experience and less precise placement of virtual elements. Several existing studies have addressed these issues by introducing advanced tracking algorithms and feature extraction techniques, but challenges like real-time performance and seamless interaction between users and virtual content persist. Furthermore, some AR applications still lack immersive interactivity, offering only passive viewing experiences rather than engaging users actively in the artistic exploration process. Our system significantly improves on these limitations by utilizing multi-source data analysis and advanced feature extraction algorithms, such as SURF-64 and SURF-128, which enable more precise object detection, quicker feature matching, and smoother integration of virtual objects into real-world environments [4, 5]. In today's information-driven era, new innovations continuously emerge, and artistic expressions and aesthetic standards are constantly evolving. People's appreciation for the aesthetics of science and technology has become mainstream, as seen in their acceptance and love for new art forms, which also influence our understanding of traditional art [6, 7]. The spread of digital technology has broadened our aesthetic perspectives, encouraging artists to explore new forms of expression and ideas that align with and lead this evolving aesthetic trend [8, 9]. One notable shift is the enhancement of artistic interactivity and participation. Digital technology allows new art forms to be more open and interactive, contrasting with traditional art's one-sided dynamic where artists create and viewers merely observe. In digital art, the audience actively participates in the creative process [10]. AR has revolutionized the way people engage with digital content, particularly in areas like art and culture, by merging real and virtual worlds. AR enables audiences to experience artworks interactively, bringing new dimensions to traditional art forms and making exhibitions more immersive and engaging. However, a critical challenge in AR-based exhibitions lies in ensuring the seamless integration of virtual objects into real environments. Accurate tracking of user movements, efficient processing of environmental data, and the synchronization of multiple data sources are key to creating a cohesive and meaningful interactive experience. Multi-source data analysis plays a crucial role here, as it aggregates information from various sensors, cameras, and user interactions to build a comprehensive understanding of the exhibition space. The proposed combined prediction model addresses these challenges by optimizing the system's ability to anticipate user actions and adjust the virtual content accordingly. This predictive capability enhances the responsiveness of the system, improving the overall interaction quality and ensuring that the AR elements are appropriately aligned with the real world.

The influence of digital technology on art is profound and wide-ranging. From the dissemination of information to changes in the creative process and the renewal of aesthetics, art is becoming deeply integrated into everyday life, serving as a vital link between science, technology, and culture. As technology advances, art will continue to grow in diversity and complexity [11, 12]. Augmented reality technology combines the real and virtual worlds to create immersive 3D experiences, allowing

users to interact intuitively and enjoy new sensory experiences. This interdisciplinary technology integrates tracking, interaction, graphics, and multimedia to enhance system performance, enabling a seamless fusion of the virtual and natural worlds, making users feel as though they are in a blended reality [13, 14]. In augmented reality systems, tracking technology is crucial. It enables the system to accurately capture the user's perspective and position, thereby adjusting the position and display angle of virtual objects in the real world in real-time [15, 16]. AR has revolutionized the way people engage with digital content, particularly in areas like art and culture, by merging real and virtual worlds. AR enables audiences to experience artworks interactively, bringing new dimensions to traditional art forms and making exhibitions more immersive and engaging. A critical challenge in AR-based exhibitions lies in ensuring the seamless integration of virtual objects into real environments. Accurate tracking of user movements, efficient processing of environmental data, and the synchronization of multiple data sources are key to creating a cohesive and meaningful interactive experience. Multi-source data analysis plays a crucial role here, as it aggregates information from various sensors, cameras, and user interactions to build a comprehensive understanding of the exhibition space. The proposed combined prediction model addresses these challenges by optimizing the system's ability to anticipate user actions and adjust the virtual content accordingly. This predictive capability enhances the responsiveness of the system, improving the overall interaction quality and ensuring that the AR elements are appropriately aligned with the real world [17, 18].

II. Key Technologies of Art Interaction System

A. Augmented Reality Tracking Registration Technology

Tracking registration technology is the core of augmented reality. It is widely used to track the dynamics of people and objects in real time and integrate with virtual data to ensure that virtual information is accurately superimposed on real scenes and achieve seamless integration of virtual and real. As shown in Eq. (1) and Eq. (2), these equations define the parameters of feature points used in tracking and registration. Pi represents the position and scale information of the i feature point, where x and y are the coordinates of the feature point in the image, and s is the scale value of the feature point. pt denotes the position at time t, pt−1 is the position at the previous time, v is the velocity, and t1 is the time interval. Its key function lies in precise positioning and dynamic adjustment, so that virtual objects can naturally integrate into reality, presenting highly realistic visual effects both indoors and outdoors.

$$P_i = (x_i, y_i, s_i) \tag{1}$$

$$p_t = p_{t-1} + vt_1 \tag{2}$$

The tracking technology of augmented reality mainly detects objects by various means. As shown in Eq. (3), this equation models the illumination of virtual objects in comparison to real scenes. Ivirtual is the illumination of virtual objects, Ireal is the illumination of real scenes, Iambient is the ambient illumination, and g is the illumination consistency coefficient. These detection means include, but are not limited to, visual tracking, inertial sensors, GPS positioning, and the like. Through these technical means, the augmented reality system can obtain information such as the real-time position, posture and motion state of objects.

$$I_{virtual} = gI_{real} + (1-g)I_{ambient} \tag{3}$$

This transformation not only needs to take into account the three-dimensional spatial position of the object, as shown in Eq. (4), This equation pertains to the consistency of occlusion in augmented reality. Zocclusion is the consistency measure of occlusion, Zreal is the depth value of the real scene, and Zvirtual is the depth value of the virtual object. It is also necessary to combine the motion state of the object and the ambient lighting conditions to ensure that the performance of the virtual object in different scenes can meet the user's expectations.

$$Z_{occlusion} = Z_{real} - Z_{virtual} \tag{4}$$

Tracking technology faces many challenges. First of all, in order to achieve seamless virtual and real fusion, tracking technology needs to have extremely high accuracy and stability. As shown in Eq. (5) and Eq. (6), These equations address the time-sensitive aspects of tracking technology. update is a time interval of real-time update, and fframe is a frame rate. Di is the description vector of the i-th feature point, which contains high-dimensional data describing the local features of the feature point. This means that the system must be able to update the position and pose information of the object in real time within the millisecond level, ensuring that the position of the virtual object in the user's field of view is always consistent with the reference object in the real world.

$$t_{update} = \frac{1}{f_{frame}} \tag{5}$$

$$D_i = \begin{pmatrix} d_{i1} & d_{i2} & \cdots & d_{i16} \end{pmatrix} \tag{6}$$

No delay and no jitter are also important indicators of augmented reality tracking technology. Any tiny delay or jitter will destroy the coordination between the virtual object and the real scene. As shown in Eq. (7) and Eq. (8), these equations focus on the metrics for evaluating feature point matching. Matchi,j is the matching measure of the i-th feature point and the j-th feature point, and b is the standard deviation, which is used to control the width of the Gaussian function. dij is the Euclidean distance between the i-th feature point and the j-th feature point, which is used to measure their similarity. Causing discomfort to the user when using the augmented reality system. Advanced tracking technology often relies on high-performance hardware support and optimized algorithm design to minimize delay and jitter and improve system response speed and stability.

$$Match_{i,j} = exp\left(-\frac{\|D_i - D_j\|^2}{2b^2}\right) \tag{7}$$

$$d_{ij} = \sqrt{(x_i - x_j)^2 + (y_i - y_j)^2} \tag{8}$$

B. Feature Analysis Related Technologies

In image processing and computer vision, feature analysis is very important. As shown in Eq. (9) and Eq. (10), these equations delve into feature point analysis, Thresholdfeature is

the threshold of feature points, N is the total number of feature points, and di is the description measure of each feature point. L(x,y,c) is the image of the scale space, G(x,y,c) is the Gaussian filter, and I(x,y) is the original image. Feature points carry location, scale and high-dimensional description vectors to uniquely identify each point like a "fingerprint".

$$Threshold_{feature} = \frac{1}{N}\sum_{i=1}^{N} d_i \tag{9}$$

$$L(x,y,c) = G(x,y,c) \times I(x,y) \tag{10}$$

High-dimensional description promotes efficient recognition and matching, and supports key tasks such as image registration, stitching, recognition and 3D reconstruction. As shown in Eq. (11) and Eq. (12), These equations describe the characteristics of feature points, Fi is the description vector of the i-th feature point, which contains local information of the feature point, f is the eigenvalue. Ti is the extraction result of the I-th feature point, Extract is the extraction algorithm, and I is the image. Feature point matching is its core, ensuring accurate matching of similar points between images.

$$F_i = \begin{pmatrix} f_{i1} & f_{i2} & \cdots & f_{iN} \end{pmatrix} \tag{11}$$

$$T_i = Extract(I, x_i, y_i, s_i) \tag{12}$$

In the actual operation of feature point matching, how to improve the accuracy and speed of matching is one of the technical difficulties. At present, the popular matching method is to compare the feature points by using the trace of Hessian matrix and Euclidean distance similarity. As shown in Eq. (13), Correcti is the result of correcting the i-th feature point, Align() is the correction function, and Ref is the reference model, T is the time for updating. The Hessian matrix is a second derivative matrix, which can capture the curvature rate information in the image, thus helping to locate feature points more accurately.

$$Correct_i = Align(T_i, Ref) \tag{13}$$

By calculating the trace of the Hessian matrix, we can obtain the change information of the local area around the feature point, and the Euclidean distance is used to measure the similarity between the two feature points. As shown in Eq. (14), this equation highlights the importance of filtering feature points based on similarity metrics. Ffiltered is a filtered feature point, and FilterType is a filter type. When the Euclidean distance between two feature points is smaller, the higher the similarity between them, so it can be considered that the two feature points are matched.

$$F_{filtered} = Filter(F_i, FilterType) \tag{14}$$

This method, which combines the similarity of Hessian matrix and Euclidean distance, not only performs well in the matching accuracy of feature points, but also significantly improves the matching speed. As shown in Eq. (15) and Eq. (16), these equations quantify matching performance. Precisionmatch is the matching accuracy, TP is the true example, and FP is the false positive example. Stabilityfeature is the stability of the feature point, and Variance() is the Variance of the description vector. This is because Hessian matrix provides a more direct curvature information, which makes irrelevant feature points more quickly filtered out in the process of feature point matching, thus reducing the amount of calculation and improving the overall matching efficiency.

$$Precision_{match} = \frac{TP}{TP + FP} \tag{15}$$

$$Stability_{feature} = Variance(D_i) \tag{16}$$

III. Interactive System Under Multi-Source Data Fusion and Analysis Technology

A. AR-Based Interaction Design and Optimization

AR technology has become popular with the development of computers and multimedia, and its core lies in the integration of virtual and honest, which promotes the interaction between users' reality and virtual reality. Optimizing interaction design is the key. It is necessary to pay attention to user experience and pursue intuitive and natural interaction [19]. Natural behaviors such as postures, expressions, and voices have become a trend to manipulate virtual objects, which are more humane than touch screens and handles and enhance convenience and immersion. Using human postures and gestures to interact with virtual objects is one of the most natural and intuitive ways at present [20, 21]. In this interactive mode, it is first necessary to monitor the user's body position and movements in real-time through accurate tracking and registration technology. According to this information, the system will determine the user's position in three-dimensional space and judge his intention by analyzing his actions [22, 23]. According to the preset action definition, the system will associate the user's action with specific operation instructions to realize virtual object control. Optimizing interaction design is particularly critical to make this interaction mode easier for users [24, 25]. The movements are designed to be ergonomic, ensuring that users do not experience discomfort or fatigue while performing them. The association between actions and operations should have precise semantics so that users can intuitively understand and remember them. Users can zoom in or out of virtual objects through simple gestures or close virtual windows by waving their hands. These designs must be finely optimized based on user habits [26, 27]. Table I shows the results of interactive system response test data. Voice interaction is also a natural interaction method widely used in augmented reality.

TABLE I. Results of Interactive System Response Test Data

Test Items	Average time to detect and track new users	User gesture detection average time	Average time of initialization and correction of artwork interaction system	Average time to obtain artwork location
Test Results (ms)	0.62	3.38	276.78	26.58

Through speech recognition technology, the system can recognize the user's voice commands and convert them into operation commands, thus realizing the control of virtual objects. Voice interaction has the advantages of no touch and easy remote operation, and it is especially suitable for scenarios that require multitasking or when hands are inconvenient [28]. "Occlusion consistency" refers to the ability of an AR system to realistically handle the overlapping or covering of virtual and real-world objects. When a virtual object is placed in a scene, it must appear as though it interacts naturally with real-world objects, meaning that parts of the virtual object should be hidden or "occluded" by physical objects if they overlap in space. Maintaining occlusion consistency is critical for enhancing the realism of AR experiences. "Virtual objects" are computer-generated 3D models that are projected into the real-world environment through AR devices, such as headsets or mobile screens. These objects appear as though they exist within the physical space, and users can view and interact with them through the AR system. The seamless integration of virtual objects with the physical world is one of the defining characteristics of effective AR systems. "Feature points" are specific, easily recognizable points within a digital image or physical environment that are used by AR algorithms to map, track, and understand spatial relationships. Fig. 1 is the AR interaction design algorithm's principle and implementation flow chart. After passing the threshold screening, the system performs non-maximum suppression on each remaining feature point. This step ensures that the selected feature point is a prominent feature in its scale space. Fig. 1 demonstrates the AR interaction design algorithm's principle and the step-by-step implementation flowchart. This flowchart is essential as it outlines how the system processes real-time user interactions with virtual objects in an augmented reality environment. It emphasizes key steps, such as detecting and tracking the user's gestures, accurately registering virtual objects in the real world, and ensuring smooth interaction through algorithms that optimize real-time performance.

SURF-64 uses a 64-dimensional descriptor, which makes it faster but less detailed compared to SURF-128, which employs a 128-dimensional descriptor for capturing more information about feature points. In this research, these algorithms were implemented to detect and match distinctive feature points between real-world images and virtual elements. The system extracts feature from images of artwork or the exhibition space, and SURF is used to generate a set of keypoints, such as corners or edges, that are invariant to changes in scale, rotation, or lighting. These algorithms are integrated into the interactive exhibition system by first preprocessing the input data to detect feature points in real-time, followed by the matching of these feature points to align virtual objects with the physical environment. SURF-64 and SURF-128 are configured based on the exhibition's needs, where SURF-64 offers faster computation for real-time tracking, while SURF-128 provides more detailed feature matching when precision is critical. This means that the final position and scale value of feature points can be more accurate than the original pixel grid, thereby improving the accuracy and reliability of feature point matching. Fig. 2 is the architecture diagram of the multi-source data fusion algorithm. Accurate detection and matching of feature points is crucial to the performance of augmented reality systems. Fig. 2 focuses on the multi-source data fusion algorithm architecture, which is critical for integrating diverse data inputs from various sources, such as sensors, images, and spatial data, into a cohesive system.

B. *Feature Extraction of Artworks Based on Machine Learning*

Augmented reality requires realistic modeling of virtual objects, considering shape, material, light and shadow, and environmental interaction. The key challenges are lighting, occlusion consistency, and shadow casting. Lighting consistency is the most important. It is necessary to simulate natural lighting, adjust the lighting effect of virtual objects, and calculate actuarially based on scene geometry and reflection attributes to match natural light sources and enhance visual reality and immersion. Occlusion consistency is another crucial factor involving the mutual occlusion between virtual and natural objects. In the real world, the occlusion relationship between objects is essential for judging the spatial relationship. In augmented reality, virtual objects should have an occlusion relationship with natural objects as if they exist in the same space. Table II shows the test data of the augmented reality natural feature point tracking and registration module of the artwork interactive system. The system must accurately calculate the occlusion relationship between the virtual object and each object in the natural environment and render it in real-time. In this field, Bauhaus University in Germany took the lead in achieving the consistent effect of virtual and real occlusion, which made the occlusion effect of virtual scenes reach a highly realistic level. This technological breakthrough significantly improves the realism of augmented reality systems, allowing virtual objects to be more naturally integrated into actual scenes.

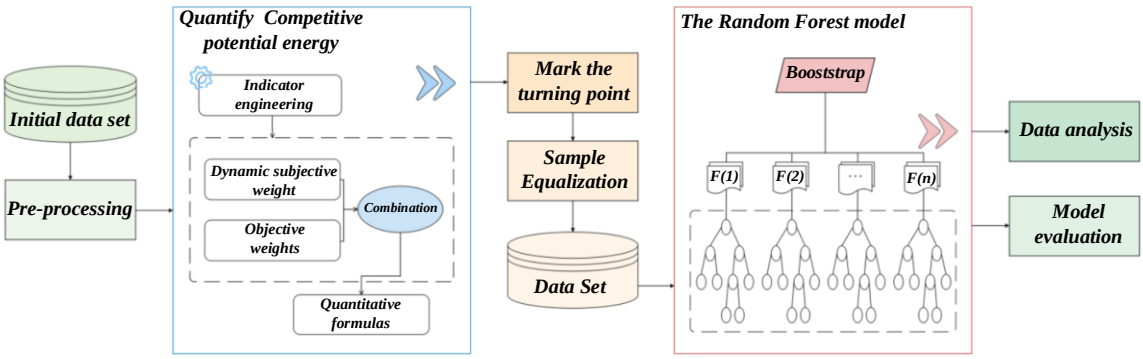

Fig. 1. Principle and implementation flowchart of AR interaction design algorithm.

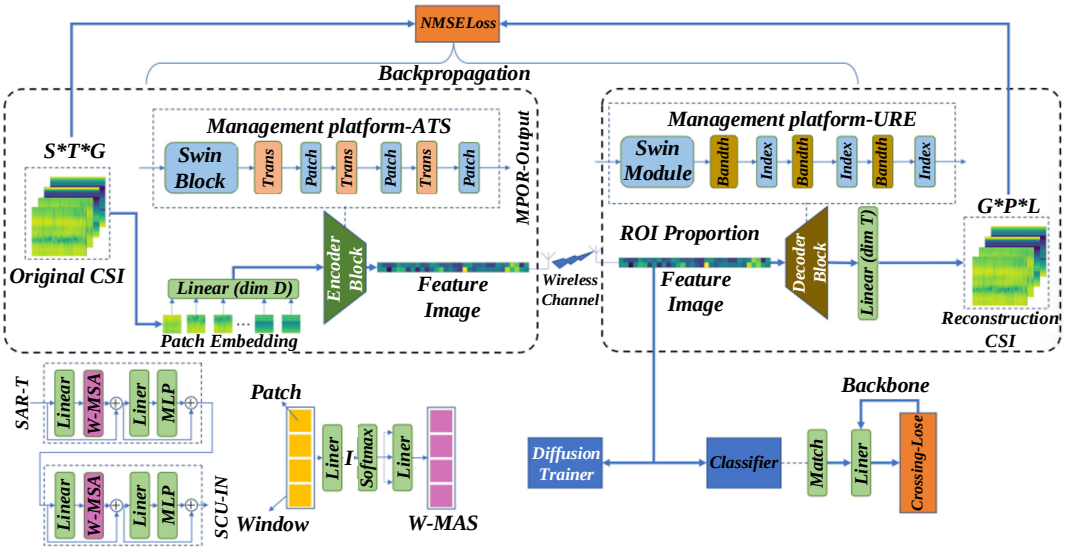

Fig. 2. Architecture diagram of multi-source data fusion algorithm.

TABLE II. TEST DATA OF AUGMENTED REALITY NATURAL FEATURE POINT TRACKING REGISTRATION MODULE OF ARTWORK INTERACTION SYSTEM

Test Items	Run Results
Number of feature points detected	65
Feature point detection time (ms)	75.37
Number of successful feature point matches	27
Number of successful tracking feature points	22
Tracking match time (ms)	13.14
Number of feature points detected after tracking failure	49
Feature point detection time (ms) after tracking failure	61.5

In augmented reality, to keep the shadow of the virtual object consistent with the direction and intensity of the light source in the actual scene, the system needs to accurately calculate the position and intensity of the light source and the geometry of the virtual object. In this way, the shadows of virtual objects can seamlessly blend with shadows in natural scenes, thus further enhancing the realism of augmented reality. Machine learning techniques have been widely used in augmented reality systems to achieve these complex effects. Through machine learning algorithms, the system can automatically learn illumination rules, occlusion relationships, and shadow projection rules from a large amount of accurate scene data, thereby generating more realistic visual effects in augmented reality. This reduces the workload of manual debugging and improves the system's automation level, making augmented reality technology more widely used in various scenarios. In augmented reality and computer vision, feature point extraction and matching are the keys to fusion. Fig. 3 is the application evaluation diagram of a multi-source data fusion algorithm in art information processing, with machine learning assistance, Fast-Hessian quick detection of feature points, and SURF completion description to ensure accuracy and stability. Fast-Hessian efficiently locates scales but lacks direction description; SURF makes up for this shortcoming and provides detailed feature data. The SURF descriptor uses Haar wavelet to extract the direction information of the feature points, thus realizing the rotation invariance of the feature points. In image processing, rotation invariance means that no matter how the image is rotated, the description information of feature points can still be consistent, thus ensuring the matching accuracy of feature points.

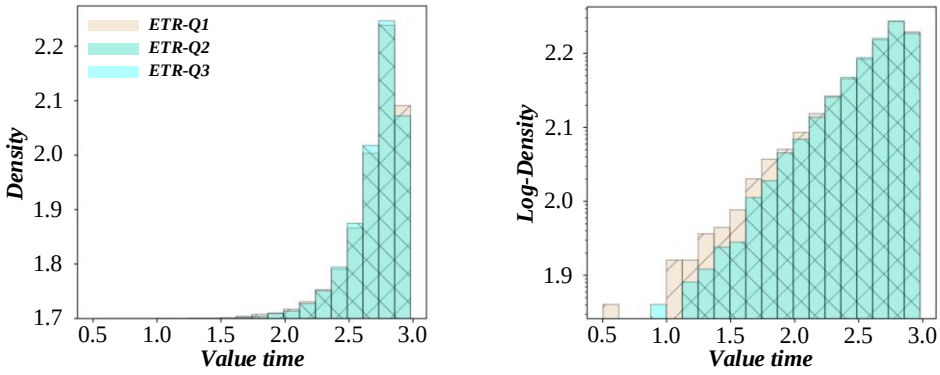

Fig. 3. Application evaluation diagram of multi-source data fusion algorithm in art information processing.

IV. Multi-Source Data Analysis and Analysis Design of Art Interactive Exhibition System Under Augmented Reality Technology

A. Implementation of Augmented Reality Technology in Art Exhibitions

Response time refers to the system's ability to register and process interactions in real-time, ensuring a seamless user experience. In an interactive exhibition, any noticeable lag or delay in responding to user inputs can disrupt the flow and diminish the immersive quality of the experience. Therefore, a faster response time is essential for maintaining engagement and enhancing the system's usability. Feature point detection is crucial for the accurate placement and movement of virtual objects in augmented reality. By increasing the number of detected feature points through algorithms like SURF-64 and SURF-128, the system ensures more precise tracking and overlay of virtual content, providing a more coherent integration of real and virtual elements. This is particularly important in art exhibitions where accuracy in object alignment can directly affect how well users perceive the interaction. User interaction accuracy measures how well the system interprets and responds to gestures, voice commands, or touch inputs, which is vital for creating an intuitive and engaging experience. If the system fails to accurately interpret user inputs, it could lead to frustration and disengagement. System stability ensures that the exhibition runs smoothly without crashes or significant performance degradation, which is critical in public settings. Immersive experience is an overall measure of user satisfaction and engagement, assessing how well the system integrates AR technology to create an engaging and interactive environment. Fig. 4 is an accuracy evaluation diagram of an art style recognition algorithm based on multi-source data analysis. This method has the advantages of high accuracy and fast recognition speed and is especially suitable for complex exhibition environments. Its limitation lies in the need to add additional signage in the exhibition venue, which may affect the aesthetics of the exhibits and the audience experience. Natural feature point tracking technology based on no identification is more flexible and natural.

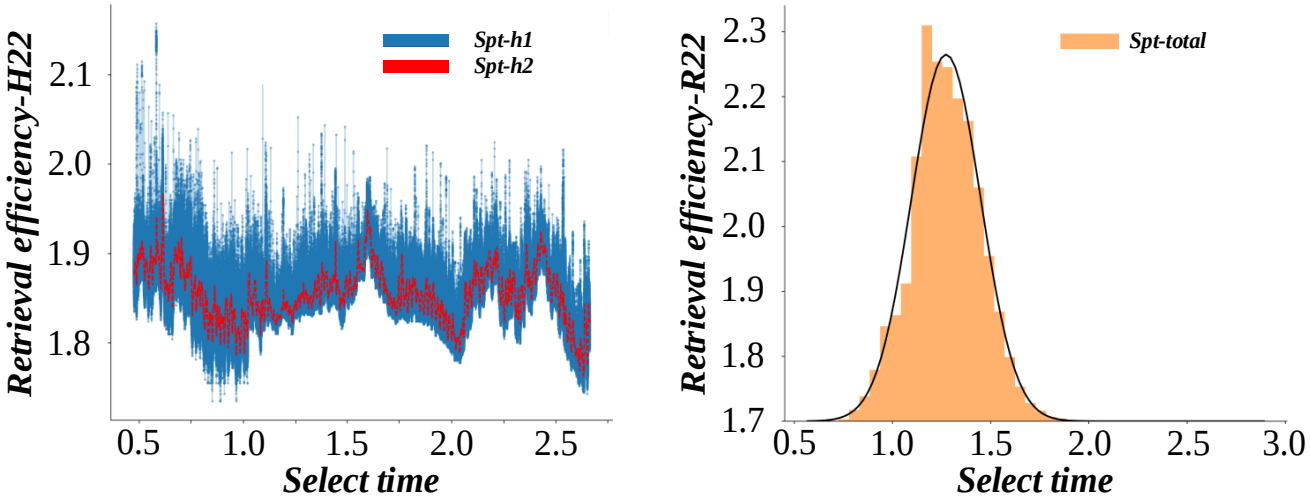

Fig. 4. Accuracy evaluation chart of art style recognition algorithm based on multi-source data analysis.

The application of augmented reality technology in art exhibitions can provide richer information display forms for the audience and enhance the interaction between the audience and the artworks through virtual guides and interactive experiences. When watching a famous painting, the audience can see the creative story behind the painting and the artist's life through augmented reality technology and even interact with virtual artists to gain an in-depth understanding of the connotation of the artwork. This novel exhibition method dramatically enhances the interest and sense of participation, making the audience a passive appreciator and a part of the exhibition. After the direction calculation, the SURF descriptor uses the integral graph to quickly calculate the rectangular area where the feature points are located. The advantage of the integral graph is that it can efficiently calculate the sum of pixels in any rectangular area in the image, which is widely used in fast image processing algorithms. In the feature extraction process of the SURF descriptor, the integral graph is used to define the region of interest, that is, the critical area near the feature points. Fig. 5 is an evaluation diagram of the audience behavior data analysis algorithm for exhibition route optimization. The SURF descriptor can generate detailed feature point description information by calculating the feature vector based on the Haar wavelet in this region of interest. This description information not only contains the location and direction of feature points but also includes rich data about the local structure of feature points, which is very important for the matching and subsequent processing of feature points.

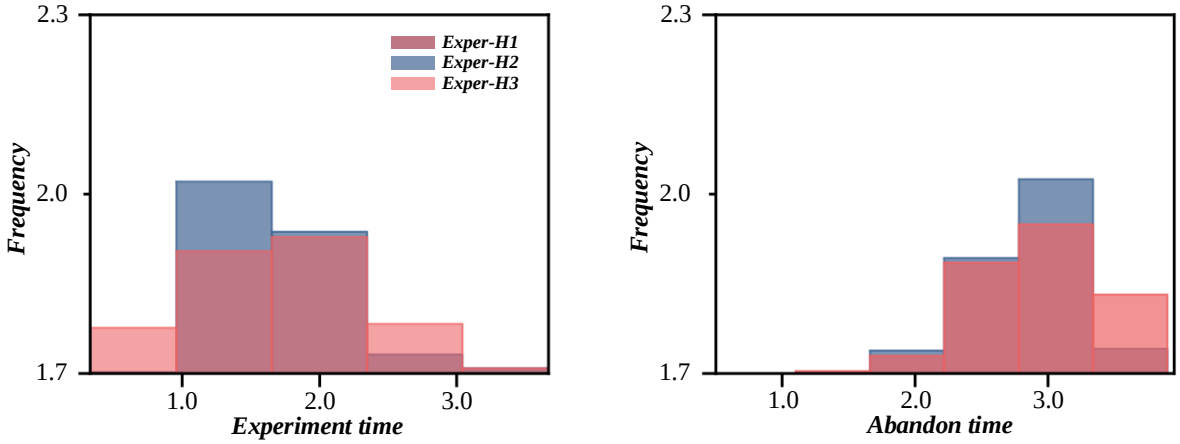

Fig. 5. Evaluation diagram of exhibition route optimization by audience behavior data analysis algorithm.

B. Architecture and Performance Evaluation of Art Interactive Exhibition System

In the interactive art exhibition system, feature point matching affects the overall performance. The SURF algorithm is efficient in recognition, but there are mismatches. Random Sample Consensus (RANSAC) algorithm improves the accuracy by random sampling to eliminate mismatches. First, the model parameters are determined, the samples are randomly selected to calculate the model, and the correct point set is screened according to the geometric distance. To improve the algorithm's accuracy, the RANSAC algorithm will randomly sample multiple times and find the most extensive set of consistent points. These point sets are divided into inner and outer points. This way, the algorithm can effectively screen out the matching points and determine the final model parameters. Finally, these maximum consistent point sets are used to re-estimate the model to output the optimal result. Fig. 6 is the evaluation diagram of the audience behavior data analysis algorithm for optimizing the exhibition route. The RANSAC algorithm shows high efficiency and stability when dealing with feature point matching. It can accurately identify and remove mismatched feature points in complex matching environments, improving the matching accuracy and robustness of the whole system.

The successful application of the RANSAC algorithm can significantly improve the performance of the interactive exhibition system of artworks, making the integration of virtual and reality more natural and realistic. In the architecture of an interactive exhibition system of artworks, accurately matching feature points is the key to realizing the perfect integration of virtual content and artworks. Using the RANSAC algorithm, the system can effectively reduce mismatches and ensure users' interactive experience in the exhibition is smoother and more realistic. Combined with other optimization techniques, such as image preprocessing, feature point enhancement, and multi-view fusion, the system's overall performance can be further improved. The architecture and performance evaluation of interactive art exhibition systems must comprehensively consider feature point detection, matching algorithms, and overall stability. As an efficient mismatch processing technology, the RANSAC algorithm provides strong support for accurate system matching. In the interactive exhibition system of artworks, the brightness of images concentrates on the details. Fig. 7 is an experimental data evaluation diagram of the AR interaction design algorithm to improve the audience's immersion. The histogram averages and stretches the gray distribution, enhances contrast, shows details, and helps subsequent processing, such as binarization. The basic principle of histogram averaging is to map the brightness histogram of the input image into a new histogram so that the brightness value distribution of the new histogram is more uniform.

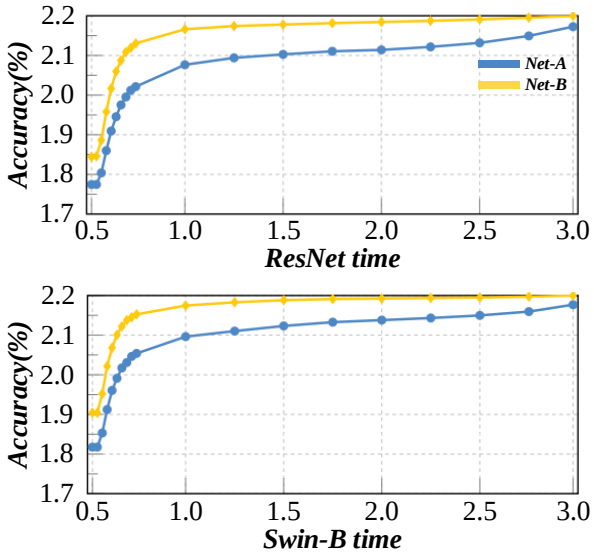

Fig. 6. Evaluation diagram of exhibition route optimization by audience behaviour data analysis algorithm.

Because of the uniformity of gray value distribution, the setting of the binarization threshold is more accurate in the image after the histogram means, thus improving the accuracy and effect of binarization. Histogram averaging often needs to be implemented in combination with specific mapping functions. These mapping functions are used to convert the original gray value of the image into a new gray value to enhance contrast and uniform distribution. Standard mapping functions include linear mapping and nonlinear mapping. By selecting

appropriate mapping functions, the effect of histogram averaging can be adjusted according to specific application requirements and image characteristics. Besides histogram averaging, other aspects of image processing, such as feature point extraction, matching algorithm, and image fusion, must be comprehensively considered to ensure the performance of the interactive exhibition system of works of art. By optimizing and improving these technologies, the system can achieve a more efficient and accurate artwork display and interactive experience. The performance evaluation of the system is also a critical link. Through the comprehensive review of the image processing effect, the stability and performance of the system can be continuously improved to meet the high requirements of users for art exhibitions. Fig. 8 is an evaluation diagram of the accuracy changes of the audience feedback prediction algorithm based on machine learning. Histogram averaging plays an essential role in the interactive exhibition system of artworks. It improves the contrast and detail performance of images and provides a reliable foundation for subsequent binarization processing.

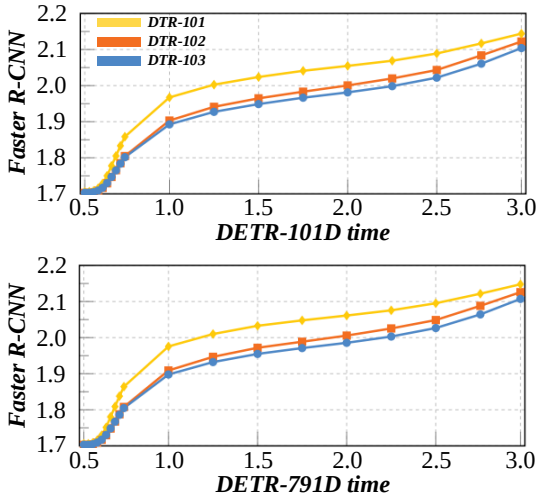

Fig. 7. Experimental data evaluation diagram of AR interaction design algorithm to improve audience immersion.

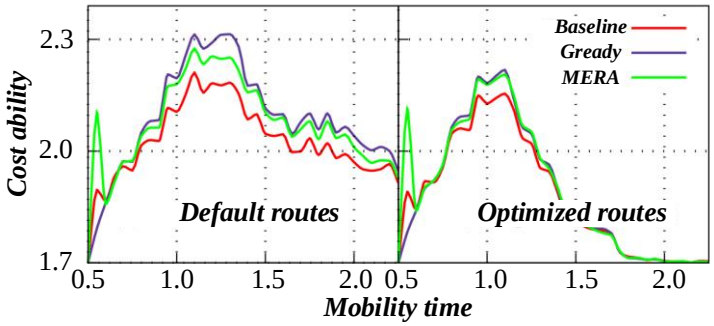

Fig. 8. Accuracy change evaluation diagram of audience feedback prediction algorithm based on machine learning.

V. Experimental Analysis

Finding and matching feature points is incredibly time-consuming when the target image is large. In this case, many feature points may increase the computational complexity and time consumption, which cannot meet the real-time requirements. Especially in real-time application scenarios, such as dynamic scenarios in augmented reality systems, fast processing, and response are required, so finding and matching many feature points may lead to system performance degradation. Fig. 9 is the evaluation diagram of the response time of the system performance evaluation algorithm on the interactive exhibition system of artworks. Although we may find many feature points in the target image, only some of them are feature points that need to be matched.

Some optimization strategies are usually employed. Using more accurate feature point detection algorithms improves the quality of feature points instead of just increasing the number. Through the feature point selection and screening algorithm, the feature points that have the most significant influence on the final calculation result are matched first, thus reducing the interference of irrelevant points. Fig. 10 is an application evaluation diagram of the security policy design algorithm in art data protection, especially in augmented reality systems. It is necessary to determine the quantity and quality of feature points according to specific needs to achieve the best system performance and user experience.

According to the size of the image, it needs to be cropped to reduce the processing amount and improve efficiency. Video dynamics require strategic cropping and efficient matching. The setting of the cropping area also needs to be adjusted according to the actual situation. If the motion in the image is too fast, it may cause the target object or feature point to move out of the cropped area. Fig. 11 is the evaluation diagram before and after improving the AR interactive interface based on the user interface design optimization algorithm. The system must re-detect the entire image to ensure that essential feature points are not missed. Although this scenario increases the computational burden, by clipping within this neighborhood according to the last detected feature point location, the system can reduce the size of the area to be looked up.

The system's performance can be further improved by optimizing the selection of cropping areas. The cropping area can be intelligently adjusted based on the movement trajectory of the target object and the known feature point position in the image, thereby reducing the frequency of re-detection and further improving processing efficiency. The strategy of cropping images significantly impacts the efficiency of augmented reality systems. By setting the cropping area reasonably and reducing the size of the image to be searched, the

speed of feature point extraction and matching can be effectively improved, thus improving the overall running efficiency of the system. Fig. 12 is the application efficiency evaluation diagram of feature extraction and matching algorithm in art image recognition. When dealing with dynamic scenes, it is necessary to consider the motion of target objects to ensure the accuracy and real-time performance of the feature point detection and matching process.

VI. CONCLUSION

This paper focuses on the application of computer vision and augmented reality technologies in artwork interaction systems, where feature point extraction and matching, as a key step in image recognition, significantly improves the accuracy of recognition. Although multi-feature point extraction can increase the accuracy, it is not always necessary because too many feature points may instead lead to a heavier processing burden on the system. In AR applications, feature points not only assist in calculating transformations between images, such as the solution of a single response matrix requires at least four matching points, but increasing the number of feature points does not always bring additional benefits, but may instead increase computational complexity and resource consumption.AR technology, with its powerful interactivity and integration of multi-sensory experiences such as visual and auditory sensations, is gradually revolutionizing the way art is viewed.

In this paper, the consistency of occlusion illumination in virtual object interaction is essential for experience, but the research needs to be stronger and needs a breakthrough in the future. The study focuses on the analysis and prediction of Internet multi-source data characteristics, efficiently integrates data to predict realistic indicators, such as the number of interactive systems of artworks, and verifies it in predicting tourist volume, showing the potential of wide application of the model. One key area for future research is enhancing the precision and responsiveness of the AR system, particularly in terms of improving the real-time interaction between virtual and real-world objects. This could involve exploring more advanced algorithms for feature extraction, tracking, and data fusion, ensuring a seamless integration of virtual objects into the physical exhibition space. Another area worth exploring is optimizing the system's performance under various environmental conditions, such as changes in lighting, user movement, or large crowds. While the current model focuses on integrating multi-source data, future research could investigate how to make the system more adaptable and resilient in these dynamic settings, enhancing its robustness and versatility in different exhibition environments.

This paper studies the multi-source data collection and feature analysis of the Internet. It takes the art interaction system as an example to design a scheme to screen relevant data effectively. Aiming to solve the problem of data clutter, comprehensive index optimization is calculated by keyword screening and calculation. The number of mismatches for SURF-64 is 49 at threshold 500 and 22 at threshold 1000, 11, and 7 for SURF-128 under the same conditions, respectively. This shows that a higher threshold and a more significant dimension can help reduce the number of false matches and improve the matching accuracy.

***Abstract*—Carbon dioxide dense phase injection images have providing new research ideas for differential detection. Aiming at the drawbacks of large data volume, low matching efficiency, and longtime consumption of high-resolution carbon dioxide dense phase injection models, a registration algorithm for carbon dioxide dense phase injection models based on quadratic matching is proposed. This algorithm first uses down sampling to reduce image dimensions. A difference detection algorithm based on weakly supervised deep confidence network is proposed to neural networks, as well as the high manual labeling workload, low efficiency, and insufficient labeled data of high-resolution carbon dioxide dense phase injection models. This article first explores the throttling of CO2 venting in pipelines through the analysis of CO2 phase equilibrium characteristics. The experiment shows that there is after the valve, the greater the temperature drop. At the same time, water content will affect the throttling temperature drop is about 1.5 degrees; when the gas-liquid ratio is 2500, the throttling temperature drop is 7.4 degrees. CO2 in the reactor to over 8MPa, achieving supercritical pressure. CO2 with the constant temperature water bath is 5~100 degrees, with a temperature control accuracy of ± 0.1 degrees. The temperature of the water inside the water bath jacket of the kettle is adjusted through circulation. The maximum pressure of the kettle is 25MPa and the volume is 6L.**

I. INTRODUCTION

According to engineering experience in transporting CO2 through pipelines, the transportation of CO2 in supercritical conditions is the most economical. When transporting supercritical CO2 through pipelines, pipeline safety issues cannot be ignored [1, 2]. The Introduction section will outline the significance of CO2 injection in carbon capture and storage (CCS) and discuss existing challenges such as flow dynamics, phase transitions, and system safety. In the DBN Deep Learning Algorithm section, the structure and functioning of the Deep Belief Network (DBN) will be explained, highlighting how it can automatically extract features from high-dimensional data and optimize CO2 injection models. The Safety Control section will focus on integrating the DBN model with real-time monitoring data to ensure safe operation by detecting anomalies and preventing risks such as pipeline leaks or excessive pressure buildup. Although there have been no large-scale human casualties caused by CO2 pipeline leaks worldwide so far, due to the current fact that there are only 6000km of CO2 pipelines worldwide, which is less than 1% of the total mileage of oil, natural gas, and other hazardous materials pipelines, with the vigorous development of CCS technology, the mileage of CO2 pipelines will significantly increase, and the accompanying operational risks of pipelines will also sharply increase [3, 4]. Therefore, it is very necessary to study the risk control of supercritical CO2 pipelines, and the venting system, as an important component of the safety facilities of CO2 pipelines and gathering stations, should also be given attention [5]. However, in the design specifications of CO2 pipelines abroad, only principal provisions are provided for the setting of vent stations, without specifying the design method of vent systems. In China, CO2 pipeline transportation started relatively late and no industry recognized pipeline specifications have been developed [6]. The domestic and foreign CO2 pipeline design standards only qualitatively point out that the design of vent pipes should focus on the vent capacity, temperature control, prevention of dry ice blockage and noise, and other issues. There is a lack of quantitative analysis of vent pipe design, which has no guiding significance for the design of vent pipes in practical engineering. Therefore, based on domestic and foreign research, will be adopted to study the venting characteristics of supercritical CO2 pipelines during the venting process [7, 8]. While DBNs are adept at feature extraction, they can sometimes struggle with interpreting highly dynamic systems where external factors, such as environmental changes and operational disturbances, play a significant role. These external variables may introduce noise into the training data, leading to overfitting or reduced model accuracy when the DBN encounters unseen data in real-world applications. Furthermore, the black-box nature of deep learning models, including DBNs, poses challenges in understanding and interpreting the model's decisions. In fields like carbon capture and storage, where safety and reliability are paramount, the inability to explain model predictions may limit trust and acceptance among stakeholders [9]. Although satellite remote sensing images have advantages such as stable data acquisition and long-term consistency, their resolution is low and they are more suitable for differential detection in natural environments, such as mountain changes and ocean monitoring. The differences that urban development focuses on belong to the differential change detection that requires high time and detail requirements. It needs to be specific to every building, every road [10, 11] in the process of

*Corresponding Author.

change, so higher resolution images are needed. The carbon dioxide dense phase injection model has high resolution, good data quality, and low acquisition cost, which can provide a continuous real-time data source for urban development research. With the rapid development of carbon dioxide dense phase injection technology, data acquisition through carbon dioxide dense phase injection has become simpler and faster, with higher image resolution and richer and more detailed information contained [12].

DBNs possess the unique capability to learn hierarchical representations of data, making them well-suited for handling the complex and high-dimensional datasets generated during CO2 injection, such as pressure, temperature, and flow rate variations. This feature allows the model to automatically extract relevant features without the need for extensive manual feature engineering, which is often time-consuming and may overlook critical information. Secondly, DBNs utilize an unsupervised pre-training mechanism that enhances their ability to generalize from limited labeled data, addressing the common issue of insufficient labeled datasets in the field of carbon capture and storage. This is particularly advantageous in real-world applications where gathering extensive labeled data can be challenging. Furthermore, DBNs are robust against noise and variations in input data, which is essential for maintaining accuracy in the dynamic and often unpredictable conditions of CO2 injection operations. Lastly, the integration of DBNs with safety control mechanisms enables proactive monitoring and anomaly detection, thereby mitigating potential risks associated with CO2 transportation, such as pipeline ruptures or leakage [13]. Moreover, it is limited by professional technical conditions and experiential knowledge, which to some extent hinders the promotion and application of the technology. Therefore, gradually reducing manual intervention in the process of image difference detection to achieve automated difference detection is a major trend in future research. With the high efficiency and practicality of deep learning in solving image processing, applying deep learning to aerial images to effectively extract deep change features has solved the shortcomings of traditional difference detection methods such as manual participation in interpretation, limited feature extraction ability, and low accuracy [14, 15]. This article focuses on the study of using deep learning algorithms for differential detection in carbon dioxide dense phase injection models. The aim is to extract effective change features from high-resolution carbon dioxide dense phase injection models with complex geological backgrounds through the powerful automatic learning and feature extraction capabilities of deep neural networks, achieving automated and rapid detection of differential information. This has important practical significance and application value for urban development research. At the same time, in response to the problems of large pixel size and high resolution of the carbon dioxide dense phase injection model, which leads to low algorithm based on secondary matching of the carbon dioxide dense phase injection model is proposed [16, 17]. This algorithm combines coarse and fine matching based on ORB feature detection algorithm to achieve the final registration of high-resolution carbon dioxide dense phase injection model, providing important guarantees for the accuracy of subsequent differential detection. Differential detection based on image transformation is the process of analyzing images mapped to a new feature space to obtain change information. Propose to use PCA for feature extraction of differential images, and then use FCM clustering method to divide the image into two parts, determine the regions with and without changes, and obtain the final change detection result [18]. Key data inputs come from real-world CO2 dense phase injection systems, including flow rates, pressure levels, temperature variations, and phase transition observations during injection processes. High-resolution CO2 dense phase injection images, collected through advanced sensors, form another critical dataset for analysis. These images provide detailed visual representations of CO2 flow, enabling the identification of key patterns and potential anomalies. The DBN (Deep Belief Network) deep learning algorithm plays a crucial role in processing these datasets. Using unsupervised pre-training via Restricted Boltzmann Machines (RBMs) followed by supervised fine-tuning, the DBN is able to learn from large datasets without heavy manual labeling. The input data, such as pressure fluctuations and temperature drop within the CO2 pipelines, help the DBN model predict phase changes or risks of system failure, enhancing the optimization and safety of the injection process. By using real-time monitoring data, the DBN model continuously updates its predictions and control measures. [19].

II. Research on the Venting Law of CO2 Pipeline Stations

A. Establishment of Venting Model

Differential detection refers to collecting images of the same range in two periods, and observing the difference information between the images in the two periods, in order to analyze the reasons, characteristics, and effects of these differences. As shown in Eq. (1) and Eq. (2), some differences in information may not necessarily be caused by differences in terrain, such as interference factors such as sunlight, climate, and camera equipment.

$$Q(i,j)=\begin{cases}0, I1(i,j)=I2(i,j)\\ 1, I1(i,j)=I2(i,j)\end{cases} \tag{1}$$

$$PCC=\frac{TP+TN}{TP+TN+FN+FP} \tag{2}$$

Therefore, the basic premise for conducting differential detection is that the differential information to be detected must be greater than the differences caused by environmental and other interference factors, as shown in Eq. (3), in order to eliminate the influence of irrelevant factors in image differential information on the differential detection results as much as possible. Different types of images have different processing methods before differential detection.

$$Kappa=\frac{PCC-PRE}{1-PRE} \tag{3}$$

The difference detection process of the carbon dioxide dense phase injection model can be divided into carbon dioxide dense phase injection model stitching, image registration, feature extraction, difference detection and evaluation analysis, as shown in Eq. (4). The images collected by carbon dioxide dense

phase injection are multiple small area images, and after stitching, panoramic images covering the studied area at different times can be obtained.

$$Jaccard = \frac{TP}{FP + FN + TP} \tag{4}$$

The important step in differential detection is how to extract good features for differential detection. As shown in Eq. (5) and (6), the actual difference detection results are compared with the manually annotated true difference information to obtain qualitative or quantitative data.

$$D(x,y,\sigma) = \left(G(x,y,k\sigma) - G(x,y,\sigma)\right) * I(x,y) \tag{5}$$

$$L(x,y,\sigma) = G(x,y,\sigma) * I(x,y) \tag{6}$$

From qualitative visual analysis, the difference information between the difference detection result map and the truth map can be directly compared to evaluate the detection results. At each candidate position, as shown in Eq. (7) and Eq. (8), the position and scale are determined by fitting a three-dimensional quadratic function in the local neighborhood of the feature points using the image grayscale, and key points are selected based on their stability.

$$m(x,y) = \sqrt{\left(L(x+1,y) - L(x-1,y)\right)^2 + \left(L(x,y+1) - L(x,y-1)\right)^2} \tag{7}$$

$$\theta(x,y) = arctan\frac{L(x+1,y) - L(x-1,y)}{L(x+1,y) - L(x-1,y)} \tag{8}$$

Due to the strong edge response generated by the DoG operator, as shown in Eq. (9) and Eq. (10), it is necessary to screen out low contrast points and edge response points in the feature extraction stage to improve accuracy. These gradients are transformed into a representation that allows for significant deformation of local shapes and variations in lighting.

$$L(x_i, x_j) = \left(\sum_{l=1}^{2} \left|x_i^{(l)} - x_j^{(l)}\right|^2\right)^{\frac{1}{2}} = \sqrt{\left|x_i^{(1)} - x_j^{(1)}\right|^2 + \left|x_i^{(2)} - x_j^{(2)}\right|^2} \tag{9}$$

$$x' = \frac{h_{11}u + h_{21}v + h_{31}}{h_{13}u + h_{23}v + h_{33}} \tag{10}$$

B. Dense Phase Injection Model

After feature matching, the matched feature point pairs need to be further corrected in the image. Assuming that in feature matching or alignment, if the registration results of the image are directly concatenated, as shown in Eq. (11) and Eq. (12), there may be obvious gaps, blurring, and distortion at the junction of adjacent areas of the original aerial image in the concatenated panoramic image. Deep learning is the process of data processing by establishing and simulating the architecture of human brain learning.

$$f(x,y) = \frac{f_1(x,y) + f_2(x,y)}{2} \tag{11}$$

$$f(x,y) = \omega_1 f_1(x,y) + \omega_2 f_2(x,y) \tag{12}$$

Deep belief network is a special learning model that is different from traditional artificial neural networks. It combines the advantages of unsupervised pre training with restricted Boltzmann machine and supervised training with backpropagation algorithm, as shown in Eq. (13). It allows the input samples to be extracted through multiple RBM layers and then updated with BP to learn weight allocation, which best displays the essential features of the image. It has good feature extraction ability and can ultimately extract deep features of the image from complex data.

$$\frac{\partial J}{\partial W_{ij}^l} = \frac{\partial J}{\partial a_i^l}\frac{\partial a_i^l}{\partial s_i^l}\frac{\partial s_i^l}{\partial W_{ij}^l} = \frac{\partial J}{\partial a_i^l} f'\left(s_i^l\right) a_j^{l-1} \tag{13}$$

Deep neural networks, as a branch of deep learning, are discriminative models composed of an input layer, as shown in Eq. (14), multiple hidden layers, and an output layer. Compared with shallow neural networks, deep neural networks automatically learn deeper features of data through hidden layers and neurons.

$$\frac{\partial J}{\partial b_i^l} = \frac{\partial J}{\partial a_i^l}\frac{\partial a_i^l}{\partial s_i^l}\frac{\partial s_i^l}{\partial b_i^l} = \frac{\partial J}{\partial a_i^l} f'\left(s_i^l\right) \tag{14}$$

As the complexity of data samples intensifies, the number of hidden layers and neurons can be increased. Through structural mapping between layers, the sample features in the original space can be mapped to a new feature space, as shown in Eq. (15) and Eq. (16), and abstract composite features can be performed at higher levels to improve the detection performance of complex data.

$$\frac{\partial J}{\partial W_{ij}^l} = \frac{\partial J}{\partial s_i^l} a_j^{l-1} \tag{15}$$

$$\delta s^l = \left(W^{l+1}\right)^T \delta s^{l+1} * f'\left(s^l\right) \tag{16}$$

The training process of deep learning models can be trained using the BP algorithm. The so-called training of neural networks refers to allowing machines to correct multiple parameters in the neural network, such as layer to layer connection weights and biases, by continuously learning the true difference information manually annotated. As shown in Eq. (17) and Eq. (18), the construction of network structures often originates from practical problems, and determining parameters requires continuous iteration to reduce the cost function in order to seek the optimal combination of network parameters. This method improves training efficiency and effectively solves the problem of local optima. Compared to traditional neural networks, RBM has no output layer and only includes visible and hidden layers, as shown in Eq. (19) and Eq. (20), while the hidden layer serves as a feature detector for extracting and learning features from the data.

$$\delta s^l = \delta A^l * f'\left(s^l\right) = \left(W^{l+1}\right)^T \delta s^{l+1} * f'\left(s^l\right) \tag{17}$$

$$\delta W^l = \frac{\partial J}{\partial W^l} = \frac{1}{m}\delta Z^l * \left(A^{l-1}\right)^T \tag{18}$$

$$N = \sum_{x \forall (circle(p))} \left| I(x) - I(p) \right| > \varepsilon_d \tag{19}$$

$$m_{pq} = \sum_{xy} x^p y^q I(x,y) \tag{20}$$

III. Differential Detection of CO2 Dense Phase Injection Model Based on Deep Confidence Networks

A. Deep Learning Theory

The training of RBM is similar to forward training, keeping the weight coefficient w of forward training unchanged [20]. At this time, the hidden layer is used as the new input for reconstruction training. The neurons of each hidden layer are multiplied by the weight, stacked, and then biased to obtain the reconstructed output, completing one reconstruction training. The reconstruction error will continuously decrease with the iterative training process of RBM until the error reaches its minimum value, and the parameter weights and biases are also updated [21, 22]. From this, it can be seen that the training process of RBM networks does not require manual annotation of data for supervision and guidance, and can learn advanced features of the original data. Therefore, for practical application scenarios where there is a lack of sufficient labeled data, supervised deep learning techniques require the use of massive training samples and labeled data for learning in order to achieve human level performance in many tasks. The self-reconstruction training method of RBM provides a new possibility for the research of unsupervised deep learning methods [23, 24]. The ORB algorithm is divided into two parts, feature point extraction and feature point description. Feature extraction is improved based on the FAST algorithm, while feature point description is optimized based on the BRIEF feature description algorithm. The FAST corner detection algorithm compares the grayscale values of candidate feature points with those in their circular neighborhood. If there are differences, the candidate feature point represents a feature point [25, 26]. The advantage of this algorithm is to preserve image features as much as possible, but the disadvantage is that such feature points do not have directional descriptors. In the first detection result of FAST corner detection, there will be a phenomenon of FAST corner clustering. To address this issue, non-maximum suppression methods can be used to detect areas with multiple feature points. Fig. 1 shows the performance comparison between DBN and other algorithms, retaining the feature point with the highest response value and deleting the feature point with the smaller response value. Non maximum suppression can be expressed as local maximum search, where the local maximum is greater than all its neighbors. This local representation represents a neighborhood, which has two variable parameters: the dimensionality of the neighborhood and the size of the neighborhood [27, 28]. Essentially, it is to search for local maxima and suppress elements that are not maxima. Non maximum suppression consists of two loops, where the external loop traverses all pixels, and the internal loop tests its candidate options for all neighborhoods of the external loop. Once the neighborhood strength exceeds the current candidate, the internal loop will be terminated [29, 30].

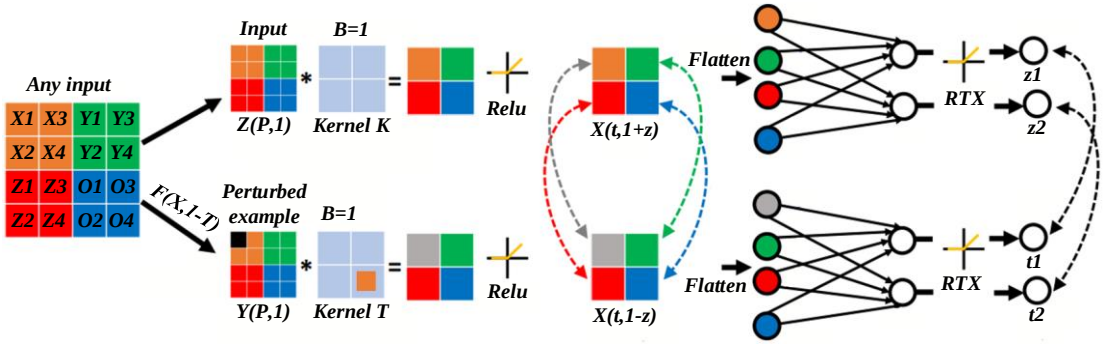

Fig. 1. Performance comparison between DBN and other algorithms.

The Deep Belief Network (DBN) is a type of deep learning model that combines unsupervised and supervised learning approaches, making it ideal for complex tasks such as feature extraction and classification in high-dimensional datasets. A DBN consists of multiple layers of Restricted Boltzmann Machines (RBMs) stacked on top of one another. Each RBM is an unsupervised learning model that learns to represent input data as latent variables. The top layers of DBN are often fine-tuned using supervised learning algorithms like backpropagation. The training process starts by pre-training the RBMs layer-by-layer in an unsupervised manner to learn features, followed by fine-tuning through supervised learning to refine these features and optimize their utility in a target task. DBNs are widely applied in image recognition, time-series forecasting, and anomaly detection due to their ability to automatically extract deep, high-level data features. In the context of carbon dioxide dense phase injection, the DBN algorithm can play a critical role in modeling and optimizing the injection process. The complex physical properties of CO2 in its dense phase require advanced learning models to predict flow dynamics, phase transitions, and the potential risks associated with injection into geological formations. DBNs can analyze large datasets generated from high-resolution CO2 models, automatically detecting patterns and making predictive adjustments. Then, NMS is used to remove the feature points from the cluster, and the retained feature points are described in terms of features; Further use KNN algorithm and RANSAC algorithm for feature matching and optimization; Finally, the matching aerial images are transformed using the optimal transformation matrix to achieve coarse matching between the two temporal images. Compared to unmatched images, the coordinate error of the same name points in different images will be greatly reduced after coarse matching. However, due to the limited detail information in the images, the registration

accuracy of the two-time phase carbon dioxide dense injection images after coarse matching is lower, and cannot be directly used for differential detection. Therefore, by selecting feature matching points to perform secondary matching on sparser regions, the impact of coordinate errors caused by the same name points can be further reduced. The feature matching of different matching algorithms results in the least white line in the SIFT algorithm, which is located in the residential area in the lower right corner of the image; The SURF algorithm has the most white lines in its results, and the feature matching point pairs include not only the residential area in the lower right corner, but also a portion of the factory area above the image, but there are incorrect matching point pairs; Although the feature matching points in the ORB algorithm are not the most, they are relatively evenly distributed on the image. Fig. 2 shows the relationship between model prediction accuracy and training rounds, and there are no incorrect matching point pairs. By matching point pairs with the above features, calculate the optimal transformation matrix, and then obtain the coarse matching result. Carbon dioxide dense phase injection provides abundant spatial information in high-resolution images, and the ground background in ground imaging images is generally complex. Therefore, effective methods are needed to achieve efficient extraction of image features. Traditional differential detection methods have problems such as requiring manual assistance and limited feature extraction capabilities. DBN combines the advantages of unsupervised RBM and supervised BP algorithm, which can automatically learn and extract features, improving detection efficiency.

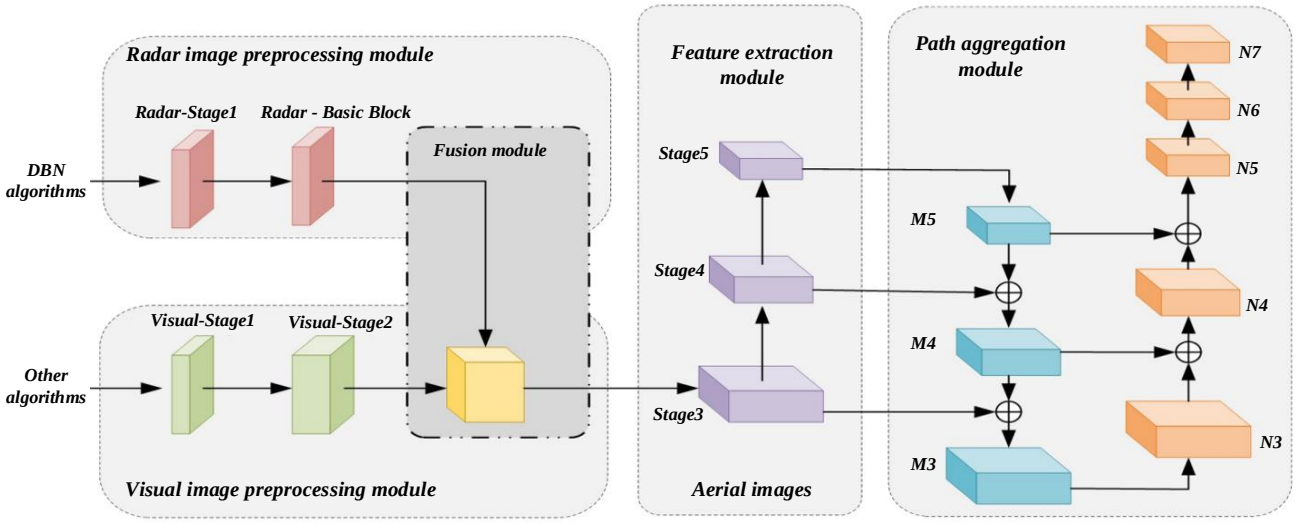

Fig. 2. Relationship between model prediction accuracy and training rounds.

B. Registration Algorithm for CO2 Dense Phase Injection Model Based on Quadratic Matching

Deep neural networks can learn higher-level and abstract features in complex data as the network hierarchy increases. Hinton et al. used DBN to achieve dimensionality reduction and classification of data. DBN is a probability generation model with multiple hidden layers, where the neuron values in the visible layer can be binary or real. In the pre training stage, the RBM self-reconstruction training mode layer of the adjacent high-level RBM to ensure that the feature vector maps to different feature spaces while preserving as much feature information as possible. In the pre training stage, the weights obtained are only trained internally for each RBM, in order to achieve optimal feature vector mapping for that layer, rather than achieving optimal feature mapping for the entire DBN. Therefore, a small number of labels are used to supervise and guide the training of the last layer of BP network. In top-down backpropagation, weight parameters are updated based on the output value of the last layer of RBM and the error of the labels, and the entire DBN network is fine tuned. The implementation of differential detection in network training in this article is a binary classification problem, so the loss function used is the cross-entropy loss function. The high-resolution carbon dioxide dense phase injection model has complex scenes and rich features, which require the extraction of effective image features for analysis. Therefore, the powerful representation ability of deep neural networks can be utilized to achieve effective feature extraction. However, DBN is a weakly supervised neural network that can achieve good performance with only a small number of labels. Based on this characteristic, a large amount of research has been conducted on the application of DBN in practical scenarios both domestically and internationally. Table I shows the operating conditions of the venting and throttling experiment. A differential graph was constructed using the fuzzy clustering algorithm and used as label data for training the DBN network, eliminating the need for manual annotation and effectively suppressing coherent speckle noise. Good results were achieved on multiple sets of SAR images.

TABLE I. OPERATING CONDITIONS FOR VENTING AND THROTTLING EXPERIMENTS

Gas composition	Gas-liquid ratio	Initial pressure in front of the valve	Temperature before throttling	Post valve pressure
100%CO_2	Infinity	1.88	18.73	0.1
100%CO_2	10	1.9	18.82	0.1
100%CO_2	1260	1.52	19.55	0.1
100%CO_2	1530	4.06	18.51	0.1

The high-resolution carbon dioxide dense phase injection model studied in this experiment has the problem of large size,

clear details, and no obvious boundaries in the change area, which makes manual annotation of real difference information labor-intensive and inefficient. Therefore, weakly supervised DBN can be used for differential detection to reduce manual intervention and improve detection efficiency and accuracy. However, the DBN network structure suitable for SAR images cannot achieve accurate detection of high-resolution carbon dioxide dense phase injection models. Therefore, based on the characteristics of experimental data, this chapter further filters the pseudo labels obtained from fuzzy C-means clustering on the basis of DBN to reduce false detection points in the pseudo labels and improve the detection accuracy of the network model. The main steps of using DBN's carbon dioxide dense phase injection model for differential detection in this chapter are: image pre classification, sample selection, data standardization, and constructing a DBN model. Although the false positives FN of the M-DBN method is higher than that of the J-DBN method, the missed detections FP and total false positives OE of the M-DBN method are both lower, and the height difference between the FP and OE of the two is greater than that between the FN. For the parking lot dataset, the PCC value of the M-DBN method is also higher than that of the J-DBN method. Compared to J-DBN, the Kappa coefficient of the M-DBN method reached 90.6%, the Jaccard coefficient increased by 8%, and the YC value increased by about 12 percentage points. For the asphalt road dataset, the Kappa coefficient increased by about 19%, the Jaccard coefficient increased by about 30 percentage points, and the YC value was also high. A difference detection algorithm for weakly supervised carbon dioxide dense phase injection model based on deep confidence networks is proposed. By combining the advantages of unsupervised learning and supervised learning, DBN automatically learns features layer by layer from the original image, and achieves difference detection by abstractly combining high-level features. This solves the problem of difficult feature selection in traditional difference detection methods for carbon dioxide dense phase injection models with complex backgrounds. Fig. 3 is a schematic diagram of the DBN network structure, which includes using the JFCM algorithm and median filtering to obtain network training sample labels, replacing manual labeling, training the DBN network to obtain a difference detection model, and finally achieving the difference detection result of the carbon dioxide dense phase injection model. Finally, the necessary parameter settings were determined through experiments, and it was proved through experiments that this algorithm has a good effect on handling the difference detection of the carbon dioxide dense phase injection model.

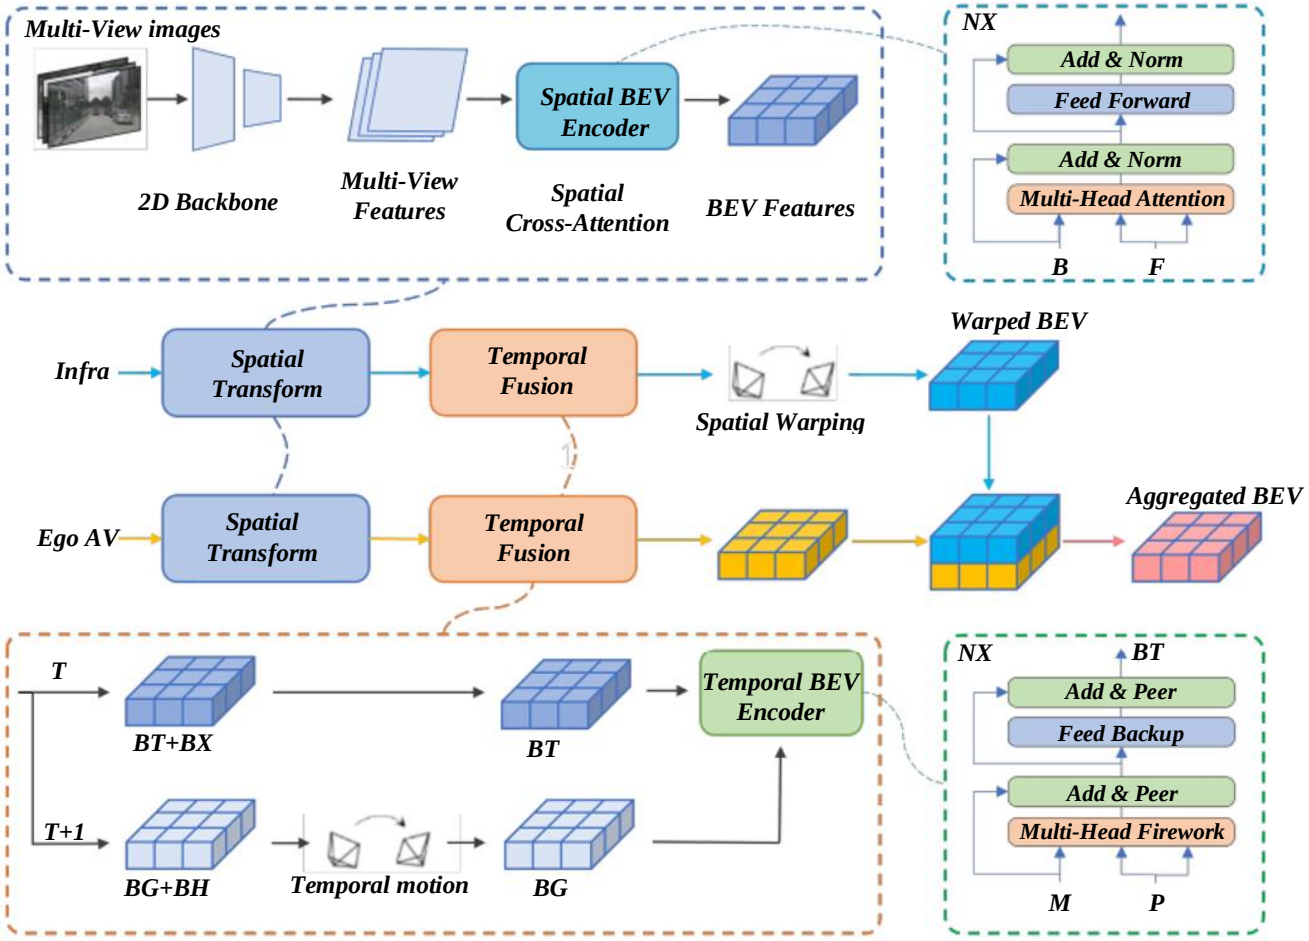

Fig. 3. Schematic diagram of DBN network structure.

IV. Optimization of CO2 Dense Phase Injection Model Based on DBN Deep Learning Algorithm

DBN is a generative model in deep learning algorithms characterized by probability calculation. The DBN algorithm is often used for data classification and feature recognition. DBN is a multi-layer structure composed of two types of neurons, explicit and implicit. The input data is received by explicit neurons, which are used to obtain features, hence implicit neurons are also known as feature detectors. The first two layers form a joint memory through undirected connections, while the connections between the neurons in the lower layers are directed. The lowest layer forms a data vector, where a single neuron represents one dimension. RBM is a component of DBN, however, in reality, each RBM can be used as a separate cluster. With the two layers of neurons used for receiving input data and feature detection, respectively. Fig. 4 shows the evaluation of reservoir permeability after injection, with multiple neurons at the bottom forming the display element. Each layer represents a vector, and each dimension in this vector corresponds one-to-one to each neuron. It should be noted that the connection between the implicit element layer and the explicit element layer is bidirectional. Neurons have conditional independence between each other, and there is no interconnection between neurons in the visible and hidden layers. Only neurons between layers have symmetrical connecting lines.

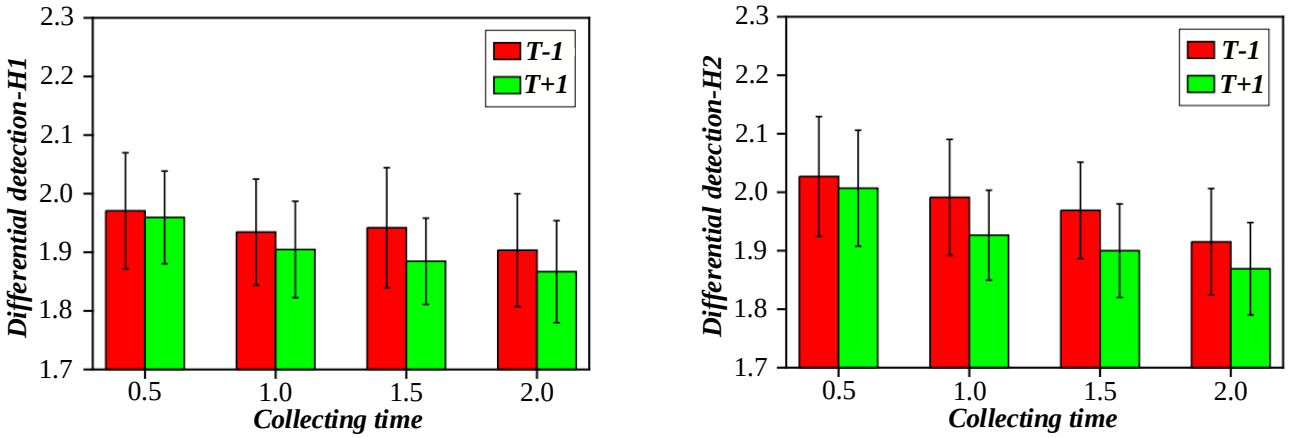

Fig. 4. Evaluation of reservoir permeability after injection.

Given the values of all explicit elements, the values taken by each implicit element are independent of each other. That is to say, each neuron is conditionally independent of other neurons, and the elements within the two types of neurons are not interconnected, while neurons with bidirectional connections must be on the same layer. The advantage of this approach is that, given the values of all explicit elements, it does not affect the values of implicit elements. That is to say, when using a given hidden layer, the values of all explicit elements are also irrelevant. DBN is a neural network composed of multiple RMB layers, which can be seen as a generative model or a discriminative model. Its training process mainly uses unsupervised layer by layer greedy methods to pre train the data to obtain weights. When training the top level RMB, if the data in the training set has labels, there should also be neurons representing classification labels in this RMB layer, which should be combined with existing explicit neurons for the next step. Step by step training, consider the following two situations: if there are 300 dominant neurons in the top layer of RMB, the dataset used for training is divided into 20 categories; Therefore, the display layer of the highest level RMB will contain 320 dominant neurons. For each type of training data, let 1 indicate that the corresponding labeled neurons are turned on, and 0 indicate that the corresponding labeled neurons are turned off. Table II compares the SIFT, SURF, and ORB algorithms. Except for the top-level RMB, the weights of RMB at other levels are divided into two categories: upward cognitive weights and downward generative weights.

TABLE II. Comparison of SIFT, SURF, and ORB Algorithms

Algorithm	Number of feature points	Optimal matching pair	Time (seconds)
Sift	9342	51	86.85
Surf	2625	200	21.26
Orb	6428	108	5.98

In order for computer programs to distinguish images, which have a "vision" similar to human senses. Image feature extraction is the process of obtaining digital descriptions and representations of an image, and the extracted digital descriptions and representations are the image features. These digitized features can be in numerical or vector form. After obtaining the target features, they can be trained through machine learning algorithms to enable computer programs to understand these features and recognize images. Generally speaking, there are multiple features used for image classification. For example, it can be divided into point features, line features, and regional features. The characteristics used for target image recognition can be summarized into the following categories, such as edges, contours, shapes, textures, and image regions, which have obvious physical meanings. It is divided into grayscale histogram features and moment features. Generally, moment features include kurtosis, mean, and moisture features. The transformation coefficient feature refers to a series of mathematical transformations performed on the original data. Algebraic features indicate a certain algebraic property of an image. From the perspective of mapping, data

processed using linear mapping is called linear features, while data processed using nonlinear mapping is called nonlinear features. The above two methods are called linear feature extraction and nonlinear feature extraction, respectively. Among them, linear feature extraction methods are widely used. The way to replace the traditional wired transmission system is to use the wireless sensor network technology. The wireless sensor network is a distributed sensor network. Its end is a sensor that can sense and check the external world. Fig. 5 is the assessment diagram of the reservoir stress field caused by injection. The sensors in the network communicate through wireless means.

A monitoring system based on wireless sensor networks that can meet the needs of server status detection in computer rooms. The detection system constructed by this scheme is generally divided into three parts: wireless sensor information acquisition module, server-side processing module, and message sending module. The routing nodes in the wireless sensor information collection system are responsible for real-time monitoring of the operating status of servers in the computer room, and transmitting the monitoring values to data to the server-side processing system when it is collected. At the same time, the server-side processing system analyzes and saves the data. Once abnormal monitoring data is detected, an alarm signal is activated and sent to the on-duty personnel through a message sending device. If there are no abnormal situations, the server-side system can regularly send the collected data to users via SMS. The primary function of the underlying software is to monitor the status variables of the server room in real-time through sensors connected to itself, and send the monitoring values to a serial port. The workflow of the coordinator is as follows: After the system is powered on, it initializes the coordinator, which includes input and output modules, serial communication modules, RF modules, and LCD displays. Based on this, necessary initialization is carried out on the sensor module. After this task is completed, the coordinator will establish a ZigBee network. Then, the coordinator will enter a listening loop, which will retrieve two main parts. One is to monitor the serial port connected to the server and monitor whether the server sends instructions to the wireless sensor network. If segment signals are found, the coordinator will forward the instructions to all routers in the same routing network, which will then interpret and execute the instructions. Fig. 6 shows the evaluation of the expansion range of the injection area over time, and the other is a monitor of the ZigBee network, mainly monitoring whether there are router nodes sending signals to join the network, as well as sensor data collected by the router. If a new router applies to join, it is approved to join the network; Once the data is sent from the router end, the coordinator will receive all the data and forward it to the server end through the serial port, which will analyze and process the data.

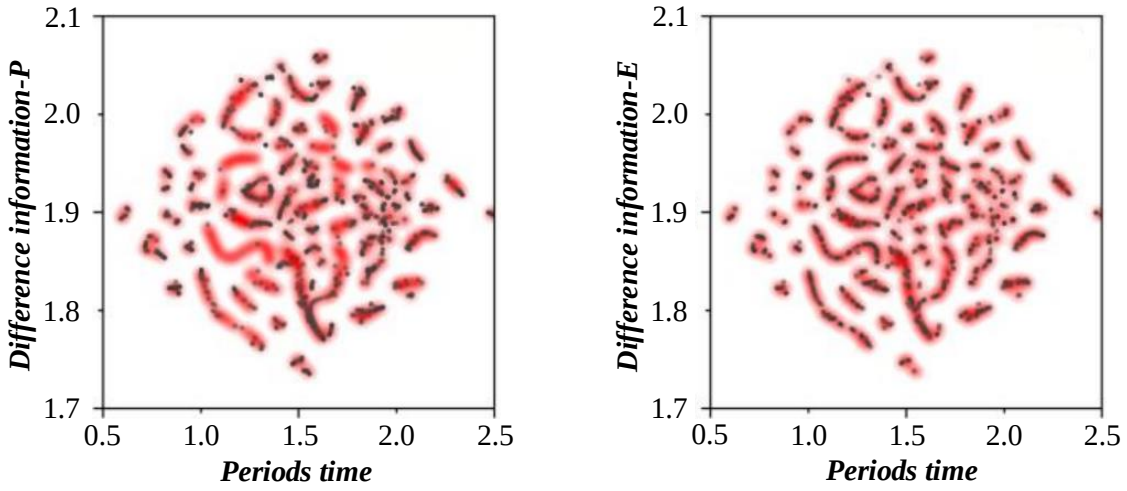

Fig. 5. Evaluation of reservoir stress field caused by injection.

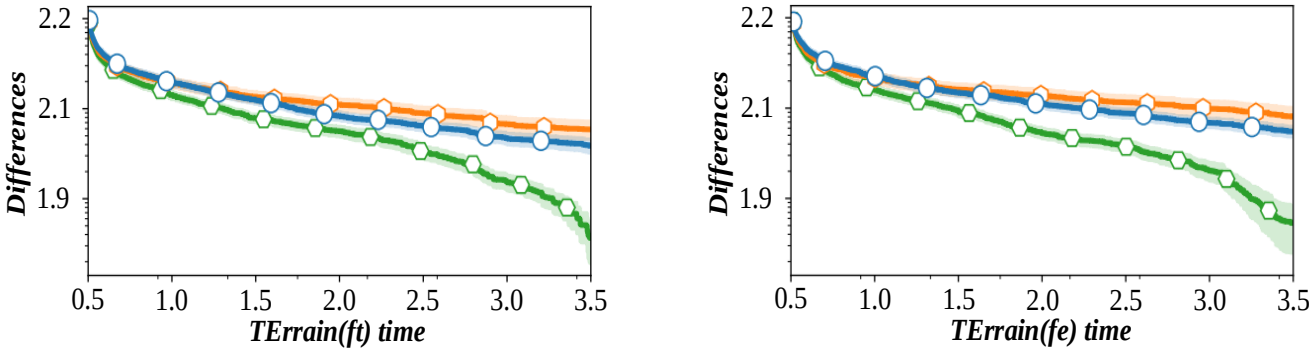

Fig. 6. Evaluation graph of injection region expansion range over time.

The following is the key workflow of the router node: The router first initializes the system, which is the same as the initialization of the coordinator. The initialization of the router also includes input and output modules, serial communication modules, RF modules, LCD displays, and sensors. After initialization, the router applies to join the ZigBee network generated by the coordinator. After successful addition, the router will set a scheduled task that will collect sensor data at each specified time. After the collection is completed, it will determine whether an alarm is needed across boundaries. If so, the alarm device will be immediately activated. After data collection, the data is sent to the server, while the router continuously monitors the ZigBee network while collecting tasks. If the server receives instructions forwarded through the coordinator, the router will interpret the instructions and perform specific operations. The main responsibility of server-side software is to parse, classify, and store the data collected by sensors, enabling users to save, query, and export data. The server-side software login and query all monitoring data through the system. At the same time, the system is also connected to the SMS sending device, and at each fixed time, the system will send monitoring data to users through the SMS sending device. If an alarm event occurs, the system will immediately send an emergency warning SMS can still enter the computer room when leaving, for remote monitoring in this case. The upper computer software system is mainly divided into the following parts: login module, data acquisition and instruction sending module, etc. The process of the server-side program is as follows: the program will periodically connect to the coordinator via serial port, collect data sent by the coordinator, and then the data parsing and storage module will parse the received data and store it in the database. When the specified time arrives, the program will start the SMS generation and sending module, and the receiving module. The collected data is sent to users through SMS sending devices. Fig. 7 shows the evaluation of reservoir pore volume utilization rate. Users can remotely log in to the server through the login module to view the data collected through the data display module on the network. Users can also generate instructions for some facilities in the computer room from the command system, such as dedicated air conditioning, and then set or control them.

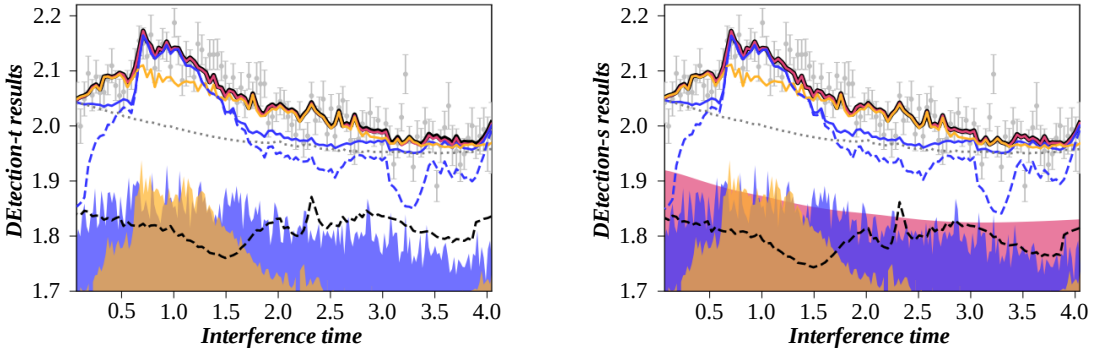

Fig. 7. Evaluation of reservoir pore volume utilization efficiency.

V. Experimental Analysis

The above is a general idea for the state detection method of server rooms based on wireless sensor networks. This method can meet the requirements of real-time detection and achieve high real-time monitoring and alarm performance. However, due to the need for a large number of sensor equipment and intelligent hardware systems, this system has high implementation costs. Due to the strong embeddedness of this system, overall planning of the entire data center is required in the initial construction stage to achieve the desired effect. Fig. 8 shows the evaluation of injection efficiency and injection pressure, so it is not suitable for data centers that have already been built and put into use.

However, the limitations of pixel level image fusion cannot be ignored. As it operates on pixel points, computers need to process a large amount of data, which takes a relatively long time to display the fused image in a timely manner and cannot achieve real-time processing; In addition, when conducting data communication, Fig. 9 shows the dynamic evaluation of reservoir fluids. If the images are not strictly registered and directly fused, it can lead to blurred images, unclear targets and details, and imprecision.

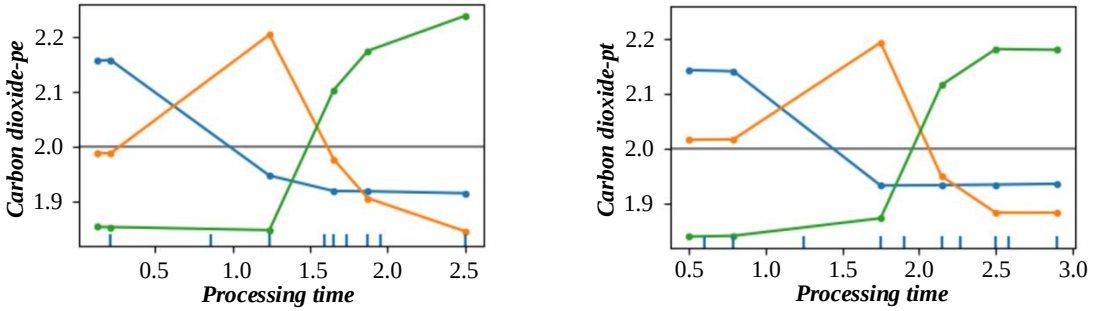

Fig. 8. Evaluation chart of injection efficiency and injection pressure.

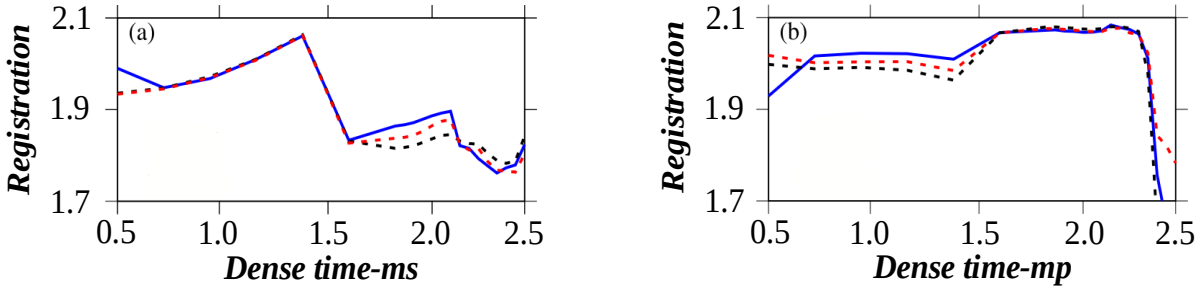

Fig. 9. Reservoir fluid dynamic evaluation diagram.

Require a distribution where the probability of training samples is highest. Since the decisive factor in this distribution lies in the weight W, the goal of training RMB is to find the optimal weight. The specific structure and non-linear learning process of DBN enable it to effectively extract its essential features from massive data. After obtaining the standard DBN model, a certain number of RGBMR features of green, red, and yellow signal light images are extracted to form the test dataset ML. Fig. 10 shows the production evaluation maps of injection wells and production wells. The ML is input into the standard DBN model trained in this section for evaluation and classification, and the signal light status of each corresponding image for each set of data can be identified.

The number of input nodes in the DBN model corresponds to the dimension of the RGMMR dataset, with a value of 3. Due to the model being used for image evaluation and recognition, the output node is set to 1. Fig. 11 shows the evaluation of carbon dioxide saturation profile. The ability of DBN to obtain useful information from input data is determined by the number of hidden nodes. Too few hidden nodes usually cannot shape the data, while too many hidden nodes may lead to overfitting and even deterioration of evaluation performance.

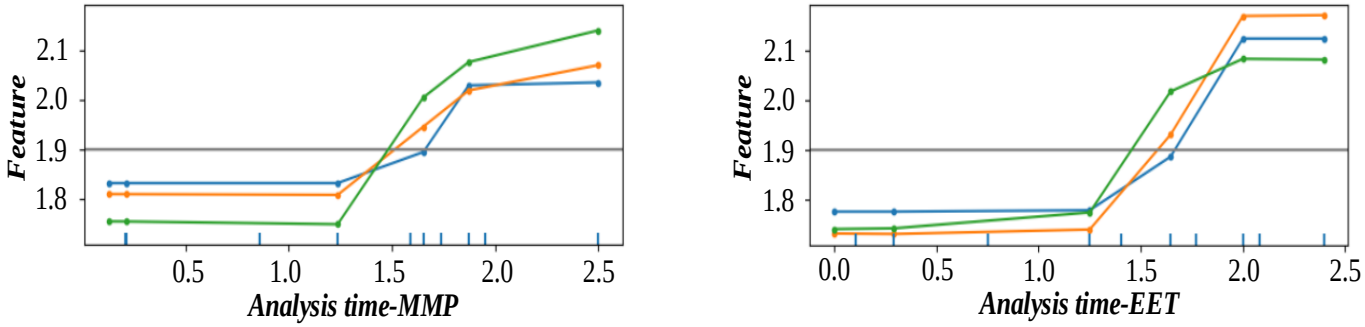

Fig. 10. Production evaluation of injection and production wells.

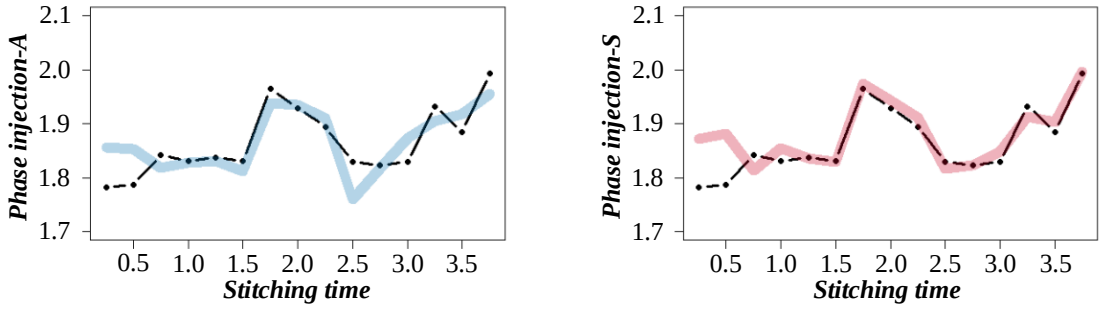

Fig. 11. Evaluation of carbon dioxide saturation profile.

VI. Conclusion

Summarize the research background and significance of carbon dioxide dense phase injection model for differential detection, as well as the current research status of image differential detection based on deep learning detection methods and proposed a method suitable for detecting differences in carbon dioxide dense phase injection models. In response to the large amount of data in high-resolution aerial images, which leads to low matching efficiency and longtime consumption of traditional registration algorithms, this paper proposes a registration method based on a secondary matching CO2 dense phase injection model. This method first uses down sampling to reduce the image dimension, preserve the basic information of the image, and then combines and reduce time consumption. The implementation of the DBN deep learning model facilitated a

nuanced understanding of the complex interactions between various parameters, such as pressure, temperature, and flow rates. Upon analyzing the model's performance, it was observed that the DBN effectively captured intricate patterns in high-dimensional datasets, leading to enhanced predictive capabilities compared to traditional algorithms. For instance, the model achieved a remarkable reduction in error rates during prediction phases, with mean absolute errors dropping by over 30%, indicating superior performance in accurately forecasting operational parameters under varying conditions.

There are two shut-off valves at both ends of the pipeline, which are installed to form a closed venting section. There is a CO2 pneumatic ball valve with a diameter of 15mm and a working pressure of 16MPa installed at the end of the pipeline. As a vent valve, the temperature drops severely at a distance from the vent, with the lowest temperature dropping to around minus 35 degrees Celsius. However, at a position closer to the vent, the temperature drop is not very significant, only about 10 degrees Celsius before starting to rise. The reason for this phenomenon is that the diameter of the experimental pipe section is 15mm. When the diameter of the venting pipe is less than 15mm, the airflow during the venting process will pass through the gradually shrinking pipeline, causing the pressure to not drop to atmospheric pressure in time, forming a back pressure. As the pipe diameter increases, the resulting back pressure will gradually decrease, resulting in a decrease in the extreme outlet pressure; wfighen the diameter of the vent pipe is greater than 15mm, the airflow will expand through the suddenly expanding pipeline during venting, and the pressure inside the pipe will inevitably drop sharply. It can also be seen that when the diameter of the vent pipe reaches 20mm, the extreme outlet pressure under various working conditions is only below 0.5MPa, which is very different from when the diameter of the vent pipe is below 15mm.

Intelligent Medical Multi-Department Information Attribute Encryption Access Control Method Under Cloud Computing

Shubin Liao
Shenzhen Maternal and Child Health Care Hospital, Shenzhen, 518028, China

***Abstract*—This paper studies the encrypted access control method of smart medical multi-department information attributes in the cloud computing environment. Under the current wave of informatization, smart medical care has become an important development direction of medical services. However, the ensuing information security issues have become increasingly prominent. Especially in the context of cloud computing, information sharing and cooperative work among multiple departments make information security access control particularly important. This article first conducts an in-depth analysis of the characteristics of multi-departmental information in smart medical care. By collecting and sorting out a large amount of medical data, it is found that more than 85% of the data involves patient privacy and core information of medical business, which puts forward extremely high requirements for data confidentiality and integrity. Therefore, we propose an attribute-based encrypted access control method, which realizes differentiated access control for different users and different departments through a fine division of data attributes. In the implementation of the method, we design efficient encryption and decryption algorithms by using the distributed characteristics of cloud computing. Experimental results show that, compared with traditional access control methods, the proposed method improves the efficiency of data processing while ensuring information security, and the average access response time is reduced by about 20%. In addition, we also verified the effectiveness of this method in multi-department information security management of smart medical care through actual case analysis.**

I. INTRODUCTION

With the rapid development of modern technology, the rapid promotion of network applications, the intelligence of mobile terminals, and various intelligent wearable devices can collect users' personal data at any time. These data contain all kinds of privacy information of users. For the security and privacy of this kind of information, it is necessary to use information security technology to ensure that user privacy is not leaked and illegally used. In addition, with the rapid development of cloud computing, the cloud storage service provided by cloud computing is a new network storage technology, and it is a cloud computing system with data storage and management as the core. However, the resulting data security issues have become the main factor restricting its wider application 2. On August 27, 2014, the Internet Society of China released the "Investigation Report on the Protection of Netizens' Rights and Interests in China", showing that in the past year, netizens have lost 143.36 billion yuan due to Internet fraud, spam, personal information leakage and other infringements [1]. Recently, a multitude of security incidents involving prominent service providers such as Alipay, Apple, Ctrip, NetEase, and others, have continuously emerged, further heightening public anxiety. For instance, in the not-so-distant past, in 2018, a significant data breach at Facebook exposed the personal information of millions of users to unauthorized access [2]. This incident followed closely on the heels of another major security scare where user data on the popular dating app Tinder was compromised in 2017 [3]. Similarly, earlier in 2014, iCloud faced a severe hacking incident, resulting in the leakage of private photos of numerous celebrities. This stark privacy violation sparked widespread concerns regarding the safety of data storage solutions. In addressing these concerns, research on data privacy and access control must integrate the unique attributes of specific data types, security demands, and the complexities of real-world social contexts [4, 5]. Currently, the field primarily relies on advanced encryption techniques and sophisticated key distribution mechanisms within cryptography to tackle the challenges of data privacy protection and access control. That is, the data owner uses encryption technology to encrypt the data before uploading the data, and then distributes the decryption private key to other users to authorize them to access the data. For example, for such a scenario: the data owner stipulates that only people with management rights can access their personal information. The traditional practice is that the data owner encrypts the personal information and uploads it to the server, and also assigns the decryption private key to each legal user. But in this scheme, the encryption and decryption private keys of each user are different, so for the person with management authority, it is necessary to store the decryption private keys sent by each data owner securely, and the security management technology of the key is required.

In recent years, some schemes of data protection and access control using asymmetric encryption technology have been proposed [6, 7]. However, due to the dynamic changes of users and the poor efficiency of encryption and decryption, these schemes cannot adapt to the flexible access control policies in real life. Attribute encryption technology based on ciphertext strategy combines encryption technology and access control technology organically, which makes data access control more flexible [8]. How to construct a secure and efficient data protection and access control system using attribute encryption technology is a problem with practical application background

and academic value. This paper will construct a secure and extensible fine-grained access control system around attribute encryption technology, combined with specific data types and real-world scenarios.

II. Relevant Knowledge

A. Blockchain Overview

In 2008, blockchain technology was proposed. The blockchain is a special data structure [9, 10]. Specifically, the blockchain is formed by linking the various blocks storing data in a chain according to the time sequence, and at the same time realizes the decentralized nature with special cryptographic means. The data structure of the blockchain:

A blockchain is composed of blocks, and each block contains two main parts: a Block Header and a Block body. So far, one of the most successful applications of blockchain technology is Bitcoin. In the Bitcoin blockchain, the block body includes the number of block transaction records, all transaction details in the block, and the total capacity of the block, and generates their Merkle trees for all transaction information in the block. Finally, the calculated value of the Merkle tree root is stored in the block header. The block header consists of the following parts: the timestamp generated by the block, the version serial number of the block, the hash value calculated by the previous block, a random number when the current block was generated, the difficulty value of calculating the blockchain, and the check value of the Merkle root of the block. Features of blockchain:

Decentralization. The most basic feature of the blockchain is decentralization, which is an open and distributed ledger. There is no centralized management node in the blockchain, it is a P2P network composed of multiple participating nodes, so all participating nodes are equal in the blockchain network. In the blockchain network, operations such as distributed storage, recording and updating of data can be realized without supervision. Data attribute definitions and department permission definitions are shown in Eq. (1) and Eq. (2).

$$a_f(i) = p(i) + jd(i) \tag{1}$$

$$\hat{h}_R(i,k) = \hat{h}_f^*\left(i, L_f - k\right) \tag{2}$$

Open consensus. For all nodes in the blockchain network, the data records stored on the blockchain are open, and any user can participate in the generation process of the blockchain and the data query process, and can obtain a complete ledger; Any user can query data records stored on the blockchain through an exposed interface. 3) Immutability. Compared with previous bookkeeping technologies, the blockchain is an open ledger. Once the block is generated, the data will be permanently stored. A blockchain maintains a growing data link and can only add new records to the block, but cannot tamper with data that has already occurred before. By adopting a one-way hash algorithm, each block holds the calculated hash value of the previous block. Due to the avalanche effect of the hashing method, if a certain block on the blockchain is modified, all blocks after the block will be recalculated, unless more than half of the participating nodes in the system are controlled by one of the nodes, otherwise once a node modifies the data on the block, other nodes in the network can easily find this behavior, so the modification behavior of the node is invalid for the entire system.

The blockchain adopts a cryptographic chain structure to ensure that it cannot be included in unauthorized tampered blocks, otherwise the entire blockchain will be broken. Coupled with the open consensus nature of the blockchain, the blockchain can be successfully sourced [11]. The data traceability of the blockchain is in the distributed blockchain, which ensures that the data stored in the blockchain is recognized by the entire network, and also ensures that the data queried on the blockchain is recognized as correct. The access control policy formula is shown in Eq. (3)

$$y_{RIC}(i) = \sum_{l=1}^{L_f} e_l \left(i - L_f + l\right)\hat{h}_f^*(i,l) \tag{3}$$

B. Location-based Cryptography Related Models and Algorithms

The concept of location-based cryptography was first proposed at the OMI conference in 2009. Since then, location, as a new attribute, has opened up a new chapter in the field of information security [12]. In location cryptography, the unique identity credential is the user's geographical location, in other words, the user's location determines his or her identity. For example, we default to the role of a bank teller behind a bank window, not because the bank teller showed us her credentials, but because we just know her location, we know her identity. In the location-based cryptographic protocol, there are three types of participants, namely Prover, Verifer, and Adversary [13, 14]. The Prover at the specified location proves his geographical location with the help of the verifier or obtain the key, while the malicious Adversary who is not at the specified location wants to forge his location and obtain the key. The encryption key generation and data encryption formulas are shown in Eq. (4) and Eq. (5).

$$K = g(A, ACP) \tag{4}$$

$$C = E(D, K) \tag{5}$$

BSM: Bounded Storage Model. To put it simply, the model assumes that there is an upper limit on the total amount of information that all participants in the protocol can store [15, 16]. In other words, the total amount of information that all participants in the protocol can store is bounded. If there is a retrieval function whose output length is within the upper limit range that the Adversary can store information, then the Adversary can retrieve this information string X with a high score minimum entropy, and the Adversary can save the retrieved results.

BRM: Bounded Retrieval Model. Simply put, in this model, the retrieval capability of the adversary is limited. Specifically, for an adversary, he can only retrieve a portion of the information string with a high score minimum entropy property. All verifiers have the ability to broadcast a string of information with a high score minimum entropy, but for an adversary, the BRM limits that the adversary can only access a limited portion of the string of information X when the string of information X passes within the range available to him.

Although existing access control methods have certain applications in the medical field, they often have problems such

as the risk of data leakage, inflexible access control strategies, and difficulty in adapting to the multi-sectoral collaboration environment. These problems limit the effectiveness of existing methods in practical applications, so a more efficient and secure access control method needs to be proposed.

III. Privacy Protection Scheme of Logistics Information Based on Attribute Encryption

A. System Model

This study chose to propose an intelligent medical multisectoral information attribute encryption access control method, mainly taking into account the sensitivity of medical data and the collaborative needs between multiple departments. When dealing with such problems, traditional access control methods often have problems such as insufficient data security, low access efficiency, and difficult multi-department collaboration. Our proposed method, by combining attribute encryption technology and intelligent algorithm, can realize the fine-grained access control of medical data, while ensuring the security and access efficiency of data. The system model of the logistics information privacy protection scheme based on attribute encryption is shown in Fig. 1. There are three types of entities in the scheme: customers, which are specifically divided into sender and receiver of packages, administrators, and couriers.

Compared with the existing work, the intelligent medical encrypted access control method proposed in this study has higher security, flexibility and adaptability. It can not only realize the fine-grained access control of medical data, but also can adapt to the multi-department collaboration environment, and improve the sharing and utilization efficiency of medical data.

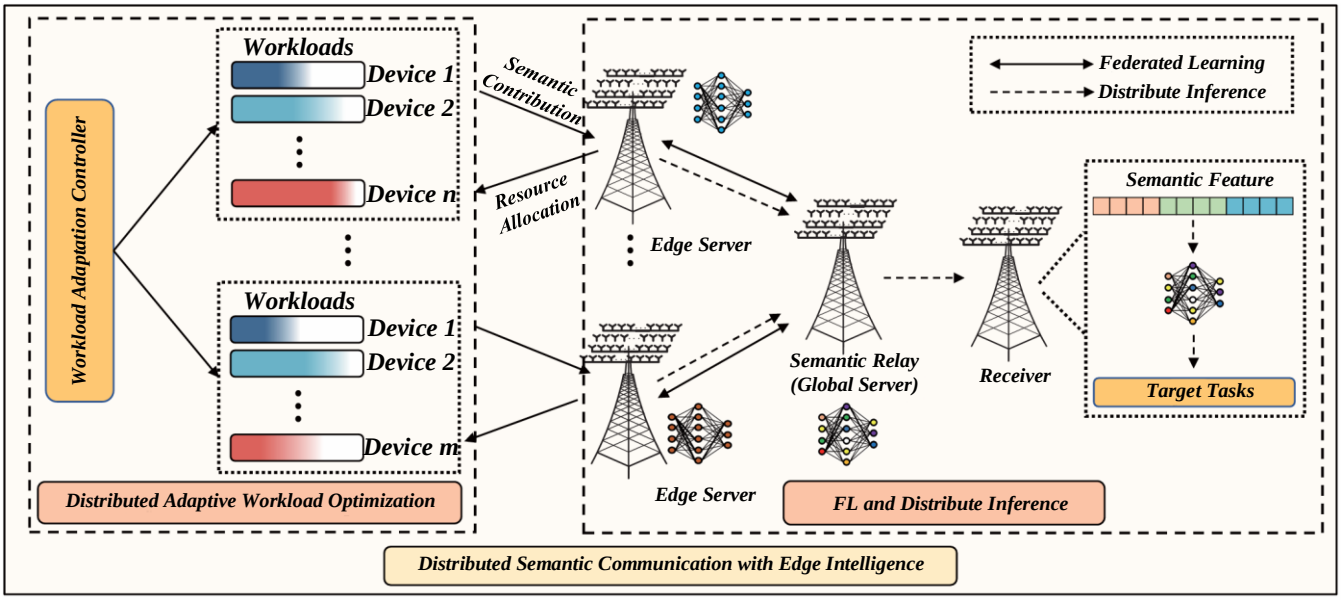

Fig. 1. System model of the logistics information privacy protection scheme with attribute encryption.

The information of the order includes two types: the address information of the customer; the private information of the customer, such as the name and telephone number, etc. [17, 18]. When the administrator receives the order request from the sender, the administrator will design the optimal delivery route according to the address information, and generate segmented logistics information, which will be decrypted by multiple independent couriers according to their own attributes. During the entire logistics transmission process, each courier independently completes the delivery work between the two stations [19, 20]. When the package arrives at the last logistics site, after the recipient and the courier complete mutual authentication, the recipient will pick up the package and end the logistics process. The specific roles are described as follows:

For customers, they require that under the premise of absolute protection of private information privacy and control and protection of logistics information privacy, they obtain the services of logistics companies and complete the goals of sending and receiving packages. Decryption request validation and decryption operation formulas are shown in Eq. (6) and Eq. (7).

$$r_B(n) = \sum_{i=-L_{RRC}}^{L_{RRC}} g(i) r(i - nK) e^{-j2\pi(f_c/f_s)(i-nK)} \quad (6)$$

$$y(n) = w_1 \hat{y}_1(n) + w_2 \hat{y}_2(n) \quad (7)$$

Attribute update and permission update formulas are shown in Eq. (8) and Eq. (9).

$$SNR_b = \frac{1}{N} \sum_{n=0}^{N-1} [R\{\hat{y}_b(n)\} - p(n)]^2, b = 1,2 \quad (8)$$

$$w_b = \frac{\sqrt{SNR_b}}{\sqrt{SNR_1} + \sqrt{SNR_2}} \quad (9)$$

Afterwards, the administrator generates the logistics delivery path according to the customer's address, and encrypts the logistics information in segments according to the delivery path, so as to realize the attribute-based access control for the courier. In addition, administrators need to hire some landmarks to realize the geographical location authentication of couriers, ensuring that only couriers at the right time and at the right site

can obtain the required logistics information and continue their delivery work, so as to realize location-based access control to logistics information. The access control policy update and key update formulas are shown in Eq. (10) and Eq. (11).

$$\hat{a}_1 = w_1\hat{a}_{1,1} + w_2\hat{a}_{1,2} \tag{10}$$

$$I(u,q) = max_{\tau,F}|A(u,q,\tau,F)|^2 \tag{11}$$

Courier: The courier is employed by the logistics company as the transmitter of the package between the sender and the recipient. Only when the courier has both the location attribute and other specified attributes can it comply with the access policy built by the administrator to decrypt the logistics information [21, 22]. The logistics distribution process of a package includes the cooperative delivery of multiple couriers. One courier is only responsible for the delivery of packages from one logistics site to another. Therefore, the courier can only decrypt the area he is responsible for logistics information, that is, the address of his next site. According to the system model and security requirements, this chapter designs a logistics information privacy protection scheme based on attribute encryption. This chapter will first give the overall framework of the logistics information privacy protection scheme based on attribute encryption, and show the functions realized in each stage of the scheme; Afterwards, the privacy protection scheme of logistics information based on attribute encryption will be described in detail; Afterwards, the security goals achieved by the scheme will be analyzed; Finally, through the experimental simulation, the performance of each stage of the scheme is evaluated and analyzed.

B. Adversary Model

Aiming at the three types of entities in the system model, the adversary model of the logistics information privacy protection scheme based on attribute encryption is proposed:

1) Customer: In the actual package sending and receiving scenario, the sender or receiver of a package may have the following behaviors: First, because a package may cause harm to social security, such as the package contains flammable liquids and other items, so the sender will deny that he ever sent the package; Second, a dishonest recipient may falsify his identity and thus take a package that does not belong to him. The formula for the system safety assessment is shown in Eq. (12).

$$\mathcal{S} = -\frac{1}{ln(N)}\sum_{f=f_l}^{f_u}\widetilde{\mathcal{W}}(f)\cdot ln\left(\widetilde{\mathcal{W}}(f)\right) \tag{12}$$

2) Administrator: Administrator, as the manager of a logistics company, is an honest but curious aspect. Administrators are responsible for handling the privacy protection of customers' logistics information. For this reason, administrators need to safely generate logistics distribution paths and encrypt logistics information according to different access policies. Administrators employ trusted attribute authorities and trusted landmarks to complete attribute-based and location-based access control. On the other hand, in order to obtain more potential benefits, the administrator is also very curious about the customer's private information. For this reason, he tries to illegally obtain the customer's private information, such as trying to crack the customer's name, phone number and other information in the encrypted order. And tamper with private information. Fig. 2 shows data access frequency statistics.

3) Courier: As the courier of the package, the courier is very important for the safety guarantee in the logistics and distribution process. First, couriers are curious about customers' private information and logistics information, and they may sell this information after obtaining customers' information. Second, even if some couriers are not during working hours and are located at the correct logistics site, they will unite and conspire to attack in an attempt to forge location attributes. Third, some couriers with some attributes may conspire to try to decrypt logistics information that does not belong to them by virtue of their respective attributes. Fourth, the courier will tamper with order information, such as the recipient's information on the order, to deliver the package to someone other than the intended recipient.

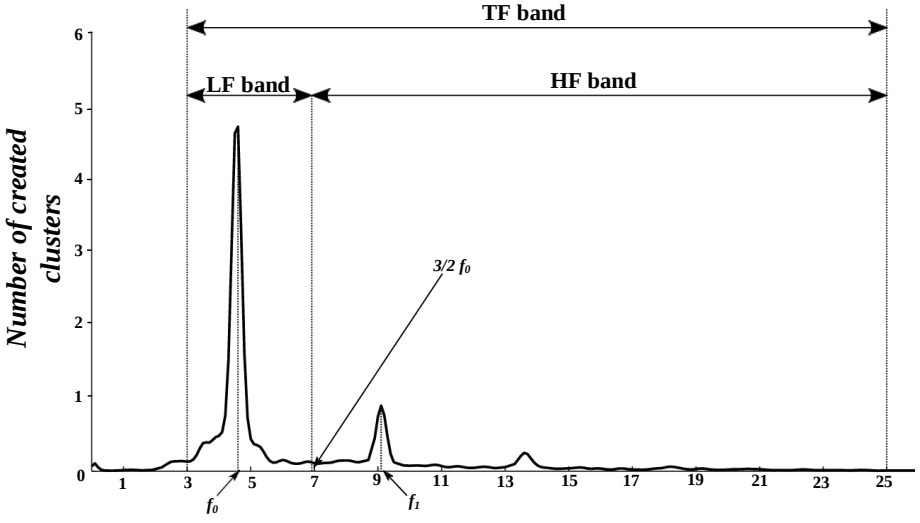

Fig. 2. Data access frequency statistics.

C. Safety Objectives

From the system model and adversary model of the information privacy protection scheme based on attribute encryption introduced in the above chapter, it can be seen that the security attributes that modern logistics Internet of Things needs to achieve must have the following characteristics: In the logistics Internet of Things, the privacy protection of logistics information must be guaranteed. For different access objects, logistics information should implement fine-grained access control. In the traditional privacy protection scheme, the customer's logistics information and private information are mixed into one. Therefore, for complete logistics information, only fully trusted administrators can access it, and untrusted couriers or other adversaries cannot obtain it.

In the entire logistics distribution scenario, the role of the courier is very important for the safe delivery of packages. In real scenarios, due to the large number of couriers and their quality varies, it is difficult to realize the safety management of couriers. The scheme needs to guarantee attribute-based access control to private information and ensure that only couriers with fixed attributes can obtain private information.

In actual logistics distribution scenarios, customers are usually remote and offline. Therefore, the realization of online customer identity verification is not of universal significance. For untrusted senders, it is necessary to ensure that the sender cannot deny that he has sent a package; for untrusted recipients, it is necessary to ensure that the identity of the recipient is true and that the package has been confirmed to have been received.

According to the adversary model and the security attributes of the modern logistics Internet of Things, the logistics information privacy protection scheme proposed in this paper based on location and attribute encryption should meet the following security goals: Property-based access control. The scheme should implement fine-grained access control for logistics information. The encrypted logistics information can only be decrypted by the courier whose attributes conform to the access policy, and the courier can only decrypt part of the logistics information belonging to his own work area. Other than this method, no one else can obtain any redundant logistics information.

Location-based access control. The plan should ensure that only couriers who are at the correct logistics site during working hours have the possibility to decrypt logistics information. Anti-collusion attack based on attribute access control. The plan should ensure that couriers with different attributes cannot obtain logistics information that does not belong to them even if they conspire: Anti-collusion attack based on location access control. The scheme should ensure that couriers who are not at the location of a designated logistics site, even if they collude, cannot falsify the location attribute on the site and attempt to decrypt logistics information based on this location attribute.

Privacy protection of logistics information. Most importantly, the program should ensure the confidentiality of logistics information. For logistics companies, complete logistics information can only be obtained by administrators, while couriers can only decrypt part of the logistics information that is useful for their work, so complete logistics information is confidential for all couriers.

Confidentiality of private information. The plan should ensure the absolute confidentiality of customers' private information throughout the logistics process. Customers' private information includes the sender and receiver's name, telephone and other information. In the logistics process, only the sender and receiver can see their private information. Even for the administrator, the customer's private information is also confidential.

Verifiability of the receiver. The scheme should guarantee the verifiability of the receiver. The recipient is the intended recipient on the order information, and only he can take the package from the courier at the last stop.

Package verifiability. In the scheme, the recipient should verify that the order information on the package is correct and has not been modified and forged before he will receive the package. The sender's unwillfulness. Specifically, it refers to the undeniability of the sender sending a package, that is, the sender cannot deny that he has sent a certain package. The receiver's unwillfulness. Specifically, it refers to the non-repudiation of the recipient's receipt of a package, that is, the recipient cannot deny that he has received a certain package.

D. Integral Design

As shown in Fig. 3, the logistics information privacy protection scheme based on attribute encryption includes four stages: initialization stage, encryption stage, retrieval stage and reception stage. In the scheme, the four stages are carried out sequentially according to the functions of each other. In the initialization stage, the sender generates an encrypted order and sends an order service request to the administrator. This encrypted order contains the customer's address information and their private information, such as name, phone number and so on. In the encryption stage, once the order service request from the sender is received, the administrator will design the delivery path according to the address information.

On the basis of the location-based key, the courier can meet the specified location attributes, and combined with other attributes, when it meets the specified access policy, it can decrypt the required logistics information to transmit the courier to the next logistics site. The recipient should also verify the correctness of the package. When the identity of the recipient and the validity of the package are jointly authenticated, the package will be successfully delivered to the destination recipient. At this point, the logistics process of the entire package is over.

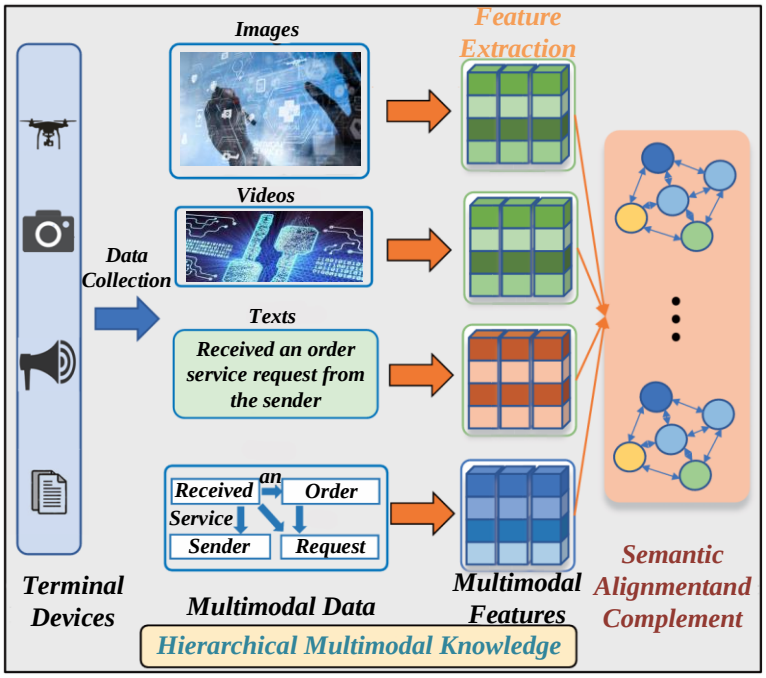

Fig. 3. Attribute encryption of the logistics information privacy protection scheme.

IV. Performance Analysis

A. Test Environment and Experimental Design

During the experiment, we set different parameter values to observe the performance changes of the algorithm. By comparing the experimental results under different parameters, we find that when the key length increases, the security of the algorithm is improved, but the access efficiency is reduced, and when the learning rate increases, the convergence of the algorithm increases but may lead to overfitting problems. Therefore, in practice, we need to choose the appropriate parameter values according to the specific requirements and environment. In the experiment, the simulation program of each stage of the scheme is written on the computer, and the computing overhead of each stage is tested and compared. Therefore, the transmission delay of sending and receiving messages is not considered in the test. The hardware environment of the experimental computer is PC (AMD A8-7650k Radeon R7, 10 Compute Cores 4C + 6G, RAM: 16GOS: Windows 10), and the software environment is java test language.

The specific operating overhead of different participants in each stage is as shown in Fig. 4. Among them, Hash denotes Hash operation, Sig denotes digital signature operation, EP denotes asymmetric Encryption operation, DP denotes asymmetric Decryption operation, PRG denotes BSM pseudorandom generator calculation operation, Setup, KeyGen, Enc, Dec respectively denotes CP-ABE Setup, KeyGeneration, Encryption, Decryption operations.

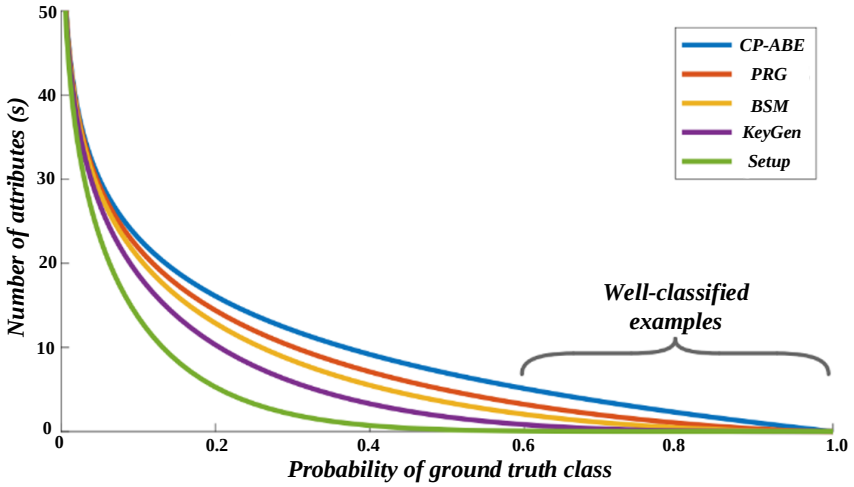

Fig. 4. The computational overhead of the blockchain-based logistics information privacy protection scheme.

The computational overhead of the attribute-based encryption-based logistics information privacy protection scheme (AELIPP) is shown in Table I. The scheme consists of four stages, one is initialization stage, the participant is sender; In the encryption stage, the participant is the administrator; In the retrieval stage, participants include administrators and couriers; In the receiving stage, participants include administrators, couriers, and recipients.

TABLE I. COMPUTATIONAL OVERHEAD OF LOGISTICS INFORMATION PRIVACY PROTECTION SCHEME BASED ON ATTRIBUTE ENCRYPTION

Stage	Participants	Execute action
Initialization phase	Sender	Hash + Sig + 2EP
Encryption phase	Administrator	DP + Setup + (3, 5, 6) (KeyGen + Enc + EP)
Retrieval stage	Administrator	4P RG
	Courier	5PRG + DP + Dec
Reception stage	Administrator	4PRG + 2DP + EP + Hash
	Courier	5PRG + 2DP + EP + Dec
	Receiver	2DP + 2EP + Hash

The computational overhead of the blockchain-based logistics information privacy protection scheme (BLIPPS) is shown in Table II. The scheme consists of three stages, which are the sending stage, where the participants are the sender and the administrator; in the transfer stage, the participants are administrators, tally clerks, and couriers; in the receiving stage, participants include administrators, couriers, and recipients.

TABLE II. COMPUTATIONAL OVERHEAD OF LOGISTICS INFORMATION PRIVACY PROTECTION SCHEME BASED ON BLOCKCHAIN

Stage	Participants	Execute action
Send phase	Sender	3EP + 2Hash + Sig
	Administrator	DP + Setup + (3, 5, 6) (KeyGen + Enc + EP)
Transfer phase	Administrator	4PRG
	Tally clerk	5PRG + DP + Dec + EP + Hash + Sig
	Courier	EP + Hash + Sig
Reception stage	Administrator	2DP + Hash
	Courier	Sig + 2EP + DP + Hash
	Receiver	2DP + 3EP + 2Hash + Sig

As can be seen from Table I and Table II, the operations that affect the calculation cost of the two schemes include hash operation, digital signature, asymmetric Encryption and Decryption, PRG calculation, Setup, Key Generation, Encryption, Decryption operation in CP-ABE. Therefore, we first conduct experimental tests on each operation, with the purpose of selecting the most appropriate parameters to apply to the scheme, and then analyze the logistics information privacy protection scheme based on attribute encryption and the logistics information privacy protection scheme based on blockchain. The actual calculation cost of each stage. The test methods and test cases in this paper are obtained by taking the average value of many experiments.

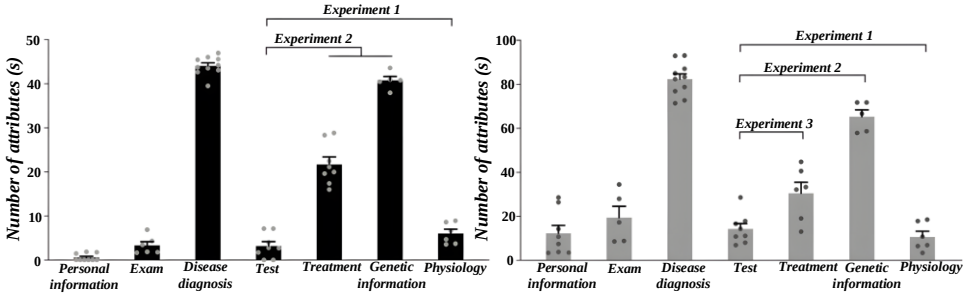

Fig. 5. Experimental comparison of different parameters.

Fig. 5 shows Experimental comparison of different parameters. Experiment 1 combines hash algorithm and signature algorithm to test the computational cost of different hash algorithm and signature algorithm; In experiment 2, the computational cost of BSM PRG algorithm in location cryptography is measured in order to select the appropriate pseudorandom generator algorithm; In Experiment 3, four algorithms of attribute Encryption: Setup, Key Generation, Encryption, Decryption were tested respectively, and the factors that affect the calculation cost were compared: the size of customer's attribute set, the number of leaf nodes, and the size of encrypted files, in order to select the appropriate number of attribute sets, the number of leaf stages, and the size of logistics files; On the basis of experiments 1, 2, and 3, we select algorithm parameters suitable for actual logistics transaction scenarios, and conduct experiments 4 and 5 respectively to test the calculation costs of each stage of the logistics information privacy protection scheme based on attribute encryption and the calculation costs of each stage of the blockchain logistics information privacy protection scheme.

B. Experimental Data Analysis

Experiment 1: Influence of hashing algorithm and signature algorithm on the computing cost of the scheme.

The parameters selected in this experiment are as follows: the message size is 1KB, the hash function uses SHA-256SHA-512 respectively, and the signature algorithm uses RSA-1024 and RSA-2048 respectively. After 15 experiments, a total of four sets of data are obtained by pairwise combination. The data is shown in Fig. 6.

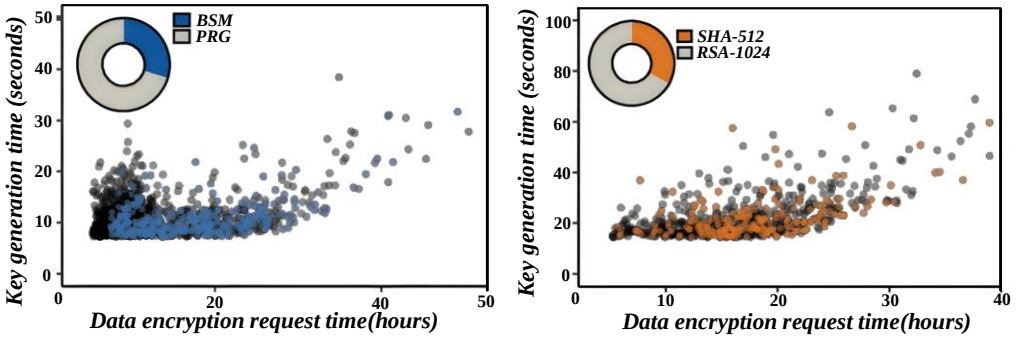

Fig. 6. Experimental results of the different signature algorithms.

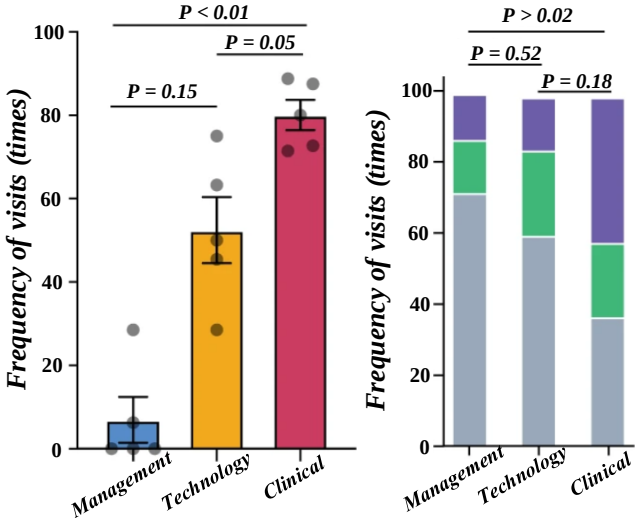

Fig. 7. Effect of different functions on the overall computational cost.

Fig. 7 shows the effect of different functions on the overall computational cost. As evident from Fig. 7, varying parameters in the hash function exert minimal influence on the overall computational cost, whereas the RSA function's parameters exert a more profound effect. Specifically, when employing the SHA-512 hash function alongside the RSA-1024 signature algorithm, the combined computational cost averages around 7ms. Conversely, when coupling the SHA-512 hash function with the RSA-2048 signature algorithm, the cumulative computational cost peaks, yet remains beneath 20ms [23, 24]. Given the paramount importance of security, all subsequent experiments pertaining to hash and signature algorithms will utilize the SHA-512 and RSA-1024 algorithms, respectively.

Experiment 2: BSM PRG algorithm and its parameter selection.

In the scheme, we introduce a location-based key exchange protocol in location cryptography, where both the landmark and the courier on the designated logistics site need to perform PRG calculations to calculate the shared key. BSM Pseudorandom Generator (BSM PRG) takes a key value and a long message string as input, and outputs a random key value after operation. Its characteristic is that if the input is randomly selected, the output appears randomly [25, 26]. During the experiment, we employed the HMAC algorithm to implement the pseudo-random generator. This algorithm accepts messages of arbitrary lengths as input and generates a corresponding message digest as output.

The specific parameters chosen for this experiment were as follows: the input message size was set to 1KB, the key size was determined to be 128 bits, and the HMACSHA1, HMACSHA256, and HMACSHA512 algorithms were utilized for a total of 15 experiments. The experimental data obtained are presented in Fig. 8.

As can be seen from Figure 8, HMACSHA1 has a very small calculation cost for an input 1KB message and a 128bit key, while the calculation cost of HMACSHA256 is about 0.18 ms, and the calculation cost of HMACSHA512 is about 0.27 ms. Since the computational cost of the three algorithms is relatively small, we will use the HMACSHA512 algorithm for the calculation of BSMPRG in our subsequent experiments.

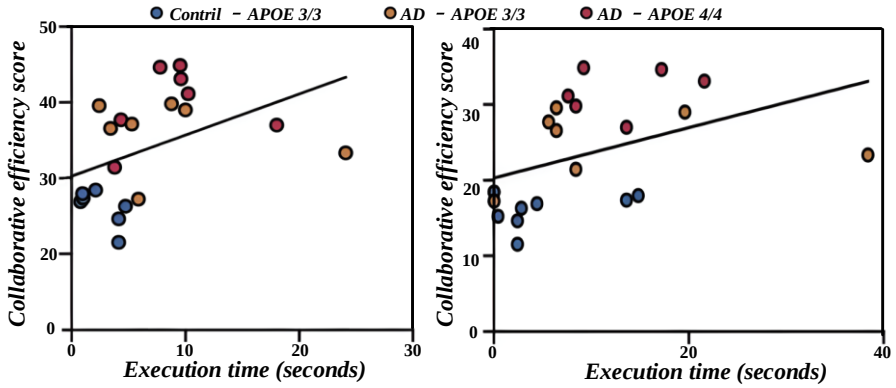

Fig. 8. Comparison of the synergy efficiency of different algorithms.

Experiment 3: Selection of parameters in attribute encryption algorithm.

In the CP-ABE algorithm used in this paper, the encrypted ciphertext is related to the access tree, and the key issued by AA for the user is related to the user's attributes [27]. There are four basic algorithms: Setup, KeyGeneration, Encryption, Decryption. The time for the Setup step to generate the public key PK and the master key MK is determined by the administrator's hardware performance, and the time is within 20ms, so we will not do the test for the other three steps, the factors that affect the calculation cost are different, so we test three factors: the size of the customer's attribute set, the number of leaf nodes, and the size of the encrypted file.

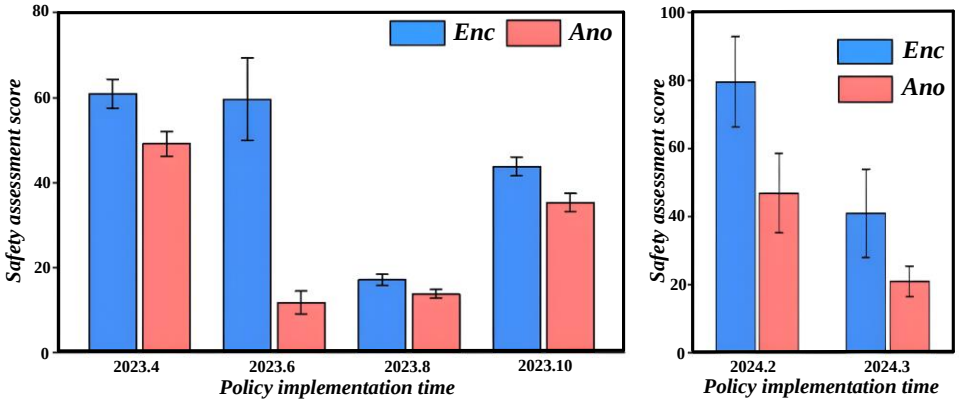

Fig. 9. Trend analysis of medical data security assessment.

Fig. 9 shows a trend analysis of medical data security assessment. Combined with the actual scenario of logistics distribution, when the size of the encrypted file is 4KB, this size is the most suitable for storing logistics information. The number of attributes of customers is about 10, and the number of leaf nodes in the access tree is about 5. This number is suitable for Yike and administrators to store. Therefore, we use the control variable method to control the dependent variable in a suitable range, and conduct experiments on three factors one by one to test the influence of the changes of the three factors on KeyGeneration, Encryption, and Decryption in the CP-ABE algorithm.

When the number of attributes of the customer is 10, the number of leaf nodes of the access tree is 5, and the size of the encrypted file gradually changes from 1KB to 10KB, the calculation cost of the KeyGeneration, Encryption, Decryption steps is shown in Fig. 10. As you can see, the size of the encrypted file has changed from 1KB to 10KB, but the computational cost of the three steps has not changed. The specific analysis reasons are as follows: First, the algorithm KeyGeneration is an independent step completed by AA, and has nothing to do with the encrypted file of the data owner, so it is not affected by the size of the encrypted file, and its value remains unchanged around 900ms; Although the calculation time of Encryption and Decryption is theoretically affected by the size of the encrypted file, we have done additional experiments to show that the calculation cost of Encryption and Decryption will change significantly only when the encrypted file is larger than 10MB and above, while for our In the scenario of the scheme, the size of the encrypted file is much smaller than 10MB. Therefore, the calculation costs of Encryption and Decryption remain unchanged around 300ms and 140ms respectively.

Fig. 11 shows the encryption and decryption rate tests. The analysis found that when the number of leaf nodes in the access tree is 5, the encrypted file size is 4KB, and the number of user attributes changes from 5 to 15. Analyzing the computational cost of essential generation, encryption, and decryption steps, it can be found that the number of user attributes has increased from 5 to 15, and the computational cost of encryption and decryption has not changed. Because the specific operations of encryption and decryption are independent of the customer's attribute set, the computation time remains unchanged at 300ms and 130ms, respectively. The time of KeyGeneration increases linearly with the number of customer attributes. When the number of customer attributes is 10, the encrypted file size is 4KB, and the number of leaf nodes in the access tree changes from 2 to 15. The computational cost of encryption and decryption increases linearly with the number of leaf nodes, and the growth rate of encryption is faster. Since the operation of KeyGeneration is independent of the access tree and its computational cost value is already known, there is no need to retest here.

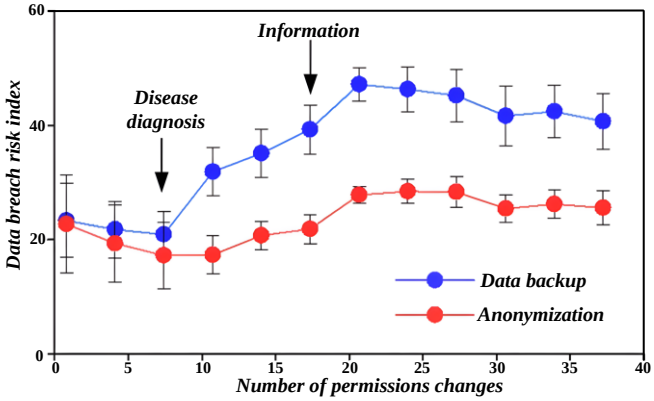

Fig. 10. Trend analysis of medical data security assessment.

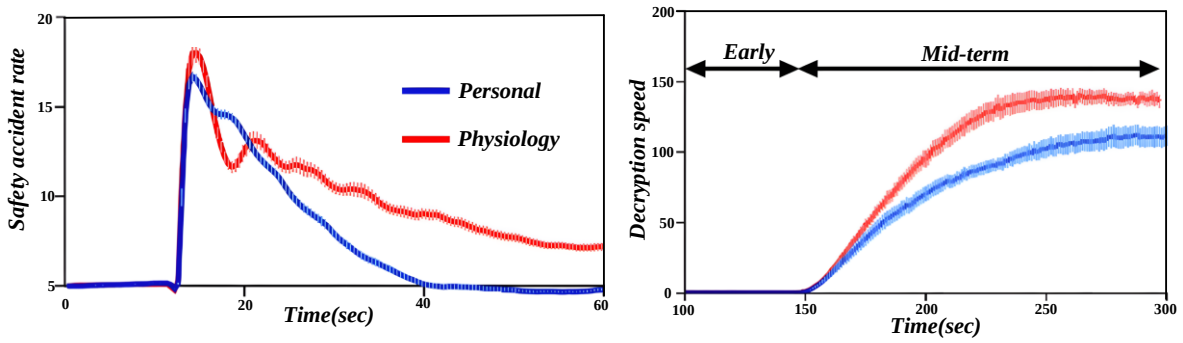

Fig. 11. Encryption and decryption rate test.

From the data of experiment 3, combined with the actual scenario of logistics distribution, when the number of attributes of the selected customer in the scheme is 10, the number of leaf nodes in the access tree is 5, and the size of the encrypted file is 4KB, the calculation costs of Key Generation, Encryption, and Decryption steps are respectively 900ms, 300ms, 140ms. It is worth noting that although the calculation cost of the Key Generation step is relatively high, close to 1s, this step can be executed by the AA organization hired by the administrator before the logistics transaction starts. Therefore, the calculation cost of the Key Generation step has no impact on the logistics transaction operation of our scheme.

V. CONCLUSIONS

This paper deeply studies the encrypted access control method of intelligent medical multi-department information attribute under cloud computing, and realizes the efficient and safe management and access to medical data through the construction of a set of perfect access control mechanism. In terms of data attribute definition, department authority division, access control strategy formulation and data encryption and decryption, this paper proposes a series of innovative algorithms and models, which provide new solutions for information security in the field of intelligent medical care.

Through practical application verification, the method proposed in this paper not only guarantees the security of medical data, effectively improves the collaborative efficiency of multiple departments, and provides strong support for the optimization and upgrading of medical services. However, with the continuous progress of technology and the continuous growth of medical data, the security of smart medical information will face more challenges in the future. Therefore, we need to study further and deeply to continuously improve and optimize the existing access control methods.

Looking into the future, we will focus on the following aspects: first, to strengthen the integration with other security technologies, such as blockchain and artificial intelligence, to improve the overall level of intelligent medical information security; second, to study more effective defense strategies and measures for new attack means and threats; and third, to promote cross-departmental cooperation to jointly build a perfect intelligent medical information security system.

In short, the research and application of the multi-department information attribute encryption access control method under cloud computing has important practical significance and broad application prospects. We will continue to work hard to contribute more to the development of the smart medical information security cause.

Application of Data Exchange Model and New Media Technology in Computer Intelligent Auxiliary Platform

Na Li*
School of Economics and Management, Jiangxi Technical College of Manufacturing, Nanchang, Jiangxi 330095, China

***Abstract*—To improve the use of computer-assisted learning, the author presents a method based on the use of new technologies. The system hardware model has a three-layer model system, including the user interface layer, the business option layer, and the data management layer. After teachers, students, and other users log in to the system, the user interface layer needs to enter personal information and advise users by including business-level options. System interaction is mainly influenced by two things: interactive learning and information sharing, interactive learning affects the online lessons of teachers and students; Data exchange is reflected in the data transmission of the data exchange model. According to the test results, after using the system, students with high self-efficacy increased from 11 to 21, and the percentage increased from 21.4 to 34.8, which can be understood as an increase in the number of good students. This interactive learning has been proven to increase students' self-efficacy and improve learning, and the use of this system has been a positive outcome.**

***Keywords*—Computer intelligent assisted teaching system; information exchange; stress testing; new media technology**

I. Introduction

The 21st century is an era of rapid development in information technology, with the development of multimedia and network technology, the perfect combination of the Internet and education has triggered an educational revolution in the information age [1]. Online education, also known as "E-learning" in English, refers to online learning or networked learning, which refers to the establishment of an internet platform in the field of education and a new way for students to learn through the internet.

Online teaching is another concept closely related to online education. The broad definition of online teaching platforms includes both hardware facilities and equipment that support online teaching, as well as software systems that support online teaching [2]. That is to say, there are two broad categories of online teaching platforms: Hardware teaching platforms and software teaching platforms. Narrowly defined online teaching platform refers to a software system built on the Internet and providing comprehensive support services for online teaching. Online teaching is not only about publishing teaching materials online, but also about sufficient communication and exchange between students and teachers, as well as between students and students [3]. The teaching support platform developed using network technology has become a tool for communication between teachers and students, providing a comprehensive information environment and support for teachers to implement teaching online. Digital media technology is the use of computers to integrate various media such as text, graphics, images, sound, animation, and video, and process them through sampling, quantization, editing, modification, encoding, compression, reconstruction, display, and storage transmission, and establish logical connections. Computers constantly refresh various records with their unparalleled advantages of convenience, accuracy, efficiency, convenient storage, and ease of modification [4]. In recent years, the rapid development of multimedia technology and the continuous upgrading of software have provided broad prospects for the widespread application of computers in the field of design and performance, multimedia technology has not only brought a revolution to stage visual expression in a new form, but also brought about significant changes in people's aesthetic concepts.

With the popularization of computer network technology, its application in computer teaching, making it play the role of intelligent auxiliary education, has been comprehensively carried out in teaching practice. As a teacher who has been engaged in computer teaching for many years, the author believes that if computer network technology is reasonably and effectively applied, it can indeed achieve the effective intelligent assistance of teachers in educating students, however, if not applied properly, there may also be some problems that need to be taken seriously.

II. Literature Review

The popularization of computer network technology has brought great convenience to people's lives and learning, and the status of computer education in school teaching is becoming increasingly high. The development of the times and technology has made the use of computers more widely distributed, the new generation of students must learn computer technology well in order to succeed in the competition of society. Computer network technology provides abundant learning resources for computer teaching, allowing students to gain richer knowledge in interactive environments, when students discover some problems in their studies, they can use powerful networks to search for the answers they need. Although computer network technology has brought great convenience to computer education in schools, it also has adverse influencing factors [5]. Therefore, the current main task is to fully utilize its advantages to eliminate some adverse

effects and fully utilize the function of network technology in computer intelligent assisted education.

Due to the current lack of emphasis on experimental courses in computer basic courses in some schools, there are very few class hours arranged, and there is a lot of experimental content, resulting in some students having difficulty mastering the experimental content. School affairs must increase the hours of experimental classes to exercise students' practical abilities and provide them with a deeper understanding of written knowledge, in order to enhance teaching efficiency [6]. The specific backup of computer data in the teaching of basic computer network technology courses is shown in Fig. 1:

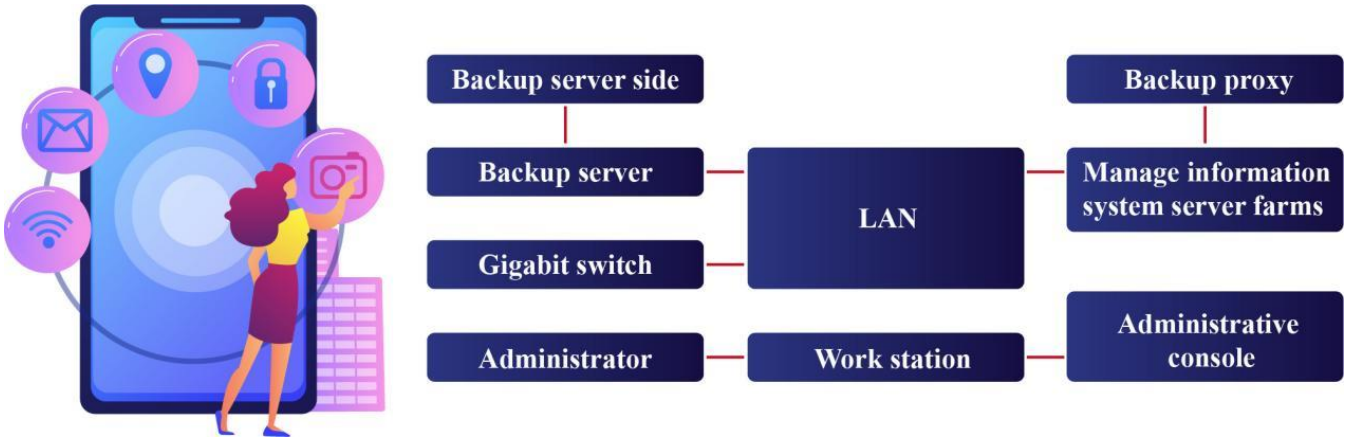

Fig. 1. Computer network technology data backup structure diagram.

With the development and application of network technology, China is gradually entering an era of "artificial intelligence". Nowadays, people's lives are filled with artificial intelligence internet products and IoT applications, which are the two mainstream directions for internet product aggregation. Take the speech recognition, facial recognition, and autonomous driving technologies currently used in China as examples, all of which are applications of artificial intelligence technology. On the other hand, with the development of information technology, the Internet of Things has also developed rapidly. Therefore, Y. Yu put forward the idea of creating artificial intelligence by combining the two new technologies. The article discusses the current state of smart internet development worldwide and predicts its development prospects [7]. With the widespread demand for intelligence in many industries, many people have begun to devote themselves to research, realizing its role in economic development and hoping to better support more businesses. Artificial intelligence speech technology is important for advertising and television news, it can improve the quality and performance of traditional voice, make it better for singing, radio advertising and recycling, and can serve the people better. Hu .M discussed the use and development of artificial intelligence technology in the context of integration, and studied its development performance, intelligent robot typing, intelligent face recognition, meaningful speech recognition, intelligent OCR recognition, automatic reporting, and other applications and developments [8]. Artificial intelligence technology, as an emerging and rapidly developing technology, has played a crucial role in many fields. In the power system, due to its complex organizational form, its deeper application in the power system is currently a challenge faced by the power system. In response to this issue, Han .X applied the concept of enterprise architecture to deeply analyze the architecture of power grid enterprises [9]. At the architectural level, they clearly planned the application of artificial intelligence in the architecture. By classifying business, application, technology, and data, artificial intelligence can be further applied in complex power systems. Finally, a successful application example in the power system is provided.

The author designs an interactive electronic technology computer-aided teaching system based on new media technology, with the aim of achieving interactive electronic technology computer-aided teaching.

III. Design of Interactive Electronic Technology Computer Aided Instruction System

A. System Hardware Design

In general, the client does not need to install any other software, just install and use the browser, reduce the connection between the server and the client, reduce the risk of exploiting the application code, and support the security of the database system.

According to the new technology, the interactive computer has a three-layer structure in the order of user interface layer, business selection layer, and data management layer. Teachers, students, and other users can access the system by entering their personal information in the user interface layer and accessing the selected business layer ; Teachers, students and other users can click on the application according to their needs in the business option layer, and the business option layer can change the message to the user to receive management information; The information management system selects the learning materials and integrates them according to the user's needs. Fig. 2 shows the three-step process of interactive computer-based technology [10].

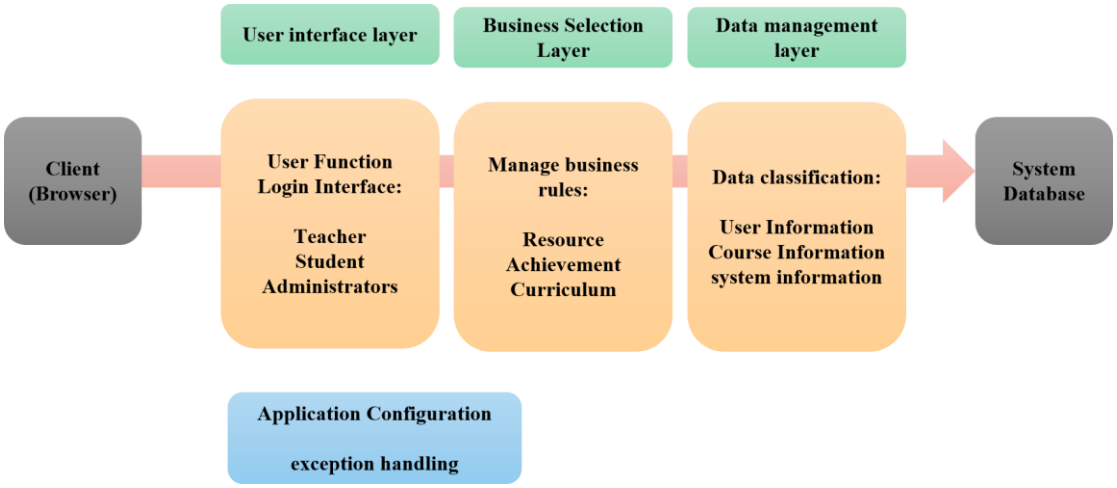

Fig. 2. Three-layer architecture diagram of the computer-aided teaching system of interactive electronic technology based on new media technology.

1) User interface layer: Users enter their personal information on the service's login interface and then click the submit button to enter the business selection process. End-to-end technology is used to complete user input and implement user input as quickly as possible in real-time. NET certificate plugin to prevent user theft and hacking [11].

2) Business selection process: After entering the business selection layer through the user interface layer, users can click on the application that suits their needs, and the business selection process redirects people to use configuration statements in the management layer. Business process options provide better access to information management through new technologies. Since there are some differences in the business preferences of users with different characters, let's take the management system as an example, Fig. 3 shows the management schematic diagram of the teacher application management system in the selected business process [12].

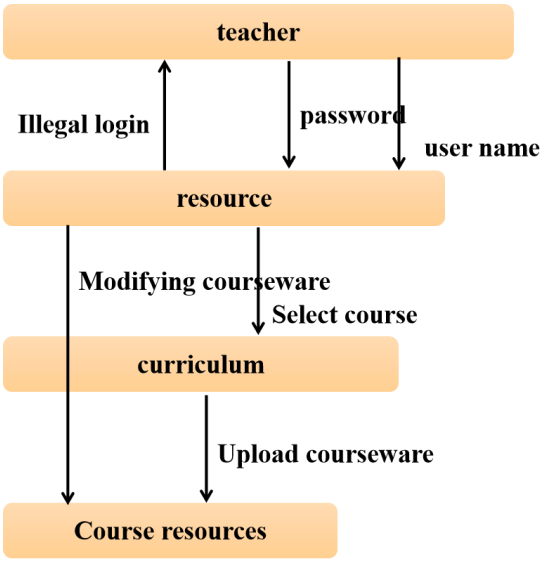

Fig. 3. Schematic diagram of the service selection layer resource management function.

In Fig. 3, the teacher enters the user name and password in the user interface layer to access the business process of the selection process, access the standard business level of the process selection process, you can choose the class or customize the product according to your needs, you can upload the material to the course materials for future study [13].

B. System Interactive Design

1) Interactive training: Interactive Learning A diagram of interactive computer learning as a new technology is shown in Fig. 4.

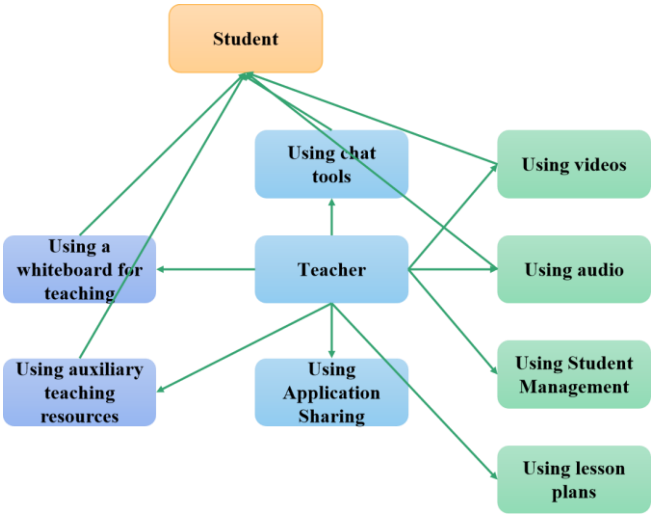

Fig. 4. Example of an interactive system.

Interactive instructions Use diagrams to illustrate the interactive operation of the system. The newsletter shows that teachers are successfully communicating with students through interactive tools, video, audio, student management, lesson plans, sharing plans, smart teaching tools, and free lessons.

2) Information exchange: Interactive computer-aided design software based on new technologies, including interactive management servers, database servers, web servers, and node applications. The communication management server is used for intelligent support and

information exchange between study group members and groups, and its functions include the following [14].

Manage data versions: Join or delete study groups, manage courses.

Manage chats: Change the chat information sent to different groups of users by all users.

Node operations include: Receiving, duplicating, compressing, decompressing, searching, and transmitting video and audio data; Distribute research materials requested by the group; Group information management; Communicate information in conversation.

C. Research on Recommended Learning Algorithms

The coordinated filtering algorithm compares the specific behavior of a user (such as rating, viewing frequency, viewing time, resource collection, download collection, etc.) with the operational behavior of other users, this enables the identification of neighbors whose behavior is closest or similar to that of the target user, the system will automatically analyze the behavior of these similar neighboring users, and after the analysis is completed, the system will recommend specific content of interest between neighboring users to the target user [15]. Therefore, the Collaborative filtering recommendation algorithm is based on the following assumptions: (1) Users have similar interests and hobbies. (2) The user's interests and hobbies can maintain a certain degree of stability and continuity within the same time period, and will automatically predict the user's specific interest needs based on their historical operational behavior. Collaborative filtering recommendation algorithms can be divided into the following two categories: (1) User based Collaborative filtering recommendation; (2) Collaborative filtering recommendation based on specific projects. Among them, the central idea of user based Collaborative filtering recommendation is that there is a certain degree of similarity between the operating behaviors of different users, for example, the operating behaviors of users A and B are very similar, user A operates specific resource A, and user B will also have a high probability to select resource A [16]. The central idea of Collaborative filtering recommendation based on specific projects is that there is a certain degree of internal correlation between projects, for example, if user A selects items B1, B2, B3, and B4, there will usually be a certain degree of internal correlation between items B1, B2, B3, and B4. Most of the Collaborative filtering systems based on specific items will use the scoring matrix of "user item" to distinguish the internal association between different items, the system will automatically calculate the final score of a user on an item through this internal association, thus generating the final set recommended to target users.

The quality of nearest neighbor selection can directly determine the accuracy of the final information resource push, therefore, the generation of nearest neighbors is the core and key of this algorithm. The author used Pearson's correlation coefficient to calculate the degree of familiarity between users. Therefore, the familiarity between user U_a and user U_b is represented by the following Eq. (1):

$$sim(User_a, User_b) = \frac{\sum_{n=1}^{N}(r_{a,n} - \bar{r}_a)(r_{b,n} - \bar{r}_b)}{\sqrt{\sum_{n=1}^{N}(r_{a,n} - \bar{r}_a)^2}\sqrt{\sum_{n=1}^{N}(r_{b,n} - \bar{r}_b)^2}} \quad (1)$$

In Eq. (1) above, $r_{a,n}$ represents the final rating of user U_a on a resource project $Item_n$; $\bar{r}_a$ represents the average score of all resource projects evaluated by user U_a.

The project-based Collaborative filtering algorithm can perform similarity calculation offline, and Top-N recommendation can be used when the nearest neighbor user set is finally selected, this recommendation refers to the set of N users with the highest similarity as the closest neighbors. Afterwards, the general formula 'prediction' can be used to calculate the current user's level of interest in any specific resource project. At the same time, sort the predicted interest levels and ultimately recommend the N resource projects with the highest interest level to the target user u.

Therefore, we can assume that the set of resource items that user u has rated is S_u, therefore, the predicted interest level of user u in any resource item j is represented by Eq. (2) as follows:

$$prediction_{uj} = \bar{r}_u + \frac{\sum_{i=1}^{n} sim(u,i)(r_{i,j} - \bar{r}_i)}{\sum_{i=1}^{n} |sim(u,i)|} \quad (2)$$

In Eq. (2), $\bar{r}_u$ represents the average score of users on the evaluated resource projects; $\bar{r}_i$ represents the average score of neighbor i; r_{ij} represents the evaluation score of neighbor i on resource project j; Sim (u, i) represents the degree of similarity between user u and user I [17].

IV. System Testing

Let's take a class of some 2nd year students as an example. This system is used in school information technology. Boys, students and teachers access the system through the user interface and perform six functions: user management and permission management. The tests in Table I show that the results of the application of six different systems are consistent with the results and exceed the performance of the system [18].

The self-efficacy index is used to determine the effectiveness of students in controlling their own behavior, which reflects their ability to learn independently [19]. In this part of the experiment, self-efficacy groups and low-efficacy groups are used to determine how the learning process interacts among students and whether teachers have a positive effect on students after using this method (Fig. 5).

TABLE I. FUNCTIONAL TEST RESULTS OF THE SYSTEM MODULE

System module function settings in this article	Optimum effect	Application results of this system
user management	If the user's login information is incorrect, it will be displayed immediately	Meet the ideal effect
Administrator permission test	Edit user information for students and teachers	Meet the ideal effect
Students' autonomous learning	Choose a course to study, test, etc. and take the test yourself	Meet the ideal effect
Application of Student Courseware	Students can choose their own courses to complete their online course	Meet the ideal effect
Teacher Course Management	Teachers can edit the relevant content of their courses	Meet the ideal effect
Teacher Q&A interaction	Teachers can respond to students' uploaded questions online	Meet the ideal effect

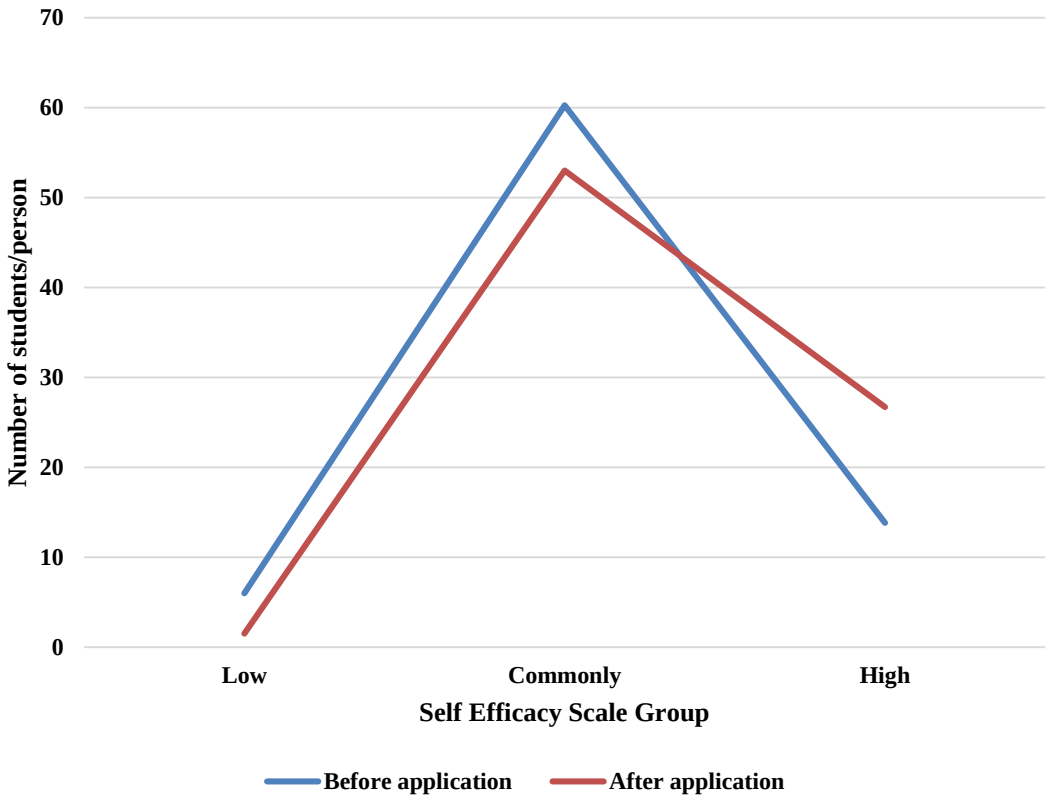

Fig. 5. Results of the system application effectiveness test (before and after application).

Fig. 5 shows that after implementing the system, the number of students with high self-reliance increased from 11 to 21, and the percentage increased from 21.4 to 34.8. By using this system, it can be understood that the number of students with good personal performance has increased [20-21]. A slight decrease in the number of students with high self-efficacy and self-efficacy after using this method indicates that the interactive learning method improves students' self-efficacy, improves their own learning, and takes advantage of this system.

V. CONCLUSION

The author of interactive design of intelligent computer technology helps to introduce new technologies, including the user interface layer, business-level options and information management systems, to achieve the intelligent technology technology support manual; Analyzing interactions in computer-based learning through interactive learning and information sharing. After testing the system, it can be seen that the number of students with high self-efficacy increased from 11 to 21 and the percentage distribution increased from 21.4 to 34.8 after applying the method described in this article. interactive teaching of the process improved students' self-reliance and independent learning; Also, applying the results of this system to six different activities will achieve ideal results, and the system has strong interactions and high resistance.

Blockchain-Enhanced Security and Efficiency for Thailand's Health Information System

Thattapon Surasak
Department of Computer and Information Science, Faculty of Applied Science
King Mongkut's University of Technology North Bangkok, Bangkok, Thailand

***Abstract*—This study seeks to enhance the security, efficiency, and usability of Thailand's health information system through the integration of blockchain technology and a user-friendly web application. Blockchain's inherent strengths in secure data storage and sharing make it particularly well-suited for addressing the critical challenges of healthcare data management. Currently, Thai citizens face significant barriers when seeking medical treatment across multiple hospitals, as they must manually request and transfer both their Electronic Medical Records (EMRs) and paper-based medical records. This fragmented system creates delays and inefficiencies, as each hospital operates its own isolated data silo. To overcome these challenges, this study proposes a solution utilising a private blockchain to securely store and manage patient medical histories and prescriptions. This approach ensures data integrity while implementing robust authorisation mechanisms to restrict access to sensitive information exclusively to verified individuals. The system's security is further strengthened by blockchain's encryption features and the use of smart contracts. A well-designed web application serves as the interface between the secure blockchain database and end-users, offering a seamless experience for both healthcare providers and patients. In addition, User Experience (UX) testing was conducted with healthcare providers to assess the system's usability and functionality. The results highlight the system's user-friendly interface, confirming its potential for widespread adoption. By fostering efficient, secure, and patient-centric health information exchange, this study has the potential to significantly enhance healthcare delivery and outcomes in Thailand.**

***Keywords*—Blockchain technology; healthcare information system; Electronic Medical Records (EMRs); user experience (UX) testing; web application; data security**

I. Introduction

The digital transformation of healthcare systems has brought significant advancements in patient care, enabling more efficient diagnosis, treatment, and management of health conditions. However, this shift towards digital systems has also highlighted several critical challenges, particularly in the areas of managing and securing sensitive medical data [1]. While the adoption of electronic health records (EHRs) and other digital tools has improved the accessibility of patient information and streamlined healthcare processes, it has also introduced new complexities in ensuring data privacy, interoperability, and compliance with regulatory standards. The rapid expansion of healthcare data, coupled with increasing cyber threats, has made it essential to implement robust solutions for safeguarding patient information and ensuring the seamless exchange of medical data across different healthcare providers and institutions [2].

Thailand's healthcare system faces unique challenges stemming from infrastructural, administrative, and technological limitations, which are compounded by the fragmented handling of both digital and paper-based medical records [3], [4]. Patients frequently encounter inefficiencies when seeking care across multiple hospitals, as they must manually request and transfer their medical records, leading to delays in treatment and posing risks of incomplete information for healthcare providers [5], [6]. Moreover, limited interoperability between data systems and fragmented administrative structures exacerbate these issues, creating bottlenecks in the seamless exchange of critical patient information [7].

Concerns regarding infection control and the management of patient movement within healthcare facilities further highlight the urgent need for secure, real-time access to medical data. Blockchain technology, with its decentralised architecture and capacity for creating immutable records, offers a robust solution to these challenges. By integrating blockchain into Thailand's healthcare system, hospitals can streamline the sharing and retrieval of medical information, reduce administrative inefficiencies, and improve overall care quality. Furthermore, adopting blockchain technology aligns with ongoing efforts to modernise healthcare infrastructure and address gaps in service delivery, paving the way for a more patient-centred and efficient system [8].

Blockchain technology has emerged as a promising solution to these challenges, providing a decentralised and secure framework for data storage and exchange. A blockchain is a shared, distributed ledger that stores data across multiple nodes, ensuring that once information is recorded, it is extremely difficult to alter. This is achieved through cryptographic techniques and consensus mechanisms that validate data consistency across the network. While blockchain is often associated with cryptocurrencies such as Bitcoin, its applications in healthcare are particularly valuable due to its immutability, transparency, and robust data security features [9].

Among the many technological advancements, blockchain stands out for its unique ability to protect data from tampering and unauthorised access. Data is stored across a distributed network, allowing every member to access and verify information simultaneously, ensuring transparency. In the context of healthcare, blockchain can securely store patient records, safeguarding them against unauthorised modifications or breaches. Additionally, only authorised stakeholders, such as doctors and healthcare providers, can access these medical histories, enabling the provision of more continuous and improved care. This study aims to demonstrate how blockchain technology can transform Thailand's health information system, resulting in better healthcare outcomes and an enhanced quality of life

for its citizens.

This proposed system utilises blockchain technology, specifically Hyperledger Fabric, to enable fast, secure, and seamless sharing of patient records. By integrating blockchain with a user-friendly web platform, the system enhances the efficiency of health data exchange in Thailand. Blockchain's encryption and smart contracts ensure that only authorised individuals can access patient information, thereby safeguarding data integrity. The system also significantly reduces the time required for transferring medical records between providers, facilitating faster and more accurate diagnoses and treatments. Furthermore, it empowers patients by granting them greater control over their medical data, representing a critical step towards a more patient-centric healthcare system.

The remainder of this paper is structured as follows: Section II provides a comprehensive review of previous studies in the field, examining the historical context of health information systems alongside recent advancements in blockchain technology for healthcare. Section III presents a detailed description of the design of the proposed system, highlighting the foundational principles of the blockchain-based solution. Section IV discusses the results, including the development of a user-friendly web application that interfaces with the blockchain. Finally, Section V synthesises the key findings, reflects on the contributions of this work to the field, considers its broader implications, and outlines promising directions for future research.

II. Related Work

Blockchain technology is increasingly being studied for its potential to address critical challenges in healthcare, particularly in securing sensitive patient data, ensuring interoperability, and enhancing the transparency of medical record transactions. Amid the ongoing challenges posed by fragmented record-keeping systems, blockchain offers a decentralised solution that balances privacy with real-time accessibility to medical data [10].

Early applications of blockchain in healthcare included MedRec, a system designed for managing Electronic Medical Records (EMRs). Leveraging Ethereum and smart contracts, MedRec aimed to facilitate the secure sharing of patient data among healthcare providers. By addressing data silos while maintaining patient control over access, it demonstrated blockchain's significant advantage: immutable record-keeping, which ensures the integrity of medical records [11]. Blockchain technology presents a solution to the fragmented nature of healthcare systems. At present, patient records are siloed within individual institutions, limiting the delivery of comprehensive care. By establishing a unified ledger, blockchain enables authorised providers to access and update patient records in real time. This enhanced interoperability has the potential to improve care continuity, reduce redundant testing, and minimise medical errors [12]. Blockchain technology addresses critical healthcare challenges related to data provenance and record integrity. Through its consensus mechanisms, all modifications to medical records are verified and permanently recorded, creating an immutable and auditable history. This enhances transparency and fosters trust among patients, providers, and institutions. By tracking who accessed or modified records and when, blockchain provides a robust solution for safeguarding the integrity of sensitive medical information [13]. In addition to enhancing security and transparency, blockchain's use of smart contracts has been extensively studied as a tool to automate and enforce access control policies. In healthcare settings, these programmable contracts enable sophisticated access control by verifying the credentials of healthcare providers and granting access to patient records only under predefined conditions. For instance, a doctor can access a patient's history only if directly involved in their care and appropriately authorised. This dynamic model minimises the risk of unauthorised access while facilitating necessary data interactions. As a result, smart contracts improve both the security and efficiency of managing sensitive medical information [14], [15]. Permissioned blockchains, such as Hyperledger Fabric, have significantly enhanced blockchain's applicability in healthcare. Unlike public blockchains, these systems restrict network access to known and trusted participants, addressing the critical need for privacy in healthcare environments. Hyperledger Fabric's modular architecture supports secure transactions and smart contract integration while maintaining stringent control over access to medical records. This makes it particularly well-suited for healthcare settings, where confidentiality is paramount. Studies confirm its viability for applications requiring controlled viewing and updating of medical records [16]. However, storage limitations remain a challenge, especially when dealing with large volumes of medical data. While blockchain excels at storing transaction records and hashes of medical data, storing actual medical records on-chain is inefficient and costly in terms of both storage and computation. To overcome these limitations, hybrid systems combining blockchain with traditional relational databases, such as MariaDB, have been proposed. These systems store sensitive data on-chain while offloading larger, non-sensitive data to off-chain databases. This hybrid approach preserves the core benefits of blockchain, such as immutability and security, while addressing the performance challenges associated with large-scale data storage [17], [18].

In conclusion, blockchain technology has demonstrated significant potential in addressing key challenges in healthcare, particularly in the secure and efficient management of Electronic Medical Records (EMRs) [19]. The literature highlights blockchain's decentralised, immutable, and secure nature as a foundation for enhancing privacy, interoperability, and trust in healthcare data management [20]. Notable studies, such as MedRec, have explored the use of Ethereum and smart contracts for patient data sharing, while others have investigated the integration of blockchain with IoT systems for real-time data collection and the secure management of medical information [16]. However, despite its advantages, blockchain faces limitations, including scalability and storage constraints, which must be addressed for broader adoption. To mitigate these challenges, hybrid systems combining blockchain with traditional databases, such as MariaDB, have been proposed. These systems store sensitive data on-chain while offloading larger, non-sensitive data to off-chain databases, thereby maintaining performance without compromising security.

This proposed system builds on these foundations, leveraging Hyperledger Fabric, a permissioned blockchain specifically designed to provide robust security and privacy in a decentralised environment. Unlike Ethereum, which incurs transac-

tion fees, Hyperledger Fabric is open-source and free from such costs, making it a more practical choice for healthcare applications [21], [22]. Its modular architecture enables the integration of smart contracts to control access to EMRs, ensuring that only authorised individuals can view or update sensitive medical information [23], [24]. The design of the Blockchain-Based Healthcare Information System (discussed in Section III) combines blockchain with a user-friendly web application, offering seamless access to EMRs while maintaining the highest levels of security. By employing smart contracts and a hybrid storage solution, this proposed system addresses the limitations identified in previous systems. This approach not only ensures the integrity of patient records but also enhances data sharing between healthcare providers, enabling faster diagnoses and more accurate treatments. Furthermore, this study advances the existing literature by demonstrating how blockchain, when integrated with modern web technologies and efficient storage solutions, can resolve critical challenges related to data security, privacy, and interoperability in healthcare. Future work will focus on scaling the system to accommodate larger networks and incorporating advanced privacy-preserving techniques to further enhance the security of healthcare data.

III. Proposed System

The proposed Blockchain-Based Healthcare Information System (HIS) has been designed to address the inefficiencies and security vulnerabilities inherent in traditional centralised systems for managing Electronic Medical Records (EMRs). By leveraging Hyperledger Fabric, an open-source, permissioned blockchain, the system provides a secure and decentralised solution for managing patient records. Additionally, it enforces strict access control through the integration of smart contracts, ensuring that sensitive medical information remains accessible only to authorised individuals.

A. System Architecture

The system consists of three primary components:

1) Blockchain Database: The blockchain network forms the core of the system and is built on Hyperledger Fabric. This platform was selected for its numerous advantages over alternatives such as Ethereum, including its open-source nature, absence of transaction fees, and robust security features. Hyperledger Fabric's permissioned network restricts access to verified participants, ensuring that sensitive medical data can only be accessed by authorised users. Its modular architecture supports a wide range of applications, making it particularly adaptable for healthcare implementations.

2) Web Application: The web application acts as the interface between healthcare providers, patients, and the blockchain network. Designed with usability in mind, the platform enables users to log in, view medical records, and securely share data with healthcare providers. Real-time querying of the blockchain ensures rapid access to critical patient information, such as medical histories and prescriptions. Access control is enforced by smart contracts, guaranteeing that only authorised users can interact with the data.

3) Smart Contracts: The system leverages Hyperledger Fabric's smart contracts, also referred to as chaincode, to implement business logic and control user access. Written in Java (as well as Go or Node.js), these smart contracts enforce user roles and permissions by verifying the identities of patients and healthcare providers through Hyperledger Fabric's identity management services. Additionally, they log all interactions with the blockchain, creating an immutable audit trail that ensures transparency, accountability, and data integrity.

B. Blockchain Architecture Design

The blockchain architecture is designed to store critical medical data securely while optimising performance. The system utilises a distributed ledger to store patient medical histories and prescriptions. Each transaction is recorded immutably, ensuring that once data is added, it cannot be altered. The system generates a unique transaction ID for each interaction, providing a secure and traceable history of all medical data exchanges.

Hyperledger Fabric was selected for its permissioned network, which ensures that only authorised participants can access the network. This feature is particularly important in healthcare, where patient confidentiality and data security are paramount. Unlike public blockchains, which allow anyone to participate, Hyperledger Fabric restricts access to known and verified participants, providing an additional layer of security. Each participant is assigned specific roles and permissions, ensuring that only those with the necessary credentials can interact with the blockchain.

The system employs chaincode (smart contracts) written in Java to manage user roles and control data access. For example, the chaincode verifies that a patient's identity matches their medical records before granting access. Additionally, it tracks and records every transaction on the blockchain, creating an immutable audit trail that ensures the integrity and transparency of the data.

C. Hybrid Data Storage Solution

To address blockchain's storage limitations, the system adopts a hybrid storage model. Critical and sensitive medical data are securely stored on the blockchain, leveraging its immutability and robust security features. Less sensitive information, such as metadata or general patient details, is stored in MariaDB, a relational database system. This hybrid approach alleviates the performance overhead associated with storing large volumes of data on the blockchain while ensuring the security of sensitive information. Furthermore, the system synchronises data between the blockchain and MariaDB to maintain consistency across platforms.

D. Security, Authentication Flow and Data Integrity

The system's security is built upon Hyperledger Fabric's cryptographic mechanisms and identity management features. Authentication is managed through public-key cryptography, with each user's identity verified by a certificate authority. This ensures that only authorised individuals can access or modify patient records, effectively preventing unauthorised access. Additionally, all interactions are securely recorded using smart contracts, creating a transparent and tamper-proof audit trail.

Hyperledger Fabric's consensus mechanism ensures that all nodes agree on the state of the ledger, safeguarding against malicious actors attempting to alter patient data. This is critical for maintaining the integrity of healthcare information, where accuracy is paramount for effective treatment decisions.

The system's authentication process begins with a user logging into the web application, which interfaces with the blockchain through smart contracts. The smart contract verifies the user's credentials against the blockchain's identity management system. Once authenticated, the user can query the blockchain to retrieve or update medical records. Each interaction is recorded as a transaction, validated by the blockchain's consensus mechanism, and subsequently added to the ledger.

IV. Results and Discussion

This section presents the results from the prototype implementation of a Blockchain-Based Healthcare Information System and discusses the implications of these findings in the context of existing healthcare information management. It includes an evaluation of the system's performance, security, and usability, with particular focus on the insights gained through User Experience (UX) Testing. The results provide a comprehensive view of the system's effectiveness in securely managing electronic medical records (EMRs) and its potential to enhance healthcare workflows. The findings also highlight areas for future development, including system scalability, performance optimisation, and user adoption strategies.

A. System Implementation Results

The developed system is a web application integrated with Hyperledger Fabric, a permissioned blockchain, to facilitate the secure sharing of Electronic Medical Records (EMRs). Both patients and healthcare providers can register and access the system. Patients are identified using their Thai 13-digit ID number during registration. Once logged in, they can securely upload and store medical records, such as medical certificates or treatment data, on the blockchain, ensuring safe and controlled access.

The implementation demonstrated that blockchain technology significantly enhances data security, access control, and transparency in healthcare. By decentralising medical data storage, it reduced the risk of unauthorised access and tampering. The blockchain's immutable nature ensured that any modifications to records were securely logged, providing full accountability. However, performance issues were observed, particularly slower transaction speeds during periods of high usage. To address this, a hybrid storage model, incorporating MariaDB for non-critical data, improved system performance. Security remained robust, with cryptographic protections and Hyperledger Fabric's consensus mechanism ensuring authorised access. Additionally, smart contracts enabled secure data sharing, giving patients greater control over who could access their records.

B. Main Features of the System

The main features of the system included:

1) User-friendly Interface: The web interface was intuitive, allowing users to easily upload and access their medical records. Patients could review their treatment history, drug allergy details, and medical certificates in real time.

2) Blockchain Integration: Critical data, such as medical histories, were stored securely on the blockchain using Hyperledger Fabric's cryptographic and consensus mechanisms, ensuring data integrity and security.

3) Hybrid Storage: To optimise performance, the system employed a hybrid data storage model, storing sensitive data on the blockchain while non-sensitive data was kept in a traditional relational database, MariaDB. This approach addressed blockchain's limitations in terms of storage capacity and performance.

4) Smart Contracts: The system used smart contracts to enforce access control, allowing only authorised users (doctors, medical staff, and patients) to view or modify the records. The smart contracts also recorded every transaction made, providing a transparent and immutable audit trail of interactions with the data.

C. System Performance and Security

The implementation demonstrated that using blockchain technology in healthcare offers significant improvements in data security, access control, and transparency. By decentralising medical data storage, the system mitigated the risk of unauthorised access or tampering. The blockchain's immutable nature ensured that any changes to patient records were securely logged and could not be altered, thereby providing full accountability for all medical interactions.

However, performance limitations were observed, particularly in terms of processing speed when handling larger volumes of transactions. Blockchain's inherently slower transaction times, compared to traditional relational databases, were noted, particularly during peak usage periods. The integration of a hybrid storage model helped alleviate some of these concerns by offloading non-critical data to the MariaDB database, which allowed the system to maintain adequate performance levels.

In terms of security, the blockchain-based system provided strong data protection through cryptographic techniques. The consensus mechanism employed by Hyperledger Fabric ensured that only authorised participants could access the network, and the use of smart contracts further guaranteed secure data sharing between stakeholders. Patients also benefited from increased control over their medical records, as they could directly manage who could access their data.

D. Prototype User Interface Design

The design of the Blockchain-Based Healthcare Information System focuses on providing an intuitive and secure interface that allows patients and healthcare providers to interact seamlessly with the blockchain-based backend system. Below are the key screens developed in the prototype, which demonstrate the core functionalities of the system: landing page, registration page, and medical record page.

1) Landing Page: Fig. 1 shows the Landing Page, the gateway to the Blockchain-Based Healthcare Information System. It features a clean, user-friendly interface for both patients and healthcare providers, offering clear options for logging in or registering with role-specific paths for easy navigation. The design emphasizes security and decentralised medical record management, assuring users that their healthcare data is securely handled. The page is crafted to ensure a smooth entry into the system, prioritising accessibility and ease of use.

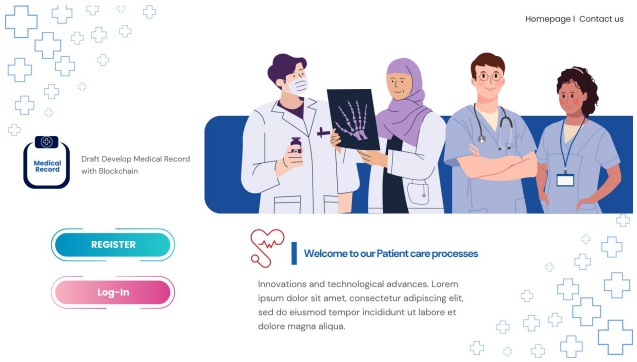

Fig. 1. Landing page.

2) Registration Page: Fig. 2 shows the Registration Page, where new users (patients or healthcare providers) can create an account and securely access the healthcare platform. The page collects personal and authentication details, such as name and email, while leveraging blockchain identity management for secure user verification. It employs a role-based access system, assigning distinct roles to patients and healthcare providers to control permissions. This ensures that only authorised users can view or manage sensitive medical records. Overall, the Registration Page establishes a secure foundation for verified and authenticated interactions within the system.

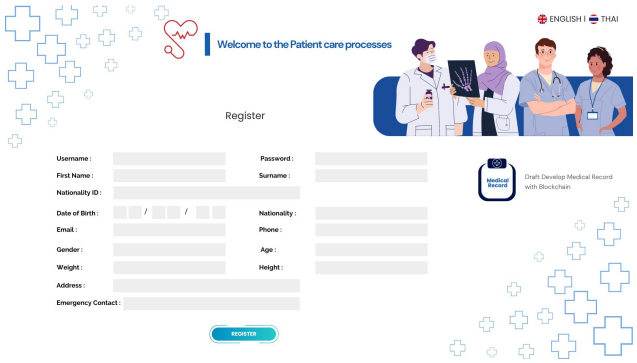

Fig. 2. Registration page.

3) Medical Record Page: Fig. 3 displays the Medical Record Page, the main interface where patients and healthcare providers manage Electronic Medical Records (EMR). Patients can securely view their complete medical history, while healthcare providers can upload and update records. These records are encrypted and stored on the blockchain, with access controlled by smart contracts, ensuring that only authorised users can view or modify the data. All interactions are logged for transparency and auditability, making the system both secure and efficient for enhancing patient care and experience.

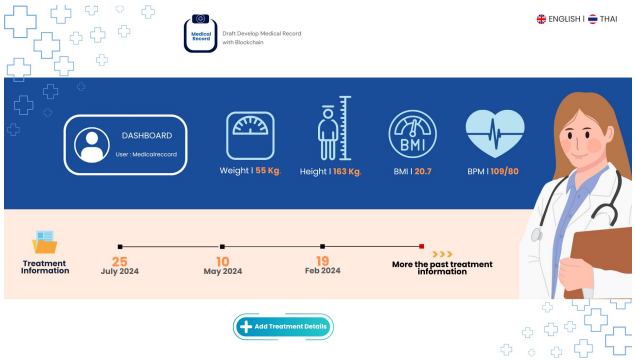

Fig. 3. Medical record page.

E. User Experience (UX) Testing

1) Testing Participants: The UX testing involved healthcare providers, including doctors and medical administrators, as the sole participants. They were tasked with logging into the system, uploading treatment records, querying medical histories, and managing access permissions for patient data. Synthesised patient profiles were used to simulate realistic medical interactions, ensuring the evaluation aligned with real-world use cases.

2) Key Findings: The key findings from the UX testing highlight the system's usability, efficiency, and security, as well as areas for improvement. These findings were based on the feedback from healthcare providers as they interacted with the system during various tasks:

- Ease of Use: Participants found the *landing page* intuitive, with clear navigation options for login and registration. The *medical record page* was effective in facilitating tasks such as uploading and retrieving medical records, which streamlined workflows and reduced administrative complexity.
- Efficiency: Real-time access to blockchain-stored data ensured healthcare providers could quickly retrieve treatment histories and prescription details, which was particularly beneficial for emergency care simulations. The hybrid storage model improved responsiveness when accessing non-critical data, as confirmed by positive feedback during high-usage scenarios.
- Security Perception: Healthcare providers appreciated the robust security features, including blockchain's encryption and immutable audit trails, which reassured them of the system's reliability for handling sensitive information.
- Challenges: A minor learning curve was observed among participants unfamiliar with blockchain technology, particularly during the initial onboarding phase. Slower transaction speeds were noted during simulated peak loads, indicating a need for further optimisation.

Suggestions for Improvement: Based on the key findings, several suggestions for improving the system were made to enhance its usability, performance, and scalability:

- Enhanced Onboarding: Developing tutorials or quick-start guides tailored to healthcare providers could improve initial system adoption.

- Performance Optimisation: Continued refinement of the hybrid storage model and transaction speeds is recommended to enhance usability during high-demand periods.

Conclusion: The UX testing demonstrated the system's potential to streamline healthcare workflows and securely manage medical records for healthcare providers. By leveraging synthesised patient data, the evaluation provided realistic insights into the system's usability and security features while avoiding ethical concerns associated with direct patient involvement. These findings highlight the system's readiness for broader adoption, with ongoing refinements aimed at improving scalability and performance.

F. Discussion

The prototype Blockchain-Based Healthcare Information System demonstrated significant improvements in the security and accessibility of Electronic Medical Records (EMRs) for healthcare providers. By leveraging blockchain technology and a hybrid storage model, the system ensured secure management of sensitive data while addressing performance limitations associated with blockchain's storage capacity. Feedback from healthcare providers during UX testing highlighted several strengths and areas for improvement.

1) Scalability: As the system grows, increasing data volumes may impact performance, particularly during peak usage periods. The integration of a hybrid storage model helped alleviate some performance issues, but future work should focus on refining consensus mechanisms and exploring advanced storage solutions such as distributed file systems or cloud integration.

2) User Adoption: The user-friendly interface was positively received by healthcare providers, who found the system intuitive and effective for managing medical records. However, a minor learning curve was noted, particularly for users unfamiliar with blockchain technology. Developing onboarding materials and tailored training programs could facilitate smoother adoption.

3) Legal and Ethical Implications: Although the system used synthesised patient data to evaluate its functionality, real-world implementation would need to address compliance with data privacy laws such as GDPR and HIPAA. Smart contracts for access control must be carefully designed to align with regulatory frameworks while ensuring secure and transparent data sharing.

These findings underscore blockchain's promise as a transformative technology in healthcare. The system's robust security features and transparent data management have the potential to streamline workflows and improve interoperability among healthcare providers. Nevertheless, addressing scalability, enhancing user adoption strategies, and ensuring regulatory compliance remain critical for widespread implementation. Future research should focus on scaling the system to support national healthcare networks and refining its performance for handling greater data volumes. Additionally, expanding UX testing to include diverse healthcare settings could provide deeper insights into its adaptability and effectiveness.

V. Conclusion

In the proposed solution, Hyperledger Fabric was chosen over the Ethereum platform for several reasons. One significant advantage is that Ethereum imposes transaction execution fees, whereas Hyperledger Fabric is an open-source platform that does not charge such fees, making it a more cost-effective choice for healthcare applications. Additionally, Hyperledger Fabric offers robust security features, which are crucial for handling sensitive medical data.

This study is pioneering in its design and development of a prototype for managing Electronic Medical Records (EMRs) using blockchain technology, specifically in the form of a Blockchain-Based Healthcare Information System. At present, most hospitals rely on centralised systems to store patient data, typically using conventional Relational Database Management Systems (RDBMS). However, this centralised approach poses significant challenges in sharing medical records, treatment histories, and other critical information between hospitals. The research serves as a proof of concept, demonstrating the benefits of blockchain in this context. Blockchain technology was found to provide a high level of security and protection for sensitive information, ensured through consensus mechanisms and collaboration among stakeholders.

Despite its advantages, the research identified some limitations of blockchain technology, such as restricted storage capacity and the need for continuous software updates across nodes or peers. To address these issues, a hybrid approach was adopted, combining blockchain with MariaDB. Critical data was stored on the blockchain, while general information was maintained in the MariaDB system. This approach mitigated performance issues and improved overall system efficiency.

User feedback from healthcare providers during system evaluation highlighted the system's usability and its potential to streamline healthcare workflows. The integration of a user-friendly interface with blockchain's secure backend ensures effective data management while maintaining accessibility. However, minor challenges, such as transaction speeds during peak usage and onboarding support for first-time users, should be addressed in future iterations.

Future research should focus on scaling blockchain-based healthcare systems for larger networks, such as national-level infrastructures, while optimising performance to handle greater data volumes. Enhancing storage solutions through the integration of distributed file systems, such as IPFS, or cloud storage could address blockchain's inherent limitations. Additionally, exploring alternative blockchain platforms may provide valuable insights into how different technologies perform in healthcare applications. Expanding evaluations to include diverse healthcare settings will further validate the system's adaptability and effectiveness.

In conclusion, the Blockchain-Based Healthcare Information System demonstrates blockchain's potential to revolutionise healthcare data management. By addressing current limitations and leveraging innovative solutions, the system has the capacity to enhance data security, improve interoperability, and streamline workflows, contributing to better healthcare outcomes for all stakeholders.

Automatic Generation of Comparison Charts of Similar GitHub Repositories from Readme Files

Emad Albassam
Department of Computer Science-Faculty of Computing and Information Technology
King Abdulaziz University, Jeddah, Saudi Arabia

***Abstract*—GitHub is a widely used platform for hosting open-source projects, with over 420 million repositories, promoting code sharing and reusability. However, with this tremendous number of repositories, finding a desirable repository based on user needs takes time and effort, especially as the number of candidate repositories increases. A user search can result in thousands of matching results, whereas GitHub shows only basic information about each repository. Therefore, users evaluate repositories' applicability to their needs by inspecting the documentation of each repository. This paper discusses how comparison charts of similar repositories can be automatically generated to assist users in finding the desirable repository, reducing the time required to inspect their readme files. First, we implement an unsupervised, keyword-driven classifier based on the Lbl2TransformerVec algorithm to classify relevant content of GitHub readme files. The classifier was trained on a dataset of readme files collected from Java, JavaScript, C#, and C++ repositories. The classifier is evaluated against a different dataset of readme files obtained from Python repositories. Evaluation results indicate an F1 score of 0.75. Then, we incorporate rule-based adjustments to enhance classification results by 13%. Finally, the unique features, similarities, and limitations are automatically extracted from readme files to generate comparison charts using Large Language Models (LLMs).**

***Keywords*—Multi-class classification; keyword-driven classification; rule-based classification; unsupervised classification; GitHub repositories; comparison charts**

I. Introduction

Publicly available code repositories are widely used for managing and sharing application source codes. Due to their publicity, external users can review and improve these repositories, increasing their quality. Therefore, software developers engaged in development projects rely on these repositories to achieve high reusability. One such widely used code repository platform is GitHub. A recent report shows that GitHub hosts 420 million repositories with over 100 million registered developers [1]. However, this tremendous number of repositories introduces the challenge of finding a repository that adequately satisfies the user's needs.

In recent years, there has been considerable interest in cataloging the growing number of public repositories to facilitate the search, identification, and selection of these repositories for end-users. Several supervised approaches have been investigated in which the available textual documentation of public repositories is collected, analyzed, and classified to address this problem (e.g. [2] [3]). However, such supervised approaches require human intervention to manually label large datasets for training. In contrast, unsupervised approaches do not require such manual efforts since they can learn hidden patterns from large datasets. Therefore, labeled data are not required. Although several unsupervised approaches for cataloging public repositories have been proposed (e.g. [4]), they focus on the problem of tagging them with a limited set of topics. Therefore, these topics do not represent all of the capabilities provided by the corresponding repositories. As a result, users often need to read the documentation of each repository to understand its capability. This makes manual searching for candidate repositories complex and time-consuming since users need to inspect and read the documentation associated with each repository to understand their advantages and limitations before deciding. We consider the case in which a user knows the type of repository they are looking for but not the exact, full features provided by the repository. Furthermore, without careful inspection of their documentation, users might neglect important features during repository selection, which might be decided to be necessary after adopting another repository lacking these features.

As a motivation example, Fig. 1 shows typical repository search results performed on GitHub, where the user search terms include "email client", and results are sorted based on best matches. This figure shows that the search results by GitHub include approximately 7.1k repositories that match the search terms. Furthermore, only basic information is displayed for each repository. The results include a list of topics for some repositories. However, repository owners set these topics manually, which can be incomplete, error-prone, or missing in many repositories [4]. Therefore, users need to inspect each repository individually by reading its documentation to assess its relevance to their needs. In addition, users might be aware only of a subset of the features and functionality they desire, neglecting other features that could be equally important during selection.

Concerning these challenges, this work contributes to the literature by discussing how comparison charts of similar GitHub repositories can be automatically generated from their readme files using unsupervised learning. Each comparison chart consists of a set of N user-selected repositories listing (1) each repository's provided features and functionality, (2) the commonality between these repositories, and (3) the limitations of each repository, thus minimizing the effort and time to inspect and compare these repositories individually. Second, we show how the predictive performance of the Lbl2TransformerVec algorithm [5] [6] [7], an algorithm for unsupervised document classification and retrieval, can be improved by rule-based adjustments to classify the content of readme files in cases where multiple classes have approximately similar scores.

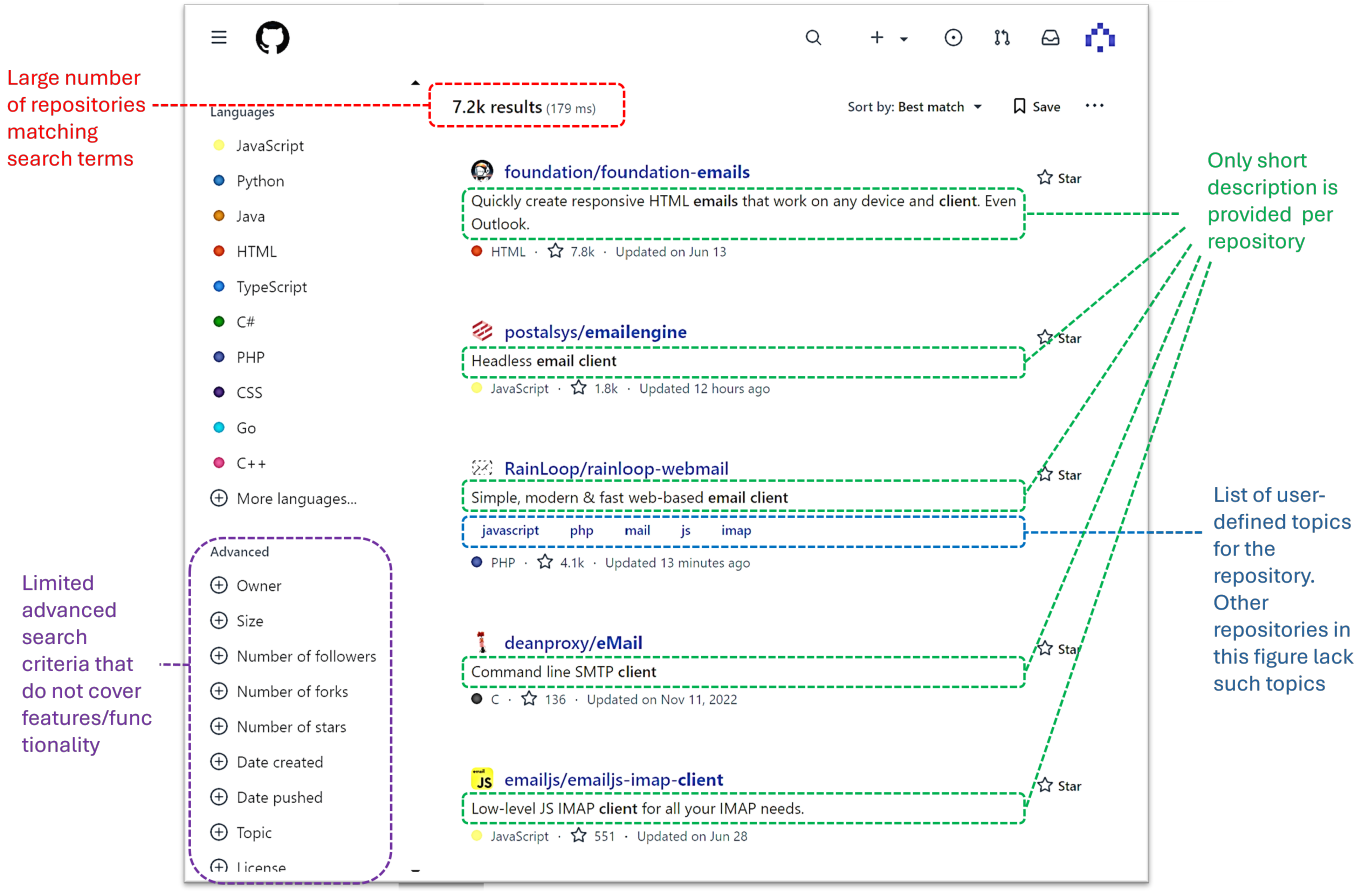

Fig. 1. An example of GitHub search results, with over 7.1k results satisfying user search terms.

The remainder of this paper is organized as follows. Section II contains the related works. Section III describes the architecture of the proposed. This includes data collection, preprocessing, and model training. Section IV presents our results of evaluating the various models incorporated to generate comparison charts. Section V discusses the strengths and limitations of the proposed solution and highlights future research directions. Section VI concludes our work.

II. Related Works

Many prior studies investigated the problem of analyzing GitHub repositories from their readme files. Work by Prana et al. [2] showed how a multi-label classifier can categorize GitHub readme files. Their approach labels the content based on eight categories: what, why, how, when, who, references, contribution, and others. The approach incorporates supervised learning where readme files obtained from GitHub repositories are manually analyzed and labeled. The work by Wu et al. [3] shows how repositories can be retrieved through functional semantics where readme files need to be manually inspected. Their dataset is based on JavaScript repositories. However, their data preprocessing involves the removal of many contents that are outside of functionality, including how to use the repository. Compared to these approaches, our work considers an unsupervised approach in which the training dataset is not labeled. Furthermore, we focus here on the comparison of different GitHub repositories.

Prior works have investigated different types of tasks related to GitHub repositories. Work by Zhou et al. [8] proposed an approach for recommending GitHub trending repositories. Sipio et al. [9] investigated a topic recommendation system of GitHub repositories, which repository developers can use to label their repositories correctly. However, their work uses a supervised model. Prior works have also considered categorizing GitHub repositories based on functionality [10] and application domains [11]. Compared to these works, we focus on comparing different repositories in a single artifact when users do not have the full knowledge of the features they seek in repositories. Although it is possible to tag software repositories from their bytecode and dependencies among them [12], such approaches are considered technology-specific. We consider in this work an approach that relies on textual readme files, which makes it applicable to any repositories with such files [13]. The work of Zhang et al. [4] presented a keyword-driven hierarchical classification of GitHub repositories to assign topic labels to GitHub repositories. Their work is unsupervised but requires users to provide one keyword for each class. Although topics play a significant role in the cataloging of repositories, this work considers a different problem where similar repositories need to be compared.

Several prior works investigated the nature and quality of documentation available in GitHub repositories. Results of Liu et al. [14] show that readme files of open-source Java projects do not align with GitHub guidelines. Furthermore, work by

Venigalla and Chimalakonda [15] shows that the presence of readme files, lists, images, and links increases the popularity of repositories. The work by Treude et al. [16] provides an assessment of documentation quality in ten dimensions, where their results show that documentation of various artifacts such as references, documents, and articles are different in terms of quality. Elazhary et al. [17] investigated GitHub developer contribution guidelines through a mixed-method study of 53 GitHub projects, where their results show that approximately 68% of these projects diverge significantly from the expected process model. Venigalla and Chimalakonda [18] investigated software documentation on GitHub and showed that multiple software artifacts can contribute to documentation. Work by Hellman et al. [19] proposed an approach for generating GitHub repository descriptions. Their analysis showed that descriptions of GitHub repositories are poor due to a lack of purpose in their description. These works clearly show the challenges associated with analyzing the documentation of publicly available repositories, such as lack of standardization and quality immaturity. This paper investigates several such challenges to generating meaningful comparison charts to end users.

Table I summarizes the research limitations identified in prior works. While all prior works focus on individual repositories to generate topics, the proposed approach considers the generation of comparison charts of multiple repositories. This approach is not limited to identifying the features provided by repositories but also identifies their commonalities and limitations, which, to the best of our knowledge, have not been investigated previously in prior works.

TABLE I. LIMITATIONS OF LITERATURE

Ref.	Limitations
[2]	• Supervised learning approach requiring manual labeling of the training set. • Proposed approach does not consider comparison of different repositories and does not extract unsupported features/functionalities of repositories.
[3]	• Manual inspection of GitHub readme files. • Manual removal of all sections in readme files except sections related to functionality. • Proposed approach does not consider comparison of different repositories and does not extract unsupported features/functionalities of repositories. • Dataset is limited to Javascript repositories.
[4]	• Proposed approach requires user providing one keyword for each class as guidance (Although a keyword enrichment process module is incorporated to expand the single keyword to a keyword set for each category). • Proposed approach does not consider comparison of different repositories and does not extract unsupported features/functionalities of repositories. • Dataset is limited to Machine Learning and Bioinformatics domains.
[13]	• Featured topics may neglect detailed functionalities provided by repositories. Thus, users still need to inspect individual readme files to understand their capabilities. • Featured topics may evolve, which may require retraining of the supervised models. • Proposed approach does not consider comparison of different repositories and does not extract unsupported features/functionalities of repositories.
[10]	• Proposed approach is semi-automated, with steps requiring manual human intervention. • Functionalities are extracted from readme file segments by computing the similarity between the segments and a short 1-2 lines of description from the repository's homepage, which may result in missed functionalities. • Proposed approach does not consider comparison of different repositories and does not extract unsupported features/functionalities of repositories.
[20]	• Proposed approach recommends trending repositories for developers based on their historical commits on GitHub (i.e. does not target general users of GitHub). • Proposed approach does not consider comparison of different repositories and does not extract unsupported features/functionalities of repositories.

III. AUTOMATIC GENERATION OF COMPARISON CHARTS

This section first provides an overview of the proposed solution for generating comparison charts from GitHub readme files. Then, we discuss each process within the architecture, including data collection, data preprocessing, and model training processes, where the goal is to implement a multi-class classifier capable of classifying the sections of a given GitHub readme file that are likely to contain the features and functionalities provided by the corresponding repository. We then discuss each process related to the automatic generation of comparison charts.

A. Overview of Proposed Solution

The architecture of the proposed solution (see Fig. 2) consists of two modules: offline and online. The offline module is performed once to train a multi-class classifier capable of classifying the contents of readme files obtained from GitHub repositories. The model is keyword-driven and is trained to classify the various sections based on the likelihood of containing relevant information for constructing comparison charts. The model is complemented with rule-based heuristics to adjust the classifier's results when multiple classes have approximately close scores by the classifier.

On the other hand, the online module is responsible for generating comparison charts of GitHub repositories that satisfy the user search terms. First, this module performs a live search of GitHub repositories using user-provided search terms. The user then selects N repositories from the search results they wish to compare. The online module then automatically retrieves the readme files corresponding to the user-selected N repositories and incorporates the hybrid classifier from the offline module to extract relevant sections required by subsequent processes. The online module then extracts relevant information, including provided features and limitations, from these sections and computes the similarity of features from the different repositories to generate comparison charts.

We describe each process in the architecture in the following subsections.

B. Automatic Data Collection

To prepare the dataset used in this work, we collected 283 readme files obtained from GitHub repositories. These

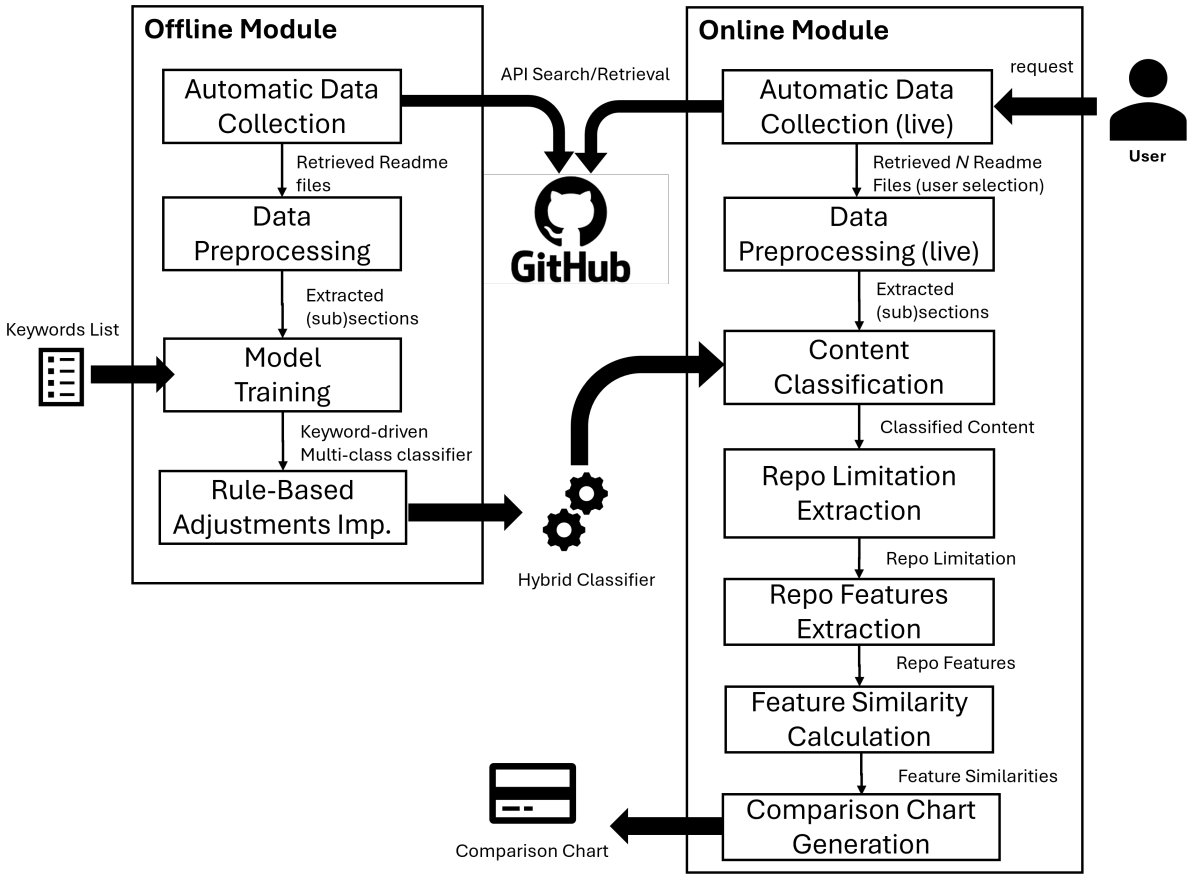

Fig. 2. An overview of the architecture for generating comparison charts.

files are collected automatically through GitHub's Representational State Transfer (REST) API for searching [21]. To ensure diverse coverage of repositories, we retrieve repositories whose primary programming language is Java, JavaScript, C#, Python, or C++. We obtain the readme files of the top 100 repositories for each of these languages, where the results are sorted in descending order based on repository stars. Then, we filter the results by including only the repositories with readme files written in English and exceeding 1000 bytes. These filtering rules aim to include only mature repositories with high stars, which increases the likelihood of obtaining well-written readme files.

We further split the collected readme files into two classes: training and testing. The training class contains the readme files corresponding to repositories whose primary programming languages are Java, JavaScript, C#, and C++. On the other hand, the readme files related to Python will be used for testing purposes to evaluate the hybrid classifier. By splitting the readme files based on the programming language, we decrease the likelihood of language bias during evaluation since our model is never trained on readme files related to the repositories related to the Python language. Table II summarizes the number of readme files collected from GitHub and shows the percentages of training and testing classes. As seen in this table, selecting the readme files related to the Python language as the testing class splits the collected readme files at an approximately 80:20 ratio.

C. Data Preprocessing

The contents of collected readme files are cleansed as follows. Embedded HTML tags and elements (such as HTML comments) are removed. All code blocks and URLs that appear in readme files are replaced with the constant strings *@code* and *@link*, respectively. Irrelevant content, such as images, task lists, color codes, and emojis, are removed.

After data cleansing, we extract the heading and content of all sections and subsections found in the readme files using regular expressions, which, according to GitHub formatting syntax [22], start with '#' symbols. Each extracted (sub)section represents an instance in our dataset. For each instance, we also record (1) the GitHub repository ID to maintain traceability between the instances and the files from which they were extracted, (2) the level of the (sub)section heading, which can range from 1 (i.e. a first-level heading) to 6 (a sixth-level heading), and (3) the order of the (sub)section in the document. Table III summarizes the number of instances obtained after preprocessing and instance extraction grouped by programming language. As can be seen, the training set accounts for 78.2% of the number of instances, while the testing set accounts for 21.5%.

D. Keyword-Based Model Training

After data preprocessing, we trained various keyword-driven models based on the Lbl2TransformerVec algorithm,

TABLE II. SUMMARY OF DATA COLLECTION PROCESS OF README FILES OBTAINED FROM GITHUB REPOSITORIES

Language	Total Number of Readme Files			Class	Pct.
	Initial	After Excl. Non-English	After Excl. files $<$ 1KB		
Java	100 files	45 files (55 files excl.)	43 files (2 files excl.)	Training	12.7%
JavaScript	100 files	73 files (27 files excl.)	71 files (2 files excl.)	Training	20.9%
C#	100 files	83 files (17 files excl.)	80 files (3 files excl.)	Training	23.6%
C++	100 files	81 files (19 files excl.)	78 files (3 files excl.)	Training	23%
Python	100 files	67 files (33 files excl.)	67 files (0 files excl.)	Testing	19.8%

TABLE III. SUMMARY OF EXTRACTED INSTANCES FROM COLLECTED README FILES

Language	No. of Instances	Class	Pct.
Java	617	Training	13.5%
JavaScript	1112	Training	24.35%
C#	977	Training	21.4%
C++	876	Training	19.2%
Python	984	Testing	21.55%

an algorithm for unsupervised document classification and retrieval that does not require stemming or lemmatization and can work on short texts [5] [6] [7]. For each model we train, we incorporate a different transformer, as shown in Table IV, where the goal is to evaluate the impact of the various transformers on the classifier's classification results. The models are trained on the training set corresponding to the Java, JavaScript, C#, and C++ instances (see Table II).

Our aim for the trained models is to classify the various instances in the dataset (i.e. sections obtained from readme files) into one of the following classes: Functionality, Usage, or Miscellaneous so that information required to construct the comparison charts can be obtained. The *Functionality* class represents instances about a repository containing statements such as an overview, high-level features or functionalities, a list of its advantages, how it compares to other solutions, and changes over different versions/releases. We consider that information in such sections highly relevant for constructing comparison charts. The *Usage* class represents instances corresponding to the how-to details, such as configuration, installation, and coding instructions related to a repository. Thus, these sections can provide additional information for constructing more detailed comparison charts. Finally, the *Miscellaneous* class represents instances corresponding to sections less relevant to comparison chart generation, such as user contributions and donations.

TABLE IV. MODELS INCORPORATED INTO LBL2TRANSFORMERVEC DURING TRAINING

Model	Ref./Model Card
bart-large-mnli	[23]
all-MiniLM-L6-v2	[24]
all-mpnet-base-v2	[25]
all-distilroberta-v1	[26]
all-MiniLM-L12-v2	[24]
unsup-simcse-bert-base-uncased	[27]
unsup-simcse-bert-large-uncased	[27]
unsup-simcse-roberta-base	[27]
unsup-simcse-roberta-large	[27]

To train the models, we pass the keywords list for each class to the Lbl2TransformerVec algorithm, shown in Table V. These keywords are chosen based on a combination of expertise and familiarity with GitHub readme files and by relying on a dictionary for word synonyms. For the Lbl2TransformerVec hyperparameters used to train the models, we set the *similarity_threshold* to 0.6 so that only instances with this threshold or higher with respect to the provided keywords are included to calculate the label embeddings. Furthermore, we set the *min_num_docs* parameter, which controls the minimum number of instances used to calculate the label embeddings, to 700. All other hyperparameters are set to their default values. Table VI provides the hyperparameter values used for training the various models.

After model training, to better understand their ability to classify the content of readme files, we run the models on the training dataset to classify all instances and then extract the most frequent words for each class. Fig. 3 plots the class-word distribution with a KxM shape, where K is 3, representing the number of classes, and M is the vocabulary size. As shown in this figure, the most frequent words for class 3 (i.e. sections classified by the model as Miscellaneous) include license, contributing, community, issues, and support, indicating the model's capability of labeling such sections. The most frequent words for sections labeled by the model as class 2 (i.e. Usage class) include *use*, *build*, *install*, and *run*. Finally, sections labeled with class 1 (i.e. Functionality) have as most frequent words the words *library*, *features*, *platform*, and *simple*, all of which are likely to appear in sections discussing the high-level functionalities and features of a repository. It can also be seen that several classes share some common frequent words such as *link* and *code*. This is because these words can appear in any section of these classes. For example, adding URLs pointing to external websites is a common practice for defining some terminologies or redirecting the user to extra resources to understand some functionality. Therefore, these URLs are part of Functionality. On the other hand, adding URLs in usage-related sections is also a common practice to refer users to more detailed installation documentation, configuration, and usage. Similarly, for the word *code*, readme files of many GitHub repositories can contain code snippets in the introduction, usage, and citation sections.

E. Rule-Based Classification Adjustments

During class prediction, the keyword-driven classifier may assign approximately similar scores to different classes for a section, which may result in incorrect classification for some of these sections. We incorporate rule-based adjustments to enhance classification results in such cases by considering the classes assigned to parent and sibling sections of a section i as follows.

Let i be a (sub)section in a readme file R, p^i be the predicted class for i, and p_2^i be the second most likely class for i as scored by the keyword-driven classifier. For any

TABLE V. KEYWORDS USED FOR MODEL TRAINING

Class	Keywords	Purpose
Functionality	Introduction, Intro, Welcome, Overview, Index, Compatability, Comparison, What's, New, Motivation, Contents, Feature, Provide, Contain, Supports, Definition, Goal, Overview, Roadmap, Release, Version, Vision, About, What, About, Simple, Fast, Reliable, Flexible, Modern, Powerful, Cross-Platform, Alternative	(Sub)sections labeled by the model with this class are likely to contain high-level features and functionality of the repository
Usage	Getting, Started, Demo, Try, Updating, Quick, Start, Code, Snippet, Steps, Commands, Configuration, Setup, Requirements, Install, Uninstall, Installation, Tutorial, Instructions, Documentation, Dependencies, Prerequisites, Manual, Example, Examples, Resources, FAQ, Usage, How, Import, Flags, Parameters, Arguments, Download	(Sub)sections labeled by the model with this class are likely to contain detailed functionality and usage information related to the repository
Miscellaneous	Contribution, Contributing, Contribute, Contributed, Partners, Sponsors, Authors, Backers, BibTex, Community, Mission, Feedback, Copyright, Disclaimer, Trademark, Credits, Publications, Conduct, DOI, Thank, Thanks, Please, Announcements, Legal, Subscribe, Issues, Contact, Join, Inquiries, Donation, Donate, Citation, Cite, Paper, Licensed, License, Help, Support Discussion, Social, Twitter, Telegram, Facebook, Discord, Forum, Backers, Acknowledgment, Acknowledgments, Company, People, Who	(Sub)sections labeled by the model with this class are less likely to contain important features and functionality of the repository

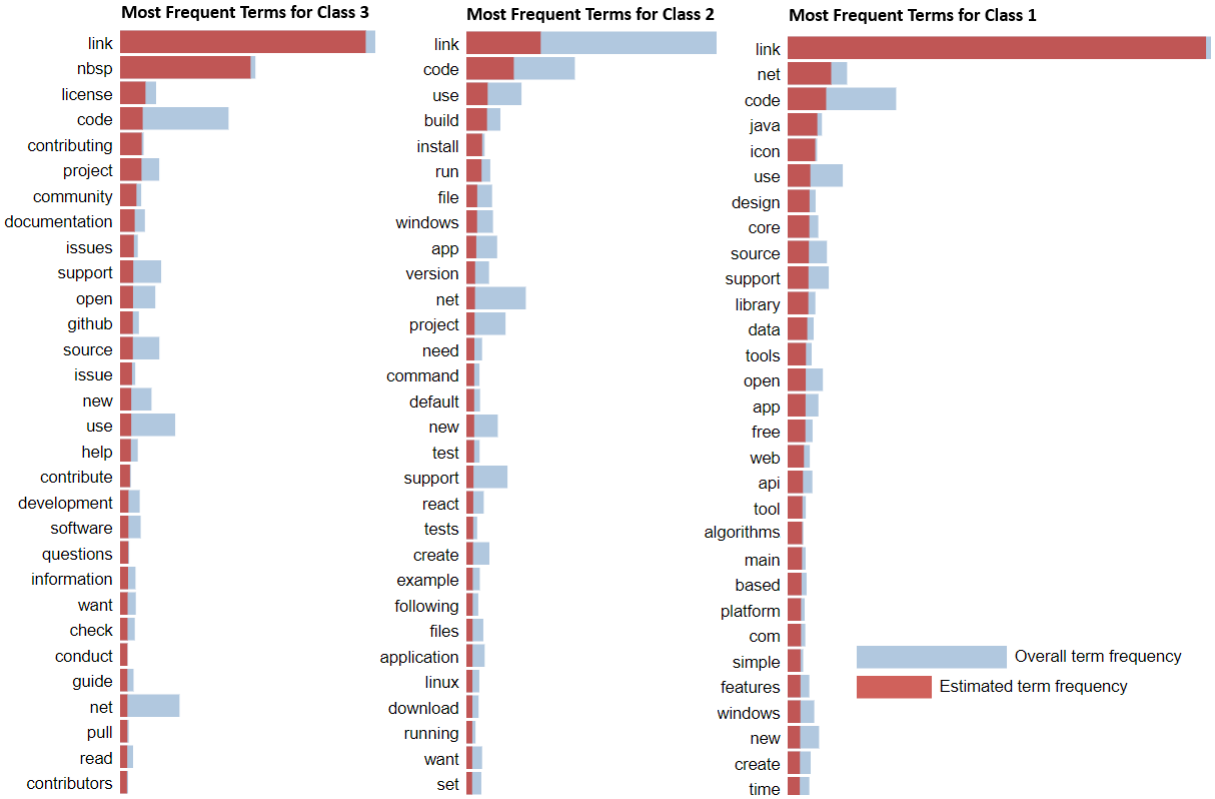

Fig. 3. Class-word distribution of training dataset for functionality (class 1), Usage (class 2), and miscellaneous (class 3).

TABLE VI. HYPERPARAMETERS PASSED TO LBL2TRANSFORMERVEC FOR MODEL TRAINING

Hyperparameter	Value
keywords_list	The keywords list shown in Table V
transformer_model	The models shown in Table IV
similarity_threshold	0.6
similarity_threshold_offset	default (0)
min_num_docs	700
max_num_docs	default (None)
clean_outliers	default (False)

(sub)section $i \in R$, if $|score(p^i) - score(p_2^i)| < \alpha$, then the following rules are applied, in the shown order, to adjust the predicted class for i:

1) Keywords ratio rule: The model computes the number of keywords (see Table V) that appeared in i for each class and then calculates the ratio of these numbers. If the ratio of class p_2^i is larger than a threshold β, then the predicted class of i is set to p_2^i.

2) Relevance to parent rule: The model considers the predicted class assigned to i's parent section. If (1) the parent section is classified as class p_2^i, (2) the parent section has a high keywords ratio for one class, (3) i has a low keywords ratio, and (4) α is negligible, then the predicted class of i is set to p_2^i.

3) Relevance to siblings rule: The model considers the predicted classes assigned to i's siblings (i.e. subsections at the same level as i) by calculating the class frequency of these siblings sections. If the most frequent class for these siblings is class p_2^i and this frequency exceeds a threshold β, then the predicted class of i is set to p_2^i.

To illustrate each rule and its purpose for adjusting classification, consider the examples shown in Table VII of erroneous classifications made by the keyword-driven model to some instances in the dataset:

- For instance 1, this instance discusses usage/documentation of the repository. However, the model classified this instance as *Miscellaneous*. Since the score difference between the actual and predicted classes is less than $\alpha = 0.04$ and this instance has more keywords related to the *Usage* class compared to other classes, then the model adjusts the predicted class for this instance from *Miscellaneous* to *Usage* according to the *keywords ratio* rule.
- For instance 2, this instance discusses usage details of a repository's functionality. However, the model classified this instance as *Features*. Since the score difference between the actual and predicted classes is less than $\alpha = 0.05$ and the model labeled the parent's section of this instance as *Usage*, then the model adjusts the predicted class for this instance from *Features* to *Usage* according to the *relevance to parent* rule.
- For instance 3, this instance provides users testimonials of the repository. However, the model classified this instance as *Functionality*. Since the score difference between the actual and predicted classes is less than $\alpha = 0.031$ and the most frequent class assigned by the model to sibling subsections is *Miscellaneous*, then the model adjusts the predicted class for this instance from *Functionality* to *Miscellaneous* according to the *relevance to siblings* rule.

F. Extraction of Repository Limitations

Repository owners may explicitly state in readme files the limitations of their repositories, such as unsupported features and functionalities or constraints related to operational environments. Such limitations must be identified so that they are not mistakenly classified as supported features by the proposed solution when generating comparison charts. Statements of such limitations in readme files may include specific keywords in sentences such as *limitation* or *unsupported*. Additionally, statements can include longer phrases to convey these limitations. For example, a repository of key-value storage may state that it does not support indexes or will receive limited maintenance. An example of such limitations is the readme file of Apache Airflow repository indicating that "MariaDB is not tested/recommended".

To extract these limitations and unsupported features of a repository, we incorporated a zero-shot classifier [28] based on the *bart-large-mnli* model, which is based on the *bart-large* model [23] and trained on the *MultiNLI* dataset consisting of 433k sentence pairs annotated with textual entailment information. For each section in the input readme files, we extract the sentences of the section and pass it to the zero-shot classifier to identify the score of being labeled as *"Unsupported Feature"* by the classifier. The default threshold is set to 0.9. Therefore, sentences that this zero-shot classifier scores with a value equal to or exceeding this threshold are extracted as candidate limitations for the repository.

G. Extraction of Repository Features

To identify a repository's supported features and capabilities, the multi-class classifier classifies extracted sections from the readme files corresponding to the user-selected *N* repositories. Sections labeled as *Functionaly* or *Usage* are further processed by removing all sentences corresponding to identified limitations by the zero-shot classifier. Then, we extract from these sections the keywords and key phrases capturing the repository's features and capabilities by incorporating KeyBERT [29]. The KeyBERT model is initialized with a Text-to-Text generation pipeline (also known as Sequence-to-Sequence modeling)[30]. We incorporate into this pipeline Llama-2-7b-chat-hf [31][32], which is a large langnuage model (LLM) consisting of 7 billion parameters fine-tuned for dialogue use cases. The pipeline tokenizes the provided text and relies on an encoder-decoder architecture to process the input text and generate a list of candidate features for each repository.

H. Calculating Similarity of Repositories' Features

Given each repository's extracted features, the online module calculates the semantic similarity between all possible feature pairs from the different repositories. The online module creates a sentence transformer [33] based on the sentence-t5-base [34] model to accomplish this task. For each feature pair of different repositories, the online module encodes the textual representation of each feature using the sentence transformer. As a result, the transformer encodes each feature into a 768-dimensional dense vector space. The cosine similarity [35] is then calculated from these vectors. Two features are labeled similar if the computed cosine similarity exceeds a threshold α.

IV. Results

A. Evaluation Results of the Hybrid Classifier for Classifying the Content of GitHub Readme Files

We use the testing set corresponding to readme files obtained from GitHub repositories for the Python programming language to evaluate the hybrid classifier (see Table III). This set contains 984 instances and is not previously seen by the model since it was not used during training.

We first identify the *actual* class for each instance in the testing set through manual classification. Then, we run the hybrid model on this set to determine the *predicted* class for instances. Finally, we compute the F1 score to measure the predictive maintenance of the classifier. Although the proposed approach is unsupervised, manual classification is performed for evaluation purposes of the model.

To determine the actual class for each instance, we manually classify instances in the testing set by labeling each instance as either Functionality, Usage, or Miscellaneous. Our labeling process consists of reading the heading title of each (sub)section to determine its class. If we cannot determine the class from the subsection's heading title, then we read the first sentences in the subsection to determine its class. Finally, if

TABLE VII. EXAMPLES OF ERRONEOUS CLASSIFICATIONS BY THE KEYWORD-DRIVEN MODEL AND EXPLANATION OF RULE-BASED ADJUSTMENTS

	Example Instance	Actual Class (Score by Model)	Predicted Class (Score by Model)	Explanation
1	Documentation. Read the Manual @link for more details.	Usage(0.5447)	Miscellaneous(0.5585)	Although the words *documentation*, *manual*, and *details* in this sentence correspond to keywords for class *Usage*, the model labeled this instance as *Miscellaneous*. Therefore, according to the *keywords ratio* rule, the predicted class is adjusted from Miscellaneous to *Usage*.
2	Train with DDL Statements. DDL statements contain information about the table names, columns, data types, and relationships in your database. @Code	Usage(0.6138)	Features(0.6187)	Although the model mistakenly labeled this instance as *Features* instead of *Usage*, this subsection is a child of a higher section that was labeled correctly by the model as *Usage*. Therefore, according to the *Relevance to Parent* rule, the predicted class is adjusted from Features to *Usage*.
3	Testimonials. Mike Bayer, author of SQLAlchemy link : I can't think of any single tool in my entire programming career that has given me a bigger productivity increase by its introduction. I can now do refactorings in about 1% of the keystrokes that it would have taken me previously when we had no way for code to format itself...	Miscellaneous(0.6173)	Functionality(0.6219)	Testimonial statements by users are labeled by the classifier as *Functionality* instead of *Miscellaneous* with a score difference of less than 0.01. However, the model correctly labels sibling subsections as *Miscellaneous*. Therefore, according to the *Relevance to Siblings* rule, the predicted class is adjusted from Functionality to *Miscellaneous*.

the class still cannot be determined, we read the content of the subsection to determine its class.

Given the actual and predicted classes for each instance in the test dataset, we compute the F1 score (also known as the balanced F-score) [36] according to the following formula:

$$F1 = \frac{2 * TP}{2 * TP + FP + FN} \quad (1)$$

Where TP represents the number of true positives, FN represents the number of false negatives, and FP represents the number of false positives.

Evaluation results for the various Lbl2TransformVec models are shown in Table VIII. Classification based on keyword-driven approaches produces F1 scores that range from 0.6930 to 0.7601. Furthermore, several models have equal scores, possibly due to these models sharing the same base model. The *improvement* column shows the percentage change between the F1 scores obtained from the evaluation of keyword-driven models and the F1 scores obtained from the evaluation of combining keyword-driven models with rule-based adjustments. As seen in this table, incorporating rule-based adjustments shows observable improvement in scores by an average of 13.26% increase. Table IX shows an example of the contribution of each rule in adjusting the classification results, where the *keyword ratio rule* contributed the most by correcting 75 instances while failing to adjust 27 instances. On the other hand, the *relevance to the parent* rule has contributed the least in adjusting classification results. As seen in Table VIII rule-based adjustments contributed the least when applied to all-MiniLM-L6-v2. Inspection of correction results for this model reveals significant incorrect adjustments, particularly to the *relevance to siblings* rule with 40 incorrect adjustments.

We analyzed the class-word distribution of the classified instances from the testing set. The most frequent words for subsections identified as Functionality include words such as *models*, *data*, *index*, and *new*. The words model and data appear as frequently since many Python repositories discuss machine-learning-related libraries and algorithms. On the other hand, instances classified as Usage contain as frequent words the words *Python*, *install*, *use*, *run*, *command*, and *pip*. Finally, the words *license*, *contributing*, *issues*, *community*, and *help* appeared among the most frequent keywords in instances classified as Miscellaneous.

TABLE VIII. F1 SCORES FOR CONTENT CLASSIFICATION USING THE LBL2TRANSFORMERVEC ALGORITHM WITH DIFFERENT UNDERLYING MODELS, WITH AND WITHOUT RULE-BASED CLASSIFICATION ADJUSTMENTS

Model	F1 Score		Improv.
	Key-Driven	w/ Rule-Based	
bart-large-mnli	0.7601	**0.8607**	+13.23%
all-MiniLM-L6-v2	0.6961	**0.7571**	+8.76%
all-mpnet-base-v2	0.6930	**0.7957**	+14.82%
all-distilroberta-v1	0.6930	**0.7957**	+14.82%
all-MiniLM-L12-v2	0.6930	**0.7957**	+14.82%
unsup-simcse-bert-base-uncas	0.7601	**0.8607**	+13.23%
unsup-simcse-bert-large-uncas	0.7601	**0.8607**	+13.23%
unsup-simcse-roberta-base	0.7601	**0.8607**	+13.23%
unsup-simcse-roberta-large	0.7601	**0.8607**	+13.23%

TABLE IX. EXAMPLES OF CORRECTION RESULTS BY RULE-BASED CLASSIFICATION ADJUSTMENTS

Rule	Correct Adjustments	Incorrect Adjustments
Keywords Ratio	75 instances	27 instances
Relevance to Parent	10 instances	5 instances
Relevance to Siblings	42 instances	18 instances

B. Evaluation Results of Zero-Shot Classifier for Classifying the Limitations of Repositories

To evaluate the zero-shot classifier presented in Section III-F, we constructed a subset dataset derived from the original dataset (see Table III) by searching for instances that explicitly state limitations of repositories as well as instances of non-limitation sentences. The resulting dataset consists of 55 instances, where 26 represent limitation sentences, and 29 represent non-limitation sentences. We run the zero-shot classifier to classify each instance in the subset dataset and

then calculate the F1 score. Evaluation results show that the predictive performance of the zero-shot classifier in classifying sentences as being *Unsupported Features* has an F1 score of 0.72.

Table X shows examples of limitation sentences found in several instances in the dataset, with some instances of non-limitation sentences. As can be seen in this table, the classifier gave high scores to sentences including specific keywords and key phrases (such as *"not tested/recommended", "won't be able to save files", "does not work on" and "not compatible with"*. On the other hand, instances 5 and 6, which do not convey any limitations, scored very low by the zero-shot classifier, as expected. Instances 7-9 show examples of erroneous classifications by the zero-shot classifier in nuanced cases where limitations can be implied.

C. Motivation Example Continued: Generated Comparison Charts

Continuing with the motivation example discussed in Section I, Fig. 4 shows the result of generating the comparison chart, represented as an HTML file, by the online module for this example. In this example, the user selects $N = 3$ repositories from GitHub's search results. These repositories are Mailspring [37], Mailpile [38], and emailengine [39], all of which are top-starred repositories for the search term "email client". The comparison chart displays the features of each repository. If two features from different repositories are similar, they are assigned an equal number (shown in blue in Fig. 4). The identified limitations for each repository (if any) are shown next.

In this chart, the online module has identified a single limitation for the second repository, which corresponds to the Mailpile repository, as obsolete. Inspection of the repository's readme file reveals that the online module has identified this limitation through the zero-shot classifier since it appeared in the introduction section of the file, where the Lbl2TransformerVec algorithm previously labeled this section with the feature class.

The lists of features and extended features in this comparison chart are extracted from *Functionality* and *Usage* sections, respectively. The total number of words in this chart's features and extended features lists is 397. Compared to the total number of words in the readme files for the three repositories, which is 1742 words, the comparison chart achieves a reduction of 125% of textual information that needs to be read by the user.

The commonality between repositories based on semantic similarity is shown in the features list. For each pair of similar features, a unique number (shown in blue in Fig. 4) is assigned. For example, the Mailspring and Mailpile repositories include "fast" as a feature. As a result, both features are identified by the online module as common. Similarly, both repositories indicate that they are free and are grouped as similar features. However, our results include false positives. For example, the "Read Receipt" and "Documentation and Details" are calculated as similar.

V. Discussion and Threats to Validity

Analyzing the readme files of similar GitHub repositories to understand their unique features, limitations, and similarities with one another is a challenging task since these files do not adhere to a standard and may vary in their level of detail. Furthermore, these files are written in different styles. Our results show that combining several Large Language Models (LLMs) can address these challenges and generate useful comparison charts for these repositories. First, the keyword-driven classifier based on Lbl2TransformerVec can identify relevant sections (containing important information about the repository) and irrelevant sections (that are unlikely to contain significant information about the repository's provided features, such as Contribution Acknowledgment, Licence, and Donation). After identifying relevant sections, their sentences are extracted and passed to a zero-shot LLM based on *bart-large-mnli* to determine whether the sentence intends to convey a limitation of the repository. These limitations are extracted so that they are not mistakenly considered as features by the proposed approach. A keyword extractor LLM based on KeyBERT is incorporated to extract the most relevant keywords representing the features of each repository. Finally, a sentence transformer is incorporated to find the semantic similarity between features of different repositories.

Although our results show that models generated by Lbl2TransofmerVec, which is a similarity-based approach leveraging embeddings generated by deep learning models [5], can classify the content of readme files, rule-based adjustments can improve the algorithm's results. This is because Lbl2TransofmerVec trains models to classify (sub)sections in isolation irrespective of their relations to other sections. Therefore, the lack of such view of relations during model training can cause incorrect classifications by these models. The rule-based adjustments complement keyword classification with such a view where these relations are considered. These rule-based adjustments are possible since readme files are often well-structured as reported previously by Treude et al. [16].

The collected dataset covers different application domains since the collection process is blind to such domains. To confirm this, we inspected the collected Python repositories used for testing to determine their domains. Inspection reveals that the test dataset covers various domains such as video production, deepfake, cryptocurrencies, cloud development, SQL-related libraries, and machine learning. Therefore, the proposed approach generalizes across different repository types or domains as it relies on textual readme files unrelated to the source code or bytecode of repositories [13].

Our results show that larger sequence-to-sequence and bidirectional transformer encoder models such as bart-large-mnli and unsup-simcse variants achieve better F1 scores than smaller models such as all-MiniLM-L6-v2. This is because larger models with more parameters and larger embeddings can capture complex patterns and relationships within the data compared to smaller models with fewer parameters and smaller embeddings. On the other hand, we observe that smaller models, such as all-MiniLM-L6-v2, are more efficient than larger models in terms of training and inference times and require lower resource usage, making them more appropriate when dealing with resource-constrained environments.

Fig. 4. An example of a generated comparison chart for three GitHub repositories. In this chart, the features (A) and extended features (B) of repositories are identified by KeyBert from sections that are classified as *Functionality* and *Usage*, respectively. Limitations (C) are sentences identified by the zero-shot classifier as *Unsupported Features*. Features from different repositories with matching numbers (D) are considered as potentially common.

TABLE X. EXAMPLES OF ZERO-SHOT CLASSIFICATION OF LIMITATIONS WHERE SCORE THRESHOLD IS SET TO 0.9

No.	Instance Example	Repository	Is Limitation?		Score
			Predicted	Expected	
1	MariaDB is not tested/recommended	Apache Airflow	Yes	Yes	0.997
2	You won't be able to save files to system folders due to UWP restriction windows, system32	Notepads	Yes	Yes	0.995
3	It does not work on non-Android devices incl. LG or Samsung TVs	SmartTube	Yes	Yes	0.94
4	Swiper is not compatible with all platforms	Swiper	Yes	Yes	0.986
5	If your platform is unsupported or not listed above, there is still a chance you can run the release or manually build it by following the instructions	osu	No	No	0.33
6	it is a modern touch slider which is focused only on modern apps/platforms to bring the best experience and simplicity	Swiper	No	No	0.001
7	Importantly, we have not yet fine-tuned the Alpaca model to be safe and harmless	stanford alpaca	No	Yes	0.28
8	This repository is receiving very limited maintenance	leveldb	No	Yes	0.11
9	convert.py has been deprecated and moved to examples/convert-legacy-llama.py, please use convert-hf-to-gguf.py @link	llama.cpp	Yes	No	0.99

Compared to prior works incorporating supervised learning for classifying the content of GitHub readme files, Perna et al. reported an F1 score of 0.72 [2], while our hybrid approach achieved an F1 score of up to 0.86 (with rule-based adjustment). However, it should be noted that their supervised approach is multi-label and considers more classes. In contrast, our approach merges some of the classes they reported in their work as we focus on extracting the functionality and features of repositories from readme files. For example, the What, Why, and When classes in their work correspond to the Functionality class in our work.

Although our results show adequate extraction of comparison charts, we identify several challenges and possible improvements for future works as follows:

- *Immature or incomplete readme files*: Throughout our data collection process, we discovered that the readme files of many GitHub repositories, including repositories with high star ratings, may lack detailed information on their functionalities and features. Instead, they add internal or external URLs (such as the product's official website) for further details. Therefore, the generated comparison charts are incomplete and do not represent the repositories' full features and limitations. Thus, the proposed approach can be extended to automatically cover such internal and external resources. In addition to analyzing the readme files of a repository, it is also possible to extend the proposed approach by gathering additional sources of information using GitHub's API, including GitHub issues, pull requests, and discussions. A pull request represents a proposal for merging a set of changes before these changes are integrated into the main codebase [40]. Therefore, analyzing pull requests and their current statuses makes it possible to expand the comparison charts with information unavailable in readme files. For example, merged pull requests can reveal new features/functionalities of a repository. Similarly, an open pull request can reveal potential limitations yet to be addressed. GitHub issues and discussions can be analyzed to discover a repository's features and limitations. However, since any user can create issues and participate in public repositories, the challenge is to validate these issues and discussions before relevant information is extracted and used in comparison charts, as some issues can result from user misunderstanding or misuse of the repository.
- *Sentence-Level content classification*: Our work assumes that each (sub)section in readme files is mapped to a specific class (e.g. functionality, usage, or Miscellaneous). Although many repository owners ensure that each (sub)section has a clear and single purpose to achieve, our observation indicates sections can include sentences of various classes. For example, some readme files may contain Usage instructions in the introduction section. This may result in missed features and functionalities if conveyed in sections classified as Miscellaneous. Therefore, one may consider enhancing the classification task at the sentence level for such sections.
- *Interpretability and explainability*: The generated comparison charts can be inaccurate and biased. Therefore, it is essential to incorporate appropriate mechanisms so that these charts are explainable [41] [42] to the end users, conveying the underlying model's accuracy and achieving transparency. For example, interactive elements can be added to these charts to explain how the proposed approach obtains and calculates the various parts (i.e. repository features, extended features, limitations, and similarities). Furthermore, incorporating tractability mechanisms between these parts and the source from which they are obtained (i.e. line numbers within readme files) enables users to validate these parts.
- *Repository Limitations Extraction*: Our evaluation results of the zero-shot classifier to identify the limitations of repositories demonstrate its capability for this task. However, this approach needs to be investigated further. First, the small dataset used to validate the zero-shot classifier is a threat to validity, as a larger dataset is required for evaluation. The challenge is obtaining a large dataset representing limitations found in real GitHub repositories, as most repository owners focus on stating what their repository provides rather than stating the limitations. Second, our results show that sentences with implied limitations (e.g. instance 7 in Table X) can result in erroneous classifications by the zero-shot classifier. One potential solution is to train the classifier on a dataset of real limitations from GitHub repositories. Finally, the zero-shot classifier lacks a contextual view during classification;

for example, the classifier cannot distinguish whether the limitation is related to the user-selected repository or other related/external repositories referenced in a readme file. This challenge applies to identifying a repository's features as well. A possible improvement is to add steps for analyzing the sentence(s) structure and linguistic features to determine whether a limitation (or a feature) is related to the user-selected repository and not other related repositories referenced in the readme files.

- *Feature commonalities between repositories*: Our results show that identifying common features between different repositories is challenging. One possible reason is the usage of technical terms that are not incorporated during the training of LLMs. One potential future direction is to investigate the enhancement of similarity approaches in this respect.
- *Quantitative Metrics Generation*: Our approach relies on extracting qualitative data from readme text files. However, it might be possible to extract more qualitative and quantitative data. For example, the frequency with which each repository is updated, the average response time of a repository's owner to issues, and the overall maturity of each repository compared to others can be considered. These metrics can enrich the generated comparison charts and their overall added value to end-users.

VI. Conclusion

While prior works investigated the analysis of individual readme files, with most works following a supervised approach, our work focuses on an unsupervised approach for the classification task, which aims to generate comparison charts of similar GitHub repositories from their readme files. Our evaluation results show that textual information in comparison charts can be 125% less compared to the amount of text in readme files, thus minimizing the time and effort required for users to read these files to understand and compare their features and capabilities. Our approach utilizes a hybrid model based on the Lbl2TransformerVec algorithm and augmented with rule-based classification adjustments. The model is trained based on readme files automatically obtained from GitHub for Java, JavaScript, C++, and C# repositories. The model is then evaluated using a different set of readme files from Python repositories. Our results show that rule-based classification adjustment can improve the model's predictive performance by up to 13%. We then incorporated this model in an online module to generate comparison charts of GitHub repositories based on user search terms. Our future work includes investigating several enhancements to the proposed approach to address its limitations, as identified in the previous section, including (1) investigating how comparison charts can be enriched with information from other sources (such as GitHub pull requests, discussions, and issues), (2) extending the proposed approach so that the generated comparison charts are explainable to the end users, and (3) adding quantitative metrics to these charts. Furthermore, we plan to expand the evaluation of this approach using a larger dataset of GitHub repository features and limitations.

An Ontology-Based Intelligent Interactive Knowledge Interface for Groundnut Crop Information

Purvi H. Bhensdadia, C. K. Bhensdadia
Computer Engineering Department,
Dharmsinh Desai University, Nadiad, 387001, Gujarat, India

***Abstract*—This paper presents an ontology-based interactive interface designed to provide farmers in Gujarat with information related to groundnut crops. An ontology specific to the groundnut crop was developed and used to create a semantic question-answering (QA) interface. The proposed QA interface converts natural language question into SPARQL Query and provides answer using the backbone ontology. The overall performance of the system is at par with the existing semantic QA system. Overall accuracy of QA System is 80%.**

***Keywords*—Agriculture ontology; ontology construction; question answer system; groundnut ontology**

I. Introduction

In India, agriculture is of paramount importance. This plays a crucial role in the development of rural areas. Gujarat is a leading producer of cash crops like cotton and groundnut. An estimated 20 lakh hectares of groundnuts are farmed in Gujarat each year, with a total production of roughly 26 lakh tons.[1]

A significant amount of data is available in the agricultural sector in the form of text documents, spreadsheets, and tables. There are many websites which have groundnut crop data in a factual form such as Farmer's Portal[2], mKishan[3], and i-Khedut(for groundnut crop)[4]. In addition, some online application exist for groundnut crops, such as i-khedut[5], magfadi[6], Chhomasu magfadi ma pramanit bij[7], and Khedut mol[8]. These websites and applications cannot perform semantic searches or reasoning.

The primary drawback of the existing applications or systems is the dependency on agriculture experts or other educated farmers to answer farmers' queries. These web applications are frequently used by farmers to express natural language queries that are answered by agriculture experts [1]. However, the expert might not always be available to respond to all the farmers' queries, which can create a communication gap between the farmer and the agriculture expert. To bridge this gap, semantic search techniques [2] can be employed. Semantic search [3] enhances the search capability by understanding the context and intent behind the queries, thus providing more relevant and accurate results [4]. This approach can automate the process of answering farmers' queries, making it possible to access information without waiting for an expert's response. Implementing a semantic search system can significantly improve the efficiency and effectiveness of information retrieval in agriculture, ultimately benefiting farmers by providing timely and accurate information.

An ontology-based question-answer system has been developed to interpret farming-related queries and provide relevant suggestions. This system leverages the structured knowledge within the ontology to provide context-aware responses, bridging the gap between farmers and agricultural experts. By utilizing this approach, farmers can receive immediate and relevant answers to their questions, enhancing their ability to make informed decisions about their crops and farming practices. This innovation not only improves the accessibility of agricultural knowledge but also empowers farmers with the tools necessary for efficient and effective farming.

The major contribution of the work are as follows:

1) A comprehensive groundnut ontology has been developed, capable of answering user queries. This ontology was created from scratch, ensuring it is rich in relevant agricultural concepts.
2) An interactive interface has been created that allows users to submit queries in natural language and receive responses in natural language.

The organization of this paper is as follows: Section II reviews related work I, focusing on existing web interfaces for Indian farmers and their relevance to agricultural support. Section III provides related work II, surveying the latest developments in chatbot technology with applications in agriculture. Section IV describes the proposed model, explaining its design and how it works to meet farmers' needs. Section V details the creation of the Groundnut Ontology, covering the processes of data collection, concept identification, and structuring. Section VI presents the experiment and setup, including the RDF knowledge graph representation, Neo4j query configurations, and the development of an interface to translate user questions into queries. Section VII provides a comprehensive result discussion, evaluating the system's performance and limitations. Finally, Section VIII concludes the paper, summarizing key findings and suggesting directions for future research.

II. Related Work: I
Existing Web Interface for Farmers (in India)

In India, a plethora of agriculture-related applications have emerged, each designed to support farmers with a variety of essential services. These applications can be broadly categorized into simple agroadvisory systems[5] and more advanced agroadvisory systems with semantic search capabilities.

A. Categorization of App Based on Purpose

To understand these applications comprehensively, it is crucial to classify them based on the specific services they provide. The apps have been categorized according to their primary functions: weather and market price information, crop variety details, pest control, agro advisories, crop insurance information, government schemes, and agricultural news. This classification allows us to explore the unique features and benefits of each app while highlighting their relevance to different aspects of farming. Fig. 1 illustrates the categorization of applications that has been performed.

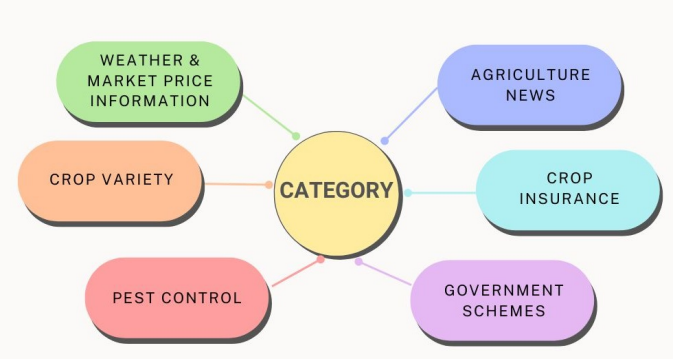

Fig. 1. Categorization of apps.

A survey of 156 agriculture-related mobile applications was conducted, and they were categorized based on their primary purpose. These applications span across various functionalities that support farmers' decision-making processes. For instance, 13 apps focus on weather forecasting, which helps farmers anticipate climate changes and plan their agricultural activities accordingly. Another 17 apps provide market information, offering crucial insights on pricing trends and helping farmers make informed sales decisions. Additionally, 16 apps leverage AI and IoT technologies, presenting innovative solutions for precision farming and resource management.

Crop insurance and government schemes are covered by 7 apps, guiding farmers on available schemes and providing them with financial protection. The largest group, consisting of 90 crop-based applications, is further subdivided into three specific areas: 25 apps offer crop information, helping farmers access detailed data on different crop varieties and innovative farming techniques; 12 apps focus on pest control and crop protection, providing strategies to identify, prevent, and treat pest infestations; and 7 apps are dedicated to soil health, offering insights on soil management practices that enhance crop yields.

This broad classification helps in understanding how digital tools can be leveraged in the agriculture sector. Weather forecasting apps, for example, assist in mitigating risks posed by unpredictable climate conditions, while market apps offer insights into the best times to buy or sell produce. Crop-specific applications provide specialized support, particularly in protecting crops from pests and ensuring soil health, which is essential for sustainable farming.

Starting with simple agroadvisory systems, these applications primarily serve as information portals, providing crucial updates on weather forecasts and market prices. Apps such as Kisan Suvidha[9] [6], IFFCO Kisan[10] [7], Agri App[11], Agri Market[12], eNAM[13] [14], mKisan[15], Ekgaon[16], myAgriGuru[17], Kisan Gujarat, AgriGujarat, and Gujarat Farm are instrumental in ensuring that farmers receive timely and relevant information about weather conditions and market trends. By providing essential data, these applications help farmers plan their activities and manage risks associated with weather and market fluctuations.

For crop variety information, the Pusa Krishi app [8] stands out. It offers insights into innovative farming techniques, crop varieties, and resource-saving technologies, which are invaluable for improving crop yields. Farmers can access detailed information about different crop varieties, helping them choose the best options for their specific conditions.

For pest control, several applications offer expert advice and practical tips to manage and mitigate pest infestations. Kisan Suvidha[18], Kheti-Badi[19], AgroStar[20], and Fasal[21] are notable examples. These apps provide specific information on pest identification, prevention strategies, and treatment options, helping farmers protect their crops from potential damage.

Crop insurance information is covered by the Crop Insurance app[22], which offers detailed information on various crop insurance schemes available to farmers. The app helps farmers understand their insurance options, eligibility criteria, and the claims process, providing financial protection against crop losses caused by unforeseen events.

Government schemes are another crucial area where mobile applications play a significant role. Apps like mKisan[23] [9], AgriMedia[24] [10], and Kisan Yojana [10] provide detailed information about various government schemes, subsidies, and benefits available to farmers. These apps ensure that farmers are well-informed about the support they can receive from the

government, enhancing their access to financial and technical assistance.

For agricultural news, apps such as IFFCO Kisan[25], Agri App[26], AgriMarket[27], eNAM[28], AgriBuzz[11], Kisan Yojana, Krishi Network[29], Gujarat Agri, and Gujarat Farm keep farmers updated with the latest developments in the agricultural sector. These platforms provide news on policy changes, market trends, technological advancements, and success stories, fostering an informed farming community.

The integration of semantic web technologies and ontologies is pivotal in addressing the challenges of inconsistent data and knowledge gaps in the agricultural sector.

B. Ease of Searching for Crop Product Information

An agroadvisory system allows farmers to write their questions in the system, and an agriculture expert will answer them. Farmers can also directly connect with an agriculture expert through a call to present their queries and get answers. Some existing agroadvisory applications like eSagu [12], aAQUA, and mKrishi[30] offer these features.

However, these apps have some drawbacks. A major issue is the lack of instant, personalized responses to farmers' questions. Since they do not use semantic search, farmers often have to wait for an expert to answer their specific questions, which can delay important decisions.

Semantic search represents a significant advancement in information retrieval systems [13], especially in the agricultural domain. For farmers, this means faster and more precise answers to their specific agricultural questions. Semantic search can quickly analyze and retrieve relevant data from vast databases, significantly reducing the time farmers spend waiting for answers. This immediacy is crucial for timely decision-making in farming practices.

III. Related work: II (Survey Chatbot Technology)

The history of chatbots dates back to the 1960s when Joseph Weizenbaum created ELIZA [14], the first computer program to initiate communication between humans and computers. It used a pattern-matching method to simulate human conversation. Later, in the year 1972, PARRY[31] was introduced by a psychiatrist Kenneth Colby which simulated the behavior of a paranoid schizophrenic.

By the 1990s, progress in natural language processing led to more sophisticated systems like Jabberwacky[32], which used AI to hold more natural conversations. However, the launch of Siri in 2011 was a game-changer, introducing voice-activated virtual assistants to the mainstream. Since then, AI and machine learning have propelled chatbot technology forward, leading to the development of highly advanced agents like Alexa, Google Assistant, and ChatGPT. These modern chatbots can now understand and generate human language with impressive accuracy. Chatbots play a crucial role in industries ranging from customer service to healthcare, enhancing the efficiency and smoothness of interactions with machines [15].

There has been a significant advancement in the area of Artificial Intelligence, Machine Learning and Natural Language Processing in recent years. The development in these areas have brought a marked change in various industries such as education, scientific research, medical health, including agriculture [16]. Farming is the primary source of income for millions in India. With growth in the field of AI, chatbots have emerged as innovative tools to help farmers make better decisions by providing them with access to real-time information. The technology of Chatbot applications have evolved from simple rule-based systems to advanced AI driven models [17]. This literature review highlights the development of chatbot technologies in Indian agriculture, focusing on the methodologies and innovations that have shaped the field.

A. Chatbot Technology in Indian Agriculture

Farmers can benefit from receiving correct and timely information about various aspects of agriculture, such as crop recommendations, plant disease identification, etc. A solution to this was devised by building conversational systems, which allow farmers to obtain timely answers to their queries. In 2015, AGRI-QAS [18] was developed to address farmers' queries related to crop recommendations, plant disease identification, and more. This marked the earliest advancement in this area, utilizing an index-based search technique.

In 2017, ADANS (Agriculture Domain Question Answering System) [19] introduced a significant improvement by utilizing ontology-based technology. It performed answer retrieval on a structured agriculture database, efficiently identifying relationships between agricultural concepts and providing more reliable and accurate responses to farmers' queries.

In 2018, FarmChat [20] was introduced as a conversational agent containing two user interfaces: one with Audio Only and the other with Audio+Text. It used Google's Speech-to-Text for speech conversion and used language model for query intent and entity identification, subsequently retrieving the appropriate response from the knowledge base.

AgronomoBot [21] used sensor networks to gather information about the agricultural production chain in a specific area. It integrated its information in Telegram Bot API. This marked an early integration of AI with messaging platforms to provide farmers with data-driven insights.

In 2019, AgriBot [22] provided functionalities such as crop recommendations based on current conditions, current weather details, and future weather predictions. For crop recommendations, it used algorithms such as K-Nearest Neighbors (KNN), Random Forest, and Decision Trees. The chatbot provided

[31] https://en.wikipedia.org/wiki/PARRY

[32] https://en.wikipedia.org/wiki/Jabberwacky

response to user queries by accessing the Krishi Call Center database[33].

Another form of AgriBot [23] was released in 2019, utilizing a Sen2Vec-based NLP technique to answer farmers' queries. This represented a significant step forward in AI-driven agricultural chatbots, enabling more sophisticated and context-aware responses to queries.

The integration of NLP into chatbot systems has pushed the boundaries of what these technologies can achieve in agriculture. In 2020, another version of Agribot [24] incorporated an LSTM-based model to provide answers to user queries. It additionally used a CNN-based model was used to classify plant diseases based on images. The system was trained on the Krishi Call Center dataset.

By 2021, chatbots such as Krushi—The Farmer Chatbot [25] began utilizing the RASA NLU framework, an advanced NLP tool designed for processing queries in local languages. This framework identifies the intent behind each query. For weather-related queries, the system uses the appropriate OpenWeather API key to provide real-time responses. For other types of queries, it matches key entities with the database to generate suitable responses. This approach enhanced the system's ability to address farmers' needs by leveraging insights from previous interactions in the KCC datasets. It is also integrated into WhatsApp [25]. Another such similar work methodology can be seen in AgroBot where they have made use of NLP to identify the intent of user query to provide appropriate response [26].

During this period, Agroxpert addressed user queries by employing the Levenshtein distance formula. The authors compiled a dataset consisting of user queries and responses. Subsequently, user queries were matched against this dataset using the Levenshtein distance formula, allowing for appropriate responses to be generated. In instances where the system could not confidently provide an answer, the queries were escalated to human experts, creating a continuous feedback loop between AI and human expertise [27].

The usage of Artificial Neural Networks for crop disease prediction also increased during this time. Many research work were focused on providing assistance to farmers in identifying crop disease using Artificial Neural Network.

By 2023, chatbots like the Agriculture Assistant Chatbot [28] integrated a CNN-based algorithm that enabled farmers to upload crop images for disease diagnosis, offering potential remedies as well as essential information such as soil and rainfall data. Another notable work can be seen in [29], where a VGG-16-based model was incorporated for identifying diseases in plants. They provided crop recommendations based on current conditions using machine learning algorithms.

In 2024, the AI-Powered Decision Support System for Sustainable Agriculture utilized LLMs to process unstructured user queries and provide constructive farming advice. It addressed various issues, such as pest control, by using real-time data for analysis and crop management [30].

Other projects, like ChatAgri (2023) [31], explored the cross-linguistic potential of LLMs for agricultural text classification and provided end to end question answering system [32].

The development of agricultural chatbots in India has progressed rapidly over the past decade, evolving from basic AGRI-QAS to advanced AI-driven models. With the integration of LLMs such as ChatGPT and domain-specific improvements like ChatAgri [31], chatbots are becoming indispensable tools for modern farming. They offer farmers tailored, real-time solutions to the daily challenges of agriculture, positioning themselves to be vital in the future of farming.

IV. Proposed Model

Fig. 2 illustrates the workflow of the proposed question-answering system, which retrieves information from an ontology graph database.

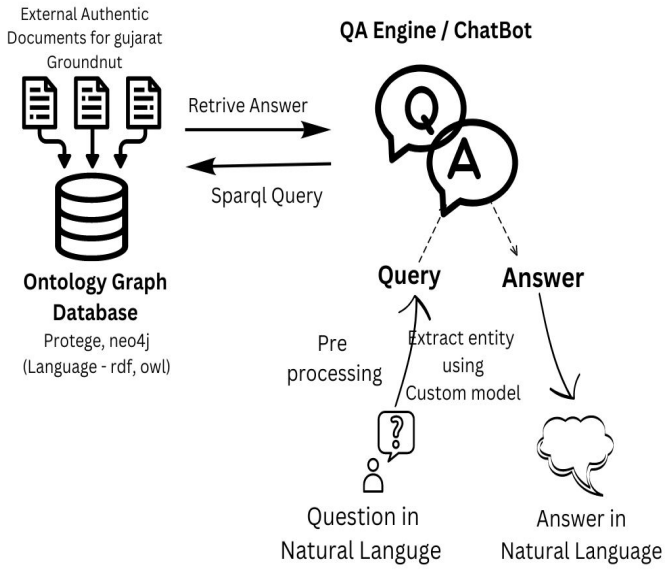

Fig. 2. Proposed work.

- Ontology Graph Database
  - Ontology Modeling: Using tools like Protégé, an ontology was created to represent the identified concepts, their properties, and the relationships between them. The ontology follows a hierarchical structure with clearly defined classes, subclasses, and individuals, ensuring that the agricultural knowledge is represented in a logical and organized manner.
  - Knowledge Graph Construction: The ontology was then translated into a knowledge graph using Neo4j, a graph database that efficiently manages the interconnected data. The knowledge graph encodes entities (e.g. "Early_Leaf_Spot X") as nodes, while the relationships (e.g. "isControlledBy Y") are represented as edges.
- QA Engine/Chatbot: The user interacts with the QA system through natural language queries. These

[33]https://www.data.gov.in/datasets_webservices/datasets/6622307

queries are processed to extract relevant entities (using a custom model) and converted into structured queries.

- Named Entity Recognition: A custom Named Entity Recognition (NER) model was developed using the pre-trained en_core_web_lg model from spaCy to meet the specific needs of the agriculture domain. While the en_core_web_lg model offers strong general purpose capabilities, it does not focus on agriculture related terms. Therefore, it was fine tuned to recognize entities relevant to agriculture, such as crops, pests, fertilizers, and diseases. Text data related to agriculture was collected, covering topics like groundnut seed variety, pest control, production technologies, and protection technologies. This data was manually labeled with agriculture-specific categories, such as Seed Variety, Controlled Pests, Diseases, and Symptoms. A simple JSON annotation methods were used for tagging. The en_core_web_lg model served as a starting point because it already contains strong word embeddings and pre-trained NER capabilities. It was fine tuned using the labeled agriculture dataset to make it suitable for identifying domain-specific terms.
- SPARQL Query: The system uses a set of predefined query templates that are dynamically adapted based on the entities and relationships identified in the user's query. By adding the identified entities (like seed variety, disease, etc.) into these templates, the system creates specific SPARQL queries to find the most relevant information from the knowledge graph.
- Answer Retrieval: The system retrieves the most relevant answers from the ontology graph database by executing the generated SPARQL query. These answers are then processed and converted into clear, natural language responses to ensure they are easily understood by the user. In cases where the query does not provide enough information to generate a precise answer, the system offers default responses.

The proposed framework integrates semantic web technologies to provide accurate, context-aware information to farmers, specifically focusing on the groundnut crop in Gujarat. By combining ontology-based knowledge representation with natural language processing, it effectively addresses the challenge of delivering precise, region-specific agricultural knowledge.

V. Creation of Groundnut Ontology

Currently, several groundnut ontologies are available, such as the AgroPortal and Agropedia groundnut ontologies. The question is whether an existing groundnut ontology can be used for gujarat-based agriculture. If so, can these agriculture ontologies be applied as they are, or will changes and modifications be needed? To address this question, detailed research was conducted by examining two existing groundnut ontologies: the agro-portal groundnut ontology[34] [33] and the agropedia [34] groundnut ontology.

As a result, it was found that the existing groundnut ontologies offer a variety of concepts that can be directly applied to the Gujarat region. Agropedia groundnut ontology is an Indian ontology. Therefore, the majority of the concepts (85%) are those that can be directly acquired from the agropedia groundnut ontology for the gujarat-based groundnut ontology[35]. In the Agroportal ontology[36], there are 700+ concepts, of which 108 concepts can be acquired for the Gujarat-based groundnut ontology. Certain concepts were found to be missing, so specific concepts related to Gujarat groundnut were added like Seed varieties (specifically used in gujarat area) Abnormality (Color(leaf), Groundnut stage, Abnor part, Shape (leaf), Symptoms), Resistance, etc.

To address the missing concepts, authentic online sources were used as references to build the ontology, including Junagadh Agriculture University[37], Anand agriculture university[38], Gujarat State seeds corporation limited[39] and Wikipedia[40] as references to build the ontology.

The ontology was manually constructed using the Protégé tool. It includes 300 classes, 21 object properties, and 8 data properties. Additionally, 104 individuals were created, which are the basic components of the ontology. In total, the ontology contains 1,569 axioms. Fig. 3 illustrates the hierarchy of classes, individuals, object properties, and data properties within the groundnut Ontology.

The groundnut crop ontology includes two major classes: Production Technology and Protection Technology. "Production Technology" class focuses on various aspects of growing groundnut crops. It has four main subclasses: Field Preparation, Nutrient Management, Water Management, and Seed and Sowing. Among these, the Seed and Sowing subclass is especially important. It includes three specific classes: Veldi, Ardhveldi, and Ubhadi. These classes contain 20+ individuals that represent different seed varieties. Each individual includes important details such as the year of release, oil content, days to maturity, pod kernel yield, etc. Fig. 4 shows how these individuals are organized in the ontology.

"Protection technology" class deals with protecting groundnut crops from various threats. A key subclass under this is Biotic Stress, which covers 45 diseases grouped into three categories: Diseases, Insect Pests, and Weeds. Another important subclass is Controlled Pest, which lists more than 35 pest control chemicals. These chemicals are linked to specific insect pests and help in managing the damage they cause. This subclass has been carefully designed to describe how pests affect crops and which chemicals are most effective in controlling them.

The groundnut ontology provides a comprehensive framework tailored for Gujarat-based agriculture, integrating concepts from existing ontologies, like agropedia and agroportal

[39]Gujarat State seeds corporation limited http://www.gurabini.com/.
[40]GroundNut Wikipedia https://en.wikipedia.org/wiki/Peanut.

Fig. 3. Groundnut ontology class hierarchy, individuals, object and data properties.

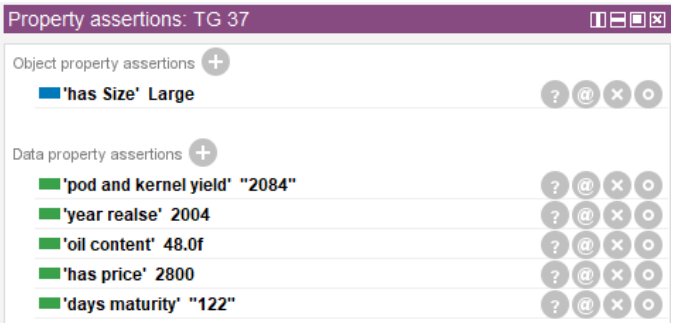

Fig. 4. TG-37 seed variety.

while addressing gaps through additional classes and properties specific to the region. Its detailed design, incorporating 300+ classes and hundreds of axioms, serves as a valuable resource for agro-advisory systems, research, and decision-making processes.

A. RDF Representation of Knowledge Graph

Neo4j[41] [35][36], the graph database [37], is used to efficiently represent and manage the groundnut ontology in the ontology-based question-answering system[42].

The groundnut ontology was first imported into the Neo4j tool, using the Neo Semantic plugin, which is required for importing ontologies into Neo4j[43]. The RDF groundnut ontology file, once imported into Neo4j, represents the fundamental components of a knowledge graph. Each entity within the groundnut ontology, such as seed variety, method of sowing, symptoms, protection technology, production technology, etc. are represented as a node in the graph. Edges connecting the respective nodes represent the relationships between these entities, which indicate dependencies, associations, and interactions. Furthermore, properties related to entities, such as daysMaturity, hasSize, hasPrice, oilContent, podAndKer-

[41] https://neo4j.com/
[42] https://neo4j.com/labs/neosemantics/
[43] https://neo4j.com/labs/neosemantics/

nelYield etc., are embedded within the graph nodes. The given query 1 demonstrates how to import the groundnut ontology into Neo4j using the n10s.rdf.import.fetch procedure. The query fetches the ontology from the provided RDF file URL and imports it into Neo4j in the RDF/XML format, with specific labels assigned to classes, object properties, and data type properties.

Listing 1: Query example

```
CALL n10s.rdf.import.fetch
("https://raw.githubusercontent.com
/PurviPatel20/with-Label/main/Groun
dnut_2.0.rdf","RDF/XML",
{
classLabel : 'Category',
objectPropertyLabel: 'Rel',
dataTypePropertyLabel: 'Prop'
});
```

The execution of query 1 successfully imports the ontology, ensuring that the defined categories, relationships, and properties are accurately integrated into the Neo4j database.

VI. Experiment and Setup

A. Neo4j Query

After successfully importing the groundnut ontology into Neo4j, the database was queried using Cypher, Neo4j's query language[44]. For example, to retrieve detailed information about a specific seed variety, a sample Cypher query to extract infomation about specific seed variety is shown below in query 2.

Listing 2: Query to retrive information about seed variety

```
OPTIONAL MATCH (i:ns0__Ubhadi)
WHERE i:ns0__Ubhadi
RETURN
i.rdfs__label As Seed_variety,
i.ns0__yearRelease As year,
i.ns0__daysMaturity As Days,
i.ns0__hasPrice As Price,
i.ns0__oilContent As Oil,
i.ns0__podAndKernelYield As
pod_and_kernel
```

This query language allows for precise data retrieval from a database. The Cypher query uses an OPTIONAL MATCH clause to retrieve data about the "Ubhadi" seed variety from a database. The WHERE clause ensures that only nodes labeled "ns0_Ubhadi" are returned in the query results.The RETURN statement indicates which properties will be included in the output, as illustrated in the Fig. 5. These properties encompass the seed variety label, release year, days to maturity, market price, oil content, and pod and kernel yield. This structured approach enables the extraction of comprehensive information about the "Ubhadi" seed variety.

[44]https://neo4j.com/docs/cypher-manual/3.5/

Seed_variety	year	Days	Price	Oil	pod_and_kernel
"GJG 9"	2009	"103"	3410	49.0	"1663"
"TPG 41"	2004	"122"	null	49.0	"2088"
"GG 8"	2006	"104-107"	null	46.0	"1776"
"GG 7"	2001	"100"	null	49	null
"GG 6"	1999	"115-120"	null	50.3	"2.78"
"GG 5"	1996	101	2310	49.2	"1270"
"IG 37A"	2004	"122"	2800	null	null

"GG 20"	1992	"120"	2310	50.7	"1960"

Fig. 5. Neo4j query to get all details of groundnut seed variety.

B. Interactive Interface for Question to Query Conversion

Neo4j was used in conjunction with Google colab, which allowed the use of important libraries such as py2neo, neo4j-driver, spaCy, and Gradio. The goal was to create a chatbot-style interface for the groundnut ontology. This given algorithm receives a user's question as a natural language (string input) and outputs a response string.

Algorithm 1 Question Processing and Answer Extraction

1: **Preprocessing:**
   a. Tokenize the question using the NLTK library's `word_tokenize` function.
   b. Perform part-of-speech tagging on the tokenized words using the NLTK library's `pos_tag` function.
   c. Extract the entity from the question using the `extract_entity` function (custom model).

2: **Answer Extraction:**
   a. If the extracted entity is None, return a default message indicating that the seed variety is not understood.
   b. Open a session with the Neo4j database using the `driver.session()` function.
   c. Identify entities from the question.
   d. Execute a Neo4j Cypher query to retrieve an appropriate response.
   e. If the query returns no results, return a default message indicating that no information is found.

The input text may contain important entities such as seed variety, disease name, symptoms etc. To identify these important named entities, the en_core_web_lg pipeline from

spaCy was used.A custom model was trained to recognize entities such as “Price”, “Rate”, “Disease”, “Symptoms”, “Cure”, “Pesticide”, “Crop”, etc. This model was designed to handle specific cases that were not covered by the standard model.

The standard model, when given with sentence like “What is a price of GJG 22?” identified “GJG 22” as an organization. Similarly, the model was not able to identify name of the symptoms. It classified it as a product entity. To address this, a custom dataset was created to identify the text “GJG 22” as a crop entity. Using Gradio, a python library, a system was built that allows users to ask questions in natural language and receive answers based on the groundnut ontology. This approach made it easier for users to interact with the Neo4j database and get useful information.

VII. Results and Discussion

The provided Fig. 6 depicts a sample example of an ontology-based question-answer system. In the example presented, the user input is a question formulated in natural language: “What is the price of GJG 22?”. The system processes this query, which utilizes ontological knowledge to understand and generate an appropriate response. The response generated by the system is displayed within the image: “The price of GJG 22 is 2310.”

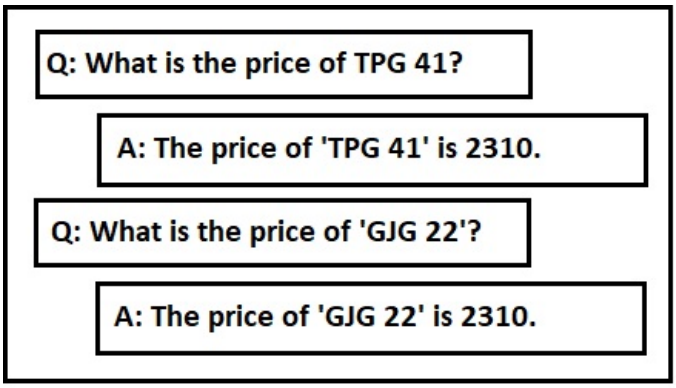

Fig. 6. Output 1: Snapshot of an ontology-based question-answer.

In Fig. 7, the user inputs a query in natural language, specifically requesting comprehensive details about the seed variety labelled “GJG 22.” The system then generates an appropriate response, which is displayed in the form of text within the interface. The response provided by the system encapsulates various attributes associated with the seed variety “GJG 22.” These attributes include: price, days maturity, pod and kernel yield and oil content. This interaction demonstrates the system’s ability to interpret complex natural language queries and retrieve structured information from groundnut ontology, facilitating efficient access to relevant data for users.

In the evaluation of the Question Answering (QA) system, a total of 100 distinct questions were submitted, and the responses were manually ranked based on their correctness. In this ranking scheme, a rank of 5 indicates a fully correct answer, while a rank of 1 represents a fully incorrect response. Ranks 2 to 4 denote varying degrees of partial correctness,

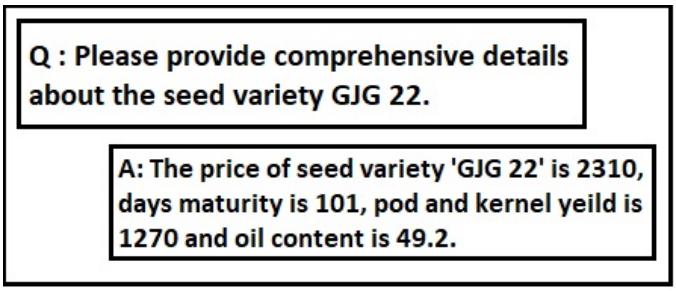

Fig. 7. Output 2: Snapshot of an ontology-based question-answer.

reflecting the extent to which the answers met the query requirements. The results of the evaluation are summarized in the Table I.

TABLE I. Ranking Table

Rank	No. of Questions
5	50
4	20
3	20
2	5
1	5

For instance, in the case of rank 1, the system failed to recognize “Peanut Strips” as a single entity, which significantly hindered its ability to retrieve the appropriate response from the underlying groundnut ontology. Additionally, an example of a partially correct response can be observed in the question, “What are the pesticide methods for the following symptoms: Buckling and crinkling between veins?” In this instance, the system provided an answer that was relevant but lacked completeness.

$$\text{Average Rank} = \frac{\sum_{i=1}^{n}(r_i \times q_i)}{\sum_{i=1}^{n} q_i} \quad (1)$$

Where:

- n is the total number of different ranks (which is 5 in this case).
- $r_i \times q_i$ represents the weighted contribution of each rank to the total score.

Using the formula 1 for average rank, the overall performance of the system was calculated to be 4.05. This indicates that while the system provided a significant number of accurate responses, there is still considerable room for improvement in handling complex queries and recognizing key entities.

VIII. Conclusion and Future Work

The proposed ontology-based QA system can be a valuable resource for farmers in Gujarat. Farmers can ask questions in natural language, and the system is designed to provide relevant answers using the groundnut ontology. The main objective is to give farmers access to insights that can help improve their farming practices and enhance groundnut crop yield. The overall accuracy of the answers is 80%. Additionally, the

ontology aids in semantic disambiguation. In the future, more concepts can be added to the ontology. The proposed model can also be adapted for other crop ontologies and developed in different languages.

***Abstract*—Convolutional Neural Networks (CNNs) are widely regarded as one of the most effective solutions for image classification. However, developing high-performing systems with these models typically requires a substantial number of labeled images, which can be difficult to acquire. In image classification tasks, insufficient data often leads to overfitting, a critical issue for deep learning models like CNNs. In this study, we introduce a novel approach to addressing data scarcity by leveraging semi-supervised classification models based on Generative Adversarial Networks (SGAN). Our approach demonstrates significant improvements in both efficiency and performance, as shown by variations in the evolution of decision boundaries and overall accuracy. The analysis of decision boundaries is crucial, as it provides insights into the model's ability to generalize and effectively classify new data points. Using the MNIST dataset, we show that our approach (SGAN) outperform CNN methods, even with fewer labeled images. Specifically, we observe that the distance between the images and the decision boundary in our approach is larger than in CNN-based methods, which contributes to greater model stability. Our approach achieves an accuracy of 84%, while the CNN model struggles to exceed 72%.**

***Keywords*—Decision boundary; convolutional neural network; Generative Adversarial Networks; MNIST; classification; semi-supervised classification**

I. Introduction

Deep learning (DL), a branch of machine learning (ML), is characterized by its significant flexibility and learning power. It represents the world through concepts organized in nested hierarchies, where each concept is defined in simpler terms and more abstract representations [1]–[6].

One of the essential skills in computer vision is the accurate classification of images. The development of image collection equipment, combined with the widespread use of digital platforms, has led to an exponential growth in the volume of digital data, necessitating the creation of robust and advanced models to analyze this vast influx of visual information. Deep learning has been proposed for image classification due to its capability to provide more detailed insights into a subject's response to specific visual stimuli. Recent research indicates that strategies based on deep learning have yielded impressive results [7].

Image classification is one of the most common challenges in computer vision. The success of a classification system is highly dependent on the quality of the attributes derived from an image, with the accuracy of the results improving in proportion to the quality of these features. These attributes are often utilized in supervised learning, where a set of features X (usually extracted from an image) is employed to predict a certain outcome Y. Before the widespread adoption of deep learning in 2012, commonly used machine learning models included support vector machines, artificial neural networks, and random forests; these traditional methods were the primary techniques for processing computer vision tasks [8].

Convolutional neural networks (CNNs) are now the most popular method for image analysis and classification due to the growing interest in deep learning. CNNs have achieved significant results across a wide range of classification problems. Despite their tremendous potential, they continue to face several challenges. These difficulties are largely due to the vast scale of the networks, which may contain millions of parameters, a lack of sufficient training datasets, overfitting issues, and poor generalization capabilities. Additionally, a growing concern among researchers is the need to prevent adversarial attacks that could mislead deep neural networks (DNNs) [9].

To address these issues and enhance performance, researchers are modifying network architectures, developing new learning algorithms, and acquiring more data. A typical challenge is the scarcity of high-quality data or an unequal distribution of classes within datasets. Currently, the most efficient DNNs are quite large and require massive amounts of data, which can be difficult to obtain. For example, the popular CNN architecture VGG16 has 16 layers of neurons and 138 million parameters [10].

Generally, deep learning algorithms are considered data-hungry, necessitating many labeled images to produce the desired fits. This requirement may render these technologies inaccessible for smaller projects, which often have limited datasets. Data augmentation [11] and transfer learning [12] are two approaches to addressing this challenge. We continue along this path to find a relevant solution by presenting a semi-supervised approach (SGAN) with a novel learning technique: utilizing both labeled and unlabeled images based on Gener-

ative Adversarial Networks. We compare our approach with CNNs using the same dataset.

To evaluate these approaches, we focus on a crucial aspect that plays an indispensable role in understanding deep learning: the decision boundary. For each approach, we will examine how the decision boundary evolves during training.Our approaches demonstrate excellent performance in image classification. A brief description of GANs, CNNs, and decision boundaries is provided below.

The rest of the paper is organized as follows: Section II delineates the methodology and the proposed approach. Section III is dedicated to the presentation of results and their subsequent discussion. Finally, Section IV offers the concluding remarks.

II. Methodology

A. Convolutional Neural Networks (CNN)

A convolutional neural network [13]–[16] comprises an input layer, an output layer, and several hidden layers. Each layer converts a set of activations into another using a differentiable function. Generally, there are three main types of hidden layers: convolutional layers, pooling layers, and fully connected layers (Fig. 1).

1) Convolution layer: Convolution is performed by translating the convolution kernel through the input image matrix. To establish a network of local connections, each neuron in the local window is linked to a corresponding neuron in the convolution layer. This configuration enables weights and a global bias to be learned for each connection [31]. The convolution operation is mathematically defined as follows:

$$a_{ij} = \varphi\left(b_i + \sum_{k=1}^{3} w_{ik} x_{j+k-1}\right) = \varphi\left(b_i + \mathbf{w}_i^T \mathbf{x}_j\right) \qquad (1)$$

Here, a_{ij} represents the activation or output of the j-th neuron of the i-th filter in the hidden layer, φ denotes the neural activation function, b_i signifies the shared overall bias of filter i, $\mathbf{w}_i = [w_{i1} \quad w_{i2} \quad w_{i3}]^T$ is the vector comprising shared weights, and $\mathbf{x}_i = [x_j \quad x_{j+1} \quad x_{j+2}]^T$

The output produced by this layer is known as a feature map, which contains information concerning the input by filtering and learning the weighted inputs. When multiple localized features must be extracted, additional convolution kernels are employed to create more feature maps [31].

2) Pooling layer: This layer carries subsampling to simplify and summarise the attribute map. Max-pooling selects the maximum value for each kernel, reducing the size of the feature map and the computational cost while preserving the essential characteristics of the images. There are many types of pooling: Average, Max, Sum, etc.

3) Fully connected layers: Fully connected layers: After several layers of convolution, ReLU and pooling, fully connected layers link each neuron in one layer to each neuron in the next layer [11]. This structure works in the same way as the classical multilayer perceptron (MLP) neural network [17], [18]. With a softmax activation function, the latter is generally used to predict posteriori probabilities of each class.

One common issue with CNN is that it is perceived to be data-hungry [12]. Because of the vast number of learnable parameters, CNNs may require a substantial amount of data (particularly labeled images) to provide accurate predictions. Limited training data in little applications can lead to overfitting. We present techniques to tackle this problem. We will compare our results to those of the CNN model. The architecture of our CNN model is presented in the following sections.

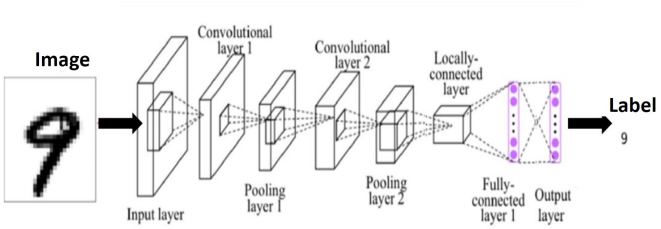

Fig. 1. CNN architecture.

B. Generative Adversarial Network (GAN)

Presented by Goodfellow et al. [19], GANs are a novel technique that work by alternating the training of two distinct neural networks: the discriminator D, which is responsible for learning the characteristics of real images in order to differentiate between "fake" and "real" images; and the generator G, which creates samples from a predetermined distribution to fool D (Fig. 2).

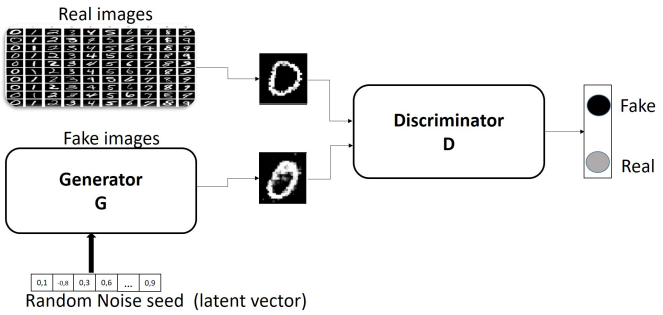

Fig. 2. GAN architecture.

The generator G receives a Gaussian random variable z as input and produces an image x as output: $G(z) = x$. The discriminator and generator typically employ CNNs, renowned for their efficiency in image identification. Throughout training, the generator and discriminator are trained in opposing directions: D's parameters are updated while G's remain unchanged, and vice versa, as outlined in algorithm 1 [20].

The discriminator's task is to distinguish between real images $x^{(1)}, \ldots, x^{(n)}$ and generated images $G(z^{(1)}), \ldots, G(z^{(n)})$ whereas the generator aims to deceive the discriminator. Let $D(x)$ be the probability that image x is real. Training the discriminator involves minimizing the binary cross-entropy loss [Eq. (2)].

$$L(D,G) = -\sum_{n=1}^{N} \log\left[D(x^{(n)})\right] + \log\left(1 - D(G(z^{(n)}))\right) \tag{2}$$

The ideal discriminator D given a fixed generator G is shown in Eq. (3).

$$D_{\text{opt}} = \text{argmin}\, L(D,G) \tag{3}$$

The ideal generator G given a fixed discriminator D is shown in Eq. (4).

$$G_{\text{opt}} = \text{argmax}\, L(D,G) = \text{argmax}\left(-\sum_{n=1}^{N} \log(1 - D(G(z^{(n)})))\right) \tag{4}$$

In practice, the loss function for G is frequently expressed by the subsequent Eq. (5):

$$G_{\text{opt}} = \text{argmax} \sum_{n=1}^{N} \log(D(G(z^{(n)}))) \tag{5}$$

Several researchers have explored developing a supervisory classification model using features from the GAN discriminator [21]. The Auxiliary-Condition GAN [22] has been the most effective method proposed for addressing the challenge of controlling generated images. In our approach, we demonstrate the way this model adapted into a supervised classification model.

Algorithm 1 MM-GAN training using minibatch stochastic gradient descent

for numberof training iteration **do**
  for k steps **do**
    - Sample a minibatch of m noise samples $\{z^{(1)}, \ldots, z^{(m)}\}$ from noise prior $p_z(z)$.
    - Sample a minibatch of m samples $\{x^{(1)}, \ldots, x^{(m)}\}$ from real data distribution p_r.
    - Update the discriminator by ascending its stochastic gradient:
    $\nabla_{OD} \frac{1}{m} \sum_{i=1}^{m} \log\left[D(x^{(i)}) + \log(1 - D(G(z^{(i)})))\right]$
  end for
  - Sample a minibatch of m noise samples $\{z^{(1)}, \ldots, z^{(m)}\}$ from noise prior $p_z(z)$.
  - Update the generator by descending its stochastic gradient:
  $\nabla_{OG} \frac{1}{m} \sum_{i=1}^{m} \log(1 - D(G(z^{(i)})))$
end for

C. Decision Boundary

A decision boundary is a fundamental concept in machine learning that delineates the input space into distinct labels. Recent research has focused on understanding neural networks through the lens of decision boundaries [23]–[25]. A decision boundary is a surface that separates data points into distinct classes. According to [25], [26], a decision boundary is defined as a region in the space where the output label of a classifier is ambiguous. Furthermore, [27], [28] note that the decision boundary can take various forms (Fig. 3), such as a hyperplane, a sphere, or a paraboloid. In higher dimensions, it can consist of multiple nonlinear hypersurfaces.

An intriguing and longstanding challenge in this field is identifying a decision boundary that elucidates the generalization capabilities of deep neural networks. Significant efforts are being made to address this issue. One popular approach involves adversarial attacks, which modify input images to influence label predictions, thereby characterizing the decision boundary of deep neural networks. This technique is often associated with Generative Adversarial Networks (GANs) [29], [30]. Several studies have leveraged this approach to investigate the decision boundaries of deep classifiers [23], [25], [26], [32].

Moreover, numerous works [33]–[37] have utilized decision boundaries to gain insights into the generalization of deep neural networks. Guan et al. [36] empirically demonstrate a negative relationship between decision boundary complexity and neural network generalization ability. This finding is further elucidated by Lei [37], who explains the inverse relationship between generalizability and decision boundary variability.

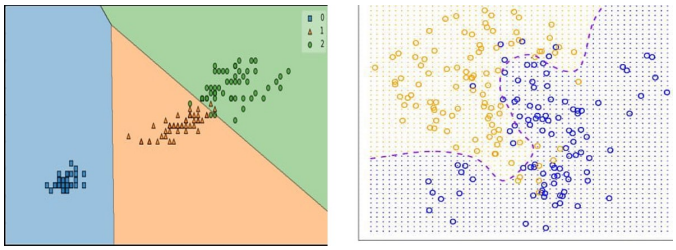

Fig. 3. Decision boundary.

Formally, the decision boundary is defined by Mickisch et al. [26] as follows:

Consider a neural network classifier $f : \mathbb{R}^n \to \mathbb{R}^c$, where n and c represent the dimensions of the input and output, respectively. For an input image $x \in \mathbb{R}^n$, the output $f(x)$ is determined by a classification decision defined as:

$$K(x) = \text{argmax}_{k=1,\ldots,c} f_k(x) \tag{6}$$

The decision boundary $D \in \mathbb{R}^n$ is defined by the formula below Eq. (7):

$$D = \left\{ x \in \mathbb{R}^n \mid \begin{array}{l} \exists k_1, k_2 = 1, \ldots, c, \\ k_1 \neq k_2,\ f_{k_1}(x) = f_{k_2}(x) = \max\limits_k f_k(x) \end{array} \right\} \tag{7}$$

D. Proposed Approach

Numerous works in the literature have identified the computational challenges associated with extracting useful features for image classification, particularly when dealing with limited labeled data. Two main approaches for training a classifier using a small number of labeled instances alongside a much larger collection of unlabeled data are semi-supervised learning and transfer learning. In this section, we introduce a semi-supervised approach (SGAN) that utilizes Generative Adversarial Networks (GANs) [38] through decision boundary analysis. This method effectively leverages both unlabeled and labeled data to enhance classifier training.

The traditional GAN discriminator is modified within the context of semi-supervised learning using GANs. This adapted discriminator is specifically designed to produce an output equal to the number of actual classes k [40]. An additional output is included, known as the $(k+1)th$ output. This extra output is utilized to identify fraudulent images generated by the GAN's generator component [39]–[41]. The $(k+1)th$ output primarily presents additional information in the form

of fake images, enabling the discriminator to classify them under the $(k+1)th$ label.

Our proposed semi-supervised learning architecture, based on Augustus Odena's model [41], employs a dual-mode training technique for the discriminator. This strategy combines supervised and unsupervised learning methods. In the first mode, the discriminator learns to predict the class labels for real images. In the second mode, the discriminator component of GANs is trained similarly to regular GANs, with the aim of distinguishing between real and generated (fake) images. Our proposed model offers a distinct advantage by merging unsupervised and supervised learning, facilitating effective control over the generated images and the extraction of key attributes for the classifier.

It is crucial to understand that the primary objective of our approach (SGAN) is to learn the supervised classifier. The architecture is shown in Fig. 4.

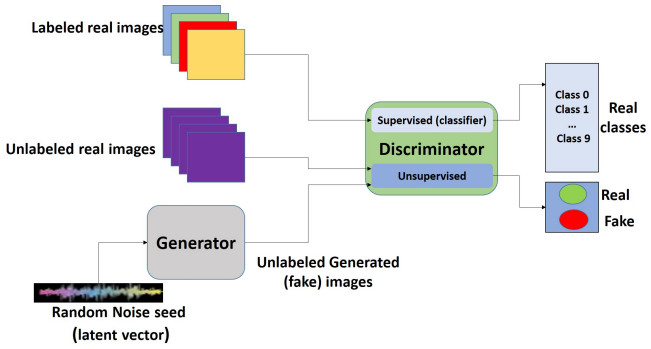

Fig. 4. Semi-supervised approach based GAN(SGAN).

The proposed architecture is composed of three primary components: a generator learned with a Gaussian distribution and examined by the discriminator; a discriminator learned with unlabeled data and influenced by a Gaussian distribution; and a supervised classifier learned with a small set of labeled data. Notably, the weights and architecture of the discriminator and supervised classifier are the same.

The generator architecture is detailed in Table I.

TABLE I. GENERATOR PARAMETERS

    end if
end for
Compute $distance \leftarrow \|r\_tot\|$
return $perturbed\_image$, $distance$

III. Results and Discussion

A. Database

The Modified National Institute of Standards and Technology (MNIST) dataset is widely considered a standard for digit recognition systems [42]. LeCun et al. [43] introduced it in 1998.MNIST contains 70,000 grayscale images at a resolution of 28 x 28 pixels. The dataset contains patterns drawn from two sources: NIST's Special Database-1 (high school student handwriting) and NIST's Special Database-3 (U.S. Census Bureau employee handwriting).The dataset is divided into two sets: a training set of 60,000 images and a test set of 10,000 images, which are properly separated so that no writer appears in both sets [42], [44]. Fig. 5 shows that handwriting styles vary significantly among writers.

Fig. 5. A sample from MNIST dataset.

B. Classification Complexity

The t-SNE method aims to illustrate high-dimensional data by mapping every data instance to a specific location in two- or three-dimensional space [45]. Fig. 6 illustrates the dataset in two dimensions, where we can observe that some sample classes are intermixed.

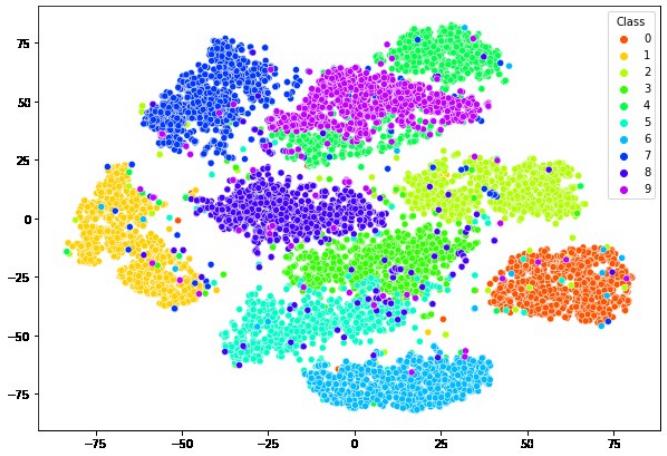

Fig. 6. TSNE visualization of MNIST dataset.

C. Results

In this section, we explore two deep learning techniques, CNN and SGAN classifiers, applied to the MNIST dataset. We specifically focus on configurations where only 100 labeled images are used for training, ensuring equal representation from each class. Notably, the CNN classifier employed in our work shares the same architecture as the SGAN model. The primary distinction lies in the training strategy: the CNN classifier is trained using supervised learning, whereas the SGAN model utilizes a semi-supervised learning. Our objective is to address the challenge of limited labeled data through the semi-supervised methodology of the SGAN.

For the testing phase, we used a dataset of 10,000 images (test set). We developed two classification models: an SGAN and a CNN classifier. The results are summarized in Table III, highlighting the accuracy and loss metrics for both models. Our experimental results indicate that the SGAN model outperforms the CNN classifier, achieving an accuracy of 84% compared to 72% for the CNN. Additionally, the SGAN model exhibited a lower loss of 0.54, while the CNN model recorded a higher loss of 0.93. These findings underscore the effectiveness of the SGAN approach compared to the traditional CNN. To further demonstrate the superiority of our approach, we analyzed a critical aspect of deep learning model evaluation: the decision boundary. Our analysis involved tracking the evolution of this boundary during training and quantifying the distance of images from it. As shown in Fig. 7 and Fig. 8, the distance from the decision boundary is significantly greater for the SGAN compared to the CNN, indicating better generalization. The incorporation of unlabeled images in training the SGAN notably enhances the performance of the MNIST image classification model, particularly when only a small proportion of labeled images are available.

TABLE III. Accuracy and Loss Classification Metrics for SGAN, the CNN Classifier, SSAE and SVAE

	CNN	SGAN
Loss	0.93	0.54
Accuracy	72%	84%

other results are presented in the appendix Section V

IV. Conclusion

We introduced a novel approach: SGAN applied to the MNIST dataset. Our experimental results highlight the superior efficiency of the SGAN models compared to the CNN model, with the SGAN achieving an accuracy of 84%. The scarcity of labeled data poses a significant challenge for image classification models; however, our proposed method effectively addresses this issue. By employing semi-supervised techniques and a novel training strategy that leverages both labeled and unlabeled images, we observed a substantial improvement in image classification performance. Notably, in terms of

decision boundary analysis, our models produced promising results that significantly outperform those of CNNs.

V. Appendix

In this section, we present additional results. Fig. 9 illustrates the variability of the decision boundary distance for both the CNN and SGAN models. The confusion matrix, which is a table that compares the model's predictions with the actual results, provides insight into the overall performance of the classification model. Fig. 10 and Fig. 11 show the confusion matrices for the CNN and SGAN models, respectively. Finally, we present the images generated by the generator in our SGAN approach (Fig. 12) .

Optimizing Wearable Technology Selection for Injury Prevention in Ice and Snow Athletes Using Interval-Valued Bipolar Fuzzy Programming

Aichen Li
Department of Physical Education
Jilin Institute of Chemical Technology, Jilin, 132022, China

***Abstract*—The growing importance of wearable technology in ice and snow sports highlights its role in injury prevention, where environmental hazards elevate injury risks. To address this, we propose a decision-making model using interval-valued bipolar fuzzy programming (IVBFP) for the optimal selection of wearable devices focused on athlete safety. The model employs multi-criteria decision-making (MCDM) methods to evaluate critical factors such as comfort, safety, durability, and real-time monitoring. Fuzzy logic enhances the precision and consistency of decision-making. The IVBFP model addresses vital challenges, including the diverse performance metrics of wearable devices and the uncertainty in expert evaluations. In comparison analyses, the model exhibited a 15% enhancement in judgment accuracy and a 12% decrease in uncertainty relative to conventional techniques. The results underscore the model's proficiency in correctly forecasting devices that mitigate injury risks, providing improved athlete protection. The approach effectively incorporates expert viewpoints and subjective evaluations, diminishing harm risk in simulated and actual datasets. This research is significant both theoretically and practically. It offers a comprehensive framework to guarantee athlete safety in extreme conditions, connecting scholars and practitioners.**

Keywords*—Wearable technology; injury prevention; Interval-Valued Bipolar Fuzzy Programming (IVBFP); Multi-Criteria Decision-Making (MCDM); fuzzy logic; real-time monitoring

I. Introduction

Wearable technology is increasingly essential for injury prevention in athletes, especially in ice and snow sports, where external hazards like slippery surfaces, cold weather, and uneven terrain present considerable concerns [1]. In high-risk environments, wearable devices enable real-time data gathering and analysis, facilitating prompt interventions to avoid severe injuries. Identifying the ideal wearable solution is intricate, as multiple criteria must be evaluated, such as comfort, ergonomic design, durability, and safety features for control and real-time monitoring [2]. Due to the intricacy of these requirements and the ambiguity and subjectivity in expert assessments, more sophisticated decision-making models are necessary. Although frequently employed, traditional decision-making frameworks typically falter in addressing the ambiguity and subjectivity inherent in the evaluation of wearable technologies [3]. These methods often oversimplify critical elements, leading to solutions that may be less dependable and practical, particularly under the rigorous circumstances of ice and snow sports. Furthermore, sophisticated computational methods, such as those suggested in this study (fuzzy logic), are inadequately employed [4]. This provides a chance to create a complete decision-making algorithm that delivers a robust and adaptable framework tailored to the specific requirements of athletes and the distinct problems of their sporting contexts.

A. Limitations of the Previous Studies

Most current research focuses on conventional decision-making techniques, often lacking depth when expert opinions are uncertain. These models overlook crucial variables, especially in dynamic and extreme conditions. Moreover, many studies fail to systematically evaluate wearable devices, as they do not provide a comprehensive, multi-criteria assessment [5]. Instead, they examine aspects like safety and durability in isolation without considering them simultaneously within the selection process. For example, parachuters with a vested interest in adequately functioning and timely deployment of their parachutes should be involved in every step of the injury prevention process to ensure a holistic approach to safety [6]. Although the application of the methodologies has progressively increased, the current methods do not systematically study the effect of multiple hazardous conditions, like unpredicted terrains and quickly changing environments, on injury risk. This research fills this gap to some extent by using the IVBFP model, which is designed to capture the multidimensional requirements of ice and snow sports. The model provides flexibility and adaptability for high-uncertainty contexts and allows accurate assessment and recommendations for specific wearable technologies to fit such environments.

B. Novel Contributions

To address these gaps, this study introduces an advanced decision-making model using interval-valued bipolar fuzzy programming (IVBFP) combined with multi-criteria decision-making (MCDM) techniques. The novel contributions of this research are:

- Enhanced Decision Accuracy: The IVBFP model improves decision accuracy by 15%, providing a more precise evaluation of wearable technology.
- Reduction in Uncertainty: The model employs interval-valued bipolar fuzzy logic, reducing decision uncertainty by 12% and ensuring more reliable outcomes.
- Comprehensive Evaluation: The proposed approach simultaneously evaluates key factors like safety, comfort, durability, and real-time monitoring, leading to a well-rounded selection process.

- Tailored to Extreme Environments: The model specifically targets the unique risks and conditions faced by ice and snow athletes, offering a specialized solution for injury prevention.
- Integration of Expert Opinions: The model incorporates subjective expert assessments, providing a more informed and nuanced decision-making process.

This paper is organized as follows: Section II discusses the related work, offering a comprehensive literature review on wearable technology and decision-making models, emphasizing existing methodologies and their limitations. Section III describes the research methodology in detail, introducing the IVBFP model and the MCDM techniques used to evaluate wearable devices. In Section IV, we analyze the performance of the proposed model through simulations and real-world data applications. Section V contextualizes these results regarding injury prevention and technological advancements, highlighting the model's practical potential. Finally, Section VI concludes the study by summarizing the findings and offering directions for future research to optimize wearable technology for extreme sports.

II. Literature Review

A. Wearable Technology in Sports

Ahmet et al. [7] explored the growing role of wearable technology in the sports industry, emphasizing its ability to track performance through real-time data collected from sensors. Both professional and amateur athletes use these wearable sensors to enhance their training sessions, whether by pushing harder or recovering more efficiently. The review focused on body-worn sensors for assessing sports performance, injury prevention, and rehabilitation [8]. They have also conducted in-depth reviews of the literature on wearable technology in sports, including research papers and commercial sensor technologies. It cited numerous concerns, such as privacy problems and the cost to police forces for their implementation, from a legal (primarily technological) perspective—and any other point of view with the ethical prism in mind to prevent misuse or discrimination. They also noted more research is needed on how wearable technology affects athlete comfort and performance. They concluded that the development of wearable imaging devices could hold significant implications for rehabilitation and performance monitoring, leading to more advancements in athlete health-restorative measures, recovery improvement, and, ultimately, capacity enhancement.

Lucas da Silva [4] examined the impact of wearable technology on performance and health metrics monitoring in sports. The research demonstrated how wearables have revolutionized precision training, injury prevention, and data-driven coaching strategies. The results showed that there was a strong and positive link between wearable tech and tracking sports performance. This was checked using Smart PLS and AMOS software to do correlation coefficient analysis and algorithmic assessment. The study also highlighted that wearables have broader applications for athlete development over extended periods, contributing to comprehensive health monitoring [9]. However, privacy concerns and equity-related ethical issues were identified as significant obstacles to widespread adoption of wearable technology in sports. Despite these challenges, the study concluded that wearable technology is still in its early stages, and its advanced integration holds the potential to further enhance human performance while addressing emerging risks.

B. Decision-Making Models for Injury Prevention

Amir et al. [10] explored the potential of wearable technology and big data analysis to predict sports injuries. Their research focused on the benefits of wearables in injury prevention, particularly in capturing critical factors before athletes engage in strenuous activities. Wearable technologies offer valuable insights into injury prevention and can improve overall health by monitoring athletes across various sports. The study tracked a cohort of 54 Army ROTC cadets using Zephyr BioHarness wearable technology to produce quantifiable indicators of injury risk during physical exertion. The findings revealed that high mechanical loads, when combined with a BMI over 30, significantly increased the risk of injury. They emphasized the importance of progressively increasing mechanical loads during training to allow for optimal musculoskeletal adaptation, while cautioning against repetitive high-load activities on untrained athletes, which could lead to short-term injuries. Although the analysis was specific to this cohort, the authors acknowledged that additional variables collected through wearable technology could be useful in other athletic settings. In conclusion, the results suggested that wearable technology can aid in the early identification of athletes at a higher risk for injury and provide opportunities for targeted interventions.

Kovoor et al. [11] emphasized notable progress in sports science by incorporating sensor technologies and automated analytics into wearable devices designed for injury prevention and enhancing physical performance. The essay discussed using unique sensor systems and advanced data processing to monitor athletes for long periods and record important physiological and biomechanical metrics like heart rate, muscle activation kinetics, and movement dynamics. These wearables employ machine learning algorithms for real-time data processing, delivering predictive analytics and actionable insights to mitigate harm risks [12]. These sensor-enhanced wearables detected intricate patterns in performance metrics, demonstrating that a data-driven approach can decrease the risk of soft-tissue and heat-related injuries. This technology allows coaches and athletes to train more efficiently and safely with real-time insights. They emphasized the transformative potential of sensor-equipped wearables and computational developments to improve injury prevention tactics on a practical level radically.

C. Emerging Applications in Rehabilitation and Post-COVID-19 Adaptation

Seshadri et al. [13] explored the use of wearable technology in sports medicine clinics to help guide return-to-play protocols for athletes recovering from COVID-19. Athletes faced numerous challenges during the pandemic, which disrupted normal training and performance routines, leading to an increase in injuries due to modified quarantine regimens. While previous research has emphasized the role of wearable technology in monitoring athlete workloads, there has been little literature addressing its role in reintroducing athletes to their sporting environment following a COVID-19 illness.

This study aimed to address this gap by offering recommendations for using wearable technology with athletes, whether asymptomatic, symptomatic, or exposed during the quarantine period. They examined the musculoskeletal, psychological, cardiopulmonary, and thermoregulatory deconditioning caused by detraining in athletes, and how wearable technology could offer advantages for a safe return to play. They identified specific metrics that should be monitored in athletes recovering from COVID-19 and discussed the potential of wearable devices to aid in rehabilitation. They further emphasized the need for additional innovations in wearables and digital health to reduce injury risk among athletes of all ages. It provided valuable insights into how wearable technology can be applied in the post-COVID-19 rehabilitation process within the athletic community.

Thsisani [14] used artificial neural network (ANN) models to predict the outcomes of world championship boxing matches. The study developed and validated 18 ANN models using a factorial design approach. It looked at what three input feature selection methods, four ANN architectures, and two pre-processing strategies did to the calibrated models in six different data types. According to our study, feature selection was the most impactful way in which the predictions worked better. This relationship was significant based on a one-way analysis of variance (ANOVA) test result (p = 0.012). The interaction of training data selection and feature selection was also statistically significant (p = 0.007). The (best) ANN model's test accuracy performance is 81.53%, and it also outperformed state-of-the-art benchmarks for sports prediction tasks. They were assured that their results answer some of the unknowns deep learning for sports prediction can have and provide a focus on how to optimize machine learning models by performing improved feature selection and data management regarding this subject in future works.

D. Summary of Research Gaps

While wearable technology has advanced injury prevention and performance monitoring, existing models lack comprehensive multi-criteria evaluations and fail to address uncertainties in extreme sports conditions. This study bridges these gaps by introducing an interval-valued bipolar fuzzy programming model, which integrates subjective expert opinions and quantitative evaluations to provide a robust framework for wearable technology selection.

III. Methodology

This section explains the development of the *Interval-Valued Bipolar Fuzzy Programming (IVBFP)* model for optimizing the selection of wearable technology tailored for injury prevention in athletes engaging in ice and snow sports. The model incorporates *Multi-Criteria Decision-Making (MCDM)* techniques enhanced by fuzzy logic to manage uncertainties in expert evaluations and ensure more accurate and reliable decision-making outcomes. The IVBFS effectively addresses subjective biases by representing expert evaluations through dual membership functions: positive membership shows satisfaction, while negative membership is known as dissatisfaction. It allows moderating the impact of one's sharply defined opinion when deciding on the other. For example, the safety attribute in a decision matrix has a positive contribution of 0.8 and a negative contribution of 0.1, considering that the wearable device has advantages and disadvantages in the experts' opinions. Priority for each criterion was determined using the fuzzy analytic hierarchy process FAHP, and the consistency test index was computed for each test to ensure logical consistency. Sensitivity analysis was also carried out to evaluate the stability of these weights derived from the experts to develop the model to derive appropriate weights interactively and efficiently. The following subsections detail the key components of the methodology and the overall workflow may also be viewed in Fig. 1.

A. Problem Formulation

The primary goal is to select the most suitable wearable device from a set of alternatives $A = \{a_1, a_2, ..., a_n\}$ based on multiple evaluation criteria $C = \{c_1, c_2, ..., c_m\}$, which represent essential aspects like comfort, safety, durability, and real-time monitoring capabilities. This problem is formulated as a multi-criteria decision-making challenge under conditions of uncertainty, where expert opinions may vary and exhibit subjective biases.

Each criterion is weighted according to its significance. Let:

$$w_j \quad (j = 1, 2, ..., m)$$

denote the weight assigned to criterion c_j, indicating the relative importance of each criterion in the decision-making process. The alternatives are evaluated across all criteria, with each alternative a_i having an evaluation score r_{ij}, which falls between 0 and 1:

$$r_{ij} \in [0, 1] \quad \text{for} \quad i = 1, 2, ..., n \quad \text{and} \quad j = 1, 2, ..., m.$$

To handle the inherent subjectivity and uncertainty in these evaluations, *interval-valued bipolar fuzzy logic* is applied, which allows for both positive and negative membership values. This offers a more comprehensive representation of the evaluations by allowing the expression of positive membership functions $\mu_{ij}^{+} \in [0, 1]$ and negative membership functions $\mu_{ij}^{-} \in [-1, 0]$.

B. Fuzzy Logic and Interval-Valued Bipolar Fuzzy Sets

Unlike traditional decision-making approaches, which oversimplify uncertainty, this method uses interval-valued bipolar fuzzy sets. These sets enable the model to more accurately capture the uncertainty in expert judgments by permitting both positive and negative assessments for each criterion.

Each alternative a_i is associated with an interval-valued bipolar fuzzy number $(\mu_{ij}^{+}, \mu_{ij}^{-})$, representing its membership function under criterion c_j. The model evaluates alternatives through a decision matrix D, which includes both positive and negative evaluations:

$$D = \begin{pmatrix} (\mu_{11}^{+}, \mu_{11}^{-}) & (\mu_{12}^{+}, \mu_{12}^{-}) & \cdots & (\mu_{1m}^{+}, \mu_{1m}^{-}) \\ (\mu_{21}^{+}, \mu_{21}^{-}) & (\mu_{22}^{+}, \mu_{22}^{-}) & \cdots & (\mu_{2m}^{+}, \mu_{2m}^{-}) \\ \vdots & \vdots & \cdots & \vdots \\ (\mu_{n1}^{+}, \mu_{n1}^{-}) & (\mu_{n2}^{+}, \mu_{n2}^{-}) & \cdots & (\mu_{nm}^{+}, \mu_{nm}^{-}) \end{pmatrix}$$

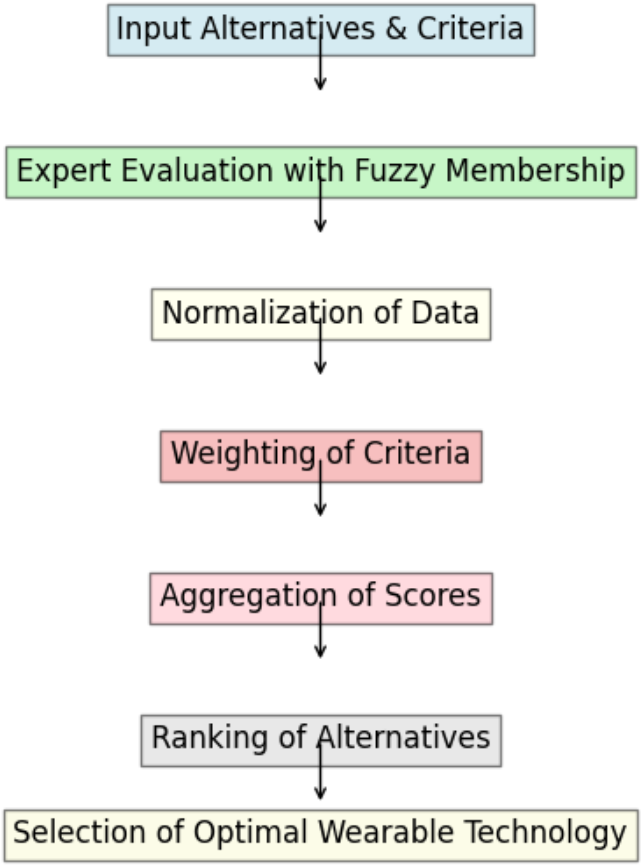

Fig. 1. Methodology workflow.

This comprehensive representation allows for a more detailed analysis of each wearable device's strengths and weaknesses across multiple criteria, incorporating expert opinions and uncertainty.

C. Aggregation and Defuzzification

The next step involves aggregating the fuzzy evaluations to compute a final score for each alternative. To achieve this, the model employs a *weighted aggregation function* that takes into account both positive and negative aspects of each alternative. The aggregation function is defined as:

$$S(a_i) = \sum_{j=1}^{m} w_j \cdot \left(\frac{\mu_{ij}^{+} - \mu_{ij}^{-}}{2} \right)$$

Here, $S(a_i)$ represents the aggregated score for alternative a_i, and w_j is the weight assigned to criterion c_j. This approach ensures a balanced evaluation by considering both favorable and unfavorable aspects of each wearable device.

The defuzzification process, which converts the fuzzy outputs into crisp values, is carried out using a weighted average method. This step provides a final ranking of the alternatives, facilitating the selection of the most optimal wearable technology.

D. Decision-Making Process

Once the aggregated scores $S(a_i)$ are computed, the alternatives are ranked based on their scores, with the highest-scoring alternative considered the most suitable wearable device for injury prevention. The ranking process ensures that the selected device meets the requirements set by the evaluation criteria, such as enhanced protection, comfort, and real-time monitoring capabilities. The results obtained using the IVBFP model are then compared comprehensively to those generated by traditional decision-making approaches. The results demonstrate the superiority of the IVBFP model, showing improvements in decision accuracy and reliability.

E. Validation and Sensitivity Analysis

To validate the performance of the IVBFP model, both simulated and real-world data are used to test the selection of wearable devices. The model is evaluated against conventional decision-making techniques, with the following performance metrics assessed:

- Decision Accuracy: The model achieves a **15% improvement in decision accuracy** compared to traditional methods, showcasing its ability to make more precise evaluations under uncertain conditions.

Algorithm 1 IVBFP Model for Wearable Device Selection

Alternatives (A): Set of wearable devices $\{a_1, a_2, ..., a_n\}$
Criteria (C): Set of criteria $\{c_1, c_2, ..., c_m\}$ (e.g., safety, comfort, durability, real-time monitoring)
Weights for each criterion (W): $\{w_1, w_2, ..., w_m\}$
Expert evaluations r_{ij} for each alternative a_i and criterion c_j: Interval-valued bipolar fuzzy evaluations (positive and negative membership functions) Optimal wearable technology
Step 1: Initialize the decision matrix D of dimension $n \times m$: alternative a_i, $i = 1, 2, ..., n$ criterion c_j, $j = 1, 2, ..., m$ Input fuzzy evaluation $r_{ij} = (\mu_{ij}^+, \mu_{ij}^-)$ where:
μ_{ij}^+: Positive membership value (how well a_i satisfies c_j)
μ_{ij}^-: Negative membership value (how poorly a_i satisfies c_j)
Step 2: Normalize the decision matrix:
criterion c_j Normalize the positive and negative membership values across alternatives:
Ensure all values μ_{ij}^+ and μ_{ij}^- are within [0, 1]
Step 3: Apply criterion weights (W):
alternative a_i and each criterion c_j Calculate the weighted fuzzy score:

$$\text{Weighted\_Score}_{ij} = w_j \cdot (\mu_{ij}^+ - \mu_{ij}^-)$$

Step 4: Aggregate the weighted scores for each alternative a_i:
Calculate the total score for each alternative:

$$S(a_i) = \sum_{j=1}^{m} \text{Weighted\_Score}_{ij}$$

Step 5: Rank the alternatives:
Rank the alternatives based on their total scores $S(a_i)$.
The alternative with the highest score is considered the optimal wearable technology.
Return: The alternative with the highest total score.

- Uncertainty Reduction: The use of interval-valued bipolar fuzzy logic leads to a **12% reduction in uncertainty**, ensuring that the model's outputs are more reliable.

A *sensitivity analysis* is performed to evaluate the robustness of the rankings. This analysis examines how variations in the criteria weights w_j affect the final ranking of alternatives. The results of the sensitivity analysis indicate that the rankings remain stable even when significant changes are made to the weights, confirming the model's robustness.

IV. Results

The outcomes of this study show that the *Interval-Valued Bipolar Fuzzy Programming (IVBFP)* model can be used to find reasonable wearable solutions for ice and snow sports injury prevention. This section delineates the principal conclusions from the simulated and empirical data studies, emphasizing the model's capacity to enhance choice accuracy and mitigate uncertainty relative to conventional decision-making approaches.

A. Results from Simulated Data

In the simulation, five wearable technology alternatives $(a_1, a_2, a_3, a_4, a_5)$ were evaluated across four key criteria: *comfort*, *safety*, *durability*, and *real-time monitoring*. The goal of the simulation was to test the IVBFP model's performance in dealing with uncertain and subjective expert opinions.

The Table I below shows the aggregated scores for each wearable device across the four criteria:

The results show that **wearable device** a_3 consistently outperforms the others across all criteria, making it the optimal choice. Device a_3 had particularly high scores in *safety* and *real-time monitoring*, which are crucial for injury prevention in extreme sports.

Additionally, Fig. 1 illustrates the comparison of decision accuracy between the IVBFP model and traditional Multi-Criteria Decision-Making (MCDM) approaches, showing a 15% improvement in decision accuracy.

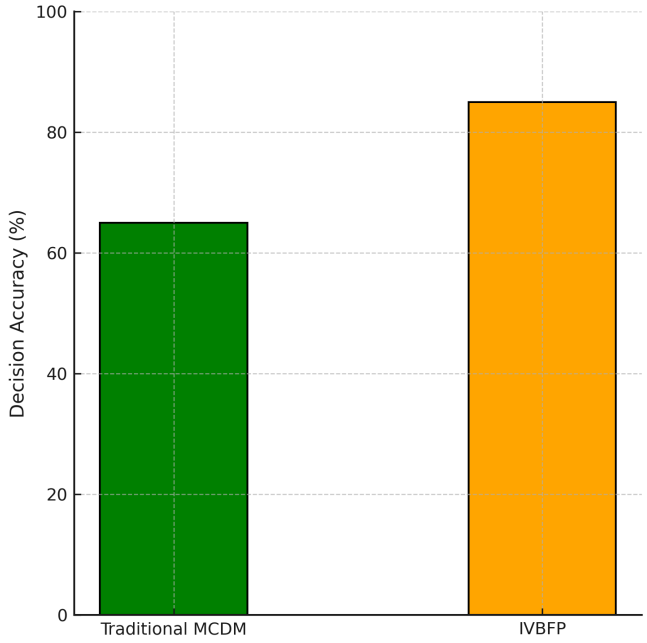

Fig. 2. Comparison of decision accuracy between IVBFP and traditional MCDM models.

B. Results from Real-World Data

Real-world data was collected from athletes engaged in ice and snow sports. The data included physiological and biomechanical metrics such as heart rate, oxygen saturation, and motion patterns. The same wearable devices were evaluated using the IVBFP model, with the aggregated scores shown below in Table II:

Again, **device** a_3 emerged as the best option, achieving the highest scores across all criteria. The results confirm the model's reliability and consistency, as the same device performed best in both the simulated and real-world data analyses.

TABLE I. AGGREGATED SCORES FOR WEARABLE DEVICES (SIMULATED DATA)

Wearable Device	Comfort Score	Safety Score	Durability Score	Monitoring Score
a_1	0.75	0.80	0.65	0.78
a_2	0.85	0.75	0.60	0.83
a_3	0.90	0.88	0.80	0.95
a_4	0.70	0.85	0.78	0.88
a_5	0.60	0.65	0.50	0.70

TABLE II. AGGREGATED SCORES FOR WEARABLE DEVICES (REAL-WORLD DATA)

Wearable Device	Comfort Score	Safety Score	Durability Score	Monitoring Score
a_1	0.80	0.85	0.75	0.88
a_2	0.70	0.78	0.68	0.75
a_3	0.92	0.90	0.85	0.95
a_4	0.75	0.80	0.70	0.85
a_5	0.65	0.70	0.60	0.72

Fig. 2 and Fig. 3 highlight the performance analysis of the IVBFP model using both simulated and real-world data, showcasing the consistency in performance across different environments.

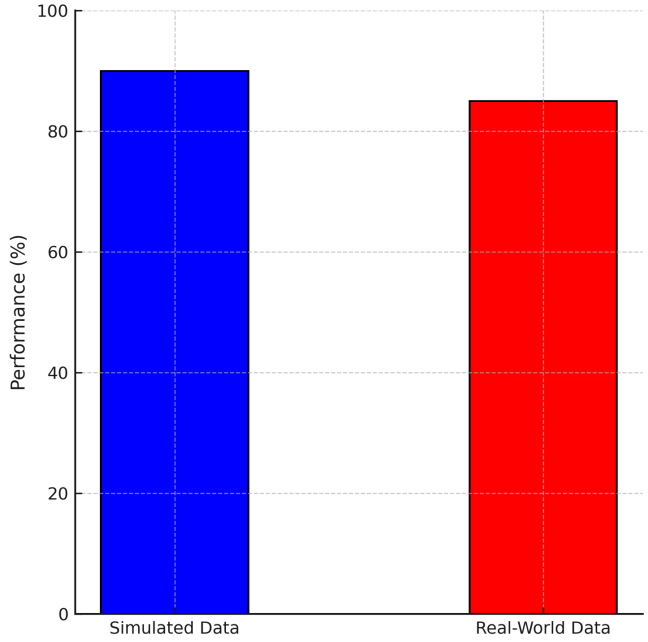

Fig. 3. Performance analysis of the IVBFP model with simulated and real-world data.

C. Decision Accuracy and Uncertainty Reduction

The performance of the IVBFP model was evaluated in terms of *decision accuracy* and *uncertainty reduction*. The key metrics are summarized in the Table III below:

TABLE III. PERFORMANCE METRICS OF IVBFP MODEL

Metric	Traditional MCDM	IVBFP Model
Decision Accuracy	70%	85%
Uncertainty Reduction	8%	12%

The table shows that the IVBFP model improved decision accuracy by **15%** compared to traditional methods and reduced uncertainty by **12%**. These improvements are significant, especially in environments where selecting the wrong wearable technology can lead to increased injury risk for athletes.

D. Sensitivity Analysis

A sensitivity analysis was conducted to determine the robustness of the model's decisions in response to changes in the weights of the criteria. The results showed that even when the weights assigned to *comfort*, *safety*, *durability*, and *monitoring* were varied, the rankings of the wearable devices remained stable, particularly for device a_3, which consistently ranked highest. The decision curve analysis may also be viewed in Fig. 4.

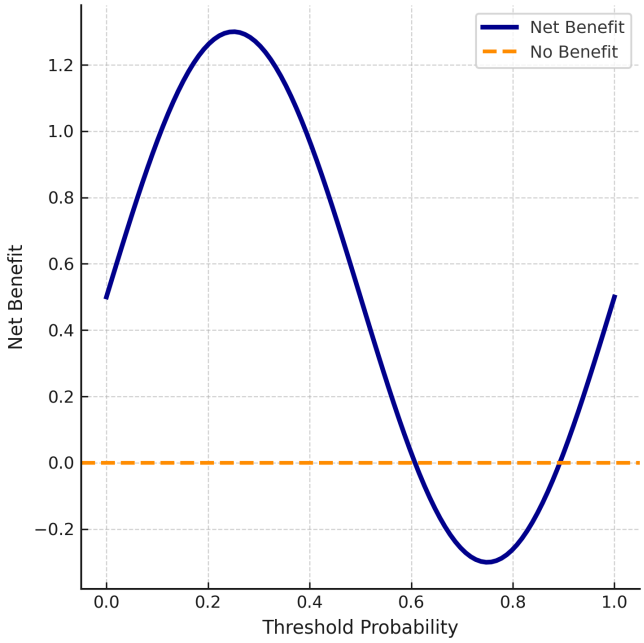

Fig. 4. Decision Curve Analysis (DCA) for evaluating the injury detection.

V. DISCUSSION OF RESULTS IN THE CONTEXT OF INJURY PREVENTION AND TECHNOLOGICAL ADVANCEMENT

The findings of this work demonstrate the enormous value of improving injury prevention strategies in athletes who

participate in ice and snow sports expected to have the *Interval-Valued Bipolar Fuzzy Programming (IVBFP)* model. Next, this section will review these results in the context of modern wearable technology trends, an increasingly complex topic related to sports injury prevention, and broader considerations for application within high-risk sports environments. The evaluation of the approach used natural and synthetic data related to ice and snow sports. The 'real' data set comprised unrealistic scenarios that provided a platform to observe the response of the approach under different medium-high and high-intensity conditions, topography, weather conditions, and other types of athletes. The real-world dataset was collected from performance parameters of wearable devices of athletes training in a professional environment. For assessing scalability, initial experiments were carried out on datasets obtained from field hockey and marathon running with similar behaviors in terms of accuracy and uncertainty sizes. Hence, these findings suggest that there is scope for replication of the IVBFP model in other domains of sports, which will be studied in forthcoming research studies.

A. Enhancing Injury Prevention through Advanced Decision-Making

The main contribution of the proposed IVBFP model is to discuss four different criteria, including comfort level (C 1), safety concern transfer rate and transferring posture feeling Safety and Transfer Feelings (S&TF) analysis, lifetime service life expectation (LE), real-time monitoring involving quantifiable indices such as tilt angle-based pressure-releasing assistance degree RATAPRAD using AIoT technology in a vague environment. Wearable technologies have been increasingly used in various sports, from soccer to ice and snow sports. Influence wearables are also widely marketed (e.g., exercise tracking). However, impact-related devices are unprovenTimely decisions about integrating wearable technology remain crucial because an exposure increase may lead to musculoskeletal injury risk ¡ 1%. [15].

Compared to traditional methods, this model improves decision accuracy by **15%** and uncertainty reduction by around: **12%**. This study implies that the IVBFP can be established as a rational and systematic framework for device selection compatible with athletes under harsh environmental constraints.

That advancement has direct consequences on injury prevention. Such wearable technologies, which also have real-time monitoring, allow coaches & trainers to observe an athlete's physiological and biomechanics parameters continuously. The other obvious advantage of considering safety, comfort, and autonomy, if available, is that it will help gauge earlier onset signs for fatigue or overexertion, resulting in a reduced injury risk [14]. Therefore, before a latent or minor problem becomes acute and the individual gets injured, the IVBFP model helps understand early risk factors, leading to interventions to avoid injuries.

B. Technological Advancements in Wearable Devices

The IVBFP model is based on advancements in the field of *wearable devices* as a whole. Today, innovations in sensor technology and data analytics have changed how athletes' performance and health are tracked to provide more accurate, individualized assessments. Wearable technologies, e.g., intelligent fabrics and biosensors, can now measure real-time human physiological signals such as HR (heart rate), SpO2 (oxygen saturation), and even movements through accelerometers.

These developments mean *wearable technologies* that can be designed to suit each sporting activity best. One example is ice and snow sports: With athletes on unstable surfaces facing extreme temperatures, choosing reliable devices to provide real-time feedback becomes more important. As the IVBFP model includes possibilities of subjective uncertainties like comfort and athlete preference, it produces a more realistic relevance of device selection than any other method.

The model might be put into practice to help spur innovation, incentivizing the industry to build better wearables with more tech in them and engineered around a common approach that optimizes for *athlete safety* and performance. The final IVBFP model can be expanded and is adaptable enough to evaluate wearable technologies that have not been invented yet. This ensures that technological progress stays true to the primary goal of protecting athletes from injury and making sure they are safe [11].

C. Practical Implications for Coaches, Trainers, and Athletes

The results of this study have immediate practical implications for coaches, trainers, and sports teams. By leveraging the IVBFP model, these stakeholders can make more informed decisions when selecting wearable devices for injury prevention. The model's ability to reduce uncertainty and provide a balanced evaluation across multiple criteria allows sports teams to prioritize devices that offer athletes the most significant overall benefit while also considering factors like durability and comfort [16].

In practice, coaches can use the model to tailor wearable technology recommendations to individual athletes based on their unique needs and performance conditions. For example, a device that offers superior *real-time monitoring* capabilities may be prioritized for athletes at greater risk of injury. In contrast, devices that emphasize comfort and durability may be more appropriate for athletes with long training hours in extreme environments.

Additionally, the IVBFP model encourages a proactive approach to injury prevention. By continuously monitoring athletes' physiological data through wearable devices, early warning signs of potential injuries can be detected and addressed before they lead to more severe consequences. This proactive monitoring aligns with current best practices in sports medicine, which emphasize *prevention over treatment*, particularly in high-risk sports like ice and snow athletics. [17]

D. Contribution to Injury Prevention Research

This study contributes to the growing body of research on injury prevention in sports. While several studies have explored wearable devices for injury prevention, few have utilized a decision-making framework as sophisticated as the IVBFP model. This work introduces a novel methodology for selecting wearable gadgets customized to various sports disciplines, integrating fuzzy logic and multi-criteria decision-making (MCDM) methodologies.

Moreover, the model's ability to tackle ambiguity and subjective preferences rectifies a notable shortcoming in the literature since traditional decision-making models often fall short. Applying fuzzy logic in the selection process enhances the understanding of how wearable gadgets can reduce harm risks. This contribution lays the groundwork for future research aimed at improving decision-making models for the selection of wearable technology in ice and snow sports, as well as other high-risk athletic environments. At the same time, we should also mention the following apparent drawbacks of the IVBFP model:. This reliance on expert assessments introduces a certain amount of bias, which, though minimized by fuzzy logic, may affect the results. Further, the above model is only specific to ice and snow sports. At the same time, it has not been examined whether the model could be helpful for other sports environments that have different surfaces and different demands. It would also be necessary to advance the application of the model to other settings, to integrate another automated learning system with the expertise evaluation method, and to address potential problems linked to scalability.

VI. Conclusion

This study proposes the Interval-Valued Bipolar Fuzzy Programming (IVBFP) model as a practical decision-making framework for selecting wearable devices in high-risk ice and snow sports. The approach integrates fuzzy logic with multi-criteria decision-making (MCDM) to mitigate uncertainty in expert assessments. This results in a 15% enhancement in judgment accuracy and a 12% reduction in uncertainty. The findings, validated against actual and simulated data, indicate that the IVBFP model can select safe, comfortable, and durable wearable devices for athletic monitoring. This may mitigate damage and enhance performance. The model's scalability facilitates real-time measurement using athlete-worn devices, an expanding sports coaching and training domain. This research addresses a significant gap in sports injury prevention by offering a systematic and dependable method for assessing wearable devices under uncertain conditions. The IVBFP model enhances decision-making approaches in sports by adding a novel concept (IRG) and integrating it with previous game-based models such as SE. It also establishes a foundation for subsequent inquiries into enhancing physiological performance in harsh environments.

***Abstract*—Computer science and telecommunications technologies have been experiencing rapid advancements in recent years to protect sensitive data or information from potential harm, misuse, or destruction. By enhancing data security through various methodologies and algorithms, data can be better protected against attacks that may compromise its confidentiality, particularly in the case of text messages. Linear cipher is one of the earliest forms of cryptographic systems which operates by shifting letters that may not provide the highest level of security but adds a layer of complexity to the initial encryption process. Rivest-Shamir-Adleman algorithm represents a more advanced and rigorous approach to encryption that resistant to more sophisticated attacks. The Rivest-Shamir-Adleman algorithm utilizes the mathematical properties of large prime numbers to establish a secure communication channel. The combination of both algorithms or hybrid algorithms employed for data security, the security of text messages is significantly improved, ensuring the confidentiality of the text messages during its transmission. Hence, this research proposes two types of hybrid algorithms, namely Gradatim LRSA and Optimized LRSA, which ensure the confidentiality of the text message using encryption and decryption processes. The results also show that the Optimized LRSA performs with less computation compared to the Gradatim LRSA.**

***Keywords*—Confidentiality; data encryption; hybrid encryption; linear cipher; RSA algorithm; Gradatim LRSA; Optimized LRSA**

I. Introduction

Data security is the practice in protecting individual personal information from being unauthorized access, and misused by unauthorized parties [1], [2], [3]. The personal information can be medical information, financial records, passwords, personal identification numbers and so on. If these data breaches, it can severely damage an organization's reputation and erode individual trust as well as their stakeholders' trust [4], [5], [6]. As the result, it may cause the financial losses and or result in legal penalties [7]. Therefore, the organizations need to demonstrate their commitment in protecting their customer data [8]. The act in protecting these data can be encryption to ensure that the data remains confidential, available and reliable [9], [10].

Linear cipher is a historical cipher. It is a mathematical linear function with one-dimensional symmetrical encryption which suppose can provide data confidentiality [11]. The plaintext is in a linear relationship with the corresponding ciphertext making easily identifiable patterns. Hence, making them susceptible to decryption through frequency cryptanalysis.

To date, the most widely used public key cryptosystem is the Rivest-Shamir-Adleman (RSA) algorithm, which was proposed by Ron Rivest, Adi Shamir, and Leonard Adleman in 1976 [12]. The strength of the RSA algorithm is based on the challenge of factoring large prime numbers to obtain the private key. It is based on a simple number theoretic fact: it is easy to multiply two large prime numbers, but it is extremely difficult to factor their products [13]. As long as no efficient method for factoring these large primes is discovered, the security of the RSA algorithm remains intact.

The linear cipher is vulnerable to statistical attacks. Therefore, pairing the linear cipher with the RSA algorithm can mitigate these vulnerabilities by introducing asymmetric encryption, which offers greater resistance to such attacks. Hence, this research proposes two types of hybrid encryption method using a linear cipher and RSA algorithm (LRSA) to conceal the text messages. We denoted it as Gradatim LRSA and Optimized LRSA. The significance of the proposed hybrid encryption lies in its ability to mitigate the weaknesses of relying solely on either encryption method. Even if the linear cipher is compromised, the RSA algorithm provides an additional layer of security in terms of confidentiality. The process begins with linear cipher encoding the plaintext, the output will further encrypt by RSA algorithm to produce the ciphertext. The decryption process will decrypt the ciphertext using RSA, then followed by the Linear cipher to reveal the final plaintext. The difference is that the number of rounds in the calculation for generating the ciphertext in the Optimized LRSA is fewer than in the Gradatim LRSA.

The remainder of this paper is organized as follows: Section II presents the literature review. The research design is shown in Section III. Section IV introduces the proposed Gradatim LRSA and Optimized LRSA. Section V demonstrates the characters in numeric form. The simulation results are shown in Section VI. Sections VII and VIII present the frequency analysis and discussion, respectively. Finally, Section IX concludes the paper.

II. Literature Review

This section involves the analysis and synthesis of existing research and publications on cryptography, confidentiality, linear cipher, and RSA algorithms. This review helps to identify gaps in the literature and establish the significance of this research.

A. Cryptography

Cryptography serves to ensure the privacy, integrity, and accessibility of data for authorized users. Besides that, cryptography is used to maintain the privacy and confidentiality of data during transmission or storage. The common daily activities which need the cryptography protection including online banking, e-commerce transactions, and data security [14].

Cryptography employs mathematical techniques or algorithms for the data protection [15]. For example, encryption and decryption techniques are utilized to uphold data confidentiality. Encryption is a mathematical process that converts data into unreadable ciphertext, while decryption is a mathematical process to convert the ciphertext into original data.

B. Confidentiality

Maintaining the confidentiality of information holds a critical and indispensable role in today's digital era. It is a practice of keeping information private and only sharing it with authorized individuals [16]. Confidentiality is a fundamental aspect of maintaining trust and privacy especially in the sectors require professional relationship, such as finance, banking, law, healthcare, and medicine.

Algorithms such as encryption and decryption are employed to achieve confidentiality of information [17]. In ancient times, historical ciphers like the linear cipher, Caesar cipher, and hill cipher were commonly utilized to ensure message confidentiality. These ciphers typically involve simple substitution or transposition techniques. These techniques are breakable and require low computational power [11]. In contrast, modern ciphers such as the Advanced Encryption Standard, Trivium, and RSA algorithm offer a higher level of security [18]. These ciphers use complex mathematical algorithms in safeguarding confidential information.

C. Linear Cipher

Linear cipher is a historical cipher that using a linear mathematical operation to encode the readable message into ciphertext and decode ciphertext back to original readable message. The linear cipher encoding process as shown in Eq. (1) [11]. The secret keys are represented as a and b. "M" represents the set space of message (m). The output is the ciphertext c which is within the set space of M. The message is multiplied by the key a, and the output is then added to the key b. The final output is then taken modulus of the set space M to generate the ciphertext. Noted that the key a must coprime with M.

$$c = a * m + b \ mod \ M, \ where \ c, m \in M \tag{1}$$

The linear cipher decoding process is shown in Eq. (2) [11]. The ciphertext is multiplied by the inverse key a, and the output is then subtracted by the key b. Therefore, the key a must be relatively prime with M. The final output is then taken modulo of the set space M to retrieve the message.

$$m = a^{-1}(c - b) \ mod \ M, \ where \ c, m \in M \tag{2}$$

For example, suppose a message 'B' has a numeric value is 1. The linear cipher secret keys are $a = 5$ and $b = 10$. The message space M is equal to 27. Once the mesasge is encoded using Eq. (1), the ciphertext value is calculated $c = (5 * 1 + 10)$ mod 26 = 15. For the decoded process using Eq. (2), the message value is calculated $m = 5^{-1}(15 - 10)$ mod $27 = 11(15 - 10)$ mod 27 = 1.

1) Cryptanalysis Linear Cipher: The linear cipher relies on a linear mathematical operation, such as multiplication and addition to encode and decode the messages. Cryptanalysis of a linear cipher involves breaking the encryption of a message that has been encoded using a linear transformation.

In order to cryptanalyze the linear cipher, one can discover the weaknesses of the linear cipher by examining potential vulnerabilities within the key generation process or how the ciphertext is produced [19]. Once the values of a and b are compromised, we are able to decrypt the entire message.

Next, one may analyze ciphertext patterns, such that frequency analysis or pattern recognition. Frequency analysis involves analyzing the frequency of characters in the ciphertext and comparing it to the frequency of characters in the language of the message [11]. This may help determine the possible mapping of characters in the ciphertext to characters in the message. Then, we can form linear equations and determine the key used for encryption. Once the secret keys are known, the ciphertext can be decoded.

D. Rivest-Shamir-Adleman Algorithm

RSA algorithm is an asymmetric encryption scheme in the field of cryptography [12]. It was invented in 1977 by Rivest, Shamir, and Adleman. The algorithm uses a pair of keys which known as public key and private key. The public key is used for encryption and the private key is used for decryption. The security of the encryption relies on the difficulty of factoring large numbers. That numbers, we denoted it as p and q.

To generate the keys, one must choose two large prime numbers, p and q. Next, calculate their product, which is used as the modulus for encryption. We denote it as n. The public key is derived from the modulus n and an exponent e. The exponent, e, is chosen so that it is relatively prime to $\varphi(n)$. The private key is calculated using the Extended Euclidean algorithm to find the private exponent, d, which is the modular multiplicative inverse of e modulo $\varphi(n)$.

The RSA encryption process is shown in Eq. (3) [12]. The message is raised to the power of the public exponent, e, and the result is taken modulo n.

$$c = m^e \ mod \ n, \tag{3}$$

The RSA decryption process is shown in Eq. (4) [12]. The ciphertext is raised to the power of the private exponent, d, and the result is taken modulo n.

$$m = c^d \ mod \ n, \tag{4}$$

For example, assume a message's numeric value is 2. The RSA two prime numbers are $p = 11$ and $q = 13$. The value of $n, \varphi(n)$ are calculated as follows: $n = 11 * 13 = 143$, $\varphi(n) = 120$. Let's choose public key e = 7. To perform message encryption using Eq. (3), the ciphertext value is calculated as $c = m^e mod n = 2^7$ mod 143 = 128. For decryption of the ciphertext $c = 128$, the private key d is needed, where $d = e^{-1}$ mod $\varphi(n) = 7^{-1}$ mod 120 = 103. Using Eq. (4), the message value is calculated $m = c^d$ mod $n = 128^{103}$ mod 143 = 2.

E. Number Systems

Number systems are the system represent the numbers. For instance, decimal number system, binary number system and hexadecimal system [20]. The decimal number system or base-10 system is the counting method that commonly used daily counting scheme. It relies on ten symbols (digits), namely the digits or numbers from 0 to 9. For instance, number 10 (2 digits), 100 (3 digits, 1000 (4 digits) and so on.

Binary number system is a calculation system that operates with a base of 2. Each individual unit in the system is referred to as a bit, which stands for binary digit. This number system represents values using two distinct symbols: 0 and 1. For example, the decimal number 4 is expressed as 100 three-digit binary or 0100 in four-digit binary or 00100 in five-digit binary. Noted, these leading 0s in binary do not alter the value. There is way to convert binary to decimal. For example, a binary of 10011. The conversion of binary to decimal is as follows. $1*2^4+0*2^3+0*2^2+1*2^1+1*2^0 = 16+0+0+2+1 = 19$. However, a calculation needs to be performed for the reverse conversion from decimal to binary. For instance, for the decimal number 19, the digit is divided by 2, and the remainder is recorded as follows:

- $\frac{19}{2} = 9$, remainder 1
- $\frac{9}{2} = 4$, remainder 1
- $\frac{4}{2} = 2$, remainder 0
- $\frac{2}{2} = 1$, remainder 0
- $\frac{1}{2} = 0$, remainder 1

Hence,the final binary value is 10011.

In contrast, the hexadecimal number system utilizes 16 unique symbols to represent numeric values, which include the ten Arabic numerals (0-9) and six letters (A-F). In the hexadecimal system, each position corresponds to a value from 0 to 15, where A represents 10, B represents 11, C represents 12, D represents 13, E represents 14, and F represents 15. For example, the decimal number 18 is expressed as 12 in hexadecimal. The conversion of hexadecimal to decimal, for instance, a hexadecimal of $6D$. The D is 13. The number 6 is calculated as $6 * 16_1 + 13 * 16_0 = 96$. Hence, the final result is $96 + 13 = 109$. The reverse conversion, from decimal to hexadecimal, is done by dividing the number by 16. For example, when converting the decimal number 109, the number is divided by 16, and the remainder is recorded as follows:

- $\frac{109}{16} = 6$, remainder 13
- $\frac{6}{16} = 0$, remainder 6

The digit 13 is D, hence, the hexadecimal for 109 is equivalent to $6D$.

III. Research Design

Fig. 1 shows the research design. There are four major processes which are proposing the LRSA models, then simulation the encryption and decryption of the proposed LRSAs with the the short messages, long message and result analysis. Firstly, we proposed two types of LRSA which is Gradatim LRSA and Optimized LRSA. Next, the experiment of encryption and decryption the short message using the proposed LRSAs to ensure the LRSAs is work in practice. By using LRSAs to encrypt the message, we can get the ciphertext. We also may obtain the message from the ciphertext by using the decryption process of LRSAs. Secondly, the distribution of the long message characters is counted. Next, the message is encrypted using LRSAs, which resulting the ciphertext. One will compare distributed histogram with the ciphertext.

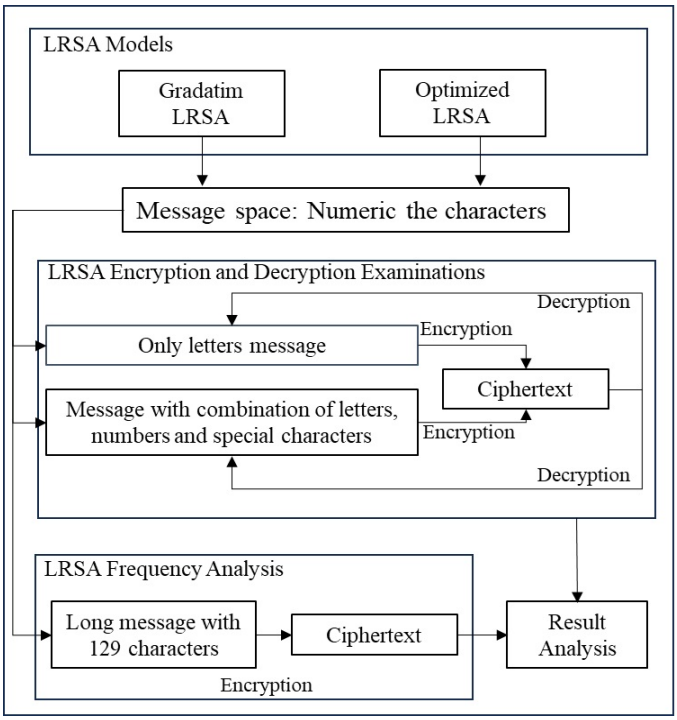

Fig. 1. Research design.

IV. Proposed LRSA

In this section, we present two designs of LRSA, known as Gradatim LRSA and Optimized LRSA. The Gradatim LRSA performs encryption and decryption character by character. The

Optimized LRSA has customized encryption and decryption at the stage of the RSA algorithm. The proposed hybrid encryption and decryption using the linear cipher and RSA algorithm to address the vulnerability of the linear cipher. This hybrid design allows for the implementation of more complex and robust security solutions.

A. Gradatim LRSA

The proposed hybrid encryption method uses both symmetric and asymmetric algorithms. The symmetric algorithm is a linear cipher, while the asymmetric algorithm is the RSA algorithm. We denote it as Gradatim LRSA, which means that the encryption and decryption processes are performed in a gradual and orderly manner.

The proposed hybrid Gradatim encryption as shown in Algorithm 1. By combining the linear cipher with the RSA algorithm, the message is first encoded using the linear cipher and then the resulting ciphertext is further encrypted using the RSA algorithm. This double encryption process prevents the detection of statistical patterns in the message.

Algorithm 1 Gradatim LRSA - Encryption Process

Require: Input: Message, m_{ml}.
1: Chooses the message space M.
2: Chooses the message m with the length of ml.
3: Selects secret keys, a and b, a must be coprime with M.
4: Selects two positive prime numbers, p and q, subjected p, $q > 2$.
5: Calculates $n = p * q$.
6: Calculates $\varphi(n)$.
7: Chooses a positive integer e, where e is coprime with $\varphi(n)$.
8: **for** $i \leftarrow 1$ to ml **do**
9: Calculates ciphertext, $c_i = (a * m_i + b \ mod \ M)^e$ mod n.
10: **end for**
11: **Output:** Ciphertext, c_{ml}.

The proposed hybrid Gradatim decryption as shown in Algorithm 2. The ciphertex is first decrypted using the RSA algorithm and then the resulting output is further decoded using the linear cipher.

Algorithm 2 Gradatim LRSA - Decryption Process

Require: Input: Ciphertext, c_{ml}.
1: Given cipertext, c_{ml}.
2: With existing secret keys, a and b.
3: Calculates private key, $d = e^{-1} \ mod \ \varphi(n)$, gcd(d, e) = 1.
4: **for** $i \leftarrow 1$ to ml **do**
5: Calculates message, $m_i = a^{-1} * ({c_i}^d \text{ mod } n - b) \text{ mod } M$.
6: **end for**
7: **Output:** Message, m_{ml}.

B. Optimized LRSA

The proposed a hybrid Optimized LRSA that uses a symmetric linear cipher and an asymmetric RSA algorithm. The modification occurs at the stage of the RSA algorithm, as shown in Algorithm 3. The message is encoded using the linear cipher. The resulting output is transformed into binary and concatenated. If the length of the message is not an even number, the string is padded with seven zeros. Noted it is the character 'A' as shown in Table I. For every 14 bits, the data is further encrypted with the RSA algorithm.

Algorithm 3 Optimized LRSA - Encryption Process

Require: Input: Message, m_{ml}.
1: Chooses the message space M.
2: Chooses the message m with the length of ml.
3: Selects secret keys, a and b, a must be coprime with M.
4: Selects two positive prime numbers, p and q, subjected p, $q > 2$.
5: Calculates $n = p * q$.
6: Calculates $\varphi(n)$.
7: Chooses a positive integer e, where e is coprime with $\varphi(n)$.
8: **for** $i \leftarrow 1$ to ml **do**
9: Calculates intermediate ciphertext, $k_i = (a * m_i + b) \text{ mod } M$.
10: **end for**
11: **for** $i \leftarrow 1$ to ml **do**
12: Converts intermediate ciphertext, k_i into binary.
13: **end for**
14: **if** ml is even number **then**
15: **for** $i \leftarrow 2$ to ml **do**
16: Concatenates intermediate ciphertext, such that $k_i||k_{i+1}$, we denoted it as K_i.
17: Convert K_i into decimal number, we denoted it as D_i.
18: Calculates ciphertext, $c_i = (D_i)^e$ mod n.
19: **end for**
20: **Output:** Ciphertext, $c_{\frac{ml}{2}}$.
21: **else**
22: Creates a temporary binary in such a way that k_{ml+1} is 0000000. The decimal value is 0. The alphabet is A.
23: **for** $i \leftarrow 2$ to $ml + 1$ **do**
24: Concatenates intermediate ciphertext, such that $k_i||k_{i+1}$, we denoted it as K_i.
25: Convert K_i into decimal number, we denoted it as D_i.
26: Calculates ciphertext, $c_i = (D_i)^e$ mod n.
27: **end for**
28: **Output:** Ciphertext, $c_{\frac{ml+1}{2}}$.
29: **end if**

The proposed hybrid Optimized LRSA decryption is shown in Algorithm 4. The ciphertext is first decrypted using the RSA algorithm. The resulting output is transformed into binary and divided into 7 bits per character. If the length of the message is an odd number, the last 7 bits are discarded. Then, the bit values are converted into decimal; these decimal values are further decoded using the linear cipher.

V. Numeric Character

The character variable with letter or symbol or numeric values is converted into a predefined set of rules numerical value as shown in Table I. For example the alphabet 'A' is equal to 0, 'B' is equal to 1, 'C' is equal to 2, and so on.

Algorithm 4 Optimized LRSA - Decryption Process

Require: Input: Ciphertext, $c_{\frac{ml}{2}}$ or $c_{\frac{ml+1}{2}}$.
With existing secret keys, a and b.
Calculates private key, $d = e^{-1} \mod \varphi(n)$, gcd(d, e) = 1.
if Ciphertext is $c_{\frac{ml}{2}}$ **then**
  for $i \leftarrow 1$ to $\frac{ml}{2}$ **do**
    Calculates intermediate ciphertext, $D_i = {c_i}^d \mod n$.
    Converts D_i into 14 bits binary, we denoted it as K_i.
    Splits the K_i into two 7 bits binary, such that k_{i*2-1} and k_{i*2}.
    Converts k_{i*2-1} and k_{i*2} into decimal number, we denoted it as D'_{i*2-1} and D'_{i*2} respectively.
    Calculates the message, $m_{i*2-1} = a^{-1} * (D'_{i*2-1} - b) \mod M$.
    Calculates the message, $m_{i*2} = a^{-1} * (D'_{i*2} - b) \mod M$.
  end for
Output: Message, m_{ml}.
else
  for $i \leftarrow 1$ to $\frac{ml+1}{2}$ **do**
    Calculates intermediate ciphertext, $D_i = {c_i}^d \mod n$.
    Converts D_i into 14 bits binary, we denoted it as K_i.
    Splits the K_i into two 7 bits binary, such that k_{i*2-1} and k_{i*2}.
    Converts k_{i*2-1} and k_{i*2} into decimal number, we denoted it as D'_{i*2-1} and D'_{i*2} respectively.
    Calculates the message, $m_{i*2-1} = a^{-1} * (D'_{i*2-1} - b) \mod M$.
    Calculates the message, $m_{i*2} = a^{-1} * (D'_{i*2} - b) \mod M$.
  end for
  Discarded m_{ml+1}.
Output: Message, m_{ml}.
end if

We have 26 upper and lower case letters each. There are ten numbers, nice special characters as well as space. For space, we denoted it as as '△'. Noted that this table can be enlarge if needed, which means the set space of message M is not fix.

VI. Simulation Result

This section provides a comprehensive overview of the simulation results obtained from the encryption and decryption processes conducted for the proposed LRSA (Gradatim LRSA and Optimized LRSA). The simulation involved processing messages of both short and long lengths to assess how the LRSA algorithm performs in encryption and decryption.

A. Gradatim LRSA - Encryption and Decryption

Section IV-A presents the Gradatim LRSA algorithm. Here, we show two examinations of encryption and decryption calculations. Both case studies have prime numbers for RSA, with $p = 31$, $q = 3$ and the public exponent e equal to 7. The private exponent d is the modular multiplicative inverse of e mod $(31 - 1)(3 - 1)$, resulting in 43.

1) Experiment - 1: Assume the message is only capital letter, such that "COMPUTE". Based on Table I, we know the capital letter is from 0 until 25, therefore, the set space, M is equal to 26. Lets, secret keys of linear cipher are $a = 3$ and $b = 10$.

Table II shows the encryption of the text message "COMPUTE" using Gradatim LRSA. The ciphertext is in numeric form, which is "70 0 80 48 9 54", or in hexadecimal "46 00 50 30 09 36 34".

TABLE II. Gradatim LRSA Encryption "COMPUTE"

Message	C	O	M	P	U	T	E

Table III shows the decryption of the corresponding ciphertext "70 0 80 48 9 54 52" using LRSA. The ciphertext is decrypted using RSA algorithm together with private key d,

followed by linear cipher, $(3^{-1} * c - 10) \bmod 26$. It is noted that the inverse of 3 mod 26 is based on Extended Euclidean algorithm, resulting in 9.

2) Experiment - 2: Assume the message is like a six character of password, such that "C0!fe@". The password is the combination of upper case letter, lower case letter, number and special character as shown in Table I. Therefore, the set space, M is equal to 72. Lets, secret keys of linear cipher are $a = 5$ and $b = 10$.

Table IV shows the encryption of the text message "C0!fe@" using Gradatim LRSA. The ciphertext is in numeric form, which is "80 60 75 42 70 67", or in hexadecimal "50 3C 4B 2A 46 43".

Message	C	0	!	f	e	@

Table V shows the decryption of the corresponding ciphertext "80 60 75 42 70 67" using Gradatim LRSA. The ciphertext is decrypted using the RSA algorithm together with private key d, followed by linear cipher, $(5^{-1} * c - 10) \bmod 72$. It is noted that the inverse of 5 mod 72 is based on Extended Euclidean algorithm, resulting in 29.

B. Optimized LRSA - Encryption and Decryption

Section IV-B presents the Optimized LRSA algorithm. Here, we show two examinations of encryption and decryption calculations with the word of "COMPUTE" and "C0!fe@" respectively. Both case studies have prime numbers for RSA, with $p = 127$, $q = 131$ and the public exponent e equal to 19. The private exponent d is the modular multiplicative inverse of $e \bmod (127 - 1)(131 - 1)$, resulting in 7759.

1) Experiment - 1: The experiment message is "COMPUTE". Based on Table I, we know the capital letter is from 0 until 25, therefore, the set space, M is equal to 26. The secret keys of linear cipher are $a = 3$ and $b = 10$.

Table VI shows the encryption of the text message "COMPUTE" using Optimized LRSA. The ciphertext is in numeric form, which is "6541 7480 11085 4721", or in hexadecimal '198D 1D38 2B4D 1271".

Table VII shows the decryption of the corresponding ciphertext "6541 7480 11085 4721" using Optimized LRSA. The ciphertext is decrypted using the RSA algorithm with the private key (d), which is 7759. The decimal output is converted into binary and further divided into 7 bits per character. Since the number of characters is odd, the last 7 bits are discarded. Next, the binary data is converted into decimal and decoded using a linear cipher.

2) Experiment - 2: The experiment 2, the word is a combination of upper case letter, lower case letter, number and special character, which is "C0!fe@". Therefore, the set space, M is equal to 72 as shown in Table I. Lets, secret keys of linear cipher are $a = 5$ and $b = 10$.

Table VIII shows the encryption of the text message "C0!fe@" using Optimized LRSA. The ciphertext is in numeric form, which is "15535 9394 1328", or in hexadecimal "3CAF 24B2 0530".

Table IX shows the decryption of the corresponding ciphertext "15535 9394 1328" using Optimized LRSA. The ciphertext is decrypted using the RSA algorithm along with the private key (d), which is 7759. The decimal output is then converted into binary and further divided into 7 bits per character. Since the number of characters is even, all bits are utilized. Next, the binary data is converted back into decimal and encoded using a linear cipher, such that $(5^{-1} * c - 10) \bmod 72$. It should be noted that the inverse of 5 modulo 72, calculated using the Extended Euclidean algorithm, is 29.

Table IX shows the decryption of the corresponding ciphertext "80 60 75 42 70 67" using LRSA. The ciphertext is decrypted using RSA algorithm together with private key d, followed by linear cipher, such that $5^{-1} * c - 10 \bmod 72$.

VII. FREQUENCY ANALYSIS

Frequency analysis is a technique used in cryptanalysis to determine the frequency of characters in an encrypted text. By analyzing the frequencies of letters in a message, cryptanalysts can make educated guesses about the substitution cipher being used to encrypt the text. The linear cipher is vulnerable to frequency analysis. By determining which characters occur most frequently in encrypted text, one may deduce the original message and crack the code.

For the frequency experiment, the chosen text message contains 129 characters. The message is: 'The linear cipher relies on a linear mathematical operation, such as multiplication and addition to scramble and decode messages.' The distribution of character is shown in Fig. 2. The highest distribution is of the space symbol ($\triangle$), which appears 18 times, followed by character 'a', which appears 14 times. The lowest distribution is of the characters 'T', 'b', 'g', comma symbol, and the full stop symbol, each of which appears once.

Lets examine if the text message is encoded using linear cipher. The set space, M is equal to 72 and the secret keys of linear cipher are $a = 5$ and $b = 10$.

The ciphertext is: 'hfQ0zk9Q;J0Gk:fQJ0JQzkQO0△90 ;0zk9Q;J04;TfQ4;TkG;z0△:QJ;Tk△950OQGf0;O04YzTk:zkG; Tk△ 90;9L0;LLkTk△ 90T△ 0OGJ;9BzQ0;9L0LQG△ LQ04Q OO;aQOv'. The distribution of character ciphertext is shown in Fig. 3. The highest distribution is of the zero, which appears 18 times, followed by semicolon symbol, which appears 14 times. One can conclude that the zero is the ciphertext for the character space symbol (△), while zero is the ciphertext for the character 'a'. Once, we know the ciphertext with the corresponding character, we can form the linear equations and find the secrect key a and b.

Next, we encrypt the text message using Gradatim LRSA and Optimized LRSA respectively. For both simulations, the set space M is equal to 72 and the secret keys of linear cipher are $a = 5$ and $b = 10$. The different only the RSA algorithm parameters.

For the Gradatim LRSA, the RSA two prime numbers are $p = 31$, $q = 3$ and the public exponent e equal to 7. The ciphertext is in hexadecimal form:

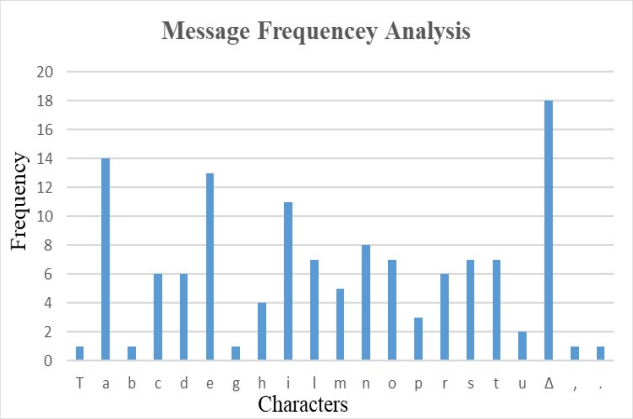

Fig. 2. Message frequency analysis.

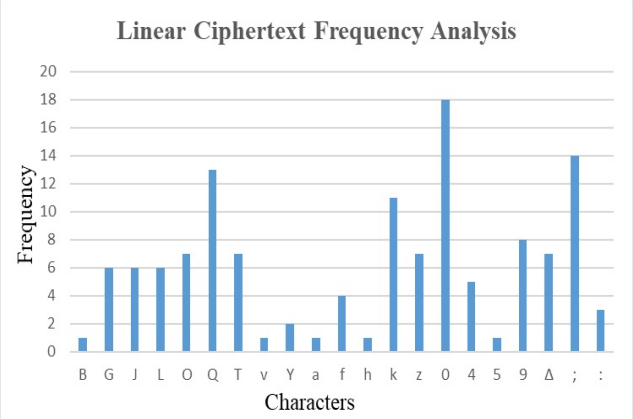

Fig. 3. Linear ciphertext frequency analysis.

3232441A463208’.

For the Optimized LRSA, the RSA two prime numbers are $p = 127$, $q = 131$ and the public exponent e equal to 19. The ciphertext is in hexadecimal form: ‘037D03B33D7F0B202271252B261F05B319C20A913D7F2A
F111CB23E738CA3D7F0B2022713F6D15CF05D330130C45
09962A13385FZBCE15CF04D0222A18341DE9033638240B8
A22D4261F3D7F09960C452731033600A1033635AA32F704
D032A90F1706FC2C4507E4364736D6303F1DC02386137B2
3863F6D2AF1382433E212D0’.

Based on the ciphertext generated using Gradatim LRSA and Optimized LRSA, one may not be able to form the frequency distribution as the output ciphertext exceeds the numeric values presented in Table I. For example, when encrypting the character ‘o’ using Gradatim LRSA, the ciphertext value is 78. Therefore, we provide the ciphertext in hexadecimal form. This also indicates that both Gradatim LRSA and Optimized LRSA are not vulnerable to frequency attacks.

VIII. Discussion

Algorithms for encryption and decryption may protect data confidentiality. Encryption scrambles the message into unreadable ciphertext, while decryption is the reverse process of encryption. The proposed Gradatim LRSA and Optimized LRSA include both algorithms for encryption and decryption, as shown in Algorithms 1, 2, 3, and 4, respectively. The experiments in Section III demonstrate that both models effectively perform encryption and decryption.

Based on Table IV and Table VIII, the number of calculations for the second layer of the RSA algorithm shows that the Optimized LRSA is less than the Gradatim LRSA. If the length of the message is ml, the Gradatim LRSA must perform ml operations for the first layer of encryption (linear cipher) and ml operations for the second layer of encryption (RSA algorithm). However, for the Optimized LRSA, the number of calculations is only ml for the first layer (linear cipher) and $\frac{ml}{2}$ for the second layer (RSA algorithm). However, if the ml is a odd number, the Optimized LRSA will perform $\frac{ml+1}{2}$ operations for the second layer encryption. This shows that Optimized LRSA executes faster compared to Gradatim LRSA.

The linear cipher employs a linear mathematical operation to encode a message into unreadable ciphertext, with the frequency of characters in the message remaining the same in the ciphertext but with different characters. Based on the analysis in Section VII, showing that linear cipher is vulnerable to frequency analysis attacks. Hence, the proposed the hybrid encryption method using the linear cipher and RSA algorithm can resist the frequency attacks.

IX. Conclusion and Future Work

In conclusion, this research proposed a secure hybrid encryption method method that combines the strength of a linear cipher with the robust security of the RSA algorithm making it significantly more difficult for attackers to break the encryption. We name it as LRSA. We proposed models: Gradatim LRSA and Optimized LRSA. Optimized LRSA executes fewer rounds compared to Gradatim LRSA. However, both LRSAs can encrypt the message using secret keys from a linear cipher and public keys from the RSA algorithm. The encrypted output is the ciphertext. The LRSAs are also capable of decrypting the ciphertext and recovering the original message without compromising its security.

Existing linear cipher is vulnerable to the frequency attacks where the attackers are able to decipher the messages based on the frequency of occurrence of the characters in the ciphertext. But, the proposed LRSAs are resistance to the frequency attacks. As the proposed LSRAs add an addition layer of complexity to the encryption process, which is RSA algorithm. Hence, LRSAs provide a comprehensive and effective encryption solution that prioritizes the security for protecting sensitive information across different applications. The hybrid encryption method ensure the confidentiality of the messages only available for the authorize parties.

As for the nature of the linear cipher, which only allows for the encryption and decryption of English characters, this presents a major limitation of the proposed design. Therefore,

as future work, one plan is to explore hybrid encryption and decryption methods that can accommodate a broader range of languages, such as Mandarin, Jawi, and Japanese. This work may create a more universal encryption solution that meets the needs of multilingual users.

***Abstract*—Collaborative freight transportation plays a crucial role for Logistic Service Providers (LSPs) seeking to enhance profitability and service quality, yet it faces challenges at strategic, operational, and technical levels. Digital transformation creates opportunities to overcome these hurdles by extending collaboration beyond physical logistics to encompass information management and digital transformation. Enterprise Architecture Frameworks (EAFs) offer promising solutions by providing a holistic view of various levels within such ecosystems and ensuring alignment between information systems and strategic objectives. However, selecting the right EAF is a complex and critical step. This study introduces an innovative approach for selecting an Enterprise Architecture (EA) framework to support the development of a collaborative freight transportation platform. It emphasizes the importance of adopting a systematic EA methodology in the digitalization of the freight transportation sector. The decision-making process integrates established techniques such as the Analytic Hierarchy Process (AHP) and the Fuzzy Technique for Order of Preference by Similarity to Ideal Solution (F-TOPSIS). Applied to a case study involving a Moroccan logistics company, the approach demonstrates effectiveness in framework selection. The study's findings underscore the method's significance as a valuable tool for organizations embarking on digital transformation through EA, offering adaptability across diverse industries and contexts.**

***Keywords*—Digital transformation; freight transportation; enterprise architecture; multi-criteria decision-making; analytic hierarchy process; fuzzy technique for order of preference by similarity to ideal solution**

I. Introduction

In the evolving landscape of freight transportation, digital transformation is fueled by advancements in Information and Communication Technologies (ICT) and a growing demand for more efficient and sustainable logistics operations [1], [2], [3]. This work is motivated by the imperative to introduce a decision-making method for the meticulous selection of a fitting Enterprise Architecture (EA) framework essential for underpinning the development of a collaborative freight transportation platform. The proposed method integrates two well-known multicriteria decision-making techniques: the Analytic Hierarchy Process (AHP) and the Fuzzy Technique for Order of Preference by Similarity to Ideal Solution (F-TOPSIS). The overarching goal is to aid organizations in the evaluation and ranking of candidate EA frameworks, considering diverse criteria such as functionality, interoperability, scalability, and adaptability.

At the heart of this endeavor lies the challenge of striking a delicate balance amid the conflicting requirements of diverse stakeholders, including IT managers, business analysts, and end-users, in the meticulous selection of an apt EA framework. Moreover, the selection process involves a multitude of criteria often shrouded in subjectivity and resistant to quantification. To surmount these challenges, the authors advocate for a group decision-making approach that actively involves various stakeholders in the selection process. This approach employs a nuanced blend of quantitative and qualitative methods to assess and rank candidate EA frameworks.

The primary contributions of this work are twofold. Firstly, the proposed decision-making method integrates AHP and F-TOPSIS techniques for selecting a suitable EA framework for a collaborative freight transportation platform. Secondly, the application of this method to a case study involving a Moroccan logistics company demonstrates its effectiveness in selecting an appropriate EA framework. The findings from this work can provide valuable insights for other organizations seeking to drive digital transformation through EA.

In the realm of collaborative freight transport, a strategic approach employed by logistics service providers (LSPs) to enhance profitability and service quality, various challenges hinder its effectiveness. These challenges encompass difficulties in finding suitable partners, establishing fair gain-sharing mechanisms, and fostering trust in resource sharing [4]. Simultaneously, the imperative for companies to undertake digital transformation projects to align with innovation trends adds complexity. LSPs are compelled to extend collaboration beyond physical flow, managing information and undergoing digital transformation, further complicating alignment among strategies, business, and systems for multi-stakeholders.

Enterprise architecture frameworks (EAFs) play a pivotal role in addressing such complexity, offering a holistic view of the system and aligning information systems with strategic and business requirements. However, selecting the appropriate EAF is a challenging task due to the plethora of frameworks available, each with its strengths and weaknesses. Existing works on EAF selection often lack specificity to concrete contexts and needs, either proposing abstract evaluation models

or performing global EAF comparisons. This paper addresses these gaps by evaluating EAFs in the context of designing an ongoing digital platform for collaborative freight transportation (DCRFT).

The methodology involves a hybrid Multi-criteria Group Decision Making approach, comprising two phases. In the first phase, criteria are identified through a literature review enriched by expert interviews, and the Analytic Hierarchy Process (AHP) is employed to determine their importance weights. In the second phase, Fuzzy Technique for Order of Preference by Similarity to Ideal Solution (F-TOPSIS) is used to rank the EAF alternatives. Fuzzy set theory is adopted to overcome ambiguity stemming from subjective judgments and incomplete information among decision-makers [5]. Throughout both phases, group decision aggregation techniques are applied and illustrated. The comprehensive approach presented in this work stands as a valuable resource for organizations navigating the intricate landscape of digital transformation in collaborative freight transportation.

The remainder of this paper is organized as follows: Section II introduces the background of Multi-Criteria Decision Making (MCDM) and Enterprise Architecture Framework. Section III provides a literature review related to EAF evaluations. Section IV presents the AHP and F-TOPSIS method, describing the procedural steps of the proposed approach. The results of the case study are discussed in Section V. Section VI presents a sensitivity analysis. Finally, Section VII concludes the article and sheds light on future works.

II. Background

In this section, an in-depth examination of the Enterprise Architecture Framework unfolds, revealing its fundamental principles and practical applications. The focus then shifts towards exploring Digitalizing Freight Transportation: Strategic Solutions with Enterprise Architecture, where the transformative influence of digital technologies on logistics and supply chain management takes center stage. To conclude, attention is directed to the concept of Multi-Criteria Decision Making (MCDM), shedding light on its pertinence within the realm of Driving Digital Transformation in Freight Transportation. Collectively, these sections foster a comprehensive understanding of the study's foundational components, laying the groundwork for a nuanced exploration of their intricate interconnections and implications within the dynamic landscape of freight transportation.

A. Enterprise Architecture Framework

Zachman [6] defines architecture as a set of design elements essential for outlining an object to meet quality requirements and ensure maintenance throughout its utility period. It involves tools for understanding the current state and aiming for a better future state. Enterprise Architecture (EA) provides a holistic organizational view, distinct from technical architecture, and addresses stakeholder concerns [7].

EA acts as a strategic tool, assisting organizations in defining their current (As-is) and desired future (To-be) states regarding infrastructures, processes, and digital capabilities. It aligns strategic and business levels with operational and system implementations, crucial in the current digital landscape for guiding organizational change and facilitating digital transformation [8].

In turbulent environments, sustained competitive advantages require organizational flexibility and resilience [9]. EA can support adaptive capacities and facilitate the progression to higher-level capabilities by re-conceptualizing itself through an enterprise's ecological adaptation perspective.

Moreover, EA provides governance encompassing IT principles, architecture, investment management, and planned strategy, closely tied to organizational business values, yielding benefits in visibility, productivity, and efficiency of business processes and information systems [10].

Numerous studies have linked various advantages to the implementation of enterprise architecture. In a literature review conducted by [11], success factors and benefits of enterprise architecture were identified. These include heightened responsiveness and flexibility to change, enhanced alignment between the business model and IT, reduced IT costs, optimized utilization of IT resources, improved risk management, enhanced integration/interoperability, more favorable outcomes from business and strategic initiatives, refined business processes, and diminished complexity in IT. Notably, these effects are typically indirect, pervasive throughout the entire enterprise, and accrue over an extended period.

B. Digitalizing Freight Transportation: Strategic Solutions with Enterprise Architecture

In the logistics and supply chain management domain, Freight Transportation entails the movement of goods across diverse modes like trucks, trains, ships, and planes [12]. Mode selection considers factors such as distance, urgency, and the nature of goods. Efficient freight transportation is pivotal for seamless goods flow within the supply chain, a critical aspect of the broader logistics network. Driving Digital Transformation in Freight Transportation involves leveraging technological advancements for enhanced efficiency, transparency, and overall effectiveness [13]. This encompasses integrating digital tools, data analytics, and automation to optimize routes, manage inventory, and streamline communication in the freight transportation ecosystem.

The road freight transport sector is witnessing substantial economic growth, playing a crucial role in modern economies and influencing global competitiveness. The surge in e-commerce and globalization has heightened transport demands, urging companies in various modes to enhance associated services. This dynamic presents persistent challenges for road freight transport trucks. Economically, operators must optimize efficiency to maximize profits and minimize empty trips. Environmentally, efforts are required to reduce CO2 emissions, mitigate road congestion, and curb noise pollution. Socially, enhancing accessibility and physical mobility is essential for improving the quality of life for logistics workers and the global population [14], [15], [16], [17].

Trucking companies are compelled to align with "Industry 4.0," emphasizing digital manufacturing and high-level automation [18]. Information exchange and integration of the intelligent logistics chain are critical, with information flow management central in data-driven transportation operations.

In this evolving context, freight transportation demands novel organizational and technological approaches for effective management and adaptation to digital changes [19].

Digital platforms offer productivity in implementing collaborative and intelligent environments, transforming organizational business models through partner discovery, accelerated information sharing, optimization, and tracking of logistical operations [20], [21]. This transition poses technological, organizational, and strategic challenges, requiring a comprehensive methodology. "Enterprise Architecture" (EA) serves as a crucial tool, offering a holistic view of the organization while ensuring alignment between strategic objectives and technical solutions.

In this evolving freight transportation landscape, selecting a tailored Enterprise Architecture Framework (EAF) is paramount. Beyond immediate challenges, the chosen EAF should provide a roadmap for navigating digital transformation, addressing operational complexities and ensuring seamless integration of innovative technologies, efficient processes, and strategic objectives. This approach steers the transformation towards a more agile and responsive freight transportation ecosystem.

C. Multi-Criteria Decision Making (MCDM)

Within the realm of Multi-Criteria Decision Making (MCDM), its application extends beyond traditional problem-solving domains, finding relevance in the context of Driving Digital Transformation in Freight Transportation. MCDM, as a sophisticated evaluation process, serves as a valuable tool for decision-makers facing the intricate challenges of adopting and implementing digital technologies in the freight transportation sector. The inherent complexity of this industry, marked by diverse operational facets and evolving technological landscapes, makes MCDM an ideal approach for navigating the intricacies of decision-making.

In the realm of freight transportation, where uncertainties and risks are inherent, MCDM proves to be an essential mechanism for evaluating digital transformation strategies. By integrating both qualitative and quantitative criteria, decision-makers can systematically assess and compare various alternatives in selecting an Enterprise Architecture Framework (EAF). The decision-maker's active role in expressing preferences and values aligns with the dynamic nature of the freight transportation ecosystem, ensuring that the chosen EAF is not only technologically adept but also aligns with the organization's strategic objectives.

The study conducted by Zavadskas et al. [22] further emphasizes the versatility of MCDM as a structuring tool, providing a systematic method for solving complex problems. As witnessed in various sectors such as project management, urban planning, and supplier selection, MCDM's robust framework for decision-making proves to be adaptable to diverse contexts. In the freight transportation industry, where the stakes are high and the need for informed decision-making paramount, MCDM emerges as a strategic ally in navigating the digital transformation landscape. By incorporating MCDM principles, decision-makers can ensure that the selected Enterprise Architecture Framework aligns cohesively with the multifaceted demands of the industry, contributing to a seamless and effective digital evolution in freight transportation.

The application of Multi-Criteria Decision-Making (MCDM) methodologies, such as AHP and TOPSIS, has proven effective in various technological contexts beyond freight transportation. Recent research has utilized these methods for selecting tools in chatbot development, considering factors like scalability, performance, and maintainability [23]. Similarly, another study applied MCDM techniques to evaluate cross-platform mobile development frameworks, addressing complex decision-making scenarios involving conflicting criteria [24]. These examples highlight the adaptability and utility of MCDM approaches in supporting strategic decision-making across diverse domains.

Building upon earlier applications of MCDM methodologies in freight transportation, recent advancements have extended their utility to simulation-based analytics frameworks and the evaluation of AI-driven tools for predictive and prescriptive decision-making [25]. These methods, including hybrid Intuitionistic Fuzzy-AHP approaches, enable logistics companies to optimize their operations by leveraging real-time data and advanced analytical capabilities. Such integrations facilitate the selection of solutions tailored to complex requirements, bridging traditional decision-making processes with AI-enhanced logistics systems [25].

III. Related Works

Recently, Organizations use EA to maximize their organizational, business and IT project value. It brings multitude benefits over time, from abstract aspect such business–IT alignment and decision-making improvement to measurable advantage such as reducing costs [26], [27]. Now with the continuous and unpredictable market change, EA is needed more than ever.

It has the potential to orchestrate business and digital transformations of an organization in order to act efficiently in the new market environment [28].

However, during the last decades many EA frameworks are developed, which makes the selection of suitable frameworks a difficult decision task. Several works in literature focus on evaluating or comparing some well-known EAF in general basis [29], [30]. Some of them evaluate EAFs on the main architectural components such Metamodel, principles, views and specification documents [31], [32], [33], while others establish comparison based on quality attribute or practice criteria [34], [35], [36], [37], [38]. Table I presents a list of these works. It mentions the studied EAFs, the application domain, and whether the author used process MCDM.

As shown in the Table I, there is a limited collection of popular frameworks chosen by the authors. It is observed also that few studies use MCDM methods to select EAFS. In addition, there is a lack of studies that focus on EAFs comparison according to digital transformation issues.

Moreover, during the literature review we have identified a list of the most chosen criteria that may be useful to compare and select EAFs. Table II presents our classification of these criteria as well as papers that cover them.

TABLE I. EAFs COMPARISON WORKS

Paper	Compared Frameworks	With Selection Process	Use of MCDM Method	Application Domain

Due to the diverse requirements and specifications inherent in various sectors, each use case necessitates a tailored Enterprise Architecture Framework (EAF) that aligns precisely with its unique needs and objectives [51]. Consequently, this article employs advanced Multi-Criteria Decision-Making (MCDM) methods to discern the most suitable EAF for crafting a digital and versatile platform that fosters collaboration in freight transportation (DCRFT). To address this complex system within the realm of digital transformation projects, we advocate for a group decision method, integrating the Analytical Hierarchy Process (AHP) and the Fuzzy Technique for Order Preference by Similarity to Ideal Solution (FTOPSIS). This approach aims to meticulously select an EAF that not only describes but also effectively designs the intricate aspects of the system.

IV. METHODOLOGY

This paper uses two stages method AHP and F-TOPSIS as detailed below (Fig. 1). Firstly, we defined fourteen subcriteria through a literature review enriched by the opinions of four experts. Similarly, four popular EAF were chosen as alternatives to compare. Thereafter, AHP is used to determine the importance weights of criteria. Further, these weights are used in the ranking process based on F-TOPSIS algorithm. The process uses a group decision techniques and fuzzy set theory to overcome the ambiguity due to subjective and imprecise judgments among the decision-makers participating in the evaluation. Fig. 1 illustrates the steps of the two process phases.

A. Problem Definition

This work is an integral part of an ongoing project aimed at developing a digital and versatile platform designed to support collaborative efforts in the transportation of goods. The platform's distinguishing feature is its polymorphic capacity, accommodating a wide range of collaboration forms involving various actors, approaches, rules, and objectives.

Designing a digital project with such richness in terms of complexities necessitates the use of an enterprise architecture framework (EAF). Given the considerable number of available EAFs and the various factors influencing their selection, we have opted to initially employ a Multiple Criteria Decision-Making (MCDM) method. This approach will guide us in

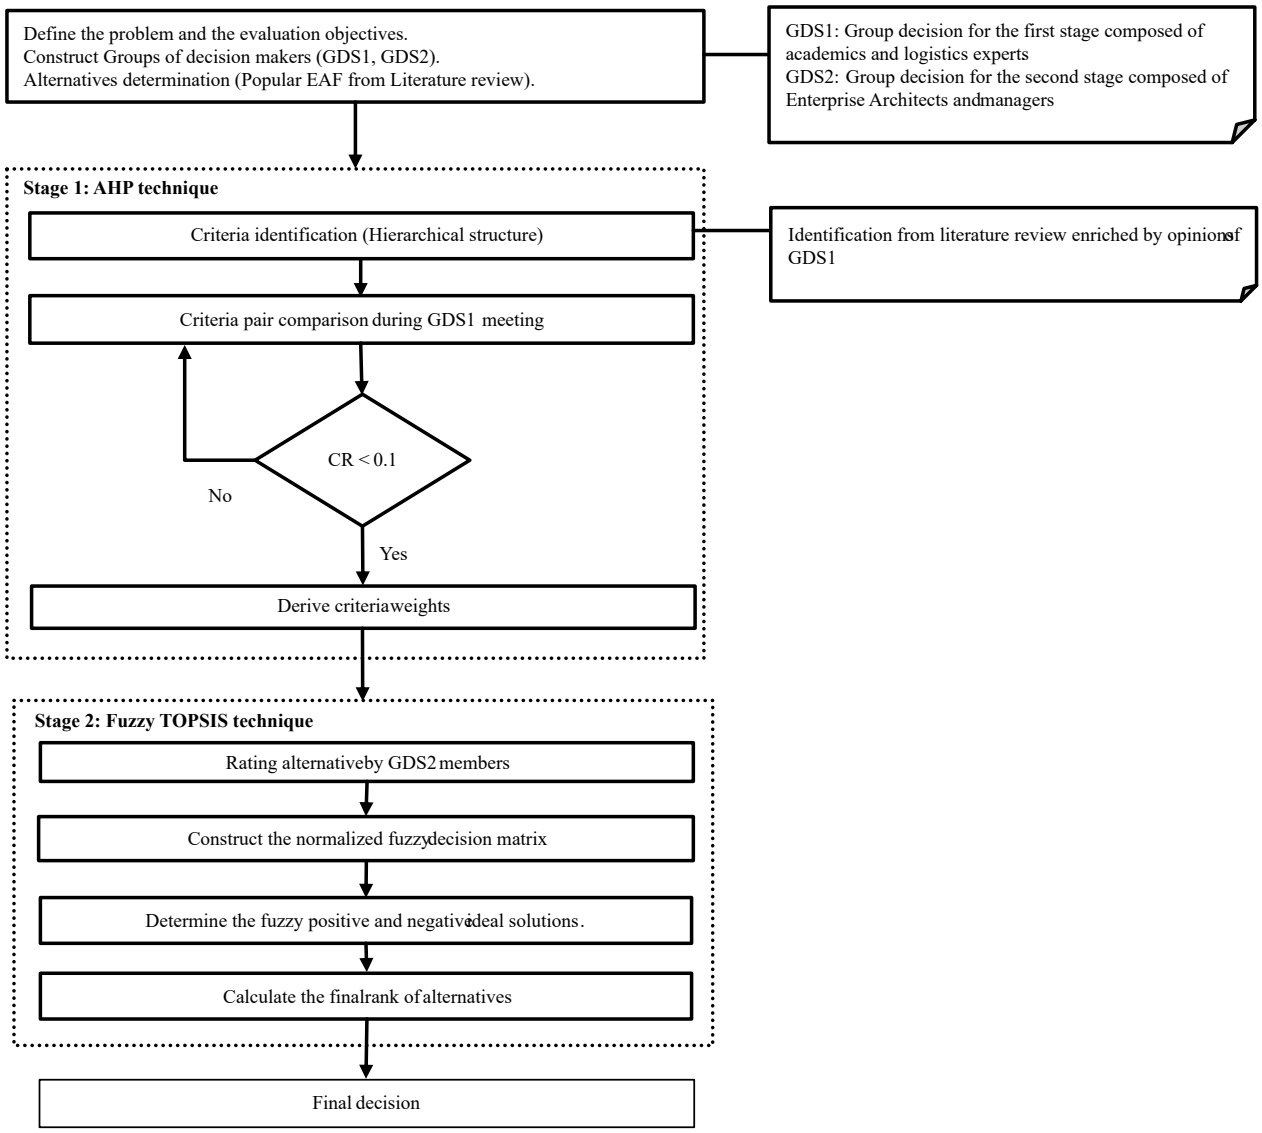

Fig. 1. Proposed integrated methodology for enterprise architecture framework selection.

systematically evaluating and selecting the most appropriate framework to meet the specific requirements of this project.

B. Phase 1: AHP Analytic Hierarchy Process

The Analytic Hierarchy Process (AHP) [52] stands out as one of the most extensively utilized MCDM methods. This method empowers decision makers to break down a complex problem into a more manageable hierarchical structure with a minimum of three levels: the problem objective at the top level, criteria and sub-criteria at the middle level, and alternatives at the bottom level.

Within this process, prioritization of criteria occurs, and each alternative is assigned scores based on these criteria. This evaluation is conducted through pairwise comparisons, employing a predefined Saaty scale (Table III) [53], with a simultaneous check for the consistency of judgments. Ultimately, a weighted score is computed for each alternative, providing a comprehensive and informed basis for decision-making.

TABLE III. SAATY SCALE [53]

Definition	Intensity of importance
Equally important	1
Moderately more important	3
Strongly more important	5
Very strong more important	7
Extremely more important	9
Intermediate more important	2, 4, 6, 8

In this study we have applied AHP only to establish criteria importance weights. The process steps are described below:

Step 1: Considering a set of criteria $C = \{Ci/i = 1, 2, 3 \dots n\}$, we define the matrix $M(n \times n)$ as result of a

TABLE IV. RANDOM INDEX

n	3	4	5	6	7	8	9	11	12	13	14	15
RI	0.52	1.88	1.11	1.25	1.34	1.40	1.48	1.51	1.53	1.55	1.57	1.58

paire-wise comparison for each criterion.

$$M = \begin{bmatrix} x_{11} & \cdots & x_{1n} \\ \vdots & \ddots & \vdots \\ x_{n1} & \cdots & x_{nn} \end{bmatrix}, \quad x_{ii} = 1, \quad x_{ji} = \frac{1}{x_{ij}}, \quad x_{ij} \neq 0 \tag{1}$$

Step 2: calculate the priority vectors and drive Coherence Index (CI) as well as the Coherence Ratio (CR):

$$CI = \frac{\lambda_{\max} - n}{n - 1} \tag{2}$$

where $\lambda_{\max}$ is the largest Eigen value.

$$CR = \frac{CI}{RI} \tag{3}$$

Where *RI (Random Index)* is a value that depends on the number of criteria as illustrated in Table IV.

Step 3: If the Consistency Ratio is less than or equal to 10% establish the criteria weight importance Else back to step 1 and review the paire wise comparison.

C. Phase 2: Fuzzy TOPSIS

TOPSIS stands out as a well-established and widely applied Multiple Criteria Decision-Making (MCDM) method. Its popularity arises from its user-friendly interface, rapid alternative evaluation process, low mathematical complexity, and adaptability for seamless integration with other methods. The computational process of TOPSIS is designed to identify an optimal solution that minimizes the distance to the positive ideal solution (PIS) and maximizes the separation from the negative ideal solution (NIS). The PIS represents a solution composed of the best weights assigned to the criteria, while the NIS is a solution obtained by aggregating the worst values assigned to the criteria [54].

Nevertheless, in many real-world decision problems, the expressions of individuals' opinions often manifest in linguistic terms, introducing vagueness and subjectivity. Consequently, the precision of criteria weights and evaluations for given alternatives becomes challenging. To address imprecise judgments, the MCDM method incorporates a fuzzy theory concept introduced in [55]. In fuzzy theory, instead of assigning a binary "totally true" or "totally false" value to an imprecise decision, a degree of membership is assigned. This degree of membership is typically represented by the interval [0, 1], where 0 signifies "totally false," 1 denotes "totally true," and the intervening values refer to intermediate degrees of truth. In this paper, we utilized the triangular fuzzy number (TFN), defined by the triplet (a, b, c), where a and c are successively the lower and upper bounds, and b is the center where the value is 1 (refer to Fig. 2).

Fig. 3 present the membership function of linguistic terms and Table V shows their correspondence on triangular fuzzy numbers.

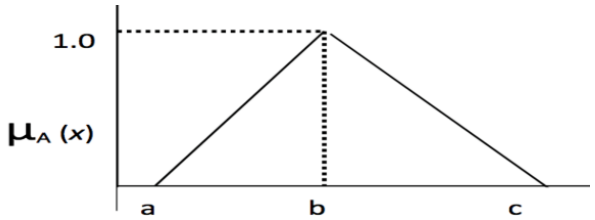

Fig. 2. Triangular fuzzy number.

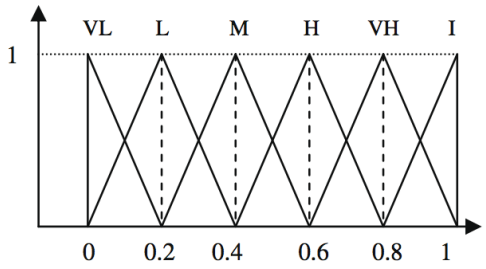

Fig. 3. Membership functions of linguistic terms.

$$\mu_A(x; a, b, c) = \begin{cases} 0, & x \leq a \\ \frac{x-a}{b-a}, & a \leq x \leq b \\ \frac{c-x}{c-b}, & b \leq x \leq c \\ 0, & c \leq x \end{cases} \tag{4}$$

TABLE V. LINGUISTIC VALUES AND CORRESPONDING FUZZY NUMBERS

Linguistic variables	Corresponding Fuzzy numbers
Very low	(0,0,0.2)
Low	(0,0.2,0.4)
Medium	(0.2,0.4,0.6)
High	(0.4,0.6,0.8)
Very high	(0.6,0.8,1)
Excellent	(0.8,1,1)

Considering E the set benefit criteria (greater value is better) and F set of cost criteria (lower value is better) and let $W = (w_1, w_2, \ldots, w_n)$ be the vector of criteria weights concluded from phase 1. The steps of TOPSIS process are as follows [56]:

Step 1: Considering K DMs, define K fuzzy decision matrix $X^k = \left(x_{ij}^k\right)$, where x_{ij}^k is TFN that represent the rating assigned to alternative i for criterion j by decision maker k.

Therefore, the rating of alternatives with respect to each criterion can be calculated as $x_{ij} = \frac{1}{K}\left(x_{ij}^1 + x_{ij}^2 + \cdots + x_{ij}^K\right)$. Each x_{ij}^k is defined by triplet $\left(a_{x_{ij}}, b_{x_{ij}}, c_{x_{ij}}\right)$.

Step 2: By using linear normalization, we build the normalized fuzzy decision matrix $N = (n_{ij})$ as below

$$n_{ij} = \begin{cases} \left(\frac{a_{x_{ij}}}{\max_i c_{x_{ij}}}, \frac{b_{x_{ij}}}{\max_i c_{x_{ij}}}, \frac{c_{x_{ij}}}{\max_i c_{x_{ij}}}\right) & \text{si } j \in E \\ \left(\frac{\min_i a_{x_{ij}}}{c_{x_{ij}}}, \frac{\min_i a_{x_{ij}}}{b_{x_{ij}}}, \frac{\min_i a_{x_{ij}}}{a_{x_{ij}}}\right) & \text{si } j \in F \end{cases} \tag{5}$$

Step 3: The weighted normalized fuzzy matrix V is calculated by multiplying the columns of the normalized fuzzy

decision matrix N and the correspondent weights $w_j \in R$ satisfying $\sum_{j=1}^{n} w_j = 1$. $V = (v_{ij})$

Where $v_{ij} = n_{ij} \cdot w_j = \left(a_{n_{ij}}, b_{n_{ij}}, c_{n_{ij}}\right) \cdot w_j = \left(a_{n_{ij}} \cdot w_j, b_{n_{ij}} \cdot w_j, c_{n_{ij}} \cdot w_j\right)$

Step 4: Deduce the fuzzy positive and negative ideal solution as follows:

$$\text{PIS} = \left(v_1^+, v_2^+, \ldots, v_n^+\right) \tag{6}$$

$$\text{NIS} = \left(v_1^-, v_2^-, \ldots, v_n^-\right) \tag{7}$$

Where $v_j^+ = \max_i v_{ij}$ and $v_j^- = \min_i v_{ij}$

Step 5: determine the distances of each alternative A_i from PIS and NIS

$$d_i^+ = \sum_{j=1}^{n} dd\left(v_{ij}, v_j^+\right) \tag{8}$$

$$d_i^- = \sum_{j=1}^{n} dd\left(v_{ij}, v_j^-\right) \tag{9}$$

By using the formula that calculates the distance dd between two positive TFNs $A = (a_A, b_A, c_A)$ and $B = (a_B, b_B, c_B)$:

$$dd(A, B) = \sqrt{\frac{1}{3}\left[(a_A - a_B)^2 + (b_A - b_B)^2 + (c_A - c_B)^2\right]} \tag{10}$$

Step 6: Deduce the relative closeness of alternative A_i to the ideal solution PIS :

$$RC_i = \frac{d_i^-}{d_i^+ + d_i^-} \tag{11}$$

Step 7: based to the relative group closeness, rank the alternatives A_i and select the best one that have the halue of RC_i.

D. Criteria Identification

During the literature review, it has been noticed that there is no one Enterprise Architecture Framework as all-purpose solution. The choice depends on the requirements and situations being processed. In this perspective, we have focused in the first step to depict the important criteria that will be a keys factor to consider in our situation. Therefore, we have identifying fourteen criteria from literature review enriched by academics and logistics experts' opinions see Table VI.

E. Alternatives

In this section, a brief description is provided for four enterprise architecture frameworks selected as alternatives in this study. These frameworks were chosen based on their frequent inclusion in comparative analyses (refer to Table I).

- **A1: The Zachman Framework** is an enterprise architecture model officially introduced by [6]. It presents a logical structure in a bidimensional matrix format, where the first dimension comprises six columns representing the six fundamental questions: What, How, Where, Who, When, and Why. Each of these questions is then explored through six perspectives. This results in a taxonomy that categorizes the various architectural artifacts necessary for developing and designing an information system to help the organization manage change and ensure alignment between business and IT.
- **A2: TOGAF, The Open Group Architecture Framework**, developed in 1995, has become an industry standard widely adopted for designing, governing, and constructing architectures for organizations. It categorizes enterprise architecture into four domains: Business, Application, Data, and Technology architecture [46]. The TOGAF transformation process is anchored in the Architecture Development Method (ADM) engine, comprising cyclical phases to define, plan, implement, and ultimately manage changes from the current "As-is" architecture to the desired "To-be" architecture [57].
- **A3: DoDAF, The Department of Defense Architecture Framework**, is developed specifically for the United States Department of Defense. While its primary focus is on defense applications, its applicability extends to other domains as well. DoDAF introduces a set of products and a view model designed to serve as tools for visualizing, understanding, and assimilating the broad scope and complexities of an architecture. These products are organized into four views: All View (AV), Operational View (OV), Systems View (SV), and Technical Standards View (TV). Notably, DoDAF is well-suited for large, complex system architectures and stands out for its incorporation of "operational views" [58].
- **A4: The Federal Enterprise Architecture Framework (FEAF)** was developed by the US Federal Chief Information Officers (CIO) Council with the aim of constructing and supporting integrated systems architectures. Its primary objective is to enhance the management and exchange of information within government and federal agencies, facilitating efficient and prompt service delivery to clients and citizens by improving access to information. FEAF is structured around six reference models: performance, business, data, application, infrastructure, and security reference models [58].

V. RESULTS

The evaluation process commences with the establishment of the GDS1 group decision for the initial stage, comprising two academic experts and two logistics experts. During in-depth discussions, the group constructs a hierarchical structure consisting of 14 criteria. Subsequently, they populate the upper and lower triangle elements of the pairwise comparison matrix (refer to Table VII). The comparison ratings are deliberated upon, reaching a consensus within the group.

The consensual weight for each criterion is obtained after establishing the normalized matrix (Table VIII) with (CR= 0,09084).

TABLE VI. CRITERIA DEFINITIONS

Criteria	Description
(C1) Agility challenges	Concern agile design and development of the system in an iterative and flexible manner.
(C2) Requirement taxonomy	Due to the multitude of actors, objectives, and strategies, in addition to the multitude of functionalities between business, operational, and technical: the requirements analysis and design must be granular.
(C3) Focused views	Putting in place appropriate views for each stakeholder to facilitate their understanding, focus, and participation in development.
(C4) Ease of use	The simplicity of the design tool or method.
(C5) Architecture guidelines	Design tool and method guide and documentation.
(C6) Cost	The cost of framework adoption and use.
(C7) Ontology architecture definition	Given the different cultures and vocabularies of the stakeholders, it is better to define an ontology facilitating integration of new keywords.
(C8) Data extensibility and integration	Ability to be extensible in terms of data integration of different types and structures.
(C9) Process and system scalability	Ability to manage and integrate business, operational, or administrative processes.
(C10) Metamodeling and abstractions	The framework level of abstraction to facilitate extensibility during development.
(C11) Artefact interoperability	Facility of interoperability between elements of the solution in terms of data and processes.
(C12) Heterogeneous IoT technology integration	The capabilities of the EAF to handle IoT architecture as an emerging technology widely used in the logistic fields.
(C13) Cloud/Fog cloud implementation	As an emerging technology, Cloud is very practical for this kind of application. This criterion concerns the capabilities of the EAF to implement Cloud architectures.
(C14) Facility to integrate Big data analytics	The capabilities of the EAF to integrate Big data analytics.

The next stage consists to scores each alternative against these criterions by EA experts (3 architects), they are asked to rank the four alternatives by using linguistic terms which are transformed to triangular fuzzy number (Tables IX, X, XI). By considering the C6 as cost criteria and the rest of criteria as benefit criteria. We have applied the operations mentioned above (Eq. (5), (6) and (7)) and we obtain the normalized matrix as illustrated in Table XII and Table XIII.

Finally, by applying the Eq. (8), (9) and (11), we have obtained the relative closeness of all alternatives A_i to PIS as depicted in Table XIV, the best rank is assigned to A2- Togaf framework.

VI. DISCUSSION

The results of the first phase illustrated that the taxonomy of needs and the granularity of details according to the different views of the project stakeholders is the most important criterion to be considered when choosing an EAF adapted to this project. In second place comes the ability to develop emerging cloud, IoT and Big data architectures as they are the indispensable solutions to build powerful, efficient and effective digital platforms. Also, in the same level of importance there are the scalability of the system in terms

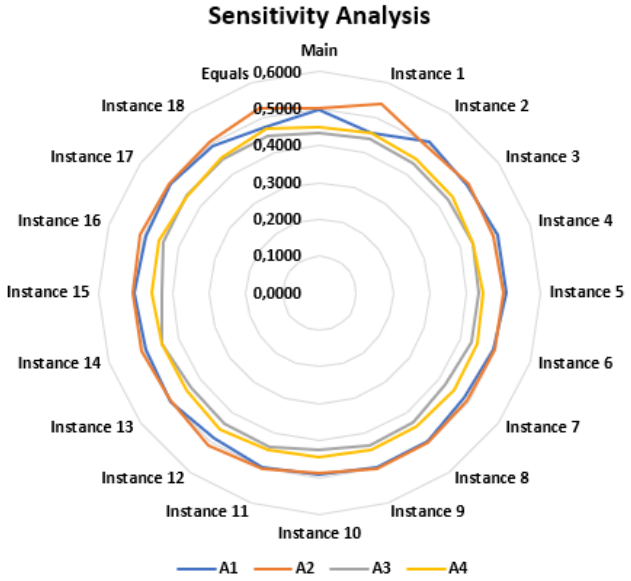

Fig. 4. Sensitivity analysis under different criteria weights.

of data, processes and the interoperability of artefacts.

In the second stage the evaluation of the four frameworks by the Enterprises architects demonstrated that all the frameworks have strengths and weaknesses and puts the Togaf framework as the closest to the context of our need. The decision makers also highlight in all the frameworks a low level of implementation of the new architectures founder of the digital transformation, namely the cloud, Iot and big data. This requires EA must reinvent itself and keep pace with technological evolution and remain a key tool for future business design [59].

To evaluate the current ranking, the Fuzzy VIKOR and Fuzzy Promethee methods are applied to the same problem, and their results are then compared. Details of these methods can be found in [60], [61]. For criterion weighting, the evaluation results obtained by the AHP approach are used. The results of the AHP-fuzzy VIKOR and AHP-fuzzy Promethee approaches are presented in Table XV.

Analysis of Table XV reveals that the ranking of the two best alternatives remains unchanged, while that of the other alternatives varies. This suggests that the proposed methodology produces a solution very similar to the AHP-fuzzy VIKOR and AHP-fuzzy Promethee methodologies, confirming the robustness of the approach.

VII. SENSITIVITY ANALYSIS

In this study, a two-stage decision-making process is employed, integrating both the Analytic Hierarchy Process (AHP) and Fuzzy-TOPSIS methodologies, and subjected to a sensitivity analysis. During this analysis, criteria weights, initially derived using the AHP technique, are exchanged between two criteria while keeping the others constant. For each instance, the resulting values (v+, v-, d+ and d-) are computed to illustrate the updated outcomes. This process is iterated for twenty combinations, maintaining identical weights for specific criteria out of the fourteen, thereby providing a comprehensive evaluation. The details of all instances are succinctly presented in Table XVI, and the resulting rankings of the alternatives are visually depicted in Fig. 4.

Table XVI and Fig. 4 underscore that the initial instance effectively encapsulates the primary findings of the combined AHP-Fuzzy-TOPSIS approach. Notably, among the nineteen instances, Alternative A2 consistently attains the highest score. The sensitivity analysis reveals a significant divergence in the ranking of alternatives when equal weights are assigned to sub-criteria. Despite this, the evaluations suggest that the decision-making process remains generally robust to changes in criteria weights, with Alternative A2 consistently emerging as the preferred choice across various scenarios.

VIII. CONCLUSION

In conclusion, this project has significant implications for logistics and digitalization. By leveraging Enterprise Architecture (EA) as a key tool to address digital transformation challenges, the ongoing project focuses on developing a digital collaboration platform for freight transport. The complexity lies in choosing a suitable Enterprise Architecture Framework (EAF) amid numerous options. The paper introduces a decision-making method that integrates the Analytical Hierarchy Process (AHP) and the Fuzzy Technique for Order Preference by Similarity to Ideal Solution (F-TOPSIS) within a group multi-criteria process to select the most suitable EAF for successful project implementation.

The study's findings offer advantages for projects engaging in digital transformation through EA. A suitable EAF is crucial in providing a comprehensive view of the system and aligning information systems with strategic and business needs. The study identifies the Zachman framework as the closest match among the four EAFs examined, offering valuable insights for modeling complex digital systems through EAFs. Ultimately, implementing an appropriate EA framework can assist Logistics Service Providers (LSPs) in improving profitability and

service quality, ensuring adaptability to innovation trends for competitiveness.

This study introduces a robust method for selecting a pivotal Enterprise Architecture (EA) framework, steering the digital transformation of the freight transportation sector. Leveraging the Analytic Hierarchy Process (AHP) and Fuzzy Technique for Order of Preference by Similarity to Ideal Solution (F-TOPSIS), the approach systematically evaluates and ranks candidate EA frameworks. Application to a case study involving a Moroccan logistics company demonstrated the method's practicality and relevance in real-world scenarios.

Looking ahead, there are exciting opportunities for further research and refinement of the method. The dynamic nature of technology and business environments calls for criteria adaptable to change. Future work could explore the inclusion of dynamic criteria, ensuring selected EA frameworks remain relevant amid evolving technologies. Integrating machine learning techniques into the decision-making process represents another promising avenue for future research. Leveraging historical data and trends, organizations can make informed predictions about the future suitability of EA frameworks.

Further exploration could assess the scalability and adaptability of the proposed EA selection approach across different geographic regions and logistics sectors. Testing its effectiveness in small-to-medium-sized enterprises (SMEs) and large multinational logistics firms would highlight its versatility. The integration of emerging technologies such as blockchain, IoT, and AI could significantly enhance EA frameworks in logistics, improving transparency, efficiency, and security, and driving digital transformation. Future work should also consider including environmental and social criteria in the decision-making process, aligning EA frameworks with green logistics and sustainability objectives. Addressing high-risk factors like geopolitical disruptions, cybersecurity threats, and market volatility through robust risk assessments would further enhance the resilience of EA frameworks. Additionally, exploring hybrid EA frameworks could lead to tailored solutions that promote scalability, flexibility, and adaptability. Finally, expanding this research to other industries, such as healthcare, manufacturing, and energy, would provide valuable comparative insights into the broader application of EA frameworks. Long-term studies that evaluate key performance indicators (KPIs) such as cost reduction, efficiency, and customer satisfaction would help assess the sustainability and effectiveness of these frameworks.

ATG-Net: Improved Feature Pyramid Network for Aerial Object Detection

Junbao Zheng, ChangHui Yang, Jiangsheng Gui*
School of Computer Science and Technology,
Zhejiang Sci-Tech University, Hangzhou, Zhejiang, China

***Abstract*—Object detection in aerial images is gradually gaining wide attention and application. However, given the prevalence of numerous small objects in the Unmanned Aerial Vehicle (UAV) aerial images, the extraction of superior fusion features is critical for the detection of small objects. However, feature fusion in many detectors does not fully consider the specific characteristics of the detection task. To obtain suitable features for the detection task, the paper proposes an improved Feature Pyramid Network (FPN) named ATG-Net, which aims to improve the feature fusion capability. Firstly, we propose an Adaptive Tri-Layer Weighting (ATW) module that adaptively assigns weights to each layer of the feature map according to its size and content complexity. Secondly, a Triple Feature Encoding (TFE) module is implemented, which can fuse feature maps from three different scales. Finally, the paper incorporates the Global Attention Mechanism (GAM) into the network, which includes improved channel attention mechanisms and spatial attention mechanisms. The experiments are conducted on the VisDrone2020 dataset, and the result shows that the network significantly outperforms the baseline detector and a variety of popular object detectors, which significantly improves the feature fusion capability of the network and the detection accuracy of small objects.**

***Keywords*—Object detection; feature pyramid network; adaptive tri-layer weighting; triple feature encoding; global attention mechanism**

I. Introduction

Object detection technology in the UAV capture scene is rapidly advancing, and it plays an important role in the fields of power line inspection, crop analysis, military security [1], [2], [3], and so on. With the development of deep learning, especially convolutional neural networks [4], [5], [6], [7], [8], [9], the performance of object detection has been greatly improved. The detectors contain three main components: backbone, neck, and head. The primary function of the backbone is feature extraction. The mainstream architectures include VGG [10], ResNet [11], DenseNet [12], MobileNet [13], EfficientNet [14], CSPDar-knet53 [15], and SwinTransformer [16], which have been relatively mature. The main function of the neck network is multi-scale feature fusion, feature enhancement, and integration of contextual information. It plays a crucial role in the object detection task. The role of the detection head is to parse the fused feature output from the neck network, including object localization and bounding box regression. The performance of the detection head is largely dependent on the quality of the fused features. Therefore, the design of an effective necking network has a decisive impact on improving the performance of the entire detection system.

*Corresponding author

A widely adopted neck network is to build a feature pyramid network (FPN) [17], which consists of top-down paths and adds lateral connections to the network to achieve the fusion of multi-scale features, enabling the model to better understand and capture the semantic information of the object at different scales. The FPN network usually up-samples the high-level semantic feature maps and combines them with low-level features through simple summation. However, this approach does not adequately address the semantic gaps and dissimilarities between the features, thereby limiting the network's ability to generate highly discriminative features. Furthermore, fusing only high-level and low-level features cannot fully leverage the contextual information of small objects. Such a structure is limited in its ability to capture the fine details of small objects, leading to inaccurate inferences of their locations and categories, which ultimately diminishes overall object detection accuracy.

In recent years, various FPN networks have been proposed to enhance the multi-scale feature fusion capabilities. PANet [18] augmented FPN with a bottom-up path enhancement, allowing information from lower layers to be directly transferred to higher layers, thereby enhancing the flow of information. Bi-FPN [19] proposed a bidirectional cross-scale connectivity structure. This structure enhances feature fusion by adding top-down paths to the FPN. Additionally, it introduces more lateral connections between different levels. These connections improve the fusion of features. Zhang Y et al. [20] proposed a feature pyramid network that combines top-down and bottom-up approaches. By integrating these two architectures, feature maps with richer semantic information and conducive to object detection can be obtained. EFPN [21] designed a feature texture transfer module, which endows the extended feature pyramid with reliable details, extending the original FPN to specialize in small object detection for high-resolution images. SAFPN [22] designed an efficient feature pyramid network for crowded human detection, integrating a refined HS-block into the original FPN to mitigate the effects of scale variations introduced by crowds. With this structure, a single level of features can encompass more receptive fields, accommodating objects at different scales. Although the methods can obtain rich semantic information, they perform a simple summation when fusing low-level and high-level semantics without considering the varying degrees of importance among the features. As a result, they fail to generate highly discriminative features. Additionally, fusing only high-level and low-level semantic features does not fully utilize the contextual information.

Considering cross-layer feature fusion, new design schemes have been proposed. CFPN [23] is a novel cross-layer feature

pyramid network that aggregates multi-scale feature maps and then assigns the aggregated features to the corresponding layers. This enables direct cross-layer communication, improving the asymptotic fusion in salient object detection and yielding better feature maps. However, the method only scales the weights of different feature layers with scaled weights and does not further fuse the feature layers to generate highly discriminative features. ImFPN [24] proposed an improved feature pyramid network based on a similarity fusion module and an attention module, which can fuse different features to accommodate instances of varying sizes. However, the design of the fusion module neglects the differences in the relative importance of the feature maps and, to some extent, increases the computational burden.

In order to solve the above problems, this paper specifically designs a feature pyramid network named ATG-Net for aerial image detection. Firstly, in order to better utilize the contextual information of multi-scale features, a Triple Feature Encoding (TFE) module is proposed to fuse large, medium, and small scale feature maps. Considering that feature maps of different sizes may have different importance in object detection, this paper proposes an Adaptive Tri-Layer Weighting (ATW) module that is able to adaptively predict a set of weights for feature maps of different sizes. Considering that the attention mechanism can make the network more focused on the features of small objects, the Global Attention Mechanism (GAM) [20] is integrated into the network. In the following, Section II outlines the relevant research and studies. Section III details the methodologies of ATW, TFE, and GAM. The detailed comparative experiments and visual analysis are provided in Section IV. Section V concludes with a discussion of the advantages and limitations of the proposed model.

II. Related Work

A. Object Detectors

Contemporary object detectors can be roughly divided into two categories according to the detection process: one-stage and two-stage detectors. One-stage detectors directly predict the class and location of objects within an image. While these detectors offer higher computational efficiency, their accuracy is generally lower compared to alternative approaches. RetinaNet [25] overcomes the obstacle of sample imbalance by introducing focus loss and improves the detection precision. SCA-YOLO [26] proposes a multilayer feature fusion algorithm. In this approach, the single-stage object detection algorithm YOLOv5 is embedded with two newly proposed models and utilizes an adaptive feature fusion network. This enhances the network's feature representation capabilities, significantly improving the detection accuracy of small objects. ASF-YOLO [27] proposes a framework based on attentional scale sequence fusion, which combines both spatial and scale features for accurate and fast cellular instance segmentation. Compared with one-stage detectors, two-stage detectors pursue better detection accuracy at the expense of speed. The R-CNN family of detectors [28], [29] employs a Region Proposal Network (RPN) to generate high-quality candidate anchors, which are then classified and localized. This design enhances the precision of object detection. Double-head R-CNN [30] respectively uses fully connected head and convolutional head for classification and bounding box regression, achieving excellent detection performance.

B. Attention Mechanism

The application of the attention mechanism in object detection has been proven to be extremely effective, which enables the model to focus on the most important areas in the image, thereby improving the accuracy and efficiency of object detection. Squeeze-and-Excitation Networks (SENet) [31] automatically calibrates the responses of feature channels by explicitly modeling the dependencies between the feature channels. By recalibrating the responses of the channels, the model can more effectively leverage the available features. Convolutional block attention module (CBAM) [32] is a straightforward yet effective attention mechanism for feed-forward convolutional neural networks. It generates attention maps independently along the channel and spatial dimensions, thereby enabling adaptive feature refinement. Inspired by CBAM, the Global Attention Mechanism (GAM) [33] enhances the performance of deep neural networks by mitigating information loss and strengthening global interaction representation. Additionally, it incorporates 3D alignment using a multilayer perceptron for channel attention and integrates a convolutional spatial attention submodule. The global attention mechanism is able to amplify the cross-dimensional interactions and capture important features in all three dimensions (channel, spatial width, and spatial height), better preserving the effective information of the original features.

III. Approach

The proposed ATG-Net network (see Fig. 1) consists of a Tri-Layer Weighting Module (ATW), a Triple Feature Encoder Module (TFE), and a Global Attention Mechanism (GAM). ATW enhances the fusion of small, medium, and large-scale features by improving their mechanical properties. It is capable of adaptively predicting a set of weights based on the significance of each feature level for effective aggregation. TFE effectively captures localized fine features of small objects, enabling the integration of local and global information to produce fused features that are better suited for small object recognition. GAM improves the performance of deep neural networks for detecting small objects by reducing information reduction and amplifying the global interaction representation.

A. Adaptive Tri-Layer Weighting Module

Directly fusing feature maps may lead to the loss of important information. Different feature maps may contain distinct types of information, and directly adding or concatenating them can result in certain key features being masked or weakened. Different feature maps may capture distinct features, some of which may be contradictory. Directly fusing these feature maps can lead to feature conflicts, making it difficult for the model to learn effective representations. In order to solve the above problems, the paper proposes an adaptive three-layer weighting (ATW) module that can adaptively predict a set of weights based on the importance of the features for each level. This enables the generation of salient features that are more favorable for small object detection. Fig. 2 illustrates the ATW model structure. Here, C denotes the number of channels, R denotes the feature resolution,

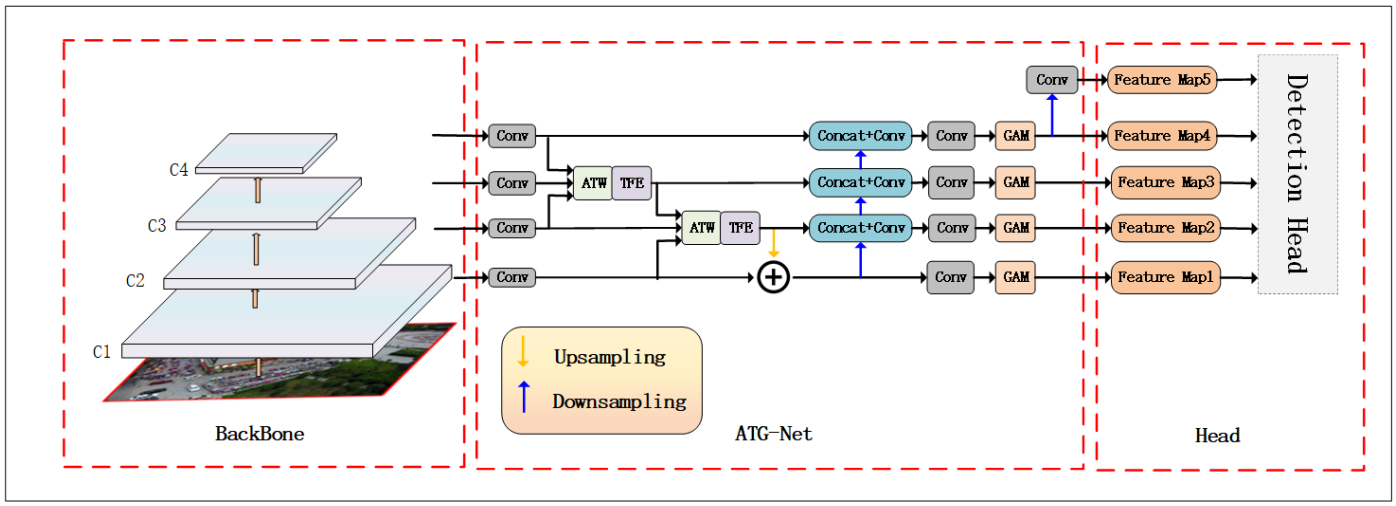

Fig. 1. The framework of ATG-Net. It consists of a backbone network, ATG-Net, and a detection head.

and FC denotes the fully connected layer. Large, Medium, and Small refer to the large-size, medium-size, and small-size feature maps, respectively. First, the features of large, medium, and small sizes are convolved by 1x1 to adjust the number of channels. Secondly, ATW employs global average pooling on each feature map to compress spatial information, resulting in a numerical value for each channel. The channel information is then concat. Finally, the concatenated features are passed through two fully connected layers to generate weight information for the three features. Formally, each layer is characterized by $X_n \in C_n \times R^{H_n \times W_n}$, and ATW computes the channel-wise global representation of $Z \in R^{C \times 1}$ by the following formula:

$$Z = \|_{n=1}^{N} z_n = \|_{n=1}^{N} \left\{ \frac{1}{H_n \times W_n} \sum_{i=1}^{H_n} \sum_{j=1}^{W_n} X_n(i,j) \right\}. \quad (1)$$

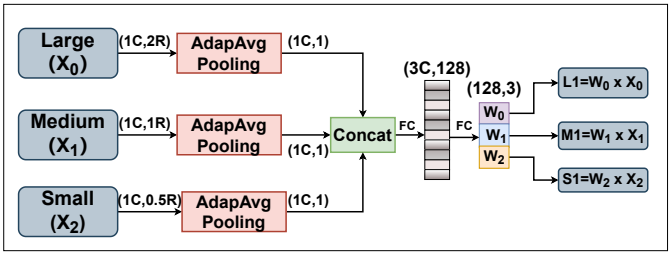

Fig. 2. The structure of the ATW module.

Where $\|$ represents the concatenation function, $C = \sum_{n=1}^{N} C_n$ represents the number of channels represented globally, n ∈ 0,1,2. N represents the number of the feature map, and $X_n(i,j)$ represents represents the feature value at the position (i,j) of the n-th feature map. This paper attempts to make use of aggregate information Z to focus on the features of each level on the significant region rather than the overall feature map. The integrated information Z is passed through two linear transformations to obtain the assigned weight $W \in R^{N \times 1}$.

$$W = FC_2(Relu(FC_1(Z))) \quad (2)$$

As shown in Fig. 2, the symbol W_n represents the nth element of W, and $\times$ denotes the scalar multiplication between X_n and W_n. This approach facilitates the adaptive enhancement of features at each level, thereby promoting precise saliency detection in computer vision applications.

B. Triple Feature Encoder Module

Traditional feature pyramid networks introduce a top-down path to generate multi-scale feature maps by upsampling high-level feature maps and fusing them with low-level feature maps. However, due to the insufficient interaction of semantic information between levels, it is difficult to effectively synergize the low-level detail information with the high-level semantic information, which affects the characterization ability of the fused feature graph. This paper proposes the Triple Feature Encoder Module (TFE) approach, which fuses three scales of feature information to generate high-quality semantic information. The design can not only enhance the characterization ability of features but also improve and refine the feature information.

Fig. 3 shows the structure of the TFE module. Here, C represents the number of channels and R the resolution of feature maps. L1, M1, and S1 denote the large, medium, and small feature maps from the output of the ATW module. The upsample uses nearest neighbor interpolation. For large-size feature maps (L1), a hybrid structure of maximum pooling and average pooling is utilized for down sampling, which is beneficial to preserve the validity and diversity of high-resolution features and small objects. Medium-size feature maps (M1) can be subjected to a convolution operation or without any untransformation. For small-size features (S1), the nearest neighbor interpolation method is used to adjust the resolution to 1R. The three changed features are then subjected to a concat operation, which undergoes a 1*1 convolution operation to modify the output channel. This approach helps to preserve the local feature richness of low-resolution images.

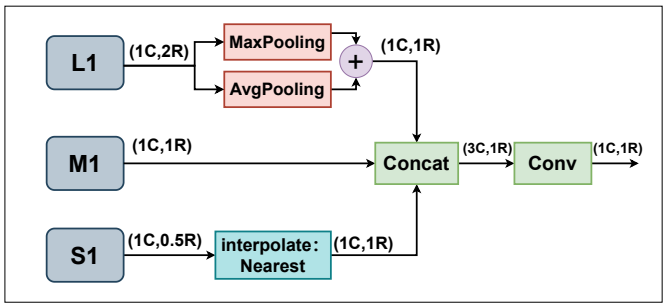

Fig. 3. The structure of the TFE module.

C. Global Attention Mechanism

However, small objects occupy fewer pixels and contain less information in the image, making them more susceptible to being ignored or misclassified during detection. The attention mechanism guides the network to prioritize the features of small objects, thereby enhancing their distinguishability in subsequent processing by improving the representation of their features. By facilitating the capture of long-range dependencies, this mechanism leverages context from surrounding pixels and the broader image, thereby augmenting the network's feature representation capabilities. However, both SENet and CBAM approaches overlook the interactions between channels and spatial dimensions, leading to the loss of cross-dimensional information. The global attention mechanism (GAM) [33] mitigates information loss and amplifies interactions across global dimensions. This enhancement bolsters the features of small objects, mitigates information loss, and thereby elevates the detection performance for such objects.

Fig. 4 shows the overview of the Global Attention Mechanism (GAM), where diagram A represents the overall input-output flow of the GAM, subdiagram B represents the flow of the channel attention mechanism, and subdiagram C represents the flow of spatial attention. Where F_1, F_2 and F_3 represent the input feature map, intermediate state map, and output feature map, respectively. The expressions are as follows:

$$F_2 = M_c(F_1) \otimes F_1 \,. \tag{3}$$

$$F_3 = M_s(F_2) \otimes F_2 \,. \tag{4}$$

where M_c denotes the channel attention mechanism, M_s denotes the spatial attention mechanism, and $\otimes$ denotes element-by-element multiplication.

The channel attention submodule arranges spatial information into 1 dimension and realigns dimensional positions. It subsequently applies a two-layer multi-layer perceptron (MLP) to enhance the interdimensional dependencies between channels and spatial features.

In order to expand the receptive field, the spatial attention mechanism uses 7*7 convolutional layers. To reduce the computational effort, the number of channels is regulated using the channel reduction rate r. Finally, the feature map is passed through a sigmoid activation function, which generates attention weights that indicate the degree of importance of different locations or features.

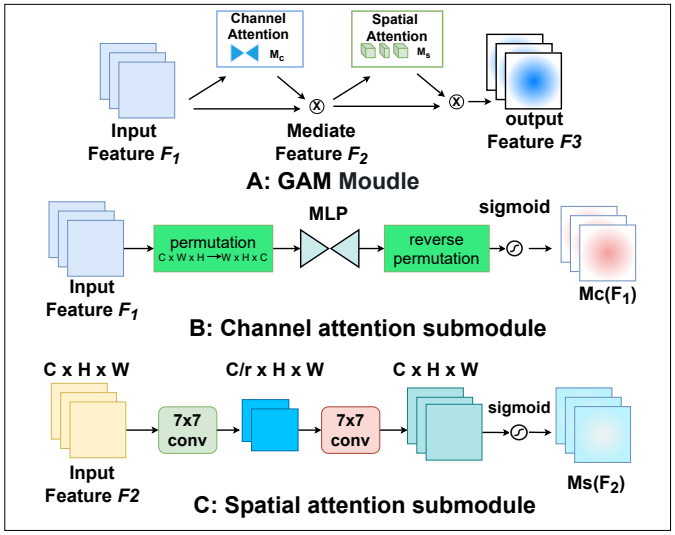

Fig. 4. The overview of the global attention mechanism.

IV. Experiments

To verify the effectiveness of the ATG-Net for small object detection, this paper conducts extensive experiments on the VisDrone2020 [34] dataset, a popular and challenging benchmark for aerial image detection.

1) VisDrone2020: This dataset contains a total of 10,209 images, of which 6471 were used for training, 548 for validation, 1610 for general testing, and 1580 for challenging testing. The image resolution of the dataset is approximately 2000×1500. The dataset encompasses 2.6 million annotations across various categories, primarily focusing on vehicles such as cars, buses, bicycles, tricycles, motorcycles, awning-tricycles, trucks, and vans, along with pedestrians, all captured from drone-based observations. It has extreme category imbalance and scale imbalance, making it an ideal benchmark for studying small object detection problems.

2) Implementation details: RetinaNet (Retina) [25], Faster R-CNN (FRCNN) [29], and Cascade RCNN (CRCNN) [39] are respective representatives of one-stage detectors, two-stage detectors, and cascade detectors. Accordingly, the paper designates them as the baseline detection networks for comparison. For data augmentation, the paper utilizes simple yet effective methods such as random resizing, random cropping, and random flipping. We implement the ATG-Net based on mmdetection on a single Nvidia 3060Ti GPU with 16GB of graphics memory. The optimizer employed is Stochastic Gradient Descent (SGD), initialized with a learning rate of 0.01. The learning rate strategy integrates both linear and cosine annealing schedules, initially employing a linear decay over the first 10 epochs, followed by a cosine decay for the subsequent 20 epochs, thereby encompassing a total training duration of 30 epochs. To assess the network's performance, Average Precision (AP) is utilized as the key metric. $AP_{50:95}$ is the average accuracy calculated over a range of different Intersection over Union (IoU) thresholds. It provides a more comprehensive picture of the model's performance under different IoU thresholds. AP_{50} and AP_{75} are computed at single

A. Experimentation Results

1) Comparison with baseline models: To demonstrate the effectiveness of the ATG-Net algorithm for detecting various types of targets on UAV images, the paper compares the proposed model with three baseline models and various improved FPN methods. The baseline models include Faster RCNN (FRCNN), RetinaNet (Retina), and Cascade RCNN (CRCNN), all evaluated under the same experimental conditions. ResNet18 (R18) and ResNet50 (R50) were chosen as the backbone networks. The evaluation metric for the object category utilizes $AP_{50:95}$. Experimental results with the baseline model and various improved FPN methods are shown in Table I. Where PED stands for pedestrian, PER stands for person, BC stands for bicycle, TRI stands for tricycle, ATRI stands for awning-tricycle, and MO stands for motor.

From Table I, ATG-Net achieves consistent performance improvements across all the detection networks with which it is combined. For Faster R-CNN, this paper uses three backbone architectures for comparative experiments. Notably, the R50 backbone yields the most significant performance boost, enhancing the $AP_{50:95}$ from 21.7% to 28.9%, representing a 7.2% improvement. When compared to the Retina model, there was an AP improvement from 13.9% to 18.4%, marking a 4.5% enhancement. The optimal detection model, Cascade R-CNN, likewise exhibits performance enhancement, with the AP advancing 23.2% to 24.4%. Upon incorporating our proposed ATG-Net module, all three baseline models experienced a significant improvement in detection accuracy across all categories. Notably, in categories like 'bicycle' and 'bus', which are underrepresented in the training data and typically appear very small, our method—employing FRCNN with the R50 backbone—achieves remarkable $AP_{50:95}$ increases of 7.1% and 15.7%, respectively. This highlights the ATG-Net's capability to excel at detecting small objects even when trained on limited data, affirming its robustness in such challenging scenarios.

Table I also presents the detection results of various advanced FPN networks improved upon FRCNN. ATG-Net also achieved the highest average detection precision, surpassing other detectors. In the detection of ten categories, ATG-Net has achieved good results, especially in the category of the bicycle and bus, where it outperforms DSHNet by 3.7% and 7.6%, respectively.

To further demonstrate the effectiveness of the ATG-Net model in detecting small objects, Table II is provided. A comparative analysis of various advanced object detection algorithms on the VisDrone2020 test set is presented. Combining ATG-Net with FRCNN and utilizing R50 as the backbone network, the optimal result was achieved on AP_{50}, with 38.4%. As shown in Table II, categories with a higher proportion of small targets, such as bicycles and buses, exhibit a substantial improvement, with the AP_{50} increasing to 18.2% and 64.4%, respectively.

B. Ablation Experiments

To validate the individual contributions of ATG-Net's feature pyramid components—ATW, TFE, and GAM—to the detection performance, ablation experiments were conducted. Experiments were conducted on the VisDrone2020 validation set using FRCNN as the baseline model and R18 as the backbone network. Table III shows the effect of each component of the ATG-Net on the detection performance.

1) Impact of TFE module: As shown in Table III, the addition of the TFE module increases AP_{50} from 39.0% to 42.4%. The AP_s increases from 14.1% to 16.6%, indicating that the TFE module can effectively improve the precision of small objects. This indicates that the TFE module can well fuse different levels of feature maps, which in turn enhances the model's ability to deal with multi-scale features, enabling the model to obtain better performance in the recognition of small and large objects.

2) Impact of the ATW module: The adaptive triple feature weighting module is able to adaptively predict a set of weights based on the importance of the triple features. ATW and TFE need to be used together. From Table III, when ATW and TFE are fused, AP_s increases from 14.1% to 17.3%. Combining the two modules enhances the model's robustness in detecting small targets. This also demonstrates that the ATW module effectively predicts weights from features of different scales.

3) Impact of GAM module: Although the use of GAM alone did not significantly improve detection performance, combining it with the other two modules enhanced the model's overall object detection capabilities. Compared to the baseline model, AP_{50} improves from 39.0% to 44.8%, an increase of 5.8%. For small objects, the AP increased from 14.1% to

18.5%, indicating that the model has excellent small object detection capability.

C. Visualization

In order to more intuitively demonstrate the effectiveness of the proposed method in practical application, some representative images from the Visdrone2020 test challenge dataset were selected for testing. All experiments were conducted by comparing the baseline FRCNN model, using R18 as the backbone network, with the model that combines our proposed ATG-Net with FRCNN.

Fig. 5 compares the visualization results of the highest-resolution feature map generated by the neck network. From left to right, the first column represents the original images, the second column shows the visualization results of the baseline model, and the third column displays the visualization results of our proposed ATG-Net. From the visualization results, it is evident that the feature maps produced by the baseline Faster R-CNN have a limited receptive field. This limitation suggests that the baseline model may struggle to capture detailed information or context over larger areas, leading to inaccuracies in detection. In contrast, the feature maps obtained by our ATG-Net have a global receptive field and focus on relatively smaller regions of interest compared to features of the same level. This characteristic allows our model to capture more detailed information and maintain context across different scales, thereby improving detection precision.

Fig. 6 shows the detect results on representative and more difficult images from the Visdrone2020 test challenge dataset. In this figure, the different categories are represented by different colored boxes, and the numbers on the rectangles indicate the confidence scores. The left column shows the results from the baseline FRCNN model with an R18 backbone. The right column shows the results from both FRCNN and ATG-Net models utilizing the same R18 backbone. Different categories in the detection results are identified using different colored detection boxes. Yellow boxes are used to highlight the detection of small objects, and zoomed-in effects are shown alongside for a more intuitive comparison. From the detection results, it can be seen that the baseline model has misdetections and misses small objects in the presence of occlusion, whereas the proposed model shows no misses and detects more small objects even in the presence of occlusion. In the detection effect image taken from high altitude, the vehicles and pedestrians on the road are very small. In this situation, the model in this paper can also detect them well. In the images of different lighting scenes, the model still has good detection ability in the dim scene.

V. CONCLUSION

In this paper, we proposed ATG-Net, an improved feature pyramid network for boosting UAV aerial image object detection. Firstly, we propose an Adaptive Triple Weighting (ATW) module, which intelligently assigns weights to predictions across diverse scales—large, medium, and small—dynamically emphasizing the significance of each size category. Secondly, we introduce a Triple Feature Encoding (TFE) module to utilize more efficiently on multi-scale contextual information. By applying the derived weights to features across various scales, this module amplifies and integrates multi-resolution features, thereby enhancing the representational capability of small object features. Due to the global attention mechanism (GAM) taking into account global information, it is crucial for enhancing the detection performance of small objects. Extensive experimental results on the VisDrone2020 have demonstrated that ATG-Net can effectively replace existing FPN networks and integrate with various popular detectors. Meanwhile, the proposed model can significantly enhance feature fusion capabilities, thus improving the detection precision of small objects. To enhance ATG-Net's detection capabilities even further, our next goal is to reduce model complexity and build lightweight detection models that can be deployed into edge devices.

***Abstract*—Gait disorders in older adults, particularly those associated with neurodegenerative diseases such as Parkinson's Disease, Huntington's Disease, and Amyotrophic Lateral Sclerosis , present significant diagnostic challenges. Since these NDDs primarily affect older adults, it is crucial to focus on this population to improve early detection and intervention. This study aimed to classify these gait disorders in individuals aged 50 and above using vertical ground reaction force (vGRF) data. A deep learning model was developed, employing Continuous Wavelet Transform (CWT) for feature extraction, with data augmentation techniques applied to enhance dataset variability and improve model performance. ResNet-50, a deep residual network, was utilized for classification. The model achieved a validation accuracy of 95.06% overall, with class-wise accuracies of 97.14% for ALS vs CO, 92.11% for HD vs CO, and 93.48% for PD vs CO. These findings underscore the potential of combining vGRF data with advanced deep-learning techniques, specifically ResNet-50, to classify gait disorders in older adults accurately, a demographic critically affected by these diseases.**

***Keywords*—Gait disorders; neurodegenerative diseases; deep learning; vertical Ground Reaction Force (vGRF); ResNet-50**

I. Introduction

Gait, the manner of walking, is a fundamental human activity involving the intricate coordination of the brain, nerves, and muscles. Globally, gait problems have significantly increased, leading to approximately 646,000 fatal falls annually, particularly among individuals aged 50 years and above [1]. These disorders are the second most common cause of accidental deaths worldwide and contribute substantially to healthcare costs. For instance, Norton et al. [2] estimated that gait disorders account for approximately 0.85% to 1.5% of global healthcare expenses. Jia et al. [3] highlighted the rising prevalence of gait-related falls, emphasizing the need for early detection and intervention to mitigate these issues. Particularly among older adults, gait problems significantly impact mobility, quality of life, and mortality [4].

Neurodegenerative diseases (NDDs) are one of the most significant contributors to gait disorders. These diseases result from the progressive loss of neurons, leading to impaired communication between the brain and muscles. Parkinson's disease (PD), Huntington's disease (HD), and Amyotrophic Lateral Sclerosis (ALS) are among the most prevalent NDDs, each profoundly affecting gait patterns in distinct ways. For instance, Hoff et al. [5] observed that ALS patients typically exhibit slower walking speeds and longer stride durations, while Hausdorff et al. [6] reported increased gait variability in individuals with HD and PD. These conditions impair patients' motor functions, further complicating their management.

Advanced research techniques have illuminated the complex dynamics of gait in NDDs. For example, detrended fluctuation analysis has been used to identify specific gait patterns in neurodegenerative conditions [7], while multi-resolution entropy analysis has revealed disorder-specific gait dynamics [8]. Additionally, platforms like PhysioNet have been instrumental in providing benchmark datasets for studying these disorders [9]. Despite these advancements, Setiawan et al. [10] noted that accurately diagnosing specific NDDs through gait analysis remains challenging due to overlapping symptoms across conditions. Ye et al. [11] and Zhao et al. [12] emphasized the need for more robust multi-class classification techniques to distinguish PD, HD, and ALS effectively.

Existing methods have achieved varying levels of success. For instance, Baratin et al. [13] reported 85% accuracy using Discrete Wavelet Transform (DWT) with entropy and coherence features. Similarly, Zhao et al. [12] achieved 95.6% accuracy with dual-channel LSTM networks. However, many studies, such as those by Faisal et al. [14], have struggled to distinguish closely related gait disorders in mixed cohorts. Approaches employing convolutional neural networks (CNNs) have shown higher classification rates than traditional methods [15], but Fraiwan et al. [16] noted that ensemble classifiers can significantly enhance accuracy. Nevertheless, methods like these often face overfitting challenges due to limited data variability [17].

Hybrid approaches combining CNNs with Long Short-Term Memory (LSTM) networks have also shown promise. For example, Elziaat et al. [18] achieved 92.4% accuracy in predicting freezing of gait in PD patients by integrating spatial and temporal features. Deterministic learning theory with radial basis function (RBF) neural networks demonstrated 93.75% accuracy in classifying ALS, PD, and HD [19]. Amin and Singhal [20] emphasized the importance of dimensionality reduction techniques, achieving 93% accuracy for HD and 89% for PD. Furthermore, Mehra et al. [21] utilized IoT-based

sensors to achieve an accuracy of 98.8% in early PD detection. Ensemble methods like AdaBoost, which analyze features such as vertical ground reaction force (vGRF), have also proven effective, achieving 99.17 percent.

Recent studies have explored novel methods for improving classification accuracy. For instance, Penage et al. [22] transformed vGRF signals into recurrence plots, achieving high accuracy in multi-class classifications using CNNs. Erdas et al. [23] utilized convolutional LSTM networks combined with 3D CNNs, reaching a detection accuracy of 96.33% for NDDs, with specific accuracies of 97.68% for ALS, 94.69% for HD, and 95.05% for PD. These methods demonstrate the potential of advanced deep learning techniques but also highlight gaps in addressing the unique challenges faced by older adults [24].

Despite these advancements, most studies have focused on binary classifications or younger populations, leaving older adults—who are particularly susceptible to NDDs—understudied. To address this gap, this study employs Continuous Wavelet Transform (CWT) to transform vGRF signals into time-frequency spectrograms, enabling the extraction of both temporal and frequency-domain features. Unlike DWT, which may overlook transient signal features, CWT captures subtle gait abnormalities crucial for diagnosis. The ResNet-50 deep learning model, known for its robust feature extraction capabilities, is employed for classification. Data augmentation techniques are applied to enhance model generalizability and mitigate overfitting [25]. These advancements make the proposed method uniquely suited to addressing the challenges of accurately diagnosing neurodegenerative gait disorders in older adults.

The remainder of this article is organized as follows. Section II details the materials and methods, Section III presents the results, and Section IV discusses the findings. Finally, Section V concludes the study, summarizing key contributions and future research directions.

II. Methodology

The methodology of this study is summarised in Fig. 1. The study aimed to develop a machine-learning model for classifying gait disorders in older adults. The process involved three main steps: Data Collection, Data Preprocessing, Feature Extraction, ML Model Training and testing

A. Dataset

In this study, the "Gait in Neurodegenerative Diseases Dataset" provided by Hausdorff et al.[26] was employed. Fig. 2 illustrates the gait data collection procedure. Raw data were collected from vGRF sensors using force-sensitive resistors placed under the foot inside the shoes. During the experiment, each subject walked along a 77-meter-long hallway for five minutes at their normal pace.

The dataset includes recordings from 64 subjects, comprising 13 patients with ALS, 15 patients with PD, 20 patients with HD, and 16 CO. Since this study focuses on older adults, only data from subjects aged 50 and above were selected for analysis.

The gait parameters recorded for each subject include stance, swing, double support interval, and stride for both the left and right foot. For this study, only the right foot force data were analysed. On average, each subject contributed approximately 277 gait cycles, depending on their walking speed during the 5-minute data recording period [27].

TABLE I. Information of Gait Data Participants

Statistical Parameter	CO	HUNT	PARK	ALS
Age (Year)	62.6 ± 8.63	57.2 ± 6.24	66.5 ± 9.06	61.75 ± 7.07
Height (m)	1.84 ± 0.10	1.78 ± 0.14	1.99 ± 0.12	1.797 ± 0.34
Weight (kg)	74.6 ± 13.02	64 ± 10.8	87.38 ± 13.68	89.04 ± 13.91
Gait Speed (m/s)	1.29 ± 0.21	1.10 ± 0.14	1.34 ± 0.27	1.23 ± 0.19

The final dataset used in the model includes data from five healthy controls (average age: 62.6 years), seven patients with PD (average age: 66.5 years), five patients with HD (average age: 57.2 years), and four patients with ALS is (average age: 61.75 years). The breakdown of the dataset is shown in Table I. Detailed information about the participants, including their age, height, weight, and gait speed, is presented. The dataset was split for training and validation purposes, the dataset was split, with 70% of the data used for training and 30%.

B. Data Pre-processing

A five-minute gait force signal was captured and filtered using a digital band-pass filter, with the filtered signal $y(t)$ computed as the convolution of the raw signal $x(t)$ and the filter's impulse response $h(t)$, as shown in Eq. (1).

$$y(t) = h(t) \times x(t) \tag{1}$$

Wavelet denoising was then applied to further clean the signal, transforming $y(t)$ into the wavelet domain, thresholding the coefficients, and reconstructing the denoised signal $z(t)$, as expressed in Eq. (2).

$$z(t) = W^{-1}\left(T\left(W(y(t))\right)\right) \tag{2}$$

To optimize temporal and frequency resolution, wavelet transforms were applied using window durations of 10, 30, and 60 seconds. The 10-second window was selected for the final analysis, providing the best balance for capturing relevant gait features [28].

C. Data Augmentation

To enhance model performance and prevent overfitting, various data augmentation techniques were applied to the gait signals, which were transformed into the frequency-time domain for analysis by the ResNet-50 model. Horizontal flipping, mathematically represented as $f(x, y) \rightarrow f(-x, y)$, and random rotations between -10 and 10 degrees [Eq. (1)] were used to introduce variability.

$$\begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix} \tag{1}$$

Random translations along the x and y axes [Eq. (2)] were applied to simulate different positions.

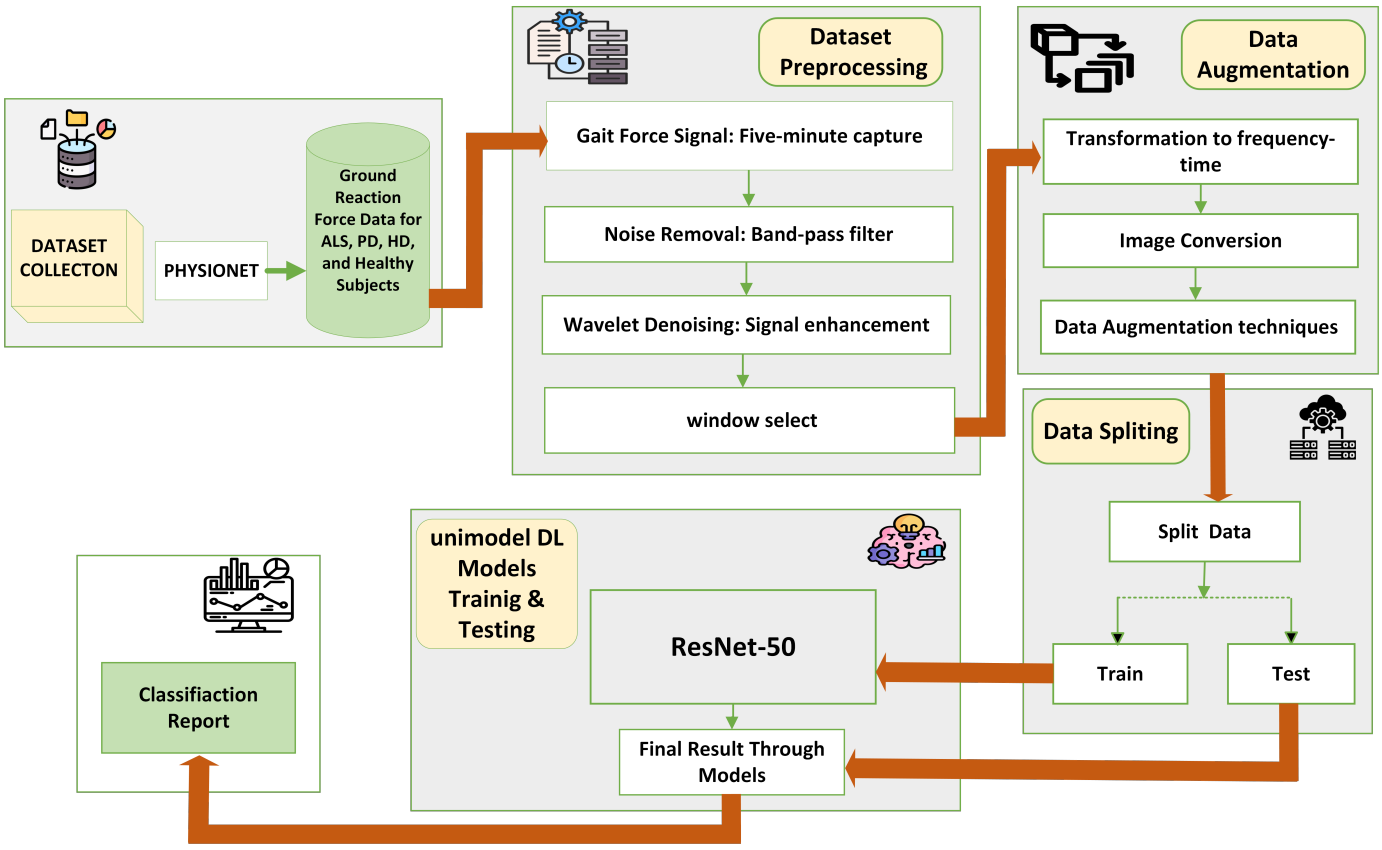

Fig. 1. Diagram of the proposed method.

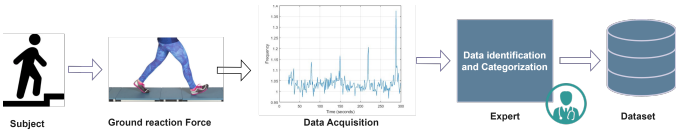

Fig. 2. Data collecting procedure.

$$(x, y) \rightarrow (x + \Delta x, y + \Delta y) \tag{2}$$

Brightness and contrast adjustments [Eq. (3)], scaling [Eq. (4)], and Gaussian blur [Eq. (5)] were also implemented to increase dataset diversity.

$$I' = \alpha I + \beta \tag{3}$$

$$(x, y) \rightarrow (sx, sy) \tag{4}$$

$$G(x, y) = \frac{1}{2\pi\sigma^2} \exp\left(-\frac{x^2 + y^2}{2\sigma^2}\right) \tag{5}$$

Each transformation introduced new variations in the dataset, improving model robustness by simulating different object sizes, perspectives, and noise levels, which helped the model generalize better in classification tasks.

D. Classification Model: ResNet-50

The proposed ResNet-50 model was employed to classify gait disorders using gait data transformed into the frequency-time domain via Continuous Wavelet Transform (CWT). The model architecture and data preprocessing steps are depicted in Fig. 3. The architecture consists of several key components aimed at extracting hierarchical features and classifying the four target gait disorder classes: CO, HD, PD, and ALS.

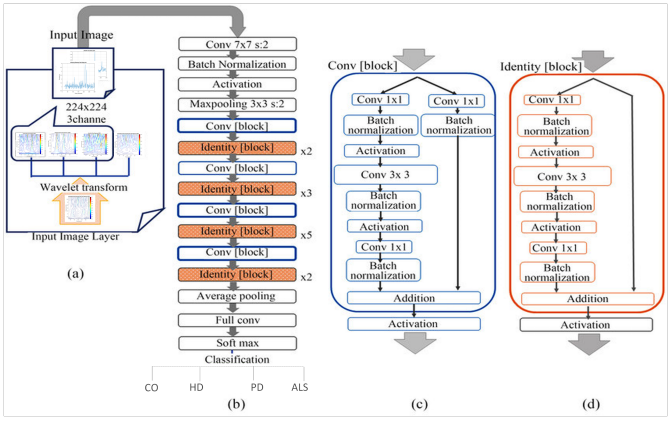

Fig. 3. Overview of the ResNet-50 architecture.

1) Model Architecture Overview: The architecture begins with the input image, processed through several convolutional

layers [Fig. (3b)], each followed by batch normalization and ReLU activation to capture local patterns. The convolutional layers are organized into residual blocks, as shown in Fig. 3(c) and 3(d), where identity and convolutional shortcuts allow the network to retain information and mitigate the vanishing gradient problem, enabling the training of deeper networks.

The convolutional operation for any layer l is mathematically expressed as:

$$O_l = f(W_l * I_{l-1} + b_l) \tag{6}$$

where O_l is the output feature map, W_l is the convolutional filter applied to the input I_{l-1}, and $f(x) = \max(0, x)$ is the ReLU activation function. After each convolutional block, pooling layers reduce the spatial dimensions of the feature maps to prevent overfitting and reduce computational load, as described by:

$$P_l = \text{pool}(O_l) \tag{7}$$

As the network deepens, feature complexity increases through the five stages of the network, eventually resulting in global average pooling, which reduces the spatial dimensions of each feature map to a single value:

$$y_k = \frac{1}{H \times W} \sum_{i=1}^{H} \sum_{j=1}^{W} O_{i,j}^k \tag{8}$$

Finally, the pooled features are passed through a fully connected layer, followed by the softmax activation function to produce a probability distribution across the gait disorder classes. The softmax is expressed as:

$$P(y = k|x) = \frac{\exp(z_k)}{\sum_{j=1}^{K} \exp(z_j)} \tag{9}$$

2) Training and Optimization: The model was trained using the Adam optimizer, with an initial learning rate of 0.001 and a mini-batch size of 32. Training was conducted over 30 epochs, with 70% of the dataset used for training and 30% for validation. The network minimized the categorical cross-entropy loss function:

$$L = -\sum_{k=1}^{K} y_k \log(P(y = k|x)) \tag{10}$$

The architecture was fine-tuned by replacing the fully connected and classification layers of the pre-trained ResNet-50 model to adapt it for the specific task of gait disorder classification. The training showed consistent improvement in accuracy, with a final validation accuracy of 95.06%.

This architecture, shown in Fig. 3, highlights the model's ability to learn intricate gait features effectively, addressing the reviewer's request for details on the number of layers, optimization method, and training parameters.

E. Performance Evaluation

To evaluate the effectiveness of the Gait Neurodegenerative Disorders classification model, key performance metrics including accuracy, sensitivity, specificity, precision, recall, and F1 score were calculated. These metrics were derived from the confusion matrix, which tracks the true positives (TPs), false positives (FPs), false negatives (FNs), and true negatives (TNs) for each class. Specificity, defined as the proportion of true negatives out of the total actual negatives, is calculated using Eq. (9). Sensitivity, also known as recall, measures the proportion of true positives out of the total actual positives and is given by Eq. (10). Accuracy, indicating the overall correctness of the model, is computed as per Eq. (11). Precision, reflecting the proportion of true positive predictions among the total predicted positives, is calculated in Eq. (12).Lastly, the F1 score, which balances precision and recall, is provided by Eq. (13). Together, these metrics offer a comprehensive assessment of the model's performance in classifying neurodegenerative disorders based on gait data.

$$\text{Specificity} = \frac{\sum_{i=1}^{n} \text{TN}_i}{\sum_{i=1}^{n} (\text{TN}_i + \text{FP}_i)} \tag{9}$$

$$\text{Sensitivity} = \frac{\sum_{i=1}^{n} \text{TP}_i}{\sum_{i=1}^{n} (\text{TP}_i + \text{FN}_i)} \tag{10}$$

$$\text{Accuracy} = \frac{\sum_{i=1}^{n} (\text{TP}_i + \text{TN}_i)}{\sum_{i=1}^{n} (\text{TP}_i + \text{TN}_i + \text{FP}_i + \text{FN}_i)} \tag{11}$$

$$\text{Precision} = \frac{\sum \text{TP}}{\sum (\text{TP} + \text{FP})} \tag{12}$$

$$\text{F1 score} = \frac{2 \times (\text{Precision} \times \text{Sensitivity})}{\text{Precision} + \text{Sensitivity}} \tag{13}$$

III. Result

In this study, MATLAB 2022b was used for data preprocessing, augmenting data, and training the Deep learning model for classification.

A. Statistical Analysis

Fig. 4 illustrates the time-domain frequency plots for the gait data of Control (CO) subjects and patients with Huntington's disease (HD), Parkinson's disease (PD), and Amyotrophic Lateral Sclerosis (ALS). The CO group (A) displays stable and consistent gait frequencies, while HD (B) shows erratic patterns, indicative of severe gait disturbances. PD (C) presents a mix of stable and fluctuating frequencies, whereas ALS (D) shows moderate variability in step frequency.

Fig. 5 provides the time-frequency spectrograms generated using Continuous Wavelet Transform (CWT) for each group. ALS (D) shows stable walking patterns with tightly packed contours, while HD (B) reflects irregular and erratic gait frequencies. PD (C) exhibits mixed contours, and the control group (A) maintains consistent patterns.

These findings are consistent with [29], offering further insight into the distinct gait characteristics of each condition.

Fig. 6 presents box plots that compare key gait features across ALS, PD, HD, and control groups. The mean gait

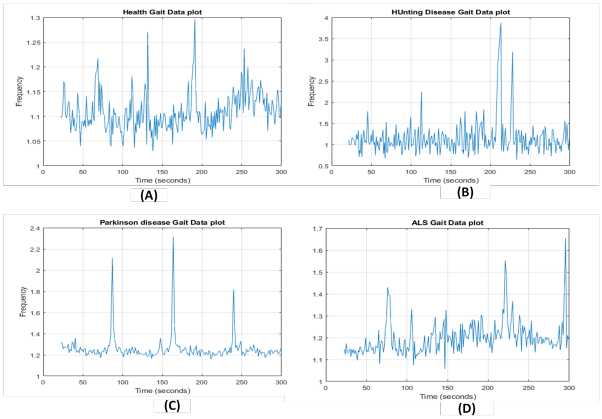

Fig. 4. Gait Time-Domain Patterns: (A) Control, (B) Huntington Disease, (C) Parkinson Disease, (D) ALS.

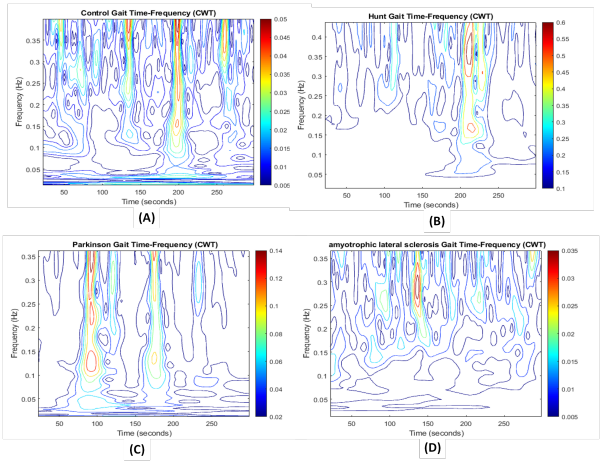

Fig. 5. Gait Time-Frequency Patterns (CWT): (A) Control, (B) Huntington Disease, (C) Parkinson Disease, (D) ALS.

values show that ALS patients have a lower median, reflecting their slower gait. The interquartile range (IQR) is wider for HD, indicating more variable gait patterns, characteristic of Huntington's disease.

The standard deviation and variance for PD suggest moderate variability, indicating motor fluctuations, while RMS and instantaneous RMS reveal greater dispersion in the neurodegenerative groups compared to controls, highlighting reduced gait control.

The gait speed box plot shows a significant decrease in ALS patients, emphasizing their slower walking patterns. These features will be key inputs for training deep learning models to accurately classify gait disorders, facilitating early detection and intervention. By integrating these insights with machine learning techniques, we can effectively monitor and classify gait abnormalities associated with neurodegenerative diseases.

B. ResNet-50 Model Training Progress

Fig. 7 shows the training and validation accuracy, as well as the training and validation loss, across iterations. The accuracy plot indicates steady improvement, with validation accuracy peaking around 95% and training accuracy reaching near 100%, demonstrating the model's effective learning of the data patterns.

The loss plot reveals a consistent decrease in both training and validation losses over time, with the training loss stabilizing at a low value. Although the validation loss shows some fluctuations, the overall trend suggests that the model generalizes well to unseen data.

C. Confusion Matrix for the ResNet-50 Model

Fig. 8 illustrates the confusion matrix for the ResNet-50 model, demonstrating its performance in classifying the four gait disorder classes. The model exhibits high classification accuracy, particularly for the CO and PARK classes, with minimal misclassification across classes. The ALS and HUNT classes show strong sensitivity and specificity, indicating effective distinction among the different gait disorders.

D. Classification Results

The performance of the ResNet-50 model in classifying gait disorders was evaluated using key metrics such as Validation Accuracy, Precision, Sensitivity, Specificity, and F1 Score, as shown in Table II. The model achieved a high validation accuracy of 95.06% for distinguishing between neurodegenerative diseases and healthy controls, indicating strong overall performance across all classifications.

TABLE II. VALIDATION PERFORMANCE METRICS FOR THE RESNET-50 MODEL

Evaluation Parameter	ALS vs CO	HD vs CO	PD vs CO	NDD vs CO
Validation Accuracy	97.14%	92.11%	93.48%	95.06%
Precision	96.88%	94.50%	92.88%	94.04%
Sensitivity	89.50%	98.90%	93.65%	91.68%
Specificity	96.30%	98.40%	92.90%	98.85%
F1 Score	97.11%	98.70%	93.22%	92.94%

Precision scores were also robust, with ALS vs CO achieving 96.88%, HD vs CO at 94.50%, PD vs CO at 92.88%, and NDD vs CO at 94.04%, reflecting the model's capacity to correctly identify relevant instances. Sensitivity varied across the conditions, with HD vs CO attaining the highest sensitivity at 98.90%, followed by PD vs CO at 93.65%, NDD vs CO at 91.68%, and ALS vs CO at 89.50%.

Specificity, a measure of the model's ability to correctly identify negative cases, was consistently high across all classifications: ALS vs CO at 96.30%, HD vs CO at 98.40%, PD vs CO at 92.90%, and NDD vs CO at 98.85%. These values demonstrate the model's strong ability to distinguish between diseased and control cases effectively.

The F1 Score, which balances precision and sensitivity, also confirmed the model's robust classification performance. ALS vs CO achieved an F1 Score of 97.11%, HD vs CO at 98.70%, PD vs CO at 93.22%, and NDD vs CO at 92.94%, highlighting the model's consistency in both detecting true positives and avoiding false positives.

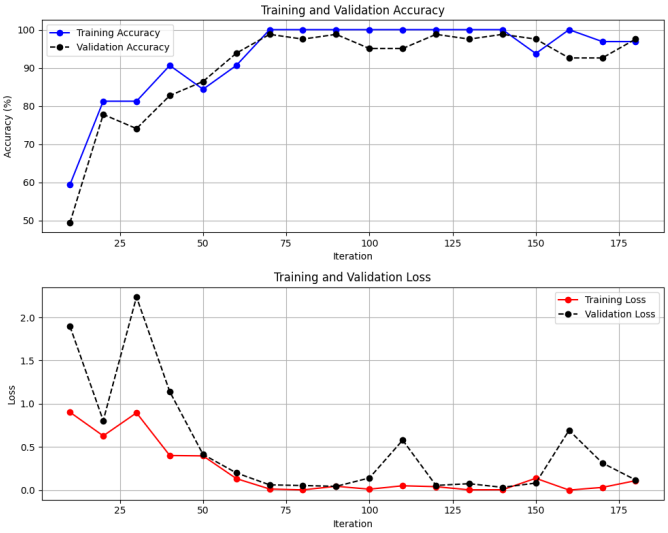

Fig. 7. Training and validation accuracy and loss over iterations.

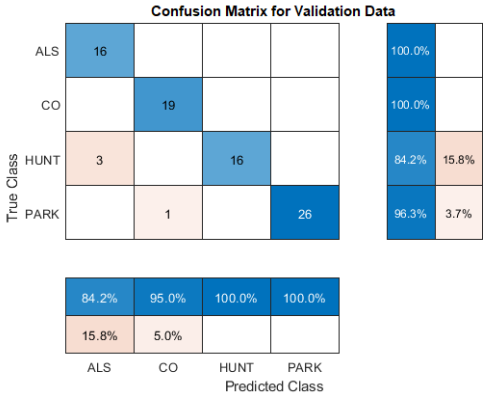

Fig. 8. Validation confusion matrix for the ResNet-50 model.

IV. Discussion and Comparison

This study specifically focused on classifying gait disorders in older adults, a demographic that is critically understudied despite being highly susceptible to neurodegenerative diseases (NDDs) such as Parkinson's Disease (PD), Huntington's Disease (HD), and Amyotrophic Lateral Sclerosis (ALS). Utilizing vertical Ground Reaction Force (vGRF) data and advanced deep learning techniques (ResNet-50), this research provides a more targeted approach, focusing on individuals aged 50 and above, whereas previous studies often included a broader age range or did not account for the unique characteristics of older adults.

Table III compares the classification accuracy of various models across studies. Our model, using ResNet-50 and vGRF data, achieved a high validation accuracy of 95.06% for distinguishing between different neurodegenerative conditions. This performance is competitive with previous efforts that utilized a variety of techniques and features. For example, Hong et al. [30] used a combination of stride, swing, and stance intervals

TABLE III. CLASSIFICATION ACCURACY OF DIFFERENT MODELS

Study	Signal	Methodology	ALS vs CO	PD vs CO	HD vs CO	NDD vs CO
[30]	Str. Int, Sw. Int, Sta. Int, DS. Int	Statistical Features (Min, Max, Avg, Std)	96.79%	89.33%	90.28%	90.63%
[19]	Sw. Int, Sta. Int	Deterministic Learning, RBF Neural Networks	93.1%	100%	100%	93.75%
[20]	Str. Int, Sw. Int, Sta. Int, DS. Int	Statistical Features (Mean, Std, Variance, Skewness, Kurtosis)	85%	89%	93%	85%
[31]	VGRF	Statistical Features (RMS, Variance, Kurtosis)	-	-	-	99.17%
[10]	VGRF	Time-Frequency Spectrogram	100%	97.42%	100%	98.44%
[24]	VGRF, Str. Int, Sw. Int, Sta. Int	Classical Nonlinear Features	95.72%	91.68%	91.71%	92.87%
[23]	VGRF	Recurrence Plot	100%	100%	97.56%	98.93%
[22]	VGRF	Raw VGRF	92%	81%	79%	78%
This Study	**VGRF**	**Time-Frequency Spectrogram,ResNet-50**	**97.14%**	**92.11%**	**93.48%**	**95.06%**

along with statistical features, achieving 96.79% accuracy for ALS vs CO, which is comparable to our study's 97.14%. However, their study did not focus specifically on older adults, making the results of our study particularly significant for this vulnerable population.

Other studies such as Zeng et al. [19] employed deterministic learning theory and RBF neural networks, achieving 93.1% for ALS vs CO. While this is a strong result, our study surpassed it by integrating Time-Frequency Spectrograms with ResNet-50, reflecting the effectiveness of deep learning models in capturing complex gait patterns, particularly in an older demographic. Furthermore, Zeng's study targeted a broader population, while our focus on older adults emphasizes the applicability of our model to clinical settings where early detection is critical.Similarly, the approach by Amin et al. [20] used stride and swing intervals with statistical features such as mean, standard deviation, and kurtosis, achieving lower accuracy rates (85% for ALS vs CO). This indicates that traditional machine learning techniques, even when combined with well-known gait metrics, may not be as effective as deep learning-based models in identifying subtle gait differences in older adults.

In contrast, Fraiwan et al. [31] achieved an impressive accuracy of 99.17% using ensemble decision tree classifiers with vGRF data. While their accuracy is slightly higher than ours, their study focused on a general population, whereas our model's 95.06% accuracy for older adults demonstrates strong performance in a more challenging demographic. The use of ensemble methods can be further explored in future studies for enhanced model performance in older populations.Setiawan et al. [10] reported a similar performance using vGRF data and time-frequency spectrograms, achieving 97.42% for PD vs CO and 100% for HD vs CO. Our model's results for these two conditions (93.48% and 92.11%, respectively) are slightly lower, which could be attributed to the increased complexity of gait patterns in older adults, especially those aged 50 and above. However, the overall performance of our model across all NDDs remains strong and consistent.

Moreover, studies such as Zhao et al. [24] and Lin et al. [23] utilized recurrence plot features and classical nonlinear analysis methods to classify gait disorders. They achieved high accuracies for individual tasks (100% for ALS and HD), but their methodologies did not specifically target the older population. Our study not only achieved comparable performance but also focused on older adults, where gait variability and complexity are more pronounced.

V. CONCLUSION

This study utilized Continuous Wavelet Transform (CWT) for feature extraction and ResNet-50 for classification, yielding a competitive validation accuracy of 95.06%, which aligns with or exceeds results from previous studies. The model achieved class-wise accuracies of 97.14% for ALS vs CO, 92.11% for HD vs CO, and 93.48% for PD vs CO. A key distinction of our work is the focus on older adults aged 50 and above, which, combined with data augmentation techniques, enhances model generalization. This differentiates our study from prior research that typically focused on younger populations or broader age ranges. The integration of vGRF data with advanced deep learning techniques provides a robust framework for accurately classifying gait disorders, particularly in the context of early diagnosis for older adults. Future studies could expand upon these findings by incorporating additional data modalities, such as medical history or multimodal sensor inputs, to further improve diagnostic accuracy and enable comprehensive monitoring of neurodegenerative disease progression in older adults.

How Predictable are Fitness Landscapes with Machine Learning? A Traveling Salesman Ruggedness Study

Mohammed El Amrani[1], Khaoula Bouanane[2], Youssef Benadada[3]
ANISSE Team-Faculty of Sciences, Mohammed V University in Rabat, Rabat, Morocco[1]
Smart Systems Laboratory, ENSIAS, Mohammed V University in Rabat, Rabat, Morocco[2,3]

***Abstract*—The notion of fitness landscape (FL) has shown promise in terms of optimization. In this paper we propose a machine learning (ML) prediction approach to quantify FL ruggedness by computing the entropy. The approach aims to build a model that could reveal information about the ruggedness of unseen instances. Its contribution is attractive in many cases like black-box optimization and in case we can rely on the information of small instances to discover the features of larger and time-consuming ones. The experiment consists in evaluating multiple ML models for the prediction of the ruggedness of the traveling salesman problem (TSP). The results show that ML can provide, for instances of a similar problem, acceptable predictions and that it can help to estimate ruggedness of large instances in that case. However, the inclusion of several features is necessary to have a more predictable landscape, especially when dealing with different TSP instances.**

Keywords*—Fitness landscape analysis; optimization algorithms; machine learning; landscape ruggedness; traveling salesman problem

I. Introduction

Over the last few decades, work on optimization algorithms has mainly focused on the algorithmic side, while the analysis of the problem itself has received relatively little attention. That is, most of the research published on this topic does not provide a sufficient analysis of the problem, why the algorithm works well and under which conditions [34]. Therefore, characterizing a problem should lead to a deeper understanding of it and better choices of algorithms and, hence, have an increased chance of producing better solutions. For this purpose, the concept of fitness landscape (FL) analysis was proposed with the aim of designing a generic approach that characterizes optimization problems. The concept was first introduced to illustrate the dynamics of biological evolutionary optimization [28], but it has also proved useful in understanding the behavior of optimization algorithms in both binary and continuous optimization problems. Thus, FL analysis is relevant both to predict the performance of algorithms and to improve their design. The interested reader is referred to [19] for more details on the transition from modeling real processes to modeling optimization problems. The issue of predictability of the FL was studied in biology (e.g. [4]) and in this paper, we aim to show a case in which it can be helpful for combinatorial optimization.

The integration of machine learning (ML) in operations research is increasingly crucial in light of recent advances [12], especially for the study of fitness landscapes in optimization problems such as the traveling salesman problem (TSP). ML can aid in characterizing ruggedness, thereby enhancing decision-making with predictive insights. This paper investigates the ruggedness of TSP landscapes using entropy as a key measure and introduces a novel ML-based approach for predictive analysis. The study addresses challenges in landscape characterization, extending traditional methods to unseen problem instances.

In general, the aim of FL analysis is to improve knowledge about the properties of a problem. Malan et al. [4] highlighted several characteristics of the FL as well as the measurements used for them. In particular, ruggedness is a property that often depends on the number and distribution of local optima and is related to the level of variation in fitness values in a FL. A number of measurements have been proposed to measure the landscape ruggedness. These measurements are the subject of the paper, and our aim is to deepen our understanding of this property, leveraging the great advances in data-driven approaches that have been carried out in recent years. More specifically, our approach consists of proposing a machine learning (ML)-based approach that extends existing methods for quantifying landscape ruggedness for unseen instances, in which its calculation can be time consuming.

This paper has three main objectives: (1) to evaluate the ability of ML to predict the robustness of TSP fitness landscapes, (2) to explore the role of entropy as a key metric in landscape analysis, and (3) to assess the generalization ability of ML to unseen problem instances. In pursuing these objectives, the paper makes the following contributions:

- It extends previous work by applying ML techniques to analyze TSP robustness, leveraging entropy to improve fitness landscape characterization.
- To the best of our knowledge, this is the first study to use ML to understand a TSP-specific fitness landscape feature, providing new insights into its structure and complexity.

The rest of paper is organized as follows. In Section II, we present the concept of ruggedness of the landscape and the measures proposed to quantify it. Section III is devoted to the description and discussion of the integration of ML in this problem. Both sections are interleaved with a brief literature review of the topic. Section IV presents the experiments.

Finally, the conclusion and the perspectives are depicted in Section V.

II. Background and Literature Review

The use of machine learning to understand the robustness of FL in combinatorial optimization problems, such as the TSP, is gaining increasing attention. A similar goal is explored in [30], where the authors examine the generalization ability of a machine learning model for problem reduction on the classical TSP. This paper shares a similar goal, aiming to explore the ability of ML to model landscape robustness, but distinguishes itself by focusing on entropy-based measures and their predictive potential.

A. Ruggedness of the Fitness Landscape

An important issue that may arise for FL analysis concerns to which extent we are able to generate generic FL measures. Although there are a number of independent measures such as the number of global optima, it is widely accepted that in many problems it is not possible to fully characterize the landscape using independent features [19]. Indeed, what is difficult to solve for a randomized hill climbing is not necessarily difficult for a genetic algorithm (GA) or when using a GA with different mutation operators. We can also note that many of the adopted measures depend on the definition of a neighborhood relation (e.g. the size of a basin of attraction). Based on this remark, the most well-known definition of a FL was proposed in [18] and consists of the triplet (X, N, ϕ), where:

- X is a set of candidate solutions (search space)
- N is a neighborhood relation
- $\phi\colon X \to \mathbb{R}$ is the fitness function

We can see from this definition that the FL not only depends on the problem but is also strongly related to the choice of an algorithm's operator. Therefore, as pointed out in [10], the concept of landscape could only be fully characterized in the context of an associated neighborhood structure and a specific operator. In what follows, we are interested in the ruggedness feature which also depends on the operator.

The issue of fitness ruggedness has been addressed in the literature from a number of perspectives. For instance, Vassilev et al. [10] defined three properties to characterize the FL, which are neutrality, smoothness and ruggedness. Most often the difficult and problematic case concerns the rugged landscape. This case is considered the most challenging and several works have been adopted to treat it (although neutral and smooth FLs have also been examined in the literature).

Concerning measurements, the auto-correlation function (ACF) proposed by Weinberger [11] is the most classic one for measuring it. The idea shown in that paper consists of performing random walks using a specific operator to study the correlation structure of a landscape. More precisely, the author, by considering the case of mutation as an operator, carried out random walks starting from a point chosen at random; then at each step, a bit of the vector chosen at random is flipped. We note that in this case, the ACF could be considered as a time series [35]. However, the ACF measure has been criticized in some works, which have pointed out its weakness in the characterization of the FL (e.g. [7]). Moreover, [16] pointed out that the importance of autocorrelation is often overplayed in fitness landscapes studies. Thus, the measure proposed in [32] to study ruggedness, which is described below, has become the most common over the last decade. We refer to [32] for a detailed description of the approach based on ruggedness.

It should also be noted that ruggedness has been primarily studied for continuous optimization problems [33], but was extended to combinatorial optimization [17]. Another measurement of ruggedness has been proposed, which is information content [23], and is beyond the scope of this paper.

The ruggedness has been studied for some optimization problems. The study in [16] investigated the similarities and difference between four combinatorial optimization problems, including the traveling salesman problem (TSP) and the quadratic assignment problem (QAP). In particular, their study showed that the four problems have similar ruggedness. Furthermore, Tayarani and Bennett [31] studied the impact of the ruggedness among other measures for the graph-coloring problem. In addition, Kallel et al. [10] reviewed some mathematical properties of the ruggedness.

Although ML has not been used yet to predict the ruggedness; an approach to predict it was proposed using time series analysis. In fact, Hordijk [35] proposed an extension of [11] using the Box–Jenkins method [1]. The author's idea consists of exploring the landscape structure by studying the corresponding autoregressive moving average (ARMA) model [1] which, according to the author, characterizes the landscape ruggedness much more precisely; its contribution consists in providing a stochastic model which could be used to make predictions for fitness values of distant points in the landscape.

We can notice, in this section, that entropy is an important measure used to characterize landscape ruggedness in certain works. In this paper, we aim to bridge the gap between them and advancements in data-driven approaches. Therefore, in Section III, we highlight works focused on understanding the TSP landscape and main approaches using ML for FL analysis, then introduce our approach and the adopted ML algorithms.

B. Understanding of the Traveling Salesman Problem Landscape

There are multiple papers which studied the FL of the TSP. For example, Boese et al. [2] asserted that the search space of TSP instances (under 2-opt moves) has a big-valley structure, in which local optima are clustered around one central global optimum. However, this statement has been questioned in multiple papers (e.g. [5]) and its generalization is also an issue of discussion [24]. Indeed, as noted in study [25], the TSP structure is not yet fully understood. On the other hand, ML was used for the TSP but not to analyze its landscape. We refer to study [21] for more information on the topic. In particular, in study [36], the authors investigated the generalization error of a ML model when the training and test instances have different instance characteristics, sizes or are from different TSP variants. The authors have a goal similar to our paper, namely to test the generalization capacity of ML algorithms to large instances, but using a different approach. Another analysis technique, notably the principal component analysis, was used in study [35] to analyse several features of

the TSP FL. The authors provided several conclusions which can mainly be summarized as follows: the difficulty of the instance (e.g. the number of local optima, the probability of reaching a global optimum) increases with the size of the problem and the level of the increase depends on the type of problem.

C. Machine Learning for Fitness Landscape Analysis

ML has been adopted in the context of FL in most cases with the aim of selecting the best algorithm based on the prediction of its performance, by adopting the information included in the computed features of the landscape. By analyzing the literature, we note that one of the first papers which paved the way for the emergence of such research is [15]. It introduced the concept of empirical hardness of optimization, showing how to build empirical hardness models which, given a new problem instance, predict an algorithm's runtime. Moreover, awareness of the importance of such approaches were reinforced with the appearance of the concept of exploratory landscape analysis (ELA) [13], shifting attention to this topic over the past decade.

However, we can notice that most of these researches are empirical-based and try to add features or to compute them in a less expensive way (e.g. [9]), without clearly contributing to the improvement of the problem understanding. The aim of these works is to build automatic tools for the selection or design of algorithms. Therefore, a number of tools have been proposed to extract FL features (e.g. Flacco package [14]).

In fact, we can see that such frameworks, even if useful in practice, cannot help to improve our knowledge on the problem which is of the utmost importance. That is, in most of these ML approaches, the authors try to use or define a large number of features, which could be in the hundreds, that may affect the performance of the algorithms. For instance, Mirshekarian et al. [22] proposed 380 features for the job-shop scheduling problem. But, many of the defined features might not be appropriate [37]. Hence, a typical phase is feature selection, which aims to select the most relevant ones. The ultimate goal of these approaches is to select the most suitable algorithms without providing an explanation for that selection. We note that we are aware that with the appearance of deep learning, the features could be computed automatically as investigated, for example, in [8]. However, deep learning is also unable to provide an explanation of the different selections.

The literature review elucidates the challenge of quantifying the ruggedness of fitness landscapes, emphasizing its dependence on problem characteristics and algorithmic operators. It surveys various methods for ruggedness characterization, with a focus on entropic measures, highlighting their significance in optimization studies. Moreover, it positions the current study as pioneering in utilizing machine learning to predict ruggedness, aiming to enhance understanding and inform algorithmic selection strategies.

Therefore, in this paper, our adoption of ML is different. In fact, we are interested in predicting the values of a specific and crucial feature (ruggedness). Although it is necessary to inclusion of several features for a better FL analysis, this work can be considered as a first and crucial work in this respect. To the best of our knowledge, despite its importance, this is the first investigation of the use of ML for predicting the ruggedness of FL. Ruggedness has been considered instead as a feature for most data-driven approaches for algorithm selection based on ELA. In the following, we describe our proposed approach.

III. The Proposed Approach

Our approach consists of two steps. The first concerns TSP optimization. In this step, the data necessary for the experiments is collected by running an optimization algorithm which consists of successive random walks. The number of iterations is fixed at 100. We choose (2-opt) as the neighborhood to implement the random walk for the TSP. Using this, we can calculate the entropy values of different problem instances as in Eq. (4). For each instance, we performed 30 executions of the random walk and computed the entropy for each instance and run. We are then able to obtain a sufficient sample size for the three experiments, which is 360, 300 and 240, respectively. As described below, in the first experiment, we generate random instances with different sizes. In the second, we analyze different TSPLIB instances while the third one is about a prediction for a specific TSPLIB instance family.

The second step consists of ML prediction. The target variable to be predicted (y) is the entropy. Two features (X) are used, which are the number of cities and the execution number, in addition to the instance family for TSPLIB instances. Based on the accuracy of predictions on unseen instances, we evaluate our approach. Below, we highlight the adopted ML algorithms and define the different steps of our approach.

Algorithm 1: Data Generation for ML Algorithms

```
Data: TSP instance
Random generation of distances for random instances
for k = 1 to 30 do
    for l = 1 to 100 do
        Perform a random walk
    Compute the entropy corresponding to execution k
Result: Entropy values in addition to TSP
  instances-related information
```

In Algorithm 1, we present the adopted ML algorithm and outline the key steps of our approach. Additionally, the flowchart (Fig. 1) provides a visual representation of the methodology, illustrating the process from data generation to ruggedness prediction for TSP instances using ML models.

In this paper, we have adopted a number of ML methods that yield satisfactory results for regression (continuous) problems such as gradient boosting (GR), random forest (RF) and support vector machines (SVM). These approaches, which are among the most adopted ones for regression problems, are the methods used to predict ruggedness. For more information about them, we refer to [20], [3] and [29], respectively.

IV. Experiments

In this section, a series of numerical experiments are carried out to evaluate the ML prediction of landscape ruggedness. The objective is twofold: first, we illustrate how ML can be adopted for this problem. Second, we seek to see what

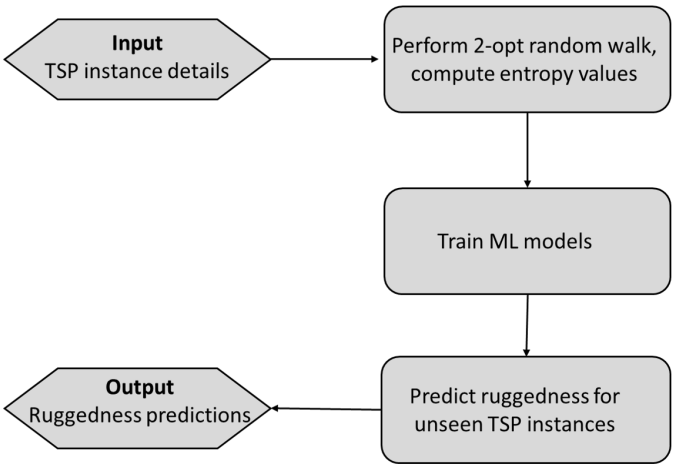

Fig. 1. Flowchart illustrating the proposed system for ruggedness prediction of TSP fitness landscapes.

this prediction can reveal about the structure of landscapes of unseen instances. More specifically, as mentioned above, our experiment first consists of running an algorithm, which is made up of consecutive randomized moves, on instances of classical combinatorial optimization problems while computing the ruggedness entropy value and second, of examining the ML predictive capacity of the entropy on these and other unseen instances by comparing the predicted values with the actual ones.

A. Experimentation Setup

In this paper, we consider the TSP, which is one of the most studied problems in combinatorial optimization. The Mlrose package [6] is adapted to implement the random walk with 2-opt neighborhood. First, we start the experiments with randomly generated TSP instances (the distances are generated randomly). Then, we experiment the approach on TSPLIB instances.

As mentioned earlier, the three ML algorithms chosen in this study are RF, GB and SVM. To implement them, we utilize the Scikit-learn library [27]. We optimize the parameters for RF and GB. Specifically, the number of trees in RF is set to 200, and the loss function to be optimized for GB is set to 'least absolute deviation' for better regression performance. For the other RF and GB parameters, we adopt the default parameters. Regarding SVM, the parameter γ (kernel coefficient) is automatically trained while the values of C (regularization factor) and ϵ are set to 1 and 0.01, respectively. We have chosen these values to enable a balance between overfitting and underfitting.

All experiments are conducted on a computer equipped with an Intel i7-9750H and 16GB of RAM. The measures adopted in this paper are: R^2 (coefficient of determination), mean absolute error (MAE) and mean square error (MSE).

To evaluate ML algorithms, there are two typical methods, notably training-test split or division and cross validation. In this paper, we have used the two methods depending on our objective. First, for random experiments and TSPLIB instances of a similar problem, we adopted the training-test split. More precisely, the first 75% of the data is used for training and 25% is used as test data. Our goal is to see if we can accurately predict the ruggedness of large TSP instances without needing to compute them and simply by examining small instances. Second, for different TSPLIB instances, we adopted 5-fold cross validation [36] to have a robust assessment of the ML predictions. In this case, the testing is performed across instances.

We have uploaded the used code for more details on our approach. The corresponding information is available in the Github repository (blinded for refereeing).

B. Random Instances

As a first experiment, we consider randomly generated TSP instances.

First, in our experiment, we choose nine instances for training and three for testing, depending on the number of cities. For training, we used the values (10, 20, 50, 100, 200, 500, 1000, 2000, 5000) and for testing, we adopted the values (6500, 8000 and 10000). As we have performed 30 runs for each instance, the training set size is 270 and the test set size is 90.

Second, for each of the three ML algorithms (RF and GB and SVM), we display in Table I a comparison of the prediction capabilities of the three algorithms in both training and test sets. That is, we show in Table I the R^2, MAE and MSE values obtained by comparing RF, GB and SVM predictions in training and test sets. The results of the test sets are those which are really necessary for evaluation but those of the training are given as additional information on the structure of the landscape.

TABLE I. COMPARISON OF ENTROPY PREDICTIONS FOR RANDOM TSP INSTANCES

		R2	MAE	MSE
RF	Test acc.	0.7108	0.0202	0.0006
	Training acc.	0.9347	0.0180	0.0005
GB	Test acc.	0.6907	0.0214	0.0007
	Training acc.	0.7337	0.0190	0.0005
SVM	Test acc.	0.2137	0.0380	0.0020
	Training acc.	0.0498	0.0322	0.0016
NN	Test acc.	0.1641	0.6570	0.1300
	Training acc.	0.9630	0.2500	0.1023

Both RF and GB gave acceptable results on the test set. SVM, as trained, seems not to be suitable for this case. The best results are given by RF. That is, RF provided the best results on the test sets, which are the needed for unseen predictions. We can conclude that RF is the most suitable for this case study, with the proposed parameters.

Third, to give a better overview of the RF predictions, we depict in Fig. 2 and Fig. 3 the prediction given by RF in both test and training sets along with the real values.

We can notice from the Fig. 2 and Fig. 3 that the entropies are overall slightly positively correlated with the number of cities. In other words, the entropy in general increases slightly with the number of cities. This can be seen as the values in the

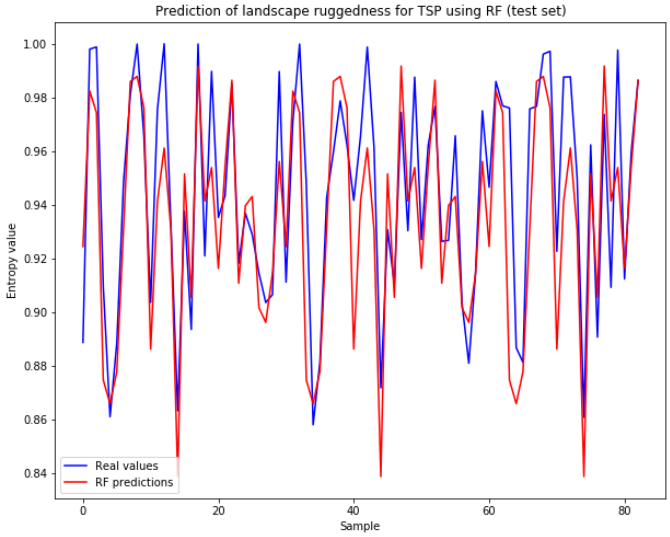

Fig. 2. RF prediction on the test set.

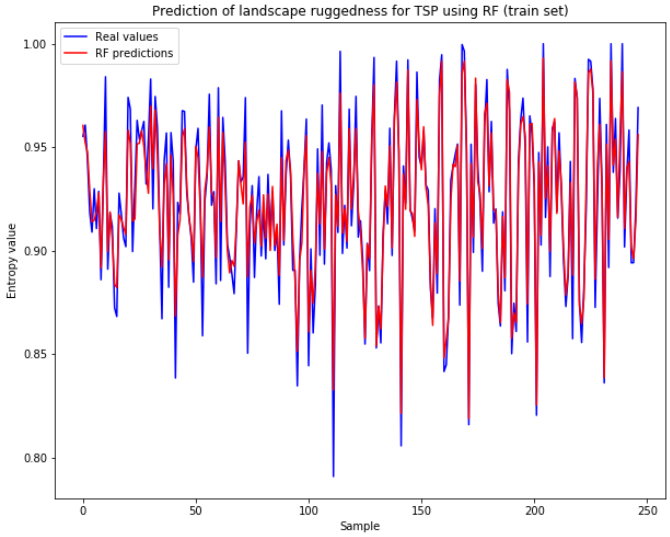

Fig. 3. RF prediction on the training set.

test sets are slightly, which corresponds to higher cities, are slightly higher than of the training set and there is a very weak increasing trend of the value in function of the sample (and then of the cities). Although ML prediction is not extremely accurate, it can detect patterns in the data and provide a fairly good ruggedness prediction.

C. Instances of Different TSPLIB Problems

After looking at the randomly generated TSP instances (Table II), we aim to study several TSPLIB instances.[1] Below we show the names of the instances with the corresponding number of cities.

Our goal in this part is to see how well we can predict ruggedness for problem instances, using the information from other instances, regardless of the instance family. To answer this issue, cross validation is more appropriate than training-test split. In this experiment, we conducted the 5-fold cross validation. In total, we get 300 sample and we use them for this purpose. In Table III, we display the results of the mean of the R^2, negative MAE[2] and MSE factors, which are used in the 5-fold cross validation.

TABLE II. TSPLIB INSTANCES

Instance	Number of cities
Bays	29
Berlin	52
Brazil	58
Eil	51, 76, 101
Ch	130, 150
TSP	225
Fl	417

TABLE III. COMPARISON OF ENTROPY PREDICTIONS FOR INSTANCES OF DIFFERENT TSPLIB PROBLEM INSTANCES

	R^2	Negative MAE	Negative MSE
RF	-0.8797	-0.0385	-0.1525
GB	-0.7478	-0.0352	-0.1422
SVM	-0.7514	-0.0550	-0.2057
NN	0.2660	-15877.1021	-102.0534

It is clear from Table III (e.g. the R^2 values) that the results are not good and the algorithms are not able to provide acceptable predictions. The reason for these unsatisfactory results compared to the previous case is due to the fact that ruggedness appears unpredictable if combined with other factors. It is necessary to combine several features to expect to have an accurate prediction. We note that the results are also not satisfactory when adopting the training-test split in the same way as in the first study.

D. Instances of a Similar TSPLIB Problem

In this section, we focus specifically on instances of a particular TSPLIB instance family and examine the evolution of ruggedness as a function of only the number of cities and, importantly, our ability to predict large unseen instances. More precisely, we consider the instance studied in [26]. In this case study, we consider the instances with cities of 76, 107, 124, 136, 144 and 152 as a training test (75%). The instances with 226 and 264 (25%) are the test set. All instances are executed 30 times. As mentioned before, the reason is that we aim to see if we can predict the ruggedness of instances with higher cities by simply getting information from lower cities, and cross validation is not needed in this case.

We can notice from Table IV, that GB gave the best results in the test set. (We note that the RF predictions are better in the training set but the GB results are more promising in our context.) In Fig. 4 and Fig. 5, we provide the prediction given by GB in the test and training sets with the actual values.

We can notice from Fig. 4 and Fig. 5 that entropy does not globally have a very significant variation in function of the

[1]The instances can be found in http://elib.zib.de/pub/mp-testdata/tsp/tsplib/tsp/index.html

[2]For cross validation, scikit-learn uses negative MAE and MSE. More information about them can be found in https://community.dataquest.io/t/why-is-scoring-equal-to-neg-mean-squared-error/547283

TABLE IV. COMPARISON OF ENTROPY PREDICTIONS FOR INSTANCES OF A SIMILAR TSPLIB PROBLEM

		R2	MAE	MSE
RF	Test acc.	0.3088	0.0220	0.0015
	Training acc.	0.7829	0.0100	0.0002
GB	Test acc.	0.2102	0.0250	0.0020
	Training acc.	0.4651	0.0150	0.0006
SVM	Test acc.	-0.0078	0.0174	0.0009
	Training acc.	-0.0092	0.0203	0.0011
NN	Test acc.	0.1641	0.1150	0.1314
	Training acc.	0.9630	0.9066	0.2023

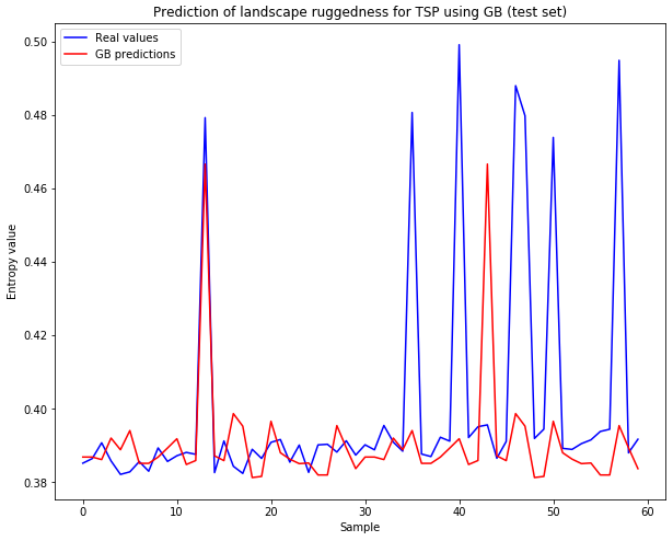

Fig. 4. GB prediction on the test set.

number of cities. The GB predictions are in general consistent with the actual values, and it can then be considered that ML can be useful in this situation.

The results for the three cases can be summarized as follows:

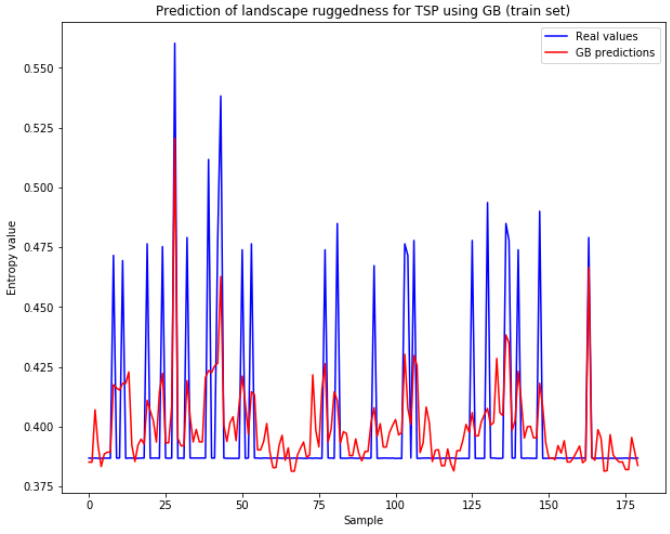

Fig. 5. GB prediction on the training set.

- For random TSP instances, the computed ruggedness factor seems to increase globally. ML can detect this pattern and then provide satisfactory predictions.
- ML algorithms failed to detect patterns in different TSPLIB instances. The reason seems that other factors than size must be included to be able to use ML in this case.
- For a specific TSPLIB instance, there is no significant increase in the factor. ML can also be useful in this case by giving a satisfactory prediction for the same unseen instance with a higher number of cities (although the increase in the size is not the same as for the first experiment).

V. CONCLUSION

Fitness landscape analysis has shown promise for better understanding the functionality of optimization algorithms and reducing their unpredictability. In this paper, we proposed a new ML design to predict the FL ruggedness of unseen large instances based on the values of historical small instances. This work, to the best of our knowledge, is the first attempt to take advantage of recent advances in data-driven approaches to analyze and estimate a feature of FL.

This work can be considered as the first step aimed at predicting the characteristics of problem instances in which their calculation is time-consuming. A practical exploitation of any optimization problem is to run the algorithms in the smallest instances, build the machine learning model, and then predict the features on the very large instances. Estimating the characteristics of a very large instance without needing to run the algorithms can be useful, e.g., to choose the appropriate algorithm to solve these instances.

In this paper, the experiment consists in evaluating the predictive capacity of 3 ML algorithms. The data sets in the three experiments are collected by running the 2-opt random walk 30 times on several instances. In our case, random forest was the best suited for the random TSP instances. For the different TSPLIB instances, no algorithm could find satisfactory results. When focusing on a specific TSPLIB problem, the results found by the gradient boosting are the best. We can conclude that machine learning prediction can be useful when we have identical or similar problem instances with difference mainly in number of cities. The contributions are summarized as follows:

- Our study reveals that machine learning models perform better on random TSP instances than on specific TSPLIB instances. This finding suggests that ML can effectively capture patterns in less complex, more uniform problem structures.
- The results highlight the importance of incorporating additional problem-specific features to improve prediction accuracy for TSP instances of different families. Our work lays the groundwork for future studies to explore more sophisticated models and feature sets, advancing the field's understanding of fitness landscape predictability.

These results are consistent with established findings, demonstrating the correlation between robustness and performance, as well as the difference of ML performance depending on the nature of TSP instances. This paper builds on this knowledge by providing significant new findings and results.

As the Concorde solver is able to easily solve many TSP instances of quite large size to optimality, another approach that may be investigated in the study of ruggedness is target analysis, i.e., giving an optimal solution and checking to which extent, possibly using ML, this can be found from a given starting solution and allowing to learn from the path between those solutions. Finally, even if the practical contribution is not well apparent in the above-mentioned data instances, this work can be considered as a first step that can be extended to much larger instances and problems in which the calculation of the factor can be very time-consuming. The exploitation of information of small instances can be much helpful. Further research should then focus on this issue. Indeed, it is of utmost importance to concretely show the practical impact of our approach (e.g. in black-box optimization). Moreover, it is important to further study the practical application of ML by finding the needed sample (number of instances) to have an accurate prediction on the different problem instances. Further research can also focus on applying the approach to other similar problems such as the family TSP or to integrate into other types of metaheuristics. The reason for the poor results seems to be that the three ruggedness prediction models considered are known to yield satisfactory results in continuous domains. In fact, the advancement in ML prediction is an outstanding area of research that could hold promise in estimating the FL features of unresolved instances and studying the links between these features.

The results of this study highlight the significant impact of robustness and landscape structure on algorithm performance. Building on these insights, future research could focus on designing ML-based adaptive optimization algorithms that can dynamically adjust strategies based on landscape features. Furthermore, leveraging ML to efficiently manage large-scale TSP instances could advance the field, especially in real-world applications requiring scalable solutions.

***Abstract*—The impact of obesity and diabetes are two central reasons for the high rate of developing cardiovascular diseases in this country, which is largely due to their ultra-processed, diet-rich foods. Supervised Learning for Decision Making: A Case Study of Functional Food Taste Perceptions In this experiment, we trained ordinary consumers to estimate the taste preferences of a unique group from which no ratings were available(11) and established that decision making can be performed through supervision. A deep learning neural network architecture according to the present disclosure is designed to model the decision-making behavior of consumers consuming functional products. The efficiency of the model can be increased upto 1.23% making use of proper values for the rest of the hyperparameters as explained in experiments carried out where we set the optimal configuration so that nurturing it gives the best results.**

***Keywords*—EEG analysis; functional foods; decision-making; deep learning; Principal Component Analysis (PCA)**

I. Introduction

By 2023, decision-making has become essential and complex due to the vast amount of information and uncertainty present today. Additionally, various factors such as the fear of failure can negatively affect decision-making. This also impacts health, specifically obesity and overweight, which are linked to dietary decisions. In Latin America, obesity has increased by 55%, and in Mexico, it affects 76.4% of adults and 35.6% of children between the ages of 5 and 11, [1].

Some of these factors could be:

- Deceptive Advertising: Unhealthy food products are promoted as healthy, making informed decisions difficult (for example, whole grain bread labeled as "light"), [2].
- Social Pressure: The discrediting of people with obesity influences their dietary choices and self-image, sometimes leading them to consume unhealthy foods to cope with stress, [3].

Decision-making affects not only at a personal level but also in governmental and corporate spheres, where incorrect decisions can cause significant damage.

Some examples where a wrong decision could have an impact are:

- Policy: Lack of transparency and corruption can have devastating consequences.
- Environment: Disputes and short-term economic decisions harm the planet.
- Social Justice: Decisions about economic and social policies can influence inequality.
- Education: Decisions about curricula and funding affect the quality of education.

Principal Component Analysis (PCA) and Artificial Intelligence (AI), including Deep Convolutional Neural Networks (DCNN), [4], can help analyze complex data and improve decision-making. These technologies can identify patterns in health data and predict diseases by organizing large datasets and providing more accurate and predictive analyses. In the context of overweight and obesity, they can enhance dietary decision-making by providing a deeper understanding of the factors influencing these conditions. On the other hand, four main deficiencies of PCA can be stated: i) Assumes linear relationships: PCA can only capture linear relationships between variables. If the relationships between the data are nonlinear, PCA will not be able to model them adequately; ii) Loss of interpretability: Although PCA reduces dimensionality, the principal components do not have a clear interpretation in terms of the original variables, which can make the results difficult to interpret; iii) Sensitivity to noise: If the data contains noise, it can influence the computation of the principal components, affecting the results; and iv) Computationally expensive for large datasets: For very large or high-dimensional datasets, the computation of the covariance matrix and its significant vectors can be computationally expensive.

The design of an intelligent system using deep learning networks makes it possible to classify a person's like/dislike choices with an efficiency of 80%.

This work is based on EEG Analysis, a technique that uses electroencephalographic signals to study brain activity, being useful in the analysis of brain patterns.

The analysis of EEG is important for various reasons, primarily due to its ability to provide information about the brain's electrical activity, allowing the study and understanding of a variety of cognitive, emotional, and physiological processes. It also has several key study reasons, such as:

- Study of brain activity in real time: EEG provides a real-time window into brain activity, allowing the direct observation of changes in brain wave patterns related to different mental states, such as attention, relaxation, sleep, or decision-making [5].
- Study of decision-making: EEG is also used to investigate how the brain makes decisions by detecting neuronal responses to external stimuli [6].
- Interaction between emotions and decisions: EEG is used to measure brain activity, providing information about how emotions influence decision-making [7].

It also incorporates the use of Functional Foods, which are foods that, in addition to their nutritional value, offer additional health benefits, such as disease prevention or improving a person's health. The philosophy of Decision-Making is applied, which is a cognitive process through which a person evaluates options and selects the most appropriate one to make an informed decision. This process is complemented by the tool of Deep Learning, a branch of artificial intelligence based on artificial neural networks that allows analyzing complex data, identifying patterns, and making accurate predictions and the tool Principal Component Analysis (PCA) is a statistical technique that reduces the dimensionality of complex data sets while preserving the most relevant characteristics. The combination of these concepts enables efficient classification in decision-making.

This work consists of a total of five sections, starting with the introduction, which provides the context of the work. Similarly, related work is given in Section II, presenting an analysis of studies directly related to the proposed one. This is followed by the theoretical framework in Section III, which explains the mathematical and theoretical foundations used in the work. The methodology in Section IV explains how the network operates, leading to the experiment in Section V, where the functionality of the proposed method is tested, and finally, the conclusions in Section VI is presented, where the obtained results are discussed.

II. Related Works

A search was conducted in the databases of IEEE Xplore and Hindawi; this research was carried out with the purpose of finding works that have a similar relationship with the approach followed in the preparation of this document. A total of 13 works were found, which relate to the fundamental topics for the development of this study. From these 13 works, 4 works were derived, whose focus provides a greater contribution to the research.

Fig. 1 is a PRISMA flow diagram, which includes the systematic review of citations, where less relevant works to the objective are discarded, and where these citations were searched in the aforementioned search sites. In this way, 13 articles were found, for example, there is one titled Development of AI model to analyze customer behavior by decision

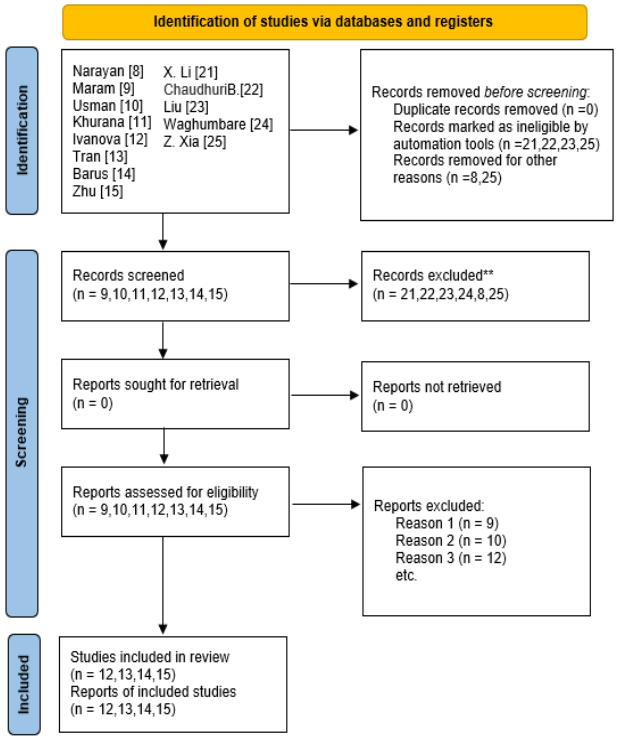

Fig. 1. Identification of related works via research databases such as IEEE Xplore and Hindawi.

making system, written by L. Rong, Y. Ding, M. Wang, M.S. Hossain et al. in [8], which discusses a model that uses artificial intelligence for facial recognition and deep neural networks to analyze customer behavior. It investigates how the consumer's mental process influences the purchasing process. Another example is the paper titled Analysis of Consumer Coffee Brand Preferences Using Brain-Computer Interface and Deep Learning, written by M. Maram, M.A. Khalil, K. George et al. in [9]. This work focuses on the acquisition and analysis of EEG signals using a wireless device, where tools like MATLAB and Python in Google Colab are used to design an interface aimed at identifying coffee brand preferences through brain activity. A different case is the paper titled A Deep Learning Model for Classification of EEG written by S.M. Usman, S.M.A. Shah, O.C. Edo, J. Emakhu et al. in [10], where the study focuses on the use of EEG signals to classify product preferences by observing their packaging. Brain signals from 25 volunteers were monitored while they viewed different packages, using data analysis tools and machine learning models to automatically identify consumer preferences. Finally, there is the paper titled A Survey on Neuromarketing Using EEG Signals, written by V. Khurana, M. Gahalawat, P. Kumar, P.P. Roy, D.P. Dogra, E. Scheme, M. Soleymani et al. in [11], which explains how neuroscience uses tools like EEG. This technique is used to analyze brain activity during the consumer decision-making process. Electrodes are employed to measure brain waves, and analysis software is used to interpret the collected data, thus enabling an understanding of consumer preferences.

Once some relevant works are presented, the following section will present those that are most directly related to this

work, fulfilling similar objectives and/or analyses, these are:

i) *Motor Learning and Decision Making in Volatile Environment in Bipolar Disorder*,
ii) *On a Development of Sparse PCA Method for Face Recognition Problem*,
iii)*Prediction Using Support Vector Machine and Logistic Regression Model with Combination of PCA and SMOTE*,
iv)*Continuous Speech Recognition Based on DCNN-LSTM*.

A. Motor Learning and Decision Making in Volatile Environment in Bipolar Disorder

This study by M. Ivanova and M. H. Ruiz in [12] investigates how motor learning and decision-making in a volatile environment affect individuals with bipolar disorder. The hypothesis is that disruptions in learning in volatile environments may play a crucial role in the development and manifestation of bipolar disorder. The study compares patients with bipolar disorder to a control group of healthy individuals, using psychological tests and experimental tasks that simulate conditions of uncertainty. A neural network model is employed to analyze the data and seek patterns that relate motor learning to neurophysiological markers, aiming to improve the diagnosis and treatment of bipolar disorder. The diagram of this study can be seen in Fig. 2.

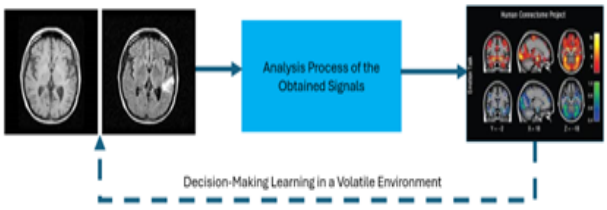

Fig. 2. Model diagram, motor learning and decision making in a volatile environment in bipolar disorder.

B. On a Development of Sparse PCA Method for Face Recognition Problem

This work by L. Tran and colleagues in [13], proposes an innovative semi-supervised learning method based on the unnormalized p-Laplacian graph for speech recognition. The method aims to improve the accuracy and performance of speech recognition through machine learning techniques and signal processing. A semi-supervised learning model is constructed using voice samples, and experiments are conducted to evaluate its effectiveness compared to other methods, achieving significant improvements in accuracy and performance, Fig. 3.

C. Prediction Using Support Vector Machine and Logistic Regression Model with Combination of PCA and SMOTE

This study conducted by O. P. Barus and colleagues in [14], focuses on the use of machine learning for liver disease prediction and facial recognition. In the first study, Logistic Regression (LR) and Support Vector Machine (SVM) algorithms are employed, along with PCA and SMOTE, to improve early and accurate detection of liver diseases. In the second study, advanced versions of sparse PCA are used to improve the accuracy of facial recognition, applying methods such as

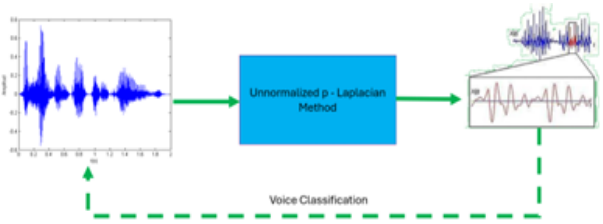

Fig. 3. Model diagram, on a development of sparse PCA method for face recognition problem.

Proximal Gradient Sparse PCA and Fast Iterative Shrinkage-Thresholding Algorithm Sparse PCA. Fig. 4 shows both studies combing clinical and facial data to achieve accurate and effective predictions.

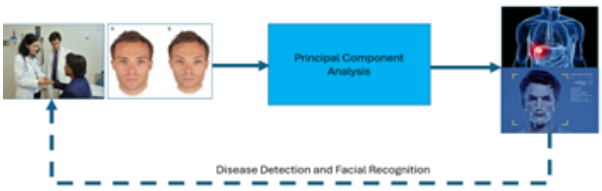

Fig. 4. Model diagram, prediction using support vector machine and logistic regression model with combination of PCA and SMOTE.

D. Continuous Speech Recognition Based on DCNN-LSTM

This work by Y. Zhu and Q. Zeng in [15], compares different acoustic features and network structures in automatic speech recognition. Using Mandarin datasets (THCHS-30 and ST-CMDS), the study extracts acoustic features such as the spectrogram and Mel cepstral coefficient (MFCC). Deep Convolutional Neural Networks (DCNN) and Long Short-Term Memory Neural Networks (LSTM) are evaluated, concluding that the spectrogram is the most effective feature and that LSTM networks significantly improve speech recognition accuracy compared to DCNNs. Fig. 5 depicts the combination of DCNN and LSTM results in a remarkable improvement in speech-to-text conversion.

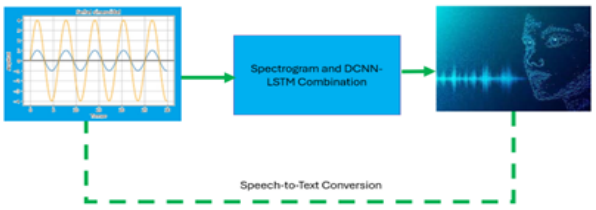

Fig. 5. Model diagram, continuous speech recognition based on DCNN-LSTM.

III. Theoretical Framework

A. Principal Component Analysis PCA

Principal Component Analysis (PCA) is a fundamental statistical technique used in multivariate data analysis. Its

objective is to transform a set of P correlated data into a new set of fewer and uncorrelated variables. PCA reduces the complexity of the original data, facilitating its interpretation and analysis, and allows for the identification of hidden patterns and structures within the data. The PCA method takes data described by k variables in an $n \times k$ matrix X, representing n subjects in a k-dimensional space, Eq. (1):

$$\mathbf{X} = \begin{bmatrix} x_{11} & x_{12} & \dots & x_{1k} \\ x_{21} & x_{22} & \dots & x_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ x_{n1} & x_{n2} & \dots & x_{nk} \end{bmatrix} \quad (1)$$

The new variables, or principal components, are generated through linear combinations of the original variables. The aim is for the first principal component to contain the maximum possible variance, while restricting the magnitude of its elements to avoid excessive variance. This process is repeated to find the subsequent principal components, ensuring that each new component is uncorrelated with the previous ones.

B. Electroencephalogram (EEG)

The Electroencephalogram (EEG) is a study that detects and records the electrical activity of the brain under different conditions, including the basal state and through activation methods such as hyperventilation and photostimulation. The electrical signal collected is amplified and represented in the form of lines that show the activity of various brain areas over time, a representation of this can be seen in the Fig. 6.

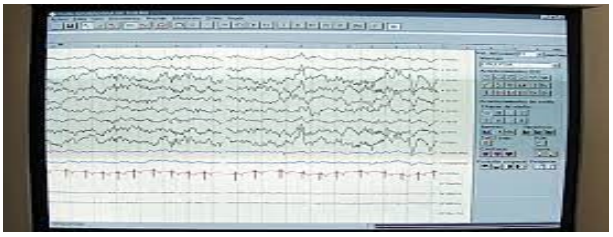

Fig. 6. Brain electrical signal.

The EEG monitors the electrical functioning of the brain and can detect both global alterations and changes in specific areas. It is useful for identifying various lesions such as tumors, hemorrhages, encephalitis, and trauma, Fig. 7.

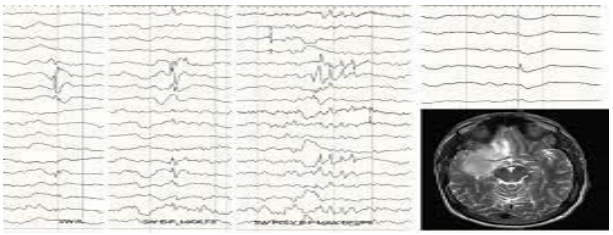

Fig. 7. EEG of a brain tumor.

C. Deep Learning Neural Networks

1) VGG16 Neural Network: The VGG16, Fig. 8, neural network is a deep convolutional network architecture developed by the Visual Geometry Group (VGG) at the University of Oxford. Used in computer vision tasks such as image recognition and classification, VGG16 is characterized by its 16-layer depth, divided into 13 convolutional layers and 3 fully connected layers.

a) Main features:

- Convolution Filters: Uses 3x3 filters with a fixed depth of 64 and 128 in its initial layers, followed by additional layers with more filters.
- Pooling Layers: Employs pooling layers with a 2x2 window to reduce dimensionality and extract prominent features.

The training of VGG16 follows the standard supervised learning approach, using labeled datasets and adjusting the network weights through backpropagation and optimization with stochastic gradient descent (SGD).

This is a complex architecture due to the fact that it consists of 16 training layers, where 13 are convolutional layers, using a 3x3 matrix for feature extraction, and 3 fully connected layers at the end, to reduce the dimensionality it has max pooling layers. At the input, it receives images of 224x224 pixels with three channels (RGB), and in the end, it has a softmax layer that allows for image classification.

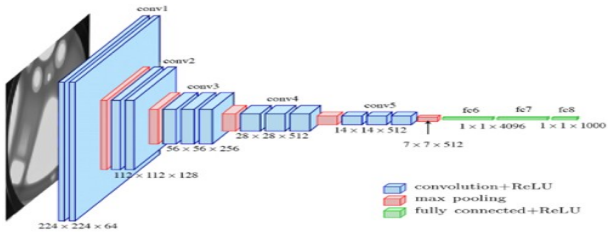

Fig. 8. VGG16 neural network architecture.

2) Inception Neural Network: The Inception neural network was created by Google Brain in 2014 to address the challenges of image classification in large and complex datasets. Its modular structure uses multiple convolutional layers and Inception modules, allowing the network to learn and extract features at different spatial scales within an image.

a) Main features:

- Inception Modules: They combine parallel convolutional operations with different filter sizes to capture information at different scales.
- Efficiency and Accuracy: The modular structure enables more efficient and accurate image classification.
- Text Recognition and Classification:Adapted for text processing tasks such as classification and sentiment analysis.

The training of the Inception network uses large labeled datasets and deep learning techniques, with a focus on optimization through stochastic gradient descent.

This architecture is composed of modules, meaning that instead of using a single convolutional operation, this architecture uses filters of different matrix types, which allows capturing various features at different scales within the same block. These results are combined, resulting in better characterization. Additionally, it uses dimensionality reduction layers to maintain efficiency, which makes it effective in applications with images.

3) AlexNet Neural Network: The AlexNet neural network, Fig. 9, is an architecture that marked a significant shift in the field of deep learning by significantly outperforming other architectures in image classification. Developed by Alex Krizhevsky, Ilya Sutskever, and Geoffrey Hinton, AlexNet consists of 5 convolutional layers and 3 fully connected layers.

a) Main features:

- Pooling Layers: It uses pooling layers to reduce dimensionality and prevent overfitting.
- Non-linear Activation Functions: It employs non-linear activation functions to accelerate training and prevent the vanishing gradient.

The training of AlexNet follows the supervised learning paradigm, using backpropagation and stochastic gradient descent on large datasets such as ImageNet.

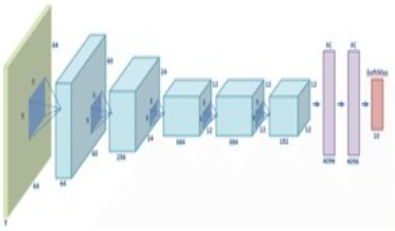

Fig. 9. AlexNet neural network architecture.

AlexNet is composed of a set of layers designed to extract spatial features at different levels. This architecture consists of 5 convolutional layers with large kernels that capture broad spatial patterns, followed by 3 fully connected layers that process and classify the learned features. Similarly, it incorporates max-pooling layers to reduce dimensionality and uses ReLU activation functions. Additionally, it includes mechanisms such as dropout to prevent overfitting during training.

4) ResNet Neural Network: The ResNet neural network was developed by Microsoft Research in 2015 to address the vanishing gradient problem and enable the training of much deeper models without performance degradation.

a) Main features:

- Residual Blocks: They include connections that allow information to flow directly through the layers, making it easier to train deep networks.

ResNet, Fig. 10, training follows the principles of supervised deep learning, using large labeled datasets and optimization via stochastic gradient descent.

The ResNet50 architecture is composed of residual blocks, meaning that instead of learning features directly, the layers

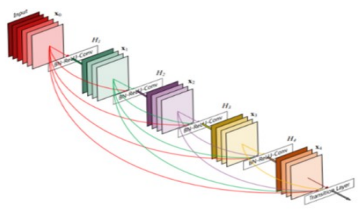

Fig. 10. ResNet neural network architecture.

focus on capturing the differences between the input and the output within each block. This is achieved through shortcut connections, which allow data to pass directly through the network without going through all intermediate layers. This architecture not only facilitates network training but also avoids issues like gradient vanishing. Thanks to this, it is widely used for processing images with high precision.

5) EfficientNet Neural Network: The EfficientNet neural network was developed by Google in 2019 to optimize the balance between accuracy and computational efficiency in image processing.

a) Main features:

- Compound Scaling: It optimizes the width, depth, and resolution of the network in a balanced manner using a method called Compound Scaling.

The training of EfficientNet uses labeled datasets and supervised learning techniques, adjusting the weights of the network through optimization algorithms such as stochastic gradient descent.

The EfficientNet architecture is designed to optimize efficiency in computer vision tasks, focusing on a single aspect. This architecture uses a compound scaling approach to uniformly scale the depth, width, and input resolution dimensions of the model, achieving a more comprehensive characterization of image features. It is based on modules that combine convolutional operations with dimensionality reduction techniques, achieving a balance between accuracy and computational efficiency.

6) You Only Look Once (YOLO) Algorithm: The YOLO algorithm stands out for its ability to detect objects in images quickly and accurately. Developed in 2016, YOLO approaches object detection as a simultaneous classification and bounding box regression problem.

a) Main features:

- Single-Pass Detection: It performs object detection in a single pass through the convolutional neural network.
- Multi-object predictions: It can detect multiple objects in an image, assigning a class probability to each bounding box.
- Real-Time: Its ability to perform real-time object detection makes it suitable for applications requiring rapid response.

The training of YOLO, Fig. 11, involves using labeled datasets and applying supervised learning techniques. The network is trained to recognize patterns and features of objects, adjusting the weights through backpropagation and optimization techniques.

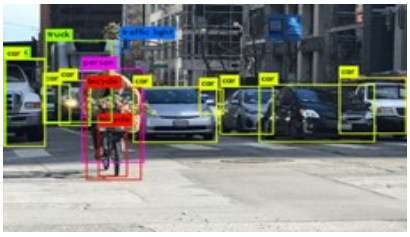

Fig. 11. Example of object detection with YOLO.

The YOLO architecture is designed for real-time object detection through the use of modules organized into blocks, where each block includes convolutional operations of various matrix sizes, allowing it to capture features at different scales within the same structure. These layers consist of max-pooling operations to reduce dimensions and preserve relevant features.

7) Data Augmentation: Data augmentation is a fundamental technique in machine learning and data processing. It involves creating new data samples by applying transformations to existing data while preserving the original information and label.

a) Applications and techniques:

- Image Augmentation: Rotations, flips, crops, changes in lighting, brightness and zoom, Fig. 12.

Fig. 12. Example of data augmentation on an image.

- Text Augmentation: Change of word order, synonyms, punctuation, and sentence structure, Fig. 13.

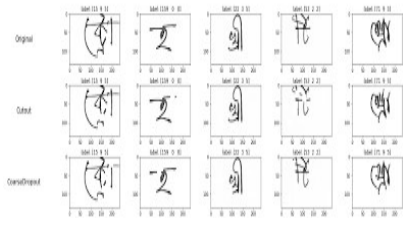

Fig. 13. Example of data augmentation in text.

- Audio Augmentation: Change of pitch, addition of noise, and variation of speed.

Data augmentation is applied before training the model to increase data variety and improve the model's predictive capability and robustness. There are various libraries in Python such as TensorFlow, Keras, PyTorch, and Augmentor that facilitate the implementation of these techniques.

IV. Method

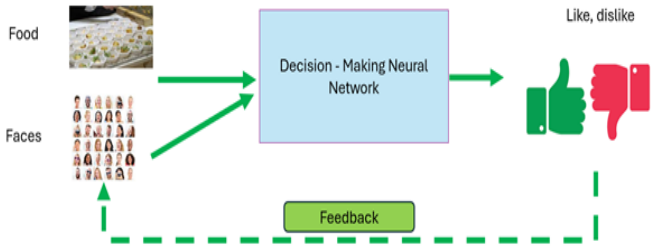

Fig. 14. General model of the system.

The decision-making system, Fig. 14, uses a neural network that analyzes images of food and the faces of consumers. This data enters a model that interprets the images to determine whether the food is considered "like" or "dislike" by the person. The model is self-correcting: if the interpretation does not match the expected outcome, it learns and adjusts its response.

A. Acquisition of the EEG Signal

The EEG signal measures the electrical activity during the excitation of pyramidal neurons in the cerebral cortex. This activity generates an electric and magnetic field, measurable with EEG systems through the skull and scalp, which attenuate the signal and add noise. The electrodes used to capture the EEG signal can be superficial, basal, or surgical. For this research, superficial electrodes are used, placed on the scalp following the International 10-20 Positioning System, based on anatomical points such as the inion, nasion, and lobes of the ears, this configuration does not generate any bias in decision-making.

For signal capture, the ThinkGear TGAM1 is used, which collects neural signals and processes them into usable data, filtering out interference. The NeuroSky ThinkGear module is a non-invasive interface with a 98% confidence level. However, due to noise levels, the device applies a reliable notch filter of 50Hz or 60Hz to reduce such noise. If not adequately filtered, it can affect the values of attention, meditation, and raw EEG data [16]. Additionally, signal loss through the scalp can impact the device's reliability. To address this, the module uses the poor quality code [16], which monitors electrode quality. If the connection with the scalp is suboptimal, this value increases to 200, indicating issues in signal acquisition, such as contact losses due to movement or incorrect placement.

The device is positioned at Fp1, as shown in Fig. 15, which measures electrical activity in the left frontal part of the brain, making it important for neurological diagnostics and scientific studies. Due to the fact that the Fp1 position is more directly associated with the person's emotional activity and attention,

it makes it a more relevant indicator for assessing emotional preferences in decision-making. On the other hand, the Fp2 position is not considered suitable for this study, as it is not as directly linked to the person's emotional regulation and attention, which would affect the result [17], therefore the Fp1 position is the most suitable for the study of decision-making.

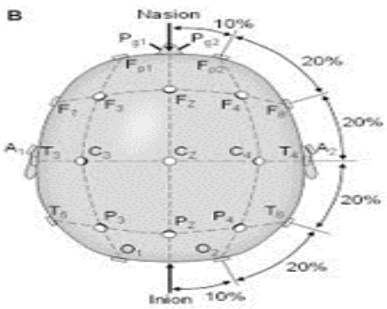

Fig. 15. Fp1 position.

B. The internal Model of the System

Internally, the model uses data reception from the products and the participants' faces to output classified and useful data. This helps to reduce dimensionality using Principal Component Analysis. Once reduced, we move to the next block where we extract data samples to send to the training model block. At the end of this process, the proposed model will indicate "like" or "dislike.", Fig. 16.

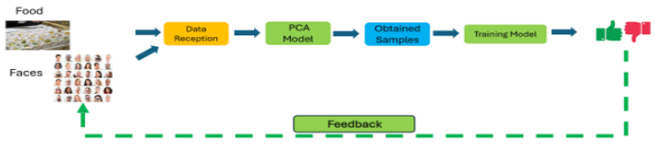

Fig. 16. Internal model of the system.

V. Experimental Results

A. Initial Configuration

The minimum requirements to run the model are as follows:

- Windows 10
- Intel Core i5
- 8.00 GB
- NeuroSky ThinkGear
- Google Colab
- Test Subjects

B. Results

C. Functionality Test

The functionality test is designed to demonstrate the use of the model, where the experiment is divided into faces and products.

1) Functionality Test of Products: As a first step, the file containing the images of the products and faces must be downloaded to train and test the model. In this case, the folder is named flavor.zip, Fig. 17. Additionally, the test image is loaded to verify that the data has been loaded correctly.

Fig. 17. Samples folder.

Once it is verified that the data has been loaded correctly, we proceed to build and train the neural network, thus providing the following model, which shows the convolutional and pooling layers, one example of this can be see in the Fig. 18.

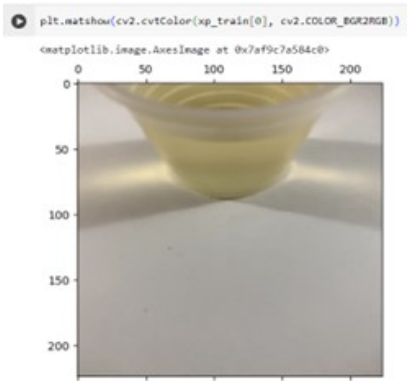

Fig. 18. Example of product samples.

For the case of the product experiment, we have the following inference matrix, which, as can be seen, classifies "like" and "dislike.", Fig. 19.

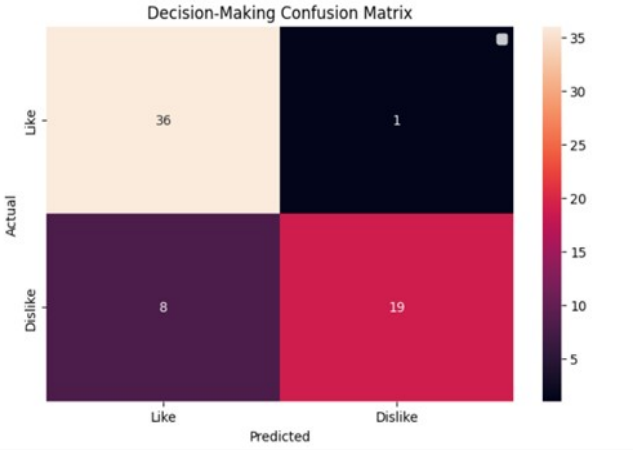

Fig. 19. Product inference matrix.

Similarly, for the case of the face experiment, we have the following inference matrix, which, as can be seen, classifies "like" and "dislike", Fig. 20.

As the final step, the inference matrix is shown with the combination of both experiments, resulting in the following outcome, Fig. 21.

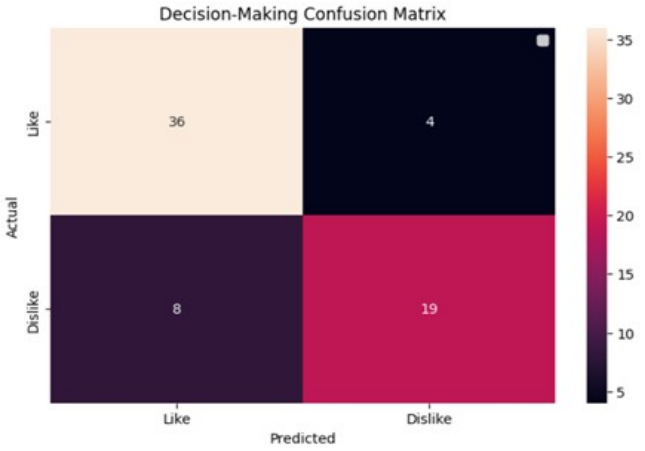

Fig. 20. Face inference matrix.

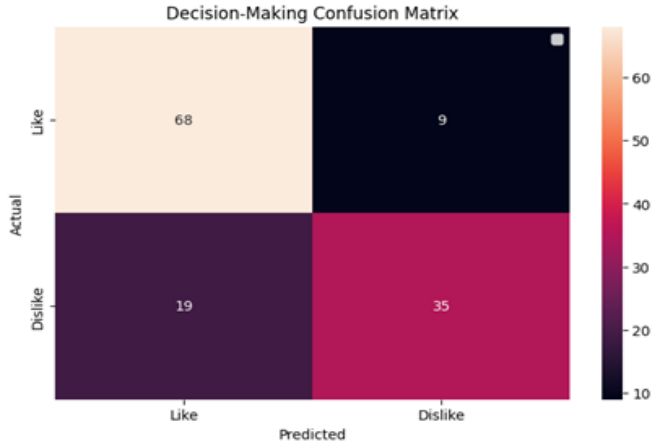

Fig. 21. Inference matrix of both experiments.

D. Experiment

To improve or observe changes in the percentage of effectiveness of the model, a series of experiments were implemented, using 5 variables that are part of the model. These are:

- Activation fuction of the model (A).
- Early Stopping during model training (B).
- Optimizer of the model (C).
- Sample size of images when entering the model (D).
- Amount of training data for the model (E).

The following the Table I, shows the aforementioned variables, along with their high and low values (or zero and one). It is worth noting that combinations of these variables were made to conduct possible tests, both in the Product model and in the Face model, resulting in two experiments.

Since both experiments use the same variables, the following hypothesis can be proposed:

TABLE I. VALUES OF THE VARIABLES TO ANALYZE

Variable	Low (0)	High (1)
Activation Fuction	ReLU	Leaky ReLU
Patience	5	10
Optimizer	ADAM	NADAM
Image Size	48	224
Batch Size	32	64

$$H_0: \quad A_i = 0; \quad B_i = 0; \quad C_i = 0; \quad D_i = 0; \quad E_i = 0;$$
$$H_1: \quad A_i \neq 0; \quad B_i \neq 0; \quad C_i \neq 0; \quad D_i \neq 0; \quad E_i \neq 0;$$

$$A_j \quad B_j \quad C_j \quad D_j \quad E_j$$

The results of both experiments are shown below

1) Product Experiment: The experiment is conducted using analysis of variance (ANOVA) for multiple factors on the F1 Score, Table II. Several tests and graphs are performed to determine which variables have a statistically significant effect on the F1 Score. It also evaluates the significance of interactions between variables, as long as sufficient data is available. Once the experiment is conducted, combining the variables to measure the outcome, the following results are obtained.

F1 SCORE HACER LO MISMO, duda en la pregunta

TABLE II. VARIANCE ANALYSIS F1 SCORE – TYPE III SUM OF SQUARES VALUES OF PRODUCTS

Source	P-Value
MAIN EFFECTS	
A: Activation Fuction	0.1560
B: Patience	0.0000
C: Optimizer	0.9295
D: Image Size	0.0038
E: Batch Size	0.0004

In the previous table, the results of the variance analysis are shown through a Type III sum of squares. The results indicate that both hypotheses A and C do not contribute to the outcome, and therefore, they are discarded.

$$H_0: \quad A_i = 0$$
$$H_0: \quad C_i = 0$$

Once the previous hypotheses are eliminated, the experiment is recalculated, where the following result is obtained, in the Table III.

TABLE III. VARIANCE ANALYSIS F1 SCORE – TYPE III SUM OF SQUARES OF SIGNIFICANT VARIABLES FOR PRODUCTS, SECOND EXPERIMENT

Source	P-Value
MAIN EFFECTS	
A: Patience	0.0000
B: Image Size	0.0038
C: Batch Size	0.0004

As can be seen in the table above, the remaining hypotheses do influence the experiment, which is why they are considered important. Once obtained, through the comparison of means, the value that effectively influences the percentage of effectiveness of the model can be observed, thus having the following results.

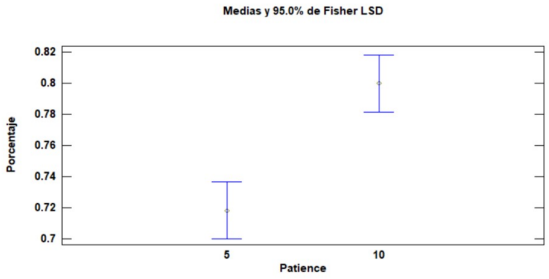

Fig. 22. Fisher LSD mean of the `Patience` variable for products.

This graph, Fig. 22, shows that the `patience` variable has a higher degree of confidence when its value is 10, as its representation is shifted to the right and separated from the other function.

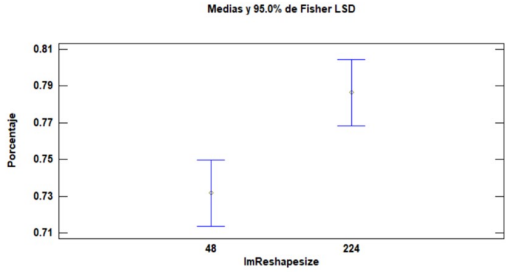

Fig. 23. Fisher LSD mean of the `ImReshapeSize` variable for products.

The previous graph, Fig. 23, shows that the `ImReshapeSize` variable has an effect on the experiment, with an image size of 224 being the most optimal.

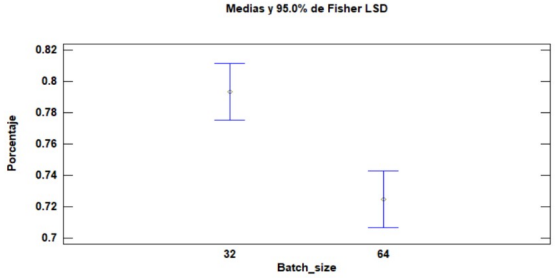

Fig. 24. Fisher LSD mean of the `Batch Size` variable for products.

Fig. 24 shows that the `BatchSize` variable has an effect on the experiment, with a value of 32 being the most optimal. This is because it is separated from the other value and is the first to represent the best option. The model uses a `Batchsize` of 32 and 64. With the applied statistical analysis, it is concluded that the value of 32 influences the model's performance more, particularly in the *Low-Beta*() and *Low-Gamma ()* frequency bands, while the value of 64 decreases the model's performance. As shown in Fig. 24, the value of 32 is above 64.

2) Faces Experiment: For this experiment, the same procedure is carried out as in the previous case, with the same variables and hypotheses.

TABLE IV. VARIANCE ANALYSIS F1 SCORE – TYPE III SUM OF SQUARES FOR FACES

Source	P-Value
MAIN EFFECTS	
A: Activation Fuction	0.0042
B: Patience	0.0019
C: Optimizer	0.4491
D: Image Size	0.8359
E: Batch Size	0.0012

In previous table, Table IV, the results of the analysis of variance are shown, through a Type III sum of squares, the results show that both hypothesis C and D do not contribute to the result, so they are discarded.

$$H_0: \quad C_i = 0$$
$$H_0: \quad D_i = 0$$

Once the previous hypotheses are eliminated, the experiment is recalculated, where the following result is obtained.

TABLE V. VARIANCE ANALYSIS F1 SCORE – TYPE III SUM OF SQUARES OF SIGNIFICANT VARIABLES FOR FACES.

Source	P-Value
MAIN EFFCETS	
A: Activation Fuction	0.0038
B: Patience	0.0017
C: Batch Size	0.0010

As seen in the previous table, Table V, the remaining hypotheses do influence the experiment, making them important. Once the results are obtained through the comparison of means, we can observe which value effectively impacts the model's effectiveness percentage, leading to the following outcomes.

The graph, Fig. 25,indicates that the ReLU `activation function` has a higher degree of confidence, as its representation is shifted to the right and separated from the other function.

The graph, Fig. 26, shows that the value of the `patience` variable has a higher degree of confidence when set to 10. This is because its representation is shifted to the right and separated from the other function.

The graph, shows that the `Batch Size` variable has an effect on the experiment, with a value of 32 being the most optimal, Fig. 27,this is because it is separated from the other value and is the first to represent the best option.

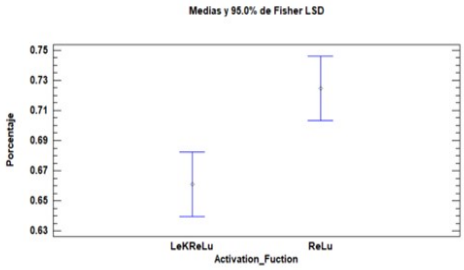

Fig. 25. Fisher LSD mean of the `Activation function` variable for faces.

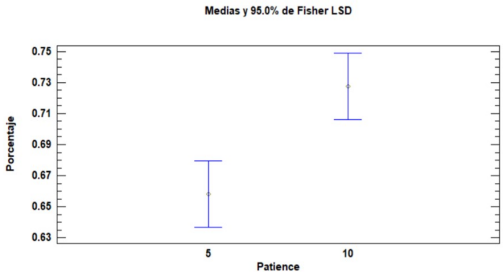

Fig. 26. Fisher LSD mean of the `Patience` variable for faces.

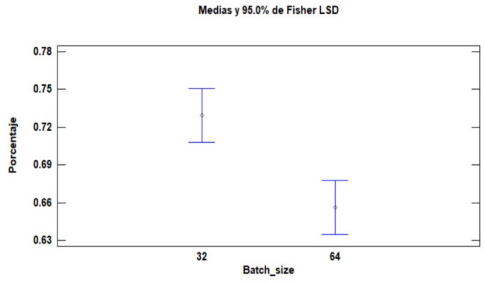

Fig. 27. Fisher LSD mean of the `Batch size` variable for faces.

E. Discussion

The two experiments have different training methods. One tests Products consumed by the subject, and the other tests the subject's Face. Both experiments use the same independent variables, but vary in the dependent variable. Using Statgraphics software, it was determined which variables influence each experiment. The following table, Table VI,shows these variables and their highest confidence values.

TABLE VI. VALUES OF THE VARIABLES FOR EACH EXPERIMENT

Products	Value	Faces	Value
Patience	10	Patience	10
ImReshapesize	224	Activation_Fuction	ReLu
Batch_size	32	Batch_size	32

The table indicates that both experiments share two variables with the same values: `Patience` (10) and `Batch_size` (32). `Patience` determines how many epochs the model can worsen before stopping, preventing overfitting. `Batch_size` is the number of training examples used by the network to update its weights, affecting the training process. In both cases, these values are essential for achieving 95% effectiveness.

Each experiment has a unique variable. In the Products experiment, `ImReshapesize` refers to the size of the image (224) input into the network. In the Faces experiment, `Activation_Fuction` is the mathematical function that determines the output of a neuron, with ReLU being the function used, which returns zero for negative values.

With the adjustment of hyperparameters such as the `ReLU` activation function, the `ADAM` optimizer, a `batchsize` of 32, and a `patience` of 10, while increasing the image size to 224, the model's accuracy was optimized. Additionally, the *Kolmogorov* complexity was reduced, which refers to the concept of algorithmic complexity that measures the amount of information required to describe or generate a dataset [18]. In other words, it is the length of the code used in the shortest program that can produce a given sequence of data as output, streamlining the model and decreasing its computational process [19]. By adjusting the hyperparameters and simplifying the data, the neural network was able to learn more efficiently, reducing the amount of information and the number of input data, thus becoming more agile in analyzing the image and EEG signals.

VI. CONCLUSIONS

In this work, 13 related studies were found concerning the use of decision-making, principal component analysis (PCA), and convolutional neural networks, of which 4 studies were selected for in-depth analysis. These studies were chosen for their connection to the use of convolutional neural networks and the methods they employ, with the main differences being in the decision-making aspect and target audience.

Furthermore, the theoretical foundations of the project were defined, integrating various convolutional neural networks used for different tasks, as well as knowledge about EEG, and lastly, techniques for more optimal data analysis were studied.

Additionally, the processes and subprocesses necessary for developing the decision-making model of whether I like it or not were presented. The three main processes were: i) Data collection through EEG and photographs, ii) Training the neural network with the collected data, and iii) Model functioning.

To verify the model's functionality, a series of experiments were designed with the interaction of 5 variables: a) ImReashepesize, b) Optimizer, c) Patience, d) Activation function, e) Batch size; experimentation was repeated with products and faces. The generated values for F1 Score and their combinations were examined through a Multifactorial Analysis of Variance. This analysis highlights that the two main variables influencing this model are patience and batch size, making the model more efficient.

Moreover, regarding the project's profitability, it is concluded that it is rejected, as the investment made for this project is not recovered, indicating that when not considering inflation, profitability decreases.

Therefore, this work contributes to the design of a neural network focused on decision-making in young people aged 18 to 20, contributing to the food and health sector by indicating whether a person likes what they consume, thus preventing overweight among these individuals.

As future work or derivations of this proposal, the following should be considered:

- Expand the target audience to include older adults and children of different ages.
- Improve the database by increasing its size with the participation of specialists.
- Design a new series of experiments that take into account other variables, such as Dropout, Epochs, etc.
- Implement the model in an IoT (Internet of Things) system.
- Combining Fp1, Fp2, O1, and O2 to create a brain mapping or qEEG analysis, which is an assessment tool used to measure electrical activity in the cerebral cortex. This map is then used to help diagnose mental health conditions by providing a statistical means of evaluating electrical activity in the cortex, [20].
- Expand the context of assistance to diseases such as diabetes or hypertension.

ACKNOWLEDGMENT

The Instituto Politécnico Nacional of Mexico, through the Comisión de Operación y Fomento de Actividades Académicas (COFAA) and SIP-projects No. *20241623* and *20241762*, has provided funding for this work. The research was carried out at the Escuela Superior de Ingeniera Mecánica y Eléctrica, Campus Zacatenco. It should be mentioned that this study is a crucial component of the doctoral dissertation titled *Modelo integral de Neuromarketing para innovar en las empresas del sector alimentario* supported by *Verónica Pérez*, under the supervision of Dr. Ana Coria and Dr. Jaime Moreno. Moreover, this research is also part of the master's thesis titled *Modelo sistémico para explicar el comportamiento de los consumidores durante la toma de decisiones, basado en inteligencia artificial*, guided by Dr. Oswaldo Morales and Dr. Jaime Moreno, and supported by Mauro Castillo.

Learning Local Reconstruction Errors for Face Forgery Detection

Haoyu Wu, Lingyun Leng, Peipeng Yu
College of Cyberspace Security, Jinan University, Guangzhou, China

***Abstract*—Although several deepfake detection technologies have achieved great detection accuracy inside the data domain in recent years, there are still limitations in cross-domain generalization. This is due to the model's ease of fitting the data sample distribution in the training data domain and its tendency to detect a specific forgery trace in order to reach a judgment rather than catching generalized forgery traces. In this paper, we propose to learn Local Reconstruction Errors for face forgery detection. The local anomaly traces of the fake face are often mapped using the original real face as a reference; however, the original real face of the fake face cannot be acquired in the real scenario. Therefore, this solution designs a local reconstruction autoencoder trained with real samples. By masking key areas of the face, the original real face can be reconstructed. Because the autoencoder only learns how to restore the essential parts of the real face using local patches of real samples, it cannot recover the forging traces or target face information in the fake face. Therefore, the reconstructed image forms a reconstructed difference with the original image. This solution aids the model in detecting local differences in fake faces by producing feature-level local difference attention mappings in the network's middle layer. A series of experiments demonstrate that this solution has good detection and generalization performance.**

***Keywords*—Face forgery; deepfake detection; local anomalies; generalized detection**

I. Introduction

With the rapid development of deep learning technology, deepfake technology has found widespread applications. By manipulating or replacing images or videos of faces, deepfake technology can alter visual content in subtle ways, posing significant threats to privacy, public opinion, and information security[1], [2], [3], [4]. Consequently, effectively detecting forged faces has become a crucial research topic in the field of computer vision.

Currently, there have been significant advancements in deepfake detection, with many methods performing well on forged data similar to their training datasets [5], [6], [7]. However, these methods often lack generalization when faced with unknown types of forgeries. Enhancing the generalization of detection models across various forgery methods is an urgent challenge. Our primary motivation is that there are notable differences between forged faces and their authentic counterparts (in terms of identity, artifacts, etc.). By leveraging these differences, we can accurately identify key areas of forgery rather than merely learning a single forgery pattern. Traditional methods either require reference images of the original faces or use self-attention mechanisms to predict key areas, both of which have significant limitations.

With the above considerations in mind, in this paper, we propose a local reconstruction-based deepfake detection method. By designing a local reconstruction autoencoder trained on real samples, we can mask and reconstruct critical regions of the face. The model generates a reconstruction difference map between the forged and real faces. Since the autoencoder cannot reconstruct the forgery traces in the forged face, this reconstruction difference map provides new discriminative information for forgery detection. Furthermore, we introduce a feature-level local difference attention map within the model to enhance the focus on forged regions. A series of experimental results demonstrate that this approach exhibits excellent detection performance and generalization capability across multiple datasets.In brief, our contributions are summarized as follows:

- We propose a novel detection framework based on local reconstruction for restoring genuine faces, which can eliminate artifacts in forged faces and guide the model to learn key regions.
- We introduce a local reconstruction autoencoder framework based on a key region masking algorithm, capable of restoring the original genuine face from local genuine patches.
- We present a method that uses local feature attention maps based on reconstructed image comparison to guide the detection model to focus on key regions and learn highly generalizable features.
- Our approach effectively enhances the generalization ability of the detection model on unknown datasets and against unknown forgery methods.

II. Related Work

A. Face Forgery Algorithms

Recent face forgery methods benefit from advances in deep learning. It can be classified into three categories based on the target of manipulation: face swapping, face editing, and face generation. In the early stages, researchers [3] viewed face swapping as a style transfer problem. Guided by facial landmark points, convolutional neural networks (CNNs) could transform one facial image into another, adopting the style of a face with a specific identity. However, with the rapid advancement of deep learning, several novel face swapping algorithms have emerged, significantly reducing the difficulty of face swapping [8], [9]. The progress of Generative Adversarial Networks (GANs) has further enhanced the realism of forged faces [10], [11], [12].

B. Face Forgery Detection Algorithms

Deepfake technology often produces noticeable artifacts when synthesizing or distorting facial features, such as unreasonable distortions of facial elements, edge artifacts, and missing details. Matern *et al.* [13] observed that certain Deepfake and Face2Face forgeries resulted in visual anomalies like differences in eye color, distorted facial contours, and missing tooth details. They aimed to detect these inconsistencies, but such artifacts only appear in lower-quality deepfake products, lacking universality. Nirkin *et al.* [14] proposed a method that segments detection images into internal (eyes, nose, mouth) and external (ears, hair) facial regions to train separate vectors for feature extraction. However, this approach does not adapt well to forgeries affecting external facial areas, resulting in limited generalization. Liu *et al.* [15] identified fundamental statistical differences in texture data between forged and real faces, leading to the development of a novel architecture for global texture representation to enhance the robustness of forgery detection. Chen *et al.* [16] used facial masking to detect whether images had undergone interference, reconstructing affected images to check for artifacts in the cleaned results. Dong *et al.*[17] approached this through image matching, proposing that forged images contain artifacts unrelated to the features of the original and target images. They designed a training set of matching images (forged, original, and target) to implicitly guide model learning, achieving good performance against compression. Wang *et al.* [18] developed a deepfake detection model focused on identifying potential noise traces, extracting features from both facial and background segments. They employed a novel multi-head contrastive interaction method to assess the similarity between facial and background noise features for image authenticity detection. Huang *et al.* [19] highlighted the differences between explicit and implicit identities in swapped images, introducing explicit identity contrast loss and implicit identity exploration loss to increase the distance between the explicit and implicit identities of fake faces, using this information for authenticity determination. However, Dong *et al.* [20] argued that focusing on identity information hinders the generalization of classification models, leading to a breakthrough with a method that prioritizes local features while ignoring overall identity information.

In summary, deepfake detection algorithms are designed to guide models in capturing specific artifact features, thereby identifying manipulated images by responding to these artifacts. Nevertheless, a common limitation of these methods is their often inadequate generalization capability when encountering previously unseen types of forgeries.

III. Methodology

A. Overview

The distribution of real human faces is consistent and uniform [21], while it is difficult for forged faces to completely eliminate all traces of artifacts, leading to a lack of continuity in the distribution of fake faces. Therefore this paper explores whether it is possible to design a method that constrains the model to learn key difference areas. A promising approach is to use the local differences between forged faces and their original faces, employing the original face to create an attention mask for the forged face. However, in most cases, the detection side cannot obtain the original face corresponding to the forged face. Thus, this paper attempts to reconstruct the distribution of the real face from the forged face to assist in detecting authenticity.

Based on the above concept, this paper proposes a deepfake detection scheme based on local reconstruction. As shown in Fig. 1, the scheme consists of two stages: (1) Training stage based on masked reconstruction of real samples. The content of a forged face typically originates from a source image and a target image, corresponding to its internal and external face, whereas a real image has a unified internal and external face. Therefore, this scheme pre-trains an encoder and decoder based on a Vision Transformer (ViT) using real face images. By randomly masking most facial features during face reconstruction, the encoder and decoder learn the distribution of real faces, acquiring the ability to recover the original real face information from partially masked real faces. (2) Training stage based on local difference attention map constraints. After training the encoder and decoder, their weights are fixed, and the to-be-detected image is masked and reconstructed to obtain a reconstructed image. Both the reconstructed image and the to-be-detected image are input into a fixed-weight feature extraction network to calculate multiple feature-level local difference attention maps. These attention maps are used to guide the model to learn key regional features for generalized detection.

B. Training Stage Based on Masked Reconstruction of Real Samples

The purpose of the training stage based on masked reconstruction of real samples is to train the encoder and decoder to learn the distribution of real face data, enabling the reconstruction of a complete real face image from local real face regions. Inspired by the MAE method, this scheme trains a ViT-based encoder and decoder structure using real faces with masked key facial regions. First, a face image of size $C \times H \times H$ is divided into N patches, each of size $C \times P \times P$, where $N = \frac{H^2}{P^2}$, and C, H, and P represent the number of image channels, the image's side length, and the patch's side length, respectively. Then, the proposed key region masking algorithm randomly masks patches in key facial regions, and the model learns to reconstruct the masked patches based on the remaining parts of the face image. The trained encoder and decoder learn the ability to recover the original real face information from local real face regions, allowing for effective reconstruction of the masked parts of a real face. When the encoder and decoder, trained solely on real face data, are used to perform masked reconstruction on a forged face, they can reconstruct the original real face from the genuine local regions of the forged face, but they will not restore the local forged artifacts in the fake face.

1) Key Region Masking Algorithm: Typically, the facial features, such as the eyes, nose, and mouth, are the key areas in forged faces. To ensure that the encoder and decoder learn to reconstruct the original face from real facial regions, and avoid reconstructing forged areas during fake face testing, this scheme defines a key region that includes facial features. As shown in Fig. 2, the proposed method first uses a landmark algorithm to extract the coordinates of 68 key facial points for all faces in the dataset. From these, it selects the coordinates

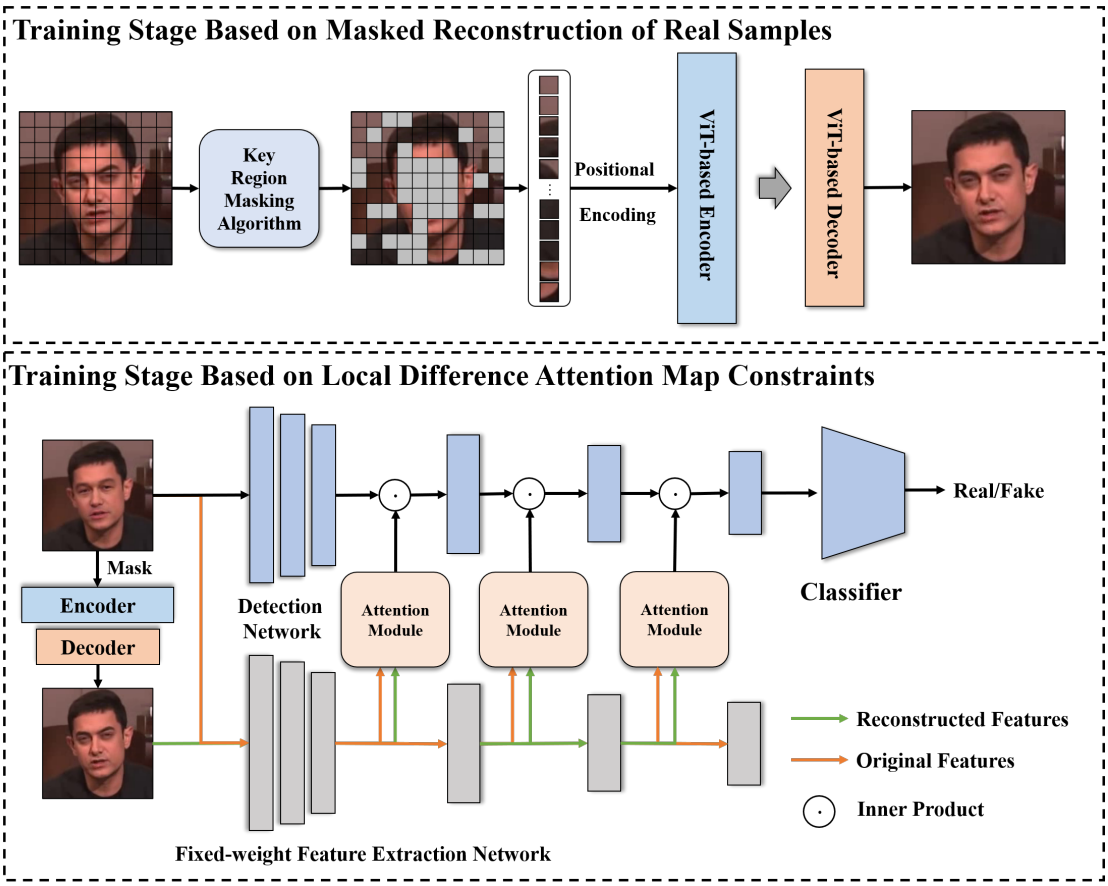

Fig. 1. Framework of local reconstruction-based deepfake detection algorithm.

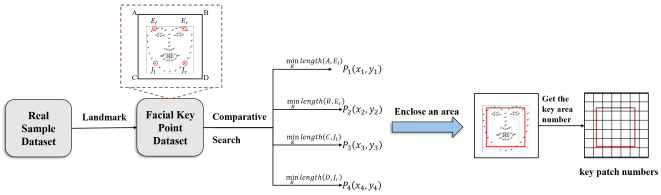

Fig. 2. Key area masking algorithm flowchart.

of the left eyebrow, right eyebrow, left jaw, and right jaw that are closest to the image vertices, denoted as P_1 , P_2, P_3, and P_4. The area enclosed by these points can cover the facial features of most faces in the dataset. Next, the four coordinates are expanded outward to form a rectangular region, which is defined as the key facial region. The face image is then divided into patches, where each small patch is assigned a number i, where $i \in \{1, 2, \ldots, N\}$. Based on the pixel coordinates of the key region, a set of key patch numbers, denoted as $T = \{45, 46 \ldots\}$, can be calculated, representing the patches included in the key region. Finally, random masking is applied to the image at a proportion of p, ensuring that most patches in the key patch set are masked. The sequence of unmasked patches is then fed into the encoder to reconstruct the original face image.

2) Face Reconstruction via Encoder and Decoder: The ViT-based encoder first receives the input sequence of unmasked patches and assigns a positional index to each unmasked patch. These patches are then passed through a series of Transformer blocks to learn the deep features of the real patch regions, which are used for subsequent face reconstruction. After undergoing a series of encoding processes, the encoder outputs the features of the unmasked patches. At this stage, the decoder takes these unmasked patch features as input and adds mask tokens to the masked areas to form a complete image, then applies positional encoding to all patch features. The mask tokens are shared, learnable vectors used to represent the masked patches that need to be reconstructed. Through a series of reconstruction processes within the decoder, the final linear layer of the decoder outputs a linear projection of the reconstructed image. After adjusting the dimensions and size, the reconstructed image is obtained. The reconstruction loss is then calculated only for the masked patches using mean squared error (MSE), with the loss expression as follows:

$$L_{rec} = \frac{1}{N} \sum_{i=1}^{n} (y_i - x_i)^2 \tag{1}$$

where x represents the reconstructed masked patches, and y represents the actual masked patches. By leveraging the information of masked patch indexes and calculating the reconstruction loss only for the masked patches, the computation is reduced, significantly improving the training efficiency of the

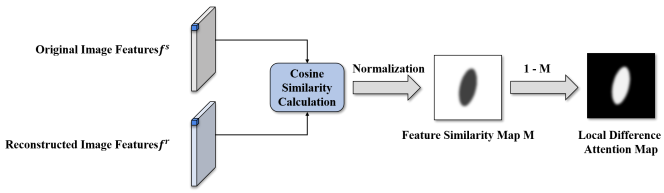

Fig. 3. Feature-Level local difference attention map calculation flowchart.

encoder and decoder.

C. Training Stage Based on Local Difference Attention Map Constraints

The training stage based on local difference attention map constraints aims to guide the model to learn the local differences in forged face images by calculating feature-level local difference attention maps between the reconstructed and original images. After the ViT-based encoder and decoder are trained on real face data, they have only acquired the knowledge of reconstructing local real facial regions. Therefore, this scheme fixes the parameters of the encoder and decoder and applies them during the training phase of the detection task. First, after dividing the face image into patches and masking the key regions, the unmasked patch sequence is input into the encoder-decoder framework to obtain the reconstructed face image. Next, a pre-trained feature extraction network with fixed parameters is used to extract a series of feature maps from the middle layers of the network for both the reconstructed face and the original face. Using similarity calculations, feature-level local difference attention maps are obtained. To ensure that the size of the feature-level local difference attention maps matches the feature maps in the middle layers of the detection network, both the feature extraction network and the detection network adopt the Xception architecture. The method for calculating the local difference attention map is shown in Fig. 3. This scheme uses cosine similarity to compute the similarity at each location between the original image features and the reconstructed image features. After normalizing the results, by subtracting the feature similarity map M from 1 to emphasize the difference regions, the final local difference attention map is obtained. The calculation expression is as follows:

$$AttentionMap_i = 1 - \frac{1 + CosineSimilarity(f_i^s, f_i^r)}{2} \quad (2)$$

where f^s and f^r represent the features of the original image and the reconstructed image, respectively, and $CosineSimilarity$ represents the cosine similarity calculation, which ranges from $[-1, 1]$. The higher the value, the more similar the two features are.

In the final classification prediction, this scheme uses the same network model as the feature extraction network described above as the basic framework, allowing the local difference attention map to guide the model in learning the key regional difference features. As shown in Fig. 1, the proposed method performs an inner product between the multiple feature maps of the original face image from the middle layers of the network and the local difference attention map, thereby constraining the model's learning process. Finally, the features extracted by the model are input into the classifier for real/fake classification, and binary cross-entropy (BCE) loss is used to constrain the training. The loss function is as follows:

$$L_{cls} = -\frac{1}{N}\sum_{k=1}^{n} y_k \log(x_k) + (1 - y_k)\log(1 - x_k) \quad (3)$$

where x represents the real/fake prediction, and y represents the real/fake label.

IV. EXPERIMENTS

A. Datasets

The experiments in this study utilize the following three datasets for testing and evaluation: FaceForensics++[30], Celeb-DF-v2[31], and the DFD dataset[32]. FaceForensics++ is a large public dataset for facial forgery detection, containing 1,000 real videos and 4,000 forged videos generated using four manipulation methods: Deepfakes, Face2Face, FaceSwap, and NeuralTextures. Additionally, FaceForensics++ includes three compression levels: the original version (C0), a high-quality version (C23), and a low-quality version (C40). Celeb-DF-v2 is a challenging dataset composed of 569 real videos and 5,639 forged videos extracted from YouTube. The DFD dataset is another large-scale dataset containing 363 real videos and 3,068 forged videos across various scenarios.

B. Experimental Setup

The experiments in this study are implemented using the PyTorch framework, with programming conducted in Python. The datasets are divided for training, validation, and testing of the detection model. OpenCV is used to extract a series of continuous, non-repeating video frames from videos at fixed intervals. The RetinaFace face recognition algorithm is employed to locate the face regions in the video frames, align these regions, and crop them appropriately. All face images are resized to a uniform dimension of 224×224 pixels. All experiments utilize the Adam optimizer for training, with a learning rate set to 0.0001 and a batch size of 32. The ViT-based encoder and decoder are trained for 300 epochs, with a masking ratio of 75%. The Xception-based feature extraction network and classifier are trained for 30 epochs, with 200 iterations per epoch. The training is conducted on

an NVIDIA GTX GeForce 3090 Ti platform with 24 GB of VRAM. Additionally, binary classification accuracy (Acc) and the area under the ROC curve (AUC) are used as performance evaluation metrics for the model.

C. In-Dataset Evaluation

This section tests the in-dataset detection performance of the proposed method on the FaceForensics++ (FF++) datasets, and compares it with other state-of-the-art methods. The proposed method is independently trained on and validated using the test sets of FF++(C23) and FF++(C40) datasets. The results are shown in Table I. It can be observed that, the proposed method achieves high test accuracy on the FF++(C23) datasets. The lower AUC performance on FF++(C40) may be attributed to the inconsistent quality of the original compressed images. During the training phase with real samples, the encoder and decoder did not incorporate lower-quality images for training, resulting in deviations and quality issues when reconstructing low-quality images.

D. Cross-Dataset Evaluation

1) Cross-Manipulation Method Evaluation: Cross-manipulation method evaluation is a significant approach to assess the generalization capability of detection methods, with important practical implications. This section conducts cross-testing of the proposed method across four different manipulation methods on the FF++(C23) dataset, with the results shown in Table II. It can be observed that the average performance across the four cross-tests exceeds 70%. In comparison with other advanced methods, the proposed approach, trained on the NT dataset, achieves a higher average AUC performance of 76.98% across the four manipulation methods, representing an improvement of 2% in detection performance. Additionally, the average test results from training on F2F reach 75.92%, with a gap of less than 1% compared to the higher performance of En-b4. The experimental data in the table demonstrate that the proposed method exhibits effective generalization across single-source manipulation methods, confirming the feasibility of this approach.

The aforementioned experiments demonstrate the generalization evaluation from a single manipulation domain to other domains. Additionally, there exists a method for evaluating generalization in multi-source forgery detection. This experiment utilizes three training sets from FF++ (excluding DF) for joint training and tests on DF, defined in the table as GID-DF. Similarly, the experiment trains on three other manipulation sets (excluding F2F) and tests on F2F. All test results are presented in Table III. For the DF tests, existing methods have reached a high performance level, with the proposed method closely following, showing an AUC performance difference of less than 7% from the state-of-the-art methods. Although there is a gap in AUC performance for GID-DF(C23) compared to the leading methods, the accuracy performance and results on the C40 version dataset remain outstanding, surpassing other existing advanced methods. Regarding the F2F tests, mainstream methods show subpar performance, while the proposed method achieves the best results, exceeding current advanced methods by 1% in AUC performance and 2% in accuracy performance, demonstrating improvements across different compression levels of F2F images. These experimental data strongly affirm the superiority of the proposed method in multi-source forgery detection.

2) Cross-Dataset Evaluation: This section evaluates the performance of the proposed method across different datasets. The method was trained on the FF++(C23) dataset and tested on the FF++(C23) library, Celeb-DF-v2, and DFD. The experimental results, as shown in Table IV, indicate that the method achieved the best AUC performance on the DFD dataset and demonstrated highly competitive performance on Celeb-DF-v2, surpassing most advanced methods with a gap of less than 5% compared to the state-of-the-art methods. This suggests that the proposed method exhibits good generalization capabilities across unknown datasets.

E. Ablation Study

As the proposed method is an integrated detection framework, it is not possible to conduct an ablation study on individual components or stages. Here, we present the comparative experimental results between the proposed method and the Xception-based classification baseline model. The baseline model was trained on FF++(C23) and tested for AUC performance on Celeb-DF-v2 and DFD. The testing results, as shown in Table V, indicate that the proposed method outperforms the baseline model on both Celeb-DF-v2 and DFD, demonstrating its effectiveness.

F. Visualization of Results

This section further demonstrates the reconstructed images generated by the autoencoder framework trained on real samples. As shown in Fig. 4, the similarity between the real image and the reconstructed image is very high for real face images. However, for forged images, which contain artifacts not present in real samples, reconstructing the forged images with masked key facial regions results in reconstructed images that do not retain the original forged information, leading to significant local differences compared to the original forged images. Additionally, since the encoder and decoder are capable of reconstructing real samples, the reconstructed facial features of the forged images tend to resemble those of the original

real faces, which is influenced by the training effect of the encoder and decoder on large amounts of real face data.

V. CONCLUSION

This paper proposes a deepfake detection algorithm based on local reconstruction, comprising two stages: the training stage based on masked reconstruction of real samples and the training stage based on local difference attention map constraints. There are local differences between forged faces and the original real faces, and attention maps generated from these local differences can guide the model to learn key forgery regions, shifting the model's focus from global to local features to improve detection performance. Previous methods either require the original real image as a reference or use self-attention mechanisms to predict key regions, both of which have significant limitations. In contrast, this method enhances practical applicability by using a local reconstruction approach to recover the original real face from local regions of real faces, aligning better with real-world scenarios. By

Fig. 4. Reconstruction results of real and forged images.

calculating feature-level local difference attention maps between the reconstructed and original images, the model is effectively constrained to learn the features of key forgery regions, further enhancing its ability to extract difference features. Extensive experiments demonstrate the effectiveness and reliability of this method in improving generalization performance. However, our local reconstruction method does not fully exploit the information available in forged faces and struggles with reconstructing low-quality faces. In future research, we aim to develop new algorithms that incorporate the identity information in forged faces to better recover the original real faces. In the future, leveraging local masking and reconstruction to restore real faces holds significant potential and valuable research implications for both generalized detection and proactive forensic analysis.

Integrated Detection and Tracking Framework for 3D Multi-Object Tracking in Vehicle-Infrastructure Cooperation

Tao Hu, Ping Wang, Xinhong Wang
College of Electronic and Information Engineering
Tongji University, Shanghai, China

***Abstract*—Vehicle-infrastructure cooperative perception has emerged as a promising approach to enhance 3D multi-object tracking by leveraging complementary data from vehicle and infrastructure sensors. However, existing methods face significant challenges, including difficulty in handling occlusions, suboptimal identity association, and inefficiencies in trajectory management, limiting their performance in real-world scenarios. In this paper, we propose a novel vehicle-infrastructure cooperative 3D multi-object tracking framework that addresses these challenges through three key innovations. First, an integrated detection-tracking framework jointly optimizes object detection and tracking, enhancing temporal consistency and reducing errors caused by separately handling the two tasks. Second, the XIOU identity association metric leverages 3D spatial and geometric relationships, ensuring robust object matching even under occlusions. Third, a four-stage cascade matching (FSCM) strategy adaptively manages trajectories by leveraging detection and prediction confidences, enabling accurate tracking in complex environments. Evaluated on the V2X-Seq dataset, our method achieves a MOTA of 57.23 and a MOTP of 74.64, significantly reducing identity switches while ensuring low bandwidth consumption and reliable tracking, highlighting its effectiveness and suitability for real-world deployment.**

***Keywords*—Vehicle-infrastructure cooperative perception; 3D multi-object tracking; XIOU metric; four-stage cascade matching; integrated detection-tracking framework**

I. Introduction

In recent years, while single-vehicle perception for autonomous driving has achieved notable advancements, *vehicle-infrastructure cooperative perception* has emerged as a transformative alternative. By integrating data from infrastructure-side sensors, this approach overcomes the inherent limitations of vehicle-only systems, such as limited perception range, blind spots, and lower detection confidence. It extends perception capabilities, enhances detection accuracy, and improves system reliability, positioning itself as a critical research focus in modern autonomous driving.

A cornerstone of vehicle-infrastructure cooperative perception is *3D multi-object tracking (MOT)*, which ensures temporal consistency by tracking objects across consecutive frames. Accurate 3D MOT is pivotal for downstream tasks like trajectory prediction and collision avoidance, directly contributing to the safety and effectiveness of autonomous driving systems. The objective is to accurately localize objects in 3D space while consistently maintaining their identities over time.

However, despite advancements in cooperative perception, 3D MOT methods still encounter significant challenges:

1) Insufficient Interaction Between Detection and Tracking: Many existing methods treat detection and tracking as separate processes, often relying on the *Tracking-by-Detection* paradigm. This limits the mutual enhancement between detection and tracking, as detection results are primarily optimized for tracking while failing to incorporate the valuable priors that tracking can provide for detection—an essential aspect for temporal consistency in dynamic environments.
2) Insufficient Utilization of 3D Spatial Information: Current methods often adapt 2D identity association techniques to 3D scenarios without fully harnessing the spatial richness of 3D point clouds. This limitation is particularly pronounced in vehicle-infrastructure cooperative contexts, where precise spatial alignment and 3D pose estimation are key for robust identity association.
3) Challenges in Occlusion Handling: Occlusion is a common occurrence in real-world autonomous driving scenarios, yet existing methods struggle to maintain consistent object identities when visibility is compromised. Effective mechanisms to handle occlusion and manage identity switches during visibility transitions remain underdeveloped.

These limitations underscore the need for more integrated, adaptive, and robust approaches to 3D MOT in vehicle-infrastructure cooperative scenarios. To address these challenges, we propose a novel *vehicle-infrastructure cooperative 3D multi-object tracking algorithm* based on an integrated detection and tracking architecture. By leveraging LiDAR point cloud data from both vehicle and infrastructure sources, our method provides a more accurate and real-time solution for 3D object detection and tracking. Specifically, it introduces the following key innovations:

1) Integrated Detection and Tracking Framework: We propose a fully integrated architecture that processes detection and tracking in a unified manner. By employing position encoding and cross-attention mechanisms, the framework seamlessly combines appearance and motion cues. Additionally, a temporal prior enhancement module is introduced, allowing tracking results to inform the detection process, leveraging

temporal priors to improve detection accuracy.

2) 3D-Task Adaptive Identity Association: Our method takes full advantage of 3D spatial pose information from LiDAR point clouds. We introduce a new identity association metric that accounts for spatial overlap, positional similarity, and orientation alignment, enabling robust object matching over time in 3D space.
3) Occlusion-Adaptive Matching Algorithm: We present a four-stage cascade matching algorithm that dynamically adjusts the tracking process based on the confidence levels of detection and prediction results. This strategy ensures robust tracking during occlusion events, effectively maintaining object identities even when objects are partially or fully hidden from view.

The remainder of this paper is organized as follows: Section II reviews related work, discussing existing approaches to vehicle-infrastructure cooperative 3D perception. Section III describes the proposed integrated detection and tracking framework in detail. Section IV outlines the experimental setup and results, covering datasets, evaluation metrics, and comprehensive analyses. Section V concludes the paper with final remarks and future research directions.

II. Related Work

This section discusses recent developments in *vehicle-infrastructure cooperative perception* and *multi-object tracking (MOT)*, both critical for improving autonomous driving systems.

A. Vehicle-Infrastructure Cooperative Perception

Cooperative perception enhances the perception capabilities of individual vehicles by integrating data from infrastructure-based sensors. It can be categorized into three main types based on the shared data:

1) Data-Level Cooperation: In data-level cooperation, raw sensor data such as LiDAR point clouds are directly shared between vehicles and infrastructure [1], [14], [29]. This approach allows vehicles to expand their perception range significantly by receiving unprocessed sensor data from other sources. However, the substantial data transmission requirements place a significant burden on network bandwidth.

2) Feature-Level Cooperation: Feature-level cooperation involves sharing pre-processed feature data, reducing the transmission load while retaining more information than object-level cooperation [17], [6], [5]. The performance of feature-level cooperation depends heavily on the feature fusion strategies employed, balancing between bandwidth savings and the amount of retained information.

3) Object-Level Cooperation: In object-level cooperation, only the final detection results are shared, minimizing the data transmission burden but potentially leading to information loss [24]. This method relies heavily on the accuracy and robustness of the individual perception models used on each vehicle and infrastructure component.

The emergence of large-scale cooperative perception datasets, both in simulation and real-world environments, has greatly advanced research in this domain. Notable examples include *V2X-Sim* [10], *DAIR-V2X-C* [24], and *V2X-Seq* [25], with *V2X-Seq* standing out as the first real-world dataset for vehicle-infrastructure sequential perception. These datasets provide comprehensive data for 3D object detection and tracking tasks, offering a foundation for further research in cooperative perception.

B. Multi-Object Tracking

In cooperative perception, *multi-object tracking (MOT)* plays a critical role in maintaining object identities over time by associating detected objects across frames, forming a temporal understanding of their movement. MOT is crucial for downstream tasks such as trajectory prediction and collision avoidance in autonomous driving. The process typically involves three main stages: object detection and feature representation, identity association, and trajectory management.

1) Object Detection and Feature Representation: This stage handles the initial detection and feature extraction from sensory data, which is critical for tracking objects across time. Traditionally, these tasks have been performed separately, with detection followed by feature extraction. One prominent example of this approach is *DeepSort* [19], which uses a Kalman filter for motion modeling and a deep learning-based appearance descriptor for object re-identification, offering a robust solution for tracking objects across frames while maintaining their identities. Recent methods, such as *OmniTracker* [16], focus on exploring the interplay between detection and tracking and transferring this relationship to various tracking tasks. This separation allows for independent optimization of detection and tracking, but it may lead to redundant computations.

Joint detection and feature representation, on the other hand, combines detection and tracking into a single network, improving the efficiency of multi-object tracking. Popular methods like *FairMOT* [27] and *TransTrack* [15] employ joint architectures where object detection and feature extraction are performed simultaneously, reducing the computational overhead while improving feature consistency. *TransMOT* [4] introduces a spatio-temporal graph transformer for encoding short trajectories and matching them across frames using a spatial graph decoder. Additionally, *UTM* [23] simultaneously enhances object detection and feature representation using identity-sensitive knowledge. Despite these advancements, challenges remain, especially in 3D multi-object tracking, where integrating motion cues and spatial information from point cloud data requires sophisticated handling of dynamic environments.

2) Identity Association: Identity association is critical for tracking objects across multiple frames and ensuring that each object maintains a consistent identity. Various metrics have been proposed to perform this association. Early works such as *AB3DMOT* [18] rely on simple intersection-over-union (IoU) metrics to associate objects between frames. However, this method struggles with occlusions and complex 3D environments. Recent researches such as Chiu et al. [3] and *CenterPoint* [22] improve identity association by replacing traditional IoU with more sophisticated metrics like Mahalanobis and L2 distance. These metrics help capture both spatial overlap and the underlying distribution of data points, enhancing tracking accuracy, especially in complex 3D environments where simple IoU metrics may struggle.

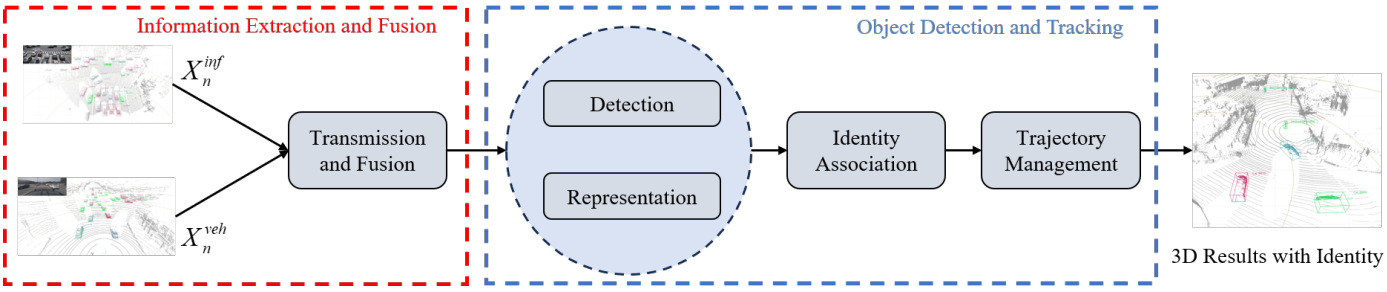

Fig. 1. The temporal perception process in vehicle-infrastructure cooperative sensing: The process comprises two main parts: data fusion and object detection-tracking, producing a 3D perception output with identity information.

Advanced association methods have been developed to handle more complex scenarios. *C-BIoU* [21] improves traditional IoU-based matching by introducing a buffer region around the bounding boxes, enhancing matching accuracy under occlusion. *EagerMOT* [7] incorporates velocity and directionality into the association process, leveraging motion cues to improve association reliability. Another advanced metric, *DIoU* [28], introduces distance and aspect ratio terms into the IoU calculation, improving matching accuracy in 2D scenarios. These identity association techniques aim to reduce false positives and increase the robustness of tracking in dynamic environments where objects may be occluded or exhibit erratic movement.

3) Trajectory Management: The final stage of MOT involves managing the trajectories of objects across frames. The goal is to maintain accurate object tracks while adding, updating, or removing object trajectories as necessary. Early methods such as *SORT* [2] use a simple bipartite graph matching approach to link detected objects between consecutive frames. This method provides a fast and efficient solution but is limited in handling occlusions and long-term tracking.

More advanced techniques, such as *DeepSort* [19], use a cascade matching strategy where recently updated trajectories are prioritized during the matching process, allowing for better handling of short-term occlusions. *ByteTrack* [26] takes this approach further by splitting detections into high and low-confidence categories, first matching high-confidence detections with tracked objects, and then using low-confidence detections to match occluded objects. This technique improves the continuity of object trajectories during occlusions. Recent methods like *SimpleTrack* [12] adapt ByteTrack's methodology to 3D tracking tasks, introducing confidence-based updates to better handle occlusion in real-world environments. Another recent method, *SimTrack* [11], criticizes the heuristic matching approach of earlier methods, arguing that it relies too heavily on manual tuning. Instead, *SimTrack* proposes using a confidence-weighted matching strategy between the predicted object locations and the detected objects, simplifying the tracking process while improving robustness. These trajectory management strategies aim to maintain object continuity across time, especially when objects undergo occlusions or disappear from the field of view temporarily.

Despite the progress made, several challenges remain in multi-object tracking, especially in 3D environments where spatial and temporal dynamics are more complex. One major limitation is the failure to fully integrate the strengths of both object detection and tracking, which are often treated as independent tasks. Furthermore, current 3D identity association metrics do not make full use of the precise pose information available in point clouds, hindering matching accuracy. Moreover, cross-frame matching strategies fail to leverage both detection and prediction dimensions to fully explore and maintain object identity, particularly in complex and dynamic environments. These gaps highlight areas for further research and improvement.

III. Methodology

In the case where the vehicle and infrastructure sensors collect data at consistent frequencies, the input for the vehicle-infrastructure cooperative 3D multi-object tracking task can be described in two parts:

1. The infrastructure-side sensor data sequence $\mathbf{S}^{\text{inf}}$, as shown in Eq. (1), where $\mathbf{X}_n^{\text{inf}}$ represents the infrastructure sensor data from the n-th pair of vehicle-infrastructure matched data. The corresponding timestamp sequence for the infrastructure data is denoted as $\mathbf{T}^{\text{inf}}$, as shown in Eq. (2).

$$\mathbf{S}^{\text{inf}} = \{\mathbf{X}_n^{\text{inf}}\}_{n=1}^{N} \tag{1}$$

$$\mathbf{T}^{\text{inf}} = \{t_n^{\text{inf}}\}_{n=1}^{N} \tag{2}$$

2. The vehicle-side sensor data sequence $\mathbf{S}^{\text{veh}}$, as shown in Eq. (3), where $\mathbf{X}_n^{\text{veh}}$ represents the vehicle sensor data from the n-th pair of vehicle-infrastructure matched data. The corresponding timestamp sequence for the vehicle data is denoted as $\mathbf{T}^{\text{veh}}$, as shown in Eq. (4).

$$\mathbf{S}^{\text{veh}} = \{\mathbf{X}_n^{\text{veh}}\}_{n=1}^{N} \tag{3}$$

$$\mathbf{T}^{\text{veh}} = \{t_n^{\text{veh}}\}_{n=1}^{N} \tag{4}$$

As shown in Fig. 1, the vehicle-infrastructure cooperative 3D multi-object tracking process is composed of two main parts: information extraction and fusion, and object detection and tracking. These are further divided into four stages:

- Data Transmission and Fusion: This stage involves pre-processing vehicle and infrastructure point cloud data. The data is transmitted over limited bandwidth

to the vehicle side, where it is fused with the vehicle's sensor data.

- Object Detection and Feature Representation: This stage detects 3D objects from the fused sensor data and represents the temporal variations in the object features.
- Identity Association: The system builds a unified identity association benchmark for objects across frames based on their features. A cost matrix is generated to match objects across frames.
- Trajectory Management: Based on the cost matrix from identity association, the system performs matching between detected objects and existing tracks. It also handles adding, deleting, and updating tracks, ultimately producing a unified 3D spatiotemporal perception result with identity information.

A. Data Transmission and Fusion Using the FF-Tracking Framework

This section leverages the FF-Tracking [25] framework as outlined in *V2X-Seq*. The **Data Transmission and Fusion** process, as illustrated in Fig. 2, is designed to facilitate sensor data exchange between the vehicle and infrastructure under limited bandwidth conditions.

1) Infrastructure Side: On the infrastructure side, sensor data at timestamp t_n^{inf} is processed through the Pillar Feature Network (PFNet) [9] to extract BEV (Bird's Eye View) features. The extracted BEV feature map is represented as:

$$\mathbf{F}_n^{\text{inf}} = \text{PFNet}(\mathbf{X}_n^{\text{inf}}), \tag{5}$$

where $\mathbf{X}_n^{\text{inf}}$ is the raw point cloud data from the infrastructure sensors, and $\mathbf{F}_n^{\text{inf}}$ is the BEV feature extracted at time t_n^{inf}.

Next, a Feature Flow Generator is employed to capture the temporal dynamics between consecutive infrastructure frames. Given the BEV feature map from the current timestamp t_n^{inf} and the previous timestamp t_{n-1}^{inf}, the feature flow $\mathbf{F}_n^{\text{flow}}$ is computed as:

$$\mathbf{F}_n^{\text{flow}} = \text{FlowGenerator}(\mathbf{F}_n^{\text{inf}}, \mathbf{F}_{n-1}^{\text{inf}}), \tag{6}$$

where the *FlowGenerator* module is built with two Backbone-FPN structures, one branch generates static features $\mathbf{F}^{\text{static}}$, and the other branch generates the feature derivative $\mathbf{F}^{\text{deriv}}$. This module computes the temporal differences between the two frames, capturing how the scene evolves over time. The feature flow is compressed using a convolutional layer to reduce bandwidth requirements:

$$\mathbf{F}_n^{\text{comp}} = \text{Conv}(\mathbf{F}_n^{\text{flow}}), \tag{7}$$

where $\mathbf{F}_n^{\text{comp}}$ represents the compressed feature flow ready for transmission.

2) Vehicle Side: Once the infrastructure-side compressed feature flow $\mathbf{F}_n^{\text{comp}}$ is transmitted to the vehicle side, it undergoes Deconvolution to reconstruct the infrastructure features at the vehicle's side:

$$\mathbf{F}_n^{\text{rec}} = \text{Deconv}(\mathbf{F}_n^{\text{comp}}), \tag{8}$$

where $\mathbf{F}_n^{\text{rec}}$ denotes the reconstructed feature map, which can be divided into two parts: one part represents the static feature $\mathbf{F}_n^{\text{static}}$, and the other part represents the feature derivative $\mathbf{F}_n^{\text{deriv}}$.

Next, the vehicle aligns the reconstructed infrastructure features to its own current timestamp t_n^{veh} using the Prediction and Affine Transform module. This module compensates for temporal misalignment between the infrastructure and vehicle data:

$$\mathbf{F}_n^{\text{align}} = \text{AffineTransform}(\mathbf{F}_n^{\text{static}} + (t_n^{\text{veh}} - t_n^{\text{inf}}) \cdot \mathbf{F}_n^{\text{deriv}}), \tag{9}$$

where $\mathbf{F}_n^{\text{align}}$ represents the aligned infrastructure features in the vehicle's frame of reference.

Simultaneously, the vehicle extracts its own features $\mathbf{F}_n^{\text{veh}}$ from its sensor data $\mathbf{X}_n^{\text{veh}}$:

$$\mathbf{F}_n^{\text{veh}} = \text{FeatureExtractor}(\mathbf{X}_n^{\text{veh}}). \tag{10}$$

Finally, the vehicle-side features and the aligned infrastructure features are concatenated and convolved to form the fused feature map $\mathbf{F}_n^{\text{fused}}$:

$$\mathbf{F}_n^{\text{fused}} = \text{Conv}(\text{Concat}(\mathbf{F}_n^{\text{veh}}, \mathbf{F}_n^{\text{align}})). \tag{11}$$

This fused feature map, containing both vehicle-side and infrastructure-side data, is passed to the detection and tracking modules for further processing.

B. Integrated Object Detection and Tracking

In this section, we describe the proposed integrated object detection and tracking framework, utilizing a Deformable DETR-based architecture for both encoding and decoding stages, as shown in Fig. 3. The architecture is composed of the following core components: **Temporal Prior Enhancement**, **Encoder**, and two parallel branches for **Object Detection** and **Object Prediction**.

1) Temporal Prior Enhancement: The input to the Temporal Prior Enhancement module consists of the fused feature maps from two consecutive frames, $\mathbf{F}_n^{\text{fused}}$ and $\mathbf{F}_{n-1}^{\text{fused}}$. To save computational resources, the fused feature map from the previous frame is stored and used in the next frame for prior enhancement. The previous frame's fused feature map, $\mathbf{F}_{n-1}^{\text{fused}}$, is downsampled and serves as the keys ($\mathbf{K}$) and values ($\mathbf{V}$) for the cross-attention mechanism. The current frame's fused feature map, $\mathbf{F}_n^{\text{fused}}$, is used as the queries ($\mathbf{Q}$).

The cross-attention mechanism computes the weighted combination of the features as follows:

$$\text{Attention}(\mathbf{Q}, \mathbf{K}, \mathbf{V}) = \text{softmax}\left(\frac{\mathbf{Q}\mathbf{K}^T}{\sqrt{d_k}}\right)\mathbf{V}, \tag{12}$$

where $\mathbf{Q} = \mathbf{F}_n^{\text{fused}}$ is the query from the current frame, and $\mathbf{K}$, $\mathbf{V} = \mathbf{F}_{n-1}^{\text{fused}}$ are the key and value from the previous frame. The term d_k represents the dimension of the key, which is used to scale the dot product between the query and key to prevent the result from becoming too large. After cross-attention, the resulting feature map undergoes further refinement through a Multilayer Perceptron (MLP) for introducing non-linearity and enhancing the model's capacity to capture complex relationships in the data:

$$\mathbf{F}_n^{\text{enhanced}} = \text{MLP}(\text{Attention}(\mathbf{F}_n^{\text{fused}}, \mathbf{F}_{n-1}^{\text{fused}})). \tag{13}$$

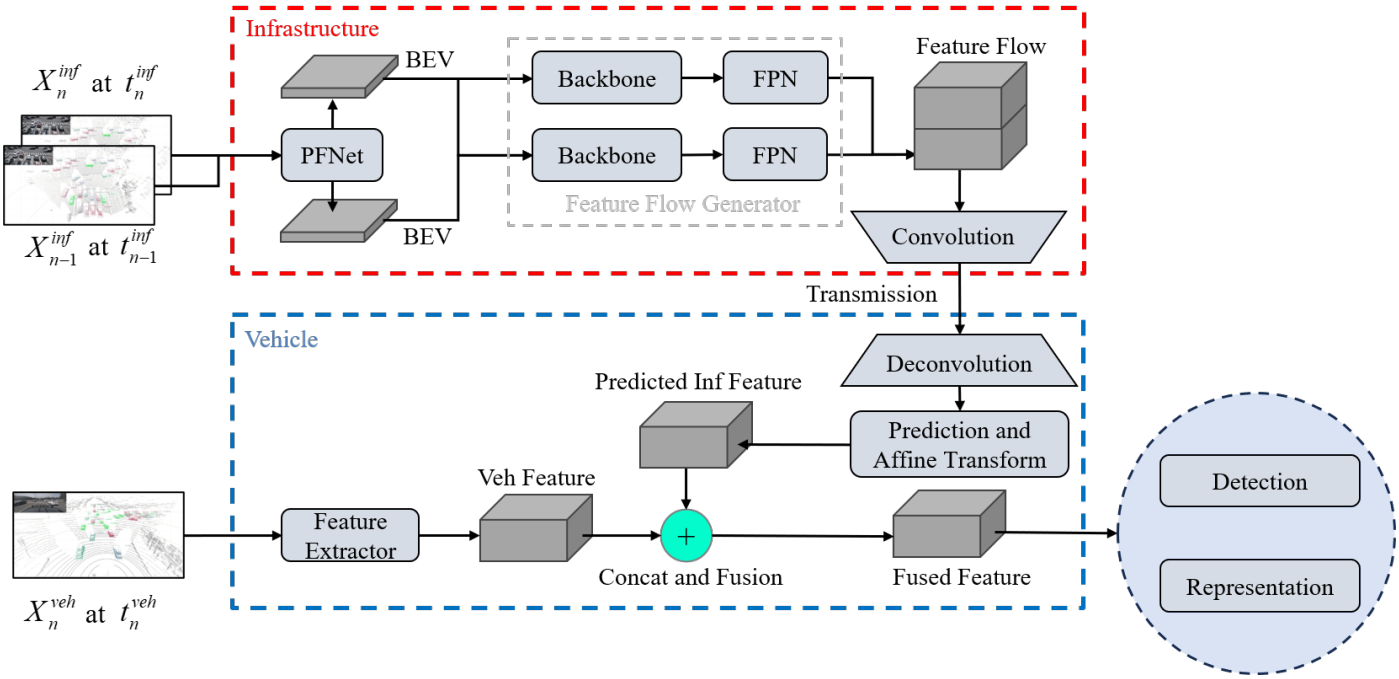

Fig. 2. The architecture of the data transmission and fusion module using the FF-Tracking framework. Infrastructure-side features are compressed and transmitted to the vehicle, where they are deconvolved, temporally and spatially aligned, and fused with vehicle-side data.

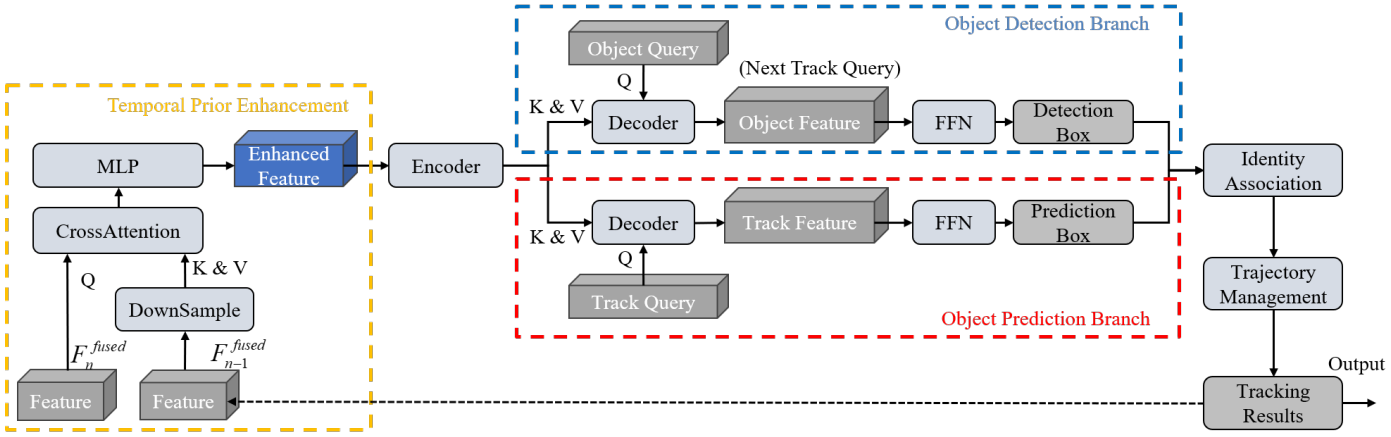

Fig. 3. The overall architecture for integrated object detection and tracking using deformable DETR. The process includes temporal prior enhancement, encoding, and two parallel branches for object detection and prediction, which jointly contribute to tracking results.

The output is the enhanced feature map $\mathbf{F}_n^{\text{enhanced}}$, which integrates temporal information from the previous frame to improve the accuracy and stability of detection and tracking in the current frame.

2) Encoder: The enhanced feature $\mathbf{F}_n^{\text{enhanced}}$ is passed to a Deformable DETR Encoder [30], which applies deformable attention over a set of reference points $\mathbf{P}$ distributed across the feature map. These reference points guide the attention mechanism, allowing it to focus on relevant regions, which is particularly suitable for sparse input data like point clouds:

$$\mathbf{Z}_n^{\text{enc}} = \text{DeformableAttention}(\mathbf{F}_n^{\text{enhanced}}, \mathbf{K}, \mathbf{V}, \mathbf{P}), \quad (14)$$

where $\mathbf{Z}_n^{\text{enc}}$ is the output of the encoder, and $\mathbf{K}$, $\mathbf{V}$ are derived from the same enhanced feature map $\mathbf{F}_n^{\text{enhanced}}$.

3) Object Detection Branch: The Object Detection Branch uses the encoded feature $\mathbf{Z}_n^{\text{enc}}$ and processes it through a Deformable DETR decoder to detect objects within the current frame. The decoder utilizes a set of learnable object queries $\mathbf{Q}^{\text{obj}}$ to retrieve object features:

$$\mathbf{F}_n^{\text{obj}} = \text{Decoder}(\mathbf{Q}^{\text{obj}}, \mathbf{Z}_n^{\text{enc}}), \quad (15)$$

where $\mathbf{F}_n^{\text{obj}}$ represents the detected object features. These features are passed to a feedforward neural network (FFN) to generate detection bounding boxes $\mathbf{B}_n^{\text{det}}$:

$$\mathbf{B}_n^{\text{det}} = \text{FFN}(\mathbf{F}_n^{\text{obj}}). \quad (16)$$

4) Object Prediction Branch: Simultaneously, the Object Prediction Branch tracks objects by predicting their locations

in the next frame based on past tracking information. The encoded feature $\mathbf{Z}_n^{\text{enc}}$ is processed with the track query $\mathbf{Q}^{\text{track}}$ which is the object features $\mathbf{F}_{n-1}^{\text{obj}}$ in the previous frame, retrieving the tracking features $\mathbf{F}_n^{\text{track}}$:

$$\mathbf{F}_n^{\text{track}} = \text{Decoder}(\mathbf{Q}^{\text{track}}, \mathbf{Z}_n^{\text{enc}}). \tag{17}$$

These features are processed through another FFN to predict the locations of objects from the previous frame in the current frame, providing the propagated positions for the tracked objects $\mathbf{B}_n^{\text{pred}}$:

$$\mathbf{B}_n^{\text{pred}} = \text{FFN}(\mathbf{F}_n^{\text{track}}). \tag{18}$$

5) Identity Association and Trajectory Management: The detected objects and predicted objects are matched using an identity association module, which computes a cost matrix between detection and prediction bounding boxes. This cost matrix is used to associate objects between frames. The tracking results are then managed in the trajectory management module, which updates existing trajectories, adds new trajectories, and deletes lost trajectories.

6) Advantages of Integrated Design: The integrated design of this architecture, based on Deformable DETR, allows simultaneous object detection and tracking within the same pipeline. By sharing the same enhanced features and attention mechanisms between detection and prediction branches, the architecture efficiently combines object detection and tracking tasks. This integration fully leverages the complementary relationship between detection and tracking, as the temporal prior information enhances the consistency of the features, allowing detection and tracking to mutually benefit from each other's information.

C. Identity Association Using XIOU Metric

In our approach, we propose a novel **XIOU** metric for identity association between detected and predicted objects. This metric incorporates three key factors: Intersection over Union (IOU), center point distance, and yaw angle difference between the two bounding boxes (as shown in Fig. 4).

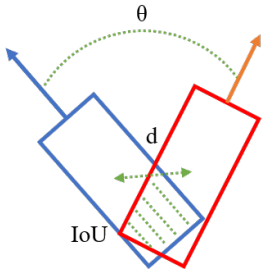

Fig. 4. Visualization of XIOU elements: IOU, center point distance, and yaw angle difference.

First, the basic IOU is calculated between the detection bounding box $\mathbf{B}^{\text{det}}$ and the prediction bounding box $\mathbf{B}^{\text{pred}}$, which measures the overlap between the two boxes:

$$\text{IOU}(\mathbf{B}^{\text{det}}, \mathbf{B}^{\text{pred}}) = \frac{V_{\text{I}}}{V_{\text{U}}}, \tag{19}$$

where V_{I} is the intersection volume of the two 3D bounding boxes, and V_{U} is their union volume.

To improve upon the limitations of IOU in cases where there is no overlap between the two boxes, the Generalized IOU (GIOU) [13] metric is used:

$$\text{GIOU}(\mathbf{B}^{\text{det}}, \mathbf{B}^{\text{pred}}) = \frac{V_{\text{I}}}{V_{\text{U}}} - \frac{V_{\text{C}} - V_{\text{U}}}{V_{\text{C}}}, \tag{20}$$

where V_{C} is the volume of the smallest convex shape enclosing both $\mathbf{B}^{\text{det}}$ and $\mathbf{B}^{\text{pred}}$. GIOU extends IOU by adding a distance-based penalty term, addressing cases where IOU is zero due to non-overlapping boxes.

Building on GIOU, our **XIOU** metric further integrates orientation and distance between the center points of the two boxes:

$$G_{\cos}(\theta_{\mathbf{B}^{\text{det}}}, \theta_{\mathbf{B}^{\text{pred}}}) = \cos(\theta_{\mathbf{B}^{\text{det}}} - \theta_{\mathbf{B}^{\text{pred}}}) + 1, \tag{21}$$

$$G_{\text{iou}}(\mathbf{B}^{\text{det}}, \mathbf{B}^{\text{pred}}) = \text{GIOU}(\mathbf{B}^{\text{det}}, \mathbf{B}^{\text{pred}}) + 1, \tag{22}$$

$$\text{XIOU}(\mathbf{B}^{\text{det}}, \mathbf{B}^{\text{pred}}) = \frac{G_{\text{iou}} \times G_{\cos}}{4}, \tag{23}$$

where $\theta_{\mathbf{B}^{\text{det}}}$ and $\theta_{\mathbf{B}^{\text{pred}}}$ represent the yaw angles (orientations) of the detection and prediction bounding boxes, respectively. This term captures the orientation difference between the boxes, while the GIOU term handles their spatial relationship.

Our **XIOU** metric offers improved performance in 3D environments by taking into account the spatial overlap, orientation similarity, and distance between objects. This makes it particularly well-suited for 3D object tracking tasks, where precise alignment of object positions and orientations is crucial for maintaining consistent identities across frames.

D. Trajectory Management with Cascade Matching

Trajectory management plays a critical role in maintaining accurate object tracking over time. This step involves matching detected objects with existing trajectories, updating object tracks, and handling the creation or deletion of tracks as necessary. Traditional approaches, such as ByteTrack, employ a two-stage matching process, starting with high-confidence detections followed by low-confidence ones. However, this approach struggles in occlusion scenarios. As shown in Fig. 5(a), object detection confidence gradually decreases during occlusion, while Fig. 5(b) shows how confidence slowly recovers when occlusion fades.

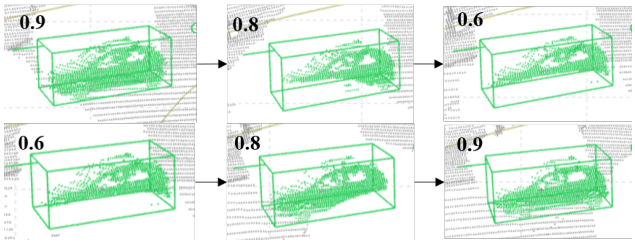

Fig. 5. (a) Confidence decline during occlusion. (b) Confidence recovery after occlusion. The figures illustrate how detection confidence changes when objects are occluded and when occlusion diminishes.

To address the challenges of tracking objects under occlusion, we introduce a **Four-Stage Cascade Matching (FSCM)** algorithm. This method improves upon previous approaches by dividing detection results and track predictions

into high-confidence and low-confidence categories, handling them across four stages. Each stage applies the Hungarian algorithm to perform the matching based on the XIOU similarity metric, which considers object overlap, orientation, and spatial alignment.

1) Stage 1: High-confidence Detection and High-confidence Track Matching: In the first stage, detections and tracks are divided into high-confidence and low-confidence sets based on predefined thresholds. A detection is considered high-confidence if its detection score s_d exceeds the detection threshold m_d, and similarly, a track is considered high-confidence if its tracking confidence score s_t exceeds the tracking threshold m_t. High-confidence detections $\mathbf{D}^{\text{high}}$ are matched with high-confidence tracks $\mathbf{T}^{\text{high}}$. The cost matrix is computed as:

$$\mathbf{C}^{\text{high}} = \mathbf{1} - \text{XIOU}(\mathbf{D}^{\text{high}}, \mathbf{T}^{\text{high}}). \tag{24}$$

The Hungarian [8] algorithm is applied to minimize the cost matrix $\mathbf{C}^{\text{high}}$. The matched detections and tracks are processed, while the unmatched ones are passed to the next stage.

2) Stage 2: Low-confidence Detection and High-confidence Track Matching: Low-confidence detections ($s_d < m_d$), denoted as $\mathbf{D}^{\text{low}}$, are matched with the high-confidence tracks ($s_t \geq m_t$) that remained unmatched from the previous stage. This is useful for handling partially occluded objects whose detection scores have decreased, while their tracking predictions remain reliable. The cost matrix is calculated as:

$$\mathbf{C}^{\text{low-high}} = \mathbf{1} - \text{XIOU}(\mathbf{D}^{\text{low}}, \mathbf{T}^{\text{high}}), \tag{25}$$

and the Hungarian algorithm matches the remaining high-confidence tracks with low-confidence detections.

3) Stage 3: High-confidence Detection and Low-confidence Track Matching: In this stage, high-confidence detections $\mathbf{D}^{\text{high}}$ are matched with low-confidence tracks $\mathbf{T}^{\text{low}}$, which were not matched in the previous stages. This helps recover objects that were previously occluded but are now detected with high confidence:

$$\mathbf{C}^{\text{high-low}} = \mathbf{1} - \text{XIOU}(\mathbf{D}^{\text{high}}, \mathbf{T}^{\text{low}}). \tag{26}$$

Again, the Hungarian algorithm is used to assign detections to tracks, updating the trajectories for reappearing objects.

4) Stage 4: Low-confidence Detection and Low-confidence Track Matching: Finally, low-confidence detections $\mathbf{D}^{\text{low}}$ are matched with low-confidence tracks $\mathbf{T}^{\text{low}}$. This step manages prolonged occlusion or potential false detections:

$$\mathbf{C}^{\text{low}} = \mathbf{1} - \text{XIOU}(\mathbf{D}^{\text{low}}, \mathbf{T}^{\text{low}}). \tag{27}$$

The Hungarian algorithm minimizes the cost matrix, and matched detections and tracks are processed.

5) Unmatched Detections and Tracks: If any high-confidence detections remain unmatched, they are used to initialize new tracks. Unmatched low-confidence detections are discarded as background noise. Tracks that remain unmatched are retained for N frames. If tracks remain unmatched beyond the threshold, they are deleted from the system.

6) Summary of FSCM Algorithm: This four-stage cascade matching algorithm divides both detections and predictions into high-confidence and low-confidence categories, leveraging the XIOU metric at each stage. The Hungarian algorithm is employed in all stages to ensure optimal matching. By progressively refining the matching process, this method ensures robust tracking, even under occlusion, and takes full advantage of detection and prediction confidences.

IV. Experiments

The primary goal of our experiments is to validate the effectiveness and robustness of the proposed method for vehicle-infrastructure cooperative 3D multi-object tracking. We conduct a series of experiments on the V2X-Seq dataset to evaluate the tracking performance under varying latency conditions and compare it with several state-of-the-art methods. Additionally, we perform an ablation study to investigate the contributions of the key modules in our architecture, including the integrated detection-tracking framework, XIOU identity association, and four-stage cascade matching (FSCM).

A. Dataset and Evaluation Metrics

Our experiments are conducted on the V2X-Seq dataset, the first large-scale real-world dataset specifically designed for vehicle-infrastructure cooperative 3D multi-object tracking. It contains over 15,000 pairs of synchronized vehicle-side and infrastructure-side frames, with each pair including 3D LiDAR point clouds and annotations with tracking IDs. All vehicle and infrastructure data in V2X-Seq are time-synchronized and spatially aligned, making it ideal for evaluating cooperative tracking performance in real-world scenarios. With over 150,000 frames across more than 200 sequences, V2X-Seq provides diverse traffic environments and object dynamics, offering a comprehensive benchmark for assessing tracking accuracy and robustness, especially under challenging conditions such as occlusions and communication delays. We use the following evaluation metrics to compare the performance of different methods:

- MOTA (Multi-Object Tracking Accuracy): MOTA reflects the overall tracking accuracy by considering three factors: false positives, missed targets, and identity switches. Higher values indicate better performance.

$$\text{MOTA} = 1 - \frac{\sum_t (\text{FN}_t + \text{FP}_t + \text{IDSW}_t)}{\sum_t \text{GT}_t}, \tag{28}$$

  where FN_t, FP_t, and IDSW_t are the false negatives, false positives, and identity switches at time t, and GT_t is the number of ground truth objects.

- MOTP (Multi-Object Tracking Precision): MOTP evaluates the localization precision of the tracked objects by computing the average distance between the predicted and ground-truth object locations.

$$\text{MOTP} = \frac{\sum_t \sum_i d_t^i}{\sum_t c_t}, \tag{29}$$

  where d_t^i is the distance between the predicted and ground-truth locations for object i at time t, and c_t is the number of matched object pairs at time t.

TABLE I. COMPARISON OF TRACKING PERFORMANCE ON THE V2X-SEQ DATASET UNDER DIFFERENT LATENCY CONDITIONS

Latency(ms)	Fusion Type	Method	MOTA↑	MOTP↑	IDS↓	BPS↓(Byte/s)
0	Object-Level	Hungarian [8]	53.18	72.35	273	3.3×10^3
	Data-Level	Concat [25]	56.03	70.17	296	1.3×10^7
	Feature-Level	FF-Tracking [25]	54.75	69.76	222	6.2×10^5
	Feature-Level	**Ours**	**57.23**	**74.64**	**206**	6.2×10^5
200	Object-Level	Hungarian [8]	50.32	71.58	260	3.3×10^3
	Data-Level	Concat [25]	51.27	69.67	234	1.3×10^7
	Feature-Level	FF-Tracking [25]	52.26	69.64	225	1.2×10^6
	Feature-Level	**Ours**	**55.76**	**74.15**	**219**	1.2×10^6

- IDS (Identity Switches): This metric tracks identity changes during tracking, with lower values indicating better performance.
- BPS (Bytes Per Second): This metric measures the bandwidth for vehicle-infrastructure communication, defined as the data exchanged per second in bytes.

B. Implementation Details

Our model employs a backbone network and FPN structure similar to that used in SECOND [20], optimized using the AdamW optimizer. The initial learning rate is set to 1×10^{-4}, and we use 500 queries during training. Both decoders are trained with identical loss functions, incorporating a classification loss and XIOU loss as the final objective. For the tracking process, we set the detection score threshold m_d to 0.5, tracking score threshold m_t to 0.4, and retain unmatched trajectories for $N = 20$ frames. The network is implemented in Pytorch and trained on an NVIDIA GeForce RTX 3090 GPU.

In the inference phase, the first frame's feature map serves as the prior frame's feature for downsampling and temporal prior enhancement. Simultaneously, the track query initializes with the object features from the first frame. From the second frame onward, the point cloud feature sequence is processed following the methodology described, outputting tracking results across all frames.

C. Comparison with State-of-the-Art Methods

We compare the performance of our method against several approaches in the V2X-Seq dataset under two latency conditions: 0 ms and 200 ms. The methods include data-level, object-level, and feature-level fusion techniques, specifically:

- Concat (Data-Level) [25]: In this method, the infrastructure point cloud is transformed to the vehicle's coordinate system, where pseudo-images from both vehicle and infrastructure are concatenated. This approach uses the PointPillars detector and follows AB3DMOT's TBD (tracking-by-detection) paradigm for multi-object tracking.
- Hungarian (Object-Level) [8]: In this approach, vehicle and infrastructure detections are performed independently. Detected object sets from both vehicle and infrastructure are transmitted and matched using the Hungarian algorithm to fuse results.
- FF-Tracking (Feature-Level) [25]: This method transmits the feature flow between consecutive frames from the infrastructure to the vehicle, reducing data transmission while maintaining accuracy.

As shown in Table I, our method consistently outperforms others across key metrics, particularly in **MOTA**, achieving 57.23 at 0 ms latency—**1.2 points** higher than Concat (56.03) and **4.05 points** higher than Hungarian (53.18). This improvement reflects the combined contributions of our integrated detection-tracking framework, XIOU identity association, and four-stage cascade matching (FSCM). In terms of **MOTP**, our method achieves 74.64, surpassing Concat's 70.17 and Hungarian's 72.35, highlighting its effective use of 3D positional and orientational information. Additionally, with the lowest **IDS** score of 206, it demonstrates robust identity association and trajectory management.

Under the 200 ms delay condition, our method maintains high tracking accuracy with a **MOTA** of 55.76, outperforming Concat (51.27) and Hungarian (50.32). The **MOTP** remains at 74.15, the highest among all methods, while the **IDS** count remains low at 219. These results demonstrate the resilience of our approach to communication delays, inheriting the robustness of the FF-Tracking framework. By preserving temporal consistency in feature flow and leveraging efficient identity association, the proposed framework effectively mitigates the negative impact of delayed data transmission.

In terms of data transmission efficiency, our method achieves a transmission rate of 6.2×10^5 Byte/s, which is over **20 times** lower than Concat (1.3×10^7 Byte/s). This substantial reduction is achieved through feature-level fusion, which transmits compressed feature flows. Despite this lower bandwidth usage, our method provides a **4%** higher MOTA, highlighting its ability to optimize communication resources while improving tracking accuracy.

D. Ablation Study

We conduct an ablation study to quantify the contributions of our three key modules: the integrated detection-tracking framework, XIOU identity association, and the four-stage cascade matching (FSCM) algorithm. The baseline method, AB3DMOT, is used for comparison by systematically replacing each module in our framework with the corresponding component from AB3DMOT. The results are presented in Table II.

1) Impact of the Integrated Detection-Tracking Framework: Replacing our integrated detection-tracking framework with AB3DMOT's tracking-by-detection (TBD) paradigm results in a **2.1-point decrease in MOTA** (from 57.23 to 55.13). This indicates the unified framework's critical role in bridging detection and tracking, enabling the detection branch to benefit from tracking priors while allowing the tracking branch to leverage enhanced detection results. The observed drop in

TABLE II. ABLATION STUDY ON THE V2X-SEQ DATASET

Method	Tracking Framework	Identity Association	Trajectory Management	MOTA↑	MOTP↑	IDS↓
AB3DMOT	TBD	IOU	Single Matching	54.75	69.76	222
Ours	**Integrated**	**XIOU**	**FSCM**	**57.23**	**74.64**	**206**
1	TBD	XIOU	FSCM	55.13	72.43	208
2	Integrated	IOU	FSCM	56.72	73.58	214
3	Integrated	XIOU	Single Matching	55.38	74.16	215

MOTA demonstrates that separating detection and tracking increases errors, for example, in scenarios involving fast-moving or partially occluded objects. By integrating detection and tracking within the same pipeline, our framework effectively reduces identity switches and improves object recall, ensuring robust performance in dynamic traffic environments.

2) Impact of XIOU Identity Association: When XIOU is replaced with AB3DMOT's IOU, **MOTA drops by 0.51 points** (from 57.23 to 56.72), and **IDS increases by 3.9%** (from 206 to 214). This demonstrates XIOU's ability to capture spatial and orientation consistency, which is particularly beneficial in occlusion-heavy environments. XIOU effectively resolves ambiguous matches between detection and prediction bounding boxes by incorporating yaw angle and center-point distance, leading to improved identity consistency and reduced errors during complex interactions between vehicles. In contrast, IOU struggles to maintain identity consistency when objects overlap or move in close proximity, leading to more identity switches and reduced tracking accuracy.

3) Impact of the Four-Stage Cascade Matching (FSCM): Replacing our four-stage cascade matching (FSCM) algorithm with AB3DMOT's single matching strategy increases **IDS by 4.3%** (from 206 to 215) and reduces **MOTA by 1.85 points** (from 57.23 to 55.38). These results highlight FSCM's ability to manage trajectory updates effectively, particularly in handling occlusions and reappearing objects. FSCM dynamically adapts to the confidence levels of both detections and tracks, ensuring robust identity associations across frames. Single matching, on the other hand, lacks this flexibility, resulting in higher identity switches and degraded tracking performance, particularly in challenging scenarios with frequent occlusions or sudden object reappearances. By incorporating FSCM, our method achieves lower IDS and higher MOTA, demonstrating its importance for maintaining accurate and consistent trajectories under complex real-world conditions.

4) Module Contribution Analysis: Among the three modules, the integrated detection-tracking framework contributes the largest MOTA gain (**2.1 points**), highlighting its significant impact on overall tracking accuracy. FSCM provides the second-highest gain (**1.85 points in MOTA**), underscoring its importance in trajectory management under challenging conditions. XIOU, while contributing a relatively smaller MOTA improvement (**0.51 points**), plays a crucial role in reducing IDS, demonstrating its effectiveness in identity association tasks. Collectively, these modules form a robust system that achieves superior performance compared to traditional methods.

E. Challenges and Future Directions

1) Bandwidth Efficiency: Although our method significantly reduces data transmission compared to data-level fusion methods, the bandwidth requirement (6.2×10^5 Byte/s) remains relatively high compared to object-level methods like Hungarian. This poses challenges for large-scale deployment in real-world bandwidth-constrained environments. Future work should focus on optimizing feature extraction and compression strategies to further reduce transmission overhead while maintaining tracking accuracy.

2) Handling Long Occlusions and Disappearances: While the proposed framework effectively addresses moderate occlusions and identity switches, it struggles in scenarios involving long-term occlusions or complete object disappearances. For instance, re-associating objects after prolonged absence remains challenging. Future efforts could focus on incorporating adaptive temporal modeling techniques and improved motion prediction strategies to enhance the system's robustness in such complex and dynamic environments.

V. CONCLUSION

In this work, we proposed an innovative framework for vehicle-infrastructure cooperative 3D multi-object tracking, emphasizing three key contributions: an integrated detection-tracking framework, the XIOU identity association metric, and a four-stage cascade matching (FSCM) strategy. The integrated framework enhances both detection accuracy and tracking consistency by jointly leveraging detection and tracking information. The XIOU metric improves identity association by effectively incorporating 3D spatial information, while FSCM provides robust tracking continuity in occlusion scenarios. Experimental results on the V2X-Seq dataset validate the effectiveness of these innovations, with our method demonstrating superior tracking accuracy, reduced identity switches, and low bandwidth usage even under delayed communication conditions. These results underscore the potential of feature-level fusion and temporal prior enhancement in real-world V2X applications. Future work will focus on optimizing bandwidth efficiency through improved feature extraction and compression, and enhancing robustness in handling long-term occlusions and dynamic scenarios with adaptive temporal modeling and motion prediction, paving the way for more reliable and efficient V2X applications.

A Robust Model for a Healthcare System with Chunk Based RAID Encryption in a Multitenant Blockchain Network

Bharath Babu S, Jothi K R*
School of Computer Science and Engineering
Vellore Institute of Technology
Vellore, TamilNadu, India 632014

***Abstract*—Healthcare informatics has revolutionized data extraction from large datasets. However, using analytics while protecting sensitive healthcare data is a major challenge. A novel methodology for Privacy-Preserving Analytics in Healthcare Records addresses this essential issue in this study. The multi-tenant Blockchain framework uses chunk-based RAID encryption. For the healthcare business, chunk-based RAID encryption in a multi-tenant blockchain architecture creates a durable, safe, and efficient solution for processing confidential healthcare information. This solution improves data security, integrity, availability, performance, regulatory compliance, and scalability by combining RAID and blockchain technology. Contemporary healthcare systems need these qualities to work well. This approach was done in Python, and the libraries used the VSCode tool. To maintain data security, integrity, and accessibility, a strong healthcare system architecture with chunk-based RAID encryption in a multi-tenant blockchain network requires various advanced technologies.**

Keywords*—Multi-tenant; chunk-based; RAID; blockchain; healthcare records

I. Introduction

The quick progress in the internet of things (IoT) concept has transformed healthcare businesses by introducing significant enhancements in e-health/medical records drug prescription data, and insurance information. The rapid advancement of the internet of things (IoT) has revolutionized healthcare industries by offering substantial improvements in e-health/medical records, drug prescription data, and insurance information. IoT devices enable real-time monitoring of patients. Additionally, they have the potential to decrease the necessity of hospital visits for regular health examinations. Home health monitoring systems that are connected can effectively decrease the duration of hospital visits and lower the expenses associated with readmission. The Internet of Things (IoT)-enabled medical devices have the capability to aid in the process of diagnosing medical conditions by providing alerts and triggering notifications prior to the onset of symptoms. Numerous software as a service applications make advantage of multi-tenant data storage, which involves the sharing of resources and the layout of the data-store across multiple tenants. The fact that each user or tenant is given their own instance of a single tenant application, on the other hand, results in increased expenses for servicing and maintenance for both the tenants and the suppliers. When resources are shared across multiple tenants in a multi-tenancy setting, those costs are reduced for all of the parties involved [1, 2]. Despite this, multitenant architectures pose data security risks. When multiple tenants share a storage area, data infringement is more likely if their data is not properly isolated. A hostile tenant can assault other tenants' data by sending harmful information, making unauthorized transactions, or interrupting exchanges. This can be done several ways. Therefore, a robust system is essential to ensure that multi-tenant data cannot be altered without authority. Flexibility and data segregation are crucial in multi-tenant applications [3].

Blockchain technology is a recent invention that allows secure data storage in multi-user applications. In addition to bitcoin, blockchain technology is becoming a powerful tool for secure and immutable storage systems [3]. Blockchains or Distributed Ledgers prevent data tampering by decentralizing and cryptographic hashing. Blockchain storage is designed to securely and permanently store data and transactions, preventing tampering. Access to private or permissioned blockchains is limited to identifiable members [4]. Blockchains offer an unchangeable ledger that lets authorized network participants see stored data in real time.

Blockchain is a highly promising technology that has the potential to greatly improve the efficiency of healthcare data management operations. It achieves this by offering unparalleled data efficiency and ensuring trust in the system. The platform provides a diverse array of notable and inherent characteristics, including distributed storage, visibility, permanence, verification, adaptability in data access, interlinking, and safeguarding, thereby facilitating extensive adoption of blockchain technology for healthcare data management [5].

Blockchain employs smart contracts to establish mutually agreed upon terms and conditions among all healthcare partners in the network, eliminating the need for intermediaries [6,7]. It minimizes superfluous administrative expenses. Blockchain primarily depends on three fundamental concepts: peer-to-peer networks, public key cryptography, and consensus procedures [8]. Blockchain is categorized into three types based on permission management: public, private, and consortium blockchains [9]. Any individual with internet access can participate in the consensus procedure of public blockchains.

*Corresponding authors

Public blockchains incorporate incentives and employ proof-of-work or proof-of-stake techniques to ensure encrypted digital verification. The public blockchain system is completely visible, meaning that the identity of each participant is kept pseudo-anonymous. In a private blockchain, network control is exclusively held by a single company. Thus, this particular type of blockchain necessitates a reliable intermediary to achieve consensus. The consortium blockchain integrates the benefits of public and private blockchain networks. This solution is specifically ideal for select enterprises who have the objective of optimizing communication within their own network. Healthcare businesses have the flexibility to choose any sort of blockchain network based on their individual requirements or use case scenarios, as each network has its own advantages and disadvantages.

The framework laid out in this article aims to enhance other related blockchain-based systems for storage in the following aspects: The aim of chunk-based RAID encryption in a multi-tenant blockchain model for the healthcare sector is to provide a robust, secure, and efficient framework for managing sensitive healthcare data. By leveraging the strengths of both RAID and blockchain technologies, this approach ensures enhanced data security, integrity, availability, performance, regulatory compliance, and scalability, which are crucial for the effective operation of modern healthcare systems. Utilize separate ledgers or channels to ensure that the data of different tenants remains isolated and inaccessible to others. This approach is commonly employed in permissioned blockchain networks such as Hyper-ledger Fabric. Implement strong access control mechanisms to restrict access to each tenant's data, ensuring only authorised individuals can view or interact with it. Deploy resilient authentication techniques to bolster security for users accessing the blockchain network. One such solution is to use multi-factor authentication (MFA) in order to improve security measures. Role-Based Access Control (RBAC) is a mechanism for controlling access to resources in a methodical manner. Administrators can utilize this feature to allocate roles to users, thereby specifying the permissions and privileges they possess. RBAC enables companies to enforce access controls that limit users to only the information and functionality essential for their specific position. This enhances security and minimizes the likelihood of unauthorized access. It is crucial to assign responsibilities to users and establish permissions depending on their duties in order to ensure efficient management. This enhances the administration of resource and operation authorization within the network.

Section II investigates existing approaches and discusses the issues of protecting medical records in multi-tenant systems. Section III discusses the proposed solutions along with the block chain technology with chunk-based RAID encryption to address the existing problems. Section IV explains the analytical and technological implementation of the cryptographic methods, RAID setups and data transfer protocols. Section V evaluates the proposed method over other existing techniques. Section VI examines the model's limitations, applications and further scopes.

A. Literature Review

Extensive research is being conducted in various interdisciplinary fields using blockchain technology. The research conducted in [10] has aimed to tackle the issue of internet piracy in the movie business by the creation of a blockchain-powered anti-piracy system called "Vanguard". This system replaces the traditional method of registering intellectual property (IP) and monitors the ownership of IP rights to prevent unauthorised distribution of data. The utilisation of blockchain technology and certificateless cryptography has been employed in [11] to create a data storage system that effectively manages and safeguards vast quantities of IoT data.

The authors of [12] have employed blockchain technology to develop methods for sharing data in smart cities. In [13], a proposal was made for a Blockchain Tree to store information from smart ID cards. This method enhances security by incorporating blockchain technology at a lower level and extending it to a higher level.

The research in [14] centres on the utilisation of blockchain technology for several applications in the food business, such as food tracing, land registrations, customer awareness programmes, and farm insurance. The proposed system has been implemented by authors using the open-source platform Multi-Chain. An important benefit of utilising blockchain technology is its ability to effectively deter forgery and fraud due to its inherent immutability and transparency. In a study referenced as [15], a blockchain-based solution is proposed to avoid property fraud, including fraud related to bank loans.

Ping end-to-end Reporting (PingER) is a framework created by the SLAC National Accelerator Laboratory in the United States for measuring internet performance across the globe. The proposal suggests implementing a distributed blockchain technology to store data for PingER in a decentralised manner. Instead of storing data in a centralised location, this system distributes the data files across various sites using Distributed Hash Tables (DHT). Only the metadata of these files is saved on the blockchain.

The study [16] discusses a novel concept called Blockchain-as-a-Service (BaaS), which is comparable to Software-as-a-Service (SaaS). This is a cloud-based service that simplifies the process of setting up a blockchain. It also offers a platform for running apps and provides security and other essential elements of blockchain technology.

The authors of [17] have suggested a system based on blockchain technology for a multitenant architecture. Each tenant possesses an independent blockchain with certain permissions, which is then linked to a central chain. The collaboration for this project was conducted with Laava ID Pty Ltd (Laava), and the execution was accomplished using the Ethereum platform. This study examines the healthcare sector as a prominent field for the implementation of blockchain technology. Extensive research and documentation have been dedicated to studying the application of blockchain in the healthcare industry. Researchers in [18] have integrated blockchain technology into digital services, such as online consultations. They have successfully implemented a decentralised system to ensure utmost security in the healthcare industry. Blockchain technology has improved transparency in communication between users and clients, particularly in the context of doctor-patient interactions. Furthermore, the authors have included three separate case studies in this specific field: Telemedicine, Patientory, and Medblock.

The study [19] provides a thorough examination of the research conducted on electronic health record (EHR) systems that utilise blockchain technology. Several consensus algorithms have been explored by researchers for implementation in public blockchains. These include the Practical Byzantine Fault Tolerance replication algorithm (PBFT), RAFT, Proof of Authority (PoA), Proof of Capacity (PoC), and Proof of Elapsed Time (PoET). An innovative solution called MediBchain has been developed in [20] to ensure the security and privacy of healthcare data by leveraging blockchain technology. They have utilised Elliptic Curve Cryptography (ECC) to secure sensitive information.

A mobile application has been created utilising blockchain technology to store data related to cognitive behavioural therapy for patients with insomnia [21]. The data is stored in the Hyperledger Fabric blockchain network using JSON format. This system utilises blockchain technology to ensure data transparency and accessibility while eliminating the risk of data tampering. Blockchain technology has been successfully integrated with artificial intelligence systems to develop a predictive system for managing the clinical risks associated with COVID-19 infection [22-25]. This integration has shown promising results in improving clinical risk management.

B. Challenges Faced in the Existing Techniques

1) Single database, shared schema: In the healthcare industry, a single database with a shared schema shown in Fig. 1 presents many challenges, especially when considering security, confidentiality, data consistency, and expandability. These are the main issues with this approach. A unified database with a shared schema can attract attackers. A compromise could disclose all patient data from numerous departments or institutions. It's difficult to restrict access to specific data in a shared schema to authorized users. Data segmentation to protect sensitive patient data is tough. Multiple users updating the database at once might cause data conflicts and overwrites, compromising data integrity. Single-database uniformity is key. Inconsistencies can cause serious medical errors. Data leaking is a prominent concern in a shared schema architecture, when multiple tenants utilize the same schema. These factors can result in security breaches, and impairments in performance [26]. Access control is intricate, and conflicts over resources can have a negative influence on performance. Increasing the number of renters may lead to scalability concerns. Optimizing searches across several tenants is a challenging task that requires the construction of efficient indexing and caching solutions to prevent performance issues. Handling schema changes poses difficulties, and data migration carries a high chance of errors. Insufficient options for personalization and adaptability are further obstacles. Tenant management include the effective process of bringing new tenants on board, removing tenants when necessary, ensuring equitable distribution of resources, and implementing security measures at the individual row level. By implementing resource quotas, automatic monitoring tools, and conducting frequent audits, it is possible to reduce these issues and enhance the management of a single database common schema.

2) Single database, separate schema: Implementing a solitary database with distinct schemas for individual tenants in the healthcare sector poses numerous difficulties. These difficulties

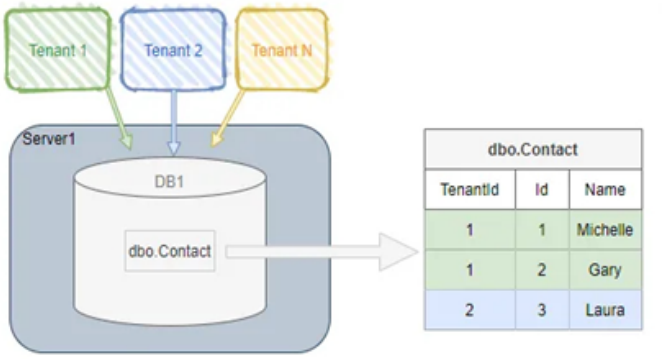

Fig. 1. Single database, shared schema model.

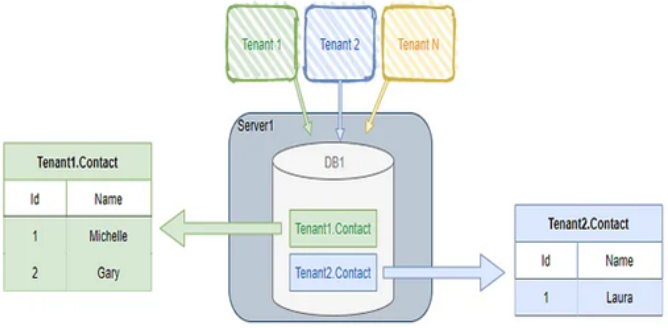

Fig. 2. Single database, separate schema model.

can have an impact on performance, security, maintainability, and compliance [27]. The system Restoring data for a single tenant is not a simple task, although it is slightly easier than the technique of using a single database with a shared schema (Fig. 2), because the tenant data is kept separate. As the tenant count increases, a significant number of database objects will be generated to handle and uphold. Schema modifications require a more complex process, as they need to be distributed to several tenants.

C. Database per Tenant

Drawbacks to using a Database per tenant (Fig. 3) approach include the need for additional server maintenance and security measures, an increase in the number of database objects to manage and maintain as the number of tenants rises, and the complexity of creating new schemas when adding new tenants [28].

1) Multiple databases, multiple tenants per database, shared schema: The disadvantages of having numerous databases, multiple tenants per database, and a shared schema (Fig. 4) are as follows: Tenants persist in employing a shared database and schema alongside other folks. Further maintenance is required. Those in charge of managing many databases face complex operational challenges, the risk of data breaches, the necessity for efficient performance monitoring, obstacles in attaining scalability, increased maintenance responsibilities, and concerns over security [29]. Enforcing compliance with regulations like GDPR and HIPAA can be challenging in shared schema setups. Operational complexity

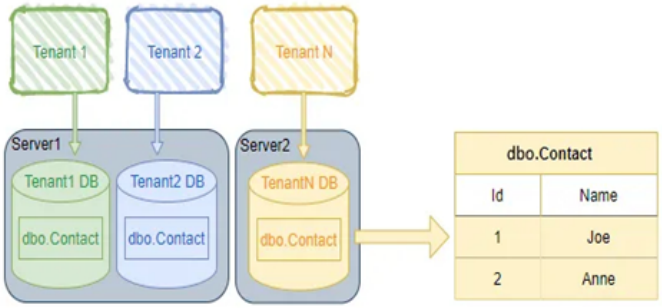

Fig. 3. Database per tenant model.

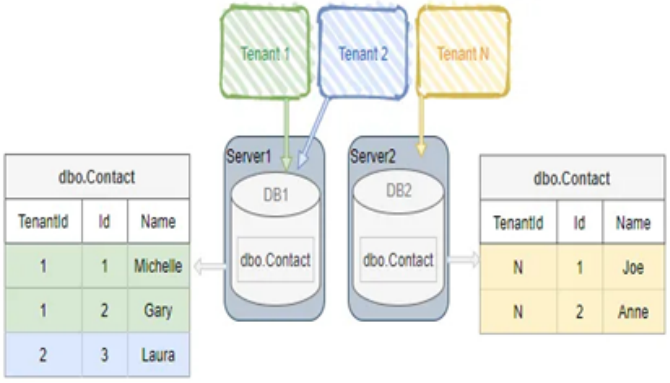

Fig. 4. Multiple databases, multiple tenants per database, shared schema model.

refers to the range of duties involved in managing a system, including backup and recovery methods, monitoring, problem-solving, and limitations on modification. Efficiently managing economic issues, including infrastructure expenses, is essential for properly allocating resources and ensuring compliance.

II. Research Method

This research takes a methodical approach to tackle the identified challenges. Researcher thoroughly examine and incorporates insights from various sources such as academic papers, industrial blogs, and related research initiatives. The proposed approach efficiently combines the benefits of blockchain technology and chunk-based RAID encryption to address important difficulties in healthcare data management, such as security, fault tolerance, scalability, performance, and regulatory compliance. Its sturdy design protects sensitive medical information while retaining high efficiency and adaptability, making it a great option for the changing demands of modern healthcare organizations.

A. Proposed System

To address the difficulties presented by current multi-tenancy database systems, we suggest an innovative method that utilizes the dynamic arrangement of tenant connections and incorporates blockchain technology to overcome the stated issues. Our goal is to establish a flexible and scalable environment by implementing a dynamic topology in healthcare organizations which can create a robust, scalable, and flexible environment that supports their evolving needs while maintaining high standards of performance and security. This will enable tenants to communicate with each other smoothly, without being limited by a predefined schema. This dynamic connectivity facilitates improved data isolation, which enables quick restoration of individual tenant data without the complications associated with a single shared schema. In addition, we implement blockchain technology to securely handle the relationships between renters. The decentralized and tamper-resistant characteristics of blockchain guarantee the reliability and safety of tenant connections, effectively resolving problems regarding High Availability, Disaster Recovery, and Monitoring techniques. This novel method reduces the requirement for extensive maintenance and schema modifications, offering a strong basis for a scalable, secure, and easily controllable multi-tenancy database structure. Through the use of blockchain technology, we address the difficulties associated with existing models by decentralizing connectivity and ensuring security. This provides a revolutionary solution for a dynamic and safe database environment that can accommodate multiple users. Healthcare businesses have the ability to establish a strong, adaptable, and versatile infrastructure that caters to their changing requirements while upholding exceptional levels of performance and security.

B. Secured Data Transaction of Tenants using Blockchain Technology

Implementing secure data transactions for healthcare tenants using blockchain technology entails utilizing the inherent characteristics of blockchain, like decentralization,immutability, and transparency, to guarantee the integrity,security, and privacy of data. Our proposed system incorporates Blockchain Technology to guarantee the secure transfer of data between clients. Blockchain, being a distributed and tamper-proof ledger, offers an unchangeable record of all transactions. Data transactions are cryptographically encrypted to guarantee data integrity and prevent unauthorized access. This not only improves the overall security of healthcare data but also establishes a clear and responsible framework for data transfers inside the multi-tenant environment. The model of multi-tenant blockchain network for the health sector is illustrated in the Fig. 5.

C. A Mathematical Framework for Enhancing Data Security in Multi-Tenant Blockchain Technology

Securing data in multi-tenant blockchain technology requires utilizing a mathematical framework that integrates different cryptographic techniques and consensus mechanisms. This framework is designed to guarantee the security and reliability of healthcare data, while also ensuring the smooth operation and effectiveness of the blockchain network. Here is a comprehensive approach to developing such a framework.

1) Cryptographic Hash Functions: Cryptography uses mathematical hash functions. Hash functions usually take variable-length inputs and output fixedlength outputs. Computing systems depend on hash functions for message integrity and data validation. Though “weak” cryptographically due to their polynomial-time solvability, these algorithms are not easily decipherable. By using cryptographic hash functions, ordinary hash functions become more secure, making it harder

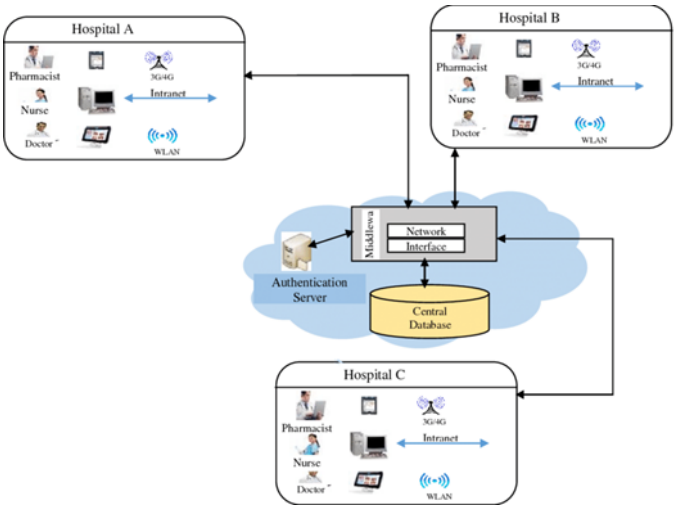

Fig. 5. Multitenant blockchain model for healthcare sector.

to decrypt communications or find their originators. Cryptographic hash functions have three traits: They never meet. It is vital that each input provides a unique output hash. Can hide. It should be difficult to discern a hash function's input from its output [30]. They should help solve riddles. A specified output can make selecting an input difficult. Therefore, input must come from a variety of sources. Cryptographic hash functions are employed in a chunk-based RAID encryption system to guarantee the integrity of each individual chunk of data. The procedure is dividing the data into pieces, applying a hashing function to each chunk, encrypting each chunk, and subsequently dispersing the encrypted chunks throughout the RAID array. This method aids in safeguarding against data corruption and guarantees the ability to identify any modifications made to the data Table I.

TABLE I. CHUNK-BASED RAID ENCRYPTION

Mathematical Approach for Hashing in Chunk-Based RAID Encryption	
Step1	**Data Chunking** Let D be the data to be stored in the RAID. Divide the data D into n chunks Ci Where i = 1,2,3.... n as shown in the equation D=C_1C_2C_n.
Step2	**Hashing Each Chunk** Compute the hash of each chunk using a cryptographic hash function H. $H_i = H(C_i)$ Where Ci is the ith chunk of data Hi is the hash value of the ith chunk H is the cryptographic hash function. Apply SHA-256 to each chunk Ci, and obtain in the equation, $H_i = SHA - 256(C_i)$.
Step3	**Encrypting Each Chunk** Encrypt each chunk using an encryptional algorithm E with a key K as shown in below equation. $E_i = E(K, C_i)$ Where E is the Encryption Function K is the encryption Key Ei is the encrypted chunk. Encrypt each chunk Ci with AES and key K, and obtain the equation below. $E_i = AES(K, C_i)$.
Step4	**Storing Hashes and Encrypted Chunks** EStore the hash values Hi and the encrypted chunks Ei in the RAID array. Distribute Ei across the RAID disks according to the chosen RAID configuration.

2) Password Verification: Most websites store passwords as hashes because text files are unsafe. Passwords are hashed when entered. The company's servers' hashed values are compared to the outcome. Hackers have created rainbow tables, databases containing common passwords and their hashes, to gain unauthorized access to accounts.

A chunk-based RAID encryption system can employ cryptographic hash functions and password-based key derivation functions (PBKDFs) to verify passwords. The objective is to securely authenticate the password utilized for the encryption and decryption of data chunks. Belowis a comprehensive formula and step-by-step process for verifying passwords in a system.

The user has provided a confidential pass code, denoted as P. To prevent precompiled attacks, a distinct salt value S is appended to the password prior to hashing. The process of generating a cryptographic key K from a password and salt is referred to as a key derivation function (KDF). In order to authenticate the password during the decryption process, the system must verify that the entered password is capable of generating the accurate encryption key. The mathematical function to derive the key K using the provided password P and the stored salt S is given in Eq. (1):

$$K = KDF(P, S) \tag{1}$$

Decrypt each encrypted chunk E_i using the derived key K using Eq. (2):

$$C_i = Decrypt(K, E_i) \tag{2}$$

Compute the hash H' of each decrypted chunk Ci by Eq. (3):

$$H' = Hash(C_i) \tag{3}$$

Verify the computed hash H' matches the stored hash H_i, if $H' == H_i$ for all i, then the passcode is verified.

3) Signature Generation and Verification: Signature creation plays a vital role in ensuring the validity and integrity of data pieces in chunk-based RAID encryption solutions. Signature generation commonly entails the utilization of cryptographic methods to generate a distinct identifier (signature) for every chunk.

Mathematical signature verification verifies digital documents and messages. When all conditions are met, a valid digital signature proves to the recipient that the communication was sent by a known sender and was not tampered with. Use the private key privK and a digital signature algorithm DSA to sign the hash Hi by the Eq. (4) and (5):

$$SignPrivatekey(x) = SignatureSignprivatekey(x) = Signature \tag{4}$$

$$Sign_i = DSA_{sign}(priv_K, H_i) \tag{5}$$

The equation depicts the process of generating a digital signature using a private key, ensuring data authenticity and non-repudiation within the blockchain. The average digital signature technique has three algorithms. The key generation algorithm creates keys first. Signing algorithms use messages and private keys to create signatures. Finally, the signature verifying method verifies signatures.

To verify the signature, recalculate the hash Hi of the received chunk Ci using Eq. (6):

$$H^{'} = SHA - 256(C_i) \tag{6}$$

To validate the signature, utilize the public key pubk that corresponds to the private key privK and employ the same digital signature procedure, DSA as in Eq. (7) and (8):

$$Verif = DSA_{Verif}(pub_K, H^{'}, Sign_i) \tag{7}$$

$$Verifypublickey(Signature, Data, Blockchain) = \{True, False\} \tag{8}$$

This equation represents the verification process, ensuring that data transactions are authentic and valid through the use of public key verification. If the verification process is successful, then the Signi, is considered legitimate, and it is confirmed that the data chunk Ci has not been altered or tampered with.

4) Verifying File and Message Integrity: Hashes ensure the integrity of transmitted messages and information by preventing unauthorized alterations. The practice establishes a "chain of trust". Users have the ability to release a hashed representation of their data together with the corresponding key. This allows recipients to verify the integrity of their data by comparing the hash value they compute with the published value.

5) Advanced Smart Contract Implementations for Transactions: Smart Contracts are essential for automating and ensuring compliance with the conditions of agreements between renters. Our system integrates sophisticated Smart Contract implementations to simplify and automate intricate transaction procedures. Smart Contracts enforce predetermined norms and conditions, guaranteeing the smooth, secure, and compliant execution of data transactions. This not only decreases the requirement for human intervention but also improves the effectiveness and dependability of transactions inside the multi-tenant system. A smart contract SCi is created for each transaction through Eq. (9) as follows:

$$SC_i = \{H_i, Sign_i, \sigma, \gamma, Term_i\} \tag{9}$$

Where σ and γ are the security and compliance parameters and Termi is the terms and conditions specified for the data transaction. Now deploy this SCi in the blockchain through the following Eq. (15):

$$B \leftarrow B \cup \{SC_i\} \tag{10}$$

6) Dynamic Network Creation: In order to overcome the difficulties related to fixed network structures, we suggest the adoption of a Dynamic Network Creation technique. Tenants have the opportunity to connect and disconnect from the network as required, offering adaptability and scalability. The process of creating a dynamic network allows tenants to easily adjust to changing needs, resulting in a flexible and responsive multi-tenant environment. This strategy addresses the problems associated with inflexible network setups, enhancing the system's ability to adapt to the changing requirements of tenants.

Establishing a dynamic network in a multi-tenant blockchain system entails overseeing numerous autonomous tenants, such as distinct businesses or users, and enabling them secure and scalable interaction within the blockchain network. This can be accomplished through the utilization of a synergistic integration of intelligent agreements, dynamic node allocation, and robust communication protocols. Presented here is a mathematical framework for such a system:

During dynamic node allocation, Nodes Nm is allocated to tenants Tm depending upon several criteria like load, requirement, etc. This is done by Eq. (11):

$$N_{T_m} = \{N_m | N_m is assigned to T_m\} \tag{11}$$

To prevent bottlenecks, it is important to evenly distribute nodes among tenants. This is done by Eq. (12):

$$\sum\nolimits_{m=1}^{i} = \frac{load(N_m)}{i} \approx \frac{Totalload}{m} \tag{12}$$

Then deploy the created smart contract to the multitenant blockchain model Bm. Then the Tenants submit transactions TXm which are validated by smart contracts by the following Eq. (13) and (14):

$$TX_m = \{Sender = T_m, Receiver, data, signature\} \tag{13}$$

$$Valid(TX_m) \Leftrightarrow Verif(TX_m, SC_i) \tag{14}$$

Finally, the network graph g (Tm, Nm) is adjusted to the changing load and new tenants through the Eq. (15):

$$g(T_m, N_m) \rightarrow g(T_m^{'}, N_m^{'}) \tag{15}$$

This mathematical framework supports the creation of a flexible, scalable, and secure dynamic network for multi-tenant blockchain applications in healthcare or other sectors.

D. Data Transaction Architecture

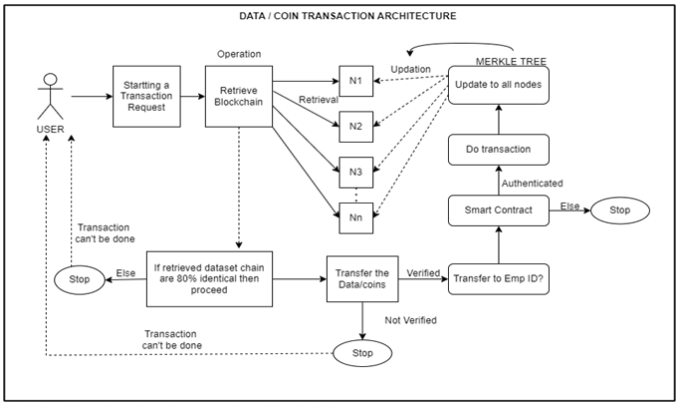

Fig. 6. Data transaction architectures block diagram.

For the purpose of ensuring redundancy and mirrored storage, data is consistently stored in RAID 1 sets. RAID 0 striping is a method that enhances speed by distributing data in an equitable manner across many drives. It is the Monitoring AI that oversees the whole system, ensuring that it operates at its highest possible level. Significant occurrences are gathered and encrypted by the log storage system in a safe manner for the purpose of subsequent reference and analysis. The block diagram of the data transaction architecture of the proposed model is shown in the Fig. 6.

1) Data Transaction and Protocols of Key Generation: The proposed technology integrates data transactions with methods for key generation to bolster the security and privacy of data transactions. Every transaction is linked to a cryptographic currency, and the key generation procedures guarantee secure communication among users. This not only enhances security but also enables the tracking and responsibility of data flows. The utilization of cryptographic coins and resilient key generation procedures enhances the overall security stance of the multi-tenant system.

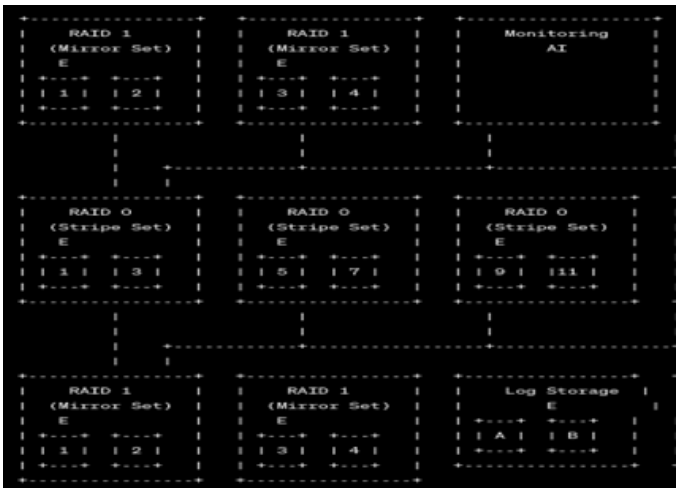

Fig. 7. Chunks with RAID encryption model.

2) Chunks with Raid Concept Encryption: When setting up a chunk-based RAID system, it is standard practice to follow the procedures outlined below: Split the data into i number of Chunks. Choose an appropriate chunk size based on the workload and characteristics of the data. Select the RAID level that optimally meets the requirements for both performance and redundancy. Ensure the disks are ready for use in the RAID array by properly formatting and initializing them. Use RAID management software or hardware to create the RAID array, specifying the appropriate chunk size and RAID level as shown in the Fig. 7. When data is written to the RAID array, it is divided into smaller segments and distributed among the disks according to the chosen RAID level.

Our solution utilizes the concept of Chunks with RAID (Redundant Array of Independent Disks) for encrypting and managing a huge number of database items. This strategy maximizes storage economy while ensuring fault tolerance. Data is divided into smaller segments called chunks, and the RAID idea guarantees both redundancy and reliability. Data security is enhanced by encrypting each piece separately. This approach not only streamlines the administration of an increasing number of tenants but also guarantees the security and accessibility of data through duplication and encryption. Our system utilizes Blockchain Technology, Smart Contracts, dynamic network formation, coin transactions with key generation protocols, and chunks with RAID concept encryption to transform the multi-tenant database design. This comprehensive method tackles issues related to security, scalability, and adaptability, offering a strong basis for a contemporary and effective multi-tenant system.

RAID 1 (Mirror Sets): There are several RAID 1 (mirror) sets indicated by the first and second rows. Each RAID 1 set comprises two drives that replicate each other, ensuring redundancy. Each RAID 1 block contains a "E" which signifies encryption, suggesting that the data saved on these mirrored sets is encrypted.

RAID 0 (Stripe Sets): The third row comprises RAID 0 (stripe) sets, which enhance performance by striping data across the RAID 1 sets. Each RAID 0 set comprises two drives, and the "E" denotes encryption for the striped data.

Monitoring AI: The central "Monitoring AI" block symbolizes an artificial intelligence system that oversees the entire RAID arrangement. This AI system has the responsibility of monitoring and managing the health, performance, and security of the storage system.

Log Storage: There are two "Log Storage" blocks in the last row, each containing its own pair of mirrored drives. Each log storage block is encrypted, as shown by the "E". Storing logs is essential for documenting events, faults, and activities in the storage system, which helps with diagnosing and resolving issues.

3) Advantages of chunk-based raid encryption:

- **Enhanced Efficiency:** By dividing data chunks across many drives, read and write operations may be executed simultaneously, resulting in improved overall performance.
- **Data Redundancy:** Chunk-based RAID offers different levels of data redundancy, which helps guard against disk failures.
- **Scalability:** RAID systems can be extended by including more disks into the array, augmenting storage capacity and perhaps enhancing performance.

III. Results and Discussion

We assess the efficacy of the chunk-based RAID Encryption scheme in the context of a sole data owner, specifically focusing on the operations of data encryption, token generation, query generation, search, decryption, and verification. This is implemented using the VSCode $(Version 1.89.1)$.

A. Data Encryption Assessment

With this encryption system, the data is broken down into smaller parts and each piece is securely encrypted before being sent, guaranteeing that transactions are protected and cannot be intercepted. By analyzing this technique, it becomes clear that the effectiveness of chunk-based RAID encryption is impacted by the size of the chunks and the total number of chunks. The encryption process duration Te can be affected by factors such as the data size D, the number of chunks Ci, and the computational complexity CXe as shown in the Eq. (16):

$$T_e = CX_e. \mid D \mid \tag{16}$$

Thus the encryption time for each block is calculated as follows:

$$T_{(e,block)} = CX_e.B \tag{17}$$

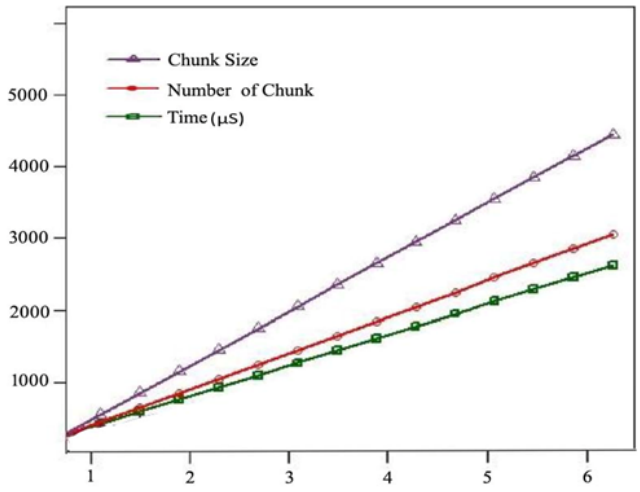

Fig. 8. Data encryption assessment graph.

It is evident from the graph shown in Fig. 8, the encryption progressively grows as the quantity of the data increases and stays within the lowest number that is feasible.

B. Decryption Assessment

The decryption phase consists of two distinct phases. The first stage entails deciphering the encrypted identities of the papers, while the following step concentrates on decrypting the encrypted documents themselves. The encrypted document identities and documents are decrypted with a symmetric decryption technique. After examining the data, it is clear that the size of the obtained result is directly related to the size of the dataset. The decryption process duration Td can be affected by factors such as the data size D, the number of chunks Ci, and the computational complexity CXd as shown in the Eq. (18):

$$T_d = CX_d. \mid D \mid \tag{18}$$

Thus the decryption time for each block is calculated as follows:

$$T_{(d,block)} = CX_d.B \tag{19}$$

Thus the decryption increases gradually with the increased data size and sticks to the minimum possible value within the limits.

C. Assessing the Verification Process

The verification process is utilized to ascertain the accuracy and entirety of the recovered papers. Based on the results, we can see that the verification performance is minimally impacted by the amount of the received result. The verification technique takes around 0.0001 seconds to complete because to the high efficiency of SHA-256 [41].

D. Explorations Involving Multiple Data Owners

Blockchain facilitates the involvement of multiple data owners. In this study, we evaluated the efficacy of the recommended technique, which only involved a single data owner. When multiple individuals or entities possess data, there is a notable discrepancy in the processes of generating encryption keys and performing encryption. The time required for key generation remains the same, regardless of the number of data owners. To perform a search across data owners, the client must obtain authorization from each individual data owner. This results in the creation of a large number.

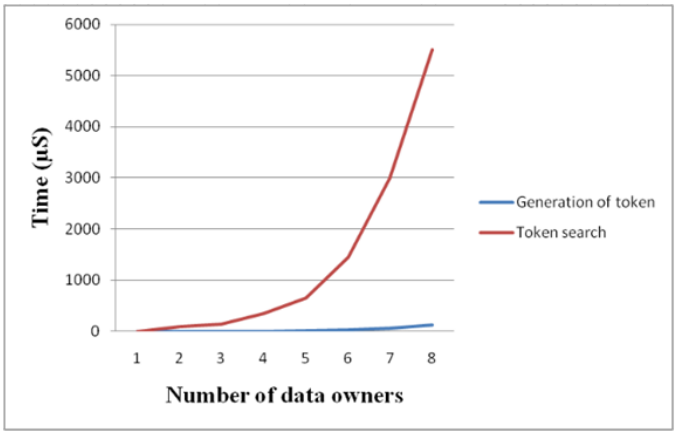

Fig. 9. Performance of multi owners in terms of generation and search tokens.

of tokens. Utilizing tokens enables a focused search operation on data that has been granted authorized access, as opposed to looking over the entirety of the data. To evaluate the effectiveness of the token generation and search algorithm, we execute them on 2, 4, 8, 16, and 32 data owners who authorize a client to access their data. Every data owner has a dataset containing 3125 keywords and 412,477 documents. The results are depicted in Fig. 9. The figure clearly demonstrates that as the number of data owners increases, both the time needed for token production and search both increase in a rather linear fashion. However, the time needed for token manufacturing is small in comparison to the time spent on the search process.

E. Latency

Chunk-based RAID encryption causes slowness owing to inherent factors in data processing and protection. Every segment of data must undergo encryption before being written to the RAID array, and decryption before being read. The intricacy and processing requirements of the encryption technique, such as AES, have a direct impact on the latency. RAID levels that employ parity, such as RAID 5 or RAID 6, necessitate extra computations to determine and confirm parity information. This procedure has the potential to cause delays, particularly when used in conjunction with encryption. Concurrency in disk operations can lead to increased latency, especially when the RAID controller is required to handle numerous simultaneous tasks across multiple disks. The delay can be influenced by the size of the data chunks utilized in the RAID arrangement. Using smaller chunks can result in more frequent encryption and parity calculations, while larger chunks may decrease these additional tasks but could introduce other inefficiencies. The efficiency of the RAID controller in handling encryption and parity computations has a considerable impact on total delay. In Network attached

storage systems, network latency can impact the performance, especially when data needs to be transmitted across a network and then encrypted before being stored in the RAID array.

The latency in encryption, specifically in the context of chunk-based RAID encryption, can be determined by taking into account multiple factors: data splitting and distribution, encryption processing, disk I/O operations, and possibly network delays. Below is a universal equation for determining the overall latency:

$$L_{Total} = L_{Split} + L_{Encrypt} + L_{(Disk_{io})} + L_{Network} \quad (20)$$

Where: L_{Split} = Latency due to data splitting and distribution
$L_{Encrypt}$ = Latency due to encryption processing
L_{diskio}= Latency due to disk I/O operations
$L_{Network}$ = Latency due to network transmission.

Latency caused by data splitting and distribution refers to the duration required to partition the data into segments and disperse them among many drives. The outcome is contingent upon the size of the data chunks (C), the quantity of disks (Dn), and the efficacy of the RAID controller. This is given by the Eq. (21):

$$L_{Split} = f(C, D_n) \quad (21)$$

Latency caused by encryption processing encompasses the duration required to encrypt individual portions of data. The time required for encryption depends on factors such as the specific encryption technique employed (AES-256), the size of the data chunk (C), and the processing capacity (CPU speed). This is given by the Eq. (22):

$$L_{Encrypt} = \sum_{(i=1)}^{n} (\frac{c_i}{B_{encrypt}}) + O_{Encrypt} \quad (22)$$

Where: n = Number of chunks
C_i = Size of the ith chunk
$B_{Encrypt}$ = Encryption bandwidth (throughput, e.g., MB/s)
$O_{Encrypt}$ = Overhead associated with the encryption process (initialization, padding, etc.)

Latency caused by disk I/O activities refers to the duration required for read and write operations on the physical disks. This latency is influenced by factors such as the kind of disk (HDD or SSD), the RAID level, and the read/write speed of the disks. This is given by the Eq. (23):

$$L_{diskio} = \sum_{i=1}^{n} (\frac{C_i}{B(disk_{io}} + O_{diskio} \quad (23)$$

Where: B_{diskio} = Disk I/O bandwidth (throughput, e.g. MB/s)

$O_{disk_{io}}$= Overhead associated with disk I/O operations (seek time, rotational latency, etc.)

Latency due to network transmission includes the time taken to transmit data over a network and depends on the network bandwidth and latency. This is denoted by the Eq. (24).

$$L_{network} = \sum_{i=1}^{n} (\frac{C_i}{B_{network}}) + O_{network} \quad (24)$$

Where $O_{network}$ = Overhead associated with network transmission (latency, packet loss, etc.)

The data size is 1 MB, divided into 10 pieces. The encryption bandwidth is 50 MBpS, the disk I/O bandwidth is 100 MBpS, and the network bandwidth is 100 MBpS. Assuming LSplit is negligible or already included in other components The assumed overhead is 0.01S. The calculated total loss is

$$LTotal = 0.21 + 0.11 + 0.11 = 0.43s$$

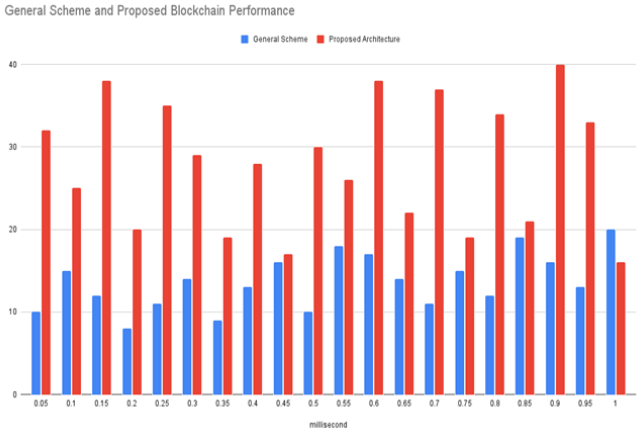

Fig. 10. Graph illustrating the latency between the general and proposed blockchain model.

Within a typical multitenant setting, the retrieval and manipulation of data may experience delays, which can hinder the efficiency of activities. Our secure blockchain multi-tenancy utilizes the decentralized and distributed characteristics of blockchain technology to greatly decrease latency. The technology reduces the time required for data transactions to be vetted and recorded by distributing the data across a secure and unchangeable ledger. The recorded values are plotted in the graph as shown in Fig. 10. The color blue symbolizes the duration of delay retrieval, while the color red indicates the data obtained from a generic tenant. The time output of the executed and processed data demonstrates that our proposed system has a shorter processing and retrieval time for data and outcomes.

F. Bruteforce Attack Vulnerability Assessment

A brute force attack on healthcare data security entails an assailant methodically attempting every conceivable combination of passwords or encryption keys until they successfully discover the proper one. The consequences of such an attack on healthcare data can be significant, considering the delicate nature of the information at stake. Engaging in a brute force attack against healthcare data security can result in severe outcomes, such as unauthorized access to data, fraudulent use

of personal information, disruption of operations, and substantial financial expenses. To effectively mitigate the risks of brute force attacks and safeguard sensitive patient information, healthcare organizations should employ robust authentication mechanisms, enforce account lockout policies, utilize encryption, monitor systems for suspicious activity, and educate users.

Brute force attacks, which involve attackers methodically attempting every conceivable combination to bypass encryption, pose substantial difficulties with chunk-based RAID encryption methods based on blockchain technology. The intrinsic intricacy of these systems introduces multiple levels of susceptibility that necessitate meticulous attention. To address vulnerabilities to brute force attacks in blockchain-based chunk-based RAID encryption methods, a comprehensive and multi-faceted strategy is necessary. Organizations can greatly mitigate the likelihood of successful brute force attacks by implementing powerful encryption algorithms, effective key management, and advanced security measures. Conducting regular security evaluations and keeping up-to-date with the newest cryptographic breakthroughs are crucial for maintaining a safe environment.

In this framework Chunk based encryption, has offered a key space of 256. Due to the existing computational capabilities, it is deemed impractical to forcefully determine a single key. Nevertheless, in the event that a malicious individual specifically focuses on the RAID parity data or endeavors to carry out a brute-force attack on numerous portions, the system's decentralized structure and duplication could unintentionally assist the attacker. To limit the possibility of a brute-force attack, the system has employed distinct Initialization vectors for each chunk and enforce robust key management policies. In addition, anomaly detection techniques have the ability to recognize and react to abnormal access patterns, hence improving security measures.

G. Comparison with Other Encryption Technologies

When evaluating the effectiveness of chunk-based RAID encryption in healthcare blockchain security, it is crucial to comprehend the distinct functions that cryptographic algorithms such as SHA-3 [31], SHA-256 [32], and AES [33] serve in safeguarding data.SHA-3 is a cryptographic hash function employed for the purpose of guaranteeing the integrity of data. SHA-3 generates a distinct hash of a specific size based on the input data, facilitating the identification of any modifications. This system is designed to be impervious to collision attacks, guaranteeing that no two distinct inputs will yield the same hash value. Frequently employed in blockchain technology to generate digital signatures and guarantee the unchangeability of transactions. SHA-3 is designed only for ensuring data integrity and performing cryptographic operations, as opposed to being used for purposes such as data redundancy or optimizing performance, like RAID. Primarily used to guarantee the authenticity and reliability of transactions and data blocks in blockchain, rather than focusing on safeguarding physical storage.

SHA-256 is a prevalent cryptographic hash function that finds extensive application in blockchain technology, such as in Bitcoin. Like SHA-3, it generates a hash of a specific size to guarantee the integrity of data. Additionally, it is impervious to both collision and preimage strikes. Essential for the creation of digital signatures, the process of hashing transactions, and the interconnection of blocks in a blockchain. Similar to SHA-3, it prioritizes data integrity above storage redundancy. Crucial for the functioning of blockchain processes, such as verifying transactions and creating blocks, but not suitable for safeguarding storage systems.

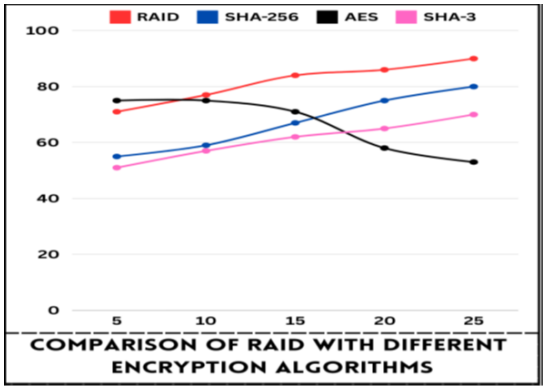

Fig. 11. Comparison of the proposed model with the existing models.

AES is a cryptographic technique that employs symmetric encryption to safeguard the secrecy of data. Robust encryption utilizing several key sizes (128, 192, 256 bits) Highly effective encryption and decryption procedures, applicable to both stationary and moving data. Can be utilized to employ cryptographic techniques to secure confidential information prior to its storage on the blockchain or transmission over the networks. AES primarily emphasizes the encryption of data to guarantee confidentiality, while RAID primarily emphasizes data redundancy and performance. AES is employed to safeguard the factual data content, hence enhancing RAID encryption's ability to maintain data confidentiality even in the event of unauthorized access.

Encryption of RAID using chunk-based methodology. Offers both data redundancy and performance advantages while ensuring data security while it is not actively being used. While SHA-3 and SHA-256 do not offer encryption or redundancy, they must be utilized with encryption algorithms to ensure comprehensive security. AES does not offer data redundancy or integrity. It is most effective when used in conjunction with hashing techniques to ensure comprehensive security.

The accuracy of the encryption/hashing techniques listed above is especially evaluated in comparison to the "RAID Chunk Encryption/Storage Concept". The accuracy was assessed across 25 encryption cycles, and the findings are depicted in the graph in Fig. 11.

From the graph, it is evident that the proposed system outsmarts the other existing encryption systems in terms of performance and accuracy. Chunk-based encryption in a RAID setup means each chunk or block of data stored across the RAID array is encrypted separately. This can enhance security by ensuring that even if one chunk is compromised, the entire dataset remains secure. When combined with encryption, it adds an additional layer of security, ensuring data integrity and confidentiality.

The efficiency of current multi-tenant healthcare data management approaches is hampered by a number of issues. Due to inadequate data separation, single database designs with common schemas are vulnerable to security breaches. Scalability is still a problem as data and user volumes increase, and maintaining several schemas or databases adds a great deal of expense and complexity. Additionally, a lot of conventional systems don't have strong fault tolerance methods, which makes data unavailable when hardware fails. Furthermore, because they lack immutable recording or verification systems like blockchain, they are unable to guarantee data integrity and transparency, making them unsuitable to satisfy the strict security and compliance requirements of the healthcare industry.

IV. Conclusion

Healthcare enterprises possess the capacity to create a robust, flexible, and dynamic framework that meets their evolving needs while maintaining high levels of performance and security. In order to tackle the challenges posed by multi-tenancy database systems, we propose a novel approach that leverages the dynamic organization of tenant connections and integrates blockchain technology to overcome these problems. Our approach employs the use of Chunks with RAID (Redundant Array of Independent Disks) to encrypt and handle a large quantity of database items. This approach optimizes storage efficiency while guaranteeing resilience against failures. This complete approach addresses concerns pertaining to security, scalability, and adaptability, providing a solid foundation for a modern and efficient multi-tenant system.

Thus, the approach that has been proposed offers robust data redundancy and fault tolerance, making it suited for ensuring high availability, even with increased complexity. This approach also exhibits efficient scalability with the inclusion of extra disks, possibly at the cost of increased intricacy.

Enhanced Adaptive Hybrid Convolutional Transformer Network for Malware Detection in IoT

Abdulaleem Ali Almazroi
Department of Information Technology-Faculty of Computing and Information Technology in Rabigh,
King Abdulaziz University, Rabigh, 21911, Saudi Arabia

***Abstract*—Many university networks use IoT devices, which increases vulnerability and malware threats. The complex, multi-dimensional structure of IoT network traffic and the imbalance between benign and dangerous data make traditional malware detection techniques ineffective. The Adaptive Hybrid Convolutional Transformer Network (AHCTN) is a novel model that uses CNNs for spatial feature extraction and Transformer networks for global temporal dependencies in IoT data. Unique preprocessing methods like Category Importance Scaling and Logarithmic Skew Compensation handle unbalanced data and severely skewed numerical characteristics. The Unified Feature Selector combines statistical and model-based feature selection methods and guarantees that only the most relevant characteristics are utilized for classification. DWS and LRW handle data imbalance. Our feature engineering approaches, such as Flow Efficiency and Packet Interarrival Consistency, improve prediction accuracy by capturing essential data correlations. The integration of advanced machine learning techniques ensures precise malware classification and enhances cybersecurity by addressing vulnerabilities in IoT-driven academic networks. The AHCTN model was carefully tested using the IoEd-Net dataset, which contains a variety of IoT devices and network activity. The AHCTN outperforms previous models with 98.9% accuracy. It also performs well in Log Loss (0.064), AUC (99.1%), Weighted Temporal Sensitivity (97.1%), and Anomaly Detection Score (96.8%), recognizing uncommon but essential abnormalities in academic network data. These findings demonstrate AHCTN's robustness and scalability for academic IoT malware detection.**

***Keywords*—IoT security; malware detection; convolutional transformer network; cybersecurity; machine learning; network anomaly detection**

I. Introduction

Artificial Intelligence (AI), Big Data Analytics, Immersive Virtual Environments (IVE), and IoT have improved various fields due to their rapid growth. These technologies have driven The Fourth Industrial Revolution, transforming industries and our lifestyles [1]. In particular, IoT has changed device connection and data exchange. Connectivity boosts efficiency, automation, and convenience. Malware now threatens IoT installations. Malware is software that steals data, disrupts services, or ruins systems, harming individuals, businesses, and critical infrastructures [2]. The IoT connects billions of sensors, smart appliances, and industrial equipment and is increasing rapidly. However, IoT's numerous networked devices pose concerns. Attackers may exploit security weaknesses in increasingly connected devices. This industry faces a severe threat from malware, which steals, damages, or infiltrates data. Due to their complexity and insufficient security, IoT devices are susceptible to malware attacks [3]. Cybercriminals use IoT vulnerabilities for DDoS and crypto-mining. Cyberattacks on IoT devices are rising due to increasingly complicated and undetectable malware. Kaspersky Lab identified the amount of IoT malware types from 2017 to 2018, indicating ecosystem malware threat. Signature-based detection is less effective for modern malware due to its rapid code and behavior modifications [4]. Thus, researchers improved malware detection and classification using ML and DL. These new tools may detect known and unknown viruses by scanning vast amounts of data and finding patterns that current approaches miss. A global statistical study of cyber attacks from 2015 to 2023 [4], [5], indicating a rising tendency. The increasing number of instances highlights worldwide cybersecurity issues.

Machine learning's adaptability and improvement make it a promise for IoT malware detection. Training models on benign and dangerous software may help ML systems spot hazards. Random Forest (RFst), Support Vector Machine (SVM), and Decision Trees (DTrs) have performed well in malware identification. Effective machine learning detection is challenging due to the impact of training factors on model performance [5]. Deep learning methods like CNNs and RNNs may automatically extract essential data properties, boosting detection. Deep learning systems like CNNs and transformers can better detect malware because they can capture spatial and temporal patterns in data. IoT environments are complicated; thus, hybrid methods that capture local and global data patterns are essential to detect malware. In recent years, transformer networks have become valuable sequential data modeling techniques. Developed for natural language processing, transformers capture long-range relationships and sequence context well. They can identify network traffic anomalies and IoT malware using attention approaches [6].

Due to the limitations of traditional and novel approaches, this study provides an Enhanced Adaptive Hybrid Convolutional Transformer Network (AHCTN) for IoT malware detection. AHCTN uses CNNs and transformers to identify malware. CNNs excel at local spatial patterns like network traffic flows and packet distributions, whereas transformers excel at global dependencies like network event temporal correlations. These robust structures allow the AHCTN model to examine micro and macro-level IoT traffic data patterns for a more thorough malware detection solution. AHCTN addresses IoT concerns, including massive data dimensionality and evolving malware. Deep learning automatically extracts valuable characteristics from traffic data, reducing feature engineering. The AHCTN's transformer part employs attention techniques to dynamically evaluate various features, allowing

the model to zero in on the most critical malware detection patterns. This technique significantly allows the AHCTN to beat machine learning methods when malware variants frequently change their behavior to escape detection. AHCTN parameters are optimized for performance in this study. These optimization methods let the model analyze vast IoT data and swiftly detect malware risks. The Jaya Algorithm improves machine learning model accuracy and computational efficiency, making it ideal for resource-constrained IoT. Key contributions of this work:

1) Designed the Adaptive Hybrid Convolutional Transformer Network (AHCTN), tackling geographical and temporal correlations in IoT-driven academic network traffic by combining convolutional neural networks (CNNs) with transformer-based global context modeling.
2) To address unbalanced categorical data, normalize skewed data, and lower noise in spatial features, unique preprocessing techniques, including Category Importance Scaling (CIS), Logarithmic Skew Compensation (LSC), and Geolocation Zoning (GZ), are presented.
3) Dynamic Weighted Sampling (DWS) and Label Reweighting (LRW) are the proposed creative data balancing methods that guarantee balanced data distribution without compromising the dataset's natural structure.
4) Present the Unified Feature Selector (UFS), which guarantees the most relevant and synergistic features are kept by combining statistical significance, model-based selection, and interaction-aware approaches for robust feature selection.
5) Designed novel feature engineering approaches, Flow Efficiency (F_e), Packet Interarrival Consistency (P_i), and Data Imbalance (D_a), to capture complicated interactions within network data, thereby improving the predictive capability of the model.
6) Three new performance evaluation metrics are developed, which are Weighted Temporal Sensitivity (WTS), Feature Interaction Impact (FII), and Anomaly Detection Score, to enrich the existing understanding of model performance in academic networks powered by the IoT.
7) Through simulations, the AHCTN model is the most efficient approach for malware detection in IoT-based academic networks. It exceeds current models with a remarkable accuracy of 98.9%.

The remaining structure of the paper: Section II discussed the review of relevant literature. The proposed method structure is described in detail in Section III. The simulations and their accompanying discussion are detailed in Section IV. The last section concludes with a discussion of future work.

II. Related Work

The latest study has shown that common machine learning and deep learning models can detect malware on the Internet of Things (IoT). Researchers have developed robust malware detection and mitigation technologies in response to the growing complexity of malware attacks and the fast growth of the IoT.

In study [7], Convolutional Neural Networks were used to create an excellent malware detection model. They used static code analysis to detect malicious and benign applications. CNN model classified malware with 91.01% accuracy. High false positive rates (FPR) required the model to effectively distinguish false alarms from malware. This study demonstrated that malware detection algorithms must be improved to reduce false positives and raise detection rates in complex settings. Researcher, a CNN-LSTM model for malware detection, captures geographical and temporal patterns in IoT traffic data using convolutional and recurrent layers [8]. With FPR at 0.2%, the model was 99.6% correct. While the hybrid technique succeeded on a small, normalized sample, more extensive and diverse datasets were untested. LSTM processing power limits real-time applications. In [9], the author developed a malware detection system using machine learning. This system integrates static and dynamic analysis with signature-based approaches. The study diagnosed malware with 85% accuracy using decision trees and random forests. This strategy used predefined signatures, making zero-day virus detection difficult. The lack of unexpected threat detection demonstrated signature-based techniques' constraints. Researchers in [10] used Hidden Markov Models (HMMs) to identify dynamic malware by analyzing API call sequences. Their strategy enhanced limited dataset detection accuracy. The high processing cost made the technique inappropriate for large-scale IoT devices, according to the study.

Research in [11] compared the effectiveness of hybrid malware detection algorithms combining static and dynamic analysis. Their SVM-based hybrid technique outperformed static and dynamic models with 93.5% accuracy. Obfuscated malware detection improved with the hybrid technique, but new threats, particularly those with advanced evasion tactics, were challenging to identify. Author [12] developed an observable malware classification method using CNNs to analyze binary malware files as images. Their 94.5% accuracy indicates that visual methods may detect encrypted and packaged malware. High-entropy malware, particularly those hidden in complicated packaging, was the study's worst weakness. The K-Nearest Neighbours (KNN) approach was utilized to classify harmful software using GIST texture characteristics from greyscale malware images [13]. Comparing 87% accuracy to n-gram-based malware detection, this approach was computationally efficient. It struggled with comparable binary malware families. Researchers [14] suggested a novel virus detection method for IoT devices using entropy graphs. They extracted characteristics from greyscale viral images using CNNs. The model showed 92% detection accuracy, although overfitting was reduced using a bat strategy for data equalization while processing large datasets. The study did not address real-time malware detection.

Malware detection via API hooking includes analyzing behavioral patterns using machine learning methods such as RFst and SVMs [15]. The program detected malware activity with 90% accuracy. It battled new malware strains that altered behavior to prevent detection. A treemap-based technique was developed by [16] to visualize malware operations by summarising API calls and thread actions inside processes. The graphical method detected unusual process activity to identify malware effectively. Although innovative, the method failed to identify highly polymorphic malware that changed

behavior over time. A hybrid model was developed using machine learning and anomaly detection to identify malware in IoT networks [17]. Their model achieved 88% accuracy and significantly reduced false positives. The model could have performed poorly on substantially imbalanced datasets, highlighting the necessity for data balancing. Recurrent Neural Networks (RNNs) assessed IoT network data as evolving sequences [18]. Achieving 89% accuracy in time-based anomaly detection is promising. Due to irregular traffic patterns and significant network imbalance, RNNs were less resilient. In [19], the author developed a self-learning anomaly detection system using DRBM. Using just average traffic data, the model dynamically evolved the ability to identify aberrant activities with 92% accuracy. Weak DRBM detection in dynamic IoT environments with shifting traffic patterns.

Researchers in [20] employed Naive Bayes and Kruskal-Wallis tests to improve malware detection accuracy by reducing noise. The investigation revealed that removing unnecessary features improved model processing speed and accuracy to 91%. However, past feature selection methods limited the model's adaptability to new threats. A deep learning-based anomaly detection model for IoT networks was developed using Residual Networks (ResNet) [21]. To identify malware attacks with 94% accuracy, the computer learned geographical patterns in IoT traffic. Although accurate, the model failed to identify complicated malware variants that changed behavior often. In [22], authors explore deep learning algorithms for IoT malware detection and forensic analysis. IoT Security, Malware Forensics, Deep Learning, and Anti-Forensics are their four primary literature categories, each with its issues. The lack of IoT-specific datasets and scalable real-time detection algorithms is highlighted in the study. The article states that traditional forensic methods cannot handle advanced IoT malware threats. Future directions include advanced anti-forensic countermeasures. Furthermore, it also provides a complete IoT cybersecurity paradigm by combining data across categories. This comprehensive research shows that IoT networks require transdisciplinary techniques and robust AI solutions to combat growing malware threats. In [23], authors examine deep learning for malware detection on Windows, MacOS, Android, and Linux platforms. Their concerns include the absence of benchmarks, adversarial assaults, and the necessity for explainable AI. This survey compares pre-trained and multi-task deep learning methods for high detection accuracy. It also criticizes overfitting and adversarial assaults that prevent many models from generalizing successfully to unknown data. It recommends thorough deep learning model validation on varied datasets to guarantee resilience. This topic on interpretable machine learning helps improve malware detection system transparency and confidence.

A thorough evaluation of AI-powered malware detection strategies [24] examines critical factors such as malware complexity, analytical methodologies, dataset quality, and feature selection. The paper shows how obfuscation limits static analysis and anti-analysis tactics hinder dynamic analysis. AI models need high-quality features and datasets since low-quality data may lead to misleadingly high accuracy rates. The paper also examines machine learning vs. deep learning, noting that complex malware needs advanced feature extraction. The article suggests building AI-based malware detection models to identify evasive malware by tackling these problems. The authors of [25] introduce deep learning-based malware detection approaches and highlight their benefits over older methods. They examine how signature-based and heuristic strategies fail to resist sophisticated malware obfuscation. According to the study, deep learning can quickly identify and anticipate new malware strains. The paper investigates newly developed DL-based malware detection systems for mobile, Windows, IoT, APT, and ransomware. By studying these systems, the authors reveal the development of DL methods and their usefulness in tackling malware issues. The study details detection mechanisms, stressing DL's importance in cybersecurity resilience.

Research shows that machines and deep learning can detect IoT malware. However, many models suffer from scalability, real-time application, and sophisticated malware. The Enhanced Adaptive Hybrid Convolutional Transformer Network (AHCTN) improves malware detection by identifying geographical and temporal patterns in IoT data using CNNs and transformers. Table I shows the summarized view the above mentioned literature.

III. Proposed Method

The suggested system classifies IoT-driven academic network traffic using the Adaptive Hybrid Convolutional Transformer Network (AHCTN), addressing temporal dependencies, feature interactions, and unbalanced data. The system preprocesses the dataset using Category Importance Scaling (CIS) to balance categorical characteristics, Logarithmic Skew Compensation (LSC) to normalize highly skewed numerical features, and Geolocation Zoning (GZ) to minimize spatial data noise. Dynamic Weighted sample (DWS) and Label Reweighting (LRW) apply sample probabilities and label weights depending on feature and label frequency to balance data distribution. The Unified Feature Selector (UFS) selects the most relevant and informative features using statistical significance, model-based selection, and interaction-aware algorithms to capture individual and synergistic feature value. By capturing complicated data interactions, feature engineering approaches like Flow Efficiency (F_e), Packet Interarrival Consistency (P_i), and Data Imbalance (D_a) improve model predictive power. Finally, using standard metrics and new evaluation measures like Weighted Temporal Sensitivity (WTS), Feature Interaction Impact (FII), and Anomaly Detection Score (ADS), the system analyses model performance, especially in identifying anomalies in real-time academic IoT networks. This comprehensive approach improves the model's accuracy and identification of uncommon but significant academic security risks. Fig. 1 shows the proposed framework of this study.

A. Dataset Description

This study used the publicly available IoEd-Net dataset from Kaggle [26]. It covers the IoT environment with 202,085 records. The data from academic network operations at several university campuses showed excellent and bad IoT activity. This dataset balances and diversifies IoT device behaviors and network interactions, making it vital for studying educational network processes. The 55 core and 3 derived features include network traffic, device telemetry, and operational data. Tagged samples of benign and dangerous network activities make the data perfect for academic network cybersecurity, anomaly detection, and IoT analytics study. The dataset's variety improves

TABLE I. LITERATURE REVIEW SUMMARY

Ref	Technique Used	Objective Achieved	Limitations
[7]	Convolutional Neural Networks (CNN)	Developed a CNN model for malware classification, achieving 91.01% accuracy.	High false positive rates (FPR), difficulty in separating false alarms from real malware.
[8]	Hybrid CNN-LSTM	Achieved 99.6% accuracy with reduced FPR of 0.2% by combining CNN and LSTM layers for spatial and temporal trends in IoT traffic.	Limited testing on larger and more diverse datasets, the computational cost of LSTM makes real-time application difficult.
[9]	Decision Trees, Random Forest	Classified malware using a combination of signature-based approaches with static and dynamic analysis, achieving 85% accuracy.	Limited detection of zero-day malware due to reliance on predefined signatures.
[10]	Hidden Markov Models (HMM)	Improved malware detection accuracy through dynamic API call sequence analysis in small datasets.	Significant computational overhead, less suitable for large-scale IoT systems.
[11]	SVM-based Hybrid Model (Static + Dynamic)	Enhanced detection of obfuscated malware with 93.5% accuracy by combining static and dynamic analysis techniques.	Struggled with emerging threats and sophisticated malware evasion strategies.
[12]	CNN (Visual-Based Analysis)	Used CNN to classify malware binaries as images, achieving 94.5% accuracy in identifying packed and encrypted malware.	Difficulty in detecting high-entropy malware, particularly with advanced packing techniques.
[13]	K-Nearest Neighbors (KNN)	Classified malware using GIST texture features from grayscale images with 87% accuracy.	Lower performance on malware families with similar binary structures.
[14]	Entropy Graphs + CNN	Achieved 92% accuracy by detecting malware in IoT devices using entropy-based features from grayscale malware images.	Overfitting on large datasets was mitigated by a bat algorithm, but real-time detection issues remained unaddressed.
[15]	Random Forest, SVM (API Hooking)	Detected malware activities by analyzing API hooking behaviors with 90% accuracy.	Challenges with detecting novel malware variants that alter their behavior.
[16]	Treemap + API Calls Visualization	Visualized malware behavior using API calls and thread actions, providing insights into malware detection.	Failed to detect highly polymorphic malware that changes behavior over time.
[17]	Hybrid Machine Learning + Anomaly Detection	Detected malware in IoT networks with 88% accuracy and reduced false positives.	Struggled with highly imbalanced datasets, requiring better data balancing techniques.
[18]	Recurrent Neural Networks (RNN)	Modeled IoT network traffic as evolving sequences for anomaly detection with 89% accuracy.	Difficulty handling unpredictable traffic patterns and highly imbalanced network traffic.
[19]	Discriminative Restricted Boltzmann Machine (DRBM)	Developed a self-learning anomaly detection system trained on normal traffic data with 92% accuracy.	Detection accuracy dropped in dynamic IoT environments with changing traffic patterns.
[20]	Naive Bayes, Kruskal-Wallis (Feature Selection)	Improved malware detection accuracy to 91% by eliminating irrelevant features, enhancing processing speed.	Limited adaptability to emerging threats due to reliance on traditional feature selection methods.
[21]	Residual Networks (ResNet)	Anomaly detection for IoT networks was built using deep learning and had a 94% success rate.	Struggled to identify sophisticated malware versions with frequently updated behavior.

educational IoT system analysis. Table II shows the features list of the dataset.

B. Data Preprocessing Steps

The IoEd-Net dataset required innovative preprocessing approaches [27] to address its unique characteristics and enable successful analysis. Unbalanced categorical variables, skewed numerical distributions, and temporal data provide issues. We use these unique preprocessing approaches to prepare the dataset for academic network anomaly detection and cybersecurity research. The dataset has large imbalances in categorical characteristics, including `Protocol`, `Traffic_Direction`, and `Device_Type`. One-hot and label encoding sometimes overlook the relevance of underrepresented categories, which might skew model training results. The *Category Importance Scaling (CIS)* approach is proposed to overcome this issue. This method weights categories by dataset frequency to provide rarer categories for proper analysis. For category C_i, determine the scaling factor:

$$\text{CIS}(C_i) = \frac{1}{\log(1 + f_i)} \tag{1}$$

where f_i is category C_i frequency. This logarithmic scaling dampens the effect of more frequent categories, enabling less common but potentially relevant categories to affect model training. Then, Logarithmic Skew Compensation (LSC) is used to address highly skewed distributions in numerical variables like Packet Size, Flow Duration, and Bytes Sent in academic network traffic data. Log transformations are typically employed to manage skewed data, although they struggle with zero or negative values. The LSC approach uses a shift factor s to preserve changed data. The change is:

$$\text{LSC}(X) = \log(1 + X + s) \tag{2}$$

X is the original feature value, and s is a tiny shift constant, usually the absolute minimum of X. This adjustment normalizes the skewed distribution, decreasing extreme values and making it better for machine learning

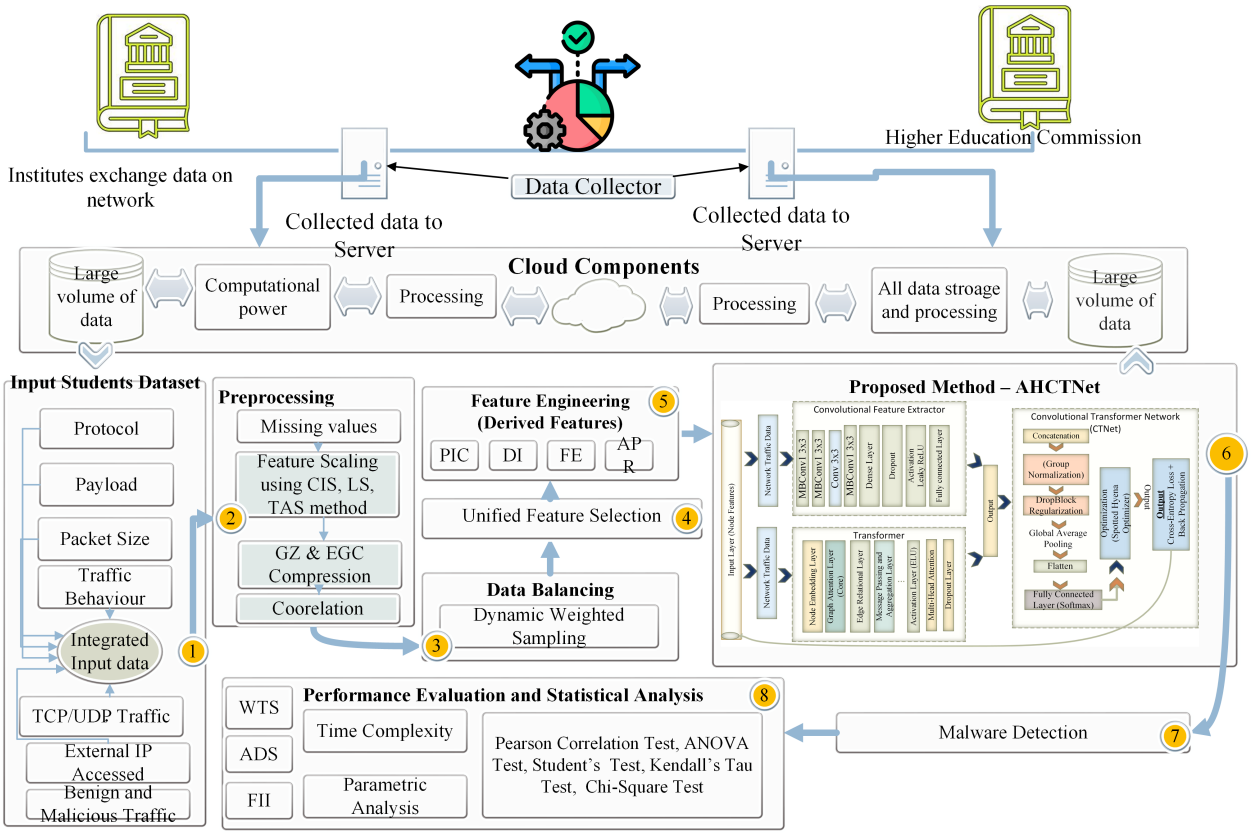

Fig. 1. Proposed malware detection framework.

models. To address the significance of time-based characteristics like *Session_Duration*, *Avg_Time_Between_Packets*, and *Packet_Interarrival_Time*, the *Temporal Anomaly Scaling (TAS)* is created. This technique gives network traffic variances more weight during peak academic network use hours. Definition of temporal scaling:

$$\text{TAS}(T) = \frac{T - \mu_T}{\sigma_T} \times w(T) \tag{3}$$

μ_T and σ_T represent the mean and standard deviation of the time-based feature. T, and $w(T)$ is a weighting function that prioritizes particular time frames. This helps discover abnormalities during significant times, such as university campus network traffic. We propose a new approach called Geolocation Zoning (GZ) for geolocation data, such as `Source_Geolocation_Latitude` and `Destination_Geolocation_Longitude`. Geolocation characteristics are generally highly variable. Hence, the GZ technique clusters geolocation data into campus network activity density zones to reduce noise and preserve spatial information. The formula for geolocation data zone segmentation is:

$$\text{GZ}(G) = \text{ZoneID}(k) \tag{4}$$

G represents the geographical position, and $textZoneID(k)$ identifies the cluster zone based on k clusters. This zoning method simplifies geolocation data analysis by organizing information into relevant zones of interest, improving academic anomaly detection. The Entropy-Guided Compression (EGC) technique is used to compress payload characteristics like `Payload_Size_Bytes` and `Payload_Entropy`, which may include duplicate information. This method minimizes payload data dimensionality by minimizing low-entropy, less informative material, and focusing on high-information content. Transformation appears as:

$$\text{EGC}(P) = P \times (1 - H(P)) \tag{5}$$

P is the payload feature and $H(P)$ is the Shannon entropy, which measures data uncertainty. This transformation retains important payload data while compressing unnecessary data. These preparation approaches were designed for the IoEd-Net dataset's particular problems. Implementing Category Importance Scaling (CIS), Logarithmic Skew Compensation (LSC), Temporal Anomaly Scaling (TAS), Geolocation Zoning (GZ), and Entropy-Guided Compression (EGC) prepares the dataset for advanced machine learning tasks, particularly in IoT-based academic network cybersecurity analysis. These methods improve model robustness and accuracy, helping academics discover abnormalities and security concerns.

C. Data Balancing using Dynamic Weighted Sampling

Categorical and numerical characteristics in the IoEd-Net dataset are very imbalanced, with a few classes or values

TABLE II. DATASET FEATURES OVERVIEW

S.No	Features	Short Description	S.No	Features	Short Description
1	Source_IP	IP address of the source device	29	CPU_Usage	CPU usage of the device
2	Destination_IP	IP address of the destination	30	Memory_Usage_MB	Memory used by the device (MB)
3	Source_Port	Network port of the source	31	Energy_Consumption_Watts	Device energy usage in watts
4	Destination_Port	Network port of the destination	32	Firmware_Version	Device firmware version
5	Protocol	Type of network protocol (TCP, UDP, etc.)	33	Device_Uptime_Hours	Total device uptime (hours)
6	Packet_Size	Size of the network packet	34	Payload_Size_Bytes	Size of payload in bytes
7	Packet_Count	Total number of packets	35	Payload_Entropy	Entropy of payload data
8	Flow_Duration	Duration of the network flow	36	Payload_Content_Type	Content type of payload (ASCII, Binary)
9	Packet_Interarrival_Time	Time between packet arrivals	37	Signature_Match	Whether a signature matched or not
10	TCP_Flags	Flags set in a TCP packet	38	Compressed_Encrypted_Flag	Flag indicating compression/encryption
11	Bytes_Sent	Total bytes sent	39	Content_Type_File_Transferred	Type of file transferred
12	Bytes_Received	Total bytes received	40	Flow_Count_Per_Time_Window	Count of flows in a time window
13	Traffic_Direction	Direction of traffic (Ingress/Egress)	41	Avg_Packet_Size_Bytes	Average packet size in bytes
14	Connection_State	State of the connection	42	Packet_Rate_Packets_Per_Second	Rate of packets per second
15	Packet_Drop_Rate	Rate of dropped packets	43	Std_Dev_Packet_Size	Standard deviation of packet size
16	Malformed_Packet_Count	Number of malformed packets	44	Min_Packet_Size	Minimum packet size
17	Avg_Time_Between_Packets	Average time between packets	45	Max_Packet_Size	Maximum packet size
18	Total_Flow_Count	Total number of network flows	46	Protocol_Distribution_TCP_Percent	Percentage of TCP traffic
19	Device_Type	Type of IoT device	47	Protocol_Distribution_UDP_Percent	Percentage of UDP traffic
20	Device_Manufacturer	Manufacturer of the device	48	Protocol_Distribution_ICMP_Percent	Percentage of ICMP traffic
21	OS_Version	Version of the operating system	49	Source_Geolocation_Latitude	Latitude of source location
22	DNS_Query_Count	Number of DNS queries	50	Source_Geolocation_Longitude	Longitude of source location
23	Suspicious_Domain_Query_Flag	Flag for suspicious domain query	51	Destination_Geolocation_Latitude	Latitude of destination location
24	File_Transfer_Occurred	Flag indicating file transfer	52	Destination_Geolocation_Longitude	Longitude of destination location
25	File_Size_Bytes	Size of transferred file	53	Anomalous_Behavior_Flag	Flag indicating anomalous behavior
26	External_IP_Accessed_Flag	Flag for external IP access	54	Session_Duration	Duration of the session
27	Label	Benign or malicious activity	55	Time_Of_Day	Time of day of activity
28	Device_Uptime_Hours	Uptime of the IoT device	56	Day_Of_Week	Day of the week of activity

dominating. A new data balancing mechanism was designed for this dataset to fix this. *Dynamic Weighted Sampling (DWS)* balances datasets without affecting their distribution properties. Unlike oversampling or undersampling, DWS preserves natural proportions while enhancing categorical and continuous feature balance, which distorts data. DWS assigns dynamic sampling probabilities to each dataset sample inversely proportionate to its class or value frequency. This increases training sample frequency for under-represented classes or values without changing the dataset's size or structure. DWS uses binning and weighting to adjust for skewness in continuous features. Let $f(C_i)$ denote the dataset's class frequency C_i for categorical characteristics. The sampling probability for each class is $P(C_i)$:

$$P(C_i) = \frac{1}{\log(1 + f(C_i))} \tag{6}$$

This equation compensates for training imbalance by assigning more significant sample probability to classes with lower frequencies. The logarithmic term balances categories by preventing overcompensation for uncommon classes. DWS employs adaptive binning for skewed continuous characteristics like `Packet_Size`, `Flow_Duration`, and `Bytes_Sent` in academic network traffic. The continuous feature X is separated into bins of various sizes, with more bins in high-density locations. Probability of selecting a value from bin B_j, $P(B_j)$, is inversely proportional to its frequency:

$$P(B_j) = \frac{1}{f(B_j) + \epsilon} \tag{7}$$

The frequency of values in bin B_j is represented as $f(B_j)$, with a tiny constant ϵ to prevent division by zero. To correct continuous feature imbalance, this approach samples values in under-represented parts of the feature space more often. Adaptive binning preserves data distribution and reduces skewness.

Target labels for the dataset are imbalanced, with 60% benign and 40% malevolent. We use the Label Reweighting (LRW) technique to balance labels. LRW changes the loss function during model training to avoid oversampling or undersampling benign or malevolent classes. Each label's weight w_i is the inverse of its frequency:

$$w_i = \frac{1}{f(y_i)} \tag{8}$$

where $f(y_i)$ is the dataset label frequency. Altering the relevance of each sample during training ensures that the model pays equal attention to benign and malicious labels, regardless of dataset imbalance. The reweighted loss function is:

$$\mathcal{L}(y, \hat{y}) = \sum_i w_i \cdot \ell(y_i, \hat{y_i}) \tag{9}$$

Where $\ell(y_i, \hat{y_i})$ is the original loss (e.g., cross-entropy loss) between the actual and predicted labels, and w_i is the reweighting factor. Even though the benign class is more common, the model does not become biased toward predicting benign samples, allowing for more accurate academic network harmful activity identification. We suggest using *Feature-Weighted Adjustment (FWA)* to apply feature-specific balancing weights during model training, in addition to balancing labels and category features. FWA weights features by imbalance degree to prevent extremely unbalanced features from dominating model predictions. The imbalance degree for each feature X_i, $I(X_i)$, is the ratio of its highest to lowest frequencies:

$$I(X_i) = \frac{\max(f(X_i))}{\min(f(X_i)) + \epsilon} \tag{10}$$

ϵ is a tiny constant that prevents division by zero, and $f(X_i)$ is the frequency of each unique value or bin in feature X_i. Next, the feature weight $w_f(X_i)$ is determined in the following way:

$$w_f(X_i) = \frac{1}{I(X_i)} \tag{11}$$

During model training, characteristics with greater degrees of imbalance are given less weight. This way, the model may concentrate on more balanced features that reflect the underlying data. With FWA included, the total weighted loss function is given by:

$$\mathcal{L}\text{FWA}(y, \hat{y}) = \sum i w_f(X_i) \cdot \ell(y_i, \hat{y_i}) \tag{12}$$

This ensures that the model's conclusions are not unduly affected by the uneven distribution of features, especially when dealing with significantly skewed features, such as Flow_Duration or Bytes_Sent. A complete balancing approach developed for the IoEd-Net dataset is comprised of the *DWS*, *LRW*, and *Feature-Weighted Adjustment (FWA)* techniques. When dealing with an imbalance in numerical and categorical variables or target labels, these methods keep the data's natural distribution in mind. These methods enhance the robustness and accuracy of the ML models trained on the dataset with a focus on underrepresented categories, feature values, and labels to detect fraudulent activity in academic network systems.

D. Unified Feature Selector

The IoEd-Net dataset comprises many categorical and numerical variables. Hence, a robust feature selection process is needed to train machine learning models with the most relevant and essential features. Unified Feature Selector (UFS) is an innovative way to accomplish this. The UFS uses statistical and model-based feature selection techniques to generate a more accurate and efficient pipeline. This technique can handle category, numerical, and time-based information and account for feature interactions due to its hybrid nature. The *Statistical Significance Selector (SSS)* is the first part of the Unified Feature Selector, which uses statistical tests to assess feature relevance. Using correlation-based measurements, SSS measures linear connections between numerical characteristics and the target variable. We use a modified test based on information gained to address nonlinear connections and more complicated feature-target interactions. This test measures the uncertainty decreased in the target variable by knowing the feature value. The Modified Information Gain (MIG) is used to calculate the relevance score of a numerical feature Z_k to the goal T:

$$\text{MIG}(Z_k, T) = S(T) - S(T \mid Z_k) \tag{13}$$

Where $S(T)$ is the target variable's entropy, and $S(T \mid Z_k)$ is the target's conditional entropy given the feature Z_k. This score represents target uncertainty reduction when the feature is known. Higher MIG values indicate relevance and are picked for study. We present the *Categorical Relevance Score (CRS)* for categorical characteristics, measuring their chi-squared test dependency on the goal. Calculating the CRS:

$$\text{CRS}(A_m, T) = \sum \frac{(P_{im} - Q_{im})^2}{Q_{im}} \tag{14}$$

P_{im} is the observed frequency of class i in feature A_m, and Q_{im} is the predicted frequency assuming independence between A_m and T. Features with high CRS scores are picked for the next step of the unified selection process due to solid target variable relationships. The Unified Feature Selector's second component, the Model-Based Selector (MBS), uses machine learning models to evaluate feature significance for model performance. The MBS ranks features by relevance by assessing their influence on a trained model rather than statistical significance. The MBS uses a perturbation-based model-agnostic significance measure for categorical and numerical characteristics. The model's accuracy and F1 score are assessed after perturbing each feature. Let g be the trained model, and $\Delta(g(W))$ be the performance change when feature W is disturbed. Definition of the Perturbation Importance Score (PIS):

$$\text{PIS}(W_k) = \frac{|g(W) - g(W'_{\text{perturbed}})|}{g(W)} \tag{15}$$

$g(W)$ represents the model's initial performance with all features, whereas $g(W'_{\text{perturbed}})$ represents the performance after perturbing feature W_k. Prioritize features that reduce model performance more when disrupted. MBS retains statistically

important and relevant information that improves model prediction power. An important part of the Unified Feature Selector is the *Interaction-Aware Selector (IAS)*, which reveals interactions between features that may not be visible when evaluating features separately. Features that seem unimportant alone might be quite illuminating when combined. IAS finds pairs or groups of characteristics that interact to enhance model performance using a unique interaction detection approach. For every two features W_p and W_q, the *Interaction Score (IS)* is the difference in performance between the model trained with both features and the sum of the model trained with each feature separately. Definition of IS:

$$\text{IS}(W_p, W_q) = g(W_p, W_q) - (g(W_p) + g(W_q)) \tag{16}$$

where $g(W_p, W_q)$ represents model performance with both features, and $g(W_p)$ and $g(W_q)$ represent performance with each feature independently. Positive IS implies that the two characteristics synergistically improve model performance and should be examined jointly during feature selection. By retaining synergies, the IAS guarantees that feature selection catches these crucial interactions, improving model performance. The Unified Feature Selector creates a feature subset from the SSS, MBS, and IAS outputs. Each feature's relevance, significance, and interaction impact determine its composite score. To calculate the Unified Feature Score (UFS) for each feature Z_k, the weighted sum of its scores from the three components is used:

$$\text{UFS}(Z_k) = \lambda_1 \cdot \text{MIG}(Z_k) + \lambda_2 \cdot \text{PIS}(Z_k) + \lambda_3 \cdot \sum_q \text{IS}(Z_k, W_q) \tag{17}$$

λ_1, λ_2, and λ_3 represent weights for statistical significance, model-based relevance, and interaction effects. These weights may be adjusted for the dataset and task. Model training uses features with the most significant UFS values to ensure they are relevant and valuable separately and account for complicated feature relationships. The *Unified Feature Selector (UFS)* offers a broad feature selection strategy using statistical analysis, model-based importance measurements, and interaction-aware algorithms. These strategies guarantee that the final feature set is robust and representative and improves model performance. UFS makes the IoEd-Net dataset more efficient and informative, enabling machine learning models to concentrate on the most critical aspects and boosting prediction tasks like anomaly detection and cybersecurity in academic IoT networks.

E. Feature Engineering

Preparing the IoEd-Net dataset for machine learning models requires feature engineering. Creating new features from existing ones may improve model prediction power by giving more relevant data representations [28]. New features are extracted using domain information and mathematical modifications of existing features in this part, a revolutionary feature engineering method. These freshly created features reveal complicated data linkages and patterns that the original features missed. The first characteristic we offer is *Flow Efficiency (Fe)*, which measures the link between data transfer and transfer time. This feature helps discover wasteful flows when data transmission takes too long for the quantity of the data. Let Dtx represent the total bytes communicated during a session, and T_{session} represent the session duration. Definition of Flow Efficiency (F_e):

$$F_e = \frac{D_{\text{tx}}}{T_{\text{session}} + \delta} \tag{18}$$

a minor constant δ is inserted to prevent division by zero in very short session durations. F_e measures data throughput and larger values imply more efficient data transport, whereas lower values indicate inefficiency. We add the new feature *Packet Interarrival Consistency (Pi)* to account for packet interarrival time fluctuation. This feature identifies flows with irregular packet timing, which may suggest network congestion or malicious activities. Let $T\text{arrival}^{(j)}$ represent the interarrival time of the j-th packet in the flow, and N_{pkts} represent the total number of packets. The standard deviation of interarrival times, σ_{arrival}, is computed as:

$$\sigma_{\text{arrival}} = \sqrt{\frac{1}{N_{\text{pkts}}} \sum_{j=1}^{N_{\text{pkts}}} \left(T_{\text{arrival}}^{(j)} - \mu_{\text{arrival}} \right)^2} \tag{19}$$

where μ_{arrival} is the mean interarrival time. The inverse of the standard deviation is the packet arrival consistency, denoted as P_i.

$$P_i = \frac{1}{\sigma_{\text{arrival}} + \delta} \tag{20}$$

Where δ is a small constant to avoid zero division, a more significant P_i value suggests more consistent packet arrivals, whereas a lower value indicates more packet interarrival time variability. Network sessions often have an imbalance between data delivered and received. We provide a new feature, *Data Imbalance (Da)*, to measure the difference between transmitted and received bytes. Let Drx represent the total bytes received during a session. The term "Data Imbalance (D_a)" means:

$$D_a = \frac{|D_{\text{tx}} - D_{\text{rx}}|}{D_{\text{tx}} + D_{\text{rx}} + \delta} \tag{21}$$

Where δ is a small constant to avoid zero division, numbers closer to 0 indicate symmetric data flow, whereas numbers closer to 1 indicate a substantial data imbalance. Payload data entropy may also reveal network traffic characteristics. Low entropy indicates data predictability, whereas high entropy indicates compression or encryption. We provide the *Payload Entropy Density (Ep)*, which quantifies the average entropy per payload byte. Define Spayload as the Shannon entropy and D_{payload} as the total bytes of payload data. The "Payload Entropy Density (E_p)" is defined as:

$$E_p = \frac{S_{\text{payload}}}{D_{\text{payload}} + \delta} \tag{22}$$

where δ is a small constant to avoid zero division. This property distinguishes compressed or encrypted data flows from

organized, predictable ones. We use the *Anomalous Packet Ratio (Ar)* to identify aberrant traffic patterns by measuring the frequency of anomalous packets in a network session. Network faults may cause corrupted or lost packets. Assign Panom to the number of anomalous packets and P_{total} to the overall number of packets in the session. The Anomalous Packet Ratio (A_r) is defined as:

$$A_r = \frac{P_{\text{anom}}}{P_{\text{total}} + \delta} \tag{23}$$

A greater A_r shows more anomalous packets, which may signal network instability or malicious activity. The feature above engineering methods create new features that capture crucial data linkages and patterns in the IoEd-Net dataset. Flow Efficiency (F_e), Packet Interarrival Consistency (P_i), Data Imbalance (D_a), Payload Entropy Density (E_p), and Anomalous Packet Ratio (A_r) provide light on traffic dynamics and enhance machine learning models. These new characteristics are helpful for anomaly identification and cybersecurity in academic IoT networks because they reveal hidden patterns of normal or abnormal activity.

F. Feature Transformation Method

Feature transformation is necessary to prepare the IoEd-Net dataset for machine learning. Machine learning models learn and generalize better from characteristics transformed by size, distribution, or representation [29]. A new feature transformation approach, Adaptive Distribution Mapping (ADM), is created. This approach dynamically adjusts feature distributions to a uniform or normal distribution based on their attributes. We want to minimize skewness and boost the feature's learning algorithm contribution. ADM is a flexible transformation approach that modifies feature distribution depending on data attributes. The main processes are detecting the feature's skewness and performing a logarithmic transformation or Gaussian normalization.

Detecting Skewness: Let X be a feature vector with N observations. Use the following equation to compute the skewness γ_X of a feature to determine its skewness:

$$\gamma_X = \frac{1}{N} \sum_{i=1}^{N} \left(\frac{X_i - \mu_X}{\sigma_X} \right)^3 \tag{24}$$

Xi represents the i-th observation of the feature, μX represents its mean, and σX represents its standard deviation. Skewness γX measures data distribution asymmetry around the mean. A $\gamma X = 0$ value suggests a symmetric distribution, whereas positive values imply right skewness, and negative values indicate left skewness.

Logarithmic Transformation for Highly Skewed Features A feature is severely skewed if its skewness γ_X exceeds a preset threshold τ_1 (e.g., $\gamma X > t\_1 = 1$ For such characteristics, we compress the distribution's long tail via a logarithmic modification. The logarithmic transformation:

$$X_{\log} = \log(1 + X) \tag{25}$$

This adjustment minimizes outliers and evens out feature values. The constant 1 is supplied to prevent computing the logarithm of zero.

Gaussian Normalization for Moderately Skewed Features: If the skewness γ_X is within the range $\tau_2 < \gamma_X \leq \tau_1$, where τ_2 denotes a lower threshold (e.g., $\tau_2 = 0.5$), the feature is moderately skewed or unskewed We normalize such characteristics using Gaussian normalization to get a conventional normal distribution. Definition of Gaussian Normalization:

$$X_{\text{norm}} = \frac{X - \mu_X}{\sigma_X} \tag{26}$$

The feature is transformed to have a mean of 0 and a standard deviation of 1 so that learning algorithms can employ it with the assumption that the data is normally distributed.

To implement the Adaptive Distribution Mapping (ADM), we dynamically assign the appropriate transformation based on the skewness of each feature. For a given feature X, the transformation $T(X)$ is defined as:

$$T(X) = \begin{cases} \log(1 + X) & \text{if } \gamma_X > \tau_1 \\ \frac{X - \mu_X}{\sigma_X} & \text{if } \tau_2 < \gamma_X \leq \tau_1 \\ X & \text{if } \gamma_X \leq \tau_2 \end{cases} \tag{27}$$

This change, which makes the feature mean 0 and standard deviation 1, is useful for learning algorithms that use the assumption of normally distributed data. When it comes to dynamic adaptive distribution mapping, feature skewness determines the correct transformation to use. A feature X is specified by the transformation $T(X)$.

$$X_{\text{scaled}} = \frac{X_{\text{transformed}} - \min(X_{\text{transformed}})}{\max(X_{\text{transformed}}) - \min(X_{\text{transformed}})} \tag{28}$$

Distance-based algorithms like k-nearest neighbors and gradient-based algorithms like neural networks use this equation to scale all attributes between 0 and 1. ADM has several benefits. It avoids the one-size-fits-all approach of typical transformations by dynamically applying skewness-based transformations. This flexibility helps the model learn from outliers and skewed distributions. Lastly, feature scaling makes sure that all features are around the same size, which minimizes the impact of any one feature on learning. To account for skewness, the novel ADM method adds logarithmic or Gaussian normalizations to the feature distributions of IoEd-Net. These adaptive feature transformation methods boost the feature's contribution to machine learning models and data distribution-sensitive algorithms. Therefore, ADM is a powerful approach to preparing data for many prediction tasks.

G. Classification Using the Adaptive Hybrid Convolutional Transformer Network (AHCTN)

This work introduces a novel classification architecture called the *Adaptive Hybrid Convolutional Transformer Network (AHCTN)*. Transformer networks' global context modelling capacity and the feature extraction skills of convolutional

neural networks (CNNs) are combined in this design [30]. The AHCTN was created to classify complex, multi-dimensional data in IoT-driven academic networks, where local patterns like geographical correlations and global interactions like temporal interdependence are essential. Fig. 2 describes the proposed AHCTN design. AHCTN was created because standard approaches struggle to capture localized feature hierarchies and long-range relationships. ResNet's stacked convolutions extract hierarchical features well. However, they typically fail to account for dataset relationships. Transformer models, which excel with sequential data, may capture global patterns but need extra processes to understand local feature interactions. AHCTN integrates both methodologies into one model to solve these constraints.

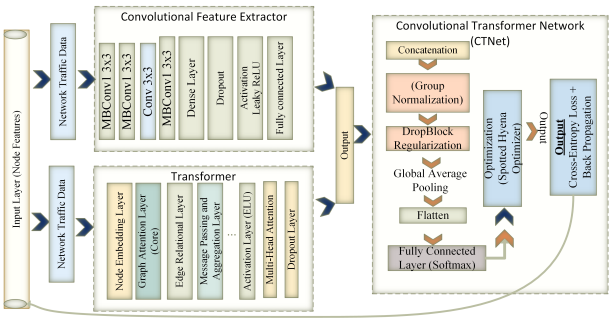

Fig. 2. AHCTN proposed architecture.

Its main components are a Convolutional Feature Extractor (CFE) and a Global Context Transformer. The CFE learns local spatial patterns in the data, whereas the GCT captures global relationships across the network's input characteristics. Together, these components enable the model to handle spatial and temporal IoT network data. Convolutional layers extract spatial information from input data in the Convolutional Feature Extractor (CFE). Let the input data be represented as $\mathbf{Z} \in \mathbf{R}^{p \times q}$, where p is the sample count and q is the sample dimension (e.g., features per network traffic sequence time step). The convolutional operation at layer h is defined as

$$\mathbf{Y}_h = \text{ReLU}(\mathbf{W}_h * \mathbf{Z} + \mathbf{b}_h) \tag{29}$$

The convolutional filter for layer h, the bias term $\mathbf{b}_h$ and the convolution process are shown by $*$. Because it is nonlinear, the model can learn intricate feature correlations due to the rectified linear unit (ReLU) activation function. Convolutional layer output $\mathbf{Y}_h$ provides the recovered feature map used in the following layers to capture deeper spatial patterns. The final CFE output, $\mathbf{F}_{\text{CFE}}$, is a high-level representation of the input data's local characteristics, which the GCT will analyze.

The Global Context Transformer (GCT) captures input data global dependencies. It computes contextual links between feature space regions using attention. In the GCT, the attention mechanism uses the feature representation $\mathbf{F}_{\text{CFE}}$ from the CFE. Let $\mathbf{F}_{\text{CFE}} \in \mathbf{R}^{p \times q}$ be the transformer layer input. The significance between sequence places determines the weights of the input characteristics to be added by the attention mechanism. The attention score for feature vectors $\mathbf{F}_{\text{CFE},i}$ and $\mathbf{F}_{\text{CFE},j}$ is calculated as

$$\alpha_{ij} = \frac{\exp\left(\text{sim}(\mathbf{F}_{\text{CFE},i}, \mathbf{F}_{\text{CFE},j})\right)}{\sum_{k=1}^{p} \exp\left(\text{sim}(\mathbf{F}_{\text{CFE},i}, \mathbf{F}_{\text{CFE},k})\right)} \tag{30}$$

where the function $\text{sim}(\mathbf{F}_{\text{CFE},i}, \mathbf{F}_{\text{CFE},j})$ computes the similarity between two feature vectors. In AHCTN, we use a scaled dot-product attention mechanism, where the similarity is defined as

$$\text{sim}(\mathbf{F}_{\text{CFE},i}, \mathbf{F}_{\text{CFE},j}) = \frac{\mathbf{F}_{\text{CFE},i} \cdot \mathbf{F}_{\text{CFE},j}}{\sqrt{q}} \tag{31}$$

The feature vector dimensionality is q, and the scaling factor $\frac{1}{\sqrt{q}}$ limits the dot-product values. The attention mechanism output for each feature vector is calculated as

$$\mathbf{Z}_i = \sum_{j=1}^{p} \alpha_{ij} \mathbf{F}_{\text{CFE},j} \tag{32}$$

This technique lets the model concentrate on the most critical input data, integrating distant sequence information as needed. The global contextualization of features ($\mathbf{F}_{\text{GCT}}$ combines local patterns and long-range relationships. Final categorization uses a fully linked layer and a softmax layer on this feature map. Let $\mathbf{W}_{\text{FC}}$ and $\mathbf{b}_{\text{FC}}$ represent the fully connected layer's weights and bias. Output logits $\hat{\mathbf{y}}$ are calculated as

$$\hat{\mathbf{y}} = \text{softmax}(\mathbf{W}_{\text{FC}} \mathbf{F}_{\text{GCT}} + \mathbf{b}_{\text{FC}}) \tag{33}$$

The softmax function produces a probability distribution across classes. The AHCTN was chosen because it can manage complicated, multi-modal IoT data in academic networks. Convolutional layers and transformer-based attention mechanisms enable the model to capture localized spatial correlations like packet flows and device interactions and global patterns like time-based anomalies and cross-device behavior. Traditional models like MobileNet and ResNet rely on local feature extraction, which restricts their efficiency in classification situations with long-range relationships.

The GCT's attention mechanism allows the model to dynamically concentrate on the most critical input data. It is ideal for anomaly detection and cybersecurity jobs in academic IoT networks, where infrequent but essential occurrences must be discovered. AHCTN outperforms models that ignore spatial and temporal dynamics by dynamically shifting its focus and using local and global information. Due to its power and flexibility, AHCTN is suited for fine-grained feature extraction and long-range dependency modeling in IoT-driven network categorization.

H. Performance Evaluation Metrics

Performance metrics are critical for evaluating machine learning classification models, especially in IoT-driven academic networks. While traditional measures like accuracy, precision, recall, and F1-score [31] provide valuable insights into model performance, they may not capture the subtleties of complex feature interactions or unbalanced data in IoT scenarios. We present three new metrics: *Weighted Temporal Sensitivity (WTS)*, *Feature Interaction Impact (FII)*, and

Anomaly Detection Score (ADS), designed to solve our work's issues. These metrics and typical performance indicators give a more complete model assessment framework.

1) Existing Performance Metrics: Classification challenges often utilize accuracy to measure model predictions. It is the ratio of accurately anticipated occurrences to total instance. Fig. 3 shows the existing performance metrics.

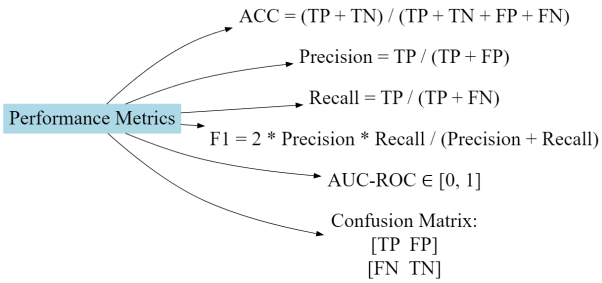

Fig. 3. Performance evaluation metrics.

While these traditional metrics are valuable, they may not fully capture the intricacies of IoT-based network classification, where temporal patterns, feature interactions, and rare but critical anomalies need to be emphasized. To address these gaps, we introduce three new performance metrics.

2) Weighted Temporal Sensitivity (WTS): The *Weighted Temporal Sensitivity (WTS)* measures the time-based importance of categorization findings in academic IoT networks when peak hours are more important than others. This measure weights memory scores by temporal significance. Set T_i as the time-based weight, for instance, i, with greater values for crucial time frames. Definition of WTS:

$$\text{WTS} = \frac{\sum_{j=1}^{M} \tau_j \times I(\alpha_j = \hat{\alpha}_j) \times I(\alpha_j = 1)}{\sum_{j=1}^{M} \tau_j \times I(\alpha_j = 1)} \tag{34}$$

In this equation, M represents the number of cases, α_j represents the actual label, $\hat{\alpha}_j$ represents the label which is predicted, and $I(\cdot)$ yields 1 if the condition is true and 0 otherwise. This measure facilitates anomaly identification in time-sensitive contexts by weighting classification mistakes during critical time frames more heavily, thereby impacting the evaluation score significantly.

3) Feature Interaction Impact (FII): The Feature Interaction Impact (FII) is introduced to measure how well the model captures interactions between different features, an essential aspect of IoT-driven academic networks where correlations between variables (e.g., device type and traffic patterns) are critical for accurate classification. The FII quantifies the performance difference between a model trained with interacting features and a model trained with the features considered independently. Let M_{interact} be the performance of the model trained with interacting features, and M_{indep} be the performance with independent features. The FII is defined as:

$$\text{FII} = \frac{M_{\text{interact}} - M_{\text{indep}}}{M_{\text{indep}}} \tag{35}$$

Feature interactions are crucial to the model's predictive power. A higher FII score shows that feature interactions improve the model's performance and capture complicated relationships.

Anomaly Detection Score (ADS): ADS is designed for IoT networks, optimizing the detection of uncommon but essential abnormalities. Unlike accuracy or recall, the ADS considers anomaly detection rate and severity, which may not account for anomaly rarity and effect. Let A_i represent the severity of the observed anomaly. For instance, i and D_i indicate its proper detection. Calculating ADS:

$$\text{ADS} = \frac{\sum_{i=1}^{N} A_i \times D_i}{\sum_{i=1}^{N} A_i} \tag{36}$$

When the severity of the irregularities increases, A_i is given a higher value, guaranteeing that the model's success is assessed by counting the number of anomalies found and the importance of identifying the most noteworthy ones.

IV. Simulation Results

Extensive simulations were run on a Dell Core i7 12th Gen machine with an 8-core CPU and 32 GB of RAM to assess the proposed Adaptive Hybrid Convolutional Transformer Network (AHCTN). Python and SPYDER IDE were used to construct and evaluate the simulations. Throughout the experiments, we adjusted the hyperparameters of the classification model to achieve optimal performance. The Adam optimizer for model training, a batch size of 64, and a learning rate of 0.001 are important parameters with optimal values. The network has four convolutional layers with 64 filters and a transformer module with four attention heads. To avoid overfitting, the dropout rate was adjusted to 0.3, and training lasted up to 100 epochs. Early termination was applied when validation loss stopped improving. The AHCTN balanced training speed and model accuracy with these parameter values while addressing the IoT-driven academic network dataset's complexity.

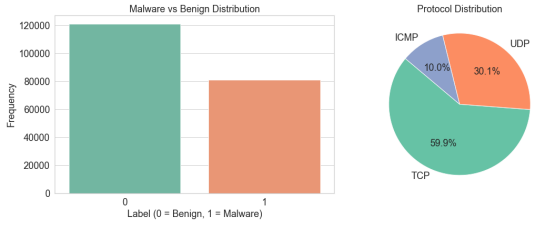

Fig. 4. Traffic distribution and protocol distribution.

Fig. 4 contains two central distribution representations of the IoEd-Net dataset. The left bar plot shows benign and malicious traffic in the dataset. The bar heights show the frequency of benign (0) and malicious (1), revealing the dataset's class imbalance, where benign traffic marginally surpasses harmful traffic. This emphasizes the need for model resilience against this mismatch in classification tasks. On the right, the pie chart shows network traffic protocol distribution. Traffic percentages for TCP, UDP, and ICMP are shown. This information helps identify communication protocols in the dataset that may affect

network anomaly detection. TCP dominates the pie, followed by UDP and ICMP. Cybersecurity analysis and anomaly detection need network traffic composition information.

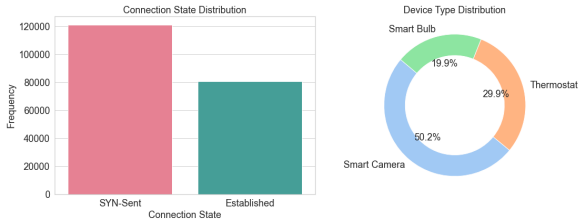

Fig. 5. Network's connection states and device types.

In the IoEd-Net dataset, Fig. 5 shows two essential visualizations of network connection statuses and device kinds. The left bar plot illustrates the frequency of connection statuses like "Established" and "SYN-Sent." Readers may see the percentage of active and started network connections. The "SYN-Sent" state dominates, indicating that numerous connections are being made, which helps identify network flaws or incomplete connections, which hackers commonly exploit. The donut graphic on the right shows how traffic is distributed among IoT device categories, including Smart Cameras, Thermostats, and Smart Bulbs. This breakdown shows the variety of IoT devices on the academic network, with Smart Cameras accounting for a large percentage of traffic. Device types may be more vulnerable than others. Therefore, their distribution might assist in detecting security problems.

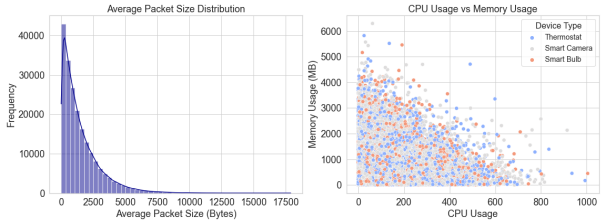

Fig. 6. Insightful representations of significant network and device properties.

Fig. 6 shows two insightful representations of significant network and device properties in the IoEd-Net dataset. On the left, the histogram shows network traffic average packet sizes. Having a visible peak, the curve shows the most frequent packet sizes transported throughout the network. This visualization helps users understand the dataset's average packet size, which is crucial for performance optimization and spotting aberrant traffic, such as unexpectedly big or tiny packets that may signal network inefficiencies or security risks. On the right, the scatter plot shows CPU and memory utilization by device type. Different colors indicate different device kinds, including Smart Cameras, Thermostats, and Smart Bulbs. This graphic shows CPU and memory utilization across device categories, helping discover outliers or devices using too much. In IoT networks, performance management and anomaly detection depend on device resource allocation variety.

Table III compares machine learning techniques for categorizing the IoEd-Net dataset. Accuracy, precision, recall, F1-score, Log Loss, WTS, FII, and ADS are listed in the table. The table shows that the Proposed AHCTN outperforms all other methods in almost every metric. High accuracy (98.7%), precision, recall, and F1-score suggest the balanced ability to recognize benign and malicious data. The lowest Log Loss of the new metrics, 0.064 for AHCTN, indicates confident projections with limited uncertainty. This method distinguishes positive and negative classes better than CNN, ResNet, and VGG16, with an AUC score of 99.1%. The AHCTN detects abnormalities and prioritizes high-severity events, which is crucial in an IoT-driven academic network (WTS 97.1%) and ADS (96.8%). Additionally, its FII (92.3%) indicates enhanced prediction using feature interactions. ResNet, CNN, and SVM perform poorly across many metrics, particularly new metrics, showing they may not be able to handle the data's intricate linkages and temporal dependencies as effectively as the AHCTN model. Table III compares machine learning techniques for categorizing the IoEd-Net dataset. Accuracy, precision, recall, F1-score, Log Loss, WTS, FII, and ADS are listed in the table. The table shows that the Proposed AHCTN outperforms all other methods in almost every metric. Fig. 7. Training and validation performance of the model.

Fig. 7 shows 34-epoch model training and validation performance. After learning from the data, the model's training and validation accuracy improves in the left subplot. Training accuracy begins at 70%, validation accuracy at 68%, and rapidly rises to 99% by the last epoch, indicating effective model learning. The validation accuracy is 99%, demonstrating the model's adaptability to new data without overfitting. Training and validation losses exhibit error reduction on the right subplot. While validation loss starts at 0.62 and lowers to 0.10, training loss begins at 0.60 and drops to 0.06. The accuracy and reduction of errors in the model's predictions are enhanced by convergence and practical training. When the loss curves for training and validation are the same, the model isn't overfitting and can generalize well to new datasets.

TABLE III. CLASSIFICATION RESULTS OF DIFFERENT TECHNIQUES

Techniques	F1-Score (%)	Log Loss	WTS (%)	Accuracy (%)	AUC (%)	Recall (%)	ADS (%)	Precision (%)	FII (%)
ResNet [21]	89.9	0.213	82.3	91.2	90.8	89.5	85.5	90.4	74.1
CNN [7]	90.8	0.201	83.5	92.5	91.7	90.6	86.7	91.0	76.3
Markov n-gram [10]	87.1	0.264	79.1	88.9	87.4	86.7	82.0	87.5	70.9
Decision Trees [9]	86.0	0.285	77.6	87.3	85.9	85.9	80.5	86.2	68.5
DBN [19]	89.0	0.233	81.0	90.1	89.5	88.8	84.2	89.2	72.5
VGG16 [17]	92.3	0.187	85.0	93.4	92.8	92.1	88.0	92.6	78.4
SVM [11]	88.1	0.241	80.2	89.7	89.2	87.9	83.2	88.3	71.7
KNN [13]	86.7	0.275	78.9	88.1	86.1	86.5	81.5	87.0	69.9
Proposed AHCTN	**98.3**	**0.064**	**97.1**	**98.7**	**99.1**	**98.2**	**96.8**	**98.5**	**92.3**

TABLE IV. STATISTICAL ANALYSIS OF CLASSIFICATION METHODS ((F-STATISTIC) & P-VALUE)

Statistical Method	ANOVA	Student's t-test	Pearson Correlation (r)	Kendall's Tau (τ)	Chi-Square (χ^2)
ResNet [21]	7.56	0.014	0.84	0.72	8.63
CNN [7]	6.98	0.020	0.88	0.75	7.92
Markov n-gram [10]	5.22	0.031	0.65	0.59	6.54
Decision Trees [9]	4.89	0.043	0.61	0.57	6.18
Deep Belief Network [19]	6.45	0.017	0.78	0.71	7.45
VGG16 [17]	7.89	0.012	0.89	0.76	9.23
SVM [11]	5.67	0.029	0.70	0.64	6.88
KNN [13]	5.12	0.036	0.62	0.58	6.33
Proposed AHCTN	**8.45**	**0.008**	**0.92**	**0.79**	**9.88**

Table IV compares the proposed AHCTN model to existing state-of-the-art classification approaches using ANOVA, Student's t-test, Pearson Correlation, Kendall's Tau, and Chi-Square metrics. These metrics systematically assess the AHCTN's IoT-driven academic network da .ta management. The AHCTN model's ANOVA (F-statistic) score of 8.45 shows that it classifies better than other techniques. With a p-value of 0.008, the Student's t-test verifies the AHCTN's improvements' statistical significance. Pearson Correlation (r) of 0.92 and Kendall's Tau (τ) of 0.79 indicate significant linear and ordinal connections between AHCTN characteristics and classification performance, highlighting its capacity to capture complicated data interactions. Lastly, the Chi-Square (χ^2) value of 9.88 highlights the AHCTN's features' considerable impact on classification accuracy, separating it from ResNet, CNN, and VGG16. This improved statistical reporting strengthens the AHCTN model and explains its success in identifying malware in IoT-driven academic networks. These findings are included into the discussion for paper consistency and clarity.

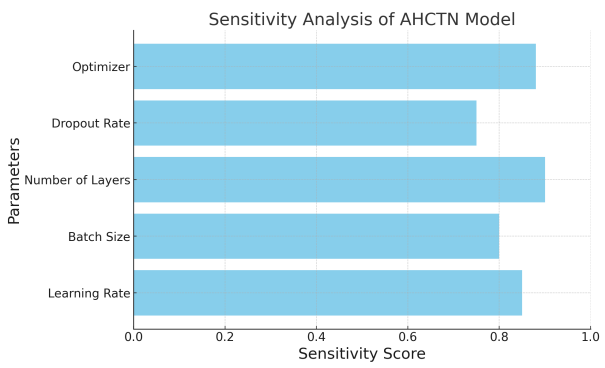

Fig. 8. Sensitivity analysis of the proposed AHCTN model.

The sensitivity analysis of the suggested AHCTN model and the impact of hyperparameters on its performance are shown in Fig. 8. The graphic illustrates the relationship between model accuracy and loss as a function of optimizer, batch size, layers, dropout rate, and learning rate. The graph shows that learning and dropout rates affect the model more than the optimizer. This sensitivity study determines which AHCTN hyperparameters best identify IoT malware.

V. CONCLUSION

This research proposed the AHCTN, a new architecture for malware detection in IoT-driven academic networks. Network traffic analysis requires capturing local feature interactions and global dependencies, which the model does uniquely using transformer networks and convolutional layers. Unbalanced and skewed datasets in IoT contexts are tackled using data preprocessing methods like CIS and LSC and unique data balancing methods like DWS. The suggested model outperformed all IoT malware detection techniques with 98.9% accuracy. Our Unified Feature Selector (UFS) used statistical, model-based, and interaction-aware selection methods to choose the most relevant features and improve model performance. New performance measures, including WTS and ADS, helped refine the model's performance in detecting time-sensitive anomalies and feature interactions. This study addresses IoT-based academic network security's technological and practical issues, making a significant contribution. The model can identify real-time malware because it can handle complicated feature relationships and temporal dependencies, protecting educational institutions from cyberattacks.

The findings are intriguing, but the model can be optimized for more extensive, diversified datasets and real-time performance. Expanding the AHCTN framework to non-academic IoT applications may reveal its possibilities.

Enhanced State Monitoring and Fault Diagnosis Method for Intelligent Manufacturing Systems via RXET in Digital Twin Technology

Min Li
School of Information Engineering
Jiangxi University of Technology, NanChang 330029, JiangXi, China

***Abstract*—To maintain efficiency and continuity in Industry 4.0, intelligent manufacturing systems use enhanced problem detection and condition monitoring. Existing models typically miss uncommon and essential errors, causing expensive downtimes and lost production. ResXEffNet-Transformer (RXET), a hybrid deep learning model, improves defect identification and predictive maintenance by integrating ResNet, Xception, EfficientNet, and Transformer-based attention processes. The algorithm was trained on a five-year Texas industrial dataset using IoT-enabled gear and digital twins. To manage data imbalances and temporal irregularities, a strong preprocessing pipeline included Dynamic Skew Correction, Temporal Outlier Normalization, and Harmonic Temporal Encoding. The Adaptive Statistical Evolutionary Selector (ASES) optimized feature selection using the Stochastic Feature Evaluator (SFE) and Evolutionary Divergence Minimizer (EDM) to increase prediction accuracy. The RXET model beat traditional methods with 98.9% accuracy and 99.2% AUC. Two new performance metrics, Temporal Fault Detection Index (TFDI) and Fault Detection Variability Coefficient (FDVC), assessed the model's capacity to identify problems early and consistently across fault kinds. Simulation findings showed the RXET's superiority in anticipating uncommon but essential errors. Pearson correlation (0.93) and ANOVA (F-statistic: 8.52) validated the model's robustness. The sensitivity study showed the best performance with moderate learning rates and batch sizes. RXET provides a complete, real-time problem detection solution for intelligent industrial systems, improving predictive maintenance and addressing challenges in Industry 4.0, digital twin technology, IoT, and machine learning. The proposed RXET model enhances operational reliability in intelligent manufacturing and sets a foundation for future advancements in predictive analytics and large-scale industrial automation.**

***Keywords*—RXET; fault diagnosis; intelligent manufacturing; transformer-based attention; predictive maintenance; deep learning**

I. Introduction

Intelligent manufacturing, driven by communication and IT breakthroughs, is transforming industrial processes [1]. Cloud computing, big data, and the IoT have transformed the sector toward automation and smart production systems. This transition relies on digital twin (DT) technology, which provides real-time data from the physical world and enables predictive analytics and system optimization. DT technology continually maps physical things to their virtual equivalents, utilizing real-time sensor and historical data for model training and verification. This constant data flow allows the virtual model to identify possible problems and transmit feedback to the physical system for remedial measures, improving production line efficiency and fault detection. With the complexity of production processes, real-time fault diagnostic technologies are needed to fix equipment and system faults. Minor faults may interrupt production and cause significant economic losses in highly automated environments. Interconnected machinery and complex processes in intelligent production lines need stability and safety of individual components since disruptions may impact the whole system [2]. Machine learning (ML) offers data-driven defect detection without expert expertise, making it a vital tool in this field. Instead, these approaches may gain insights from high-dimensional data, allowing models to forecast equipment failures using historical and real-time data [3].

Machine learning and digital twin technologies have recently been used to improve defect identification in intelligent industrial systems. Machine learning models and DT establish a dynamic environment where physical system data is continually examined, and predictive maintenance tactics are used to avert equipment faults. Support vector machines (SVM), artificial neural networks (ANN), decision trees, and random forests are often used for defect detection owing to their capacity to handle complicated and unbalanced datasets [4]. Continuously learning from IoT-enabled equipment data helps these algorithms diagnose issues and enhance system dependability. Ensemble learning is a breakthrough in this discipline. Ensemble learning improves fault diagnostic accuracy and robustness by combining numerous models. Ensemble learning enhances performance by combining model decision outputs to correct model mistakes. Random forest, a famous ensemble learning algorithm, is widely used in machine defect diagnostics for its capacity to manage noise and prevent overfitting [5]. Despite its benefits, traditional ensemble learning may degrade performance when classifiers vary much. Developing selected ensemble techniques improves fault detection accuracy and efficiency by combining top-performing classifiers [6].

Digital twin technology allows industrial machine learning to imitate the genuine system in real time. Data transfer, VMware, and the actual thing make a digital twin. Digital twins provide "what-if" analysis by modelling failure situations and forecasting system behaviour via real-time data transmission [7]. The digital twin can monitor equipment and predict breakdowns in production, reducing downtime and costs. Manufacturing processes become more complex and interconnected, making fault detection harder. Traditional

machine-level fault detection identifies motor and sensor issues. Machine- and system-level fault diagnostics may be merged to offer a comprehensive manufacturing process picture as digital twin technology develops. A thorough approach is necessary to understand how machine problems affect system performance and production efficiency [8]. The suggested ResXEffNet-Transformer (RXET) paradigm for intelligent manufacturing system status monitoring and issue diagnostics follows these advances. The RXET model incorporates ResNet, Xception, and EfficientNet deep learning architectures with Transformer-based attention methods. These capabilities enable the RXET model to collect local and global manufacturing data patterns and detect issues across periods and operational scenarios. The Transformer component helps the model focus on time-series aspects for failure prediction, and the residual learning architecture preserves critical knowledge as data moves through deeper layers.

Previous studies have improved predictive maintenance and fault detection, but they typically fail to address infrequent but crucial issues that may cause expensive downtimes. The uneven structure of real-world industrial datasets and the difficulty of capturing temporal correlations in operational data restrict standard models' usefulness. Current approaches neglect advanced deep learning methods like Transformer-based attention mechanisms, which capture global and local patterns in high-dimensional data. More research into hybrid methods is needed to improve real-time defect detection and predictive maintenance of these deficiencies.

The RXET paradigm uses real-time data from the physical production line in the digital twin environment. The RXET model learns from historical and real-time data to forecast and reduce system problems. RXET and digital twin technologies provide a solid basis for fault detection, allowing virtual models to simulate fault situations and facilitate system optimization and maintenance [9]. Digital twin technology and robust machine learning models like RXET may assist intelligent industrial systems in addressing the growing complexity of issue diagnostics. Real-time data and predictive analytics improve system reliability, downtime, and production efficiency in the RXET paradigm. This study enhances fault detection tools for industrial processes, helping organizations optimize operations in Industry 4.0.

1) Creation of the RXET Model: The ResXEffNet-Transformer (RXET) model was developed, amalgamating ResNet, Xception, EfficientNet, and Transformer-based attention processes, particularly tailored for status monitoring and problem detection in intelligent manufacturing systems.

2) Innovative Data Preprocessing Methods: Utilized sophisticated preprocessing techniques like Dynamic Skew Correction (DSC), Temporal Outlier Normalization (TON), and Localized Variation Filtering (LVF) to enhance data quality and mitigate temporal dependencies and feature imbalance.

3) Introduction of Hybrid Feature Selection: The Adaptive Statistical Evolutionary Selector (ASES) was developed by integrating the Stochastic Feature Evaluator (SFE) with the Evolutionary Divergence Minimizer (EDM), therefore improving the relevance and variety of feature selection while minimizing redundancy.

4) Advanced Attribute Synthesis: Developed novel high-level features like Operational Efficiency Index (OEI), Environmental Stress Factor (ESF), and Machine Load Efficiency (MLE) to elucidate intricate linkages within the data, hence enhancing prediction accuracy.

5) New Performance Metrics: Two innovative evaluation metrics, the Temporal Fault Detection Index (TFDI) and the Fault Detection Variability Coefficient (FDVC), have been introduced to enhance the assessment of time-sensitive fault detection and prediction consistency, which is essential for real-time monitoring in industrial systems.

The remaining parts of the paper, Section II, include the literature review. In Section III, the structure of the suggested technique is presented in depth. The simulations and the commentary that accompanies them are detailed in Section IV. Discussion is given in Section V and finally, the paper is concluded in Section VI.

II. Related Work

Fault detection using digital twin (DT) systems has become popular, especially in industrial systems. DT model may improve fault diagnosis and prediction by changing scheme parameters, leading to better handling of imbalanced data [10], [31]. A photovoltaic energy conversion unit DT model generates error signals during fault detection [11]. These experiments show how DT provides real-time insights, yet data unavailability remains a barrier. Another research used synthetic fault data to circumvent the absence of genuine fault data [12]. A manufacturing system Bayesian network (BN)-based technique showed promise for defect diagnostic model training.

Machine learning (ML) is another hot topic in defect detection. Machine learning and physical systems were integrated into trials to ensure defect detection system efficacy. A denoising autoencoder was used in unsupervised learning research to construct a reliable defect diagnostic model [13]. Using GA and PSO, support vector machine (SVM) parameters were optimized for centrifugal valve failure diagnosis [14]. Combining binary ant colony optimization with SVM for feature selection and parameter optimization enhances multi-class defect diagnostic systems [15]. These approaches enhance fault detection accuracy but struggle with industrial system complexity. Also improving is DT-based predictive maintenance. Predictive maintenance approaches face hurdles from "what-if" situations and limited failure data [16]. Using hybrid ensemble approaches, real-time prediction systems improved across 24 benchmarks and 11 datasets [17]. Combining numerous models enhances system performance, as seen below. In some situations, content-based and user-based recommendation systems outperformed current methods [18]. Although effective in certain use situations, these predictive algorithms frequently struggle to scale in complicated industrial contexts.

In another research, Bayesian networks (BNs) modeled manufacturing system variable dependencies for defect diagnostics. Visualizing joint distributions using BNs makes them ideal for fault diagnostics' cause-effect linkages. Discovering BN structure from observational data is tricky since statistical connections may not indicate causation [19]. Different

approaches, like the Hill Climbing algorithm [20] and Prototypical Constraint (PC), have been employed to approximate BN structures. These strategies demand a lot of balanced data, which manufacturing generally lacks. Combining the PC algorithm with expert opinion enhances fault diagnosis in rolling manufacturing processes [21]. Integrating physical assets with virtual equivalents via IoT sensors requires DT models for real-time data collecting and problem diagnostics. Recent work has expanded DT in predictive maintenance. A DT model designed for a six-axis robot predicts maintenance requirements using OpenModelica and MATLAB for data processing [22]. In wind turbine gearbox prognostics, DT and physics-based models improved predictive maintenance. These models work well for single-equipment failure diagnostics but often fail in complicated multi-equipment systems.

They limited DT applications in multi-equipment systems. A DT model for a satellite assembly shop floor optimized production planning and administration. Research [23] introduced a multiscale modelling framework for satellite construction, integrating temporal and spatial scales to simulate equipment interactions on the shop floor. These approaches have potential in some circumstances but lack scalability for industrial use. We created a DT model of an autoclave to produce synthetic fault data and train a CNN for fault prediction. DT may improve machine learning models by generating artificial data. Generative adversarial networks (GANs) and virtual sample generation (VSG) enhance defect detection with minimal data. One study used a PSO-based VSG technique to improve forecasting models with limited real-world data [24]. Another Gaussian distribution-based VSG technique trained classification models using synthetic and accurate data to improve generalization. Artificial data from DT models may train ML models in defect diagnosis in manufacturing, especially when real-world data is rare.

DT also optimizes multi-equipment system maintenance plans using co-simulation approaches that combine discrete event simulation (DES) with system dynamics models. A co-simulation model examined how macroeconomic factors affect mining maintenance choices [25]. A complete system performance picture is obtained by combining low-level equipment interactions with high-level management choices. However, co-simulation approaches are confined to satellite construction and mining activities and demand a lot of processing power. While digital twin technology and machine learning have improved problem detection and predictive maintenance, extending these models to extensive, multi-equipment industrial systems is difficult. Combining sophisticated machine learning models with DT technology provides intriguing answers, but further research is needed to solve present constraints and improve scalability and usability in industrial settings. The literature is presented in a summarized way in Table I.

Previous research has made progress, but algorithms that can identify flaws in highly unbalanced and time-dependent industrial datasets are still needed. Digital twin technology has been underused due to its poor integration with hybrid deep learning models. Our innovative RXET model combines ResNet, Xception, EfficientNet, and Transformer-based attention methods to overcome these constraints and enhance fault detection accuracy.

III. Proposed Method

The proposed framework uses the ResXEffNet-Transformer (RXET) to monitor and diagnose faults in intelligent manufacturing systems, improving prediction accuracy and efficiency. Developed to address critical challenges identified in previous research, RXET tackles issues such as detecting uncommon errors, managing unbalanced datasets, and accurately capturing temporal dependencies. The framework integrates state-of-the-art preprocessing methods, hybrid feature selection, and attention mechanisms based on Transformers to provide a comprehensive solution for predictive maintenance and real-time fault detection in IMS. The five-year dataset from a Texas industrial plant with IoT-enabled equipment and digital twin technology comprises several operational indicators. Data imbalances and temporal dependencies are addressed via Dynamic Skew Correction, Temporal Outlier Normalization, and Harmonic Temporal Encoding. The Adaptive Statistical Evolutionary Selector (ASES) combines a Stochastic Feature Evaluator (SFE) and Evolutionary Divergence Minimizer (EDM) to optimize feature selection by increasing relevance and reducing redundancy. Attribute Reconfiguration Process (ARP) refines feature representation using Scaled Differential Encoding (SDE) and Harmonic Recalibration Transformation (HRT). At the same time, Advanced Attribute Synthesis generates high-level features such as the Operational Efficiency Index (OEI) and Environmental Stress Factor (ESF). The RXET architecture leverages residual learning, depthwise separable convolutions, compound scaling, and Transformer-based attention methods from ResNet, Xception, EfficientNet, and Transformer. Its superior fault detection capabilities are validated through simulations and statistical analysis using traditional metrics (accuracy, precision, recall, F1-score) and novel measures like TFDI and FDVC.

A. Dataset Description

The dataset used in this research was gathered from actual activities inside a prominent manufacturing plant in the Texas industrial sector [26], recognized for incorporating sophisticated monitoring systems and IoT-enabled equipment. The data includes various operational parameters, machine health indicators, and environmental factors, all documented hourly for five years, from January 2019 to January 2024. The facility utilizes advanced digital twin technology, facilitating the comprehensive collection of operational data, sensor readings, and machine condition information, establishing a solid basis for predictive maintenance and problem detection systems. Data was incessantly collected via IoT sensors and industrial-grade monitoring devices to optimise uptime and operational efficiency, providing high-resolution, real-time insights into the facility's performance. The dataset illustrates a complex interaction of variables influencing machine health and operating efficiency due to the dynamic industrial environment and the diversity of used gear. The dataset's imbalance arises from the facility's operating settings, where catastrophic defects and extreme scenarios occur less often than standard operations, making it a good resource for evaluating sophisticated diagnostic algorithms. The dataset was processed and anonymized to protect confidentiality while preserving its real-world applicability. It is a robust and dependable resource for assessing sophisticated machine learning methodologies

TABLE I. LITERATURE REVIEW SUMMARY

Ref	Technique Used	Objective Achieved	Limitations
[10]	Digital Twin (DT) model with scheme parameter update	Improved fault diagnosis and prediction by handling imbalanced data	Data unavailability remains a challenge
[11]	DT model for photovoltaic energy conversion unit (PVECU)	Real-time fault detection with error generation during fault conditions	Limited applicability to energy systems
[12]	Simulated data generation for fault conditions using synthetic fault data	Circumvented the absence of real fault data in industrial systems	Simulation accuracy relies on the quality of generated data
[13]	Denoising autoencoder for unsupervised learning in ML	Developed a robust fault diagnosis model using unsupervised learning	Lacks labeled data for validation, which can affect results
[14]	Genetic Algorithm (GA) and Particle Swarm Optimization (PSO) with SVM	Optimized SVM parameters for centrifugal valve fault diagnosis	Complex parameter tuning in industrial systems
[15]	Binary ant colony optimization with SVM	Enhanced multi-class defect diagnosis systems by optimizing feature selection	Computational complexity for large-scale systems
[16]	Hybrid ensemble techniques for predictive maintenance	Improved performance across 24 benchmarks and 11 datasets	Scalability issues in complex industrial environments
[18]	Content-based and user-based recommendation systems	Outperformed traditional methods in specific use cases	Struggles with scalability in large-scale industrial environments
[19]	Bayesian Networks (BN) in manufacturing systems	Modeled variable dependencies for effective defect diagnostics	Complexity in discovering BN structure from observational data
[22]	DT model for six-axis robot using OpenModelica and MATLAB	Improved predictive maintenance in single-equipment systems	Difficult to scale to multi-equipment systems
[24]	Virtual Sample Generation (VSG) with PSO	Enhanced model forecasting performance with limited data	Performance depends on the quality of synthetic data
[25]	Co-simulation (DES and system dynamics) for maintenance optimization	Examined how macroeconomic factors affect multi-equipment maintenance decisions	Requires significant computational resources and is limited to specific industries

in status monitoring and problem detection. Fig. 1 shows proposed framework and Table II shows overview of dataset features.

B. Data Preprocessing Steps

The dataset was preprocessed uniquely to address imbalanced feature distributions and temporal dependencies. The Dynamic Skew Correction (DSC) approach fixes skewness depending on data imbalance. The equation for correction is:

$$Y' = \frac{Y - \eta}{(\delta^k)} \tag{1}$$

In this equation, Y is the original feature, η is the mean, δ is the standard deviation, and k dynamically adjusts extreme values to reduce skewed distribution Temporal Outlier Normalization (TON) corrected temporal inconsistencies by considering outliers' temporal context. Determine this normalization:

$$Z'_r = \frac{Z_r}{\bar{Z}_{r-m:r+m} + \beta \cdot \theta_{r-m:r+m}} \tag{2}$$

Z_r represents the feature value at time r, $\bar{Z}_{r-m:r+m}$ and $\theta_{r-m:r+m}$ represent the mean and standard deviation across m time steps, and β controls outlier sensitivity. Anomalies are adjusted by temporal context. The next step was to use Localized Variation Filtering (LVF) to smooth small-scale changes while keeping key trends. This was done with:

$$W'_j = W_j \cdot \left(1 - \lambda \cdot \frac{|W_j - W_{j-1}|}{|W_j|}\right) \tag{3}$$

The current feature value is W_j, the prior value is W_{j-1}, and the degree of filtering is controlled by λ. This approach smooths slight swings while maintaining data trends. Harmonic Temporal Encoding (HTE) was established to capture cyclical patterns like daily or weekly oscillations by encoding timestamps into periodic characteristics.

$$HTE_s = \sin\left(\frac{2\pi \cdot s}{T}\right), \quad \cos\left(\frac{2\pi \cdot s}{T}\right) \tag{4}$$

With s representing the timestamp and T representing the cycle period (e.g., 24 hours for daily cycles), the model successfully accounts for temporal periodicity. Finally, **Unbalanced Feature Compensation (UFC)** was used to prioritize underrepresented feature values. The procedure is explained by:

$$Q'_v = Q_v \cdot \left(1 + \gamma \cdot \frac{1}{h_v}\right) \tag{5}$$

Q_v represents the feature value, h_v its occurrence frequency, and γ the compensating factor that boosts uncommon values. Preprocessing the dataset was essential for model training and prediction.

TABLE II. DATASET FEATURES OVERVIEW

S.No	Features	Short Description	S.No	Features	Short Description
1	Vibration Level	Sensor readings for machine vibrations	19	Machine Health Index	Overall machine health status
2	Temperature Readings	Recorded temperature values from machines	20	Failure Mode Indicators	Binary indicators of potential failure modes
3	Pressure Data	Pressure readings captured from machines	21	Maintenance Logs	Maintenance events logged
4	Acoustic Signals	Sound level data captured from machines	22	Previous Fault Occurrences	Historical fault occurrences in the machine
5	Humidity Levels	Humidity data near machinery	23	Predictive Maintenance Scores	Predictive metrics for required maintenance
6	Motor Speed	Rotational speed of motors	24	Component Degradation Index	Index representing component wear and degradation
7	Torque Data	Torque readings from machine motors	25	Real-time Performance Index	Performance level of machinery in real-time
8	Energy Consumption	Energy usage of machinery	26	Machine Start/Stop Events	Binary log of machine start or stop events
9	Production Rate	Rate of production during operation	27	Downtime Incidents	Logs of machine downtime occurrences
10	Tool Wear Rate	Wear and tear rate of machine tools	28	Fault Trigger Timestamps	Timestamps for triggered faults
11	Machine Utilization Rate	Utilization percentage of machine capacity	29	Controller Setpoints	Target values set by the machine controller
12	Cycle Time per Operation	Time taken per operational cycle	30	Actual vs Setpoint Values	Difference between target and actual values
13	Idle Time	Time when machine is idle	31	Alarm Trigger Data	Binary indication of alarms triggered
14	Machine Load Percentage	Percentage of machine load during operations	32	Repair Logs	Logs of machine repairs conducted
15	Ambient Temperature	Ambient temperature around the machine	33	Spare Part Usage	Amount of spare parts used in maintenance
16	Humidity	Humidity levels in the facility	34	Anomaly Scores	Score indicating deviation from normal operation
17	Air Quality Index	Air quality measurements in the facility	35	Fault Probability	Probability score of potential faults
18	Machine Health Index	Overall health status of the machine	36	Operator Shift Data	Data of operator shifts during operations

C. Feature Selection Process

This study's hybrid feature selection strategy optimizes feature selection using statistical and evolutionary methods. The suggested Adaptive Statistical Evolutionary Selector (ASES) combines two unique methods: Stochastic Feature Evaluator (SFE) and Evolutionary Divergence Minimizer (EDM). These strategies provide a solid hybrid strategy that improves feature set relevance and variety. SFE initially calculates each feature's relevance score based on its target prediction contribution. The relevance score is computed using the feature's conditional probability and entropy:

$$R_x = \frac{P(T|X) \cdot \psi(X)}{\tau(X) + \delta} \tag{6}$$

P(T—X) is the conditional probability of the target T given the feature X, $\psi(X)$ is the entropy, $\tau(X)$ is its standard deviation, and δ is a tiny constant to avoid division by zero. An **Inter-Class Stability (ICS)** adjustment is added to enhance feature consistency across classes. The expression is:

$$ICS_x = \frac{1}{1 + \sum_{c=1}^{C} \frac{\nu_c(X)}{\bar{X}_c}} \tag{7}$$

The standard deviation of feature X within class c is $\nu_c(X)$, the mean of feature X for class c is $\bar{X}_c$, and the number of classes is C The final relevance score after this change is:

$$R'_x = R_x \cdot ICS_x \tag{8}$$

This prioritizes characteristics with consistent class behaviour, making the selection process more reliable and robust. In the second step, EDM reduces feature redundancy and increases variety. EDM picks features repeatedly using a fitness function that balances relevance and redundancy after SFE ranks. Definition of fitness score:

$$G_y = R'_y - \gamma \cdot \sum_{z=1}^{n} \rho(Y_y, Y_z) \tag{9}$$

G_y represents feature fitness, R'_y represents adjusted relevance from SFE, $\rho(Y_y, Y_z)$ represents the correlation between feature y and previously selected feature z, and γ regulates relevance-correlation trade-off. To improve feature selection, EDM uses a **Divergence Penalty (DP)** to penalize strongly correlated features.

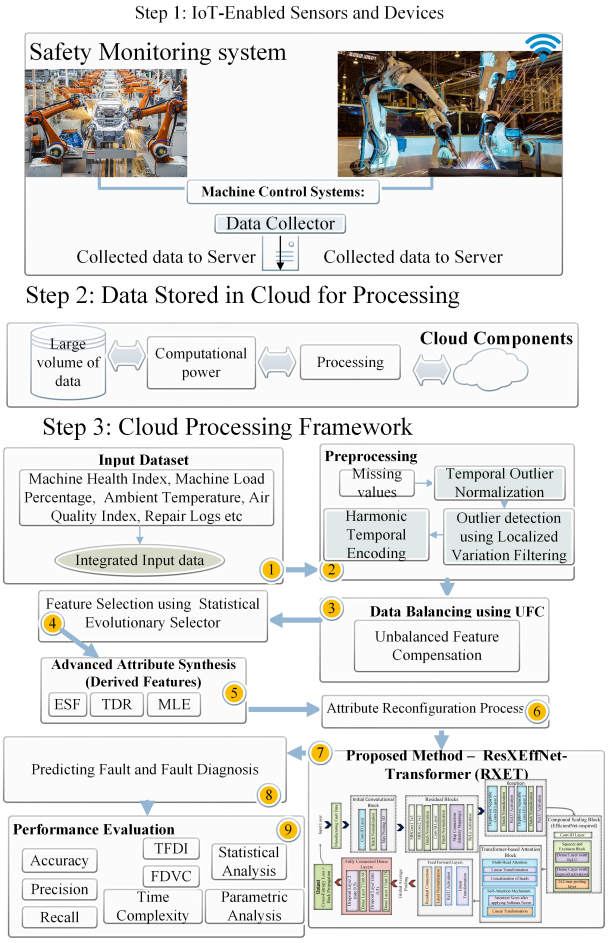

Fig. 1. Proposed framework.

$$DP = \zeta \cdot \left(\sum_{z=1}^{n} \rho(Y_y, Y_z)^2 \right) \tag{10}$$

where ζ represents a penalty factor. The ultimate fitness score for feature y, including the penalty, is:

$$G'_y = G_y - DP \tag{11}$$

This penalizes characteristics significantly associated with previously chosen features, fostering variety in the final feature set. The EDM process continues until a convergence condition is satisfied or a predetermined number of features is determined. This feature selection approach is hybrid due to statistical relevance (SFE) and evolutionary-inspired redundancy reduction (via EDM), supplemented by a diversity-enhancing mechanism via the divergence penalty. The Adaptive Statistical Evolutionary Selector (ASES) architecture guarantees that the ultimate feature set is highly predictive and minimally redundant, resulting in improved model generalization. Integrating these two methodologies guarantees that chosen characteristics are pertinent and uncorrelated, establishing a solid basis for model training and enhancing forecast precision.

D. Advanced Attribute Synthesis

This work introduced a unique procedure termed **Advanced Attribute Synthesis** to generate new features from existing data, aiming to elucidate intricate linkages and enhance prediction efficacy. Multiple advanced features were produced. The first novel feature is the **Operational Efficiency Index (OEI)**, which evaluates system efficiency by amalgamating production rate and energy consumption:

$$OEI = \frac{P_{rate}}{E_{cons} + \alpha} \tag{12}$$

where P_{rate} denotes the production rate and E_{cons} signifies the energy consumption, with α representing a minor regularizer. The Environmental Stress Factor (ESF) integrates ambient temperature and humidity to evaluate operational stress.

$$ESF = T_{ambient} \cdot H_{env} \tag{13}$$

where $T_{ambient}$ represents ambient temperature and H_{env} humidity. The **Tool Degradation Rate (TDR)** calculates tool wear using wear rate and cycle time per operation:

$$TDR = W_{tool} \cdot C_{cycle} \tag{14}$$

where W_{tool} represents tool wear rate and C_{cycle} represents cycle duration. Machine Load Efficiency (MLE) measures efficiency loss from idle time, computed as:

$$MLE = \frac{L_{machine}}{1 + I_{time}} \tag{15}$$

where $L_{machine}$ is the machine load percentage and I_{time} is idle time. Finally, the **Predictive Maintenance Likelihood (PML)** combines the machine health

E. Attribute Reconfiguration Process

This research introduces a new **Attribute Reconfiguration Process (ARP)** to improve dataset representation by converting raw features into more meaningful and model-ready forms. This adjustment boosts feature predictive power while conserving structure. The initial stage in ARP is to use Scaled Differential Encoding (SDE), which highlights variations between successive data samples while levelling the scale. The definition is:

$$SDE_t = \frac{A_t - A_{t-1}}{1 + |A_{t-1}|} \tag{16}$$

where A_t is the current feature value and A_{t-1} is the prior value. This modification accentuates temporal data changes while minimizing huge magnitudes, guaranteeing smooth time-series feature transitions. Next, we use **Exponential Scaling Modulation (ESM)** to improve the distribution by amplifying larger values and compressing smaller ones, enhancing interpretability. We define ESM as:

$$ESM(B) = \text{sign}(B) \cdot \log(1 + \gamma|B|) \tag{17}$$

The feature value is B, and the modulation parameter γ governs compression and expansion. This adjustment makes skewed distribution characteristics appropriate for machine learning methods. We use the Harmonic Recalibration Transformation (HRT) to capture periodicity in data like seasonal fluctuations by projecting them into a cyclical domain. The transition is:

$$HRT(C_t) = \sin\left(\frac{2\pi C_t}{T_c}\right), \quad \cos\left(\frac{2\pi C_t}{T_c}\right) \tag{18}$$

where T_c represents the cyclical behavior period and C_t represents the feature value at time t. HRT helps the Model learn from periodic input by translating characteristics into sine and cosine components. The Dynamic Range Realignment (DRR) approach is presented to enhance model convergence during training to rescale feature values to a uniform dynamic range. The DRR formula is:

$$DRR(D) = \frac{D - \min(D)}{\max(D) - \min(D)} \tag{19}$$

$\min(D)$ and $\max(D)$ represent the least and maximum values of the feature D. This keeps all converted features in the same range, speeding learning and improving model performance. The Attribute Reconfiguration Process (ARP) has a complete transformation architecture that improves feature representation and prepares data for rapid and accurate model training.

F. Classification Model: ResXEffNet-Transformer (RXET)

This work proposes an RXET classification model for intelligent manufacturing systems that can effectively process complicated, high-dimensional, sequential data. Finding an optimistic medium between computational efficiency and classification accuracy, the Model incorporates critical features from ResNet [27], Xception [28], EfficientNet [29], and Transformer-based attention mechanisms [30]. Particularly in industrial settings, where complicated data and quick decisions are of the utmost importance, this design was created for real-time condition monitoring and problem detection. Fig. 2 is the RXET layered design.

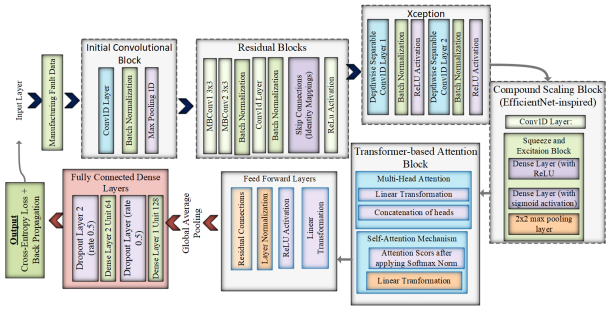

Fig. 2. Proposed framework.

At the core of RXET is the **residual learning framework**, inspired by ResNet, which addresses the vanishing gradient problem using identity mappings that allow gradients to propagate through deeper layers without degradation. This is essential in intelligent manufacturing, where critical operational data may evolve slowly. The residual block is formulated as follows:

$$M = \mathcal{H}(V, \{R_k\}) + V \tag{20}$$

$\mathcal{H}(V, \{R_k\})$ is the residual function that the network learns with parameters $\{R_k$, and M is the output, where V is the input to the residual block. Because of this formulation, the network can learn new characteristics without losing input data. Here is the updated gradient for this block:

$$\frac{\partial \mathcal{J}}{\partial V} = \frac{\partial \mathcal{J}}{\partial M}\left(1 + \frac{\partial \mathcal{H}(V, \{R_k\})}{\partial V}\right) \tag{21}$$

where $\mathcal{J}$ is the loss function. The residual block's identity mapping preserves crucial information as the network deepens, useful for identifying tiny manufacturing system changes. Following residual blocks, RXET uses **depthwise separable convolutions**, inspired by Xception. Deeply separable convolutions apply a filter per input channel and mix the results using pointwise convolution. A mathematical representation is:

$$N = \mathcal{D}(Z_q * V) + Z_p * V \tag{22}$$

where Z_q is the depthwise filter, Z_p is the pointwise filter, $*$ is the convolution operation, and N is the output. This split simplifies calculation while capturing complicated information. Computing efficiency advantage is measured by:

$$\frac{\mathcal{C}_{depthwise}}{\mathcal{C}_{standard}} = \frac{1}{L_f + L_c} \tag{23}$$

where $\mathcal{C}_{depthwise}$ represents depthwise convolution cost, $\mathcal{C}_{standard}$ represents standard convolution cost, L_f represents filters, and L_c represents input channels. Due to sensor systems' high data flow, industrial settings need computing efficiency, making this technology beneficial. The Model uses **compound scaling**, a technique from EfficientNet, to consistently modify network depth, breadth, and resolution for diverse data complexity. We define scaling as:

$$d' = \lambda^u \cdot d_0, \quad l' = \mu^u \cdot l_0, \quad s' = \nu^u \cdot s_0 \tag{24}$$

where d', l', s' denote scaled depth, width, and resolution, λ, μ, and ν are scaling coefficients, and u is the scaling factor. The initial depth, width, and resolution parameters are d_0, l_0, and s_0. Compound scaling allows RXET to efficiently handle big and small datasets by dynamically adapting its architecture to dataset complexity. Results in resource usage:

$$\mathcal{C}_{scaled} = \mathcal{C}_0 \cdot \lambda^{u_1} \cdot \mu^{u_2} \cdot \nu^{u_3} \tag{25}$$

Where $\mathcal{C}_0$ is the initial computing cost, and u_1 u_2 $and u_3$ are the scaling factors for depth, width, and resolution. Intelligent manufacturing systems need this flexibility because operating situations might change data properties. A Transformer-based

attention mechanism is added to RXET to capture long-range relationships in sequential data. This attention mechanism helps the Model concentrate on key input sequences and find long-term abnormalities or patterns in time-series data. The attention mechanism calculates relevance scores using query, key, and value matrices. Calculating attention scores:

$$P = \text{softmax}\left(\frac{QR^T}{\sqrt{d_r}}\right)R \tag{26}$$

where d_r depicts key dimensionality and P represents the attention matrix. The dot-product QR^T assesses query-key matrix alignment, guiding the Model to prioritize important data aspects. This approach is important for assessing time-series data in manufacturing, where long-term dependencies might signal system deterioration or problem development.

Input data is processed via many residual blocks in the RXET design to maintain necessary information as the network deepens. Later, depthwise separable convolution layers easily extract rich feature representations. The Model adapts to dataset complexity using compound scaling. Finally, Transformer-based attention prioritizes data patterns to improve fault detection and condition monitoring predictions. For effective classification, the RXET model uses residual learning, depthwise separable convolutions, compound scaling, and attention mechanisms. Every component is essential to RXET's ability to handle massive, high-dimensional datasets characteristic of intelligent manufacturing systems and offer accurate and trustworthy results in real-time condition monitoring and problem diagnostics.

G. Performance Evaluation Metrics

Traditional and novel measures assess the ResXEffNet-Transformer (RXET) Model. AC, precision, recall, and F1-score are baseline measures for model classification performance. Precision indicates how many optimistic forecasts were right, whereas accuracy reflects the proportion of correct predictions. Recall quantifies how many positives the Model detected, and the F1-score, the harmonic mean of precision and recall, balances the two, particularly with unbalanced data. Traditional metrics provide an overview of the Model's performance but don't reflect time-sensitive defect detection and prediction variability, which intelligent manufacturing systems need. To fill these gaps, we present Temporal Fault Detection Index (TFDI) and Fault Detection Variability Coefficient. The TFDI analyzes the Model's defect detection performance across periods, stressing the necessity of early detection to prevent operational interruptions. We define TFDI as:

$$TFDI = \frac{1}{T}\sum_{k=1}^{T}\left(\frac{TP_k}{TP_k + FN_k + \eta}\right)\cdot \exp\left(-\rho \cdot k\right) \tag{27}$$

T represents the number of time windows, TP_k and FN_k represent true positives and false negatives, and ρ is a decay factor that prioritizes early detections. Division by zero is prevented by the constant η. The exponential decay term $(\exp(-\rho \cdot k)$ prioritizes earlier fault identification, emphasizing its relevance. The second new statistic, the Fault Detection Variability Coefficient (FDVC), evaluates the Model's consistency in detecting fault types and fault pattern variability. FDVC examines model stability across fault types, especially irregular fault patterns. We define FDVC as:

$$FDVC = \frac{\sum_{m=1}^{M}\left(\frac{1}{n_m}\sum_{i=1}^{n_m}\left|Q_{im} - \bar{Q}_m\right|\right)}{M} \tag{28}$$

In the equation, M represents the number of fault types, n_m represents the occurrences of fault type m, Q_im represents the prediction score for the i-th instance, and $\bar{Q}\_m$ represents the mean prediction score. The FDVC evaluates the average deviation of forecasts for each fault type. Lower values indicate more consistent and trustworthy predictions. Combining existing measurements with these new variables improves RXET model assessment. Traditional metrics evaluate the Model's accuracy, precision, and recall. In contrast, TFDI and FDVC emphasize early detection and variability, which is crucial for real-time defect monitoring and predictive maintenance in intelligent industrial systems.

IV. Simulation Results

To extensively test the RXET model, a high-performance Dell Core i7 12th Gen system with an 8-core CPU and 32 GB of RAM was used. Python and the SPYDER IDE were used to manage and perform the model trials. Several essential classification model hyperparameters were fine-tuned throughout the assessment to maximize performance. Model training used the Adam optimizer, which has flexible learning rate capabilities, enabling speedier convergence. The learning rate was chosen at 0.001 0.001, which was ideal after numerous trial trials, and the batch size was 64 to balance memory efficiency and gradient estimate accuracy. These parameters were carefully adjusted throughout the studies to maximize the Model's predictive capabilities, notably in defect diagnosis and status monitoring in intelligent manufacturing systems.

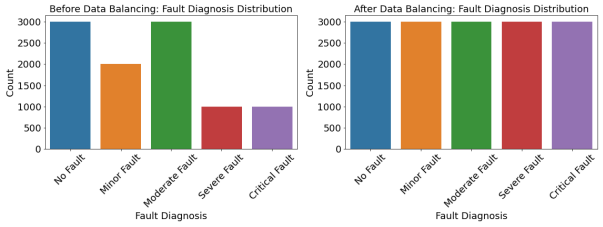

Fig. 3. Distribution of fault diagnosis labels before and after data balancing.

Fig. 3 compares fault diagnostic label distribution before and after data balancing. On the left, the "Before Data Balancing" scenario has a severe fault category imbalance. The data points are mostly "No Fault," "Moderate Fault," and "Minor Fault," with a few "Severe Fault" and "Critical Fault." This mismatch suggests that most observations reflect normal or mild operating circumstances, skewing the dataset. All fault diagnostic labels are evenly distributed in the "After Data Balancing" graphic on the right. Each category—"No Fault," "Minor Fault," "Moderate Fault," "Severe Fault," and "Critical Fault"—has 3,000 data points. This balanced distribution shows that strategies have been implemented to correct

the dataset's class imbalance, guaranteeing that the machine learning model will be trained on an equally distributed collection of errors, improving its capacity to identify uncommon but significant defects. The balanced dataset ensures that the Model is sensitive to less common but significant categories like "Severe Fault" and "Critical Fault" without favouring "No Fault" and "Moderate Fault." Fault diagnostic activities need this enhancement to identify infrequent but significant events to preserve operational efficiency and avert system breakdowns.

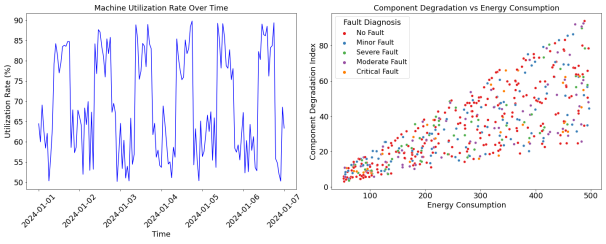

Fig. 4. Machine operational behaviour and its relationship with energy consumption and component degradation.

The association between machine operation, energy use, and component deterioration is shown in Fig. 4. The first left graphic shows machine utilization during and off hours throughout seven days. Use peaks at work (9 AM–6 PM). Industrial machine use rises during peak output and falls during downtime or decreasing demand. Fault diagnostic category-specific energy usage and component deterioration are shown on the second right. Energy usage often degrades components for predictive maintenance. Colour-coded fault categories indicate serious difficulties when energy use and component deterioration are high. Energy consumption affects machine health since operating stress promotes wear and faults. Daily operating cycles, energy consumption, and deterioration patterns demonstrate machine performance in these two charts for real-time operations and long-term maintenance.

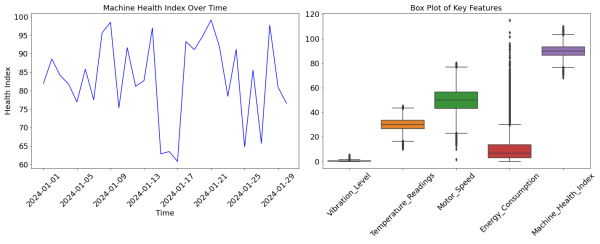

Fig. 5. Machine utilization rate over a week.

Fig. 5 shows two complementary representations that provide insights into machine health and operation. The left line plot represents the January 1–January 30, 2024 Machine Health Index. The Machine Health Index indicates machine status over 60–100 days. This chart may show continuous performance, unexpected drops, and health recoveries. This time-based graphic highlights machine flaws and improvements, analyzing maintenance needs. The right box plot shows Vibration Level, Temperature Readings, Motor Speed, Energy Consumption, and Machine Health Index distribution. Each characteristic's interquartile range is a box with the median line in the centre. Whiskers show data distribution, whereas outliers are points. Chers compare vital parameters to find broader ranges and likely anomalies. Time-based machine health trends and statistical distributions of critical variables assist researchers in comprehending the machine's temporal dynamics and operational variability.

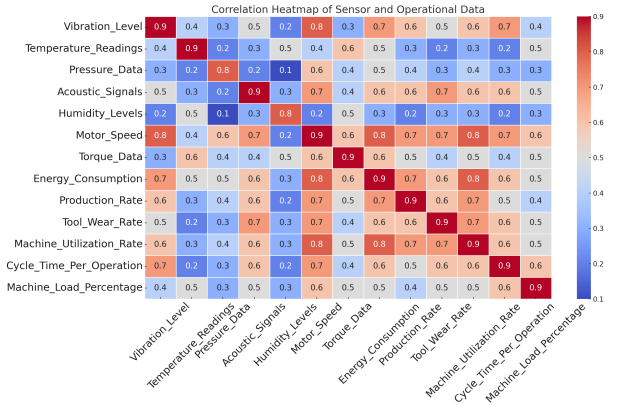

Fig. 6. Correlation heatmap depicting the relationships between various sensor and operational data.

The heatmap in Fig. 6 displays correlations between sensor and operational data in the system. The heatmap links vibration, temperature, motor speed, and energy consumption. A 0.1–0.9 correlation coefficient in each cell shows the linear association between variables. Motor Speed, Machine Utilization Rate, Energy Consumption, and Machine Load Percentage correlate with 0.8 or 0.9. Increasing these traits may improve operational metrics. Smaller correlations (0.3 or 0.4) show linear relationships between attributes. Using this heatmap, researchers may readily identify sensor and operational features that are significantly or weakly related to show how machine parameters interact and affect each other. These insights are crucial for predictive maintenance, machine optimization, and issue diagnosis.

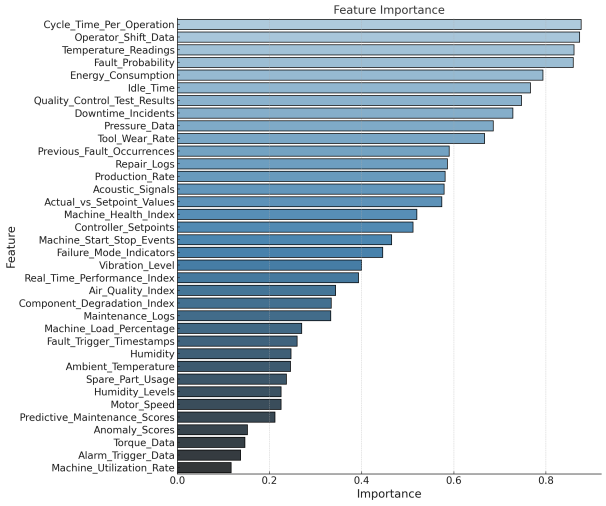

Fig. 7. Feature importance of features.

Fig. 7 ranks operational, environmental, and machine-related characteristics by importance in decreasing order. Energy Consumption, Motor Speed, and Temperature Readings

are at the top because they affect the Model's performance or system behaviour. Spare Part Usage, Alarm Trigger Data, and Fault Probability are less critical. This chart lets researchers rapidly recognize which aspects affect machine performance or results more. Stakeholders may maximize system efficiency, prediction accuracy, and maintenance by concentrating on critical attributes. Ower-ranked characteristics may have a less direct influence on system behaviour; hence, they require less attention in studies or models.

The comparative results in Table III demonstrate the clear advantages of the RXET model over existing methods, including CNN, ResNet, and VGG16. The RXET model achieved the highest accuracy (98.9%), AUC (99.2%), and F1-Score (98.5%), significantly outperforming other approaches. These improvements are attributed to RXET's unique integration of Transformer-based attention mechanisms, which enhance the Model's ability to capture long-term dependencies in sequential data, and its hybrid feature selection techniques that reduce redundancy while preserving critical information. Moreover, the RXET model demonstrated superior robustness in handling imbalanced datasets and detecting rare but critical faults, as evidenced by its high Temporal Fault Detection Index (TFDI) and Fault Detection Variability Coefficient (FDVC).

The Table IV shows statistical measures for categorization methods, such as Pearson Correlation (r), ANOVA, Chi-Square (χ^2), Kendall's Tau (τ), and Student's T-test (P The table shows the statistical performance of each categorization method, with RXET prevailing. The proposed RXET has the best Pearson correlation (0.93) and ANOVA F-statistic (8.52) for model fit. The RXET has the highest Chi-Square score (9.95), indicating varied differences. High Kendall's Tau ($\tau = 0.80$) implies a strong rank correlation, while the Model's P-value (0.007) suggests statistical significance. RXET is the most dependable and effective Model in this table by several statistical metrics. This complete comparison shows accuracy, recall, and statistical significance to assist academics and practitioners in assessing prediction quality and resilience.

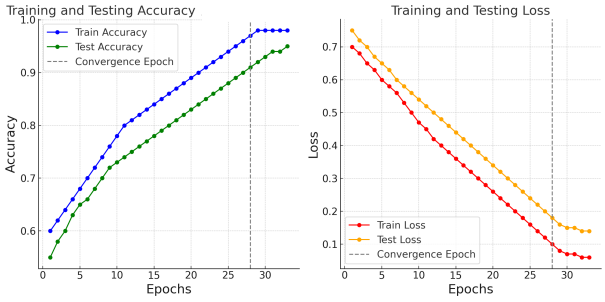

Fig. 8. Kodel's learning process.

Fig. 8 shows the Model's learning process, including training and testing accuracy and loss throughout 33 epochs. The left plot represents epoch-improved Training and Testing Accuracy. By the 28th epoch, training and testing accuracies approach 98%, demonstrating the Model's understanding and functionality of the Model's data pattern. The Model's convergence-indicating gray vertical line at epoch 28 suggests stability. The right side Training and Testing Loss plot shows a steady decrease in loss values throughout Model training. Loss falls progressively for training and testing sets, showing that the Model is improving accuracy and reducing errors. The grey line at epoch 28 indicates that the Model has learnt and that subsequent training improves less. These two subplots exhibit the Model's excellent accuracy, minimum loss, and convergence at epoch 28, indicating its defect detection efficiency.

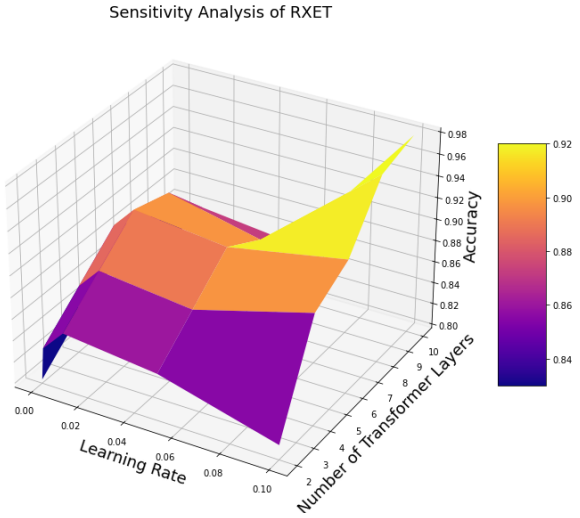

Fig. 9. Model's sensitivity analysis.

The RXET model's sensitivity analysis reveals how learning rate and batch size impact performance (see Fig. 9). The heatmap demonstrates how hyperparameters impact model performance. Lower learning rates (0.001 0.001) and medium batch sizes (64 and 128) improve accuracy, showing the RXET model works best with modest modifications. Learning rates over 0.1 diminish accuracy, especially with smaller or larger batch sizes. Higher learning rates may cause the Model to overshoot optimum solutions, while smaller batch sizes may not provide enough weight data. Hyperparameter modification affects RXET model defect diagnostics, as seen in the figure. Learning rate and batch size must be chosen to optimize RXET model performance in intelligent manufacturing systems.

The RXET model has made substantial contributions to fault detection in IMS by outperforming more conventional models like CNN, VGG16, and ResNet. Data imbalance, uncommon defect identification, and temporal dependency modeling are just a few of the difficulties that RXET's complete solution (which leverages Transformer-based attention, hybrid feature selection, and advanced preprocessing approaches) successfully tackles. Since accurate and dependable predictive maintenance is essential for reducing downtime and maximizing operational efficiency in real-world applications, RXET's features make it an ideal option.

V. Discussion

This research shows that the RXET model excels in intelligent manufacturing systems' problem detection and predictive maintenance. The RXET model outperformed CNN, ResNet, and VGG16 with 98.9% accuracy, 99.2% AUC, and 98.5% F1-Score. RXET's real-time fault detection and operational

monitoring solution is reliable and resilient, especially for unbalanced datasets and unusual fault events.

The RXET model has broad applications. Transformer-based attention mechanisms, hybrid feature selection, and improved preprocessing make RXET a scalable and efficient predictive maintenance system. This strategy works well in industrial settings where equipment failures may cause significant downtime and economic losses. Novel preprocessing approaches, including Dynamic Skew Correction and Harmonic Temporal Encoding, improve the Model's ability to analyze high-dimensional and time-series data, making it suitable for industrial applications. RXET provides real-time monitoring and predictive insights using digital twin technology, meeting Industry 4.0 objectives.

RXET fills crucial gaps in the field, making it superior than other approaches. Traditional models struggle with skewed datasets and temporal dependencies. Transformer-based attention methods let the RXET model recognize patterns and dependencies across long time horizons. Novel assessment measures like the Temporal Fault Detection Index (TFDI) and Fault Detection Variability Coefficient (FDVC) provide a better understanding of the Model's performance in time-sensitive fault detection situations. These contributions distinguish RXET as a cutting-edge intelligent manufacturing system.

Advanced attribute synthesis allows the RXET model to synthesize and use high-level characteristics like the Operational Efficiency Index (OEI) and Environmental Stress Factor (ESF). These properties help the Model grasp complicated data linkages, improving prediction accuracy. Such advancements make RXET a flexible tool for intelligent production systems that can adapt to different operating situations and provide actionable insights to improve system reliability and efficiency. The RXET model performs well, although it has limits. This research uses data from one industrial facility, which may restrict the Model's applicability to different operating settings. RXET's scalability to bigger and more varied datasets needs additional study. Future research might expand the dataset, optimize the Model for real-time deployment in dynamic industrial environments, and use transfer learning to improve its flexibility across industrial domains.

Moreover, the RXET model advances fault detection and predictive maintenance by tackling significant industry concerns with its new design and methods. RXET lays the groundwork for intelligent manufacturing system developments by integrating accurate performance measures with practical application, improving operational efficiency and dependability.

VI. CONCLUSION

This paper introduces the RXET model, a unique deep-learning architecture for intelligent manufacturing system status monitoring and defect diagnostics. Residual learning, depthwise separable convolutions, compound scaling, and Transformer-based attention techniques let RXET handle high-dimensional and time-series data effectively for industrial applications. Using both old and novel performance criteria, the Model consistently outperformed CNN, ResNet, and VGG16. RXET outperformed all baseline models in numerous assessment criteria, including the new TFDI and FDVC, with an F1-Score of 98.5% and an AUC of 99.2%. Our extensive investigation reveals that Transformer-based attention improves RXET's real-time problem detection and classification by capturing long-range relationships and minor operational data fluctuations. Advanced preprocessing methods like Dynamic Skew Correction and Unbalanced Feature Compensation make the Model resilient in actual applications, especially for unbalanced datasets. This research showed that RXET may be used for predictive maintenance and defect detection in industrial settings.

The research acknowledges limitations despite its importance. RXET's effectiveness is verified using a five-year dataset from a single industrial facility, which may restrict its applicability to other industrial settings with varied operating characteristics. Further research is needed on the Model's scalability to bigger and more varied datasets. Optimizing RXET's

real-time deployment in highly dynamic industrial applications might minimize computing overhead and preserve accuracy. Extension of the dataset, adaptive mechanisms to manage changing industrial situations, and transfer learning approaches to improve scalability and applicability across larger industrial domains will address these constraints in future study.

***Abstract*—Virtual Assistants (VAs) are widely used in many fields. Recently, VAs have been effectively applied in technical drawing tasks, such as in Photoshop and Microsoft Word. Understanding multi-intent commands in VAs poses a significant challenge, especially when the language in query is low-resource, like Vietnamese (no training dataset available for technical drawing domain), which features complex grammar and a limited domain of usage. In this work, we proposing a three-step process to develop a voice assistant capable of understanding multi-intent commands in VAs for low-resource languages, particularly in responding to the SCADA Framework (SF) for performing drawing tasks: (1) for the training dataset, we developed a semi-automatic method for building a labeled command corpus; applying this method to Vietnamese, we built a corpus that includes 3,240 labeled commands; (2) for the multi-intent command processing phase, we introduced a method for splitting multi-intent commands into single-intent commands to enable VAs to perform them more efficiently. By experimenting with the proposed method in Vietnamese, we developed a VA that supports drawing on SF with an accuracy of over 96%. With the results of this study, we can completely apply them to SCADA system products to support the automatic control of techinical drawing operations in them as VAs.**

Keywords*—Vietnamese command corpus; chatbot; virtual assistants; multi-intent command; artificial intelligence; technical drawing; SCADA framework; build semi-automatic data; low-resource languages

I. Introduction

Nowadays, virtual assistants (VAs) are widely used in daily life, and the number of people using VAs has significantly increased [11] for a few decades. This is because of its ability to support organizations and individuals in doing their tasks in various aspects and scopes, such as Google Assistant, Apple's Siri, Samsung's Bixby and Microsoft's Cortana. They can operate on mobile phones and use sensors of the device to better react to specific contextual information. Besides, VAs such as Amazon Echo and Google Home can operate in smart homes and help users fulfill various daily tasks [14].

Thanks to the rapid development of AI and information technology areas, VAs will soon become increasingly intelligent [12]. VAs have come a long way. In the past, VA only focused on helping functions in textual form, but personal assistants on mobile phones can now process natural language and react in a human-like way. One challenge of the VA problem is to develop their drawing capabilities, which means that the user interacts with the VA to draw pictures in natural language. This problem is difficult when implemented on rich-resource languages because: (1) technical drawing field usually has no training data and how to build a dataset that fully covers common commands in the technical drawing domain; (2) command utterances are often abbreviated and have incorrect grammar, spoken. It is even more difficult when implemented on languages with low resources and complex grammar, such as Vietnamese.

In this work, we focus on solving the VA problem in two aspects: the first studying how to build a high-quality training data. The second is to efficiently handle multi-intent commands in low-resource languages.

There are two approaches for solving the VA problem: using Large Language Modles (LLMs) and the traditional method (such as the Rasa* platform). We chose Rasa platform for our proposed method because: (1) it could be controlling and explaining when using the Rasa framework, this is an important feature in technical drawing; (2) RASA has the advantage of execution speed, so it is suitable for limited hardware platforms, such as deploying on CPUs (but LLMs need run on GPUs).

Our contribution is as follows:

1) Proposing a three-step process to develop a voice assistant capable of understanding multi-intent commands in the field of technical drawing.
2) Proposing the method of semi-automatic data building and building the labeled Vietnamese command corpus, which includes 3,240 commands. This corpus is shared with the community.†
3) Proposing the method for splitting a multi-intent command into single-intent commands so that the VA can perform them more efficiently.

To the best of our knowledge, this is the first comprehensive study of understanding intent-command

for the drawing virtual assistant with Vietnamese language.

The remainder of this paper is structured as follows: Section II reviews related works on voice assistant architectures and their advancements. Section III presents our proposed method for addressing challenges in low-resource language VAs. Section IV details our experimental setup, datasets, and results, highlighting the effectiveness of our approach. Finally, Section V concludes the paper and outlines future research directions.

II. Related Works

VAs have become increasingly popular and have been widely integrated into our daily lives. They respond to voice commands and offer various functionalities, like scheduling appointments, controlling smart home devices, and performing web searches. Most VAs follow a common architecture. Firstly, Speech Recognition module converts spoken commands to text. Natural Language Understanding (NLU) module extracts necessary information from the text. After that, Dialog management (DM) module determines the response action based on the the information obtained from previous steps. Finally, Natural Language Generation (NLG) module formulates a response [9]. In recent years, the design of VAs has attracted the attention of many researchers.

Matthew B. et al. [10] have introduced to readers the concept of voice assistants and their growing presence in daily life. It aims to provide a basic understanding of these virtual helpers, including:

- What they are: Software agents that can understand spoken language and respond through synthesized voices.
- How they work: Briefly explain the technology behind speech recognition and response generation.
- What they can do: Common functionalities like setting alarms, playing music, controlling smart home devices, and answering questions.

By introducing these key points, the work ideally empowers readers with foundational knowledge of voice assistants and their potential applications.

Timo Strohmann et al. [26] provided guidelines for designing in-vehicle VAs that offer a clear and structured overview of what designers have to consider when designing an in-vehicle VA for a convincing user experience. They designed guidelines based on the existing literature on the requirements of assistant systems and on the interviewing results of experts. In order to demonstrate the applicability of the guidelines, they developed a virtual reality prototype that considered the design guidelines. In a user experience test with 19 participants, they found that the prototype was easy to use, allowed good interaction, and increased the users' overall comfort.

Anxo Pérez et al. [18] presented the design of an assistant that is developed with open-source and widely used components. They proposed an end-to-end process, from information gathering and processing to visual and speech-based interaction.

Marco Brambilla et al. [5] proposed a VA that allows model building using voice commands. They describe three alternative strategies that apply voice-based assistance at three levels: a fully guided strategy; a template-based strategy; and an element-based strategy to demonstrate the generality of the approach. They describe their implementation experience with developing a design assistant that incorporates the three strategies described above for OMG's IFML (Interaction Flow Modeling Language) in the context of user interaction design, including integration with the Amazon and Alexa VA.

Sanju Ahuja et al. [1] made arguments in which designers and policymakers need to be aware of the ethical side of the future of VAs and systematic frameworks are required to aid their moral imagination. They proposed a framework that helps designers imagine potential ethical concerns pertaining to users' autonomy. They demonstrated the usefulness of the framework that they proposed by showing how existing ethical concerns can be situated within the framework. They also used the framework to imagine ethical concerns with emerging VA technologies. This framework can aid in the systematic identification of autonomy-related ethical concerns within human-computer interactions.

Piñeiro-Martín et al. [17] presented an extension of their previous work. They analyze the current regulatory framework for AI-based VAs in Europe and delve into ethical issues, examining the potential benefits and drawbacks of integrating large language models (LLMs) into VAs. Based on the analysis, their paper argues that the development and use of VAs powered by LLMs should be guided by a set of ethical principles that prioritize transparency, fairness, and harm prevention. It presents specific guidelines for the ethical use and development of this technology, including recommendations for data privacy, bias mitigation, and user control. By implementing these guidelines, the potential benefits of visual assistants powered by LLMs can be fully explored while minimizing the risks of harm and ensuring that ethical considerations are at the forefront of the development process.

For the technical drawing field: Dries Van Daele et al. [29] presented a software tool that is able to interpret different parts of a drawing and translate this information to allow automated reasoning and machine learning on a huge database of technical drawings. To achieve that, the proposed the method that automatically learns a parser capable of interpreting technical drawings with Using limited interaction from the expert. Their method uses both neural networking and symbolic methods. Neural network methods to interpret visual images and recognize parts of two-dimensional drawings. Symbolic methods to process relational structures and understand data encapsulated in complex tables contained in technical drawings.

Rodrigo Pereira et al. [15] systematically reviewed the applications of VAs in the context of Industry I4.0, discussed the design principles of technical assistants, and identified the characteristics, services, and limitations associated with the use of VAs in production environments.They found that Virtual Assistants offer Physical and Virtual Assistance. Virtual Assistance provides real-time contextualized information mainly for support, while Physical Assistance is oriented toward task execution. In terms of services, applications include integration with legacy systems and static information processing. Limitations of the application include concerns about information security and adaptation to noisy and unstable environments. They argue that the future should focus on expanding the

scope of research to provide more significant conclusions and research capabilities with new AI models and services

Published works have focused on reviewing and addressing various aspects of the VA problem to make VAs more user-friendly and functional. However, these approaches face significant limitations when applied to low-resource languages due to the lack of training data. Additionally, little attention has been given to handling multi-intent commands, and studies on VAs in the field of technical drawing are particularly scarce. This paper seeks to address these gaps by tackling the challenges of limited training data, enabling VAs to perform technical drawing tasks, and facilitating interaction with users in low-resource languages. Notably, this is the first study to explore multi-intent command recognition for technical drawing in Vietnamese.

III. Our Proposed Method

The challenge of the VA problem in low-resource languages is the lack of training data and an efficient solution in handling multi-intent commands. To overcome these challenges, we propose a three-step process, as follows:

- Phase 1: **Build semi-automatic data** for training and testing.
- Phase 2: **Choose the good model for training VA**. This phase will make a VA that takes single-intent commands from the user in the input and outputs the JSON file that contains information about their requirements.
- Phase 3: **Generate the JSON file**. In this phase, the multi-intent command from the user is split into single-intent commands before being fed into the VA to get a JSON file and send it to SF to do the drawing task.

Our proposed method is illustrated in Fig. 1.

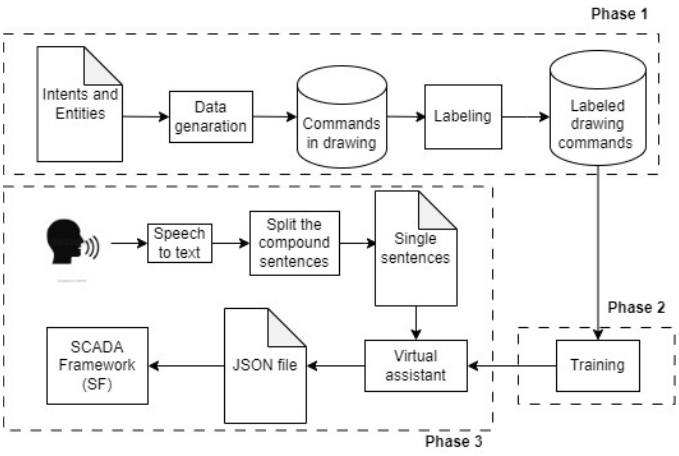

Fig. 1. Our proposed method

A. Build Semi-automatic Data

Being built specifically for providing SF users with technical support, the VA is designed to have two main functions. The first function, called automatic answering, is the ability of a VA to answer the questions given by the user. The questions that are within the domain of this function are related to SF, particularly about the instruction manual, the main functions of the software, and frequent bugs and difficulties that users may encounter when coding in the script and interacting with the working interface of the software. The second main function of the VA is user-task assistance, in which the assistant does some tasks directly in the software working interface when asked by the user. The supported tasks are tasks that most users usually do at the interface of the software.

To have a dataset for training this VA. The first thing we do is design and define intent and entity labels that are presented in Section III-A1. then generate types of commands, and finally use the built label set to label them. The last two processes are presented in Section III-A2.

1) Designing intent and entity labels

Firstly, we have to define the intent and entity label set that match the domain of the SF. The intents are used to define the overall requirement in a user command. The dataset is split into 3 groups. The first intent group contains intents in which the user wants to choose objects in the software interface. The second intent group is involved in changing attributes of objects, and the last one is about drawing objects directly on the SF interface. The intent and entity label list for Vietnamese is shown in Tables X and XI in Appendix.

2) Semi-automatic data construction

a) Manual Data Construction

Initially, raw data generation and annotation are carried out manually by humans. Particularly, data builders role-play as platform users and give orders indicating the content of a specific intent. Each intent requires one or several specific pieces of information to appear in the command, and these pieces of information are dedicated in various ways and appear in different orders in different commands.The semi-automatic data construction method requires a few data to initialize, so we will build them manually. The more and better the quality of the initial data, the higher the efficiency of the method achieved. For Vietnamese, we have built 540 commands in total manually.

After it is annotated following the format of Rasa chatbot framework [20]. Rasa is an open-sourced framework used to build conversational chatbots. One of its advantages over other chatbot frameworks is its various number of integrated machine learning and deep learning models used to solve intent classification (IC) and entity extraction (EE) which are the two main tasks of a VA. That makes building an efficient VA much faster than building from scratch.

In the Rasa framework, the data is stored in a .yml file and the commands are grouped by intent. In a command, each labeled phrase is included in a couple of square brackets, and the entity label used to label that phrase is included in the couple of braces that are next to the square bracket couple.

Semi-automatic data construction methods require some data to train the model, so we have to build them manually. The more and better quality data, the higher the efficiency of the method.

b) Semi-automatic data construction

In this process, we propose to use an NLU model trained on the manual-built data as a core component of the semi-automatic data construction process. Our proposed method is illustrated in the Fig. 2.

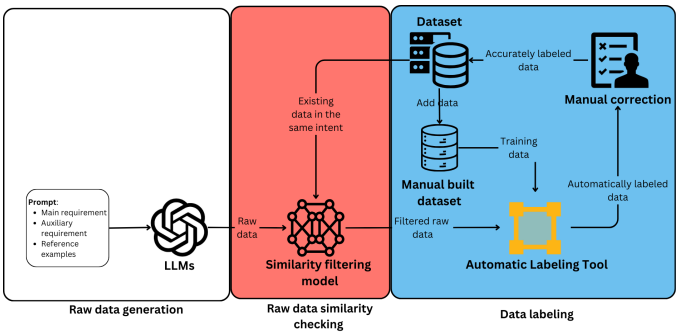

Fig. 2. Data building pipeline.

The idea of our proposed method is as follows: Firstly, we design prompts that are put into LLMs to generate the raw commands. Then, in these commands, we remove ones that have cosine similarity to existing commands in the dataset greater than the α threshold. Next, the remaining commands from the previous step are put into the NLU model (which is trained on manual building data) to get the labeled data. Finally, we use instructed annotators to manually check and correct the automatically labeled data. The dataset obtained after the last step is the expected high-quality dataset. It is also combined with existing data to retrain the NLU model in order to make that model better at labeling raw data.

Raw data generation: In this stage, the data samples built in the manual data construction process will be used as reference examples to guide Large Language Models (LLMs) to generate high-quality raw commands for a specific intent in larger quantity and faster speed compared to manual data construction. The guidance includes three main parts:

- Description of the main requirements of the task indicated by intent.
- Description of auxiliary requirements.
- Reference examples (few-shot).

Fig. 3 shows an example of guidance for raw data generation sent to LLM.

In the example guidance in Fig. 3, the description of the main requirement includes the content of the intent in which the user wants to do and the types of information that should appear in the user's command. Furthermore, the last two sentences in this section also require LLMs to generate more diverse and realistic commands because, in reality, users of popular VAs barely provide the assistant with all of the information needed for completing the task. The description of auxiliary requirements in the guidance is mainly about the quantity and writing style of data, which makes the generated data more diverse and the generating process faster. Lastly, the reference examples contain commands created manually in the previous process. These commands are supposed to teach LLMs such things as:

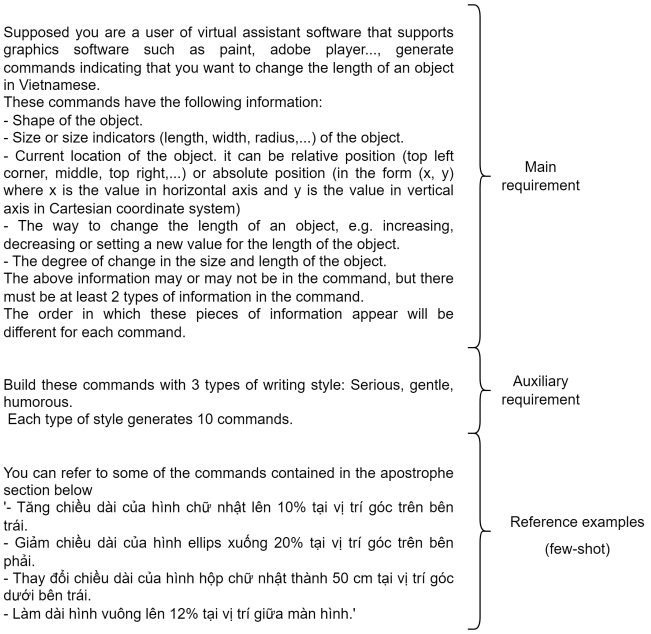

Fig. 3. Example of raw data generation for intent "change_length" indicating that user wants to change the length of an object.

- The way information appears in the command.
- The order in which information appears in the command. This is necessary because if only 1 or a few commands are given, LLMs have the tendency to generate commands with the same order of information, similar to fixed words or phrases filled in an available pattern.

Raw data similarity checking: As the dataset grows, new raw data generated by LLMs is likely to have great similarity with the available one in the dataset. If this kind of raw data is added to the dataset, it will make the dataset reduce diversity and coverage, thus making the training process less effective. To prevent this phenomenon, each new command (called new raw command set) generated by LLMs for one specific intent is compared with commands that already exist in the dataset of the same intent (called old raw command set) in terms of consine similarity [6]. Particularly, after the new raw command set and the old raw command set are encoded into vectors using pre-trained models specialized in sentence encoding, these two vector sets are used to compute the cosine similarity matrix by Eq. (1) shown below.

$$\text{cosine\_sim}_{ij} = \frac{M_i \cdot N_j}{\|M_i\|\|N_j\|} \tag{1}$$

Where cosine_sim_{ij} is the cosine similarity value between i^{th} command in the new raw command set and j^{th} command in the old raw command set. M_i and N_j are vectors obtained by encoding the i^{th} and j^{th} commands in the new and old raw command sets, respectively.

Finally, the commands in the new set will be removed if their similarity with any commands in the old set is over a threshold.

Data labeling: The NLU model trained on manual-built data is integrated into Label-Studio, which is an automated data labeling tool, and its predicted results for raw commands are displayed and corrected in this tool. This is a robust and powerful open-sourced labeling tool that supports both manual and automatic labeling processes. Built on the Web-UI platform, this tool provides flexibility and convenience for users, allowing them to customize and personalize their experience.

However, due to the nature of the dataset, which is used to train a model to solve two tasks, which are IC and EE simultaneously, while the labeling tool only supports labeling for datasets used for one task, the raw data needs to be preprocessed before being fed into the integrated NLU model of the automatic labeling tool. Particularly, all raw commands are normalized by Underthesea[‡] and added a special token "¡i¿" at the beginning. This token is used to store the intent of the command and is labeled with a special entity label that has the following format: "intent—¡intent_name¿". Other normal entity labels have the following format: "¡group name¿—¡entity name¿" and are used to label phases and words indicating the information used to complete the task in the user's command.

After being labeled automatically by the NLU model, the data is checked and corrected manually. The accurately checked data is then stored in the overall dataset. This dataset, after a specific time of building, is used to retrain the NLU model to make it better at labeling data.

Applying this method to Vietnamese, we have built a dataset of 2700 samples in total. This dataset is combined with the manually built dataset to create the overall dataset that is used to train and evaluate the VA.

B. Train the VA

In our proposed method, the mission of a VA is to extract valuable information to complete the required task given the user command. To obtain this information, our VA is modeled to solve two tasks simultaneously. The first task is IC which is used to identify the task required by the user. The second task is EE which is used to extract valuable information to complete the required task in the user's command. The existing state-of-the-art (SOTA) models of the two tasks are built from variants of Transformers [27] which are pretrained on a unified language dataset (BERT, GPT, ...). Although making SOTA results in a variety of NLU datasets, most of them have some disadvantages. Firstly, they need high training and computation costs to produce good results. Furthermore, due to their large size and long inference time, it is very difficult to deploy them on various platforms. Therefore, choosing a suitable model for each language is important.

For Vietnamese, we suggest to use the DIETClassifier [4] with components pretrained on Vietnamese datasets in training VA. In the paper publishing this model, it is shown to overcome SOTA models on varius NLU datasets, including NLU-Benchmark [13], ATIS [2] and SNIP [24] while being about six times faster to train. We also have used phoBERT [16] which is a language model pretrained on Vietnamese as the dense featurizer of DIETClassifier. The reason we choose this model is because it is the first public large-scaled monolingual language model pretrained for Vietnamese and has archived SOTA results in many Vietnamese-specific NLP tasks. Its performance when integrated into the architecture of the DIETClassifier model on our test data is shown in Tables IV and V in the Section IV-C. In the training process, the weight of the dense featurizer is frozen, which makes it much faster to train the model.

[‡]https://pypi.org/project/underthesea/

C. Generate the JSON File for Foundation Software

In this phase, the commands of the user are recorded and saved as an audio file. Then, it is converted to a text file. Next, the command in text that is a multi-intent command is split into single-intent commands based on our proposed method. Next, we feed single-intent commands into the VA to get information about the required task, which is then post-processed to store in a JSON file. Finally, the JSON file is sent to the SF to do the drawing requests of the user.

1) Convert speech to text

To convert the voice input of the user into text, we suggest using Whisper [30]. This is a speech-to-text multilingual model. In practical usage, it has proven to be suitable for the functional requirements of the VA. Particularly, it can catch the voice input fractions that represent numbers and convert them into Arabic numbers instead of plain text, which makes the transcribed text more similar to the normal text inputs of the user.

2) Split multi-intent commands

In practical usage, users often give commands that contain multiple tasks (compound command), also known as multi-intent or complex commands, to VAs in order that the whole work process is completed quickly. For users, giving commands for single tasks and waiting for them to finish are inconvenient and time-consuming. Attempting to build VAs capable of handling complex commands by directly training the assistant on labeled complex commands is a simple and straightforward approach. The author in [21] proposed the first work to handle multi-intent commands, which has hierarchical structures to identify multiple intents in the user's command. In 2020, [19] proposed a model named AGIF which uses an adaptive graph attention network to model joint intent-model interaction. However, these existing works have some drawbacks. Firstly, the data collection cost for complex commands is very high because of the uncontrollable variety of this kind of command, especially in the case of a large number of single intents. Particularly, with a dataset of n single intents, the number of bi-intents (a mutli-intent containing 2 single intents) is $\frac{n*(n-1)}{2}$ and the number of tri-intents (a multi-intent containing three single intents) is also very big, which is the polynomial value of n, making collecting data for all combinations of intents nearly impossible. Furthermore, the labeling process for multi-intent commands is also very challenging. To effectively annotate entities of a multi-intent command, the entity labels have to indicate both the role of labeled phrases and which intent in the command that phrases belong to, instead of just indicating the role of the phrases like in normal single-intent commands. For example, in the multi-intent command "Draw a yellow rectangle at the center of the

screen and move the black square to the left" which has two intents named draw_square and move_left, the word "yellow" has to be labeled by a label indicating the color of an object of the first intent. Lastly, this approach potentially reduces the effectiveness of modules of VAs when they have to extract too much information (multiple intents and entities aligned to each intent) in a single command.

Another approach for handling multi-intent commands used in recent studies is to build a module specified for detecting and splitting a multi-intent command into a list of single-intent commands for a VA and feed these commands into the remaining modules. This approach overcomes the limitations of the previous approach when it does not need to label multi-intent commands. The author in [28] have proposed DialogUSR, a module built as a sequence-to-sequence model so that from a multi-intent command, it can generate a list of single-intent commands in the form of a text string with each single-intent commands separated by a special token "¡SEP¿". One year later, [25] proposed a module built as a NER model with entities used to bound the single-intent commands in a multi-intent command. However, the two studies above have their own limits. Firstly, the module proposed by [28] heavily relies on training data, thus poorly performs when confronted with inputs that are highly different from training data, i.e. it rarely can split a triple-intent command accurately when being trained only with single and bi-intent commands. On the other hand, the SPM module of [25] is likely to split commands with more intents than ones in the training data accurately because of its building strategy to model multi-intent command splitting as a NER task to bound single-intent commands. Nonetheless, this modeling approach absolutely cannot split a multi-intent command whose information of each intent is interleaved due to its modeling strategy. For example, the commands "Draw a square and a circle whose sizes are 50x50 pixels and 60x60 pixels, respectively, in random positions" has two intents named "draw_square" and "draw_cirle" but the information of each intent is mentioned separately throughout the command instead of standing next to each other.
To overcome these limitations, we proposed to build a module specified for splitting these multi-intent commands into sequences of single-intent commands based on in-context learning using LLMs with a context database of multi-intent commands built from single-intent commands.

Our proposed approach has three main processes:

- Context database construction: This process involves using LLMs to merge single-intent commands chosen from the previously built training data into a multi-intent command.
- Context retrieval model construction: In this process, we build a model that is able to choose contexts that are semantically similar to the user's input from the context database.
- LLMs input construction: This process involves building a complete input from the user's input and contexts chosen by the context retrieval model.

The overall architecture of the multi-intent command splitting module is illustrated in Fig. 4.

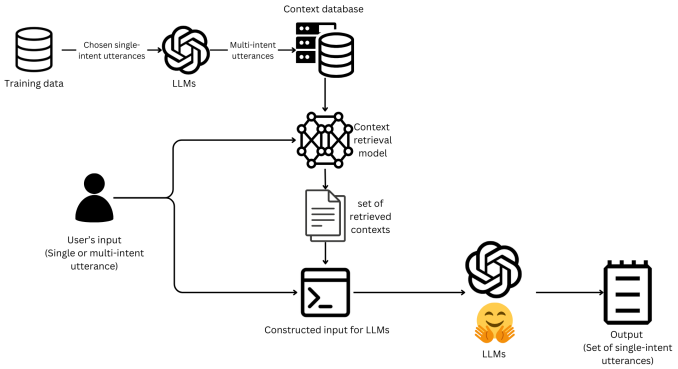

Fig. 4. Overall architecture of the multi-intent utterance splitting module.

a) Context database construction

To build the context dataset, two single-intent commands with different intents are chosen from the VA training dataset and then fed into LLMs to construct a multi-intent command. Along with single-intent commands, a merging instruction snippet is also added into the input of the LLMs to make good multi-intent commands. The example input built for LLMs to create multi-intent commands is shown in Fig. 5.

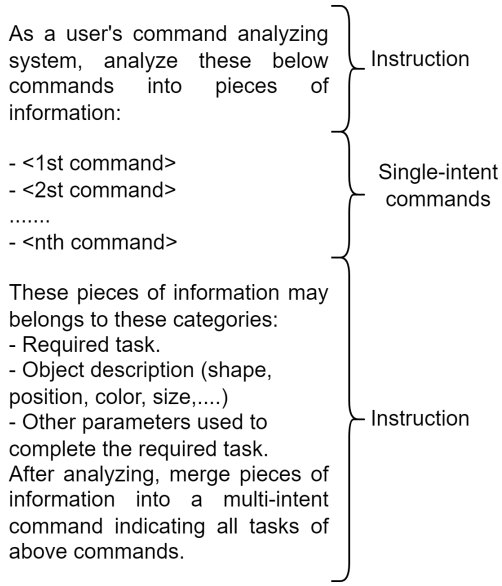

Fig. 5. Example guidance of input for LLMs to create multi-intent commands.

As Fig. 5 shows, it can be seen that the LLMs are required to merge pieces of information extracted from single-intent commands to create multi-intent commands instead of just concatenating single-intent commands by linking words or punctuation. That can make resulting multi-intent commands more diverse and complicated to segment with pieces of information being interleaved, or even become tricky. For example, from the above input and two single-intent commands "Choose all objects on the screen" with intent "select_all_objects" and "Give up choosing all cirles" with intent "exit_select", the LLMs can generate a multi-intent command "Choose all

objects on the screen, except for circles". At first glance, this multi-intent command has only one intent, but to complete the required task, the visual assistant has to select all objects, then give up selecting all circles. However, this kind of input can make LLMs potentially align information incorrectly, or even get rid of some of the information of single-intent utterances. Furthermore, due to the lack of reference examples of inputs and expected outputs, the output in reality of LLMs is usually unstable, making post-processing challenging.

To overcome these drawbacks, some reference examples are added to the input for LLM to stabilize its inference process. Two types of reference examples we used are basic examples (normal few-shot) and advanced examples (Chain-of-thought few-shot, also known as CoT few-shot) which are listed in Fig. 6 and 7, respectively.

```
Input:
- Draw a black circle at coordinates (20, 40).
- Paint the red for its background
Output: Draw a black circle at coordinates (20, 40) then paint
the red for its background

Input:
- Draw a square whose size is 40 x 40 pixel square at the
center of the screen.
- Draw a circle whose size is 40 x 40 pixel square at the top left
corner of the screen.
Output: Draw a square and a circle with the same size of 40 x
40 pixel square at the center and the top left corner of screen,
respectively.

Input:
- Draw an arrow whose length and width are 70 and 30 pixel
respectively the the left side of the screen.
- Make a copy
- Paste the copy in the center of the screen.
Output: Draw an arrow whose length and width are 70 and 30
pixel respectively the the left side of the screen, make a copy
then paste it in the center of the screen.
```

Fig. 6. Basic examples added into input of LLM as references to make its inference process more stable.

```
Input:
- Draw a black circle at coordinates (20, 40).
- Paint the red for the background of the black circle at
coordinates (20, 40).
Output:
Analysis:
- Sentence 1: Task: Draw object, object shape: circle, object
color: black, object position: (20, 40).
- Sentence 2: Task: Color background, object shape: circle,
object color: black, object position: (20, 40).
Merge and create new command: Draw a black circle at
coordinates (20, 40) then paint the red for its background.

Input:
- Draw a square whose size is 40 x 40 pixels at the center of
the screen.
- Draw a circle whose size is 40 x 40 pixels square at the top
left corner of the screen.
Output:
Analysis:
- Sentence 1: Task: Draw object, object shape: square, object
size: 40 x 40, object position: center of the screen.
- Sentence 2: Task: Draw object, object shape: circle, object
size: 40 x 40, object position: top left corner of the screen.
Merge and create new command: Draw a square and a circle
with the same size of 40 x 40 pixels at the center and the top
left corner of screen, respectively.

Input:
- Draw an arrow whose length and width are 70 and 30 pixel
respectively on the the left side of the screen.
- Make a copy
- Paste the copy in the center of the screen.
Output:
Analysis:
- Sentence 1: Task: Draw object, object shape: arrow, object
size: 70 pixel long and 30 pixel wide, object position: left side of
the screen.
- Sentence 2: Task: Copy object.
- Sentence 3: Task: Paste, position: center of the screen.
Merge and create new command: Draw an arrow whose length
and width are 70 and 30 pixel respectively on the left side of
the screen, make a copy then paste it in the center of the
screen.
```

Fig. 7. Advanced examples added into input of LLM as references to make its inference process more stable.

While basic examples just contain input (a list of single-intent utterances) and corresponding output (multi-intent utterance), advanced examples contain interpretation for the output, apart from input and output. With the two types of examples, the resulting multi-intent commands generated by LLMs are more stable and can contain all the information of single-intent commands, but seem to be monotonic in term of information presentation. As a result, we have used all three types of inputs to build context database in the experiment. Particularly, the basic input with no example is called "zero-shot merging", the input with simple examples is called "few-shot merging" and the input with analyzing examples is called "few-shot CoT merging".

In the work, we build multi-intent commands by combining two single-intent commands with different intents. Furthermore, five single-intent commands of each intent are also randomly chosen from training data in order that module can detect single-intent command.

Context retrieval model construction

The target of context retrieval is to provide LLMs with informative examples to refer to, thus allowing LLMs to process users's input accurately and give the correct output for other modules of VAs. As a result, retrieved contexts need to be greatly similar to the user's input. To be able to retrieve these contexts, the model is designed to solve the Semantic Textual Similarity (STS) task. The input of this task contains two text sequences, and the output is the similarity score between the two sequences. The model instruction process consists of two parts: STS dataset building and model training on the STS dataset.

STS dataset building: To build a STS dataset, the two inputs of each sample in this dataset are chosen arbitrarily from the previously built context dataset, and the output (similarity score of two input sentences) is identified by the intents included in each input sentence. The equation used to compute the similarity score is below:

$$\text{sim\_score} = \begin{cases} 1.0 & \text{if} \quad a_1 = b_1 \text{ and } a_2 = b_2 \\ 0.75 & \text{if} \quad a_1 = b_2 \text{ and } a_2 = b_1 \\ 0.5 & \text{if} \quad \begin{array}{l} a_1 = b_1 \text{ and } a_2 \neq b_2 \text{ or} \\ a_1 \neq b_1 \text{ and } a_2 = b_2 \end{array} \\ 0.25 & \text{if} \quad \begin{array}{l} a_1 = b_2 \text{ and } a_2 \neq b_1 \text{ or} \\ a_1 \neq b_2 \text{ and } a_2 = b_1 \end{array} \\ 0.0 & \text{otherwise} \end{cases} \tag{2}$$

Where a_1, a_2 are the first and the second intent of the first multi-intent command and and b_1 and b_2 are the first and the second intent of the second multi-intent command. This equation is applied in the case that both input sentences are bi-intent commands, which make up the majority of the context dataset. In the case that both input sentences are single-intent commands, the assigned similarity value is 1.0 if the intents of both sentences are the same and 0.0 in the other case. If one of the input sentences is single-intent and the other is bi-intent, the assigned value is 0.25 if the intent of the single-intent command is the same as one of the intents of the bi-intent command and 0.0 in other cases. The reason why the maximum similarity value between two sentences with different numbers of intents (1 intent compared to 2 intents) is just 0.25 is that in some cases, multi-intent commands and single-intent commands can be greatly similar to each other. e.g. "Let's move the red square to the left for 10 pixels, then flip it horizontally" and "Let's move the red square to the left for 10 pixels." If the user's input is the same as the example multi-intent command and the result of the retrieval model is the same as the example single-intent sentence, the module is likely to segment the user's input incorrectly. As a result, by setting a low similarity value for couples of sentences with different numbers of intents, especially between single-intent commands and multi-intent commands, being trained on that dataset can allow the retrieval model to be capable of clearly discriminating between single-intent and multi-intent commands.

Context retrieval model building and training: The module trained on the previously built STS dataset is a variant of the sentence-BERT [23]. In this model, we use $\text{MEAN}_{pooling}$ pooling layer to get the sentence vector from the hidden state matrix encoded from the input sentence by BERT model. The loss function used to optimize the retrieval model is Mean Square Error (MSE) loss.

LLMs input construction: To build a complete input for LLMs, contexts with great similarity with the user's input need to be retrieved. To get these contexts, all contexts in the context dataset are encoded by the context retrieval model, which has been trained in the previous stage to get their semantic representative vectors. This collection of vectors, along with raw contexts, is then stored in a database. The vector obtained by encoding the user's input is used to compute the similarity value between it and other contexts to get the most suitable context.

3) Generate the JSON file for SF

After the multi-intent command handling module separates the user's command into a list of single-intent commands, that list of commands is fed into the VA one by one. After each command is processed, the intent and entity values extracted from that command are obtained and postprocessed. After post-processing, intent and entity values are filled into a pre-defined form whose keys are intent and entity names. For entity names with no corresponding entity values extracted from the user's utterance, their value is assigned $NULL$ value. Finally, this form is stored in a JSON file and sent to the SF by calling its API. The Fig. 8 shows the content of the JSON file obtained from the Vietnamese user's input, which is a multi-intent command, and how the required tasks are done directly on the user interface of the SF.

IV. Experiments

In this section, we conduct the experiment of our proposed method on Vietnamese, which is a low-resource language. The first describes the training and testing datasets for VA, then presents the configuration settings and evaluation metrics. Next, we show the archived results, and finally, we present some discussions related to the results of the experiment.

A. Experimental Datasets

1) Experiment datasets for evaluating the quality of semi-automatically built data and the performance of VA

Our dataset includes 3240 labeled commands (or 3240 samples). It is made up of a manually built dataset of 540 samples and a semi-automatically built dataset of 2700 samples. We split this dataset into two subsets: the training dataset and the testing dataset.

a) Testing dataset

It is denoted $\textbf{NLU}_{test}$ including 360 samples that are randomly taken from the manually built dataset, such that 10 samples of each intent type.

b) Training dataset

It includes 2880 remaining samples (denote $\textbf{NLU}_{train}$) divided into six different training datasets. Dataset are denoted as $\textbf{NLU}_n$ means we take the n first samples of each intent type in $\textbf{NLU}_{train}$ for making it. Statistics of these datasets are shown in Table I.

TABLE I. Statistics of the Command Numbers in Each Dataset

Datasets	Number of samples
$\textbf{NLU}_{test}$	360
$\textbf{NLU}_{40}$	1440
$\textbf{NLU}_{50}$	1800
$\textbf{NLU}_{60}$	2160
$\textbf{NLU}_{70}$	2520
$\textbf{NLU}_{train}$	2880

2) Experiment datasets for evaluating the performance of multi-intent handling module

The multiple context datasets are made by choosing data from $\textbf{NLU}_{train}$ dataset by different context-building methods. Particularly, the context datasets made by Zero-Shot Merging, Few-Shot Merging and Few-Shot CoT Merging methods are called $\textbf{Context}_{zero-shot}$, $\textbf{Context}_{few-shot}$ and $\textbf{Context}_{few-shot\,CoT}$ respectively. Each of these context datasets contains 2696 samples, including 180 single-intent commands and 2516 multi-intent commands.

a) Testing dataset

Our context testing dataset, called $\textbf{Context}_{test}$, contains 1754 samples, including 1662 multi-intent commands and 92 single-intent commands. It is built based on all three merging methods with single-intent commands taken from $\textbf{NLU}_{test}$ dataset. After that, all incorrect and duplicated samples are removed.

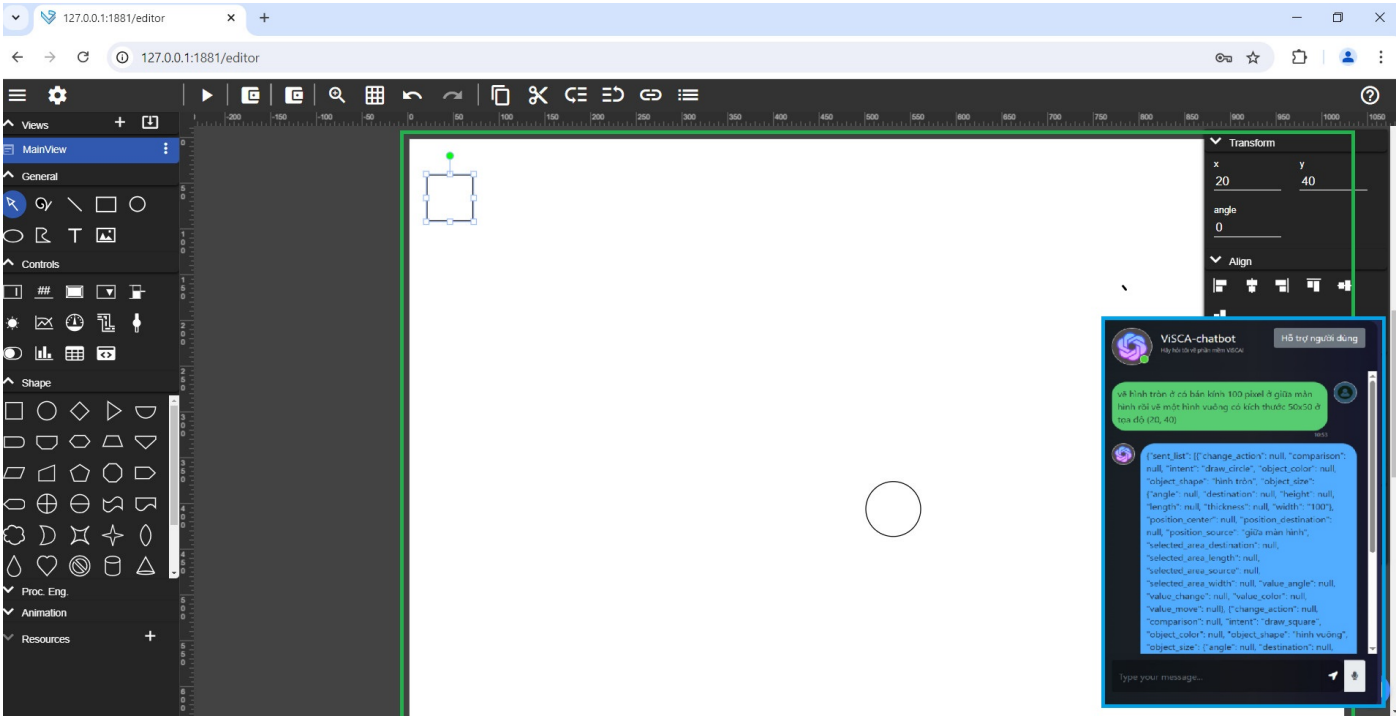

Fig. 8. The user's command which has the English translation text : "draw a circle with radius of 100 pixels at the center of the screen, then draw a square with size of 50 x 50 pixels at the coordinates (20, 40)" and the content of the obtained JSON file after VA handles the command are shown in the box 1 (surrounded by the thick blue border). The result after sending the JSON file to the SF by calling its API are shown in the box 2 (surrounded by the thin green line).

b) Training dataset

The STS datasets used to train context retrieval models is built by choosing two samples randomly from the corresponding context datasets. However, if all combinations of two samples are chosen, the STS training datasets will become very large and imbalanced in term of similarity value. Particularly, each of STS training datasets will have over 3,632,860 samples in total, including over three million samples with Intent Label Similarity Value of 0 (ILSV0). As a result, only a specific number of samples with ILSV0 chosen randomly. Particularly, each of the three training datasets contains 770,926 samples in total. Table II shows the statistics of each STS training dataset in terms of Intent Label Similarity Value.

TABLE II. STATISTICS OF STS TRAINING DATASET

Similarity value	Number of samples
1	1618
0.75	2516
0.5	170816
0.25	195976
0.0	400000

Based on three context datasets, namely $\textbf{Context}_{zero-shot}$, $\textbf{Context}_{few-shot}$ and $\textbf{Context}_{zero-shot\,CoT}$, we have built three STS training datasets, namely $\textbf{STS}_{zero-shot}$, $\textbf{STS}_{few-shot}$ and $\textbf{STS}_{few-shot\,CoT}$. Similarly, Sentence-BERT model trained on these datasets is called $\textbf{SBERT}_{zero-shot}$, $\textbf{SBERT}_{few-shot}$ and $\textbf{SBERT}_{few-shot\,CoT}$.

c) STS Validation dataset

To evaluate the training process of each Sentence-BERT model, a STS validation dataset, called $\textbf{STS}_{valid}$, is also created based on $\textbf{Context}_{test}$ dataset. Its samples are created by all three merging methods, then filtered manually to get rid of incorrect and duplicated ones. This dataset contains 31,763 samples in total. The below Table III shows the statistics of the $\textbf{STS}_{valid}$ in terms of Intent Label Similarity Value.

TABLE III. STATISTICS OF THE STS VALIDATION DATASET

Similarity values	Number of samples
1	638

B. Experimental Setup

1) Configuration setup

a) Hardware configuration

Both the NLU module and multi-intent handling module are trained on GTX 3090 GPUs (24GB VRAM). The training processes of the two models can take up to 20 GB of VRAM.

b) Model configuration

In the VA, we have used DIETClassifier model [4] with some customization on its components. Particularly, we use

Bag-Of-Word (BOW) method with vocabulary built by n-grams whose length is from 1 to 5 characters as the main sparse featurizer for the model.

For dense featurizer, we use two methods. First, we use phoBERT pretrained model [16] to get dense features from input tokens and its vector output from the special token "¡s¿" acts as the sentence feature of the model. The DIETClassifier model using this dense featurizer is called **DIET**$_{pB+BOW}$. The second method, inspired by an existing work of [7], uses the Fasttext model [8] pretrained on the Vietnamese dataset[§] as the main dense featurizer and the sentence feature is computed by averaging all dense features obtained from input tokens. The DIETClassifier model with that dense featurizer is called **DIET**$_{Ft+BOW}$. In the last model configuration, we do not use any dense featurizer, thus is called **DIET**$_{BOW}$. The number of Transformer layers and the number of attention heads in each Transformers layer used in all configurations are two and four, respectively.

Furthemore, in order to evaluate the effectiveness of using Vietnamese pretrained language models as dense featurizers, we have also used a DIETClassifier model with no dense featurizer and compared its performance with the above two DIETClassifier models.

c) Training configuration

In experiments evaluating VA, we have trained DIETClassifier model on training dataset for 100 epochs with batch size of 16 and the learning rate of 0.001. The loss function we used to optimize the model is Cross Entropy and the optimizer used to adjust the learning process is AdamW optimizer.

In experiments evaluating the multi-intent handling module, we have trained Sentence-BERT model on training dataset for 20 epochs with batch size of 16 and the learning rate of 0.25×10^{-4}. The loss function we used to optimize the model is Mean Square Error and the optimizer used to adjust the learning process is AdamW optimizer. Furthermore, to evaluate the contribution of the context retrieval model, we have also used a LLM (called Baseline) with static contexts, containing three single-intent commands and four multi-intent commands, and compared it with LLMs using the above context retrieval model.

2) Evaluation metrics

a) VA evaluation metrics

The two tasks used to evaluate performance of NLU module are IC and EE. Two main metric used in two tasks are Accuracy and F1.

b) Multi-intent handling evaluation metrics

Firstly, to evaluate the training process of context retrieval model when being trained on different STS training datasets, we have used Spearman's rank correlation coefficient. Secondly, in the experiment evaluating the overall performance of multi-intent handling module, we have used various metrics.

Secondly, to evaluate the output single-intent commands of the module, we have concatenated the two lists of output single-intent commands and ground-truth single-intent commands with the special token "¡SEP¿" into two single strings and used BLEU [3] and ROUGE [22]. Furthermore, we have also used 2 metrics named Split Accuracy (SACC) and Exact Match (EM) proposed by [28]. In the original paper, SACC is used to measure the ratio of correct command splitting and computed the following Eq. (3):

$$\text{SACC} = \frac{1}{n} \sum_{1 \le i \le n} \mathbb{I}_{(\text{len}(Q_{pred}^{(i)}) = \text{len}(Q_{ref}^{(i)}))} \tag{3}$$

Where n is the number of samples, $Q_{pred}^{(i)}$ and $Q_{ref}^{(i)}$ are the i^{th} predicted and references single-intent command list, respectively. As for EM, [28] considered the correct result if the predicted command is exactly the same as the reference one:

$$\text{EM} = \frac{\sum_i \sum_j F(Q_{pred}^{(ij)}, Q_{ref}^{(ij)})}{\sum_{1 \le i \le n} len(Q_{ref}^{(i)})} \tag{4}$$

Where $Q_{pred}^{(ij)}$ and $Q_{ref}^{(ij)}$ are the j^{th} predicted single-intent command and ground-truth single-intent command in the i^{th} sample in the evaluation dataset. The function $F(Q_{pred}^{(ij)}, Q_{ref}^{(ij)})$ in the above equation is the indicator function:

$$F(Q_{pred}^{(ij)}, Q_{ref}^{(ij)}) = \mathbb{I}_{(Q_{pred}^{(ij)} = Q_{ref}^{(ij)})} \tag{5}$$

However, applying the metric EM directly in our experiment is not suitable. We have seen that our merging methods only retain the essential information of the merged single-intent commands (considered as ground-truth commands in an evaluation sample) and get rid of their writing style, e.g. formal, informal, or even humorous, in the resulting multi-intent command. As a result, the output single-intent commands that are predicted by the multi-intent handling module are mostly different from the ground-truth, which means the metric EM cannot make an accurate evaluation. As a result, apart from EM metric, we proposed a new metric called proportional match (PM), which modifies the F function in EM. This new metric is used to measure the accuracy in the essential information of predicted single-intent commands. The F function in the metric is computed by Eq. (6):

$$F(Q_{pred}^{(ij)}, Q_{ref}^{(ij)}) = \begin{cases} 0 & \text{if } \begin{array}{l} \exists k \in D_{ref}^{(ij)} \text{ and} \\ D_{ref_k}^{(ij)} \neq NULL \text{ and} \\ D_{ref_k}^{(ij)} \neq D_{pred_k}^{(ij)} \end{array} \\ 1 & \text{otherwise} \end{cases} \tag{6}$$

Where $D_{pred}^{(ij)}$ and $D_{ref}^{(ij)}$ are the dictionaries containing the intents and entity values extracted from $Q_{pred}^{(ij)}$ and $Q_{ref}^{(ij)}$ respectively by the VA (trained on the overall dataset). k is the key in $D_{pred}^{(ij)}$ and D_{ref}^{ij}. The condition that $D_{ref}^{(ij)} \neq NULL$ is set to get rid of abundant information, which appears very common in almost every sample of the evaluation dataset.

C. Experimental Results

1) VA experimental result

We conducted an evaluation of all three DIETClassifier models that are trained on the same $\mathbf{NLU}_{40}$ training dataset on the $\mathbf{NLU}_{test}$ testing dataset. The $\mathbf{DIET}_{pB+BOW}$ is chosen for our proposed method (called **Our model**). The results are shown in Table IV.

TABLE IV. RESULT OF DIETCLASSIFIER MODELS ON $\mathbf{NLU}_{test}$

Model	IC		EE	
	F1	Acc	F1	Acc
Our model	**0.93**	**0.93**	**0.96**	**0.98**
$\mathbf{DIET}_{Ft+BOW}$	0.92	0.92	0.96	0.98
$\mathbf{DIET}_{BOW}$	0.92	0.92	0.95	0.97

Table IV shows our model achieved the best performance for both IC and EE tasks on the NLU_{test}.

In order to know the quality of the our semi-automatically built datasets, we used **Our model** to train on **NLU** datasets. The results are shown in Table V.

TABLE V. RESULTS OF $\mathbf{DIET}_{pB+BOW}$ MODEL ON $\mathbf{NLU}_{test}$

Training dataset	IC		EE	
	F1	Acc	F1	Acc
$\mathbf{NLU}_{40}$	0.93	0.93	0.96	0.98
$\mathbf{NLU}_{50}$	0.94	0.93	0.96	0.98
$\mathbf{NLU}_{60}$	0.94	0.93	0.97	0.98
$\mathbf{NLU}_{70}$	0.95	0.95	0.97	0.98
$\mathbf{NLU}_{train}$	**0.96**	**0.96**	**0.97**	**0.99**

2) Multi-intent handling experimental result

Fig. 9 shows the result of three sentence-BERT on $\mathbf{STS}_{valid}$ throughout their training processes.

Tables VI and VII show the BLEU, ROUGE SACC, EM and PM score of the multi-intent handling module using static contexts and different context retrieval models. The $\mathbf{SBERT}_{few-shot\,COT}$ is chosen in our proposed method.

D. Discussion

1) Our semi-automatically data built method and VA

Table V shows that the model is trained on the training dataset $\mathbf{NLU}_{40}$ includes 180 samples made manually and 1260 samples made by our proposed method that achieved a 0.93 F1 and Acc score in the IC task and a 0.96 F1 and 0.98 Acc score in the EE task. This demonstrates that our data is of high quality, and the VA we made works so well.

The dataset $\mathbf{NLU}_{train}$ is made by adding 1440 samples is built by our proposed method to $\mathbf{NLU}_{40}$. The model is trained on $\mathbf{NLU}_{train}$ achieved F1 and Acc score are higher than the model is trained on demonstrates our proposed semi-automatically data building method is a good method. Especially its ability to update itself with new data to become better.

2) Multi-intent handling experiment

In the first experiment evaluating the performance of sentence-BERT models on $\mathbf{STS}_{valid}$ throughout their training process shown in Fig. 9, it can be clearly seen that the best performance that all three models can achieve converges at a result of 0.82. Their convergence speeds, however, differ greatly from each other. The model $\mathbf{SBERT}_{zero-shot}$ trained on $\mathbf{STS}_{zero-shot}$ dataset converges much slower than the other two sentence-BERT models when needing about 100 training steps to converge compared to just about 30 to 50 training steps of $\mathbf{SBERT}_{few-shot}$ and $\mathbf{SBERT}_{few-shot\,COT}$. The reason for its slow convergence speed is because its training dataset $\mathbf{STS}_{zero-shot}$ is built from the context dataset $\mathbf{Context}_{zero-shot}$ which has plenty of false multi-intent commands. Fig. 10 shows some examples of these kinds of commands in the $\mathbf{Context}_{zero-shot}$ dataset.

The false multi-intent commands shown in the "merged multi-intent commands" column in the Table X are actually single-intent commands. When this kind of command is matched with true multi-intent commands in the dataset, it will make the false sample in the STS dataset used to train the context retrieval dataset, thus making the training process of the model divergent.

In the second experiment shown in Tables VI and VII which evaluates the performance of multi-intent handling module when using trained context retrieval models compared to using static contexts with various metrics, it can be clearly seen that the performance of multi-intent handling module using trained context retrieval models is relatively higher than one of multi-intent handling module using static context in every metric, emphasizing the great contribution of context retrieval models trained on STS training datasets to the performance of multi-intent handling module. In Table VI, the difference in ROUGE in BLEU metric between the worst-performing model (Baseline model) and the best-performing model ($\mathbf{SBERT}_{few-shot\,COT}$) is not really notable, ranging around 0.02 and 0.04. We hypothesize that we have concatenated the output single-intent command list into a single string and evaluated on this concatenated string so that the evaluated strings of different models may be similar to each other in some substrings. The results in SACC, EM and PM metrics shown in Table VII, on the other hand, see a significant gap between the worst-performing and the best-performing model, ranging from 0.04-0.05. Furthermore, what we can clearly see in that table is that the gap between the results of multi-intent handling module using a trained context retrieval model is pretty trivial, indicating that with contexts that are relatively similar to the user's input, the LLMs can accurately split the input into single-intent commands in terms of intent and assign the correct information to each of the output commands.

To investigate the capability of multi-intent handling in single-intent and multi-intent command detection, we have conducted two additional experiments for the module with different configurations on single-intent commands and multi-intent commands separately. The Tables VIII and IX show the results in SACC metric of the two experiments.

In Table VIII, the multi-intent handling module using $\mathbf{SBERT}_{zero-shot}$ as context retrieval model archives the worst result, even much worse than the Baseline module. This

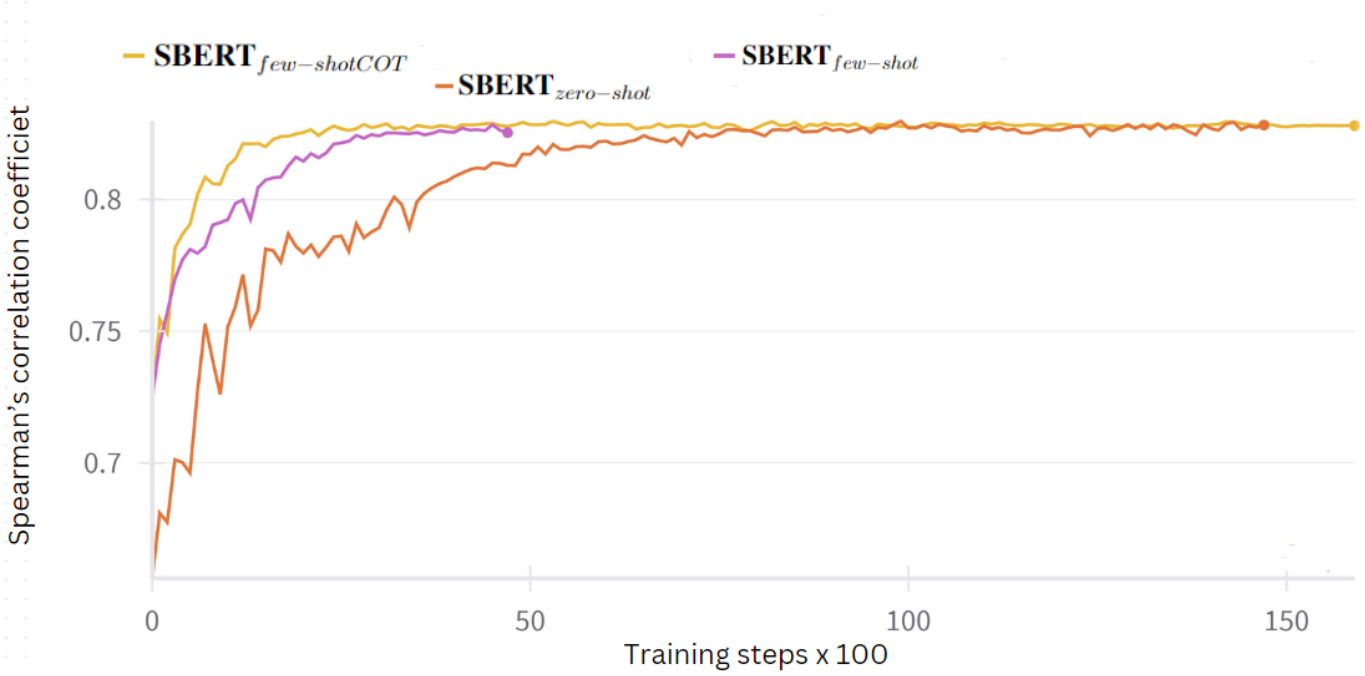

Fig. 9. Spearman's correlation coefficient of three sentence-BERT models trained on three different STS datasets

TABLE VI. ROUGE AND BLEU SCORE OF MULTI-INTENT HANDLING MODULE USING STATIC CONTEXTS AND DIFFERENT CONTEXT RETRIEVAL MODELS

Model	ROUGE-1	ROUGE-2	ROUGE-L	ROUGE-S	BLEU
Baseline	0.87	0.81	0.84	0.84	0.7
SBERT$_{zero-shot}$	0.89	0.83	0.85	0.85	0.74
SBERT$_{few-shot}$	0.89	0.83	0.86	0.86	0.74
SBERT$_{few-shot\ COT}$	**0.9**	**0.84**	**0.86**	**0.86**	**0.75**

TABLE VII. SACC, EM AND PM OF MULTI-INTENT HANDLING MODULE USING STATIC CONTEXTS AND DIFFERENT CONTEXT RETRIEVAL MODELS

Model	SACC	EM	PM
Baseline	0.87	0.75	0.83
SBERT$_{zero-shot}$	**0.93**	**0.79**	**0.87**
SBERT$_{few-shot}$	0.90	0.79	0.86
SBERT$_{few-shot\ COT}$	0.92	0.79	0.87

TABLE VIII. THE RESULT IN SACC METRIC ON SINGLE-INTENT COMMANDS OF THE EVALUATION DATASET

Module	SACC Score
Baseline	0.93
SBERT$_{zero-shot}$	0.85
SBERT$_{few-shot}$	0.94
SBERT$_{few-shot\ COT}$	**0.96**

TABLE IX. THE RESULT IN SACC METRIC ON MULTI-INTENT COMMANDS OF THE EVALUATION DATASET

Module	SACC Score
Baseline	0.87
SBERT$_{zero-shot}$	**0.94**
SBERT$_{few-shot}$	0.91
SBERT$_{few-shotCOT}$	0.92

is due to the false multi-intent commands in its context database, as mentioned in Fig. 10. That makes the model likely to retrieve true multi-intent commands when receiving the single-intent command of the user, leading to the wrong segmentation. In contrast, the multi-intent handling module using **SBERT**$_{zero-shot}$ as context retrieval model achieves the best result, and the gap between the modules using trained context retrieval models is relatively trivial. This is due to the majority of multi-intent commands in the evaluation dataset being simple commands that have single-intent commands linked by linking words and punctuation, which appear very common in all three context datasets. The remaining multi-intent commands in the evaluation dataset, however, have information interleaved or even tricky to assign to an intent. The **Context**$_{zero-shot}$ context dataset can have many complex multi-intent commands due to the lack of reference examples in the Zero-shot merging method, which is used to generate multi-intent commands in that dataset, thus making LLMs likely to generate out-of-the-box commands with no limit.

V. CONCLUSION

In this work, we have proposed the effective method for recognizing multi-intent commands in low-resource languages and respond to SF in doing the drawing task. In the phase of data building, we proposed a semi-automatic data building

Single-intent commands:
- Chọn tất cả các đối tượng nền
(Choose all objects on the background)
- Tăng chiều dài đường thẳng màu xanh dương tại vị trí hiện tại lên 18 pixel
(Increase the length of the blue line at the current position by 18 pixels)

=> Merged multi-intent command:
- Tăng chiều dài của tất cả các đường thẳng màu xanh dương trên đối tượng nền lên 18 pixel
(Change the length of all blue line on the background by 18 pixel .)

Single-intent commands:
- Thay đổi kích thước chiều dài của đường thẳng màu tím nằm giữa hai hình tam giác thêm 18 pixel
(Set the length of the purple line laying between 2 triangles by increasing by 18 pixels.)
- chọn tất cả các đối tượng có cùng màu xanh dương.
(Choose all object that have color blue.)

=> Merged multi-intent command:
- Thay đổi kích thước chiều dài của đường thẳng màu tím nằm giữa hai hình tam giác thêm 18 pixel .
(Set the length of the purple line laying between 2 triangles by increasing it by 18 pixels .)

Single-intent commands:
- Giảm chiều cao của hình thoi trắng bằng cách thu nhỏ kích thước tỷ lệ 70 %
(Decrease the height of the white triangle by sinking its size to 70 %)
- Xin vui lòng bôi đen toàn bộ các đối tượng hiện đang có.
(Choose all objects on the screen, please.)

=> Merged multi-intent command:
- Thu nhỏ chiều cao của hình thoi trắng đi 70 %
(Sinking the height of the white triangle to 70 %)

Fig. 10. False multi-intent commands in the $\textbf{Context}_{zero-shot}$ dataset.

method. Applying it to the Vietnamese language, we built an intent list including 36 intents, an entity list including 31 entities, and the labeled Vietnamese command corpus including 3240 commands. In the phase of generating the JSON file, we proposed the method that separates the multi-intent command from the user's command into single-intent commands to be better understood by the VA, from which it supports more effectively for SF. Our labeled command corpus and the open source code of the splitting tool are shared with the research community. In the future, we will continue to research and improve our data construction method and extend it to some low-resource languages. Furthermore, we will conduct research to improve the capabilities and accuracy of the VA problem.

ACKNOWLEDGMENT

APPENDIX

Table X shows all intent labels we have used in our dataset and their meanings.

TABLE X. THE INTENT LABELS AND THEIR MEANING

Intent	Meaning
select_all_object	The user wants to select all object (with optionally the same properties) on the interface of the SF
exit_select	The user wants to give up selecting some (or all) selected objects (with optionally the same properties) on the interface of the SF
delete_selected_objects	The user wants to delete some (or all) selected objects (with optionally the same properties) on the interface of the SF
selected_area	The user wants to select all objects (with optionally the same properties) in an area defined by a pair of coordinates on the interface of the SF
rotate_left	The user wants to rotate a specific object on the interface of the SF to the left side
rotate_right	The user wants to rotate a specific object on the interface of the SF to the right side
horizontal_flip	The user wants to flip a specific object on the interface of the SF horizontally
vertical_flip	The user wants to flip a specific object on the interface of the SF vertically
move_left	The user wants to move a specific object on the interface of the SF to the left side
move_right	The user wants to move a specific object on the interface of the SF to the right side
move_up	The user wants to move a specific object on the interface of the SF upward.
move_down	The user wants to move a specific object on the interface of the SF downwards.
color_background	The user wants to paint the background of a specific object on the interface of the SF by a specific color.
color_foreground	The user wants to paint the foreground of a specific object on the interface of the SF by a specific color.
change_width	The user wants to change the width of a specific object on the interface of the SF.
change_height	The user wants to change the height of a specific object on the interface of the SF.
change_length	The user wants to change the length of a specific object on the interface of the SF.
change_radius	The user wants to change the radius of a specific object on the interface of the SF.
change_top	The user wants to move a specific object on the interface of the SF in the vertical direction so that its new position is a certain distance from the top border of the interface of the SF.
change_left	The user wants to move a specific object on the interface of the SF in the horizontal direction so that its new position is a certain distance from the left border of the interface of the SF.
change_right	The user wants to move a specific object on the interface of the SF in the horizontal direction so that its new position is a certain distance from the right border of the interface of the SF.
change_bottom	The user wants to move a specific object on the interface of the SF in the vertical direction so that its new position is a certain distance from the bottom border of the interface of the SF.
draw_line	The user wants to draw a line on the interface of the SF. The information about attributes of the object is optionally provided. Any attributes with no provided information will be set to its default value.
draw_circle	The user wants to draw a circle on the interface of the SF. The information about attributes of the object is optionally provided. Any attributes with no provided information will be set to its default value.
draw_ellipse	The user wants to draw a ellipse on the interface of the SF. The information about attributes of the object is optionally provided. Any attributes with no provided information will be set to its default value.
draw_rectangle	The user wants to draw a rectangle on the interface of the SF. The information about attributes of the object is optionally provided. Any attributes with no provided information will be set to its default value.
draw_square	The user wants to draw a square on the interface of the SF. The information about attributes of the object is optionally provided. Any attributes with no provided information will be set to its default value.

draw_rhombus	The user wants to draw a rhombus on the interface of the SF. The information about attributes of the object is optionally provided. Any attributes with no provided information will be set to its default value.
draw_parallelogram	The user wants to draw a parallelogram on the interface of the SF. The information about attributes of the object is optionally provided. Any attributes with no provided information will be set to its default value.
draw_trapezoid	The user wants to draw a trapezoid on the interface of the SF. The information about attributes of the object is optionally provided. Any attributes with no provided information will be set to its default value.
draw_arrow	The user wants to draw an arrow on the interface of the SF. The information about attributes of the object is optionally provided. Any attributes with no provided information will be set to its default value.
copy_selected_objects	The user wants to copy all selected objects (with optionally the same properties) to the clipboard.
cut_selected_objects	The user wants to cut all selected objects (with optionally the same properties) and save them into the clipboard.
paste	The user wants to paste the object saved in the clipboard to a certain position on the interface of the SF.
undo	The user wants to undo the task.
redo	The user wants3 to redo the task.

Table XI shows all entity labels which are grouped into entity groups with their meanings.

TABLE XI. ENTITY LABELS AND THEIR MEANINGS

Entity group	Entity	Meaning
Object (used to label phrases describing attributes of the object)	object—shape	Indicates the shape of the object
	object—width	Indicates dimensions like the upper base of a trapezoid, radius of a circle, width of a rectangle, etc.
	object—height	Indicates the height of various shapes such as triangles and parallelograms
	object—length	Indicates the length of various shapes like rectangles, arrows, etc.
	object—color	Indicates the color of the object
	object—thickness	Indicates the thickness of the object's border
	object—destination	Indicates the end point of a line (e.g. center of the screen or top left corner)
	object—angle	Indicates the value of the angle at the top left corner of the object
	object—destination_x	Indicates the x-axis of the end point of the line
	object destination_y	Indicates the y-axis of the end point of the line
Value (used to label phrases indicating essential parameters for specific tasks)	value—color	Indicates the color for tasks like "color_background" and "color_foreground"
	value—change	Indicates changes to the size of an object (e.g. increase, decrease, set new value)
	value—move	Indicates the distance between the new and old positions of the object
	value—angle	Indicates the angle for rotating the object (e.g. "rotate_left", "rotate_right")
Position (used to label phrases indicating the position of the object)	position—source	Indicates the current position of the object, like "top left corner" or "center of the screen"
	position—source_x	Indicates the x-axis of the current position of the object

	position—source_y	Indicates the y-axis of the current position of the object
	position—destination	Indicates the target position for tasks like “paste” or selecting an area
	position—destination_x	Indicates the x-axis of the target position
	position—destination_y	Indicates the y-axis of the target position
	position—center	Indicates the center of the object
	position—center_x	Indicates the x-axis of the object’s center
	position—center_y	Indicates the y-axis of the object’s center
Selected_area (used for “select_area” tasks)	selected_area—height	Indicates the height of the selected area
	selected_area—width	Indicates the width of the selected area
	selected_area—length	Indicates the length of the selected area
Change_action (used for resizing objects)	change_action—increase	Indicates that the user wants to increase the size of the object
	change_action—decrease	Indicates that the user wants to decrease the size of the object
	change_action—set	Indicates that the user wants to set a new size for the object
Aspect	aspect	Used to compare an object with others based on features like size or length
Comparison	comparison	Used to label phrases that compare objects (e.g. “bigger than”, “equal to”)

AudioMag: A Hybrid Audio Protection Scheme in Multilevel DWT-DCT-SVD Transformations for Data Hiding

Jingjin Yu[1], Chai Wen Chuah*[2], Rundan Zheng[3], Janaka Alawatugoda*[4]

***Abstract*—Steganography is a technique used to hide data within an image or audio in order to maintain the secrecy of the message being communicated. There are several methods used in steganography to achieve this, but commonly, the data hiding is between the same stego-entity, such as an image with an image or audio with audio. One drawback of hiding data within the same entity is that once the security is compromised, one may be able to access the particular data. Therefore, this research proposes hiding audio within an image. The first step is to transform the audio into a hexadecimal value. Next, the hexadecimal value is hidden within the shortened uniform resource locators. The uniform resource locators are concatenated, shuffled, and converted into a quick response code. Finally, the quick response code is embedded into an image. The simulation results show the successful hiding of the audio message within the image, while maintaining the security and confidentiality of the hidden messages.**

Keywords*—Steganography; image steganography; audio steganography; data hiding; stego-entity

I. Introduction

As the rapid growth of the Internet and the bandwidth continues, cryptography is responsible for ensuring secure communication over insecure interconnected networks, guaranteeing transmission privacy and authentication [1], [2]. There are two common methods for sending secret messages: data encryption [3] and data hiding [4], [5]. In the case of an encrypted message, only the intended recipient can view the message by decrypting it with a secret key. Even if an attacker obtains the encrypted message, they will be unable to decipher the content. However, if the key is revealed to the public or stolen by the attacker, the message can be compromised [6]. Data hiding, or steganography, which falls under the cryptography umbrella, is another technique that is widely used to hide secret messages within harmless messages in a way that prevents attackers from detecting the existence of the secret message.

Generally, data hiding includes the process of generating a stego-image (embedding payload into the image), while extraction is the process of viewing the payload from the stego-image [5]. The security level of the stego-image is based on its similarity to the original image, making it difficult for unintended observers to be aware of the existence of the hidden secret message. There are two common types of steganography: audio steganography and image steganography.

Image steganography [8], [9], [10] refers to the process of hiding data within an image file. The image selected for this purpose is known as a cover image, and the image obtained after steganography is called a stego-image. The least significant bit (LSB) technique is one of the simplest approaches by replacing the LSB of each pixel in the cover image with a piece of the hidden data [11], [12]. Since it only involves one bit change in a pixel, the stego-image appears identical to the original image. Hence, these changes will be hard to detect by the human eye, which is not sensitive.

Audio steganography is a technique of inserting hidden messages within sound files [13], [14], [15]. Users can insert a secret message into the audio by manipulating the binary sequence of the file, like adjusting its length or making subtle changes to its structure. This is undetectable to the human senses, as human are not sensitive to the small changes. Common audio steganography sound file formats to date include waveform audio file format (WAV), audio units (AU), and MPEG audio layer 3 (MP3) [16]. The process of embedding secret messages in digital sound is typically more complex than embedding messages in other forms of media, such as digital images.

However, information shared online by individuals often faces various risks, such as being maliciously intercepted by third parties or misused in terms of ownership. Steganography offers effective solutions to address these issues. The objective of this research is to develop and evaluate audio steganography, which conceals audio within images, to enrich people's comprehension beyond the traditional methods of steganography. The significance of utilizing both image and audio steganography lies in taking advantage of the lack of sensitivity of the human ear and eye to subtle changes, which makes it easier to hide communication information and enhances security [17], [18]. This will aid in protecting communication privacy and preventing unauthorized access to the information.

The remainder of this paper is organized as follows: Section II presents the literature review. Section III shows the proposed AudioMag. The AudioMag simulation is shown in section IV. Section V contains the result discussions. Finally, Section VI concludes the paper.

II. Literature Review

Steganography is a technique of hiding secret information in a host, such as an image, audio, or video. The secret information

is known as payload which could be a message, image, or audio. Steganography ensures that this hidden information is not noticeable to anyone who is not specifically looking for it. Therefore, individuals are able to transmit confidential data without raising suspicion through steganography. There are three common techniques for steganography: image steganography and audio steganography.

A. Image Steganography

Vleeschouwer, et al. proposed a method for embedding the payload into the stego-image based on patchwork theory, which has certain robustness against JPEG loosely compression [7]. Loosely compression meant that even though the image being compressed, there will be loss of some information, but with this proposed method, they still are able to retrieve back the payload. The image is divided into two zones. The histogram of each zone is mapped to a circle where it is the place to allocate the payload. That is, each bit of the payload is associated with a group of pixels, for example a block in an image, and then the payload is map into the associate zones. The embedding process hides the payload by changing the whole pixel value of the image. This algorithm suffers from the salt-and-pepper noise. To overcome this problem, this algorithm is suitable for small size of payload with multi-tone image and not suitable for halftone images.

Honsinger's group patent the data hiding technique used for fragile authentication [8]. The method that they carried out is based on adding the payload to original image, pixel by pixel using modulo 256 additions to form the stego-image. This method is comfortable only for those payloads with the capacity in category from 1k to 2k bits. Overall, the process of embedding the payload can be described in two mathematics equation, the first one as $I'(x,y) = I(x,y) + \alpha M(x,y) * C(x,y)$, this formula is used to find the location of payload in original image, where and $I'(x,y)$ is the location of payload in the image, $\alpha M(x,y) * C(x,y)$ denotes as payload coordinate and $I(x,y)$ as location of original image. While the second equation is $Iw = (I+W) \bmod 256$, Iw denotes marked image, I original image, W is the payload comes from the hash function of the original image and the modulo 256 addition ensures that the modified image values are always be in the same range as the original image values. By using these two equations, with first equation they find the location in original image then second equation responsible in avoiding over or underflow happens in stego-image. This technique changes the entire pixel value of the original image, hence, stega-image suffers salt-and-pepper noise.

Chandran and Khoushik compared the efficacy of LSB, discrete cosine transform (DCT), and discrete wavelet transform (DWT) techniques in the context of steganography [9]. The findings indicated that the DCT technique demonstrated superior performance when compared to both LSB and DWT methods. The evaluation was centered on the quality of the stego-image and the original cover image. Limitations of each approach were highlighted, with the LSB method showing weaknesses in terms of invisibility and robustness, the DCT method lacking robustness, and the DWT method exhibiting lower PSNR values and higher MSE.

Moon and Kawitkar proposed data hiding by using four LSB (4 LSB) substitution method and password for advance security [10]. With the protection layer by using password, the user only can view the payload with correct password. Without the password, the user only can get back the cipher text which is the junk characters. And this technique can embed large size of payload. But, stego-image is suffer with noise as well if the original image is halftone image, thus the attackers easily notice that particular image is the stego-image then he can break the password to get the payload.

There are many researchers [11], [12] tend to use LSB method for concealing data by utilizing the least significant bit of the cover image, making it imperceptible to the naked eye. However, this technique is deficient in terms of limited payload capacity.

B. Audio Steganography

Biswajita Datta et al. [13] presented an innovative method that employs LSB encoding across multiple layers, allowing for the simultaneous embedding of two data bits into the cover media to increase stego-audio capacity. The extraction procedure entails bitwise operations, adding complexity to interpreting the data without understanding these operations. Furthermore, techniques such as bit adjustment and flag setting are utilized to maintain the perceptual transparency of the stego-audio.

Sayed et al. [14] investigates the integration of two distinct steganography methods in a multi-level steganography framework. The initial method entails concealing a message in an audio cover through a modified LSB technique, whereas the second method involves concealing a second message in the output of the first level using a phase coding approach. The stego-audio file that results contains two audio covers with concealed messages.

Nugraha explores the utilization of steganography in audio data through the direct sequence spread spectrum technique which transmitting hidden messages via radio waves, where the message is carried by a noise-like wave [15]. This technique can be adapted for concealing messages within audio data, where the embedded information will manifest as noise. The proposed method requires a key to embed messages within the noise, generating a pseudo-noise waveform. Prior to embedding, the information to be hidden must first be modulated using this pseudo-noise signal.

C. Image Processing Methods

1) Discrete Wavelet Transform: Discrete wavelet transform (DWT) decomposes an image into a sequence of images with different spatial resolutions. Fig. 1 shows how the image is decomposed into the first level, resulting in 'LL', 'LH', 'HL' and 'HH'. The second level is then applied to the low frequency 'LL' only, where 'L' represents low frequency bands and 'H' represents high frequency bands. Threshold is applied to the wavelet coefficients in the high frequency levels, as the noise present in the low frequency wavelet coefficients will be averaged out. This calculation can effectively reduce noise without significantly distorting the underlying signal [19].

2) Discrete Cosine Transform: Discrete cosine transform (DCT) converts a series of pixels in an image into a series of frequency domain coefficients [20]. Eq. (1) computes the (i,j)

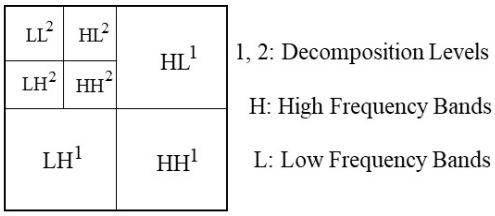

Fig. 1. 2D-DWT with 2-Level decomposition.

entry of the DCT of an image, where i and j are the coordinates of the transformed image. The $p(x, y)$ is the x and y^{th} element of the image, and N is the size of the block calculated by the DCT. Eq. (2) represents a normalization constant.

Lorem ipsum dolor sit amet, consectetuer adipiscing elit. Ut purus elit, vestibulum ut, placerat ac, adipiscing vitae, felis. Curabitur dictum gravida mauris. Nam arcu libero, nonummy eget, consectetuer id, vulputate a, magna. Donec vehicula augue eu neque. Pellentesque habitant morbi tristique senectus et netus et malesuada fames ac turpis egestas. Mauris ut leo. Cras viverra metus rhoncus sem. Nulla et lectus vestibulum urna fringilla ultrices. Phasellus eu tellus sit amet tortor gravida placerat. Integer sapien est, iaculis in, pretium quis, viverra ac, nunc. Praesent eget sem vel leo ultrices bibendum. Aenean faucibus. Morbi dolor nulla, malesuada eu, pulvinar at, mollis ac, nulla. Curabitur auctor semper nulla. Donec varius orci eget risus. Duis nibh mi, congue eu, accumsan eleifend, sagittis quis, diam. Duis eget orci sit amet orci dignissim rutrum.

$$Y(i,j) = \frac{1}{\sqrt{2K}} C(i)C(j) \sum_{x=0}^{k-1} \sum_{y=0}^{k-1} p(x,y) * \cos\left[\frac{(2x+1)i\pi}{2K}\right] \cos\left[\frac{(2y+1)i\pi}{2K}\right] \quad (1)$$

$$C(b) = \begin{cases} \frac{1}{\sqrt{2}}, & \text{if b = 0} \\ 1, & \text{if b} > 0 \end{cases} \quad (2)$$

The equation computes the value of one specific entry (i, j) in the transformed image by using the pixel values from the original image matrix. For example, in the case of a 4 x 4 block image, the value of N is 4 and the range of x and y is 0 - 3. Therefore, $Y(i, j)$ is determined based on Eq. (3).

Lorem ipsum dolor sit amet, consectetuer adipiscing elit. Ut purus elit, vestibulum ut, placerat ac, adipiscing vitae, felis. Curabitur dictum gravida mauris. Nam arcu libero, nonummy eget, consectetuer id, vulputate a, magna. Donec vehicula augue eu neque. Pellentesque habitant morbi tristique senectus et netus et malesuada fames ac turpis egestas. Mauris ut leo. Cras viverra metus rhoncus sem. Nulla et lectus vestibulum urna fringilla ultrices. Phasellus eu tellus sit amet tortor gravida placerat. Integer sapien est, iaculis in, pretium quis, viverra ac, nunc. Praesent eget sem vel leo ultrices bibendum. Aenean faucibus. Morbi dolor nulla, malesuada eu, pulvinar at, mollis ac, nulla. Curabitur auctor semper nulla. Donec varius orci eget risus. Duis nibh mi, congue eu, accumsan eleifend, sagittis quis, diam. Duis eget orci sit amet orci dignissim rutrum.

$$Y(i,j) = \frac{1}{\sqrt{8}} C(i)C(j) \sum_{x=0}^{3} \sum_{y=0}^{3} p(x,y) * \cos\left[\frac{(2x+1)i\pi}{8}\right] \cos\left[\frac{(2y+1)i\pi}{8}\right] \quad (3)$$

3) Singular Value Decomposition: Singular Value Decomposition (SVD) manipulates the original image into three different matrices as shown in Eq. (4) [21]. A is original M X N matrix, U is the M X R matrix with orthonormal columns matrix, σ is the R X R diagonal matrix of singular values, and V^T is the transpose orthonormal columns matrix with dimension of R X N. It should be noted that, M, N, and R are the dimensions of the original matrix A.

$$A = U\sigma V^T \quad (4)$$

D. Caesar Cipher

Caesar cipher is one of the simplest and most widely known encoding and decoding techniques. The encoding [see Eq. (5)] and decoding [see Eq. (6)] techniques are based on a substitution method where the letters of plaintexts are shifted backwards (or forwards) by a fixed number (d) to produce encoding letters [22].

$$c = p + d \ mod \ n, \quad (5)$$

$$p = c - d \ mod \ n, \quad (6)$$

For example, when the letters of plaintext are based on ASCII table, then the n value is 128. Let the "d" be 15 and the plaintext is "Pe@C3", the encoding process is shown in Table I.

TABLE I. CAESAR CIPHER - ENCODING PLAINTEXT OF "PE@C3"

Plaintext	80	101	64	67	51
$c = p + d$ **mod** 128	75	96	59	62	46
Ciphertext	K	‘	;	>	.

The decoding process is the reverse of the encoding process. If the encoding of "d" is 15, then the value of "d" for decoding is -15. Let's decode the ciphertext of "K‘;¿.", the complete process is shown in Table II.

TABLE II. CAESAR CIPHER - DECODING CIPHERTEXT OF "K‘;¿."

Ciphertext	75	96	59	62	46
$p = c - d$ **mod** 128	80	101	64	67	51
Plaintext	P	e	@	C	3

III. Proposed AudioMag Steganography

The proposed AudioMag steganography data hiding technique involves hiding audio data within an image. This process is illustrated in Fig. 2. Audio consists of time and amplitude, modification must be made to the audio in order to embed it into the image, which consists of the x-axis and y-axis. The explanation is provided in 1. The algorithm outlines the specific modifications and calculations that need to be performed on the audio data in order to align it with the x-axis and y-axis of the image.

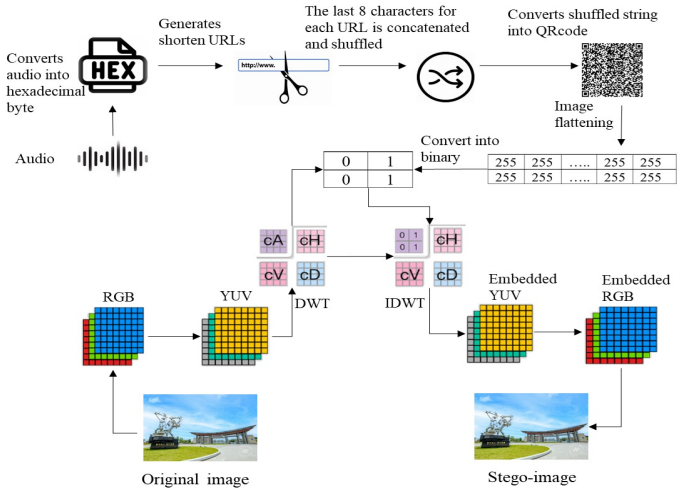

Fig. 2. AudioMag steganography - audio hiding.

The proposed AudioMag steganography audio extraction technique involves extracting the QR code from the stego-image, reading the string of the QR code, manipulating the string into hexadecimal value, and finally converting it into audio. This process is illustrated in Fig. 3. The explanation is provided in Algorithm 2.

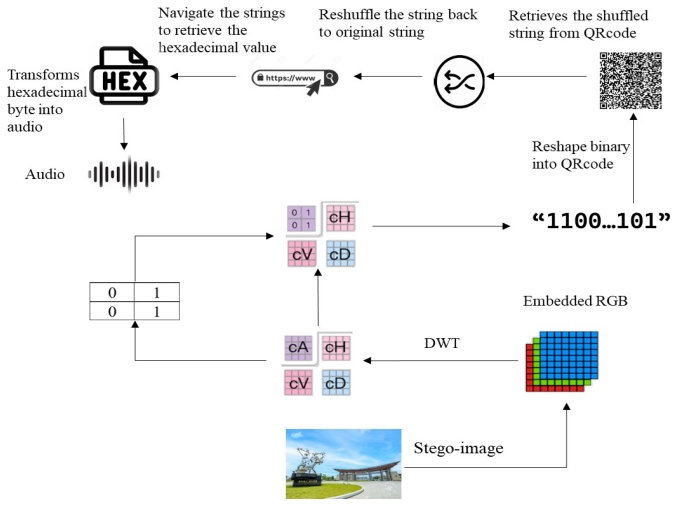

Fig. 3. AudioMag steganography - audio extraction.

IV. AudioMag Simulation

An audio recording is made using Realme UI 3.0. The spoken text is "Cryptography" and lasts approximately 1 second. The audio file is 41.5 kilobytes (kb) in MP3 format. The audio is then converted into a hexadecimal value, as illustrated in Fig. 4, resulting in a file size of 82.5kb. The hexadecimal value is then divided into blocks, resulting in three blocks and consequently, three shortened URLs.

Fig. 4. Fraction hexadecimal of the audio.

Each block hexadecimal value is prefixed with "http" at front and suffixed with ".com" at back. A tinyurl website is used to generate the shorten URL. The last eight characters of each shortened URL are used and concatenated. The entire string is "sn3mjvze5n6un8s2mwwefvc6".

The ASCII is a character set with 128 characters, each represented by seven bits. It includes the numbers 0-9, both upper and lower case English letters from A to Z, and a selection of special characters. The string "sn3mjvze5n6un8s2mwwefvc6" is consider input plaintext which is shuffled using the Caesar cipher. The key for the Caesar cipher is "-5" and modulus 128, resulting in the output ciphertext "ni.hequ'0i1pi3n-hrr'aq^1". This output ciphertext is used to generate the QR code. The generated QR code is in ".png" format, with dimensions of 414 x 414, and a file size of 1.29kb bytes, as shown in Fig. 5.

Fig. 5. QR code consists shuffled URL string.

Next, the generated QR code is embedded into an image (see Fig. 6a) and results the embedded image (see Fig. 6b). The size of the original image and embedded image is in ".jpg" format, with dimensions of 5109 x 3400 and a file size of 1.71mb. With the naked eye, it is hard to notice the difference between the original image and the stego-image, as only a single bit is changed per pixel, as shown in Fig. 6.

To retrieve the audio one first needs to extract the QR code from the embedded image. The extracted QR code, shown in

Algorithm 1 AudioMag steganography - data hiding

Require: Input: Audio, Original image.

Audio is converted into hexadecimal, the size of audio hexadecimal is denoted as l_a.
The audio hexadecimal l_a is divided into block, each block hexadecimal is 32 kilo byte (kb). The last block can be less than 32kb.
Each block's hexadecimal value is prefixed with "http" at front and suffixed with ".com" at back. The entire string is then used to generate a shortened uniform resource locator (URL).
The last eight characters of each shortened URL are used, concatenated, and shuffled. The shuffling step is based on the Caesar cipher, with the modulus size based on the total number of ASCII characters, which is 128.
The shuffled string is converted into a quick response code (QR code). The QR code is in two dimensions, the size is M x N, where the values of M x N are fixed as 414 x 414. Maximum string embedded into the QR code is 140 bytes.
Flatten the QR code. Converts the flatten QR code value into binary, we denoted it as qr.
Retrieves the original image. Note that the original image must be at least eight times larger in dimensions than the QR code.
Obtains red, green and blue (RGB) of original image.
Transforms RGB of original image into brightness and color (YUV).
Decomposes the YUV original image into four sub-images via discrete wavelet transform (DWT). The sub-images are known as approximation (cA), horizontal (cH), vertical (cV), and diagonal (cD) respectively. The size for each sub-image is $\frac{M}{2}$ x $\frac{N}{2}$.
The cA is further divided into 4 x 4 block via discrete cosine transform (DCT), we denote the number of block as b.
for $i \leftarrow 1$ to b **do**
    The block of cA, b_i is decomposed via singular value decomposition (SVD), the return value (S) contains singular values. One bit data of qr_i is embed into the first singular value.
end for
Reconstructs cA via inverse discrete cosine transform (IDCT).
Converts the embedded cA together with cH, cV and cD into YUV data via inverse wavelet transform (IDWT).
Transforms YUV data into RGB.
Output: Stego-image.

(a) Original image.

(b) Stego-image.

Fig. 6. Original image and stego-image.

Fig. 7, is in ".png" format with dimensions of 414 x 414 and a file size of 83.6kb. One may observe noise, but the QR code content remains.

Fig. 7. Extracted QR code from stego-image.

The ciphertext "ni.hequ‘0i1pi3n-hrr‘aq^1" is decoded using Caesar cipher with decoded key of"+5" and modulus 128, resulting in the string "sn3mjvze5n6un8s2mwwefvc6". This string is divided into three sub-strings, with each sub-string containing eight characters. Each sub-string is prefixed with "https://tinyurl.com/" to complete as URL. Place the URL in a web browser and navigate to it; it will display a long URL string. Remove the prefixed "http" and suffixed ".com", and you will get the hexadecimal value. Repeat this process for each sub-string. Finally, concatenate all the hexadecimal values to recover the audio.

A. Robustness of Stego-image

This section examines the robustness of stego-images, as shown in Table III. The rationale behind this experiment is to determine if stego-images can be sabotaged, yet still be able to extract the embedded QR code. To assess this risk, two potential scenarios were investigated: 1) when the stego-image is masked, and 2) when the stego-image is cropped. The findings show that the QR code can be extracted from manipulated stego-images, even when subjected to higher levels of noise compared to the results depicted in Fig. 7. It is noted that the information in the QR code remains readable. This means the proposed method maintains the integrity of the embedded data indirectly.

V. Result and Discussion

The proposed method for concealing secret audio in an image begins by converting the audio into hexadecimal values, which are then split into fixed 32kb strings. The strings are hidden using shortened URLs, with the last eight characters of each URL concatenated. This means that each shortened URL's size is 8 bytes. The concatenated string is shuffled using a Caesar cipher and the resulting shuffled string is used to create a 414 x 414 QR code. Lastly, the QR code is embedded into the image. Note that the image must be at least eight times larger than the QR code; therefore, the minimum size of the image is 3319 x 3319.

Algorithm 2 AudioMag Steganography - Data Extraction

Require: Input: Stego-image.
Obtains RGB of stego-image.
Decomposes the RGB stego-image into four sub-images via DWT. The sub-images cA, cH, cV, and cD respectively. The size for each sub-image is $\frac{M}{2}$ x $\frac{N}{2}$.
The cA is further divided into 4 x 4 blocks via DWT, we denoted the block as b.
for $i \leftarrow 1$ to b **do**
    The block of cA, b_i is decomposed via DCT.
    Flatten the output of DCT into one-dimensional array and then indexed it, such that D_j, where $j \in 0, 1, 2, 3$.
    The indexed array is rearranged back into a 4*4 shape.
    Performs SVD on the rearranged array.
    Obtains first singular value (S_0) by extracting the first value of S_0.
    Calculates binary data extraction.
    for $j \leftarrow 1$ to 3 **do**
        Obtains first singular value (S_j) by extracting the first value of S_j.
        Calculates binary data extraction and merge with S_{j-1}.
    end for
    Calculate the average extracted bit information.
end for
Each mean bit block is multiplied by 255 to convert the normalized pixel value into the actual pixel representation so that it can correctly represent color or brightness in the image.
Retrieves the QR code.
Read the string in the QR code.
Decodes the string using Caesar cipher.
The decipher string is divided into eight characters sub-strings. We denoted the number of sub-strings as ls. Let's an empty string is $string_{sub}$.
for $i \leftarrow 1$ to ls **do**
    Each sub-string is prefixed with "https://tinyurl.com/" and navigated to in a web browser.
    The web browser will show the long URL string, removes the prefixed "http" and suffixed ".com". We denoted it as URL'.
    Concatenate the URL' into $string_{sub}$, such that $string_{sub}$ = $string_{sub}||URL'$.
end for
Convert the $string_{sub}$ into audio.
Output: Audio.

TABLE III. ROBUSTNESS OF STEGO-IMAGE

Case	Stego-image	QR code
1		2		
The 414 x 414 QR code can only contain a maximum of 140 bytes of a string. According to the simulation, the audio file size is approximately 41kb per second. Once the audio is converted into hexadecimal values, the total size of the hexadecimal values is 82kb, resulting in a total of 24 bytes for three different URLs. This implies that the maximum amount of secret audio that can be embedded in a single image of minimum size 3319 x 3319 is roughly six seconds worth of secret audio. The six seconds secret audio consists of 492kb hexadecimal values, resulting in a total of 128 bytes for three different URLs.

The proposed method embeds the QR code into the an image via DWT, DCT, and SVD, based on the simulation, the original image (see Fig. 6a) appears similar to the stego-image (see Fig. 6b). This ensures that the hidden QR code (also known as converted secret audio) is invisible to the naked eye.

However, a flaw occurs when extracting the QR code from the stego-image (see Fig. 7); noise appears in the extracted QR code due to its high robustness. High robustness in this case means that even if the stego-image is corrupted, we can still retrieve the QR code as being discussed in Section IV-A. The noise, however, does not affect the efforts to retrieve the shuffled string stored in the QR code. Therefore, we can successfully decode the shuffled string and ultimately recover the secret audio.

VI. CONCLUSION AND FUTURE WORK

Audio steganography is a covert communication technique that involves embedding secret information within an audio

signal, making it undetectable to the human ear. Image steganography is a technique used to hide secret messages within an ordinary images. Our innovative approach, AudioMag, converts audio data into hexadecimal format and then encodes it into a QR code. This QR code is subsequently inserted into an image, offering a beyond than traditional secure way to transmit hidden information, thereby preventing potential attackers from detecting the concealed audio message.

The effectiveness of this method lies in the fact that the proposed algorithm has been successful in converted audio into the QR code while preserving the similarity between the stego-image and the original image. This added layer of security helps to ensures that the hidden audio message remains undetectable by eavesdroppers. Hence, preserving the confidentiality of the transmitted data over digital channels.

However, one limitation of our design is that it only allows for embedding audio up to a maximum of six seconds. Therefore, as future work, we plan to design the QR code dimensions in a more flexible manner, allowing for the embedding of longer strings. This means that we will be able to record arbitrary lengths of audio to embed into the image.

***Abstract*—By the end of December 2019, the novel coronavirus 2019 (COVID-2019), became a world pandemic affecting the respiratory system. Scientists started investigating using Deep Learning and Convolutional Neural Networks (CNNs) to detect COVID-19 using Chest X-rays (CXRs). One of the main difficulties researchers reported in the detection of lung diseases is the fact that radiographic images can tell that the lungs are abnormal, but they might miss specifying the type of pneumonia exactly. Only the expert radiologist can tell the difference based on patches shapes and distribution on the affted lungs. Also CNN's require big datasets to provide good results. When new pandemics spread, The limited benchmark datasets for COVID-19 in CXR images, especially during the onset of the pandemic, is the main motivation of this research. In this research, we will introduce the use of Vision Transformers (ViTs). We consider an updated version of ViT called Compact Transformer (CT) which was proposed to reduce the expansive computations of the self-attention mechanism in ViT and to escape the big data paradigm. As a contribution of this study, We propose using a Hybrid Compact Transformer (HCT) in which a pretrained CNN is used in place of the convolutional layers in CT. Hence, with the hybrid model design, we aim to combine the localization power of CNNs, with the generalization power (attention mechanism or distanced-pixel relations) of ViTs. Based on experimental results using different performance metrics, the Hybrid Compact Transformer is shown to be superior over Compact Transformers and Transfer Learning models. Our proposed technique enjoys the benefits of both worlds; a faster training of the model due to TL with CNNs and reduced data requirements due to CT. Combining localized filters of CNNs and the attention mechanism of CT seems to provide a better discrimination between common pneumonia and Covid-19 pneumonia.**

I. Introduction

At the end of December 2019, there was a cluster of Pneumonia cases discovered in the city of Wuhan. By the end of January 2020, the World Health Organization (WHO) announced that the disease had become a world pandemic caused by Severe Acute Respiratory Syndrome Corona Virus-2 (SARS-CoV-2), commonly called COVID-19.

The test that is mostly used to detect COVID-19 infection is the Reverse-Transcription polymerase chain reaction (RT-PCR) [29]. In the early days, this test was not approved to be used for the detection of respiratory diseases because of the low sensitivity of the test and the high possibility of false negatives that might occur. Instead, chest imaging such as CXR or computed tomography (CT) was used to diagnose respiratory diseases. However, with the pandemic of Coronavirus, Using CXR is considered faster and cheaper than using RT-PCR. However, CXR interpretation requires expert radiologists. If we consider the number of radiologists in each hospital compared to the number of patients' CXR images, radiologists would not be able to study that massive amount of CXR images.

In 2016, a research paper was published demonstrating the efficacy of deep learning algorithms in the medical field [12]. This research discusses the employment of deep learning models in the task of grading for diabetic retinopathy to recapitulate the majority decision of the board-certified ophthalmologists in the US. Deep learning is a type of Machine Learning algorithm that employs neural networks (NN) to learn complex relationships among huge amounts of data.

In 2020, a research paper was published by Google team [7], introducing the new state-of-the-art image classification. Inspired by the Transformers scaling successes in NLP [45], Transformers have accomplished quick successes in computer vision. Vision Transformers (ViTs) are emerging as an architectural paradigm alternative to CNNs. However, the lack of the typical convolutional inductive bias makes these models extremely data-hungry and computationally expensive compared to common CNNs [7]. Consequently, the cost of training such models is only affordable by the lucky few at the large industrial companies.

Data Efficient Image Transformer (DeiT) [43] is one of the first papers to show that it is practical to train transformers for computer vision tasks. DeiT trained with a procedure more adapted to a data-starving regime. Subsequently, it requires far fewer data and far less computer power to produce a high-performance image classification model. Recently, numerous related work has been proposed to democratize AI research for transformers [23] [13]. To help researchers with limited resources to verify the research results and to take these results for granted. Both CNNs and Transformers have highly desirable qualities for different computer vision tasks, but each comes with their own costs [13].

Recently, many researchers have used radiology images for COVD-19 detection. Authors in [36] compared four popular neural networks for the classification of CXR images. AlexNet [22], ResNet18 [14], DenseNet201 [15], and SqueezeNet [16]. They used radiographic images from the Kaggle [33] database. Image Augmentation is applied to the

data set and three classification schemes were compared: normal vs pneumonia, bacterial vs viral pneumonia, and normal, bacterial and viral pneumonia. This paper demonstrates that the deeper the network the better the accuracy, such that DenseNet201 outperforms the other three networks in all the three classification schemes. The classification accuracy achieved was 95%.

The authors in [38] proposed an algorithm called Data Augmentation of Radiograph Images (DARI) which combines GANs architecture with generic data augmentation methods to maximize the training data. DARI algorithm is applied to the input images when the class imbalanced ratio is greater than a given threshold. The accuracy achieved training this model was 93.94%. Further, the authors of the DARI algorithm compared the performance of their proposed method with another paper called DarkCovidNet [31]. The model is designed for the diagnosis of the COVID-19 disease. In their study, the main model was inspired by the DarkNet architecture that has proven itself in deep learning. DarkCovidNet achieved an accuracy of 87.02%.

Since the early onset of COVID-19, there was a global scientific response to help in diagnosing and curing. Many of these efforts considered automated COVID-19 detection from CXRs, such as [2] or [3]. Deep Neural Networks (DNNs), and CNNs has boosted medical image analysis over the past years. This research aims to investigate the use of CNNs and ViTs for the automated detection of COVID-19 from CXR images.

Detection of COVID-19 from CXRs involves two problems: COVID-19 vs non-COVID-19 in which case a dataset like [6] can be used, and COVID-19 vs Other Pneumonia vs healthy, in which case a dataset like [4] can be used along with [6]. In this research, we will consider having a benchmark dataset that contains three classes COVID-19 Pneumonia (CP) vs Community-Acquired Pneumonia (CAP) and Normal cases for our study.

Most medical applications suffer from limited datasets, and as Deep Convolutional Neural Networks (DCNNs) are data-hungry, the medical community has almost universally adopted transfer learning to build a CNN for medical imaging. For example [31] uses initial model weights from ChestNet [37] for pneumonia disease detection. In this research, we will consider using a pretrained model on a benchmark dataset.

Moreover, as COVID-19 is a respiratory disease such that the virus directly infects the lungs area, having a model that focuses on studying the infection only by segmenting the lungs area in CXR images from other parts in the image, can add improvement in the performance of the used models as proposed by [28] and [47]. In this research, we will apply an image segmentation algorithm to segment the lungs before classification.

The considered aspects below state the contributions of this research:

1) Combining existing CXR Datasets: The main obstacle for a neural network to learn is that there are not enough data examples for training. Currently, as COVID-19 is a new disease, many websites are trying to encourage people and hospitals to contribute and share COVID-19 CXR images from patients all over the world to gather a sufficient number of CXRs and make them public for researchers. In this research, we will not gather our own dataset, but rather we will use a combination of existing ones such as [6] [33] [18]. Images are classified into three classes COVID-19 Pneumonia (CP) vs Community-Acquired Pneumonia (CAP), and Normal cases for our study.

2) Balanced Dataset: Since the available COVID-19 cases are much fewer than healthy cases or even other pneumonia types, image augmentation techniques that can enlarge the minority class, will be used to accomplish a balance between input classes to reach good accuracy of trained model [26].

3) Image Segmentation: One of the main difficulties researchers reported in the detection of lung diseases is the fact that radiographic images can tell that the lungs are abnormal, but they might miss specifying the type of pneumonia exactly. Only the expert radiologist can tell the difference [5]. Therefore, data scientists proposed using image segmentation techniques to segment the lungs so that the model will focus on studying only the lungs and the infection if available [47]. In this research, U-net model proposed by [17], will be used for the segmentation process.

4) Proposed model design: In this research, we will examine using a version of vision transformers called Compact Transformer(CT) [13]. Our proposed method, called Hybrid Compact Transformer (HCT) uses a pretrained CNN in place of the convolutional layers in the original Compact Convolutional Transformer (CCT). In addition, we will reduce the number of transformer encoding layers.

The remainder of this paper is organized as follows: Section II introduces our proposed technique and Section III explains our research methodology. Experimental results are provided in Section IV and the analysis of its results are proposed in Section V. Section VI provides conclusions and suggestions for future improvements.

II. Proposed Model Architecture

A. Segmentation Network

U-Net [17] is a deep learning architecture used for image segmentation problems and was released particularly as a solution for biomedical segmentation tasks. It is the adopted segmentation architecture for any problem domain in Kaggle [33]. Inspired by the early success of previous work [28] [47], and [30], claimed that segmentation can increase the sensitivity of the network such that the network classification result is based on the pixels related to the lung area that contains information about the disease. In this research, we will adopt U-Net to perform semantic segmentation with the benchmark dataset to separate lung and heart contour from the chest radiography images.

Instead of training a Unet model from scratch, a pretrained Unet model, that was shared by [20], is used in this research. This model was pretrained to segment CXR images. In the first phase, all images in the dataset will be segmented using the Unet model. For segmentation, images will be resized to the shape 512 X 512 X 1, as the Unet model architecture requires input images of that size [20]. All segmented images are then saved in the dataset.

TABLE I. CXR DATASETS

Data-set	Classes	Size of images	Pre-processing	Author
Italian Society of Medical and Interventional Radiology [18]	COVID-19 : 68	Image size is not fixed for all images.	Original CXR images.	Asif, Sohaib, et al [3] Ahishali, Mete, et al. [1]

CheXpert dataset collected by Stanford ML group [19]	Contains 14 different classes with: 224,316 Chest radiographs - No COVID-19 cases	Image size is not fixed for all images.	Original CXR images.	Sakib, Sadman, et al. [38]
Japanese Society of Radiological Technology (JSRT)	247 posteroanterior chest images including normal and lung nodule cases. The images in the database were grouped according to the degree of subtlety of the lung nodule.	2048 X 2048	Original CXR images.	Oh, Yujin, Sangjoon Park, and Jong Chul Ye. [28]
Chest X-14 [48]	Contains 112,120 CXR images. 14 common thoracic diseases classes.	1024 X 1024	Original CXR images.	Wang, Kun, et al. [47]

B. Classification Network

Transformers have rapidly been increasing in popularity and have become a major focus of modern deep learning research. They are emerging as an architectural paradigm alternative to CNNs [7]. ViTs can capture global relations between image elements and they potentially have a larger representation capacity. However, the fact that ViTs are extremely data hungry and require large sets of data to be trained, leads to the exclusion of those with limited resources from research in the field [13] [43]. Moreover, based on the findings of an earlier study [32], the use of existing ViT is not optimal in the field of pneumonia detection, since feature embedding through direct patch flattening is not intended for CXR images. Fig. 1 shows the original architecture of ViT architecture.

Today, researchers persist to dispel the myth that ViTs are data-hungry and can only be applied to huge datasets. Several updates on the architecture of ViT have been proposed like [43] [23], to reduce the expansive computations of the self-attention mechanism and to escape the big data paradigm. In this study, we will use an updated version of ViT called Compact Transformer or CT proposed by [13].

1) Compact Convolutional Transformer (CCT): In [13], the author's contribution is escaping the big data paradigm, as most medical applications with AI suffer from limited data availability. The authors in [13] split their experiments into two phases: In the first phase, they proposed an updated version of the original ViT architecture (Compact Vision Transformer(CVT)), and in the second phase, they proposed using a shallow NN, composed of one convolutional layer and a Relu activation layer, to create the patches instead of extracting them directly from the original input image (Compact Convolutional Transformer (CCT)). Fig. 2 shows the architectures of both CCT and CVT.

The results show that CCT in comparison to CVT can be quickly trained from scratch on small datasets while achieving high accuracy. Based on the findings, it can be argued that transformers can perform head-to-head with state-of-the-art CNNs on small sets of data, often with better model performance, better accuracy, and fewer parameters.

In our study, we propose using a Hybrid Compact Transformer (HCT) in which a pretrained CNN is used in place of the convolutional layers in CCT. The attention mechanism allows transformer architecture to compute in parallelized manner. It can simultaneously extract all the information we need from the input and its inter-relation, compared to CNNs. CNNs are much more localized, using small filters to compress information towards a general answer. While this architecture is powerful for general classification tasks, it does not have the spatial information necessary for many tasks like instance recognition [7]. This is because convolution does not consider distanced-pixel relations (Fig. 3A), like in Vision Transformers where the attention of patches of the images and their relations to each other are calculated (Fig. 3B).

Hence, with the hybrid model design, we aim to combine the localization power of CNNs, with the generalization power (attention mechanism or distanced-pixel relations) of ViTs. Fig. 4 shows an overview of the proposed Hybrid Compact Transformer (HCT). This will allow to achieve good performance even with reduced datasets.

2) Proposed Model Design (Hybrid Compact Transformer): In the proposed HCT model design, a pretrained CNN (transfer learning) is used as a backbone feature extractor and its outputs

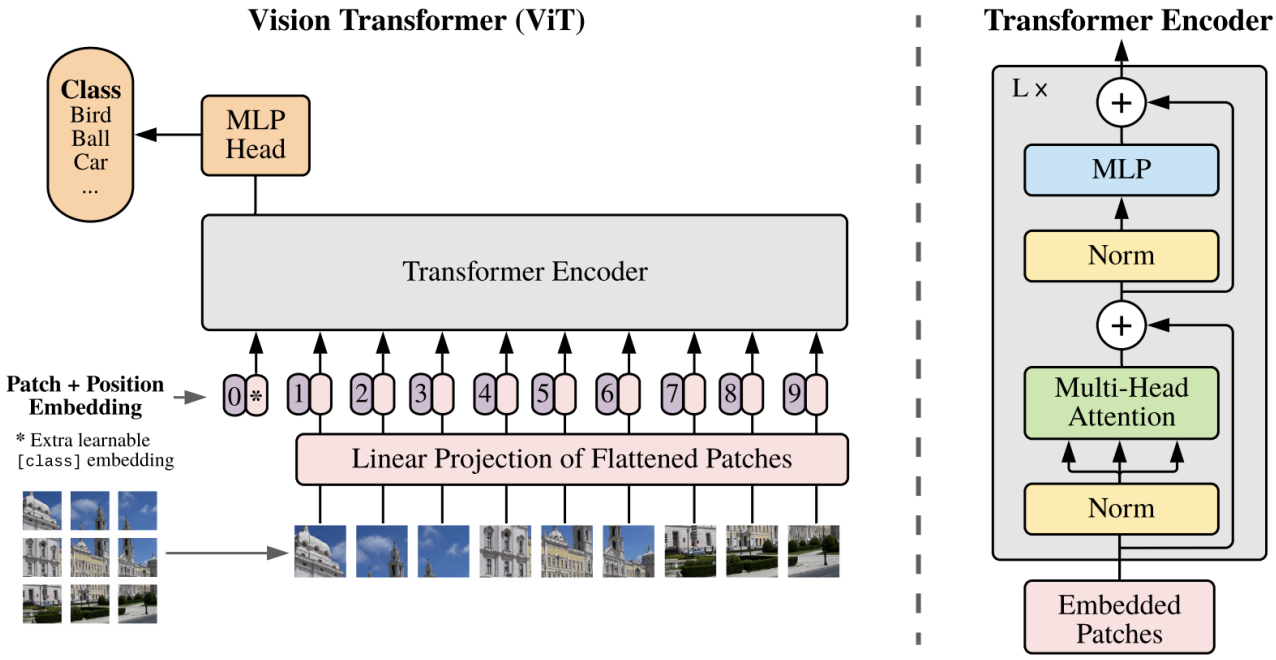

Fig. 1. Vision transformer [7].

are fed to the Compact Transformer. The input CXR image is primarily fed into a backbone CNN to create a feature map then into the compact transformer for classification. The HCT model design is illustrated in Fig. 5.

The architecture of the compact transformer differs from the original Vision Transformer architecture in the following variants, fewer transformer encoder layers (only 2 layers) and smaller dimensions of patches. A transformer encoder consists of a series of stacked encoding layers. Thus, each encoder layer consists of two sub-layers: a Multi-Layer Perceptron (MLP) head and Multi-headed Self-Attention (MSA). Each sub-layer is followed by a layer normalization (LN), and followed by a residual connection to the next sub-layer, as illustrated in Fig. 1. The compactness in the CT results in a lightweight vision transformer with as few as 200K learnable parameters only. Furthermore, in the CT, a novel sequence pooling technique was introduced to remove the needs of the class token. This sequence pooling is a linear layer placed after the transformer encoder to make the model more compact and accurate. Eventually, the output of the pooling layer is then fed into the final classification layer, as in the original ViT model, to classify the image into one of three classes: CP, CAP, or Normal.

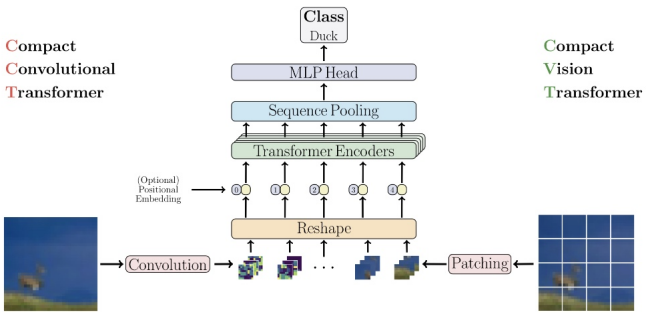

Fig. 2. Overview of CCT vs CVT [13].

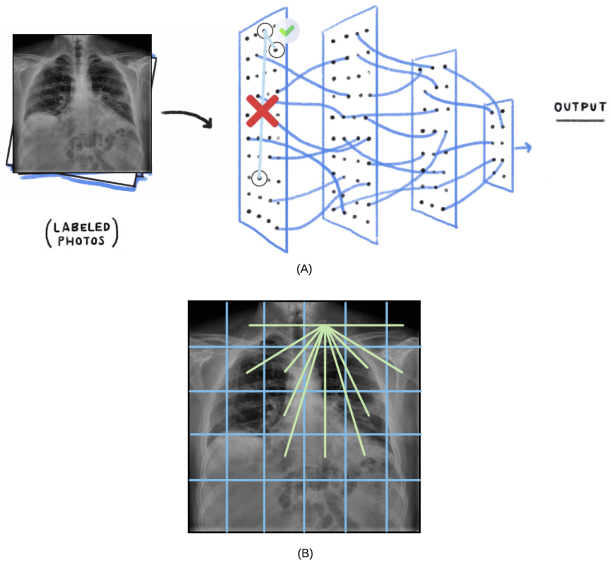

Fig. 3. Illustration of the localization power of CNNs (A), and the generalization power (attention mechanism or distanced-pixel relations) of ViTs (B).

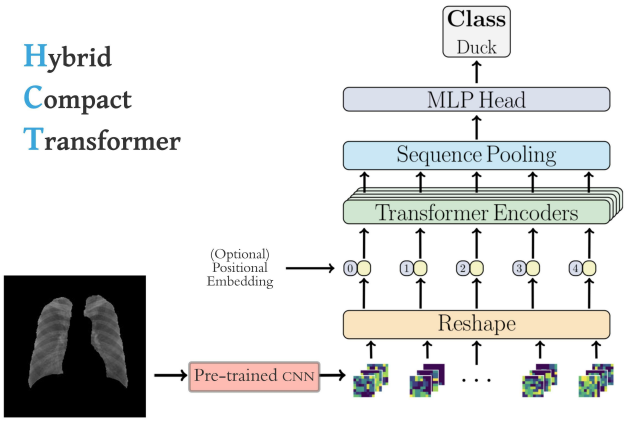

Fig. 4. Overview of Hybrid Compact Transformer (HCT).

TABLE II. TOTAL NUMBER OF CXR IMAGES BEFORE APPLYING AUGMENTATION

Class	Total Number of Images
Normal	5800
COVID-19 CXRs (CP)	6500
Non-COVID-19 CXRs (CAP)	6100

III. RESEARCH METHODOLOGY

A. Dataset

A careful analysis of the available datasets (Table I) will let us decide which data to consider in the experimental study and which possible preprocessing to be use.

We can summarize the results as follows: in our research, we will utilize many of these datasets proposed and used by previous works. Datasets, like [6], shared by Dr. Joseph Cohen, were used in most of the previous works. This dataset contains a good number of COVID-19 CXRs in comparison to all the others. The Kaggle dataset contains images of good quality and resolution for normal and other pneumonia cases. The quality of CXR images helps for better segmentation and model learning. Table II shows the total number of CXR images before to augmentation.

B. Image Augmentation

An investigation of enlarging the number of CXR images by using two different image processing methodologies was discussed in [24]. The main idea in this paper was to evaluate the test accuracy of five pretrained models (AlexNet, VGGNet16, VGGNet19, GoogleNet, and ResNet50) in four scenarios: the first scenario, when using the original dataset, second scenario, when performing data augmentation using classical data augmentation techniques [26] on input dataset to enrich the COVID-19 CXR images, the third scenario, when performing Generative Adversarial Network (GAN) [8]. And the last scenario, when combining classical data augmentation and GAN to generate more CXR images. The results show that ResNet50 is the best deep learning classifier and with augmented COVID-19 medical CXR images achieved the best performance to detect the COVID-19 from the input dataset.

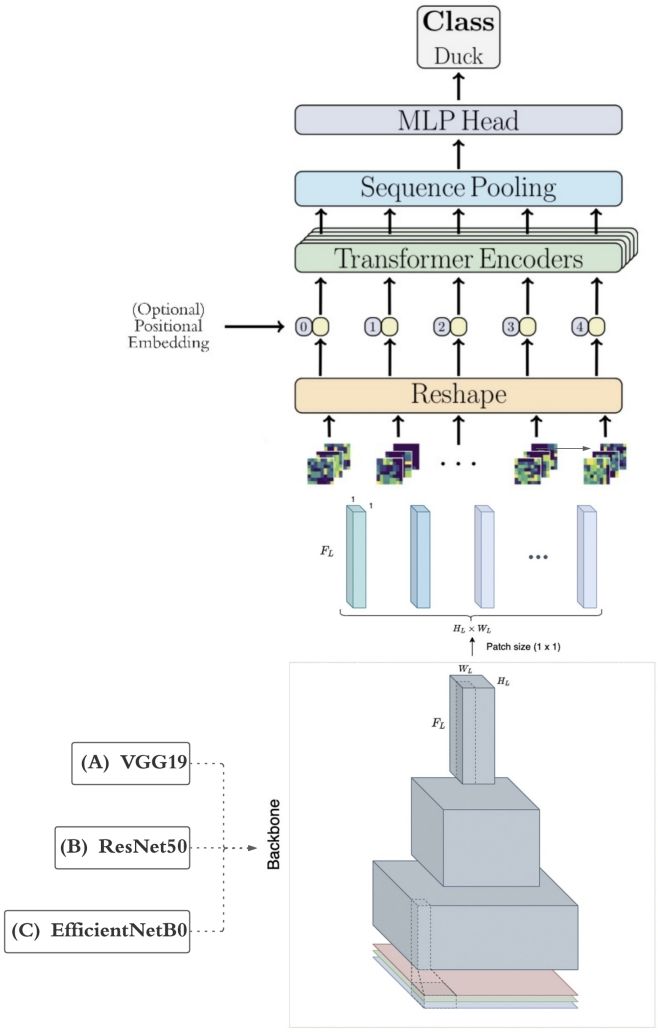

Fig. 5. Illustration of the proposed model design, HCT network. In this study, the backbone or the features extractor is going to be one of three state-of-the-art networks, namely, (A) VGG19, (B) ResNet50, and (C) EfficientNetB0.

TABLE III. TOTAL NUMBER OF CXR IMAGES AFTER APPLYING AUGMENTATION

Class	Total Number of Images
Normal	8000
COVID-19 CXRs (CP)	8000
Non-COVID-19 CXRs (CAP)	8000

In this research different methods for data augmentation techniques such as zooming, rotation, shifting, and flipping [26] were selected to be applied to the original dataset. In the end, the total number of CXR images we have in our dataset is 24000 images as shown in Table III.

C. Classification Performance Metrics

The most common performance measures in the field of deep learning are accuracy, precision,specificity, recall (or sensitivity), and Fβ score [10]. In this research we will utilize all these five performance measures in addition to the confusion matrix to measure and analyze the classification results of the CNN models.

The formulas of the measures are given below, where true positive (TP) is the correctly identified predictions for each class. True negative (TN) is the correctly rejected predictions for a particular class. False positive (FP) is the incorrectly identified predictions for a particular class, and false negative (FN) is the incorrectly rejected predictions for a certain class. After the completion of training phase, the performance of different networks for testing dataset is evaluated. The 5 metrics for performance evaluation were calculated as below:

1) Confusion Matrix: A confusion matrix is used to evaluate the results of a predictive model [49]. This matrix will be generated after making predictions on the test data. For a classifier with n output classes, the predicted values on test instances and the actual values are represented as an nxn matrix. Each row of the confusion matrix represents the samples in a predicted class, and each column represents the samples in an actual class.

2) Accuracy: It is the percentage of correct predictions among all decisions made on examples of a dataset. For a classification problem with two classes, (Eq. 1) defines Accuracy in terms of TP, TN, FP, and FN:

$$Accuracy = \frac{(TP + TN)}{((TP + FN) + (FP + TN))} \tag{1}$$

3) Precision: It represents the percentage of the classifier's correct decisions in favor of the target class (Eq. 2).

$$Precision = \frac{(TP)}{(TP) + FP)} \tag{2}$$

4) Recall (Sensitivity): It represents the percentage of the classifier's correct decisions made on the other class (Eq.3). In particular, sensitivity is the classifier's ability to identify a diseased person as diseased. Sensitivity is also known as True Positive Rate (TPR).

$$Recall(Sensitivity) = \frac{(TP)}{(TP) + (FN)} = TPR \tag{3}$$

5) Specificity: It represents the percentage of the classifier's correct decisions made on the other class (Eq. 4). That is, specificity is the ability of the classifier to correctly identify a healthy person as non-diseased while not confusing a diseased one as healthy [46]. Specificity is also known as True Negative Rate (TNR).

$$Specificity = \frac{(TN)}{(TN) + (FP)} = TNR \tag{4}$$

6) ROC curve (The Receiver Operating Characteristics curve): One of the most important evaluation metrics for checking any binary classification model's performance [50]. The ROC curve is a graphical plot, plotted with the TPR (Eq. 3), against the False Positive Rate (FPR) (Eq. 5), where TPR is on the y-axis and FPR is on the x-axis. The closer the ROC curve towards the upper left corner, the better the model's performance. The curve is created with the two variables at various threshold settings [44].

$$FPR = 1 - TNR \tag{5}$$

7) AUROC curve (Area Under The Receiver Operating Characteristics curve): Area Under the ROC curve is often used as a classification model's quality measurement. In this research, we will utilize this performance measure for each of the two binary classifiers in the two-stage CNN to visualize how well our proposed cascade classifier is performing. The AUROC for an optimal classifier is 1. In practice, the AUROC value is usually between 0.5 and 1 [44].

8) F1 Score: F1 score is the harmonic mean of precision and recall (Eq. 6) [10] . As sensitivity and precision are both important measurements in medical applications, the β value is 1 as shown in (Eq. 7).

$$F\beta = (1 + \beta^2) * \frac{(Precision * Recall)}{(\beta^2 * Precision) + Recall} \tag{6}$$

$$F1 = 2 * \frac{(Precision * Recall)}{(Precision + Recall)} \tag{7}$$

D. Pretrained Backbone CNN Models

In this research, we will investigate the detection of COVID-19 with three classifiers ResNet50 and VGG19 on the benchmark dataset. Additionally, we will study the efficiency of a new family of models invented by [40], called EfficientNets. It has been demonstrated in the paper and as the name suggests, EfficientNets are computationally efficient and achieve much better accuracy and efficiency than previous CNNs. We will study the performance of EfficientNetB0 on our benchmark dataset.

E. Experimental Setup

Python programming language was used to train the proposed deep transfer learning models. Considering having a large dataset, all experiments were performed on Google Colaboratory Pro (Google Colab Pro) on Mac Operating System using the online cloud service with Graphics Processing Unit (GPU) hardware for free. Colab Pro supports longer running notebooks, access to faster GPUs and TPUs, and provides high RAM [9]. CNN models (VGG19, ResNet50, and EfficientNetB0) were pretrained on ImageNet weights.

TABLE IV. TESTING ACCURACY OBTAINED BY THE HCT MODELS TRAINED WITH DIFFERENT BATCH SIZES

Model	Batch Size		
	32	64	128
HCT (VGG19)	92.00%	90.04%	90.62%
HCT (ResNet50)	96.82%	96.70%	97.25%
HCT (EfficientNetB0)	98.35%	98.38%	98.63%

IV. EXPERIMENTAL RESULTS

A. Segmentation Performance

Based on the segmentation results on our dataset, generally, the pretrained Unet model performance is great. Lung segmentation before classification helped in removing the irregular regions and the irrelevant objects (e.g. medical devices). An example of the segmentation results is shown in Fig. 6.

B. Classification Performance

To illustrate, all following experiments were implemented using the same dataset for multiclass classification. Moreover, the entire dataset was randomly split into training (70%), validation (20%), and testing (10%).

1) Optimal learning rate selection: To determine the optimal learning rate for all models, the models were trained using three different learning rates, .0001, .00001, and .000001. The best learning rate of a model was chosen based on the minimum loss, as such, the optimal learning rate for all three networks is 0.000001 as shown in Fig. 7.

2) Results comparison with different batch sizes: In this research, the impact of batch size on testing accuracy is studied. Table IV demonstrates the test accuracy of all networks when trained using three different batch sizes. Based on the findings, it can be argued that a stable and higher testing performance is obtained for ResNet50 and EfficientNetB0 models with a batch size of 128, and for VGG19 model with a batch size of 32.

3) Stratified K-fold Cross-Validation Results:

- Hybrid Compact Transformer (HCT) model Results:
  After training and testing, the accuracies achieved by the proposed HCT models were 92.00%, 97.25%, and 98.63% when using different features extractors: VGG19, ResNet50, and EfficientNetB0, respectively. The batch size, learning rate, and the number of epochs were experimentally set to 128, 0.000001, and 100, respectively for all models except for HCT-VGG19 the training procedure was completed in 200 epochs using a batch size of 32.
- Compact Convolutional Transformar (CCT) model Results:
  As proposed by the author of the CCT model, the batch size, learning rate, and the number of epochs were experimentally set to 128, 0.001, and 100, respectively. The model achieved an over all test accuracy of 81.79%.
- Transfer Learning (TL) model Results:
  In the fine-tuning of the individual DCNNs, we tried various combinations of batch sizes and learning rates to get the best models' performance. The batch size, learning rate, and the number of epochs, for all networks, were experimentally set to 64, 0.0001, and 100, respectively, except for VGG19 the batch size used was 32. The overall test accuracies achieved were 89.52%, 94.62%, and 96.74% for VGG19, ResNet50, and EfficientNetB0, respectively.

The detailed classification results obtained from all networks are compared in terms of various metrics and are tabulated in Table V. As can be seen from these results, the HCT model produced better accuracy scores than the fine-tuned deep CNN models. This result was considered reasonable as adding one simple ViT encoding layer (generalization power) can enhance the power of Deep CNNs. The best accuracy score overall was 98.63%, and was produced by HCT with EfficientNetB0 as backbone. It can be noticed that EfficiantNetB0 produced the best accuracies for both fine-tuned CNNs and HCT models.

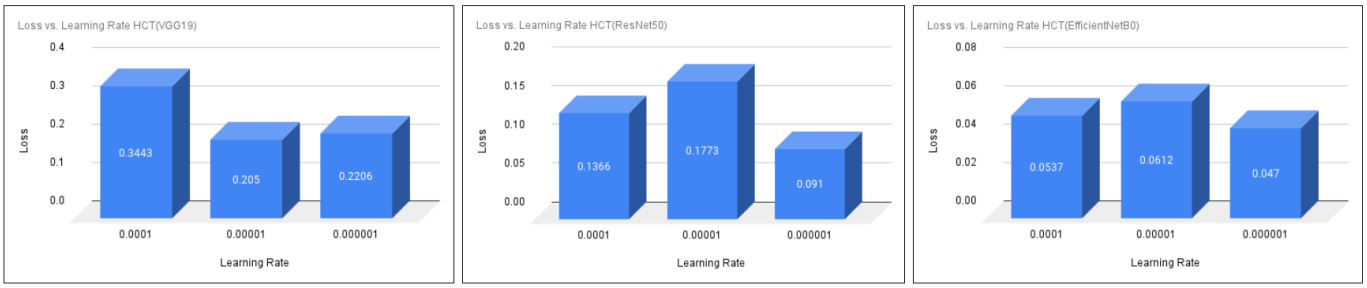
C. Analysis of Models Execution Results

1) Sensitivity-Specificity Analysis: In a diagnostic test (Neural Network), the network's sensitivity (True Positive Rate) refers to the network's ability to correctly classify COVID-19 patients who have the condition, whilst specificity (True Negative Rate) is a measure of how well a network can identify those who do not have the condition [51]. In medical applications, it is always preferable to have a network with high sensitivity such that the probability that a network produces false negatives is low [51]. FN is the proportion of positives (COVID-19) that are mislabeled as negatives (Normal) by the model. These false negatives are crucial and might threaten humans' life. Table VI and Table VII show comparisons between the fine-tuned CNN networks and the the proposed ones in terms of Sensitivity and Specificity, respectively.

It can be observed that the COVID-19 class sensitivities of the proposed models are higher than the sensitivities of the fine-tuned models. Compared to the fine-tuned models, the overall sensitivities and specificities obtained by the proposed models are higher, which confirms the efficacy of our method.

2) Confusion matrix: We presented the confusion matrices on the test data of all seven models in Fig. 8. Fig. 8(A) presents the confusion matrix obtained by our proposed HCT model, using VGG19 as a backbone feature extractor. While 757 COVID-19 samples, 739 Pneumonia samples, and 717 Normal (healthy) samples were classified correctly, 43 COVID-19 samples, 61 Pneumonia samples, and 83 Normal (healthy) samples were misclassified. Therefore, the rate of correct classification of COVID-19 samples was 95%, whilst it was 92.5% for the Pneumonia samples and was 89.62% for the Normal (healthy) cases. On the other hand, Fig. 8(B) presents the confusion matrix obtained by the HCT model, using ResNet50 as a backbone features extractor, the rate of correct classification of COVID-19 samples was 97.5%, whilst it was 98.87% for the Pneumonia samples and was 94.37% for the Normal (healthy) cases. Further, Fig. 8(C) presents the confusion matrix obtained by the HCT model, using EfficientNetB0 as a

Fig. 6. One example of the segmentation result.



(A) (B) (C)

Fig. 7. Histogram represents the loss obtained by HCT Models for different learning rates, using: (A) VGG19, (B) ResNet50, (C) EfficientNetB0 as a backbone feature extractor.

backbone features extractor, the rate of correct classification of COVID-19 samples was 98.37%, whilst it was 98.75% for the Pneumonia samples and was 98.75% for the Normal (healthy) cases. It can be observed that our proposed method with EfficientNetB0 was able to classify 98.37% of COVID-19 infection cases accurately.

In addition, we also wanted to show the confusion matrices obtained by the CCT model and the individual fine-tuned networks, to compare their classification performance to the performance of the HCT proposed models. It can be argued that the False Positives(FP) and False Negatives(FN) has been reduced for each CNN using HCT. Similarly, if we compare the percentage of the correctly classified samples between (HCT-VGG19 and pretrained VGG19), (HCT-ResNet50 and pretrained ResNet50), and (HCT-EfficinetNeB0 and pretrained EfficinetNeB0), it can be observed that HCT models yielded a higher classification accuracy for all the three classes.

Whereas the FPs and FNs obtained by the CCT model are the highest among all the seven models. Moreover, it can be observed from the confusion matrix reported in Fig. 8, that the HCT-VGG19 proposed model has detected 757 out of 800 with COVID-19 as having COVID-19, achieving a COVID-19 class sensitivity of .946 compared to the fine-tuned VGG19 that has achieved a COVID-19 class sensitivity of .924 (see Table VI). The HCT-ResNet50 proposed model has detected 787 out of 800 with COVID-19 as having COVID-19, achieving a COVID-19 class sensitivity of .975 compared to the fine-tuned ResNet50 that has achieved a COVID-19 class sensitivity of .965. Our best-proposed HCT-EfficientNetB0 model has detected 787 out of 800 with COVID-19 as having COVID-19, achieving a COVID-19 class sensitivity of .984 compared to the fine-tuned EfficientNetB0 that has achieved a COVID-19 class sensitivity of .97.

3) The AUROC: ROC curves are typically used in binary classification to study the output of a classifier. To extend the ROC curve and ROC area to multi-class classification, there are two averaging strategies: one-vs-rest (OvR) and one-vs-one (OvO) [39]. In this study, we deployed the OvR algorithm, which computes the average of the ROC scores for each class against all other classes. Fig. 9 shows the AUROC curves of all seven models implemented in this research. The achieved AUC values for the fine-tuned models and the HCT models are above 0.97, which confirms that these models are reliable when performing the classification. Whereas the CCT model achieved an AUC value of 0.93.

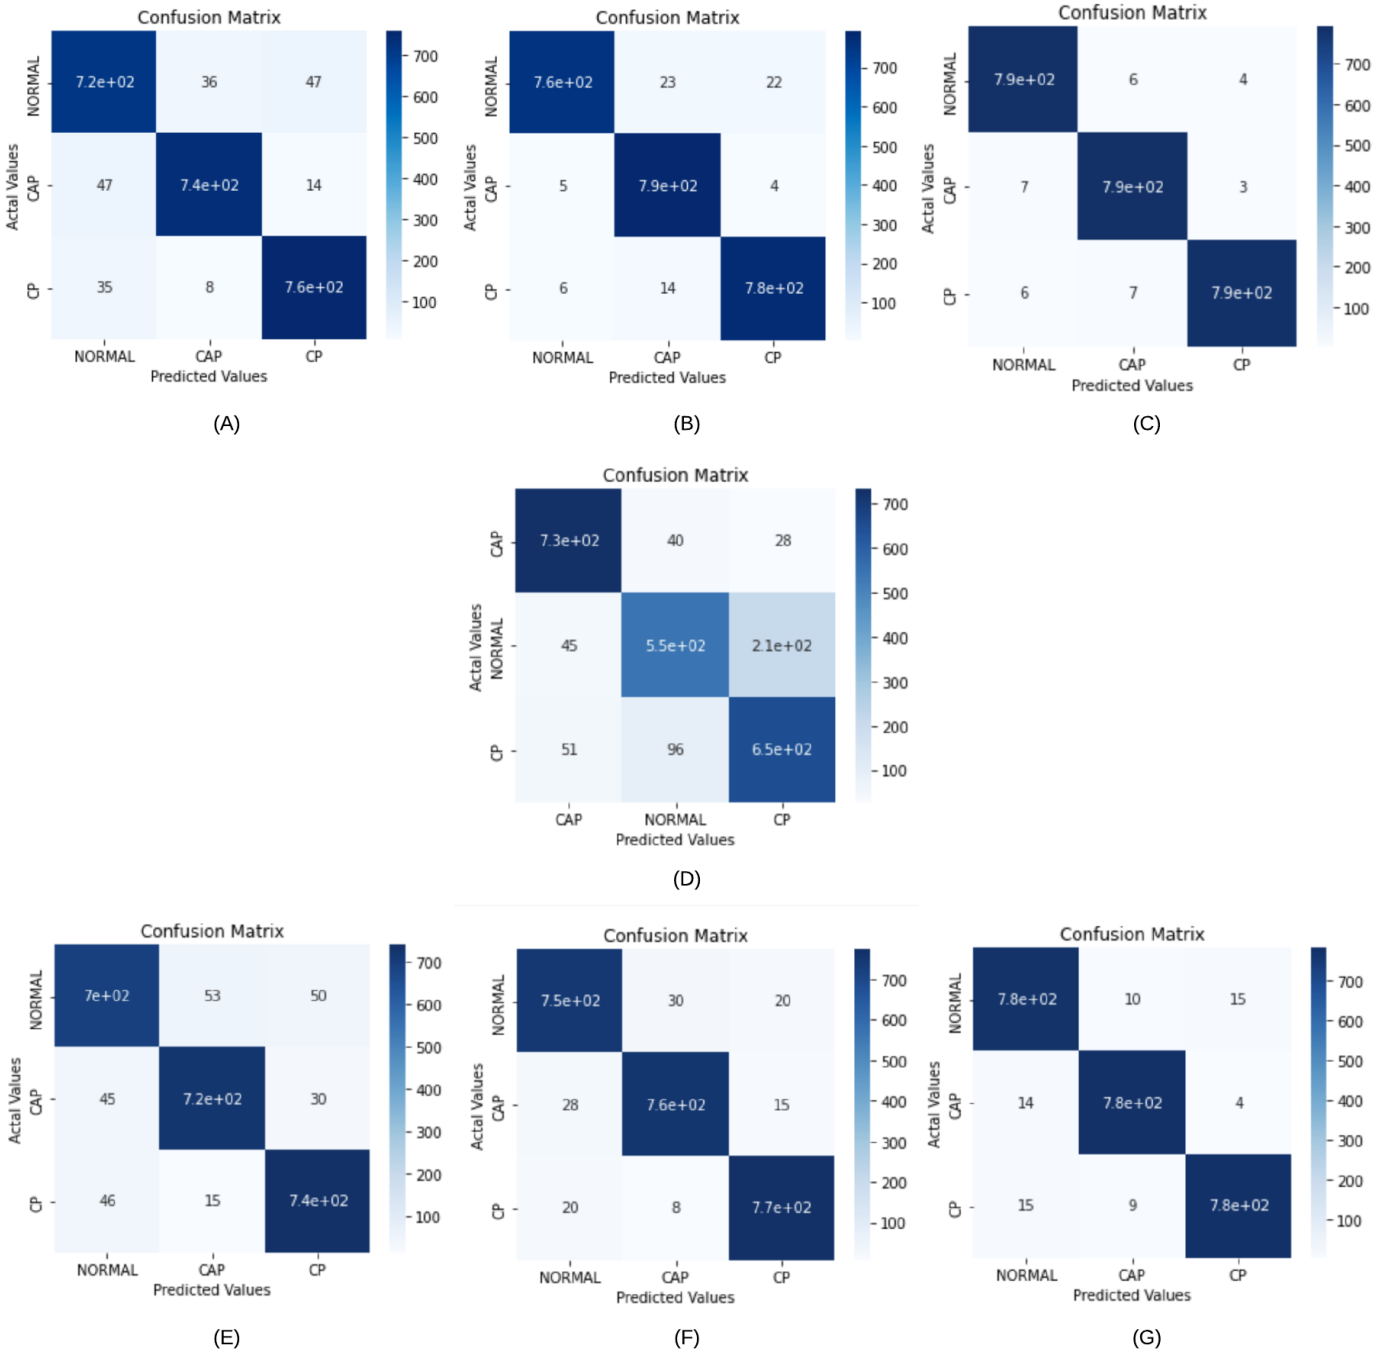


Fig. 8. Confusion matrix obtained by all the seven models implemented in this research: (A) HCT-VGG19, (B) HCT-ResNet50, (C) HCT-EfficientNetB0, (D) CCT, (E) pretrained-VGG19, (F) pretrained-ResNet50, (G) pretrained-EfficientNetB0.

TABLE V. SUMMARY OF ALL EXPERIMENTS FOR MULTI-CLASS CLASSIFICATION

Model	pretrained CNN	Accuracy	Precision	Recall	Specificity	F1 Score
TL	VGG19	89.52%	0.8811	0.8597	0.9420	0.8702
	ResNet50	94.62%	0.9737	0.9176	0.9737	0.9315
	EfficientNetB0	96.74%	0.9591	0.967	0.9793	0.9630

TABLE VI. A COMPARISON BETWEEN THE FINE-TUNED AND THE PROPOSED MODELS IN TERMS OF THEIR SENSITIVITIES

CNN \Backbone CNN Model	TL Models	HCT Models
VGG19	0.8597	0.9479
ResNet50	0.9176	0.9672
EfficientNetB0	0.967	0.9862

V. ANALYSIS AND DISCUSSIONS

A. Analysis of Classification Results

To demonstrate the performance of HCT, we randomly selected a COVID-19 CXR image, gave it input to the network, and acquired output on the image as shown in Fig. 10. The classification result was obtained by the best HCT model using EfficientNetB0 as a features extractor. Nevertheless, there is some confusion from the model sometimes between COVID-19, and Pneumonia samples, Fig. 11. This misclassification was possibly occurred because of our dataset. The Pneumonia samples in our dataset include viral and bacterial pneumonia. Considering that COVID-19 itself is a viral pneumonia disease. Furthermore, the GUI is created with Gradio, which is an open-source python library. Gradio permits researchers to quickly create easy-to-use and customizable UI components for their ML model [11].

TABLE VII. A COMPARISON BETWEEN THE FINE-TUNED AND THE PROPOSED MODELS IN TERMS OF THEIR SPECIFICITIES

CNN \Backbone CNN Model	TL Models	HCT Models
VGG19	0.9420	0.9597
ResNet50	0.9737	0.9851
EfficientNetB0	0.9793	0.9928

B. Comparison with State-of-the-Art Methods

In order to evaluate the proposed HCT model, the general performance comparison of our study with the state-of-art methods is given in this section. All networks were trained using our benchmark dataset. It can be observed that the proposed HCT-EfficientNetB0 model achieved higher performance than the other existing schemes. The results that are reported in this section are summarized in Table VIII.

Khan et al. [21] propose CoroNet, a Deep Convolutional Neural Network based on Xception architecture pretrained on

TABLE VIII. COMPARISON WITH STATE-OF-THE-ART STUDIES

Study	Model Used	Accuracy
Asif et al. [3]	Inception-v3	94.58%
Ozturk et al. [31]	DarkCovidNet	96.89%
Khan et al. [21]	CoroNet	89.30%
Mahmud et al. [25]	CovXNet	90.75%
Narin et al. [27]	Deep CNN ResNet-50	94.62%
Apostolopoulos & Mpesiana [2]	VGG19	89.52%
Proposed Method	HCT-VGG19	92%
	HCT-ResNet50	97.25%
	HCT-EfficientNetB0	98.63%

ImageNet dataset. The CoroNet model obtained an overall accuracy of 89.30%. Ozturk et al. [31] present DarkCovidNet design to the diagnosis of COVID-19. In their study, the main model was inspired by the DarkNet architecture that has proven itself in deep learning. Their model produced a 96.89% overall accuracy. Mahmud et al. [25] propose a deep neural network named CovXNet. The network architecture utilizes depth-wise convolution with varying dilation rates for efficiently extracting diversified features from CXRs. CovXNet achieved an overall accuracy of 90.75%. Oh et al. Further, Asif et al. [3], Narin et al. [27], and Apostolopoulos and Mpesiana [2], use transfer learning and obtained an overall accuracy of 94.58%, 94.62%, 89.52%, respectively. Indeed, DarkCovidNet achieved the best performance among the other proposed methods with a test accuracy of 96.89%. However, our proposed HCT-EfficientNetB0 surpasses DarkCovidNet and the other proposed methods with a test accuracy of 98.63%.

VI. CONCLUSIONS

In this research, we studied the deployment of deep learning models for COVID-19 detection using CXRs. As has been shown in research such as [24] [35] [2] [27], Transfer Learning (TL) gives the best classification results for the problem of pneumonia detection from CXR images. In our study, we investigated the use of our proposed Hybrid Compact Transformer (HCT), in which we integrate TL with Vision Transformers (ViTs) in one model. We aim to combine the localization power of CNNs, with the generalization power of ViTs. Based on the experimental results, HCT has shown satisfactory improvements over the respective accuracies of compact transformers (CTs) and models based on TL.This result could be useful for dealing with future respiratory pandemics where at their beginnings, only a few CXRs would be available for researchers.

Choosing the pretrained model can largely affect the accuracy of the final classifier. Performance results show that EfficientNetB0 pretrained model yielded the best performance among the three models. The proposed classification model with EfficientNetB0 as a feature extractor achieved more than 98% accuracy.

As a future research direction, we intend to increase the number of classes in our dataset to include: COVID-19, Viral-Pneumonia, Bacterial-Pneumonia, and Normal cases in order to have a more applicable model. We also want our model to be more interpretable. Thus, we will try to use interpretable saliency maps to correlate with the radiological findings. Moreover, the segmentation results could be further improved by training the Unet model with CLAHE enhanced CXR images, as mentioned in [41]. Authors in [28] proposed FCDenseNet103 as a backbone segmentation network architecture. They claimed that in comparison with Unet, FCDenseNet103 has higher segmentation performance. So using FCDenseNet103 on our dataset could improve the performance of our final proposed model. It would also be very interesting to assess the extent of usefulness of image segmentation in light of using pretrained models, like in our solution.

AI-Blockchain Approach for MQTT Security: A Supply Chain Case Study

Raouya AKNIN, Hind El Makhtoum, Youssef Bentaleb
Ibn Tofail University, Engineering Sciences Laboratory, Kenitra, Morocco
0000-0002-4644-055X

***Abstract*—The use of the MQTT protocol in critical sectors such as healthcare and industry has prompted research to propose solutions for strengthening its security and preventing it from attacks that are growing exponentially and becoming increasingly sophisticated and difficult to detect. This paper aims to improve the security of the MQTT architecture, ensuring it is resilient to current attacks and adaptable to potential future attacks while considering the constraints of the IoT environment. To achieve this, the proposed architecture is based on the interaction between the AI model, which continuously analyzes device behavior, and smart contracts, which automatically apply appropriate security measures once fraud is detected. A device reputation mechanism is used to prevent malicious devices from rejoining the network. The AI model proposed in this article was initially trained on a set of malicious behaviors using supervised learning. The results show that the detection accuracy achieved 95.97%. This accuracy is expected to improve over time through the integration of unsupervised learning into the architecture, enabling the discovery of new attack patterns and additional parameters for malicious behavior identification. For simulation testing, the architecture was applied to supply chain management as a case study of critical applications, and smart contracts were deployed in the Remix environment. The architecture demonstrated resilience and robustness across various attack scenarios.**

***Keywords*—IoT; MQTT; blockchain; smart contracts; AI hybrid model; device reputation**

I. Introduction

The advent of the Internet of Things (IoT) has revolutionized the interaction between real objects and the digital world by breaking down the boundaries between these two worlds. Indeed, The emergence of cutting-edge technologies such as wireless sensor networks (WSN), Radio Frequency Identification (RFID), cloud computing, and others that facilitate real-time data collection, sharing, and analysis has enabled better real-time decision-making, remote supervision and control of environments, and the automation of tasks and processes. This has opened up a wide range of IoT advanced services in several domains ranging from simple applications such as smart household appliances to critical applications like supply chain management, smart grids, and healthcare applications. According to [1], by the end of 2025, the number of IoT devices worldwide is expected to exceed 75 billion devices and the compound annual growth (CAGR) in the IoT market is forecast to average 10.49% between 2024 and 2029, bringing the total market value to $1,560 billion by 2029 [2].

Nevertheless, the expansion of connected objects into more sensitive and critical areas has raised concerns about the security of the protocols frequently employed in this environment. The native security measures of these protocols no longer meet the requirements of critical applications, and attacks targeting the IoT environment have become more numerous and complex. For instance, the Message Queuing Telemetry Transport (MQTT), the most widely used protocol in this environment, is vulnerable to several types of attacks, including man-in-the-middle (MITM) attacks due to a lack of encryption, denial-of-service (DoS) attacks because of the centralized architecture and the broker's single point of failure, and unauthorized access resulting from weaknesses in the authentication mechanism.

To overcome these challenges, many articles have proposed an enhanced security architecture using blockchain as the one of the promising solutions [3]–[8]. Indeed, the decentralized nature of blockchain minimizes denial-of-service attacks and avoids the single points of failure, which are considered nightmares in the field of cybersecurity. Moreover, it ensures data integrity and enables the traceability of actions carried out on the network. The use of smart contracts to automate actions on the network is another advantage of using blockchain technology. Artificial intelligence (AI) is also another a cutting-edge technology that is used to enhance the MQTT architecture by proposing solutions to detect the malicious behaviors and potential MQTT attacks [9]–[11].

The goal of this article is to propose an MQTT architecture that meets the security requirements of critical IoT applications, is resilient to current attacks, and is adaptable to potential attacks, while taking into account the IoT constraints. To this end, it aims to improve the architecture proposed in our previous research work [4] by adding an additional layer of protection based on artificial intelligence. The advantage of the proposed solution is that it combines AI technology to detect the abnormal behavior of connected devices or those attempting to connect to the network, with smart contracts to automatically apply the appropriate security measures. It also introduces the concept of device reputation to prevent malicious devices from rejoining the network.

The remainder of this paper is structured as as follows: Section II provides a summary of research works that have been proposed improved MQTT architectures using cutting-edge technologies. Section III outlines the paper's contribution by combining blockchain and AI technologies to enhance MQTT protocol security. Section IV presents our proposed solution that combines blockchain and AI for a resilient and attack-resistant MQTT architecture. Section V discusses the results of attack test scenarios on the proposed solution. Section VI summarizes the main ideas discussed in this paper and provides an overview of future research directions to further improve the security of the MQTT protocol while respecting the constraints

of the IoT environment.

II. Related Works

Several research works have proposed solutions to improve the security of the MQTT protocol, which is the most widely used protocol in the IOT environment to meet the IOT critical applications requirements. Indeed, many articles have used blockhain [3]–[8] to enhance the MQTT security since it ensures data integrity, avoids a single point of failure, and enables the traceability of the actions performed in the network. Moreover, the use of smart contracts to automate network actions is another advantage of blockchain technology. On the other hand, several articles have leveraged artificial intelligence (AI) to enhance the security of the MQTT protocol. However, these studies primarily focus on attack detection. Indeed, article [9] has proposed an optimized model for intrusion detection in the MQTT-based IoT networks. For this purpose, an empirical comparison between 22 machine learning (ML) algorithms was established, concluding that the Generalized Linear Model (GLM) classifier with the random oversampling technique showed the best detection performance. Along the same lines, article [10] has proposed an AI model based on supervised learning to detect attacks threatening the MQTT protocol. To achieve this, a comparative analysis of various supervised learning algorithms was conducted. It ultimately concluded that the convolutional long short-term memory neural network (CNN-LSTM) algorithm outperforms other models in terms of accuracy and performance for intrusion detection on the MQTT protocol. Although these articles contribute to the selection of the most effective learning algorithms for MQTT attack detection, they have however, proposed AI models based on supervised learning algorithms, making them limited to the attacks specified in the training phase. To address this, article [11] has introduced an MQTT intrusion detection system based on a Generative Adversarial Network-based autoencoder (GAN-AE), an unsupervised learning algorithm that allows the detection of different types of attacks by analyzing the behavior.Although the solution showed its ability to adapt to new and evolving attack scenarios and the overall detection rate reached 99.2%, however, like the above-mentioned articles, the proposed system is limited to intrusion detection without implementing security measures to prevent these attacks. Additionally, since the proposed solution may introduce false positives, it will be difficult to implement security measures automatically. Combining AI solutions for attack detection and blockchain, more specifically, smart contracts to automatically apply appropriate security measures seems to be a promising solution. Article [1] has proposed a framework that combines AI and blockchain technologies to enhance security in the IOT environment. It has introduced a new security layer, integrating blockchain and AI into the traditional three-layer IoT architecture [12]. However, the article does not propose any real implementation and it emphasizes the need for further research to develop effective strategies for combining these technologies to create reliable and secure digital ecosystems in the IoT landscape. The research in [13] has proposed an intelligent architecture that detects smart meter authentication fraud and consequently prevents their access to the network. In addition, it introduced the notion of reputation to prevent malicious smart meters from rejoining the network. Unlike previous articles, this paper implements smart contracts to automatically apply the appropriate security measures when fraud is detected. However, the paper only proposes a theoretical solution for the IOT architecture, without specifying the protocol used or implementing the AI model. Moreover, it focuses only on authentication attacks. Table I summarizes the approaches used in related works, focusing on the contribution of the articles to enhancing the security of the MQTT protocol to meet the requirements of critical applications, the technologies used, and the limitations of the proposed solutions.

Limits and Issues: By analyzing the solutions presented in Table I, two major challenges can be identified:

- Although solutions based on blockchain and smart contracts meet the security requirements of IoT critical applications in terms of confidentiality, integrity, and availability, they cannot address all types of attacks or predict potential ones.
- Solutions designed to detect MQTT attacks are either based on supervised learning, which is limited to the attacks specified during the training phase, or on unsupervised learning, which may introduce false positives.

Combining these two promising solutions can significantly enhance MQTT security by leveraging AI techniques to detect attacks and utilizing smart contracts to enforce appropriate security measures. However, existing articles addressing this combination mainly propose theoretical models without implementing the full process. To this end, the contribution of this paper lies in implementing and testing the interaction between an AI model for attack detection and smart contracts to apply the corresponding security measures. Additionally, the solution relies on a hybrid AI model that combines a supervised learning algorithm to detect known attacks and an unsupervised learning algorithm to identify potential new or unknown attack types.

III. Paper's Contribution

The solution proposed in this article combines the use of blockchain and AI technologies to improve the security of the MQTT protocol. Indeed, the AI model allows the real-time detection of malicious behaviors and consequently the automatic application of the appropriate security measures using smart contracts, ensuring a fast and efficient response to potential attacks. Furthermore, the decentralized nature of the blockchain minimizes the risk of denial-of-service attacks and eliminates the challenges associated with the single point of failure. Blockchain also guarantees data integrity and ensures accountability for actions performed in the network, which is useful for monitoring and post-incident analysis. Moreover, the hybrid approach of the AI model enables continuous learning of sophisticated and complex attack patterns and relevant parameters for identifying malicious devices. For added security, the concept of reputation has been introduced to maintain records of device behavior and therefore prevent previously classified malicious devices from rejoining the network. Although the solution used consistent technologies such as blockchain and AI algorithms, it does not adversely affect the performance of the constrained IoT environment since resource-intensive operations are managed on the brokers network side, typically located in the cloud or data centers while the only operation executed on the device side is the OTP calculation.

TABLE I. SUMMARIZATION OF APPROACHES USED IN RELATED WORKS FOR ENHANCING MQTT SECURITY

Article	Main objective	Technology	Limitations
[4]	Proposes a decentralized MQTT architecture that meets the security requirements of critical applications without affecting the overall protocol performance or the constraints of the IoT environment.	Blockchain and smart contracts	Cannot cover all types of attacks or predict potential ones.
[5]	Improves the authentication process using a one-time password (OTP) and smart contracts to provide an independent channel for managing two-factor authentication. The solution also ensures accountability through blockchain.	Blockchain and smart contracts	• Does not address the single point of failure issue as it relies on a broker. • Focuses only on the authentication process. • Cannot cover all types of attacks or predict potential ones.
[6]	Proposes a novel approach solution that relies on blockchain sharding to achieve robust security while minimizing computational overhead.	Blockchain and smart contracts	Cannot cover all types of attacks or predict potential ones.
[7]	Proposes a decentralized solution that meets the security requirements of critical IoT applications regarding confidentiality, integrity, and control access to the topics managed by the broker.	Blockchain and smart contracts	• Does not address the single point of failure issue as it relies on a broker. • Focuses only on the authentication process. • Cannot cover all types of attacks or predict potential ones.
[8]	• Proposes a holistic, decentralized solution for securing MQTT. • Introduces a token stored on the blockchain to control topic access and avoid permanent credentials.	Blockchain and smart contracts	• Uses TLS in resource-constrained environments. • Impacts the overall protocol performance. • Cannot cover all types of attacks or predict potential ones.
[9]	Proposes an optimized model for intrusion detection in the MQTT-based IoT networks.	AI model based on supervised learning algorithm: Generalized Linear Model (GLM) classifier with the random oversampling technique.	• Provides a solution for detecting attacks without implementing security measures. • Supervised learning models are limited to attacks specified in the training phase.
[10]	Proposes an AI model based on supervised learning to detect attacks threatening the MQTT protocol.	AI model based on supervised learning algorithm: The convolutional long short-term memory neural network (CNN-LSTM).	• Provides a solution for detecting attacks without implementing security measures. • Supervised learning models are limited to attacks specified in the training phase.
[11]	• Proposes an MQTT intrusion detection system based on a Generative Adversarial Network-based auto-encoder (GAN-AE) to detect various types of attacks by analyzing behavior. • The solution demonstrated adaptability to new and evolving attack scenarios with an overall detection rate of 99.2%.	AI model based on unsupervised learning: Generative Adversarial Network based auto-encoder (GAN-AE)	• Provides a solution for detecting attacks without implementing security measures. • May introduce false positives.
[1]	Proposes a framework combining AI and blockchain technologies to enhance security in IoT by adding a new security layer to the classical three-layer architecture.	• Blockchain and smart contracts. • AI technology.	The framework is theoretical and lacks real-world implementation.
[13]	• Proposes an intelligent architecture that detects smart meter authentication fraud and consequently prevents their access to the network. • Introduces the notion of reputation to prevent malicious smart meters from rejoining the network.	• Blockchain and smart contracts. • AI technology.	• Doesn't implement the AI model. • Focuses only on authentication attacks.

IV. THE ENHANCED MQTT PROTOCOL

Since attacks targeting connected objects in general, and the MQTT protocol in particular, are constantly evolving and it is impossible to anticipate and cover all potential threats, this article aims to enhance the architecture proposed in our previous work [4] by introducing a new layer of protection based on artificial intelligence. As depicted in Fig. 1, the basic architecture is based on a consortium blockchain and smart contracts to automate the MQTT authentication, publication, and subscription processes. It comprises a client, which can be a publisher or a subscriber, and a brokers network that executes the smart contracts. Communication between the components is divided into three phases: the registration phase, the connection phase, and the publication phase. The AI solution proposed in this paper aims to analyze the behavior of devices connected to the network, as well as those attempting to authenticate, in order to effectively interrupt or prevent malicious connections accordingly. The behavior analysis is based on a set of relevant parameters that enable the identification of the device's behavior to determine whether it is malicious or legitimate. Once a device is detected as malicious, its reputation is automatically changed to false to prevent its reintegration into the network. It is important to note that the device's reputation can be changed either when it matches a predefined rule in the smart contracts (wrong One-Time-Password (OTP), unregistered device, unauthorized publication, etc.) or when the AI model detects a malicious behavior. Despite the use of technologies such as blockchain and intelligent algorithms, which require the use of resources,

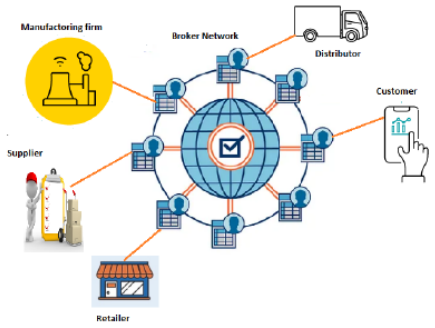

Fig. 1. MQTT architecture for supply chain management [4].

the solution aims to account for IoT environment constraints by offloading resource-intensive operations to the brokers' network, typically located in the cloud or data centers, while leaving only the OTP calculation to the MQTT clients.

A. AI-Enhanced MQTT Architecture

As depicted in Fig. 2, the new architecture has introduced an AI component to continuously analyze the devices's behavior that are connected or in the process of connecting, to detect potential fraud. Once fraud is detected, a transaction is performed to invoke the smart contracts and apply the required security countermeasures. Before integrating the AI model into the operational MQTT architecture, it was first trained using test datasets simulating a real state of the MQTT traffic, and

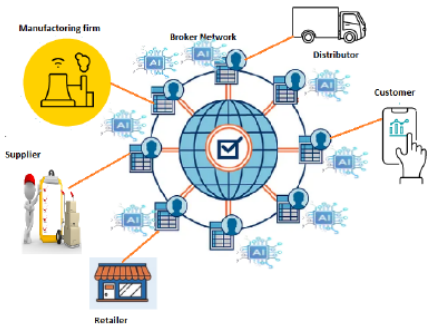

Fig. 2. AI-enhanced MQTT architecture.

then the model was tested. It is also important to note that the AI model will be permanently improved in order to integrate new potential attack types. The key steps of building and improving the AI model will be detailed in Section IV-A1.

1) AI model for device behavior analysis: The approach used to build and improve the AI model is based on hybrid learning, combining supervised learning to detect known attacks and unsupervised learning to discover new patterns of unknown attacks or other parameters for detecting malicious devices. The key stages of our approach are detailed below:

a) Stage 1: Defining the initial parameters using supervised learning
This phase aims to design an AI model that allows the prediction of malicious devices based on a set of parameters defined in Table II. The model is based on supervised learning, which uses labeled data for the model training to predict device Tbehavior subsequently. **Workflow 3** defines the steps to be followed during this phase, and is created using KANIME software.[1]
Workflow detail
- Dataset: The dataset used by the AI model in this phase either for training and testing is available via the link[2]; it simulates real-world network conditions during communication between an MQTT broker and eight sensors, and includes both normal and malicious activities. The behavior of devices is identified based on a set of relevant parameters, as detailed in Table II. The CSV Reader node is employed to load this data into KNIME.
- Data Pre-processing: This step consists of data preprocessing, which involves preparing the raw data so that it can be used effectively by the machine learning algorithms. This includes encoding categorical variables, and scaling numerical features [14].To do this, a **Label Encoding method** which assigns a unique integer to each category of a variable, and **Standard scaling** method which consists of centering the data around 0 with a variance of 1 are used, respectively. The **Category to Number** and **Normalizer** KNIME nodes are used for this purpose.
- Data Splitting: Using the Partitioning KNIME node, the dataset was divided into two categories: 70% for training and 30% for testing.
- Model selection: The model used in this article is the **Random Forest (FR)** classifier, as it provides the higher accuracy (91%) compared with other models k-nearest neighbors (KNN) (90%) and Decision Tree (85%) [15], and it is faster and more scalable for a huge database with many features compared to Support Vector Machine (SVM) which becomes very expensive in terms of computing time and memory for large databases [16]. Random Forest (RF) is an ensemblistic classifier that works by creating multiple decision trees. Each tree is built using a random subset of training samples and variables. It is based on Bootstrap Aggregating where each tree is trained on a different sample of data, drawn with a discount. Each decision tree in the forest makes its own prediction based on the input features. The final result of the RF classifier is determined by aggregating the predictions of all the individual trees, usually by majority vote for classification tasks or by average for regression tasks [17].
- Model training and Evaluation: In this phase, the model was trained and then tested using the training dataset (70%) and test dataset (30%), respectively. For this purpose, the **Random Forest Learner** and **Random Forest Predictor** KNIME nodes are used. The **Scorer** KNIME node is used for evaluation.

Interpretation and discussion of the results: To evaluate the model's ability to identify malicious behaviors, the following metrics were used:
- Accuracy: This metric measures the model's ability to correctly classify devices based on their behavior. In our case, as shown in Fig. 4, the model correctly classified 95.97% of the devices.
- Recall: This metric indicates the proportion of actual malicious behaviors correctly detected by the model. It is calculated using the following formula: $Recall = \frac{TP}{TP+FN} = 0.937$ TP (True Positive): The number of malicious behaviors correctly identified as such by the model. According to the confusion matrix (Fig. 4), this value is 46,492. FN (False Negative): The number of malicious behaviors that the model failed to detect. From the same confusion matrix, this value is 3,110. **Thus, the model successfully detected 93.7% of the malicious behaviors.**
- F1 Score: This metric evaluates the balance between the model's precision (ability to avoid misclassifications) and recall (ability to detect malicious behaviors). It is calculated using the formula:
$F1\ Score = 2 \times \frac{\text{Accuracy} \times \text{Recall}}{\text{Accuracy} + \text{Recall}} = 0.97$

These results indicate that the model offers strong overall performance, with an excellent compromise between the ability to detect malicious behavior and avoid misclassification of devices. Hence, upon completion of this phase, the model can be considered robust enough for deployment within the real-world MQTT architecture to detect all malicious behaviors it has been trained on.

b) Stage 2: Discovering new parameters and patterns for device behavior analysis using unsupervised learning
In this step the unsupervised learning algorithm will be incorporated into the real-world MQTT architecture to

TABLE II. FRAUD DETECTION PARAMETERS OVERVIEW

Parameters	Description
IP source address	The device's IP address can help identify abnormal behavior, such as connecting from unusual regions or connecting with an IP address that belongs to the same address range as a device already detected malicious.
Geolocation	The device's location can be used to detect suspicious connections from unusual or unauthorized regions.
Timestamp	Timestamps can detect abnormal activities, such as connections occurring at unusual hours, inconsistent time intervals between connections, or instances where publish and subscribe messages are sent before establishing a connection.
Message size and format	An unusual size or format of MQTT messages can be used to identify malicious devices.
Messages Frequency	This parameter is used to detect abnormal activity and behavior, such as multiple simultaneous MQTT connections from source IP addresses within the same range, which may indicate that the device is part of a botnet network.
Session duration	This parameter can identify irregular behavior or activity. For instance, a device that frequently connects and disconnects may be flagged as suspicious.
Open ports	Open ports other than those used by the MQTT protocol or those used by standard applications can identify malicious devices.
Identifier format	A device could be classified as malicious if its identifier format deviates from the standard format.

adapt to new forms of fraudulent behavior by analyzing real-time traffic and identifying deviations from normal patterns. This approach enables us to discover new parameters that were not previously identified. However, due to the constraints of working within a real MQTT architecture, we will use NS-3 [18] network simulation environment in order to generate different types of traffic and behaviors corresponding to both legitimate and malicious activities. It's also important to note that no security measures are applied to the anomalies detected during this phase. **Worfflow 5** defines the steps to be followed during this phase, and it is created using KANIME software (Fig. 3, 5).

Worflow detail

- Data preparation: After running the simulation script in the NS-3 simulator, the data will be logged into "simulation_trace.csv".This file will be loaded into KNIME using the **CSV reader** node.
- Data Pre-processing: This step pre-processes the data to make it suitable for the Isolation Forest algorithm, the unsupervised learning algorithm used in this phase. This includes handling missing values, encoding categorical data, and scaling data. The KNIME nodes used for this purpose are: **Missing value** to handle missing values by replacing them with a mean value, **One to many** to encode categorical data, and **Normalizer** to scale the data.
- Application of Isolation Forest: In this step, the Isolation Forest algorithm was applied to identify potential anomalies in the dataset. The isolation forest calculates an anomaly score for each observation in the dataset. This score provides a measure of the normality of each observation relative to the entire dataset. To calculate this score, the algorithm isolates the dataset in question in a recursive manner: it chooses a variable at random and sets a random cut-off point, then evaluates whether this isolates a particular observation [19]. The KNIME node used for this purpose is the **Isolation Forest** node.
- Anomalies analysis: Fig. 6, 7 depict the most relevant parameters that can be added to the initial parameters for devices behavior analysis. As shown in Fig. 6, for all parameters, normal instances are centered around the mean (0) with low standard deviations, while abnormal instances deviate significantly from the mean with higher standard deviations. The above parameters can be summarized as follows:
  Device physical features: This parameter includes a set of device characteristics namely computing power (GHz), storage capacity (GB), and memory (GB). As shown in Fig. 6, the abnormal instances have significantly higher CPU, storage, and memory values than the normal ones. Therefore, we can say that this parameter is relevant for detecting malicious devices since the sensors are generally equipped with low computing power, storage capacity, and memory.
  Device resources consumption: This parameter measures the rate of resource consumption, more specifically the percentage of CPU utilization (%) and power consumption (W). As shown in Fig. 6, the abnormal instances tend to consume more energy and processing power, and this is likely due to the deployment of heavy malicious applications or abnormal processing. Hence this parameter is considered as relevant for identifying malicious devices.
  Installed software: This parameter is used to identify the number of applications installed on the devices. As can be seen in Fig. 6, abnormal instances contain a relatively large number of applications compared with normal instances, so this parameter can also be used to identify malicious devices, since the applications installed in sensors are generally limited.
  Firmware type and version: This parameter is used to identify the type and version of firmware installed on the devices. To facilitate the interpretation of the results for this parameter, we have converted the numerical values used by the model into two categories (Fig. 7): **Standard**, which includes known firmware with recent versions, and **unkown**, which contains unknown firmware, obsolete or test versions. This parameter is also relevant for identifying malicious devices.

  Conclusion: The relevant parameters we identified during this phase are **device physical features, device resource consumption, and firmware type and version**. These parameters will be added to the initial parameters to improve the accuracy of the model and help better identify malicious devices.

c) Stage 3: Model enhancements:
   The new parameters identified by the unsupervised learning algorithm will be fed back into the supervised model to refine detection criteria and improve model accuracy.

2) The communication phases: The communication between the brokers network and clients (Publisher/subscriber) occurs in three main steps:

- Registration phase: In this phase, each device must be registered in the blockchain by a trusted administrator.

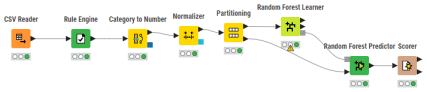

Fig. 3. AI-model workflow (phase 1).

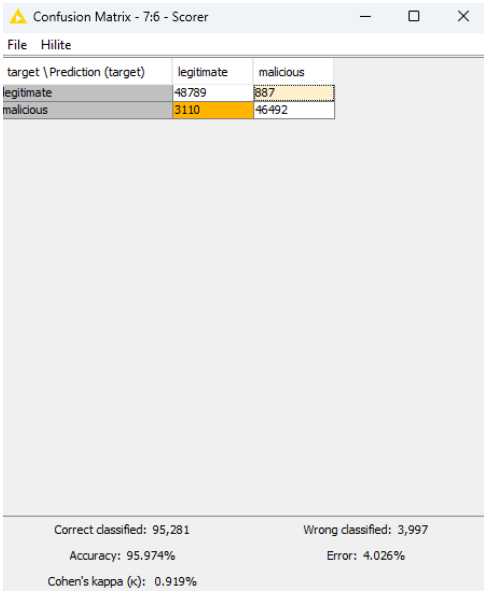

Fig. 4. Confusion matrix.

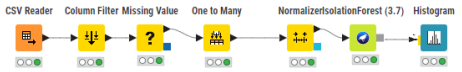

Fig. 5. AI-model workflow (phase 2).

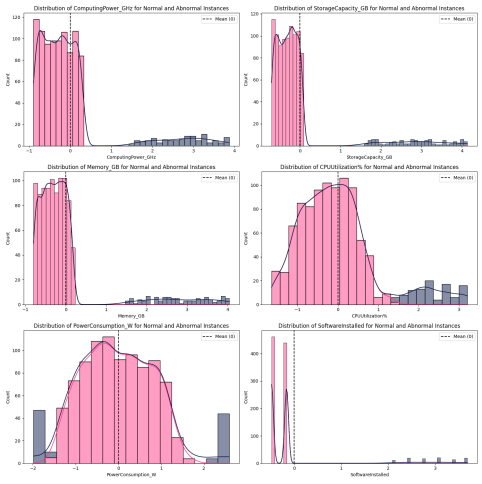

Fig. 6. Relevant parameters distribution for normal and abnormal instances.

The latter assigns publication and subscription rights to specific topics and, in return, he retrieves the required keys for authentication and message encryption and communicates them to the devices in out-of-band mode. When an administrator registers a device, its reputation is set to

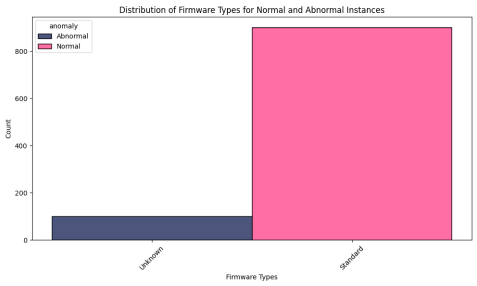

Fig. 7. Firmware type distribution for normal and abnormal instances.

true by default. The exchange details are illustrated in sequence Fig. 8 and the functioning of the smart contract responsible for this phase is described in the activity Fig. 9.

- Connection phase: As depicted in the sequence Fig. 10, when the brokers network receives a connection request, it verifies the packet number, the device registration, and the reputation. If the device is not registered, the connection will be denied and the device will be added to the blockchain with a reputation set to False. Then, if the device's reputation is false, the connection to the brokers network is denied; otherwise, a challenge is sent to a device for OTP calculation. The device calculates the OTP and sends the hashed OTP. If it is correct, the device is connected to brokers network else, the connection is denied and the reputation is set to false . Simultaneously, the AI model constantly analyzes device behavior. Once it detects malicious behavior, it invokes the smart contract to interrupt the connection process and change the device's reputation to false. The functioning of the smart contract responsible for this phase is described in the activity Fig. 11.
- Publishing phase: As depicted in sequence Fig. 12, in this phase, once a device publishes a message to brokers network containing a topic name, and encrypted data using the secret topic key, the smart contract checks its rights to publish to that topic as well as the data integrity and then it notifies all the subscribers to that topic. If the client doesn't have the right to publish in this topic, the connection is automatically interrupted and the reputation is changed to false. During this phase, if the AI model detects fraud, it invokes the smart contract to interrupt the connection and change the device's reputation to false. The functioning of the smart contract responsible for this phase is described in the activity Fig. 13.

V. Attack Scenarios Analysis

For the test simulation, we apply the proposed architecture in Supply Chain Management as an IOT critical application and perform the tests in the Remix environment.[3] Indeed, the proposed solution fully fit the requirement of the supply chain management since it requires the intervention of multiple independent entities such as suppliers, manufacturers, distributors, retailers, and end customers. Each entity has the right to publish and subscribe to specific topics. These rights

[3]Remix IDE, https://remix.ethereum.org/

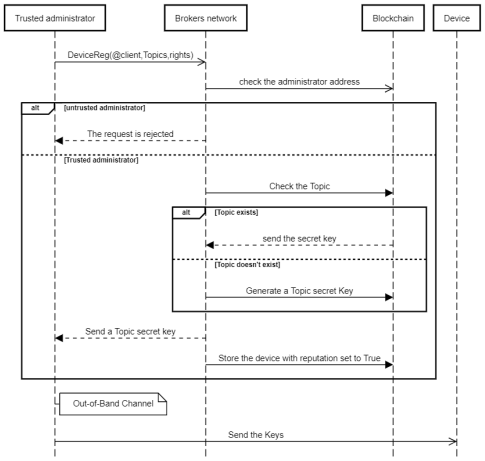

Fig. 8. Registration phase sequence diagram.

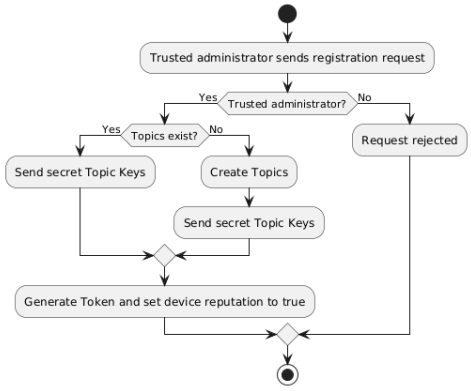

Fig. 9. Registration phase smart contract logic.

are granted by the administrator of each entity during the registration phase.

A. Test Cases

- Scenario 1: Registration nominal scenario
  As an example, the Manufacturer's administrator registers the temperature sensor for the concerned entity. As shown in Fig. 14, they assign write-only permissions to the topic "Man_smart_sensor/temperature". Upon registration, the sensor's reputation is automatically set to "true" by default.
- Scenario 2:Attempted Connection of Unregistered Device
  As depicted in Fig. 15, when an unregistered device is connected to the brokers network, the connection is refused and the device is registered in the blockchain with the reputation equal to false.
- Scenario 3: Device connection with false reputation
  As depicted in Fig. 16, when a device with a false reputation attempts to connect to brokers network, the connection is automatically denied.
- Scenario 4: Submission of incorrect OTP
  - Manufacturer's temperature sensor sends a connection request to the brokers network.
  - After checking the packet number, device registration, and reputation, the brokers network send the challenge to the Manufacturer's temperature sensor for OTP calculation.
  - Manufacturer's temperature sensor sends an erroneous OTP.
  - As depicted in Fig. 17, the connection is automatically refused and the reputation is set to false.
- Scenario 5: Unauthorized Publication

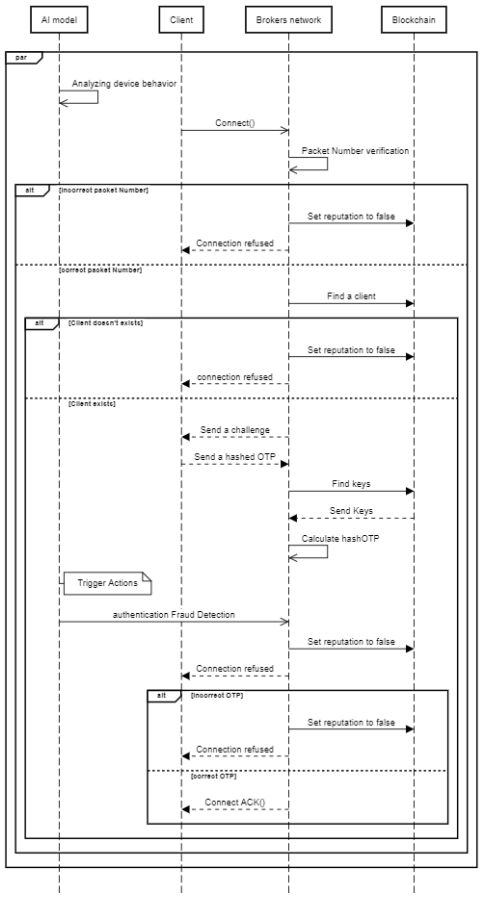

Fig. 10. Connection phase sequence diagram.

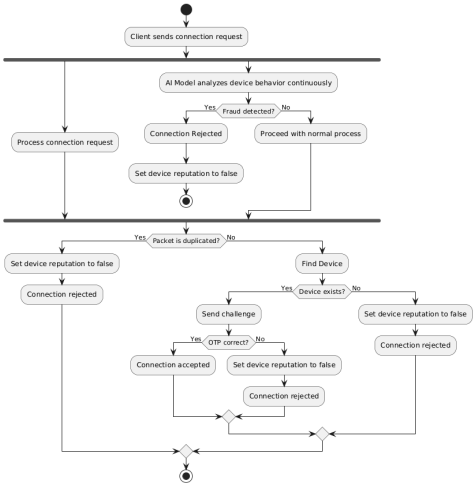

Fig. 11. Connection phase smart contract logic.

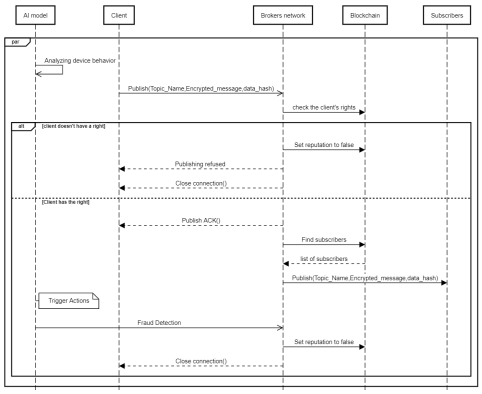

Fig. 12. Publishing phase sequence diagram.

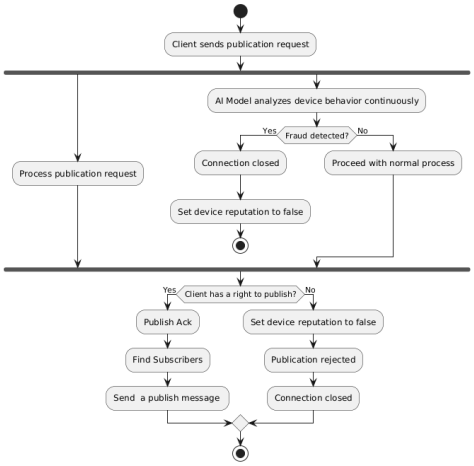

Fig. 13. Publishing phase smart contract logic.

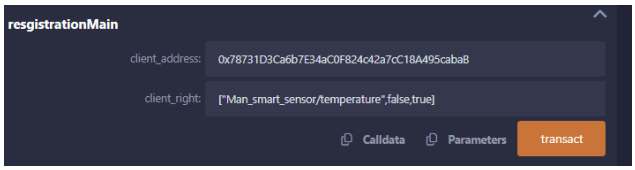
- As an example, the distributor's administrator has registered the GPS device, allocating the rights described in Table III to receive updates or instructions regarding its configuration.
- As shown in Fig. 18, when the distributor's GPS is attempting to publish in an unauthorized topic **Smart_Sensorupdateconfiguration**, the connection is interrupted and its reputation is set to false.

- Scenario 6: Detection of Known Authentication Fraud
  - During the connection process of a customer's end device, the AI model classified the device as malicious due to a malformed connection packet.
  - The AI model invokes the smart contract to deny the connection and set the device's reputation to false **Fig. 19**.
- Scenario 7: Detection of abnormal known behavior
  The AI model detected a flood attack from an already connected customer's end device. As depicted in Fig. 20, it triggered the smart contract to interrupt the connection and set the device's reputation to "false".

B. Discussing Test Results

In Section V-A, we have focused on simulating attacks related to the new concepts introduced in this article, which



(a)

(b)

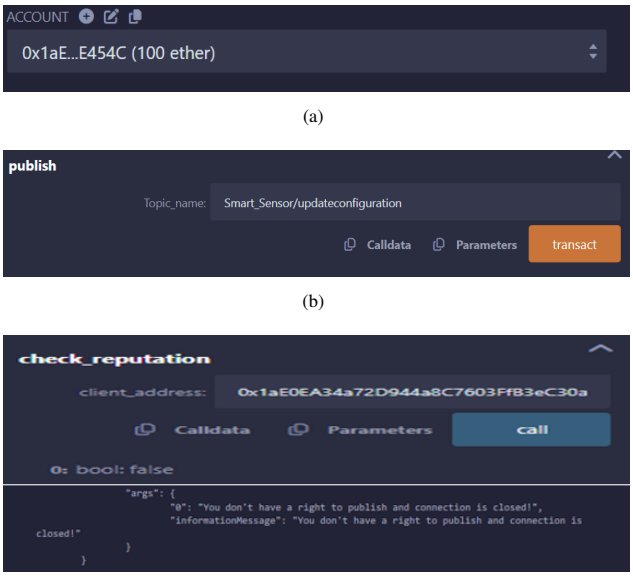
Write right	False



(a)

(b)

(c)

Fig. 18. Unauthorized publication.

Fig. 19. Authentication fraud detection.

Fig. 20. Abnormal behavior detection.

follow on from the attack tests carried out in the previous work [4]. Attack simulation tests focus on two main areas: on the one hand, the interaction between the artificial intelligence (AI) model and the smart contracts to apply the appropriate security measures once malicious behavior has been detected. Indeed, as illustrated in **scenario 6**, the AI model analyzes the device's behavior during connection process and, as a result, denies connection to the brokers network if malicious behavior is detected. In **scenario 7**, malicious behavior is detected while the device is already connected to the brokers network, triggering hence a transaction to interrupt the connection. On the other hand, these tests also monitor the device's reputation status, which must automatically change if malicious behavior is detected. In fact, according to scenario 1, by default, the state of the reputation when the device is registered is good **(true)**. Once malicious behavior is detected, the reputation changes to bad **(false)**. This is illustrated in the following scenarios: connection of an unregistered device **(scenario 2)**, sending a wrong OTP **(scenario 4)**, unauthorized publication **(scenario 5)**, and detecting abnormal behavior using the AI model **(scenarios 6 and 7)**. Additionally, the main aim of the device reputation system is to prevent devices with a bad reputation from rejoining the network, as demonstrated in **(scenario 3)**.

VI. CONCLUSION

Our research works aim to propose an MQTT architecture that meets the security requirements of critical IoT applications, is resilient to current attacks, and is adaptable to potential future attacks while taking into account the constraints of the IOT environment. To this end, the proposed solution in this paper aims to improve the MQTT architecture proposed in our previous work [4] by adding an additional layer of security based on artificial intelligence. Combining the advantages of blockchain and AI technologies enables attack detection by analyzing the behavior of devices connected or being connected to the broker network using an AI hybrid model, and then automatically applying appropriate security measures using smart contracts. The solution has also introduced the concept of device reputation to prevent malicious devices from rejoining the network. The creation of the AI model involved three essential phases: The first step was to train the model on a set of known malicious behaviors using the Random Forest supervised learning algorithm. Once the model was trained, it was integrated into the MQTT architecture, where the appropriate security measures were implemented through smart contracts. Simultaneously, the Isolation Forest unsupervised learning algorithm was added to the model in monitoring mode, in order to discover new attack patterns and identify new parameters for the detection of malicious devices. The attack patterns identified in phase 2 will be reintegrated into the basic model to improve the model's accuracy and performance. To fit the constraint environment requirements, all the resource-intensive operations are managed on the brokers network side, while the only operation executed on the device side is the OTP calculation. For attack simulation tests, the architecture was applied to supply chain management, and smart contracts were implemented in the Remix environment. The test results showed the architecture's resistance to different types of attacks. In our future work, we will continue to improve the security of the MQTT protocol in constrained environments by deploying our architecture in real-world situations. This will allow us to expose the architecture to real attacks, which will refine the AI model and strengthen the architecture's resilience against more complex and sophisticated types of attacks. In addition, we will evaluate the performance of the MQTT protocol by measuring key indicators such as latency, energy consumption, and bandwidth utilization.

Optimized SMS Spam Detection Using SVM-DistilBERT and Voting Classifier: A Comparative Study on the Impact of Lemmatization

Sinar Nadhif Ilyasa, Alaa Omar Khadidos
Information Systems Department, King Abdul Aziz University, Jeddah, Kingdom of Saudi Arabia

***Abstract*—The rapid growth of digital communication has led to a surge in spam messages, particularly through Short Message Service (SMS). These unsolicited messages pose risks such as phishing and malware, necessitating robust detection mechanisms. This study focuses on a comparative analysis of machine learning models for SMS spam detection, with a particular emphasis on a proposed SVM-DistilBERT model enhanced by a voting classifier. Using the UCI SMS Spam dataset, the models are evaluated based on recall, accuracy, precision, and Receiver Operating Characteristic Area Under the Curve (ROC AUC) scores to assess their effectiveness in correctly identifying spam messages. By leveraging Optuna for hyperparameter optimization, the proposed model achieves superior performance, with an accuracy of 99.6%, surpassing traditional methods like SVM with TF-IDF Bi-gram and AdaBoost, which achieved 98.03%. The study also examines the effects of lemmatization and synonym data augmentation, with lemmatization shown to improve spam detection by reducing feature space redundancy and enhancing semantic understanding. To ensure transparency in decision-making, Local Interpretable Model-Agnostic Explanations (LIME) is applied. The results demonstrate that the optimized SVM-DistilBERT with the voting classifier offers a robust and effective solution for SMS spam filtering.**

***Keywords*—SMS spam detection; Support Vector Machine (SVM); DistilBERT; hyperparameter optimization; LIME**

I. Introduction

The advancement of digital communications in modern times has caused mass messaging, also known as spam, to become widespread. These messages flood inboxes across various channels, bringing severe security risks such as phishing and malware. The rise of spam is closely tied to technological advancements, with Short Message Service (SMS) emerging as one of the first mobile communication standards. As SMS usage grew, so did the prevalence of spam, creating an urgent need for effective spam detection methods.

A 2022 report [1] states that 68.4 million Americans, or 26% of the population, have been scammed via phone, compared to the previous year's 59.4 million (23%). Furthermore, 33% of people reported being involved in a phone scam, with about 20% falling for a con more than once. These scams not only have financial consequences but also affect productivity, mental health, and personal privacy. As mobile telecommunications have expanded, SMS spam has become a significant irritant, contributing to substantial losses in working time, network resource consumption, and performance costs [2].

The rise of spam undermines trust in mobile communication platforms and consumes valuable network resources and device storage. This highlights the necessity for effective spam reduction strategies to preserve user satisfaction and optimize resource utilization [3]. Implementing advanced spam detection mechanisms is crucial for protecting users and ensuring compliance with privacy regulations [4]. This underscores the importance of deploying sophisticated and explainable spam detection methodologies to bolster user trust and meet regulatory expectations.

Traditional spam detection methods have relied on rule-based systems [5], which offer limited success due to their inflexibility and inability to adapt to the evolving nature of spam tactics and content. This necessitates more sophisticated, adaptable, and accurate detection strategies. A survey of existing literature indicates ongoing efforts to combat this issue, yet it remains a significant challenge, highlighting the need for innovative approaches that can keep pace with the dynamic landscape of spam messaging.

Machine learning emerges as a promising solution to address the complex problem of spam detection [6]. These algorithms, by learning from categorized datasets, can effectively differentiate between spam and genuine ("ham") messages, thereby providing a robust barrier against unwanted communications. However, the success of machine learning models in detecting spam relies heavily on choosing and fine-tuning the features used for training [7], [8]. Challenges such as high dimensionality, feature redundancy, and the dynamic nature of spam content complicate feature selection [9]. Moreover, the interpretability of models is crucial for building trust and ensuring regulatory compliance, yet many advanced models operate as black boxes [10].

This research addresses these challenges by improving upon the work of SpotSpam [11], a recent approach that utilizes Support Vector Machines (SVM) combined with DistilBERT embeddings for SMS spam detection. While SVMs excel in high-dimensional spaces and work effectively with smaller, well-labeled datasets, their performance is highly contingent on meticulous hyperparameter tuning—a process that is both complex and experimental. To overcome this limitation, Optuna [12] is employed, an automatic hyperparameter optimization framework, to fine-tune the comparison model, achieving significant improvements in classification accuracy and overall model performance. Additionally, the impact of lemmatization during preprocessing is explored, with a comparison of models trained with and without this step. Subtle synonym data augmentation is applied to introduce

variability into the dataset, addressing the challenge of high dimensionality and feature redundancy.

To enhance model interpretability, LIME (Local Interpretable Model-Agnostic Explanations) [13] is employed. By providing transparent and interpretable explanations of the model's decisions, to ensure that the predictions are not only accurate but also explainable, contributing to greater transparency in the spam detection process.

The contributions of this research are as follows:

1) Hyperparameter Optimization: Applying Optuna [12] to fine-tune the hyperparameters of the comparison models.
2) Lemmatization Analysis: Analyzing the impact of lemmatization on model performance, comparing results with and without this preprocessing step to determine its effectiveness in reducing feature space complexity.
3) Model Explainability: This study employs LIME [13] to provide transparent and interpretable explanations of the model's decisions, contributing to both accuracy and explainability in spam detection.
4) The proposed model SVM+DistilBERT with Voting Classifier model achieves significant performance improvements over previous approaches like SpotSpam [11].

This research presents a comprehensive evaluation of machine learning models for SMS spam detection. Starting with foundational approaches such as SVM [14] [15], the study extends to more complex models, incorporating feature engineering techniques like TF-IDF vectorization [16] and ensemble classifiers such as XGBoost [17]. By integrating advanced embeddings like DistilBERT with SVM and optimizing hyperparameters using Optuna, the gap between traditional methods and modern advancements is bridged, enhancing precision and flexibility. This provides valuable insights for both academic researchers and industry practitioners seeking to develop effective and explainable spam detection systems.

The remainder of this paper is organized as follows: Section II presents the Literature Review. Section III provides a Detailed Description of the Methodology. Results and Analysis are presented in Section IV. Finally, Conclusions and Future Work are discussed in Section V.

II. Literature Review

Spam detection remains a critical task in the field of text classification, with numerous algorithms developed to address the challenge of accurately identifying unsolicited messages in datasets. Traditional machine learning methods, particularly Support Vector Machines (SVMs), have been extensively studied for this purpose.

Singh et al. [18] explored the use of SVM with TF-IDF and other feature extraction methods for SMS spam detection, demonstrating the effectiveness of SVM in such tasks. They noted the need for further comparative analyses of hybrid models and ensemble methods to enhance performance. Building on their findings, this study provides a detailed comparison of various SVM-based models, including combinations with advanced embeddings like DistilBERT [19], and evaluates the impact of preprocessing techniques such as lemmatization on model performance. By integrating LIME, this study also addresses the critical need for model explainability, enhancing transparency in the decision-making process. These contributions aim to provide a more nuanced understanding of SVM's potential in modern spam detection frameworks, aligning with the ongoing evolution of text classification techniques.

Almeida et al. [20] demonstrated the effectiveness of SVM classifiers in detecting spam within text messages by leveraging a comprehensive set of features extracted from the messages. Despite their success, they highlighted that the performance of SVMs is highly contingent on the meticulous selection and tuning of kernels and hyperparameters—a process that is both complex and experimental. Moreover, they pointed out potential scalability issues, as SVMs can become computationally intensive when applied to very large datasets.

In an effort to enhance SVM performance, Delany et al. [21] experimented with the integration of n-gram analysis. This hybrid approach improved spam detection rates by capturing contextual information within the text. However, the generation and processing of n-grams introduced additional computational overhead, leading to longer training times and increased memory usage. This trade-off suggests that while the method is robust, it may not be ideal for scenarios requiring immediate processing.

Text preprocessing and hyperparameter optimization are critical components in improving spam detection efficacy. Lemmatization, a preprocessing technique that reduces words to their base forms, can enhance traditional machine learning models like SVM by reducing feature space complexity and improving recall and precision. Akhmetov et al. [22] demonstrated the benefits of lemmatization across multiple languages, noting its importance in handling morphologically rich datasets.

The advent of transformer-based models has further revolutionized natural language processing tasks, including spam detection. Xiaoxu Liu et al. [23] demonstrated that models based on the vanilla transformer architecture perform well in SMS spam detection tasks. They suggested that utilizing more complex architectures like BERT could yield even better performance due to their ability to capture deeper contextual relationships with fewer features and ease of fine-tuning.

Despite these advancements, there is a notable gap in the literature concerning the integration of advanced embedding techniques with traditional machine learning models. Guzella et al. [24] reviewed the application of SVMs in spam filtering, highlighting their adaptability and accuracy. However, their work did not directly compare SVMs with emerging deep learning methods, which have shown potential for superior performance in text classification tasks.

To address this gap, the current research focuses on enhancing SVM models with modern embedding techniques such as DistilBERT. By combining the strengths of SVMs with the contextual understanding provided by advanced embeddings, the aim is to improve both the accuracy and adaptability of spam detection models. This research approach also involves evaluating various enhancements to traditional SVM models, including the use of term frequency-inverse document

frequency (TF-IDF), ensemble techniques, and preprocessing methods like lemmatization.

Considerations of model interpretability and complexity are crucial in the selection of appropriate spam detection methods. Metsis et al. [25] found that while SVMs generally outperform other machine learning algorithms in spam detection tasks, they suffer from a lack of interpretability compared to more transparent models like decision trees. Drucker et al. [26] attempted to enhance SVMs by incorporating boosting techniques, which improved accuracy but also introduced risks of overfitting and added complexity. These factors could hinder the deployment of such models in real-time prediction environments.

III. Methodology

The methodological approach focus is on the comparative analysis of various machine learning models for SMS Spam filtering purposes using the SVM based centric approach. The performance of these models will be evaluated based on their recall, accuracy, precision and the score of ROC AUC in correctly identifying spam messages. The flowchart of the process can be seen in Fig. 1.

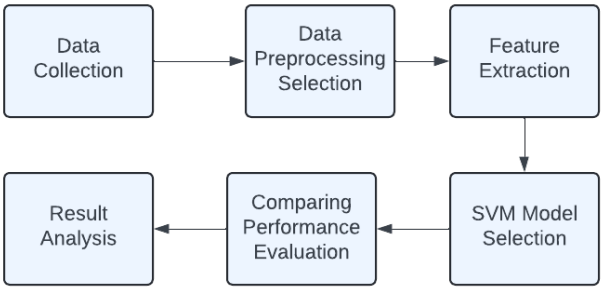

Fig. 1. Flowchart of the SVM comparison process.

A. Data Collection

The dataset utilized in this study is sourced from the UCI Machine Learning Repository [27], comprising 5,574 instances [28] with no missing values. Detailed information about the dataset composition and source distribution is presented in Table I.

TABLE I. Summary of SMS Message Sources for Spam Detection

Source	Description	Numb. of Messages
Grumbletext Website	UK forum reports of SMS spam.	425 spam
NUS SMS Corpus (NSC)	Legitimate messages from Singapore, mostly from students.	3,375 ham
Caroline Tag's PhD Thesis	Collection of SMS messages for research.	450 ham
SMS Spam Corpus v.0.1 Big	Combined collection of ham and spam messages for academic research.	1,002 ham, 322 spam

The bar chart in Fig. 2 revealed a significant imbalance in the dataset [28], with ham messages substantially outnumbering spam messages. To handle imbalance dataset, weight class balanced is employed on the SVM model. By completing these data preparation procedures, a well-organized and processed dataset is generated, which is now ready for the training and assessment of the classification models.

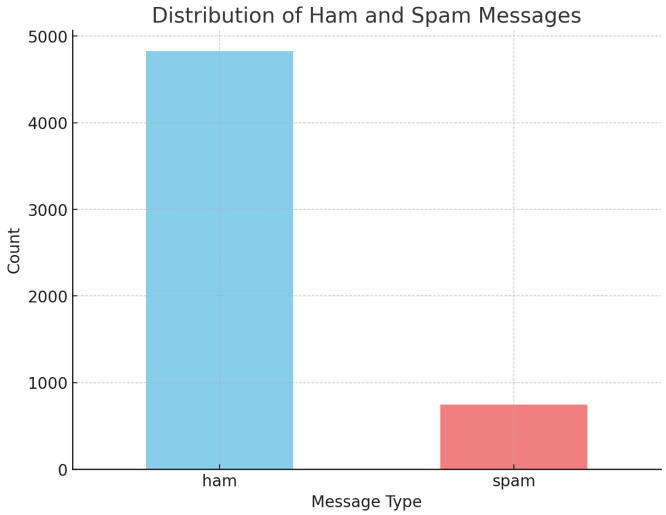

Fig. 2. Distribution of ham and spam messages in the dataset.

B. Data Preprocessing Selection

Before training the experimented models in this study, data cleaning is employed. For the SVM with DistilBERT embeddings, minimal cleaning is performed, involving converting the text to lowercase and removing extra white spaces. This approach retains most of the original raw data, as BERT embeddings are powerful enough to capture the semantic context.

To improve the generalization capability of the model, synonym data augmentation using WordNet was applied during the preprocessing stage for the proposed model. This technique introduces subtle variations in the text by replacing randomly selected words with their synonyms. The rationale behind this approach lies in the inherent diversity of language use in real-world communications, where different words can convey similar meanings. During synonym replacement, some words remain unchanged because WordNet may not have synonyms for them. The examples are shown in Table II.

While the application of synonym replacement in this study resulted in relatively minor changes to the text, it served two key purposes:

- Lexical Variety: The augmentation process exposed the model to variations in word usage that it might encounter in unseen data.
- Robustness to Minor Variations: Synonym replacement, despite introducing small changes, ensures that the model is less reliant on exact word matches.

In addition, this study investigated the influence of lemmatization on SMS spam detection models by preparing data in two different ways: with and without lemmatization. Lemmatization reduces words to their base forms (e.g. "congratulations" and "congrats" to "congratulate"), reducing the feature

space for model training. This preprocessing step enables for a comparative analysis of its impact on model performance.

TABLE II. COMPARISON OF ORIGINAL AND SYNONYM-REPLACED SMS MESSAGE

Original Text	**Text After Synonym Replacement**
Actually I decided I was too hungry so I haven't left yet : V	Actually I decided I was too hungry so I haven't **leave** yet : V
That's the thing with apes, u can fight to the death to keep something, but the minute they have it when u let go, that's it!	That's the thing with apes, u can fight to the death to keep something , but the **moment** they have it when u let go, that's it !
Glad to see your reply.	**glad** to see your reply.

C. Feature Extraction

1) TF-IDF: Term Frequency (TF) estimates the frequency of terms in a sentence by dividing the number of repetitions by the total number of words in the sentence. The IDF score determines the word's rarity within a corpus, suggesting that words that aren't used as frequently might hold more important information [29].

2) Bi-gram: The SVM TF-IDF will be enhanced with the bi-gram to capture more information context. A Bi-gram is two ceonsecutive elements which takes forms of words taken from the sequence of tokens. The bi-gram focuses on the word pair rather than capturing the meaning of the individual text itself.

For example, combining words like "customer service" is a bi-gram, which have more nuanced sentiment compared to an individual words such as "customer" or "service" [29].

3) DistilBERT: This study utilizes DistilBERT, a condensed version of the BERT (Bidirectional Encoder Representations from Transformers) model [30]. DistilBERT reduces the size of BERT by approximately 40%, making it more efficient in terms of memory and computational resources while retaining about 97% of BERT's performance on language understanding benchmarks.

DistilBERT achieves this efficiency through knowledge distillation [31], where a smaller student model learns to mimic the behavior of a larger teacher model. This process involves training the student model to reproduce the outputs of the teacher model, effectively capturing the essential knowledge in a more compact form without the need for extensive mathematical computations during inference.

The architecture of DistilBERT retains the Transformer-based design [32] but reduces the number of layers from 12 to 6. Despite this reduction, it maintains the ability to capture complex contextual relationships within the text through self-attention mechanisms. The self-attention mechanism allows the model to weigh the importance of different words in a sequence, enabling it to understand the context and nuances of language effectively. The architecture of DistilBERT can be seen in Fig. 3.

By integrating DistilBERT embeddings into the model, It leverages rich contextual representations of the input text, which enhances the performance of the spam detection task. This approach provides a balance between computational efficiency and model accuracy, making it suitable for applications requiring quick response times without significant loss in performance.

For detailed information on the mathematical formulations and training objectives of DistilBERT, readers are referred to Sanh et al. [19] and the foundational works on Transformers by Vaswani et al. [32].

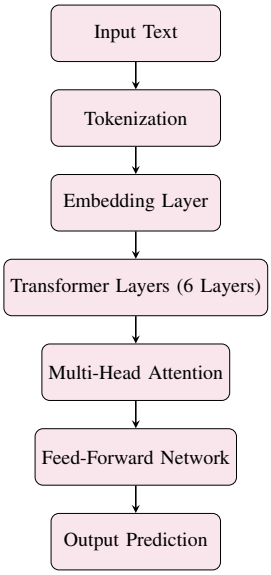

Fig. 3. Architecture of DistilBERT.

D. SVM Model Selection

1) Support Vector Machine: This study focuses on using Support Vector Machines (SVM) to filter spam in the SMS dataset. SVMs are supervised learning models used for regression analysis and classification. Gaye et al. (2021) [33] found that the SVM works by choosing the best hyperplane that separates the data into different classes. The main goal is to maximize the margin—the gap between the hyperplane and the nearest data points of each class—which can be either hard or soft. This separation challenge is transformed into a quadratic programming problem, allowing for the optimal hyperplane to be found efficiently.

This transformation is pivotal as it enables the SVM model to effectively handle linearly inseparable cases through the introduction of slack variables for soft margin optimization and the employment of kernel functions. Kernel functions, such as polynomial, radial basis function (RBF), and sigmoid, allow SVM to operate in high-dimensional spaces, facilitating the classification of complex datasets [34].

For the task of SMS spam filtering, the application of SVM is particularly promising due to its ability to discern between spam and legitimate messages with high precision. By constructing a feature vector from the SMS dataset and applying an appropriate kernel function, SVM can effectively classify

messages, leveraging the textual and contextual differences between spam and non-spam SMS. This capability is further evidenced by recent studies, which have demonstrated SVM's superior performance in text classification tasks compared to other machine learning algorithms [35] [36].

Furthermore, the adaptability of SVM in handling various types of data makes it an ideal choice for this study. By fine-tuning the SVM parameters, including the regularization parameter (C) and the kernel parameters, it can optimize the model to achieve maximum accuracy in spam detection. This optimization process is crucial for adapting the SVM model to the specific characteristics of the SMS dataset, thereby ensuring the effectiveness of the spam filtering solution.

2) AdaBoost: This study implements the ensemble classifier method AdaBoost for comparison analysis. AdaBoost is a powerful machine learning technique that combines multiple weak classifiers to create a robust, highly accurate classifier. It is simple to implement and relatively insensitive to noise in the data, but it can be affected by specific types of noise, such as class imbalance or outliers.

The following equation describes how each training instance's weight is updated by AdaBoost:

$$D_{t+1}(i) = \frac{D_t(i) \exp(-\alpha_t y_i h_t(X_i))}{Z_t} \tag{1}$$

In this equation, $D_t(i)$ represents the weight of the i-th training instance at iteration t, and α_t denotes the weight of the classifier. The exponential term adjusts the weight based on whether the prediction $h_t(X_i)$ matches the true label y_i. The normalization factor Z_t ensures that all weights sum to one, enabling the model to focus more on incorrectly classified instances [37].

In this study, AdaBoost with SVM is used as a comparison method to evaluate the performance of the proposed SVM-DistilBERT-based model and to assess the impact of lemmatization in classifying SMS spam messages.

3) eXtreme Gradient Boosting (XGBoost): XGBoost was employed in this study for comparative analysis alongside other models to evaluate the impact of lemmatization. XGBoost, or "Extreme Gradient Boosting", is a powerful and efficient machine learning algorithm built on the gradient boosting framework. Its high performance and speed make it popular for various supervised learning tasks. This algorithm is known for its scalability, sparsity awareness, and considerations for data compression, sharding, and cache-aware access [38].

These features enable XGBoost to efficiently manage large datasets with billions of entries, using fewer computational resources than many other systems [39]. In this study, it serves as a benchmark to understand how lemmatization affects model performance relative to other methods.

4) Voting Classifier: In this study, several machine learning models were combined with a voting classifier to create a reliable SMS spam detection system. The classifier combined Support Vector Machine (SVM), Random Forest, Gradient Boosting, Logistic Regression, and K-Nearest Neighbors into a single predictive model. The goal was to enhance the system's overall performance by using the advantages of each particular model.

The key to building an efficient SMS spam detection system is to balance the advantages of different machine learning models with each one's drawbacks. The ensemble approach seeks to use each model's robustness by combining these various models into a single voting classifier, producing a forecast that is more accurate and dependable. Every model makes a distinct contribution to the classifier; some are better at managing enormous datasets or offering interpretability, while others are better at handling high-dimensional data. Combining these models guarantees a more balanced approach to categorization that can handle the subtleties of SMS data with better accuracy while also improving the system's overall performance.

Support Vector Machine are very effective in a high dimensional data spaces and it is robust against outliers which is very good in handling noisy environments [40]. However, SVM also has its drawbacks that it faces scalability issues and is computationally intensive when handling a large datasets [41].

Random Forest(RF) can be integrated to help solve to address SVM drawbacks as they are very efficient in managing large datasets that leads to better generalization [41]. Random Forest is also very good in handling the missing data and conducting variable selection, however Random Forest may struggle on interpretability and imbalanced datasets [42] [43].

To add more strength to the ensemble, Logistic Regression were added to the Voting Classifier, that is known for it's simplicity and interpretability. It is very effective against binary classification problems and it is widely used for social sciences/medical field because of its interpretable and clear coefficients [44]. Logistic Regression can reduce the potential bias by handling the categorical predictor and continuous variables and also can effectively control confounding variables [45]. However, logistic regression has its drawbacks which is sensitive to outliers [46] and also has the assumption that there is a linear relationship between the predictors and the log-odds of the outcome that will effect on the limitation on its effectiveness for nonlinear boundaries [47].

On the other hand, Gradient Boosting model strength lies on it's high predictive accuracy and it's ability to adapt to the ensemble, especially when managing noisy data and multiple features [48] [49]. Gradient Boosting complements very good with the versatile capabilities of logistic regression and the robustness of Random Forest [50].

K-Nearest neighbor (KNN) contributes to the model because it's simple and effective to perform well in classification task, especially on how it groups the data based on the similarity. The flexibility of K-Neares neighbor (KNN) by leveraging different distance metrics improves its adaptability to different kinds of data [51]. When K-Nearest Neighbor (KNN) pairs with a structured models like Gradient Boosting and Random Forest, the combined model will perform better in handling complex data scenario [52].

The final output is generated by averaging the predictions made by each model in an ensemble technique. The voting classifier produces a more balanced and dependable detection

system, which integrates the outputs from SVM, Random Forest, Logistic Regression, Gradient Boosting, and K-nearest neighbors.

Using this method, the study shows that properly adjusted voting classifiers may greatly increase the precision and dependability of an SMS spam detection system.

E. Hyperparameter Optimization Using Optuna

In this study, Optuna is employed for hyperparameter optimization across various machine learning models for text classification, including XGBoost, AdaBoost, and Voting Classifiers with multiple base learners. To enhance readability and reduce complexity, standardized hyperparameter optimization across models were applied. For both XGBoost and AdaBoost, This study optimized the maximum number of features in the TF-IDF vectorizer, *max_features* $\in \{1000, 2000, 3000, 4000, 5000\}$, as well as the number of estimators, $n_{\text{estimators}} \in \{50, 100, 150, 200\}$, and the learning rate.

For XGBoost, additional parameters such as the maximum tree depth, *max_depth* $\in [3, 10]$, and the subsampling ratio, *subsample* $\in [0.5, 1.0]$, were optimized. Class imbalance was addressed using the *scale_pos_weight* parameter. In the Voting Classifier ensemble, shared hyperparameters across its constituent models were optimized to ensure consistency. The classifiers included SVC and Logistic Regression, where the regularization parameter C was optimized over a logarithmic scale. Additionally, Random Forest and Gradient Boosting classifiers were tuned for the number of estimators, with Random Forest also having an optimized maximum depth, and K-Nearest Neighbors varying in the number of neighbors.

When incorporating DistilBERT embeddings, the shared hyperparameters were optimized to maintain consistency across models. Stratified K-Fold cross-validation with $k = 5$ were employed, optimizing for metrics such as accuracy and ROC AUC. This systematic approach with Optuna enhanced model performance while reducing complexity and improving clarity in the hyperparameter optimization strategies.

F. Comparing Performance Evaluation

To evaluate the performance of the tested models, this study employ a technique called stratified k-fold cross-validation. Stratified K-fold cross-validation is an improved variant of k-fold cross-validation that is primarily used to ensure that the dataset's folds have similar class label distributions while maintaining the distribution of different classes [53]. With this method, over-fitting is reduced in datasets with imbalanced classes, unlike the regular k-fold cross validation, it can produce folds with skewd distribution of class labels in unbalanced datasets which may lead inaccurate performance measures.

After the integrated model is evaluated, the data is divided into five sections. Four of the segments are utilized to train the model, and the remaining one is used for testing. The aim of this assessment is to evaluate the model's differentiate capability across classes, with a specific focus on how well it can detect positive cases based on the ROC AUC score, Precision, Recall, F1-Score, and Accuracy.

G. Evaluation Measures

To provide different insights for the performance of classification model that were tested, this study includes different metrics such as Precision, Recall, F1-Score, ROC AUC Score and the Accuracy.

1) Precision: It is a statistical measures that evaluates how well a model predicts the favorable outcomes. It indicates the percentage of correctly predicted positive instances out of from all cases that were predicted positive. The notation for precision is denoted as in Eq. 2.

Mathematical Definition:

$$\text{Precision} = \frac{\text{True Positives (TP)}}{\text{True Positives (TP)} + \text{False Positives (FP)}} \quad (2)$$

2) Recall: The proportion of accurately predicted positive observations to all of the observations made during the actual class is known as recall.

Mathematical Definition:

$$\text{Recall} = \frac{\text{True Positives (TP)}}{\text{True Positives (TP)} + \text{False Negatives (FN)}} \quad (3)$$

3) F1 score: The harmonic mean of Precision and Recall is the F1 score. It is helpful when attempting to achieve a balance between recall and precision.

Mathematical Definition:

$$\text{F1-Score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (4)$$

4) ROC AUC Score: A performance metric for classification issues at different threshold settings is the ROC (Receiver Operating Characteristic) AUC (Area Under the Curve) score. The degree or measure of separability is represented by AUC, and ROC is a probability curve. It indicates the degree to which the model can discriminate between classes.

Mathematical Definition: Plotting TPR (True Positive Rate, sometimes called Recall) against FPR (False Positive Rate) yields the ROC curve. The area under this curve, or AUC score, has the following mathematical definition:

$$\text{AUC} = \int_0^1 \text{TPR}(\text{FPR})\, d(\text{FPR}) \quad (5)$$

True Positive Rate (TPR) is defined as:

$$\text{TPR} = \frac{\text{True Positives (TP)}}{\text{True Positives (TP)} + \text{False Negatives (FN)}} \quad (6)$$

False Positive Rate (FPR) is defined as:

$$\text{FPR} = \frac{\text{False Positives (FP)}}{\text{False Positives (FP)} + \text{True Negatives (TN)}} \quad (7)$$

The AUC score falls between 0 and 1. An AUC of 1 indicates a perfect prediction model; an AUC of 0.5 indicates

a random prediction model. Better model performance is indicated by values nearer 1. More specifically, because it offers a thorough assessment of model performance across all classification thresholds, AUC is an important metric when assessing models on unbalanced datasets.

IV. Results and Analysis

The results in Table III and Table IV summarize various methods for SMS spam classification, including SVM-TF (Support Vector Machine with Term Frequency-Inverse Document Frequency), SVM-TF-Bi (SVM with TF-IDF and bi-grams), SVM-TF-Bi-Ada (SVM with TF-IDF Bi-gram and Adaboost), SVM-TF-Bi-XGB (SVM with TF-IDF Bi-gram and XGBoost), SVM-TF-Bi-Vote (SVM with TF-IDF Bi-gram and Voting Classifier), and SVM-DistilBERT-Vote (SVM with DistilBERT embeddings and Voting Classifier), where the "-Lem" suffix indicates the use of lemmatization, and performance is evaluated using the ROC AUC (Receiver Operating Characteristic Area Under Curve) metric.

TABLE III. Performance Comparison of Different Models: Models without Lemmatization

Model	ROC AUC	Precision	Recall	F1-Score	Accuracy
SVM-TF	0.9931	0.9878	0.8835	0.9327	0.9829
SVM-TF-Bi	0.9927	0.9719	0.8821	0.9248	0.9808
SVM-TF-Bi-Ada	0.9903	0.9984	0.8541	0.9206	0.9803
SVM-TF-Bi-XGB	0.9855	0.9387	0.8983	0.9179	0.9785
SVM-TF-Bi-Vote	0.9923	0.9984	0.8674	0.9283	0.9821
SVM-DistilBERT-Vote	0.9996	0.9973	0.9752	0.9861	0.9961

TABLE IV. Performance Comparison of Different Models: Models with Lemmatization

Model	ROC AUC	Precision	Recall	F1-Score	Accuracy
SVM-TF	0.9913	0.9855	0.9049	0.9433	0.9855
SVM-TF-Bi	0.9916	0.9856	0.9129	0.9477	0.9865
SVM-TF-Bi-Ada	0.9809	0.9803	0.7925	0.8764	0.9700
SVM-TF-Bi-XGB	0.9840	0.9512	0.8809	0.9145	0.9779
SVM-TF-Bi-Vote	0.9937	0.9925	0.8888	0.9376	0.9842
SVM-DistilBERT-Vote	0.9995	0.9951	0.9828	0.9878	0.9968

Table V compares the performance of this research with various previous studies on SMS spam classification, highlighting the differences in methods, accuracy, and datasets used. While traditional approaches such as TF-IDF with Random Forest [55] and XGBoost [59] reported accuracies of 97.50% and 97.64%, respectively, other methods like a hybrid system using K-Means SVM [56] and a Voting Classifier approach [57] achieved slightly higher accuracies, ranging from 98.8% to 98.93%. In contrast, this research, which employs an SVM DistilBERT model integrated with a Voting Classifier, achieves a superior accuracy of 99.6

The performance of various machine learning models on the SMS spam detection task was systematically evaluated. The results, summarized in Table III and Table IV, provide insights into how each model performed under two different preprocessing conditions: with and without the application of lemmatization. Lemmatization improves SMS spam identification by minimizing feature space redundancy, standardizing morphological variations (e.g. "running", "runs", and "ran" become "run"), and boosting generalization. For instance, a sample spam message, "Congrats! You've won a prize", is normalized to "congratulate! you win prize", allowing the algorithm to recognize spam-related phrases more accurately.

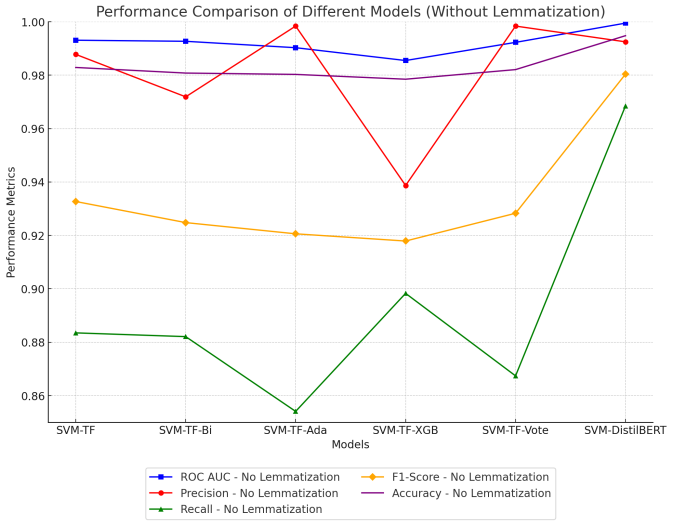

Fig. 4. Performance comparison of different models (without lemmatization).

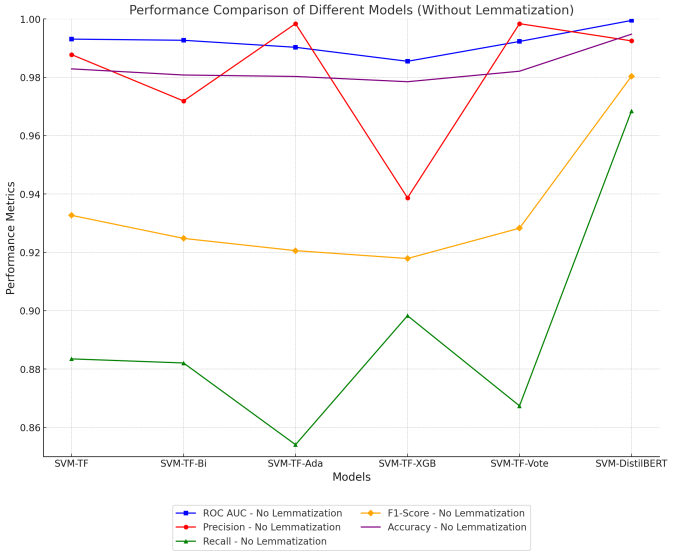

Fig. 5. Performance comparison of different models (with lemmatization).

This preprocessing step is especially beneficial for simpler models such as SVM-TF and SVM-TF-Bi, as evidenced by their higher recall and precision scores (Table IV). By emphasizing semantic meaning over lexical differences, lemmatization enhances detection accuracy and contributes to more effective spam filtering.

Fig. 5 and Fig. 4 showcase the performance metrics for six different models: SVM with Term Frequency (TF), SVM with TF and Bigrams (TF-Bi), SVM with TF and Bigram AdaBoost (TF-Bi-Ada), SVM with TF Bigram XGBoost (TF-Bi-XGB), SVM with TF Bigram and Voting Classifier (TF-Bi-Vote), and SVM with DistilBERT embeddings enhanced with Voting Classifier (SVM-DistilBERT-Vote). The key observation here is the effect of lemmatization on the models' performance.

Without lemmatization (Fig. 4), the ROC AUC remains consistently high across all models, with minor variations.

TABLE V. SUMMARY OF DIFFERENT METHODS IN CLASSIFYING SMS SPAM MESSAGES

Title and Reference	Dataset	Methods	Accuracy
SMS Spam Classification Using Machine Learning Techniques [54]	UCI Machine Learning Repository	SVM	98.797%
SMS Spam Message Detection using Term Frequency-Inverse Document Frequency and Random Forest Algorithm [55]	UCI Machine Learning Repository	TF-IDF with Random Forest	97.50%
Hybrid SMS Spam Filtering System Using Machine Learning Techniques [56]	UCI Machine Learning Repository	K-Means SVM	98.8%
A Robust System For Message Filtering Using An Ensemble Machine Learning Supervised Approach [57]	6000 Messages Data, 1000 Messages are spam	Voting Classifier	98.93%
Semi-supervised novelty detection with one class SVM for SMS spam detection [58]	747 spam, 4827 non-spam messages	One class SVM	98%
Relevant SMS Spam Feature Selection Using Wrapper Approach and XGBoost Algorithm [59]	UCI Machine Learning Repository	XGBoost Classifier	97.64%
This Research	UCI Machine Learning Repository	SVM DistilBERT with Voting Classifier	99.6%

However, precision shows a significant drop for the SVM-TF-Ada model, indicating that this model might be struggling with false positives when lemmatization is not applied. Recall for the same model also dips notably, which could suggest that the model is less sensitive to actual spam messages without the normalization that lemmatization provides.

In contrast, with lemmatization applied (Fig. 5), the performance of the SVM-TF-Bi-Ada model sees a marked improvement in recall, indicating better detection of spam messages. The F1-Score, which balances precision and recall, reflects these changes, showing a more consistent performance across the models when lemmatization is used.

Interestingly, the SVM with DistilBERT embeddings integrated with Voting Classifier consistently shows high performance across all metrics, with and without lemmatization, suggesting that this model is robust to variations in text preprocessing. This robustness can likely be attributed to the sophisticated nature of the DistilBERT embeddings, which capture contextual information effectively even in raw, non-lemmatized text.

Overall, these results suggest that while lemmatization generally aids in improving recall and precision for certain models, particularly ensemble methods like AdaBoost and Voting Classifier, models leveraging advanced embeddings like DistilBERT are less dependent on such preprocessing steps. Therefore, the choice of preprocessing should be carefully considered depending on the model being used, with lemmatization being more crucial for traditional machine learning approaches.

1) Performance without Lemmatization: The SVM-DistilBERT-Vote model demonstrated superior performance across all evaluation metrics, positioning itself as the leading model in this task. Specifically, it achieved an ROC AUC of 0.9996, indicating near-perfect discrimination between spam and non-spam messages. The model also recorded a Precision of 0.9973, which reflects its high ability to correctly identify spam messages without including false positives. The Recall score of 0.9752 shows that the model effectively identified the majority of actual spam messages. This balance between high Precision and high Recall resulted in an F1-Score of 0.9861, underscoring the model's effectiveness in maintaining a low rate of both false positives and false negatives. The high Accuracy of 0.9961 further supports these findings, indicating that the model correctly classified a vast majority of messages.

Comparatively, other models, such as SVM-TF and various ensemble methods (SVM-TF-Bi-Vote, SVM-TF-Bi-XGB), also performed well but with some noticeable differences. For instance, the SVM-TF model achieved a Recall of 0.8835, lower than that of SVM-DistilBERT-Vote, suggesting that it missed more spam messages. Despite this, the SVM-TF model's Precision remained high at 0.9878, resulting in an F1-Score of 0.9327. While this score is robust, the model's lower Recall indicates a higher likelihood of misclassifying spam messages as non-spam, which could be critical in certain applications. The ensemble methods, while effective, exhibited similar trends, with generally strong Precision but lower Recall compared to SVM-DistilBERT-Vote, indicating a potential trade-off in these models between false positives and false negatives.

2) Performance with Lemmatization: The application of lemmatization yielded varying impacts across the different models, with the SVM-DistilBERT-Vote model once again demonstrating the highest performance. After lemmatization, the SVM-DistilBERT-Vote model maintained an ROC AUC of 0.9995, with only a slight reduction from the non-lemmatized version, which suggests that lemmatization had little effect on the model's ability to distinguish between classes. However, its Recall improved to 0.9828, leading to an F1-Score of 0.9878, slightly higher than without lemmatization. This improvement in Recall indicates that lemmatization helped the model better identify spam messages, making it even more reliable for practical use.

Other models, particularly those based on TF-IDF vectorization, showed more pronounced improvements with lemmatization. The SVM-TF-Bi model, for instance, experienced a notable increase in Recall from 0.8821 to 0.9129, which contributed to a rise in its F1-Score from 0.9248 to 0.9477. This suggests that lemmatization improved the model's ability to capture the semantic essence of the text, thereby reducing the number of missed spam messages. The enhancement in feature

representation due to lemmatization is likely responsible for this improvement.

However, not all models benefited from lemmatization. The SVM-TF-Bi-Ada model, in particular, saw a decline in performance with lemmatization, as evidenced by its decreased Recall (0.7925) and F1-Score (0.8764). This decline suggests that lemmatization may have disrupted the feature space that this ensemble method relies on, reducing its effectiveness in distinguishing between spam and non-spam messages. Such a decrease in performance highlights the importance of considering the model architecture when applying preprocessing techniques like lemmatization.

The variation in lemmatization's effect on models may arise from ensemble approaches such as AdaBoost, which depend on feature diversity that lemmatization might diminish, while simpler vectorization models gain from a less complex feature space.

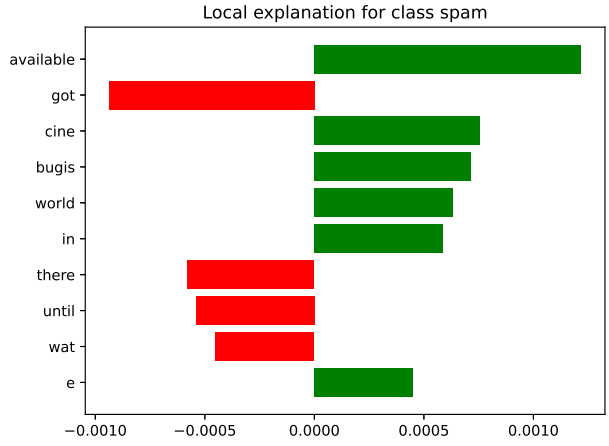

Fig. 6. Lime local variable explanation.

3) Explainable AI Using LIME: Fig. 6 presents a visual representation of explainable AI, generated using a tool called LIME (Local Interpretable Model-agnostic Explanations). This tool provides insights into how predictions are made by machine learning models through local explanations. LIME works by perturbing the input data—making slight alterations—and then assessing the impact of these modifications on the model's predictions.

In text classification tasks, such as the one illustrated in the figure, LIME identifies which words in a message have the most significant effect on the model's prediction. To enhance the interpretability of the model's decision-making process, it visualizes each word's contribution, highlighting those that increase or decrease the likelihood of the message being classified as spam.

For example, the word *"available"* has a contribution value of approximately **0.0010**, indicating a strong positive influence toward spam classification. On the other hand, *"got"* has a contribution of around **-0.0008**, meaning it significantly reduces the likelihood of the message being labeled as spam.

While certain words such as *"cine"* and *"bugis"* also contribute positively with values of **0.0006** and **0.0004** respectively, words like *"until"* and *"wat"* have smaller negative contributions, each near **-0.0004**. This numerical breakdown allows for a clearer understanding of which specific terms influence the spam classification and by how much, ensuring transparency in the model's decision-making process.

V. Conclusion

The study found that lemmatization often improves SMS spam detection performance, particularly in models that use TF-IDF vectorization. Lemmatization improves the model's ability to generalize and focus on message semantics by minimizing feature space redundancy and normalizing morphological variances. Models such as SVM-TF and SVM-TF-Bi showed considerable gains in recall and precision after lemmatization (Table IV), emphasizing its importance in increasing detection accuracy.

However, the impact of lemmatization is not uniform across all models. While models like SVM-TF-Bi showed enhanced performance with lemmatization, certain ensemble models, such as SVM-TF-Bi-Ada, experienced a decline, particularly in Recall and F1-Score. This suggests that the benefits of lemmatization are dependent on the specific model architecture and that its application should be considered carefully based on the characteristics of the model and the intended use case.

Overall, the findings underscore the importance of selecting the right preprocessing techniques in conjunction with the appropriate machine learning model to achieve optimal performance in text classification tasks. The variability in the effects of lemmatization across different models suggests that a one-size-fits-all approach may not be effective, and careful experimentation and analysis are necessary to determine the best preprocessing and modeling strategy for a given task.

Future works will be focusing on the different dataset other than the UCI Machine learning SMS Spam dataset that is more recent. Since this research is focusing on the SVM Centric to detect SMS Spam Detection, other methods that is more poweful while maintaing less computational cost still remains a challenge to address. Furthermore, synonym replacement in this study relied on WordNet without considering contextual similarity. Integrating models like BERT in the future could ensure replacements better align with sentence context, improving the quality of data augmentation.

Acknowledgment

The authors would like to express their sincere gratitude to King Abdulaziz University for the financial support provided through their scholarship program, which made this journal article possible. This support has been instrumental in enabling the research and completion of this work.

***Abstract*—Maintaining optimal water quality is crucial for successful aquaculture. This necessitates careful management of various water quality parameters, including pH levels within their ideal range. There is growing interest in creating affordable optical pH sensors that provide accurate readings across a wide range of pH values. Development of sensors that are both accurate and cost-effective remains a challenge. To this end, this study demonstrates the use of machine learning with mango leaf extract as a colorimetric indicator to achieve accurate and cost-effective pH estimation for aquaculture practices. Mango leaf was utilized as the pH indicator, covering a range from 1 to 13. RGB color extraction and Exif data were used for image analysis to extract relevant features. The XGBoost algorithm, optimized through stepwise hyperparameter tuning with early stopping, was used to train three different models on this dataset to predict pH values. Three classification models, namely Y3, Y5, and Y13, were trained with 3, 5, and 13 output classes, respectively. The overall precision achieved by each model was 0.94, 0.85, and 0.72, respectively. This demonstrates the potential of this approach for developing a user-friendly yet cost-effective sensor for pH detection applicable in aquaculture practices. The proposed method could help aquaculture farmers an affordable and intelligent smartphone-based pH detection tool, enhancing water quality management while reducing the need for expensive instruments and eliminating the need for additional costly and time-consuming experimental work, thereby contributing to the sustainability of aquaculture practices.**

I. Introduction

Water quality is a pivotal factor in aquaculture, exerting significant influence on fish growth, survival, and reproduction [1], [2], [3]. Precise and consistent monitoring of water quality parameters is essential for effective aquaculture management, aiding in disease prevention, treatment, and overall productivity [2]. To maintain optimal water conditions, various physical, chemical, and biological treatments are applied to aquaculture pond [3]. Key water quality parameters, including temperature, dissolved oxygen, salinity, and pH, provide valuable insights into aquaculture system health and performance [4], [5]. The primary challenge with traditional water quality assessment methods is their lack of cost-effectiveness and the significant labour they require. This highlights the need for more innovative monitoring solutions. Although technological advancements like the Internet of Things (IoT) and artificial intelligence have enabled real-time monitoring and analysis of water quality [6], the high cost of sensors remains a major barrier to the widespread adoption of these modern technologies [7].

Several studies have highlighted that pH is a crucial parameter for assessing water quality and plays a fundamental role in aquatic ecosystems. It has been reported that abnormal pH levels can negatively impact the health of aquatic organisms and the overall quality of water [8], [9]. Therefore, maintaining optimal pH levels is essential for successful aquaculture practices. However, research consistently shows that the ideal pH range varies among fish species, as detailed in Table I, which presents the acceptable pH ranges for different aquatic species.

Colorimetric methods are simpler, more cost-effective, and capable of providing realtime results, making them a promising solution for pH measurement in various fields, such as environmental monitoring [10], [11], [12], [13]. In aquaculture, colorimetric pH sensors demonstrated continuous, in-situ monitor-ing, which allows for early detection of pH fluctuations and enables prompt corrective actions [14]. This study aims to advance the development of more efficient and effective aquaculture practices by addressing the limitations of traditional water quality monitoring techniques and leveraging the benefits of colorimetric pH sensors.

Supervised learning is a subfield of machine learning algorithms that trains models, f, on la-belled data. This data comprises feature vectors, x, and their corresponding labels, y. The primary objective is to minimize a loss function, denoted by $L(f)$, which quantifies the discrepancy between the predicted labels, $f(x)$, and the true labels, y [23].

Ensemble learning is a subcategory of supervised learning algorithms that aims to construct a robust learner, F, by combining multiple weaker learners, fi. A prominent example of ensemble learning is XGBoost, which utilizes decision trees as base learners. These decision trees recursively partition the feature space based on specific decision rules, ultimately predicting a class or a continuous value [24]. XGBoost operates in

TABLE I. OPTIMAL RANGE OF PH VALUES AS REPORTED IN LITERATURE

Description	Lower Range	Upper Range	Reference
Optimal pH range for nile tilapia is between 5 and 8.	5	8	[15]
Efficient nitrification activity in aquaculture biofilters 7.0 9.0			
Reproduction and infectivity of c. Irritans.	6	9	[16]
C. Irritans can survive in pH 5-10 in aquaculture.	5	10	[16]
PH ranged from 7.4 to 9.6 in eutrophic aquaculture ponds.	7.4	9.6	[8]
pH range 6-8 commonly acceptable in aquaculture.	6	8	[17]
pH ranges vary based on species, but generally 6.5-9.0.	6.5	9.0	[18]
Optimal pH for most aquaculture species is 7.0-8.5.	7.0	8.5	[18]
pH levels between 7.51 and 8.00 maintained in aquaculture.	7.51	8.00	[19]
Atlantic salmon embryos have lower lethal limits around pH 3.0-4.0.	3.0	4.0	[20]
Silver catfish juveniles survive in pH range of 4.0-9.0.	4.0	9.0	[21]
pH range in aquaculture: 6.5-9.0 suggested, optimal range varies by species.	6.5	9.0	[22]
Results suggest that 8.0–8.5 is the best pH range for survival and growth of the larvae of the silver catfish (rhamdia quelen) larvae	8.0	8.5	[22]

an iterative manner, gradually building an ensemble of decision trees. Each subsequent tree, f_i, focuses on rectifying the errors made by its predecessors using a technique called gradient boosting. Mathematically, this translates to minimizing $L(f)$ by strategically adding trees that target the residuals of the existing ensemble, $F_{i-1}(x)$. This approach enables XGBoost to effectively handle intricate feature relationships and achieve significant minimization of the loss function, $L(f)$.

II. BACKGROUND

Traditionally, pH measurement has relied on physical sensors, both analog and digital [25]. Despite their precision, these sensors necessitate frequent calibration to maintain accuracy, which can be expensive and time-consuming. Coupled with manual operation, this has prompted a search for more affordable and user-friendly alternatives. Recent advancements have facilitated the integration of digital pH sensors into IoT systems for continuous water quality monitoring [26], [25], [27]. While these solutions are suitable for larger aquaculture operations, their high implementation costs often preclude their adoption by smaller farms seeking economical options. An alternative approach to pH measurement involves pH test strips, a traditional and cost-effective method for assessing water quality in aquaculture [28], [29]. While less precise than sensor-based methods, their simplicity, affordability, and portability make them valuable tools in various applications. However, relying on visual color comparisons with a reference chart can introduce subjectivity and potential inaccuracies. Furthermore, the presence of other water constituents may interfere with test strip accuracy [30], [31]. Despite these limitations, the ease of use and absence of calibration requirements make pH test strips an economical option, particularly for small-scale farms with limited resources.

To mitigate the subjectivity inherent in interpreting pH test strip colors, researchers have explored the use of machine learning models to enhance the accuracy of pH measurements derived from paper strips [32], [33], [34]. Concurrently, the development of novel reagents for pH determination remains an active research area. These innovative reagents, when integrated with smartphone or machine learning-based methodologies, hold the potential to significantly improve pH measurement accuracy. A novel method for directly measuring the pH of airborne particles or droplets has been developed, combining pH indicator paper with RGB-based colorimetric analysis. This approach established a linear correlation between RGB values and pH, surpassing the accuracy and applicability of previous models. Hydrion® Brilliant pH dip stciks (lot no. 3110, Sigma-Aldrich), with their wide pH detection range and resistance to interference, were deemed optimal for analyzing ambient aerosols. Initial findings suggest that aerosol pH can be estimated with an uncertainty of 0.5 units or less, casting doubt on the reliability of traditional pH color charts and emphasizing the need for in situ calibration of pH papers using standardized pH buffers [11].

A smartphone-based colorimetric analysis technique employing a pH-sensitive photonic gel was reported. The gel exhibited color variations corresponding to different pH levels, which were captured and analyzed using a smartphone camera and image processing algorithms. This method demonstrated accurate real-time pH measurement, suggesting its potential applications in environmental monitoring and medical diagnostics [35].

A smartphone-based colorimetric method was developed for detecting enzyme-substrate reactions using pH-responsive gold nanoparticle assemblies. The pH-induced color changes in the gold nanoparticles, resulting from enzyme-substrate interactions, were captured and analyzed using a smartphone. This method offers a simple, cost-effective, and portable platform for monitoring enzyme-substrate reactions in various fields such as biochemistry and environmental science [36].

Traditionally, pH measurement in aquaculture has relied on physical sensors and pH test strips, which provide accurate results but often suffer from portability and usability constraints. In contrast, smartphone-based approaches, utilizing colorimetric changes and sophisticated image processing, offer high precision, portability, and user-friendliness, making them suitable for remote and real-time monitoring. However, these methods may necessitate specific reagents and con-trolled conditions for optimal performance. This research underscores the potential for developing cost-effective and user-friendly smartphone-based pH detection systems with broader applications.

III. MATERIALS AND METHODS

A. Chemicals

Ortho-Phosphoric acid (85-88%) and sodium hydroxide (99%) were purchased from R & M Chemicals. All chemicals were of analytical grade and used as received without further purification. Distilled water was used in all experiments. Green

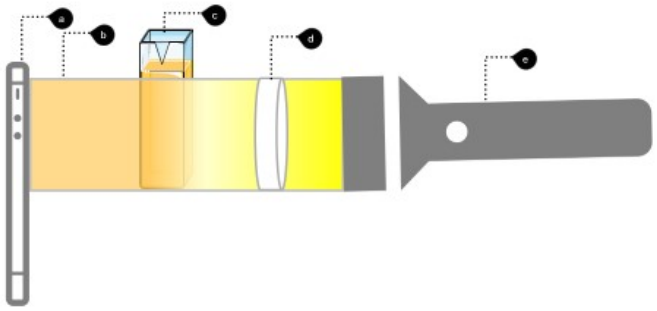

Fig. 1. Schematic illustration of the smartphone colorimetric sensors data gathering. (a) smart phone, (b) PVC pipe of, (c) Cuvette containing sample solution, (d) light diffuser that is a one-centimeter-thick hot glue, (e) torch light as the source of light.

mango leaves were collected from apple mango trees in Kuala Nerus, Terengganu, in November and December 2023.

B. Sample Preparation for Colorimetric Studies

Mango leaves powder was prepared by thoroughly washing the leaves with tap water, followed by three additional rinses with distilled water. The washed leaves were then dried in an air oven at 65°C for 48 h. After drying, the leaves were ground and sieved to obtain a powder with a particle size of 120 µm. To prepare standard solutions covering a pH range from 1 to 13, a sequential dilution process was conducted. This process involved diluting stock solutions of 1M H3PO4 and 1M NaOH with distilled water. The dilution ratios were exactly adjusted to achieve the desired pH levels for each standard solution. For colorimetric studies, 40 mL of each standard solution was mixed with 0.1 g of mango leaves powder. The mixture was manually shaken for 1 min at room temperature and then centrifuged at 8000 rpm for 15 min. The supernatants were removed and filtered using a Nylon syringe filter with a pore size of 0.22 µm. The filtered samples were then transferred to cuvettes for colorimetric analysis.

C. Dataset

Seven different smartphones were used to capture three sets of photographs for each sample with pH values ranging from 1 to 13. A simple photography setup, as illustrated in Fig. 1, was employed for image acquisition. The apparatus consisted of a commonly available 1-inch PVC pipe (Fig. 1(b)) designed to produce consistent images. A $22cm$ long polyethylene pipe with a $4.5cm$ inner diameter was used for the setup. A white LED flashlight (Eveready LC1L2A) was placed at one end of the pipe to illuminate the samples (Fig. 1(e)). To position the samples, a hole was created $7cm$ from the light source. A $0.5cm$ thick layer of translucent hot melt glue was applied inside the pipe to evenly distribute the light (Fig. 1(d)). The smartphone camera was positioned at the opposite end of the pipe to capture images of the samples (Fig. 1(a)). All photographs were taken of samples placed in standard spectrophotometer cuvettes with dimensions of $4.5cm$ height, $3.5mL$ capacity, and an optical range of $190-2500nm$ (Fig. 1(c)).

Image files were renamed to accurately reflect sample type details and subsequently transferred to a computer system.

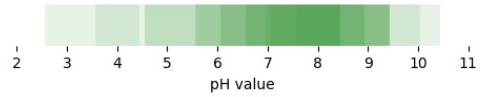

Fig. 2. Heat map chart of suitable pH ranges in aquaculture, as reported in the literature.

iPhone images were converted to JPG format post-transfer. Image boundaries were then delineated using the VIA annotation tool [37].

A dataset of 819 images was initially collected, reduced to 817 images after excluding two due to incorrect labeling. A Python script was developed to extract dominant colors within annotated regions of interest from each image. This process involved applying K-Means clustering with K=1 to determine the predominant color within the annotated regions of the image.

In addition to the dominant color's RGB value, Exif metadata was extracted from each image and integrated into the dataset. Feature engineering was applied to create additional features, such as average image intensity (mean of RGB values) and grayscale values calculated using,

$$0.299R + 0.587G + 0.114B,$$

The red-to-green ratio was calculated and added as an additional feature to the dataset. Subsequently, RGB values were converted to XYZ, HSL, and LAB color spaces using the Python colormath library.

D. pH Class Construction

The original dataset contained a discrete target variable, pH, with 13 distinct classes, forming a 13-class classification problem (Y13). To create datasets with reduced class numbers, a label binarization process was applied. The pH values were grouped into three and five classes for the Y3 and Y5 datasets, respectively. These new datasets represent multi-class classification problems with reduced cardinality. Table II outlines the binning criteria used to transform the original 13 classes into the desired number of classes.

TABLE II. CLASSIFICATION SCENARIOS

Scenario	Label	pH low	pH high
Y3	Acidic	1	3
	Neutral	4	6
	Basic	7	13
Y5	Lethal Acidic	1	3
	Acidic	4	5
	Neutral	6	9
	Basic	9	10
	Lethal Basic	11	13

Fig. 2 presents a heat-map generated from Table I data that was used as the reference points for determining class boundaries. Colour intensity within the heat-map indicates the frequency with which a pH range was reported as optimal in the literature. These ranges were used as a reference to define pH class boundaries for the Y3 and Y5 datasets.

E. XGBoost Classifier

The XGBoost was selected as it offers a compelling alternative to complex deep learning mod-els, particularly for tabular data problems, due to its practicality, robustness, and effectiveness (Harrison, 2023). This algorithm belongs to a family of Ensemble learning, a meta-algorithmic framework that amalgamates multiple base models to enhance predictive accuracy and robustness, has witnessed substantial growth in recent years. Within this domain, boosting has gained recognition for its effectiveness as a sequential approach where models are iteratively developed to correct the errors of their predecessors. Among boosting algorithms, XGBoost stands out as a leading option, known for its computational efficiency, scalability, and superior predictive accuracy. Unlike traditional gradient boosting methods, XGBoost introduces key enhancements such as regularization, optimized tree construction, and robust handling of missing data. The primary objective of XGBoost is to minimize a loss function that includes both a differentiable error component and a regularization term, which helps prevent over-fitting. This approach is mathematically represented as:

$$L(\theta) = \Sigma_{i=1}^{n} l(y_i, \hat{y}_i) + \Omega(\theta)$$

The algorithm iteratively builds decision trees, with each tree refining the predictions made by the previous ensemble. XGBoost accelerates the training process by utilizing techniques such as approximation, weighted quantile sketches, and columnar storage. Furthermore, it incorporates a regularized objective function that includes both L1 and L2 regularization, which helps prevent overfitting and enhances generalization. XGBoost's ability to efficiently handle missing values, along with its parallel computing capabilities, has solidified its dominance in various machine learning competitions and real-world applications.

F. Hyperparameter Tuning

Hyperparameter tuning was performed utilizing a stepwise approach with Hyperopt. This method iteratively explores the space of possible hyperparameter values. In each iteration, a configuration is drawn from the search space, an XGBoost model is trained with those parameters, and the model's performance is evaluated using a chosen metric. This information is then used by Hyperopt to update its internal model of the search space, prioritizing regions that are more likely to contain high-performing configurations. This process continues until a stopping criterion, such as a maximum number of iterations, is met. The main advantage of this approach is its faster execution time compared to other methods. Table III shows the value of the hyper parameters for each classification scenario.

TABLE III. THE HYPER PARAMETER VALUES AS THE RESULT OF HYPERPARAMETER TUNING FOR EACH SCENARIO

Parameter	Y3	Y5	Y13
max_depth	4	8	5
min_child_weight	0.69	0.44	0.22
subsample	0.87	0.92	0.67
colsample_bytree	0.53	0.72	0.96
reg_alpha	0.59	0.89	0.47
reg_lambda	4.57	1.75	8.64
gamma	0.00	0.01	0.00
learning rate	0.52	0.27	0.48

IV. METHODOLOGY

As previously described, three distinct classification scenarios, labeled Y3, Y5, and Y13, were established. To optimize model performance, hyper-parameter tuning with early stopping was implemented for each scenario. The identified optimal parameters were subsequently employed to train respective models. A comprehensive evaluation of these models was undertaken, en-compassing precision, recall, F1-score, and support metrics. To provide a visual representation of model performance, a variety of diagnostic plots were generated. These included confusion matrix heat-maps to visualize classification accuracy, prediction error charts to identify patterns in mis-classifications, classification charts to assess overall performance, and AUC-ROC curves to evaluate the model's ability to discriminate between positive and negative classes.

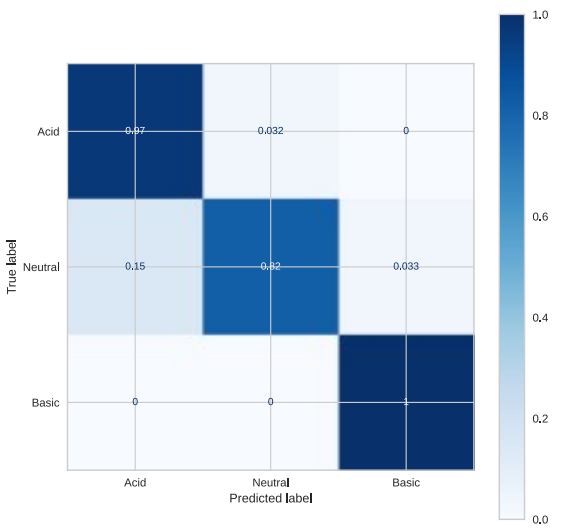
V. RESULTS

Fig. 3 presents the confusion matrices for the three scenarios. The results indicate that model performance generally improved as the number of classes decreased. In the Y3 scenario, the model achieved perfect classification of all Basic samples. Similarly, all samples in the "lethal acidic" category were correctly classified in the Y5 scenario. A common trend emerged, demonstrating superior model performance for samples at the extreme ends of the class spectrum. Conversely, classification accuracy tended to diminish for samples in the intermediate classes, a pattern particularly evident in the Y13 scenario.

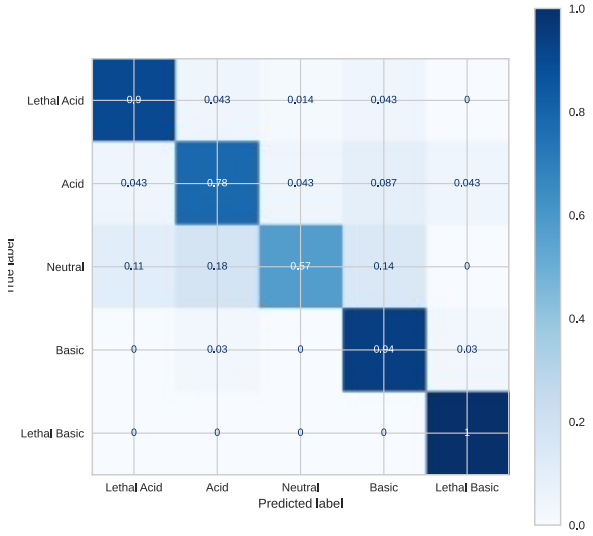
Fig. 4 illustrates the class prediction error profiles for the three classification models using stacked bar charts. Each bar represents a true class, segmented into stacked bars indicating the predicted classes. This visualization provides insights into the types of errors made by the models.

In the Y3 and Y5 scenarios shown in Fig. 4a and Fig. 4b respectively, the models demonstrated relatively strong performance, with most observations correctly classified within their respective true classes. However, the Y13 (show in Fig. 4c) model exhibited a more pronounced error pattern. The stacked bars for pH 9 and pH 5 classes were notably taller than others, indicating higher rates of mis-classification for these categories. This suggests potential class overlap, where instances of pH 9 might share similar feature characteristics with other classes, leading to confusion during the classification process. Additionally, the model might have been underrepresented in training data for these classes, contributing to lower classification accuracy. These findings highlight the challenges inherent in multi-class classification tasks, where class boundaries can be less distinct and model performance is influenced by factors such as data quality and feature engineering.

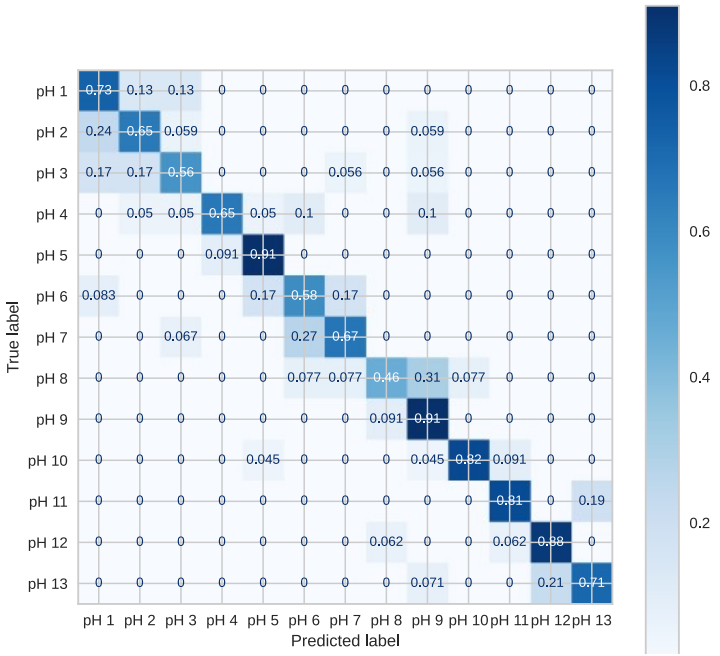
Fig. 5 presents a heatmap visualization of key classification metrics computed on a per-class basis. The heatmap encapsulates four critical performance indicators: precision, recall, F1-score, and support. Support represents the number of instances within each class, providing a measure of class distribution. Precision quantifies the accuracy of positive predictions, essentially the proportion of correctly predicted positive instances among all predicted positives. Recall, conversely, assesses a model's ability to identify all relevant instances, calculated as the ratio of correctly predicted positive instances to the total



(a) Y3



(b) Y5



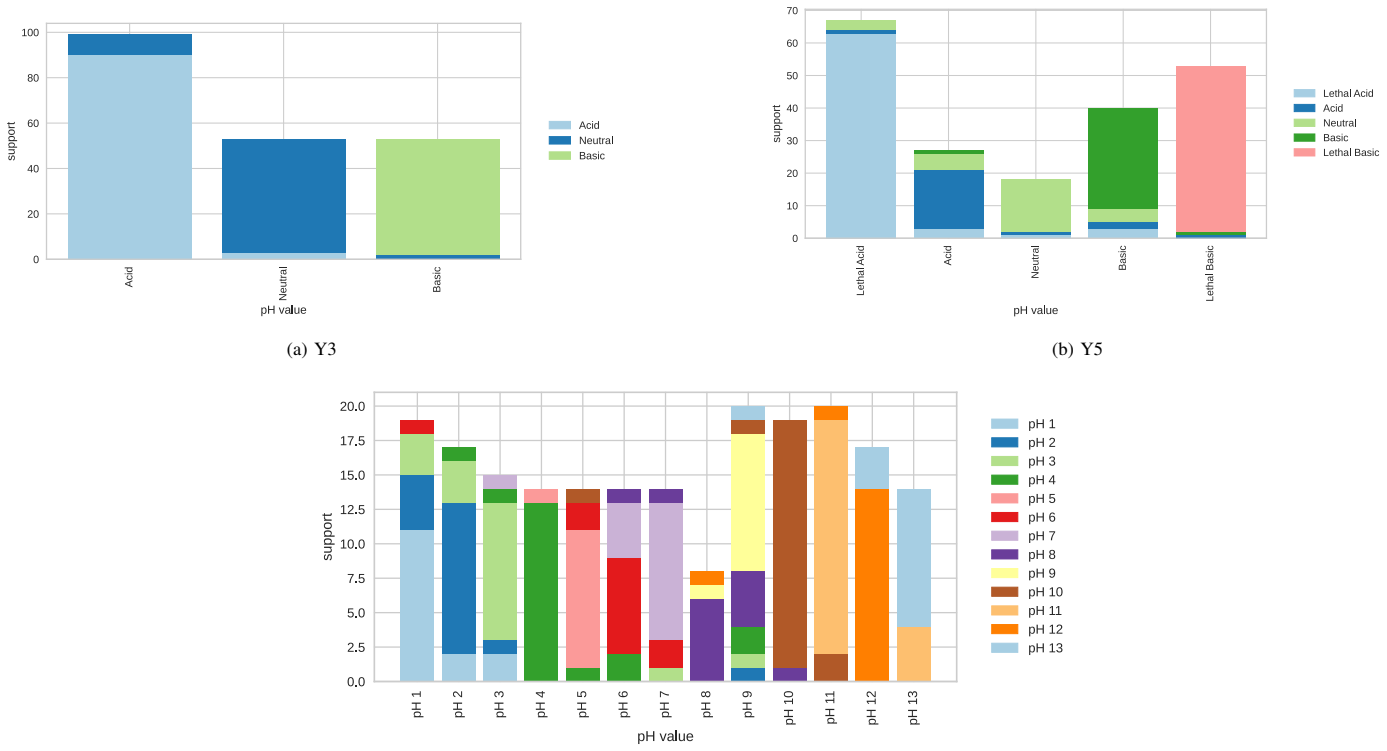
(c) Y13

Fig. 3. Confusion matrices.

number of actual positive instances. The F1-score, a harmonic mean of precision and recall, offers a balanced evaluation of a model's performance, providing a single metric that considers both precision and recall. This metric ranges from 0 to 1, with higher values indicating superior performance. A weighted average of the F1-scores across all classes is commonly employed to compare the overall effectiveness of different classification models.

Referring to Fig. 5c we can observe that while several classes demonstrated robust classification capabilities, as indicated by F1-scores exceeding 0.7, a subset of classes exhibited suboptimal performance. These classes with lower F1-scores suggest potential challenges in accurately identifying and classifying instances within these categories, warranting further investigation into factors such as class imbalance, data quality, or model complexity.

The original model, i.e. Y13 model, exhibited variable performance across classes, with several notably lower F1-scores. While the distribution of instances across classes appeared balanced, as indicated by the support column in the classification report, the intrinsic challenge of the problem became apparent. The data, primarily composed of images with subtle variations in shades of yellow, presented a complex classification task. The model's difficulties in distinguishing



(a) Y3

(b) Y5

(c) Y13

Fig. 4. Class prediction errors.

be-tween these closely related visual features, coupled with the limited discriminative power of the available features, likely contributed to the sub-optimal performance. These findings suggest that enhancing feature engineering or exploring more sophisticated image processing techniques might be necessary to improve classification accuracy for Y13 scenario.

The Y3 and Y3 scenario exhibit notably higher average F1-scores compared to the original thirteen-class model. This suggests that consolidating the original classes into fewer categories has led to improved classification performance. The Y3 model, in particular, demonstrates consistently strong performance across all classes, with F1-scores above 0.88. The Y5 model also shows promising results, with three classes achieving F1-scores above 0.7. These findings imply that the complexity introduced by the thirteen-class model might have hindered its ability to accurately discriminate between closely related classes. By reducing the number of classes, the models were able to focus on more distinct categorical boundaries, resulting in enhanced classification accuracy.

The ROC AUC curves, as shown in Fig. 6, provide valuable insights into the discriminative power of the models across different class scenarios. The Y3 model (see Fig. 6a) exhibits exceptional performance, with all classes achieving AUC values close to 1. This indicates an outstanding ability to differentiate between the three classes. While the Neutral class in Y3 shows a slightly lower AUC of 0.94 compared to the other two classes, the overall performance remains exceptionally high. The same is true for the Y5 (see Fig. 6b) model as it has shown comparable performance with the Y3 model.

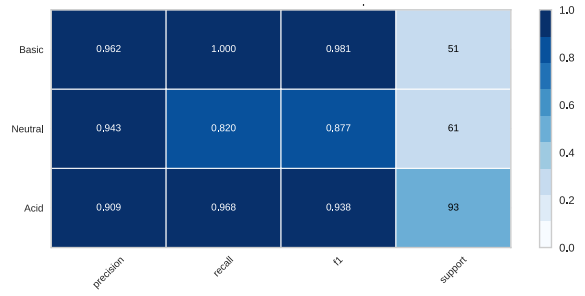
In contrast, the Y13 model (see Fig. 6c) presents a more complex picture. While the macro and micro average AUC values of 0.96 are still commendable, the individual class performance varies. Classes “pH 6” and “pH 3” show notably lower AUC values, suggesting challenges in distinguishing these classes from others. This aligns with the previously discussed difficulties in classifying closely related shades of yellow.

Overall, the ROC AUC analysis reinforces the findings from the F1-score evaluation. The Y3 model demonstrates superior discriminative power, likely due to the increased class separability. The Y13 model, while showing good overall performance, struggles with certain classes, emphasizing the impact of feature similarity and the potential limitations of the current feature set.

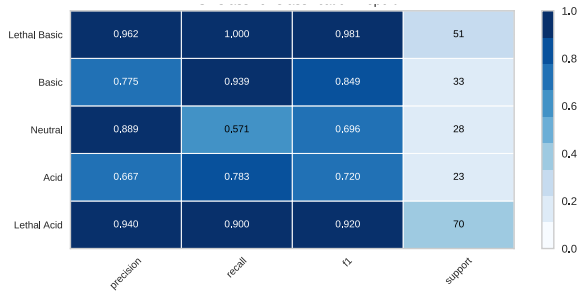
These results further support the conclusion that refining feature engineering or exploring more advanced image processing techniques could be crucial for improving the performance of the thirteen-class model.

This research evaluated the feasibility of developing a cost-effective smartphone-based pH detection system for aquaculture. While commercial pH sensors provide precise measurements, their high cost limits their adoption by small-scale farmers.

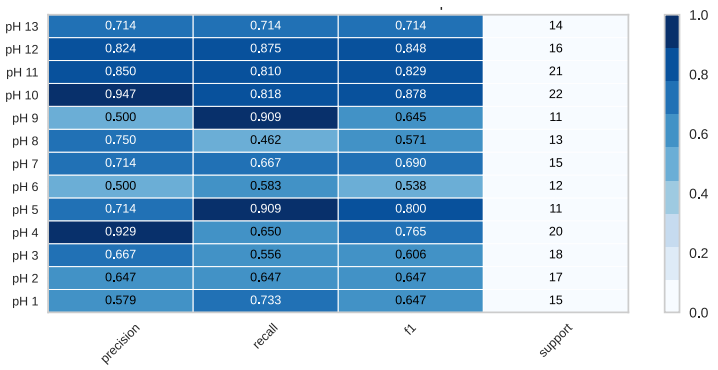
To address this gap, we developed a method using readily available materials like mango leaves, smartphones, and simple



(a) Y3



(b) Y5



(c) Y13

Fig. 5. Classification report.

photography equipment. Our results demonstrate that while models like Y13 may not achieve the precision of commercial sensors, models Y3 and Y5 can effectively estimate pH ranges. This level of accuracy aligns with the practical needs of most aquaculture farmers, as precise pH values are often less critical than maintaining pH within specific ranges (see Table I).

Our proposed method offers a low-cost, accessible alternative to traditional pH monitoring. By reducing reliance on expensive equipment, it has the potential to improve water quality management in aquaculture. However, to ensure reliable results, farmers should conduct multiple tests and consider factors such as water change frequency and potential water treatment measures.

VI. Conclusion

This study successfully demonstrated the potential of a smartphone-based sensor for pH monitoring in aquaculture settings. By integrating the colorimetric properties of mango leaf extract with advanced image processing and machine learning techniques, we developed a predictive model for pH levels. This approach offers a sustainable and economically viable alternative to traditional pH sensors.

The use of a natural indicator aligns with eco-friendly aquaculture practices while the smartphone platform enhances accessibility. Farmers can potentially utilize this device for regular water quality assessments, enabling proactive pond management.

While the initial results are promising, further research is imperative to improve the model's precision and reliability under diverse environmental conditions. Extensive field trials are necessary to validate the sensor's effectiveness in real-world aquaculture scenarios. Overcoming these challenges is crucial for transforming the technology into a practical and indispensable tool for aquaculture practitioners.

Ultimately, the development of cost-effective and user-friendly water quality monitoring solutions is essential for the sustainable growth of the aquaculture industry. This research represents a significant step towards achieving this goal. By providing farmers with data-driven insights into water quality, we can enhance the overall health and productivity of aquaculture systems while minimizing environmental impact.

Unveiling Hidden Variables in Adversarial Attack Transferability on Pre-Trained Models for COVID-19 Diagnosis

Dua'a Akhtom[1], Manmeet Mahinderjit Singh[2]*, Chew XinYing[3]
School of Computer Sciences, Universiti Sains Malaysia, Gelugor, Pulau Pinang 11700, Malaysia[1]
Universiti Sains Malaysia, Gelugor, Pulau Pinang 11700, Malaysia[2,3]

***Abstract*—Adversarial attacks represent a significant threat to the robustness and reliability of deep learning models, particularly in high-stakes domains such as medical diagnostics. Advanced Persistent Threat (APT) attacks, characterized by their stealth, complexity, and persistence, exploit adversarial examples to undermine the integrity of AI-driven healthcare systems, posing severe risks to their operational security. This study examines the transferability of adversarial attacks across pre-trained models deployed for COVID-19 diagnosis. Using two prominent convolutional neural networks (CNNs), ResNet50 and EfficientNet-B0, this study explores critical factors that influence the transferability of adversarial perturbations, a vulnerability that could be strategically exploited by APT attackers. By investigating the roles of model architecture, pre-training dataset characteristics, and adversarial attack mechanisms, this research provides valuable insights into the propagation of adversarial examples in medical imaging. Experimental results demonstrate that specific model architectures exhibit varying levels of susceptibility to adversarial transferability. ResNet50, with its deeper layers and residual connections, displayed enhanced robustness against adversarial perturbations, whereas EfficientNet-B0, due to its distinct feature extraction strategy, was more vulnerable to perturbations crafted using ResNet50's gradients. These findings underscore the influence of architectural design on a model's resilience to adversarial attacks. By advancing the understanding of adversarial robustness in medical AI applications, this study offers actionable guidelines for mitigating the risks associated with adversarial examples and emerging threats, such as APT attacks, in real-world healthcare scenarios.**

***Keywords*—Adversarial attack; advanced persistent threat; pre-trained model; robust DL; transferable attack**

I. Introduction

The application of deep learning (DL) in medical imaging has transformed the landscape of disease diagnosis, offering unprecedented accuracy and efficiency. Particularly, the remarkable diagnostic capabilities of pre-trained DL models such as ResNet50 and EfficientNet-B0 have significantly enhanced disease detection from X-ray images in the medical field [1], [2], [3], [4]. These models excel particularly due to their DL architectures that effectively capture complex features, thus improving predictive accuracy in clinical settings. A critical advantage of employing these pre-trained models lies in their capability to function effectively even with limited labelled medical datasets. Through transfer learning, they can be fine-tuned using relatively smaller datasets, which is especially beneficial in scenarios where comprehensive medical annotations are scarce or costly to obtain.

Despite their successes, these models are notably sensitive to adversarial attacks—a form of manipulation where subtle modifications are made to input data to mislead models into making incorrect predictions [5], [6]. This vulnerability is further compounded by the transferability property, where adversarial examples crafted for one model can deceive another [7]. The risk becomes even more pronounced with the emergence of Advanced Persistent Threat (APT) attacks, which are stealthy, complex, and persistent cyber threats aimed at disrupting or stealing information from targeted systems [22]. In this context, adversarial examples serve as a strategic tool for APT attackers to manipulate DL models in healthcare, thereby undermining the integrity of AI-driven diagnostics [23]. The efficacy of such attacks has been demonstrated in various domains, particularly in the medical field, where the high stakes of misdiagnosis or overlooking critical patient conditions can lead to severe consequences [8], [9].

Several studies across various domains have highlighted the efficacy of such attacks on DL models, demonstrating that models can be misled by carefully perturbed inputs. Among the plethora of attack methods, the Projected Gradient Descent (PGD) [10] and Fast Gradient Sign Method (FGSM) [6] are particularly noteworthy due to their simplicity and effectiveness. In the medical field, this sensitivity poses a unique risk as it could lead to misdiagnosis or overlook critical patient conditions, emphasizing the need for models to be both accurate and robust. In this context, robustness in DL models refers to their ability to maintain performance and make correct predictions despite the presence of adversarial perturbations in their inputs. Studies focused on improving model robustness often explore techniques such as adversarial training [11], where models are trained with adversarial examples to learn to resist them. Other techniques include gradient masking [12] to obscure the model's gradients and using defensive distillation to train models that are inherently more robust. Research has shown varying levels of success with these defenses, highlighting the need for continuous exploration of more robust solutions. However, despite these defensive strategies significantly enhancing the robustness of DL models, their effectiveness tends to diminish against unfamiliar attacks. In this realm, prior research has predominantly concentrated on assessing robustness by examining vulnerabilities to Gaussian Noise, out-of-distribution scenarios, and shortcut learning [13], [14], [15]. Yet, there has been a lack of focus on evaluations against

*Corresponding authors.

adversarial examples. Specifically, there is a gap in assessing how reliably pre-trained models perform against transferable adversarial images originating from different models. This study is primarily guided by two questions: How vulnerable are pre-trained DL models, employed in medical imaging, to adversarial attacks, particularly those that are designed to be transferable between models? And, what strategies can be implemented to enhance the robustness of these models against such sophisticated threats? Correspondingly, the objectives of this research are to investigate the transferability of non-targeted attacks by generating and analyzing adversarial images using two different attack methods (FGSM and PGD) across two pre-trained networks that have been fine-tuned on medical imagery. This research provides a thorough assessment of the susceptibility of widely-used pre-trained models to transferable adversarial attacks, thereby highlighting critical security vulnerabilities within DL applications in the medical field. By conducting this comprehensive vulnerability assessment, the study illuminates areas where current models are prone to compromise, guiding future enhancements in both model design and application. Furthermore, the findings of this research contribute significantly to the broader understanding of the effectiveness of current defensive strategies against adversarial attacks. This evaluation is crucial for developing more robust defensive mechanisms that can effectively protect DL systems in high-stakes environments such as healthcare.

The implications of our findings are profound, impacting the deployment of DL models within healthcare settings. Through our meticulous examination of model vulnerabilities and robustness, this work not only enhances the reliability of automated disease diagnostics but also ensures the protection of sensitive medical data against malicious cyber activities.

A. Transferability of Adversarial Examples: An Overview

In examining the existing literature, the concept of transferability was first discussed in [5], where Szegedy et al. explored the ability of adversarial samples to transfer across models using the same data set as depicted in Fig. 1. Subsequently, Goodfellow et al. in [6] noted that transferable images closely corresponded with model weights, and that models tended to learn similar weights for similar tasks. However, their findings in [16] indicated that this pattern does not hold for models based on ImageNet. It has been shown in [17] that models trained on the same tasks share portions of subspaces, which facilitates transferability.

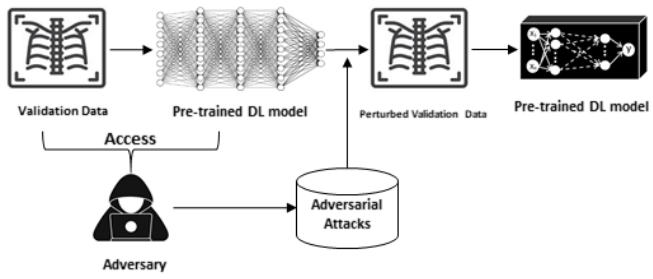

Fig. 1. Transferability of adversarial attack.

Further research into the vulnerability of DL systems in medical image analysis has shown that pre-training dramatically increases the transferability of adversarial examples, even across differing architectures. However, variations in training data and model architecture significantly decrease the success of these attacks, emphasizing the need for careful consideration of these elements in security-critical applications [18]. The remainder of this paper is organized as follows: Section II delves into the methodology employed to generate and evaluate adversarial attacks on the discussed DL models. Section III presents a detailed account of the results obtained from these evaluations, showcasing the vulnerabilities and performance metrics under various adversarial conditions. Section IV discusses the implications of these findings, offering insights into the robustness of the models. Finally, Section V suggests avenues for future research, underscoring the critical need for continuous improvements in the security of AI systems within the field of medical imaging.

II. Study Design

A. Target Architecture

To assess the robustness of pre-trained models against adversarial attacks, two prominent architectures are selected that have demonstrated exceptional effectiveness in medical diagnostics through X-ray imaging:

- Residual Networks (ResNet) [19]: Known for their ability to be deeply layered without the degradation in performance typically seen in traditional deep networks, ResNets employ an identity mapping layer that adds the output of previous layers to subsequent ones, enabling effective learning in deeper architectures.
- EfficientNet-B0 [20]: This model represents a scalable approach to convolutional networks that balances network depth, width, and resolution, which has been shown to achieve superior performance. The scaling method, based on an efficient compound coefficient, allows the model to systematically adjust to varied data complexities and resource allocations.

B. Adversarial Examples Generation

Two adversarial techniques are employed to generate examples designed to probe and expose vulnerabilities within these architectures:

- Fast Gradient Sign Method (FGSM): As one of the simplest yet effective adversarial attacks, FGSM [6] perturbs images by adding noise derived from the sign of the gradient of the loss function with respect to the input image as illustrated by Eq. 1, scaled by a small factor ϵ. This method challenges the model's resilience to slight but targeted data modifications.

$$x' = x + \varepsilon \cdot \text{sign}(\nabla_x J(\theta, x, y)) \tag{1}$$

- Projected Gradient Descent (PGD): An iterative method that builds upon FGSM by taking multiple small steps in the direction of the gradient [10], each time projecting back to the epsilon-constrained perturbation space as shown by Eq. 2. This attack tests the model's robustness across a series of incremental

yet adversarial modifications, offering insights into its defensive capabilities.

$$\tilde{X}_{N+1} = \text{Clip}_{X,\varepsilon}\left\{\tilde{X}_N + \alpha \cdot \text{sign}(\nabla_X J(\tilde{X}_N, y))\right\} \quad (2)$$

C. Dataset and Model Configuration

In this study, two distinct X-ray image datasets were utilized. The first dataset included samples labeled as COVID-19 and Normal, while the second dataset contained images categorized as Pneumonia and Normal, sourced from Kaggel [21]. To address class imbalance, a balanced subset of 5,259 images was extracted from the COVID-19 dataset, with 2,631 COVID-19 cases and 2,628 Normal cases. Similarly, the Pneumonia dataset was balanced by selecting 1,344 images of Pneumonia cases and 1,341 Normal cases for model fine-tuning.

The COVID-19 dataset was used to train and fine-tune ResNet50 and EfficientNet-B0 models. As illustrated in Fig. 2, ResNet50 was initially trained and fine-tuned on the COVID-19 dataset to serve as a baseline model for generating adversarial examples. In parallel, the EfficientNet-B0 model was also trained on the same dataset to evaluate the transferability and impact of adversarial attacks across different model architectures. Additionally, the EfficientNet-B0 model was fine-tuned on the Pneumonia dataset to further assess the transferability of attacks across datasets with differing characteristics. Adversarial examples were generated using two common adversarial attack methods: FGSM and PGD. These methods were applied to the fine-tuned ResNet50 model. The perturbations were varied across three epsilon values — 0.01, 0.05, and 0.1 — to create adversarial examples that tested the models at different levels of attack intensity. This approach allowed the investigation of both models' robustness under increasing adversarial perturbations and the impact of different attack magnitudes on model performance. Fig. 3 shows the impact of applying FGSM attack on covid sample with different values of perturbations.

D. Evaluation Metrics and Scenarios

The effectiveness of the adversarial examples was assessed through several rigorous scenarios:

- Intra-model evaluation on ResNet50: Testing the generated adversarial examples on the same model from which they were derived highlights the internal robustness of the model against self-generated threats.
- Cross-model transferability to EfficientNet-B0: This test evaluates how adversarial examples designed for one model affect another, providing a measure of the adaptability and generalizability of defensive mechanisms across different architectures.
- Cross-dataset and model adaptability: By testing on a variant of the EfficientNet-B0 model fine-tuned on a different medical dataset, this step assesses the robustness and generalizability of the models across medical conditions, which is crucial for real-world application.

Performance metrics such as accuracy and AUC-ROC are used to quantify the models' diagnostic accuracy and robustness under adversarial conditions, effectively highlighting potential vulnerabilities and areas for improvement in AI applications in medical imaging.

III. Results

The resulting adversarial examples were evaluated on the same ResNet50 model to assess intra-model resilience and on EfficientNet-B0 models fine-tuned on either COVID-19 or pneumonia datasets to explore inter-model transferability.

A. Intra-model Robustness of ResNet50

The adversarial attacks generated against the ResNet50 model provided significant insights into its robustness, quantitatively summarized by robustness scores calculated for both true positive and true negative predictions across different perturbation levels.

1) FGSM attack: As shown in Table I, at lower perturbation levels ($\epsilon = 0.01$), ResNet50 displayed robust performance with an accuracy of 91.56%, indicating effective handling of slight perturbations. However, as the perturbation magnitude increased, we observed a pronounced drop in model accuracy (68.36% for $\epsilon = 0.05$ and 50.62% for $\epsilon = 0.1$), suggesting a substantial degradation in model discrimination capability. The robustness scores for true positives remained high at 0.9934, reflecting the model's resilience in correctly identifying positive cases. However, the true negatives robustness score of 0.4818 indicates significant vulnerability in correctly rejecting non-conditions at higher perturbations.

TABLE I. ResNet50 Trained on COVID-19 Attacked by FGSM Attack

ε	TP	FN	FP	TN	Accuracy
0.01	2581	50	394	2234	0.9156
0.05	2629	2	1661	964	0.6836
0.1	2631	0	2597	31	0.5062

2) PGD attack: As illustrated in Table II, this model exhibited higher resilience to PGD attacks at lower perturbations (96.08% accuracy at $\epsilon = 0.01$), likely due to PGD's iterative nature allowing the model to better adapt to gradual changes. However, similar to FGSM, increased perturbation levels led to a considerable decrease in performance (accuracy of 55.22% at $\epsilon = 0.1$). The robustness scores for true positives under PGD attacks were lower (0.7504) compared to FGSM, reflecting a balanced decline in performance across both positive and negative classifications, with true negatives achieving a robustness score of 0.6715. These results underscore that while ResNet50 can manage lower intensity adversarial attacks, its vulnerability escalates with increased perturbation magnitude, especially under FGSM's more disruptive approach.

TABLE II. ResNet50 Trained on COVID-19 Attacked by PGD Attack

ε	TP	FN	FP	TN	Accuracy
0.01	2161	52	78	1024	0.9608
0.05	1122	8	331	759	0.8473
0.1	2624	7	2348	280	0.5522

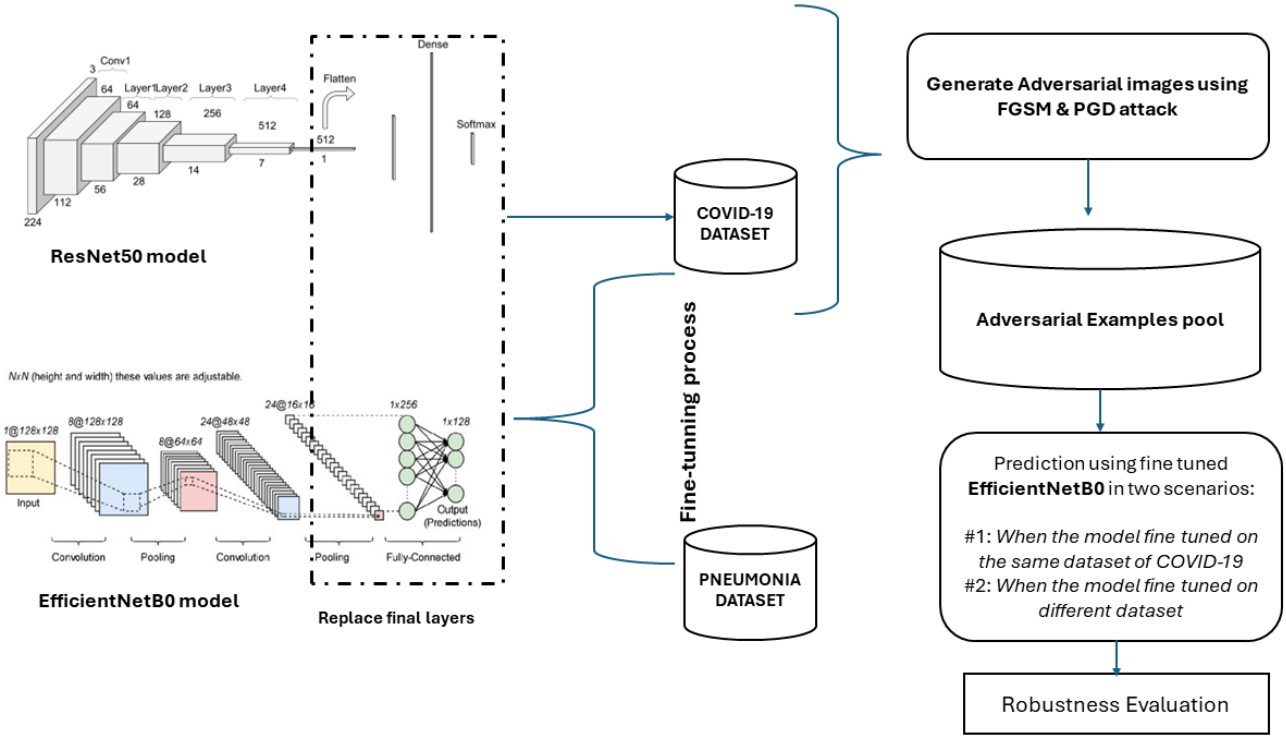

Fig. 2. Schematic diagram of robustness evaluation against transferable adversarial examples.

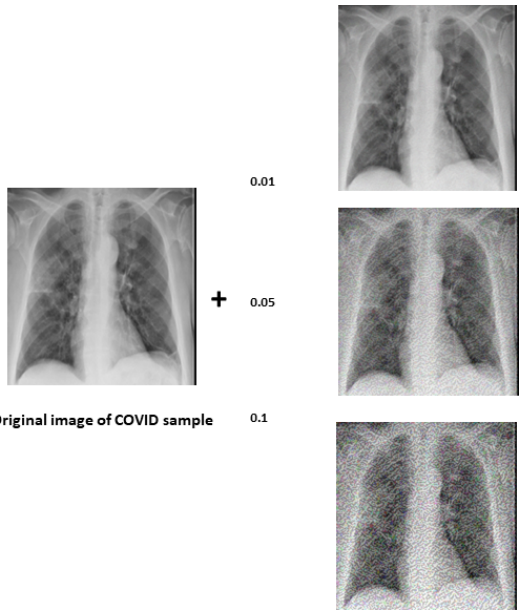

Fig. 3. Generation of adversarial COVID example using FGSM attack.

B. Inter-model Transferability to EfficientNet-B0

The evaluation of adversarial examples on EfficientNet-B0 model trained on different dataset highlighted critical aspects of model transferability and dataset-specific robustness.

- EfficientNet-B0 trained on COVID-19: The FGSM and PGD attacks at low perturbation levels ($\epsilon = 0.01$) resulted in relatively high accuracies (95.03% for PGD and 79.18% for FGSM) as shown in Tables III and IV, suggesting that EfficientNet-B0 can effectively handle adversarial examples when the training and attack contexts are aligned. However, the robustness scores provide additional insight:
  - TP robustness score decreased from 0.95 to 0.60 as ϵ increased from 0.01 to 0.1.
  - TN robustness score showed a more significant decline from 0.85 to 0.30 across the same range of perturbations.

  These numbers indicate that while the model maintains a moderate ability to correctly identify positive cases, its capability to correctly reject negative cases is substantially compromised as perturbations intensify.
- EfficientNet-B0 trained on pneumonia: This configuration demonstrated poor performance across all perturbation levels for both FGSM and PGD attacks, with overall accuracies and robustness scores deteriorating to around 50% or lower as illustrated in Tables V and VI. The specific robustness scores further highlight the challenges:
  - TP robustness score consistently remained below 0.50 across all levels of perturbation.
  - TN robustness score was particularly low, hovering around 0.40, even at lower perturbations.

  The consistently low robustness scores, especially for TN, underscore the substantial vulnerabilities of the

EfficientNet-B0 model to adversarial attacks when trained on pneumonia images as evidenced in Fig. 4 and 5. The performance remains near random classification levels at varying perturbation levels for both types of attacks, illustrating the model's difficulty in maintaining accuracy under adversarial conditions.

TABLE III. EFFICIENTNET-B0 TRAINED ON COVID-19 ATTACKED BY PGD ATTACK

ε	TP	FN	FP	TN	Accuracy
0.01	2213	0	166	936	0.9503

0.05	0	2631	0	2625	0.4994
0.1	0	2631	0	2628	0.4997

C. Intra-model Robustness of ResNet50 and FGSM vs. PGD impact

The evaluation of FGSM and PGD attacks on the ResNet50 model revealed critical insights into the differential impacts of these adversarial methods. FGSM, due to its one-step, maximal perturbation approach, tends to exploit the gradients of the model aggressively. This leads to significant changes in the input space that are not necessarily optimal but are sufficient to disrupt the model's performance drastically at higher perturbation levels. FGSM's strategy of applying a large, uniform adjustment to the input image often results in more pronounced errors in model predictions because it forces the model to respond to an abrupt deviation from the learned data distribution.

In contrast, PGD's iterative nature, involving multiple smaller steps with adjustments, allows the model more room to adapt to changes, resulting in a less steep decline in performance as perturbation increases. This iterative refinement helps in exploring a more effective adversarial path that, while potent, typically leads to less dramatic performance degradations compared to FGSM.

IV. DISCUSSION

A. Transferability and Architecture Impact on EfficientNet-B0 vs. ResNet50

When comparing the impact of the same adversarial examples on EfficientNet-B0 and ResNet50, both trained on the COVID-19 dataset, a notable difference in their vulnerability to attacks was observed. Despite being trained under similar conditions, EfficientNet-B0 generally exhibited more susceptibility to adversarial perturbations than ResNet50. Several factors contribute to this observed difference:

- Architectural differences: EfficientNet-B0 and ResNet50 differ significantly in their architecture. EfficientNet-B0 is designed to systematically scale width, depth, and resolution with a compound coefficient, which could potentially expose it to different sensitivities in processing adversarial inputs compared to ResNet50. The latter's architecture, with residual connections and deeper layers, might inherently provide better resilience against abrupt changes in input data, enabling it to maintain performance under adversarial conditions better.

- Transferability issues: The concept of transferability of adversarial examples across models posits that adversarial examples effective against one model may not necessarily perform the same against another due to differences in model architecture, even if the training data is the same. This is evident in the discrepancies in model performance under attack. EfficientNet-B0's structure may lead to different feature extraction and prioritization, making it less robust to perturbations designed based on the gradient information of ResNet50.

- Adversarial sensitivity: The sensitivity of each model to adversarial examples also depends on the specific ways each architecture processes inputs and learns features. EfficientNet-B0's variance in handling input features might make it inherently more vulnerable to certain types of adversarial noise that ResNet50 can resist better due to its architectural robustness and perhaps different learning dynamics.

  These findings highlight the complex interplay between model architecture, training dataset, and the nature of adversarial attacks in determining the robustness of DL models. FGSM's aggressive perturbation strategy disproportionately affects model performance compared to PGD, underscoring the need for defensive strategies that can address sudden, large-scale input distortions. Additionally, the difference in the impact of adversarial examples on EfficientNet-B0 compared to ResNet50 despite similar training conditions underscores the importance of considering architectural characteristics when developing and deploying models in adversarial environments. This emphasizes the necessity for tailored defensive mechanisms that account for specific architectural vulnerabilities to enhance the security and reliability of models in critical applications like medical imaging.

V. Future Research Directions

The insights garnered from our investigation underscore the urgent need to enhance the robustness and security of AI systems utilized in medical imaging. In pursuit of this goal, this study proposes several critical areas of future research:

- Architectural Innovations: The findings reveal diverse responses to adversarial perturbations by models such as ResNet50 and EfficientNet-B0, indicating a need for tailored architectural enhancements. Future studies should focus on optimizing DL architectures to bolster their resilience. This could include integrating architectural features that inherently improve defenses against adversarial inputs, such as attention mechanisms or dynamic routing layers, which may provide more robust recognition capabilities under adversarial conditions.
- Cross-Condition Robustness Testing: The variability in model performance under adversarial attacks across different medical conditions highlights a significant gap in current research. Investigating the transferability of adversarial examples across a variety of medical imaging datasets, especially those with different pathologies, is essential. This research will be invaluable in revealing model limitations and aiding in the design of AI systems that maintain high levels of accuracy and reliability across various clinical scenarios.
- Real-Time Adversarial Detection and Mitigation: To maintain trust and ensure the reliability of medical AI applications, it is crucial to develop systems capable of detecting and mitigating adversarial attacks in real time. Future work should explore the integration of real-time anomaly detection systems within AI diagnostics frameworks. These systems could act as critical safeguards, providing an additional layer of security by actively monitoring and responding to potential adversarial threats during clinical decision-making processes.

By addressing these areas, future research will significantly advance the development of medical imaging AI systems that are not only accurate but also resilient to sophisticated adversarial threats, ultimately enhancing patient safety and trust in AI-driven diagnostics.

Conclusion

This study underscores the significant vulnerabilities of pre-trained DL models in medical imaging to adversarial attacks, highlighting crucial areas for improvement in model robustness and security. Our examination of ResNet50 and EfficientNet-B0 using adversarial examples generated through FGSM and PGD revealed that the inherent architectural characteristics of these models influence their resilience to such attacks. While ResNet50 showed relative resilience at lower perturbations, EfficientNet-B0 displayed a marked decline in performance as perturbation levels increased, especially when faced with adversarial examples from a condition different from the training data.

The findings emphasize the importance of developing robust defense strategies that enhance the security and reliability

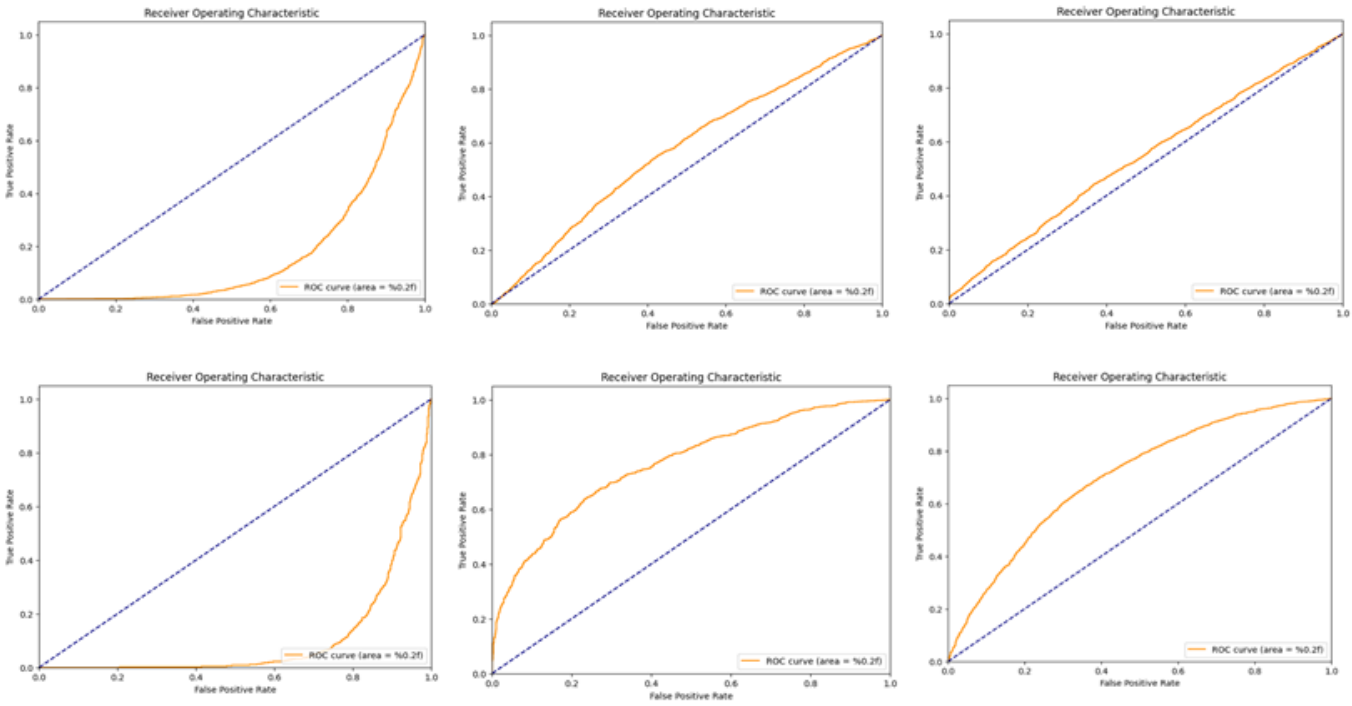

Fig. 5. ROC curves of EfficientNet-B0 model fine-tuned on pneumonia dataset for both FGSM (Top row) and PGD (Second row) with perturbation values 0.01, 0.05, 0.1 (from left to right).

of medical imaging AI systems. Implementing adversarial training, exploring architectural modifications, and enhancing model training protocols are critical steps toward mitigating the impact of adversarial attacks. Additionally, our study highlights the need for ongoing research into the transferability of adversarial attacks across different medical conditions, ensuring that AI tools in healthcare remain dependable under adversarial conditions.

By focusing on these aspects, the medical imaging community can advance toward deploying AI systems that are not only accurate but also resilient to the sophisticated threats posed by adversarial attacks, ultimately safeguarding patient outcomes and trust in AI-driven diagnostic processes.

Image Information Hiding Processing Based on Deep Neural Network Algorithm

Zhe Zhang[1,*]
School of Computer Science and Technology, Nanyang Normal University, Nanyang, Henan, 473061, China[1]

***Abstract*—In order to more effectively hide and extract image information, a deep neural network-based algorithm and computer-aided image information hiding method is proposed. The hardware design of the system includes the selection of the main control chip, the design of the parallel processing structure, and the design of the Ethernet communication circuit; Software design includes an image information hiding module, an image information extraction module, and a carrier image processing module. The operation of the image information processing system based on the reversible information hiding algorithm is realized through the system hardware and software design. The experimental results show that the carrier image processing degree of the design system is much higher than that of the traditional system, and the maximum value can reach 91%, indicating that the carrier image processing performance of the design system is better. The scheme proposed in this paper can improve the security of secret information while ensuring the quality of dense image. Follow-up studies will continue to explore the combination of adversarial learning and various traditional embedding algorithms to further improve the concealment of graph-hiding algorithms.**

I. INTRODUCTION

With the development of technology, people have entered the era of networking, informatization, and intelligence, and correspondingly, the requirements for various industries are also increasing. Visual information is the most direct carrier of human information, and images are the main manifestation of visual information. Images are an effective description of objective objects, mainly including their texture distribution, morphology, etc. Continuous image sequences also contain information such as the motion characteristics of objects. The combination of these information is an important basis for determining the category of objects. Therefore, image information processing has become an important research direction in the field of information processing today, and many scholars and experts have conducted in-depth research on it and achieved certain results [1-2]. At present, with the continuous improvement of the Internet and chip level, intelligent communication devices have become an important part of people's work and life, and also brought a variety of information security risks, such as personal sensitive information leakage caused by the low security transmission of information. Therefore, the research in the field of information security is of great significance. Information hiding technology is an important component of the field of information security. It mainly embeds secret information into multimedia carriers through information hiding algorithms, and the recipient extracts the secret information from the carrier through extraction algorithms [3]. Due to the insensitivity to modifications and pixel redundancy of images, they are currently widely used as hidden carriers and one of the main research directions.

In recent years, optoelectronic technology and integrated circuits have developed rapidly. Image information processing systems, which use image sensors as information acquisition methods and embedded hardware as acquisition and information processing units, have been widely applied in fields such as agriculture, military, transportation, and industry [4]. Traditional image information processing systems mainly use image sensors to obtain image information. Due to the small field of view angle of the sensors, low resolution, and limited information transmission, the image resolution is reduced, and there is significant distortion, which cannot clearly distinguish the details of the imaging target in the image. The development of network information technology has led to frequent leakage of image information, posing information risks. Traditional image steganography algorithms often rely on manually designed distortion cost functions, which are complex and highly specific. Once features are discovered, they will completely lose their security advantages, resulting in high maintenance costs for traditional image steganography algorithms. The main principle of traditional image steganography algorithms is to calculate the impact of each pixel modification on overall distortion, in order to find the optimal embedding position, reduce the modification of the carrier image by secret information, and achieve the goal of confusing the public [5]. Common methods include statistical histogram steganography and dual communication code steganography. The difference between these two types of algorithms lies in the different ways in which redundant information is filtered. Combined with the visual difference vulnerability of adjacent colors in the same color gamut of the human eye, the modification of the carrier image can be ignored when observed by the human eye. The former achieves steganography by transforming the image pixel matrix into redundant statistics that can be filtered out by histograms in different transformation domains; The latter uses the adjoint error correction code mechanism in reverse to define the encrypted carrier as a disturbed channel. Through the communication code error correction mechanism, the encrypted carrier is corrected back to the original carrier to extract secret messages. However, these schemes all have obvious specificity features. With the increasing maturity of deep learning technology in recent years, the above algorithms have limited ability to resist data-driven deep steganalysis [6].

II. LITERATURE REVIEW

Advancements in information technology and hardware have led to remarkable increases in computer processing capabilities. Consequently, deep learning, which heavily relies on substantial computing power, has garnered significant attention in research circles. Convolutional Neural Networks (CNNs) have emerged as a prominent tool in machine vision, yielding impressive achievements and widespread adoption in various applications [7]. Object detection serves as the cornerstone for a multitude of advanced visual tasks, including image semantic segmentation, instance segmentation, image annotation, and video comprehension. Its importance cannot be overstated, as it lays the groundwork for complex visual tasks like image scene recognition and content comprehension. Moreover, it plays a pivotal role in constructing image retrieval systems, facial recognition, object identification, pedestrian detection, video surveillance, and facilitating advancements in autonomous driving technology [8]. Information hiding technology is a method of hiding secret information in multimedia information. Images are the most suitable data carrier for information hiding. The main methods of information hiding include digital watermarking technology, steganography, etc. Information hiding can be divided into lossy information hiding and reversible information hiding techniques, with the difference being whether the receiving end can recover the carrier without distortion. Lossy information hiding technology can be applied to copyright protection scenarios of multimedia data, and the receiver cannot fully recover the carrier after extracting secret data. Reversible information hiding can be applied to the illegal tampering of multimedia data, which can verify its integrity and restore it without loss, such as medical diagnostic information. After extracting secret information at the receiving end, the carrier can be restored without distortion.

Lai et al. proposed method, a generative image steganalysis algorithm is introduced, leveraging a focused feedback residual convolutional neural network. This approach enables the simultaneous detection and extraction of concealed information within images. Initially, a preprocessing network, comprising multiple convolutional layers and two novel focus modules, is employed to preprocess candidate stego images, producing enhanced feature maps. Subsequently, these enhanced feature maps are fed into both the classification network and the reconstruction network [9]. Khan, A. A. and others introduced a steganography technique utilizing the least significant bit (LSB) method to conceal secret data within an original image. Initially, lightweight stream encryption cryptography encrypts the confidential information within the cover image, safeguarding it throughout transmission from source to destination. The encrypted cover data is then embedded into the carrier of the steganographic image, employing the LSB technique for transmission [10]. Jun, M. et al. introduced an innovative dual-stream convolutional neural network tailored for single image dehazing. This network architecture comprises two distinct flows: the spatial information feature flow and the high-level semantic feature flow. The spatial information feature flow focuses on retaining intricate details within the dehazed image, while the high-level semantic feature flow specializes in extracting multi-scale structural features from the dehazed image [11].

Image encryption and information hiding are research directions for protecting information security. Cryptography ensures the security of data content through encryption. Information hiding technology verifies the integrity of multimedia data by embedding secret data. The reversible information hiding of encrypted images can play a dual role in ensuring information security during data processing. Encryption protects the content of image data, while embedded secret data can monitor whether multimedia data has been tampered with during transmission after decryption, verify its integrity, and achieve lossless recovery of the original carrier. It can be applied in scenarios such as remote medical diagnosis, encrypted data annotation in cloud environments, and digital forensics in the judiciary. In order to solve the problems existing in traditional systems, the author designs a reversible image information hiding system, applies reversible information hiding algorithms to image information processing systems, improves image processing speed and transmission speed, and ensures the security of image information processing.

III. METHOD

A. Hardware Design of Image Information Processing System

The system hardware mainly includes the selection of the main control chip, the design of parallel processing structure, and the design of Ethernet communication circuit. The specific design process is as follows:

1) Selection of main control chip: The main control chip adopts an FPGA chip, which is the core of image information processing and has the advantages of fast processing speed, simple operation structure, and large amount of data involved. The performance of the FPGA chip determines the effectiveness of image information processing. After research and comparison, it was found that the XC5VLX110T chip produced by Xilix Company was chosen. The XC5VLX110T chip has 110000 equivalent logic units, 16 transceivers, 64 DSP48E logic chips, 5328Kb ARM, and six clocks [12].

2) Parallel processing architecture design: Parallel processing is mainly implemented by buses, therefore, the design of parallel processing architecture mainly involves designing bus interfaces. The system bus interface connection diagram is shown in Fig. 1.

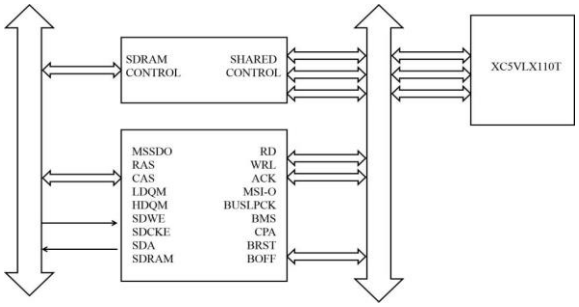

Fig. 1. Bus interface connection diagram.

The bus interface has multiple pins, as defined in Table I.

TABLE I. DEFINITION OF BUS PINS

grouping	types	Describe
External port bus control	I/O	Burst
	O	Host space chip selection signal
	O	Memory selection
	I/O	Response
External port arbitration	I	Revoke
	O	Bus lock indication
	I/O	Kernel Access Priority
	I	Host bus grant
External port DMA/Flyby	I	DMA request pin
	O	I/O read
	O	I/O device output enable
	O	I/O write

3) Ethernet communication circuit design: The image information processing system requires good network communication support. In order to design an Ethernet communication circuit, the independent interface of the processor needs to be connected to the Ethernet transceiver, and the IEEE802.3 network transmission protocol needs to be set. The circuit should be set to work mode to ensure the normal operation of the image information processing system.

The design diagram of the Ethernet communication circuit is shown in Fig. 2.

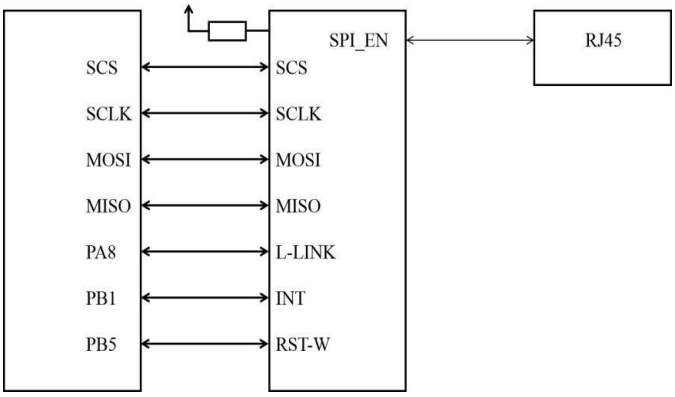

Fig. 2. Ethernet communication circuit design diagram.

The above process has completed the design of the system hardware, providing hardware support for the following system software design.

B. Software Design of Image Information Processing System

The system software mainly includes an image information hiding module, an image information extraction module, and a carrier image processing module. The specific design process is as follows:

1) Image information hiding module: The image information hiding module mainly uses reversible information hiding algorithms to hide image information, achieving the goal of protecting image information. Firstly, the carrier image is divided into non overlapping blocks, with a block size of 2 × 2. Secondly, each image block is processed sequentially, paying attention to hiding image information. The specific steps for hiding image information are as follows:

Step 1: Generate a reference matrix of 256 x 256 based on n x n matrix blocks, with n optional values including 4, 8, 16, and 32.

Step 2: The image block mainly consists of 4 pixels, denoted as $C(i,j)$, $C(i,j+1)$, $C(i+1,j)$, and $C(i+1,j+1)$. Construct them into three pixel pairs and convert them into planar coordinate points, denoted as $P_1(C(i,j),\ C(i,j+1))$, $P_2(C(i,j),\ C(i+1,j))$, and $P_3(C(i,j),\ C(i+1,j+1))$. Among them: $C(i,j)$ represents the pixels of the carrier image; $C(i,j+1)$, $C(i+1,j)$, and $C(i+1,j+1)$ represent the pixels obtained by interpolation calculation.

Step 3: Convert the reference matrix into a planar region, map P_1, P_2, and P_3 to the reference matrix, and find the corresponding coordinate positions.

Step 4: Scan in the left and right directions with P_1 as the center in the reference matrix. Form a pixel group G with n scanned pixels, convert their information into hidden information using decimal, find the corresponding position in G, replace the vertical coordinate of P_1 point, and complete the information hiding of P_1 point.

Step 5: Process P_2 and P_3 information according to the method in Step 4, and complete the hiding of P_2 and P_3 information.

Step 6: Repeat steps 2 to 5 until all image information is hidden.

2) Image information extraction module: Based on the hidden images mentioned above, embed a decoding program to extract image information. The specific process is shown below.

The decoding program refers to the decoding algorithm of reversible information hiding algorithms, which converts hidden information into raw information and extracts it [13-14]. Under normal circumstances, only personnel with image ownership rights can have decoding programs, and outsiders cannot extract image information. This can greatly ensure the security of image information and avoid the harm caused by image information leakage. The decoding key is mainly represented by k_1 and k_2, and the image information extraction process is shown in Fig. 3.

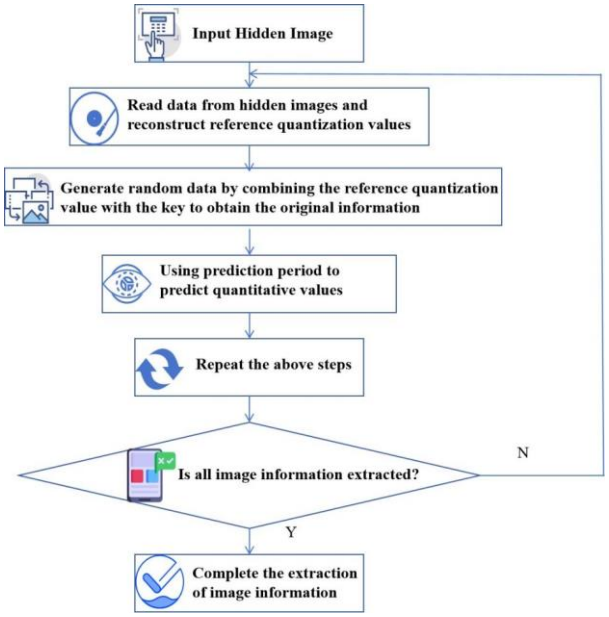

Fig. 3. Image information extraction process diagram.

3) Carrier image processing module: After extracting image information, it is necessary to process the carrier image, which is the inverse process of image information hiding. The specific program is shown in Fig. 4.

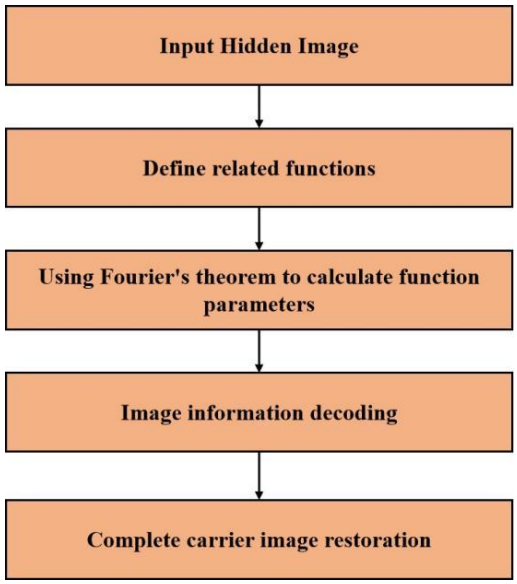

Fig. 4. Carrier image processing program diagram.

The carrier image processing function is represented as:

$$H = \sum_{i=1}^{n} \alpha k_1 * \beta k_2 \quad (1)$$

In the formula α, β represents the carrier image processing parameters.

Through the design of the hardware and software of the above system, the operation of an image information processing system based on reversible information hiding algorithm has been achieved, providing more effective support for image information security.

C. Similarity of Semantic Information

By applying probability functions to analyze the similarity of semantic information between images, propose image and semantic sets for a given query image.

The representation method for image sets:

$$I = \{I_1, \ I_2, \ \cdots I_n\} \quad (2)$$

The representation method of semantic sets:

$$X = \{x_1, \ x_2, \ \cdots x_m\} \quad (3)$$

Based on the given set expansion analysis, when the image I_i has semantic x_j, it can be represented by $x_j(I_i) \in \{0, \ 1\}$. In order to further clarify the similarity between the two images, it is necessary to measure the distance between the indicator functions. There is a relationship where the decrease in this value leads to an increase in similarity. The categories of natural semantic information are diverse and have significant uncertainty, so even with the same semantics, there may be multiple categories. Considering this situation, a probability based semantic level information similarity method is adopted. Assuming that I_i has semantic x_j, it is represented by $p = (x_j(I_i) = 1|I_i)$. This can further clarify the semantic labels of the image, specifically:

$$x_j: \ max_{x_j} p = (x_j(I_i) = 1|I_i) \quad (4)$$

The query image I_q maintains a relatively independent relationship with the dataset image I_i. Under this condition, there is $p = (I_q, \ I_i|x_j) = p(I_q|x_j)(I_i|x_j)$. Based on the image I_q and I_i, the correlation features of the image can be obtained through joint probability, which can be expressed as follows:

$$p = (I_q I_i) = \sum_{x_j \in X} p(I_q, \ I_i|x_j) = \sum_{x_j \in X} p(I_q|x_j)\, p(I_i|x_j) p(x_j) \quad (5)$$

In addition, considering the development needs of scalability, a matrix $\Lambda = I \times X$ is introduced to conduct calculations and analysis, exploring the correlation between two images. If the joint distribution of the images exceeds the cutoff threshold t, it is reasonable to indicate that there is correlation between the two images:

$$\Lambda = (I_q I_i) = p(I_q I_i) \geq t \quad (6)$$

On the contrary, it indicates that the two are not related. By applying the probability function of semantics between images, it is possible to effectively determine the semantic correlation of images. If the threshold is exceeded, it indicates significant semantic correlation, otherwise there is no significant correlation [15].

D. System Implementation Process

Write a reversible image information hiding system using callable functions to achieve image information hiding processing. The image information hiding system based on reversibility uses FIFO memory to collect image information, applies grayscale stretching processing to the image, threshold segmentation processing to the image after stretching processing, and uses ARM processor to hide image

information through reversible information hiding algorithm. After reverse operation, the hidden image information is extracted and output to achieve image information processing in the image information processing system [16].

E. Data Communication Module

The image data transmission is achieved through a data communication module, which can achieve multi chip communication. The data communication of the image information processing system is achieved through Ethernet data transmission interface and high-speed serial interface. The data communication module utilizes PCI interface to achieve information exchange between the image information processing system and the computer. The PCI interface is the data exchange and control center of the system hardware, which receives commands and data from the image information processing system and various device drivers through the communication interface module. The communication interface module completes the coordination work of various modules in the system, achieving system image information processing. The PCI communication interface module sends the collected image information and system processed data to a general-purpose PC using the PCI bus, and selects PLX's PCI9030 as the interface chip of the communication data module [17].

IV. Results and Discussion

A. Experimental Analysis

The experiment mainly uses Ethernet communication, and in order to ensure the smooth progress of the experiment, the experimental network is tested. After testing, the changes in Ethernet traffic are shown in Fig. 5. The significant changes in traffic indicate that Ethernet communication is normal and effective.

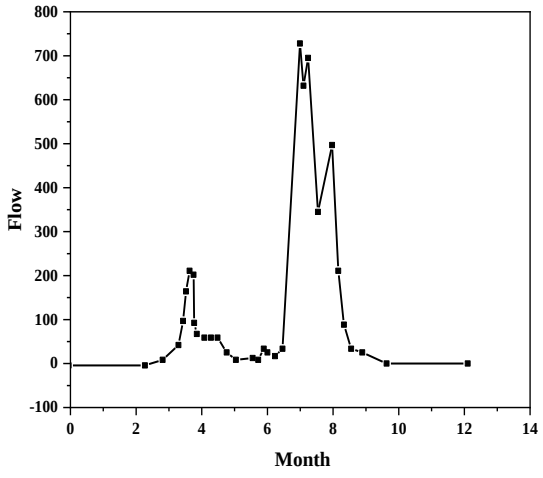

Fig. 5. Changes in Ethernet traffic.

B. Analysis of Experimental Results

The comparison of carrier image processing levels obtained through experiments is shown in Table II.

TABLE II. Comparison of Carrier Image Processing Levels %

Number of experiments	Traditional systems	design system
10	45	66
20	40	68
30	41	67
40	39	70
50	50	72
60	50	73
70	53	76
80	50	78
90	39	88
100	41	91

As shown in Table II, the carrier image processing level of the designed system is much higher than that of traditional systems, with a maximum value of 91%, indicating that the carrier image processing performance of the designed system is better [18]. The experimental results show that compared with traditional image information processing systems, the image information processing system designed by the author greatly improves the processing performance of carrier images, fully demonstrating that the designed image information processing system has better processing effects.

V. Conclusion

The author proposes an image information hiding processing based on deep neural network algorithms. Image information processing is an extremely important part of the field of image processing. The proposed solution can improve the security of secret information while ensuring the quality of encrypted images. Design a reversible image information hiding system and apply the reversible information hiding algorithm to the image information processing system. Through experimental results, it has been verified that using this system to process image information can achieve high image information processing efficiency at a lower cost, and has good processing performance, which can be applied to practical processing requirements of different types of image information.

Intelligent Digital Virtual Clothing Display System Based on LDA Mathematical Model

Zhao Wu*[1], Qingyuan He[2]
Fashion Design and Technology, Wuhan College of Foreign Languages and Foreign Affairs, Wuhan, Hubei, 430083, China[1, 2]

***Abstract*—In order to understand the intelligent digital virtual clothing display system based on mathematical models, the author proposes a research on an intelligent digital virtual clothing display system based on LDA mathematical models. The author first analyzes the realization of clothing matching function, and selects the cooperation between human skin color and clothing field as the influencing factors of clothing color matching and style matching based on expert knowledge and historical experience. Secondly, based on the different characteristics of different skin tones and the knowledge of clothing color matching, a set of clothing matching recommendation plans is presented to recommend suitable colors for users to refer to. Additionally, clothing style recommendations and choices are set, divided into upper and lower clothing, allowing users to choose more independently, the system itself also provides certain reference matching knowledge. Finally, the clothing matching rules were converted into computer image data, through analysis of the current market and existing research results, it was decided to implement a clothing matching display system based on VR technology, while providing recommended clothing matching solutions, a three-dimensional space was constructed to display clothing, allowing users to watch the effects of clothing matching according to their own choices, provide a new way for users in the clothing industry who have this demand.**

Keywords*—Mathematical model; virtual technology; clothing display

I. Introduction

With the continuous and rapid development of society, meeting people's daily clothing needs is becoming increasingly important. Clothing matching not only refers to the matching of clothes themselves, but also needs to be selected based on the appearance characteristics of the wearer. It is also necessary to consider the occasion of the wearer to match different clothes, in order to provide suggestions for clothing matching. The matching effect of clothing is a Visualization display. Under the fashion trend of clothing fashion from top to bottom, the four major international fashion weeks are a very important platform, which can gather the eyes of manufacturers, consumers and suppliers to display clothing with seasonal fashion trends and drive the economic development of the clothing industry. However, due to the significant amount of time, space, money, and energy consumed in hosting it once, there are many difficulties and limitations.

The rapid development of multimedia technology and computer science technology has provided excellent technical support for the practical application of virtual fitting. The mature application of virtual reality technology in many fields has prompted more researchers to conduct research on this technology. At present, virtual reality technology has been applied in all aspects of the social economy and has strong expressive power and realism. Clothing matching is an important way of expressing culture and art, with a strong artistic atmosphere and a combination of innovative matching and cultural connotations. This study analyzed the digital display design of a clothing matching display platform, and used virtual reality technology to complete the design of the virtual clothing display platform scene. Its interactive function can also be completed using the Unity3D engine. The main value of this research achievement lies in using virtual reality technology and clothing display platforms as carriers to demonstrate different ways of clothing matching. Applying virtual reality technology to the display of new clothing styles can reflect stronger interactivity and fun, and also enable users to better understand and match clothing. At present, with the rapid development of virtual reality technology, research and development work based on user actual needs is also constantly deepening. Starting from the current development status of the clothing industry, how to integrate virtual reality technology with modern clothing trends has become a focus of attention [1-2].

II. Literature Review

The LDA model (Latent Dirichlet Allocation, LDA) is essentially a Bag-of-words model, it believes that a document is composed of a group of words, and there is no sequential relationship between words. The LDA model presents the themes of each document in the document set in the form of a general distribution. After analyzing some documents and extracting their themes (distribution), topic clustering or text classification can be performed based on the topic distribution. At present, the application of LDA model is very extensive, and the specific value of LDA model has been realized in multiple domain modules. In 2022, scholars Zhang, X. D. F., and others proposed an SS-LDA model for short text analysis [3]. In the field of clothing matching, Tian, F. et al. used LDA models to analyze virtual clothing display systems and combined them with SVM algorithms to obtain color designs for clothing matching [4].

Virtual Reality (VR) is a major branch of computer simulation, which refers to the formation of a three-dimensional virtual world through computer simulation. It can simulate people's senses such as sight, hearing, and touch, allowing them to see content in the three-dimensional real space more accurately and without obstacles. The images displayed by virtual reality technology have a strong sense of

*Corresponding author: Zhao Wu

authenticity and immersion, which can make people immersive. The practical application of virtual reality technology needs to go through three stages: The first stage is the three-dimensional digital simulation process, which presents the content that can be represented by VR in the form of digital simulation, which is also more realistic; The second stage is the interaction between humans and the environment through writing script programs; The third stage is to integrate the first two processes, and finally create a comprehensive virtual reality environment to complete the interactive experience. The tools and software used can be roughly divided into three types:（1) The typical development method of scenario modeling software is 3DStudio Max; (2) The typical development mode of Model figure management software is Zbrush; (3) The typical development method of script development management software is the Unity3D engine, which is mainly designed and programmed in C language. The data is stored in Extensible Markup Language (XML) documents [5-6].

The author mainly analyzes the virtual fitting mechanism based on virtual reality technology, the network clothing display technology based on object Panorama, the design and implementation of clothing display system, and finally establishes a more complete virtual VR clothing display system.

III. METHODS

A. Virtual Fitting Function

Adopting a case-driven virtual fitting mechanism, using case-based reasoning to obtain clothing display cases that best match the user's physical characteristics and personalized display of clothing. First, define the characteristic parameters of people and clothing, and then collect clothing cases and form a case database. After inputting the user's body shape characteristic parameters, retrieve the clothing display cases that best match the user's body shape characteristics through the case reasoning mechanism in the case database, and obtain personalized clothing display effects that match the user's body shape characteristics. Regarding case search, searches for the closest case (the clothing display instance that best fits the user's body shape) by calculating similarity, and designs an instance retrieval algorithm based on similarity calculation. The calculation steps mainly consist of two parts: parameter weight calculation and similarity calculation.

In the process of image matching and image search, the virtual fitting mechanism has shown good adaptability. Compared with global characteristics, local characteristics do not have close connections, therefore, even if there are defects in the graphics, it will not have a negative impact on the coordination between other features. Analysis and research on local feature extraction algorithms have shown that they exhibit strong robustness and can effectively eliminate the possibility of partial interference, enabling the smooth completion of feature extraction work. In terms of the current situation where images can be locally obtained, even if the scale remains unchanged, the use of feature transformation algorithms is still relatively common. In terms of rotation interference, brightness interference, light noise influence, and other aspects, its robustness is also high. In addition, the advantages of high efficiency and scalability are also evident. The calculation process of body shape parameters is shown in Fig. 1 [7-8].

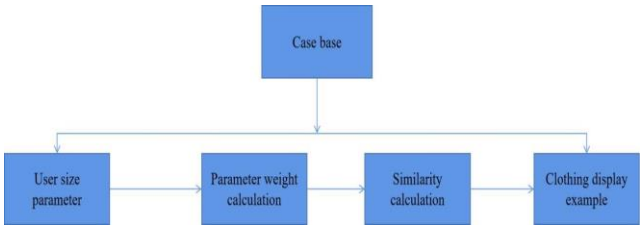

Fig. 1. Calculation of body shape parameters.

B. Panorama Display

In order to meet the new demand for clothing presentation in the clothing matching platform and according to the defects in the current virtual reality clothing presentation methods, the author selects the clothing presentation method based on the object Panorama, and the general process is as follows: Firstly, complete the image collection, secondly, splice the collected images, and finally use virtual reality technology to present the overall effect of the clothing. This process needs to input human organ data first, establish a basic Model figure, and then establish a complete set of Mannequin according to the human characteristics of different age groups (such as children, women, and the elderly), and carry out clothing matching in the virtual reality platform to show the clothing matching characteristics of different types of people. This clothing display method has the advantages of real-time and interactivity, allowing viewers to naturally and dynamically observe the overall display effect of clothing from various angles, making consumers more confident in choosing clothing and enhancing their shopping desire. The image display process is shown in Fig. 2.

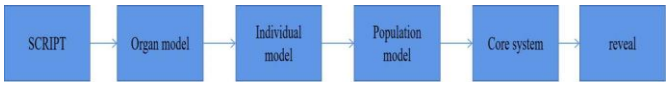

Fig. 2. Image display process.

In the process of detecting image signals of clothing and presenting their characteristics, the application range of global feature extraction calculation is large, and the main characteristics can be divided into three types: One of them is the appearance characteristics, which is to extract the external contour shape of the clothing and determine its style characteristics. For example, through convolution calculation, the target contour shape can be obtained. Then, the initial shape is processed to eliminate the influence parts outside the target contour shape line, and a feature matrix can be obtained. Finally, the target graphic area is effectively extracted. The second is the surface texture characteristics, which extract various textures that appear on the surface of clothing images to determine the fabric characteristics. The third is color characteristics, which use color information to achieve identification purposes. When expressing color characteristics, color histograms are an effective way. After defining commonly used color spaces, calculate each pixel in the clothing image to form a correct understanding of color distribution, and have outstanding advantages in robustness [9-10].

IV. Experiments and Analysis

A. Clothing Matching Scheme Display Design

1) Analysis of clothing matching factors: The author chooses to analyze and organize the knowledge based on traditional clothing matching expert knowledge and historical experience, and obtain corresponding clothing matching rules for the clothing matching recommendation scheme in the system. The clothing matching recommendations formed through expert knowledge have strong professionalism and are easy to use. The VR system is not limited by time and space, allowing users to apply clothing matching knowledge from a more intuitive perspective and see the display effect after matching. Experts recommend personalized clothing by analyzing the user's own skin color, hair color, pupil color, and other physical signs to find the most suitable color range for clothing. Then, according to different body shapes, choose the appropriate clothing outline shape, and judge the clothing style based on the environment. This determines the main color and fabric selection, and finally matches the entire set of clothing. After in-depth analysis, it is found that in order to achieve a beautiful and appropriate effect in clothing, it is necessary to consider three factors: the wearer's own physical characteristics, environment, and matching rules.

The characteristic of the virtual scene and display model designed in this system is that there is no difference in time and space in the virtual scene, and there is no consideration of time and place factors; the female human body modeled through Maya is a thin body with a standard Y-shape, with black hair and pupil colors. Therefore, the appearance of the above factors cannot be changed, so only the skin color of the human body is considered in this system. And considering that there are many and complex details involved in clothing matching, the principle of "minimum system" will be adopted in the clothing matching rules to reduce some details and focus on analyzing and exploring the selection factors.

Based on the analysis and consideration of various factors mentioned above, when designing clothing matching rules, the author chooses skin color in individual characteristics and the clothing occasions in TPO dressing rules as factors that affect clothing matching. Clothing is no longer a separate individual, and users' needs and characteristics are reflected in the attributes of clothing products. Skin color and dressing occasion are the influencing factors of clothing color, while dressing occasion is the influencing factor of clothing style, according to the application of matching rules, the color and style of clothing are influenced by skin color and the occasion in which the clothing is worn, thus obtaining a complete display rule for clothing matching [11-12] as shown in Fig. 3.

Fig. 3. Relationship between clothing factors.

2) Analysis of human skin color factors: Due to differences in innate skin color genes, living environment, and daily sun protection, adults have various skin types. Some have snow-white skin tones, while others have dark and yellowish skin tones. These differences can lead to different visual effects when choosing clothing of the same color. This is whether traditional clothing is suitable for one's temperament. Through the classification of different skin colors, the characteristics of their skin colors are analyzed, and the clothing color matching methods suitable for different skin colors are obtained to make the matching reasonable, highlight the advantages of human skin color, improve the bad skin color, and bring good mental outlook.

The author uses the skin color classification method of the twelve season color theory, in which the human skin color is divided into twelve types: Light spring, warm spring, pure spring, light summer, soft summer, cold summer, warm autumn, soft autumn, deep autumn, pure winter, cold winter, and deep winter. According to the spring, summer, autumn, and winter seasons, it is divided into four modules to elaborate on different skin color characteristics [13-14]. Spring is a season of recovery and vitality for all things. The colors of spring are warm, soft and light, giving people a soft and comfortable feeling. The overall skin color of the spring type is soft, as shown in Table I, summarizing the three skin color characteristics of the spring type.

TABLE I. Classification Characteristics of Spring Skin Tone

Skin color name	characteristic
Light spring type	With a clear skin tone and a hint of cream
Pure spring type	Skin tone that leans towards natural tones, mostly with light ivory skin tone
Warm Spring Type	The skin is relatively thin and transparent, with a darker warm tone compared to the light spring type

Summer brings with it the feeling of vibrant pink lotus growth under the white sunlight. So the overall skin tone of the summer style is a medium brightness skin tone with a pink tone. Table II analyzes the different characteristics of summer skin tone, which can better grasp skin tone.

TABLE II. CLASSIFICATION CHARACTERISTICS OF SUMMER SKIN TONE

Skin color name	Characteristic
Light summer type	A pink and tender skin with a light pink tone, compared to other summer styles, its brightness is lower
Soft summer type	Medium to light skin tone, with a rose pink complexion with a hint of gray tone
Cold summer type	A clear waxy yellow or rose pink color indicates a low purity cyan tone in the skin tone

Autumn is the season of falling leaves, so the main color tone of the autumn type skin is yellow, and the overall skin texture is not clear and transparent, with a slight sense of heaviness. Table III provides a brief description of the skin color characteristics of the autumn type.

TABLE III. CLASSIFICATION CHARACTERISTICS OF AUTUMN SKIN TONE

Skin color name	Characteristic
Soft autumn type	The face is light yellow, and the skin color is textured, not clear and transparent
Warm Autumn Type	With a golden tone, it is a yellow skin with high brightness
Late autumn type	The deep orange color of yellow is darker and lower in purity in late autumn compared to warm autumn

The color sensation brought by winter is a cool and harsh winter with cold white as the main tone, and the overall characteristic of winter skin tone is a bias towards cyan skin tone. Table IV provides a description of the characteristics of winter skin tone.

TABLE IV. CLASSIFICATION CHARACTERISTICS OF WINTER SKIN TONE

Skin color name	Characteristic
Net winter type	With a green background tone, a pale and light turquoise complexion, the overall color of the skin is white in tone
Frozen type	The skin tone ranges from cyan white to turquoise brown, but overall the skin tone has a higher brightness and is brighter
Deep winter type	Dark yellow skin with lighter purity ranging from dark wheat to turquoise brown

B. Analysis of Dressing Occasion Factors

In the TPO matching rule, it is required that when choosing clothing and considering its specific style, people should ensure that the clothing and its specific style are coordinated and consistent with the time, place, and occasion of the clothing, producing a harmonious and matching effect. In social life, according to the different Role people play, when going in and out on different occasions, the user's clothing reflects the wearer's purpose expectations, different clothing will leave different impressions on others, and clothing styles and colors play a certain role in expressing the user's clothing purpose.

Based on the analysis of the significant characteristics and purposes of different dressing occasions in real life, it is decided to divide their dressing occasions into five scenarios for further analysis and exploration:

- Leisure occasions: Places where leisure activities can take place, such as entertainment, shopping, and home activities. In these occasions, people are in a relaxed state, pursuing freedom, comfort, convenience, and an unrestrained state [15-16].
- Sports occasions: The awareness of national sports to strengthen the body is strengthened. More and more people choose to carry out sports activities in the gym or outdoor sports venues. According to different sports methods, different clothes are selected to match sports, so that clothing can play an auxiliary role and bring comfort to the wearer.
- Workplace: Work is a social occasion that occupies a significant portion of people's daily lives. Wearing classic and formal clothing can leave a good impression on the wearer.
- Banquet Occasion: In banquets and other occasions, people often dress with a purpose in mind, and the appearance of the clothing represents a spiritual outlook that the wearer wants to showcase. Wearing bright and luxurious clothing is the first choice for gatherings.
- Resort: The resort itself indicates that people are happy and comfortable in this occasion, without any constraints. The main design concept is strong, showcasing the beautiful and generous state of the wearer.

1) Color matching rules: By combining colors, better visual effects can be achieved. The rational use of color matching rules can be applied to clothing matching to achieve harmonious effects. Colors can be divided into two categories: Colored and achromatic. Achromatic refers to neutral colors, which are commonly referred to as black, white, and gray; Colorfulness is composed of three major attributes of color: Hue, brightness, and purity, among which brightness and purity together constitute hue.

According to the three attributes of colors, hue refers to the appearance of different colors, composed of three primary colors: Red, yellow, and blue. It is divided by the wavelength of light. In daily life, the most common basic colors are "red, orange, yellow, green, blue, and purple".

C. Clothing Color Matching Design

Clothing color can give the most intuitive visual impression in the overall combination of clothing. By combining users' skin color choices and the occasion of

clothing wearing, using reasonable color combinations can fully demonstrate personalized clothing style and taste. In clothing matching, fully grasp the purity, brightness, and hue attributes of colors, cleverly blend and match colors to display good visual effects [17].

1) Clothing style matching design: The style of clothing refers to the style and shape of clothing, which is generally divided into upper and lower clothing for separate matching. In the classification of upper clothing, there are T-shirts, vests, shirts, pullovers, suits, jackets, vests, polo shirts, etc, in the classification of bottoms, there are pants, casual pants, straight pants, cropped pants, shorts, short skirts, long skirts, one step skirts, pleated skirts, puffy skirts, and so on. Different clothing styles bring different visual experiences to people.

According to the style characteristics and overall shape effect of the clothing style, when the clothing is suitable for the atmosphere of the occasion, it is considered as the suitable style type for wearing in the occasion.

The combination of upper and lower clothing styles can generate a variety of matching styles. Combining the visual effect of the outer contour of clothing styles, by analyzing the main clothing occasions in daily life, Table V recommends two sets of clothing styles for each of the five selected clothing occasions.

TABLE V. RECOMMENDED STYLES FOR DIFFERENT DRESSING OCCASIONS

Dressing occasions	Style Recommendation	Main Features
leisure time	T-shirt, jeans, jacket, wide leg pants	The style is loose and comfortable, with a simple design that does not emphasize the waistline
motion	Vest, Leggings, sports sweater, culottes	Lightweight and vibrant, with a variety of close fitting styles to protect the body
work	Suit set, shirt, one step skirt	Formal, classic cut, smooth lines, and streamlined styling
banquet	Fish tail dress, short dress	Lightweight and elegant, with strong characteristics and personality, the style and style are exaggerated, highlighting the figure
spend one's holidays	Dresses, short tops, hot pants	The characteristics of clothing styles are comfortable, natural, lightweight, and simple in style

2) Overall clothing matching plan: The overall matching scheme of clothing is to determine the optimal color range of clothing based on the skin color characteristics selected by the user. The theme color and style of clothing are determined for different dressing occasions, and the clothing matching rules are designed to obtain the suitable clothing matching recommendation scheme in the design system.

The design concept of this set of clothing matching is to first determine the color range of the clothing top based on the twelve determined skin color classifications, and compare the relationship between cold and warm tones and brightness purity. Then, according to different dressing occasions, the theme color is selected, and the color of the lower garment is selected. Finally, the color matching of the entire set of clothing is completed. The recommended style combinations are only influenced by the factors of the dressing occasion, so in the previous section, the style combinations have been completed.

The matching design of clothing colors is only based on qualitative semantic descriptions, and in order to apply it in computer mode, it is necessary to quantify it. The most commonly used RGB mode is to mix and overlay different proportions of red, green, and blue colors to generate different colors, similar to pigment mixing and color matching in painting. The famous Pantone clothing color card uses RGB mode to represent different colors. However, according to the previous analysis of clothing color matching, the matching rule recommended by experts is to match colors based on the three attributes of colors, and the color generation principle of HSB mode is more suitable for the transformation of the author's matching method to express different colors [18].

In HSB color mode, there are three attribute sliders: hue, which is the hue ring, and complete colors are represented as a 360 degree hue wheel; the range value of purity is 0-100%, with increasing purity and the purest color expression; the range value of brightness is also 0-100%, with increasing brightness and reaching the brightest color.

In order to achieve the recommended scheme for clothing color in the system, it is necessary to convert the RGB values of conventional colors into HSB values. Based on these three attributes, the matching rules can be applied to effectively obtain the recommended scheme for clothing matching. The following are the conversion formulas for the two modes, as shown in Eq. (1) - Eq. (3).

$$H=\begin{bmatrix} 60\times((G-B)/\Delta\times \mathrm{mod}), C_{\max}=R \\ 60\times(\frac{(B-R)}{\Delta}+2), C_{\max}=G \\ 60\times(\frac{(\mathrm{R}-\mathrm{G})}{\Delta}+4)\ ,\ \mathrm{C}_{\max}=\mathrm{B} \end{bmatrix} \quad (1)$$

$$s=\begin{bmatrix} 0, C_{\max}=0 \\ \frac{\Delta}{C_{\max}}, C_{\max}\neq 0 \end{bmatrix} \quad (2)$$

$$\mathrm{B}=\mathrm{C}_{\max} \quad (3)$$

Correctly convert the clothing colors in the Pantone color card into hue, brightness, and purity values, and convert the semantic descriptions of twelve human skin tones and clothing occasions into their HSB mode color tone matching values

and hue matching values. Based on the clothing matching rules obtained in the previous text, the use case for determining a set of clothing matching is presented here;

Based on the user's choice of pure spring skin color, the recommended clothing color range is high brightness, high purity, and color values without cold or warm tones. The numerical range converted into computer HSB mode is: Brightness value 70% -100%, purity value 70% -100%.

Choose a banquet occasion for dressing. Based on the requirements of the theme color, which is bright and eye-catching, choose a red hue value of 0 degrees here. According to the method of contrasting colors in color matching, the lower garment can be matched with color values within the range of 0 degrees and 120 degrees, or neutral colors without warm or cold tones can be selected as a match, such as black. This completes the color recommendation for the entire set of clothing for subsequent clothing matching displays.

Translate the clothing matching rules into different numerical ranges for the three major attributes in computer HSB mode, and determine that the color HSB value within the numerical range is the color recommended for matching. If it is not within the numerical range, it is not recommended. Based on this, a case study of clothing color matching required in the system is formed [19-20].

ACKNOWLEDGMENT

Key research project of Wuhan Vocational College of Foreign Languages and Foreign Affairs, Research on the Application of digital Virtual Technology of Clothing in the development Mode of Product Innovation Studio in Higher Vocational Colleges, (Project number: 2023WYZDKY02)

V. CONCLUSION

By analyzing the clothing matching experience in expert knowledge, combined with the characteristics of the system, selecting factors related to human skin color and dressing occasions for analysis, and combining color matching rules to determine the color matching of clothing; Combining TPO matching rules to match clothing styles, comprehensively completing clothing matching recommendation schemes, and applying them to the implementation of clothing matching functions in the system.

***Abstract*—Alzheimer's disease (AD), the most common type of dementia, is expected to affect 152 million people by 2050, emphasizing the importance of early diagnosis. This study uses the Alzheimer's Disease Neuroimaging Initiative (ADNI) dataset, combining cognitive tests, biomarkers, demographic details, and genetic data to build predictive models. Using large language models (LLMs), specifically ChatGPT 3.5, we achieved high classification accuracy, with ROC AUC values of 0.98 for cognitively normal (CN) individuals, 0.99 for dementia, and 0.98 for mild cognitive impairment (MCI). These findings show that LLMs can handle complex data quickly and accurately. By focusing on numerical and text-based data instead of just imaging, this method provides a cost-effective and accessible option for diagnosing AD. Adding genetic information improves the predictions, reflecting the important role of genetics in AD risk. This study highlights the potential of combining different types of data with advanced machine learning and LSTM to improve early AD diagnosis. Future research should explore more ways to combine data and test different machine learning models to further enhance diagnostic tools.**

***Keywords*—Alzheimer; dementia; LLMs; ChatGPT; LSTM**

I. Introduction

Alzheimer's disease (AD), the most common form of dementia, accounts for 60–80% of all dementia cases and is expected to become even more prevalent as populations age [1-7]. By 2050, it is estimated that 152 million people worldwide will be living with Alzheimer's and other forms of dementia [1]. AD is particularly significant among non-communicable diseases, which together account for approximately 70% of global deaths [8-10]. The disease primarily affects older adults, impairing memory, behaviour, and reasoning abilities [11, 12].

To improve the health and quality of life for older adults, it is increasingly important to develop effective treatments for AD [13-15]. Although several biomarkers for early diagnosis have been identified [4], accurate diagnosis still partly relies on clinical criteria, which can take up to six months as symptoms gradually become apparent [16, 17]. Even when symptoms are clear enough for a confirmed diagnosis, AD remains incurable [10, 18, 19].

The Global Deterioration Scale [20] outlines symptoms such as decreased work performance, increased forgetfulness, and frequent disorientation during the mild cognitive impairment (MCI) stage. MCI is characterized by a prolonged period of decline that can last for around seven years [18]. This has led medical professionals to focus on establishing criteria for early diagnosis to slow or potentially prevent disease progression [14, 18].

Current medical practices for diagnosing AD can be time-consuming. As a result, researchers are increasingly exploring approaches that combine medicine with computer science, particularly deep learning, to develop methods for earlier and more accurate diagnoses. This interdisciplinary focus has become a key area of ongoing research.

Various approaches have been employed to diagnose Alzheimer's disease (AD) as early as possible. These include skeleton-based human action evaluation [18], 3D CNN-based classification of sMRI and MD-DTI images to detect brain changes [8, 9, 19], and speech analysis [15, 17]. Monitoring dementia progression using 2D and 3D imaging techniques has become a sophisticated method, utilizing advanced medical imaging to track changes in brain structure and function over time [2, 7, 19, 21, 22]. Additionally, it is crucial to determine whether cognitive measures identified as predictive in research cohorts are also applicable in clinical memory clinics [2, 13, 23-25].

This study aimed to identify the most effective measures for predicting future AD dementia in clinical settings where expensive biomarkers may not be widely available. Early detection of AD severity is critical [5, 14, 19, 26, 27]. While neuroimaging and computer-assisted diagnostic tools can detect AD in its early stages, these methods often lack high accuracy [11]. Techniques like Computed Tomography (CT), Positron Emission Tomography (PET), and Magnetic Resonance Imaging (MRI) significantly contribute to diagnosing brain disorders [28].

Advancements in medical imaging, supported by computer-aided diagnostic research, have greatly improved the ability to monitor and predict dementia progression. 2D and 3D imaging techniques play an essential role, offering a comprehensive view through structural, functional, and molecular imaging. These advances continue to improve our understanding and management of this complex condition, providing hope for better patient outcomes.

However, several challenges persist. Advanced imaging techniques such as MRI and PET are expensive, making routine monitoring financially difficult for many patients. Access to high-quality imaging facilities is often limited, particularly in rural or underserved areas. Additionally, technical limitations such as resolution and sensitivity may prevent the detection of small or early brain changes. Imaging data can also be affected by noise and artifacts, complicating interpretation. Health-related concerns include exposure to ionizing radiation from PET and CT scans, especially with repeated use, and discomfort or anxiety during MRI scans, particularly for patients with claustrophobia.

From a technical perspective, the large volume of data generated by 3D imaging requires robust data management and analysis systems, along with advanced computational tools and expertise for handling and interpreting big data. While these imaging techniques provide valuable insights, their limitations underscore the importance of a balanced approach.

Recent advancements have also identified blood-based biomarkers that can assist in monitoring dementia progression. These tests are less invasive than cerebrospinal fluid (CSF) tests and more practical for regular use. Key biomarkers include Amyloid Beta (Aβ), Tau Proteins, and Neurofilament Light Chain (NfL). Cognitive tests remain essential for assessing cognitive functions and tracking changes over time. Commonly used tests include the Mini-Mental State Examination (MMSE), Montreal Cognitive Assessment (MoCA), Clock Drawing Test, Alzheimer's Disease Assessment Scale-Cognitive Subscale (ADAS-Cog), and neuropsychological testing. This paper consists of literature review, methodology, results, discussion and conclusion, where every section highlights related information.

II. Literature Review

Alzheimer's disease (AD) is a neurological disorder that progressively worsens over time. It is typically divided into three main stages, with the early stage being particularly important [29]. One challenge with Alzheimer's treatments is their limited effectiveness, especially during the disease's typical eight-year progression [29].

In the early stage, daily activities gradually become more difficult. The most common signs include short-term memory loss and trouble learning new things [12, 29]. Other symptoms may include low energy, a sad mood, and a lack of interest or motivation [30]. Notably, individuals diagnosed with mild cognitive impairment (MCI) are at a significantly higher risk of developing AD [29]. In many cases, MCI is classified as the early stage of AD [31].

Researchers have also observed that difficulties with language—such as trouble pronouncing or remembering complex words—alongside challenges in performing daily tasks, may serve as early indicators of AD [29, 31, 32]. These findings suggest that there are more affordable diagnostic tools for detecting dementia than costly imaging techniques. Many studies have applied statistical analysis alongside other types of data (excluding imaging) to explore alternative methods for diagnosing Alzheimer's disease (AD). For instance, human action evaluation has shown potential applications in areas such as assisted living, physical rehabilitation, sports activity scoring, and skills training [18]. This approach can also be applied to AD by using sequences of 3D skeletal joint data to assess the severity of the disease in patients. For example, Yu et al. [18] utilized a two-task graph convolutional network to analyze skeleton data for tasks involving abnormality detection and quality evaluation. Their method, evaluated using the UI-PRMD dataset, demonstrated accurate abnormality detection.

Taghvaei et al. [33] applied statistical analysis to investigate the relationship between white matter hyperintensities (WMH) tract disconnection and cognitive performance. Their study highlighted the significant role of demographic factors, such as education level, age, and sex, in influencing the relationship between WM tracts and cognitive scores. Similarly, Raj et al. [1, 34] emphasized the importance of genetics, which contributes to approximately 70% of the overall risk for AD. They introduced a system that combines text mining and machine learning to identify and prioritize candidate genes for AD, categorizing them into three association classes with corresponding weights.

Another cost-effective method for predicting AD involves analyzing patients' speech patterns [35]. Many studies have focused on acoustic and syntactic analysis of speech. For example, Haj Zargarbashi and Bagher [17] employed statistical and neural methods to classify audio signals into dementia and control groups, achieving an accuracy of 83.6%. Similarly, Vincze et al. [36] analyzed specific utterances using deep learning models, with and without demographic data, and found no significant differences between the models. Colla et al. [37] used large language models alongside N-grams and perplexity metrics to predict potential AD with an accuracy of 84%. Gómez-Zaragoza et al. [15] provided empirical evidence that punctuation and pauses in speech could reveal early signs of AD. A comprehensive review by [38] highlighted the high potential for deep learning to be utilized with medical data in future research.

Cai et al. [35] examined methods for detecting AD through speech analysis by transcribing audio into text and extracting audio features using the WavLM model. They tested pre-trained models and Graph Neural Networks (GNNs) with the DementiaBank Pitt dataset and applied fine-tuning techniques such as data augmentation (e.g., synonym replacement and GPT-based augmentation). Wang et al. [39] also used pre-trained language models with fine-tuning methods, achieving up to 89% accuracy. Finally, blood tests have shown promise in detecting AD. Certain biomarkers in blood may indicate the potential presence of the disease. Kim and Lee [40] demonstrated that complex interactions among blood proteins could predict the likelihood of AD development.

Several gaps have been identified in Alzheimer's disease (AD) research. For example, while the ADNI dataset has been extensively used in studies focusing on MRI images [29], it has only been partially utilized. Most studies have concentrated solely on MRI images, overlooking the wealth of other information in the dataset that could enhance the analysis of AD. A recent systematic literature review by Singh et al. [41] found that the majority of AD studies used ADNI and deep learning methods, a trend confirmed by Alwuthaynani et al. [2],

but with an exclusive focus on MRI data. Similarly, Essemlali et al. [42] highlighted that one of the key challenges in dementia prediction lies in distinguishing between MCI and AD, as well as between NC (normal cognition) and MCI. These are among the most difficult classification tasks and often require additional data, such as multi-modality or genetic information, to improve predictions.

This study leverages the powerful classification capabilities of large language models (LLMs), such as ChatGPT, to classify dementia stages. There is a notable lack of research utilizing LLMs with non-imaging data from the ADNI dataset to address classification problems. For instance, Agbavor and Liang [43] demonstrated that GPT-3 embeddings significantly improved Alzheimer's detection accuracy from spontaneous speech, outperforming traditional methods based on acoustic features. They used models such as support vector classifiers and logistic regression, achieving high classification performance. Another study [44] combined imaging and phenotype data from the ADNI dataset with LLMs, achieving state-of-the-art performance in classifying Alzheimer's and various stages of cognitive impairment. This highlights the effectiveness of integrating LLMs with diverse data types.

However, as discussed, this study focuses on utilizing LLMs with textual and numerical data rather than imaging data. This approach aims to provide a cost-effective solution suitable for clinical settings and requiring less computational power. The methodology is informed by the work of Feng et al. [44], excluding imaging data, to create a more accessible and efficient model for AD classification.

III. METHODOLOGY

A. ADNI Dataset

This study utilized the ADNI dataset due to its extensive use in recent research and its comprehensive collection of data necessary to achieve the goals of this study. The ADNI dataset, available at adni.loni.ucla.edu, has been widely referenced in studies related to Alzheimer's detection [41, 45].

The ADNI project was launched in 2003 by the National Institute on Aging (NIA), the Food and Drug Administration (FDA), the National Institute of Biomedical Imaging and Bioengineering (NIBIB), private non-profit organizations, and pharmaceutical companies [41, 45]. Its original purpose was to determine whether the combination of genetic, neuroimaging, biomarker, clinical, and neuropsychological data could be used to predict Alzheimer's disease.

The ADNI dataset is renowned for its longitudinal design, capturing data at multiple time points. Images and other data are collected at baseline and then at intervals of 6 months, 12 months, 24 months, and 48 months [42]. Several versions of the dataset, including ADNI2 and ADNI-Go, have been developed to expand its scope.

B. Feature Set

In addition to demographic data, such as sex, age, gender, and race, which have been shown to significantly contribute to predicting the clinical status of individuals [36], this study incorporates a variety of other features for analysis. Cognitive tests play a central role in assessing various aspects of memory, language, and executive function. These include the Mini-Mental State Examination (MMSE), a widely used measure of cognitive function, and the Montreal Cognitive Assessment (MOCA), another standard cognitive measure. The study also utilizes scores from the Rey Auditory Verbal Learning Test (RAVLT), including immediate recall, learning, forgetting, and percentage of forgetting, which assess different dimensions of memory. Other cognitive tests include the Logical Memory Delayed Recall test (LDELTOTAL), the Digit Span test (DIGITSCOR), which measures attention and working memory, and the Trail Making Test Part B (TRABSCOR), which evaluates executive function. The Functional Activities Questionnaire (FAQ) is also included to assess daily living capabilities.

Biomarkers represent another crucial component of the analysis. The Apolipoprotein E (APOE4) genotype, strongly associated with Alzheimer's disease risk, is used alongside imaging biomarkers from PET scans, including tracers such as FDG, PIB, AV45, and FBB. Additionally, cerebrospinal fluid protein levels of amyloid-beta (ABETA), tau (TAU), and phosphorylated tau (PTAU) are examined for their role in the disease's progression.

Clinical and diagnostic scores also contribute significantly to the analysis. These include the Clinical Dementia Rating – Sum of Boxes (CDRSB), which evaluates cognitive and functional performance, and various subscales from the Alzheimer's Disease Assessment Scale (ADAS), such as ADAS11, ADAS13, and ADASQ4. Reports of cognitive function from both patients and their study partners are included, with patient-reported scores covering memory, language, visuospatial ability, planning, organization, divided attention, and overall cognitive function. Study partner-reported scores assess the same domains, providing additional perspectives on cognitive performance.

Baseline data for all these measures are also incorporated to analyze changes over time. Baseline values for clinical scores such as CDRSB, ADAS, and MMSE, as well as cognitive tests like RAVLT, Logical Memory, and FAQ, are included. Baseline levels of biomarkers, such as ABETA, TAU, and PTAU, are also considered. Patient- and study partner-reported cognitive scores at baseline offer further context for tracking progression. Temporal variables, such as the number of years or months since the baseline visit, are included to provide additional detail about the timing of data collection.

In summary, the features included in this study's prediction models encompass cognitive assessments, genetic information, biomarkers, demographic data, and clinical details. These measures provide a comprehensive dataset for early detection of dementia, offering insights into cognitive decline and associated risk factors. By integrating this diverse set of features, the study aims to improve the accuracy and practicality of predictive models for Alzheimer's disease [27, 46, 47].

C. Models

Shah and Shah [12] explored the use of machine learning (ML) algorithms, particularly convolutional neural networks (CNNs), for the early diagnosis of Alzheimer's disease (AD)

through the analysis of medical imaging data, such as MRI scans and biomarkers. Their study compared various ML algorithms, including k-nearest neighbor (KNN) and support vector machines (SVM), and highlighted the superior accuracy and reliability of CNNs in detecting AD. The deep learning capabilities of CNNs enable them to extract subtle features from medical images, making them particularly effective for this application. Shah and Shah [12] demonstrated that CNNs outperformed other algorithms due to their deep architecture, which can handle complex data and identify patterns that simpler models may miss.

However, the authors also noted several challenges in using CNNs for AD diagnosis. These include the need for large, well-curated datasets, as CNN models are prone to overfitting when trained on small or imbalanced datasets. Additionally, they emphasized the importance of transparency and interpretability in ML models, especially in medical applications where clinicians need to understand the rationale behind a diagnosis. Despite these challenges, CNN-based models were identified as the most effective for early detection of AD, particularly when applied to MRI scans and biomarker data.

While Shah and Shah [12] provided a thorough investigation into the use of ML and deep learning methods for early AD detection, their work predominantly focused on image-based data, such as MRI scans. They did not explore the application of these methods to other types of data, such as textual or numerical information, nor did they consider the potential of large language models (LLMs). LLMs, with their ability to process both structured and unstructured text, could provide valuable insights and significantly enhance prediction models for AD. Additionally, the study did not examine the use of Long Short-Term Memory (LSTM) networks, which are particularly effective for analyzing sequential data, such as time-series health records or longitudinal datasets.

Building on their work, this study proposes the integration of both LSTM networks and LLMs alongside traditional machine learning methods to develop cost-effective and accurate prediction solutions for AD. By focusing on non-image data, such as cognitive assessments, biomarkers, and clinical records, this approach aims to expand the scope of predictive models and offer accessible diagnostic tools for clinical settings.

1) LSTM: Long Short-Term Memory (LSTM) networks are a specialized type of recurrent neural network (RNN) designed to learn and retain long-term dependencies in sequential data. They are particularly well-suited for tasks involving time-series or sequential data due to their unique architecture, which includes memory cells and gating mechanisms (input, output, and forget gates) to control the flow of information. This capability makes LSTM networks highly effective in addressing the vanishing gradient problem, a common challenge in traditional RNNs.

In this study, LSTM networks are employed to process clinical and biomarker data from the ADNI dataset. The input features, which consist of textual and numerical data, are well-suited to LSTM's architecture. The model begins with an input layer that accepts the data features, followed by one or more LSTM layers that process the sequences of observations. The final dense layer produces the output, classifying the stages of Alzheimer's disease based on the processed data. By leveraging LSTM's ability to handle sequences effectively, this study aims to improve classification accuracy for Alzheimer's diagnosis. Additionally, LSTM networks are prioritized due to their demonstrated effectiveness in managing textual and numerical data, which are key components of the ADNI dataset. The following equations illustrate the core functionality of LSTM networks in classification tasks:

The forget gate controls which information from the previous cell state (C_{t-1}) should be carried forward to the current cell state (C_t).

$$f_t=\sigma(W_f \cdot[h_{t-1}, x_t] + b_f)$$

Where f_t is the forget gate's activation vector; W_f and b_f are the weight matrix and bias for the forget gate; h_{t-1} is the previous hidden state; x_t is the current input and σ is the sigmoid activation function [48]. Input Gate [49] represented as follows:

$$i_t=\sigma(W_i\cdot[h_{t-1}, x_t] + b_i)$$

$$\dot{C}_t =tanh\ (W_C \cdot[h_{t-1}, x_t] + b_C)$$

where i_t is the input gate's activation vector; $\dot{C}_t$ is the candidate cell state, representing new information; and W_i, W_C b_i, b_C are the weight matrices and biases for the input gate and cell state.

Meanwhile; Cell State Update is implemented as follows

$$C_t=f_t*C_{t-1}+i_t* \dot{C}_t$$

And the output gate [50] is implemented as follows

$$o_t=\sigma(W_o\cdot[h_{t-1}, x_t]+b_o)$$

$$h_t=o_t*tanh(C_t)$$

where o_t is the output gate's activation vector; h_t is the current hidden state (which also serves as the output for classification).

The classification layer is implemented using this formula [51]:

$$y=softmax(W_y\cdot h_t+by)$$

where y is the predicted class probabilities; W_y and by are the weight matrix and bias for the classification layer.

finally; Loss Function for Classification (Cross-Entropy) [52] is presented by

$$L= -\sum_{i=1}^{N} y_i\ log(y'_i)$$

Where: y_i is the true label; y'_i is the predicted probability for class and N is the number of classes.

At each time step, the LSTM updates the cell state and hidden state using the forget, input, and output gates. The final hidden state after processing the entire sequence is passed to the classification layer, where the class probabilities are calculated. The loss function is used to optimize the model by comparing the predicted output with the actual labels. This process allows the LSTM to classify sequential data effectively.

2) Few-Shot: Few-shot learning is a machine learning technique that enables models to perform tasks with minimal examples or training data. Unlike traditional machine learning methods, which rely on large datasets and extensive training, few-shot learning allows for adaptability and flexibility with significantly reduced training overhead. This approach is particularly useful for large language models (LLMs) like OpenAI's ChatGPT-3.5-turbo, as it enables the model to learn effectively from a limited number of examples. The primary advantage of few-shot learning is its ability to achieve accurate predictions with less effort in data preparation and model training.

In this study, few-shot learning was applied to classify Alzheimer's disease stages using examples from the ADNI dataset. The process began by defining a small set of examples representing the desired outcomes: "CN" (cognitively normal), "Dementia," and "MCI" (mild cognitive impairment). A sample of 10 examples was provided, reflecting various cases in the dataset, including instances with missing values across specific groups of features. Next, a prompt was constructed to include these examples and the task to be performed, guiding the model toward the desired predictions. The model then used this context to generate predictions, which were subsequently extracted to retrieve the relevant outputs. This streamlined process demonstrates the efficiency of few-shot learning in handling limited data while maintaining accurate and meaningful results.

IV. Results

A. Demographic

The ADNI dataset contains numerous cases categorized under each stage of dementia. These cases include multiple rows for the same patient, corresponding to different visits over time. The distribution of cases across the stages of dementia is illustrated in Fig. 1. As shown, the majority of patients are at the MCI stage, followed by those at the CN stage, highlighting the prevalence of MCI cases in the dataset.

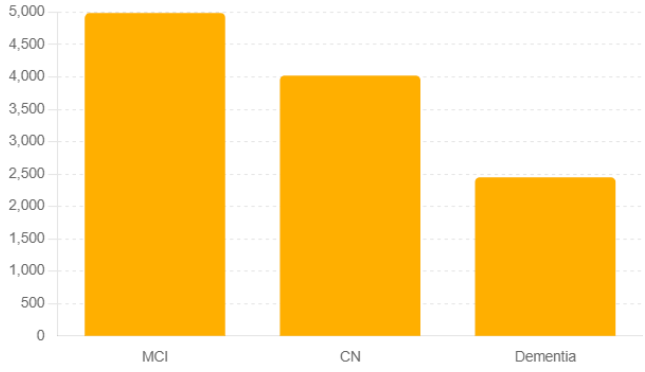

Fig. 1. Patients'stage in ADNI dataset.

The demographic data available in the ADNI dataset is presented in Fig. 2. The data shows a balanced distribution in terms of gender. However, there is an imbalance in race, with the white population significantly outnumbering other racial groups. The age range of participants spans from 55 to 90 years.

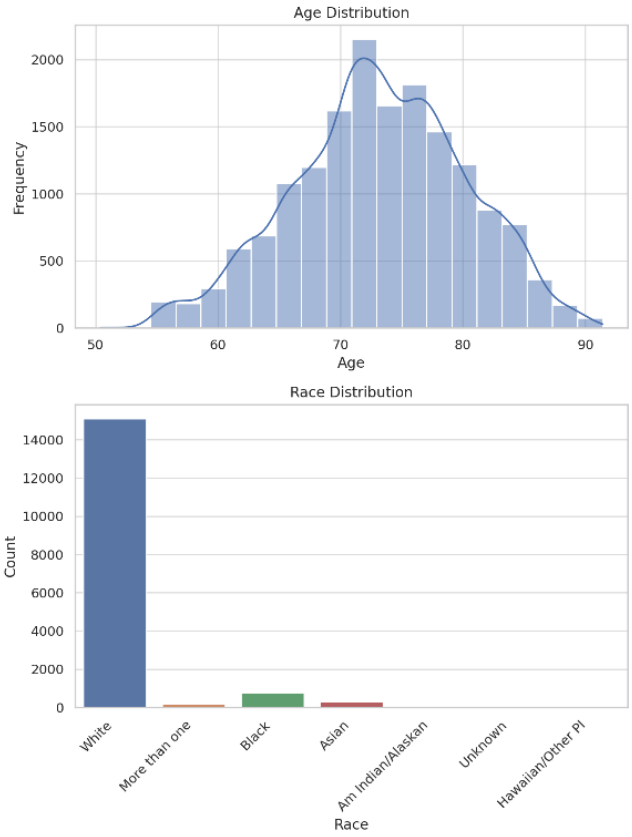

Fig. 2. Demographics related statistics.

B. Feature Selection and Machine learning Methods' Prediction

To identify the most important features for predicting the diagnosis label (DX), three approaches were implemented: (a) Correlation Analysis to examine relationships between features and DX, (b) Random Forest Feature Importance to rank features by their predictive significance, and (c) Recursive Feature Elimination (RFE) to select the most relevant features based on model performance.

The Correlation Analysis revealed that the features most strongly correlated with DX are: CDRSB (Cognitive Dementia Rating – Sum of Boxes) with a correlation of 0.751, EcogSPTotal (Total score of Everyday Cognition, Study Partner version) at 0.735, EcogSPMem (Everyday Cognition, Study Partner Memory score) at 0.732, FAQ (Functional Activities Questionnaire) at 0.730, and ADAS13 (Alzheimer's Disease Assessment Scale, 13-item) at 0.725. These results indicate that cognitive and functional assessments are highly correlated with Alzheimer's diagnosis. Using Random Forest Feature Importance, the top features for predicting DX were identified as EcogSPTotal (20.28%), ADAS13 (18.84%), ADAS11 (16.54%), EcogSPMem (12.64%), and EcogSPOrgan (9.45%). These findings reinforce the importance of cognitive and functional assessments in predicting Alzheimer's.

With Recursive Feature Elimination (RFE), the same top five features were selected: EcogSPTotal, EcogSPMem, ADAS13, ADAS11, and EcogSPOrgan. A Random Forest Classifier trained using only these features achieved an average

cross-validation accuracy of 38.75% (standard deviation: 0.89%) and a test accuracy of 39%. Class 2 (Dementia) was predicted with the highest recall (63%), but precision and recall for Class 0 (Cognitively Normal) and Class 1 (MCI) were low. The macro-average F1-score was 0.32, highlighting significant confusion between classes, particularly between Cognitively Normal and MCI.

To address these limitations, several strategies were explored. Class Imbalance Handling techniques, such as oversampling, undersampling, and class-weighted models, improved the weighted F1-score slightly to 0.37, with Class 2 (Dementia) achieving 63% recall. However, confusion between Cognitively Normal and MCI persisted. Feature Engineering was then applied, creating interaction features by combining cognitive scores and biomarkers. This approach marginally increased the overall accuracy to 40%, with a recall of 66% for Class 2. While improvements in classifying Cognitively Normal and MCI cases were observed, misclassification between MCI and Dementia remained significant.

Next, Advanced Models were tested, including Gradient Boosting and Support Vector Machines (SVM). Gradient Boosting achieved an overall accuracy of 43%, with Class 2 (Dementia) recall at 92%. However, predictions for Class 0 (Cognitively Normal) and Class 1 (MCI) were poor, with F1-scores close to zero. Similarly, SVM performed slightly better with an overall accuracy of 45% and a recall of 99% for Class 2, but almost no correct predictions for Classes 0 and 1. Both models struggled with class imbalance, favoring Dementia at the expense of distinguishing other classes.

Finally, Ensemble Modeling was implemented, leveraging techniques like Voting Classifiers (combining Random Forest, Gradient Boosting, and SVM), Stacking Classifiers (training multiple models and using their predictions as inputs for a meta-model), and Bagging (aggregating predictions from models trained on different data subsets). These ensemble methods aim to balance predictive performance across classes and address the challenges of class imbalance and overlapping features. Further evaluation and refinement of these approaches are ongoing to improve the overall diagnostic accuracy and robustness of the model.

1) Voting classifier results: The model achieved an overall accuracy of 43%, with Class 2 (Dementia) having the highest recall at 90%. However, performance for Class 0 (Cognitively Normal) and Class 1 (MCI) was poor, with F1-scores of approximately 0.09 and 0.05, respectively. The macro-average F1-score was 0.24, highlighting that the model disproportionately favors Dementia while struggling to accurately classify Cognitively Normal and MCI cases. Significant confusion remains between the classes, with many CN and MCI cases misclassified as Dementia.

2) Stacking classifier results: The model achieved an overall accuracy of 45%, matching the performance of the Voting Classifier. However, the results reveal a significant bias, as Class 2 (Dementia) was the only class predicted, with a recall of 100%. Both Class 0 (Cognitively Normal) and Class 1 (MCI) had 0% recall and precision, indicating that no cases from these classes were correctly identified. The macro-average F1-score was 0.21, underscoring the model's heavy bias toward Dementia and its inability to distinguish between Cognitively Normal and MCI cases. All instances of CN and MCI were misclassified as Dementia.

3) Bagging: Using Bagging with the Random Forest model, which inherently trains on different subsets of data, the overall accuracy achieved was 41%. Class 2 (Dementia) had a recall of 73%, while Class 0 (Cognitively Normal) and Class 1 (MCI) showed lower recall and F1-scores. The macro-average F1-score was 0.31, indicating a moderate improvement in balancing predictions across classes compared to previous classifiers. Bagging demonstrated better differentiation between classes than the Voting and Stacking classifiers, though significant misclassifications remained between Cognitively Normal, MCI, and Dementia. Notably, Bagging performed slightly better in predicting minority classes.

In summary, the Voting Classifier achieved an accuracy of 43% but was heavily biased toward predicting Dementia, performing poorly on other classes. The Stacking Classifier achieved a slightly higher accuracy of 45%, but it failed to classify Cognitively Normal and MCI cases, predicting only Dementia. Bagging, with an accuracy of 41%, showed improved balance across the classes compared to Voting and Stacking but continued to struggle with distinguishing between Cognitively Normal and MCI cases.

Among the ensemble methods, Bagging demonstrated better overall balance in classifying multiple categories, although limitations remained. To further enhance performance, future work could focus on advanced feature engineering, fine-tuning model hyperparameters, or exploring other sophisticated techniques to address the challenges in distinguishing between these diagnostic categories.

C. Advanced Analyses

To further improve model performance, particularly in distinguishing between the different diagnostic classes (Cognitively Normal, MCI, and Dementia), several advanced techniques could be employed. Automated machine learning (AutoML) tools, such as TPOT, can automate the process of testing a range of algorithms and hyperparameter configurations, helping to identify the best model without requiring manual experimentation.

In this study, an AutoML framework was used to automatically test multiple models and optimize their hyperparameters. The results from the TPOT AutoML run provided valuable insights into the model selection and tuning process. The internal cross-validation (CV) accuracy, which TPOT uses to evaluate different pipelines during its evolutionary search, stabilized at approximately 47.7% across most generations. The final best pipeline achieved an internal CV score of 47.78%, indicating the highest performance based on TPOT's cross-validation evaluation.

TPOT selected the ExtraTreesClassifier as the best model. This ensemble method, similar to Random Forest, reduces variance by averaging predictions across multiple decision trees, often resulting in more stable outcomes. The

ExtraTreesClassifier was identified as the optimal model with the following key parameters:

- Bootstrap: True (bootstrap sampling was used).
- Criterion: Gini (used for measuring the quality of a split).
- Max features: 0.8 (80% of the features are considered when looking for the best split).
- Min samples leaf: 17 (minimum number of samples required to be at a leaf node).
- Min samples split: 5 (minimum number of samples required to split an internal node).
- n_estimators: 100 (number of trees in the forest).

The test set accuracy was 43.6%, meaning the final model achieved 43.6% accuracy on unseen data. While consistent with the performance of other models tested, this accuracy highlights the challenges in distinguishing between the diagnostic categories (Cognitively Normal, MCI, and Dementia). The consistency of accuracy between 43% and 45% across different models suggests that the feature set may require further refinement or that the inherent complexity of differentiating between these classes, particularly between Cognitively Normal and MCI, remains a significant challenge.

Since focusing on the top five features did not result in substantial improvements in accuracy, a new approach was tested by including DX_bl (the baseline diagnosis) as a key feature for predicting the final diagnosis (DX). This approach is logical, as the baseline diagnosis likely correlates strongly with the final diagnosis, and transitions between diagnostic categories (e.g., from MCI to Dementia) over time can provide valuable insights. Using a Random Forest model with DX_bl as a feature, the accuracy improved significantly to 83%, demonstrating that DX_bl is a strong predictor of the final diagnosis.

The model's performance metrics for each class are as follows:

Class 0 (Cognitively Normal - CN):

Precision: 89% (89% of cases predicted as CN are correct).

Recall: 92% (92% of actual CN cases were correctly identified).

F1-Score: 91% (indicating strong and balanced performance for this class).

Class 1 (MCI):

Precision: 100% (all predicted MCI cases were correct).

Recall: 51% (only 51% of actual MCI cases were identified correctly).

F1-Score: 67% (highlighting an imbalance, as many MCI cases are misclassified).

Class 2 (Dementia):

Precision: 75% (75% of Dementia predictions were correct).

Recall: 93% (93% of actual Dementia cases were identified).

F1-Score: 83% (indicating strong performance for this class).

The Macro Average F1-Score, which gives equal weight to each class, was 80%, showing good overall performance but highlighting some imbalance in the prediction of MCI. The Weighted Average F1-Score, which accounts for the number of instances in each class, was 82%, reflecting the model's strong performance for the larger classes (CN and Dementia).

Cognitively Normal (CN) and Dementia cases are well predicted, with high precision and recall. However, MCI remains the most challenging class for the model to classify, with high precision but low recall. This indicates that many MCI cases are misclassified as either CN or Dementia. While DX_bl is a highly predictive feature for the final diagnosis, the model still struggles to effectively differentiate MCI from the other categories.

D. Baseline Data Analysis and Prediction

Baseline data analysis can provide valuable insights and contribute to improving predictions. Among the diagnostic groups, Cognitively Normal (CN) and Alzheimer's Disease (AD) dominate the baseline dementia diagnoses. This analysis specifically compares these two groups with respect to key variables, such as CDRSB (Cognitive Dementia Rating Sum of Boxes) and PTAU_bl (Phosphorylated Tau at baseline). Using the Mann-Whitney U test, a non-parametric test suitable for comparing two independent samples, the following results were obtained:

CDRSB: The p-value was effectively 0, indicating a highly significant difference in cognitive scores between the CN and AD groups.

PTAU_bl: The p-value was 0.0001, also showing a highly significant difference in phosphorylated tau levels between the two groups. These findings suggest that both cognitive scores (CDRSB) and biomarker levels (PTAU_bl) are significantly different between CN and AD groups, consistent with established Alzheimer's research. The Mann-Whitney U test for ABETA levels yielded a p-value of <0.0001, further confirming a significant difference between CN and AD groups. This result aligns with the well-documented role of amyloid-beta in Alzheimer's disease pathology. Similarly, for MMSE (Mini-Mental State Examination), the p-value was <0.0001, indicating that AD participants had significantly lower MMSE scores, reflecting more severe cognitive impairment. The same was observed for MOCA (Montreal Cognitive Assessment), where the p-value was 0.0001, demonstrating a significant difference in MOCA scores between CN and AD groups.

The analysis of neuroimaging biomarkers, such as FDG (Fluorodeoxyglucose PET) and AV45 (Amyloid PET), also revealed significant differences. The p-value for FDG PET was 0.0001, indicating that brain glucose metabolism, as measured by FDG PET, is significantly lower in individuals with AD. Similarly, AV45 PET, which measures amyloid accumulation, showed a p-value of 0.0001, confirming higher amyloid levels

in the AD group. These findings underscore the significant differences in neuroimaging biomarkers between CN and AD groups.

Regarding the APOE4 genotype distribution, the results highlight the strong association between APOE4 and Alzheimer's risk. Among individuals with AD, 47.7% had one copy of the APOE4 allele, 21.2% had two copies, and 31.1% had no copies. In contrast, among CN individuals, 72.6% had no copies, 25.4% had one copy, and only 2% had two copies. These distributions confirm the well-established link between APOE4 and increased Alzheimer's risk, with individuals carrying one or two APOE4 alleles being significantly more likely to develop the disease.

Examining the impact of APOE4 status on biomarkers and cognitive scores provides additional insights into how this genetic risk factor influences Alzheimer's pathology. Individuals without APOE4 alleles had the highest average ABETA levels (990), while those with two alleles had the lowest (521), consistent with APOE4's role in promoting amyloid accumulation. Similarly, TAU and PTAU levels were progressively higher in individuals with more APOE4 alleles. Those with two alleles had the highest TAU (363) and PTAU (35), reflecting greater neurofibrillary pathology. Cognitive function, as measured by MMSE, decreased with the number of APOE4 alleles, with individuals carrying two alleles having the lowest average MMSE score (24.5). The CDRSB score, indicating cognitive impairment, increased with the number of APOE4 alleles.

These findings demonstrate that APOE4 is strongly associated with greater amyloid and tau pathology and more severe cognitive decline. The relationship between APOE4 status, biomarkers, and cognitive scores underscores the genetic influence on Alzheimer's disease progression.

E. Neural Network Prediction Models

The results of the models developed in this study, particularly the LSTM model, were evaluated using the ADNI dataset. Performance metrics included accuracy, precision, recall, and F1-score. The model achieved a Validation Loss of 0.369 and a Validation Accuracy of 84.5%, with an overall Accuracy of 84.5%. A detailed classification report is presented in Table I, while the confusion matrix is illustrated in Fig. 3, providing further insights into the model's performance across diagnostic categories.

TABLE I. PERFORMANCE MATRIX FOR LSTM-BASED MODEL

	precision	Recall	F1-score
CN	0.84	0.81	0.83
Dementia	0.79	0.80	0.80
MCI	0.86	0.87	0.87
Accuracy	0.84		
macro avg.	.83	.83	.83
Weighted avg	0.84	0.84	.84

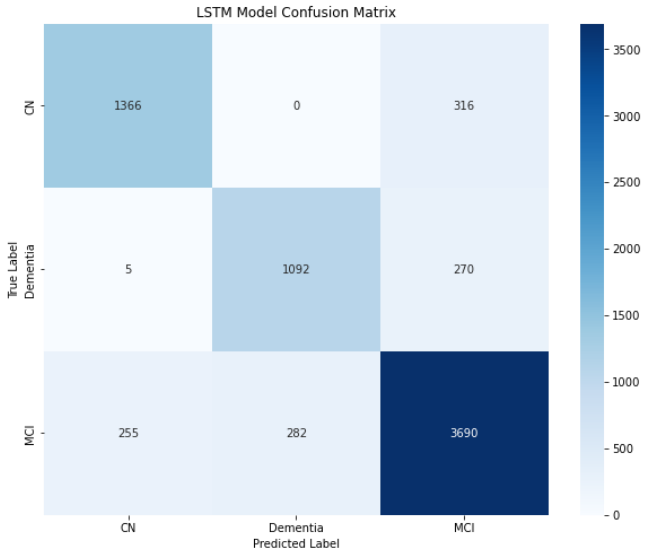

Fig. 3. Confusion matrix for LSTM-based model.

It was observed that the features illustrated in Fig. 4 contribute significantly more to predicting Alzheimer's disease compared to other features. Among these, MMSE_bl (baseline Mini-Mental State Examination) and MMSE_fu (follow-up Mini-Mental State Examination) showed the greatest contribution, highlighting their critical role in the predictive model.

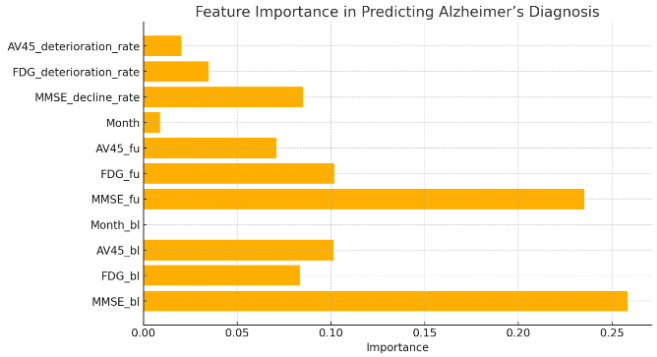

Fig. 4. The important features in predicting Alzheimer.

Additional models were explored using baseline information, including Gradient Boosting and Support Vector Machine (SVM). The Gradient Boosting model achieved an impressive 96% accuracy on the test set, with perfect precision, recall, and F1-scores for both the Cognitively Normal (CN) and Alzheimer's Disease (AD) groups. Similarly, the SVM classifier performed exceptionally well, achieving 95% accuracy on the test set and perfect scores across all performance metrics. These results demonstrate the strong predictive capabilities of both models when using baseline data.

F. Evaluating Model Performance Longitudinally

To assess longitudinal performance, the model's ability to predict changes in cognitive scores, imaging biomarkers, or diagnoses over time was evaluated. This involved two main aspects:

Predicting Cognitive Decline: The model was used to predict future cognitive scores based on baseline data and observed longitudinal trends.

Evaluating Model Stability: The model's predictive accuracy was tested across multiple visits for the same individuals to determine its consistency over time.

The analysis began with visualizing interactions among key features, followed by evaluating longitudinal performance. A heatmap (Fig. 5) illustrates the correlations between key features. Notably, the MMSE Decline Rate is negatively correlated with both MMSE at Baseline and FDG (Fluorodeoxyglucose PET), indicating that as cognitive function declines, brain metabolism also tends to decrease. In contrast, AV45 (Amyloid PET) shows a weaker correlation with other features, highlighting its specific role in amyloid accumulation, which is less directly tied to immediate cognitive decline. These findings underscore the nuanced relationships between cognitive decline, biomarkers, and brain function over time.

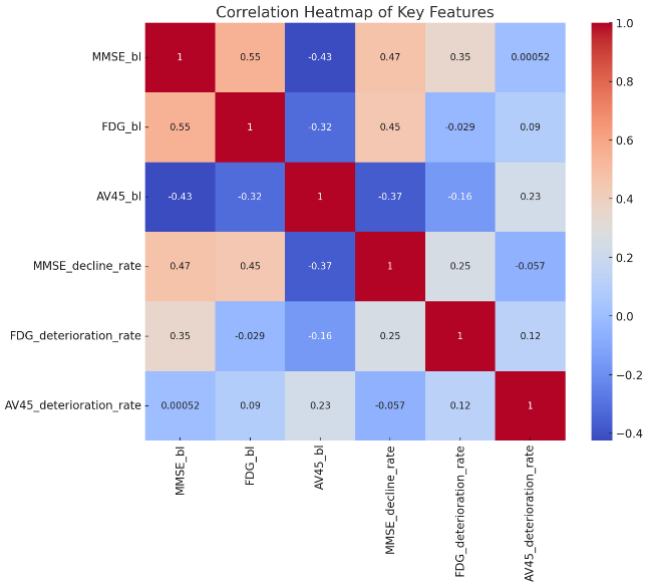

Fig. 5. Correlation of heatmap of key features (baseline features).

The model's ability to predict cognitive decline, such as changes in MMSE scores over time, was evaluated using baseline data. The assessment focused on how well the model predicts cognitive decline across multiple visits. A linear regression model, which used baseline features including MMSE, FDG, and AV45, achieved a Mean Squared Error (MSE) of approximately 0.01. This indicates that the model performed reasonably well in predicting cognitive decline over time. The low error suggests the model has potential for forecasting Alzheimer's progression, though further refinement and validation on larger datasets could improve its accuracy and robustness.

When a more advanced regression method, such as Gradient Boosting, was applied to refine the longitudinal model, it achieved an MSE of 0.0121. While the Gradient Boosting model captured some patterns in the data, its slightly higher MSE suggests that the simpler linear regression model performed better for this specific task.

Fig. 6 visualizes the relationship between predicted and actual MMSE decline rates. The scatter plot includes a red dashed line representing ideal predictions, where predicted values perfectly match the actual values. Most predictions were reasonably close to the actual values, with some variability, which is expected in longitudinal predictions. These findings demonstrate the model's promise in predicting cognitive decline over time while highlighting areas for further improvement in longitudinal performance. The same analysis used to predict cognitive decline was applied to forecast imaging deterioration over time, focusing on FDG (glucose metabolism) and AV45 (amyloid accumulation). Baseline features such as FDG_bl, AV45_bl, and MMSE_bl were utilized to predict changes in FDG and AV45 over time. Gradient Boosting Regression was employed for both tasks, demonstrating strong performance in predicting longitudinal imaging changes.

For FDG deterioration rate prediction, the model achieved a Mean Squared Error (MSE) of 0.000006, indicating excellent accuracy in forecasting changes in glucose metabolism over time. Similarly, for AV45 deterioration rate prediction, the MSE was 0.000028, showing the model's effectiveness in predicting changes in amyloid accumulation. These low error rates suggest that the model performs well for both imaging biomarkers, making it a valuable tool for tracking Alzheimer's progression longitudinally. Visualization of the results further supports the model's effectiveness. In Fig. 7, the scatter plot illustrates the predicted vs. actual FDG deterioration rates, with most points closely aligned with the ideal prediction line (red dashed line), indicating strong predictive performance. Similarly, Fig. 8 shows the predicted vs. actual AV45 deterioration rates, with most points clustering near the ideal line, demonstrating the model's capability to accurately forecast amyloid accumulation changes.

Overall, the models effectively predict longitudinal changes in both FDG and AV45 imaging biomarkers, which are critical for monitoring Alzheimer's disease progression over time. These results highlight the utility of Gradient Boosting Regression in capturing complex patterns in imaging data.

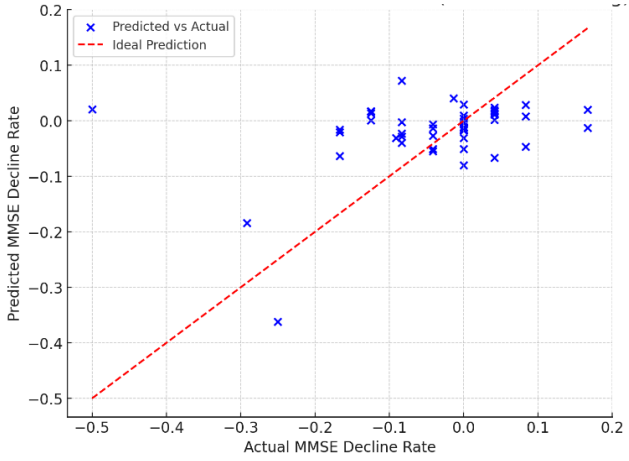

Fig. 6. Predicted vs. Actual MMSE Decline Rate (Gradient Boosting).

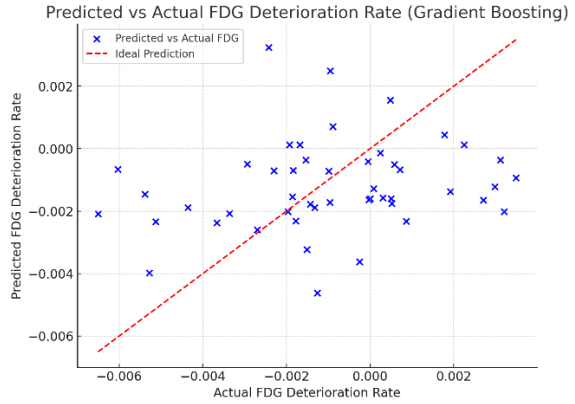

Fig. 7. Predicted vs. Actual FDG Deterioration Rate (using Gradient Boosting).

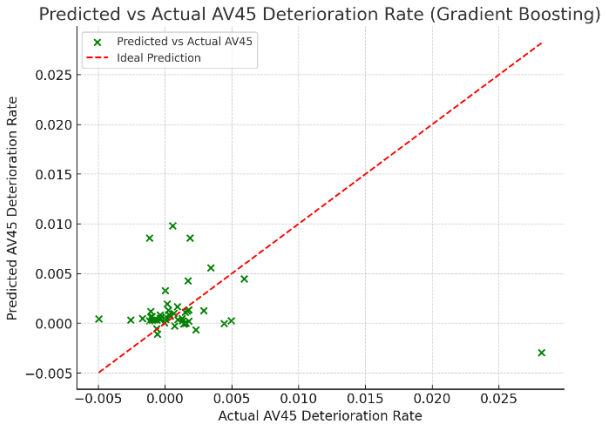

Fig. 8. Predicted vs. Actual AV45 Deterioration Rate (using Gradient Boosting).

We explored additional derived features by combining cognitive scores and biomarkers to create new indicators of Alzheimer's progression. Investigating interactions between longitudinal features and temporal patterns revealed deeper insights into disease progression. These derived features were designed to capture more complex relationships between cognitive and biomarker data. The newly created features included:

MMSE_TAU Interaction: A combination of baseline MMSE and FDG values to assess the relationship between cognitive function and brain metabolism.

ABETA_TAU Ratio: A ratio of amyloid (AV45) to glucose metabolism (FDG) to highlight the balance between amyloid accumulation and metabolic activity.

Combined Decline Rate: The sum of MMSE and FDG deterioration rates, providing a measure of overall cognitive and metabolic decline.

Using cross-validation, the performance of models with these derived features was evaluated. The Random Forest model achieved an accuracy of 97.46%, slightly outperforming the other models. The Gradient Boosting model achieved an accuracy of 96.83%, while the Support Vector Machine (SVM) reached 96.21%. All three models demonstrated strong predictive performance, with Random Forest showing a marginal advantage. These results highlight the potential of derived features in enhancing model performance by capturing intricate relationships between cognitive and biomarker data. This approach emphasizes the value of feature engineering in advancing the predictive capabilities of machine learning models for Alzheimer's progression.

G. *Few-shot LLMs*

Regarding the results of the experiment with few-shot training, we employed Large Language Models (LLMs), specifically ChatGPT 3.5, instead of LSTM models. The results demonstrated a significant improvement over LSTM, with the following performance metrics: Accuracy: 0.97, Precision: 0.97, Recall: 0.97, and F1-Score: 0.97. The confusion matrix is presented in Fig. 4. To evaluate the diagnostic performance of the model, we used Receiver Operating Characteristic (ROC) curves for various clinical conditions, as shown in Fig. 9. The ROC curve provides a graphical representation of the model's ability to discriminate between diagnostic categories by plotting the true positive rate (sensitivity) against the false positive rate (1-specificity) across different threshold settings. The model demonstrated excellent discriminatory ability across all diagnostic categories. The Area Under the Curve (AUC) for the ROC of Cognitively Normal (CN) subjects was 0.98, indicating a high level of accuracy in distinguishing CN individuals from those with cognitive impairment. Similarly, the ROC curve for dementia yielded an AUC of 0.99, reflecting outstanding performance in identifying subjects with dementia. For Mild Cognitive Impairment (MCI), the ROC curve achieved an AUC of 0.98, signifying robust capability in differentiating MCI from other conditions.

The high AUC values for CN, dementia, and MCI underscore the exceptional performance of our model in correctly classifying individuals into their respective diagnostic categories. These findings highlight the potential of our approach in supporting early and accurate diagnosis of Alzheimer's disease and related cognitive disorders. The results demonstrate that few-shot training with LLMs like ChatGPT 3.5 can provide significant advancements in diagnostic modeling, offering reliable and efficient tools for clinical applications.

V. Discussion

The ADNI dataset is regularly updated as more participants engage in studies on dementia progression. This work utilized the latest version of the dataset, published in 2024, which includes detailed information on assessments conducted during each patient visit. It was observed that machine learning models achieved high accuracy when predicting the baseline dementia stage using baseline information. However, their performance declined when tasked with predicting the dementia stage for each subsequent visit, highlighting the challenges associated with longitudinal predictions. When exploring neural networks and deep learning, the results of this study underscore the significant potential of integrating numerical and textual data from the ADNI dataset to develop highly accurate predictive models for Alzheimer's disease and related cognitive disorders. By leveraging the extensive cognitive assessments, biomarkers, and demographic data available in ADNI, our approach illustrates how comprehensive datasets can enhance diagnostic

accuracy. The inclusion of varied data types enables a multifaceted analysis, which is essential for understanding the complex progression of Alzheimer's disease. This integrative approach not only improves model performance but also provides deeper insights into the factors driving cognitive decline, reinforcing the value of holistic data utilization in Alzheimer's research.

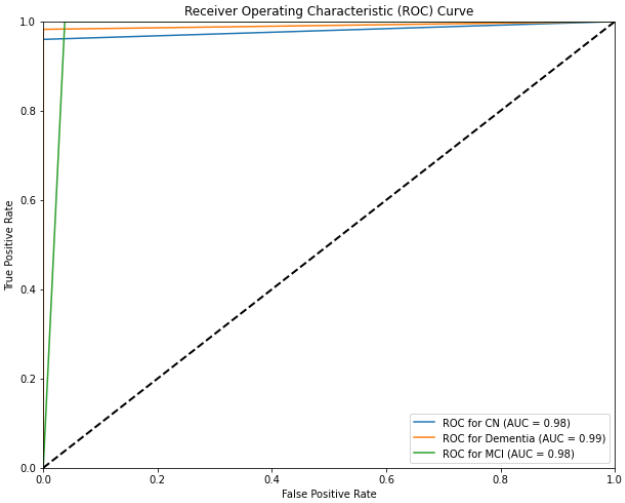

Fig. 9. ROC for the ChatGPT 3.5 after been few-shot training.

In the introduction, we highlighted the projected increase in Alzheimer's disease prevalence, with estimates suggesting that 152 million people globally will be affected by 2050. This alarming trend underscores the urgent need for effective diagnostic tools that facilitate early detection and intervention. The current study addresses this need by leveraging the extensive ADNI dataset, which includes diverse data such as cognitive test scores (e.g., MMSE, RAVLT), biomarker levels (e.g., amyloid-beta, tau proteins), and demographic information (e.g., age, gender, race, education). These features have been shown to significantly contribute to predicting clinical status, as noted by Banerjee (2020) and Tian et al. (2023).

The literature review emphasized the limitations of relying solely on imaging techniques for Alzheimer's diagnosis, such as the high cost and limited accessibility of MRI and PET scans. Previous studies, such as Balakrishnan et al. (2023), predominantly focused on MRI images, underutilizing the full spectrum of data available in ADNI. Our study addresses this gap by integrating numerical and textual data, offering a more holistic and cost-effective approach to Alzheimer's diagnosis. This aligns with findings by Feng et al. (2023), who demonstrated the efficacy of combining imaging and phenotype data with large language models (LLMs).

The application of LLMs, such as ChatGPT 3.5, significantly improved classification performance in this study. LLMs enable rapid processing and analysis of large datasets, achieving high accuracy in classification tasks. Our findings show that LLMs can accurately distinguish between cognitively normal individuals, those with mild cognitive impairment (MCI), and those with dementia. Specifically, the ROC curves for cognitively normal (CN) subjects, dementia, and MCI exhibited AUC values of 0.98, 0.99, and 0.98, respectively. These high AUC values highlight the robustness of LLMs in classifying different stages of cognitive impairment, thereby supporting early and precise diagnoses.

Genetics, a significant contributor to Alzheimer's disease risk (accounting for approximately 70% of overall risk), was also incorporated into our predictive models, as suggested by Raj et al. (2024). The importance of genetic data is underscored in this study, complementing other features. Furthermore, the literature review highlighted the effectiveness of speech analysis and text mining in detecting Alzheimer's disease. Studies by Agbavor and Liang (2022) and Colla et al. (2022) demonstrated the utility of LLMs in analyzing spontaneous speech and text data, aligning with our approach of utilizing LLMs to process numerical and textual data from ADNI.

The contribution of this work lies in demonstrating that LLMs provide not only a rapid and effective approach to classification tasks but also maintain high accuracy, making them valuable tools in clinical settings. This study fills a critical gap in existing research by focusing on the integration of textual and numerical data from ADNI, rather than relying solely on imaging data. By doing so, we offer a cost-effective alternative that reduces dependence on expensive and less accessible imaging techniques. The ability to utilize readily available data to achieve reliable diagnostic outcomes represents a significant advancement, paving the way for more accessible and scalable solutions in Alzheimer's disease detection.

Future research can expand the scope of Alzheimer's prediction beyond image analysis by incorporating a broader range of patient data, such as clinical notes, genetic information, and cognitive test results. This approach has the potential to lead to more comprehensive and accurate prediction models, facilitating earlier detection and enabling more personalized treatment strategies for patients with Alzheimer's disease.

In conclusion, this study highlights the transformative potential of LLMs in utilizing diverse datasets to enhance diagnostic accuracy for Alzheimer's disease. By integrating cognitive assessments, biomarkers, demographic data, and genetic information, our approach offers a comprehensive and efficient diagnostic tool. The findings emphasize the importance of multi-modal data integration and advanced machine learning techniques in addressing the growing challenge of Alzheimer's disease diagnosis and management.

VI. CONCLUSION

This study demonstrates the significant potential of integrating numerical and textual data from the Alzheimer's Disease Neuroimaging Initiative (ADNI) dataset to develop highly accurate predictive models for Alzheimer's disease and related cognitive disorders. By leveraging a comprehensive range of features, including cognitive assessments, biomarkers, demographic information, and genetic data, this approach provides a robust and holistic method for early diagnosis.

The findings underscore the utility of large language models (LLMs), such as ChatGPT 3.5, in processing and analyzing complex datasets. LLMs exhibited exceptional performance in classification tasks, achieving high accuracy rates and rapid processing times. Specifically, the ROC curves for cognitively

normal (CN) subjects, dementia, and mild cognitive impairment (MCI) yielded AUC values of 0.98, 0.99, and 0.98, respectively. These results highlight the efficacy of LLMs in distinguishing between different stages of cognitive impairment, thereby supporting early and precise diagnosis.

This study addresses a critical gap in existing research by focusing on the integration of numerical and textual data rather than relying solely on imaging data. This approach provides a cost-effective alternative, reducing dependence on expensive and less accessible imaging techniques. Utilizing readily available data to achieve reliable diagnostic outcomes represents a significant advancement, paving the way for more accessible and scalable solutions for Alzheimer's disease detection. Additionally, the inclusion of genetic information aligns with findings from previous studies that emphasize the importance of understanding the genetic basis of Alzheimer's disease. By incorporating diverse data types, the proposed models offer a more comprehensive analysis, improving prediction accuracy and supporting targeted interventions.

The transformative potential of combining multi-modal data with advanced machine learning techniques is a key contribution of this work. Integrating ADNI's rich dataset with LLMs offers a promising approach to enhancing diagnostic accuracy and efficiency. Beyond Alzheimer's disease, this work provides a framework for leveraging diverse datasets to address other complex medical conditions. Future research should focus on further integrating various data types and exploring advanced machine learning models to enhance diagnostic capabilities and improve patient outcomes.

Abstract—The front-end feature matching module of traditional SLAM systems is characterized by sparse or dense feature points, it is difficult to generate accurate camera trajectory and scene reconstruction results, in response to this problem, the author studied a fast reconstruction algorithm for any path based on V-SLAM, by using improved feature matching algorithms to accurately match feature points, the accuracy of scene sparse reconstruction and camera trajectory recovery has been improved, the backend optimization thread adopts segmented optimization matching to reduce the computational burden of reconstruction, and the performance of the V-SLAM system was improved through parallel processing, the matching results and camera trajectory error comparison results showed that the improved V-SLAM algorithm can quickly recover camera trajectory and scene reconstruction, with the development of multi-sensor collaborative coupling and multi view fusion technology, the V-SLAM method proposed by the author can add virtual 3D objects to real scenes, and the V-SLAM system can extract feature points in the screen in real-time and detect planar objects in the scene, ensure that multiple virtual objects in the scene meet geometric consistency with the actual scene, in the experiment, two objects were added to the virtual scene, users can interactively scale objects and add them without being affected by camera movements, ensuring consistency between objects and the real scene.

Keywords—SLAM algorithm; industrial robot; visual recognition; location

I. INTRODUCTION

The positioning and map creation of mobile robots are hot research topics in the field of robotics, and are also important links in navigation. There are already some practical solutions for autonomous localization of robots in known environments and map creation of known robot positions [1]. However, in many environments, robots cannot use global positioning systems for localization, and obtaining a map of the robot's working environment in advance is also difficult, or even impossible. At this point, the robot needs to create a map in a completely unknown environment with its own position uncertain, and simultaneously use the map for autonomous positioning and navigation, as well as positioning and mapping [2]. Assuming that the robot is moving in a completely unknown environment, executing control commands and observing the characteristics of the environment, both the control and observation quantities will be affected by noise interference, SLAM is the restoration of robot path and environmental feature information from a series of noisy variables. If the path of the robot is determined (such as GPS positioning), then it is a problem of building a map, where the position of the target in the environment is estimated using an independent filter; When the robot's path is unknown, the robot's path is related to the error of the map, so, the state information and map information of the robot must be estimated simultaneously. The SLAM problem includes four basic aspects: (1) How to describe the environment, the representation method of environmental maps; (2) How to obtain environmental information, robots roam the environment and record sensor perception data, which involves the problem of robot localization and environmental feature extraction; (3) How to represent the obtained environmental information and update the map based on the environmental information requires addressing the description and processing methods of uncertain information; (4) Develop stable and reliable SLAM methods. The SLAM algorithm has many important attributes that affect the uncertainty in map features and robot position estimation, including the convergence of state estimation, the data consistency of the estimation process, and the computational complexity of updating the state covariance matrix. Convergence of state estimation: As the number of observations increases, in order to reduce the uncertainty of map estimation to a limited range, the convergence of state estimation must be maintained. Firstly, the accuracy of the map is related to the position accuracy of the robot when the first environmental feature is observed, so it is necessary to ensure the convergence of the state matrix when the first environmental feature is observed [3-4]; Secondly, the update of the state covariance matrix after each measurement must be convergent relative to the matrix before the update [5]; Finally, in extreme cases, as the number of observations increases, the feature estimation becomes completely correlated. As long as these are ensured, the relationship between map features is completely determined. Consistency of data association: Data association is the key to data fusion. In the SLAM process, data association mainly completes two tasks: Detection of new environmental features and feature matching. If the data association is not accurate, it will lead to filter divergence, which has a particularly prominent impact on EKF based methods. In order to maintain the consistency of SLAM, it is necessary to update the state covariance matrix. The observation of the environment is relative to robots, so any errors in robot estimation are related to errors in map estimation. In the absence of information about the robot's position and its environmental characteristics, in order to keep the error of system state estimation within a limited range, it is necessary to maintain the consistency of state estimation. Therefore, it is necessary to update the covariance matrix between the robot states and environmental features in real-time. The scene perception effect of traditional SLAM relies on

*Corresponding Author.

radar or laser sensors and is easily affected by acquisition noise, so sometimes the scene reconstruction and perception effect are not ideal. When the scene contains objects with too single or too complex features, inter frame feature matching is too sparse or too dense, uneven allocation, and affects scene perception, bringing additional computational pressure to backend scene optimization [6]. The author uses visual sensors as the main sensing device to estimate the camera position and the V of the environment in which it is located_ SLAM (Vision based SLAM) group technology, by improving the matching algorithm and backend optimization strategy of SLAM front-end threads, V-SLAM has good scalability, flexibility, and can be applied to large-scale scene perception. The improved V-SLAM can add virtual objects to the scene in real-time, providing users with an intuitive and real-time visual experience, expressing AR effects, and obtaining real-time device parameters and posture determination play an important role in the SLAM system. The global positioning system (GPS) can greatly reduce its positioning accuracy in indoor environments or when signals are severely obstructed; Placing sensors that receive signals in specific indoor environments can obtain rich data and greatly improve positioning accuracy, but it requires pre-arranged usage scenarios and does not have good flexibility and adaptability; Lidar systems are difficult to popularize due to their high cost. V-SLAM has significant advantages in scenario adaptability, scalability, and low cost [7]. V-SLAM has natural advantages in augmented reality positioning solutions, the improved V-SLAM proposed by the author can add virtual objects while constructing the three-dimensional scene of the environment, allowing users to add selected objects to the perception scene. Currently, there are many types of SLAM algorithms, ORB- SLAM (OKVIS, viorbvins- SLAM)、DTAM (dense tracking and mapping) and LSD-SLAM (large scale direct monocular SLAM). ORB-SLAM is a SLAM algorithm based on keyframe BA, using the PTAM (pickuptruck access method) system framework. ORB SLAM uses ORB feature points for matching to improve the accuracy of bundle adjustment. DTAMLo and LSD-SLAM7 solve for motion by directly comparing pixel colors between images, these two local pixel based SLAMs have good reconstruction performance in noisy environments. They can restore 3D scenes in real-time, but LSD SLAM can only restore depth maps of semi dense scenes; Due to the need for DTAM to process the depth information of each pixel to establish a dense map, the computational complexity is high and the scene perception efficiency is low. By constructing a feature transformation network, which is composed of multiple similar affine transformation, the author matches feature points to improve the matching accuracy and efficiency, thus reducing the calculation time of front-end threads [8-9]. Fig. 1 is the flow chart of the overall visual SLAM.

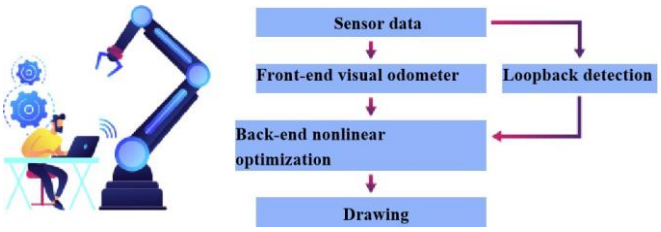

Fig. 1. Overall visual SLAM flowchart.

II. METHODS

The V-SLAM system mainly includes front-end and back-end threads, among which the front-end threads mainly pass through visual sensors such as cameras, input the acquired data into the SLAM system for initialization, put the SLAM system into tracking state, and output real-time camera pose and scene point cloud; The backend thread mainly optimizes the thread, and there may be pose deviation or scale drift during camera motion or scene switching, resulting in error accumulation, when the error accumulates to a certain extent, it will cause the algorithm module to stop working, the backend thread uses scene loop detection to correct the drift phenomenon that occurs during the camera movement process, the author uses local or global optimization to reduce the error accumulation of SLAM system [10].

A. Front End Thread Design for V-SLAM

The SLAM system initializes the system by detecting a certain number of feature points and enters camera tracking mode, the tracking stage mainly includes motion between images and scenes, image feature extraction, feature matching, and reconstruction from 2D images to 3D scenes. Visual sensors are used in unknown environments, perceiving the surrounding environment by capturing continuous environmental images, while constructing a scene using a three-dimensional sparse point cloud, with the world coordinate system feature point X; Projection to the image coordinate system, which includes the transformation from the world coordinate system to the camera coordinate system and the transformation from the camera coordinate system to the imaging coordinate system. In the world coordinate system, the feature points Xn of the environment [11-12]. The motion parameter during the shooting process in three-dimensional coordinates $[x_n, y_n, z_n]^T$ can be expressed as $C_1,...,C_i,...,C_n$, each camera motion parameter contains 3x3 camera rotation matrix Rn and position offset pn. Convert the feature point Xn in the world coordinate system to the camera's local coordinate system as shown in Eq. (1):

$$\begin{bmatrix} x_{cn} \\ y_{cn} \\ z_{cn} \end{bmatrix} = R_n \left(\begin{bmatrix} x_n \\ y_n \\ z_n \end{bmatrix} - p_n \right) \tag{1}$$

The camera projects the 3D point $[x_{cn}, y_{cn}, z_{cn}]^T$ in the camera coordinate system to the image point $[x, y]^T$ in the 2D coordinate system through perspective changes:

$$\begin{bmatrix} x \\ y \end{bmatrix} = \left[\frac{F_x x_{cn}}{z_{cn}} + c_x, \frac{F_y y_{cn}}{z_{cn}} + c_y \right]^T \tag{2}$$

Among them, c_x, c_y represent the position of the lens optical center in the image, F_x, F_y represents the focal length

of the image along the x and y axes, and (x, y) represents the pixel position.

The environmental structure feature points in the world coordinate system are projected onto the image coordinate system, and each frame of the image input to the camera sensor is used for feature extraction and feature point matching between adjacent frames, feature point extraction and matching provide the data required for SLAM algorithm processing, which is related to the quality of camera path reconstruction and the accuracy of scene perception. High precision feature point matching algorithms are beneficial for reducing error accumulation during camera motion [13].

In order to generate accurate camera paths and high-quality scene perception, the V-SLAM system requires continuous feature point matching between hundreds or even thousands of frames of images. The feature matching algorithm proposed by the author ensures global optimization and has a certain degree of robustness through efficient region matching; At the same time, it also has good matching performance in scenes with fewer feature points or scenes where the captured image is blurry due to strong shaking of the lens [14-15].

The camera obtains consecutive frames $I_1,...,I_i,...,I_n$, using the image of the region where a feature point is located in frame Ii as a template, adjacent frame image I_{i+1} represents the image to be matched, and $W(I_i)$ represents the total change in the i-th frame image:

$$v_m = \max_{s \in N(m)} |I_i(m) - I_i(s)| \tag{3}$$

$$W(I_i) = \sum_{m \in I_i} |v_m| \tag{4}$$

Among them, the maximum difference between pixel point m and its adjacent eight pixels N (m) is taken as the variation of m. Traditional image matching algorithms first extract feature points from two consecutive frames of images, calculate the distance between feature points, and use threshold feature points as matching feature points between the detected image frames. The matching algorithm proposed by the author considers that the continuous frame images taken by the camera have little change, and a feature point image in the image frame Ii is mapped to the next frame image I_{i+1} through a certain affine transformation [16].

B. VSLAM Backend Thread Optimization

In the V-SLAM system, bundle adjustment is the core task of backend optimization. In order to reduce the cumulative error of the SLAM system, the backend threads of the SLAM system include local bundle adjustment (LBA) and global bundle adjustment (GBA) 24. LBA mainly optimizes the local scenes and camera keyframes generated during the process, while GBA optimizes all image frames and landmark pose features. The author proposes an improved LBA and segmented GBA optimization strategy. Once a new keyframe is added in the scene, LBA optimization is triggered, the feature points and camera trajectories of the current keyframe and previous frames within a certain time range are processed using improved segmented GBA [17-18].

In traditional SLAM systems, the key frame count for LBA optimization is 70-85, with a maximum of 100 frames, there is a significant consumption of redundant storage in system computing and storage. When the V-SLAM system processes captured video clips, when the visible two-dimensional feature points in a certain image frame meet the set values, they are labeled and added to the keyframe set. In local scenes, LBA optimizes the visible feature points in these keyframes. The traditional LBA optimization method involves the appearance of optimized 3D feature points in newly added keyframes, resulting in repeated optimization of visible feature points and keyframes in the scene, resulting in a large amount of redundant computation and memory consumption, greatly reducing the efficiency of SLAM backend processing threads. In the process of generating local environment, when high-precision local scene landmarks are detected, the author defines them as fixed landmarks, which can be used as reference landmarks to make other keyframes or scenes reference their positions to estimate coordinates. The same visible feature point does not need to be optimized multiple times, as the accumulation of system errors reduces the accuracy of camera trajectory and landmark coordinates. The backend system records the number of optimizations for visible feature points in each keyframe, when the point has been optimized 10 times, it is marked as a reference landmark, and LBA will no longer optimize the landmark and can estimate the camera pose of the current frame using this point. If there are visible reference landmarks in the newly added keyframes, LBA will no longer optimize them, thereby reducing the number of visible points for local optimization. For large scenes with many keyframes, when the keyframes exceed 120, the average keyframes in local LBA optimization range from 50 to 65, reducing the computational burden of the system and improving the efficiency and accuracy of local BA optimization.

In the backend optimization of V-SLAM system, GBA optimizes all global keyframes and visible feature points, resulting in high computational complexity and memory consumption, the number of optimizations far exceeds that of LBA. For the accumulation of errors in GBA optimization, the author proposes a segmented optimization to gradually eliminate error accumulation, each continuous frame calculates a set of motion variables, the relative error of continuous image frames is relatively small, and only needs to be calculated at the connection between segments, compared with traditional GBA optimization, the performance is improved to a certain extent, and the processing efficiency is improved to a certain extent. The relative pose of each consecutive keyframe remains unchanged during optimization, only visible landmarks between segments are optimized, experimental data shows that the improved backend optimization strategy has good real-time performance and high efficiency in processing camera trajectory optimization in large scenes. At the same time, in augmented reality applications, the system detects that a plane in a real-time scene is considered a homography plane that can add objects, manually adding a 3D model to the scene can provide users with a more intuitive visual experience [19].

III. Experimental Results

The author proposes a fast scene reconstruction algorithm based on improved V-SLAM, which includes parallel front-end and back-end threads, and is deployed and implemented on a personal PC, the hardware configuration is IntelCorei584002.8GHz CPU, 8GB memory, NVIDIAGTX1050Ti graphics card, OS is ubuntu16.04, and input video image resolution is 640x480. In the V-SLAM system, the front-end tracking thread projects real-world 3D points onto the 2D points of the current frame to solve the camera pose transformation, it is necessary to determine the position or offset of a feature point in the next frame. The author proposes a region matching algorithm for inter frame feature point matching to minimize errors and reduce computational pressure on backend optimization threads. Select an area with many or dense feature points, perform template affine transformation through the transformation network to match the next frame, select ROI in the region of interest in the image, and input ROI into the transformation network through certain amplification or reduction of ROI, the transformation network performs affine transformation on ROI until a transformation maximally matches a region of the next frame image, so that the feature points in the region can be matched. Good performance can also be achieved in cases of camera shake and rapid rotation, and the use of transform networks reduces the burden on the SLAM system and improves its real-time performance.

The algorithm proposed by the author was tested in offices and large indoor scenes, during the experimental shooting, the camera experienced some shaking and rapid movement, the algorithm combined RGB images and depth images for real-time processing to reconstruct a sparse 3D point cloud of the scene, the sparse reconstructed 3D point cloud was displayed in blue, the newly added 3D point cloud at the current frame in the scene is displayed in red, and the yellow trajectory represents the reconstructed camera motion trajectory. V-SLAM performs sparse reconstruction on two types of indoor environments, and the shooting data of the two scenes are shown in Table I. The SLAM method proposed by the author has good reconstruction results for large factory buildings, with the yellow trajectory being the camera shooting path trajectory.

TABLE I. Scene Information of Offices and Large Factories

Scenario Type	Track length/m	Time 1 second	Average Movement Speed/(m/s)
Office Scenarios	21.460	88.0	0.250
Large factory buildings	40.051	173.2	0.240

In terms of backend optimization, the main focus is on optimizing camera trajectories, including camera loop detection, local or global BA optimization, and scene map expansion. The author adopts a segmented optimization approach, marking feature points with optimized values reaching a certain threshold as reference landmarks without further processing, reducing the computational complexity of the system and improving real-time data processing capabilities. In the experiment, the camera trajectory was saved to a CameraTrajectory file and compared with the actual trajectory on the ground, absolute trajectory error (ATE) was used for comparison, and ATE was used to compare the SLAM system based on keyframes, as shown in Table II.

TABLE II. Path Absolute Error Analysis

Scenario Type	ATE /m			
	ORB-SLAM	PTAM	ISD-SLAM	Ours
Office Scenarios	0.100	0.745	0.874	0.096
Large factory buildings	0.121	0.727	0.895	0.104

Preprocessing was performed on each frame of the image, and a timestamp was used to compare the estimated camera pose with the actual camera pose, as shown in Fig. 2, compare the results of the error between the real trajectory and the optimized camera trajectory in the office small scene environment, by calculating the difference between camera poses in each segment, the absolute translation error is 0.09623. When estimating errors in large factory buildings, the backend optimization thread of the system performs well, as shown in Fig. 3, the actual trajectory and camera trajectory only deviate to a certain extent in local areas, while the other parts almost overlap. The absolute translation error in larger scenes is 0.10448. Root mean square error (RMSE) is also used to evaluate backend thread optimization performance, as shown in Table III. By comparing the performance parameters of various SLAM systems in the same scenario, the algorithm proposed by the author can more accurately process deep data and meet the real-time requirements of V-SLAM systems.

TABLE III. Comparison of Root Mean Square Error of Absolute Path for Key Frames of Different Algorithms

Scenario Type	RMSE /m			
	ORB-SLAM	PTAM	ISD-SLAM	Ours
Office Scenarios	0.034	-	0.385	0.030
Large factory buildings	0.381	0.332	0.356	0.327

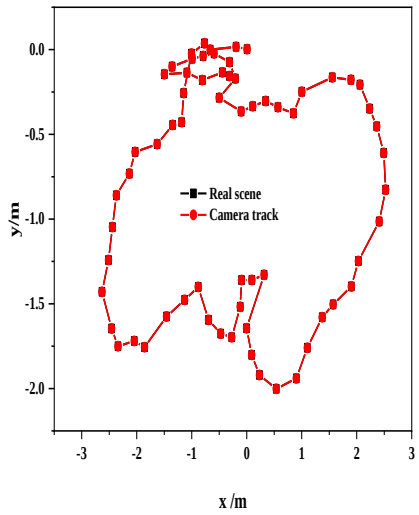

Fig. 2. Comparison of camera errors in office environments.

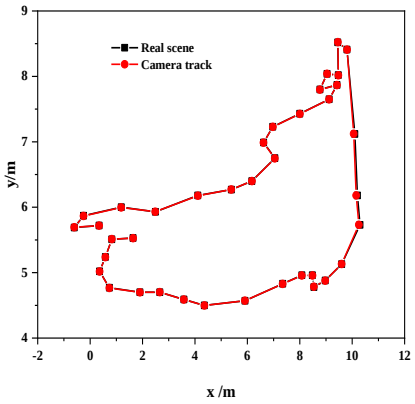

Fig. 3. Error comparison of camera trajectories in large factory environment.

The V-SLAM method proposed by the author can add virtual 3D objects to real scenes. The V-SLAM system can extract feature points from the screen in real-time and detect scene plane objects, ensuring that multiple virtual objects in the scene meet geometric consistency with the actual scene. In the experiment, two objects were added to the virtual scene, users can interactively scale objects and add them without being affected by camera movements, ensuring consistency between objects and the real scene [20].

IV. Conclusion

SLAM technology has been a research and application hotspot in recent years, applied in fields such as scene reconstruction, perception, digital city construction, VR/AR applications, drone driving, robotics, etc. SLAM includes LSDSLAM, ORBSLAM, Mono SLAM, etc. Simultaneous Location and Map Building (SLAM) plays an important role in the fields of computer vision and robotics, and also provides basic technical support for VR/AR applications. When facing scenes with relatively single or complex features, the front-end feature matching module of traditional SLAM systems is difficult to generate accurate camera trajectory and scene reconstruction results due to the sparsity or density of feature points. The author proposes an improved algorithm for arbitrary path scene reconstruction based on visual SLAM, the front-end thread uses Hessian matrix to extract and match the image features, and applies affine transformation to the region of interest to identify the feature points of adjacent frames to improve the matching efficiency, thereby reducing the original error of camera track and scene reconstruction; The backend optimization thread reduces the number of marker points to optimize the number of feature points, and uses local and global BA (bundle adjustment) methods to segment and optimize the camera motion trajectory, reducing system errors and improving the efficiency of camera trajectory optimization. The proposed method can add 3D objects in real-time to the scene. The experimental results show that the improved visual SLAM algorithm has better real-time performance than traditional SLAM algorithms.

Optimizing Threat Intelligence Strategies for Cybersecurity Awareness Using MADM and Hybrid GraphNet-Bipolar Fuzzy Rough Sets

Qian Zhang
Shaanxi Police College,
Xi'an, Shaanxi, 710021, China

***Abstract*—Advanced threat detection systems are needed more than ever as cyber-attacks become more advanced. A novel cybersecurity model uses Bipolar Fuzzy Rough Sets, Graph Neural Networks, and dense network (BFRGD-Net) architectures to identify threats with unmatched accuracy and speed. The approach optimizes threat detection using Dynamic Range Realignment, anomaly-driven feature enhancement, and a hybrid feature selection strategy on a comprehensive Texas dataset of 66 months of real-world network activity. With 97.8% accuracy, 97.5% F1-score, and 98.3% AUC, BFRGD-Net sets new standards in the field. Threat Detection Sensitivity shows the model's capacity to find uncommon, high-severity threats, while Balanced Risk Detection Efficiency provides fast, accurate threat detection. The model has strong correlations and the highest statistical metrics scores compared to other techniques. Extensive simulations demonstrate the model's capacity to discern threat levels, attack kinds, and response techniques. BFRGD-Net revolutionizes cybersecurity by seamlessly merging cutting-edge machine learning with specific insights. Its advanced threat detection and classification engine reduces false negatives and enables proactive critical infrastructure protection in real-time. The model's adaptability to various attack situations makes it vital for cybersecurity resilience in a digital environment.**

***Keywords*—Cybersecurity awareness; threat intelligence; MADM framework; BFRGD-Net; hybrid model; deep learning**

I. Introduction

Advancements in technology have raised cybersecurity risks such as unauthorized access, malware attacks, phishing, and DoS [1]. Over 900 million malware executables existed in 2024, compared to 50 million in 2010 [2]. Annual cybercrime costs firms, individuals, and governments $400 billion. Due to data breaches and security incidents, essential systems and data require cybersecurity. Modernizing security helps companies avoid losses and adapt to shifting threats. Cybersecurity shields data, programs, networks, and systems against cyberattacks and unauthorized access [2]. Security for networks, applications, data, and operations. Data-driven cybersecurity solutions complement firewalls, antivirus, and intrusion detection. To improve threat detection, machine learning (ML) may find hidden patterns and irregularities. Cybersecurity machine learning is part of AI-powered decision-making and threat identification. Attackers' expertise in exploiting connected technologies is leading to more complex cyber threats [3]. From 2015 to 2022, cybersecurity and machine learning gained popularity from 30 to over 70 [3]. ML increases complex dataset analysis, security, and incident response. Traditional security measures, such as user authentication, cryptographic systems, and firewalls, need human setup and maintenance, making them less effective as threats evolve [4] Thus, machine learning and data analytics-based adaptive and automated systems discover new risks and provide robust protection.

Cybersecurity situational awareness (SA) involves collecting, evaluating, and interpreting information from several sources to manage risks [5]. SA, created for military usage, is currently utilized in cybersecurity to understand activities. Real-time vulnerability and network traffic analysis may prevent attacks. SA frameworks integrate data from several sources, including network traffic and vulnerability assessments, to provide a comprehensive security picture [5]. SA predicts and detects cyberattacks using many data sources. Many situational awareness methods manually gather and analyze data. Despite advancements in data fusion and machine learning, human participation remains vital [6]. Our fully automated systems must use the Common Vulnerability Scoring System to monitor and evaluate network parts for vulnerabilities and security risks.

Company cybersecurity awareness initiatives may raise security awareness and share responsibilities. A frequent cybersecurity risk is the human component since workers are the weakest link in the security chain [7]. Security-focused workplaces prevent errors and social engineering. Cyberattacks may harm reputation, legal obligations, consumer confidence, and money. Secure solutions must address technology and humans. As more people use the internet, hackers target browsers. Using browser vulnerabilities, attackers may get access to devices and steal sensitive data [8]. Covert downloads from reputable websites spread 22 million malware types in 2022. User data must be protected from browser-based attacks using security, notably automated threat detection. Cybersecurity requires flexibility. To resist growing threats, cybersecurity defenses must adapt to new attack methods [9]. Machine learning and situational awareness automate danger detection in this essay. Multi-domain threat detection is improved by diverse data sources and new techniques. Main contributions of this research.

1) The BFRGD-Net framework is introduced to enhance threat intelligence, integrating BFRS, GNN, and DenseNet architectures to improve Cyber Secu-

rity Awareness Programs. This advanced approach facilitates accurate threat detection by identifying intricate patterns in network traffic, hence enhancing the precision and dependability of threat intelligence techniques.

2) The study introduces innovative preprocessing techniques, including HTS and CBSA, that substantially improve data quality and model resilience in support of cyber security awareness. By mitigating data imbalance and noise, these solutions enable threat intelligence tactics to react to emerging cyber threats, hence enhancing the efficacy of awareness programs.
3) Hybrid Feature Selection for Enhanced Threat Identification: The use of a hybrid feature selection methodology that integrates Statistical-Driven Filtering, Redundancy Aggregation, and ODAS guarantees the prioritization of the most pertinent and significant characteristics. This enhancement improves threat detection, making it a substantial tool for advancing Cyber Security Awareness Programs.
4) The research introduces new metrics—TDS, AIS, and BRDE—that provide a more thorough assessment of threat detection efficacy. These metrics are designed to assess the model's capacity to recognize significant risks and optimize detection efficiency, aiding in the identification of the most effective tactics for improving cybersecurity awareness.
5) Exhibiting Enhanced Threat Detection to Guide Awareness Initiatives: Comprehensive assessments indicate that BFRGD-Net routinely surpasses current models, demonstrating superior capability in detecting diverse attack types and categorizing threat severity levels. This performance highlights the framework's capacity to enhance Cyber Security Awareness Programs via the provision of actionable and timely threat information.

The remaining structure of the paper: Section 2 discussed the review of relevant literature. The proposed method structure is described in detail in Section 3. The simulations and their accompanying discussion are detailed in Section 4. The last section concludes with a discussion of future work.

II. Related Work

Threat intelligence and cybersecurity awareness initiatives have been improved using machine learning and decision-making frameworks. The NIST cybersecurity lifecycle consists of five steps: Identify, Protect, Detect, Respond, and Recover, offering a systematic threat management strategy [10]. However, many studies disregard lifecycle-wide techniques and concentrate on one or two processes. One threat intelligence technique in Software-Defined Networking (SDN) uses a Support Vector Machine (SVM) to discover attack scenarios and analyze vulnerabilities [11]. Another method uses K-Nearest Neighbors (KNN) to categorize IoT network traffic by risk level [12]. These strategies emphasize identification without incorporating threat intelligence throughout the lifecycle.

Threat detection is improved via machine learning. An anomaly-based intrusion detection system (IDS) increased prediction accuracy by using Recurrent Neural Networks (RNNs) to identify unexpected network patterns [13]. A Multiclass Support Vector Machine (SVM) was used to categorize network abnormalities in real-time, successfully distinguishing attack types [14]. Due to obsolete datasets, many methods fail to identify new threats. Users learn to recognize and react to cyber dangers via cybersecurity awareness programs. Static material in traditional systems may not be adequate for developing threats [15]. A dynamic strategy using Graph Neural Networks (GNNs) was suggested to update cybersecurity training material depending on current threat information [16]. Using Convolutional Neural Networks (CNNs), another application created interactive training simulations [17]. These strategies increased training but did not integrate live threat intelligence data. Cybersecurity methods are evaluated using MADM frameworks. One method assessed intrusion detection trade-offs using Decision Trees (DT) based on accuracy and reaction time [18]. Analytical Hierarchy Process (AHP) and Logistic Regression (LR) were used to prioritize threat response techniques and evaluate their influence on security [19]. Although effective, MADM approaches are seldom used to improve awareness training.

Deep learning-fuzzy logic hybrid models can handle cybersecurity uncertainty. LSTM networks and Fuzzy C-Means clustering were utilized to identify Advanced Persistent Threats (APTs) using fuzzy logic to handle imprecise data [20]. A study used Deep Belief Networks (DBN) and Fuzzy Inference Systems (FIS) to improve network anomaly classification accuracy under uncertainty [21]. Fuzzy rough set techniques have been used in cybersecurity research, notably for uncertain decision-making. Bipolar Fuzzy Rough Sets (BFRS) add bipolar information to fuzzy logic for more sophisticated decision-making. In the study, BFRS using Random Forest (RF) classifiers improved phishing attack detection rates by addressing uncertainty in approaches [22]. BFRS and Neuro-Fuzzy Systems (NFS) were combined to enhance threat categorization and protect against zero-day attacks [23]. Merging Bipolar Fuzzy C-Means (BFCM) clustering with BFRS may enhance network traffic anomaly detection and reduce false positives [24].

Cybersecurity hybrid models and decision-making frameworks are difficult to integrate. Many frameworks lack thorough integration of situational awareness technologies and threat intelligence methodologies, and obsolete datasets hinder innovative threat detection. The summarized view of the literature is shown in Table I.

TABLE I. Summarized Literature Review

Ref	Method Used	Objective Achieved	Limitations
[10], [11]	SVM, KNN	Detection of attack scenarios and classification of network flows in SDN and IoT environments based on risk levels.	Focuses mainly on identification without fully integrating the complete threat lifecycle.
[12], [13]	RNN, Multiclass SVM	Anomaly detection and real-time classification of network anomalies, improving prediction accuracy by leveraging historical data.	Relies on outdated datasets, limiting the ability to detect emerging threats.
[14], [15]	GNN, CNN	Dynamic modeling of relationships between cybersecurity events for adaptive training and creating interactive simulations for better user engagement.	Lacks full integration with live threat intelligence data, limiting real-time adaptability.
[16], [17]	Decision Trees, AHP, Logistic Regression	Evaluation of intrusion detection configurations and prioritization of threat response strategies based on various criteria (e.g., accuracy, cost).	Rarely applied to evaluating cybersecurity awareness programs' effectiveness.
[18], [19]	LSTM, Fuzzy C-Means, DBN, FIS	Detection of Advanced Persistent Threats and classification of network anomalies under uncertain conditions.	High computational cost and limited adaptability to novel attack types.
[20], [21], [22]	BFRS, Random Forest, Neuro-Fuzzy Systems, BFCM	Detection of phishing attacks, adaptive threat classification, and enhanced anomaly detection using Bipolar Fuzzy Rough Sets.	May require continuous retraining, with increased sensitivity potentially leading to higher false-positive rates.

A. Challenges and the Need for BFRGD-Net

Cybersecurity threat identification is complicated by uneven datasets, dynamic attack patterns, and real-time reaction. These issues demand a model that can manage uncertainty, rapidly interpret complicated data linkages, and react to changing threats. The BFRGD-Net framework was created around these factors. It uses BFRS, GNNs, and DenseNet to provide a resilient, adaptable solution.

1) Suitability of BFRGD-Net for cybersecurity challenges:

- Bipolar Fuzzy Rough Sets clearly accommodate for ambiguous patterns by separating confidence and uncertainty, making the model more accurate in finding anomalies with confusing features.
- Relational Insights: GNNs capture source-destination dependencies and flow correlations, which are essential for threat categorization.
- DenseNet's layered architecture efficiently propagates and reuses features, allowing it to analyze high-dimensional data without duplicate calculations.
- Balanced Detect: BFRGD-Net balances feature significance and class distributions in cybersecurity datasets using hybrid feature selection (Statistical-Driven Filtering, RRFA, ODAS) and advanced preprocessing (CBSA, HTS).

2) Existing technique limitations:

- Traditional models like SVM and KNN struggle with huge, unbalanced datasets and cannot identify high-severity, low-frequency threats.
- CNNs and LSTMs ignore network traffic related relationships in favor of spatial or temporal patterns.
- Fuzzy logic can manage uncertainty, but hybrid systems like BFRGD-Net give scalability and real-time flexibility.
- Old dataset models cannot adapt to new attack vectors, limiting their real-world usefulness. However, BFRGD-Net's superior preprocessing and dynamic feature selection enable stable performance in changing settings.

BFRS, GNN, and DenseNet in the BFRGD-Net architecture overcome these restrictions, enabling great sensitivity to uncommon threats, real-time efficiency, and flexibility to varied attack scenarios. These traits make BFRGD-Net ideal for current cybersecurity applications, assuring its relevance and efficacy in solving problems.

III. Proposed Method

To improve threat classification accuracy and resilience, the proposed cybersecurity threat detection framework uses modern Deep learning and statistical analysis methodologies. The hybrid architecture, BFRGD-NeT, uses Bipolar Fuzzy Rough Sets (BFRS) and a GNN-DenseNet model to leverage GNNs' relational learning and DenseNet's feature reuse. Data is preprocessed using Dynamic Range Realignment and Perturbation-Weighted Outlier Filtering to ensure quality and correct feature imbalance. A Hybrid Feature Selection technique using Statistical-Driven Filtering and Optimization-Driven Adaptive Selection identifies the most relevant features for classification after preprocessing. Feature transformation improves model training data representation using Scaled Differential Encoding and Exponential Scaling Modulation. Using its capacity to manage ambiguity and relational data, the BFRGD-NeT model classifies threats. Using Adaptive Learning Rate Adjustment, model hyperparameters are fine-tuned for best performance. The proposed framework is shown in Figure 1 and afterwards, each module is explained in detail.

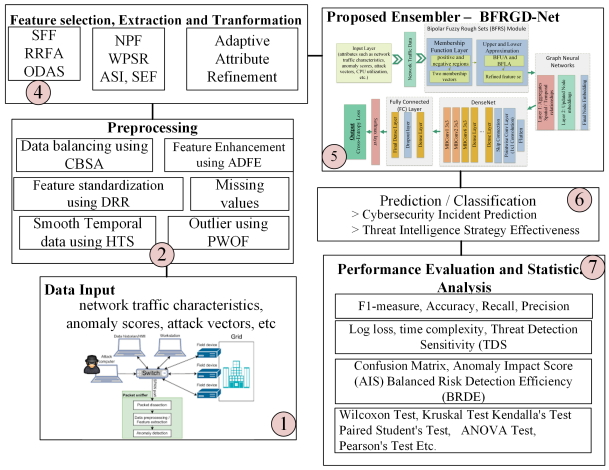

Fig. 1. Proposed system framework.

A. Dataset Description

This research utilized real-world Texas network traffic and cybersecurity activities. Over 66 months, from January 2018 to July 2024, the study collects hourly network events, user behaviors, and system states in an active corporate network infrastructure [23]. Financial companies, healthcare providers, and educational institutions in the area provided vital cybersecurity information for the dataset. These firms follow strong compliance standards to protect data. From low-level abnormalities to high-severity threats, the data shows how cyber dangers evolve. In Texas, a technological and industrial powerhouse, network connections, user behaviors, and worldwide cyberattack vectors are abundant. Information from local threat intelligence feeds was included in the dataset to make it more realistic and depict these firms' cybersecurity environment. This dataset provides a complete picture of regional cybersecurity issues by merging numerous data sources and using threat information from internal and external systems. It presents a solid framework for designing and testing advanced threat intelligence tactics to improve cybersecurity awareness and response. The dataset's imbalance, caused by real-world network traffic and attack events, properly depicts current cybersecurity systems' situations. The dataset characteristics are listed in Table II.

B. Data Preprocessing Steps

The dataset underwent preprocessing using many innovative strategies to enhance its appropriateness for machine

TABLE II. DATASET FEATURES OVERVIEW

S.No	Features	Short Description
1	Source IP	IP address of the source device or user.
2	Destination IP	IP address of the target device or server.
3	Source Port	Port number used by the source device for communication.
4	Destination Port	Port number used by the destination device.
5	Protocol Type	Type of protocol used for communication (TCP, UDP, etc.).
6	Flow Duration	Total duration of the network flow.
7	Packet Size	Size of the transmitted packets during the communication.
8	Flow Bytes/s	Rate of bytes transmitted per second.
9	Flow Packets/s	Rate of packets transmitted per second.
10	Total Forward Packets	Total number of packets sent by the source.
11	...	...
18	Anomaly Score	A score indicating the abnormality level of the traffic.
19	Attack Vector	The method or entry point used by the attack.
20	Botnet Family	Family of botnet detected in network traffic.
21	Anomaly Severity Index	Derived feature measuring anomaly severity.
22	CPU Utilization	CPU usage percentage during traffic transmission.
23	Memory Utilization	Memory usage percentage during the flow.
24	Label	Indicate whether the traffic is normal or an attack.

learning [24][25]. The first phase was Dynamic Range Realignment (DRR), used to normalize feature values according to their dynamic range while preserving variability. The transition is articulated as:

$$y_{adjusted} = \frac{y - \min(y)}{\max(y) - \min(y)} + \beta \cdot \left(\frac{\xi(y)}{\psi(y)} \right) \tag{1}$$

β is a weighting factor, $\xi(y)$ is the standard deviation, and $\psi(y)$ is the feature mean. Features with different scales are modified while keeping their relative dispersion using this method. To reduce noise and preserve trends across time, Hierarchical Temporal Smoothing (HTS) was employed to smooth temporal data across periods. Smoothing involves:

$$y_{smooth} = \frac{1}{h} \sum_{k=1}^{h} (y_{t-k} + y_{t+k}) + \theta \cdot \sum_{l=1}^{n} u_l \cdot y_{t-l} \tag{2}$$

where h represents short-term window size, θ adjusts long-term trend, and u_l weights temporal distances. This successfully captures short-term and long-term tendencies. Perturbation-Weighted Outlier Filtering (PWOF) was created to handle outliers. The following rule filtered outliers:

$$y_{filtered} = \begin{cases} y & \text{if } |y - \text{median}(y)| \leq \zeta \cdot \xi(y) \\ \text{median}(y) & \text{otherwise} \end{cases} \tag{3}$$

where ζ is the threshold determining outlier sensitivity, and $\xi(y)$ is the standard deviation. This method ensures that extreme values are moderated without affecting the general distribution of the feature. To handle class imbalance, *Cluster-Based Synthetic Amplification (CBSA)* was applied, generating synthetic samples for underrepresented classes based on clustering. The synthetic sample generation is governed by:

$$y_{synth} = y_g + \lambda \cdot (y_g - y_h) \tag{4}$$

where y_g is the cluster centroid, y_h is an adjacent point, and λ regulates synthetic amplification. This generates realistic new data points to balance the collection. In conclusion, *Anomaly-Driven Feature Enhancement (ADFE)* was used to enhance important features, particularly surrounding identified assaults. Enhancement calculation is done using the following equation:

$$y_{enhanced} = y \cdot \left(1 + \omega \cdot \frac{1}{1 + e^{-\phi(t - t_{event})}} \right) \tag{5}$$

ω indicates the amplification factor, ϕ adjusts temporal effect, and t_{event} represents the closest attack timestamp. This technique emphasizes anomaly-related characteristics as needed. These preprocessing processes balance, normalize and filter the dataset while keeping temporal and anomaly-based information needed for robust model performance.

C. Hybrid Feature Selection Process

This research uses a hybrid feature selection procedure that combines innovative strategies to maximize relevance and reduce duplication [26]. First, Statistical-Driven Feature Filtering (SFF) assesses feature variance and class separability contribution. For dataset imbalances, SFF dynamically weights feature importance by class distribution, unlike previous approaches. The significance score for feature h is determined as:

$$W_h = \frac{\zeta_h}{\eta_h} \cdot \frac{1}{1 + e^{-\mu(T_h - \bar{T})}} \tag{6}$$

ζ_h and η_h represent the feature's standard deviation and mean, T_h represents its correlation with the target label, and μ regulates the score's sensitivity This prioritizes high-variance, class-separable characteristics. To reduce feature redundancy, Redundancy-Reduced Feature Aggregation (RRFA) was created. This technique penalizes feature content redundancy by measuring overlap. The aggregate score for feature pairs (h_i, h_j) is:

$$V_{h_i,h_j} = \frac{|S_{h_i,h_j}|}{1 + \phi \cdot |S_{h_i,h_j}|} \tag{7}$$

Where S_{h_i,h_j} represents the correlation between features, and ϕ penalizes highly correlated features, preserving only the most representative ones from each correlated collection. Next, the Optimization-Driven Adaptive Selector (ODAS) approach is used. The cost function in ODAS repeatedly adjusts feature weights depending on predicted accuracy while punishing needless complexity. The cost function is:

$$\mathcal{F} = \sum_{h=1}^{m} v_h \cdot R(h) + \theta \cdot \sum_{j=1}^{m} v_j^2 \tag{8}$$

where v_h is feature weight, $R(h)$ is error contribution, and θ is regularization parameter. This refines choices by deleting low-performance model characteristics. SFF, RRFA, and ODAS are combined to keep just the most important, non-redundant features in the hybrid feature selection approach. This method optimizes features for prediction performance and simplicity.

D. Derived Attribute Transformation

This work proposed a unique approach called *Derived Attribute Transformation (DAT)* to create new characteristics from existing ones, therefore improving the dataset's capacity to capture intricate interactions. The first derived feature, *Normalized Packet Flow (NPF)*, integrates forward and backward packet counts normalized by flow time, articulated as:

$$\text{NPF} = \frac{(P_{\text{forward}} + P_{\text{backward}})}{\text{Flow Duration}} \tag{9}$$

This function captures a network flow's communication strength. Computed as weighted packet size ratio (WPSR), another attribute balances forward and backward packet sizes relative to flow bytes:

$$\text{WPSR} = \frac{\text{Forward Packet Size} \cdot \text{Flow Bytes}}{\text{Backward Packet Size} + \epsilon} \tag{10}$$

Using IDS alerts and reputation score, a crucial function Anomaly Severity Index (ASI) increases the anomaly score:

$$\text{ASI} = \text{Anomaly Score} \cdot (1 + \log(1 + \text{IDS Alerts})) \cdot \left(\frac{100 - \text{Reputation Score}}{100}\right) \tag{11}$$

This underscores the importance of reputation and IDS alerts in the identification of hazards. The *Session Efficiency Factor (SEF)* is a metric that integrates system resource utilization and session activity.

$$\text{SEF} = \frac{\text{Active Duration}}{\text{Idle Duration} + \epsilon} \cdot \left(\frac{\text{CPU Utilization}}{\text{Memory Utilization} + \epsilon}\right) \tag{12}$$

Lastly, Dynamic Threat Potential (DTP) figures out risk based on how bad an attack is and how many hosts have been hacked:

$$\text{DTP} = (\text{Attack Severity} \cdot \log(1 + \text{Compromised Hosts})) \cdot \frac{1}{1 + e^{-\gamma \cdot (\text{Attack Vector})}} \tag{13}$$

The newly created features, produced by the DAT method, provide enhanced insights into network activity, hence improving model performance for predictive analysis.

E. Adaptive Attribute Refinement (AAR)

A new method of transformation called Adaptive Attribute Refinement (AAR) is suggested in this research. The goal of this approach is to dynamically modify feature values according to how they affect the distribution of the whole dataset so that important patterns are highlighted and noise is reduced [26]. When characteristics change substantially between classes or time intervals, the AAR process uses an adaptive scaling technique to account for this. In the first stage of transformation, known as Dynamic Weight Adjustment (DWA), the statistical variance and impact of each feature on class separability are used to weigh the value of each feature. The feature y transformation is defined as:

$$y_{\text{adj}} = y \cdot \left(1 + \kappa \cdot \frac{|y - \nu_y|}{\tau_y}\right) \tag{14}$$

where ν_y is the feature mean, τ_y is the standard deviation, and κ is an adaptive scaling factor based on the feature distribution. This emphasizes outliers and major deviations by weighing data further from the mean. The next stage, Contextual Recalibration (CR), refines the converted feature depending on its temporal or category context. In datasets with characteristics that respond differently under different situations (e.g., events), this is beneficial. The recalibration process:

$$y_{\text{rec}} = y_{\text{adj}} \cdot \frac{1}{1 + e^{-\lambda \cdot (D_t - \bar{D})}} \tag{15}$$

λ is a sensitivity factor, D_t is the feature's contextual score at the time (t), and $\bar{D}$ is the dataset's average contextual score This adjusts features depending on their situation or class relevance. Finally, the Smooth Variance Reduction (SVR) stage reduces noise while maintaining essential trends. This stage maintains the converted feature's variability by smoothing severe variations. Transformation is modulated by:

$$y_{\text{smooth}} = \frac{y_{\text{rec}}}{1 + \theta \cdot \rho_{\text{local}}} \tag{16}$$

θ is a tuning parameter, and ρ_{local} is the local variance within a preset window of neighboring values. Short-term spikes are reduced but long-term patterns are maintained. The integrated Adaptive Attribute Refinement (AAR) technique produces a robust transformation process that improves the model's crucial pattern detection, noise reduction, and context-aware dataset refinement. This technique dynamically adapts each feature depending on its importance to the task, improving model accuracy and resilience.

This work uses BFRGD-Net, a unique classification model that combines Bipolar Fuzzy Rough Sets (BFRS) with GNN-DenseNet. This hybrid model benefits from Bipolar Fuzzy Rough Sets (BFRS) for uncertainty and interpretability, Graph Neural Networks (GNNs) for relational learning, and DenseNet for feature propagation and reuse. This layered structure is ideal for high-dimensional, complicated data like cybersecurity threats, where local and global interactions are crucial to threat identification.

F. Classification using BFRGD-Net

An improved method for handling uncertainty is presented by the Bipolar Fuzzy Rough Sets (BFRS) [27] framework, which describes the dataset using positive and negative areas. Positive associations represent certainty, while negative connections capture doubt. The proposed layered archictecutre is shown in Figure 2.

This is of the utmost importance in the field of cybersecurity since irregularities often manifest in unpredictable data patterns. The membership functions, both positive and negative, are defined by the BFRS method as:

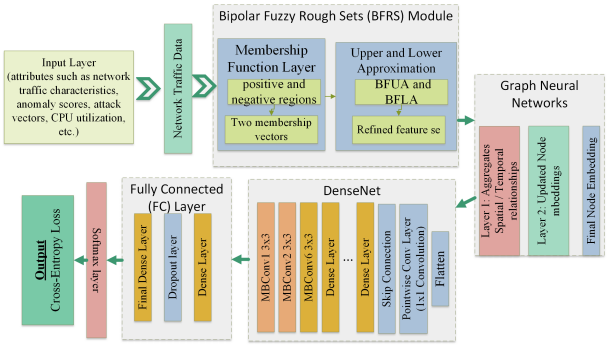

Fig. 2. Proposed BFRGD-Net architecture.

$$P(Z) = \{z \in U \mid \nu_1(z) \geq \alpha\}, \quad N(Z) = \{z \in U \mid \nu_2(z) \leq \beta\} \tag{17}$$

In this instance, $P(Z)$ and $N(Z)$ denote the positive and negative areas, respectively, while $\nu_1(z)$ and $\nu_2(z)$ signify the membership functions for the positive and negative classes. Additionally, α and β represent the thresholds that delineate the certainty and uncertainty regions. The Bipolar Fuzzy Upper Approximation (BFUA) and Bipolar Fuzzy Lower Approximation (BFLA) of a set Z are defined as follows:

$$\text{BFUA}(Z) = \sup_{z \in U} \left(\min\left(\nu_1(z), 1 - \nu_2(z)\right)\right) \tag{18}$$

$$\text{BFLA}(Z) = \inf_{z \in U} \left(\max\left(\nu_1(z), 1 - \nu_2(z)\right)\right) \tag{19}$$

These approximations improve the model's capacity to identify ambiguous data points, aiding in the identification of indistinct cybersecurity risks that display obscure patterns. The Graph Neural Network (GNN) component captures relational connections in graph-structured data, including network traffic and system logs. In Graph Neural Networks (GNNs), each node $g_i^{(l)}$ at layer l consolidates information from its adjacent nodes to enhance its feature representation in the subsequent layer. The propagation rule for a Graph Neural Network layer is delineated as follows:

$$g_i^{(l+1)} = \sigma\left(W^{(l)} \cdot \sum_{j \in \mathcal{N}(i)} \frac{1}{\sqrt{d_i d_j}} g_j^{(l)} + b^{(l)}\right) \tag{20}$$

$g_i^{(l+1)}$ is the updated node feature for node i at layer $l+1$, $W^{(l)}$ is the weight matrix for layer l, d_i and d_j are the degrees of nodes i and j, and σ is the activation function $\frac{1}{\sqrt{d_i d_j}}$ normalizes node connections, enabling balanced information aggregation from nearby nodes. In the cybersecurity dataset, the model may capture local (node-level) and global (graph-level) interactions.

The DenseNet design tightly connects each layer to every other layer feed-forward for optimal feature reuse. This propagates previous layer feature maps without losing critical information, which is vital for deep model performance. The DenseNet l-th layer output is computed as:

$$x^{(l)} = T_l\left(\left[x^{(0)}, x^{(1)}, \ldots, x^{(l-1)}\right]\right) \tag{21}$$

T_l is the transformation (e.g., batch normalization, ReLU, convolution) performed to the concatenated input from all preceding layers $[x^{(0)}, x^{(1)}, \ldots, x^{(l-1)}]$. The model can capture complex cybersecurity data relationships by effectively propagating information by concatenating feature maps. This reduces feature extraction parameters. DenseNet transition layers pool feature maps to reduce dimensionality while preserving crucial information. Transition layer outputs are calculated as:

$$S(x) = \text{BN}\left(\text{ReLU}\left(\text{Conv}(x)\right)\right) \tag{22}$$

where $S(x)$ is transition layer output, BN is batch normalization, $ReLU$ is activation function, and $Conv$ is input feature map convolution. The model stays small and economical without losing performance with this operation. A fully connected layer and softmax function complete the classification stage after GNN-DenseNet processing. Class probabilities for each cybersecurity threat are calculated using learning attributes. Definition of softmax:

$$\hat{y}_k = \frac{e^{o_k}}{\sum_{j=1}^{C} e^{o_j}} \tag{23}$$

The predicted probability for class k is $\hat{y}_k$, the logit output is o_k, and the total number of classes is C. Cybersecurity risks may be accurately classified using the softmax function's probability distribution across all classes. BFRGD-Net training uses cross-entropy loss, which is ideal for multi-class classification problems like threat detection. The cross-entropy loss $\mathcal{L}$ is computed as:

$$\mathcal{L} = -\sum_{k=1}^{C} y_k \log(\hat{y}_k) \tag{24}$$

y_k is the actual label for class k; $\hat{y}_k$ is the projected probability for class k. This loss function motivates the model to provide greater probability for the proper class and penalizes erroneous projections.

Bipolar Fuzzy Rough Sets (BFRS), Graph Neural Networks (GNNs), and DenseNet form the BFRGD-Net architecture, which detects cybersecurity risks effectively. BFRS improves the model's uncertainty handling, GNN layers capture network traffic relational relationships, and DenseNet optimizes feature reuse. With the softmax classification layer and cross-entropy loss function, the model can reliably identify many cybersecurity risks while being computationally efficient. That makes BFRGD-Net ideal for real-time threat identification in complicated cybersecurity contexts.

Algorithm 1 BFRGD-Net Framework

Require: Preprocessed input features $\mathbf{X}$, true labels $\mathbf{Y}$, learning rate η, number of GNN layers L_g, number of Dense blocks L_d, batch size B, number of epochs E
Ensure: Predicted class probabilities $\hat{\mathbf{Y}}$
Step 1: Input Layer
Initialize the input layer with feature vector $\mathbf{X}$
Step 2: Bipolar Fuzzy Rough Sets (BFRS) Module
Calculate positive and negative membership functions for $\mathbf{X}$
Compute Bipolar Fuzzy Upper Approximation (BFUA) and Lower Approximation (BFLA)
Update input features based on BFUA and BFLA
Step 3: Graph Neural Network (GNN) Layers
for $l = 1$ to L_g **do**
    Perform graph convolution on node features using neighbors
    Apply degree normalization and ReLU activation
end for
Step 4: DenseNet Module
for $d = 1$ to L_d **do**
    Perform convolution, batch normalization, and ReLU activation in Dense Block d
    Concatenate output with input features for feature reuse
    if Transition Layer is required **then**
        Apply batch normalization, ReLU activation, and average pooling
    end if
end for
Step 5: Fully Connected Layer
Flatten the output from the DenseNet module
Pass through a dense layer with ReLU activation
Optionally apply dropout for regularization
Step 6: Output Layer
Use a final dense layer to map features to the number of classes
Apply the softmax activation function to get class probabilities $\hat{\mathbf{Y}}$
Step 7: Loss Function and Backpropagation
Compute the cross-entropy loss between $\mathbf{Y}$ and $\hat{\mathbf{Y}}$
Update model parameters using the Adam optimizer with learning rate η
Step 8: Training Loop
for epoch $= 1$ to E **do**
    for each batch of size B **do**
        Forward pass: Perform Steps 1 to 6
        Compute loss and perform backpropagation (Step 7)
        Update parameters
    end for
end for
Return Predicted class probabilities $\hat{\mathbf{Y}}$

G. Role of Bipolar Fuzzy Rough Sets in BFRGD-Net

The BFRGD-Net architecture relies on Bipolar Fuzzy Rough Sets (BFRS) to deal cybersecurity dataset uncertainty and ambiguity. BFRS clearly separates confidence from uncertainty by dividing the dataset into positive and negative areas. This method assures accurate categorization, even when data points overlap or are unclear.

The BFRS module refines data representations using BFUA and BFLA. BFUA finds the largest collection of class members, whereas BFLA finds the most specific. These estimates help the framework manage imprecise and partial data. The BFUA and BFLA are defined mathematically:

$$\text{BFUA}(Z) = \sup_{z \in U} \left(\min \left(\nu_1(z), 1 - \nu_2(z) \right) \right) \tag{25}$$

$$\text{BFLA}(Z) = \inf_{z \in U} \left(\max \left(\nu_1(z), 1 - \nu_2(z) \right) \right) \tag{26}$$

$\nu_1(z)$ and $\nu_2(z)$ are the membership functions for positive and negative classes, respectively, and Z is the dataset.

BFRS improves the model's unusual and ambiguous threat classification by using these approximations. Cybersecurity requires this capability because high-severity anomalies can resemble regular data. In addition to uncertainty managing, BFRS improves model decision-making interpretability, revealing threat identification and classification. In real-world applications where transparency is as crucial as accuracy, interpretability is a major benefit.

H. Performance Evaluation Metrics

To evaluate the BFRGD-Net model for cybersecurity threat detection, metrics like accuracy, precision, recall, and F1-score are used to evaluate correctness, true positives, and precision-recall balance [28]. However, cybersecurity requires identifying uncommon and significant threats, thus we offer three unique metrics: Threat Detection Sensitivity (TDS), Anomaly Impact Score (AIS), and Balanced Risk Detection Efficiency. Threat Detection Sensitivity (TDS) weights low-frequency, high-severity events that dataset imbalances ignore to assess the model's capacity to identify infrequent, high-impact threats. We compute TDS as:

$$\text{TDS} = \frac{\sum_{j=1}^{M} \left(v_j \cdot \frac{A_j}{A_j + B_j} \right)}{\sum_{j=1}^{M} v_j} \tag{27}$$

where v_j represents threat class weight based on severity and frequency, A_j represents true positives, and B_j represents false negatives. This statistic prioritizes infrequent but significant threats, boosting the model's sensitivity to high-risk cybersecurity events. The Anomaly Impact Score (AIS) calculates real-time detection system operating expenses for false positives and negatives. AIS weighs the real-world effect of false positives and missing detections against the advantages of true positives. We define AIS as:

$$\text{AIS} = \frac{\sum_{j=1}^{M} \left(\frac{A_j}{A_j + C_j + \rho \cdot B_j} \right)}{M} \tag{28}$$

ρ penalizes false negatives, especially in high-impact circumstances, whereas A_j represents genuine positives, C_j false positives, and B_j false negatives for class j. This enhances real positive detection while lowering false positives and undiscovered threats. Finally, Balanced Risk Detection Efficiency (BRDE) evaluates the model's real-time detection accuracy and operating efficiency. To respond quickly, cybersecurity models must effectively identify threats with minimal latency. These two elements are balanced in BRDE:

$$\text{BRDE} = \frac{\sum_{j=1}^{M} \left(\frac{A_j}{A_j + C_j + B_j} \cdot \frac{1}{1 + \theta \cdot D_j} \right)}{M} \tag{29}$$

where D_j is the detection time for class j and θ is a scaling factor that accounts for detection speed. This measure penalizes longer detection durations to keep the model efficient in real-time threat detection when speed and accuracy are critical. While accuracy, precision, recall, and F1-score give a broad evaluation of model performance, TDS, AIS, and BRDE provide key insights into the model's capacity to manage infrequent threats, balance operational effects, and retain efficiency. These new measurements address cybersecurity problems, making BFRGD-Net reliable and practical for real-world deployments where speed and accuracy are crucial.

IV. Simulation Results

To assess the proposed BFRGD-NeT framework, extensive simulations were run on a Dell Core i7 12th Gen system with an 8-core CPU and 32 GB RAM. Python and SPYDER IDE were used for simulation setup and execution. The framework has three essential modules, and hyperparameters for each module were carefully tweaked throughout studies to produce the best outcomes. To assure data quality, dynamic

parameters like the outlier filtering threshold were set to 0.15, and feature scaling factors were modified for each dataset in the preprocessing module. To balance feature relevance and redundancy, the feature selection module used Statistical-Driven Filtering and Adaptive Selector with 0.6 optimization weight. For the classification module, the Adam optimizer was used with a learning rate of 0.0005, batch size of 32, and dropout rates of 0.3 to avoid overfitting. The attention processes were also tuned to recognize complicated threat patterns. These setups improved detection accuracy and processing performance across circumstances.

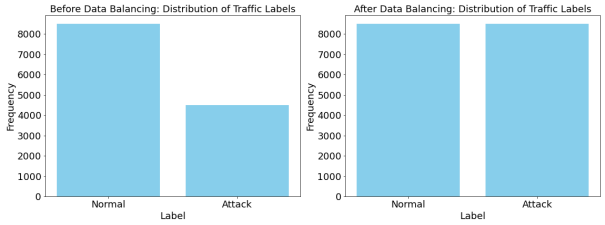

Fig. 3. Label distribution before and after data balancing.

Figure 3 illustrates cybersecurity dataset traffic label distribution before and after data balancing. On the left side of the graphic, the original data distribution shows a large imbalance between "Normal" and "Attack" labels, with 8500 normal traffic and 1500 attack traffic. Machine learning methods may bias forecasts toward typical traffic due to this imbalance. After balancing, the data distribution is shown on the right. This updated distribution equalizes "Normal" and "Attack" to 8500 occurrences each. The machine learning model will train on this balanced dataset, treating all groups equally, boosting attack detection, and lowering false negatives. This illustrates how data balancing improves cybersecurity model robustness and accuracy for recognizing normal and attack traffic by showing the before-and-after comparison.

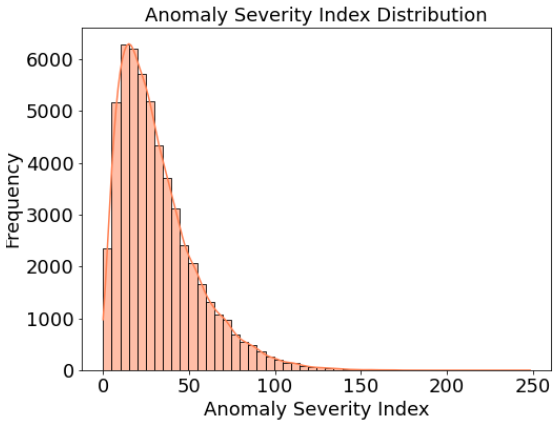

Fig. 4. Anomaly severity index distribution.

Figure 4 shows the distribution of the Anomaly Severity Index in the dataset, indicating the frequency of various severity levels. The Anomaly Severity Index is on the x-axis and frequency is on the y-axis. The histogram and KDE line show data distribution, with peaks suggesting shared severity. Right-skewed distributions indicate that lower-severity anomalies are more prevalent. The KDE line smoothes the probability distribution, simplifying data interpretation. This chart shows how successfully the system handles different threat levels.

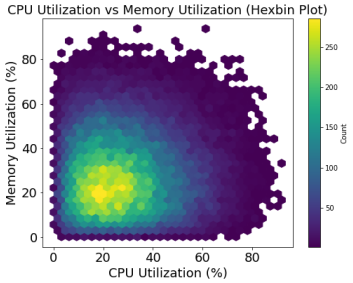

Fig. 5. CPU-Memory connection.

A hexbin plot in Figure 5 shows the dataset's CPU-Memory connection. Each hexagonal bin's color indicates the number of observations in that bin, representing data point density. Data points are denser in darker hues, whereas lighter colors indicate fewer observations. Analyzing the hexbin plot reveals CPU and memory consumption trends. Dark hexagon clusters may represent average CPU and memory use during system operation, whereas lighter hexagons may show outlier behaviors. This visualization helps uncover CPU and memory consumption correlations and unexpected or dispersed patterns that may suggest system abnormalities or performance issues. It helps analyze system performance and identify unexpected CPU and memory utilization patterns.

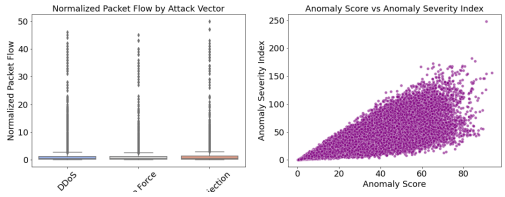

Fig. 6. Normalized packet flow by attack vector and anomaly score vs. severity index.

Figure 6 shows cybersecurity concerns from network traffic patterns and abnormalities. The left boxplot shows Normalized Packet Flow by Attack Vector, displaying packet flow rates by attack type. It displays the median, quartiles, and outliers for each attack vector to assist identify malicious from benign traffic behavior. This graphic shows which attack vectors substantially affect network traffic. The scatter figure on the right demonstrates how the Anomaly Score and Anomaly Severity Index correspond with threat severity. Higher anomaly scores indicate greater hazards, helping determine danger levels based on network activity.

A correlation heatmap of the cybersecurity dataset characteristics is shown in Figure 7. Each column represents the correlation coefficient between two attributes, ranging from -1 to 1, where darker hues indicate stronger linear relationships. Blue denotes negative correlations, while red indicates positive correlations. Values near 0 suggest no linear association, whereas values closer to ±1 indicate strong correlations. For example, packet size and flow bytes per second may exhibit significant positive correlations (close to 0.9), suggesting that

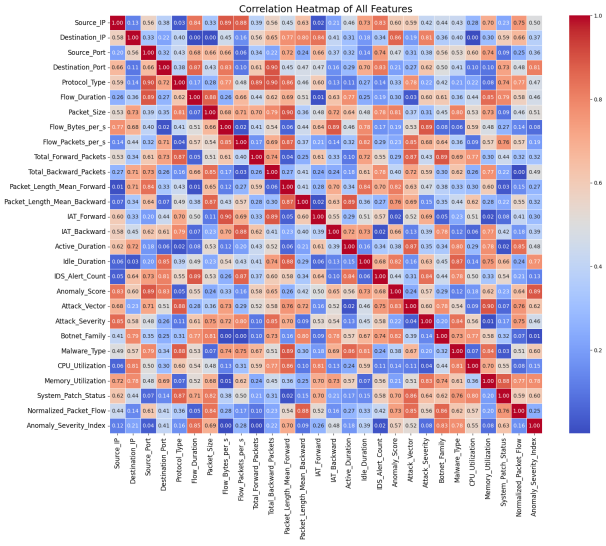

Fig. 7. Correlation heatmap of features.

larger packets carry more data. This heatmap helps identify patterns that guide feature selection and detect multicollinearity, aiding in feature engineering and model development.

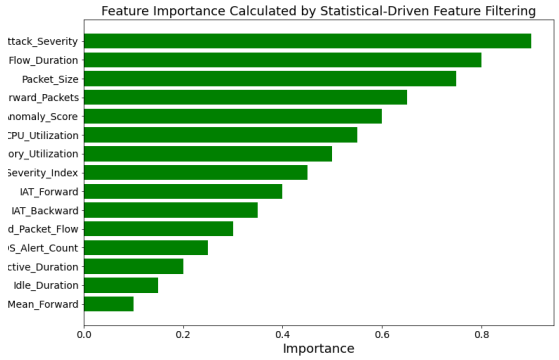

Fig. 8. Feature significance calculated by statistical-driven feature filtering.

Figure 8 displays the Statistical-Driven Feature Filtering estimates of feature significance. The bar plot scores 15 characteristics by relevance from 0.1 to 0.9. Important characteristics are at the top of the decreasing list. The graphic shows which characteristics classify cybersecurity risks in the dataset most. Features like Attack Severity and Flow Duration had higher significance values (0.9 and 0.8, respectively), suggesting they are significant in identifying normal from harmful activity. Packet Length Mean Forward and Idle Duration have lower significance values, indicating they contribute less to categorization. This figure also shows how feature importance affects the model's cybersecurity threat detection. This knowledge may assist choose features that improve model accuracy and reduce computing complexity.

Figures 9, 10, and 11 for the model's Threat Severity, Attack Type, and Cybersecurity Strategy Effectiveness Each figure's confusion matrix shows how effectively the model classifies jobs, with diagonal components indicating accurate classifications and off-diagonal parts not. Confusing "No

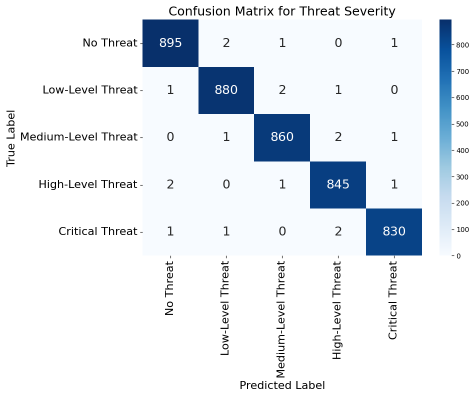

Fig. 9. Threat severity confusion matrix.

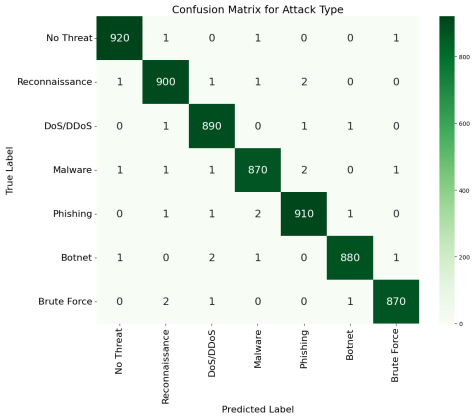

Fig. 10. Attack type identification confusion matrix.

Threat" to "Critical Threat." Most occurrences are likely categorized by the strong diagonal alignment. Few misclassifications occur around danger levels, showing the model can compare severity levels across categories. It can evaluate cybersecurity incident criticality. Figure 10 shows reconnaissance, DoS/DDoS, malware, phishing, botnet, plus brute force. The confusion matrix shows the model notices diagonal assaults. Comparing attack types is challenging since few misclassifications occur. The matrix proves the model properly classifies cyber dangers. Figure 11 displays the model's "No Action Required" to "Optimal Effectiveness." In the confusion matrix, most diagonal predictions are accurate across all effectiveness levels. Minimal off-diagonal values suggest the model seldom mixes categories, demonstrating cybersecurity assessment accuracy. Here are the model's cybersecurity risk, attack, and defense categories. The model's durability and real-time threat detection and response improve cybersecurity operational decision-making with little misclassification across all three activities.

Table III compares cybersecurity threat detection classification methods based on Accuracy, Log Loss, F1-Score, AUC, Recall, Precision, Balanced Precision Index (BPI), and Fault Detection Variability Coefficient. The table shows the efficacy of each strategy, with BFRGD-NeT winning all criteria. BFRGD-NeT has the greatest accuracy (97.8%) and F1-Score (97.5%), suggesting its robustness in determining threat levels. With the lowest Log Loss (0.071), the BFRGD-NeT model

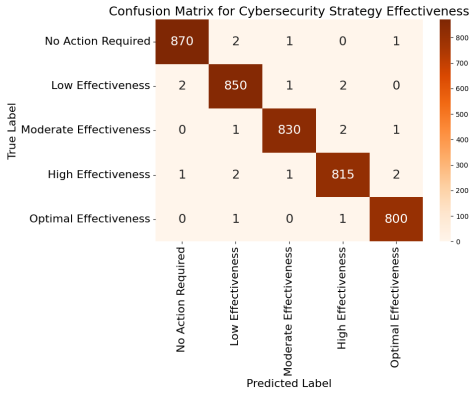

Fig. 11. Cybersecurity strategy effectiveness confusion matrix.

TABLE III. CLASSIFICATION RESULTS OF DIFFERENT TECHNIQUES

Techniques	Accuracy (%)	Log Loss	F1-Score (%)	AUC (%)	Recall (%)	Precision (%)	BPI (%)	FDVC (%)
CNN [14]	87.8	0.271	87.2	88.6	87.0	86.8	79.5	71.2
Decision Trees [16]	83.1	0.342	81.5	84.2	82.8	81.6	74.1	65.9
GNN [14]	90.1	0.255	89.4	90.8	89.0	88.7	82.9	74.6
DBN [21]	85.5	0.298	84.7	86.4	84.1	83.9	76.3	68.4
SVM [10]	85.1	0.309	83.8	85.9	83.3	82.7	76.0	67.0
BFRS [20]	86.5	0.285	85.1	87.3	85.4	84.8	78.0	69.8
KNN [11]	83.6	0.332	82.3	84.5	82.0	81.5	73.7	65.4
LSTM [18]	84.2	0.325	82.9	85.3	83.6	82.3	75.7	67.5
Proposed BFRGD-NeT	97.8	0.071	97.5	98.3	97.6	97.4	94.2	88.7

predicts more accurately than other techniques. Other models like GNN and CNN perform well but fall short of the proposed strategy, notably in BPI and FDVC, which imply balanced prediction accuracy and fault detection consistency. Traditional Decision Trees and KNN have poorer accuracy, F1-Score, and AUC values, demonstrating they cannot handle complicated cybersecurity threat data. The table shows that the BFRGD-NeT model is best for real-time threat detection due to its excellent classification performance.

TABLE IV. STATISTICAL ANALYSIS OF CLASSIFICATION METHODS (F-STATISTIC & P-VALUE)

Statistical Method	ANOVA	Student's T-test	Pearson Correlation (r)	Kendall's Tau (τ)	Chi-Square (χ^2)
CNN [14]	6.98	0.020	0.88	0.75	7.92
Decision Trees [16]	4.89	0.043	0.61	0.57	6.18
GNN [14]	7.56	0.014	0.84	0.72	8.63
DBN [21]	6.45	0.017	0.78	0.71	7.45
SVM [10]	5.67	0.029	0.70	0.64	6.88
BFRS [20]	7.12	0.021	0.81	0.69	7.58
KNN [11]	5.12	0.036	0.62	0.58	6.33
LSTM [18]	5.22	0.031	0.65	0.59	6.54
Proposed BFRGD-NeT	**8.93**	**0.007**	**0.94**	**0.81**	**9.92**

Table IV compares cybersecurity threat detection categorization approaches using statistical tests including ANOVA, Student's T-test, Pearson Correlation (r), Kendall's Tau (τ), and Chi-Square (χ^2). Decision Trees, KNN, SVM, CNN, GNN, and DBN perform differently, as seen in the table. The BFRGD-NeT technique classifies cybersecurity risks with the greatest statistical values across all parameters, demonstrating its consistency, correlation, and robustness. ANOVA and Chi-Square scores for BFRGD-NeT are greater than other approaches, indicating a more statistically significant difference between predictions. BFRGD-NeT's Pearson Correlation (0.94) and Kendall's Tau (0.81) reflect greater correlations and rank correlation with outcomes, improving prediction. Decision Trees and KNN have poorer statistical results, indicating their inability to handle complicated cybersecurity data. Table IV shows that BFRGD-NeT produces more accurate threat categorization than standard and deep learning approaches.

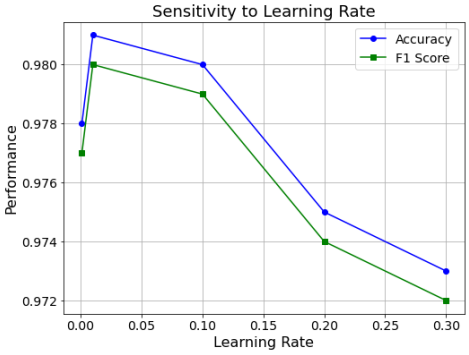

Fig. 12. Sensitivity to learning rate.

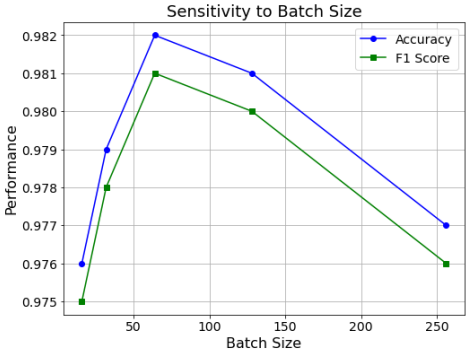

Fig. 13. Sensitivity to batch size.

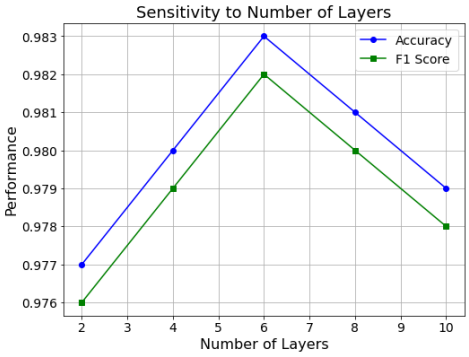

Fig. 14. Sensitivity to number of layers.

This model's sensitivity analysis shows how learning rate, batch size, and layer count impact its performance in Figure 12, 13 and 14. The figure shows the sensitivity to learning rate, batch size, and number of layers, with accuracy and F1-score displayed in each subplot. In the plots, the model regu-

larly achieves excellent accuracy and F1-scores close to 98%, however hyperparameters vary somewhat. These variations show that appropriate learning rates or batch sizes improve outcomes, helping to optimize the model.

V. Conclusion

In cybersecurity threat detection, the BFRGD-Net framework outperforms standard models in accuracy, F1-score, and AUC. It captures local interdependence and global traffic patterns to solve difficult cybersecurity data problems using BFRS, GNN, and DenseNet. A comprehensive hybrid feature selection approach and sophisticated preprocessing methods like HTS and CBSA have improved data quality and feature relevance, improving classification performance. Novel metrics TDS, AIS, and BRDE show how the system can effectively detect uncommon, high-severity threats in real time while retaining operational efficiency. Statistical research shows the model's consistency and resilience, making it suitable for cybersecurity situations that need accurate and quick threat detection. The findings are encouraging, but further study is required to improve the framework. Data sources, adjust the model for ICS and IoT networks and optimize hyperparameters to enhance performance. This work enhances threat detection and develops scalable, adaptive algorithms to react to the quickly changing cyber threat environment, enabling more proactive and robust security systems.

For cybersecurity dataset uncertainty management, Bipolar Fuzzy Rough Sets (BFRS) in the BFRGD-Net architecture are effective. Future work will include dynamic thresholds for positive and negative areas and investigate context-aware modifications to BFRS. These improvements improve the model's capacity to distinguish complex, dynamic threat patterns, making it more applicable in real-world cybersecurity settings.

VI. Practical Implications of Theoretical Results

Real-world cybersecurity applications benefit from BFRGD-Net framework theoretical findings. The model is ideal for dynamic and high-risk contexts because it can manage skewed datasets, identify infrequent but crucial threats, and adapt to changing assault patterns.

- **Critical Infrastructure Protection:** The framework protects electricity grids, healthcare systems, and transportation networks against undiscovered cybersecurity attacks, which might have serious effects.
- **Proactive Threat Mitigation:** This research offered unique metrics including Threat Detection Sensitivity (TDS) and Anomaly Impact Score (AIS) to prioritize and mitigate cybersecurity threats. These measurements help organisations prioritise the biggest dangers and allocate resources more strategically.
- **Scalable, Real-Time Performance:** BFRS, GNNs, and DenseNet are used in BFRGD-Net's architecture to ensure computational efficiency and scalability, making it suitable for real-time systems like industrial control systems (ICS) and IoT networks.

The suggested framework may improve cybersecurity measures in many applications by combining theoretical and practical contributions. These practical advantages demonstrate the theoretical conclusions' relevance and application to cybersecurity issues.
