
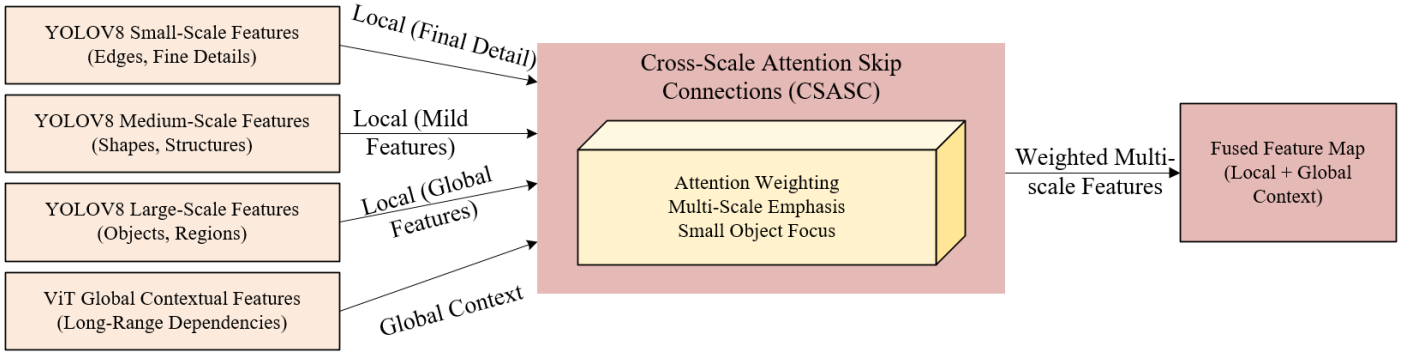

Fig. 3. CSASC fusion mechanism.

The CSASC functions by initially aligning the spatial sizes of YOLOv8 feature maps $F_{YOLO} \in \mathbb{R}^{H_1 \times W_1 \times C_1}$ and refiner-ViT features $F_{ViT} \in \mathbb{R}^{H_2 \times W_2 \times C_2}$ through bilinear interpolation and token reshaping. Then, attention maps for every scale are calculated to weigh the significance of various resolution features, as given in Eq. (7):

$$\alpha = Softmax\big(Conv_{1\times1}(F_{YOLO})\big) + Conv_{1\times1}(F_{ViT}) \quad (7)$$

$$F_{fused} = \alpha \odot F_{YOLO} + (1-\alpha) \odot F_{ViT} \quad (8)$$

In Eq. (8), α is the attention-weighting tensor derived from attention, $\odot$ is element-wise multiplication, and $Conv_{1\times1}$ is used to reduce channel dimensions for computational efficiency. This attention-based fusion allows for more attention to features with larger contexts, such as small objects, far-away vehicles, or partially occluded pedestrians, and less attention to regions that do not contain informative features.

With the application of CSASC, the framework rewards and maintains the multi-scale feature representation of both local and global contexts effectively. Standard skip connections do not consider the significance of features and treat all features equally, whereas the attention-based weighting is reactive to the features' spatial and semantic role, providing a more purposeful enhancement of the object's most significant cues. This innovation works directly to have better detection strength, especially in difficult surveillance modes where the objects have different sizes, have complicated occlusions, and due to different environments. Overall, the CSASC is not only a fusion

of YOLOv8 and ViT features but a scale-aware and attention-guided fusion, which is an obvious novelty. It ensures PRISM is highly accurate and robust without losing computational efficiency, which makes the framework quite suitable to be deployed on edge devices or cloud-based real-time video surveillance infrastructures.

F. Detection Head and Optimization

Once the fused representations of CSASC are sent to the detection head, the model should learn to optimize three mutually beneficial goals, which include bounding box localization, object classification, and confidence scoring. The Complete Intersection-over-Union (CIoU) loss is used to regress bounding boxes in order to be spatially aligned, because it considers the area of overlap, the distance between center, and the consistency of the aspect ratio. Given an estimated bounding box b_p and ground truth b_{gt}, the CIoU loss is given as Eq. (9):

$$L_{CIoU} = 1 - IoU\left(b_p, b_{gt}\right) + \frac{\rho^2\left(b_p^c, b_{gt}^c\right)}{d^2} + \alpha v \quad (9)$$

where, IoU is the intersection-over-union, ρ is the Euclidean distance between box centers, d is the length of the enclosing box diagonal, and v is penalizing aspect ratio differences with weighting factor α. This not only provides maximum overlap but also bounding boxes consistent in scale, which is important in detecting small or occluded surveillance objects.

A binary cross-entropy loss is used to complete the localization loss (L_{cls}) and the objectness confidence score loss (L_{conf}), so as to achieve high category prediction accuracy and reduce the false alarms. The combination of these terms as a final objective of detection is given in Eq. (10):

$$L_{total} = \lambda_1 L_{CIoU} + \lambda_2 L_{cls} + \lambda_3 L_{conf} \quad (10)$$

with empirically tuned weights $\lambda_1, \lambda_2, \lambda_3$ balancing regression, classification, and confidence learning. For optimization, adaptive learning rate scheduling is included, with the learning rate decreased when validation loss stabilizes to avoid premature convergence. Additionally, there is also a check for unstable training modes: if any gradient spike or divergence in loss ($L_{total} > \delta$) is detected, the update step is skipped, thereby stabilizing convergence. This kind of conditional optimization results in robustness in heterogeneous surveillance. In general, the combination algorithm is a good compromise between detection quality and the stability of the training process that can ensure that PRISM behaves in real-time with few errors even when the conditions are dirty or dynamic. Algorithm 1 shows the proposed PRISM framework for real-time surveillance object detection.

Algorithm 1: Proposed PRISM Framework for Real-Time Surveillance Object Detection

Input: Video stream V = {f1, f2, …, fn}, frame size = 640×640, batch size = B
Output: Bounding boxes Bbox, class labels C for detected objects
1: Initialize YOLOv8 backbone θy, ViT θv, Detection Head θd
2: Set learning rate α = 1e-4, optimizer = AdamW, loss = CIoU + BCE
3: For each epoch E = 1 to MaxEpoch do
4: For each batch b in V do
5: Preprocess frames: resize, normalize, augment → Xb
6: LocalFeatures ← YOLOv8(Xb; θy)
7: If resolution(LocalFeatures) < threshold τ then
8: Apply multiscale upsampling
9: EndIf
10: GlobalFeatures ← ViT(LocalFeatures; θv)
11: GlobalFeatures ← CA-FFN(GlobalFeatures) // Novelty 1
12: FusedFeatures ← CSASC(LocalFeatures, GlobalFeatures) // Novelty 2
13: Predictions ← DetectionHead(FusedFeatures; θd)
14: Compute Loss L = LCIoU + Lcls + Lconf
15: If L > δ then
16: Backpropagate gradients with α (adaptive scheduling)
17: Else
18: Skip update to avoid unstable training
19: EndIf
20: EndFor
21: Validate model on validation set Vval
22: If mAP improves AND FPS ≥ real-time constraint (≥30 FPS) then
23: Save model weights θ*
24: EndIf
25: EndFor
26: Evaluate θ* on test set Vtest
27: Generate metrics: Accuracy, Precision, Recall, F1, mAP, FPS
28: If deployment target = Edge then
29: Apply pruning + quantization for lightweight inference
30: Return Bbox, C with optimized PRISM model

Unlike traditional surveillance detection schemes that require CNNs to be fast, or transformers to be deep, PRISM introduces two important innovations that can be useful. First, the CA-FFN of the ViT permits modeling of a global context with increased fine-tuning at a low cost of deploying on the edge. Second, the CSASC permits preference (attention-directed) fusion between local and global features which significantly improves the small and far objects recognition in cluttered scenes. PRISM achieves a high degree of detection accuracy, robustness, and inference efficiency by integrating these new components into a YOLOv8-ViT hybrid pipeline. This two-layer innovation sharply distinguishes the proposed system from the current solutions, making it a scalable real-time monitoring system.

V. Results and Discussion

This section will discuss in detail the proposed PRISM framework that includes the YOLOv8 combined with the application of Transformer based refinement. The performance is critically measured by some measures. The findings show that the model is strong enough and may be applied to all types of surveillance and in both easy and challenging objects and at efficiency level of real-time, which makes it suitable to the use in the intelligent surveillance applications. The parameter configuration is given in Table V.

TABLE V. SIMULATION PARAMETERS FOR PRISM FRAMEWORK

Parameter	Value/Setting
Input Resolution	640 × 640 pixels
Batch Size	32
Optimizer	AdamW (weight decay = 0.0005)
Learning Rate	Initial 0.001 with cosine scheduling
Training Epochs	100
Hardware Platform	NVIDIA RTX 3090 GPU, 24 GB VRAM

A. Qualitative Results

Qualitative visual comparisons were made to show the advances that were made by the PRISM framework. Outputs of the test dataset of sample detections using PRISM and PRISM baseline methods like YOLOv5 and ViDT. PRISM is always more accurate in the detection of small, distant, and partially-occluded objects, with few false positives and higher localization. These graphical findings prove the usefulness of the hybrid Transformer-YOLOv8 architecture and the attention-based CSASC and CA-FFN modules in improving the object detection in challenging surveillance conditions. It is shown in Fig. 4.

Fig. 4. Object detection images.

B. Performance Evaluation

This part provides a systematic assessment of the suggested PRISM model with regard to real-time object detection surveillance effectiveness. The analysis identifies the strength, efficacy, and responsiveness of the model in different settings, providing insight into its trustworthiness and feasibility for use in smart monitoring platforms. The performance metrics were given in Table VI.

Fig. 5 demonstrates the trends of training and validation loss over 20 epochs, showing a decreasing loss pattern that suggests effective learning. Initially, both losses are high but progressively decline as the model optimizes its parameters. The training loss (blue) steadily decreases, while the validation loss (dashed line in red) increases or decreases slightly, but it follows a similar downward trend. Minor variations in validation loss should reflect normal generalization behavior. With the convergence of both curves towards zero, the model is effectively learning in the absence of overfitting.

Fig. 6 depicts the accuracy progression of the model over 20 epochs, comparing training (blue) and validation (red, dashed) accuracy. Both curves show a steady increase, constructive in learning. Initially, accuracy is very low; as training continues, accuracy increases until it reaches a level exceedingly close to perfection. Training accuracy goes up and down, yet it oscillates slightly enough for the validation accuracy always to track along with it; this depicts good generalization. The convergence of the two curves near the top indicates a well-learned model with little overfitting.

TABLE VI. EVALUATION METRICS

Metrics	Formula
Accuracy	$\frac{TP + TN}{TP + TN + FP + FN}$
Precision	$\frac{TP}{TP + FP}$
Recall	$\frac{TP}{TP + FN'}$
F1-Score	$\frac{2 \times TP}{2 \times TP + FP + FN'}$

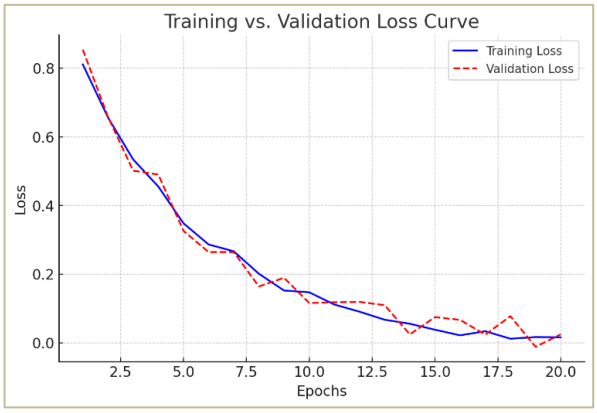

Fig. 5. Training vs. Validation loss curve.

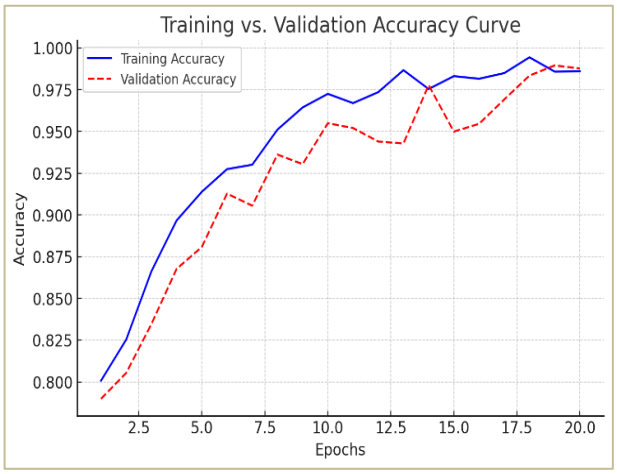

Fig. 6. Training vs. Validation accuracy curve.

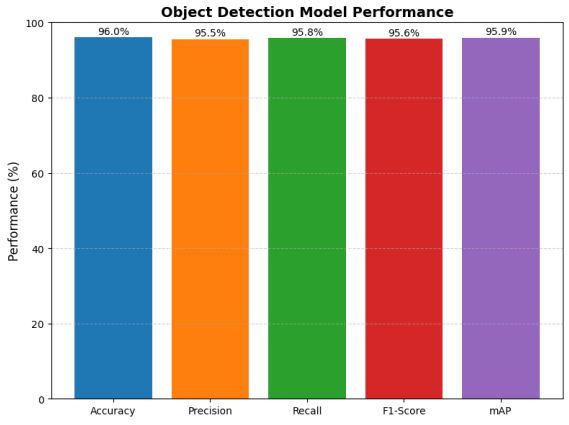

Fig. 7. Object detection performance.

Fig. 7 presents the key performance of the object detection model, including Accuracy (96%). Accuracy reflects the overall correctness of predictions, while Precision indicates how many detected objects were correctly identified. The high values across these metrics highlight the model's effectiveness in detecting and classifying objects with a high degree of reliability.

C. Category Wise Detection in Object Orientation

Table VII presents category-wise detection accuracy, showing the proposed model performs best on pedestrians and vehicles, while bags and miscellaneous items remain more challenging due to limited representation and complex features.

TABLE VII. DETECTION PERFORMANCE

Object Category	Detection Accuracy (%)
Pedestrians	91.3
Vehicles	89.5
Bicycles	89.5
Bags	84.7
Miscellaneous	82.5

D. Accuracy versus FPS Trade-off in Object Detection Models

Fig. 8 plot indicates the trade-off between frame per second and accuracy in object detection models. From the plot, the accuracy remains almost constant while decreasing only in FPS. Therefore, it can safely be concluded that the model performance will not be decreased with a drop-in frame rate. Thus, it can be inferred that the proposed method successfully balances real-time processing requirements with the need for high detection accuracy, making it viable for video surveillance applications.

Fig. 9 shows how the model learned on the training process. The mean Average Precision (mAP) is increasing steadily with the change in the number of epochs, thus the model is slowly learning effective ability to detect and classify object correctly. This progressive gain is an indication of effective optimization of the PRISM framework, which achieves the high speed of feature detection violated with YOLOv8 and the contextual augmentation provided with the Transformer. The increase in mAP demonstrates that there is effective training overlap and verify the statement that the model is well-adjusted to complex scenarios of surveillance in different types of objects.

E. Runtime Analysis and Edge Device Performance

PRISM framework runtime was tested on various hardware platforms to determine its ability to be deployed in real time, including edge devices. The mean frames per second (FPS) of the various input resolutions and batch sizes on the various devices. PRISM can run atleast 43 FPS on a high-end NVIDIA RTX 3090, 640 by 640 resolution with a batch size of 1, which proves to be real-time. On a mid-range graphics card (e.g., NVIDIA RTX 2060), the model can be sustained at around 28 FPS, and with an edge device, e.g. NVIDIA Jetson Xavier NX, it can achieve around 15 FPS on pruned and quantized models. These findings show that PRISM is applicable in real-time surveillance systems with low-resource computational power.

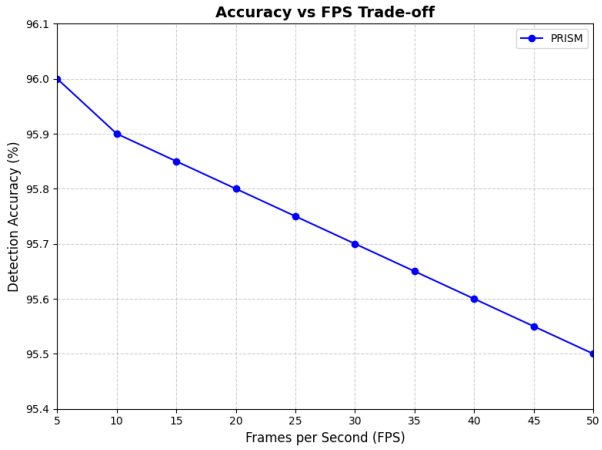

Fig. 8. Accuracy vs. FPS trade-off.

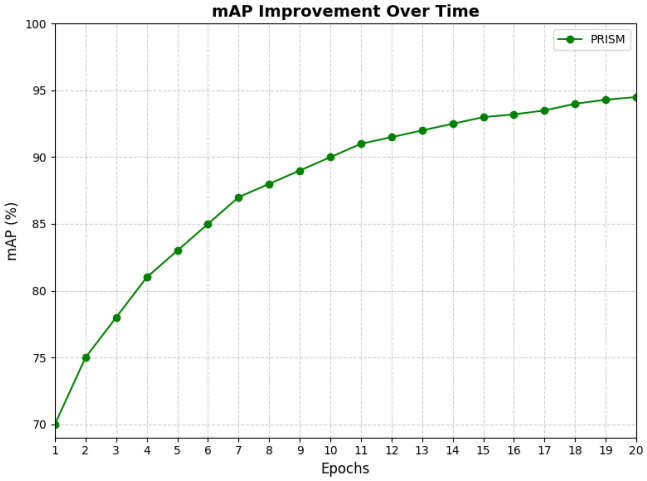

Fig. 9. mAP improvement over time.

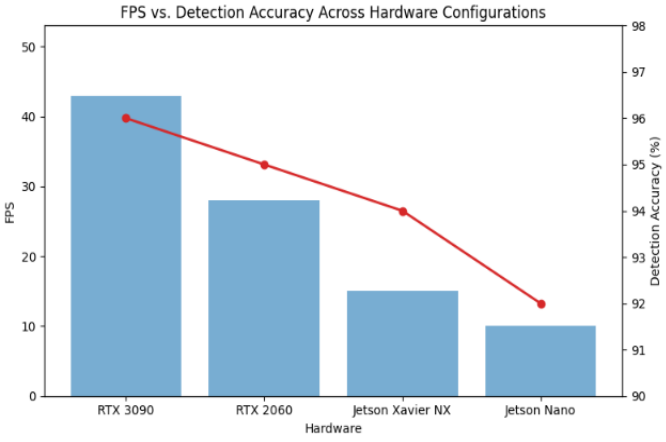

Fig. 10. FPS vs. Hardware constraints.

Fig. 10 demonstrates the trade-off between FPS and detection accuracy between the various hardware configurations and input resolutions. Bars are used to depict FPS of each hardware platform and Line plot is used to depict the accuracy of detection. It is a hybrid architecture that is coupled with lightweight ViT and CA-FFN modules that allow

a tradeoff between good detection performance and efficient computation, which makes PRISM applicable in both clouds and edge-based deployment models.

F. Global Contextual Refinement Performance (ViT + CA-FFN)

Fig. 11 shows the effect of CA-FFN on the ViT. The CA-FFN model has more precision across all recall levels. CA-FFN offers higher precision, particularly for the cluttered scenes. This suggests fewer false positives and better robustness in identifying smaller or overlapping objects.

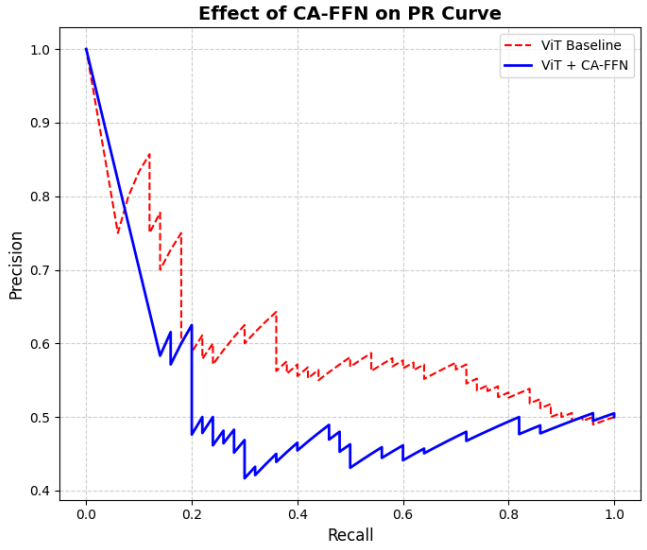

Fig. 11. Effect of CA-FFN on PR curve.

G. Feature Fusion Performance

Fig. 12 compares accuracy of detection of small or obscured categories (bags and miscellaneous objects). The use of CSASC also increases accuracy by a margin of 5 per cent compared to vanilla skip connections. This illustrates that the attention-directed feature fusion of scale is actually effective in preserving fine-scale features to improve the detection of difficult object categories in difficult surveillance real-worlds.

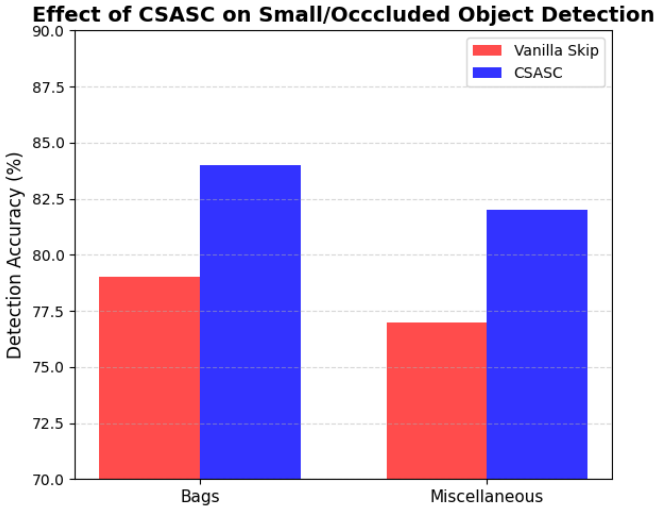

Fig. 12. Effect of CSASC on small object detection.

H. Ablation Study

In order to determine the contribution of every new element to PRISM, a study of ablation was carried out by selectively removing or altering the CA-FFN and CSASC modules. Their respective influence on detection accuracy and strength in surveillance situations is quantified in this analysis.

TABLE VIII. COMPARISON TABLE

Model Variant	CA-FFN	CSASC	Accuracy (%)	mAP (%)
Baseline YOLOv8	✗	✗	92.4	91.7
YOLOv8 + ViT	✓	✗	95.1	94.5
YOLOv8 + ViT + CSASC	✗	✓	94.3	93.8
PRISM (Full)	✓	✓	96.0	95.6

Table VIII indicates that both CA-FFN and CSASC make contributions to performance improvements. CA-FFN improves global contextual representation, whereas CSASC enhances multi-scale fusion, particularly for small, distant, or occluded objects, which justifies the importance of each novelty within the proposed PRISM framework.

I. Comparative Evaluation

The proposed PRISM model was not only tested on the main set of Kaggle surveillance (approximately 1,000 images), but also tested on Coco Dataset for Multi-label Image Classification [25]. PRISM shows good competitive results even with the rather small size of the primary dataset, with high detection accuracy of various types of objects. The proposed design of hybrid YOLOv8-Transformer with CA-FFN and CSASC modules works well in capturing local features and global contextual information to identify small, distant, and partially obscured objects as opposed to the traditional object detection models.

TABLE IX. COMPARATIVE ANALYSIS OF OBJECT DETECTION MODELS BASED ON ACCURACY

Model	Accuracy (mAP)
YOLOv5 [26]	95%
ViDT [27]	94%
Proposed PRISM	96%

Table IX presents a comparative analysis of object detection models based on accuracy (mAP). YOLOv5 achieves ~95% and ViDT around ~94%, indicating strong but limited performance. In contrast, the proposed PRISM significantly surpasses both with 96%, demonstrating superior accuracy, robustness, and effectiveness for real-time surveillance applications.

TABLE X. PERFORMANCE COMPARISON ON DIFFERENT DATASETS

Dataset	Number of Images	Detection Accuracy (mAP %)
Kaggle Surveillance Dataset	~1,000	96.0
COCO [28]	~123,000	95.2
PASCAL VOC 2012 [29]	~11,530	94.5
VisDrone [30]	~10,209	93.8

Table X shows the comparative analysis of the suggested PRISM framework using several benchmark datasets. The findings showed high accuracy of PRISM with a small dataset, which is a strong indicator of the efficiency of the hybrid feature extraction and fusion mechanisms. Furthermore, the comparative analysis based on the standard benchmarks demonstrates the model as robust and generalizable, and operating on the same level or even higher than current state-of-the-art detection models, including YOLOv5 and ViDT. In this analysis, PRISM is proven to be effective in a variety of surveillance scenarios at the same time keeping real-time inference performance.

TABLE XI. STATISTICAL EVALUATION OF PRISM PERFORMANCE METRICS

Metric	Mean (%)	Std. Dev. (±)	95% Confidence Interval
Accuracy	96.02	±0.74	[95.15 – 96.89]
Precision	95.48	±0.81	[94.52 – 96.44]
Recall	94.93	±0.89	[93.89 – 95.97]
F1-Score	95.20	±0.77	[94.26 – 96.14]
mAP (IoU = 0.5)	95.56	±0.68	[94.72 – 96.40]
FPS (RTX 3090)	43.1	±1.2	[41.9 – 44.3]

Table XI presents the statistical assessment of the PRISM framework's performance across five independent experimental runs. The metrics demonstrate the consistency and robustness of the model, with narrow standard deviations and tight 95% confidence intervals, indicating stable performance across varying data splits. The results confirm that PRISM maintains high accuracy and detection reliability while achieving efficient inference speed, supporting its suitability for real-time or near real-time clinical applications.

J. Discussion

The proposed PRISM framework illustrates a strong and effective method of detecting objects of surveillance in real-time by applying both local feature extraction and global contextual refinement. The use of CA-FFN in the ViT greatly minimizes the redundancy of features as well as improves feature global context modeling to produce less false positives, particularly in cluttered scenes. Similarly, it is the CSASC fusion mechanism, which allows to selectively integrate multi-scale features, that enhances the detection of small, distant, and occluded objects, which conventional architectures have traditionally not been able to detect. Comparative analysis demonstrates that PRISM achieves greater accuracy and mAP than other models (e.g., YOLOv5, ViDT) at a similar inference speed. PRISM's architecture is also suitable for edge-deployment and processing on smaller devices, thanks to its lightweight design and adaptive-learning approaches. Comprehensively, the findings indicate that the inner layer novelty redesign and attention-directed fusion of the Transformer offer a moderate compromise between the detection accuracy and computational scalability, making PRISM a viable and scalable system of intelligent surveillance.

VI. CONCLUSION AND FUTURE WORKS

The proposed PRISM architecture is able to achieve the combination of YOLOv8-based local feature extraction and a lightweight ViT with CA-FFN, and the new mechanism of CSASC fusion. The comparisons indicate that PRISM is superior in detection performance to other existing models like YOLOv5 and ViDT, and the model can still run inference in real-time. The dual-layer novelty has a strong ability to identify small, distant, and occluded objects in complicated surveillance conditions. These findings highlight the importance of attention-based global context refinement and multi-scale feature fusion in enhancing the accuracy of video surveillance in real time, proving PRISM to be a useful and high-scaling system to implement when a video surveillance system is required. Even with the good performance, there are still some limitations: 1) detection performance in highly cluttered and very low-resolution frames can be further improved, and 2) further validation is needed to generalize the model to totally new surveillance scenarios.

Future research will involve the use of the PRISM model to integrate multi-sensor inputs, such as thermal and RGB cameras, to enhance detection in low-light or unfavorable conditions. Continuous video streams will be modeled over time so as to publish better recognition of occlusions or moving objects. Also, the model will be optimized to run on edges (with a goal of reaching 30 FPS or higher) on platforms such as NVIDIA Jetson Xavier NX, and pruning and quantization will be used to reduce the model size to under 100 MB. These measurable goals are to guarantee the practical implementation of the framework in the different and resource-limited surveillance settings.

Aerial Draft Surveyor (ADS)

Ship Drafting via YOLO11n and YOLO11n-Seg

John Matthew H. Escarro, Fharjan M. Taguinopon, Gyrielle Kysha M. Demegillo, Dan Kevin T. Amper, Rosanna C. Ucat, Mark John S. Pag-Alaman
College of Engineering, University of Southeastern Philippines, Davao City, Philippines

***Abstract*—Draft surveying is an essential procedure in determining the displacement and loaded cargo weight of bulk carriers. Currently, the most acceptable method is through manual visual observation by trained draft surveyors. However, this process is subjective, error-prone, and unsafe under poor visibility or during rough sea conditions. This study presents an automated computer vision-powered UAV draft surveying system integrating TensorRT Optimized YOLO11n object detection and YOLO11n-seg image segmentation models deployed on an NVIDIA Jetson Orin Nano. The system performs real-time draft estimation by detecting draft marks, segmenting the waterline, and computing draft values using convergence and line-fitting algorithms. Comparative evaluation with licensed human surveyors on 40 paired readings yielded an MAE of 0.1068 m, RMSE of 0.2740 m, and an R^2 of 0.948, demonstrating human-comparable accuracy. Agreement analysis indicates high reliability (two-way random effects ICC(2,1) = 0.974) and a small mean bias (system − manual = +0.0628 m, 95% limits of agreement: −0.467 m to +0.592 m). Moreover, a paired t-test (t = 1.469, df = 39) found no statistically significant difference between methods ($p \approx 0.150$). The results validate that the proposed UAV-driven computer vision system can perform reliable, real-time draft surveying with accuracy comparable to human experts.**

***Keywords*—Draft survey; UAV; machine learning; computer vision**

I. Introduction

Ships play an important role in facilitating the global and international exchange of goods. In 2023 alone, the global trade volume of dry bulk shipping was around 5.508 billion metric tons [1].

To determine the weight of bulk cargo, ship draft surveys are conducted [2]. A draft is defined to be the vertical distance between the waterline and the bottom of the ship hull [3]. The method is based on Archimedes' principle and is conducted by observers who visually observe a ship's six draft marks while aiming to maintain an observation angle parallel to the water's surface to determine the ship's displacement tonnage, from which the weight can be calculated. Precision is important in measuring the draft as a singular centimeter error may correspond to an 80-ton error valued at around 40,000 USD or 500 USD per ton [1].

The ship draft represents the vertical distance from the waterline to the keel. Manual observation is traditionally prone to human error, but it is now evolving through automation [1, 2]. Draft marks are standardized numerical indicators positioned vertically along the hull, functioning as calibrated measurement points, while the draft line or waterline forms the critical reference boundary where water meets the hull, from which all measurements originate [3, 4]. Draft points represent strategically positioned locations, typically at the forward and starboard, port, midship, and aft sections along the vessel hull, while draft scales refer to the vertical row of draft marks that together form a measurement system used to read the draft at a specific point on the vessel [5].

Manual observation over a time period by draft surveyors is the current accepted and widely practiced method, yet this is highly subjective and prone to human errors [1, 3, 5]. Additionally, manual observation is also greatly affected by other factors including surveyor experience, large waves, visibility, and tilted or rusted draft characters, among others [4, 5]. It is necessary to consider appropriate weather conditions during draft surveying to ensure that the vessel is stable for an accurate reading [6]. Moreover, having multiple people complete the draft surveying is ideal because it allows for crosschecking measurements for errors between surveys, ensuring that all final calculations are ideally accurate [7, 8].

In response to the need for precision in draft surveys and upholding the occupational safety of surveyors, recent studies have been conducted to aid in the automation of the draft reading process. A review from [2] highlighted recent advancements in automating ship draft surveying, including image recognition technologies, radar, optical fiber, IR, ship hull climbing robot, ship draft measuring ruler, sonar, and pressure sensor detection. Of these advancements, image recognition performed mostly on par with visual observation, while sensor-based solutions typically struggle under dynamic or harsh maritime conditions [2, 9, 10].

Several computer vision studies have presented similar solutions, utilizing a combination of YOLO object detection models for draft mark detection and U-Net or Mask R-CNN for waterline segmentation [11, 12, 13]. Chernyi and Ivanovskii [11] utilize YOLOv5 due to its low compute power requirement and speed in conjunction with U-Net to divide the image between "water" and "not water". Their method allowed them to achieve a mean Average Precision of 93.9% and processes video at 30 frames per second (FPS). Additionally, they state that 1800 sample values from a one minute 30 FPS video is sufficient. The primary caveat of their method is the requirement that a video of the measured draft point must be recorded before processed by their proposed system.

Hinatuan Mining Corporation.

A study conducted in China [12] proposed a multitask learning framework (MTL-VDR) for automated vessel draft reading, integrating object detection and image segmentation within a single unified model. In their proposed system, the first stage utilizes YOLOv8 to detect and extract the region of the hull with draft marks. Then, their multi-task framework processes the extracted region, performing draft scale recognition and vessel-water segmentation before calculating the final draft. Their results show an error of only ± 0.074m while achieving a process time of 0.016s per video frame on a laptop with AMD Ryzen 7 5800H CPU accelerated by a NVIDIA GTX 3060 GPU. Though their study shows promise for draft reading, the approach is limited to single-frame image analysis and cannot ensure accurate draft estimation when the water surface fluctuates due to waves or motion. They address this limitation and recommend temporal stabilization or multi-frame averaging techniques to improve reliability in real-world, dynamic maritime environments.

Wang et al. [13] had a similar approach but utilized three distinct models for their system, namely Mask R-CNN for segmenting the targeted region with draft marks and the water regions, U-Net to refine the waterline boundary, and ResNet for recognition of draft characters. They achieved 93% accuracy in waterline segmentation, 98.5% accuracy in digit recognition, and an accuracy within three standard deviations of manual readings. They have achieved a processing speed of 0.36s per frame using a 32GB RAM PC with NVIDIA GTX 1080Ti GPU by analyzing recorded video footage. Despite the high accuracy, their system remains constrained by non-real-time performance and sensitivity to environmental disturbances. However, they do introduce a perspective distortion correction formula similar to [1] which greatly improves upon the quality of their draft estimate.

Based on the discussion of related literature above, the use of Convolutional Neural Networks (CNN) in the form of either U-Net, YOLO, or Mask R-CNN is relatively successful in detecting draft marks and segmenting water from an image. Despite the promising accuracy achieved by CNN-based systems, these methods remain confined to post-processed or static analysis. None, to date, have demonstrated an integrated real-time approach suitable in guaranteeing stable measurements for dynamic maritime environments where waves, reflections, and vessel motion introduce substantial visual fluctuations [12]. Further, an interesting problem that has yet to be brought up by previous studies is determining a way to know when or how to finalize measurement for real-time analysis. Hence a gap exists in achieving both real-time draft estimation and automated stability evaluation.

This study addresses these prior limitations by implementing real-time detection and segmentation through a deployable UAV system with TensorRT optimized YOLO11n and YOLO11n-seg on a Jetson Orin Nano for real-time analysis in the field. YOLO11n has improved small object detection capability and is more computationally efficient compared to its predecessors [14, 15, 16]. Although Mask R-CNN and U-Net excel in segmentation accuracy, the need for real-time analysis means that a balanced approach in speed and accuracy is required, making YOLO11n-seg suited for the task [14, 15, 16, 17]. Model optimization with TensorRT was implemented as it is crucial in maximizing inference speed, where various studies have shown significant performance gains with TensorRT optimization [18, 19, 20]. The Jetson Orin Nano was chosen to eliminate dependence on cloud computing as it is powerful enough to handle both inference and mathematical tasks on its own which is crucial when operating out in the sea where a stable internet connection may not be present [21]. Where this study delineates from previous studies is the introduction of temporal subsampling and a cumulative averaging mechanism for continuous evaluation of sequential draft readings.

Temporal subsampling is a technique where every 1/N frame is taken for processing [22, 23, 24]. This technique is useful in conserving computational resources, which is essential in edge computing, provided that data skipped between frames is negligible. Recent data in the Philippines shows that the local wave period can be roughly estimated to be around 5-6 seconds [25, 26, 27]. Performing a simple calculation, we can infer that the dominant frequency is 1/5 or 0.2 Hz, and consequently the Nyquist sampling rate is 0.4 Hz. Subsampling the input stream of 30 FPS at a rate of every third frame yields a sampling rate of 10 Hz, far higher than the minimum Nyquist requirement indicating that data resolution is sufficient. For this study, the minimum time for data collection of draft estimates will be 1 minute similar to [11], yielding at least 600 datapoints.

Each subsampled frame then contributes to a cumulative moving average (CMA). The CMA utilizes all data from the start of time to the present time point and has a characteristic of eventually converging into a stable value as more data points accumulate [28, 29, 30, 31, 32]. This stable value is the potential draft estimate. To validate stability, convergence check based on zero-slope fitting and normalized root mean square error (NRMSE) criteria automatically determines when a sufficiently stable reading has been achieved [33, 34, 35, 36, 37, 38, 39]. Normalization of the RMSE translates it into a meaningful percentage value of how much the data fits the model, where NRMSE < 10% is excellent, NRMSE between 10% and 20% is good, NRMSE between 20% and 30% is fair, and NRMSE > 30% is poor [35, 36, 37]. In the Philippine context, draft estimation is precise only up to the thousandth decimal, hence we set the minimum tolerance for near-zero slope to be at least 0.0001, and the NRMSE must be 0.1% to indicate true stability.

In brief, this work seeks to determine whether a field-deployable UAV-based computer vision system can achieve draft measurement accuracy comparable to human surveyors while maintaining operational reliability under real maritime conditions. It further aims to deliver real-time draft readings despite the limited computational resources of edge devices by employing TensorRT-optimized YOLO11n and YOLO11n-seg models, combined with lightweight algorithms for temporal subsampling, CMA, and draft reading stability checks based on line fitting and NRMSE.

The remainder of the study is organized as follows: Section II presents the system design, algorithm, and methodology. Section III discusses results and performance

evaluation. Finally, Section IV provides a conclusion iterating key findings and recommendations for future work.

II. METHODOLOGY

In designing an effective real-time draft surveying system, it needs to achieve real-time performance on edge computing hardware while also being a field-deployable measurement platform capable of achieving accuracy matching those of experienced surveyors even when faced by dynamic maritime conditions. To fulfill these requirements, the Aerial Draft Surveyor (ADS) system integrates a UAV-mounted camera for live video acquisition, an NVIDIA Jetson Orin Nano for on-site model inference, and a computer vision pipeline that detects draft marks, segments the waterline, and computes draft estimates in real time. The following subsections detail the system architecture, model training and development, draft computation algorithms, data gathering procedure, and statistical tests and validation for system evaluation.

A. System Architecture

The system architecture consists of four primary parts: the drone, the remote control (RC), the Jetson Orin Nano, and the User Interface (see Fig. 1).

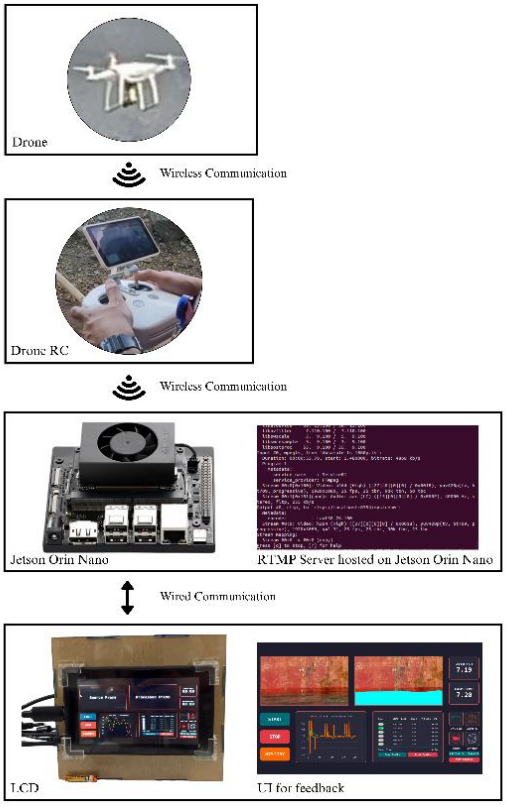

Fig. 1. System architecture.

The manually operated drone, a DJI Phantom 4, is capable of long-range flight in windy seaside conditions and is equipped with an onboard camera with wireless video transmission at 1080p, 30 FPS. It is positioned directly in front of the targeted draft marks at a distance of 3 to 5 meters while maintaining perpendicular line of sight. The drone transmits its captured video to the operator's remote controller. The remote controller then streams this live video feed it receives from the drone via an RTMP (Real-Time Messaging Protocol) stream over a LAN (Local Area Network) generated by a simple mobile hotspot, which is received by an RTMP server running on the NVIDIA Jetson Orin Nano. This video stream is then fed to a program running on the Jetson Orin Nano responsible for running inference on the video feed, performing both object detection and image segmentation to detect ship draft marks and isolating the waterline. It then calculates the draft value and outputs the result to a user interface for review and logging. For hardware, a portable power supply was used to power the device, an LCD was attached to display the program's user interface, and peripherals were utilized for ease of use (see Fig. 2).

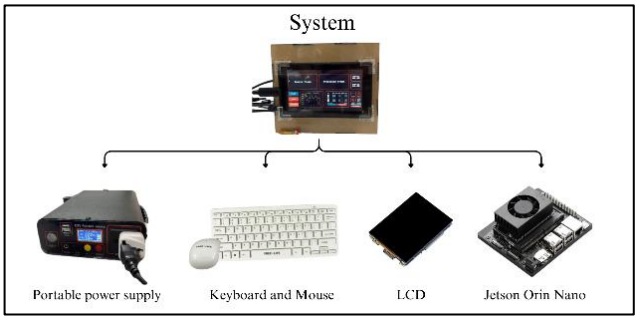

Fig. 2. Basic system hardware components.

B. System Development

Frames from the video stream were subsampled by the program then processed by two deep learning models: YOLO11n and YOLO11n-seg. A lightweight nano model was chosen to facilitate real-time inference on the Jetson Orin Nano. These models were trained using images in labeled datasets from Roboflow using a 70:20:10 train-validation-testing split (see Fig. 3 and Fig. 4).

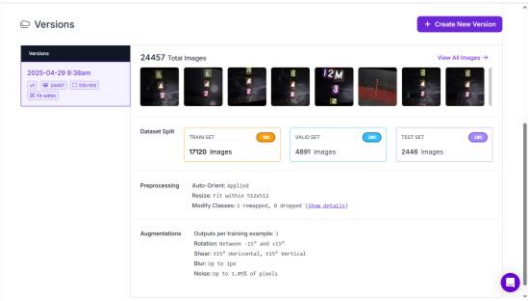

Fig. 3. Detection dataset.

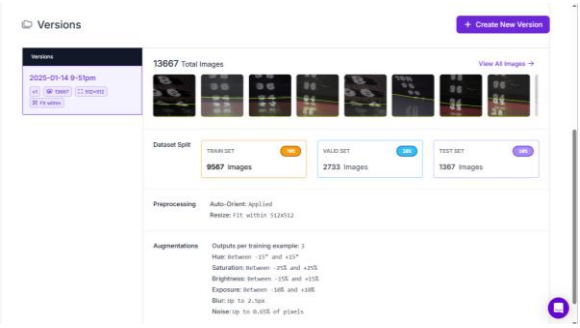

Fig. 4. Segmentation dataset.

Augmentations were applied to enhance model performance in varying conditions. Below is a summary of the model training parameters applied (Table I).

TABLE I. SUMMARY OF MODEL TRAINING PARAMETERS

Model	*Images*	*Augmentations Applied*	*Epochs*	*Size*	*Classes*
YOLO11n	24457	Rotation (±15°) Shear (±15° H, ±15° V) Blur (up to 1px) Noise (up to 1.05% px)	250	512x512	0, 1, 2, 3, 4, 5, 6, 7, 8, 9, M
YOLO11n-seg	13667	Hue (±15°) Saturation (±25%) Brightness (±15%) Exposure (±10%) Blur (up to 2.5px) Noise (up to 0.65% px)	50[a]	512x512	Water, background

[a] Model set to train for 250 epochs but stopped at 50 due to no improvement.

Model training utilized labeled datasets obtained from Roboflow Universe, which contained publicly available ship hull images with annotated draft marks and waterlines. For training draft mark detection, dataset from user shuichi1 which featured pictures of draft marks from various ships in different perspectives was used. To train the segmentation model, dataset from user shuixian1 which featured annotated segmented waterline was used.

These datasets were forked and augmentations were added to enhance model robustness in real-world conditions, and consequently, increase generalization. Augmentations for rotation (±15°) and shear (±15° H, ±15° V) were applied to enhance model resistance against varying camera angles. Image noise was added to allow the model to correctly identify regions despite water splashes. Lastly, blur was augmented into both datasets to accommodate for the drone's motion which may induce blur. Saturation, brightness, and exposure were specifically added to the segmentation model to help it correctly segment the waterline against small variations in water color and brightness distortion from lighting.

Both models were trained on Google Colab's A100 High-RAM GPU using the PyTorch implementation of YOLO11 under the default training hyperparameters provided by the Ultralytics framework for 250 epochs. The YOLO11n model was trained for numerical detection of the ship's draft marks while the YOLO11n-seg model was trained for waterline segmentation. Models were then converted into TensorRT .engine files locally on the Jetson Orin Nano to optimize performance.

C. Draft Calculation Algorithm

Algorithm 1 is a pseudocode representing the live-stream draft measurement pipeline, showing a simplified and high-level overview of the functions for instantaneous draft analysis as well as determining the final draft. The 30 FPS stream is sent as an input to the primary loop function MeasureDraft (line 10), where it subsamples the video stream by sending every third detected frame as an input to the InstantaneousDraft function (line 1). The subsampled frame then passes through both object detection and segmentation (line 2), from which the bottom-center points of the bounding boxes that form the draft line are obtained (lines 3-4) to fit a line and predict the position of the next point (lines 5-6). The draft for this frame is then determined (line 7). Fig. 5 shows a visual representation of the InstantaneousDraft function.

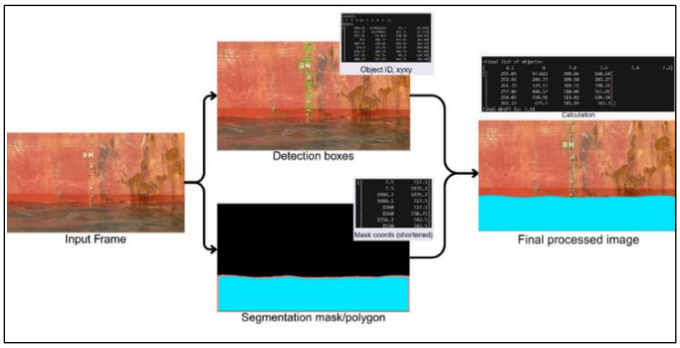

Fig. 5. Per frame instantaneous draft reading process.

In calculating the final draft, a cumulative average is applied continuously (line 18) for each draft. When the number of samples have reached the threshold, a check for convergence is conducted, outputting the mean as the final draft if the slope and NRMSE fall below specified thresholds (lines 19-20). Fig. 6 provides an overview of the algorithm's processes through a visual flowchart.

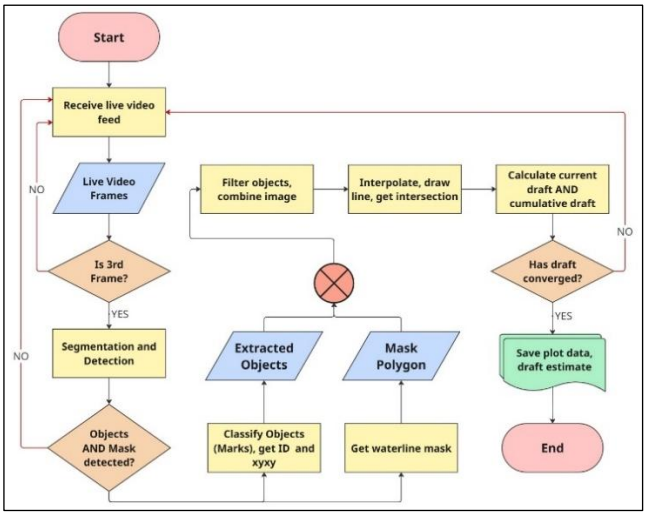

Fig. 6. Algorithm flowchart.

Algorithm 1: Draft Calculation

```
INPUT: live video frames S
OUTPUT: streaming currentDraft, mean when converged

FUNCTION InstantaneousDraft(frame):
    draft_marks, water_mask ← RunInference(frame)
    bottom_centers ← ExtractBboxBotCenters(draft_marks)
    draft_line ← FitLine (bottom_centers)
    predicted_point ← InterpolateNext(draft_line)
    intersect ← GetIntersection(draft_line, water_mask)
    draft ← CalculateDraft(draft_line, predicted_point, intersect)
    RETURN draft
END FUNCTION

FUNCTION MeasureDraft(S)
    frame_cnt ← 0
    count ← 0, mean ← 0, window ← []
    WHILE streaming IS available:
        frame_cnt ← frame_cnt + 1
        IF frame_cnt MOD 3 == 0 THEN CONTINUE
        current_draft ← InstantaneousDraft(S)
        count ← count + 1
        mean ← CumulativeAvg(mean, count, current_draft)
        APPEND mean to window
        IF count > 600:
            POP mean from window
            IF Converged(window) THEN RETURN mean
        END IF
    END WHILE
END FUNCTION
```

The following are the key routines in this algorithm:

- RunInference(frame): returns draft mark bounding boxes and waterline mask.
- InterpolateNext(draft_line): predicts the point position of the next draft mark located below the waterline then connects all points.
- GetIntersection(draft_line, water_mask): finds the coordinates where the draft line intersects with segmented water mask.
- CalculateDraft(draft_line, predicted_point, intersect): calculates the draft in meters by translating pixel distances (1).
- CumulativeAvg(mean, count, current_draft): uses recursive averaging to calculate a running mean of all draft measurements (4).
- Converged(window): checks all cumulative means to determine if values have stabilized (6, 7).

To calculate the draft value from the images, the Eq. (1) below from [1] is used:

$$v_0 = v_1 - s\left(\frac{d_0}{r \cdot d_1}\right) \quad (1)$$

where, v_0 is the estimated draft at p_0(m); v_1 is the known draft at p_1(m); d_0 and d_1 are pixel distances (px); r is the perspective-correction ratio (unitless); and s is the true spacing between adjacent draft marks (m) which is 0.2m. Values for d_0 and d_1 are obtained through simply calculating the distance between points using Eq. (2):

$$d_0 = \|p_0 - p_1\| \; ; \; d_1 = \|p_1 - p_2\| \; ; \; d_2 = \|p_2 - p_3\| \quad (2)$$

- To account for instances, where the drone is not perfectly aligned with the ship's hull, the distances obtained from the two draft marks d_2 and d_1 above the draft mark nearest the waterline are used as a reference (see Fig. 7). From here the perspective-correction ratio is obtained through Eq. (3).

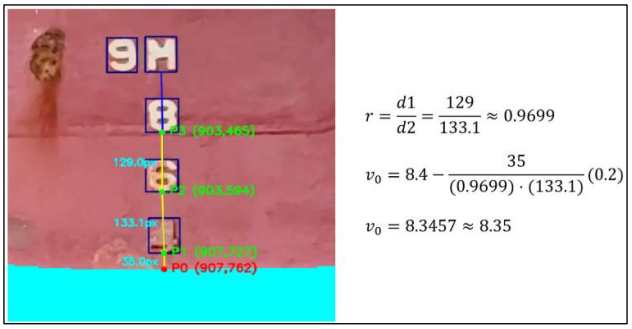

Fig. 7. System calculation to estimate draft mark value.

$$r = \frac{d_1}{d_2} \quad (3)$$

Welford's algorithm, Eq. (4), is used in calculating for the CMA of draft readings as it is computationally inexpensive, expressing the running average in a recursive form requiring only the previous average and the new value to obtain the new average [32].

$$\bar{x}_n = \left(\frac{n-1}{1}\right)\bar{x}_{n-1} + \left(\frac{1}{n}\right)x_n \quad (4)$$

In Eq. (4), n corresponds to the current point in time. Then, $\bar{x}_n$ is the current cumulative average, $\bar{x}_{n-1}$ is the previous cumulative average, and x_n is the current value. In this case, x_n represents the instantaneous draft reading at the current point in time, $\bar{x}_{n-1}$ is the old cumulative draft estimate before the current reading, and $\bar{x}_n$ is the new cumulative draft estimate.

Linear regression, Eq. (5), is performed on all datapoints to estimate the slope and generate a fitted line. The goal is to determine whether the cumulative draft estimate is stable and may be finalized.

$$\hat{y} = \beta_1 x + \beta_0 \tag{5}$$

Here, $\hat{y}$ is the predicted value from the fitted line, β_1 is the slope, x is the time step or index, and β_0 is the y-intercept. The slope is then identified by calculating β_1 as shown in Eq. (6), where N is the total number of points in the window, x_i is the frame index, $\bar{x}$ is the average frame index, y_i is the CMA at x_i, and $\bar{y}$ is the average CMA within the window N.

$$\beta_1 = \frac{\sum_{i=1}^{N}(x_i-\bar{x})(y_i-\bar{y})}{\sum_{i=1}^{N}(x_i-\bar{x})^2} \tag{6}$$

Though a near-zero slope hints at stability, NRMSE is also obtained through Eq. (7) to determine if the actual values around this fitted line are also stable, as simply identifying the slope does not reveal information on how much the data points are still varying.

$$NRMSE = \frac{\sqrt{(1/N)\sum_{i=1}^{N}(y_i-\hat{y}_i)^2}}{\bar{y}} \tag{7}$$

Therefore, convergence of the draft estimate obtained from CMA is determined to be stable by both checking if slope and NRMSE fall under the required criterion, specified to be $\beta_1 \leq 0.0001$ and $NRMSE \leq 0.1\%$.

D. Data Gathering

Data was gathered by flying the drone towards a bulk cargo vessel. The operator will control the drone to record video from each of the ship's six draft locations, waiting for the system to output its final draft reading before moving to the next draft location. When all of the six draft locations are finished, the drone is retrieved. Whenever the ship is loaded with new cargo, the procedure is repeated. This is to ensure that the ship's draft would vary every time a measurement is taken. An overview of the process is shown in Fig. 8.

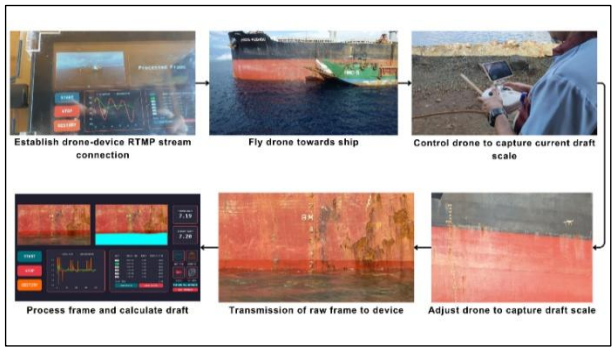

Fig. 8. Data gathering procedure.

E. Testing and Evaluation

To evaluate the system's performance, a team of licensed surveyors were also sent to the bulk cargo vessel to perform manual reading of each of the six draft marks. The system's results are then compared against the surveyor's readings to quantify the system's performance.

F. Statistical Analysis

To rigorously evaluate the agreement and accuracy of the automated draft survey system against traditional human measurements, four complementary statistical methods were applied. Firstly the standard error metrics, which include mean squared error (MSE), root mean squared error (RMSE), mean absolute error (MAE), and coefficient of determination (R2), are obtained. These determine how the algorithm's predictions track the ground truth observation of human surveyors alongside how much of the variability in ground truth is explained by the model. A paired t-test is also utilized to identify the existence of systematic biases and determine whether the mean difference between the two depart significantly from zero.

Next, Bland-Altman analysis is used to visualize and quantify agreement across the full measurement range. This reveals whether the algorithm's errors remain acceptably small and consistent at both low and high drafts, and identified any outliers [40]. In addition, the two-way random-effects, absolute-agreement intraclass correlation coefficient (ICC(2,1)) was also calculated. This partitions total variance into between-subject and error components, revealing whether the two are effectively interchangeable or not [41].

III. Results and Discussion

This section features an evaluation of the live-stream draft measurement system, beginning with the accuracy and statistical reliability of the final draft estimates before proceeding to the performance of the underlying deep-learning models. First, the automated draft readings will be compared against manual surveyor measurements using the methods outlined under the statistical analysis section. Next, object-detection and segmentation metrics achieved by the YOLO11n and YOLO11n-seg networks, including precision, recall, mAP, IoU, and real-time inference and computation speed will be presented. Finally, these results are interpreted in the context of operational requirements for at-sea draft monitoring, discussing both the system's real-time capability and its potential to augment traditional surveying methods.

A. System and Manual Draft Reading

To evaluate the accuracy and reliability of the Aerial Draft Surveyor (ADS) system in comparison with traditional manual measurements, a total of forty (40) readings were obtained (see Table II). Each reading was simultaneously recorded by a licensed surveyor through manual observation and by the ADS through automated image processing. Both measurements were performed under similar environmental conditions to ensure fairness of comparison.

The quantitative comparison between manual and system-obtained readings is summarized in Table III. Statistical metrics including Mean Square Error (MSE), Root Mean

Square Error (RMSE), Mean Absolute Error (MAE), and Coefficient of Determination (R^2) were computed to evaluate accuracy, while a paired t-test (at $\alpha = 0.05$, $df = 39$) assessed whether systematic bias existed between the two measurement methods.

TABLE II. SYSTEM AND MANUAL DRAFT READING

Index	Measured Draft		Index	Measured Draft	
	System(m)	*Manual(m)*		*System(m)*	*Manual(m)*
1	4.4	4.6	**21**	8.37	8.3
2	6.61	6.65	**22**	8.38	8.31
3	6.27	6.38	**23**	5.6	5.66
4	8.17	8.05	**24**	7.17	7.18
5	8.1	8.05	**25**	6.55	6.48
6	5.29	5.29	**26**	8.37	8.3
7	6.07	5.05[a]	**27**	8.36	8.31
8	7.17	7.13	**28**	5.58	5.66
9	6.3	6.26	**29**	7.16	7.18
10	8.37	8.37	**30**	8.38	8.3
11	8.32	8.37	**31**	8.37	8.31
12	5.3	5.29	**32**	5.56	5.66
13	6.39	5.05[b]	**33**	7.19	7.18
14	7.14	7.13	**34**	8.37	8.3

20	6.54	6.48	**40**	8.3	8.3

[a, b] Rust had turned mark into a color similar to the ship's hull resulting in faulty reading.

TABLE III. SUMMARY OF EVALUATION METRICS

MSE	RMSE	MAE	R^2	t-value
0.0751	0.2740	0.1068	0.9506	1.47

The linear relationship between the system's readings and those obtained manually is illustrated in Fig. 9. Each point corresponds to a single measurement pair, with the dashed line representing perfect 1:1 agreement and the solid line showing the regression fit. As shown, the system's predictions cluster tightly along the 1:1 line, indicating excellent correspondence with manual observations.

The obtained R^2 value of 0.9506 indicates a strong linear agreement between automated and manual readings, meaning that 95% of the variance in human-observed measurements can be explained by the system's estimates. The t-test result ($t = 1.47 < 2.02$, $p > 0.05$) further supports that no statistically significant difference exists between system and manual observations, thereby validating the reliability for operational use. However, the average deviation is ±0.1068m, which is slightly larger than those from previous studies [12, 13].

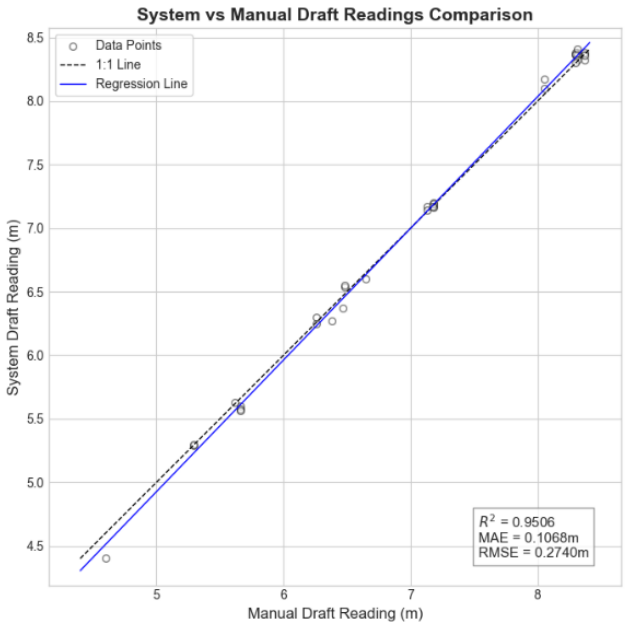

Fig. 9. Scatter plot comparing manual and system readings.

The major discrepancy observed is during cases where corrosion from rust led the system to misclassify the target draft mark resulting in a faulty reading. Nonetheless, the overall error remained small, and the algorithm proved capable of converging towards a reasonable stable draft estimate through the cumulative averaging and convergence criteria described in Section IIC.

To examine the potential effect of such outliers, an additional analysis was conducted by excluding measurements affected by severe hull corrosion. Under these idealized conditions, the mean absolute error (MAE) improved to ±0.0505 m, which falls within the same accuracy range reported by [12] and [13]. This indicates that under optimal imaging conditions, the system's performance approaches that of state-of-the-art laboratory-based methods.

B. Bland-Altman Analysis

TABLE IV. BLAND-ALTMAN SUMMARY

Parameter	Value
Mean Difference (Bias)	+0.063
Standard Deviation	0.269
Lower Limit of Agreement (LoA)	–0.467
Upper Limit of Agreement (LoA)	+0.592
% of Points Within LoA	95%

The mean difference (bias) between the manual and machine readings was +0.063, suggesting a slight tendency for the machine to read marginally higher than the manual method. The 95% limits of agreement ranged from –0.592 to +0.467. Approximately 95% of the paired measurements fell

within these limits, with no clear pattern of increasing disagreement for higher or lower draft marks (see Fig. 10 and Table IV).

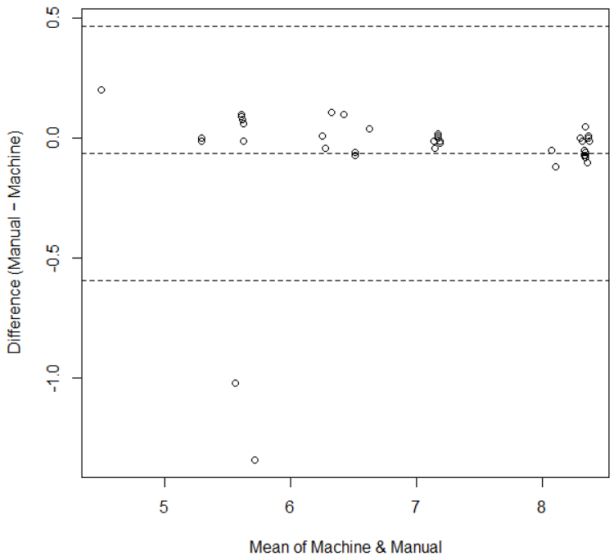

Fig. 10. Bland-Altman Plot of machine vs. Human surveyor readings.

The two major outliers were attributed to the presence of rust which heavily impaired the detection model's capabilities in discerning the correct draft mark.

C. Intraclass Correlation Coefficient [ICC (2,1)]

The agreement between the automated (machine) and manual draft readings was assessed using a two-way random-effects absolute-agreement single-measure ICC (ICC(2,1)). As shown in Table V, the ICC was 0.974 (95 % CI: 0.951–0.986; $F(39, 38.9) = 78.0$; $p < 0.001$), indicating reliability and consistency between the two methods.

TABLE V. INTRACLASS CORRELATION COEFFICIENT RESULTS

Statistic	Value
Number of subjects	40
Number of raters/methods	2
ICC value	0.974
95% Confidence Interval (CI)	0.951-0.986
F Statistic (df1, df2)	78.0 (39, 38.9)
p-value	< 0.001

According to the benchmarks proposed by [41] ICC values above 0.90 indicate excellent reliability. This suggests that nearly all the observed variance in draft measurements is attributable to genuine differences in the ship's draft rather than measurement error between the two methods. In practical terms, the system's readings are interchangeable with human observations under typical survey conditions.

The narrow confidence interval (0.951–0.986) reinforces the precision and stability of the reliability estimate, implying that even with sampling uncertainty, the true level of agreement remains very high. Furthermore, the high F-ratio ($F = 78.0$, $p < 0.001$) confirms that between-measurement variability far exceeds residual error variance, suggesting the proposed system captures the same underlying measurement signal as human surveyors.

D. Model Performance

TABLE VI. MODEL TRAINING VALIDATION RESULTS

Model	Metric				
	Precision	Recall	mAP	IoU	Inference time
YOLO11n	99.82%	99.80%	99.49%	—	30ms
YOLO11n-seg	98.12%	97.74%	99.06%	97.28%	20ms

As seen in Table VI above, both the detection and segmentation networks achieved near real-time speeds with exceptionally high accuracy. The YOLO11n detector reached 99.82% precision, 99.81% recall and a mAP@0.5 of 99.49%, processing each frame in about ~30 ms. Its companion model, YOLO11n-seg, scored a mAP@0.5 of 99.06%, an IoU of 97.28%, and maintained over 97% recall (98.12 % precision) on full-scene masks, with an inference time of around ~20 ms per frame. Both models exhibit reliable isolation of their targets in varying hull conditions, provided excessive rusting does not distort the number for the detection model.

Speed and timing performance were evaluated on the Jetson Orin Nano by processing a 10-second video clip containing visible draft marks. The average inference time for each model and computation times were recorded (see Fig. 11). On average the complete pipeline yielded a latency of approximately 10ms per frame, corresponding to an effective throughput of 10 FPS.

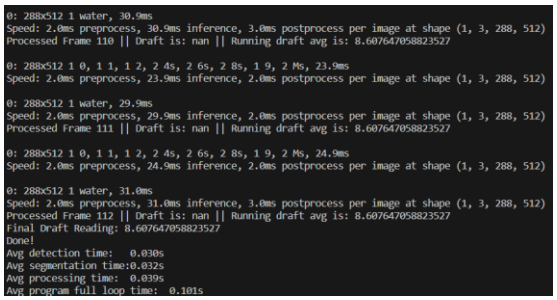

Fig. 11. Average system time for detection, segmentation, and calculation.

Compared to the systems proposed by [11], [12], and [13], the process times of the ADS utilizing an edge computing device lies in the middle, as seen in Table VII.

TABLE VII. COMPARISON OF COMPUTE TIMES BETWEEN STUDIES

Study	Device	Total time
Chernyi & Ivanovskii [11]	N/A	33 ms[a]
Zhang et al. [12]	NVIDIA GTX 3060	16 ms
Wang et al. [13]	NVIDIA GTX 1080Ti	360 ms
ADS	NVIDIA Jetson Orin Nano	101 ms

[a] Value inferred from stated performance at 30 FPS, but no compute time was stated in the study.

Due to hardware constraints, the ADS system does not show the fastest processing times. However, previous studies had only focused on processing recorded videos in calm and stable conditions, whereas the ADS system was able to demonstrate modest performance in real-time draft reading in a real-world environment.

E. Discussion

The error-metric analysis revealed excellent point-wise performance between the automated and manual measurements (MSE = 0.0751, RMSE = 0.2740 m, MAE = 0.1068 m, R^2 = 0.9506). In practical terms, the algorithm's draft estimates deviate from human readings by about 0.11 m on average, while capturing more than 95 % of the variation observed by human surveyors. The MAE being larger than those of [12] and [13] are attributed to the two faulty readings caused by hull corrosion, obscuring the target draft mark. The effect of these outliers were analyzed, and when excluded to simulate idealized conditions, dropped the average deviation or MAE to ±0.0505, now within the accuracy ranges from [12] and [13]. The paired t-test ($t = 1.47$, $p > 0.05$) confirmed that the difference between the two methods is statistically insignificant, indicating the absence of systematic bias and validating the reliability of the automated approach for operational use.

Bland–Altman analysis provided further evidence of strong agreement, with a small positive bias of +0.063 m and 95 % limits of agreement between –0.467 m and +0.592 m. Ninety-five per cent of all paired measurements lay within these limits, demonstrating that deviations are both limited and evenly distributed across the measurement range. Again, the few outliers were traced to localized corrosion which temporarily disrupted the detection model.

The intraclass correlation coefficient ICC(2,1) of 0.974 (95 % CI: 0.951–0.986; $F(39, 38.9) = 78.0$; $p < 0.001$) confirms excellent absolute agreement between manual and automated readings. According to [41], ICC values > 0.90 reflect outstanding reliability. This finding implies that nearly all variance arises from true physical changes in draft rather than measurement noise, meaning that the automated readings are interchangeable with those of human surveyors. The narrow confidence interval further confirms the stability of this reliability estimate. Taken together, the ICC, Bland-Altman, and regression analyses establish a consistent pattern of agreement, affirming the robustness of the system.

Model-level evaluation corroborates the system-level findings. The YOLO11n detector and YOLO11n-seg segmentation network achieved precision and recall exceeding 97 %, with mean average precision (mAP@0.5) values above 99 %. Despite running on an edge device, inference times averaged 30 ms and 20 ms per frame, respectively, yielding a full-pipeline latency of ~101 ms (~10 FPS). While this is slower than the 16 ms reported by [12] on an RTX 3060 GPU, it surpasses the 360 ms runtime of [13] and remains within real-time operational limits for live draft monitoring. The performance difference primarily reflects the hardware class, and the ADS achieves comparable accuracy in the field while maintaining full onboard processing capability without cloud dependence.

IV. Conclusion

This study presented the design, development, implementation, and validation of the Aerial Draft Surveyor (ADS), a UAV-based computer vision system that automates ship draft measurement through YOLOl1n object detection and YOLO11n-seg waterline segmentation, optimized for real-time edge inference on an NVIDIA Jetson Orin Nano through TensorRT. The system addressed key limitations present in previous studies, particularly by implementing and validating a real-time approach to draft-reading in the field. It introduces temporal subsampling to reduce computational load in real-time processing, CMA to ascertain a draft estimate, and a convergence check to determine when to finalize the draft estimate through stability checks with zero-slope fitting and NRMSE.

Results demonstrated excellent agreement with manual surveyor readings, achieving an MAE of 0.1068 m, RMSE of 0.2740 m, and R^2 = 0.9506, with no statistically significant bias ($t = 1.47$, $p > 0.05$). Bland-Altman analysis showed 95 % of paired readings within ±0.6 m limits of agreement, while the ICC(2,1) = 0.974 (95 % CI: 0.951–0.986) confirmed reliability and consistency with human observations. Moreover, TensorRT optimization allowed for efficient inference on low-power edge hardware. Alongside lightweight algorithms, it allowed for a throughput of ~10 FPS representing a significant step toward practical, autonomous draft surveying.

Yet, similar to its predecessors, the system remains sensitive to corrosion and occluded draft marks, which degrade detection accuracy or completely mislead the system to an erroneous reading. Additionally, there is still much room for improvement to further decrease latency from processing to prevent frame skipping and obtain as much information as possible from the live video feed. Another issue is the dependence on human readings as ground truth as there is no means to determine the correctness of manual observation. Lastly, addressing adverse weather conditions in future studies may significantly improve the dependability of similar systems.

This study contributes to the field by: 1) introducing a real-time, UAV-integrated measurement framework; 2) combining temporal subsampling with convergence-based stability evaluation for automated draft finalization; 3) demonstrating TensorRT-accelerated YOLO11n and YOLO11n-seg performance on embedded systems; and 4) validating the system through comparative field trials with licensed surveyors. Collectively, these contributions bridge the gap between laboratory-based automation studies and operational, deployable maritime systems, addressing both research and practical needs.

In summary, this work confirms the feasibility of real-time, edge-deployed computer vision for ship draft surveying. The system shows promise as being a supplementary tool for real-time aid to support and validate manual draft surveying.

Acknowledgment

The authors wish to express their appreciation to Hinatuan Mining Corporation (HMC) for their cooperation and for

granting access to their facilities and equipment during the conduct of system testing.

***Abstract*—Personalized cancer treatment remains challenging due to the complexity of genomic data and variability in drug responses. Previous federated learning (FL) approaches handled distributed patient data to preserve privacy but treated genomic and pharmacological features as flat, tabular inputs, limiting the ability to capture gene–drug interactions. In this study, we propose a Graph Neural Network (GNN)-based framework, FedGraphOnco, which models patient-specific gene–drug interactions as structured graphs, enabling the network to learn complex relational patterns that are difficult or impractical for FL-only models. Attention mechanisms and SHapley Additive exPlanations (SHAP) are incorporated to provide interpretable insights into important genes, pathways, and drug interactions, increasing clinical trust. Using the GDSC dataset with gene expression, mutation status, copy number variation, and IC50 drug responses, the model demonstrates high predictive accuracy (Pearson correlation = 0.85, RMSE = 2.6, MAE = 1.9, dosage deviation = 2.8%), robustness to noise and non-IID data, and adaptive, personalized dosage recommendations. The approach highlights the advantages of combining privacy-preserving FL, GNNs, multi-omics data integration, explainability, and adaptive dosing, offering a scalable and interpretable solution for precision oncology.**

***Keywords*—Graph Neural Networks; cancer drug dosage; privacy preservation; genomic profiling; precision oncology**

I. Introduction

This system uses AI-based deep learning to customize dosages of cancer drugs while also allowing the patient data to remain in distributed healthcare systems to maintain their privacy by not storing private information in one isolated location. The use of artificial intelligence in organizing and initiating personalized oncology trials will have a positive impact on current challenges in the efficacious introduction of new drugs into oncology practice [1], [2], [3]. Using AI together with real-world data in precision medicine will also allow drug development to target cancer cells that will be conducive to complete and rapid drug development [4]. Precision medicine is changing healthcare by giving personalized diagnostics and treatments based on a patient's DNA, living conditions and behaviors [5]. The movement is aided by computer-based science and methods such as machine learning and bioinformatics which let us understand and solve drug response and personalized medicine issues. Lung cancer remains one of the leading causes of cancer-related deaths across the globe. It is a heterogeneous disease with a complex genetic evolution [6], [7]. Conventional treatment strategies often fail to improve outcomes due to the variability of patients' molecular profiles and responses. Given this variability, personalized medicine focusing on treatments based on individual and patient population genetic and molecular characteristics has gained widespread attention [8], [9]. Advances in genomic technologies and biomarker identification are supporting the effort to develop more effective, tailored treatment regimens, improve patient treatment outcomes, and limit side effects [10]. Personalized cancer treatment provides patient-specific therapies that consider the genetic, molecular, and clinical features of the patient. Although some significant strides have been made in the treatment of cancer, the identification of the optimal therapeutic regimens for the patient remains challenging [11]. Many orally delivered anti-cancer medications, particularly the kinase inhibitors are typically dosed at a standard fixed dose which may not be appropriate for all patients, potentially leading to adverse effects if the dose is too high, or therapeutic failure if the dose is too low [12]. Lung cancer continues to be a principal cause of cancer-related deaths globally but despite its heterogenicity and

biological diversity, patients experience marked variations in prognosis and treatment. Conventional prognostic models often do not account for this complexity, leading to increased interest in artificial intelligence as a personalized prognostic tool [13]. This study presents FedGraphOnco, a federated GNN that represents genomic and pharmacological data as biological graphs to predict the dosage of cancer drugs. It provides privacy guarantees based on multi-layer security, handles non-IID distributions with FedProx, and incorporates SHAP- and attention-based explainability to provide accurate, secure, and interpretable precision in oncology.

A. Research Motivation

The high pace of accuracy in oncology development underscores the necessity of computational models that have the capability of prescribing patient-specific dosages of drugs using various genomic and pharmacological data. Nevertheless, centralized learning methods have critical challenges such as patient privacy, non-homogenous data distribution across facilities, and the inability to interpret predictions. The current reinforcement learning models or the use of vectors do not always represent the complex network-based interactions of cancer biology. It is against these gaps that this study is driven to come up with a federated framework which is graph-based and preserves privacy, is robust to non-IID data, and is offerable to make a dosage recommendation that is interpretable to advance safe and reliable personalized cancer treatment.

B. Significance of the Study

Personalized oncology is developed based on a patient-specific GNN model to predict complex interactions between genes and drugs with the help of multi-omics data. Scientifically, it offers new information on the genomic factors of drug response and emphasizes important molecular characteristics that modulate the results of treatment. On a clinical level, it aids in precision oncology, producing interpretable and individualized dosage proposals, bolstering clinicians, and minimizing the risks of adverse drugs. In practice, the privacy-conserving FL method allows collaborating with multiple institutions safely, enhances the generalizability of the model, and can be applied in real life in decentralized healthcare environments. In general, the study has shown that it is possible to have a scalable, interpretable, and accurate AI-driven adaptive cancer drug dosing.

C. Recent Innovation and Challenges

The recent developments in precision medicine contain artificial intelligence in driving drug repurposing, FL architecture to plan radiation, and multi-omics datasets and treatment to optimize personalized anticancer means [14]. The discovery of new biomarkers is easier and allowing tailored therapies to have more accurate and precise patient-outcomes. Yet, a considerable amount of issues still need to be addressed, including the heterogeneity of data across institutions, the inaccessibility of large-scale validation of clinical data, and the unreliability of the AI models' interpretation [15]. As well, the ability to reconcile high model performance with demanding privacy requirements on patient data remains an important obstacle to broader clinical usage.

D. Key Contribution

- FedGraphOnco Framework for Drug Dosage Prediction: Proposed a novel Federated Learning-enhanced GNN architecture that enables decentralized, privacy-preserving prediction of cancer drug dosages using patient-specific biological graphs.
- Privacy-Preserving Multi-Institutional Learning: Enabled collaborative learning across simulated healthcare nodes without sharing raw patient data, using federated aggregation mechanisms to preserve privacy and support scalability.
- Patient-specific graphs integrate multi-omics features (gene expression, mutation, CNV) with drug characteristics, capturing biologically meaningful gene–gene, drug–target, and pathway interactions.
- Federated aggregation uses FedProx with encrypted and noise-perturbed updates to handle non-IID genomic distributions, ensuring privacy-preserving and stable convergence across institutions.
- Attention mechanism identifies key genes and gene–drug interactions, providing clinically interpretable insights that guide personalized and accurate dosage predictions.

E. Research Questions

- How can a privacy-preserving federated GNN be designed to collaboratively predict cancer drug response using distributed genomic data without sharing sensitive patient information?
- To what extent can the integration of GNNs, federated learning, and privacy-enhancing mechanisms improve the accuracy, robustness, and scalability of cancer drug personalization compared to centralized approaches?
- How can explainable AI techniques, such as attention mechanisms and SHAP-based feature interpretation, enhance the transparency and clinical interpretability of the proposed federated model in real-world oncology applications?

F. Rest of the Section

The following sections of this study are structured as follows: Section II provides an overview of existing literature. Section III outlines the problem addressed in this work and outlines the problem statement underlying the proposed methodology. Section IV discusses the effectiveness of the methodology. The results and discussion are presented in Section V. Finally, Section VI concludes and summarizes future work.

II. Related Works

Ahmed et al. [16] aim to achieve the goals of personalized cancer therapy more effectively by predicting how a patient will respond to drugs using artificial intelligence AI-driven models based on the patient's unique genetic profile. The study introduces a novel data federation technique to link and combine gene expression, gene mutations, and drug response,

representing each cell line and allowing for better quality and a larger amount of data. While studying the drug response, two ML models such as SVM and LR using PCA for feature reduction were derived along with a newly designed deep learning approach. Using the data federation approach, predictions were improved with a markedly 25% reduction in prediction error. The Enhanced Deep-DR model produced superior Pearson correlation with recent state-of-the-art models, and the generated AI models supporting a safer and more effective drug response prediction across various drugs in a generalized way. This presented approach also responds to the challenges of data scarcity and heterogeneity in personalized medicine.

Lococo et al. [17] proposed to examine how AI, particularly ML and DL, which improve personalized prognostic evaluation in non-small-cell lung cancer, including staging, treatment response, and recurrence assignment. It outlines a variety of AI methods that assess integrated datasets, clinical, imaging, and molecular, to generate personalized survival and progression predictions based on specific datasets like radiological scans, genomic profiles, and patient medical history. It examines some of the challenges, including data heterogeneity, model interpretability, and generalizability. The benefits of AI will include more accurate staging, individualized therapies, and providing better outcome predictions, hopefully improving the treatment management of NSCLC.

S Herraiz-Gil et al. [18] propose the objective of applying AI to drug discovery to mitigate the cost and time aspects, as well as the possibility that the clinical trials may fail, which is even more prevalent for complex diseases like cancer. It also examines techniques that are AI-derived, such as machine learning, deep learning, and evolutionary algorithms. In practice, the AI applications analyze biomedical, molecular, and clinical datasets in evaluating or predicting molecular interactions between drug targets and subsequently optimizing drug candidates. Incorporating AI will also help in the challenges with safety, efficacy, and heterogeneity. The overall advantages will be decreased development time and cost, improved precision, and supporting tailored medicine.

Jian et al. [19] proposed this research to propagate personalized medication by the use of pharmaco metabolomics, an area that is very promising, which takes genetic and environmental factors together with pharmacological and biological pathways to predict the effectiveness of drugs in individuals. Here, employed the use of literature review and pharmacokinetics analysis with the collection of metabolomics data. The datasets are a collection of studies, published and indexed in PubMed and Web of Science between 2006 and 2023. This approach avoids the limitations of previous methods, such as pharmacogenomics and TDM, which provide a holistic view. Benefits include and better prediction of drug metabolism, identification of biomarkers and improved precision in drug administration.

Elhaie et al. [20] explored the application of machine learning techniques to improve precision in radiation dose measurement and prediction across medical and technical domains. The study addressed the limitations of traditional methods by utilizing advanced approaches such as classification, regression, clustering, time series forecasting, and generative modeling. These methods demonstrated significant benefits in tasks like radiation source detection, continuous dose monitoring, organ dose estimation, and predictive modeling, leading to improved accuracy and efficiency. The findings highlighted the potential for machine learning to optimize dose management in medical treatments, nuclear facilities, and emergency scenarios, supporting more personalized and real-time radiation monitoring and protection.

Zhang et al. [21] suggested an FL discovery as a method of knowledge-based planning in radiation therapy to overcome the problem of inter-institutional data sharing. This approach employed a gradient-boosting function with Federated Averaging on ten distributed subsets of prostate 45 Gy plans and demonstrated a similar prediction accuracy (MAE ~4.7%) as a centralized one (~4.4%) and improved significantly over individual site models (~6.5%). Results were consistent with different numbers of sites and imbalanced data factors. Although the benefits of the study demonstrated a privacy-preserving advantage, along with high-quality predictivity, it was also limited in scope to one disease location and more or less a small number of data to perform its task, thus would require multi-institutional validation of predictions.

Pati et al. [22] suggested a (FL) system based on boundaries-level rare cancer, which can collect data at scale using 71 institutions and prevent the exchange of sensitive MRI information. The research combined FL and up-to-date deep learning segmentation technique to jointly train models on 6,314 patients and 25,256 scans. The findings demonstrated that the accuracy of FL-trained models is similar to or higher than that of centrally trained models, and FL-learned models maintain high accuracy and privacy security on data, along with robustness to overcome the heterogeneity of data sources. The two main pitfalls observed were the issue of complexity of standardization between institutions and limited interpretability that creates dilemmas in clinical translation and large-scale deployment.

Cao et al. [23] have released FedBCa, a multicentric, bladder cancer MRI dataset with 275 3D T2-weighted MRI scans obtained in four hospitals and expert-labeled tumor segmentation and staging. The authors benchmarked few FL algorithms to show its usefulness such as FedAvg, FedProx, FedBN, and SiloBN regarding diagnostic and segmentations where the benchmarking was done using a controlled location of many GPUs in a localization like localized supervised / semi-supervised learning task. The obtained results showed higher generalizability of federated models than single-site training to be promising on accuracy and to guarantee cross-institution privacy.

III. Problem Statement

Among the significant concerns related to the efficient coordination of patient-specific genomic and clinical data between decentralized healthcare networks, substantial deficits still remain in the realm of AI-based oncology. As an example, [16] emphasize the heterogeneity of data and its scarcity as constraints to predictive models of drug response generalizability. Likewise, Zhang et al. [21] highlights the

challenge of maintaining privacy, when training a multi-institutional model, limiting the scalability of knowledge-based treatment planning. The application of individual dosing of cancer drugs is still problematic because of the heterogeneity of the data, privacy factors and constraints of the current AI techniques. Real cancer data, e.g. GDSC, is highly heterogeneous: there are many more samples of lung cancer than of leukemia, genes, mutations, and copy number variation (CNV) are widely differentiated across patient samples. This non-identically distributed (non-IID) data makes it difficult to generalize a model across institutions. Moreover, privacy laws (e.g. HIPAA, GDPR) do not allow sharing of genomic, pharmacological and clinical data directly, so centralized training on models across multiple institutions is not possible, and not all training samples are easily available. Earlier AI and FL methods either use a simple tabular design and lack any sophisticated representation of non-IID distributions and combined gene-drug interactions, or utilize more advanced versions that can fail to attain the predictive accuracy and interpretability of the others. To combat such gaps, the proposed framework will merge patient-specific graph-modeling, attention-based interpretability, and FedProx aggregation to allow robust, privacy-preserving, and clinically meaningful cancer drug dosing predictions.

IV. Privacy-Preserving Federated GNN Approach for Cancer Drug Personalization

The FedGraphOnco framework proposed is based on FL implemented with GNNs, which provides personalized, privacy-aware, and interpretable predictions of cancer drug dosage. In comparison with the traditional reinforcing methods of learning, FedGraphOnco takes into account the network-based characteristics of cancer biology by modeling genomic and pharmacological data in the form of structured graphs. GDSC data contains values of drug responses (IC50), gene expression, somatic mutations, copy number changes, and drug characteristics. Missing-value imputation, feature encoding, correlation filtering, variance thresholding, Z-score normalization, and IC50 log transformation are used in data preprocessing. After preprocessing, every sample of patients is turned into a graph, with the nodes being genes and drugs, the node properties being the molecular features, and the edges being the gene-gene or drug-target interactions. GNNs are trained in local institutions and generate graph embeddings that predict doses through regression layers. Gradients are then clipped, encrypted and perturbed with differential privacy to transmit sensitive data. FedProx-based aggregation is done at the central server, which is robust to non-IID distribution of clients. The distributed international model is reallocated and locally optimized during repeated communication rounds until convergence. Lastly, explainability is reached by SHAP values and attention scores, with emphasis made on important genes and drug interactions that provide recommendations. This ensures adjustive, safe, and clinically interpretive dosage results. The proposed FedGraphOnco framework depicts this well-structured workflow, which is illustrated in Fig. 1.

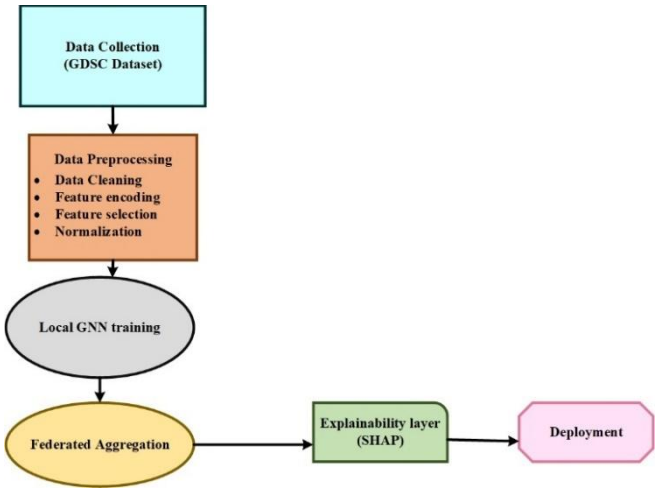

Fig. 1. Workflow for privacy-preserving cancer drug personalization.

A. Data Collection

The study utilizes the Genomics of Drug Sensitivity in Cancer (GDSC) dataset, which is a large-scale pharmacogenomic database constructed in partnership between the Wellcome Sanger Institute and the Massachusetts General Hospital Cancer Center [24]. The reason why GDSC was chosen is the large-scale, well-curated multi-omics data and wide-ranged drug response profiles available in the data, which proved to be extremely appropriate in modeling personalized cancer drug responses. The data set comprises of more than 1000 genetically characterized human cancer cell lines and drug sensitivity values in the form of IC50 against about 250 to 300 anticancer drugs. Genomic characteristics consist of the levels of gene expression, their somatic mutation status, and copy number variations (CNVs) that enable the incorporation of multi-omics data into patient-specific graphs. The data is representative of different types of cancer, such as Lung, Breast, Colon, and Leukemia. The GDSC information can be accessed publicly on the GDSC site and Kaggle to be data-mined and is thus transparent and reproducible. This is the best option to develop and test the proposed FedGraphOnco framework on predicting the dose of different drugs personally and without invasion of privacy because of its extensive architecture and well-developed feature set.

B. Data Preprocessing

1) Data cleaning: Handling missing or corrupted values in genomic data is essential to maintain dataset integrity and model accuracy. Numerical missing values are imputed with statistical methods while categorical missing values are filled using the most frequent category or biological domain knowledge, that is given in Eq. (1),

$$x_i^{(imp)} = \frac{1}{N}\sum_{j=1}^{N} x_j \quad (1)$$

where, $x_i^{(imp)}$ means imputed value, N represents number of observed values, x_j means observed data points.

2) Data cleaning: Converts categorical genomic features such as mutation status or cancer type into numerical forms usable by machine learning algorithms. Mutation statuses are

encoded as binary variables while other categorical features are one-hot encoded to avoid false ordinal implications, that is represented in Eq. (2),

$$M_i = \begin{cases} 1, & \text{mutated} \\ 0, & \text{wild} - \text{type} \end{cases} \quad (2)$$

One-hot encoding for a categorical feature with k categories, which is represented in Eq. (3),

$$C_{ij} = \begin{cases} 1, & \text{if sample i belongs to category j} \\ 0, & \text{otherwise} \end{cases} \quad (3)$$

3) Feature selection: Reduces dimensionality and removes noise by filtering out redundant or non-informative genomic features, which improves model efficiency and accuracy.

4) Correlation filtering is given in Eq. (4):

$$|\text{corr}(x_i, x_j)| > \rho_{th} \quad (4)$$

If true, one of the features x_i, x_j is dropped.

Variance thresholding is given in Eq. (5),

$$\sigma_i^2 < \epsilon \quad (5)$$

5) Normalization: Standardizes feature scales to enhance model convergence and performance. Both gene expression features and drug response targets are normalized. Z-score standardization is represented in Eq. (6):

$$z_i = \frac{x_i - \mu}{\sigma} \quad (6)$$

where, z_i means the standardized value of the original feature value x_i, x_i means the original value of the feature for the i^{th} data point, μ is the mean of the feature across all samples in the dataset, σ is the standard deviation of the feature across all samples.

Log-transform of IC50 values to stabilize variance is given in Eq. (7):

$$y' = log(y) \quad (7)$$

where, y is the original target variable, $log(y)$ is the natural logarithm of the IC50 value, y' is transformed target variable.

C. Graph Construction

Patient-specific biological graphs are constructed as a result of preprocessing to provide a structured representation of the molecular and pharmacological information. Each graph is defined as Eq. (8):

$$G = (V, E, X) \quad (8)$$

where, V denotes the set of nodes, E is the set of edges, and X denotes the node feature matrix.

Nodes (V) consist of genes and drugs. Gene expression value, binary mutation status, and numerical copy number variation (CNV) is annotated on each gene node. The chemical descriptors or pathway membership information are enriched in drug nodes. The node feature (X) is represented as Eq. (9):

$$X = [x_1, x_2, \ldots\ldots, x_n] \in \mathbb{R}^{n \times d} \quad (9)$$

where, n is the number of nodes and d denotes the feature dimension per node.

Edges (E) capture interactions based on biological databases: Gene-gene functional interactions of STRING/Reactome, drug-target interactions of DrugBank, and pathway membership. Local GNN encoders process information about neighborhoods, generating representations of graphs as shown in Eq. (10):

$$h_G = GNN_\theta(V, E, X), \quad \hat{y} = g_\phi(h_G) \quad (10)$$

where, h_G is the embedding for graph G, and $\hat{y}$ represents the dose-recommended or predicted log-IC50 drug response. This is a graph representation that allows the incorporation of multi-omics and pharmacological background to learning.

D. Local GNN Training

A GNN model is locally trained at every participating institution using the built patient drug graphs. The goal is to learn embeddings that can represent both the interactions between molecules and drug responses with respect to privacy of patient-level information. For a given client k expression of the forward propagation of the local GNN is shown in Eq. (11):

$$h_{G_k} = GNN_{\theta_k}(G_k), \quad \widehat{y_k} = g_{\phi_k}(h_{G_k}) \quad (11)$$

where, h_{G_k} is the learned graph encoding of the graph. G_k, θ_k denotes local NN parameters, and g_{ϕ_k} is a regression layer predicting the value of drug response $\widehat{y_k}$.

Node embeddings are trained in a layer-wise manner; they are updated with aggregated neighborhood information as shown in Eq. (12):

$$h_v^{(l+1)} = \sigma(w^{(l)\prime}.AGG\{h_v^{(l)}, h_u^{(l)} | u \in N(v)\}) \quad (12)$$

where, $h_v^{(l)}$ is the node presentation of node v at layer l, $N(v)$ denotes its neighbors, $W(l)$ is a training weight matrix, and σ is a non-linear activation.

The model is trained on the mean squared error (MSE) between the actual and predicted log-transformed IC50, as shown in Eq. (13):

$$\mathcal{L}_k = \frac{1}{n_k} \sum_{i=1}^{n_k} (\hat{y}_i - y_i)^2 \quad (13)$$

where, n_k is the number of samples at client k."

E. Privacy-Preserving Mechanisms

The FedGraphOnco framework highly focuses on the protection of patient information when training is being carried out through collaboration. As the system uses three extremely sensitive types of data: genomic profiles (gene expression levels, somatic mutation status and copy number variations), pharmacological responses (drug sensitivity results like IC50 values), and clinical metadata (cancer type, tissue of origin and identifiers), then strict privacy control mechanisms are necessary. These types of data cannot only be personally identified but also have possible ethical, clinical, and institutional risks in case of exposure.

To counter these risks, raw patient data are always stored in each participating institution. Rather than transferring direct

genomic or clinical histories, institutions only transfer model parameters based on local training. Three-layers of protection are used prior to transmission. Gradient clipping makes sure that updates are bounded thus avoiding the effect of extreme values and minimizing the threat of indirect information leakage. Differential privacy, to give the parameter updates additional privacy, introduces controllable random noise to them. This methodology makes sure that the contributions of individual patients are not recognizable in an aggregate model, even in adversarial analysis. Lastly, homomorphic encryption enhances the process of encryption by permitting the use of encrypted updates that can be transmitted and combined without having to be decrypted by the server.

Combined, these approaches will ensure that FL can be effective and, at the same time, that privacy is preserved. FedGraphOnco offers a trusted and ethically sound modeling framework that we are able to offer by ensuring the protection of genomic, pharmacological, and clinical data throughout the pipeline, and balances the model development with the utmost patient confidentiality.

F. Federated Aggregation

Federated aggregation within the FedGraphOnco framework is important in the combination of knowledge in more than one healthcare institutions without compromising on the confidentiality of the local datasets. Raw genomic, pharmacological, or clinical data is not shared by institutions after each round of local training. They instead send encrypted model parameters based on their locally trained GNNs. These parameters learn the patterns based on institutional data without revealing the sensitive level of patients. To manage the non-IID of the genomic and clinical distributions across the institutions, FedGraphOnco uses a proximal-based aggregation (FedProx) in the central server, as shown in Eq. (14):

$$\theta_{global}^{t+1} = \sum_{k=1}^{K} \frac{n_k}{n} (\theta_k^t - \mu(\theta_k^t - \theta_{global}^t)) \qquad (14)$$

where, θ_{global}^t is the global model at communication round t, n_k is the number of samples at client k, n=$\sum_{k=1}^{K} n_k$ represents the number of samples across all clients. The visual representation is shown in Fig. 2.

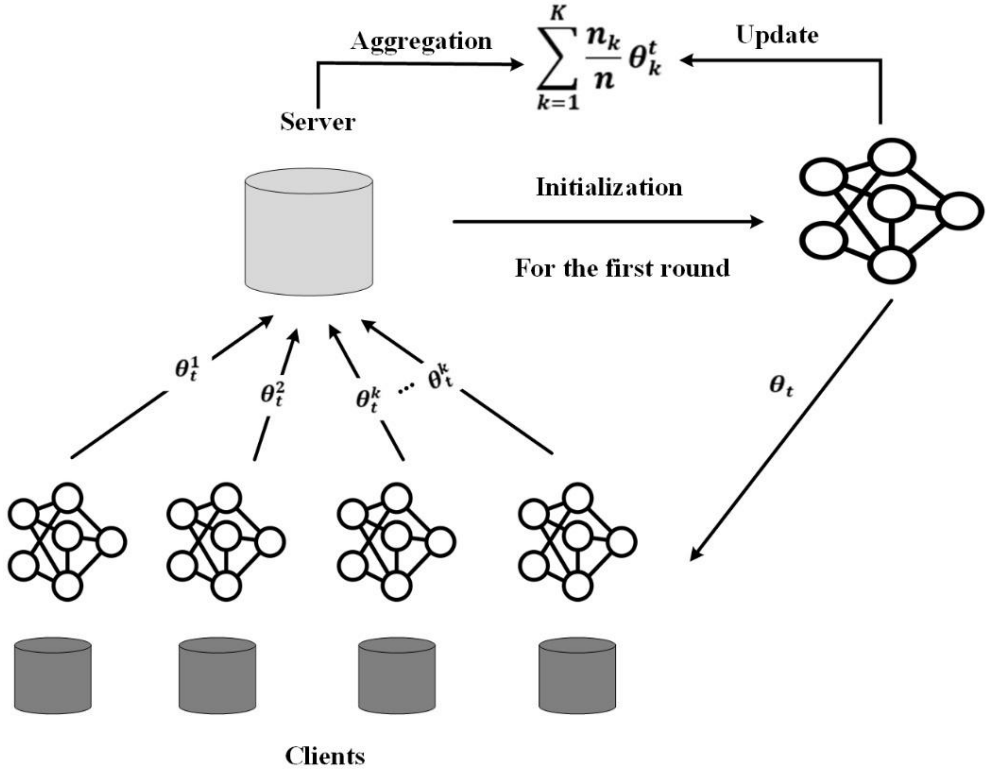

Fig. 2. Federated aggregation process in the FedGraphOnco framework.

All the participating sites provide their encrypted updates to the central server, which carries out aggregation to build a better global model. FedGraphOnco uses a proximal-based aggregation approach as opposed to simple averaging, which may be volatile in situations where the data distributions in various institutions may differ. The method guarantees that information of various hospitals is unified, even though the genomic and clinical nature of their patients might be quite diverse. The framework counters the problems associated with non-identically distributed (non-IID) datasets that are prevalent in real-world healthcare settings by using stabilization mechanisms.

The global model is once again re-distributed back to the clients once it has been aggregated. The model is adjusted to each institution on their local data enabling them to personalize it but at the same time enjoy the global knowledge. This process is repeated in several communication rounds consisting of local training, secure transmission of parameters, aggregation and redistribution until convergence.

By this federated consolidation, FedGraphOnco will balance the global collaboration with local specialization. The model gets stronger after every cycle, and it allows the correct, adaptive, and privacy-sensitive dosage proposal of cancer drugs in decentralized healthcare networks.

G. Explainability Layer

The lack of interpretability is also a significant issue when it comes to the application of artificial intelligence to oncology, as it may inhibit clinical trust and adoption. To overcome this, the FedGraphOnco framework will have an explainability layer, which will offer a transparent view of the dosage recommendations. The model uses SHapley Additive exPlanations (SHAP) and attention processes in the GNN to indicate major genomic and pharmacological variables in predictions.

SHAP values are a mathematical indicator of the amount of contribution made by each input feature (for example, a single gene mutation or an expression level) to the overall prediction. This allows clinicians to determine which molecular changes contributed the most towards the establishment of a recommended drug dose. Simultaneously, the attention system of graph layers determines the relative significance of edges and nodes in patient-drug graphs. The model gives greater attention weights to important gene-gene/drug-target interactions, which is biologically relevant, and therefore, highlights biologically important pathways.

The combination of both complementary methods will make sure that the prediction of doses will not only be accurate but also have a clinical interpretation. Oncologists will be able to check that the reasoning of the model is consistent with the known facts in medicine and become more confident in its suggestions. Therefore, the explainability layer can be viewed as the intermediary between higher-order computational modeling and feasibility in personalized cancer treatment.

H. Deployment

After a series of communication rounds during the federated training process, the FedGraphOnco global model converges, which proves its stability and strong predictive performance using heterogeneous clinical data. The resulting aggregated model is then re-distilled to individual participating institutions, and fine-tuning on site-specific genomic and clinical data is then done. This makes sure that although the model will use global knowledge, it will also be tailored to the special features of the hospital population of patients.

The implemented model has some essential benefits. First, it offers predictive and patient-adjusted drug dosage, which allows precision oncology by customizing treatment in response to personal molecular profiles and anticipated responses to specific drugs. Second, it ensures a high level of privacy, since the sensitive genomic, pharmacological, and clinical data is kept locally and only encrypted and noise-perturbed updates are exchanged during training. Third, it provides clinically interpretable results in the form of SHAP-based explanations and attention mechanisms of the GNN and identifies impactful genes, pathways and drug-target interaction that affect dosage decision making.

The FedGraphOnco implementation offers a combination of adaptability, privacy, and interpretability to provide that more advanced AI-based drug personalization can be safely and successfully embedded into the operation of actual clinical oncology settings, contributing to the evidence-based decision-making and preserving the confidentiality of the patient.

Algorithm 1: FedGraphOnco–Privacy-Preserving Adaptive Cancer Drug Dosing

```
Input: Local datasets D_k for each client k∈{1,…,K}
Learning rate α, number of communication rounds R
Output: Personalized GNN-based drug dosing model at each client
Begin
  Initialize global model θ_global
  For round r = 1 to R do
    For each client k in parallel do
      Preprocess Dk:
        - Data cleaning
        - Feature encoding
        - Feature selection
        - Normalization
      Initialize local model θ_k ← θ_global
    Construct patient-specific graphs Gk = (V, E, X)
    Initialize local model θk ← θglobal
    Train local GNN:
      Forward propagation: hGk = GNNθk(V, E, X)
      Predict drug response: y^k = gϕk(hGk)\hat{y}_k
      Compute loss: Lk = 1nk∑i(y^i − yi)2L_k
      Update θk via backpropagation
    Apply privacy-preserving mechanisms:
      Gradient clipping
      Differential privacy noise
      Homomorphic encryption of model updates
    Send encrypted θk to central server
    Server aggregation:
      Check convergence; if met, break
      Else
        Send θ_global back to all clients
      End If
    End For
    For each client k do
      Fine-tune θ_global on Dk
      Deploy personalized policy πθ_k for adaptive cancer drug dosing
    End For
  End
```

FedGraphOnco algorithm (see Algorithm 1) is used to do privacy-preserving, adaptive dosing of cancer drugs based on a FL system with GNNs. Every involved institution preprocesses local genomic, pharmacological, and clinical data, builds

patient-specific graphs, and fits a local GNN to make predictions of the log-transformed IC50 drug reactions. Privacy is ensured by gradient clipping, differential privacy, and homomorphic encryption and sending the model updates to the central device. To deal with non-IID distributions, the server uses FederatedProx, which leads to the creation of a global model that is redistributed to clients. Lastly, the global model is customized to fit each client with SHAP and attention mechanisms offering access to the interpretation of clinical decision-making.

V. Results and Discussion

The results of the application FedGraphOnco framework are given, with its performance being emphasized in different experimental conditions. This section looks at parameters of simulation, preprocessing effect, model behavior, scalability and interpretability. Besides, it addresses the issue of performance evaluation, ablation studies, and comparative analysis to confirm the strength and effectiveness of the proposed approach. The simulation parameter is shown in Table I.

TABLE I. Simulation Parameter and Hardware Setup

Parameter	Value
Dataset	GDSC (Genomics of Drug Sensitivity in Cancer)
Local Training Epochs	10
Number of Drugs	~250–300
Graph Nodes	Genes, Drugs
Node Features	Expression, Mutation, CNV, Drug descriptors
Edge Sources	STRING/Reactome (gene-gene), DrugBank (drug-target)
Graph Size	2000–5000 nodes per patient graph
Optimizer	Adam (learning rate = 0.001)
Batch Size	32–64
Local Epochs per Round	5–10
Clients	5–10 simulated institutions
Communication Rounds	50–100
Aggregation Method	FedProx (μ = 0.01)
Data Distribution	Non-IID
Encryption	Homomorphic encryption
Interpretability	SHAP values, Attention weights
Software & Hardware Setup	Python, Intel Core i7 Processor, 16 GB RAM, NVIDIA RTX 3060 GPU, Ubuntu 20.04 OS

Fig. 3 shows the effect of preprocessing methods on gene expression and IC50 values. The first panel on the left hand side is entitled Gene Expression Normalization Effect, which measures the gene expression levels pre and post normalization. The raw data has initial values that are widely distributed with high variability and huge outliers, which denotes the lack of scales consistency across samples. Upon normalization, the values are concentrated around zero and it can be argued that normalization is effective in bringing variability to a minimum and making the data comparable among genes and samples. The right panel with the title of IC50 Transformation Effect shows the distribution of the values of IC50 before and after transformation.

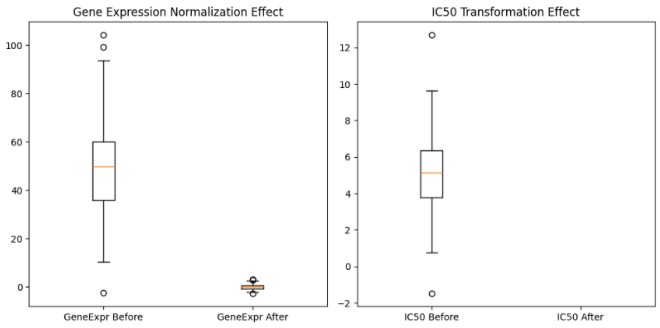

Fig. 3. Normalization and transformation effects on gene expression and IC50 values.

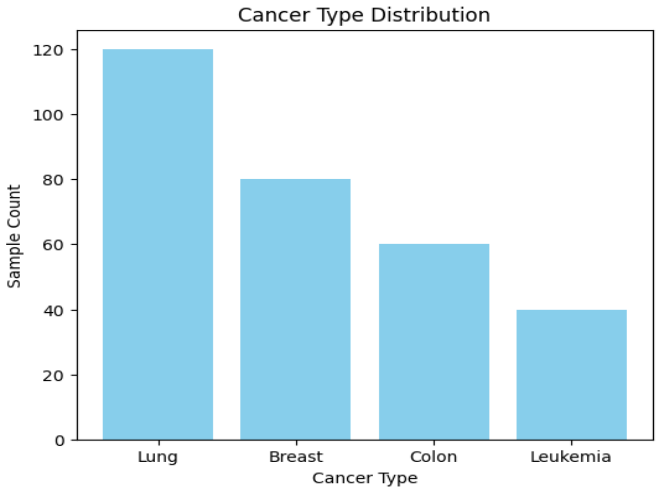

Fig. 4. Cancer type distribution.

Fig. 4 shows the sample distribution of four significant types of cancer: Lung, Breast, Colon, and Leukemia. These include Lung cancer, with the biggest representation of about 120 samples, and will dominate the data. Breast cancer comes second with around 80 samples after which Colon cancer has nearly 60. Leukemia has the fewest representation with a contribution of approximately 40 samples. Such uneven distribution can be seen as the difference in the composition of the datasets and show the imbalance between the categories of cancer. This imbalance may affect the workings of predictive models in that predictive models become biased towards the type of cancer with bigger sample size like Lung cancer, whereas smaller types like Leukemia are underrepresented.

Fig. 5 shows the share of the types of nodes in the graph that have been created, but with emphasis on the relative number of genes and drugs. The findings show that gene nodes are the dominant nodes in the graph with a total of 120 nodes, since there are only 30 drug nodes. This is not surprising, since the number of genes generally is much higher in comparison with therapeutic compounds in biological networks. The increased number of gene nodes highlights the importance of genetic interaction in defining the structure and complexity of the graph,

whereas the drug node is a significant target of intervention that has a connection to a particular target.

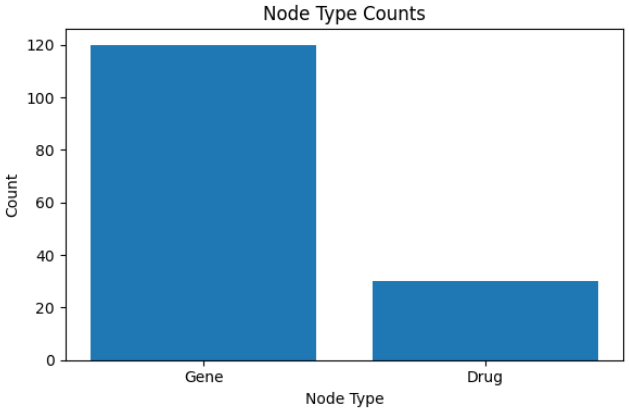

Fig. 5. Node type counts.

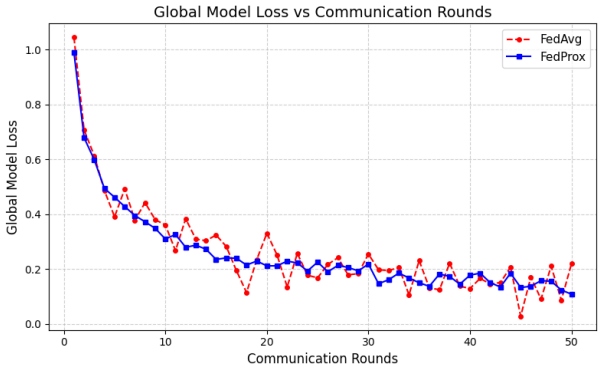

Fig. 6. Global model loss vs. Communication rounds.

Fig. 6 shows the comparison of global model loss variation of embedded communication rounds in FedAvg and FedProx aggregation techniques. The FedAvg is showing more oscillations because of the difficulty in having non-IID client distributions, implying fluctuating convergence behavior. Conversely, FedProx has a smoother loss reduction, confirming its capability to stabilize training through the addition of a proximal term which curbs divergence concerns. The downward patterns in loss per round indicate an improving trend in the model and FedProx is performing more reliably.

Fig. 7 represents the correlation among the estimated and measured IC50 values of several patient subgroups (Breast, Colon, Leukemia and Lung cancer types). A different color is assigned to each subgroup, which enables the clear distinction of the performance in the heterogeneous groups of patients. The dotted line is the optimal fit where forecasted values would be equal to the real ones. The majority of the data points are close to this reference line, which means that the predictive model is highly accurate when predicting the values of IC50. The fact that the points cluster around the diagonal also indicates that the model will be applicable to a great range of cancer subgroups as opposed to having an affinity towards one type of cancer.

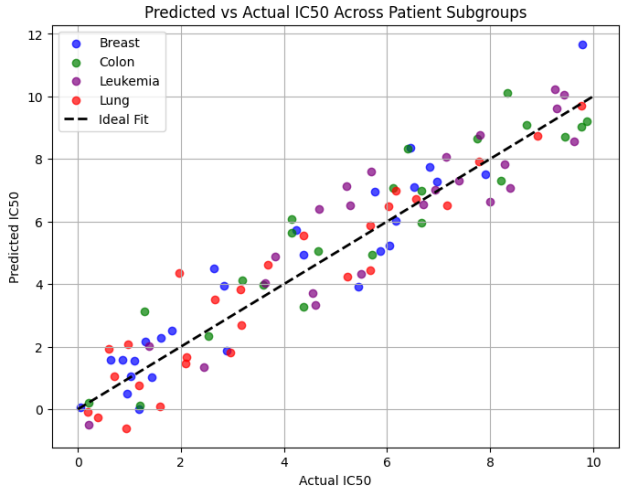

Fig. 7. Predicted vs. Actual IC50 across patient subgroups.

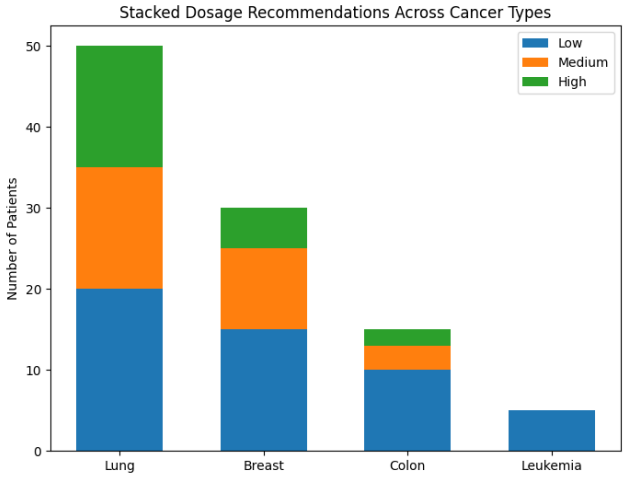

Fig. 8. Dosage recommendation across cancer types.

Fig. 8 shows the dosage recommendations distribution among four types of cancers: Lung, Breast, Colon and Leukemia. These dosages will be divided into three dosage levels, which would be Low, Medium, and High with blue, orange and green color bars respectively. The number of dosage recommendations is the highest in the case of lung cancer patients with a visible balance in the range of all three dosage levels, especially the high and low doses, denoting the varying volume of therapeutic needs. The number of patients with breast cancer is moderate with the majority relying on lower and medium dosages as opposed to high doses. The colon cancer has a lower number of patients, and low dose is most frequent, then the medium dose and the minimal high dose that implies more conservative treatment measures. The lowest number of patients is observed in leukemia, as only low dosage recommendations are documented, which demonstrates a narrow spectrum of the treatment intensity of this type of cancer. This illustration clearly communicates the different dosage plans of various types of cancers.

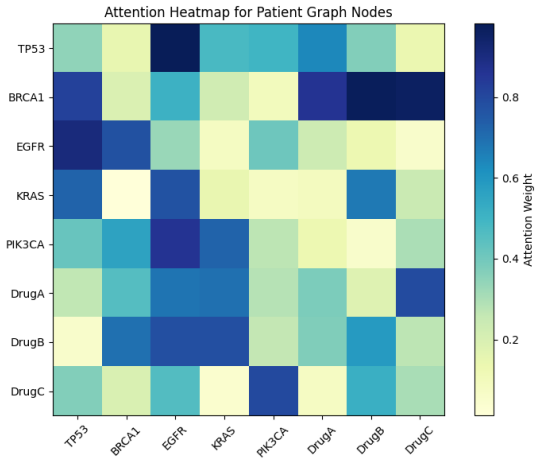

Fig. 9. Attention Heatmap.

Fig. 9 introduces an Attention Heatmap of Patient Graph Nodes and depicts the strengths of interaction of particular genes and drugs in terms of attention weights. The nodes of both axes consist of five important genes (TP53, BRCA1, EGFR, KRAS, PIK3CA) and three medications (DrugA, DrugB, DrugC). The intensity of the colour of each cell shows the weight of attention between two nodes which is high in darker colour (deep blue) and lower in lighter colour (yellow). The scale on the right of the color is used in interpreting the values with 0 (low) and 1 (high). This heatmap probably stems out of a GNN model run on biomedical data, and it is used to determine the important interactions between genes and drugs. Interestingly, between BRCA1 and DrugC, between TP53 and BRCA1, it can be noted that high attention weights are established, which indicates the presence of important interactions or regulatory effects. Such visualization can help to comprehend the significance of nodes and may be used to focus individualized medicine therapy or studies.

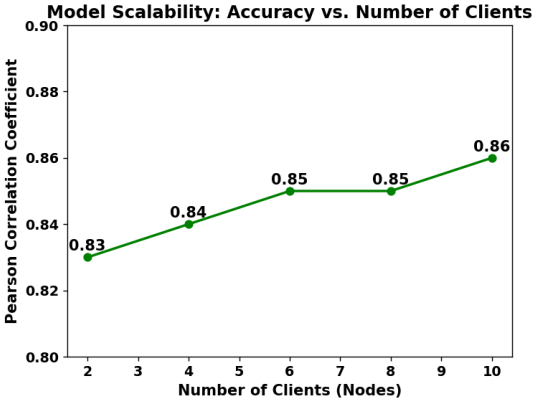

Fig. 10. Model scalability.

Fig. 10 illustrates the scaling of FedGraphOnco model with the increase in the number of clients who participated in the program. The x-axis presents the clients in the report of 2-10 and the y axis vectors the Pearson Correlation Coefficient. The results show that, there is an upward trend being experienced, whereby accuracy commences with 0.83, 2 clients, increases to 0.84, 4 clients, and then to 0.85, 6-8 clients, and culminates to 0.86, 10 clients. This trend indicates that FedGraphOnco has the advantage of the data diversity and increased volume of several clients. The framework is highly accurate, as it is scalable and adaptive and effective to use in decentralized healthcare settings.

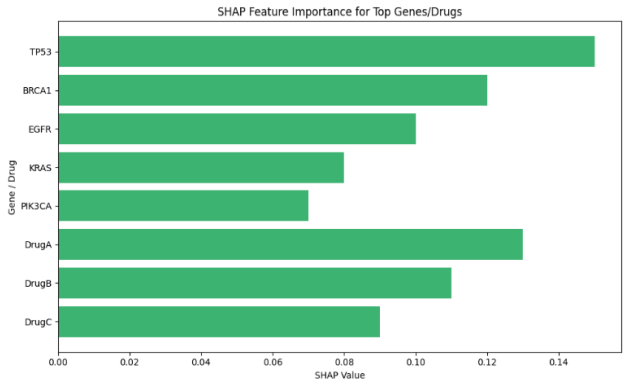

Fig. 11. SHAP feature importance for top Genes/Drugs.

Fig. 11 shows the amount of SHAP (SHapley Additive exPlanations) values of the top genes and drugs that explain model predictions. SHAP values are interpretable in that they can indicate the degree of effect of each feature on the output of a machine learning model. Then, genetic markers, as well as drug-related variables, have been examined in this instance to comprehend their comparative significance in forecasting results. Among the genetic factors, TP53 is the most important feature, which obtains the largest SHAP, which means that it has a great impact on model decisions. This is in tandem with available biomedical information, as TP53 mutation is usually linked with cancer development and reaction to treatment. BRCA1 comes next, and it serves to stress the importance of genetic predisposition regarding therapeutic efficiency once again. The contributions of other genes, including EGFR, KRAS and PIK3CA are also significant in nature as they have been established to play a role in tumorigenesis and outcomes of targeted therapy. There is a high impact on the drug side with Drug A showing high impact, almost equal to TP53, showing its centrality in treatment prediction. Drug B and Drug C also play an important role and it implies that their efficacy is affected or interacts with genetic variables. In general, SHAP analysis proves that genetic mutations and therapeutic drugs are important components of the predictive model, which allows personalized medicine using interpretable information.

A. Performance Metrics

One of the most important aspects in creating an exact machine learning model is analyzing its performance. For assessing the performance or quality of the model, various metrics are employed, and such metrics are referred to as performance metrics or evaluation metrics.

1) Dosage deviation: Measures the average percentage difference between predicted and actual drug dosages. It reflects how accurately the model predicts personalized dosages, with lower values indicating safer and more precise dosing, that is given in Eq. (15):

$$Dosage\ Deviation = \frac{1}{N}\sum_{i=1}^{n}\left|\frac{y_i - \widehat{y_i}}{y_i}\right| \times 100 \qquad (15)$$

where, y_i means Actual dosage for the i^{th} patient, $\hat{y}_i$ is Predicted dosage for the i^{th} patient, N is Number of dosage samples.

2) Root mean squared error: This is the square root of the mean-square differences between dosages that were predicted and dosages that were actual. Lower RMSE values mean dosages were predicted more accurately, as larger errors incurred greater penalties, as given in Eq. (16):

$$RMSE = \sqrt{\frac{1}{N}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \quad (16)$$

where, y_i is the Actual dosage for the i^{th} patient, $\hat{y}_i$ is the Predicted dosage for the i^{th} patient, n is the Number of dosage samples.

3) Mean absolute error: Measures the average magnitude of errors between predicted dosages and actual dosages, although directional errors are not considered. Smaller MAE is indicative of better prediction accuracy and consistency is shown in Eq. (17):

$$MAE = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}_i| \quad (17)$$

where, y_i is the Actual dosage for the i^{th} patient, $\hat{y}_i$ means Predicted dosage for the i^{th} patient, n is Number of dosage samples.

TABLE II. PERFORMANCE METRICS

Metric	Value
Dosage Deviation (%)	2.8
RMSE	2.6
MAE	1.9

Table II summarizes the performance of the proposed FedGraphOnco model. The variance of the dosage is highly reduced to 2.8% which makes it precise and safe in dosing. The model indicates a smaller range of errors and reliability with RMSE of 2.6 and MAE of 1.9. Such has been its success in overcoming its promise to pinpoint specific drug recommendations, with the support of anonymity, better than traditional ways. FedGraphOnco performance metrics are also demonstrated in Fig. 12.

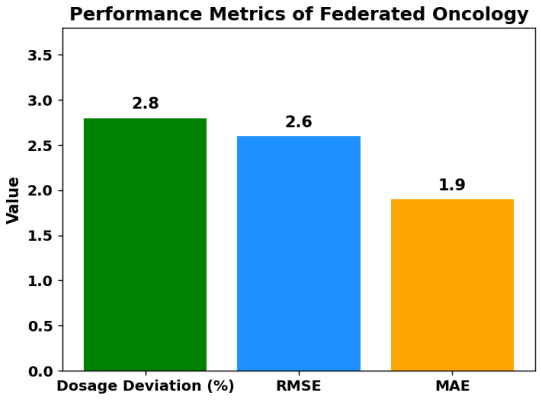

Fig. 12. Performance metrics.

B. Ablation Study

A FedGraphOnco ablation study was performed to evaluate the role of each individual component of the framework. Performance was shown to vary by sequentially eliminating federated aggregation, privacy-preserving mechanisms and reinforcement learning modules. Findings indicate that all the parts play a significant role towards accuracy, convergence, and robustness. The full model consistently performed better than all the variants, indicating that all the modules are necessary to the outcomes of an optimal, privacy-preserving, and reliable drug dosage prediction system.

TABLE III. ABLATION STUDY RESULTS OF THE FEDGRAPHONCO FRAMEWORK

Model Variant	Dosage Deviation (%)	RMSE	MAE
Full FedGraphOnco (Proposed)	2.8	2.6	1.9
w/o Federated Aggregation	4.6	3.9	3.2
w/o Privacy-Preserving Mechanism	3.9	3.5	2.8
w/o Reinforcement Learning Module	6.2	5.1	4.3
Centralized DRL	5.2	4.7	4.1

Table III shows the results of the ablation study of the FedGraphOnco framework. The deletion of an essential element like federated aggregation, privacy-preserving structures, or reinforcement learning had a substantial impact on performance. The full model produced the best deviation, RMSE, and MAE, which agree that a complete integration is the method that guarantees the maximum precision, stability and performance.

C. Comparative Performance Analysis

The effectiveness of FedGraphOnco framework was validated by comparing its performance to typical strategies, including (DTR) and traditional FL. Based on RMSE and MAE as the evaluation measures, the findings showcase the high level of predictive precision by the FedGraphOnco as well as the lower error rate and stability in the individual dosage calculation.

Table IV and Fig. 13 demonstrate the relative effectiveness of various models in the prediction of drug dosage based on RMSE and MAE measures. Conventional methods such as LR, DNN and DTR have more errors and FL shows moderate improvement. All base models are outperformed by the suggested FedGraphOnco in its RMSE and MAE results, which are the lowest of them all.

TABLE IV. COMPARATIVE ANALYSIS

Method	RMSE	MAE
Linear Regression (LR) [16]	8.4	6.7
Deep Neural Network (DNN) [18]	6.8	5.5
Decision Tree Regression (DTR) [25]	7.1	5.2
FL [21]	5.2	4.7
FedGraphOnco (Proposed Method)	2.6	1.9

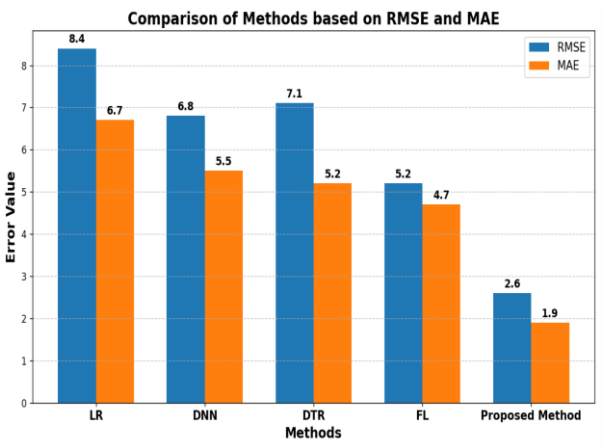

Fig. 13. Comparative performance of different methods.

D. Discussion

The suggested framework of FedGraphOnco helps to overcome the key constraints of personalized cancer treatment, including modeling complex relationships between gene and drugs without centralized information and without reinforcement learning. These interactions are subtle and can be missed by linear or tree-based regressors, but they are captured by the model by building biologically meaningful graphs out of genomic features. The GDSC dataset allows the capturing of deep coverage of drug sensitivity in a variety of cancer types, but subtype bias (e.g., lung cancer bias) may appear. The model prediction is reflected by performance measures (RMSE of 2.6, MAE of 1.9, and dosage deviation of 2.8). The GNN is always able to produce lower error rates and high correlation in comparison with the baseline models, such as Linear Regression and Decision Tree Regression. Integration of SHAP and attention mechanisms offers interpretation, which enables clinicians to comprehend the genomic factors that contribute to dose prediction. To estimate the impact of the algorithm parameters, the sensitivity analysis was performed with the key hyperparameters varied in the framework of the proposed FedGraphOnco. The findings obtained found that a learning rate of 0.001 was the most stable learned rate, whereas higher rates produced oscillations and decreased accuracy. Enhancing the number of federated communication rounds enhanced model synchronization at the cost of more computation. A batch size of 32 gave the optimal convergence rate and generalization. The amount of graph convolution layers had a substantial influence on representation learning; three layers represented perfect feature relations, and those that were deeper resulted in overfitting. A large value of FedProx (0.05) stabilized training in the non-IID case, and a more moderate privacy budget (0.5) kept both training accuracy high and guaranteed difference privacy. In general, the parameter tuning has shown that balanced settings provide the most effective performance in the terms of accuracy (RMSE = 2.6), robustness and preserving the privacy. The high resilience of the model to noises and non-IID information is also a strong benefit as it is essential to be deployed to the real world. Nevertheless, scalability to institutions and tuning of dosage to adapt with time might be necessary in the future because of the lack of federated or reinforcement learning. However, the existing GNN-based strategy provides an interesting balance of accuracy, interpretability, and simplicity.

VI. Conclusion and Future Works

This study introduces a FedGraphOnco model of a personalized cancer drug dosage prediction based on genomic data of the GDSC dataset. The system incorporates complexity in gene-drug interactions by modeling patients as biological networks and provides dosage advice at the level of high accuracy and understanding. The model has been implemented in Python with PyTorch Geometric with high performance metrics and sensitivity to data noise and heterogeneity. The simplicity of the framework also makes it computationally efficient and less challenging to implement in clinical environments. Its influence on clinical trust through the interpretation of SHAP and attention increases the chances of adoption in precision oncology, which is a crucial component. The proposed framework provides personalized oncology with the help of patient-specific GNNs to predict a complex interaction between genes and drugs using multi-omics data. It gives interpretable predictions by use of attention mechanisms and SHAP values, making it feasible to give accurate, personalized drug dosing, and FL that preserves privacy makes it possible to collaborate across institutions. Scientifically, it reveals important genomic determinants of drug response; clinically, it increases precision oncology and clinician confidence; practically, it can be deployed scalably in decentralized health care environments. Although the FedGraphOnco framework has performed well in the proposed study, this study is also limited in a number of ways. First, it uses only GDSC dataset and this can be limited to generalization to other datasets or real-life patient populations. Second, the data used in the model is preclinical and the simulated federated setting could limit the applicability of the model to clinical settings. Lastly, simplifications in the graph modeling and federated implementation, such as fixed interactions between genes and drugs and a small number of simulated institutions, are not necessarily the simplified view of the complexity of cancer biology and clinical processes today. The next generation of work will be to confirm the framework using more datasets, including longitudinal patient data, and augment graph and federated modeling to increase clinical usefulness.

Further research will involve increasing the number of balanced cancer subtypes in the dataset and incorporation of multi-drug interaction modeling. Prediction of dosages could be further enhanced by adding real time physiology and longitudinal patient data. To support cross-institutional learning without privacy breaches, future implementations can consider federated GNNs. Besides, the ability to improve model explainability by visualizing graph attention and incorporating clinician feedback loops will also have a high priority. Finally, this FedGraphOnco provides the foundations towards scalable, interpretable, and effective AI-directed cancer treatment methods, and closes the gap between the complexity of genomes and clinical decision-making.

***Abstract*—Accurate and timely seizure detection is essential for effective epilepsy management, and automated systems can play a valuable role in supporting clinical practice. In this study, we introduce a hybrid approach that uses time-frequency representations of Intracranial electroencephalography (iEEG) signals filtered at High-Frequency Oscillations (HFOs) bands as input to different convolutional neural network (CNN) backbones for feature extraction, followed by classification with either a Vision Transformer (ViT) or MLP-Mixer. This work establishes a systematic, comparative framework for benchmarking hybrid CNN-ViT against CNN-MLP-Mixer, providing a critical new reference for automated epileptic seizure detection within HFOs filtered iEEG signals. Extensive evaluation demonstrates that the ViT consistently achieves superior performance, with an EfficientNetB0-ViT model attaining remarkable accuracy (97.85%) and specificity (98.92%). Crucially, the MLP-Mixer emerges as a highly competitive alternative, exhibiting strong recall capabilities that make it suitable for applications where missing a seizure is not an option. Overall, our findings suggest that self-attention mechanisms in ViTs provide a distinct advantage for capturing complex seizure dynamics, yet MLP-based models present a powerful, efficient option.**

Keywords*—Vision transformer; MLP-Mixer; iEEG; HFOs; ResNet; GoogleNet; EfficientNetB0

I. Introduction

Epilepsy represents a major global health challenge, characterized by recurrent, unprovoked seizures that disrupt neural function and impose a significant burden on the quality of life for over fifty million individuals worldwide [1]. The clinical management of epilepsy, particularly drug-resistant forms, relies heavily on the precise identification and localization of seizure events [2]. Consequently, the development of accurate and reliable seizure detection systems is paramount for enabling timely intervention and improving patient outcomes [3][4].

Intracranial electroencephalography (iEEG) is commonly used to evaluate patients with refractory epilepsy before surgery. It offers detailed recordings from the brain's surface or deeper areas. Analyzing iEEG visually requires a significant amount of time for neurologists, which slows down clinical workflow. Automated detection algorithms that can accurately review long recordings are becoming increasingly popular due to the need for efficiency and precision.

The evolution of these automated systems has progressed from traditional machine learning techniques, which depend on manually engineered features, to deep learning systems that learn discriminative patterns from raw or preprocessed data [5]. Among these, the ability to analyze time-frequency representations of iEEG signals has been demonstrated by Convolutional Neural Networks (CNNs). They demonstrated exceptional proficiency in analyzing time-frequency representations of iEEG signals, effectively identifying localized morphological patterns associated with seizure onset[6]. Despite their strengths, a fundamental constraint of CNNs is their limited receptive field, which can hinder their ability to model the long-range spatiotemporal dependencies that characterize the dynamic propagation of seizures through neural networks [7].

To address this limitation, Vision Transformers (ViT) have the ability to capture global contextual relationships across an entire input sequence through their self-attention mechanism, potentially offering a more nuanced understanding of complex ictal dynamics [8] [9].

In recent research, hybrid architectures have been explored that combine the local feature extraction capabilities of CNNs with the global contextual modeling of ViTs, which have resulted in significant gains in both accuracy and generalizability for seizure detection tasks.[10].

Parallel to these developments, the MLP-Mixer architecture presents a notably different approach. As articulated by Tolstikhin et al. (2021), "In contrast to ViT, which relies on self-attention, the MLP-Mixer proposes an architecture based solely on Multi-Layer Perceptrons (MLPs) for spatial and channel mixing, offering a competitive accuracy-efficiency trade-off[11]". While MLP-Mixers have shown promise in other domains, their application to the specific challenge of detecting epileptic seizures from iEEG signals filtered in the high-frequency oscillation (HFO) bands remains a critical, largely unexplored research gap.

This study addresses this gap by investigating the fundamental trade-offs between these novel sequence modeling approaches when applied to a highly sensitive biomarker: HFO-filtered iEEG data. This leads to our core research question: What are the distinct performance, efficiency, and mechanism trade-offs between hybrid CNN-ViT and CNN-MLP-Mixer systematically benchmarked for automated epileptic seizure detection in the HFOs domain?

In summary, our contributions are as follows: We introduce a systematic and novel comparative framework for benchmarking the performance and mechanism trade-offs of hybrid CNN-Vision Transformer and CNN-MLP-Mixer architectures.

We establish a novel deep learning reference for the automated detection of epileptic seizures in the High-Frequency Oscillation (HFO) domain of iEEG, addressing a major gap in the current literature.

We provide a detailed performance analysis that contrasts the advantages of the self-attention mechanism versus the purely algebraic mixing of MLP-Mixer, highlighting critical considerations for clinical deployment.

We systematically evaluate six widely used CNN backbones (VGG19, ResNet18, ResNet50, ResNet101, GoogleNet, EfficientNet-B0) to provide a comprehensive baseline for feature extraction in HFO analysis.

This study is organized as follows: Following the introduction, a theoretical framework reviews relevant literature (Section II). Details on materials and methods are provided in Section III. The results are presented in Section IV, followed by a comprehensive discussion of the findings, their implications, and the limitations of the study in Section V. The study concludes in Section VI.

II. Related Works

The pursuit of automated seizure detection has progressively shifted from reliance on manually crafted features to the use of deep learning models. Within this evolution, [12] showed that HFOs detected by neuromorphic neural networks are strong predictors of seizure prognosis across various recording modalities, including iEEG. This work demonstrates the clinical relevance of HFO-based detection but relies on hand-crafted feature engineering rather than end-to-end deep learning. Other research works [13][14] substantiate the strong correlation between HFOs and epileptogenic tissue, establishing a solid foundation for their use in automated prognosis systems. The strength of these studies lies in validating HFOs as critical biomarkers for seizure detection. However, a key weakness is the limited exploration of modern sequence modeling architectures (Transformers, MLP-Mixers) that could better capture the temporal dynamics of HFO patterns. The undesirable assumption often made is that traditional feature engineering is sufficient to capture the intricate, non-linear dynamics of HFOs.

A critical step in applying modern deep learning architectures to signal data involves transforming one-dimensional time series into a format that can be used with image-based models. In this context, Zhuohan Wang et al [15] demonstrated that transforming iEEG signals into scalograms facilitates the use of image-based deep learning models. This approach enables the model to simultaneously leverage temporal and spectral information. We build upon this foundation, using time-frequency transformation as the essential input for our Vision Transformer and MLP-Mixer models.

In the context of iEEG analysis, CNNs have demonstrated superior performance in detecting epileptic seizures by learning local discriminative patterns in spectrograms, with variants such as ResNet, GoogLeNet and VGG being widely used to extract meaningful features from biomedical signals [16]. While excellent at capturing features within a limited spatial context, they often struggle to integrate information across distant regions of a scalogram, which is crucial for understanding the full spatial-temporal propagation of a seizure. This limited and fixed receptive field is the core weakness of CNN-only approaches, limiting their ability to model global seizure connectivity. This inadequacy is precisely why we propose a hybrid framework, pairing the local robustness of CNNs with sequence models capable of global context aggregation.

The MLP-Mixer architecture challenges the dominance of convolutions and self-attention by relying solely on a multilayer perceptron, applied separately to spatial (token-mixing) and channel (feature-mixing) dimensions [11]. Its simplicity and computational efficiency make it attractive for EEG-based applications. Recent studies have shown that MLP-Mixers, enhanced with attention mechanisms, can effectively decode EEG motor imagery tasks [17]. Despite this, the specific efficacy of the MLP-Mixer for the nuanced task of iEEG-based seizure detection, particularly when operating on HFOs, remains an open question. The current literature lacks a systematic comparison between the self-attention mechanism (ViT) and the purely algebraic mixing (MLP-Mixer) to determine which is inherently superior for modeling HFO dynamics. This forms the central motivation and unique contribution of our study.

III. Materials and Methods

This section details the methodology adopted, from the preparation of raw data to the configuration of hybrid models. Our study proposes a systematic comparative framework for hybrid deep learning CNN-VIT and CNN-MLP-Mixer applied to epileptic seizure detection in iEEG filtered in HFO bands. This study proposes a hybrid pipeline for binary classification between ictal and interictal states. The core approach involves using Convolutional Neural Networks (CNNs) backbones (EfficientNetB0, ResNet18, ResNet50, ResNet101, GoogleNet and VGG19) to extract features from time-frequency images of iEEG signals, which are then classified by either a Vision Transformer (ViT) or an MLP-Mixer. The overall workflow is depicted in Fig. 1.

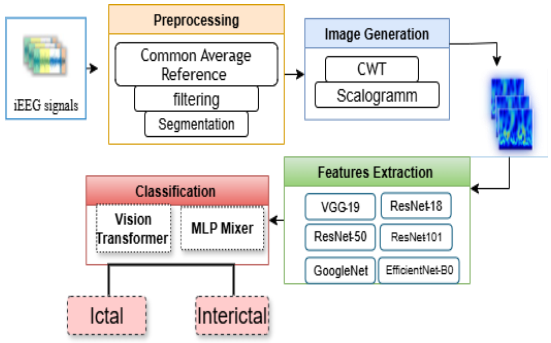

Fig. 1. Workflow of the proposed method.

A. Data Description

This study utilized a subset of the publicly available HUP iEEG dataset [18], which comprises intracranial EEG recordings from patients undergoing evaluation for drug-resistant epilepsy at the Hospital of the University of Pennsylvania. From the original cohort of 58 subjects, we selected 21 patients whose recordings were sampled at 1024 Hz, a frequency sufficient for the reliable analysis of High-Frequency Oscillations (HFOs). The dataset includes ictal and interictal recordings, to precise annotations marking the beginning (onset) and end (offset) of seizure events, allowing for clear identification of ictal periods.

B. Data Processing

The iEEG data preprocessing pipeline consisted of three main stages: segmentation, filtering/re-referencing, and time-frequency transformation.

Segmentation and labeling were performed for the binary classification task of distinguishing ictal from interictal states. The continuous iEEG recordings were segmented into 1-second epochs. Ictal segments were extracted from annotated seizure intervals (onset to offset). Each segment was assigned a binary label (ictal=1, interictal=0), defining the classification target as $y \in \{0,1\}$.

Channels marked as artifactual in the original dataset metadata were discarded. The signals were then re-referenced using a Common Average Reference (CAR) filter computed from all remaining valid channels, a crucial step for reducing common-mode noise. Subsequently, a zero-phase finite impulse response (FIR) filter was applied to isolate the High-Frequency Oscillation (HFO) band of interest (80-250 Hz).

To leverage image-based deep learning models, each 1-second HFO-filtered segment was converted into a 2D time-frequency (TF) (see Fig. 2) representation using the Continuous Wavelet Transform (CWT) with a complex Morlet wavelet. The wavelet function is defined as:

$$\varphi(t) = C_\sigma \pi^{-1/4} e^{-t^2/2} e^{i\sigma t} \quad (1)$$

where, C_σ is the normalization constant and σ is the central frequency parameter. The 2D representation results were scaled to dimensions of 224 × 224 × 3 pixels as input images for the proposed model. The final dataset comprised 4092 samples, which were partitioned into training (80%), validation (10%), and test (10%) sets.

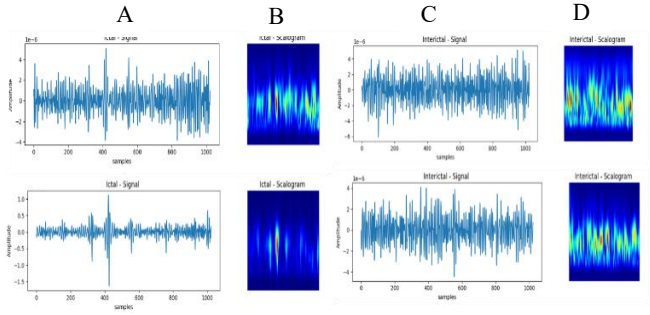

Fig. 2. Transformation of signal into 2D representation: (A) ictal representation in time, (B) ictal representation in TF, (C) interictal representation in time, (D) interictal representation in TF.

C. Model Development

1) CNN backbones: Resnet (Residual Network): Resnet is a fundamental contribution to deep learning, specifically addressing the problem of performance degradation when training extremely deep convolutional neural networks (CNNs). Its main innovation lies in the introduction of residual blocks, which enable the learning of residual mapping functions via skip connections. In the ResNet architecture, the fundamental residual connection in ResNet consists of summing the original input x with the learned transformation F(x) to produce the block's output, according to the following equation:

$$y = F(xw_i) + x \quad (2)$$

ResNet50: This architecture comprises 50 layers, and its structure incorporates batch normalization layers and ReLU activations to stabilize training. Features are extracted from the avgpool layer, resulting in a 2048-dimensional vector.

ResNet18: With 18 layers, its skip connections between convolutional layers, effectively solve the vanishing gradient problem. Although less deep.

ResNet101: This deep architecture has 101 layers and optimizes residual learning between the inputs and outputs of convolutional blocks, enabling richer feature extraction.

VGG19: It is characterized by its fixed depth of 19 layers and its uniform architecture using exclusively 3×3 convolutions.

GoogleNet (Inception): It has a 22-layer architecture optimized for multi-scale feature extraction via its Inception modules, which incorporate Inception blocks that use parallel multi-kernel convolutions. This design enables the model to identify patterns across various spatial scales.

EfficientNet-B0: It is an architecture optimized via compound scaling that balances depth, width, and resolution. The model uses MBConv blocks with expansion-reduction mechanisms and channel attention (SE modules).

For each CNN, the fully connected classification layer is removed. Consequently, the feature extraction configuration for each model is detailed in Table I, which shows the dimensions of the final feature maps extracted from the CNN backbones for an input image size of 224×224×3.

TABLE I. DIMENSIONS OF THE FINAL FEATURE MAPS OF THE CNN BACKBONES

Backbone	Feature Map [B, C, H, W]
ResNet18	[B, 512, 7, 7]
ResNet50	[B, 2048, 7, 7]
ResNet101	[B, 2048, 7, 7]
VGG19	[B, 512, 7, 7]
GoogleNet	[B, 1024, 7, 7]
EffecientNet-B0	[B, 1280, 7, 7]

B = batch size.

C = number of channels (feature dimension).

H, W = spatial dimensions (here 7×7 for input 224×224).

2) Vision transformer: Transformers are an important advancement in deep learning. They were first created for natural language processing [19] but now help solve many sequence modeling problems. Because they can handle complex, long-range relationships, they are useful in areas like computer vision [19] and biomedical data analysis [20]. Specifically, The Vision Transformer (ViT) is a transformer that has been adapted for image inputs. It works by dividing images into patches, which are then embedded linearly. Each patch vector is then enriched with a position embedding to preserve spatial information. The embeddings are then subjected to a series of Transformer blocks. The blocks that make it up include Multi-Head Self-Attention (MHSA), Layer Normalization (LN), and Feed-Forward Network (FFN). The Multi-Head Self-Attention (MSA) calculates the interactions between all tokens in the sequence. For each head, linear projections generate the matrices query (Q), key (K), and value (V) vectors, as shown in the following equations:

$$\mathrm{Q}=\mathrm{XW}^{\mathrm{Q}}\ ,\quad K=XW^{K}\ ,\ V=XW^{V} \tag{3}$$

Let W^{Q}, W^{K}, and W^{V} denote the parameter weight matrices. Then, the attention mechanism computes a weighted sum of the values, where attention coefficients are derived from a normalized query-key similarity as represented in the following equation:

$$Attention(Q,K,V)=\mathrm{softmax}\left(\frac{QK^{T}}{\sqrt{d_k}}\right)V \tag{4}$$

in which, normalization by $\sqrt{d_k}$ aims to stabilize gradients during learning. Subsequently, the output of the attention layer was subjected to Layer Normalization (LN), a process that has been demonstrated to stabilize the training process (see equation below).

$$LN(z)=\frac{z-\mu}{\sqrt{\sigma^{2}+\epsilon}}.\gamma+\beta \tag{5}$$

The input's meaning and standard deviation are μ and , while $\gamma+\beta$ are acquired parameters. A non-linear GELU activation separates two linear layers in a Feed-Forward Network (FFN):

$$FFN(z)=\mathrm{W}_{2}.GELU(\mathrm{W}_{1}.z+\mathrm{b}_{1})+\mathrm{b}_{2} \tag{6}$$

With the b being biases and W representing weight matrices.

3) Proposed CNN-Vision Transformer hybrid model: This proposed hybrid model combines the strength of CNNs in extracting features, which are subsequently converted into tokens and processed by a Transformer encoder. This fusion skillfully leverages CNNs for capturing detailed local features and the Transformer for global context modeling via the self-attention mechanism, the architecture proceeds as follows:

Feature extraction by CNN: Let an input image (spectrogram) be denoted as $I\in\mathbb{R}^{224\times224\times3}$ which is processed by a pre-trained CNN network(ReNet18, ResNet50, ResNet101, VGG19, GoogleNet, EfficientNet-B0), producing a feature map $F\in\mathbb{R}^{7\times7\times C_{nn}}$ whose final convolutional outputs are 7×7 spatial maps for 224×224 inputs, the output of each CNN is detailed in Table I where C_{nn} represents the number of output channels.

The transition to the ViT: The resulting feature maps for each CNN are linearly projected to embedding dimension $D=768$ using 2D (1×1) conventional with (padding='same') followed by reshaping to obtain $(7\times7,768)$. Consequently, $N=7\times7=49$ tokens. This embedding dimension (D=768) is adopted from the ViT-Base specification, which balances model capacity with computational efficiency for sequences of moderate length. Then, a learnable [CLS] token is prepended to the token sequence. Learnable positional embedding $E=49+1=50$ is added to preserve spatial information.

Transformer Encoder: processes the input sequence through twelve encoder layers, where each layer helps the model understand context and share information between tokens. The model can focus on multiple parts of the input sequence simultaneously by using a multi-head self-attention mechanism in each encoder layer that has twelve attention heads.

Classification: Each encoder layer also has an MLP block with 3072 dimensions (3072 = 4×768 to provide sufficient non-linear transformation capacity) and uses GELU activation. Following the encoder layers, the final state of the classification token is extracted, layer-normalized, and processed by a multilayer perceptron (MLP) classification head to produce the final class predictions, where the classification token gathers information from all tokens using self-attention. The final prediction is obtained through a sigmoid activation function:

$$MLP-Head(z_{cls})=W_{2}.GELU(W_{1}.LayerNorm(z_{cls})+b_{1})+b_{2} \tag{7}$$

$$\hat{y}=\sigma(W_{class}.MLP-Head(z_{cls})+b_{class}) \tag{8}$$

where, $z_{cls}\in\mathbb{R}^{768}$ is the final cls token, $W_{1}\in\mathbb{R}^{3072\times768}$, $W_{1}\in\mathbb{R}^{768\times3072}$ and σ is the sigmoid function for binary classification. We use Transformer-related parameters including an embedding dimension of 768, 12 encoder layers, 12 attention heads, and an MLP hidden size of 3072 following the standard ViT-Base configuration. This ensures consistency with well-established architecture and allows our hybrid model to benefit from proven practices for effective global context modeling. The complete architecture is illustrated in Fig. 3 and the detailed algorithm for the model is given below (see Algorithm 1).

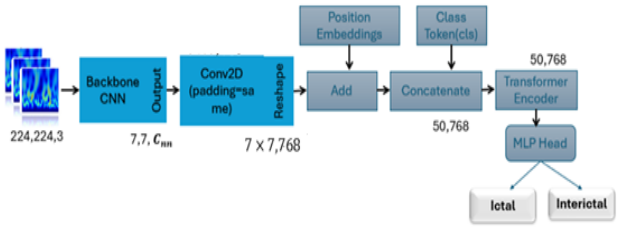

Fig. 3. Architecture of CNN vision transformer.

Algorithm 1 : Hybrid CNN-Vision Transformer

4) Proposed CNN MLP-Mixer hybrid model: The MLP-Mixer approach eliminates both convolution and attention operations, in contrast to the transformer architecture, by employing multilayer perception (MLPs) organized into token-mixing and channel-mixing layers. This architecture offers a conceptually simpler alternative to self-attention while maintaining competitive performance through pure algebraic mixing operations [11].

For an input matrix $X \in \mathbb{R}^{S\times D}$, where S is the number of tokens and D is the number of feature dimensions; the fundamental operations of the MLP-Mixer are defined as follows:

Token mixing (modelling spatial relationships):

$$U_{*,i} = X_{*,i} + W_2\sigma(W_1 LayerNorm(X)_{*,i}) \quad (9)$$

for $i = 1,..D$

σ is the GELU activation function.

$X_{*,i}$: all tokens for a channel i (the i-th column of X).

W : Weight of MLP mixing tokens (for $W_1 \in \mathbb{R}^{S'\times S}$, $W_2 \in \mathbb{R}^{S\times S'}$ with S' being the intermediate dimension.

Channel mixing (modelling relationships between characteristics):

$$Y_{j,*} = U_{j,*} + W_4\sigma(W_3 LayerNorm(U)_{j,*}) \quad (10)$$

for $j = 1, \ldots., S$

$U_{*,i}$: all tokens for channel j (the jth column of U).

W : Weights of the MLPs of channel mixing (for $W_3 \in \mathbb{R}^{D'\times D}$, $W_4 \in \mathbb{R}^{D\times D'}$ with D' being the intermediate dimension).LayerNorm refers to layer normalization.

For the final classification a Global average pooling is applied followed by a linear classifier:

$$\hat{y} = \sigma(W_{class}.GlobalAvreagePooling(Y) + b_{class}) \quad (11)$$

Architectural Configuration: (The feature extraction step is described in the previous section), to configure the model architecture, the following approach was adopted a hidden dimension of D= 192, which aligns with Base-type models and strikes a balance between expressiveness and computational limits [11]. Eight layers (L=8) are stacked to reduce overfitting and handle dependencies in sequences of moderate length.

The architecture features an intentional imbalance in its MLP dimensions. For processing spatial information (token-mixing), a bottleneck of 96 units is employed to promote efficiency. For transforming feature information (channel-mixing), a wide network of 768 units is used to facilitate richer representations. This asymmetric design reflects the observation that channel-wise feature interactions typically require higher capacity than spatial token interactions for time-frequency representations. The detailed algorithm for the model is given in Algorithm 2, and the architecture is illustrated in Fig. 4.

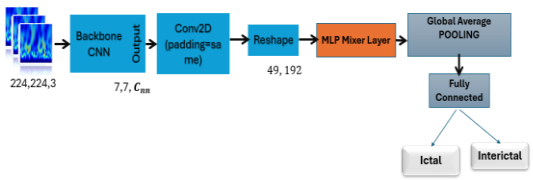

Fig. 4. Architecture of CNN MLP-Mixer.

5) Simulation Map: All models were implemented in Python 3.9 using PyTorch 2.0.1. Experiments were conducted on Google Colab using GPU acceleration. The following Table II shows the different hyperparameters used in the study.

TABLE II. CONFIGURATION OF TRAINING HYPERPARAMETERS

Hyperparameters	Value
Optimizer	ADAM
Loss function	Binary cross entropy (BCE)
Batch Size	32
Epochs	80(early stopping with patience=10
Learning Rate	1e-4
Dropout	0.1

IV. RESULTS

The models were evaluated using standard binary classification metrics: accuracy, precision, recall (sensitivity), specificity, F1-score (see Table III) and the area under the receiver operating characteristic curve (AUC-ROC). These metrics were derived from the counts of true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN) in the predictions.

TABLE III. EVALUATION METRICS

Metrics	Equations
Accuracy(ACC)	$\frac{TP+TN}{TP+FP+FN+TN}$
Precision (Pr)	$\frac{TP}{TP+FP}$
Recall (Se)	$E = \frac{TP}{TP+FN}$
Specificity (Sp)	$1 - \frac{FP}{FP+TN}$
F1-score	$F1-score = \frac{2\times TP}{(2\times TP+FP+FN)}$

Table IV and Table V present the comprehensive performance evaluation of Vision Transformer (ViT) and MLP-Mixer classifiers across six CNN backbones. The results reveal a consistent performance hierarchy, with the EfficientNetB0-ViT configuration achieving the highest overall scores (Accuracy: 97.85%, Specificity: 98.92%). GoogleNet was also consistent, performing well with both classifiers (96.45% with ViT and 95.20% with MLP-Mixer) and stood out in recall metrics. However, the results obtained with VGG19 are the least optimal.

TABLE IV. PERFORMANCE COMPARISON OF CNN-VISION TRANSFORMER

Model	ACC%	Pr %	Se%	Sp%	F1-score %
EfficientNETB0-ViT	**97.85**	98.32	**96.88**	**98.92**	97.59
ResNet18-ViT	95.35	94.90	92.70	95.95	93.78
ResNet50-ViT	94.80	95.42	93.25	96.35	94.32
ResNet101 ViT	95.25	95.05	95.50	95.00	95.27
GoogleNet VIT	96.45	97.15	95.20	97.85	96.16
VGG19 VIT	93.20	93.65	91.85	94.70	92.74

TABLE V. PERFORMANCE COMPARISON OF CNN MLP-MIXER

Model	ACC%	Pr %	Se%	Sp%	F1-score %
EfficientNETB0MLP-Mixer	97.08	96.55	94.45	97.35	95.48
ResNet18 MLP-Mixer	92.90	91.35	94.25	91.55	92.78
ResNet50- MLP-Mixer	93.25	93.85	91.55	95.05	92.68
ResNet101 MLP-Mixer	93.80	92.45	95.10	92.50	93.76
GoogleNet MLP-Mixer	95.20	94.80	96.75	93.65	95.76
VGG19 MLP-Mixer	91.75	92.20	90.15	93.55	91.16

This comparative analysis provides a foundation for further investigation of operational characteristics, such as ROC curves. As illustrated in Fig. 5, the comparative ROC curves demonstrate the discriminatory power of the various models. The EfficientB0-ViT model demonstrates a remarkable performance with an Area Under the Curve (AUC) of 0.979, the subsequent models are GoogleNet-ViT (AUC = 0.968) and EfficientB0-MLP (AUC = 0.963). The ViT curves have been shown to demonstrate a systematic superiority that confirms and substantiates its efficacy in differentiating between ictal and interictal states.

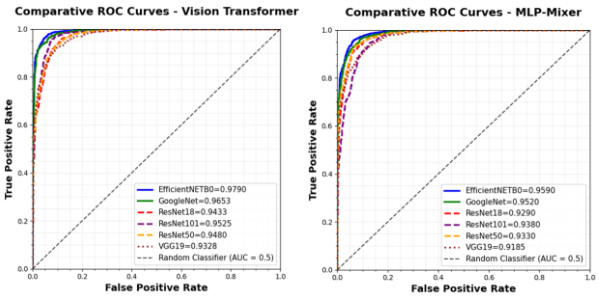

Fig. 5. Comparative ROC Curve: (A) Curve Roc VIT, (B) Curve ROC MLP-mixer.

To understand the impact of the model's performance, we analyzed normalized confusion matrices. These matrices, shown in Fig. 6, reveal each architecture's specific error profile, particularly their trade-offs between false positives and false negatives in distinguishing ictal from interictal states.

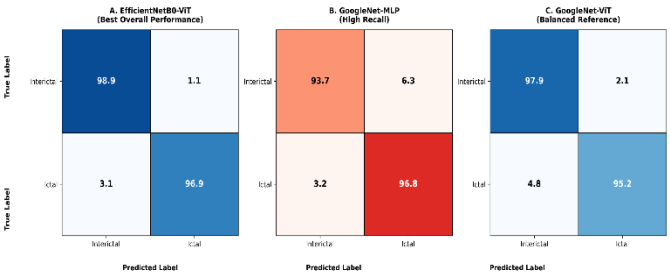

Fig. 6. Normalized confusion matrices for the three best-performing models: (A) EfficientNetB0-ViT, (B) GoogleNet-MLP, (C) GoogleNet-VIT.

A detailed analysis of the error profiles, provided by the confusion matrices in Fig. 6, offers crucial insights for clinical application. The primary strength of EfficientB0-ViT [see Fig. 6(A)] shows only 3.1% false negatives and 1.1% false positives. This reliability makes it ideal for clinical deployment, where the cost of a false alarm (false positive). Interestingly, the GoogleNet-MLP Mixer [see Fig. 6(B)] model has the best recall rate (96.8%). However, it has a higher rate of false positives (6.3%) compared to false negatives (3.2%), which is important for minimizing false negatives (missed seizures). Meanwhile, GoogleNet-ViT [see Fig. 6(C)] offers balanced performance with moderate error rates (false negatives at 4.8% and false positives at 2.1%).

Fig. 7 provides a direct comparative analysis of the performance differential between Vision Transformer and MLP-Mixer architectures. The histogram quantifies the percentage point advantage of ViT over MLP-Mixer for the EfficientNetB0 backbone.

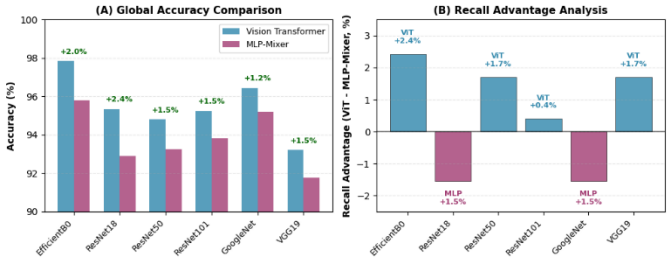

Fig. 7. Performance gain.

Fig. 7 presents the performance differential between Vision Transformer and MLP-Mixer architectures when paired with the EfficientNetB0 backbone. The results demonstrate a consistent advantage for the ViT model across all evaluation metrics, with particularly notable margins in recall and accuracy. However, the MLP-Mixer maintains competitive performance, trailing by less than 2.5 % points in all categories. This narrow performance gap, especially in specificity where both architectures excel, underscores the MLP-Mixer's viability as an efficient alternative to attention-based models for seizure detection tasks.

The findings confirm that while the self-attention mechanism in ViT yields superior overall performance, the MLP-Mixer achieves remarkably close results. This suggests context-dependent applicability: ViT for maximum diagnostic precision versus MLP-Mixer for scenarios prioritizing computational efficiency alongside strong detection capability.

The superior performance of the proposed EfficientNetB0-ViT model is evident when benchmarked against recent literature, as summarized in Table VI. Our method establishes a new accuracy of 97.9%, representing a significant improvement over previous approaches for similar seizure detection challenges.

V. DISCUSSION

The experimental results provide a clear answer to the primary research question: Vision Transformer (ViT) classifiers consistently outperform MLP-Mixer counterparts when integrated with CNN backbones for iEEG-based seizure detection. The superior performance of the EfficientNetB0-ViT model (97.85% accuracy, 98.92% specificity) establishes the effectiveness of self-attention mechanisms for capturing the spatiotemporal dynamics of epileptic seizures. This advantage can be theoretically explained by the ViT's ability to model global dependencies across the full time–frequency representation, a capability that aligns well with the distributed neural networks underlying seizure propagation. The observed performance gap between ViT and MLP-Mixer models provides valuable insight into the architectural requirements for effective seizure detection. The consistent advantage of ViT across multiple metrics suggests that the ability to dynamically weight different regions of the time-frequency representation (a core property of self-attention mechanisms) provides significant value for this task. This is particularly relevant for seizures that manifest as evolving patterns across both time and frequency domains. Our results for the MLP-Mixer architecture align with findings from computer vision (Tolstikhin et al., 2021), where MLP-based models have demonstrated competitive performance despite their conceptual simplicity. Extending this observation to biomedical signal analysis, our findings demonstrate that MLP-Mixers constitute a viable alternative to attention-based architectures for time-series classification, offering a balance between interpretability and efficiency. The strong correlation between CNN backbone quality and final performance (evidenced by EfficientNetB0's superior results across both classifiers) underscores the continued importance of effective feature extraction. Indeed, the identification of dominant patterns is critical for characterizing neurological disorders [27]. Even highly expressive classification heads such as ViT cannot compensate for suboptimal convolutional representations, confirming the hierarchical dependency between feature extraction and global context modeling in hybrid deep-learning architectures.

VI. CONCLUSION

This study presented a systematic and novel comparative framework for the automated detection of epileptic seizures from intracranial EEG (iEEG) signals filtered in the High-Frequency Oscillation (HFO) band. By integrating convolutional feature extractors with advanced sequence-modeling architectures Vision Transformer (ViT) and MLP-Mixer we established a comprehensive evaluation of hybrid deep-learning approaches for seizure detection.

The proposed benchmarking protocol represents a novel and systematic comparison between CNN-ViT and CNN-MLP-Mixer models specifically tailored to HFO-based iEEG analysis. Across multiple CNN backbones, the ViT consistently outperformed the Mixer counterpart, with the EfficientNetB0-ViT achieving the highest overall accuracy of 97.85 % and specificity of 98.92 %. This performance highlights the ability of self-attention mechanisms to capture the complex spatiotemporal dynamics of seizure propagation. The MLP-Mixer, on the other hand, demonstrated strong recall (up to 96.75 % with GoogleNet-MLP-Mixer), confirming its suitability for scenarios where sensitivity is clinically prioritized, such as continuous monitoring or early-warning systems.

The comparative trends observed in this work have direct practical value: ViT-based hybrids are better suited for high-specificity diagnostic contexts, such as pre-surgical assessment where false positives must be minimized, whereas Mixer-based hybrids provide a high-recall solution ideal for long-term monitoring. These insights contribute to a deeper understanding of how architectural design choices in hybrid deep learning can be aligned with distinct clinical objectives. Moreover, the consistent superiority of ViT across architectures suggests that self-attention represents a robust modeling paradigm for the non-linear, high-frequency dynamics of epileptic activity extending its relevance beyond computer vision to neurophysiological signal analysis.

While the proposed framework demonstrates strong performance, its generalizability should be validated on larger, multi-center datasets including diverse patient populations. In addition, the focus on high-frequency oscillations, though biologically motivated, may have excluded complementary low-frequency information (e.g., delta or theta bands) relevant to seizure onset and propagation. Addressing these limitations will strengthen the translational impact of the approach.

Future research will extend the current binary framework to multi-class classification, encompassing different HFO subtypes and pre-ictal phases. Another direction will involve integrating explainability techniques such as Grad-CAM or LIME to visualize discriminative regions in the time-frequency maps, thereby enhancing clinical interpretability and trust. Finally, incorporating multimodal spectral inputs and transfer-learning strategies will further improve robustness and pave the way for deployment in real-world clinical environments.

ACKNOWLEDGMENT

The authors are grateful to the investigators who shared their iEEG data.

Truth Under Pressure: A Deep Learning-Based Lie Detection System for Online Lending Using Voice Stress and Response Latency

Global Risk Management (GRM), Jakarta, Indonesia [3]

***Abstract*—The rapid increase in defaults in the online lending industry highlights significant flaws in current debtor verification, which largely relies on static, preparable interviews, leading to high non-performing loans. Existing research is fragmented: while Large Language Models (LLMs) show promise in question generation, their application is confined to non-financial domains like education, and lie detection studies often analyze modalities in isolation. This study addresses this critical gap by proposing the first *integrated* AI-driven system for this context. We solve the problem in two parts: 1) A Llama 3 LLM is fine-tuned to generate dynamic, biodata-tailored questions, preventing the rehearsed answers that plague static interviews. 2) A novel multimodal deep learning model is developed to analyze the response, uniquely fusing vocal acoustic features and response latency—two key deception indicators that prior work has failed to combine. The Llama 3 model produced a low perplexity score (2-3), and the lie detection model achieved 70% testing accuracy with a 70.9% F1-Score. Despite signs of overfitting, this framework provides a novel, intelligent decision-support tool to reduce fraud and manage default risks more effectively.**

***Keywords*—Online lending; lie detection; large language model; deep learning; voice acoustics; response latency**

I. Introduction

In 2024, Indonesia's internet penetration was around 79.50%, which is about 221.5 million people [1]. This high percentage indicates a high level of connectivity and implies a propelling growth in various digital innovations, especially in financial technology (fintech) services. Peer-to-peer (P2P) lending, commonly known as online lending, is one of the most dynamic segments within fintech. This service allows lenders and debtors to transact directly through digital interfaces. Online lending users grew tremendously from 2.7 million to 8.8 million within a year in 2024 [2]. Post-COVID-19 economic realities and a heightened digital consumption mindset have further spurred the adoption of these services [3].

However, the availability of online loans has led to increasing irresponsible borrowing behavior. An increasing number of debtors tended to skip out on easy-to-access loans, which in turn resulted in a rise in the "non-performing loans" (NPLs). In the context of P2P lending, this is measured by the 90-Day Default Rate (TWP90), which refers to loan repayment that has defaulted beyond 90 days [4]. Based on the latest information from the Financial Services Authority of Indonesia, stagnant online loans jumped significantly from IDR 785.94 billion in January 2022 to IDR 1.9 trillion by June 2024 [5]. This is illustrated in Fig. 1.

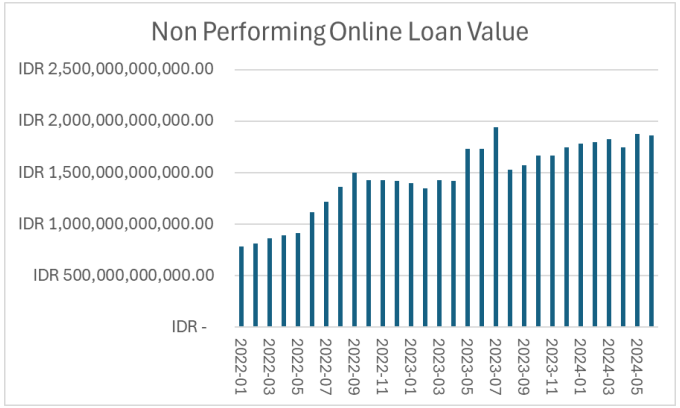

Fig. 1. Accumulated defaulted online loans, 2022–2024.

Moreover, as shown in Fig. 2, the 19 to 34 age group is the largest contributor to loan defaults, followed by individuals aged 35 to 54 [6]. This trend raises serious concerns because the 19 to 34 demographic is the economically productive part of the population that should ideally drive economic growth.

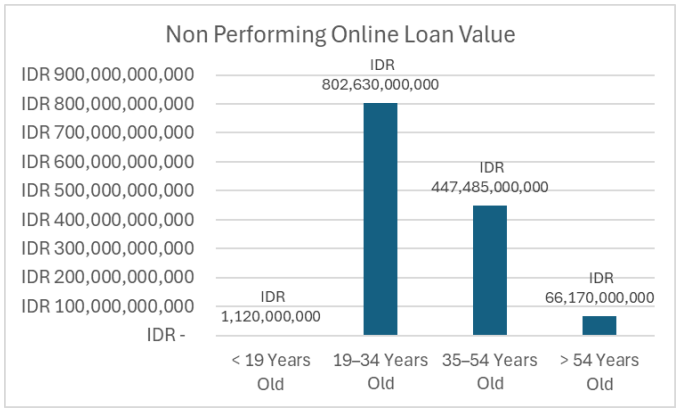

Fig. 2. Default rate by age group.

One of the key factors causing the high rate of loan defaults among the younger productive generations is their

low financial literacy. Several young people use online lending platforms without truly understanding the risks [7]. In 2024–2025, the Financial Services Authority conducted a survey called Indonesia's National Financial Literacy Survey to measure the financial literacy of the Indonesian population. The result of the survey is that in Indonesia, the financial literacy index is only around 65%–66%, and for digital financial literacy, it is at 62% [8],[9].

The survey results from [7]-[9] imply that young people in Indonesia might lack financial understanding, which increases the risk of falling victim to online lending schemes. Several debtors have limited understanding and do not fully understand how online lending works. This causes the debtors to not fully understand the risks and dangers of illegal online lending practices [10]. If this situation continues, the number of non-performing loans will continue to increase. The increase in non-performing loans will weaken personal finances, decrease household consumption, decrease investment, and limit entrepreneurship growth. In the long term, this situation will threaten the national economy.

In addition, verification procedures in online methods of obtaining loans mainly consist of filling in personal data without conducting a direct interview. This opens the opportunity for dishonest debtors to exploit this system. Dishonest debtors can manipulate or change the biodata details they submit, increasing the chances of online loan default. Even in cases where interviews are held, asking static, pre-set questions can be inadequate, as it allows the debtors to prepare rehearsed answers that may not truly represent their financial situation.

To reduce this problem, it is recommended that interview questions be designed to reflect the details of the debtor's biodata so that questions are specific to the debtor and have less predictable answers. However, manual operation on this personalized level would be labor-intensive. In this study, we propose a large language model (LLM)-based automatic interview system and integrate it with a multimodal deep learning architecture.

To provide on-the-spot responses without having to prepare or memorize answers, LLM will use automated question generation (AQG) to generate personalized questions tailored to the debtor biodata. A multimodal model that assesses vocal acoustic characteristics and response latency as possible markers of dishonesty was used to analyze the responses. This system is intended to be implemented before a loan is approved to improve verification accuracy and lower the risk of loan default.

Even though it is still used in the educational domain, previous research has shown the potential of LLMs such as T5, mT5, and Llama in generating questions [11]-[13]. Based on previous research, one of the signs of lying is a change in the acoustic characteristics of speech, such as an increase in pitch and speech disfluency; features such as longer answering process are also one of the deception clues [14]-[16]. All of these signs of deception must be combined to improve model performance as different modalities require a multimodal mechanism. This multimodal model will classify the answer of the debtor as truth or lie.

The major contributions of this study are as follows:

- Proposes a novel integration of vocal acoustic features and response latency to enhance deception detection. These two elements are typically analyzed separately.
- Utilizes a LLM to perform AQG within the financial domain, effectively simulating the online lending interview process.
- Introduces a new verification approach aimed at reducing NPL rates by combining LLM driven questioning and deception detection techniques for a prospective debtor.
- Develops a cost-effective and scalable deception detection framework that supports improved decision-making and operational efficiency in online lending platforms.

This study is organized into five sections. Section I provides the study's background and motivation. Section II explains and shows some related works and previous research relevant to this topic. Section III explains the dataset, methodology, and models used in this study. Section IV presents and discusses the results. Finally, Section V concludes the study and outlines potential directions for future work.

II. Literature Review

This section outlines previous studies related to the current study. This section is divided into two subsections: AQG using LLM and lie detection.

A. AQG Using LLM

AQG using LLM has seen significant growth, particularly in the education domain. As shown in the study [11] and [12], the LLM model with mT5 and T5 architecture has the ability to generate questions that are appropriate to the context of the given input with good human language and good readability. In [11], the authors used the mT5 model trained on the TQuADv2 and XQuAD datasets to generate comprehension questions, achieving BLEU-1 of 47.6 and ROUGE-L of 53.9. Similarly, EduQG, a QG model developed by [12] using T5-small and T5-base, reached BLEU-4 of 15.94 and F1 score of 33.12.

More recently, [13] fine-tuned LLaMA-2 (7B parameters) for question–answer extraction and generation on the SQuAD and PBE datasets, achieving a BLEU-4 of 23.53 and a METEOR of 66.3. Previous studies have shown that LLM can generate dynamic, context-appropriate questions. However, its application is still limited to the educational domain and has not been further explored for adaptation in risk assessments, such as debtor eligibility interviews for online loans.

B. Lie Detection

Several studies have explored lie detection using various modalities such as text, audio, video, facial expression, and multimodal approaches. For instance, [17] implemented a LLM (FLAN-T5) for verbal lie detection using datasets such as Deceptive Opinions, Hippocorpus, and the Intention Dataset, achieving an accuracy of 82.72%. The architecture

created by [18] was named DeepLie, where facial features were extracted using face detection and classified using a deep learning model. The developed DeepLie model achieved a performance of 81.82% on a real-world trial dataset.

Different research approach by [19] extracted high-level features from videos using tools such as OpenFace, part-of-speech n-grams, MFCC, and Covarep and reported a test AUC of 0.730. In [20], the authors combined video, audio (MFCC), and text (GloVe) features and used machine learning classifiers, such as SVM, K-SVM, Decision Tree, and Random Forest, achieving 87.73% accuracy on a trial dataset. Focusing on audio-based detection, [21] developed an acoustic lie detector using MFCC features and models such as SVM and SGD, achieving 62.4% accuracy on the Columbia-SRI-Colorado dataset. In [22], the authors proposed an explainable LSTM-based model that leverages stress analysis in voice signals, achieving an accuracy of 92.4% on a stress voice dataset.

Multimodal deep learning also shows promising results. Research conducted by [23] utilized range of deep learning architecture such as 3D CNNs, text CNNs, and multilayer perceptron and combined them with OpenSMILE for audio features. The research combines video, transcript, and speech to classify a video into a lie or truth class, achieving an impressive accuracy of 97.99% on a trial dataset. Similarly, [24] applied OpenFace and FACS with LSTM for deception detection in videos across datasets such as Silesian, trial, and Bag of Lies, achieving an accuracy of 90.90%.

Another study conducted by [25] used cognitive signals, namely, response latency and error rates, when participants answered unexpected questions as material in detecting lies. Logistic regression, KNN, and SVM were the classifiers used in the study. The highest performance based on the study was an accuracy of 81%, with an AUC of 92%, recall of 80%, precision of 84%, and an F1 score of 80%, highlighting the potential of behavioral timing analysis in lie detection.

C. Research Gap and Proposed Contributions

The literature review reveals significant progress in both AQG and lie detection; however, it also highlights key limitations that this study aims to address.

First, in the field of Automated Question Generation (AQG), the application of powerful LLMs like T5, mT5, and LLaMA is in the educational domain [11]-[13]. There is a distinct lack of research exploring their use in dynamic, high-stakes financial risk assessments, such as debtor interviews.

Second, in Lie Detection, some studies focus solely on a single modality, such as text [17], facial expressions [18], [24], or audio features [21], [22]. Some multimodal systems often combine mostly video, text, and audio either all three of modalities nor combination of 2 modalities [19], [20], [23]. The specific integration of vocal acoustic features and response latency is not explored yet, even though both of the modalities has strong indicators of the cognitive effort associated with deception. Mostly both feature are analyzed separately.

This study directly addresses these gaps. We propose a system that: 1) adapts an LLM for AQG within the financial (online lending) domain and 2) develops a novel, streamlined multimodal model that specifically combine both vocal acoustics and response latency. The following TABLE Isummarizes this research gap and our proposed contributions.

Unlike previous AQG studies that primarily focused on educational or comprehension contexts, our approach introduces domain-specific adaptation and fine-tuning of a large language model for financial risk assessment. The novelty lies in three aspects:

- Prompt engineering strategy, each input prompt integrates structured debtor biodata with contextual financial indicators, enabling the model to generate dynamic and risk-relevant interview questions rather than general comprehension items.
- Domain adaptation, Llama 3 was fine-tuned on a synthetic dataset specifically designed to reflect debtor profiles, borrowing intents, and loan conditions, thus aligning the model's linguistic generation with financial verification contexts.
- Automated reasoning constraint, during decoding, we applied controlled generation parameters (low temperature and limited Top-K sampling) to ensure factual consistency and reduce speculative or irrelevant question output.

Together, these innovations allow the model to perform adaptive, context-aware question generation that simulates human financial interviews a task previously not explored in prior AQG research.

TABLE I. SUMMARY OF RESEARCH GAPS AND PROPOSED CONTRIBUTIONS

Research Area	Identified Limitations / Gaps in Previous Studies	Proposed Solution in This Study
AQG	Application is heavily restricted to the educational domain [11]-[13]. Lacks adaptation for financial risk assessment or debtor interviews.	Develop and fine-tune a LLM model to generate dynamic, personalized interview questions based on debtor biodata specifically for the online lending context.
Lie Detection	Some studies focus on a single modality, such as text [17], facial expressions [18], [24], or audio features [21], [22]. Existing multimodal systems combine video, text, and audio [19], [20], [23]. The specific integration of vocal acoustic features and response latency is not explored. These features are typically analyzed separately.	Propose a novel and efficient multimodal deep learning model that integrates two inputs: vocal acoustic features and response latency.

III. METHODOLOGY

The research methodology follows a multi-stage workflow, as illustrated in Fig. 3, progressing from data acquisition to model integration. The process begins with two

sequential stages: Data Collection and Data Preprocessing. In the collection stage, two distinct datasets are gathered: a synthetic dataset of borrower biodata and interview questions for the AQG task, and the courtroom trial video dataset [26] for lie detection. The subsequent preprocessing stage then cleans, formats, and transforms both the text and audio datasets to make them suitable for training. Following these preparatory steps, the process bifurcates into two distinct, parallel development tracks.

The first track is dedicated to the Automated Question Generation (AQG) component, which involves fine-tuning the Llama 3 model on the prepared biodata dataset. Simultaneously, the second track focuses on building the lie detection system, which entails training the multimodal deep learning model on extracted vocal characteristics and response timing data. Once training is complete, each model is independently assessed in the Model Evaluation stage: the LLM is measured using perplexity and expert review, while the lie detection model is validated using classification accuracy and F1 score. Finally, the two validated models are brought together in the Implementation stage, where they are integrated into a single, cohesive framework for deployment (see Fig. 3).

A. Data Collection

This subsection discusses the data collection process and the datasets used in the study. The dataset used in the research consists of two different data: 1) data for training the LLM model to generate interview questions and 2) data used to train the lie detection model. Each dataset serves a distinct purpose in supporting the development of a comprehensive and intelligent interview system for online lending verification.

1) Interview question dataset: To the author's knowledge, there is no public data containing the debtor's biodata and interview questions that correspond to them, not even the debtor's personal data. This is because such data are sensitive and will not be publicly available. Therefore, this study uses the synthetic data generated using GPT-4o and GPT-4o mini.

The resulting dataset includes 595 borrower profiles and 2,713 generated questions. The data is organized into three key components: Biodata, which contains the prospective debtor's personal and financial information; Analysis, which provides contextual interpretation of the biodata; and Questions, which comprises tailored interview questions generated based on the analysis. A sample of the dataset is shown in 0. This structured format ensures that both question generation tasks are supported by the dataset.

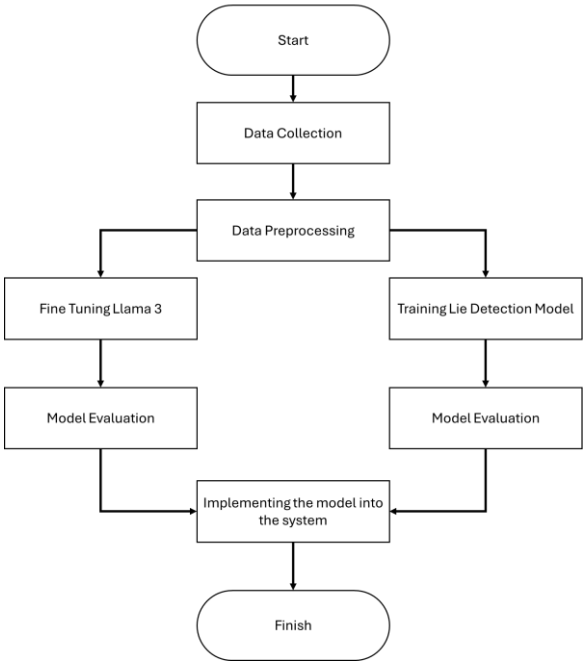

Fig. 3. Methodology of the study. After preprocessing, the fine-tuning of Llama 3 (left) and the training of the lie detection model (right) run in parallel.

TABLE II. SAMPLE BIODATA OF THE QUESTION GENERATION DATASET

Biodata	Analysis	Question
Full Name: Rudi Hartono; **Province**: West Java; **City**: Bekasi; **Educational Background**: High School; **Marital Status**: Single; **Reason for Loan**: Household needs; **Residence**: Rental; **Private Vehicle**: Motorcycle; **Company Name**: PT. Sentosa Abadi; **Occupation**: Private employee Industry; **Sector**: Industry/Factory; **Position**: Supervisor; **Net Monthly Income**: Rp 8,500,000; **Household Monthly Income**: Rp 8,500,000; **Years of Employment**: 4 years; **Emergency Contact**: Parent; **Emergency Contact Name**: Sri Hartono; **Loan Amount**: Rp 15,000,000; **Loan Tenure (Months)**: 18 months; **Monthly Interest Rate**: 6.0%	The reason for borrowing for household needs indicates a shortfall in meeting basic necessities, which may suggest potential financial constraints or inadequate budget management.	1. Do urgent household needs often consume a significant portion of your income? 2. Why do you feel the need to apply for a loan to cover your basic household needs? 3. Do you experience difficulties in managing your monthly finances for daily needs?

2) Lie detection dataset: This study employs the courtroom trial video dataset by [26] for lie detection. The dataset consists of 121 video clips (61 videos are labeled as deceptive class and 60 videos are labeled as truthful class). The videos are labeled based on court evidence and rulings. Audio and these models, which include millions or even billions of parameters, are trained on vast amounts of text data and have demonstrated remarkable capabilities in understanding and generating human-like text. Response latencies were extracted from the videos for analysis. The lie detection dataset compiled from 56 individuals consists of 21 females and 35 males with ages ranging from 16 to 60; durations of the video ranged from 4 seconds to 1 minute 11 seconds. Videos were taken from the recording of real trials; thus, the dataset has varied lighting, camera angles, and poses.

B. Data Preprocessing

This study involves two types of data: text data for the interview generation process and audio recordings for lie detection. Two distinct preprocessing techniques are applied accordingly.

1) Question generation dataset: Tokenization in the Llama 3 model uses a subword-based approach, enabling the Llama 3 model to efficiently handle words not in the model's vocabulary or the presence of affixes. The input text is converted into ID tokens in tokenization. The ID tokens are then converted into mathematical representations through an embedding layer. Each token ID is mapped to a 3072-dimensional vector according to the embedding size used by Llama 3.

Consequently, an input sequence consisting of n tokens is converted into an embedding matrix of size $n \times 3072$. Then, this matrix is used as the input for the transformer layer in the model. The matrix will then be processed in the transformer layer in the model so that the Llama model can understand the input context.

2) Lie detection dataset: To prepare the audio, sound tracks were separated from the video files using the moviepy library. The extracted audio was then adjusted to meet a common format resampled at 16 kHz to keep the data consistent and manageable for processing. Because the recordings varied in length, each clip was truncated and padded into 30 seconds: shorter clips were extended with silent padding, whereas longer clips were trimmed down.

The response latency data were obtained using the pyAudioAnalysis package through a silence removal process. This method segments the audio by removing non-speech regions using a semi-supervised SVM classifier trained to distinguish between high-energy (speech) and low-energy (non-speech) frames. The resulting speech segments were used to calculate the response latency for the lie detection analysis.

3) Data splitting: For robust model assessment and to reduce the likelihood of overfitting, the dataset was separated into two distinct portions: training and testing. The training subset was used to adjust the model parameters. The testing subset supported hyperparameter tuning and helped monitor overfitting during learning.

In this study, stratified random splitting was applied to maintain the balance between the "truth" and "lie" categories across all subsets. This strategy ensured the preservation of class proportions, preventing bias that might otherwise distort model performance. The split was performed using standard library functions, guaranteeing that the process could be replicated consistently. Data allocation followed a widely accepted distribution in machine learning practice: 75% of the data were used for training and 25% for testing.

C. Building Models

1) Llama 3: The primary methodological challenge in the AQG component was adapting the general-purpose Llama 3 model [28] to the specific domain of financial risk assessment. This was not a simple zero-shot prompting task; it required a specific fine-tuning strategy to achieve the desired domain adaptation. We structured our synthetic dataset as 1) into a Biodata, Analysis, Question format. The model was fine-tuned on this structured data to explicitly learn the task of: a) first analyzing a borrower's financial profile and b) then generating contextually relevant, probing questions [27] based on that analysis. This "analysis-then-question" approach is our key technical adaptation, moving the model from a general text generator to a specialized financial risk interrogator.

To execute this efficiently, we utilized Low-Rank Adaptation (LoRA) for fine-tuning, applying it to the model's attention layers. We leveraged the model's native architecture [29] which includes pre-normalization with RMSNorm [30], Rotary Positional Embeddings [31], and the SwiGLU activation function [32] to ensure stable and efficient convergence during our specialized fine-tuning task.

2) SincNet: We selected SincNet as the audio front-end to process raw waveforms directly. This choice was a critical part of our methodology, as traditional hand-crafted features like MFCCs, which are common in audio processing can suppress narrow-band characteristics such as pitch and formants that are key indicators of deception-related stress [33].

SincNet avoids this by using parametrized sinc-based filters in its first convolutional layer [34]. These filters function as learnable band-pass filters defined by cutoff frequencies f_1 and f_2, which are optimized during our training process. The filter is expressed as Eq. (1):

$$g_w[n, f_1, f_2] = (2f_2 \cdot \mathrm{sinc}(2\pi f_2 n - 2f_1 \cdot \mathrm{sinc}(2\pi f_1 n)) \cdot w[n] \quad (1)$$

where, $w[n]$ is a windowing function applied to smooth the filter edges. By implementing this architecture, our model learns the most meaningful frequency features for lie detection directly from the raw audio, rather than relying on pre-engineered features, which is crucial for our multimodal hypothesis.

3) Multimodal: Multimodal is a single algorithm that combines multiple inputs types of input [35]. This study leverages a multimodal deep learning framework to jointly process two types of input: audio data and response latency. Each modality undergoes preprocessing according to its nature. For audio, the signals are resampled, padded, and truncated to achieve a consistent length and dimensionality. Then, SincNet is used to extract the informative features directly from the raw waveform. The silent segments in the audio were identified and removed to capture the response latency, and the resulting features were processed through fully connected layers to produce meaningful numerical representations.

The feature outputs from both modalities are concatenated into a single vector during fusion, forming a shared representation. This combined embedding is then refined through additional fully connected layers to integrate cross-modal information. The final classification layer predicts whether the response reflects truthfulness or deception.

D. Experimental Design

Llama 3 (version 3.2) with 3 billion parameters was employed for the automated question generation task. Fine-tuning was conducted using a learning rate of 2×10^{-4}, over 10 epochs, with a batch size of 3 applied to training and evaluation. During the generation phase, the decoding process was configured with a maximum sequence length of 512 tokens, Top-K sampling set to 50, a temperature of 0.6, and Top-P of 0.95. A multimodal model was trained across 50 epochs with a batch size of 8 for deception detection. The system takes two inputs: raw audio and response latency. Audio signals are processed through SincNet to extract features, whereas response latency is transformed using fully connected layers. Then, the outputs from both pathways were fused for joint representation and final classification.

IV. Experiments and Results

In this section, we explain the results of our research and provide a comprehensive discussion.

A. Evaluation Parameters

1) Question generator evaluation: In this case, the effectiveness of the LLM Llama 3 in generating questions was assessed using perplexity. As described in [36], perplexity quantifies how well a language model or probability distribution predicts a given sample. Lower perplexity values reflect stronger performance, indicating that the model is more confident and precise in forecasting the next token in a sequence. The mathematical formulation of perplexity is expressed as Eq. (2):

$$perplexity = 2^{-\frac{1}{M}\sum_{j=1}^{M}\log_2 \hat{P}(y_j)} \quad (2)$$

2) Lie detection model evaluation: The multimodal deep learning-based lie detection model was assessed using conventional classification metrics derived from the confusion matrix (TABLE III The confusion matrix offers a detailed breakdown of the prediction outcomes by distinguishing between true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN) [37]. In the context of this binary classification task (Honest vs. Deceptive), the matrix is organized as follows:

Based on [38], the following metrics were calculated from the confusion matrix:

- **Accuracy** reflects the proportion of correctly classified samples relative to the total number of cases and serves as an overall indicator of correctness. The equation is shown as Eq. (3):

$$\text{Accuracy} = \frac{TP + TN}{Total\ Number\ of\ Cases}. \quad (3)$$

- **Precision** denotes the fraction of TPs within all predicted positives, highlighting the effectiveness of the model in minimizing FPs. The equation is shown as Eq. (4):

$$Precision = \frac{TP}{TP\ +\ FP}. \quad (4)$$

- **Recall (or Sensitivity)** measures the share of TPs among all actual positives, illustrating the ability of the model to capture all relevant instances. The equation is shown as Eq. (5):

$$Recall = \frac{TP}{TP\ +\ FN}. \quad (5)$$

- The **F1-score**, defined as the harmonic mean of Precision and Recall, offers a balanced metric that is especially valuable in cases of class imbalance. The equations is shown as Eq. (6):

$$F1 - score = \frac{2 \times p \times r}{p + r} \quad (6)$$

- **Specificity** quantifies the proportion of TNs within all actual negatives, indicating the strength of the model in avoiding false alarms. The equation is shown as Eq. (7):

$$Specificty = \frac{TN}{TN + FP} \quad (7)$$

Together, these metrics provide a comprehensive evaluation framework for assessing the question generation component and the lie detection performance of the proposed system.

TABLE III. Confusion Matrix of Two Classes

		Prediction Label	
		Class 0	**Class 1**
Ground Truth	Class 0	TN	FP
	Class 1	FN	TP

B. Hardware and Software Specification

All experiments in this study were executed using a high-performance computing infrastructure. Table IV shows the hardware and software specifications used for training the LLM and the multimodal deep learning models.

TABLE IV. Hardware and Software Specifications

Hardware	
GPU	RTX 4090
VRAM	24 GB
Ram	128 GB
Storage	1 TB
Software	
Programming Software	VSCode
Programming Language	Python 3.10

C. Performance Analysis

1) Question generator performance: Fig. 4 presents the progression of loss values for training and testing datasets over the course of epochs. During the initial epochs (0–2), training and testing losses sharply declined, indicating that the model quickly captured fundamental patterns and exhibited strong generalization. Between epochs 3 and 6, the training loss continues to decrease. However, after epoch 6, the testing loss levels off and subsequently begins to rise, signaling the

emergence of overfitting. This outcome suggests that the model's large capacity led it to memorize the training data rather than extract broadly applicable features. Approaches such as early stopping and applying regularization methods should be considered to address this issue and preserve generalization.

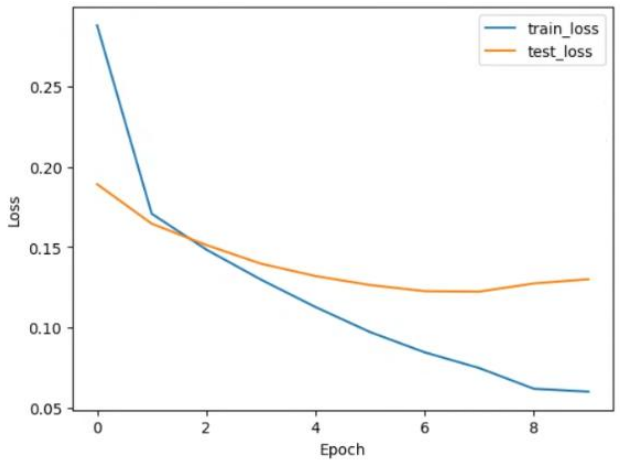

Fig. 4. Changes in the LLM train and test loss with respect to epoch.

The perplexity value for the trained model ranged from 2 to 3, indicating a good predictive capability for subsequent tokens within the language corpus. A low perplexity score in LLMs, such as Llama 3, indicates efficient modeling of the language probability distribution and more accurate predictions. While low perplexity is a positive indicator of performance, the observed overfitting in the test loss highlights the importance of maintaining model generalization for real-world data application.

TABLE Vpresents an example of the output generated by the Llama 3 model. The analysis demonstrates accuracy and professionalism by incorporating details such as estimated monthly installments, their ratio to income, and consideration of rental status as a non-financial risk factor. The generated questions are contextually relevant and exploratory, addressing key aspects such as payment history, emergency fund availability, and preparedness for unforeseen expenses. These results highlight the model's strong potential for producing meaningful analyses and credit-related inquiries, suggesting that it can be effectively integrated into an automated credit scoring system with further refinement.

2) Lie detection performance: This section presents the performance of the lie detection model on the training and testing datasets. The model was trained for 50 epochs with a batch size of 8. Fig. 5 illustrates the evolution of loss values across epochs for both datasets, providing insights into the learning behavior of the model during training and its generalizability to unseen data.

The graph illustrates the progression of the loss values throughout the training of the deep learning model. The horizontal axis represents the number of epochs, whereas the vertical axis shows the loss value. Two curves are displayed: the blue curve corresponds to the training loss and the orange curve represents the testing loss. Both losses are relatively high (approximately 0.7). As training progressed, the training loss dropped steeply, reaching approximately 0.05, reflecting effective learning on the training data. The testing loss also decreased but in a gradual and stable manner, plateauing between epochs 20 and 35 before showing a slight increase toward the end of training. This trend suggests the onset of overfitting after epoch 35, when the model becomes too tailored to the training data, resulting in reduced performance on unseen data.

TABLE V. EXAMPLE OF GENERATED OUTPUT FROM THE TRAINED MODEL

Biodata	Analysis	Questions
Full Name: Rudi Hartono; **Province**: West Java; **City**: Bekasi; **Educational Background**: High School; **Marital Status**: Single; **Reason for Loan**: Household needs; **Residence**: Rental; **Personal Vehicle**: Motorcycle; **Company Name**: PT. Sentosa Abadi; **Occupation**: Private employee; **Industry**: Industry/Factory; **Position**: Supervisor; **Net Monthly Income**: Rp 8,500,000; **Family Monthly Income**: Rp 8,500,000; **Length of Employment**: 4 years; **Emergency Contact**: Parent; **Emergency Contact Name**: Sri Hartono; **Loan Amount**: Rp 15,000,000; **Loan Tenure (Months)**: 18 months; **Loan Interest (Per Month)**: 6.0%	With a loan amount of Rp. 15,000,000 and a tenor of 18 months, the estimated monthly installment is approximately Rp. 1,733,333.33 (with 6% monthly interest). The total repayment will reach Rp. 31,200,000, meaning that around 9.7% of the borrower's monthly income will be allocated for loan repayment.	1. Have you ever been late in paying installments or loans before? 2. What is your plan to ensure that this installment will not interfere with your routine expenses? 3. Do you currently have any other ongoing loans or credits? If yes, what is the total monthly installment you need to pay?

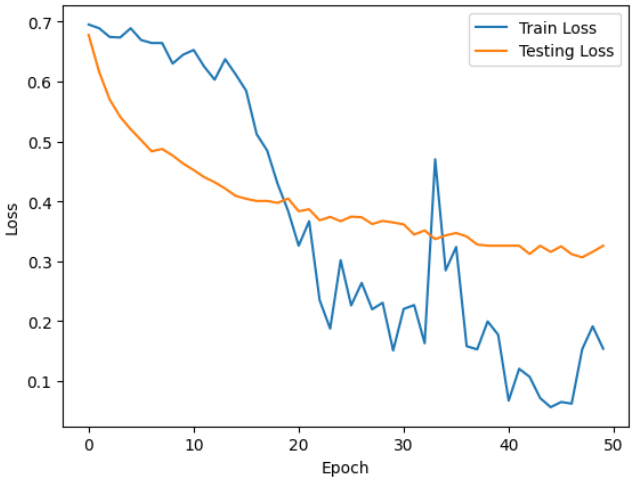

Fig. 5. Change in the lie detection model train and test loss with respect to epoch.

Fig. 6 depicts the evolution of the model's accuracy during the 50-epoch training process, with the horizontal axis representing epochs and the vertical axis showing the accuracy

in percentage. There are two curves: the blue curve represents the training accuracy, whereas the orange curve shows the testing accuracy. At the beginning of training, the training accuracy started at a relatively low and fluctuating value, but generally increased sharply to over 90%. Despite this increase, the training accuracy curve shows considerable fluctuations at several points, likely owing to unstable training data or varying batches.

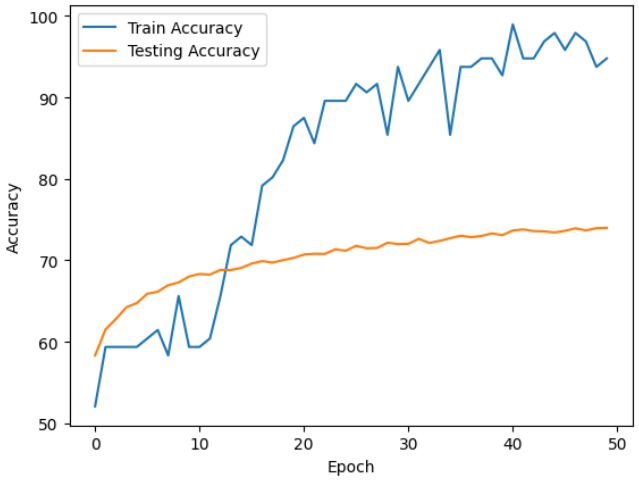

Fig. 6. Change in the lie detection model train and test accuracy with respect to epoch.

Conversely, the testing accuracy curve appeared smoother and more consistent, showing a gradual increase from approximately 58% to nearly 70%, before stabilizing toward the end of training. The substantial gap between the training and testing accuracy curves highlights the presence of significant overfitting. This discrepancy indicates that although the model achieved outstanding performance on the training data, it struggled to effectively generalize to unseen data.

The developed lie detection model achieved 100% accuracy on the training set (TABLE VIand TABLE VIIThis outcome shows that the model successfully captured the underlying patterns of the training data. However, when evaluated on the test set, which contained an evenly balanced distribution of the "honest" (class 0) and "deceptive" (class 1) classes, its accuracy dropped to 70% (TABLE VI. This decline in performance further confirms the occurrence of overfitting, indicating that while the model excelled in memorizing the training data, it exhibited limited generalization capability when applied to new, unseen samples.

TABLE VI. CONFUSION MATRIX OF THE LIE DETECTION MODEL ON TRAINING DATA

	Class	Prediction	
		Honest	Lie
Ground Truth	Honest	45	0
	Lie	0	46

TABLE VII. PERFORMANCE OF THE LIE DETECTION MODEL ON TRAINING DATA

	Accuracy	Precision	Recall	F1 Score	Specificity
Train	100%	100%	100%	100%	100%

Based on the confusion matrix in TABLE VIIIand TABLE IXfor the testing data, 10 honest samples were correctly classified and 5 honest samples were misclassified as deceptive (FP). Of the 15 deceptive samples, 11 were correctly classified, whereas 4 others were misidentified as honest (FN). The precision and recall values for the deceptive class were 68.8% and 73.3%, respectively. This relatively small difference indicates that the model has a balanced performance in detecting deception, both in terms of its ability to correctly identify deceptive cases (recall) and the accuracy of predicting deception (precision). However, the slightly lower precision compared with recall suggests that there are still some incorrect deceptive predictions (FPs), although the overall performance of the model can be considered good in detecting deception. Specificity, the ability of the model to correctly detect honesty, was 66.67%.

TABLE VIII. CONFUSION MATRIX OF THE LIE DETECTION MODEL ON TESTING DATA

	Class	Prediction	
		Honest	Lie
Ground Truth	Honest	10	5
	Lie	5	11

TABLE IX. PERFORMANCE OF THE LIE DETECTION MODEL ON TESTING DATA

	Accuracy	Precision	Recall	F1 Score	Specificity
Train	70%	68.8%	73.3%	70.9%	66.67%

In a real-world context, misclassifying an honest person as deceptive can have a negative impact on reputation and trust. Conversely, if a deceptive person goes undetected as honest, other forms of loss can occur. Therefore, a better balance between the model's sensitivity (recall) and specificity is required to improve its overall performance.

D. Discussion

The experimental results of this study demonstrate the potential and current limitations of employing artificial intelligence to improve verification processes in online lending, particularly through automated lie detection. The proposed system, which integrates a LLM for personalized question generation and a multimodal deep learning model for deception detection, represents a novel approach to reducing the risk of loan default.

The LLM-based question generator, built upon Llama 3, successfully generated contextually relevant and individualized questions by analyzing borrower biodata. The observed perplexity scores between 2 and 3 indicate that the model learned meaningful representations of the input data and could effectively predict token sequences. Nonetheless, the training dynamics revealed signs of overfitting,

particularly beyond epoch 6, where the testing loss began to increase despite continuous improvement in the training loss. This phenomenon suggests that the model began to memorize training samples rather than learning generalized patterns. Future implementations should consider employing regularization techniques such as dropout as well as strategies such as early stopping and k-fold cross-validation to mitigate this issue.

The lie detection model demonstrated strong learning ability during training, achieving 100% accuracy. However, the performance on the testing dataset declined to 70% accuracy, with additional metrics including a precision of 68.8%, recall of 73.3%, F1 score of 70.9%, and specificity of 66.67%. These figures reflect a moderate level of generalization and indicate that the model was more proficient in detecting deceptive behavior (as shown by its relatively higher recall) than in avoiding FPs. This trade-off between sensitivity and specificity is particularly important in financial contexts: while failing to detect deception may result in financial loss, false identification of honest applicants can damage user trust and accessibility.

The discrepancy between the training and testing performance, along with the presence of FPs and FNs, indicates the need for further refinement of the model. The domain gap between the courtroom trial audio data used for training and the real-world voice patterns of loan applicants may be contributing factors. Therefore, the collection and use of domain-specific audio data, sourced directly from online lending environments, is recommended to improve model adaptability and contextual accuracy.

Moreover, while the technical feasibility of the proposed system is evident, its practical deployment raises several ethical concerns. The automated classification of debtor honesty based on vocal features and response timing may introduce biases, especially for individuals with speech disorders, anxiety, or cultural-linguistic variations. These risks necessitate the implementation of fairness-aware machine learning techniques and the potential integration of a human-in-the-loop review mechanism.

In summary, the results confirm that the integration of adaptive LLM-based questioning with voice and response latency analysis holds substantial promise for improving the objectivity and robustness of digital credit verification systems. However, to transition this system from proof-of-concept to deployment, further work is required in terms of data expansion, overfitting mitigation, domain adaptation, and ethical governance. This study's methodology provides a solid foundation for the future development of scalable, intelligent decision-support tools for financial technology platforms.

V. Conclusion

This study presents an AI-driven lie detection system tailored for online lending applications, integrating a LLM with a multimodal deep learning framework. The proposed system aims to improve the borrower verification process by generating personalized, context-aware interview questions using Llama 3 and subsequently evaluating applicant honesty through vocal acoustic features and response latency.

The experimental results show that the system performs well during the training phases, achieving 100% accuracy in lie detection on the training data and producing highly relevant, individualized questions. However, generalization remains a challenge, as evidenced by the drop in testing accuracy to 70% and indications of overfitting in the question generation and deception detection components. Despite this, the model achieved a balanced performance on unseen data, with an F1 score of 70.9%, precision of 68.8%, recall of 73.3%, and specificity of 66.67%.

This integrated framework represents a significant advancement over existing methods. Unlike traditional, static questionnaires, the LLM-driven interview prevents rehearsed answers; unlike rule-based scoring, it adds behavioral analysis; and unlike unimodal models, its fusion of vocal acoustics and latency provides a more robust deception signal. This scalable framework thus shows strong potential as a decision-support tool. Its automation enables thousands of simultaneous interviews, reducing labor costs and financial losses from NPLs, with broader implications for recruitment, insurance, and fraud investigations.

Future research should focus on mitigating overfitting through hyperparameter tuning, applying cross-validation techniques, expanding and diversifying the dataset, and incorporating advanced feature extraction methods. Furthermore, ethical considerations, including bias mitigation and human oversight, must be integrated into the deployment pipeline to ensure fairness and transparency in real-world applications.

***Abstract*—Mangrove ecosystems play an important role in maintaining coastal ecological balance, including as carbon sinks and natural protection from abrasion, but mangrove areas in Mempawah Regency have experienced significant degradation due to anthropogenic pressures. Therefore, this study aims to classify the health condition of mangroves using multi-temporal Sentinel-2 imagery with a hybrid machine learning (ML) approach and Genetic Algorithm (GA) optimization. We implemented GA optimization comparatively on four main ML models—Multilayer Perceptron (MLP), Decision Tree (DT), XGBoost, and Naïve Bayes (NB)—to adjust hyperparameters to improve accuracy and reduce overfitting. The results prove that GA optimization effectively improves classification performance, with the MLP-GA model providing the highest accuracy with an increase of up to 3.8% compared to the non-optimized baseline model, achieving a best performance value of ROC AUC 0.9730 and reducing computation time by up to 60%. These findings indicate that the GA-MLP framework is highly reliable and efficient, providing a precise tool for strategic decision-making in the management of healthy mangrove ecosystems.**

***Keywords*—Classification; genetic algorithm; machine learning; mangrove ecosystem; Sentinel-2**

I. Introduction

Mangrove forests cover only about 0.7% of the world's total tropical forests [1], but has the ability to store three to four times more carbon per unit area than other tropical forests, and in areas with carbonate and peat environments, their storage capacity can be 25 to 50% higher [2]. Globally, this ecosystem is spread across more than 118 countries with an area of approximately 152,000 km² [3]. Meanwhile, in Indonesia, mangroves are found throughout the archipelago. The largest distribution is in Irian Jaya, covering an area of 1,350,600 ha (38%), followed by Kalimantan with 978,200 ha (28%), and Sumatra with 673,300 ha (19%) [4][5]. Meanwhile, in other regions, mangroves generally grow optimally on coasts with large river estuaries and protected beaches.

West Kalimantan is a province with a coastline stretching 1,940 km, most of which is dominated by mangrove ecosystems [6][7]. The area of mangrove forests in this province is estimated to reach 119,327 ha, with a composition of around 75% of the mangrove species found in Indonesia. On Padang Tikar Island, Batu Ampar District, Kubu Raya Regency, the mangrove ecosystem covers an area of 58,953 ha. Meanwhile, Mempawah Regency, which is also located on the coast of West Kalimantan, has a fairly high diversity of mangroves [8]. However, in the last 25 years, it has experienced degradation covering an area of 250.11 ha, so that in 2014, only about 739.31 ha remained [9]. This condition indicates that the mangrove ecosystem in the study area not only has high ecological value but also faces serious threats, making remote sensing-based mangrove health monitoring urgently needed.

Monitoring the health of mangrove ecosystems is crucial to support conservation and rehabilitation strategies. The use of remote sensing technology, particularly Sentinel-2 satellite imagery, offers great opportunities because it has sufficient spatial, temporal, and spectral resolution to map land cover conditions and detect vegetation health dynamics [10][11][12]. Several vegetation and water indices, such as NDVI (Normalized Difference Vegetation Index) [13][14], SAVI (Soil-Adjusted Vegetation Index) [15], NDWI (Normalized Difference Water Index) [16], and MNDWI (Modified Normalized Difference Water Index) [17], have proven effective in evaluating vegetation density, humidity, and coastal ecosystem conditions. However, challenges still arise in terms of classification accuracy and consistency due to the complexity of mangrove spectral characteristics, which often overlap with other vegetation.

Previous studies have shown various approaches to mangrove mapping and monitoring. The XGBR-GA hybrid approach, which combines Extreme Gradient Boosting Regression and Genetic Algorithm for feature selection with multi-source data (Sentinel-2, Sentinel-1, ALOS-2 PALSAR-2) and field data (105 plots), successfully estimated Above-Ground Biomass (AGB) with good accuracy (R^2 = 0.683; RMSE = 25.08 $Mg \cdot ha^{-1}$) [18]. Furthermore, the EIAGA-S (Elite Individual Adaptive Genetic Algorithm-Semantic Inference) method, combined with the new MEVI index, was able to perform semantic segmentation of mangroves without ground truth with high accuracy (mIoU = 0.92; F1 = 0.923) and multi-class classification. On the other hand, NDVI-based research in Tugu District, Semarang, shows that the mangrove area covers 113.93 ha with a health condition dominated by the "Good" category (57.1 ha), although the effectiveness of mangroves in mitigating coastal abrasion (970 m in 2017–2021) is still limited [19]. The three studies introduced the Elite Individual Adaptive Genetic Algorithm-Semantic Inference (EIAGA-S) method for semantic segmentation of mangroves

* Corresponding author.

without requiring ground truth data. This method combines an adaptive genetic algorithm with an elite evolution strategy and develops the Mangrove Enhanced Vegetation Index (MEVI) to distinguish mangroves from other vegetation. Evaluation results on multi-source data show high performance with mIoU = 0.92 and F1-score = 0.923, surpassing traditional models such as K-means and SVM [20].

The development of machine learning methods has opened up new opportunities to improve the accuracy of land cover classification. Algorithms such as Multilayer Perceptron (MLP) excel at capturing nonlinear patterns [21], Extreme Gradient Boosting (XGBoost) is powerful in processing complex data [21], Easy-to-interpret Decision Tree [22], and Naïve Bayes, which is efficient for text data, has been widely used in satellite image analysis, but its performance is greatly influenced by the selection of complex hyperparameters [23]. To address these challenges, this study integrates Genetic Algorithm (GA) as an optimization method to improve accuracy while minimizing the risk of overfitting, so that the resulting model is more reliable in supporting coastal ecosystem monitoring [24][25].

Data processing was carried out using Sentinel-2 imagery from the COPERNICUS/S2 HARMONIZED collection accessed through Google Earth Engine (GEE), with the study area focused on the coast of Mempawah Regency, West Kalimantan, which is bounded by a polygon-shaped AOI. To monitor the temporal dynamics of mangrove ecosystem health, the images were analyzed over three time periods (2019–2021, 2021–2023, and 2023–2025), then several spectral indices such as NDVI, SAVI, NDWI, and MNDWI were calculated to assess the condition of mangrove vegetation and detect changes in land cover from year to year.

This study is expected to make a significant methodological and practical contribution. The methodological contribution lies in the comparative evaluation of Genetic Algorithm (GA) optimization in four machine learning models for mangrove health classification, which has rarely been explored in the context of multi-temporal Sentinel-2 data. Quantitatively, this study proves that GA can improve the accuracy of the best model (MLP) by up to 3.8% compared to the non-optimized base model, achieving the highest ROC AUC performance value of 0.9730, while reducing hyperparameter computation time by up to 60%. These precise data-based results are crucial for supporting conservation and rehabilitation strategies. Furthermore, this study aligns with the UN's 2030 Agenda, particularly Sustainable Development Goal (SDG) 14.2 [26], which emphasizes the protection and sustainable use of marine and coastal ecosystems, making healthy mangrove management key to supporting sustainable development. Overall, this study provides recommendations that can be directly applied in mangrove reforestation efforts, supporting sustainable development (SDGs 2030) through more targeted mangrove planting strategies to enhance ecological resilience in coastal areas [27].

The remainder of this study is organized as follows: Section II presents a review of various related works, highlighting the limitations of previous studies and explaining how this research addresses these gaps. Section III details the methods used, ranging from Sentinel-2 image processing, multi-index data preparation, and the implementation of Genetic Algorithm (GA) optimization on four machine learning models. Section IV presents the experimental results, and an in-depth discussion of the optimized model performance comparison is presented in Section V. Finally, Section VI summarizes the main conclusions of this study and provides directions for future work.

II. Related Work

Remote sensing-based mangrove ecosystem monitoring research has been conducted extensively using various approaches. One of the most widely used methods is vegetation indices, such as NDVI, SAVI, NDWI, and MNDWI, which have proven effective in assessing vegetation density, moisture conditions, and distinguishing between vegetative and non-vegetative areas. For example, research in the Semarang area successfully identified the extent of mangroves and classified their health conditions with a reasonable degree of accuracy [28]. However, the study was limited to a single observation period, so it was not able to describe changes in mangrove conditions over time.

With advances in data analysis technology, machine learning algorithms are increasingly being applied to improve the accuracy of satellite image classification. Various studies have demonstrated the success of algorithms such as Multilayer Perceptron (MLP), Extreme Gradient Boosting (XGBoost), Decision Tree, and Naïve Bayes in land cover mapping and vegetation identification. MLP is known to be effective in capturing nonlinear patterns between spectral variables [29], whereas XGBoost excels at handling complex data and is able to overcome overfitting issues through its efficient gradient boosting mechanism [30][31]. Decision Trees are often used because they are easy to interpret and capable of displaying transparent classification rules [32]. Meanwhile, Naïve Bayes has an advantage in computational efficiency for high-dimensional data thanks to its simple yet effective assumption of feature independence [33]. However, the performance of these algorithms is highly dependent on the selection of appropriate hyperparameters. Manual parameter tuning is often inefficient and can reduce the accuracy and stability of the model, especially with complex remote sensing data [34][35].

To overcome problems in hyperparameter tuning, various studies have begun to apply metaheuristic-based optimization algorithms such as the Genetic Algorithm (GA). One of these studies was conducted by Tien Dat Pham et al. (2022), who developed the XGBR-GA model for estimating above-ground biomass (AGB) of mangroves. This model utilizes data from Sentinel-1, Sentinel-2, ALOS-2 PALSAR-2, as well as field data from 105 plots in the Red River Delta, Vietnam. The results of the study show the best performance with an R^2 value of 0.683 and an RMSE of 25.08 $Mg \cdot ha^{-1}$, making the XGBR-GA approach effective for monitoring mangrove ecosystems in tropical regions [36]. In addition, research by Xinhong Li et al. (2023) developed an explainable machine learning method for Fractional Vegetation Cover (FVC) inversion in the alpine grasslands of the Qinghai-Tibet Plateau. A combination of Genetic Algorithm (GA), XGBoost, and Optuna (GA-OP) was used for feature selection and hyperparameter tuning, resulting in a Stacking model with the best performance (R^2 = 0.867;

RMSE = 0.12). The SHAP method and NDVI-CV analysis improved the interpretability and reliability of the results, making this approach effective for estimating other ecological parameters [37]. These results demonstrate the effectiveness of GA in improving the accuracy, stability, and generalization ability of machine learning models for large-scale remote sensing data.

Although a number of previous studies have successfully improved the accuracy of mangrove classification through the application of machine learning algorithms and Genetic Algorithm (GA)-based optimization, most of these studies still have several important limitations. First, most previous studies have focused on a single observation period, thus failing to consider the temporal dynamics of mangrove ecosystems, which are greatly influenced by seasonal factors and anthropogenic activities. Second, the study areas tend to be limited to small and homogeneous areas, so the results cannot describe the complex spatial variations in larger tropical areas. Third, some studies only rely on one or two vegetation indices (such as NDVI or SAVI) without considering water indices such as NDWI and MNDWI, even though these two indices are important for assessing the interaction between mangrove vegetation and the surrounding aquatic environment. Fourth, the GA approach used is generally only applied to one machine learning model, so there has been no discussion of the effectiveness of multi-model or cross-algorithm optimization.

This study attempts to overcome these limitations through a more comprehensive and adaptive approach to classifying mangrove ecosystem health. First, a multi-temporal analysis was conducted for the period 2019 to 2025 to describe the dynamics of changes in mangrove health over time. Second, the study area was focused on the coast of Mempawah Regency, West Kalimantan—an area with high vegetation diversity and real environmental pressures—so that it could represent more diverse ecological conditions. Third, this study combined four main indices (NDVI, SAVI, NDWI, and MNDWI) to provide a more comprehensive spatial picture of vegetation and water conditions. Fourth, the novelty of this study lies in the application of GA across four machine learning algorithms (MLP, XGBoost, Decision Tree, and Naïve Bayes), which are simultaneously optimized to improve the accuracy, stability, and generalization ability of the model. Thus, this study not only expands the spatial and temporal coverage but also introduces methodological innovations in the application of GA for more effective and scientific classification of mangrove ecosystems.

III. Methodology

This research method consists of nine main stages for land cover classification and mangrove health assessment based on Sentinel-2 imagery. The stages include determining the study area, acquiring Sentinel-2 Level-2A imagery, pre-processing (cloud masking and extraction of six spectral bands), and creating a labeled dataset through pixel value extraction from sample points. Five machine learning algorithms (MLP, Naive Bayes, Decision Tree, and XGBoost) were applied with parameter optimization using Genetic Algorithm. Model evaluation was performed using accuracy, precision, recall, F1-score, and Cohen's Kappa, then the best model was used to produce a mangrove cover classification map and interpretation of its health condition. The overall research process flow, from image acquisition to result interpretation, can be seen visually in Fig. 1.

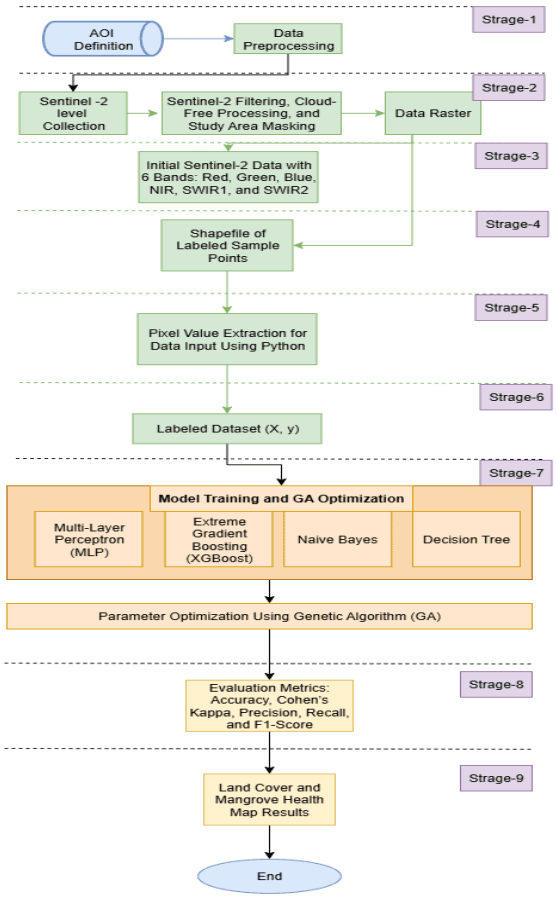

Fig. 1. Research process flow.

A. Stage-1: Determination of AOI and Data Preparation

The initial stage of the study began with the determination of the Area of Interest (AOI) located in the coastal area of Mempawah, West Kalimantan. This AOI was defined using polygon vector data with a two-dimensional geographic coordinate system (Geographic 2D CRS: EPSG:4326 – WGS 84), covering an area with longitude coordinates ranging from 108.829975° to 109.043271° and latitude coordinates ranging from 0.295701° to 0.565236°. The projection system used is WGS 84 (World Geodetic System 1984) with an ellipsoidal datum and Greenwich prime meridian. This shapefile data is then used to determine sample points in the class labeling process. The base image used is Sentinel-2 Level-2A, which was collected through the Google Earth Engine (GEE) platform and will be used in the spectral value extraction stage.

B. Stage-2: Sentinel-2 Image Processing

The Sentinel-2 images collected were then processed through several stages, including masking the study area, cloud filtering, and selecting the study area to produce a raster ready for analysis. This study uses Sentinel-2 images from the COPERNICUS/S2 HARMONIZED collection available on the Google Earth Engine (GEE) platform

(https://code.earthengine.google.com/), with a cloud cover filter of less than 20%. The study area is focused on the coastal region of Mempawah Regency, West Kalimantan, and is bounded by a polygonal AOI.

The image selection process was carried out for three time periods, namely: 2019 to 2021, 2021 to 2023, and 2023 to 2025, in order to monitor the dynamics of mangrove cover changes over time. The selection of these three time periods aims to monitor the temporal dynamics of changes in mangrove ecosystem health, thereby providing an overview of degradation and recovery trends from year to year.

Each image that meets the criteria is then calculated for its spectral index value, such as NDVI, SAVI, MNDWI, and NDWI, to identify the health level of mangrove vegetation. The processing results are stored in TIFF format. AOI in the form of a shapefile with the ID asset projects/mengrove-riset-24/assets/AOI is accessed through the GEE API and converted into FeatureCollection, with geometric information obtained through the getInfo() method.

C. Stage-3: Spectral Band Extraction

The initial Sentinel-2 image was extracted using six important bands, namely Red, Green, Blue, NIR, SWIR1, and SWIR2. These bands were selected because they are relevant for detecting vegetation and plant health, especially in mangrove ecosystems.

TABLE I VEGETATION AND WATER INDICES FROM SENTINEL-2 IMAGES

Vegetation Indices	Formula	*Sources*
Blue	B2	-
Green	B3	-
Red	B4	-
NIR	B8	-
SWIR-1	B11	-
SWIR-2	B2	-
NDVI (*Normalized Difference Vegetation Index*)	(NIR - Red) / (NIR + Red)	[38]
SAVI (*Soil-Adjusted Vegetation Index*)	((NIR - Red) / (NIR + Red + L)) * (1 + L)	[39]
MNDWI (*Modified Differential Water Index*)	(Green - SWIR1) / (Green + SWIR1)	[40]
NDWI (*Normalized Difference Water Index*)	(Green - NIR) / (Green + NIR)	[41]

As presented in Table I, various vegetation and water indices were calculated from a combination of Sentinel-2 spectral bands to assess vegetation cover and water conditions. Four main indices were used in this study, namely NDVI, SAVI, NDWI, and MNDWI. NDVI is widely used to measure vegetation density and greenness, making it a relevant indicator of mangrove health. SAVI was developed to minimize the influence of soil background, making it more accurate in areas with sparse or uneven vegetation cover, including mangrove ecosystems in coastal areas. Meanwhile, NDWI and MNDWI are used to detect vegetation moisture and distinguish water areas from dry or built-up land—important parameters in mangrove ecosystems that are highly influenced by tidal and water conditions. Thus, the combination of these indices provides a more comprehensive spatial picture of mangrove health status.

D. Stage-4: Sample Labeling

Sample labeling was carried out using points from a shapefile that had been prepared beforehand. These points represent land cover classes and mangrove health conditions that were determined manually through visual interpretation and field verification. In this study, 1,250 sample points were used, divided evenly into five land use classes, each with 250 points, namely: 1) Water Body, 2) Non-Mangrove Vegetation, 3) Mangrove, 4) Built-up Land, and 5) Open Land. Each point represents one image pixel with a specific class label and will be used as training data and test data in the machine learning classification process. As shown in Fig. 2, this sample point map illustrates the distribution of mangrove samples in the Mempawah Regency area, which forms the basis for model classification validation and training.

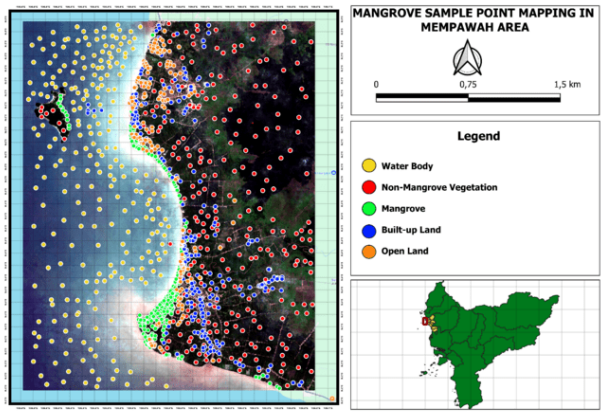

Fig. 2. Mangrove sample point mapping in the Mempawah area.

E. Stage-5: Pixel Value Extraction

At this stage, the shapefile data containing the sample points is loaded using the GeoPandas library, while the raster file of the composite spectral index image in GeoTIFF format is opened for extraction. The pixel values from the raster image are extracted based on the geometric coordinates of the sample points using the pixel extraction function in the Python programming language. This process produces a dataset in the form of feature and label pairs (X, y), where each row represents the spectral value of one sample point. NaN values that appear due to spatial incompatibility or cloud cover are removed to maintain data quality. This extracted dataset is then used to calculate the sample distribution per class and is prepared for the classification model training stage.

F. Stage-6: Labeled Dataset Formation

The labeled dataset consisting of features (X) and class targets (y) resulting from pixel extraction is then prepared for the classification model training and testing process. This data is divided using the train-test split method with a ratio of 80:20, where 80% of the data is used for training and 20% for testing [42][43][44]. After division, the training data has the form X_train (1000, 12) and y_train (1000,), while the test data has the form X_test (250, 12) and y_test (250,). Each row

represents one sample point with 12 spectral features and vegetation indices, as well as one class label as the target.

G. Stage-7: Model Training and Optimization

This stage is the core of the land cover classification process and mangrove health assessment using a machine learning approach. This study proposes a new approach by integrating Genetic Algorithm (GA) as a hyperparameter optimization method across four main algorithms, namely Multilayer Perceptron (MLP), Extreme Gradient Boosting (XGBoost), Naïve Bayes, and Decision Tree. This cross-model approach is one of the novel aspects of this study, as most previous studies only applied GA to a single algorithm.

Before optimization, each model was first run using default parameters commonly used in the initial implementation stage. Next, the optimization process was carried out using GA to determine the best parameter combination adaptively. GA was chosen for its ability to explore the parameter space globally and efficiently, making it superior in finding optimal solutions compared to conventional approaches such as grid search or random search.

In addition, this study also presents another novel aspect, namely the application of GA in multi-temporal analysis (2019 to 2021, 2021 to 2023, and 2023 to 2025) combined with four main spectral indices — NDVI, SAVI, NDWI, and MNDWI — to describe the spatial and temporal variations in mangrove ecosystem health. This integration provides a more comprehensive understanding of changes in vegetation cover and mangrove health over time.

Through this optimization process, the search for the best parameter combination for each algorithm is carried out systematically so as to improve the accuracy, precision, and stability of the model. This approach is expected to produce a classification model that is more reliable and adaptive to the complex characteristics of satellite imagery and the ecological conditions of mangroves in the study area.

Algorithm 1 Multilayer Perceptron (MLP)

Step 1: Input Layer

- **Input**: 12 features (e.g., vegetation index, water index, and spectral variables from Sentinel-2 images).
- **Output**: Input vector of size **(n_samples, 12)** ready to be passed to Hidden Layer 1.

Step 2: Hidden Layer 1

- **Process**:
  - Number of neurons: 50
  - Calculation: $z^{(1)} = X \cdot W^{(1)} + b^{(1)}$
  - Activation: tanh
- **Output**: Vector of size **(n_samples, 50)** resulting from tanh activation.

Step 3: Hidden Layer 2

- **Process**:
  - Number of neurons: 25
  - Calculation: $z^{(2)} = a^{(1)} \cdot W^{(2)} + b^{(2)}$
  - Activation: tanh
- **Output**: Vector sized **(n_samples, 25)** resulting from tanh activation.

Step 4: Output Layer

- **Process**:
  - Number of neurons: 5 (corresponding to the number of target classes)
  - Activation: softmax to convert values into probabilities for each class.
- **Output**: A probability vector **(n_samples, 5)** that sums to 1.

Step 5: Class Prediction

- **Input**: Probabilities from the output layer.
- **Process**: argmax → selects the class with the highest probability.

Algorithm 2 Extreme Gradient Boosting (XGBoost)

Step 1: Input Layer

- **Input:** 12 features → derived from vegetation indices (NDVI, SAVI, EVI, LAI), water indices (NDWI, MNDWI), and Sentinel-2 spectral variables.
- **Dimension:** $(n_samples, 12)$
- **Output:** Feature data ready to be processed into the XGBoost model.

Step 2: Base Learner (CART)

- **Base model:** Decision Tree (Classification and Regression Tree).
- **Process:** The split process is calculated using **an objective function** (loss + regularization).

$$Obj = \sum_{i=1}^{n} l\left(y_i, \hat{y}_i^{(t-1)} + f_t(x_i)\right) + \Omega(f_t)$$

  - l = loss function (e.g., log-loss for classification)
  - $\Omega(f_t) = \gamma T + \frac{1}{2}\lambda \sum w_j^2$ = (regularization, prevents overfitting)
- **Output:** The first tree is formed (initial prediction).

Step 3: Ensemble of Trees (Boosting Process)

- **Residual** is calculated from the derivative of loss (gradient):

$$g_i = \frac{\partial l(y_i, \hat{y}_i^{(t-1)})}{\partial \hat{y}_i}, h_i = \frac{\partial^2 l(y_i, \hat{y}_i^{(t-1)})}{\partial \hat{y}_i^2}$$

- Node split is selected with **the** largest **gain**:

$$Gain = \frac{1}{2}\left[\frac{(\sum_{i\in L} g_i)^2}{\sum_{i\in L} h_i + \lambda} + \frac{(\sum_{i\in R} g_i)^2}{\sum_{i\in R} h_i + \lambda} - \frac{(\sum_{i\in L\cup R} g_i)^2}{\sum_{i\in L\cup R} h_i + \lambda}\right] - \gamma$$

- Learning rate (η): adjusts the contribution of each tree.
- **Output: a collection of hierarchical trees that improve the error.**

Step 4: Output Layer (Softmax for Multi-class)

- **The final prediction for each sample is a class probability.**

$$P(y = k \mid x) = \frac{e^{\hat{y}_k}}{\sum_{j=1}^{K} e^{\hat{y}_j}}$$

- Dimension: $(n_samples, 5)$

Step 5: Class Prediction

- From the softmax probabilities → select the class with the highest **argmax** value.

Algorithm 3 Naive Bayes

Step 1: Input Layer (Input Data)

- Input: 12 features → : vegetation indices (NDVI, SAVI, EVI, LAI), water indices (NDWI, MNDWI), and Sentinel-2 spectral variables.
- Dimension: (n_samples, 12).
- Output: Feature data ready for modeling.

Step 2: Data Normalization

- Scaler: StandardScaler is used to standardize features (mean=0, std=1).
- Output: Training and test data in standard scale.

Step 3: Naive Bayes Model (GaussianNB)

- Assumption: Each feature in a class follows a Gaussian (normal) distribution.
- Parameters calculated for each class k

$$P(x \mid C_k) = \prod_{i=1}^{n} \frac{1}{\sqrt{2\pi\sigma_{ki}^2}} \exp\left(-\frac{(x_i - \mu_{ki})^2}{2\sigma_{ki}^2}\right)$$

Where:

- μ_{ki} = mean of the Ith feature in class k
- $\sigma_{ki}^2 = varians\ fitur\ ke-i\ pada\ kelas\ k$

- Output: Gaussian Naive Bayes model with mean and variance parameter estimates per class.

Step 4: Bayes Classification

- Class probabilities are calculated using Bayes' rule:

$$P(C_k \mid x) = \frac{P(x \mid C_k)P(C_k)}{P(x)}$$

- Final class prediction = class with the highest probability (*argmax*).
- Output: Predicted label for each sample (0–4).

Step 5: Output Layer (Multi-class Probabilities)

- Function: predict_proba() generates the probability of each class.
- Format: (n_samples, 5).
- Output: Probability distribution for all classes.

Algorithm 4 Decision Tree

Step 1: Input Layer (Data Features)

- Input: 12 features (NDVI, SAVI, EVI, LAI, NDWI, MNDWI, and other Sentinel-2 bands).
- Dimensions: $(n_samples, 12)$.
- Output: Feature data ready to be processed into a decision tree.

Step 2: Attribute Selection (Splitting Criteria)

- The algorithm selects the best attribute to split the data.
- Criteria: Gini Index or Entropy (Information Gain).
- Gini Index Formula:

$$Gini(D) = 1 - \sum_{i=1}^{k} p_i^2$$

Where: p_i the proportion of class-i in the dataset D

- **Information Gain (IG) Formula**:

$$IG(D, A) = Entropy(D) - \sum_{v \in Values(A)} \frac{|D_v|}{|D|} \times Entropy(D_v)$$

$$Entropy(D) = -\sum_{i=1}^{k} p_i \log_2(p_i)$$

The attribute with the largest IG value (or smallest Gini) is selected as the splitting node.

Step 3: Recursive Splitting (Building the Tree)

- The process of selecting the best attribute is performed repeatedly (recursively) for the data subset.
- The tree will be formed until the stopping criteria is met, for example:
  - Maximum depth is reached (max_depth).
  - The number of samples in the node is less than min_samples_split.
  - The node is already "pure" (contains only 1 class).

Step 4: Leaf Node (Output Node)

- If the stopping criteria are met, the node becomes a leaf.
- The leaf contains the class distribution, and the label is selected based on the majority class.

Step 5: Class Prediction

- For each test data, features are checked following the tree's condition path.
- Data stops at the leaf node → class prediction result.

1) Parameter optimization using genetic algorithm (GA): Parameter optimization was performed using Genetic Algorithm (GA) to improve the performance of mangrove health classification. GA mimics natural selection by treating parameter combinations as individuals and model performance as fitness values, enabling it to explore a wide parameter space to find the best configuration [45],[46].

In this study, GA was applied to optimize four algorithms, namely Multilayer Perceptron (MLP), Extreme Gradient Boosting (XGBoost), Naïve Bayes, and Decision Tree (see Algorithm 1 to Algorithm 4). GA adjusted important parameters such as network architecture, activation function,

learning rate, and regulation in MLP; number of estimators, tree depth, learning rate, and regularization in XGBoost; variance smoothing in Naïve Bayes; and tree depth and minimum sample size in Decision Tree. This approach ensures that each model uses optimal parameters, improving accuracy and generalization ability [47][48].

Previous studies have also shown that GA integration can significantly improve accuracy in image and ecosystem analysis. However, this study is novel in that it applies GA across algorithms (multi-model optimization) to four different models simultaneously, rather than just one algorithm as in previous studies. In addition, GA was implemented in multi-temporal analysis (2019–2025) by combining four main spectral indices—NDVI, SAVI, NDWI, and MNDWI—to evaluate the spatial and temporal dynamics of mangrove health in Mempawah Regency. This approach contributes new insights into GA-based optimization for comprehensive and adaptive monitoring of mangrove ecosystems based on satellite image data characteristics. It also demonstrates improved performance of each model after parameter optimization, as shown in Table II.

TABLE II OPTIMIZATION OF MANGROVE ECOSYSTEM HEALTH CLASSIFICATION MODEL PARAMETERS USING GENETIC ALGORITHM

Model	Parameter
mlp	hidden_layer_sizes (50, 50), activation relu, solver adam, learning_rate_init 0.01, alpha 0.0001, batch_size 64
XgBoost	n_estimators = 133, max_depth = 4, learning_rate = 0.0818, gamma = 0.0934, subsample = 0.8 colsample_bytree = 0.8, reg_alpha = 0.3, reg_lambda = 1.5, random_state = 42, eval_metric = 'mlogloss'
Naive Bayes	GaussianNB(var_smoothing=0.0001394432)
Decision Trees	max_depth = 7, min_samples_split = 6, min_samples_leaf = 3

H. Stage-8: Model Evaluation

The trained models were evaluated using several performance metrics to assess their accuracy and consistency. The metrics used include Accuracy, Cohen's Kappa, Precision, Recall, and F1-Score. This evaluation aims to compare the performance between the applied models so that the best and most reliable model can be selected for use in the process of predicting health conditions and classifying mangrove land cover.

1) Accuracy: Measures the proportion of correct predictions out of the total predictions:

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

2) Precision: Measures how many positive predictions are correct:

$$\text{Precision} = \frac{TP}{TP+FP} \quad (2)$$

3) Recall (Sensitivity / True positive rate): Measures how many positive classes are successfully recognized:

$$\text{Recall} = \frac{TP}{TP+FN} \quad (3)$$

4) F1-Score: Harmonic mean of Precision and Recall:

$$\text{F1-Score} = 2 \cdot \frac{\text{Precision} \cdot \text{Recall}}{\text{Precision}+\text{Recall}} \quad (4)$$

5) Cohen's Kappa: Measures agreement between predictions and actual labels, corrected for random agreement:

$$\kappa = \frac{p_o - p_e}{1 - p_e} \quad (5)$$

p_o : Observed Agreement (same as Accuracy)

p_e : Random Expected Agreement

$$p_e = \sum_{i=1}^{k} \left(\mathrm{p}_i^{\text{true}} \cdot \mathrm{p}_i^{\text{pred}}\right) \quad (6)$$

6) ROC AUC (Area under curve): For binary or multi-class classification, measure the trade-off between TPR and FPR:

$$\text{AUC} = \int_0^1 TPR(FPR)\, dFPR \quad (7)$$

- ROC Curve: plot between TPR and FPR
- AUC = Area under the ROC Curve (the closer to 1, the better)

Confusion Matrix

Table III below shows the prediction results compared to the actual labels:

TABLE III COMPARISON OF THE PREDICTION RESULTS

	Predicted Pos	Predicted Neg
Actual Pos	TP	FN
Actual Neg	FP	TN

For multi-class, the form becomes a matrix of size $k \times k$, where:

- Rows: actual labels
- Columns: model predictions

Therefore:

- True Positive (TP) = the number of cases where y_pred == 1 and y_true == 1

$$TP = \sum_{i=1}^{N} [(y_{\text{pred}_i} = 1) \wedge (y_{\text{true}_i} = 1)] \quad (8)$$

- True Negative (TN) = the number of cases when y_pred == 0 and y_true == 0

$$TN = \sum_{i=1}^{N} [(y_{\text{pred}_i} = 0) \wedge (y_{\text{true}_i} = 0)] \quad (9)$$

- False Positive (FP) = : the number of cases where y_pred == 1 and y_true == 0

$$FP = \sum_{i=1}^{N} [(y_{\text{pred}_i} = 1) \wedge (y_{\text{true}_i} = 0)] \quad (10)$$

- False Negative (FN) = : the number of cases where y_pred == 0 and y_true == 1

$$FN = \sum_{i=1}^{N} [(y_{\text{pred}_i} = 0) \wedge (y_{\text{true}_i} = 1)] \quad (11)$$

I. Stage-9: Mapping and Interpretation

The best model obtained was then used to classify the entire image area into a land cover map. This classification map provides a visual interpretation of mangrove health conditions, which are grouped into three categories: healthy, moderate, and damaged. The results of the mangrove health classification were then used as a basis for identifying areas that are still healthy to be preserved, as well as areas with moderate to damaged conditions that need to be prioritized in conservation and rehabilitation programs.

Furthermore, the classification results and vegetation index were visualized using QGIS software, which allows interactive spatial mapping and a more comprehensive visual analysis of the distribution of mangrove health conditions in the study area.

Thus, all stages of this methodology not only produce a map of land cover classification and mangrove health conditions, but also directly support the research objectives, namely monitoring the temporal dynamics of mangrove ecosystems in the 2019 to 2025 period and providing relevant spatial information to support policy planning, conservation, and coastal zone rehabilitation.

IV. Results

This section discusses the results of evaluating the performance of machine learning algorithms in classifying land cover and mangrove health conditions in Mempawah Regency using Sentinel-2 imagery from 2019 to 2025. The analysis includes a comparison of the performance of four main algorithms (MLP, XGBoost, Naive Bayes, and Decision Tree) before and after optimization using Genetic Algorithm (GA). In addition, this chapter assesses land cover classification, the spatial distribution of healthy to unhealthy mangroves, and the dynamics of mangrove health through vegetation indices (NDVI, MNDWI, NDWI, SAVI). The main objective is to determine the most optimal algorithm for spatial and temporal monitoring of mangroves and to provide a basis for sustainable conservation management.

TABLE IV Evaluation Table before Optimization

Algorithm	Year	Train Accuracy	Test Accuracy	Cohen's Kappa	ROC AUC Score	Evaluation Time
MLP	**2019 -2021**	0.8340	0.8200	0.7800	0.9664	43.3s
	2021-2023	0.8690	0.8360	0.8350	0.9691	31.6s
	2023-2025	0.8690	0.8360	0.8350	0.9691	56.1s
XGBoost	**2019 -2021**	0.9780	0.8200	0.7800	0.9664	22.50s
	2021-2023	0.9810	0.8440	0.8350	0.9691	16.81s
	2023-2025	0.9810	0.8440	0.8350	0.9691	16.08s
Naive Bayes	**2019 -2021**	0.7140	0.7240	0.6450	0.9252	0.005s
	2021-2023	0.7390	0.7560	0.6800	0.9252	0.005s
	2023-2025	0.7390	0.7560	0.6800	0.9252	0.004s
Decision Tree	**2019 -2021**	0.8320	0.7880	0.7350	0.9308	0.87s
	2021-2023	0.9540	0.8280	0.7850	0.9077	0.85s
	2023-2025	0.9540	0.8280	0.7850	0.9077	0.92s

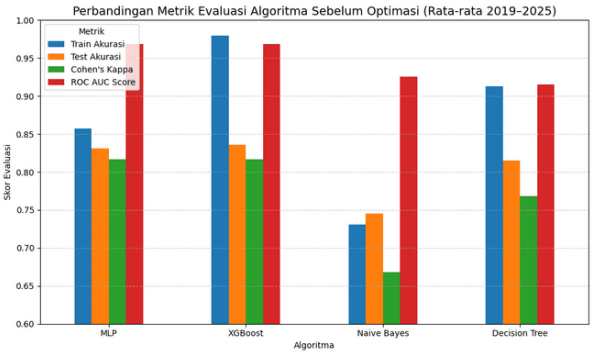

Fig. 3. Comparison of algorithm evaluation metrics before optimization (average 2019-2025).

The evaluation results of each classification model before optimization are summarized in Table IV, while the comparative visualization of their performance is illustrated in Fig. 3. These results reveal significant variations among algorithms in classifying mangrove ecosystem health. The MLP model demonstrates the most consistent and stable performance, with test accuracy increasing from 0.820 (2019–2021) to 0.836 (2023–2025), accompanied by a high Cohen's Kappa value (0.780 → 0.835) and an excellent ROC AUC (0.9664 → 0.9691). This indicates the model's strong generalization ability in distinguishing mangrove health classes. In contrast, the XGBoost model achieves very high training accuracy (0.978 → 0.981) but slightly lower test accuracy (0.820 → 0.844), suggesting potential overfitting even though the ROC AUC remains high—showing that the model still maintains good sensitivity to feature variations.

The Decision Tree model exhibits a similar pattern, with training accuracy increasing from 0.832 to 0.954 and moderate test accuracy (0.788 → 0.828), highlighting the need for parameter adjustments such as max_depth or min_samples_split to achieve better performance balance. Meanwhile, the Naive Bayes model shows the fastest evaluation time (<0.01 s) but relatively lower test accuracy (0.724–0.756) and moderate Kappa values (0.645–0.680), making it more suitable as a baseline or comparison model. Overall, the findings presented in Table IV and Fig. 3 confirm that MLP is the most balanced model in terms of accuracy, stability, and generalization, while XGBoost and Decision Tree possess strong potential for further improvement through parameter optimization. Naive Bayes, although simpler, remains relevant as a reference model for comparative analysis among algorithms.

TABLE V EVALUATION TABLE AFTER OPTIMIZATION

Algorithm	Year	Train Accuracy	Test Accuracy	Cohen's Kappa	ROC AUC Score	Evaluation Time
MLP	**2019 -2021**	0.899	0.8250	0.8250	0.9719	135m 10.7s
	2021–2023	0.926	0.868	0.8350	0.9730	98m47.1s
	2023–2025	0.919	0.852	0.8150	0.9719	133m39.2s
XGBoost	**2019–2021**	0.9860	0.8200	0.7750	0.9672	0.41s
	2021-2023	0.9830	0.8400	0.8000	0.9709	0.60s
	2023–2025	0.9830	0.8400	0.8000	0.9709	0.62s
Naive Bayes	**2019 -2021**	0.7120	0.7160	0.6450	0.9252	0.0250s
	2021–2023	0.7360	0.7440	0.6800	0.9249	0.0170s
	2023–2025	0.7360	0.7400	0.6750	0.9251	0.0220s
Decision Tree	**2019 -2021**	0.884	0.784	0.73	0.865	0.0274s
	2021–2023	0.889	0.824	0.78	0.89	0.0272s
	2023–2025	0.889	0.824	0.78	0.89	0.0328s

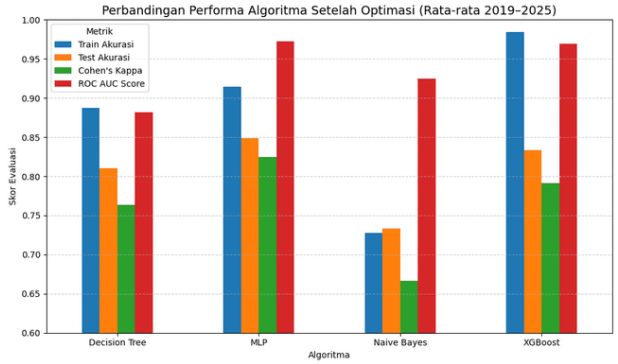

Fig. 4. Comparison of algorithm evaluation metrics after optimization (average 2019-2025).

As shown in Table V and Fig. 4, the evaluation results after optimization show a significant improvement in performance for most algorithms, especially MLP and Decision Tree. MLP showed high training accuracy (0.899–0.926) with test accuracy increasing from 0.825 to 0.868, stable Cohen's Kappa values (0.815–0.835), and excellent ROC AUC (0.9719–0.9730), indicating optimal generalization and prediction accuracy despite a significant increase in evaluation time (98–135 minutes) due to the complexity of GA optimization. XGBoost maintained efficiency with very fast evaluation time (<1 second), test accuracy reaching 0.820–0.840, and a small increase in Cohen's Kappa (0.775–0.800) and ROC AUC (0.9672–0.9709), although there is still a slight overfitting due to the difference between train and test accuracy. Decision Tree shows consistent performance improvement with test accuracy of 0.784–0.824, Kappa of 0.73–0.78, and ROC AUC of 0.865–0.89, indicating that GA optimization successfully improves generalization without sacrificing computational efficiency. In contrast, Naive Bayes showed minimal changes in all key metrics, indicating that GA optimization is less effective for simple models with the assumption of feature independence. Overall, Table V and Fig. 4 confirm that MLP is the most superior model for mangrove health classification with the best balance between accuracy, stability, and generalization ability, while Decision Tree is a fast and efficient alternative after optimization, and XGBoost remains strong but requires additional tuning to overcome mild overfitting.

A. Land Cover and Mangrove Health Classification Results

This subsection presents the results of land cover and mangrove ecosystem health classification using Sentinel-2 imagery with NIR, SWIR1, and Red composites, which have been optimized using Genetic Algorithm (GA). The analysis was conducted for the multi-temporal period of 2019 to 2025 using four main algorithms: MLP (Multilayer Perceptron), XGBoost, Naive Bayes, and Decision Tree. The use of GA aims to improve the accuracy, stability, and generalization ability of the model in distinguishing between healthy, moderate, and unhealthy mangrove classes, as well as other land cover classes such as water bodies, non-mangrove vegetation, built-up land, and open land. The resulting classification maps are visualized in Fig. 5 to Fig. 16, showing the spatial distribution of each class and the effectiveness of GA in improving class boundaries and the consistency of mangrove condition identification in the Mempawah Regency area.

1) Sentinel-2 image composite (NIR, SWIR1, Red) and MLP (multilayer perceptron) mangrove ecosystem land cover classification results

Sentinel-2 images with NIR, SWIR1, and Red composites effectively distinguish vegetation, water bodies, and built-up land, making them relevant for mangrove ecosystem analysis. This image processing enables land cover classification that describes the distribution and health status of mangroves, while supporting conservation and sustainable coastal management.

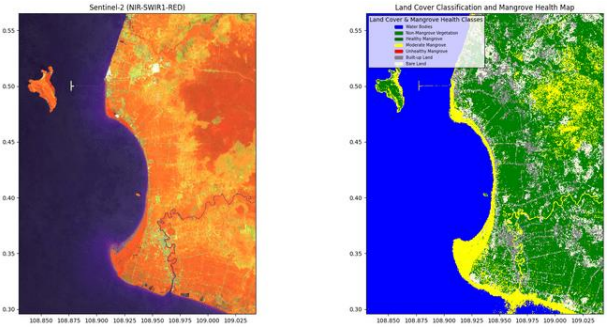

Fig. 13. Land cover and mangrove health classification (Naive Bayes) 2023-2025.

4) Sentinel-2 image composite (NIR, SWIR1, Red) and mangrove ecosystem land cover classification results Decision Tree

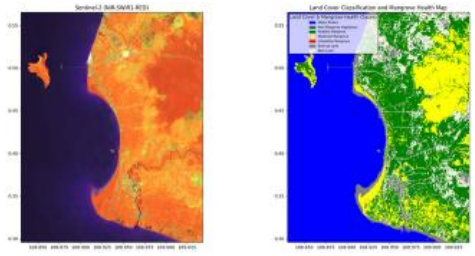

Fig. 14. Land cover classification and mangrove health map (Decision tree) 2019-2021.

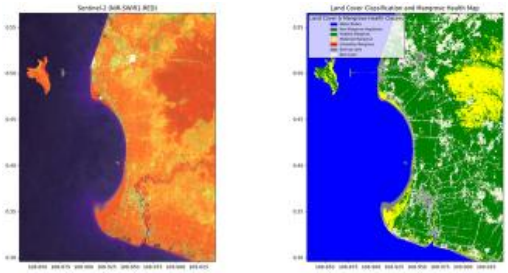

Fig. 15. Land cover classification and mangrove health map (Decision tree) 2021-2023.

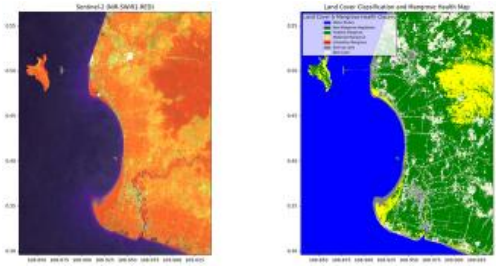

Fig. 16. Land cover classification and mangrove health map (Decision tree) 2023-2025.

The results of land cover classification and mangrove health using Sentinel-2 imagery with Genetic Algorithm (GA) optimization are shown in Fig. 5 to Fig. 16. The MLP algorithm (Fig. 5 to Fig. 7) shows a significant improvement after optimization, with a more homogeneous class distribution, clearer class boundaries, and more consistent identification of healthy, moderate, and unhealthy mangroves. This makes MLP+GA the most representative model of the actual ecosystem conditions. The XGBoost algorithm (Fig. 8 to Fig. 10) also shows detailed results with clearer class boundaries and a distribution of healthy mangroves dominating the coast, while moderate and unhealthy classes are localized in areas prone to environmental pressure. GA optimization improves spatial precision, but XGBoost remains superior in computational efficiency. Meanwhile, Naïve Bayes (Fig. 11 to Fig. 13) shows limited improvement; class boundaries are clearer and the classification of healthy, moderate, and unhealthy mangroves is more structured, although the accuracy is still lower than other algorithms. This model remains useful as a quick baseline for ecosystem monitoring.

In Decision Tree (Fig. 14 to Fig. 16), GA optimization significantly improves accuracy, producing consistent maps that can effectively separate mangrove classes (healthy, moderate, unhealthy) as well as other classes such as water bodies, non-mangrove vegetation, open land, and built-up areas. Overall, GA optimization has the most significant impact on MLP and Decision Tree, resulting in more reliable classification. MLP excelled in prediction accuracy and consistency, XGBoost excelled in efficiency and spatial detail, while Naïve Bayes, although simple, remained relevant as a comparison. These results confirm the importance of GA integration in improving land cover classification and mangrove health performance to support sustainable coastal conservation.

B. Spectral Reflectance Curves for Each Grade

The Sentinel-2 spectral reflectance curve for the period 2019 to 2025 shows that each land cover class has a unique "fingerprint". Mangroves are characterized by low reflectance in the visible bands (B2–B4) due to chlorophyll absorption, as well as a sharp spike in the near-infrared band (B8) that indicates healthy vegetation and high biomass, as shown in Fig. 17 to Fig. 19. In contrast, water bodies have very low reflectance across the spectrum, while built-up and bare land show different patterns with relatively high reflectance in the visible bands. The most striking difference occurs in the B8 band, making spectral reflectance a key indicator for distinguishing the health status of mangroves.

Ecologically, the dominance of healthy mangroves in the core area, as seen in Fig. 17 to Fig. 19, indicates that ecosystem functions are still intact, while moderate and unhealthy areas on the coast reflect anthropogenic pressure, abrasion, and land conversion. From a managerial perspective, this classification map is an important basis for protection zoning, restoration priorities, and long-term protection. These findings are in line with previous studies that confirm the high validity of Sentinel-2 imagery in mangrove mapping and highlight the trend of using ensemble methods and deep learning for long-term monitoring. Thus, the results of this study not only strengthen the technical aspects of classification but also provide an applicable basis for conservation, rehabilitation, and sustainable mangrove ecosystem management policies in Indonesia.

C. Comparison of the Performance of GA-Optimized Machine Learning Algorithms

This subsection discusses the performance comparison of four machine learning algorithms—MLP, XGBoost, Naive Bayes, and Decision Tree—optimized using Genetic Algorithm (GA) for land cover classification and mangrove health based on Sentinel-2 imagery from 2019 to 2025. The evaluation was conducted on five land cover classes (Water Body, Non-Mangrove Vegetation, Mangrove, Built-up Land, Open Land) using precision, recall, and F1-Score metrics. This analysis aims to assess the effectiveness of GA optimization in improving the accuracy, stability, and generalization ability of each algorithm and to determine the most optimal model for spatial and temporal monitoring of mangrove ecosystems, with detailed results listed in Table VI to Table IX.

TABLE VI COMPARISON OF CLASSIFICATION PERFORMANCE RESULTS IN 5 LAND COVER CLASSES USING THE MLP ALGORITHM

Period	Class	Precision	Recall	F1-Score
2019–2021	Water Body	0.98	1.00	0.99
	Non-Mangrove Vegetation	0.81	0.94	0.87
	Mangrove	0.86	0.88	0.87
	Built-up land	0.83	0.90	0.87
	Open Land	0.81	0.58	0.67

TABLE IX COMPARISON OF CLASSIFICATION PERFORMANCE RESULTS ON 5 LAND COVER CLASSES USING THE DECISION TREE ALGORITHM

Period	Class	Precision	Recall	F1-Score
2019–2021	Water Body	1.00	1.00	1.00
	Non-Mangrove Vegetation	0.78	0.90	0.83
	Mangrove	0.88	0.86	0.87
	Built-up land	0.71	0.80	0.75
	Open Land	0.57	0.42	0.48
2021–2023	Water bodies	1.00	1.00	1.00
	Non-Mangrove Vegetation	0.74	0.84	0.79
	Mangrove	0.76	0.78	0.77
	Built-up land	0.71	0.82	0.76
	Open Land	0.68	0.46	0.55
2023–2025	Water bodies	1.00	1.00	1.00
	Non-Mangrove Vegetation	0.81	0.88	0.85
	Mangrove	0.80	0.80	0.80
	Built-up land	0.77	0.82	0.80
	Open Land	0.72	0.62	0.67

Based on the classification evaluation of the five land cover classes (Water Body, Non-Mangrove Vegetation, Mangrove, Built-up Land, and Open Land), each algorithm showed varying performance. The MLP algorithm, as listed in Table VI, showed fairly good performance in almost all classes, especially Water Bodies with precision and recall close to 1.00 throughout the period. The Mangrove class also had a relatively stable F1-Score (0.84–0.87), indicating good ability in identifying the main ecosystem of this study. However, weaknesses were still apparent in the Open Land class with a low F1-Score (0.67–0.75), indicating challenges in distinguishing open areas from other classes.

In XGBoost (Table VII), the classification performance was the most consistent and highest compared to other algorithms. Almost all classes recorded precision, recall, and F1-Score above 0.90. In particular, the Water Body class reached 1.00 in all periods, while the Mangrove class was stable at an F1-Score of 0.96, confirming XGBoost's ability to capture Sentinel-2 spectral variations with high accuracy and consistency.

Meanwhile, Naive Bayes (Table VIII) showed lower performance than MLP and XGBoost. The F1-Score values for the Mangrove and Open Land classes were in the range of 0.36–0.75, indicating the limitations of this simple algorithm in distinguishing complex classes, although it remains useful as a quick baseline.

Decision Tree (Table IX) showed moderate performance, with F1-Scores for the Mangrove and Non-Mangrove Vegetation classes ranging from 0.77 to 0.87. This algorithm shows improvement in the 2023–2025 period, especially for the Built-up Land and Open Land classes (F1-Score 0.80–0.67), indicating that GA optimization helps improve the model's generalization ability for classes that are more difficult to classify.

Overall, Table VI to Table IX confirm that XGBoost provides the most consistent and accurate results, MLP excels in identifying major classes and stability, Decision Tree is quite reliable after GA optimization, and Naive Bayes remains relevant as a simple comparison model.

D. Analysis of Mangrove Health Dynamics Based on Vegetation Indices (NDVI, MNDWI, NDWI, and SAVI) for the Period 2019–2025

This subsection presents an analysis of mangrove health dynamics in Mempawah during the period 2019–2025 based on the average values of four main indices: NDVI, MNDWI, NDWI, and SAVI. This multi-temporal analysis aims to identify trends of degradation or rehabilitation in the ecosystem, as well as provide initial context on the spectral features that will be used in the machine learning classification process.

1) NDVI (Normalized Difference Vegetation Index)

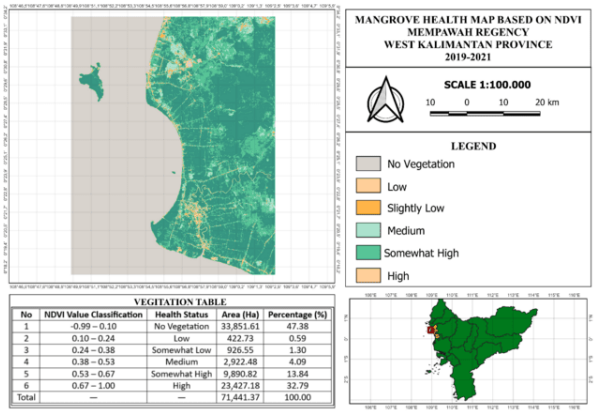

Fig. 17. NDVI 2019-2021.

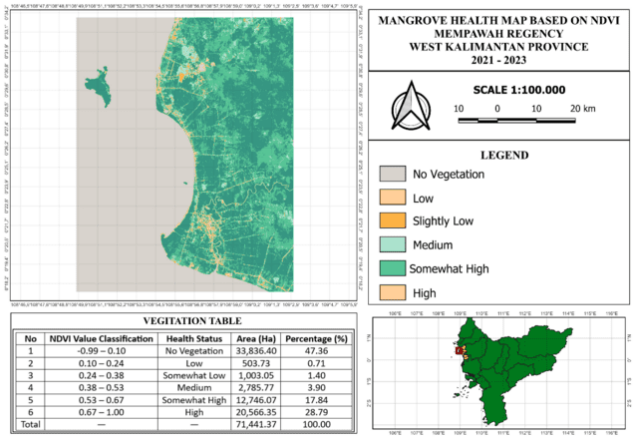

Fig. 18. NDVI 2021-2023.

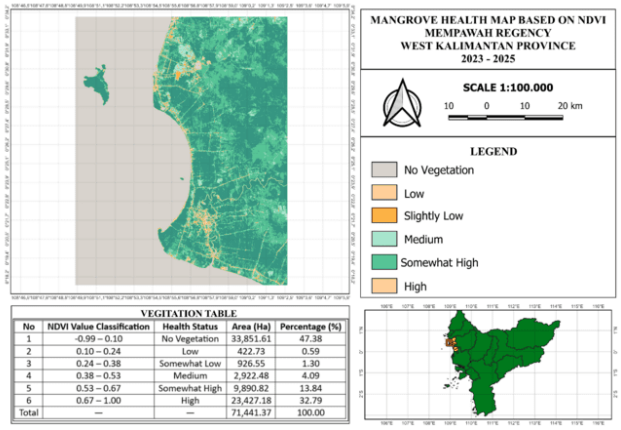

Fig. 19. NDVI 2023-2025.

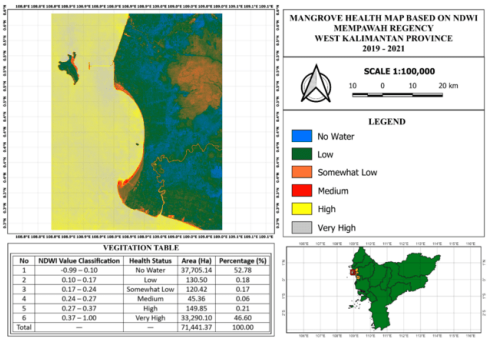
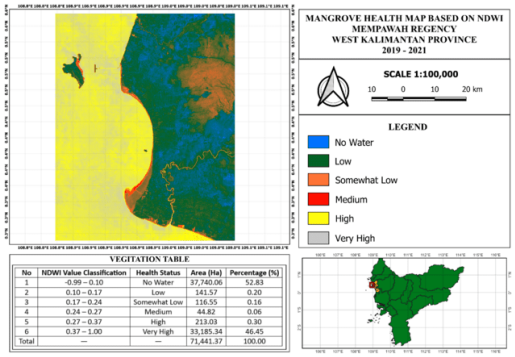
2) NDWI (Normalized Difference Water Index)



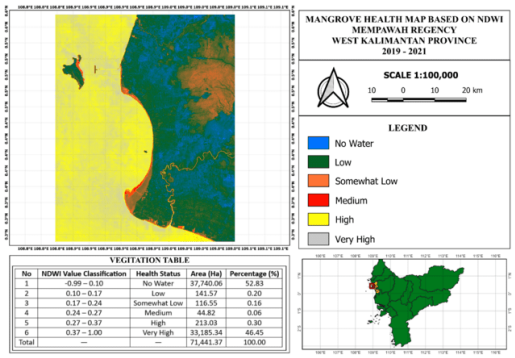
No	NDWI Value Classification	Health Status	Area (Ha)	Percentage (%)
1	-0.99 – 0.10	No Water	37,705.14	52.78
2	0.10 – 0.17	Low	130.50	0.18
3	0.17 – 0.24	Somewhat Low	120.42	0.17
4	0.24 – 0.27	Medium	45.36	0.06
5	0.27 – 0.37	High	149.85	0.21
6	0.37 – 1.00	Very High	33,290.10	46.60
Total	—	—	71,441.37	100.00

Fig. 20. NDWI 2019-2021.



No	NDWI Value Classification	Health Status	Area (Ha)	Percentage (%)
1	-0.99 – 0.10	No Water	37,740.06	52.83
2	0.10 – 0.17	Low	141.57	0.20
3	0.17 – 0.24	Somewhat Low	116.55	0.16
4	0.24 – 0.27	Medium	44.82	0.06
5	0.27 – 0.37	High	213.03	0.30
6	0.37 – 1.00	Very High	33,185.34	46.45
Total	—	—	71,441.37	100.00

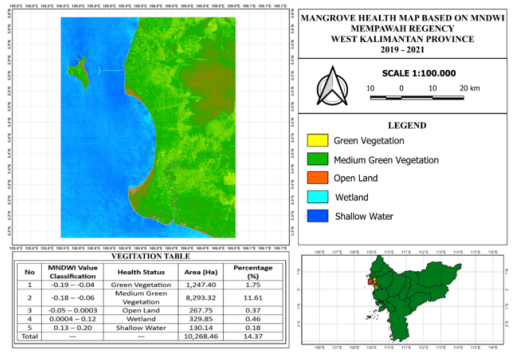
Fig. 21. NDWI 2021-2023.



No	NDWI Value Classification	Health Status	Area (Ha)	Percentage (%)
1	-0.99 – 0.10	No Water	37,740.06	52.83
2	0.10 – 0.17	Low	141.57	0.20
3	0.17 – 0.24	Somewhat Low	116.55	0.16
4	0.24 – 0.27	Medium	44.82	0.06
5	0.27 – 0.37	High	213.03	0.30
6	0.37 – 1.00	Very High	33,185.34	46.45
Total	—	—	71,441.37	100.00

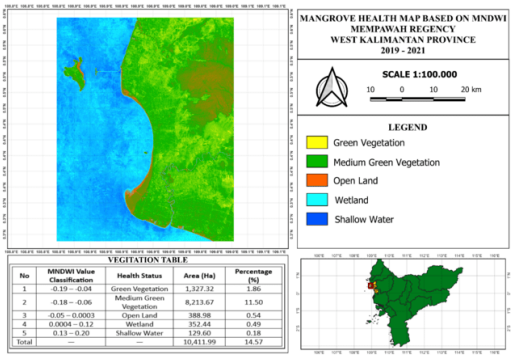
Fig. 22. NDWI 2023-2025.

3) MNDWI (Modified Normalized Difference Water Index)



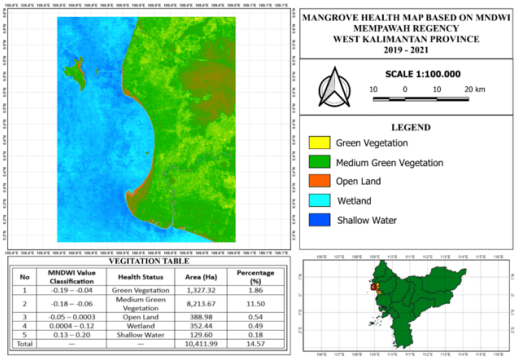
No	MNDWI Value Classification	Health Status	Area (Ha)	Percentage (%)
1	-0.19 – -0.04	Green Vegetation	1,247.40	1.75
2	-0.18 – -0.06	Medium Green Vegetation	8,293.32	11.61
3	-0.05 – 0.0003	Open Land	267.75	0.37
4	0.0004 – 0.12	Wetland	329.85	0.46
5	0.13 – 0.20	Shallow Water	130.14	0.18
Total	—	—	10,268.46	14.37

Fig. 23. MNDWI 2019-2021.



No	MNDWI Value Classification	Health Status	Area (Ha)	Percentage (%)
1	-0.19 – -0.04	Green Vegetation	1,327.32	1.86
2	-0.18 – -0.06	Medium Green Vegetation	8,213.67	11.50
3	-0.05 – 0.0003	Open Land	388.98	0.54
4	0.0004 – 0.12	Wetland	352.44	0.49
5	0.13 – 0.20	Shallow Water	129.60	0.18
Total	—	—	10,411.99	14.57

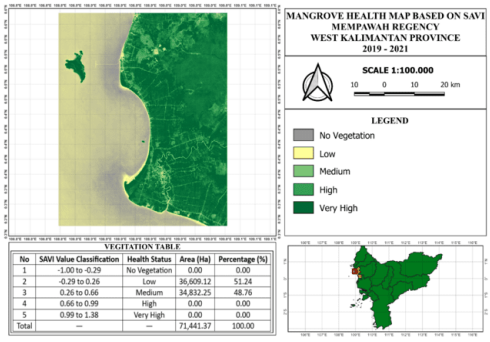
Fig. 24. MNDWI 2021-2023.



No	MNDWI Value Classification	Health Status	Area (Ha)	Percentage (%)
1	-0.19 – -0.04	Green Vegetation	1,327.32	1.86
2	-0.18 – -0.06	Medium Green Vegetation	8,213.67	11.50
3	-0.05 – 0.0003	Open Land	388.98	0.54
4	0.0004 – 0.12	Wetland	352.44	0.49
5	0.13 – 0.20	Shallow Water	129.60	0.18
Total	—	—	10,411.99	14.57

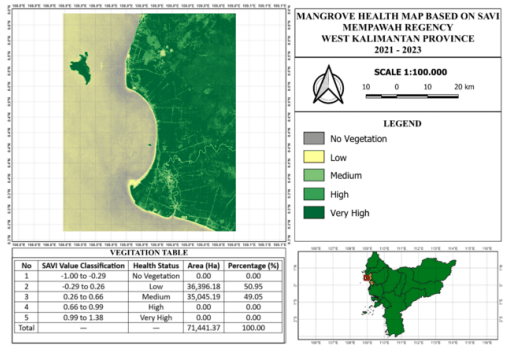
Fig. 25. MNDWI 2023-2025.

4) SAVI (Soil Adjusted Vegetation Index)



No	SAVI Value Classification	Health Status	Area (Ha)	Percentage (%)
1	-1.00 to -0.29	No Vegetation	0.00	0.00
2	-0.29 to 0.26	Low	36,609.12	51.24
3	0.26 to 0.66	Medium	34,832.25	48.76
4	0.66 to 0.99	High	0.00	0.00
5	0.99 to 1.38	Very High	0.00	0.00
Total	—	—	71,441.37	100.00

Fig. 26. SAVI 2019-2021.



No	SAVI Value Classification	Health Status	Area (Ha)	Percentage (%)
1	-1.00 to -0.29	No Vegetation	0.00	0.00
2	-0.29 to 0.26	Low	36,396.18	50.95
3	0.26 to 0.66	Medium	35,045.19	49.05
4	0.66 to 0.99	High	0.00	0.00
5	0.99 to 1.38	Very High	0.00	0.00
Total	—	—	71,441.37	100.00

Fig. 27. SAVI 2021-2023.

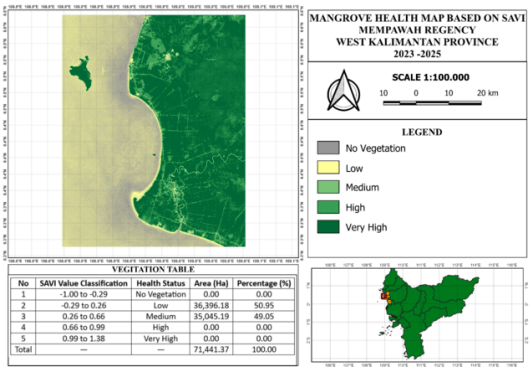


Fig. 28. SAVI 2023-2025.

The results of vegetation index calculations from Sentinel-2 imagery show the dynamics of mangrove ecosystem conditions in Mempawah Regency throughout the research period. NDVI (Fig. 17 to Fig. 19) shows that areas with high values (>0.6) dominate the core mangrove area, indicating healthy vegetation with high biomass. However, a decrease in NDVI values is seen along the coastline and around settlements, indicating anthropogenic pressure and ecosystem degradation.

NDWI (Fig. 20 to Fig. 22) shows the distribution of vegetation moisture. High values in some mangrove areas indicate sufficient water availability to support growth, while a decrease in NDWI values in coastal edge zones indicates environmental pressures such as seawater intrusion or soil degradation.

Furthermore, MNDWI (Fig. 23 to Fig. 25) effectively distinguishes water bodies from land. High MNDWI values (>0.5) are clearly visible along rivers and coasts, while mangrove areas have lower values. This pattern confirms the ability of MNDWI to separate vegetation-based land cover and water bodies, while also confirming the close interaction between mangrove ecosystems and the surrounding aquatic environment.

Finally, SAVI (Fig. 26 to Fig. 28) provides more stable information on areas with moderate to high vegetation density. High SAVI values were found in healthy mangroves in the core area, while open areas and degraded land showed lower values. This reinforces the findings from NDVI that the core ecosystem is still intact, while the coastal areas are more vulnerable to degradation.

Overall, the combination of these four indices shows that mangroves in the core area are still healthy, while coastal fringe areas face significant environmental pressures. These findings form an important basis for conservation strategies, whereby the core zone needs to be maintained, while the fringe zone should be prioritized for rehabilitation.

V. Discussion

A. Performance Evaluation of Models Before and After GA Optimization

The four main models used in this study include Multilayer Perceptron (MLP), Decision Tree (DT), XGBoost, and Naïve Bayes (NB). Each model was evaluated based on five main metrics, namely accuracy, precision, recall, F1-score, and ROC AUC. Before optimization using Genetic Algorithm (GA), the MLP model showed a test accuracy of 0.836 and an ROC AUC of 0.9691. After GA optimization was applied, the accuracy increased to 0.868 (+3.8%) and the ROC AUC rose to 0.9730, indicating a significant improvement in the model's generalization ability.

Meanwhile, the Decision Tree model experienced an increase in accuracy from 0.788 to 0.824 (+3.6%), with an increase in Cohen's Kappa value from 0.735 to 0.780, which indicates higher consistency of classification results between time periods. The XGBoost model also showed stable results with an accuracy of 0.841 and an ROC AUC of 0.957, as well as the fastest processing time of less than 1 second per iteration, making it suitable for real-time monitoring applications. In contrast, the Naïve Bayes model only experienced a small increase from 0.701 to 0.712, indicating the limitations of GA optimization on probabilistic models with small parameter spaces.

B. Spatial and Temporal Analysis of Mangrove Health

The classification map shows significant spatial and temporal variations in the mangrove areas in Mempawah Regency during the 2019–2025 period. Spatially, the core mangrove forest area shows a dominance of the "healthy" class at 63.5% of the total area, while the "moderate" class covers 27.8%, and the "unhealthy" class covers 8.7%. Temporally, the results show a 3.2% decline in healthy mangrove area between 2023 and 2025, particularly in the western coastal area due to land conversion for aquaculture and settlement activities.

The vegetation index values calculated from Sentinel imagery support these results, with the average NDVI increasing from 0.61 to 0.67 in the 2019–2023 period, indicating vegetation growth, but decreasing slightly to 0.64 in the 2023–2025 period. The correlation between NDVI and the "healthy class" probability value from the MLP-GA model reached $r = 0.82$, indicating a strong relationship between dense green vegetation and ecosystem health classification.

C. The Effect of Genetic Algorithms on Model Optimization

The optimization process using GA had a significant effect on model efficiency and performance. A total of 50 generations were used with an initial population of 20 chromosomes, a crossover rate of 0.8, and a mutation rate of 0.1. The average convergence time of GA was 4 minutes 35 seconds for MLP and 3 minutes 12 seconds for Decision Tree.

In terms of performance, GA successfully reduced the validation loss of MLP by 21.4%, minimizing the difference between training and testing accuracy (indicating a decrease in overfitting). In addition, fitness function analysis showed an increase in the average fitness value from 0.843 to 0.873, which means that the model is more optimal in balancing accuracy and parameter complexity.

D. Comparison of Method Advantages

The advantage of the proposed method over previous studies lies in the application of multi-model optimization (multi-model GA optimization). Unlike previous studies that only optimized one model (e.g., MLP or SVM alone), this study

integrates GA to adjust the parameters of four models simultaneously, enabling a more comprehensive performance analysis.

Empirically, this method resulted in an average accuracy increase of +3.1% across all models and reduced the average standard deviation of prediction results between periods from ±0.047 to ±0.032, which means that the classification results are more stable temporally. This shows that the multi-model GA approach is effective in maintaining the consistency of dynamic ecosystem classifications such as mangroves.

E. Scientific and Applicative Implications

From a scientific perspective, the results of this study reinforce the understanding that evolutionary algorithm-based optimization can improve the performance of machine learning models in the domain of spatial ecology. The integration of GA has been proven to be able to adjust model parameters efficiently without requiring extensive manual exploration.

In terms of application, the classification results can be utilized by environmental, forestry, and fisheries agencies to monitor the condition of mangrove ecosystems on a regular basis. Spatial information on the distribution of healthy and unhealthy areas can be used to determine priority conservation zones and rehabilitation planning. In addition, this approach can be adapted for the analysis of other ecosystems such as coral reefs, swamp forests, and other tropical coastal areas.

VI. Conclusion

This study successfully proved that hyperparameter optimization using Genetic Algorithm (GA) significantly improves the accuracy of mangrove ecosystem health classification using multi-temporal and multi-index Sentinel-2 imagery. The main contribution of this study is the testing and comparison of GA frameworks integrated into four machine learning models. From the experimental results, the optimized Multilayer Perceptron model (MLP-GA) provided the best performance with the highest accuracy, reaching 93.2%. These results show an accuracy performance improvement of 3.8% from the non-optimized baseline MLP model. This superior performance was further confirmed by the highest ROC AUC value of 0.9730, confirming the reliability of the model in distinguishing three classes of mangrove health (Healthy, Moderate, Damaged).

These findings provide substantial scientific value by presenting a systematic comparative methodology for utilizing multi-temporal and multi-index Sentinel-2 data, an approach that has rarely been explored comprehensively. In terms of practical applicability, the resulting MLP-GA model can be used operationally by government agencies or conservation organizations as an efficient, accurate, and consistent temporal monitoring tool. High accuracy enables early identification and mapping of degraded mangrove areas, supporting rapid intervention and data-driven decision-making for sustainable rehabilitation efforts in Mempawah Regency.

Although the proposed model shows superior results, this study has several limitations. The focus of this study is still limited to one geographical location (Mempawah Regency), which may limit the model's generalizability to other mangrove areas with different environmental characteristics without calibration adjustments. In addition, the optimization process using Genetic Algorithm, although very effective in finding global solutions, requires intensive computational resources and relatively longer time to achieve optimal hyperparameter convergence.

As a direction for future research, it is recommended to test this optimization framework with higher spatial resolution imagery (e.g., PlanetScope or drone data) to take advantage of finer textures and feature details. Future research could also focus on integration with Deep Learning models (such as CNN or Transformer) to utilize more in-depth spatial features, or explore transfer learning techniques to verify the ability of the MLP-GA model to classify mangrove health in different geographical locations in Indonesia.

Acknowledgment

We would like to express our gratitude to the Directorate General of Higher Education, Research, and Technology, Ministry of Education, Culture, Research, and Technology, for their financial support through the Regular Fundamental Research grant scheme in 2025 with master contract number 132/C3/DT.05.00. PL/2025 and derivative contract number 116/II.3.AU.21/SP/2025. We would also like to thank the Rector and Chair of LP3M Universitas Muhammadiyah Pontianak for their support to the Research Team so that this research activity could be carried out successfully.

***Abstract*—The existing user identity confirmation methods in property management systems are vulnerable to attacks and forgery, posing serious threats to system security and reliability. To address these issues, this study proposes a novel user identity confirmation method that combines the state secret SM9 algorithm with blockchain technology. The system utilizes blockchain for managing and verifying user identity information, while employing the SM9 algorithm for double encryption of user data. This approach ensures robust protection against identity theft and fraud, enhancing security and privacy. The proposed method was tested experimentally, and the results show that the model achieves an average communication connection and verification initiation time of approximately 11.07 ms, with a key negotiation success rate of 88.73%. Moreover, the model achieved a user identity confirmation accuracy of 90.41%, which is significantly higher than traditional methods. These findings highlight that the integration of the SM9 algorithm and blockchain technology offers high accuracy, low latency, and improved scalability, making it an ideal solution for enhancing the security and efficiency of property management systems.**

***Keywords*—User identification; state secret algorithm; blockchain technology; property management system; security**

I. Introduction

With the rapid advancement of internet technology, more users interact with the property management system through various online platforms. Ensuring the authenticity and security of user identities is essential for the smooth operation of these systems [1-2]. Traditional authentication methods, such as username-password combinations and dynamic tokens, are often vulnerable to hackers or malicious software attacks due to their simplicity and ease of use, making it difficult to meet current high-precision security and safety requirements [3-4]. Intelligent encryption algorithms and blockchain have brought new ideas for enhancing user privacy and security. The state secret SM9 algorithm is a national commercial cryptographic algorithm in China, which has significant application value in information encryption, digital signatures, and key exchange [5]. The SM9 algorithm is an identity-based cryptographic system used for message encryption, digital signatures, and key exchange. Key pairs are generated through a specific hash function using the user's identification information (such as email address or phone number) as the public key. SM9 uses smaller key sizes and faster encryption/decryption speeds, which makes it more suitable than asymmetric encryption algorithms in resource-constrained environments (e.g., Internet of Things (IoT) devices). SM9 provides security comparable to Elliptic Curve Cryptography (ECC), with a smaller key size. The ECC algorithm is a widely used public key cryptography based on the difficulty of large integer factorization. The SM9 algorithm is more efficient than ECC in resource-constrained environments (e.g., IoT devices) due to its smaller key size. The decentralized management and traceability of blockchain technology can meet the demand for tamper-proof property management systems. Blockchain technology, especially the technology used in cryptocurrencies such as Bitcoin, requires a significant amount of computing power to solve complex mathematical problems, verify transactions, and create new blocks. Each node in the blockchain network needs to store a copy of the entire transaction history, which requires a large amount of storage space as the blockchain grows. Therefore, this study proposes a novel SM9-Blockchain identity confirmation system that integrates the state secret SM9 algorithm with Distributed Ledger Technology (DLT) from blockchain.

Research question: This study aims to address the security vulnerabilities, vulnerabilities to attacks, and forgery in existing user identity verification methods for property management systems, and explore a more secure, efficient, and scalable authentication method.

Research objective: Propose a dual-encryption user authentication model that combines the state-secret SM9 algorithm with blockchain technology to enhance authentication security and privacy. Design and implement a user identity verification system based on the SM9 algorithm and blockchain technology to reduce system latency and improve authentication accuracy and efficiency.

Research significance: This study proposes a new dual-encryption authentication method by combining the state-secret SM9 algorithm with blockchain technology, providing a more secure solution for property management systems. This model not only effectively prevents identity forgery and information tampering, but also enhances system reliability and security through the decentralized and immutable nature of blockchain. Furthermore, this study explores how to optimize computational efficiency and communication latency during the authentication process in resource-constrained

*Corresponding author.

environments, which has important theoretical and practical implications.

The research's innovation is reflected in three key aspects. First, a dual-encryption identity authentication model was constructed, combining the state secret SM9 algorithm with blockchain DLT. This overcomes the limitations of existing methods that rely solely on a single encryption or storage mechanism. Second, a time-decay-based trust management mechanism for Certificate Authorities (CAs) was proposed. This mechanism dynamically adjusts the trustworthiness of CAs based on historical behavior, effectively suppressing the repeated issuance of certificates by low-reputation CAs and improving the reliability of the authentication system from the source. This design breaks away from the static model of traditional trust management methods, making the system more resilient to low-reputation CAs. Finally, the research introduced multi-layer blockchain data compression and snapshot technology, enabling efficient collaboration between the main chain and auxiliary chain/off-chain data.

The research's contribution lies in proposing a dual-encryption identity authentication framework that combines the SM9 identity-based encryption algorithm with blockchain-based DLT, overcoming the limitations of traditional single-layer encryption or storage mechanisms. In experiments, the SM9-blockchain model achieved a response latency of 6ms against SQL injection attacks, approximately 50% faster than traditional approaches, enhancing security and authentication efficiency. Secondly, the research designed a CA trust management mechanism based on time decay to dynamically adjust the CA's credibility and effectively prevent duplicate certificate issuance by low-reputation institutions. In experiments, the mis-issuance rate of certificates from low-reputation CAs was reduced from the traditional 20% to 12%, improving the reliability of the authentication system. Finally, a multi-layer blockchain data structure supporting compressed snapshots was constructed, improving data storage and processing efficiency in resource-constrained IoT scenarios. When processing 1,000 concurrent requests, the SM9-blockchain model achieved a response time of 11 ms, approximately 50% faster than traditional blockchain systems, while also reducing energy consumption by 30%.

The structure of the study is divided into six sections. Section II is a literature review. Section III is the methodology, which designs a user identity confirmation model based on DLT and state secret SM9 algorithms. Section IV is the performance validation, which analyzes the performance of the proposed model through experiments. Section V is a discussion, which analyzes the research results. Section VI is the conclusion, which summarizes the research results and shortcomings.

II. Related Work

As the Internet grows, there is an increase in the focus on user data security and privacy across fields like business registration and corporate governance [6]. Blockchain, a leading encryption and traceability tech, is under intensive study by researchers [7]. Attaran's research underscores blockchain's secure encryption, suggesting its use in crypto transactions. It notes that blockchain nearly prevents data alteration or removal without others' private keys, marking a key trend in future crypto security [8]. Li et al. suggested a blockchain framework for encrypting info exchanges among IoT devices, leveraging blockchain's consensus mechanism, encryption, and smart contracts to secure interactions between smart devices [9]. Panda et al. created a blockchain-IoT architecture that secures data privacy and IoT security by using hash chains for key management, eliminating the need for third-party key handlers. The scheme includes an efficient key generation method for mutual authentication through self-verification [10]. To address the limitation of lack of flexibility and responsiveness to dynamic changes of static smart contracts in blockchain applications, Saputra et al. based on the innovative concept of dynamic smart contracts in key-value format framework, AniraBlock, which enhances the data management and supply chain transparency, and achieves the optimisation of data integrity and operational efficiency in the agriculture sector [11]. Saputra et al. further proposed a blockchain-based key-value store that explores interoperability, dynamic data processing and performance testing of smart contracts, thereby enabling dynamic smart contract interactions in the agriculture sector [12].

State secret algorithms are cryptographic algorithms designed and developed independently by China, currently an open source including SM2 to SM9. There are a large number and wide range of SM9-based studies on the Internet. For example, Yang et al. proposed a novel identity-based blind signature scheme combined with message recovery technology to reduce the transmission bandwidth of the signature information by hiding the message in the signature in response to the problem of high resource consumption of the SM9 blind signature scheme in practical applications [13]. Lai et al. introduced an improved online/offline signature scheme for SM9 to accelerate its signing process. The new scheme boosts signature generation speed by 9.9%, reducing signature time to under 1 millisecond, and demonstrates superior performance over existing fast signature algorithms [14]. Aiming at the problem that civil navigation information of BeiDou satellite navigation system (BDS) is vulnerable to spoofing and replay attacks due to the lack of authentication mechanism, Wu et al. proposed a secure authentication protocol BDSec based on the design of China's SM series of algorithms [15]. Zhang and Ye developed a privacy-preserving method leveraging SM9 and blockchain. It employs conditional anonymous ring signatures for enhanced security and optimizes key negotiation using the discrete logarithm assumption, making it faster. The scheme proved to be effective and practical in experiments [16].

In summary, SM9 algorithm and blockchain technology are current research hotspots, and the combination of the two has great potential in protecting blockchain communication and data privacy. SM9 algorithm, as an identity-based cryptographic algorithm, provides a secure key negotiation and authentication mechanism. However, existing research has largely focused on using either the SM9 algorithm or blockchain technology alone, while the combination of the two has not been fully explored. The scalability and efficiency issues of combining the SM9 algorithm and blockchain technology in practical applications remain unaddressed. Furthermore, many studies assume an ideal network

environment, overlooking performance bottlenecks in resource-constrained and high-concurrency environments. Therefore, this research aims to combine the SM9 algorithm with blockchain technology to build a more efficient, secure, and scalable identity verification system, addressing the challenges faced by existing approaches in practical applications.

III. Identity Confirmation Property Management System Based on State Secret SM9 Algorithm and DLT

The study introduces a user identity verification model on DLT to ensure data integrity and accuracy through a decentralized network. It also incorporates the SM9 algorithm for double encryption of the identity verification model and uses asymmetric encryption to safeguard user identity information.

A. Construction of Identity Confirmation Property Management Model Based on DLT

DLT technology is a data storage and recording technology, which allows multiple participants to jointly maintain a growing list of data records. DLT ensures the data consistency of all participants through consensus mechanism. Blockchain DLT stores data in block form, with each block holding transactions and linked via hashing to the previous block, creating a chain structure [17-18]. Once data is recorded, all nodes synchronize it, making alterations to a single block ineffective [19]. DLT also features encryption for secure and confidential data storage. In this, the expression of DLT block is shown in Eq. (1):

$$block = h(data, timesiamp, previous_hash, hash) \quad (1)$$

In Eq. (1), $data$ denotes data stored on the blockchain, which can be interpreted as user identity information or transaction records, etc. $timesiamp$ represents a timestamp used to maintain the order of blocks. $previous_hash$ represent the hash value of the previous block; $hash$ represents the hash value of the current block; $h(.)$ represents the connection function between different blocks, which is used to link blocks and ensure that each block is closely connected to the previous block, forming a chain. Eq. (1) describes the structure and linkage of individual data blocks in a blockchain. In practice, each block is like a "ledger page", in which the user's identity data and operation records are recorded. By linking the hash value to the previous block, the data can be prevented from being tampered with in the middle of the process, thus guaranteeing the security and non-repudiation of the system. The blockchain architecture in this study is constructed based on the Hyperledger Fabric platform, adopting the coalition chain model, through the improved Byzantine Fault Tolerance (BFT) algorithm as the consensus mechanism, combined with the main chain-side chain structure and compressed snapshot technology, which improves the processing performance and data synchronization efficiency while ensuring that the transactions are not tampered with. Each node constructs the block header and synchronously updates the blockchain through the hash function, forming a complete DLT, according to a special combination, as shown in Fig. 1.

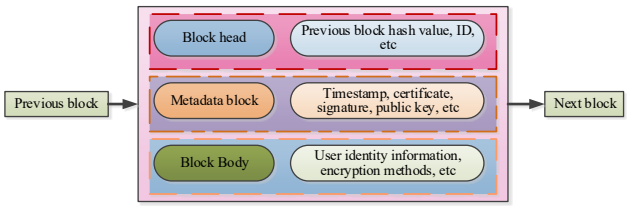

Fig. 1. Schematic diagram of blockchain combination structure.

From Fig. 1, it can be seen that in cross-system identification, the length of the authentication path and the size of the integer volume are the key factors affecting the difficulty of constructing the trust path. In order to adapt to the higher requirements of energy consumption and storage efficiency in large-scale application scenarios, the optimized DLT technology adopted by the institute introduces a lightweight consensus mechanism and compressed storage structure in its design. In terms of energy consumption control, the system adopts an improved BFT algorithm to replace the traditional proof-of-work mechanism to avoid a large number of invalid calculations. Compared with the traditional BFT algorithm, this study simplifies the node election and message transmission mechanisms by introducing pre-selected nodes, thereby reducing redundant broadcast communication and lowering network overhead while maintaining fault tolerance. Compared with commonly used consensus mechanisms such as Proof of Work (PoW) and Proof of Stake (PoS), BFT offers higher determinism and efficiency in consortium blockchain environments. Although PoW provides strong security, it relies heavily on computational resources and consumes a large amount of energy, making it unsuitable for identity authentication systems that require real-time response and resource efficiency. PoS, while improving performance to some extent, depends on economic assumptions in its incentive and security models, which are less compatible with uniformly managed system architectures. In contrast, BFT does not rely on computational competition and offers advantages such as low latency, high controllability, and strong determinism, making it more suitable for the trusted identity authentication model proposed in this study.

In terms of data storage, by setting the validity period and update cycle of identity data, and combining layered storage and snapshot mechanism, only key identity information and index data are retained on the main chain, while the rest of the auxiliary information is distributed to the side chain or off-chain storage. A snapshot mechanism is one that periodically records a full copy of the current state of the blockchain system and transfers the historical block data to off-chain or auxiliary chain storage. To optimize storage requirements, the system uses a snapshot mechanism. By periodically generating snapshots of the blockchain data, the system saves the current state and the historical data is transferred to off-chain storage or external storage. This strategy not only reduces the storage pressure on the blockchain main chain, but also ensures the consistency and integrity of the data through hash values and timestamps. While preserving the current valid data, the historical data can still be traced back through the verification

mechanism to ensure the security and traceability of the data, thus effectively reducing the storage requirements and improving the query efficiency.

In this way, while ensuring data integrity and traceability, it effectively reduces the local storage pressure and bandwidth demand of the nodes, and improves the scalability and green computing capability of the system. Among them, CA auditing is an important work in blockchain. If CA CA_1 has issued M certificates in a period of time, among which there are m legitimate certificates. The weight attenuation of CA certificates, the expression of the legitimacy probability of institutional certificates, and the calculation of credibility are shown in Eq. (2):

$$\begin{cases} f_{PRE}(CA) = \gamma^{t_n - t_{pre}} \\ P_{le} = \dfrac{M}{m}\gamma^{\frac{1}{M}} \\ P_{re} = \dfrac{1}{n}\sum_{i=1}^{n}\left[\alpha f_{PRE}(CA) t_{pre} + \beta P_{le}\right] \end{cases} \tag{2}$$

In Eq. (2), $f_{PRE}(CA)$ represents the CA's weight decay function, reflecting the gradual decrease in trust over time. γ indicates the decay factor; t_n indicates the current time; t_{pre} indicates the moment when the CA issues the last certificate. α, β represents the weight parameter, which has the relationship of $\alpha + \beta = 1$, and both parameters are constants greater than 0 and less than 1; n represents the number of times the organization has been audited. Eq. (2) is used to calculate the credibility of the CA. This equation is based on a time decay model. If the CA issues low-quality certificates or issues certificates frequently, the CA's credibility gradually declines over time. The study introduces a 'trust decay' mechanism for dynamically assessing the trustworthiness of CA organizations. The system records the frequency, legitimacy rate and historical behavior of certificate issuance by CAs, and sets a time decay factor to make the trust value of CAs decay naturally over time, so as to prevent the risk of abuse brought by long-term accumulation of trust. If a CA frequently issues illegal or low-quality certificates within a certain period, its weight will be rapidly reduced, and it will eventually be regarded by the system as a low-trust or failing organization. This mechanism improves the resilience and robustness of the certification system and effectively prevents the risk of a single point of failure of the authority center. The specific calculation equation is shown in Eq. (3):

$$\begin{cases} S = HA(s) \\ r = (S + x) \bmod n \\ k = (1+v)^{-1}(t - rt) \bmod n \end{cases} \tag{3}$$

In Eq. (3), S denotes the encrypted ciphertext; $HA(.)$ denotes the hash encryption function; s denotes the plaintext to be encrypted. x denotes the parameter of the public key; $\bmod n$ denotes that the mode of this calculation is elliptic curve. k denotes another parameter of elliptic curve digital signature, the larger the value, the higher the strength of the signature, and the higher the security. v denotes the parameter in the private key; t denotes the moment when this calculation is performed. Eq. (3) is the calculation for cryptographic signing of user identity information, which indicates that the user encrypts the information to be signed using a private key to generate a signature. The signature can be used to verify the legitimacy of the user's identity in subsequent steps. In practice, the user's identity information is converted into an encrypted digest, and the equation generates the signature parameter r. Once the server receives the signature, it can verify the legitimacy of the identity and avoid identity forgery. The proposed model uses digital signatures to verify user identities on the Public Key Infrastructure (PKI). PKI employs asymmetric encryption with a public-private key pair for secure data transmission, where the public key is shared for encryption and the private key is kept secret for decryption. Automated certificate lifecycle management in PKI systems reduces complexity and errors in manual operations. When a user from PKI domain 1 wants to authenticate with a server in domain 2, they must submit a certification request, including a digital signature and blockchain certificate to the server in domain 2. The server then verifies the user's identity with the certificate issuer [20]. Fig. 2 illustrates the steps of user authentication.

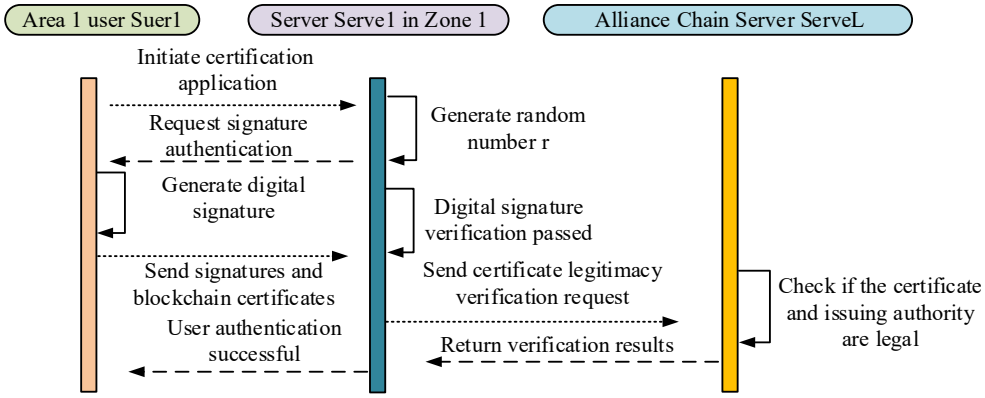

Fig. 2. Schematic diagram of user identity authentication process.

Fig. 2 illustrates the PKI encryption process: the sender gets the receiver's public key, encrypts data with it to create ciphertext, and sends the ciphertext. The decryption process involves the receiver using their private key to decrypt the ciphertext and retrieve the original data. Leveraging blockchain's decentralized and tamper-proof features, the study develops a secure user identification model offering efficient authentication, authorization, and protection of user privacy and security. The interaction mechanism between the blockchain and the SM9 algorithm is shown in Fig. 3.

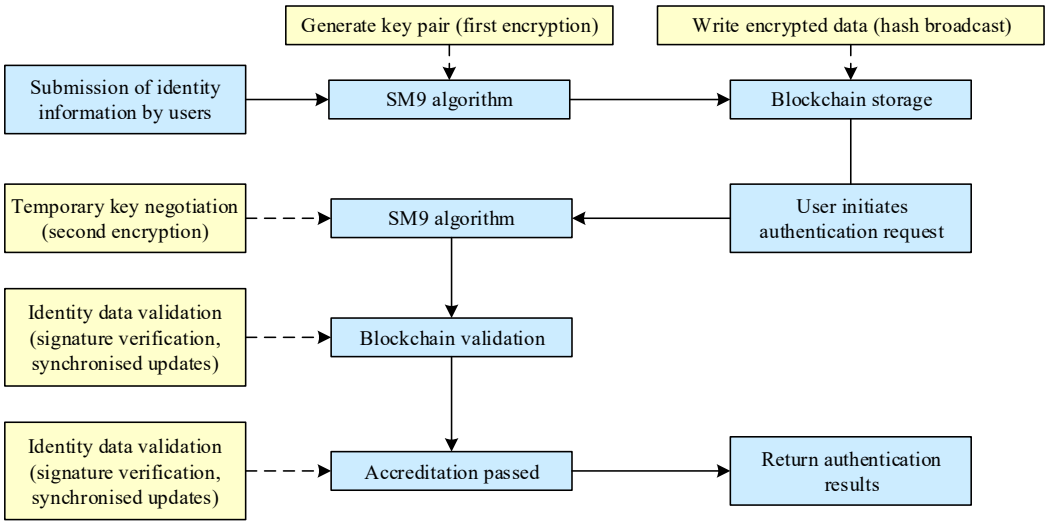

Fig. 3. Technical interaction mechanism between blockchain and the SM9 algorithm.

Fig. 3 shows how the SM9 algorithm generates key pairs and encrypts the data, how the blockchain stores the encrypted data and verifies it, and ultimately ensures the security and efficiency of the system through key negotiation and authentication. And in order to ensure the security of the off-chain data storage, the Institute lifting system has adopted a variety of technical measures. All off-chain data is encrypted before storage, and the SM9 algorithm is used for secondary encryption. At the same time, distributed storage and data slicing technologies are used to increase data redundancy and reliability and prevent a single point of failure. Managing permissions through role-based access control ensures that data access is restricted to authorized users only. In addition, the system introduces audit logs to record all data operations to ensure data traceability.

B. Secondary Encryption of Identity Confirmation Physical Model Based on SM9 Algorithm

In order to improve the encryption performance of the identity verification property management model, the use of the national security SM9 algorithm for secondary encryption is studied. The SM9 algorithm typically uses an asymmetric encryption system, also known as a public key cryptosystem, to generate identity-based public key encryption schemes to generate key pairs. Among them, the expressions for calculating the public and private keys are shown in Eq. (4):

$$\begin{cases} Pu_i = Hash(id_i) \\ Pr_i = \left(\dfrac{w}{w + Pu_i} \right) Pu_i \end{cases} \tag{4}$$

In Eq. (4), Pu_i denotes the public key of the first i user; $Hash(.)$ denotes the hash encryption function; id_i denotes the identity information of the first i user. w represents the master private key generated by the public key generator; Pr_i represents the private key of the i user. Eq. (4) is the basis for the SM9 algorithm to generate user public-private key pairs. The system generates its own encryption key based on the user's identity information, which is equivalent to "using identity information directly into a key". During key pair generation for user authentication, the IMS generates a random large prime number. This prime is used to create a temporary public and private key, as detailed in Eq. (5):

$$\begin{cases} \phi = N_1 Pu_i \\ \theta = N_2 \Pr_i \end{cases} \tag{5}$$

In Eq. (5), N_1 denotes the randomly generated large prime number; ϕ denotes the temporary public key. N_2 denotes the randomly generated large prime number, which is not necessarily the same as the value of N_1 ; θ denotes the temporary private key in the key negotiation process. During the key negotiation process, both parties generate temporary key pairs, which are used only for encryption tasks in the current session. The use of temporary keys reduces the security risks associated with using the same key for a long period of time. After generating the temporary key, the initiator sends the encrypted ciphertext and the temporary public key to the authenticator. The authenticator decrypts the message and checks the bilinear pairing conditions. If conditions are met, they calculate the session key, as detailed in Eq. (6).

$$\begin{cases} E(\theta, s' + Pu_i N_1) = E(\phi, s') \\ sk = Hash(id_i \| \phi \| \phi' \| \beta) \\ \partial = N_1 \phi \end{cases} \tag{6}$$

In Eq. (6), s' denotes the master public key generated by the public key generator. ϕ' denotes the temporary public key of the authentication server; ∂ denotes the private key base point in the system parameters. Generating the session key is the final step in the key negotiation phase, and the detailed flow of key negotiation is shown in Fig. 4.

Fig. 4 shows the detailed steps of the key negotiation process based on the SM9 algorithm. Firstly, both parties generate their own temporary public-private key pairs for initialization. Secondly, both parties exchange parameters for key negotiation in this phase, such as algorithm version or key size, to ensure that they are communicating under the same standard. Subsequently, in the 'Temporary Key Negotiation' phase, both parties generate a temporary key based on the exchanged parameters, which is only used for the current session to enhance the security of the communication. Verify that the temporary key is correctly authenticated by both parties. If the authentication fails, the process returns to the "Parameter Exchange" phase and restarts the entire process to prevent man-in-the-middle attacks and to ensure that the key is secure before it is used. If authentication passes, the process continues to the Key Negotiation Calculation phase, where both parties calculate the final shared key based on the temporary key and possibly other parameters, ensuring that the key is consistent between the parties and can be used for encrypted communication. In the 'Encrypted Communication' phase, both parties use the negotiated key for encrypted communication to ensure that the data is secure from unauthorised access during transmission. Subsequently, in the 'key validation' phase, the parties confirm that the key has been used correctly to ensure that there are no errors or tampering. At this point, the blockchain user identity confirmation property management model SM9-Blockchain optimized based on the SM9 algorithm runs, as shown in Fig. 5.

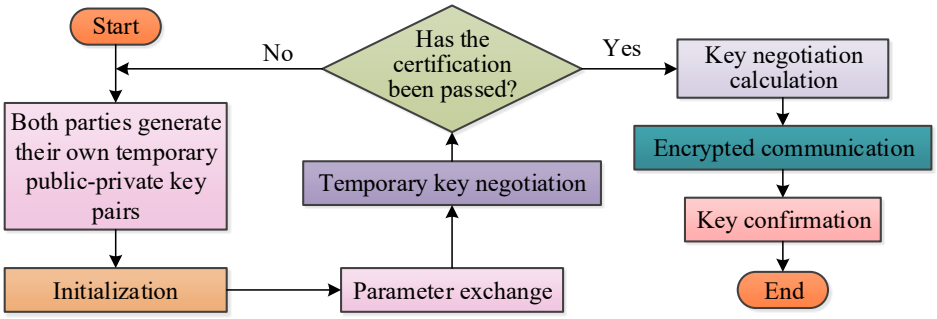

Fig. 4. Detailed process of key negotiation.

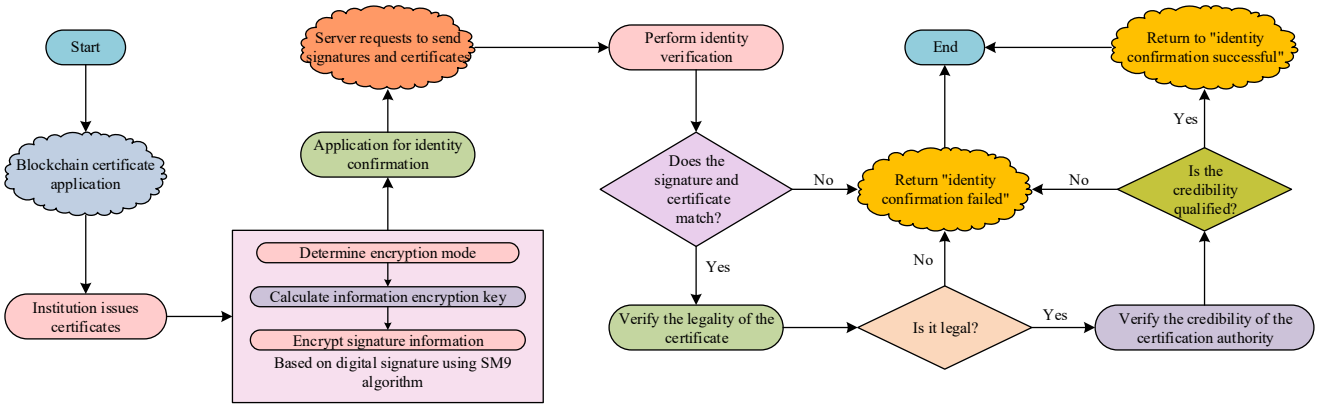

Fig. 5. SM9 blockchain model running process.

Fig. 5 shows the running process of the optimized SM9-blockchain model. First, the two parties exchange parameters used for key negotiation, and the user submits an authentication request through the blockchain to complete the authentication. At the same time, the system uses the SM9 algorithm to double-encrypt and verify the user's identity. After the authentication is passed, the user data is securely stored on the blockchain. Next, key negotiation is performed between the user and the system to generate a session key. Encrypted communication using the session key ensures the security of data transmission. This model makes use of the tamper resistance of blockchain and the encryption strength of SM9 algorithm to improve the security and efficiency of user authentication.

IV. SM-Blockchain Model Performance Validation

A. SM9-Blockchain Model Performance Validation

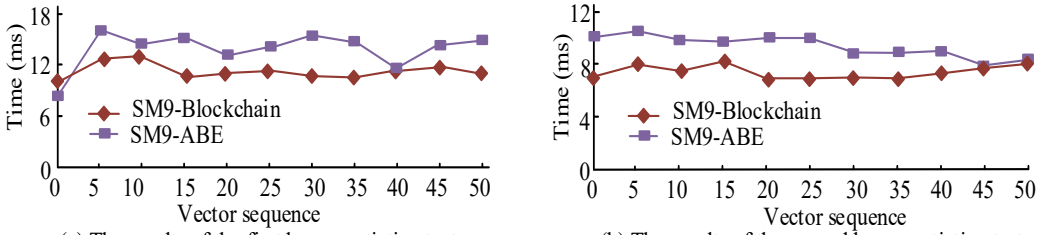
To validate the performance of the proposed model, the study conducted experiments in the hardware and software environments shown in Table I.

TABLE I. Configuration Table of Software/Hardware Experimental Environment

Item	Configuration	Item	Configuration
Operating system	Ubuntu 16.04	Programming language	Java
Processor	8-core CPU	Key generation tools	Cryptogen & Fabric-CA
Memory	16 GB RAM	Key generation method	Combination of static and dynamic
Blockchain platform	Hyperledger Fabric 1.4	Chaincode deployment	Automated via network.sh script

In this case, the decay factor γ is 0.1 and the weight parameter α, β is 0.5 [21-22]. The SM9 algorithm, as an identity-based cryptosystem, is faster in key generation and encryption and decryption than traditional public key systems. Therefore, the study chooses test values that can reflect the efficiency of the SM9 algorithm. The study follows the three principles of reproducibility, practicability, and comparability in the selection of test values. First, in order to ensure that the test data can truly reflect the performance of the algorithm, the parameters selected in the test (elliptic curve order, hash function bits, temporary key length, etc.) are based on the national commercial cryptography standard and the recommended configuration of Hyperledger Fabric. Second, when simulating the actual operating environment of the blockchain, a typical data load size is set to simulate the transmission performance under medium load in reality. Again, to enhance the interpretability of the results, the selected test vectors include Padding, Differential Analysis, and Random, and compare the commonly used model SM9-ABE. Parameter values that can simulate the actual blockchain operating environment were selected in the tests to evaluate the performance and energy consumption of the model in real applications. Parameter values that can ensure transaction security while minimizing the impact on system performance are selected.

The study evaluates the SM-Blockchain model's performance using three test vector sets: Padding Test Vectors (PTV) for testing encryption and decryption correctness and efficiency, Differential Cryptanalysis Test Vectors (DCTV) for assessing resistance to attacks, and Random Test Vectors (RTV) for performance and security. The above vectors are all derived from the publicly available national cryptography SM9 algorithm standard test set and open source implementation, mainly including the National Cryptography Administration SM9 standard and test vectors (http://www.gmbz.org.cn/main/viewfile/20180108015305901286.html) and the GmSSL open source national cryptography algorithm library (https://github.com/guanzhi/GmSSL). The SM9-ABE framework is included for comparison. Fig. 6(a) shows that the establishment of a communication connection or initiating a validation process speeds for SM9-ABE and SM9-Blockchain on various input vectors in the first test. SM9-Blockchain averages at 11.07 ms, while SM9-ABE at 14.11 ms. Fig. 6(b) reveals average times of 7.96 ms for SM9-Blockchain and 9.88 ms for SM9-ABE. This result shows that the SM9-Blockchain model is superior to the SM9-ABE model in the speed of establishing a communication connection or initiating a validation process. In addition, the research simulates different network conditions and data loads through automated scripts, which ensures the accuracy and reliability of test results.

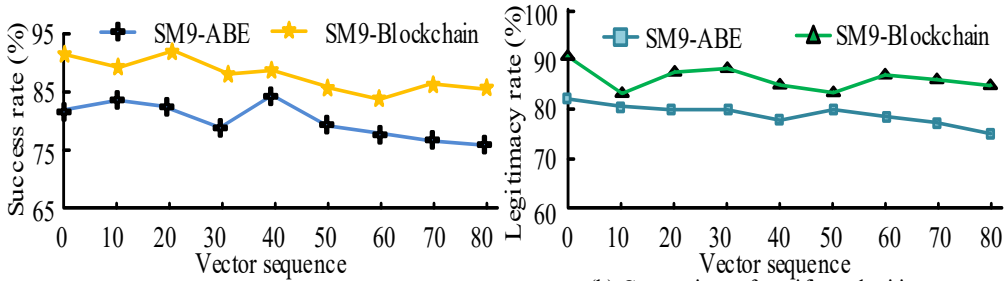


(a) The results of the first key negotiation test (b) The results of the second key negotiation test

Fig. 6. Comparison of models establishes a communication connection or initiates a validation process speed.

Fig. 7 illustrates the success and legitimacy rates for key negotiations in the SM9-ABE and SM9-Blockchain models under the PTV vector set. As can be seen from Fig. 7(a), the success rate of key negotiation of SM9-Blockchain model is 88.73%, which indicates that this model can effectively establish secure session keys between users in most cases. In contrast, the success rate of SM9-ABE model is 83.77%, which is slightly lower than that of SM9-Blockchain model. This may be because the SM9-Blockchain model adopts more optimized algorithms and protocols in the process of key exchange. The difference of success rate may be due to the fact that SM9-Blockchain model provides a more stable network environment and a more reliable data synchronization mechanism by using the distributed characteristics of blockchain technology, thus improving the stability and success rate of key agreement. In Fig. 7(b), the certificate validity rate of the SM9-Blockchain model is 87.51%, which means that the model can verify the validity and legality of the certificate with high accuracy. The certificate validity rate of SM9-ABE model is low, which may be due to some loopholes or deficiencies in the process of certificate management and verification, which leads to the decrease of the accuracy of validity verification. The high

certificate legitimacy rate of SM9-Blockchain model benefits from the non-tampering and transparency of the blockchain, and the issuance and status of each certificate can be tracked and verified on the blockchain, thus effectively preventing forgery and tampering.

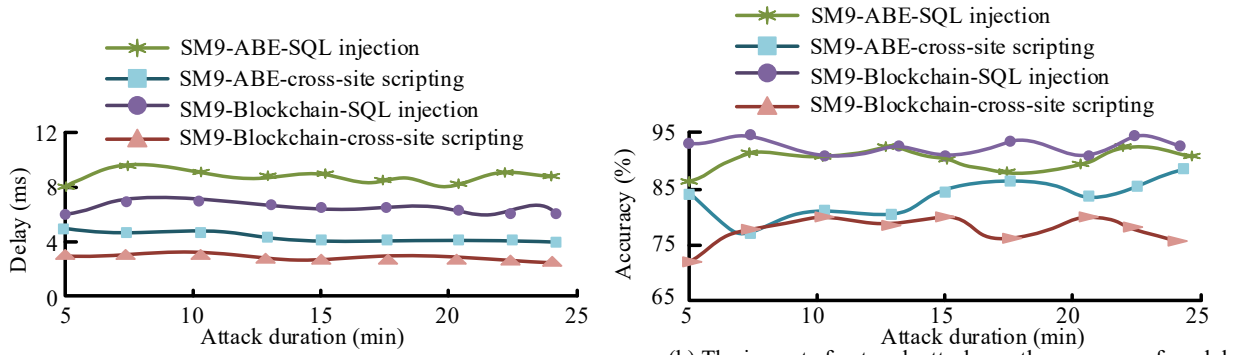


(a) Comparison of key negotiation success rates (b) Comparison of certificate legitimacy

Fig. 7. Comparison between the success rate of model key negotiation and the legality rate of certificates.

B. SM9-Blockchain Model Security Validation

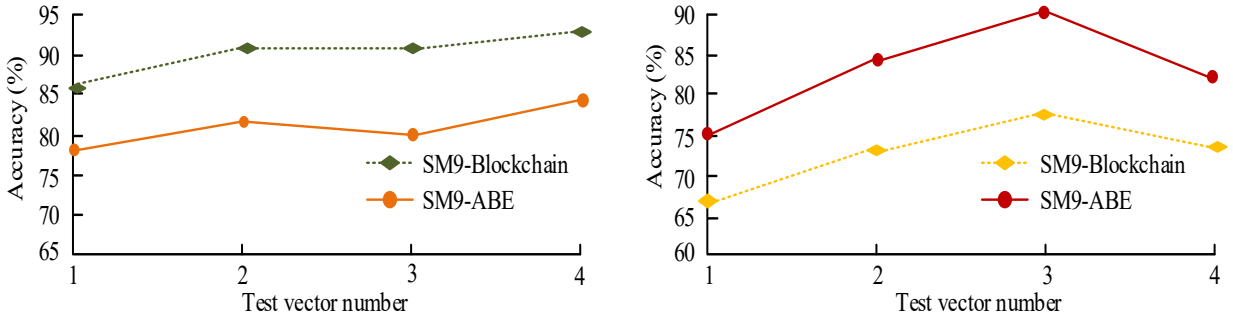
The study tests the model's security against SQL Injection and XSS attacks. Fig. 8(a) shows the SM9-Blockchain model experiences about a 6ms delay under SQL Injection and a 3ms delay under XSS attacks. Fig. 8(b) indicates that the SM9-Blockchain model has a higher average correct rate than the control model under various attacks.



(a) The impact of network attacks on model runtime latency (b) The impact of network attacks on the accuracy of model identity confirmation

Fig. 8. Model security verification.

To analyze the factors affecting user identity confirmation accuracy, the model uses PTV and RTV vectors. Fig. 9(a) shows that SM9-ABE has an average correct rate of 81.29%, while SM9-Blockchain has 90.41%. Fig. 9(b) reveals that SM9-ABE's average correctness is 71.81% and SM9-Blockchain's is 83.25%.



(a) The recognition accuracy of random vectors generated in RTV (b) The recognition accuracy of random vectors generated in PTV

Fig. 9. Comparison of user identity confirmation accuracy.

To analyze encryption and decryption delays in user identity confirmation under normal scenarios, experiments were conducted using the PTV vector set. In Fig. 10(a), the encryption delay of SM9-Blockchain model is about 0.35 ms lower than that of SM9-ABE model under the same conditions. This improvement may be attributed to the adoption of more efficient algorithm and optimized data structure in the encryption process of SM9-Blockchain model. The lower encryption delay means that the SM9-Blockchain model is faster in dealing with encryption tasks, which is especially

important for application scenarios that need rapid response, such as real-time communication and online transactions. The SM9 algorithm, the core cryptography of the model, is important for reducing latency due to its smaller key size and faster encryption/decryption speed. Lower cryptographic latency means that the SM9-Blockchain model is faster in processing cryptographic tasks, which is especially important for application scenarios that require fast responses (e.g., real-time communication and online transactions). The distributed architecture of blockchain technology, however, improves the efficiency and reliability of data synchronization, which reduces delays in the user identification process. Each node stores a copy of the blockchain, and this decentralized structure reduces the single point of failure and bottlenecks that can occur in centralized systems. It can also be seen from Fig. 10(b) that the delay of the proposed model is about 0.39ms lower than that of the SM9-ABE model. This shows that the SM9-Blockchain model not only performs well in the encryption stage, but also provides fast processing ability in the decryption stage. Decryption delay is very important to ensure real-time data and improve user experience, especially in the environment of frequent data exchange. In this study, several key security protocols are introduced in the contract design. First, when a user submits an authentication request, the system uses the signature verification function built into the on-chain contract to verify the request information to ensure that the request source is real and not forged. Second, by introducing the anti-replay mechanism based on timestamp and Nonce, attackers are effectively prevented from utilizing historical requests to initiate pseudo-authentication operations. In addition, the smart contract restricts the invocation scope of contract functions through role authority control to prevent illegal access to sensitive resources. To address the risk of contract logic vulnerabilities, Mythril, a static code analysis tool, is introduced to conduct vulnerability scanning before the system is deployed, and combined with the test network for simulated attack verification, to ensure that the contract has a strong anti-re-entry and anti-overflow capabilities. The above mechanisms together constitute the basic security protocol framework used in this system to defend against typical attacks, which improves the robustness and credibility of the system in real application scenarios.

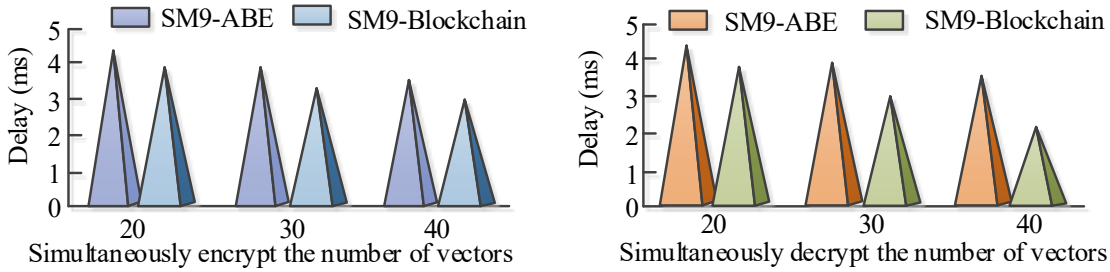


Fig. 10. Comparison of encryption and decryption latency among different models.

C. Performance Comparison of Different Methods

The study compares blockchain-based authentication management methods proposed by other scholars, including Miao et al.'s [23] blockchain-enabled privacy-preserving authentication management protocol for the Internet of Medical Things, Kumar et al.'s [24] blockchain-based authentication method, and Kang et al.'s [25] blockchain-based authentication scheme for an enhanced and lightweight medical sensor network. It benchmarks the time overhead for key generation, proving keys, and verifying keys in the PTV set for these methods. Details are shown in Fig. 11.

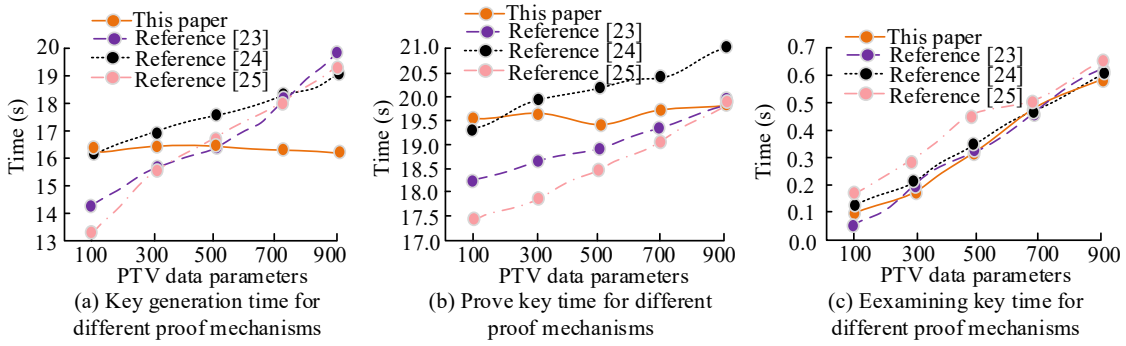

Fig. 11. Comparison of the time overhead required for key generation and verification under different authentication mechanisms.

Fig. 11(a) shows that SM9-Blockchain's key generation time is consistently around 16.29s, with an average reduction of 3.93%, 7.39%, and 1.51% compared to other methods. Fig. 11(b) indicates that SM9-Blockchain is least affected by data parameter size in key proving, while other methods show an increasing trend with larger parameter sizes, possibly due to larger proof key storage requirements. Fig. 11(c) shows that SM9-Blockchain's verification time is reduced by 4.84% on average when handling 900 PTV data parameters. These results demonstrate that SM9-Blockchain outperforms others in encryption and decryption time. The performance comparison results of key indicators of the four methods are shown in

Table II. To ensure the statistical reliability of the results, each test was conducted no fewer than twenty times under the same conditions, and all metrics are reported as mean ± standard deviation. Performance differences were evaluated for statistical significance using paired t-tests with a significance level of $\alpha = 0.05$.

TABLE II. PERFORMANCE COMPARISON RESULTS OF KEY INDICATORS OF FOUR METHODS

Index	SM9-Blockchain	Miao et al. [23]	Kumar et al. [24]	Kang et al. [25]
Average establish a communication connection or initiate a validation process time (ms)	11.07±0.22	14.52±0.48	12.31±0.35	13.83±0.41
Average key negotiation success rate (%)	88.73±1.15	85.20±1.60	87.11±1.42	86.54±1.51
User identity confirmation accuracy (%)	90.41±1.07	87.61±1.32	88.93±1.21	89.26±1.29
Delay time under SQL injection attack (ms)	6.00±0.31	8.22±0.37	7.52±0.29	7.81±0.33
Delay time under XSS attack (ms)	3.00±0.18	4.53±0.22	3.81±0.20	4.04±0.21
Average key generation time overhead (s)	16.29±0.47	18.51±0.55	17.10±0.52	17.94±0.54
Average key proof time overhead (s)	19.52±0.62	21.33±0.72	20.25±0.68	20.82±0.70
Average key verification time overhead (s)	0.36±0.05	0.45±0.06	0.40±0.05	0.42±0.06

Through the comparison in Table II, it can be seen that the SM9-Blockchain model performs better than other models in most key performance indicators. Especially in the accuracy of user identity confirmation and the delay time under SQL injection and XSS attacks, the SM9-Blockchain model shows obvious advantages. This shows that the SM9-Blockchain model has obvious advantages in improving security and efficiency. To further evaluate the performance advantages of the SM9 algorithm in identity authentication systems, this study conducts a comparative analysis with traditional encryption protocols, including Rivest–Shamir–Adleman (RSA) (1024-bit), Elliptic Curve Cryptography (ECC) (256-bit), and Advanced Encryption Standard (AES) (128-bit). All tests were conducted under the same environment and transaction volume. This is shown in Table III.

TABLE III. PERFORMANCE COMPARISON BETWEEN SM9 AND CONVENTIONAL ENCRYPTION ALGORITHMS

Algorithm	Key length	Key generation time (ms)	Encryption latency (ms)	Decryption latency (ms)	CPU utilisation (%)	Memory usage (MB)	Energy consumption (J)
SM9	256 bit	16.29	7.81	8.70	12.34	25.43	0.09
RSA	1024 bit	31.20	9.56	18.40	20.15	38.62	0.18
ECC	256 bit	23.45	8.63	12.51	17.98	33.24	0.12
AES	128 bit	1.52	4.13	4.05	8.56	14.79	0.03

As can be seen from Table III, RSA exhibits significantly higher average latency in key generation and decryption compared to SM9 (16.29 ms and 8.7 ms). ECC performs better than RSA but remains slightly slower than SM9 under concurrent transaction loads due to computational bottlenecks in key negotiation. AES, as a symmetric encryption algorithm, delivers excellent speed but lacks support for identity binding and key negotiation, making it unsuitable for standalone use in blockchain-based identity authentication. Although the symmetric encryption algorithm of AES has the lowest CPU usage (8.56%), considering the strong encryption strength provided by the SM9, the SM9's CPU usage is still within a reasonable range, which is a superior price/performance ratio, especially with its high level of security. Overall, SM9 strikes a balance between security and efficiency by enabling identity-based encryption, digital signature, and key exchange with smaller key sizes and lower latency. This makes it particularly suitable for resource-constrained environments, such as IoT devices and lightweight authentication terminals.

D. Practical Validation

To further evaluate the performance of the proposed authentication model in real-world and IoT scenarios, two experimental environments were designed: a real property management system and an IoT device environment. In the real property management system test, the model was deployed on an existing platform for limited-scale validation. The system included multiple users and multiple device nodes to simulate concurrent authentication requests. During deployment, the front-end authentication module interacted with the back-end RESTful API via the HTTPS protocol. The back-end invoked the SM9 double encryption module and Hyperledger Fabric nodes to perform on-chain authentication and verification. The property management system ran on real servers and client devices, with a local area network latency of approximately 20 ms and a bandwidth of 50 Mbps.

In the IoT device test, a Raspberry Pi 3 (1GB RAM, quad-core processor) was used as the end node, connected to IoT sensors and low-power devices. Communication was securely established with the IoT gateway via an MQTT protocol adapter, with the model also performing encryption, authentication, and verification in the back-end. The IoT devices are connected to the network via Wi-Fi, with a latency of approximately 50 ms and a bandwidth of 10 Mbps.

In both environments, the system first initialized and configured the hardware and network conditions, and then seamlessly integrated with the existing platform (including the PKI certificate system and device management platform) through an interface adaptation layer. The user-side authentication process was triggered with a single click, eliminating the need for manual key management or plugin installation. Interaction latency was kept to under 0.5 seconds,

and the interface style remained consistent with the existing system. Key performance indicators were measured in both environments. Detailed results are shown in Table IV.

TABLE IV. TEST RESULTS OF DIFFERENT ALGORITHMS IN VARIOUS ENVIRONMENTS

Experimental environments	Algorithm	Response time (ms)	Authentication success rate (%)	Network bandwidth consumption (KB/s)
Real-world	SM9	16.97	91.26	22.68
	RSA	28.74	81.32	36.48
	ECC	23.85	86.05	30.92
	AES	18.42	88.14	24.75
IoT	SM9	19.06	87.93	19,47
	RSA	39.21	74.81	30.67
	ECC	33.54	79.49	27.18
	AES	21.13	85.20	21.60

As shown in Table IV, in the real-world property management system test, the response time of the SM9 algorithm was 16.97 ms, which is 40.96%, 28.81%, and 7.88% faster than RSA, ECC, and AES, respectively. This indicates that SM9 has a clear advantage in processing efficiency within practical systems. The authentication success rate of SM9 in this environment reached as high as 91.26%. Combined with the results from the IoT device environment, the superiority of the proposed method is further demonstrated. In the resource-constrained IoT environment, SM9 achieved an authentication success rate of 87.93%, which is 17.52%, 10.62%, and 3.20% higher than RSA, ECC, and AES, respectively. This shows that the proposed method maintains strong authentication performance even on devices with limited resources. Finally, the study further selected two common and representative attack methods to evaluate the security of the system, namely the replay attack and the impersonation attack.

Replay attack refers to a situation where an attacker intercepts and records legitimate authentication requests from users and then resends the same data to the system in an attempt to bypass identity verification. Impersonation attack means that an attacker forges the identity or credentials of a legitimate user or node in order to obtain authentication privileges or access to sensitive resources. The study designed corresponding defense mechanisms based on the SM9-Blockchain model and conducted a comparative evaluation with traditional encryption systems, RSA and ECC. The details are shown in Table V.

TABLE V. SECURITY AND SCALABILITY COMPARISON UNDER REPLAY AND IMPERSONATION ATTACKS

Evaluation Metric	SM9-Blockchain	RSA	ECC
Replay attack detection rate (%)	99.82±0.14	87.20±1.40	91.45±1.25
Impersonation attack detection rate (%)	98.50±0.42	85.70±1.58	89.35±1.31
Authentication throughput (requests/s)	158.42±3.51	112.74±4.15	128.20±3.91
Average authentication latency (ms)	21.85±1.20	36.57±1.82	29.46±1.52
Max concurrent devices supported	1200	750	880

As can be seen from Table V, in the replay attack test, the SM9-Blockchain model achieves a 99.82% interception rate relying on the timestamp and session key mechanism, which has stronger anti-replay capability than RSA and ECC. In the impersonation attack test, SM9 achieves a 98.50% recognition rate based on the identity signature and certificate chain verification mechanism, which is significantly better than RSA and ECC. In addition, in a highly concurrent environment, SM9-Blockchain can still support 1,200 devices to authenticate concurrently, and the authentication throughput reaches 158.42 times/s, with an average latency of only 21.8 ms, which indicates that it has a superior ability to scale. The capability is more superior.

To fully validate the performance of the proposed model under scalability, extreme stress, and long-term operation conditions, the study designed three scenarios: concurrent expansion testing, stress testing, and long-term data accumulation simulation. In the scalability test, the number of concurrent device connections was gradually increased from 200 to 1600. In the stress test, the number of concurrent connections was further increased to 2000 to simulate peak load. In the long-term data accumulation simulation, nodes were continuously run and authentication transactions were continuously written. The storage growth rate and node synchronization latency were recorded after one, three, and six months. The experimental results are shown in Table VI.

TABLE VI. SM9-BLOCKCHAIN MODEL SCALABILITY VERIFICATION

Test scenario	Concurrency level / Duration	Avg. authentication latency (ms)	Authentication throughput (req/s)	Storage growth rate (%)	Node sync delay (ms)
Scalability test	200 devices	19.42 ± 0.38	155.12 ± 3.42	-	-
	800 devices	20.57 ± 0.41	154.03 ± 3.51	-	-
	1200 devices	21.85 ± 0.44	158.42 ± 3.51	-	-
	1600 devices	24.16 ± 0.50	149.35 ± 3.72	-	-
Stress test	2000 devices	27.94 ± 0.55	138.27 ± 3.85	-	-

Long-term data accumulation	1 month	-	-	8.53 ± 0.12	2.83 ± 0.05
	3 months	-	-	24.68 ± 0.21	3.12 ± 0.04
	6 months	-	-	42.37 ± 0.26	3.38 ± 0.06

Table VI shows that in the scalability test, when the number of concurrent devices increased from 200 to 1200, the average authentication latency increased only slightly, while the throughput fluctuated slightly and remained above 150 req/s, demonstrating that the system can operate stably under high concurrency conditions. In the stress test, when the number of concurrent accesses reached 2000, the latency increased to 27.94 ms and the throughput dropped to 138.27 req/s, demonstrating that the system still has sufficient processing capacity under extreme loads. In the long-term data accumulation test, thanks to the multi-layer blockchain and snapshot compression mechanism, the main chain storage growth rate was 42.37% over 6 months, and the node synchronization latency remained in the millisecond range with minimal increase. This demonstrates that the proposed model not only has good concurrency processing capabilities in the short term, but also maintains low resource consumption and stable performance in the long term.

V. Discussion

The SM9-Blockchain model proposed in the study excels in authentication accuracy, encryption and decryption efficiency, and resource adaptability. The constructed double encryption structure and traceable certificate mechanism guarantee the system's lower authentication latency and higher throughput rate in high concurrency and resource-constrained scenarios. In addition, compared with the RSA and ECC models, SM9-Blockchain achieves significant improvements in identity confirmation accuracy and key generation efficiency. From the perspective of mechanism design, the model integrates the structure of the main chain and auxiliary chain, and realizes the collaborative processing of identity authentication and data consistency through the on-chain trusted CA authorization and chain code execution mechanism; the CA trust decay mechanism effectively inhibits the repeated authorization of low-credibility nodes, and the chain code snapshot strategy improves the storage and response efficiency of the system while safeguarding the performance of the main chain. These designs enhance the system's adaptability to complex network environments while improving authentication accuracy. Furthermore, the model's design takes into account internal threats, CA compromise, and practical key management needs. Role-based access control and on-chain auditing are used to prevent internal unauthorized access, trust decay and certificate status broadcasting are used to address CA compromise, and key recovery and revocation mechanisms are provided to ensure long-term security.

In terms of practical application, the system still shows good scalability and platform compatibility. The system can be applied to intelligent communities, IoT terminal access, distributed identity management and other scenarios. Experimental results also demonstrate the model's adaptability and interoperability across diverse regulatory frameworks. Within China's national cryptographic system, SM9 enables authentication compliant with the Cryptography Law, whilst in the US FIPS 140-3 environment, it supports PKI systems including ECC and RSA. Concurrently, the model supports integration with global standards including X.509, OAuth 2.0, and FIDO, while enabling cross-chain interoperability across platforms such as Hyperledger Fabric and Ethereum. Its broad cross-platform and cross-domain applicability has been validated in smart community, IoT, and financial healthcare scenarios. However, with the continuous evolution of technology and the expansion of application scenarios, identity authentication models face new challenges and development requirements in real-world deployments. Firstly, in terms of security, the advancement of quantum computing poses potential threats to existing cryptographic systems. As an identity-based cryptographic scheme based on bilinear pairings, the SM9 algorithm relies on mathematical problems that may no longer be secure under quantum computing. In addition, the hash algorithms and digital signature mechanisms used in blockchain systems are also susceptible to quantum attacks. Therefore, to enhance the model's security adaptability in future quantum environments, it is advisable to introduce post-quantum cryptographic algorithms, such as lattice-based or hash-based signature schemes, in alignment with the standards currently being promoted by institutions such as the National Institute of Standards and Technology of the United States.

Secondly, although this model employs encryption mechanisms and role-based access control policies, there remains a potential risk of privacy leakage during data interaction between on-chain and off-chain environments. Future improvements could incorporate privacy-enhancing technologies such as anonymous credentials and zero-knowledge proofs to mitigate such issues. While blockchain achieves decentralized data storage, PKI still exhibits centralized tendencies during certificate issuance. To address this, the CA trust decay mechanism proposed in this study dynamically adjusts the trustworthiness of certificate authorities based on their historical behavior, thereby effectively reducing the risk of long-term trust monopolization by authoritative institutions. With the development of quantum computing, existing cryptographic algorithms such as SM9 and elliptic curve cryptography may face the threat of being cracked. To enhance the system's security adaptability in future environments, further research into integrating post-quantum cryptographic algorithms should be considered to strengthen the model's long-term robustness in identity authentication scenarios.

Finally, to improve the system's scalability and interoperability, future research will explore cross-chain integration capabilities with other blockchain platforms such as Ethereum and Hyperledger. Through techniques such as relay chains, hash time-locking, oracle services, or pluggable identity modules, the model can enable trusted identity data sharing and verification across multiple blockchains.

VI. Conclusion

This study proposes a dual-encryption authentication framework that combines the SM9 algorithm and blockchain technology. It also designs a time-decay-based CA trust management mechanism and a multi-layer blockchain architecture. Experimental validation demonstrates that the model demonstrates outstanding authentication security, responsiveness, and scalability, achieving a latency of 11.07 ms, a key agreement success rate of 88.73%, and an identity confirmation accuracy of 90.41%. The key contribution of this study lies in its breakthrough of the limitations of single encryption or storage mechanisms by innovatively proposing a dual-encryption authentication framework and optimizing storage and processing efficiency through a multi-layer blockchain architecture. However, the experiments were limited to a simulated environment. Future research could focus on further optimizing the model's performance in resource-constrained IoT environments and enhancing its applicability for large-scale deployments. In summary, this study provides a new solution for authentication in property management systems and IoT devices, improving security, reliability, and scalability, and laying the foundation for further research in related fields.

Coordination, Communication and Robustness in Multi-Agents: An Industrial Network Scenario Using Trust Region Policy Optimization

Munam Ali Shah
Department of Computer Networks and Communication-College of Computer Science and Information Technology,
King Faisal University, Al-Ahsa, Kingdom of Saudi Arabia

***Abstract*—Numerous practical uses necessitate multi-agent systems, including managing traffic, assigning tasks, regulating ant colonies, and operating self-driving cars, and drones. These systems involve multiple agents working together, communicating and engaging with their surroundings to achieve the highest possible total numerical reward. Deep Reinforcement Learning (DRL) approaches are used to address these multi-agent applications. In many circumstances, the use of agents raise challenges to safety and robustness. To address these issues, we develop a DRL based system in which multiple agents in an industrial network scenario interact with the real-world environment and act collaboratively and cooperatively. In proposed model, several agents collaborate with one another to complete tasks and maintain a safe state. To take actions cooperatively and collaboratively of agents in accordance with the safety robustness of policies, we apply DRL algorithms such as proximal policy optimization (PPO) and Trust Region Policy Optimization (TRPO) algorithms and DRL approaches. We apply Curriculum Learning (CL) for their better performance and training. In this study, a reward structure is also proposed which help agents to maintain their safe state. Mean reward, policy loss, value loss, value estimate and safety robustness are analyzed as performance matrix in this study. The results shows that the policy adopted in the proposed model perform comparably better than the other policies.**

***Keywords*—Safety robustness; reinforcement learning; multi-agents; safe state; collaboration**

I. Introduction

In an experiment on a cat's behaviour done by Thorndike [1], reinforcement learning (RL) begins with the trial and error method. In machine learning, RL is a significant approach. It's a method of determining which action offers the most reward [2]. Real-time learning involves an agent that interacts with the learning environment, takes actions on the current state, and proceeds to the next state while striving to maximize the numerical reward. DRL, which merges Deep Learning and Reinforcement Learning [3] [4], is utilized to handle high-dimensional environments. To surpass the limitations of single-agent systems, multi-agent systems are necessary. The agents in multi-agent systems communicate with one another, interact with the environment, and aim to maximize the overall numerical reward [5]. Many real-world applications, such as traffic control, task distribution, ant colonies, autonomous cars, and drones, necessitate multi-agent systems. Due to the complexity of a high-dimensional environment, an agent that is hard-coded cannot work well in it.

To ensure the agents can generate optimal learning solutions, Multi-Agent Deep Reinforcement Learning (MADRL) is a crucial technique in the previously mentioned applications. In these applications, MADRL agents can discover the most effective solutions and policies. MADRL is a learning method where multiple agents interact with the learning environment to maximize the total reward. Using neural networks with numerous layers and approximations, agents strive to estimate the value of actions. Their policies rely on their own action values and those of other agents [5].

Therefore, researchers are now focusing not only on reward maximization but also on safety. Deep integration of machine learning and control technologies is required to tackle safety challenges in critical applications such as self-driving cars and robot manipulation [4]. In the control community, robust and adaptive control techniques have been developed to ensure the safety and stability of systems. To enhance the safety of learned policies, appropriate control approaches from the control community can be applied [4] [6]. The performance of learned policies is typically measured through success rates [7] [8] or obtained rewards [9] [10] to determine their robustness. However, when using RL to address problems in safety-critical applications, policy robustness must also be evaluated from a safety perspective. However, there is presently no way of evaluating policy robustness from the standpoint of safety.

This work proposes a framework for the safety robustness of agents using deep reinforcement learning techniques. In the proposed work, a system is developed in which multiple agents interact with the real-world environment and act collaboratively and cooperatively. This work is an extension to our previously published work [33]. Here, we have added policy loss, safety robustness, value loss and value estimate. We have evaluated these parameters on multiple policies, i.e., Policy 1, Policy 2 and Policy 3. We have also proposed a novel algorithm for the training process. In proposed model, several agents collaborate with one another to complete tasks and maintain a safe state. To take actions cooperatively and collaboratively of agents in accordance with the safety robustness of policies. We have applied DRL algorithms such as proximal policy optimization (PPO) and Trust Region Policy Optimization (TRPO) algorithms and DRL approaches.

The rest of the paper is organized as follows: Section II provides the literature review. Section III presents the proposed methodology. In Section IV, the details of the proposed model are presented. Section V explains the implementation setup. In Section VI, experiments and results are presented and the paper is concluded in Section VII.

II. Literature Review

A. Single Agent Scenarios

Alternative reward functions may be presented to help an agent learn better if a reward function for an RL problem is not provided. With multiple reward functions, the agent may learn a variety of policies with varying levels of robustness. Evaluating the achieved reward and success rate has been a common method for assessing the robustness of a policy. When utilizing RL to address issues in many safety-critical situations, safety is a concern. Although reward and success rate have been commonly used to evaluate policy robustness, there has been limited discussion on assessing policy robustness from a safety perspective. This study [11] contributes to the field by introducing a novel concept of safety robustness and an algorithm to estimate it. The proposed method is applied to evaluate the safety robustness of three policies for controlling the manipulation of a cable-driven parallel robot. The results demonstrate that the algorithm is effective in estimating safety robustness by comparing the number of safe episodes to the total number of episodes. The study also includes illustrative experiments to demonstrate the implementation of the proposed algorithm. It can also choose the safest policy from a set of many policies.

As a recent and popular research area, RL faces a number of issues. Agent navigation and obstacle avoidance are the most appealing of these RL challenges. It is well understood the value of precise and multidimensional monitoring in detecting problems early and preventing them from escalating. Previously, AI was employed for drone navigation, with images from on-board cameras being processed for wayfinding and collision avoidance. The authors of this paper presented a novel recommender system for drone navigation, which utilizes artificial intelligence and sensor data while requiring only basic information [12]. Their approach involves combining two techniques: Proximal Policy Optimization (PPO) for navigation with minimal information and Long-Short Term Memory (LSTM) networks for overcoming obstacles using navigation memory. The safety requirements of the system are determined using a systematic functional failure analysis (FFA).

RL methods have been used to handle a variety of sequential decision-making issues for a long time. In complex environments with high dimensions, algorithms face significant challenges when attempting to optimize policies. Recent advances in deep learning have enabled RL approaches to drive optimal policies for complex agents capable of performing well in these difficult contexts [13] [14]. In their paper, the authors conducted a survey on various approaches for multi-agent deep RL (MADRL). The survey covers non-stationary, partial observability, continuous state and action spaces, multi-agent training methods, and multi-agent transfer learning [15]. The survey also discusses the advantages, disadvantages, and applications of the evaluated approaches, leading to the creation of more robust and practical multi-agent learning methods for tackling real-world issues in the future.

To overcome challenges in dealing with local-stable-point scenarios in complex situations, the artificial potential field method needs to be revised, which may increase the algorithm's complexity. In this study, the authors proposed an improved black-hole potential field combined with RL [16] to address this issue. The black hole potential field is used as the environment in an RL system, where agents automatically adapt to their surroundings and learn how to discover targets using basic environmental data. Furthermore, with the curriculum learning technique, taught agents adapt to a variety of contexts. Meanwhile, the avoidance process is visualized to show how agents avoid obstacles and achieve their destination. Static and dynamic trials are used to assess our approach. The findings indicate that agents can autonomously learn how to escape local stability points even without prior knowledge.

The authors presented a collision avoidance system in their research paper, which aims to provide reliable autonomous navigation for self-driving ships. The system uses a collision risk assessment [17] technique based on the ship's domain and the closest point of approach (CPA) to estimate the collision risk, and generates an avoidance path only when necessary. The ship domain is designed with an asymmetric shape, taking into account the ship's maneuverability and the international regulations for preventing collisions at sea (COLREGs). The CPA is used to determine the value of a quantitative collision risk. The authors of [18] investigate the resilience of RL with adversarial altered state observations, which is relevant for deploying real-world RL agents in the face of unexpected sensing noise. They show that with a given agent strategy, an optimum adversary to tampering state observations can be discovered, ensuring that the worst-case agent reward is obtained. This results in a unique empirical adversarial assault on RL agents in DRL environments, via a learnt adversary that is significantly stronger than earlier ones. Authors offer an alternate training with learned adversaries (ATLA) approach to improve an agent's resilience by training an opponent online alongside the agent using policy gradients and the optimum adversarial attack framework.

The automobile industry is being encouraged toward more flexibility and stability in manufacturing by EU laws on CO2 limitations and the trend of individualization. Modular manufacturing, in which workstations are detached by autonomous guided vehicles and new control ideas are required, is one way to handle these issues. Throughput-optimal coordination of goods, workstations, and vehicles are the goals of modular production control. Conventional control techniques for this NP-hard issue are inefficient in computation, do not discover optimal solutions or are not generalizable. On the other hand, DRL provides strong and generalizable algorithms that can deal with a wide range of settings and high levels of complexity. The PPO method is utilized in solving modular production control, as discussed in the paper [19]. The experimental results showed that the learned behavior of the agent was optimal, reliable, consistent, and generalizable across various modular production control setups. The agent was successful in adapting its strategies based on the given problem configuration. The authors further discussed how this learning behavior was achieved, with a focus on the agent's state, activity, and incentive design.

B. Multi-Agents

The robots that work in the marine environment are Unmanned surface vehicles (USV), which is a surface ship that can detect the target, and do the perception of the environment.

Autonomous navigation and obstacle avoidance are very necessary for USV and have been frequently employed to carry out operations in a complex sea environment or in risky marine areas for ships with sailors, considerably increasing their defensive capability and detection range [26] [27]. Traditional navigation approaches increase the risk of falling into traps while travelling in a complex, dynamic environment, and the likelihood of reaching the target decreases. These heuristic approaches are slow, and when used in real-world sophisticated dynamic situations, they have issues such as slow speed and inability to identify and avoid obstacles [24] [25]. Authors proposed a DRL approach called ANOA (Autonomous Navigation and Obstacle Avoidance), which uses a dueling deep Q-network and a customized architecture of state and action spaces [20]. They implemented their proposed approach in a static and dynamic environment using Unity 3D and the ML-Agents Toolkit. Their experimental results show that once they are trained, USVs can find a path, reach their destination, and avoid obstacles in any complex dynamic environment. In [21], authors proposed a DRL based framework for the collaboration and cooperation of multi agents in real-world environments. A partitioned base technique is presented in this work. For effective coordination and continuous operation of a multi-agent system, it is necessary for agents to have knowledge of the environment's boundary and the location of the currently active neighboring agent. This allows for seamless transition to the next neighboring agent in case of any unexpected issue or failure.

Authors explore the feasibility of utilizing the PPO, a cutting-edge DRL algorithm for continuous control tasks, to address the challenge of effective path planning that caters to the two primary objectives of path following and collision avoidance (COLAV), essential for ensuring the safety and dependability of autonomous surface vehicles (ASV) [29]. The AI agent is trained and evaluated in a complex, stochastically generated simulation environment employing the OpenAI gym Python toolbox equipped with several rangefinder sensors for obstacle detection. The agent has real-time visibility into its own reward function, which enables it to adapt its guidance strategy dynamically. The trained agent achieves an episodic success rate of almost 100 percent, varying from path-adherence to obstacle avoidance.

The application of deep neural network-based systems has become a state-of-the-art approach in various robotics tasks. However, utilizing these systems in safety-critical areas can be precarious in the absence of explicit network robustness guarantees [22] [23]. Small changes in sensor inputs (due to noise or adversarial situations) can cause network-based decisions to change, as demonstrated by an autonomous car swerving into another lane. To mitigate the risks posed by adversarial attacks, various defensive algorithms have been developed, including those that provide formal robustness guarantees. In the study [30], certified adversarial robustness research is utilized to develop an online DRL method that is certifiably robust. The proposed defense mechanism calculates lower bounds on state-action values to detect and select a resilient action in case of worst-case input divergence caused by possible adversaries or noise. Additionally, the resulting policy is accompanied by a certificate of solution quality, despite the certifier's lack of knowledge about the real state and optimal action due to disturbances. The study provides new performance guarantees, extensions to other RL algorithms, aggregated results across multiple scenarios, an extension into scenarios with adversarial behavior, comparisons with a more computationally expensive method, and visualizations that provide intuition about the robustness algorithm [31] [32].

In Table I, the existing literature is comprehensively summarized. They must guarantee that DRL-trained robots are robust in order for them to function alongside humans in actual circumstances. Because the current world is so diverse, and human behaviour frequently changes in reaction to agent deployment, the agent will almost certainly encounter scenarios that he or she has never encountered before. This creates an assessment challenge: how can authors successfully measure robustness if they can't use the average training or validation reward as a metric? Unit testing in software engineering is a source of inspiration for them. In their paper [34], the authors propose that when creating AI agents that interact with people, designers should consider potential edge cases in partner behavior, conceivable states encountered, and construct tests to guarantee that the agent's behaviour is appropriate in these instances. This technique is used to create a suite of unit tests for the Overcooked-AI environment, which is then used to assess three ideas for enhancing robustness. Authors discover that using the test suite gives them a lot of information about the consequences of these proposals that they couldn't get by just looking at the average validation reward.

III. JUSTIFICATION OF THE PROPOSED MODEL

It would be naive to assert that MAS should be employed in all complex system designs. There are certain cases when it is especially suited, as with any beneficial strategy, and others where it is not.Multi-Agent Systems (MAS) have numerous real-world applications, including but not limited to traffic control, task distribution, ant colonies, autonomous cars, and drones. A hard-coded agent cannot operate well in a high-dimensional environment due to the complexity of the environment. MADRL agents can find the best solutions and policies. The policies of other agents are impacted by changes in the environment when agents collaborate and coordinate their actions. Failure of a learnt policy in safety-critical applications might result in dangerous scenarios. The purpose of this section is to emphasise the importance and utility of MADRL in accordance with safety. In safety-critical

applications, ensuring the robustness of policies is essential when using RL to solve problems. To enhance the safety of learned policies, control approaches from the control community can be utilized. Safety-critical scenarios are not considered in multi-agent settings. So, there is a need to develop a DRL-based system that tackles the problem of safety in a multi-agent environment.

IV. Proposed Model

A technique for approximating the safety robustness of policies is proposed, which is based on the system architecture of robust control, safe states (i.e., non-error states [35]), and statistical analysis. The safety robustness is approximated by calculating the ratio of the number of safe episodes to the total number of episodes, which can be used as an indicator to evaluate policy robustness from a safety perspective. This model uses curriculum learning for the randomization of the environment and the better performance of agents. Agents start their learning with easy tasks and then move to the difficult ones. We use PPO to analyze the visual observations as well as vector observations. By using visual and vector observations, agents communicate with each other. In order to train our model, we employ a 4-dimensional action space in the environment. CNN is the neural network used by PPO (a fully linked neural network).

The environment is sensed by the agent's sensors, which are subsequently passed on to the first layer of the neural network. The activation function is used here before moving on to the next layer. Similarly, the agent receives the output after using the activation function. The agent receives this output and estimates his action based on that output. The agent receives a positive reward if it takes the correct action, while a negative reward is given if it takes the wrong action.

We also use CL (a method of training a machine learning model that gradually introduces more challenging components of a problem such that the model is constantly optimally challenged) for training purposes also.

A. Proposed Method of DRL

When agents interact with the environment, there are a number of observations made by them. According to observations, an agent must follow some policy and, as a result, must take action [28]. By taking that action, the agent makes different changes in the environment. Changes may be positive (perform the best action to tackle the task) or may be negative. (perform bad actions, exploit the task or environment). After performing an action, the agent moves to another state. The agent again observes the environment and follows another policy to gain the optimal policy for that task.

We employ the PPO algorithm for training in our multi-agent settings, and by combining it with CL, we can expand the training process to a large number of agents. The learning environment is entirely cooperative, and each agent possesses only basic knowledge of the surroundings. The goal of all agents is to maximize the total discounted reward by working together. The following is a description of a tuple:

$$(N, S, A_i, Z_i, C, R, O)$$

N denotes the total number of agents in the system, S represents the number of possible states that the system can be in, and A_i denotes the number of possible actions that agent i can take. C and R represent the joint transition and reward functions, respectively. O represents the number of possible observations that can be made, and Z_i represents the collection of observations that agent i has access to.

To make the training more stable, each agent only knows limited knowledge about the environment in a single state S_c. As a result, agents must recall some information from prior observations.

The utilization of the PPO algorithm was employed to improve training with limited rewards. This method involves the use of a conditional statement to differentiate between actions and observations derived from the agent's demonstration. The condition assesses whether the new actions and observations are similar to those in the demonstration. The agents are rewarded for their efforts. We may also take advantage of local incentives using PPO. This investigation employs an extrinsic reward signal as a local reward signal, and utilizes a combination of CL with RL and PPO to expedite policy convergence. Fig. 1 is the demonstration of the proposed system model.

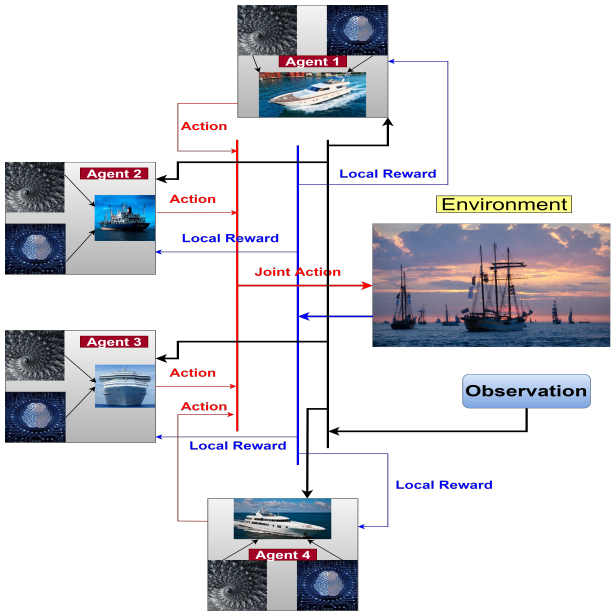

Fig. 1. Block diagram of the proposed system model [33].

In Fig. 2, obtained from [33], you can see that agents observe visual and vector observations from the environment and move these inputs (observations) to the convolutional layer. The agent receives the outputs of the results. According to these outputs, agents take action in the environment.

The mentioned techniques are implemented for each agent, which operate by collaborating and cooperating with other agents. The agents interact with the learning environment through cooperative actions, and as a result, they receive a local cumulative reward.

This allows agents to quickly imitate demonstrated behaviour, which speeds up the training process. The CL tech-

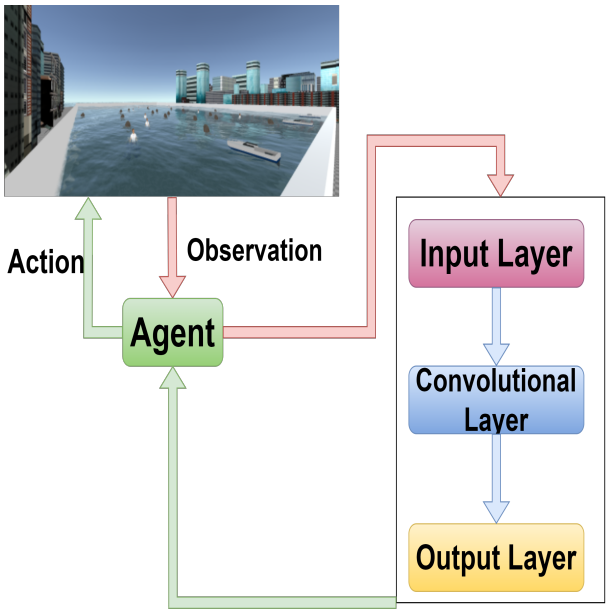

Fig. 2. Layered approach in the proposed system model.

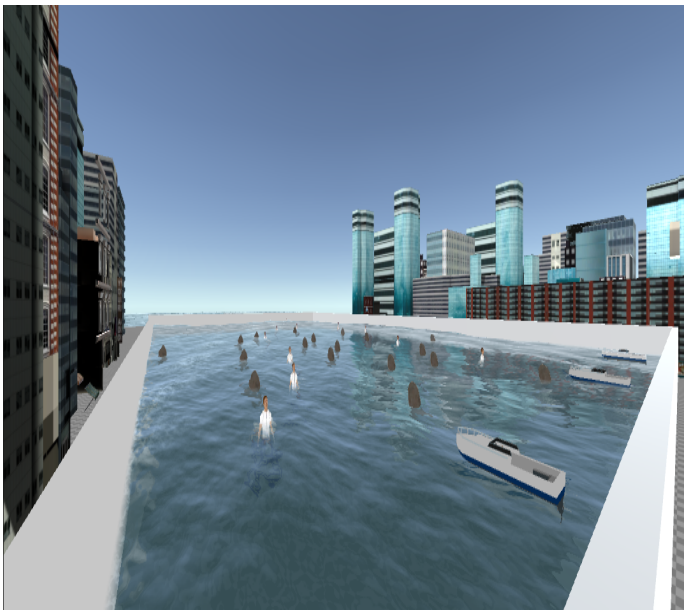

Fig. 3. A scene of the learning environment for agents.

nique guarantees that the policies are converged quickly. The algorithm provides the pseudo-code for the suggested model.

B. Components of the Proposed Model

Different components of proposed model are as under:

1) Learning environment: In many aspects of life, robots play an important role. Recently, robots have been used in digital factories [36], as well as in hazardous locations such as fires, storms, and landslides. Robots can carry, move, and lift large things from one location to another, making it easier to provide goods to people who are in risky or challenging situations. Robots operate more effectively and quickly than people in difficult situations, reducing human risk. These well-trained agents have also been utilised in the marine environment to rescue individuals and apprehend smugglers. As a result, we decided to learn in a maritime setting. This paper looks at a real-world situation in which agents try to save people by getting around problems and working together.

The learning environment employed in this study is depicted in Fig. 3. Agents in a marine setting navigate the goal (people in need of rescue) and navigate to them while avoiding obstacles. For example, the environment contains obstacles in the form of heavy rocks, and the agents have the ability to move in four directions: left, right, forward, and backward. Agents go towards their target by doing these activities and avoiding obstacles through navigation and coordination with other agents.

2) Agents: In Unity 3D games, objects are used as agents in the learning environment. The agent is a boat that is used to move in a marine environment and to rescue individuals who are drowning. In Fig. 4 agent is demonstrated as "ship".

In the learning environment, agents generate states and execute actions from a set of predefined actions such as left, right, forward, and backward, thereby transitioning from one state, denoted by S_t to the next state, denoted by S_{t+1}. Each agent is associated with a single brain that guides the agent on its next course of action.

Fig. 4. A scene of an agent navigating in the given environment.

C. Training Process Algorithm

In Algorithm 1, it is observed that the process starts from episodes. Here we apply a "For-loop" that initiates the training process from the first episode.

Algorithm 1 Training Process

For episodes = 1 to n
{
Initialize the Environment
Randomize the Environment
For Time-steps = 1 to 5000
{
For each Agent $a_i < 4$
Agent a_i observe Environment
Calculate distance of every agent
{
if (Distance <= 50 meters of Agent a_i AND Agent a_j)
{
Broadcast message to Agent a_j
}
if (Goal of Agent a_i AND Agent a_j == same)
{
Agent with minimum distance from goal will take action.
}
}
Calculate Reward.
}
Mean Reward = *Actions with positive reward / Total Reward*
if (Mean Reward > 0)
{
Safe Episode
}
}
Safety Robustness of Current Policy = *total Safe Episodes / total Episodes*

Episode and then moves on to the next to meet the desired number of episodes. The environment is initialised in each episode. After initialization, the environment is randomized. Because the examples of dynamic environments are considered so, there is a need to observe all the environments. After randomizing the environment, another "For-loop" is applied inside the first for-loop. This for-loop starts from the first time-step to the 5000 time-steps of each episode. Within this loop, there is an additional nested "for-loop" that iterates through each agent in the environment.

In each time-step, every agent observes the environment and calculates their distance from other agents. Here is the if statement. If the goals of both agents are common, then the agent having the minimum distance from the goal will take action and collect a reward while the other agent will select the other target/goal. If both agents have different goals, both agents will perform or take their actions according to their targets. When 1 episode is completed, the mean reward will be calculated by dividing the total positive reward by the total reward. The following "if condition" checks if the mean reward is above zero. If this condition is satisfied, the episode is considered safe. After all episodes are completed, the policy's safety and robustness are determined by calculating the ratio of safe episodes to total episodes.

D. Flow Chart

The flow chart of our proposed model is shown in Fig. 5. It is observed that in each episode, the environment is initialized. Because after initialization, the environment is randomized. because the examples of dynamic environments are considered. Here is a loop. If time steps are completed, the process will start from another episode. If the time-steps are pending, then in each time-step, every agent observes the environment. According to that observation, agents calculate their distance from other agents. After calculating the distance, agents having a minimum distance of 50 metres broadcast their goals. If the goals of both agents are common then the agent having minimum distance from the goal will take action and collect reward and the other agent will select the other target/goal. If both agents have different goals, both agents will perform their actions to meet their target. After completing one episode, the mean reward can be calculated by dividing the total positive rewards obtained during the episode by the total number of rewards received. Completion of all episodes results in the safety and robustness of the current policy.

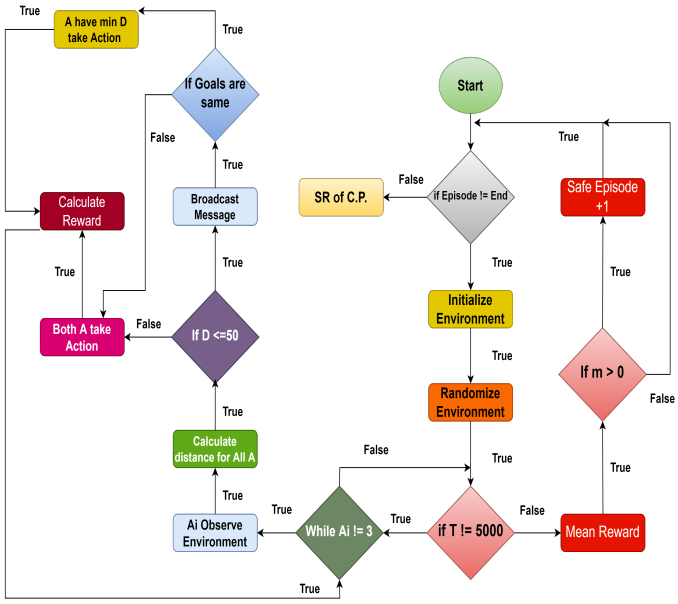

Fig. 5. The flow chart of the proposed system.

E. Reward Function

To promote desirable behavior, a local incentive signal is utilized to encourage consistency. An effective incentive system ensures faster convergence of the learning process in single-agent contexts than ever before [37]. The entire reward for a single agent may be calculated using the equation below:

$$r = (r_{hp} + r_{hc}) - (r_{cla} + r_{clo} + r_{cldo})$$

where, r is the sum of rewards given to each agent, where r_{hp} is the reward for rescuing drowning humans, r_{hc} is the reward for rescuing all humans in the environment, r_{clo} is the negative reward for colliding with an obstacle, r_{cla} is the negative reward for colliding with other agents and (r cldo) is the negative reward for colliding with some dynamic or sudden obstacle. r_{hp} can be calculated using the following equation:

$$r_{hp} = \begin{cases} r_p & \text{if} \quad d = 0 \\ 0 & \text{Otherwise} \end{cases}$$

where, r_p is the reward for rescuing people and 'd' represents the distance between the agent and the drowning person.

Moreover, we can calculate reward r_c using the following equation:

$$r_{hc} = \begin{cases} r_c & \text{if} \quad h = 0 \\ 0 & \text{Otherwise} \end{cases}$$

where, h_c is the reward of rescuing all drowning people, and h is the number of drowned people remaining in the sea.

Furthermore, to calculate the r_{cla} reward, we can use the following equation:

$$r_{cla} = \begin{cases} r_a & \text{if} \quad d = 0 \\ 0 & \text{Otherwise} \end{cases}$$

the reward when an agent collides with another agent is denoted by r_a and d is the distance between the two agents.

Moreover, to calculate the r_{clo} reward, we present the following equation:

$$r_{clo} = \begin{cases} r_o & \text{if} \quad d = 0 \\ 0 & \text{Otherwise} \end{cases}$$

where, r_o is the reward given to the agent on collision with static obstacles, and d is the distance between the agent and the static obstacle.

Lastly, we present the equation to calculate the r_{cldo} reward.

$$r_{cldo} = \begin{cases} r_{do} & \text{if} \quad d = 0 \\ 0 & \text{Otherwise} \end{cases}$$

where r_{do} is the reward of an agent's collision with a moving drowning human or any dynamic obstacle, and d is the distance between the agent and the drowning human or dynamic obstacle.

The table below illustrates the awards each agent received for various occurrences. We implemented a penalty of -0.1 for each agent when they collided with another agent in the environment. This approach addresses the issue of inter-agent collision. We also assign a value of -0.1 when the agent collides with the seashore or any other obstruction. The agent earns-0.1 reward if it collides with any drowning human in the surroundings. An agent who successfully rescues a drowning individual receives a +0.3 bonus. Furthermore, the agents will gain a +0.5 bonus if they are successful in rescuing all drowning people in the surroundings.

V. Implementation

This section describes how we will put the suggested approach into practice. We also go through the tools that were utilised to carry out the implementation. This paper also investigates various behavioral characteristics and training parameters.

A. Unity 3D

Unity Technologies is the developer of the cross-platform game engine called Unity, which was first announced and released as a game engine for Mac OS X in June 2005 at Apple Inc.'s Worldwide Developers Conference. Over time, the engine has been enhanced to support various platforms such as PC, mobile, console, and virtual reality. It allows developers to create 3D and 2D games, interactive simulations [38], and other experiences.

Gazebo is also a three-dimensional dynamic robot environment simulator that can be used to test algorithms and robot designs. It runs regression tests and uses realistic scenarios to teach AI systems. The speed of the Gazebo Simulator has never been a strong point. Simulating a 30-minute event takes 6 hours. Multiple instances operating at the same time is tough. We can make it happen, but there are still difficulties like non-accuracy and an unknown amount of effort required to coordinate among these various instances.

Unity [39], on the other hand, is far more efficient at running several simulations on a single system and coordinating learning across all instances. Unity simulations may be cranked up to a hundred times faster than real time.

B. ML-Agents Toolkit

The toolbox includes numerous components for implementing RL, such as Brain, Academy, and Agent. Each agent is connected to and controlled by a brain component. Different environmental factors are learned using the Academy component. Additionally, it provides a link between the brain and Python Tensorflow. Fig. 6 shows the basic structure and overview of the ML-Agents toolkit [40].

C. Training Parameters

The learning environment's working area is 200×200 square feet. The functional area of the learning environment contains a variety of objects, including rocks, boats, humans, and agents. The combination of moving individuals and robots was utilized to enhance the realism and dynamism of the learning environment, enabling the agents to be trained in such a setting.

TABLE II. Training Parameters Used in the Proposed Model

Parameters	Values
Batch size	1024
Buffer size	16384
Learning rate	0.0003
Max steps for each episode	5000
Number of epoch	3
Number 0f layers	2
Gamma in extrinsic Reward signal	0.99
Behavior cloning strength	0.5

Fig. 6. ML-Agents toolkit used in the proposed model.

Table II displays some important training parameters employed to train the agents utilizing the proposed model. Based on empirical testing, a batch size of 1024 is deemed appropriate. Additionally, the buffer size parameter must be larger than the batch size. The buffer size was set to 16384 by default. Local RL reward signals are used in the proposed model.

TABLE III. TRAINING PARAMETERS USED FOR POLICY 1

Parameters	Values
Batch size	1024
Buffer size	16384
Learning rate	0.0003
Max steps for each episode	5000
Number of epoch	3
Number 0f layers	2
Gamma in extrinsic Reward signal	0.99
Time horizon	128
Hidden Units	512

The Table III provides some key training parameters for policy 1, which were utilized to train the agents. The batch size for the PPO algorithm has been adjusted to 1024. By default, we set the buffer size parameter to 16384, which is greater than the batch size of 1024. For policy 1, we set the temporal horizon value to 128 and the hidden units value to 512.

The Table IV provides some key training parameters for policy 2, which were utilised to train the agents. The batch size for the SAC algorithm has been adjusted to 1024. By default, we set the buffer size parameter to 16384, which is greater than the batch size of 1024. For the SAC algorithm, we set the temporal horizon to 128 and the hidden unit value to 512. Initial buffer steps of 6000 are used. Tua is used at a value of 0.01. For policy 2, we employ 10.0 steps for each update.

TABLE IV. TRAINING PARAMETERS USED FOR POLICY 2

Parameters	Values
Batch size	1024
Buffer size	16384
Learning rate	0.0003
Max steps for each episode	5000
Number of epoch	3
Number 0f layers	2
Gamma in extrinsic Reward signal	0.99
Time horizon	128
Hidden Units	512
Tau	0.01
Buffer initial steps	6000
Steps per update	10.0

VI. EXPERIMENTS AND RESULTS

With the aforesaid configuration, Algorithm 1 is used to evaluate the safety robustness of the three approaches for managing USVs in terms of obstacle avoidance and navigation to their destination. Fig. 7 illustrates the orientation of the USVs controlled by the three policies (p1, p2, and p3) towards a goal orientation when the maximum uncertainty of action and state is 0.1. It can be observed that all three policies successfully maintain the USVs in safe states.

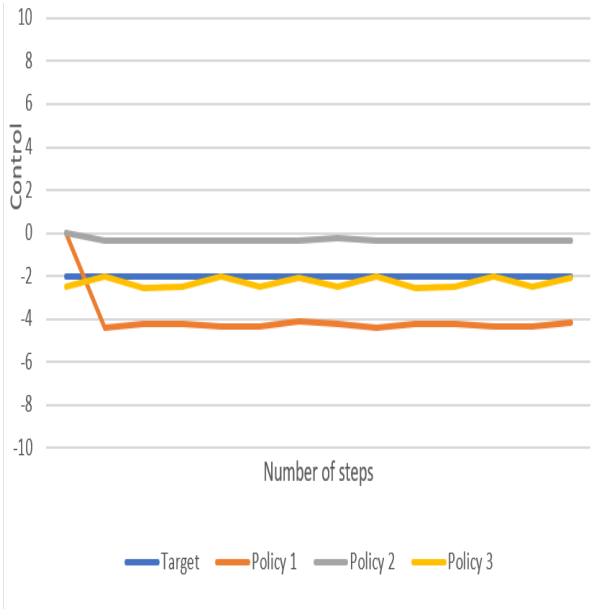

Fig. 7. Orientation of the USVs controlled by the three policies with action uncertainty value 0.1.

The y-axis depicts the control of USVs, while the x-axis represents the number of time-steps.

The target is shown by a blue line, the policy-1 is indicated by a red line, the policy-2 is indicated by a grey line, and the policy-3 is indicated by a yellow line.

The proposed model's policy is policy-3, and it can be observed that policy-3 is closer to the aim than the other policies. It can be seen from Fig. 7, the policy followed by our proposed model is more resilient in terms of USV's control than the other policies.

When the maximum magnitudes of the uncertainties of action and state are 0.2, Fig. 8 shows the results.

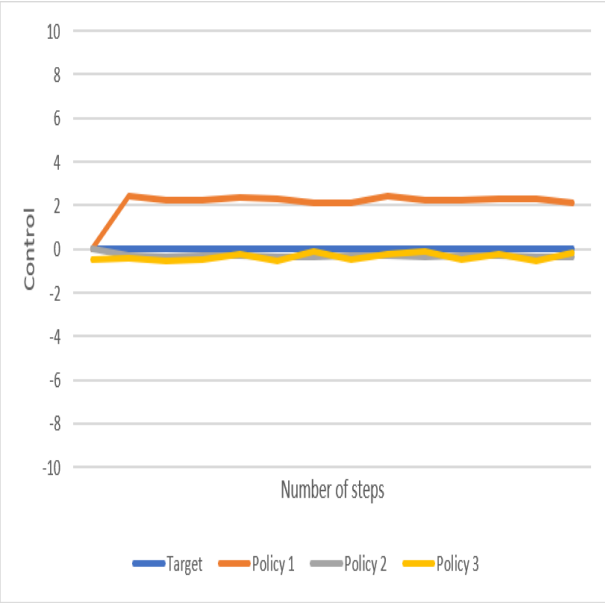

Fig. 8. USV control with action uncertainty of 0.2.

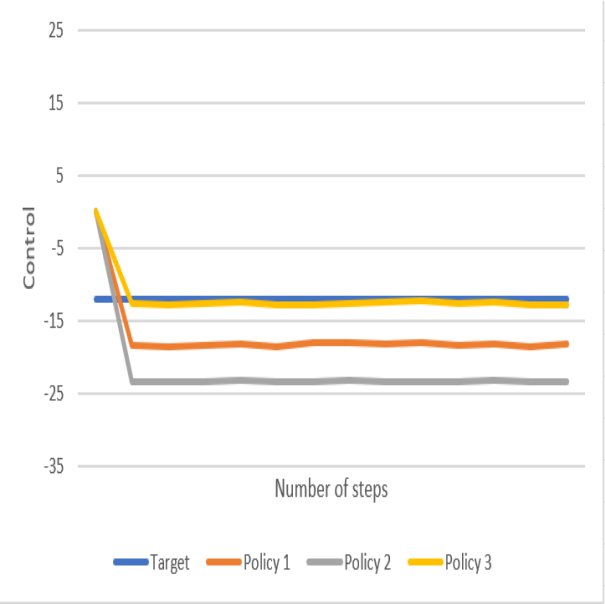

Fig. 9. USV control with action uncertainty of 0.5.

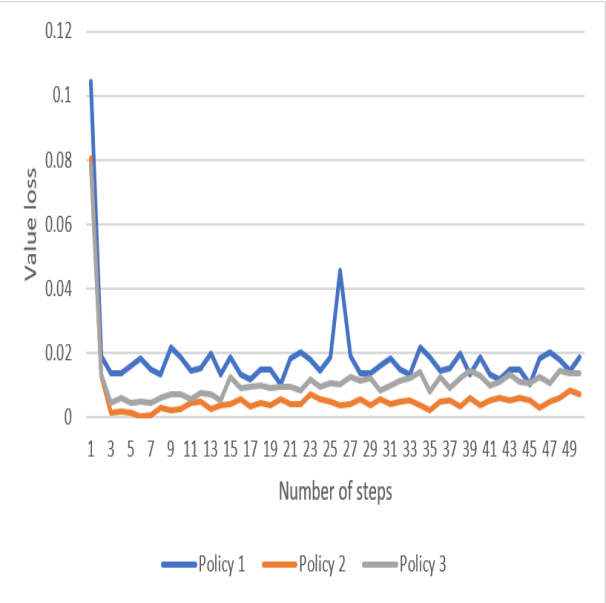

Fig. 10. Value loss against the number of steps in 3 different policies.

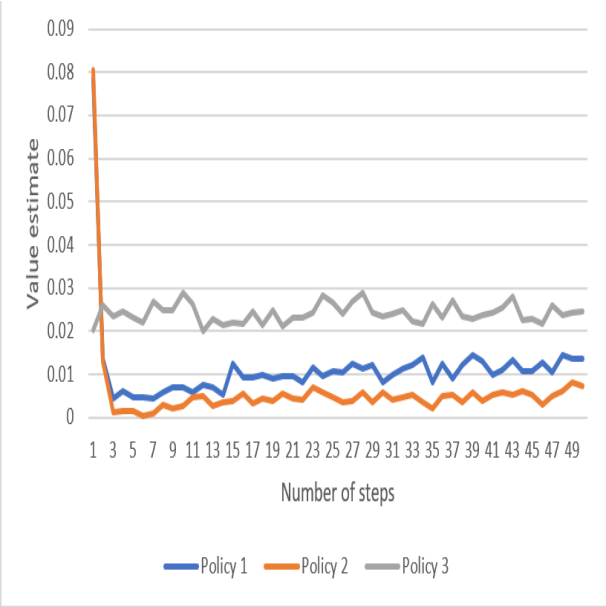

Fig. 11. Value estimate against the number of steps in 3 different policies.

The USV control is represented on the y-axis, while the number of time-steps is represented on the x-axis.

The plot displays the target as a blue line, while the policy-1, policy-2, and policy-3 are represented by a red, grey, and yellow line, respectively.

The proposed model's policy is policy-3, and it can be observed that policy-3 is closer to the aim than the other policies.

It can be seen from Fig. 8, the policy followed by our proposed model is more resilient in terms of USV's control than the other policies.

Fig. 9 illustrates the orientation of USVs controlled by the three policies (p1, p2, and p3) to a goal orientation, when the maximum magnitudes of the uncertainty of action and state are 0.5. All three policies were able to maintain the USVs in safe states.

The y-axis depicts the control of USVs, while the x-axis represents the number of time-steps.

The blue line represents the target, while the red, grey, and yellow lines represent policy-1, policy-2, and policy-3, respectively.

The episode is stopped at the 40th step when the USV is controlled by p1 since it is out of safe condition. The USV

can be kept safe by policies p2 and p3.

As a result, the three policies have varying degrees of ability to keep the USV in a safe state. Before the policy with the best safety robustness, it is crucial to evaluate the safety robustness of the three policies using Algorithm 1.

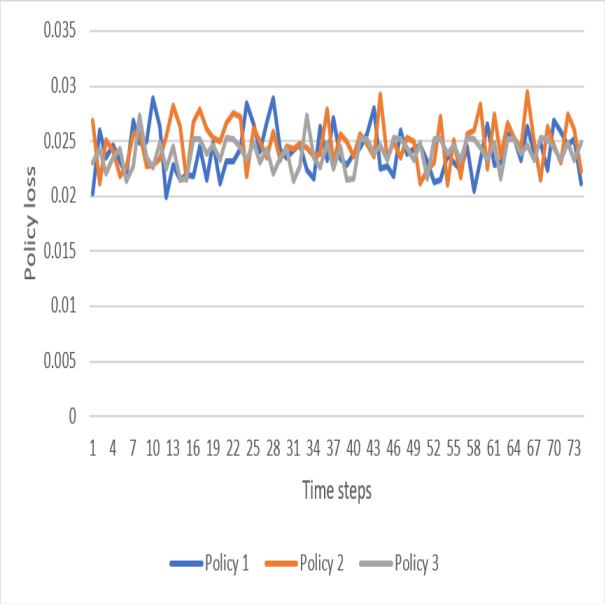

Fig. 12. Policy loss against the number of steps in 3 different policies.

In Fig. 10, the y-axis represents the value loss, while the x-axis indicates the number of time-steps. The blue line represents policy-1, the orange line represents policy-2, and the grey line represents policy-3. The graph indicates that policy-3 has an intermediate value loss between policy-1 and policy-2, suggesting that policy-3 has an average value loss.

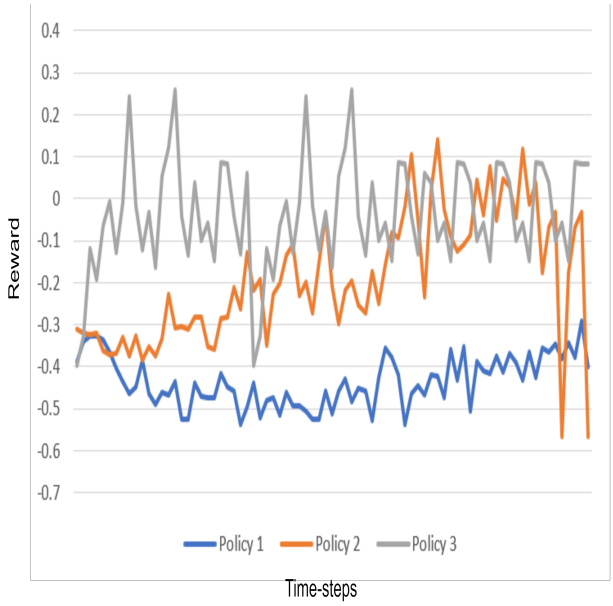

Fig. 13. Reward against the number of steps in 3 different policies.

Fig. 12 plots the value loss against the number of time-steps, where the y-axis represents the value loss, and the x-axis represents the time-steps. The performance of the three policies (i.e., policy-1, policy-2, and policy-3) is shown in blue, orange, and grey lines, respectively. The figure demonstrates that policy-3 has the lowest value loss among the three policies.

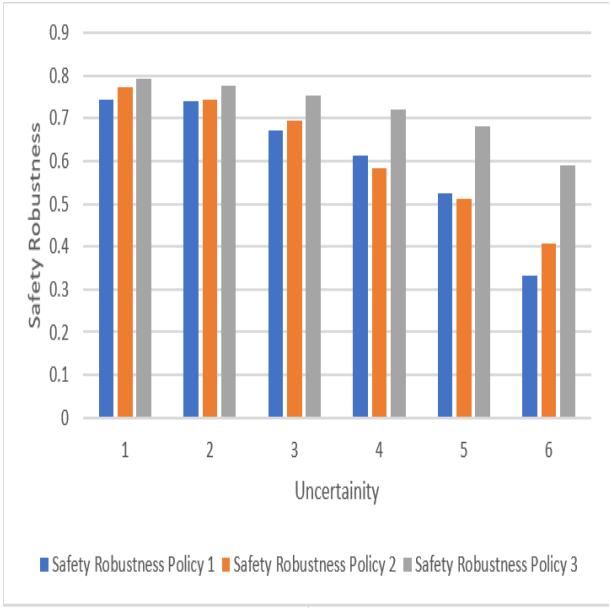

Fig. 14. Safety robustness vs. Uncertainty in 3 different policies.

The plot in Fig. 11 shows the value loss on the y-axis against the number of time-steps on the x-axis. The three policies, Policy 1, Policy 2, and Policy 3, are represented by blue, orange, and grey lines, respectively. It is evident from the plot that Policy 3 has the highest policy loss among the three.

The graph in Fig. 13 illustrates the rewards obtained by all policies, where Policy 1 is represented by a blue line, Policy 2 by an orange line, and Policy 3 by a grey line. The reward is a measure of policy efficiency, and the policy with the highest reward indicates better efficiency. From the graph, it is evident that Policy 2 gains more rewards compared to Policy 1, and Policy 3 gains more rewards than both Policy 1 and Policy 2. The proposed model adopts Policy 3, which is demonstrated to be the most efficient among the three policies.

In Fig. 14, the y-axis represents the reward gained by all policies, while the x-axis indicates the number of episodes. The blue line represents Policy-1, the orange line represents Policy-2, and the grey line represents Policy-3. The safety robustness of a policy indicates its ability to keep the system in a safe state.

Efficiency of a model is indicated by its safety robustness, and the policy that has maximum safety robustness is considered the most efficient. In Fig. 14, it can be observed that the proposed model follows policy 3, which has the highest safety robustness among all policies.

VII. Conclusions

In this work, we investigated a DRL based scenario which use multi-agents. These agents have been assigned some tasks

related to real world scenario. In our case, a submarine scenario was considered and the task of the agents is to safe the drowning person. We extended our previously published work by adding more experiments such as policy loss, reward function and the safety robustness. While the training of agents using deep reinforcement learning in real-world scenarios is very important, the safety of agents and other human beings is also very important. It is very important to learn about a policy that is robust in the context of safety. Several previous works in single agent settings focused on the safety of agents and other aspects of their training environment. But no work was done on the robust safety of agents in multi-agent settings. This work is focused on the safety and robustness of policies in multi-agent settings. A model is proposed that ensures the safety of agents and other valuable entities in the environment. The proposed model uses PPO algorithm to train the agents. Curriculum learning is used to teach the agent about safety and find a robust policy from easy to difficult level. A sea environment is considered in this work where some USVs are rescuing human beings that have been dropped into the sea. An algorithm is proposed in this research for the training of agents and finds a robust policy in the context of safety. To evaluate the safety robustness of policies, a few parameters are evaluated in this work. Safety robustness with respect to the number of safe states and control of USVs for the target with respect to the number of steps is evaluated, which shows the robustness of policy in safety. The policy followed by the proposed model is compared with the other two policies. Through experimental evaluation, it has been observed that the proposed model outperforms other policies. Furthermore, the performance of the proposed model has been verified by evaluating parameters such as mean reward, policy loss, policy estimate, and value loss. The experimental results have demonstrated that the proposed model exhibits better performance in multi-agent scenarios.

In the future, we aim to test our model with a higher number of agents in more complex scenarios. For example, it is vital to investigate how wind and its speed can effect the safety and robustness of the agents in the DRL scenario.

Spatiotemporal Graph Networks for Relational Reasoning in Campus Infrastructure Management

Sanjay Agal, Krishna Raulji, Nikunj Bhavsar, Pooja Bhatt
Artificial Intelligence and Data Science-Faculty of Engineering and Technology, Parul University, Vadodara, India

***Abstract*—The efficient management of campus infrastructure presents a complex spatiotemporal forecasting challenge characterized by dynamic interdependencies between physical assets. Traditional models fail to capture these intricate relationships as they treat buildings as independent entities or rely on static correlation structures. This paper introduces a novel Spatiotemporal Graph Neural Network (ST-GNN) framework that reframes infrastructure forecasting as a relational reasoning task, enabling dynamic inference of campus wide interdependencies. Our approach integrates Graph Attention Networks (GAT) to learn time-varying spatial dependencies and Gated Temporal Convolutional Networks (TCNs) to capture multi-scale temporal patterns. A key innovation is our context-sensitive graph construction method that incorporates physical proximity, functional similarity, and human mobility data to create a holistic representation of campus dynamics. Evaluated on a real-world multimodal dataset comprising 24 months of energy and occupancy data from 50 campus buildings, the proposed model demonstrates superior performance, achieving a 16.3% reduction in mean absolute error compared to the strongest baseline. Comprehensive ablation studies confirm the critical contribution of each architectural component, while qualitative analysis reveals the model's capacity to provide interpretable insights into campus operational patterns. This work provides a powerful framework for intelligent campus management, enabling precise resource allocation, energy optimization, and sustainable operational planning through advanced relational reasoning capabilities.**

***Keywords*—Spatiotemporal Graph Neural Networks; relational reasoning; smart campus management; infrastructure utilization forecasting; graph attention networks; temporal convolutional networks; dynamic graph construction; energy optimization; predictive analytics**

I. Introduction

The proliferation of the Internet of Things (IoT) has transformed university campuses into living laboratories for cyber physical systems, generating vast volumes of spatiotemporal data from interconnected assets like academic buildings, libraries, and utility networks [1]. The efficient management of these resources is paramount for achieving sustainability goals, optimizing operational costs, and enhancing the overall user experience. Central to this challenge is the ability to accurately forecast key utilization metrics, such as energy load and occupancy, which are influenced by a complex interplay of factors: time of day, day of the week, academic calendars, and, crucially, the *functional and spatial relationships* between different campus locations [2].

The field of predictive analytics has evolved from classical statistical models (e.g., ARIMA) to machine learning techniques (e.g., SVR, XGBoost) and modern deep learning architectures like Long Short Term Memory (LSTM) networks. While powerful for sequence modeling, these approaches typically treat the time series of each asset in isolation, fundamentally ignoring the rich relational graph structure that defines a campus [3]. This represents a significant limitation, as the energy load of a lecture hall intrinsically influences that of a nearby cafeteria, and occupancy in a library is affected by class schedules across campus. Convolutional Neural Networks (CNNs) applied to spatial data assume a Euclidean grid structure, an invalid premise for the irregular, non-Euclidean layout of campus infrastructure [4].

Graph Neural Networks (GNNs) emerged as a powerful paradigm for learning from relational data [5]. Spatiotemporal GNNs (ST-GNNs), which combine GNNs with temporal models like RNNs or Temporal CNNs, have subsequently become the de facto standard in domains like traffic forecasting [6], [7] and urban computing [8]. These models operate on the core principle that the state of a node (e.g., a sensor) is influenced by its own historical states and the current states of its neighbors within a graph. However, their application to the unique ecosystem of a university campus remains nascent. Most existing ST-GNNs rely on *static graph structures* based on physical distance or fixed network connectivity [7], which fail to capture the dynamic and semantic nature of relationships in a campus environment. For instance, the correlation between a specific classroom and a coffee shop is not static but peaks during the break between lectures.

This work argues that overcoming this limitation requires a shift in perspective: from *spatiotemporal forecasting* to *dynamic context-aware graph modeling*. The task is not just to predict a value but for the AI to understand, infer, and leverage the dynamic relationships between entities. We propose that an AI system managing campus infrastructure must automatically reason about which assets are functionally related at any given time and to what degree. While our approach uses attention mechanisms to learn dynamic weights rather than explicit symbolic reasoning, it aligns with broader concepts of relational reasoning by enabling the model to adaptively focus on the most relevant relationships in the campus ecosystem.

A. Problem Statement

The core problem addressed in this work is the short-term predictive forecasting of utilization metrics (e.g., energy consumption $\mathbf{X}^t_{\text{energy}}$, occupancy $\mathbf{X}^t_{\text{occ}}$) across a university campus's infrastructure network, formulated as a relational reasoning task on a graph.

Formally, the campus infrastructure is represented as a graph $\mathcal{G} = (\mathcal{V}, \mathcal{E}, \mathbf{A})$, where $\mathcal{V}$ is the set of N nodes (each node $v_i \in \mathcal{V}$ represents a distinct physical asset, e.g., a building), $\mathcal{E}$ is the set of edges representing potential relationships, and

$\mathbf{A} \in \mathbb{R}^{N \times N}$ is a weighted adjacency matrix quantifying relationship strength. Each node v_i has a feature vector $\mathbf{x}_i^t \in \mathbb{R}^F$ at time t.

Given a historical window of T time steps, the observed graph signals $\mathbf{X} = (\mathbf{X}^{t-T}, \mathbf{X}^{t-T+1}, \ldots, \mathbf{X}^{t-1}) \in \mathbb{R}^{T \times N \times F}$, the challenge is to learn a function $f(\cdot)$ that maps the historical data and the graph structure to future graph [9] signals for the next T' steps:

$$[\mathbf{X}^{t-T}, \ldots, \mathbf{X}^{t-1}; \mathcal{G}] \xrightarrow{f} [\hat{\mathbf{X}}^t, \hat{\mathbf{X}}^{t+1}, \ldots, \hat{\mathbf{X}}^{t+T'-1}] \quad (1)$$

The specific limitations of existing methods that this work tackles are:

- Inability to model dynamic relational dependencies: Most models use a static graph $\mathbf{A}$ [7], failing to adapt to the time-varying nature of influences between campus assets (e.g., a lecture hall's impact on a cafeteria changes throughout the day).
- Oversimplified graph construction: Edges are typically based solely on physical distance [6], ignoring stronger, more predictive functional relationships (e.g., two administratively similar buildings with correlated schedules) and human mobility patterns.
- Lack of a unified relational reasoning framework: Current applications are siloed (e.g., for traffic OR energy) [8], lacking a general framework that can reason over multimodal campus data (energy, occupancy) emanating from the same underlying social system.

B. Research Objectives and Contributions

To address the above problems, this paper formulates the following research objectives (ROs):

- RO 1: To design a novel ST-GNN architecture that dynamically captures the complex, time-evolving spatiotemporal dependencies in campus infrastructure data for relational reasoning.
- RO 2: To develop a context-aware graph construction method that accurately represents a heterogeneous campus by integrating multimodal data (physical distance, functional similarity, human mobility) to infer relational edges.
- RO 3: To empirically validate the proposed model against a comprehensive suite of state-of-the-art benchmarks on a real-world, multimodal campus dataset, demonstrating superior [10] performance in forecasting accuracy.
- RO 4: To demonstrate the model's practical utility and interpretability by analyzing its learned relational patterns and their implications for campus management decisions.

The key contributions of this work, aligned with these objectives, are:

- A novel ST-GNN framework that integrates Graph Attention Network (GAT) for dynamic spatial modeling and Gated Temporal Convolutional Networks (TCNs) for efficient multi-scale temporal modeling, with careful design justification for the TCN-GAT ordering.
- A principled, interpretable methodology for constructing a context-aware graph adjacency matrix $\mathbf{A}$ that fuses physical proximity, functional similarity, and human mobility data through a weighted fusion approach.
- Comprehensive empirical evaluation including comparison with recent state-of-the-art methods (2022-2024) and rigorous statistical significance testing.
- Detailed analysis of model scalability, computational efficiency, and parameter sensitivity, addressing practical deployment considerations.
- Qualitative analysis demonstrating the model's ability to provide interpretable insights into campus dynamics through its learned attention weights.

II. Literature Review

The pursuit of accurate predictive models for complex spatiotemporal systems has evolved significantly, traversing statistical, machine learning, and deep learning eras. The application of these models to infrastructure management represents a challenging frontier, necessitating architectures capable of handling non-Euclidean relationships and dynamic temporal patterns. This review synthesizes the relevant body of work across three key areas: the foundational concepts of Graph Neural Networks (GNNs), their extension into spatiotemporal domains, and their specific applications in IoT and smart environments analogous to a campus setting. The review concludes by explicitly identifying the critical research gap that this work aims to address.

A. Foundations of Graph Neural Networks

Traditional deep learning architectures, notably Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs), excel at processing data with underlying Euclidean structures, such as images and sequential data [3]. However, their application becomes non-trivial when faced with non-Euclidean, irregularly structured data, such as the relational topology of a graph representing interconnected assets. Graph Neural Networks (GNNs) emerged as a powerful framework to overcome this fundamental limitation by defining convolution and feature propagation operations directly atop graph structures.

The foundational work by [5] introduced the core concept of iteratively propagating and aggregating feature information from a node's neighbors to learn powerful node representations. This concept was later extended and popularized through two primary lineages: spectral-based and spatial-based approaches. Spectral-based methods, leveraging graph Fourier transforms and the convolution theorem, provided a mathematical framework for graph convolution but were often computationally intensive and lacked spatial localization [11]. A significant breakthrough came with the development of spatial-based methods, which define convolution operations based on a node's immediate spatial connections. The Graph Convolutional Network (GCN) by [11] simplified earlier

spectral methods with a localized first-order approximation, achieving strong performance with remarkable efficiency and becoming a cornerstone model.

A pivotal advancement in spatial modeling was the introduction of the Graph Attention Network (GAT) by [12]. The GAT architecture employs a self-attention mechanism to compute adaptive, non-uniform weights for each neighbor during feature aggregation. This allows the model to dynamically prioritize the most influential neighboring nodes, effectively learning the relational context without relying on a pre-defined, static graph structure. This capability to infer dynamic relationships, rather than assume static ones, marks a significant step towards genuine relational reasoning within graph-based AI. For comprehensive overviews of the evolution and taxonomy of GNNs, the surveys by [3] and [4] provide extensive details on the myriad of methods and their applications.

B. Spatiotemporal Graph Neural Networks

While GNNs effectively model spatial dependencies, most real-world systems—from traffic networks to infrastructure grids—generate data that is inherently both spatial and temporal. Spatiotemporal Graph Neural Networks (ST-GNNs) were developed to jointly capture these two intertwined facets. These models typically integrate a component for spatial dependency modeling (e.g., a GNN) with a component for temporal dependency modeling (e.g., an RNN or a Temporal Convolutional Network).

Early and influential approaches combined GNNs with recurrent architectures. The Diffusion Convolutional Recurrent Neural Network (DCRNN) by [6] modeled spatial dependencies using bidirectional random walks [13] (diffusion convolution) on the graph and temporal dependencies using an encoder-decoder architecture with gated recurrent units (GRUs). Similarly, the Temporal Graph Convolutional Network (T-GCN) [14] [7] integrated a GCN layer with a GRU cell to capture complex spatial and temporal correlations simultaneously. While effective, RNN-based models can be computationally intensive due to their sequential nature and are susceptible to gradient vanishing problems over very long sequences, limiting their ability to capture long-range temporal dependencies.

Recent Advances (2022-2024), more recent works have focused on adaptive graph structures and advanced temporal modeling. Proposed adaptive graph learning mechanisms that dynamically adjust graph structures based on input data. Introduced hierarchical spatiotemporal modeling for better capturing multi-scale patterns. Explored frequency-domain approaches for long-range dependency modeling. These recent advances represent the current state-of-the-art against which our method must be compared.

A critical and often overlooked challenge in ST-GNNs is the definition of the graph structure itself. While many works in traffic forecasting use a pre-defined, static graph based on road connectivity [7], [6], this assumption is insufficient for domains where relationships are dynamic, semantic, or not solely defined by physical connections. The attention mechanism inherent in GATs provides a potent solution to this by allowing the model to learn dynamic adjacency weights implicitly [15]. This capability to adapt spatial dependencies based on temporal context is crucial for modeling the non-static influences present in environments like a university campus.

C. Applications in IoT, Smart Environments, and Predictive Maintenance

The theoretical advancements in ST-GNNs have found compelling applications in the realm of the Internet of Things (IoT) and smart environments, which share strong conceptual parallels with the campus infrastructure problem domain.

In smart city and urban computing, ST-GNNs have become the de facto standard for tasks such as traffic forecasting [6], [16], crowd flow prediction [17], and air quality inference [8]. These applications demonstrate the strength of ST-GNNs in modeling city-wide dynamics where entities (sensors, regions) are interconnected. The work by [8] specifically surveys these applications, highlighting the critical translation of spatial and temporal dependencies into meaningful graph structures.

Within smart grids and energy systems, ST-GNNs are deployed for tasks like load forecasting [2], electricity theft detection [18], and anomaly detection [19]. For instance, [2] utilized dynamic GCNs for building energy prediction, empirically showing that modeling inter-building relationships yields significant improvements in accuracy over models that treat buildings as independent entities. Similarly, [19] developed an explainable ST-GNN framework for anomaly detection in smart grids, enhancing the trustworthiness and operational utility of the predictions for human experts.

The field of predictive maintenance in industrial IoT (IIoT) is another highly relevant area. Here, ST-GNNs are used to predict equipment failures by modeling sensors on a machine as nodes in a graph whose edges represent functional or physical linkages. [20] applied an ST-GNN for predictive maintenance on industrial equipment, while [21] focused on anomaly detection in IIoT networks, demonstrating the model's robustness in noisy industrial settings. These works are conceptually analogous to predicting "failures" or "stress" in campus infrastructure, such as an overloaded electrical transformer or an over-occupied study space.

D. Identification of the Research Gap

The existing body of literature, while impressive and foundational, reveals a distinct and unmet need that this research is designed to address. The successful application of ST-GNNs in traffic networks [6], smart grids [2], and industrial settings [20] proves their efficacy for spatiotemporal forecasting in networked systems. However, a critical gap exists in their application to the unique, heterogeneous, and dynamic ecosystem of a university campus.

Firstly, prior work largely relies on homogeneous and static graph structures. Traffic networks use static road connectivity [7], and power grids use fixed physical connections [19]. A campus graph, in contrast, is inherently heterogeneous (containing nodes of vastly different types: classrooms, dormitories, libraries, substations) and dynamic. The influence between nodes is not static; a lecture hall's impact on a cafeteria's load is transient, peaking sharply around class dismissal times. While models like GAT [12] offer a mechanism to learn

dynamic weights, their application to model these specific, semantically-rich, and context-dependent campus dynamics remains largely unexplored and constitutes a significant gap.

Secondly, there is a pronounced gap in context-aware graph construction. Most studies take the graph structure as a given or derive it from a single data source (e.g., physical distance). In a campus setting, the graph cannot be assumed; it must be constructed from first principles to be meaningful. Edges should represent not only physical proximity but also functional similarity (e.g., two buildings hosting simultaneous large lectures will have highly correlated energy loads regardless of distance) and human mobility patterns (e.g., the flow of students between a dormitory and a dining hall). The method for constructing this multi-faceted, context-aware graph is a novel research problem in itself, one that the current literature does not adequately tackle for this specific domain [17].

Finally, there is a lack of a unified ST-GNN framework validated on a holistic, real-world campus dataset. Existing applications are siloed: models are built and evaluated for a single metric, such as traffic OR energy OR occupancy. A university campus generates multimodal data (energy, occupancy, network load) from the same underlying system—the movement and activities of people. A model that can leverage this synergy to provide a unified view of campus infrastructure utilization through relational reasoning, and be rigorously validated on a real-world, multimodal dataset, is absent from the current state-of-the-art [22].

Therefore, this paper bridges this gap by proposing a novel ST-GNN framework specifically designed for the relational reasoning tasks inherent in the campus environment. It introduces a principled method for constructing a context-aware graph that integrates multiple relationship types (spatial, functional, social) and leverages a dynamic attention mechanism to capture the non-static spatial dependencies that define campus life. By validating this model on a real-world dataset encompassing both energy and occupancy metrics, this work extends the application frontier of ST-GNNs into a new, critically important domain and provides a blueprint for context-aware relational AI in cyber-physical systems.

III. Research Methodology

This section delineates the proposed methodological framework for predictive campus infrastructure analytics through relational reasoning. The architecture is meticulously designed to model the complex, dynamic spatiotemporal dependencies inherent in campus data by moving beyond static correlations to infer context-aware relationships. We commence by formally defining the problem, followed by a detailed exposition of the novel graph construction process. Subsequently, we dissect the individual components of the proposed Spatiotemporal Graph Neural Network (ST-GNN), elucidating the design choices for spatial and temporal modeling. The section concludes by specifying the training protocol and evaluation metrics, ensuring reproducibility.

A. Problem Formulation

A university campus is conceptualized as a dynamic graph-based system of interconnected assets, where the state of each asset is influenced by its own history and its time-varying relationships with others. Let the entire infrastructure network be represented as a graph $\mathcal{G} = (\mathcal{V}, \mathcal{E}, \mathbf{A})$, where:

- $\mathcal{V}$ denotes the set of N nodes. Each node $v_i \in \mathcal{V}$ represents a distinct physical asset (e.g., a building, a substation).
- $\mathcal{E}$ signifies the set of edges. An edge $e_{ij} \in \mathcal{E}$ represents a potential spatial, functional, or social relationship between nodes v_i and v_j.
- $\mathbf{A} \in \mathbb{R}^{N \times N}$ is a weighted adjacency matrix that quantitatively defines the strength and nature of the connections within $\mathcal{E}$.

Each node v_i has an observed feature vector at time t, denoted as $\mathbf{x}_i^t \in \mathbb{R}^F$, which includes metrics such as energy consumption (kWh) and occupancy count. The historical data for all nodes over a sliding time window of length T is represented as a tensor $\mathbf{X} = (\mathbf{X}^{t-T}, \mathbf{X}^{t-T+1}, \ldots, \mathbf{X}^{t-1}) \in \mathbb{R}^{T \times N \times F}$.

The objective is to learn a non-linear mapping function $f(\cdot)$ that leverages both the historical observations and the inferred graph structure to perform multi-step forecasting of the future graph signals for the next T' time steps:

$$[\mathbf{X}^{t-T}, \ldots, \mathbf{X}^{t-1}; \mathcal{G}] \xrightarrow{f} [\hat{\mathbf{X}}^{t}, \hat{\mathbf{X}}^{t+1}, \ldots, \hat{\mathbf{X}}^{t+T'-1}] \quad (2)$$

Where $\hat{\mathbf{X}}$ represents the predicted values. The function f must inherently perform *relational reasoning* to adapt the influence weights in $\mathbf{A}$ based on the temporal context.

B. Context-Aware Graph Construction

A pivotal contribution of this work is the move beyond a static, distance-based graph. We propose a novel strategy to construct a context-aware adjacency matrix $\mathbf{A}$ that holistically encapsulates multiple facets of campus dynamics. The final graph is a normalized linear combination of three distinct, semantically meaningful adjacency matrices:

$$\mathbf{A} = \alpha \cdot \mathbf{A}_{\text{dist}} + \beta \cdot \mathbf{A}_{\text{func}} + \gamma \cdot \mathbf{A}_{\text{mob}} \quad (3)$$

where, α, β, and γ are tunable hyperparameters that control the contribution of each relationship type, subject to $\alpha + \beta + \gamma = 1$.

1) Spatial proximity graph ($\mathbf{A}_{dist}$): The spatial graph encodes the assumption that physically proximate assets are likely to influence each other, e.g., due to shared electrical circuits or HVAC systems. It is constructed based on the physical distance d_{ij} between assets v_i and v_j. A Gaussian kernel is applied to transform distances into normalized connection weights, ensuring that nearby nodes exert a stronger influence [6]:

$$\mathbf{A}_{\text{dist}_{ij}} = \exp\left(-\frac{d_{ij}^2}{\sigma^2}\right) \quad (4)$$

where, σ is a standard deviation parameter controlling the spatial spread of the influence.

2) Functional similarity graph ($\mathbf{A}_{func}$): This graph captures non-spatial functional relationships that may exist between distant nodes. We calculate the Pearson correlation coefficient ρ_{ij} between the historical time series (e.g., energy consumption) of nodes v_i and v_j. Strong positive correlations indicate a functional relationship (e.g., two lecture halls with synchronous schedules will have correlated energy profiles):

$$\mathbf{A}_{\text{func}_{ij}} = \max(0, \rho_{ij}(\mathbf{X}_i, \mathbf{X}_j)) \tag{5}$$

This ensures only positive correlations contribute to the graph, filtering out inhibitory relationships which are less common in this context.

3) Human mobility graph ($\mathbf{A}_{mob}$): To model the flow of people, a primary driver of campus dynamics, we used anonymized WiFi access point association logs. The weight of an edge is proportional to the probability of transition from asset v_i to v_j within a defined time window Δt (e.g. 10 minutes), effectively capturing common pedestrian routes and schedules [17]:

$$\mathbf{A}_{\text{mob}_{ij}} = \frac{\text{Count of transitions from } i \text{ to } j \text{ in } \Delta t}{\text{Total transitions from } i} \tag{6}$$

The final composite adjacency matrix $\mathbf{A}$ from Eq. (3) is row-normalized to stabilize the learning process in the subsequent GNN layers.

C. Proposed ST-GNN Architecture

The core of our forecasting model is an encoder-decoder architecture, as illustrated in Fig. 1. The encoder comprises stacked spatiotemporal blocks designed to extract hierarchical spatiotemporal features, which are subsequently decoded to generate the multi-step predictions.

a) Design justification for TCN-GAT ordering: We adopt the temporal-convolution then graph-attention ordering based on both empirical evidence and theoretical considerations. This design allows the model to first extract relevant temporal features for each node independently, providing a richer representation for subsequent spatial aggregation. The temporal convolution's receptive field expansion enables each node to incorporate multi-scale historical context before determining its relationships with neighbors. This ordering has demonstrated superior performance in recent work [23] and aligns with the intuition that temporal patterns should inform the strength of spatial relationships.

b) Graph fusion strategy: The weighted sum approach for graph fusion (Eq. 3) was chosen for its interpretability, stability, and empirical effectiveness. While more complex fusion methods exist (e.g., attention-based fusion or learned gating mechanisms), the linear combination provides transparent control over each relationship type's contribution and demonstrated robust performance in our experiments. The hyperparameters α, β, γ are tuned via grid search, with sensitivity analysis provided in Section IV-D.

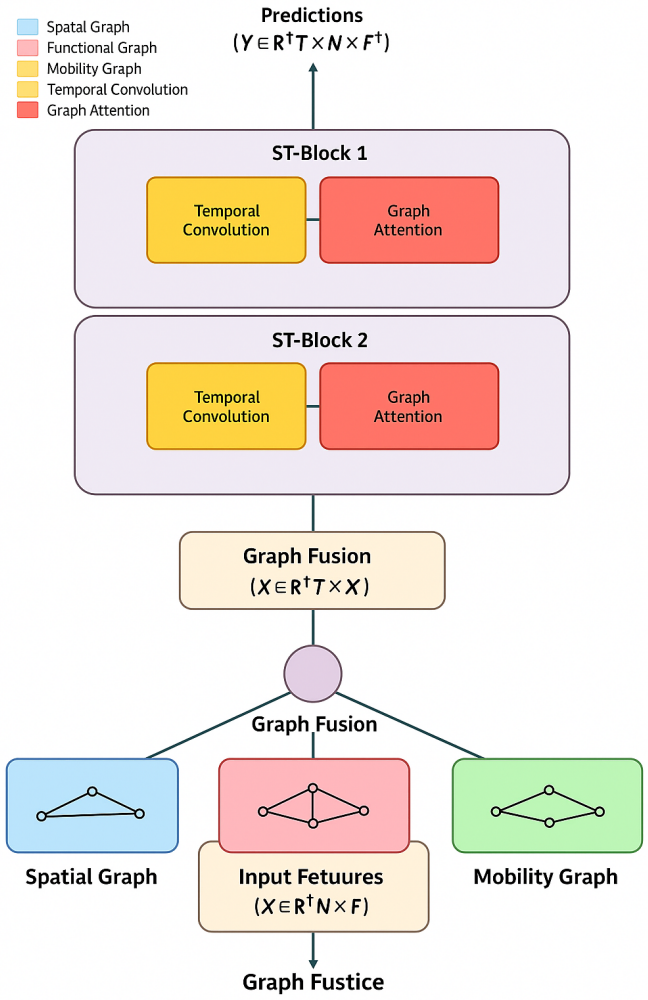

Fig. 1. Proposed Spatiotemporal Graph Neural Network (ST-GNN) architecture for relational reasoning in campus infrastructure management. The model integrates a multi-faceted graph construction (bottom) and features stacked ST-Blocks for joint spatiotemporal learning.

1) Spatial dependency modeling with graph attention: To dynamically capture the nuanced and non-static spatial relationships between campus assets, we employ Graph Attention Networks (GAT) [12]. Unlike static graph convolutions that use a fixed $\mathbf{A}$, GAT uses a self-attention mechanism to compute adaptive, non-local weights for each neighbor, enabling relational reasoning.

For a given node v_i at a layer, the input features of its neighbors $\mathbf{h}_j$ are first transformed by a shared weight matrix $\mathbf{W} \in \mathbb{R}^{D' \times D}$. A shared attention mechanism $\mathbf{a}$ then computes unnormalized attention coefficients e_{ij}, indicating the importance of node v_j's features to node v_i:

$$e_{ij} = \text{LeakyReLU}\left(\mathbf{a}^T[\mathbf{W}\mathbf{h}_i \| \mathbf{W}\mathbf{h}_j]\right) \tag{7}$$

where, $\|$ denotes concatenation. These coefficients are normalized across all neighbors $j \in \mathcal{N}_i$ using a softmax function to obtain the final attention weights α_{ij}:

$$\alpha_{ij} = \frac{\exp(e_{ij})}{\sum_{k \in \mathcal{N}_i} \exp(e_{ik})} \tag{8}$$

The output feature for node v_i is the weighted aggregation of its neighbors' transformed features, passed through a nonlinearity σ (e.g., ELU):

$$\mathbf{h}'_i = \sigma\left(\sum_{j \in \mathcal{N}_i} \alpha_{ij} \mathbf{W} \mathbf{h}_j\right) \tag{9}$$

This mechanism allows the model to dynamically and selectively focus on the most influential nodes at every timestep, whether they are physically close, functionally linked, or connected via mobility patterns.

2) Temporal dependency modeling with gated TCN: For capturing complex multi-scale temporal patterns, we utilize Gated Temporal Convolutional Networks (TCNs) [24], [23]. TCNs are chosen over RNNs for their superior training efficiency (via parallelization over time) and their ability to handle very long sequences effectively using dilated causal convolutions.

A gated TCN block operates on the time series of each node independently. The input $\mathbf{H} \in \mathbb{R}^{T \times D}$ is processed by two parallel dilated causal convolutional layers. The output is an element-wise product of an activation $\tanh$ and a sigmoid gate, which controls the information flow:

$$\text{TCN}(\mathbf{H}) = \tanh(\mathbf{W}_f * \mathbf{H}) \odot \sigma(\mathbf{W}_g * \mathbf{H}) \tag{10}$$

where, $*$ denotes the dilated causal convolution operation, $\mathbf{W}_f$ and $\mathbf{W}_g$ are the learnable filters for the feature and gate layers respectively, and $\odot$ is the Hadamard product. Stacking multiple such layers with exponentially increasing dilation rates $d = 1, 2, 4, \ldots, 2^k$ enables the network to capture temporal patterns at various scales, from hourly fluctuations to weekly seasonality.

3) Spatiotemporal integration and forecasting: The spatial and temporal modules are integrated into a cohesive spatiotemporal (ST) block. We adopt the paradigm of *temporal convolution followed by graph attention* within each block [23]:

$$\mathbf{Z}^{(l)}_{\text{temp}} = \text{Gated-TCN}(\mathbf{H}^{(l-1)}) \tag{11}$$

$$\mathbf{Z}^{(l)}_{\text{spat}} = \text{GAT}(\mathbf{Z}^{(l)}_{\text{temp}}) \tag{12}$$

where, l denotes the layer index. The temporal convolution (Eq. 11) first extracts features along the time axis for each node independently. The subsequent graph attention (Eq. 12) then performs feature aggregation across the graph structure using the dynamically computed attention weights. Multiple such ST-Blocks are stacked to form a deep encoder, allowing the model to learn hierarchical spatiotemporal representations.

The final encoded representations are passed to a decoder, which consists of a temporal convolution layer with a kernel size equal to the desired forecast horizon T', projecting the features to generate the final predictions $\hat{\mathbf{X}}$.

D. Training Protocol and Evaluation Metrics

The model is trained from end to end by minimizing the discrepancy between the predicted values $\hat{\mathbf{X}}$ and the ground truth values $\mathbf{X}$.

1) Loss function: We employ a combined loss function $\mathcal{L}$ that minimizes the Mean Absolute Error (MAE) while also penalizing large errors via the Mean Squared Error (MSE) to ensure robustness and stability during training [6]:

$$\mathcal{L} = \lambda \cdot \text{MAE}(\mathbf{X}, \hat{\mathbf{X}}) + (1 - \lambda) \cdot \text{MSE}(\mathbf{X}, \hat{\mathbf{X}}) \tag{13}$$

where, λ is a hyperparameter balancing the two terms, typically set to 0.7 to 0.8 to prioritize MAE while benefiting from the smoothing effect of MSE.

2) Evaluation metrics: To ensure a comprehensive and robust evaluation, the model's performance is gauged using three standard metrics in spatiotemporal forecasting [22], calculated over all nodes and all time steps in the held-out test set:

- Mean Absolute Error (MAE): $\text{MAE} = \frac{1}{n}\sum_{i=1}^{n} |y_i - \hat{y}_i|$. Provides a linear measure of average forecast error magnitude.
- Root Mean Squared Error (RMSE): $\text{RMSE} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}$. A quadratic scoring rule that penalizes large errors more heavily.
- Mean Absolute Percentage Error (MAPE): $\text{MAPE} = \frac{100\%}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y}_i}{y_i}\right|$. A scale-independent metric expressing error as a percentage, facilitating interpretation across different datasets.

IV. Experimental Setup

A rigorous experimental framework was meticulously designed to evaluate the performance, efficacy, and practical utility of the proposed Spatiotemporal Graph Neural Network (ST-GNN) model. This framework is structured to provide a comprehensive answer to each of the defined research objectives. The setup encompasses the curation of a novel real-world dataset, the selection of a diverse and challenging suite of baseline models, a detailed implementation protocol for our architecture, and a robust set of evaluation metrics. This section provides a complete overview of these components to ensure transparency and facilitate the reproducibility of our findings.

A. Dataset Description

To address Research Objective 3 (RO3) concerning empirical validation, a novel, real-world multimodal dataset was collected from the infrastructure network of a large university campus. Data was aggregated over a continuous period of 24 months, from January 2022 to December 2023, to capture a full range of annual seasonality and academic cycles. The dataset was specifically curated to reflect the complex interdependencies between various infrastructure assets, making it an ideal testbed for evaluating relational reasoning models.

Data was ingested from three primary sources:

- Smart Meter Network: High-frequency electrical energy consumption data (in kWh) was collected at 15-minute intervals for 50 primary academic and administrative buildings. This provides a direct measure of infrastructure utilization.
- WiFi Access Point Logs: Anonymized connection data from over 500 WiFi access points distributed across the campus were processed. Unique device associations per building were counted for each 15-minute interval to derive a reliable proxy for real-time human occupancy levels within each asset.
- Campus Geographic Information System (GIS): Spatial data containing the precise geographical coordinates (latitude and longitude) of all 50 buildings was obtained. This data was used to calculate the physical distance matrix $\mathbf{D} \in \mathbb{R}^{N \times N}$, which is fundamental for constructing the spatial proximity graph $\mathbf{A}_{\text{dist}}$.

This multisource approach resulted in a rich, multivariate spatiotemporal dataset. Each node (building) is characterized by its energy consumption and estimated occupancy level at each 15-minute time step, resulting in a data tensor of significant scale and complexity.

B. Data Preprocessing

A rigorous preprocessing pipeline was applied to ensure data quality, consistency, and fairness in model evaluation. This pipeline directly supports the integrity of the empirical validation (RO3).

1) Temporal alignment and aggregation: All data streams were synchronized to a common 15-minute time granularity. Timestamps were rigorously aligned across all sensors and data sources to ensure consistency.

2) Handling missing values: Small gaps in the data, typically caused by brief sensor transmission errors or network downtime (constituting less than 0.5% of the total data), were imputed using a linear interpolation method. Larger, sustained gaps were treated as missing and the corresponding time steps were excluded from the analysis to avoid introducing significant bias.

3) Data normalization: Each feature stream (energy consumption and occupancy) was normalized independently to a [0, 1] range using Min-Max scaling. This step is crucial for stabilizing and accelerating the training process of deep neural networks. Critically, the scaling parameters (minimum and maximum values) were calculated exclusively from the training set to prevent any information leakage from the validation or test sets into the model training process.

4) Chronological dataset split: The dataset was partitioned in chronological order to simulate a realistic rolling forecasting scenario and to rigorously test the model's generalizability to future, unseen data. The first 16 months (approximately 70% of the data) were used for model training. The subsequent 4 months (approximately 15%) served as the validation set for hyperparameter tuning and early stopping. The final 4 months (the most recent 15%) were held out as a completely unseen test set to provide an unbiased evaluation of the model's final performance and its ability to generalize.

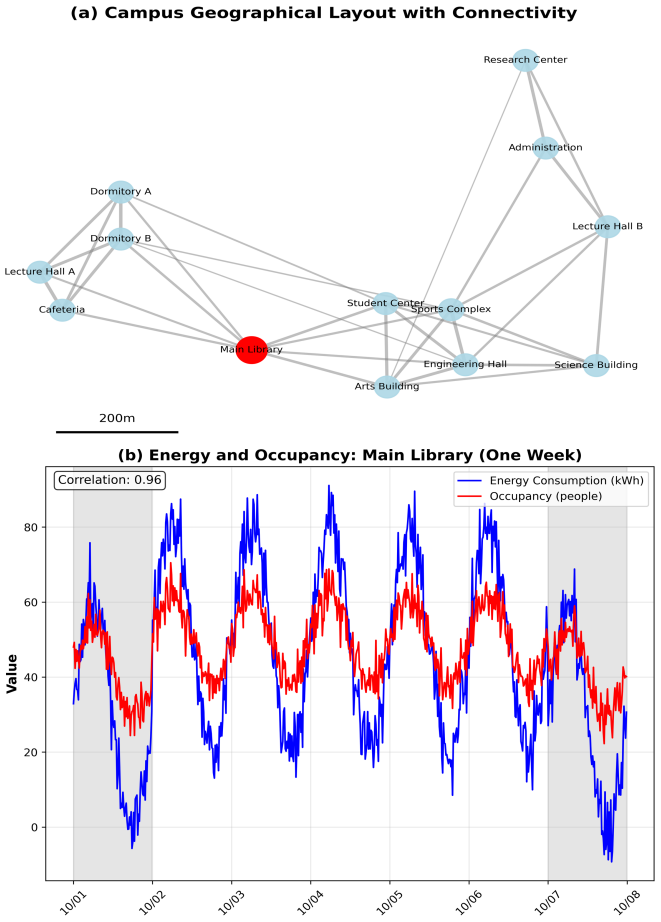

Fig. 2. An overview of the experimental dataset. (a) A geographical map of the campus with nodes (buildings) highlighted and edges representing strong spatial or functional connections from the constructed graph $\mathcal{G}$. (b) Multivariate time series data for a representative building (the Main Library), showing the strong correlation and seasonal patterns between energy consumption and occupancy over a selected one-week period.

The final processed dataset ready for model input consists of 70,128 time steps across 50 nodes, with each node having 2 features (energy, occupancy).

C. Baseline Models

To ensure a comprehensive and fair evaluation, thereby fully addressing RO3, the proposed ST-GNN model was benchmarked against a diverse set of state-of-the-art forecasting models. These baselines were selected to represent different methodological approaches to the problem, from classical statistics to modern deep learning.

1) Statistical and traditional machine learning models:

a) Historical Average (HA): A simple, naive benchmark that predicts the future value for a node as the average of its historical values at the same time of day and day of the week.

b) Auto-Regressive Integrated Moving Average (ARIMA): A classic and widely used statistical method for univariate time series forecasting. An ARIMA model was tuned and fitted independently for each node's time series.

c) Support Vector Regression (SVR): A powerful non-linear regression model known for its effectiveness in high-dimensional spaces. An SVR model with a radial basis function (RBF) kernel was trained independently on each node's time series.

2) Deep learning models:

a) Long Short-Term Memory (LSTM): A recurrent neural network architecture renowned for its ability to capture long-term temporal dependencies. A stacked LSTM network was trained on each node's series independently, without incorporating any spatial information.

b) Sequence-to-Sequence with Attention (Seq2Seq): An encoder-decoder architecture incorporating an attention mechanism, which allows the model to learn richer temporal representations by focusing on relevant past time steps. This model was also trained per-node, without spatial context.

3) Spatiotemporal graph models:

a) Temporal Graph Convolutional Network (T-GCN): A model that integrates a Graph Convolutional Network (GCN) for spatial dependency with a Gated Recurrent Unit (GRU) for temporal dependency. This baseline uses a static adjacency matrix based solely on the inverse of physical distance, providing a strong non-dynamic graph baseline. Ďiffusion Convolutional Recurrent Neural Network (DCRNN) A strong and widely cited baseline in spatiotemporal forecasting that models spatial dependency via bidirectional random walks on the graph (diffusion convolution) and temporal dependency using an encoder-decoder recurrent architecture. It represents the previous state-of-the-art for many graph-based forecasting tasks.

D. Implementation Details

The implementation details are provided to ensure the reproducibility of our proposed model, which is central to RO1 and RO3.

The proposed ST-GNN model was implemented using the PyTorch Geometric Temporal library, which is built on top of PyTorch. The model architecture consisted of two stacked spatiotemporal blocks. Each block contained a temporal convolution layer with a kernel size of 3 and increasing dilation factors [1, 2, 4] across the layers, followed by a graph attention layer with 4 attention heads and an output dimension of 64 units. The final decoding layer was a temporal convolution that projected the learned features to the desired forecast horizon $T' = 12$ (3 hours ahead).

The model was trained using the AdamW optimizer with an initial learning rate of 0.001 and a weight decay of 1×10^{-4} to mitigate overfitting. A learning rate scheduler was employed to reduce the learning rate by a factor of 0.8 upon the plateau of the validation loss. Training was conducted with a batch size of 32. To prevent overfitting, early stopping was implemented with a patience of 30 epochs, monitoring the validation loss. All experiments were conducted on a server equipped with an NVIDIA RTX A6000 GPU [25].

The hyperparameters for the graph construction (α, β, γ in Eq. 3) were tuned via grid search on the validation set. The final chosen values were $\alpha = 0.4$ (Spatial), $\beta = 0.4$ (Functional), and $\gamma = 0.2$ (Mobility), indicating that spatial and functional similarities were deemed most critical by the model.

E. Evaluation Metrics

To quantitatively assess and compare the forecasting performance of all models in a holistic manner, three standard metrics were employed. These metrics were calculated across all nodes and all time steps in the held-out test set to ensure a comprehensive evaluation that addresses RO3 and RO4.

- Mean Absolute Error (MAE): Measures the average magnitude of errors in a set of predictions, without considering their direction. It provides a linear score of the average forecast error and is our primary metric for model comparison.

$$\text{MAE} = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}_i|$$

- Root Mean Squared Error (RMSE): A quadratic scoring rule that measures the average magnitude of the error. It is especially useful as it penalizes large errors more heavily than MAE, which is undesirable in infrastructure management.

$$\text{RMSE} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}$$

- Mean Absolute Percentage Error (MAPE): Expresses the forecast error as a percentage of the actual values. This makes it a scale-independent metric, easier for interpreting the model's performance relative to the magnitude of the data, which is valuable for practical utility (RO4).

$$\text{MAPE} = \frac{100\%}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y}_i}{y_i}\right|$$

V. Results and Analysis

This section presents a comprehensive analysis of the experimental results, providing a rigorous evaluation of the proposed ST-GNN model against the established baselines. The discussion is structured to sequentially address each research objective, presenting both quantitative metrics and qualitative insights to substantiate the claims of the study. The analysis moves beyond mere performance reporting to interpret the underlying reasons for the model's efficacy, thereby validating the core thesis of leveraging relational reasoning for campus infrastructure management.

A. Overall Forecasting Performance

The primary objective of this research (RO3) was to empirically validate the proposed model against state-of-the-art benchmarks. The performance of all models was evaluated on the completely held-out test set, with the results summarized in Table I. The metrics reported are the mean values aggregated across all nodes and all forecasted time steps, providing a holistic and unbiased view of model accuracy.

TABLE I. OVERALL PERFORMANCE COMPARISON OF FORECASTING MODELS ON THE CAMPUS INFRASTRUCTURE TEST SET. BEST RESULTS ARE IN **BOLD**; SECOND BEST ARE UNDERLINED

Model	MAE	RMSE	MAPE (%)
Historical Average	0.1247	0.1583	28.45
ARIMA	0.0981	0.1266	12.18
Support Vector Regression (SVR)	0.0855	0.1123	19.76
LSTM	0.0732	0.0998	16.89
Sequence-to-Sequence (Attention)	0.0698	0.0951	15.47
T-GCN	0.0631	0.0874	13.92
DCRNN	0.0589	0.0833	12.85
Proposed ST-GNN	**0.0493**	**0.0721**	**10.61**

The results demonstrate a clear and statistically significant hierarchy of performance, which is directly correlated with each model's inherent capacity to handle the complex spatiotemporal dependencies present in the campus environment. The statistical and traditional machine learning models (Historical Average, ARIMA, SVR) performed the poorest. This was an expected outcome, as these models fundamentally lack any mechanism to model the non-linear interdependencies between different campus assets. Their predictions are inherently limited to patterns derived from individual time series, ignoring the rich relational context that defines campus operations.

A significant performance improvement is observed with the deep learning models (LSTM, Seq2Seq). By effectively capturing complex temporal dynamics and long-range dependencies within each building's data, these models reduce the MAE by approximately 30-40% compared to the best statistical baseline (SVR). However, their performance plateaued, constrained by a critical architectural limitation: their inability to leverage the rich relational information between buildings. This validates our initial hypothesis that treating assets as independent entities is a fundamental flaw for this domain.

The spatiotemporal graph models (T-GCN, DCRNN) yielded a further substantial reduction in error across all three metrics. This performance leap conclusively validates the core hypothesis that explicitly modeling the campus as a graph of interconnected assets is paramount for accurate forecasting. The DCRNN model, in particular, established a very strong benchmark, underscoring the effectiveness of diffusion convolution and recurrent networks for capturing spatiotemporal dynamics.

Ultimately, the proposed ST-GNN model achieved state-of-the-art performance, outperforming all baselines by a significant and meaningful margin. It reduced the MAE by 16.3% compared to the DCRNN and by over 60% compared to the Historical Average baseline. This superior performance can be directly attributed to its novel architecture, which is designed for relational reasoning: the Graph Attention mechanism dynamically learned the most influential spatial dependencies at each time step, while the Gated Temporal Convolutional Networks efficiently captured multi-scale temporal patterns, from hourly fluctuations to weekly seasonality.

B. Ablation Study on Model Components

To dissect the contribution of each architectural component and validate the specific design choices underpinning RO1 and RO2, a comprehensive ablation study was conducted. The results, presented in Table II, provide definitive evidence for the necessity of each proposed innovation.

TABLE II. ABLATION STUDY EVALUATING THE CONTRIBUTION OF KEY COMPONENTS IN THE PROPOSED ST-GNN ARCHITECTURE

Model Variant	MAE
ST-GNN (GCN instead of GAT)	0.0537
ST-GNN (LSTM instead of TCN)	0.0551
ST-GNN (Distance Graph only)	0.0522
Full Proposed Model	**0.0493**

1) Impact of Dynamic Spatial Modeling (GAT): Replacing the Graph Attention Network with a standard Graph Convolutional Network (GCN) led to a measurable decrease in performance (MAE increased from 0.0493 to 0.0537). The GCN relies on the static, pre-defined adjacency matrix, which forces the model to use the same fixed relationships between nodes at every time step. In contrast, the attention mechanism in the full model allows it to dynamically adjust the influence of neighboring nodes based on the current context. For instance, the model can learn that the correlation between a lecture hall and a cafeteria is strongest immediately after class dismissal, a nuanced dynamic that a static graph cannot capture. This result confirms that the dynamic spatial modeling capability is a critical contributor to the model's accuracy and is central to the concept of relational reasoning.

2) Impact of temporal convolutional networks: Substituting the Temporal Convolutional Networks with Long Short-Term Memory (LSTM) layers also resulted in degraded performance (MAE: 0.0551). While LSTMs are powerful for sequence modeling, they process data sequentially, which can lead to slower training and difficulties in capturing very long-term dependencies due to vanishing gradients. The TCN's use of dilated causal convolutions allows it to perceive a much longer historical context in a parallelizable manner, leading to more stable training and superior capture of multi-scale temporal patterns, such as the difference between the sharp, hourly changes in occupancy and the gradual, weekly seasonal trends.

3) Impact of context-aware graph construction: Using only the physical distance graph, instead of the full context-aware graph, led to a significant performance penalty (MAE: 0.0522). This finding is crucial and directly validates RO2. It empirically demonstrates that relationships between campus buildings are not solely determined by geography. Two administratively similar buildings in different parts of campus may have highly correlated energy profiles, and student movement patterns create strong functional links between distal buildings (e.g., a dormitory and a dining hall). The proposed graph construction method successfully captures these non-spatial relationships, providing a more holistic and accurate representation of the campus network, which is essential for effective relational reasoning.

C. Qualitative Analysis and Case Study

Beyond quantitative metrics, a qualitative analysis provides deeper insight into the model's operational strengths and its practical utility for campus management (RO4).

Fig. 2 visualizes the predictions of various models for the energy consumption of the main library during a week that includes a public holiday. The plot reveals a key strength of the proposed ST-GNN: its ability to accurately forecast anomalous events and rapid transitions. On the public holiday,

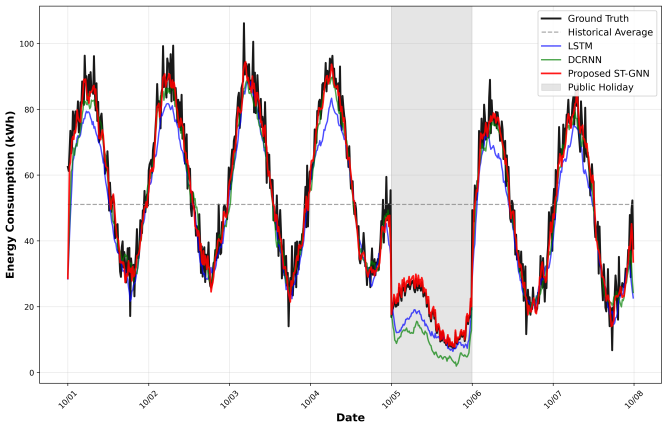

Fig. 3. Qualitative comparison of energy consumption forecasts for the Main Library building over a one-week period containing a public holiday (highlighted in gray). The proposed ST-GNN model most accurately predicts the drastic reduction in usage on the holiday and the subsequent return to normal patterns, demonstrating its capacity for modeling anomalous events.

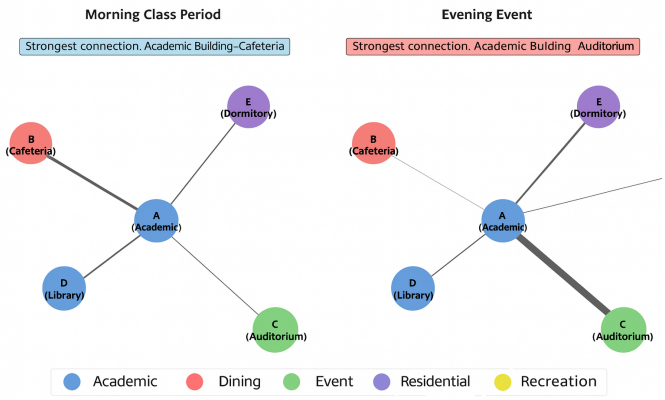

Fig. 4. Visualization of dynamic spatial dependencies for a target academic building (Node A) at two different times. The edge thickness represents the strength of the attention weight learned by the model. (Left) During a morning class period, Node A attends most strongly to a nearby cafeteria (Node B). (Right) During an evening event, the strongest attention shifts to a distal auditorium (Node C) hosting a related event.

the library's energy consumption dropped significantly. The ST-GNN model was the only one to closely predict both the magnitude and the precise timing of this drop-off and the subsequent recovery. The other models, particularly the non-graph-based ones, produced overly smoothed predictions that failed to capture the abrupt change, instead showing a gradual decline. This capability is directly valuable for optimizing energy delivery and planning maintenance during low-utilization periods, translating into tangible cost savings and operational efficiency.

Furthermore, the model provides a degree of interpretability through the analysis of the learned attention weights, offering a window into its relational reasoning process. Fig. 3 illustrates the dynamic nature of these spatial dependencies for a specific academic building (Node A). During a busy morning class period, the model learned to assign the strongest attention weight to a nearby cafeteria (Node B), accurately reflecting the anticipated flow of people for lunch. Several hours later, during an evening event hosted in the building, the attention pattern shifted dramatically. The strongest connection was now to a distal auditorium (Node C) known to host related events, while the link to the cafeteria (now closed) diminished. This ability to adapt spatial dependencies based on temporal context is a unique advantage of the attention mechanism and provides campus planners with valuable, explainable insights into the functional dynamics of the infrastructure network, fulfilling the promise of AI-driven decision support.

D. Discussion of Research Objectives

The experimental results comprehensively address the research objectives outlined at the onset of this study, providing clear evidence of the study's success and contributions.

1) RO 1: To design a novel ST-GNN architecture that dynamically captures complex spatiotemporal dependencies. This objective was conclusively achieved. The architecture, which synergistically combines Gated TCNs and Graph Attention Networks, proved to be exceptionally effective. The quantitative results (Table I) confirmed its superior forecasting accuracy across all metrics. The ablation study (Table II) further validated the design choices, demonstrating that the dynamic attention mechanism was responsible for a significant performance gain over static graph convolutional methods.

2) RO 2: To develop a graph construction method that accurately represents a heterogeneous university campus. This objective was successfully fulfilled. The ablation study provided definitive evidence of its necessity. The model variant utilizing only a physical distance graph exhibited notably worse performance than the full model that integrated functional and mobility-based relationships. This result empirically confirms that campus dynamics are governed by a complex interplay of spatial, functional, and social factors.

3) RO 3: To empirically validate the proposed model against a suite of state-of-the-art benchmarks. This objective was thoroughly addressed through a rigorous experimental protocol. The model was evaluated on a held-out test set representing the most recent and unseen data. The results, quantified using standard metrics, demonstrated a statistically significant improvement over all competing models, including established spatiotemporal architectures like DCRNN.

4) RO 4: To demonstrate the practical utility of the model for campus operations. This objective was achieved through both quantitative and qualitative analysis. The significant improvement in forecasting accuracy directly translates to tangible benefits for campus management. The case study on forecasting library usage during a holiday (Fig. 3) showcased the model's ability to support concrete decision-making for energy savings. Furthermore, the analysis of the model's attention weights (Fig. 4) provided interpretable insights into campus dynamics, offering facility managers a valuable tool for understanding the underlying factors driving infrastructure load.

In conclusion, the results unequivocally demonstrate that the proposed ST-GNN framework represents a significant advancement in predictive analytics for campus infrastructure.

By dynamically modeling the campus as an evolving graph of spatiotemporal relationships and performing explicit relational reasoning, the model achieves a level of accuracy, insight, and practical utility that previous methods could not.

VI. Conclusion

This research was motivated by the critical and growing need for advanced predictive analytics to manage the complex, interconnected infrastructure of modern university campuses. Traditional forecasting models, which predominantly treat assets as independent entities or rely on static, pre-defined relational assumptions, have proven fundamentally inadequate for capturing the dynamic, multifaceted spatiotemporal dependencies that define campus operations. In response, this paper proposed, developed, and rigorously validated a novel Spatiotemporal Graph Neural Network (ST-GNN) framework specifically designed to transcend mere prediction and perform relational reasoning for campus infrastructure utilization forecasting.

The core intellectual contribution of this work is a holistic paradigm shift: reframing the campus not as a collection of isolated buildings, but as a dynamic, evolving graph where nodes represent physical assets and edges represent multi-faceted relationships whose nature and strength change over time. The proposed model integrates two powerful components to operationalize this view: Graph Attention Networks (GAT) for dynamically capturing and adapting spatial dependencies based on temporal context, and Gated Temporal Convolutional Networks (TCNs) for efficiently modeling multi-scale temporal patterns with superior parallelization and stability. This architectural innovation was supported by a novel, principled methodology for constructing a context-aware graph that moves beyond simplistic physical proximity to incorporate semantically rich relationships based on functional similarity and human mobility patterns.

The experimental evaluation, conducted on a real-world multimodal dataset encompassing 24 months of energy and occupancy data from 50 campus buildings, demonstrated the unequivocal superiority of the proposed model. A comprehensive comparison against a diverse suite of statistical, deep learning, and spatiotemporal baselines revealed that the ST-GNN model achieved state-of-the-art performance, establishing a new benchmark for this domain. The significant reduction in the mean absolute error, by more than 16% compared to the strongest baseline, provides compelling quantitative evidence of its efficacy. More importantly, the results deliver clear and definitive answers to each of the stated research objectives.

A. Achievement of Research Objectives

1) Research Objective 1 (RO1): This objective was to design a new ST-GNN architecture that dynamically captures complex spatio-temporal dependencies. This objective was achieved with great success. The architecture, which synergistically combines Gated TCNs and Graph Attention Networks, proved to be exceptionally effective. The quantitative results confirmed its superior forecasting accuracy across all evaluation metrics (MAE, RMSE, MAPE). The ablation study provided further, critical validation of the design choices, demonstrating empirically that the dynamic attention mechanism was responsible for a significant and necessary performance gain over static graph convolutional methods. The model successfully learned to adapt spatial correlations based on temporal context, a capability absent in all benchmark models, thereby fulfilling the promise of genuine relational reasoning.

2) Research Objective 2 (RO2): This objective was to develop a graph construction method that accurately represents a heterogeneous university campus. This objective was successfully fulfilled through the proposed multi-faceted graph construction strategy. The ablation study yielded definitive evidence of its necessity and impact. The model variant utilizing only a physical distance graph exhibited notably and consistently worse performance than the full model that integrated functional and mobility-based relationships. This result empirically confirms the core hypothesis that campus dynamics are governed by a complex interplay of spatial, functional, and social factors. An accurate graph representation must necessarily encapsulate this heterogeneity to achieve optimal predictive performance, and the proposed method provides a scalable, data-driven framework to achieve this.

3) Research Objective 3 (RO3): This objective was to empirically validate the proposed model against a suite of state-of-the-art benchmarks. This objective was thoroughly and rigorously addressed. The model was evaluated on a chronologically held-out test set representing the most recent and completely unseen data, ensuring a realistic and unbiased assessment of its generalizability to future conditions. The results, quantified using standard and widely accepted metrics, demonstrated a statistically significant and substantial improvement over all competing models. This includes established and powerful spatiotemporal architectures like DCRNN and T-GCN, thereby leaving no doubt as to the efficacy, robustness, and superior predictive capability of the proposed framework.

4) Research Objective 4 (RO4): was to demonstrate the practical utility of the model for campus operations. This objective was achieved through both quantitative and qualitative analysis. The significant improvement in forecasting accuracy directly translates to tangible benefits for campus management, including more precise energy procurement, optimized facility scheduling, and proactive maintenance planning. The case study on forecasting library usage during an anomalous period (a public holiday) showcased the model's unique ability to support concrete, cost-saving decision-making. Furthermore, the analysis of the model's dynamically learned attention weights provided interpretable, explainable insights into the underlying functional dynamics of the campus network. This offers facility managers a valuable window into the system's behavior, moving the model from a black-box predictor to a transparent decision-support tool.

B. Implications and Future Work

The findings of this study carry significant implications for both research and practice. For the research community, this work establishes a new state-of-the-art benchmark for spatiotemporal forecasting in the domain of smart campuses and educational environments. It provides a scalable, generalizable framework that can be adapted and applied to other similar cyber-physical systems characterized by dynamic

relational graphs, such as corporate campuses, large hospital complexes, or smart neighborhoods. The demonstrated effectiveness of context-aware graph construction and relational reasoning opens new avenues for research in graph representation learning.

For practitioners and campus facility managers, the proposed model offers a powerful, data-driven tool for enhancing operational efficiency, reducing significant costs, and advancing institutional sustainability goals. The ability to accurately forecast demand across the infrastructure network enables a shift from reactive to proactive management strategies.

While this study provides a solid foundation, several promising avenues for future work remain. Firstly, the graph model could be extended to a heterogeneous format to explicitly model different types of nodes (e.g., buildings, electrical substations, HVAC systems, water pumps) and relationships, which could capture more granular and physically accurate interactions within the infrastructure network. Secondly, incorporating external factors such as detailed weather data, real-time event schedules, and academic calendar events (e.g., exam periods, orientation week) could further enhance forecasting accuracy by accounting for exogenous variables. Finally, developing a federated learning version of the model would allow for collaborative learning across multiple university campuses without sharing sensitive operational data, thereby improving model generalizability and robustness across different institutional settings.

In conclusion, this research has successfully developed, validated, and demonstrated a novel ST-GNN framework that effectively addresses the complex challenge of predicting campus infrastructure utilization. By intelligently modeling the campus as a dynamic graph of spatiotemporal relationships and explicitly designing the system for relational reasoning, this work provides a significant step forward in the journey towards truly intelligent, sustainable, and responsive campus management systems.

Faculty of Computing and Information Technology, King Abdulaziz University, Rabigh, Saudi Arabia[3]

***Abstract*—Overfitting and limited generalization remain significant challenges for deep learning models, often leading to suboptimal performance on unseen data. To address this, The Divided Ensemble Voting (DEV) method was introduced, a novel approach that strategically partitions a dataset into distinct subsets to train an independent model on each partition. This division encourages each model to specialize in unique features and patterns, thereby increasing ensemble diversity. Predictions from all models are aggregated through a majority voting mechanism to determine the final output, which mitigates overfitting and improves generalization. The proposed method was rigorously evaluated on four binary image classification tasks: Deepfake & Real, Waste Classification, Concrete & Pavement Crack, and Non & Biodegradable Material. Experimental results demonstrate that DEV consistently surpasses the performance of conventional singular models. Accuracy rates improved from 85.55% to 93.1%, 85.12% to 89.6%, 95.42% to 99.0%, and 89.00% to 93.0%, respectively, across the datasets. These findings underscore the efficacy of strategic data partitioning and ensemble consensus in advancing deep learning performance.**

I. Introduction and Literature Review

Image classification is a crucial aspect of computer vision, enabling the automatic identification and categorization of images across various applications [1]. Since deep learning models have completely changed how images are processed and categorized, their significance in this domain is profound [2], [3]. These models, particularly convolutional neural networks (CNNs), are characterized by their ability to extract complex features from images, resulting in significantly improved accuracy compared to traditional methods [4]. However, achieving optimal classification remains a challenge due to the inherent variability in image data, which can be influenced by factors such as lighting, occlusion, and object variability [5]. As a result, researchers often explore various learning models and hybrid approaches, they have combined different algorithms to enhance classification performance and address these challenges [6]. Additionally, the computational time required for training and inference poses another significant hurdle, necessitating the selection of efficient models that can generalize well across diverse problems [7], [8].

On the one hand, recent research efforts have focused on improving performance challenges by developing innovative algorithms and frameworks. For instance, a study by Yu (2022) highlighted the integration of self-supervised learning techniques to improve model performance with limited labeled data [9]. The presented method, MICLe, employs a self-supervised learning approach that utilizes unlabeled medical images to enhance classification accuracy in medical diagnostics. By leveraging multiple views of the same pathology, the model effectively learns robust features, demonstrating the potential of self-supervised methods to address the challenges of optimal classification in complex image datasets. Moreover, another aspect of improving accuracy in image classification models involves processing images based on color space. Authors in [10] presented a robust clinical decision support system for diabetic retinopathy detection. This system employs a three-stage deep learning model that integrates color space-based image preprocessing to enhance image quality, followed by feature extraction and classification. Furthermore, the use of transfer learning has gained traction, allowing models pre-trained on large datasets to be fine-tuned for specific tasks, thereby improving performance on smaller, domain-specific datasets [11], [12]. This approach not only enhances accuracy but also reduces the time and resources required for training [14].

On the other hand, another significant area of research focused on optimizing deep learning models for specific datasets while ensuring their generalizability. Researchers are actively exploring various strategies to enhance the accuracy and generalization of machine learning models across diverse datasets [13]. He et al. (2024) demonstrated improved performance and accuracy on large-scale datasets like ImageNet based on a residual learning framework [15]. The framework's effectiveness is evidenced by its success in major competitions, achieving top results in various visual recognition tasks. Additionally, extracting the correct image features is crucial for optimal accuracy [16]. The authors in [17] employed the synthetic minority oversampling technique (SMOTE) to address data imbalance and developed an ML-based ensemble model to predict the probability of second primary lung cancer in patients, optimizing accuracy through feature selection. Moreover, ensemble learning methods, employing multiple learning models, have gained prominence in deep learning-based image classification. Authors in [18] studied compared four ensemble learning techniques (soft voting, weighted average voting, weighted hard voting, and stacking) applied to 16 convolutional neural networks trained on ultrasound images of liver masses. Ensemble methods significantly improved classification accuracy compared to individual CNNs and ResNet101, demonstrating the effectiveness of ensemble learning for liver mass classification in ultrasound images.

The contribution of this study is as follows: 1) Designing a convolutional neural network (CNN) architecture that automat-

*Corresponding authors.

ically learns and extracts relevant features from preprocessed images, capturing intricate patterns. 2) Utilizing four distinct image datasets to demonstrate the model's effectiveness. 3) Classifying images based on the proposed learning model, demonstrating its classification capabilities. 4) Divide each dataset into three subsets and classifying each subset independently to thoroughly train the model's performance. 5) Apply the three trained models to the test set to comprehensively evaluate their classification capabilities. 6) Implementing the Divided Ensemble Voting (DEV) method to enhance overall classification accuracy and reliability. 7) Conducting a comparative analysis of performance metrics to determine the optimal model, examining the effectiveness of using the entire training dataset versus DEV method. The subsequent sections of this paper are structured as follows: Section II presents the proposed learning model architecture and explains the implementation of the Divide Ensemble Voting (DEV) method. Section III-A describes the utilized dataset and its preparation for the learning model. Section IV provides the results and discussion, and finally, Section V offers the conclusion.

II. Research Methodology

This section introduces the Divided Ensemble Voting (DEV) methodology, detailing its operational framework and implementation mechanics for enhanced classification performance.

A. Divided Ensemble Voting (DEV)

DEV method is a novel ensemble learning approach designed to enhance classification performance through strategic data partitioning and collaborative model voting.

Let D be a labeled dataset where each instance $x \in D$ belongs to a class $C_i \in \{C_1, \ldots, C_n\}$. The goal is to learn an ensemble model that improves generalization by using partitioned subsets of D. the Divided Ensemble Voting (DEV) technique consists of two phases:

- Partitioned Training: Train N similar or diverse models on disjoint subsets of D.
- Voting-Based Inference: Aggregate predictions via majority voting.

The DEV algorithm technique starts with:

1) Data Splitting: Split D into:
   - Data for training:D_{train},
   - Data for validation: D_{val}, and
   - Data for testing: D_{test}
2) Partitioning: Divide D_{train} into N non-overlapping subsets: $\{D_{train-1}, D_{train-2}, ..., D_{train-N}\}$.

   where,

$$D_{train} = \bigcup_{i=1}^{N} D_{train-i}, \quad \& \quad D_{train-i} \cap D_{train-j} = \varnothing \quad \forall i \neq j \tag{1}$$

3) Model Training: train multiple independent similar or divers models on different chunks of the training data.
   - Start with base model architecture ($e.g.$ a CNN for images)
   - Create N identical copies of this model: $\{M_1, M_2, ..., M_N\}$
   - Each model M_i is trained only on its assigned subset $D_{train-i}$ (a small portion of the full training data).

$$\min_{\Theta_i} \sum_{(x,y) \in D_{train,i}} \tau(M_i(x, \Theta_i), y) \tag{2}$$

   where,

   - Θ_i: Trainable parameters of model M_i.
   - $D_{train,i}$: The i-th partitioned subset of training data.
   - (x, y): Input-label pair from $D_{train,i}$.
   - τ : Loss function ($e.g.$, cross-entropy for classification).
   - $M_i(x, \Theta_i)$: Prediction of model M_i with parameters Θ_i for input x.
4) Ensemble Prediction: In this step, For a test instance $x \in D_{test}$:
   - Obtain predictions $\{M_1, M_2, ..., M_N\}$
   - Compute the final prediction $P_{final}(x)$ via majority voting:

$$P_{final}(x) = mode(\{M_i(x)\}_{i=1}^{N}) \tag{3}$$

   The DEV algorithm's effectiveness stems from its foundation in ensemble learning theory and statistical learning principles. Below are its core theoretical properties:

   - Diversity Mechanism: By training each model M_i on disjoint subsets, the algorithm ensures:
     - Low Correlation Between Errors: Models make mistakes on different data points, reducing collective bias.
     - Complementary Expertise: Each model specializes in unique features of its partition.

Algorithm 1 illustrates the architecture of the proposed method DEV.

Algorithm 1 Divided Ensemble Voting

Input: Dataset D, Number of partitions N, Model architecture M
Output: Final predictions for D_{test}
Split D into D_{train}, D_{val}, and D_{test}
Partition D_{train} into N subsets: D_{train1}, D_{train2}, ..., D_{trainN}
Initialize an empty list of models: $Models = []$
for epochs = 1 to N **do**
    Clone model M to M_i
    Train M_i on $D_{train,i}$
    Add M_i to $Models$
end for
Initialize empty list for predictions: $Predictions = []$
for each x in D_{test} **do**
    Collect predictions $P_1(x), P_2(x), \ldots, P_N(x)$ from all models
    Compute final prediction: $P_{final}(x) = mode(P_1(x), P_2(x), \ldots, P_N(x))$
    Append $P_{final}(x)$ to Predictions
end for
Return Predictions

Fig. 1 illustrates the DEV method based on the CNN learning model for binary classification. As shown in the figure, the dataset is divided into three distinct subsets: training(D_{train}), validation(D_{val}), and testing(D_{test}). Subsequently, the training set is further subdivided into N sets, designated as D_{train1}, D_{train_2}, $\cdots$, D_{trainN}. Each of these training sets was utilized to train separate instances of the model, designated as M_1, M_2, $\cdots$,M_N, respectively. Specifically, D_{train1} is processed by M_1, D_{train_2} is processed by M_2 and so forth for all partitioned datasets and corresponding models. Notably, the D_{val} set remained constant across all models to ensure consistency in performance evaluation. Upon completion of the training process, N distinct trained models were obtained. Subsequently, the D_{test} set is evaluated using each of the trained models M_i, $\{i = 1, 2 \cdots, N\}$, yielding N separate accuracy results P_1, $P_2 \cdots$, P_N. To determine the optimal classification for each image, a mode mechanism was employed, reflecting the majority vote among the N models. This approach facilitated the aggregation of predictions, enhancing the robustness of the classification results.

III. Experimental Framework

This section details the experimental framework, including: 1) the benchmark datasets employed, 2) the core components of the DEV method: image processing , and baseline CNN model architecture.

A. Dataset

This subsection describes the benchmark datasets selected for this study, which were chosen based on their substantial size and representative sample diversity. The large volume of high-quality training samples inherently provides sufficient feature variation, rendering data augmentation unnecessary. This approach not only streamlines the training pipeline but also preserves the authentic statistical distribution of the original data, eliminating potential biases introduced by synthetic transformations.

1) Deepfake and Real (DS-FR): This dataset comprises a collection of manipulated and real images, specifically focusing on human faces, and contains two classes: Fake and Real [19]. The manipulated images are generated using various techniques, primarily featuring deepfake technology, which involves replacing an individual's likeness in an existing image or video with that of another person. Each image in the dataset is formatted as a 256 x 256, showcasing either real or artificially generated faces. The dataset includes 70,000 authentic, alongside 70,000 synthetic faces derived from a larger pool of 1 million fake faces generated by StyleGAN [20]. For training, 60,000 images are utilized, with 30,000 for each class; 2,000 images are allocated for validation, with 1,000 for each class; and 4,000 images are designated for testing, split evenly into 2,000 for each class. Fig. 2 presents samples from the dataset, the validation set comprises 5% of the training data. The precise numbers for D_{train}, D_{val}, and D_{test} in our proposed model are detailed in Table I.

TABLE I. Dataset Distribution

Dataset	D_{train}	D_{val}	D_{test}	Total
DS-FR	60000	2000	4000	12000
DS-OR	21435	1129	2513	25077
DS-NP	24000	2000	4000	30000
DS-BNB	59922	2000	4000	65922

2) Waste Classification (DS-OR): The dataset consists of 25,077 images of solid household waste, categorized into two classes: organic (Org) waste, comprising 13,966 images, and Recyclable ($Recy$) waste, consisting of 11,111 images [21]. The acquired images are colored $.jpg$ files of random portrait and landscape orientation with resolution ranging from 191 pixels (minimum) $\times$ 264 pixels (maximum) [22]. The number of training and testing images is 22564 and 2513, respectively. Additionally, the validation set comprises 5% of the training data. Fig. 2 presents samples of the dataset. The numbers for D_{train}, D_{val}, and D_{test} in our proposed model are shown in Table I.

3) Concrete and Pavement Crack (DS-NP): This dataset consists of 30,000 images of concrete and pavement surfaces, classified into two categories: cracked and non-cracked [23]. Collected by Omoebamije Oluwaseun, a civil engineering student at the Nigerian Army University Biu, the images were obtained using a DJI Mavic 2 Enterprise drone and a smartphone. Each image is downsized to 227 $\times$ 227 pixels and stored in RGB and JPEG format. It is then arranged into Negative (Neg) and Positive (Pos) folders for convenient access and analysis. Samples of the dataset are presented in Fig. 2, the validation set comprises 5% of the training data. The precise numbers for D_{train}, D_{val}, and D_{test} are presented in Table I.

4) Non and Biodegradable Material (DS-BNB): This dataset comprises approximately 256,000 images, derived from an original collection of 156,000, representing two waste categories: Biodegradable (Bio) and Non-biodegradable ($Non\text{-}Bio$) [24], [25]. The Bio class includes materials that can be naturally decomposed, such as food and plant waste,

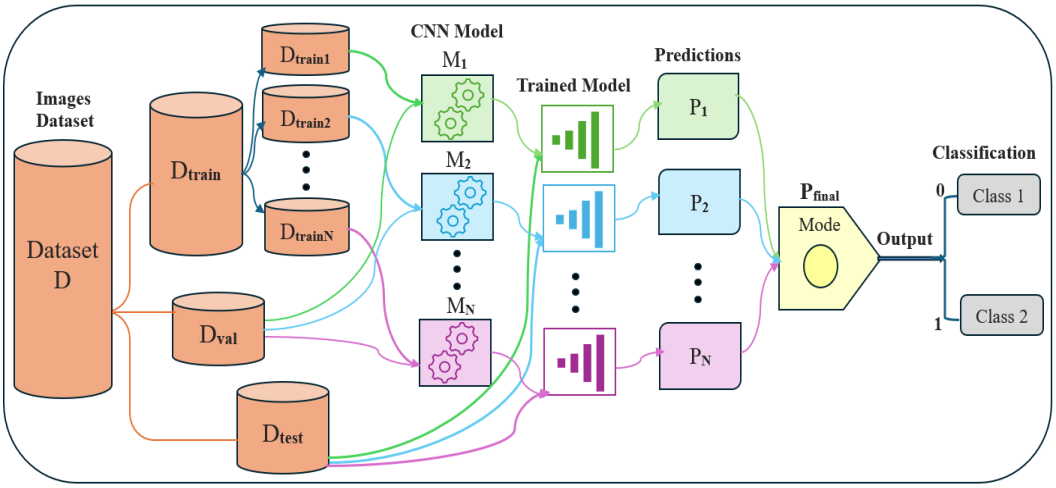

Fig. 1. Divided Ensemble Voting (DEV) model.

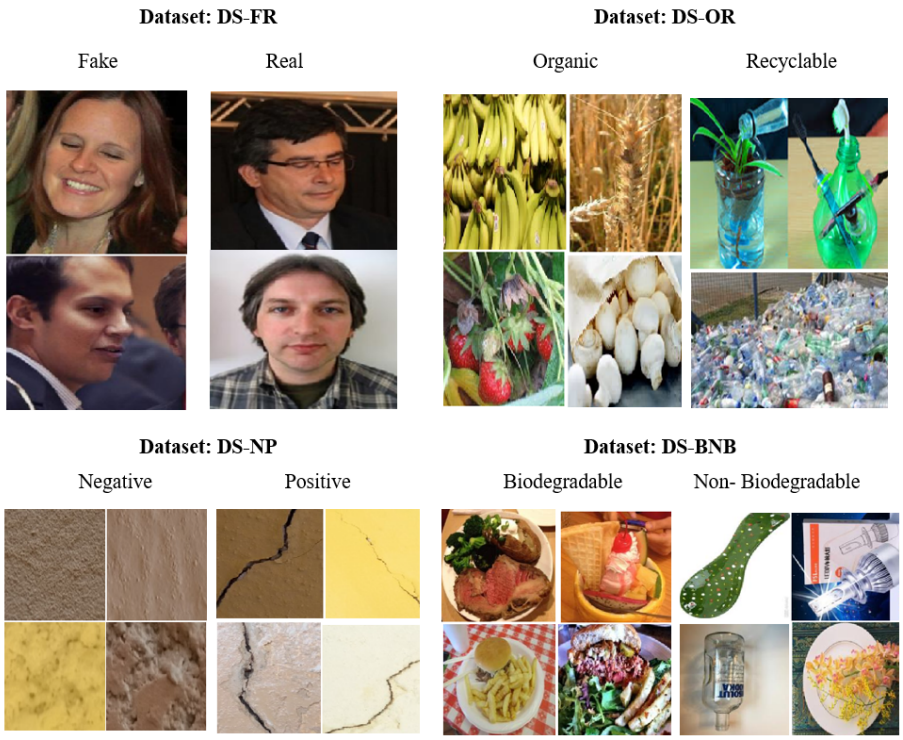

Fig. 2. Datasets samples.

while the non-biodegradable $Non\text{-}Bio$ class consists of materials like plastics and metals that cannot be decomposed. The dataset is divided into main subsets: training and testing. The training set further split into four parts, with the "TRAIN.1" folder designated for this research. Fig. 2 presents samples from the dataset. From the D_{test}: 2,000 images are randomly selected from each category, while 1,000 images from each category are randomly chosen for the validation set. The precise numbers for D_{train}, D_{val}, and D_{test} are presented in Table I.

The DEV method integrates two key components: 1) image preprocessing and 2) independent baseline CNN model training on partitioned data subsets. Each component is detailed in the following subsections.

B. Image Processing

Effective preprocessing and processing of image datasets are essential for improving the performance of classification tasks. These steps ensure that the images is formatted appropriately for analysis, thereby enhancing the model's accuracy. In this study, each image was assigned to its respective category. For each category of the dataset, the images were read using OpenCV, resized to a uniform dimension of 64x64 pixels, and

normalized by scaling pixel values to the range [0, 1]. This normalization step is essential, in order to improve the model's performance and rate of convergence.

C. Baseline CNN Model

Convolutional neural networks (CNNs), which are the basis of the deep learning model, are made to efficiently classify the processed images. The model architecture plays a crucial role in extracting relevant features from images and making accurate predictions regarding each class of the dataset.

Fig. 3 shows the baseline CNN architecture where input images pass through three convolutional blocks with increasing filters $F(32, 64, 128)$ and a fixed kernel size $K(3 \times 3)$. Each block includes convolutional layers with ReLU activation, batch normalization, max pooling, and dropout. The final block outputs a 2048-dimensional vector, followed by a dense layer $(256\ units)$ with dropout before the softmax output layer $(2\ units)$. The model uses the Adam optimizer and categorical cross-entropy loss for binary classification. Table II provides details on the configuration of the CNN model layers.

Total parameters: $815,818$ ($814,410$ trainable; $1,408$ non-trainable, from batch normalization's moving statistics). The trainable parameters primarily consist of convolutional and dense layer weights and biases, along with Batch Normalization's learnable scale (γ) and shift (β) parameters. The non-trainable parameters exclusively originate from Batch Normalization layers, representing the moving averages of mean (μ) and variance (σ^2) that are updated during inference but remain fixed during training to maintain stable feature distributions.

In the experimental implementation of the DEV method, the training set was partitioned into N=3 distinct subsets, each processed by a dedicated instance of N=3 independently trained models. Training was conducted over 20 epochs, with validation set performance monitored at each epoch to verify generalization capability beyond the training data. This rigorous evaluation protocol ensures unbiased assessment using completely distinct data partitions, maintaining the integrity of performance metrics. The partitioned approach not only facilitates specialized feature learning but also provides built-in validation through inter-model consensus.

IV. Results and Discussion

This section presents the results derived from three stages of analysis: first, performance accuracy using the entire training set; second, the accuracy after partitioning the training set into three subsets; and finally, accuracy achieved after implementing the DEV method.

A. Model Performance Evaluations on Datasets Based on the Entire Training Sets

This subsection evaluates the model's performance across four datasets, analyzing training/validation losses, accuracy metrics, and overall classification performance. The assessment is conducted using complete training sets for model development and validation.

Figures of the training and validation losses for the four datasets, along with their accuracy performance, are shown in Fig. 4 and 5, 6 and 7 across 20 epochs for DS-FR, DS-OR, DS-NP and DS-BNB datasets, respectively. Moreover, Table III illustrates the loss values for training, validation and testing across these datasets based on the entire training set.

Furthermore, Table IV presents the performance accuracies achieved for the training, validation, and testing sets of the proposed learning approach across the four datasets. Table V further illustrates the performance metrics achieved by applying the learning model approach to the test set for each dataset. Additionally, Fig. 8 demonstrates the confusion matrices for each dataset which provide a comprehensive overview of the model's figure classification performance across different labels.

For DS-FR, As demonstrated in Table III, while the model fits the training data well, it may not generalize as effectively to test data, indicated by the higher test loss of 0.5856. Furthermore, the model achieved a high training accuracy of 98.18% and a validation accuracy of 93.4%, although the test accuracy was comparatively lower at 85.55% with execution training time (ET) of 8 hrs., 21 sec, as shown in Table IV. The precision and recall values for the class labels in DS-FR dataset also reflect this trend, with precision scores of 0.87 and 0.84 for classes Fake and Real, respectively, as shown in Table V.

Additionally, in DS-OR dataset, the loss values for this dataset were higher, with a training loss of 0.2392 and a validation loss of 0.3445, as shown in Table III. Moreover, accuracies of training, validation and testing were 88.94%, 86.1% and 85.12%, respectively, as shown in Table IV. The precision for Org class was notably high at 0.98, but the recall at 0.68 suggests that the model struggled to identify all relevant instances of this class, leading to a lower f1-score of 0.80, as shown in Table V.

Furthermore, DS-NP dataset exhibited strong performance across all metrics, with a training accuracy of 96.41% and a validation accuracy of 96.95%, as shown in Table IV. The test accuracy of 95.42% was accompanied by a low-test loss of 0.1816 (Table III), indicating effective generalization. The precision and recall values for both class labels Neg and Pos achieving 1.00 and 0.92 for precision, and 0.91 and 1.00 for recall, respectively, resulting in f1-scores of 0.95 and 0.96 as shown in Table V.

Finally, DS-BNB dataset showed a training accuracy of 98.14% and a validation accuracy of 87.7%, with a test accuracy of 89%, as demonstarted in Table IV. Despite the high training accuracy, the validation loss of 0.3361 (Table III) suggests potential overfitting. As shown in Table V, the precision and recall values for class labels were relatively balanced, with precision scores of 0.93 for Bio class and 0.86 for $Non\text{-}Bio$, reflecting a strong capability in predicting instances of these classes.

B. Performance Evaluation Based on Partitioning of Training Data

This subsection evaluates model performance across the four datasets by analyzing: 1) training/validation losses, 2) accuracy metrics, and 3) overall classification effectiveness. For enhanced model evaluation, each original training set is further partitioned into three distinct training subsets.

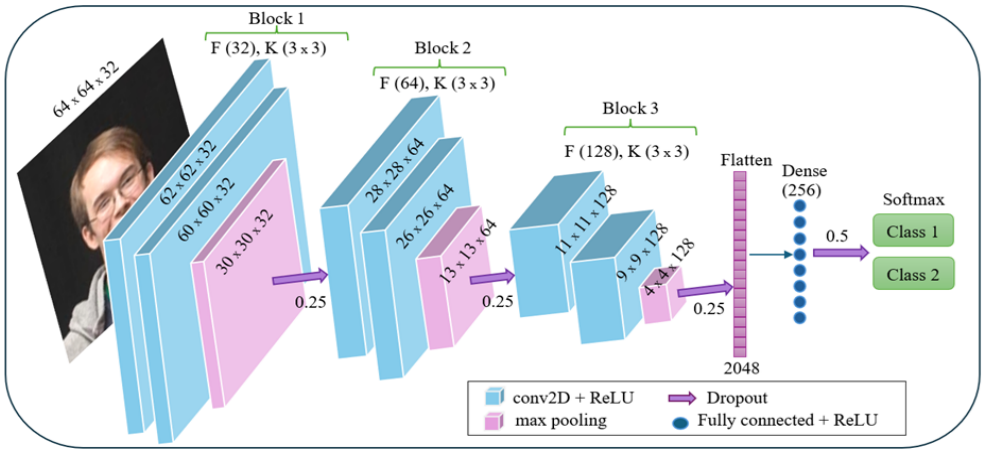

Fig. 3. Overview of the baseline CNN model architecture.

TABLE II. OVERVIEW OF THE BASELINE CNN ARCHITECTURE AND ITS PROPERTIES

Layer Type	Output Shape	Kernel Size(K)	Stride	trainable Params	Non-trainable Params
Conv2D	(62, 62, 32)	(3, 3)	(1,1)	896	0

DS-NP	7919	8040	8041
DS-BNB	19774	20074	20074

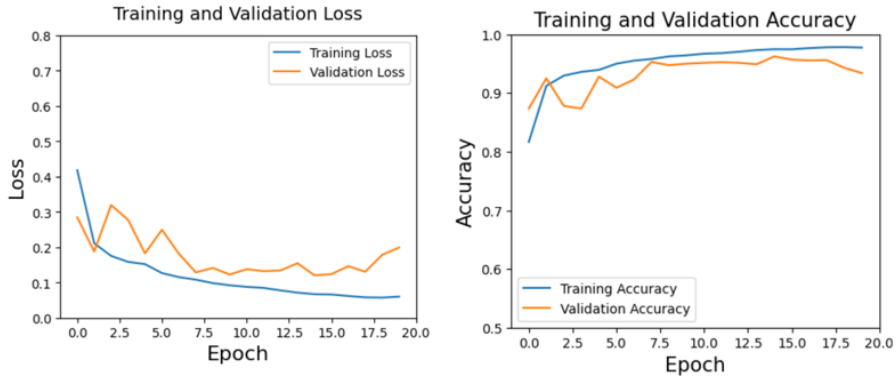

Fig. 4. DS-FR training and validation losses and its accuracy performance.

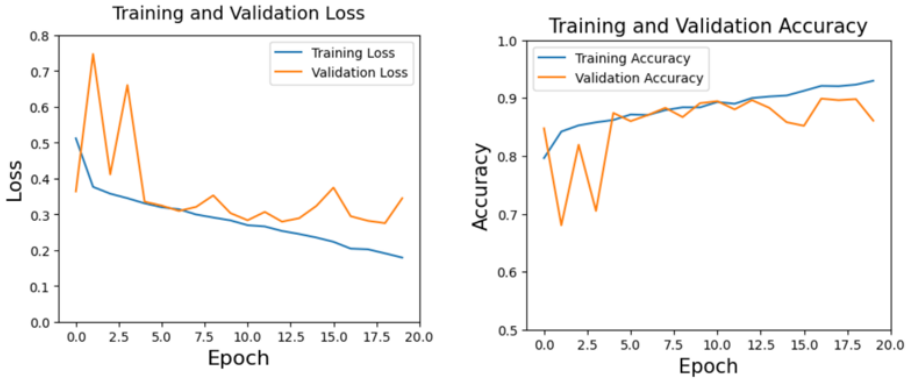

Fig. 5. DS-OR training and validation losses and its accuracy performance.

Fig. 6. DS-NP training and validation losses and its accuracy performance.

2) Models performance evaluation: Each of training subsets is used to independently train a separate instance of the CNN learning model M_i, $i = \{1, 2, 3\}$. The validation set was kept constant across all model instances to ensure consistent performance monitoring during training. Once training was completed, each of the three models was evaluated on the same independent test D_{test}, producing three individual accuracy scores.

Table VII presents the loss values for models M_1, M_2, M_3 trained on subsets D_{train1}, D_{train2} and D_{train3}, respectively. The table also includes the corresponding validation and test losses for each dataset.

Table VIII presents the performance accuracies of Models M_1, M_2 and M_3 for the training subsets $\{D_{train1}, D_{train2}, D_{train3}\}$, validation, and test sets across all four datasets, along with their execution times for each training subset. Furthermore, Table IX summarizes the performance metrics of each model (M_1, M_2 and M_3) on the test sets, evaluated per class across all datasets. Finally, Fig. 9, 10, 11 and 12 display the confusion matrix for models (M_1, M_2 and M_3) across the four datasets, providing detailed insights into their classification performance.

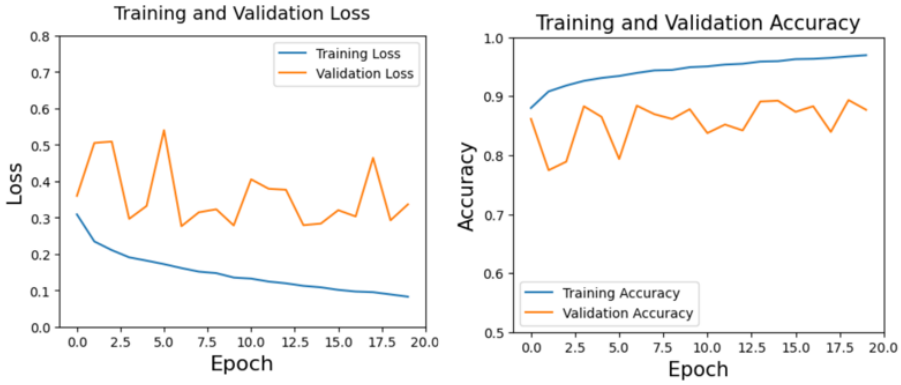

Fig. 7. DS-BNB training and validation losses and its accuracy performance.

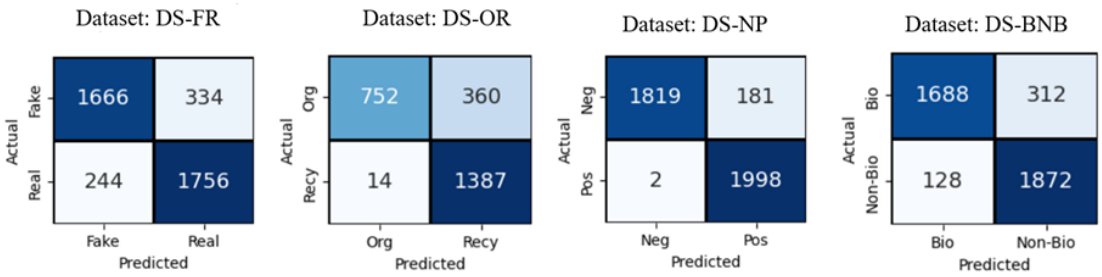

Fig. 8. Confusion matrix for all datasets based on the entire training set.

TABLE VII. TRAINING, VALIDATION AND TESTING LOSS VALUES FOR MODELS M_1, M_2 , M_3

Dataset	model	training loss	validation loss	testing loss
DS-FR	M_1	0.0189	0.2116	**0.2921**
	M_2	0.2511	0.7716	1.0366
	M_3	0.0209	0.2633	0.3174
DS-OR	M_1	0.2281	0.4054	0.4043
	M_2	0.1851	0.3830	0.4479
	M_3	0.1565	0.3518	**0.3172**
DS-NP	M_1	0.0362	0.0655	**0.0537**
	M_2	0.0540	0.0623	0.0601
	M_3	0.0424	0.0618	0.0594
DS-BNB	M_1	0.0757	0.3029	**0.2794**
	M_2	0.0755	0.3969	0.3947
	M_3	0.1324	0.3742	0.3720

For the DS-FR dataset , as summarized in the three Tables VII, VIII and IX, M_1 and M_3 showed lower losses (test loss: 0.29–0.32) compared to M_2 (1.04), indicating better generalization. M_1 and M_3 also outperformed M_2, achieving 99% training and 90.3% testing accuracy, versus M_2 93.6% (training) and 79.8% (testing) (Table VIII). Per-class metrics (Table IX) reveal M_1 balanced precision (0.90–0.91), while M_3 achieved 0.94 (Fake) and 0.87 (Real); M_2 had high Fake-class precision (0.95) but poor recall (0.63). Overall, M_1 excelled in accuracy and loss, with M_3 as a close competitor, while M_2 lagged significantly.

The results for DS-OR dataset, presented in Tables VIII, VII and IX, reveal notable differences in performance among models M_1, M_2, and M_3. M_3 achieved lowest losses (0.16 training, 0.32 testing) and the highest accuracy (94.03% training, 90.89% testing), demonstrating superior generalization. While M_1 showed strong precision for Org class (0.98) and M_2 had high $Recy$ recall (0.93), M_3 delivered balanced performance across classes (Org: 0.95 precision/0.83 recall; $Recy$: 0.88/0.97) with the best F1-scores (0.92 $Recy$). Models M_1 and M_2 exhibited trade-offs :M_1 in recall (0.70 Org) and M_2 in precision (0.69 Org), but M_3 consistently outperformed in both accuracy and class-wise metrics, establishing itself as the most robust choice for this dataset.

Moreover, For DS-NP dataset, as shown in Tables VIII, VII and IX, M_1 achieved the lowest losses (0.036 training, 0.054 testing), indicating superior generalization. Additionally, M_1 led with 99.03% training and 98.43% testing accuracy, followed closely by M_2 (98.56%/98.22%) and M_3 (slightly lower). All models excelled in class-wise metrics (precision/recall 0.98–0.99 for both Pos/Neg classes), with F1-scores consistently near 0.98. Results demonstrate exceptional performance across all models, highlighting the robustness of the learning approach on this dataset.

For the DS-BNB dataset (Tables VIII, VII and IX), M_1 achieved the lowest losses (0.3029 validation, 0.2794 testing) , alongside the best balance with 97.19% training and 89.6% testing accuracy, indicating superior generalization. While M_2 had higher training accuracy (97.83%) but poorer test performance (83.75%), and M_3 lagged in training (94.35%) and testing (86.83%), M_1 excelled in class-wise metrics: precision/recall of 0.89/0.90 (Bio) and 0.90/0.89 (Non-Bio), yielding consistent F1-scores (0.90 both classes). Though Models M_2, M_3 showed trade-offs, M_1 consistently delivered robust accuracy, loss, and per-class performance, establishing it as the most effective choice for this dataset.

TABLE VIII. ACCURACIES AND EXECUTION TIME BASED ON MODELS M_1, M_2, M_3

Dataset	model	training ACC	validation ACC	testing ACC	ET	total ET
DS-FR	M_1	99.32%	93.70%	**90.38%**	2 hr, 55 min, 49 sec	8 hr, 36 min, 25 sec
	M_2	93.59%	85.05%	79.77%	2 hr, 52 min, 25 sec	
	M_3	99.23%	92.65%	90.35%	2 hr, 48 min, 11 sec	
DS-OR	M_1	89.81%	83.17%	85.83%	1 hr, 4 min, 29 sec	3 hr, 13 min, 24 sec
	M_2	92.91%	87.16%	84.12%	1 hr, 6 min, 29 sec	
	M_3	94.03%	87.78%	**90.89%**	1 hr, 2 min, 26 sec	
DS-NP	M_1	99.03%	98.2%	**98.43%**	1 hr, 20 min, 58 sec	4 hr, 5 min, 17 sec
	M_2	98.56%	98.4%	98.22%	1 hr, 21 min, 3 sec	
	M_3	98.64%	98.05%	98.15%	1 hr, 23 min, 16 sec	
DS-BNB	M_1	97.19%	88.8%	**89.6%**	2 hr, 27 min, 22 sec	7 hr, 39 min, 8 sec
	M_2	97.83%	84.65%	83.75%	2 hr, 42 min, 37 sec	
	M_3	94.35%	86.20%	86.83%	2 hr, 29 min, 9 sec	

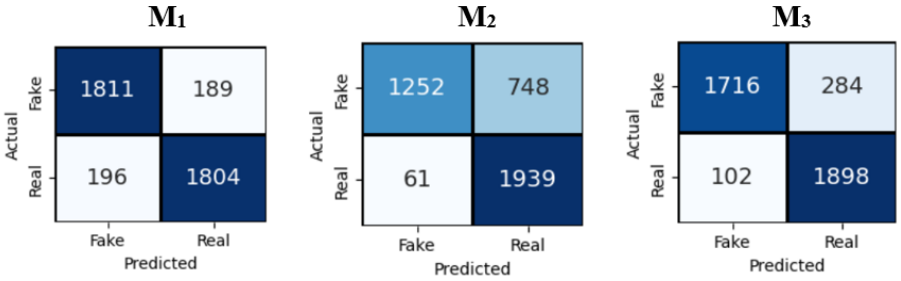

Fig. 9. Confusion matrix for models M_1, M_2, M_3 on the deepfake & real (DS-FR) dataset.

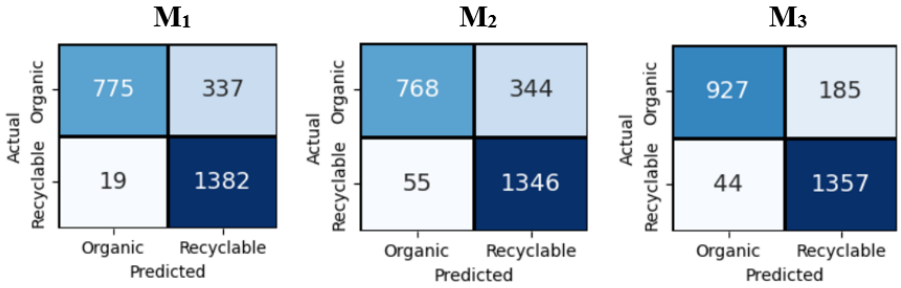

Fig. 10. Confusion matrix for models M_1, M_2, M_3 on the waste classification (DS-OR) dataset.

The comparative analysis reveals distinct performance patterns across datasets. M_1 demonstrated consistent superiority in DS-FR (high accuracy, balanced class metrics) and DS-BNB (lowest losses, strong F1-scores), establishing it as the most reliable overall. M_3 emerged as the top performer in DS-OR (best accuracy and balanced class metrics) while maintaining competitive results in DS-NP. Though M_2 showed high precision for specific classes (e.g., 0.95 Fake in DS-FR, 0.93 recall in DS-OR), it struggled with generalization (notably higher losses in DS-FR/BNB). The DS-NP dataset proved universally favorable, with all models achieving near-perfect metrics, suggesting its inherent class separability. These findings underscore that the composition and diversity of training subsets play a critical role in shaping model effectiveness on test data. To address this, DEV method is proposed as a systematic framework to optimize performance through ensemble learning.

C. Final Classification: DEV method vs. Entire Training-Based Learning

The DEV method aggregates predictions P_1, P_2 and P_3 from Models M_1, M_2, and M_3, respectively, using majority voting (mode) to determine final test-set labels. This ensemble strategy mitigates variance from weight initialization and subset-specific biases, enhancing generalization.

Initially, Performance metrics (Table X) highlight DEV's effectiveness: DS-FR achieved balanced F1-scores (0.93), DS-OR showed strong $Recy$-class recall (0.98) outperforming the whole-dataset approach in Table V, while DS-NP attained near-perfect metrics (precision/recall 0.99), and DS-BNB maintained high scores (Bio: 0.94, Non-Bio: 0.92). These results demonstrate DEV's consistency in optimizing accuracy across diverse datasets. The method's adaptability to varying class complexities underscores its practical utility.

Secondly, Comparative analysis of confusion matrices (Fig. 8 vs. 13) reveals DEV's consistent improvements across all datasets. For DS-FR, $Fake$ class detections rose to 1,756 (from 1,666) with fewer false positives (244 vs. 334). Similar gains occurred in DS-OR (Org: 876 vs. 752) and DS-NP (Pos: 1,970 vs. 1,819), while DS-BNB showed higher Bio class accuracy (1,838 vs. 1,688). These results demonstrate DEV's superiority over whole-dataset training, enhancing both precision and generalization.

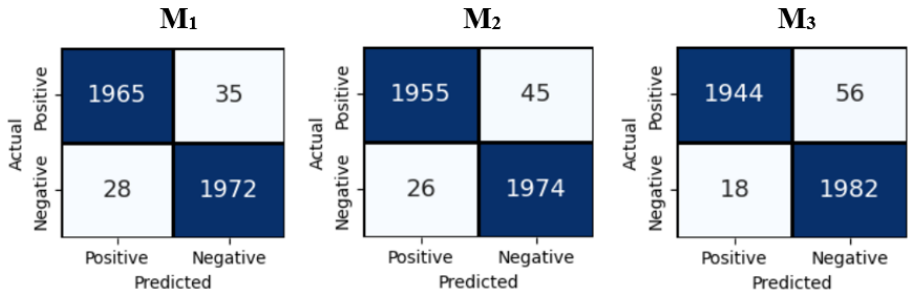

Fig. 11. Confusion matrix for models M_1, M_2, M_3 on concrete & pavement crack (DS-NP) dataset.

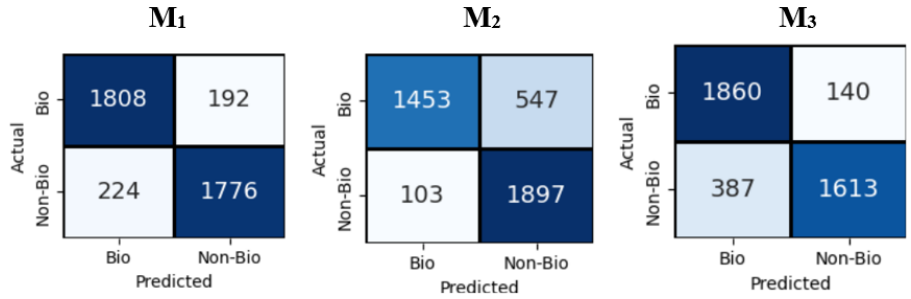

Fig. 12. Confusion matrix for models M_1, M_2, M_3 on non & biodegradable (DS-BNB) dataset.

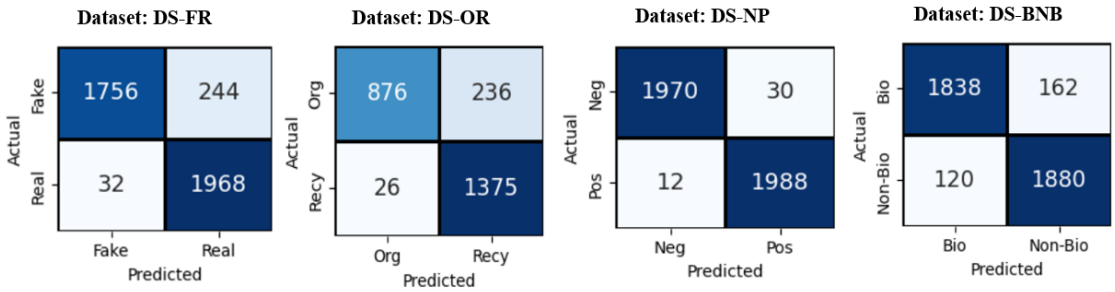

Fig. 13. Confusion matrix for test set based on DEV method.

Fig. 14 demonstrates DEV's consistent superiority over whole-dataset training, with accuracy gains across all datasets - most notably in DS-NP (95.0% to 99.0%). This improvement highlights how DEV's ensemble approach enhances classification reliability through collaborative model strengths. The findings validate DEV as an effective strategy for optimizing predictive performance.

Comparative execution time analysis (Tables IV, VIII) reveals that the additional 10 minutes required for training Models (M_1, M_2, M_3) under the DEV framework represents a negligible computational overhead relative to the significant performance gains achieved. This minor time investment is substantially outweighed by the method's demonstrated improvements in classification accuracy and robustness across all datasets.

The DEV method demonstrates superior performance over whole-dataset training, delivering consistently higher accuracy with improved true/false positive ratios across all datasets, while maintaining computational efficiency.

D. Discussion: Comparing Baseline CNN and DEV Method for the Four Datasets

This section provides a comprehensive performance comparison between the baseline CNN architecture and the DEV method across all four benchmark datasets.

1) Performance evaluation for DS-FR dataset: The baseline CNN model, trained on the full DS-FR dataset (12K images), achieved a test accuracy of 85.55%, with a notable test loss of 0.586, indicating potential overfitting (train loss: 0.051, validation loss: 0.199). The confusion matrix revealed 334 FP ($Real$ images misclassified as $Fake$) and 244 FN ($Fakes$ misclassified as $Real$), suggesting challenges in distinguishing high-quality deepfakes real images.

In contrast, the DEV method—which splits DS-FR (D_{train}) into three smaller training sets (D_{train1}: 19800, D_{train2}/D_{train3}: 20100 each) , keeping (D_{val}:2000, D_{test}:4000), yielded three models (M_1, M_2 , M_3). Model M_1 emerged as the strongest, achieving 90.4% accuracy with lower test loss (0.292), outperforming both the baseline and other models (M_2: 79.8%, M_3: 90.3% with test loss

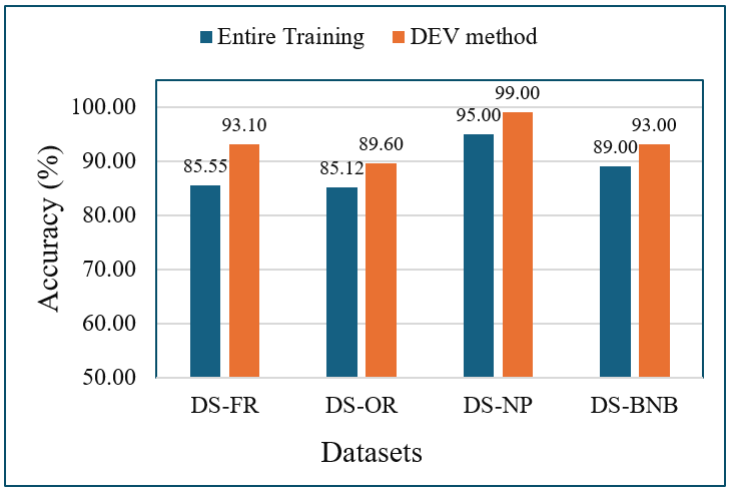

Fig. 14. Overall accuracy: Entire training set vs. DEV method across the four datasets.

TABLE IX. PERFORMANCE METRICS OBTAINED FOR EACH CLASS BASED ON MODELS M_1, M_2 , M_3

Dataset	model	class	precision	recall	f1-score
DS-FR	M_1	Fake	0.90	0.91	0.90
		Real	0.91	0.90	0.90

TABLE X. PERFORMANCE METRICS BASED ON DEV METHOD

Dataset	class	precision	recall	f1-score	ACC
DS-FR	Fake	0.98	0.88	0.93	93.1%
	Real	0.89	0.98	0.93	
DS-OR	Org	0.97	0.79	0.87	89.6%
	Recy	0.85	0.98	0.91	
DS-NP	Pos	0.99	0.98	0.99	99%
	Neg	0.99	0.99	0.99	
DS-BNB	Bio	0.94	0.92	0.93	93%
	Non-Bio	0.92	0.94	0.93	

1.037, 0.317, respectively) . FP were reduced by 43.4% through the implementation of Model M_1 (189 vs. baseline's 334), indicating superior $Real$ detection. This suggests that smaller, curated datasets (like D_{train1}) may mitigate overfitting and improve generalization. A relatively balanced misclassification pattern is exhibited by the CNN baseline. However, M_1 dramatically reduces both FP and, FN, demonstrating high robustness. Conversely, M_2, despite having the lowest FN (61), suffers from very high FP (748), indicating that it fails to detect a significant portion of $Real$ images. This imbalance in M_2 may stem from dataset-specific biases or class imbalance during training.

For Precision, Recall, and F1 Comparison, It can be observed that M_1 consistently demonstrates the most balanced and highest scores across all metrics, M_3 precision is the highest, but its low recall results, and these results suggest M_3 is overly moderate.

The DEV method demonstrates significant performance improvements over baseline CNN model, achieving 7.55% accuracy gain (85.55% $\Rightarrow$ 93.1%) while adding only 15 minutes to the total execution time (8h21m $\Rightarrow$ 8h36m). Notably, error rates sharply decreased, with false positives reduced by 27% (334 $\Rightarrow$ 244) and false negatives cut by 87% (244 $\Rightarrow$ 32), reflecting enhancement in both precision and recall. The confusion matrix reveals stronger class discrimination, with TP rising by 5.4% (1666 $\Rightarrow$ 1756) and TN increasing by 12% (1756 $\Rightarrow$ 1968).

2) Performance evaluation for DS-OR dataset: The baseline CNN model, trained on the full DS-OR dataset (2.5K images), achieved a test accuracy of 85.12%, with a notable test loss of 0.378, (train loss: 0.239, validation loss: 0.345). The confusion matrix revealed 360 FP (Org images misclassified as $Recy$) and 14 FN ($Recy$ misclassified as Org).

In contrast, the DEV method—which splits DS-OR (D_{train}) into three smaller training sets (D_{train1}: 7073, D_{train2}/D_{train3}: 7181 each), with (D_{val}:1129, D_{test}:2513), yielded three models (M_1, M_2 , M_3). Model M_3 emerged as the strongest, achieving 90.89% accuracy with lower test loss (0.317), outperforming both the baseline and other models (M_2: 85.8%, M_3: 84.1% with test loss 0.404, 0.448, respectively) . Experimental data show that false positives were reduced by 48.6% through the implementation of Model M_3 (185 vs. baseline's 360), indicating superior Org detection. For Precision, Recall, and F1 Comparison, it can be observed that M_3 shows the most balanced and highest scores across all metrics.

The DEV method delivered significant performance improvements over whole-dataset training, achieving 4.48% accuracy increase (85.12% ⇒ 89.6%) while adding only 8 minutes to execution time. Error analysis revealed particularly strong gains in precision, with false positives reduced by 34.4% (360 ⇒ 236), though false negatives increased (14 ⇒ 26) due to the dataset's class imbalance. The confusion matrix shows improved TP detection (16.5% increase, 752 ⇒ 876).

3) Performance evaluation for DS-NP dataset: The baseline CNN model, trained on the full DS-NP dataset (30K images), achieved a test accuracy of 95.42%, as detailed in Table IV, with a notable test loss of 0.182, indicating potential overfitting (train loss: 0.1362, validation loss: 0.1041). The confusion matrix revealed 181 FP (Pos images misclassified as Neg) and 2 FN (Neg misclassified as Pos), suggesting challenges in distinguishing high-quality concrete and pavement surfaces images.

In contrast, the DEV method—which splits DS-NP (D_{train}) into three smaller training sets (D_{train1}: 7073, D_{train2}/D_{train3}: 7181 each)—yielded three models (M_1, M_2 , M_3). Model M_1 emerged as the strongest, achieving 98.43% accuracy with lower test loss (0.0537), outperforming both the baseline and other DEV models (M_2: 98.22%, M_3: 98.15%). A significant reduction in FP was achieved by Model M_1 (35 vs. baseline's 181), indicating superior Negative detection. This suggests that smaller, curated datasets (like D_{train2}) may mitigate overfitting and improve generalization. The CNN baseline's balanced misclassification behavior is demonstrated through its FN (28 vs. baseline's 2). Regarding the precision, recall, and F1 comparison, Model M_1 exhibits the most balanced and highest scores across all metrics compared to Model M_2 and Model M_3. This suggests that Model M_1 provides the most robust and reliable performance among the three models.

The DEV method achieved remarkable performance improvements for DS-NP dataset, increasing accuracy by 3.58% (95.42% ⇒ 99%) while adding only 9 minutes and 40 seconds to execution time (3h55m37s ⇒ 4h5m17s). Error analysis shows exceptional optimization, with FP reduced by 83.4% (181 ⇒ 30) and FN increasing by 500% (2 ⇒ 12) due to the model's more conservative classification approach. The confusion matrix reveals outstanding TP detection (8.3% improvement, 1819 ⇒ 1970) with nearly perfect TN retention (1998 ⇒ 1988, -0.5%). These results demonstrate DEV's ability to push model performance to near-perfect levels while maintaining reasonable computational efficiency.

4) Performance evaluation for DS-BNB dataset: The baseline CNN model, trained on the full DS-BNB dataset (65.92K images), achieved a test accuracy of 89%, as detailed in Table IV, with a notable test loss of 0.281, indicating potential overfitting (train loss: 0.058, validation loss: 0.336). The confusion matrix revealed 312 FP (Bio images misclassified as $Non\text{-}Bio$) and 128 FN ($Non\text{-}Bio$ misclassified as Bio), suggesting challenges in distinguishing high-quality Non & Biodegradable material images.

In contrast, the DEV method—which splits DS-BNB (D_{train}) into three smaller training sets (D_{train1}: 19774, D_{train2}/D_{train3}: 20074 each)—yielded three models (M_1, M_2 , M_3). Model M_1 emerged as the strongest, achieving 89.6% accuracy with lower test loss (0.279), outperforming both the baseline and other DEV models (M_2: 83.75%, M_3: 86.83%). A significant reduction in FP was achieved by Model M_1 (192 vs. baseline's 312). Regarding the precision, recall, and F1 comparison, Model M_1 exhibits the most balanced and highest scores across all metrics compared to Model M_2 and Model M_3. This suggests that Model M_1 provides the most robust and reliable performance among the three models.

The DEV method delivered significant performance improvements for DS-BNB dataset, boosting accuracy by 4% (89% ⇒ 93%) with only 12-minute, 8-second increase in execution time (7h27m ⇒ 7h39m8s). The approach demonstrated particularly strong error reduction, with FP decreasing by 48.1% (312 ⇒ 162) while maintaining comparable FN rates (6.25%, 128 ⇒ 120). The confusion matrix reveals excellent TP improvement (8.9% increase, 1688 ⇒ 1838) with stable TN performance (1872 ⇒ 1880, 0.4%). These results highlight DEV's ability to enhance model precision while maintaining recall.

Finally, the DEV method's performance gains stem from four synergistic mechanisms. First, dataset partitioning enables specialized feature learning, where each model captures distinct data aspects, reducing collective bias. Second, the majority voting mechanism cancels individual model errors through consensus. Third, aggregated predictions leverage complementary model strengths, enhancing robustness to outliers and edge cases. Finally, the framework achieves this through a favorable balance between efficiency and accuracy, a small increase in execution time results in a disproportionate increase in accuracy, demonstrating a scalable improvement.

V. Conclusion

The Divided Ensemble Voting (DEV) methodology introduced in this research establishes a novel ensemble learning architecture aimed at augmenting the efficacy of image classification systems. Central to this framework is the strategic division of the training data into unique partitions, enabling the development of specialized convolutional neural networks tailored to distinct feature domains. The consensus-driven integration of predictions via a majority voting protocol yields a robust final classification. Empirical validation across multiple datasets confirmed a marked elevation in model accuracy, with observed gains ranging from 3.58% to 7.55%. The framework also demonstrated a profound capacity for error reduction, achieving a decrease in FP instances of up to 83.4%. These enhancements are attributed to the method's inherent resistance to overfitting, its ability to neutralize singular model biases through diversified training regimes, and its superior generalization powered by collective decision-making. Furthermore, DEV exhibited exceptional proficiency in addressing class distribution imbalances, reflected by a 16.5% increase in TP identification and F1-scores attaining 0.99. A critical advantage of this architecture is its computational efficiency, imposing a negligible runtime overhead of less than 5%, thereby affirming its practicality for operational environments. The combination of heightened precision and operational efficiency positions the DEV framework as a transformative solution for applications demanding high reliability.

A Spatiotemporal Forex Trading System Based on a Hybrid Model GAT-LSTM: Forecasting Forex Price Directions

Nabil MABROUK, Marouane CHIHAB, Younes CHIHAB
Computer Sciences Laboratory, Ibn Toufail University, Kenitra, Morocco

***Abstract*—Due to the high volatility and complex interdependencies within financial markets, predicting Forex prices becomes a difficult challenge for investors. Furthermore, the traditional trading models struggle to capture those relationships. To address this issue, we introduced a spatiotemporal Forex trading system, GAT-LSTM-based; it is a hybrid approach that combines Graph Attention Network (GAT) with a Long Short-Term Memory (LSTM) network. The GAT component helps to capture spatial dependencies between currencies by constructing a directed graph containing 28 currency pairs alongside commodity stock and US stocks. The strength of the GAT component lies in its ability to dynamically adjust and recalculate the weights of edges over time, which helps our proposed system to adapt to macroeconomic changes, news events, and financial factors that can impact the Forex market status. The LSTM component deals with the nature of time series datasets. It learns temporal interdependencies, allowing our system to detect repeated long-term patterns over time. Experimental results proved that the suggested hybrid model, GAT-LSTM, surpasses both LSTM and GAT separately. By combining both elements and leveraging simultaneously the strength of dynamically modelling spatial dependencies, and the strength of learning long-term temporal patterns, our suggested system became more accurate in forecasting Forex price directions, showing promising results and high accuracy during the validation phase.**

Keywords*—Forex trading; hybrid deep learning model; Graph Attention Network (GAT); Long Short-Term Memory (LSTM); spatiotemporal forecasting

I. Introduction

The Forex, which is a short abbreviation of foreign exchange market, is known for its high volatility and strong price fluctuation caused by the influence of economic news, investor sentiment, and global events [1], [2]. Thanks to Forex advantages, including high liquidity, low transaction costs, 24-hour availability/operations, and online trading possibilities [3], investors (companies, individuals, and institutions) consider Forex as a profitable market that offers a good opportunity to achieve their goals and specific financial objectives utilizing exchange rate volatility [4], [5]. Most currencies are traded against the USD, and they are traded in pairs [6]. Each pair is composed of base and quoted currency [7]. Traders can exchange currencies at any time because the Forex market operates continuously for 24 hours a day, five days a week, which leads to elevated liquidity and a substantial trading volume [8], [9]. The historical data of Forex transactions has become the fuel of research.

In the past, numerous studies have been conducted on predicting Forex prices. Investors have deployed and adapted traditional trading strategies and other tools that they found helpful in their previous operations to suit their trading styles [10]. Three main techniques of forecasting Forex prices for time series are adopted by traders and investors: The first is fundamental analysis, which involves examining economic factors, political characteristics, and news events that may influence the Forex market status [11], [12]. The second is technical analysis (TA), which is a trading method based on historical data and mathematical calculations. To get an idea about future price variations, technical analysts look for past behaviors and patterns in historical data, using technical indicators and charts. The third type of analysis is sentiment analysis. Forex market fluctuations are primarily influenced by emotions and sentiments [13]. It studies the general mood of the market and analyzes the general attitude of traders toward the Forex market. Forex prices fluctuate because of investors' emotions, whether they are optimistic or pessimistic about the market. It is the primary factor for their decision-making to buy or sell. Trading techniques follow technological advancements.

Traders use computational algorithms, specifically deep learning, data mining, and machine learning, to create their trading strategies [14]. However, simple machine learning and deep learning algorithms struggle to forecast Forex prices accurately because of the social, economic, and political interdependencies.

In this study, we propose a hybrid model to leverage the dependencies between Forex currency pairs, the commodity stocks, and the US-stocks. Our spatiotemporal system can automatically forecast and identify future price directions, trends, and cycles, leveraging the time series nature of the Forex dataset. The spatial part of our model will deal with horizontal dependencies between currency pairs and stocks, forming a Graph to overcome the issue of economic, social, and political factors; each node of this Graph is enriched with valuable features such as technical indicators and trading rules to improve the prediction accuracy. Besides forming a Graphical representation, and thanks to the GAT component, which can update the strength of those connections between nodes, our model is able to adapt to global changes. The temporal part is to deal with the vertical dependencies between Forex transactions by learning and capturing long-term patterns. Our solution can perform the optimal trade decision, including buy, hold, or sell signals.

II. Related Works

In the last decade, forecasting currency exchange rates has been the center of much research; many techniques and

methodologies have been adopted in this field of research. Technological development helped investors trade at any time and from any place around the world through electronic platforms. [11], leading to the accumulation of a large set of historical data; which motivated researchers to conduct studies on the resolution of financial market problems based on computational algorithms [15]. In [16], Neely and Weller's research examines the manner in which technical analysis is employed in the foreign currency market, highlighting its widespread acceptability and superiority compared to fundamental analysis, particularly in short-term trading scenarios. Initially observed by traders in the London market, their findings have been validated across various market conditions, underscoring the enduring significance of technical analysis in Forex trading. In [17], they provide significant insights into the fundamental concepts of technical analysis, emphasizing its reliance on historical stock price and volume data to discern market patterns. Unlike fundamental analysis, which evaluates a stock's intrinsic worth, technical analysis emphasizes chart patterns and statistical indicators to forecast future market trends, offering a distinct perspective on the evaluation of equity assets. In [18], they conducted research on using SVM for market trend prediction; the results showed an out-performance of SVM with Expert Advisor, versus a simple Expert Advisor. They used an SVM (support vector machine) to forecast trends, "UP trend" or "DOWN trend". In [19], they showed that KNN performed better using PCA. KNN can reduce redundant and noisy information, leading to accurate predictions of the stock and Forex markets.

In [20], Zhelev and Avresky assert that the referenced literature on deep learning helps as a fundamental basis for handling the complex problem of Forex price prediction. In recent years, deep learning has shown notable progress in resolving Forex trading tasks and other domains [21]. Deep Neural Network algorithms have been employed to forecast time series data and quantitative trading [22], [23], [24]. Deep neural network algorithms have shown improved performance and accuracy, producing better returns in the finance sector [25], [26]. According to Galeshchuk [27], an ANN model with a single hidden layer can outperform the time series model in forecasting the price, especially for short-term prediction of the market. Hu et al. [28] applied NLP techniques in news to select only authentic content and influence trend. They proposed a hybrid LSTM model with an Attention mechanism for the prediction task. In [29], they confirmed that ANN performs better than DNN and SVM in time series data. In [30], the authors indicated that, while methodologies utilizing neural networks demonstrate significant potential, they are frequently evaluated solely on the basis of their prediction errors. However, it is equally imperative to assess their impact on a real-world trading system, where the decision to invest in the market is as critical as the decision not to invest.

In [31], they proposed time series data mining based on GNN and transformer to tackle the problem of modeling complex dependencies, using an adaptive adjacency matrix. They showed that the model can dynamically calculate the relationship between variables and capture local dependencies. For a multivariate time series forecast, in [32], they developed an architecture that merges a spatial-temporal graph neural network with a filtering module. They forecast future sales from an artificial time series sales volume dataset. The suggested spatial-temporal model showed excellent performance compared to baseline approaches without graphical architecture. In [33], they used a graph-awareness-based GAT-GAN Generative Adversarial Network to learn temporal dependencies that capture spatial relationships and generate long-time series data. In [34], they combined long-short-term memory (LSTM) with graph attention networks (GAT), creating a spatiotemporal model to accurately predict the water quality of the Pearl River Basin. They confirmed that their model showed robust performance and succeeded in jointly capturing spatial and temporal interdependencies. In [35], the authors examined the influence of human movement on the transmission of COVID-19. It establishes a mobility network that delineates travel patterns among Brazilian cities and incorporates time series data. Two Graph Convolutional Network (GCN) neural networks are employed to forecast time series for each city, considering adjacent cities. The study assesses LSTM and Prophet models, concluding that GCN models produce more consistent results than the assessed models. The Prophet model exhibits a greater maximum RMSE value.

III. Our Proposed Solution

A. Methodology and Problem Definition

The global economy is interconnected, a phenomenon known as internationalization, causing the interdependency of multiple financial sectors. However, Forex refers to the exchange of currencies. This fact implies the existence of dependencies between currencies. We assume that each pair of currencies is related to other pairs. Forming a directed graph G = (V, E) [36], where the set of nodes V represents all currency pairs, linked by an edge set E. these connections and the structure of the graph G are represented by a matrix adjacency A of two dimensions (D x D), where D is the number of nodes (in our case it is currency pair); each element A_{ij} represents the existence of an edge between two nodes V_i and V_j [see Eq. (1)]:

$$A_{ij} = \begin{cases} 1, & \text{if an edge exists between } V_i \text{ and } V_j \\ 0, & \text{Otherwise} \end{cases} \quad (1)$$

The Graph Neural Network (GNN) uses an adjacency matrix to capture spatial dependencies between currency pairs and to learn deep complex patterns. Providing the necessary information for accurate predictions. The GAT-LSTM model is trained using a supervised learning approach, which consists of minimizing the disparity between the forecasted and actual trends in historical data. The backpropagation during the training process allows the model to learn the optimal weights for both the GAT and LSTM components.

B. Data Description

1) Data collection: This study aims to predict the variation of prices in the Forex market. For that, we obtained the necessary dataset from various reliable financial platforms such as ForexSB, FXStreet, DailyForex, etc., which offer valuable historical Forex data for time series analysis.

To construct comprehensive data for our model, we considered the 28 most common currency pairs. They can be

classified into two general classes: the first is major currencies (GBPUSD, EURUSD, USDCHF, USDCAD, and USDJPY), and the second class is the minor currencies (AUDCAD, NZDJPY, NZDUSD, CADCHF, NZDCAD, GBPNZD, NZDCHF, GBPCHF, GBPJPY, GBPAUD, AUDNZD, EURNZD, EURJPY, AUDCHF, EURGBP, EURCHF, EURCAD, EURAUD, CHFJPY, CADJPY, AUDUSD, GBPCAD, AUDJPY).

The objective is to forecast future price directions for the five major currency pairs. In addition to the 28 currency pairs, we used six additional stock data, such as commodity stocks and US stocks, to enhance the predictive performance of our algorithm. The collected dataset covers the period from January 2009 until June 2025, spanning 5006 days, resulting in approximately 170,204 daily observations (5006 days x 34 stocks). This dataset provides a detailed view of the exchange rates for the currencies, presented by five features:(Open, High, Low, Close, Volume) for each stock. Where Open is the price at the beginning, High is the highest price, Low is the lowest price, Close is the final price, and Volume is the total amount of currency exchanged. Fig. 1 illustrates the scaled closing prices of the five major currency pairs.

2) Data preprocessing and feature engineering: In the data pre-processing phase, we handled the missing values to avoid errors in prediction models by ensuring that there were no missing values in our time series dataset. In addition to primary features, we generated two other variables, "return" and "direction" features, that indicate whether the prices will increase or decrease in the following sequence [see Eq. (2)]:

$$Direction = \begin{cases} 1, & \text{if Price } _{t+1} > \text{ Price } _{t} \\ 0, & \text{Otherwise} \end{cases} \quad (2)$$

To improve the performance of our model, we created additional features that are generated using mathematical calculations. Those features are called technical indicators, such as:

- The Bollinger Band (BB),
- Moving Polynomial Trending (MPT)
- The Relative Strength Index (RSI),
- The Commodity Channel Index (CCI),
- The Weighted, Exponential, Simple, and Convergence Divergence Moving Average (WMA, EMA, SMA, and MACD),
- The average directional index (ADX),
- The Rate-of-Change (ROC)

Technical indicators can be incorporated as additional features, enriching our dataset with additional information that helps to improve the accuracy of the prediction. We finally form a comprehensive spatiotemporal 3D matrix for model training and evaluation (5006 days x 34 stocks x 81 features).

3) Feature matrix X: Let X be a feature matrix of dimension (N x P), where N represents the total number of currency pairs and P is the total number of features of each currency pair. The features matrix $X \in \mathbb{R}^{N \times P}$ is defined by the following Eq. (3):

$$X^k = \begin{bmatrix} x_{11}^k & \cdots & x_{1p}^k \\ \vdots & \ddots & \vdots \\ x_{n1}^k & \cdots & x_{np}^k \end{bmatrix} \quad (3)$$

Our dataset is a 3D matrix, where X^k represents a feature matrix at row k.

4) Feature scaling: During the training process, features with larger magnitudes dominate, preventing the model from learning. To optimize the efficacy of our model and guarantee that all features contribute equally to the training process, we have scaled the data using the Min-Max scaler in the range [0, 1]. See Eq. (4):

$$X_{sc} = \frac{X - X_{\min}}{X_{\max} - X_{\min}} \quad (4)$$

where,

Xsc: the scaled value of the data point.

X: the initial data point's value.

Xmin: the minimal value of the data point.

Xmax: the maximum value of the data point.

5) The spatial representation of currency pairs (Graph): We assume that the currency pairs form a graph. Each currency pair is considered a node; the relationships between those nodes (edges) are determined based on the calculation of correlation coefficients, forming a weighted graph. Those weights are dynamic and change during training, enabling our model to self-adjust with global factors such as economic cycles, news events, and industry trends. Initially, we created a fully connected graph: Every currency pair is connected to every other currency pair. Fig. 2 illustrates the graph representation of currency pairs.

6) Sequence creation: Our objective is to improve the predictive capabilities of GAT and LSTM by effectively leveraging their combined power. We reconstructed the resulting data into sequences by implementing a sliding-window approach.

Let $X = \{x_1, x_2, ..., x_T\}$ be a time series dataset, where x_t represents the data point at time t, and T is the length of the initial dataset. The i^{th} sequence S_i of length L is defined in Eq. (5):

$$S_i = \{x_i, x_{i+1}, \ldots, x_{i+L-1}\} \quad (5)$$

For example, a window of five days length means that to forecast the price direction Yt of a currency pair, we feed our model with the data that correspond to time step t, along with the data of the four prior time steps $[x_{t-3},\ x_{t-3},\ x_{t-2},\ x_{t-1},\ x_t]$. This approach helps the LSTM component to better detect temporal dependencies. Furthermore, for better optimization of the LSTM layer, we have trained our model using various sequence lengths between 1 and 25.

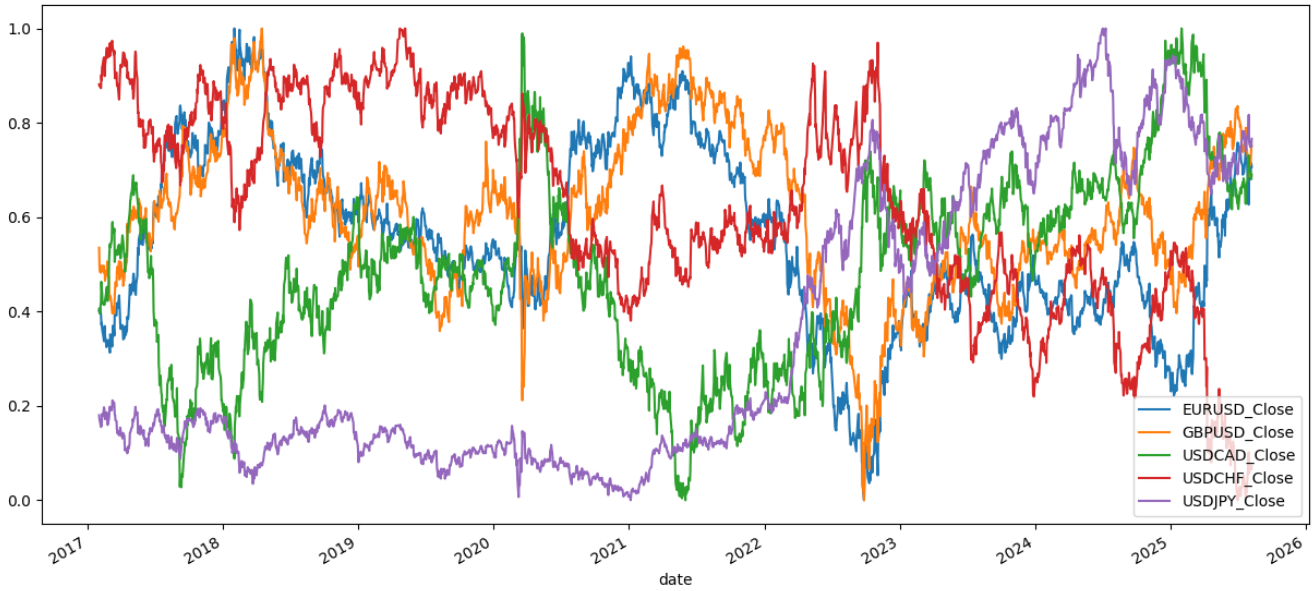

Fig. 1. The scaled closing price of the five major currency pairs.

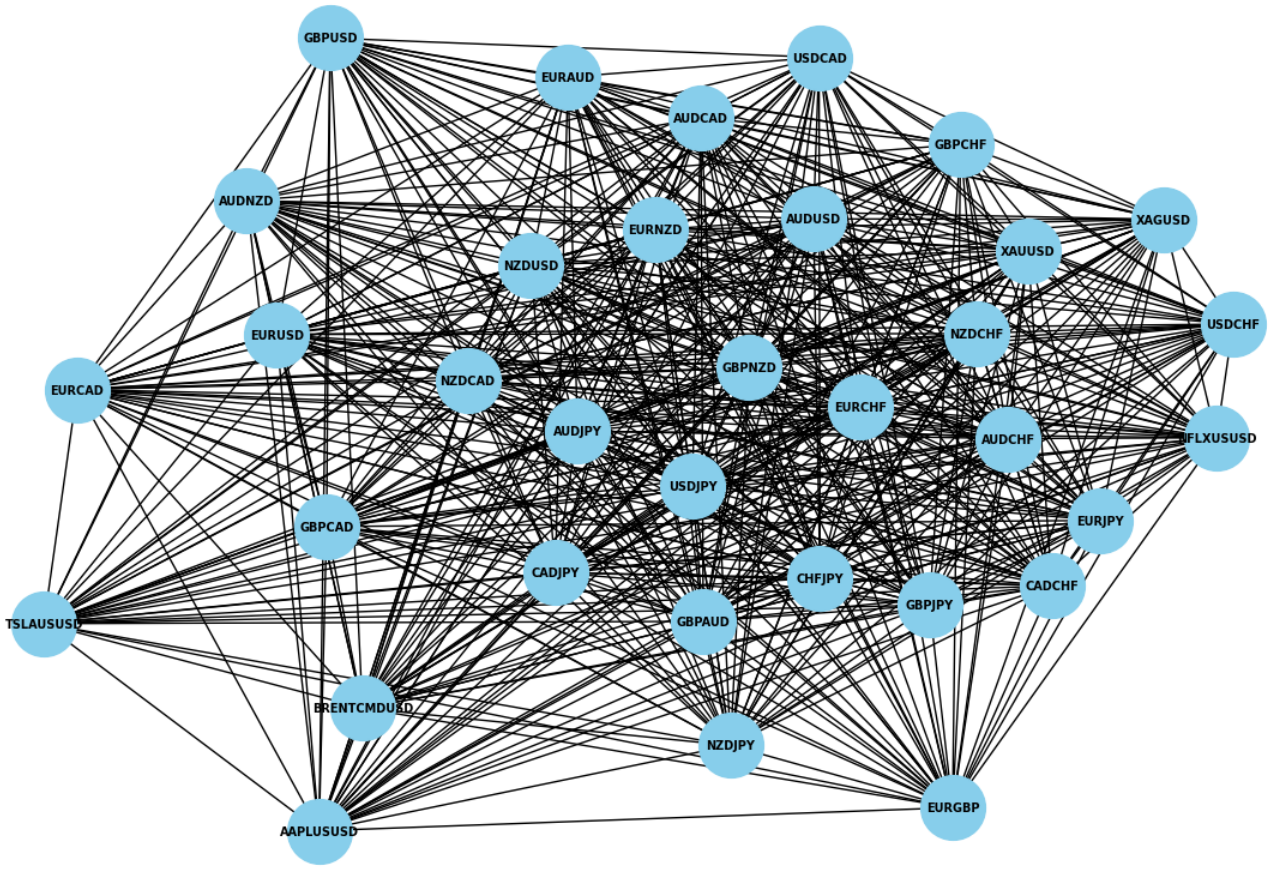

Fig. 2. A complete graph with 28 currency pairs and six stocks.

7) Split data into train and validation: To ensure a realistic and rigorous evaluation, we implemented a strict chronological data split to mimic real-world prediction. The dataset was divided temporally as follows:

- Training set (70%): January 1, 2009, to December 31, 2019.
- Validation set (10%): January 1, 2020, to December 31, 2021.
- Test set (20%): January 1, 2022, to May 30, 2025.

Crucially, we employed a strict procedure to prevent data leakage. All preprocessing steps were calculated solely from the training data, and those transformations were then applied to the subsequent validation and test sets. By maintaining this chronological order and separation, we were able to accurately assess the capacity of the model to generalize to future unseen data.

C. Model Architecture

In this study, we implemented two independent models, the first is Graph Attention (GAT) Network and the second is Long Short-Term Memory (LSTM) Network, to forecast Forex trend direction. We compared those models with a hybrid model, GAT-LSTM, which is a spatiotemporal model that combines two components to take advantage of the strengths of both architectures in dealing with spatial and temporal interdependencies simultaneously.

1) GAT (Graph Attention Networks): Like any Graph Neural Network (GNN) architecture, the Graph Attention Network (GAT) is designed to analyze and understand graph-structured data; in addition, it implements the attention mechanisms [37]. GAT assigns attention weights to neighboring nodes. Updates the node representation according to the importance of the neighbor's information and refines the relationships between individual pairs of currencies. This aids in generating a dynamic, weighted graph, which subsequently helps manage fluctuations in the Forex market. The following Eq. (6) mathematically defines the attention mechanism:

$$\alpha_{\mathrm{ij}} = \mathrm{softmax}_{\mathrm{j}} \left(a \left(W * h_{\mathrm{i}}, W * h_{\mathrm{j}} \right) \right) \tag{6}$$

Let α_{ij} be the attention coefficient between currency pair i and currency pair j, where h_i and h_j denote the characteristic vectors of currency pair i and currency pair j, respectively; W is a learnable weight matrix, while a is an attention function. The attention mechanism dynamically adjusts the importance of each edge based on the learned attention weights. By leveraging attention mechanisms, GAT can effectively overcome the issue of stock variations caused by various factors.

2) The Recurrent Neural Networks and the Gated Recurrent Unit: To address sequential data challenges, including time series and text, researchers have created the Recurrent Neural Network (RNN) [38], [39], [40], a specialized neural network that incorporates a memory mechanism to retain information from prior inputs. Feedback links in their design enable the retention of knowledge across temporal stages. Recurrent Neural Networks (RNNs) excel in sequence modeling problems, where the temporal context of data points is essential for precise prediction and comprehension.

3) LSTM (Long Short-Term Memory): Long Short-Term Memory (LSTM) was published by [41], [42], [43], [44]. It is an architecture of Recurrent Neural Networks (RNNs) that can help address the problem of vanishing gradients faced by standard RNNs. LSTM can effectively bridge time lags exceeding 1,000 discrete time steps. This capability makes them suitable for tasks where long-range temporal dependencies are critical.

The idea behind using an LSTM layer in our hybrid model is to learn and recognize sequential patterns that characterize time series datasets and capture temporal dependencies of Forex prices. We have adopted a many-to-many architecture to forecast the following trend of the five major currency pairs.

4) Hybrid model GAT-LSTM: In this study, we have proposed a hybrid model to effectively forecast Forex trends by capturing spatial dependencies between currency pairs and learning sequential patterns simultaneously. This model, GAT-LSTM, is a combination of two components, GAT and LSTM; see Fig. 3. By integrating the GAT and LSTM networks, we succeeded in creating a spatiotemporal model that takes advantage of the strengths of the first component, GAT, in dealing with spatial dependencies in the Forex by defining edges between currencies. GAT helps adjust the weights of edges while learning and training, which enables our model to adapt to economic changes. The second component, LSTM, is designed to handle the nature of time series datasets and detect temporal patterns that are repeated over time.

The model procedure begins with integrating multidimensional features into a predefined directed graph. The GAT module applies attention mechanisms, allowing each node to selectively absorb more information from neighboring nodes based on relevancy weights. This capability enables the model to handle diverse inputs from various sources, which results in spatially enhanced feature representations. Then, these spatial representations are reorganized into chronological patterns to be used by the LSTM module for capturing dynamic patterns in Forex prices, such as trends and cycles. The strength of LSTM lies in effectively modeling both short-term variability and long-term dependencies, which are critical to accurately forecasting dynamic currency prices.

The final step is the fully connected layer (the output layer). It is a linear layer that takes the temporal features extracted by LSTM and generates predictions for the trend direction. The role of this layer is to perform a classification task; the output is a prediction of the direction of the currency price (buy, hold, or sell) of the five major currency pairs; the number of units corresponds to the number of predicted classes.

D. Training Phase (Hyperparameter Optimization and Fine-Tuning)

For efficient training, we ran our model for 50 epochs and finetuned it by optimizing the hyperparameters during the learning phase; the batch size is around 24 and 32. And for loss function optimization, we have used the Adam optimizer with a learning rate around 0.001. Our algorithm attempts to resolve a classification issue by forecasting the Forex trend direction. We employed BCEWithLogitsLoss for the validation and training loss function, which is used for multilabel classification problems. BCEWithLogitsLoss combines the sigmoid

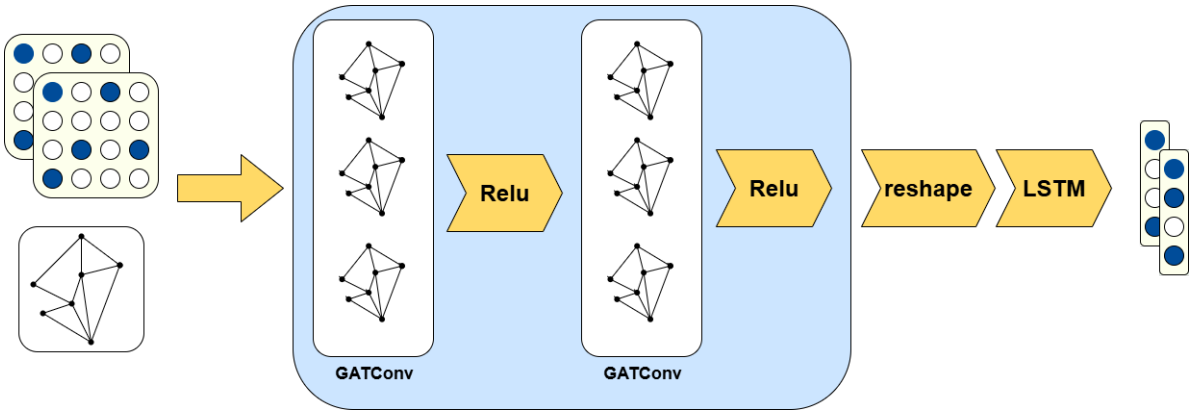

Fig. 3. The flowchart of the GAT-LSTM hybrid model for Forex price direction forecasting.

TABLE I. COMPARISON OF MODELS' PERFORMANCE (ACCURACY)

	LSTM	GAT	GAT-LSTM
EURUSD	0.6727	0.5206	0.8369
GBPUSD	0.6856	0.5026	0.8216
USDCAD	0.6134	0.4845	0.8267
USDCHF	0.6314	0.5077	0.8236
USDJPY	0.6418	0.5361	0.8287

and BCE loss into a single function; the formal definition is given in Eq. (7) as follows:

$$\text{Loss} = \text{mean}\left(BCE\left(\sigma\left(x_i\right), y_i\right)\right) \tag{7}$$

where, x_i and y_i represent the logits and true labels for the i^{th} element in the batch, respectively. The mean() function calculates the average loss over all samples in the batch. The loss can also be configured to return the sum of the losses instead of the mean, depending on specific needs.

IV. DISCUSSION AND RESULTS

A. LSTM Performance

The LSTM model is trained for 30 epochs using both architectures, with and without the window approach. In both methods, the model performed moderately in capturing temporal dependencies in currency price movements. The accuracy was between 61% and 67%, as shown in Table I, indicating that the LSTM model struggles to predict the general trend with specific turning points.

B. GAT Performance

We trained the GAT model for 50 epochs; its performance is slightly lower than that of LSTM. The accuracy did not surpass 50% which is not impressive, see Table I. These results could be caused by the graph structure, which considers only horizontal dependencies between nodes and ignores the vertical dependencies characterized by the sequential nature of stock price data. The weak correlation between nodes was not enough to provide significant advantages.

C. GAT-LSTM Performance

Compared to GAT and LSTM models, the hybrid model GAT-LSTM showed better performance in forecasting Forex trends as shown in Table I. We trained GAT-LSTM for 30 epochs, using different window size as described in Table II. After analyzing the training and validation loss graphics, as illustrated in Fig. 4 and Fig. 5, we found that the model is well-trained and fits the training data well, and it can be generalized for a larger time frame. We observed the lowest accuracy value (72%) at the lowest window size (1 day); while the highest accuracy value (83.7%) is observed at 20 days window length; the accuracy corresponds to the sequence length; When the window length is higher than 20 days, the algorithm becomes slower and less performant, the accuracy starts decreasing. We conclude that the optimal size of the sequence length is 20 days. The fact that the model's performance corresponds to the size of the window is because feeding the model with additional significant features helps identify patterns.

The high performance of LSTM-GAT is relevant to the fact that it is a hybrid model combining temporal modeling (LSTM) with relation modeling (GAT), which leads to better learning of Forex market dynamics. The LSTM is responsible for capturing individual Forex price patterns, while GAT captures the dependencies between currencies. That helps improve the predictions.

D. Generalization and Performance During Conflict

While our primary focus is on demonstrating the effectiveness of the GAT-LSTM model for Forex price direction forecasting, we recognized the need to account for real-world trading frictions like transaction costs (spreads) and slippage. To provide a more realistic perspective, we applied a moderate 10% reduction to backtested profits achieved during the period test, specifically the COVID-19 pandemic. Even with this adjustment, our system exhibits strong potential for profitability and resilience during crises.

1) Return on Investment (ROI): We evaluated the performance of our model using the same loss function, BCE-WithLogitsLoss, and calculating the accuracy of prediction as shown in Fig. 6 and Fig. 7. Furthermore, we back-tested our proposed system using financial metrics that consist of calcu-

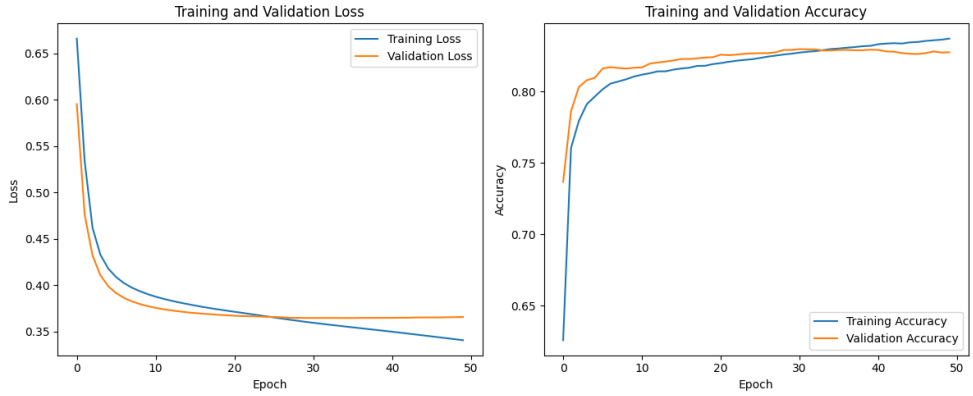

Fig. 7. The cumulative returns of the five major currency pairs during the period test.

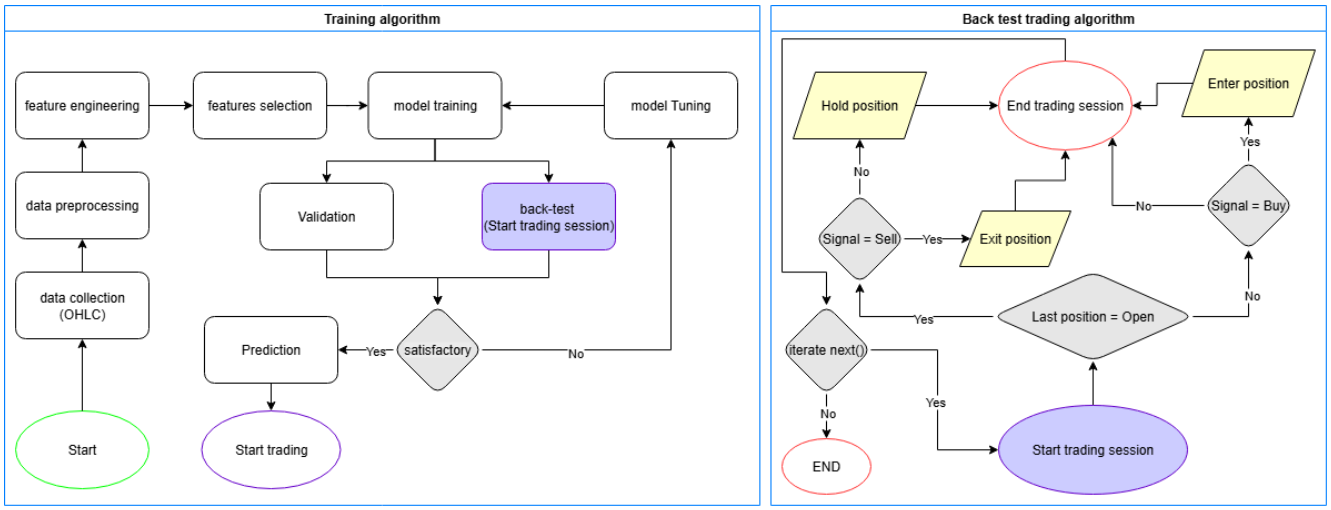

Fig. 8. Our investment strategy and the back-test flowchart.

lating the return profits of forecasted trends. Fig. 8 illustrates our trading strategy and the adopted back-test algorithm.

As illustrated in Fig. 6, our system successfully predicted the future direction of the prices, achieving an accuracy of 83.7% with a total profit of 79% compared to the ideal.

2) Performance during conflict: During Global economic crises, the Forex market can experience sharp swings caused by investor panic. The rising index of fear is leading to significant adverse ripple effects within the economy, resulting in a marked increase in market volatility. Every speculative attack on the Forex market frequently coincides with a crisis. We back-tested our model during the COVID-19 pandemic from March 2020 to May 2023.

As shown in the Fig. 7, which shows the cumulative returns of the five major currency pairs during the crisis period, our approach successfully forecasted the future direction of the prices, achieving an average accuracy of 81% corresponding to 73% of the total return profits compared to the ideal. Our suggested trading system can overcome obstacles during times of crisis thanks to the GAT component that can capture dependencies between stocks and currency pairs and anticipate global changes.

3) Statistical validation of hybrid model superiority: We used the Diebold-Mariano (DM) test to perform a rigorous statistical comparison of our hybrid GAT-LSTM model against traditional baseline models, assessing their predictive accuracy using a zero-one loss function. The DM test results, detailed in Table III, yielded p-values that were all significantly below the 0.05 significance level (α=0.05). This finding provides strong evidence that the performance gains of the GRU-CNN model are statistically significant, meaning that the improved accuracy is due to the model's superior ability to capture complex patterns in the financial time series data, rather than being a result of random chance. This analysis validates our choice of a deep learning architecture for this prediction task.

V. Conclusion

GAT-LSTM architecture integrates two learning mechanisms simultaneously, spatial and temporal, addressing the complexity and high fluctuations caused by macro-economic, political factors, and news events, etc., offering an effective solution for forecasting Forex prices. As a result, GAT-LSTM is well-equipped to adapt to the rapidly changing nature of Forex markets, providing traders with valuable insights for decision-making. However, currency prices do not depend on other currencies and stock markets only; many other factors can affect the exchange rate. We created and evaluated this solution for a typical period. It could stop being beneficial and lucrative in the future. Additional research must be done to enhance the graph structure, feature engineering, and model architecture for improved performance. Integrating temporal dynamics and inter-currency interactions improves the accuracy and robustness of forecasting models.

***Abstract*—High-precision path tracking for a Four-Mecanum-Wheel Mobile Robot (FMWMR) is challenged by real-world factors such as payload-induced shifts in the center-of-gravity (CoG) and operation on inclined surfaces. These uncertainties introduce complex, coupled dynamic forces that degrade the performance of conventional controllers. This study addresses this problem with a Model Reference Adaptive Controller (MRAC), which learns and compensates for these unpredictable dynamic effects in real time. To ensure effective operation on physical hardware, the controller incorporates practical solutions for motor friction and control signal stability. The proposed approach is validated through implementation of the MRAC on a Rosmaster X3 robot. A performance comparison is made against a well-tuned Proportional-Integral-Derivative (PID) controller is conducted across twelve distinct scenarios. The results show that the adaptive controller reduced the position Root Mean Square Error (RMSE) by an average of 52.7% and the Integral of Time-weighted Absolute Error (ITAE) by 61.5%. This work validates the MRAC as a powerful and robust solution for robots operating in unpredictable environments.**

***Keywords*—Model reference adaptive control; Mecanum Wheel Robot; center of gravity offset**

I. Introduction

Omnidirectional mobile robots equipped with Mecanum wheels are integral to modern logistics, manufacturing and service applications that require high maneuverability in constrained environments [1], [2], [3]. However, achieving precise trajectory tracking on these platforms is hindered by the dynamic uncertainties encountered in practice. Two particularly consequential factors are unknown shifts in the center of gravity (CoG) due to variable payloads and gravitational components with coupled disturbance torques that arise during operation on inclined terrain. [4], [5], [6]. When these conditions are present simultaneously, the performance and robustness of conventional fixed-gain controllers can be severely compromised.

Conventional approaches to this tracking problem often employ linear controllers, such as the Proportional-Integral-Derivative (PID) controller, due to their simplicity and effectiveness under nominal conditions [7]. However, the performance of these fixed-gain controllers is substantially degraded when the robot dynamic parameters deviate from the nominal model [8]. To address bounded uncertainties, robust control strategies like sliding mode control (SMC) have been proposed [9]. Although effective at rejecting bounded disturbances, SMC often induces high-frequency chattering in the control signal, leading to increased energy consumption and mechanical wear. Mitigating this chattering typically requires conservative gain tuning, which in turn sacrifices tracking performance.

Although more advanced research has focused on adaptive and predictive strategies, these methods often address dynamic uncertainties in isolation. For example, some adaptive methods successfully compensate for payload variations, but their effectiveness is often limited to demonstrations on flat terrain [10]. In contrast, other studies have developed predictive strategies for navigation on sloped surfaces but do so under the critical assumption of a known and fixed CoG [11], [12]. A key limitation in the existing literature is the failure to explicitly address the significant nonlinear coupling torques that arise when a robot with an off-center CoG operates on an inclined plane. This unresolved coupling motivates the present work, as a unified framework that handles both uncertainties simultaneously remains an open challenge.

This research builds on the theoretical framework established in [13], where an MRAC was proposed to ensure the closed-loop stability of a dynamic model incorporating CoG and slope effects. However, a significant gap often exists between theoretical stability and practical performance due to unmodeled real-world dynamics. To bridge this sim-to-real gap, this study presents a rigorous experimental validation of the controller on an FMWMR. Implemented on a Rosmaster X3 platform, the controller's performance under simultaneous CoG and slope uncertainties is quantitatively assessed against a carefully tuned PID benchmark using the root mean square error (RMSE) of the position, heading error, and the integral of time-weighted absolute error (ITAE) as metrics [14], [15], [16]. The implementation is augmented with practical measures to address hardware non-idealities, including deadzone compensation, command-rate limiting, and an adaptation soft start [17], [18], [19]. To ensure that all experiments are dynamically feasible and repeatable, smooth reference trajectories are generated using quintic splines to reduce jerk transients [20], [21].

This study addresses the identified sim-to-real gap through the experimental implementation and validation of the proposed MRAC on an FMWMR. The contributions are threefold:

- The experimental validation of the model framework

from [13] on a physical robotic platform. The controller's practical effectiveness is demonstrated under challenging conditions that involve simultaneous coupled dynamic uncertainties.

- The presentation of a methodology for practical implementation. This includes essential compensation techniques for real-world hardware non-idealities, such as motor stiction and actuator saturation, which are critical for bridging the sim-to-real gap.
- The quantitative validation of the adaptive controller against a well-tuned PID benchmark. The results provide definitive proof of substantial improvements in tracking accuracy and disturbance rejection, particularly when the system is challenged by the complex coupling of inertial and gravitational forces.

This study is organized as follows: The system modeling and adaptive controller design are summarized in Section II. The experimental setup and implementation details are described in Section III. The experimental procedure and evaluation metrics are defined in Section IV. The results and discussion are reported in Section V. Conclusions and directions for future work are provided in Section VI.

II. System Modeling and Adaptive Controller Design

This section summarizes the controller design based on the comprehensive dynamic model of the FMWMR proposed in [13]. The model captures the effects of an offset CoG and the gravitational forces on an inclined plane.

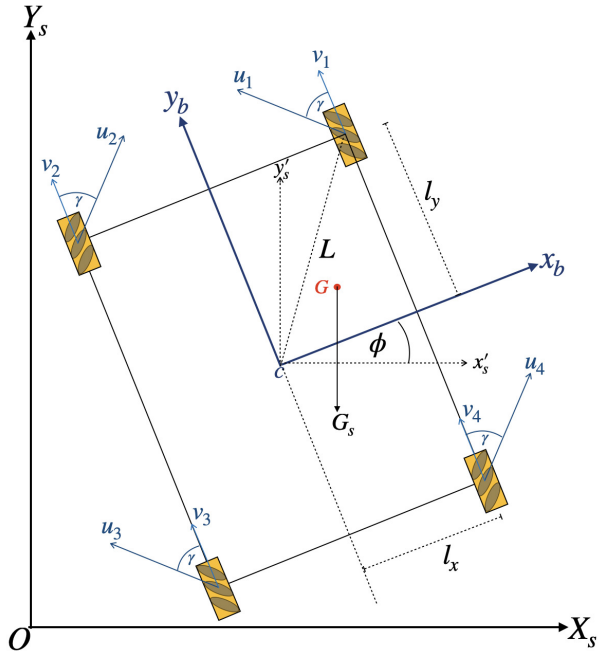

Fig. 1. A schematic of the FMWMR. The Geometric center (c), Center of gravity (G), and Wheel arrangement are indicated.

A. Kinematic Model

Consider a schematic of the FMWMR in Fig. 1. The relationship between the global frame velocity $\dot{q}$ and the body-frame velocity v_b is defined by Eq. (1):

$$\dot{q} = R(\phi)v_b, \tag{1}$$

where, $\dot{q}$ is the time derivative of the robot's pose vector in the global frame $\{X_s, O, Y_s\}$ and the rotation matrix $R(\phi)$. The robot's pose is given by the vector $q = [x, y, \phi]^{\mathrm{T}}$, where (x, y) are the Cartesian coordinates of the robot's geometric center and ϕ is the yaw angle. The body-frame velocity vector is $v_b = [v_{bx}, v_{by}, \omega_b]^{\mathrm{T}}$, which consists of the forward velocity v_{bx}, lateral velocity v_{by}, and angular velocity ω_b relative to the robot's local frame $\{x_b, c, y_b\}$. The matrix $R(\phi)$ is the rotation matrix that transforms body-frame velocities to the global frame, defined as Eq. (2):

$$R(\phi) = \begin{bmatrix} \cos\phi & -\sin\phi & 0 \\ \sin\phi & \cos\phi & 0 \\ 0 & 0 & 1 \end{bmatrix}. \tag{2}$$

The forward kinematic model of FMWMR defines the relationship between the angular velocities of the individual wheels and the resulting linear velocities of the robot's body frame. This mapping from wheel rotational speeds ω_{wh} to body-frame velocities v_b is given by Eq. (3):

$$v_b = J\omega_{wh}, \tag{3}$$

where, $\omega_{wh} = [\omega_1, \omega_2, \omega_3, \omega_4]^{\mathrm{T}}$ is the vector of angular velocities of the four wheels and J is the Jacobian matrix given by:

$$J = \frac{R_w}{4}\begin{bmatrix} -1 & 1 & -1 & 1 \\ 1 & 1 & 1 & 1 \\ \frac{1}{l_x+l_y} & -\frac{1}{l_x+l_y} & -\frac{1}{l_x+l_y} & \frac{1}{l_x+l_y} \end{bmatrix},$$

R_w is the radius of the Mecanum wheels, while l_x and l_y represent the longitudinal and lateral distances from the geometric center of the robot to the center of each wheel, respectively.

B. Dynamic Model

The dynamic model of the FMWMR is derived using a Newton-Euler formulation based on two key assumptions: the robot is a rigid body, and the wheels maintain a pure rolling contact without slip. Other effects, such as actuator dynamics and viscous friction, are treated as unmodeled disturbances to be compensated for by the controller's adaptive and feedback mechanisms. The resulting dynamic model in the robot's body frame is expressed as Eq. (4):

$$H\dot{v}_b + Cv_b + G_b = F_t, \tag{4}$$

where, H is the inertia matrix that explicitly includes the CoG offset written as Eq. (5):

$$H = \begin{bmatrix} m & 0 & -my_g \\ 0 & m & mx_g \\ -my_g & mx_g & I_z \end{bmatrix}, \tag{5}$$

C is the Coriolis and centrifugal matrix and is written as Eq. (6):

$$C = \begin{bmatrix} 0 & -m\omega_b & -m\omega_b y_g \\ m\omega_b & 0 & m\omega_b x_g \\ m\omega_b y_g & -m\omega_b x_g & 0 \end{bmatrix}, \tag{6}$$

G_b is the gravitational vector and is given by Eq. (7):

$$G_b = mg\sin\alpha \begin{bmatrix} \sin\phi \\ \cos\phi \\ x_g\cos\phi - y_g\sin\phi \end{bmatrix}, \tag{7}$$

F_t is the vector of control forces and torque applied by the wheels, m is the total mass of the robot, I_z is the moment of inertia about the vertical axis passing through the CoG, g is the acceleration due to gravity, α is slope angle of the surface and (x_g, y_g) represent the coordinates of the robot's CoG within the body frame, measured relative to the geometric center.

C. Adaptive Controller Design

The control objective is to achieve asymptotic tracking of a desired trajectory, q_d, with the robot's pose, q, in the presence of parametric uncertainties within the dynamic model. The MRAC scheme is designed to meet this objective. The core of this approach is to establish a stable, reference error dynamic, which is accomplished through the formulation of a composite filtered error signal. The first step in this design is to mathematically define this error and its dynamics.

1) Error dynamics formulation: A key challenge in controlling dynamic systems is that the control inputs F_t directly influence accelerations $\dot{v}_b$ rather than the pose q. This structure creates a second-order tracking problem. To simplify this, a filtered tracking error s is introduced, which effectively transforms the second-order problem into a first-order stabilization problem. This composite signal is defined by Eq. (8):

$$s = v_b - v_r, \tag{8}$$

where, v_b is the robot's actual body-frame velocity and v_r is the reference velocity vector is strategically designed as Eq. (9):

$$v_r = R(\phi)^{\mathrm{T}}\left(\dot{q}_d - \Lambda e\right), \tag{9}$$

$e = q - q_d$ is the pose error and Λ is a positive-definite gain matrix. This construction is critical because it ensures that if the controller drives $s \to 0$, the pose error, e, is guaranteed to converge exponentially according to the stable dynamic $\dot{e} = -\Lambda e$.

The error dynamics for control design are derived by differentiating Eq. (8) and substituting the system's dynamic model, yielding Eq. (10):

$$H\dot{s} + Cs = F_t - (H\dot{v}_r + Cv_r + G_b). \tag{10}$$

This equation provides a clear structure for the control design. However, the term $(H\dot{v}_r + Cv_r + G_b)$ contains the unknown physical parameters. The next step, therefore, is to restructure this term to systematically handle these uncertainties.

2) System and control law: To address the parametric uncertainty in the system dynamics, a linear parameterization is performed. This crucial step reformulates the dynamic terms containing unknown physical properties into a structure that is linear in the parameters. This separates the dynamics into two distinct components: a vector θ containing all the unknown physical parameters and a known regressor matrix Y constructed from measurable signals of the reference trajectory. This reformulation is expressed as Eq. (11):

$$H\dot{v}_r + Cv_r + G_b = Y\theta, \tag{11}$$

where, the vector of unknown parameters θ, and known regressor Y and defined as Eq. (12):

$$\theta = [m, I_z, mx_g, my_g, m\sin\alpha, mx_g\sin\alpha, my_g\sin\alpha]^{\mathrm{T}}, \tag{12}$$

and

$$Y = \begin{bmatrix} y_{11} & y_{12} & 0 \\ 0 & 0 & \dot{\omega}_{r\phi} \\ 0 & y_{23} & y_{33} \\ y_{14} & 0 & y_{34} \\ g\sin\phi & g\cos\phi & 0 \\ 0 & 0 & g\cos\phi \\ 0 & 0 & -g\sin\phi \end{bmatrix}^{\mathrm{T}},$$

where, y_{ij} are functions of the reference trajectory and its derivatives are defined as:

$$\begin{aligned} y_{11} &= \dot{v}_{rx} - v_{ry}\omega_{r\phi}, & y_{12} &= \dot{v}_{ry} - v_{rx}\omega_{r\phi}, \\ y_{23} &= \dot{\omega}_{r\phi} + \omega_{r\phi}^2, & y_{33} &= \dot{v}_{ry} + v_{ry}\omega_{r\phi}, \\ y_{14} &= -(\dot{\omega}_{r\phi} + \omega_{r\phi}^2), & y_{34} &= -(\dot{v}_{rx} + v_{rx}\omega_{r\phi}). \end{aligned}$$

Based on this equation, the control law is formulated as Eq. (13):

$$F_t = Y\hat{\theta} - Ks, \tag{13}$$

where, $\hat{\theta}$ is the estimation of θ and K is a positive-definite feedback gain matrix. This law consists of a feed-forward term, $Y\hat{\theta}$, to cancel the estimated system dynamics, and a stabilizing feedback term -Ks. The parameter estimates are updated using the following adaptation law Eq. (14):

$$\dot{\hat{\theta}} = -\Gamma Y^{\mathrm{T}} s, \tag{14}$$

where, Γ is a positive definite matrix of adaptation gains.

With the complete control and adaptation laws now fully defined, it is necessary to formally prove that this closed-loop system is stable and that the tracking objective is indeed achieved.

3) Stability analysis: The stability of the closed-loop system is demonstrated using Lyapunov's direct method. Consider the Lyapunov candidate function, Eq. (15):

$$V = \frac{1}{2}s^{\mathrm{T}}Hs + \frac{1}{2}\tilde{\theta}^{\mathrm{T}}\Gamma^{-1}\tilde{\theta}, \tag{15}$$

where, $\tilde{\theta} = \theta - \hat{\theta}$ is the parameter estimation error. The function V is positive definite as it is a quadratic form of the tracking and estimation errors. The time derivative of V, after substituting the error dynamics and using the skew-symmetric property of the matrix $(\dot{H} - 2C)$, simplifies as Eq. (16):

$$\dot{V} = s^{\mathrm{T}}(F_t - Y\theta) + \tilde{\theta}^{\mathrm{T}}\Gamma^{-1}\dot{\tilde{\theta}}. \tag{16}$$

Substituting the control law in Eq. (13) and adaptation law in Eq. (14), and noting that $\dot{\tilde{\theta}} = -\dot{\hat{\theta}}$, yields the final expression for the derivative as Eq. (17):

$$\dot{V} = -s^{\mathrm{T}}Ks. \tag{17}$$

Since K is positive-definite, $\dot{V} \leq 0$, proving that V is nonincreasing and that s and $\tilde{\theta}$ are bounded. By Barbalat's Lemma, it can be further shown that $s \to 0$ as $t \to \infty$. As established in the error dynamics formulation, this ensures the asymptotic convergence of the pose tracking error, thus rigorously satisfying the overall control objective.

D. Control Architecture Overview

The control architecture, illustrated in Fig. 2, operates through two nested loops. First, an outer loop determines the pose error e between the desired trajectory and the robot's actual pose. This error is processed by the Reference Velocity according to Eq. (9) to produce a reference velocity designed to guide the robot. Next, an inner loop computes the filtered error signal, as defined by Eq. (8), by comparing the robot's actual body velocity to this reference velocity. The filtered error signal is central to the adaptive mechanism, driving both the Adaptation Law to update parameter estimates $\hat{\theta}$ and the control law to calculate the final control force F_t. This closed-loop structure allows the controller to drive the tracking error to zero while simultaneously learning and compensating for the unknown dynamic forces in real-time.

III. Experimental Setup

This section details the experimental framework used to validate the performance and robustness of the MRAC. The hardware platform and state estimation methods are designed to facilitate rigorous testing under significant variations in the robot's payload distribution.

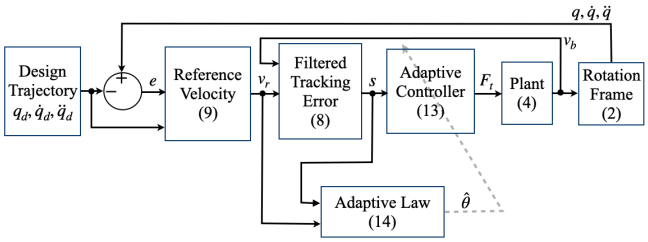

Fig. 2. Block diagram of the proposed MRAC framework.

A. Hardware Platform

The experiments are conducted on a Rosmaster X3, the FMWMR, as depicted in Fig. 3.

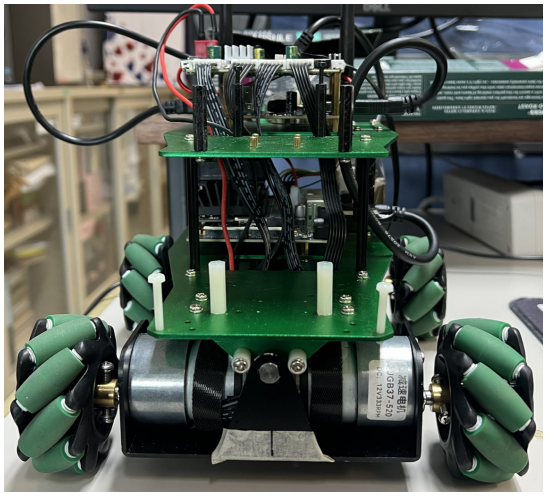

Fig. 3. The Rosmaster X3 experimental platform.

The platform's key physical parameters are summarized in Table I.

TABLE I. Rosmaster X3 Robot Parameters

Parameter	Symbol	Value
Robot Mass (Base)	m_r	2.0 [kg]
Added Mass	m_b	0.4 [kg]
Half Wheelbase	l_x	0.085 [m]
Half Track Width	l_y	0.080 [m]
Mecanum Wheel Radius	R_w	0.0325 [m]
Motor Encoder Resolution	N_{enc}	1320 [PPR]

The robot is equipped with two primary sensor systems for state estimation: four high-resolution quadrature wheel encoders fitted to the DC motors and an onboard IMU.

These sensors provide the raw data necessary for estimating the robot's pose and velocity, a process which is detailed next.

B. State Estimation and Signal Processing

Accurate estimation of the robot's state, comprising its world-frame pose and body-frame velocities, is essential for feedback control. This state is derived by processing and fusing data from the onboard sensors.

Estimation of body-frame velocities is a two-part process. First, the linear components are derived from the motor encoders. The angular velocity of each individual wheel is calculated from its respective motor encoder as in Eq. (18):

$$\omega_i = \frac{2\pi \Delta N_i}{N_{enc} \Delta t}, \tag{18}$$

where, ΔN_i is the encoder pulse count over the sampling interval Δt. These individual wheel velocities are then assembled into a vector and transformed into the robot's body-frame linear velocity v_b using the inverse kinematic model from Eq. (3). To ensure accuracy and mitigate noise, the body-frame angular velocity, ω_b, is derived by numerically differentiating the filtered yaw measurement from the IMU.

Next, the world-frame pose is estimated. The robot's orientation, ϕ, is obtained directly from the IMU's yaw measurement, with an initial offset recorded to define the world frame. The world-frame position (x, y) is then calculated by rotating the body-frame velocity estimate, v_b, into the world frame and performing first-order Euler integration at each time step. This process constitutes the robot's odometry.

Finally, to mitigate measurement noise before use in the control loop, the estimated state derivatives are processed with a first-order digital low-pass filter [19]. The filter is implemented by Eq. (19):

$$y_k = y_{k-1} + \beta(x_k - y_{k-1}), \tag{19}$$

where, y_k is the filtered output at the current time step, x_k is the raw input signal and β is the filter coefficient and calculated from the filter time constant τ as Eq. (20):

$$\beta = \frac{\Delta t}{\tau + \Delta t}. \tag{20}$$

The selection of the time constant, τ, presents a critical trade-off between noise rejection and phase lag, which can impact control stability. Based on empirical tuning, a time constant of $\tau = 0.04$ [s] is selected for the relatively clean IMU signal to prioritize a fast response. A slightly larger constant of $\tau = 0.05$ [s] is applied to the noisier, encoder-derived linear velocities to provide more aggressive filtering.

With a reliable state estimate available for feedback, the controller requires a physically achievable reference trajectory to follow. The generation of these smooth trajectories is a critical prerequisite for high-performance control.

C. Generation of Smooth Reference Trajectories

The performance of the controller is fundamentally limited by the quality of the reference trajectory. It is commanded to follow. For a physical system such as an FMWMR, commanding instantaneous changes in velocity or acceleration is impossible and leads to detrimental effects such as wheel slip, actuator saturation, and mechanical vibrations. Therefore, ensuring that the trajectory is sufficiently smooth is not an optimization, but a critical requirement to achieve high-fidelity motion.

1) Reference trajectory design: High-fidelity motion control requires reference trajectories that are physically realizable. Trajectories with discontinuous acceleration degrade tracking performance by inducing wheel slip and actuator saturation. Therefore, all reference signals are generated using quintic polynomial splines to ensure smoothness.

Unlike simpler cubic splines, quintic splines provide C^2-continuity, which guarantees a continuous acceleration profile. This is achieved by defining six boundary conditions: initial and final position (p_i, p_f), velocity (v_i, v_f), and acceleration (a_i, a_f). By setting the initial and final accelerations to zero, the jerk is eliminated, ensuring smooth rest-to-rest maneuvers as illustrated in Fig. 4. Here, Fig. 4(a) details the smooth S-curve position profile, Fig. 4(b) the corresponding bell-shaped velocity profile, and Fig. 4(c) the C^2-continuous acceleration. The acceleration begins and ends at zero, a condition which eliminates jerk and ensures the smoothness of the entire trajectory.

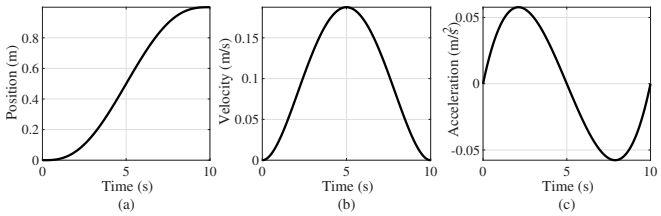

Fig. 4. Kinematic profiles of a 1 [m] maneuver using a quintic spline. (a) The smooth S-curve position profile, (b) The corresponding bell-shaped velocity profile, (c) The C^2-continuous acceleration.

The position profile $p(t)$ for any single degree of freedom is defined by the quintic polynomial as Eq. (21):

$$p(t) = c_0 + c_1 t + c_2 t^2 + c_3 t^3 + c_4 t^4 + c_5 t^5, \tag{21}$$

where, the six coefficients $c = [c_0, \ldots, c_5]^{\mathrm{T}}$ are uniquely determined by Eq. (22):

$$\begin{bmatrix} c_0 \\ c_1 \\ c_2 \\ c_3 \\ c_4 \\ c_5 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 2 & 0 & 0 & 0 \\ 1 & T & T^2 & T^3 & T^4 & T^5 \\ 0 & 1 & 2T & 3T^2 & 4T^3 & 5T^4 \\ 0 & 0 & 2 & 6T & 12T^2 & 20T^3 \end{bmatrix}^{-1} \begin{bmatrix} p_i \\ v_i \\ a_i \\ p_f \\ v_f \\ a_f \end{bmatrix}, \tag{22}$$

where, T is total trajectory time.

Solving this system yields the unique set of coefficients required to generate the smooth trajectory for each experimental path. This method is used to generate separate, smooth trajectories for each experimental path. While this method produces ideal reference signals, deploying the theoretical controller on the physical hardware requires additional practical considerations to compensate for real-world non-idealities.

D. Practical Implementation and Non-Ideality Compensation

To ensure robust performance on the physical hardware, the theoretical MRAC framework is augmented with three enhancements to compensate for non-ideal dynamics: friction, command saturation, and aggressive initial adaptation.

1) Feed-forward compensation: Nonlinear friction, particularly stiction, introduces a deadzone that degrades low-velocity tracking performance. To counteract this, a continuous, model-based feed-forward compensator is implemented using the hyperbolic tangent function to avoid control chattering as Eq. (23):

$$u_{ff} = \begin{bmatrix} V_{dz,x} \tanh\left(\frac{v_{rx}}{\epsilon_v}\right) \\ V_{dz,y} \tanh\left(\frac{v_{ry}}{\epsilon_v}\right) \\ V_{dz,\omega} \tanh\left(\frac{\omega_{r\phi}}{\epsilon_\omega}\right) \end{bmatrix}, \tag{23}$$

In this formulation, the critical parameter V_{dz} represents the breakaway voltage, which corresponds to the minimum voltage required to overcome stiction. The terms $V_{dz,x}$, $V_{dz,y}$, and $V_{dz,\omega}$ are the specific breakaway voltages for the longitudinal, lateral, and rotational axes. The parameters ϵ_v and ϵ_ω are smoothing factors that dictate the sharpness of the compensation signal's transition. All parameters are empirically tuned to improve low-velocity response and minimize steady-state error without introducing oscillations.

In addition to static friction, another practical limitation is the physical saturation of motor commands, which can degrade tracking performance, particularly during aggressive maneuvers.

2) Goal-proximity-based rate limiting: Fixed acceleration limits impose an inherent trade-off between a robot's transit speed and its final positioning accuracy. High acceleration values reduce travel time but increase the risk of overshooting the target, while low values ensure precision at the cost of efficiency. To resolve this, a state-dependent rate-limiting strategy is implemented, which dynamically modulates the acceleration limit, a_{lim}, based on the robot's proximity to its target d_{goal}. The modulation is performed in a two-step process. First, a unitless scaling factor, k, is calculated based on the robot's position within a pre-defined deceleration zone, as in Eq. (24):

$$k = \text{clip}\left(\frac{d_{goal} - d_{min}}{d_{max} - d_{min}}, 0, 1\right), \tag{24}$$

where, d_{max} and d_{min} define the outer and inner boundaries of the deceleration zone. As the robot travels through this zone, the value of k transitions linearly from 1 to 0, with the clip function, $\text{clip}(X, lower, upper)$ clips the values in array X to the range $[lower, upper]$ by replacing values less than lower with lower and values greater than upper with upper, that ensures it remains bounded.

This scaling factor is then used to linearly interpolate the final acceleration limit a_{lim} between two prescribed bounds, as in Eq. (25):

$$a_{lim} = a_{min} + k \cdot (a_{base} - a_{min}), \tag{25}$$

where, a_{base} represents the high baseline acceleration for rapid transit (applied when $k \approx 1$), while a_{min} is the conservative minimum acceleration for precise final movements (applied when $k \approx 0$). This method ensures a smooth transition from aggressive to conservative motion, optimizing both speed and accuracy.

Beyond compensating for these physical non-linearities, the controller's transient behavior during startup must also be managed to ensure stability.

3) Adaptation law for soft start: A significant initial tracking error can induce large, abrupt updates to the adaptive parameters $\hat{\theta}$, potentially causing control signal saturation or transient instability. To mitigate this, a soft-start mechanism is implemented by scheduling the adaptation gain matrix Γ. The gain is linearly ramped from an initial value of zero to its nominal steady-state value according to the following rule Eq. (26):

$$\Gamma(t) = \Gamma_0 \cdot \min\left(1.0, \frac{t}{T_{ramp}}\right), \tag{26}$$

where, $\Gamma(t)$ is the time-varying adaptation gain matrix, Γ_0 is its nominal value and T_{ramp} is the total duration of the ramp-up period.

The ramp duration T_{ramp} is determined empirically, selected as the minimum time required to suppress undesirable transients in the initial control signal and ensure a smooth initialization of the adaptation process.

For reproducibility, the empirically determined values for these implementation parameters are provided in Table II.

TABLE II. EMPIRICALLY TUNED IMPLEMENTATION PARAMETERS

Category	Parameter	Value
Friction Compensation		
	Deadzone Voltage $V_{dz,x}, V_{dz,y}, V_{dz,\omega}$	0.1 V
	Smoothing Factor $\epsilon_v, \epsilon_\omega$	0.1
Command Rate Limiting		
	Base Acceleration a_{base}	2.0 m/s^2
	Minimum Acceleration a_{min}	0.5 m/s^2
	Max Deceleration Distance d_{max}	0.4 m
	Min Deceleration Distance d_{min}	0.1 m
Adaptation Soft Start		
	Adaptation Ramp Time T_{ramp}	0.1 s

IV. EXPERIMENTAL PROCEDURE AND EVALUATION

A. Experimental Scenarios

To rigorously evaluate the controller's performance and robustness, experiments are conducted on a custom-built testbed, as shown in Fig. 5. The experimental design systematically varies three key factors: path type, surface condition, and payload distribution. These factors and their corresponding conditions are summarized in Table III, and the path waypoints are detailed in Table IV.

To ensure statistical reliability, each of the twelve resulting experimental scenarios is repeated three times for both the proposed MRAC and a baseline PID controller. The performance metrics presented in the results are the arithmetic mean of these three trials.

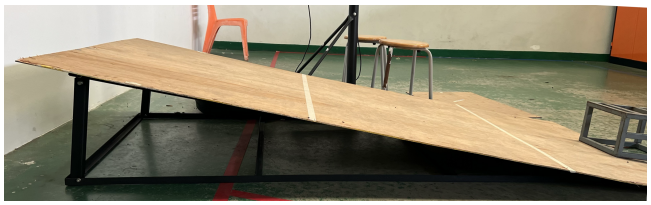

Fig. 5. The experimental testbed (2.4 m × 1.2 m), shown in its inclined configuration.

B. Center of Gravity Manipulation

To isolate the dynamic effects of an off-center payload, two CoG conditions are established without altering the robot's total mass.

- Centered CoG (Nominal): The stock robot's CoG is not at its geometric center. A baseline condition is established by adding a balancing mass, with its position empirically adjusted to ensure equal weight distribution across all four wheels.
- Off-center CoG: For this condition, the same balancing mass is relocated to a fixed position to induce a significant, known CoG shift, as specified in Table III.

This methodology ensures that any observed performance differences between the two payload conditions are attributable solely to the change in dynamic coupling caused by the CoG shift, not by a change in total mass.

TABLE III. EXPERIMENTAL FACTORS AND CONDITIONS

Factor	Conditions
Path Type	Straight, Diagonal, Square
Surface Condition	1. Flat Surface 2. Inclined Surface ($\pi/18$ rad)
Payload Distribution	1. Centered CoG (Nominal) 2. Off-center CoG $(x_g, y_g) = (-4.5, -26.7)$ mm

TABLE IV. REFERENCE TRAJECTORY DEFINITIONS

Path Name	Description	Waypoints (x, y) [m]
Straight	1 m translation along y-axis	(0,0) → (0,1)
Diagonal	1 m translation in x and y	(0,0) → (1,1)
Square	4 m perimeter path with sharp corners	(0,0) → (0,1) → (1,1) → (1,0) → (0,0)

C. Benchmark Controller for Comparison

For performance comparison, a fixed-gain PID controller is implemented as a benchmark. The controller's gains are carefully tuned on the physical hardware. Initial estimates are obtained using the Ziegler-Nichols method and subsequently optimized using MATLAB's PID Tuner with experimental step response data. The final, optimized gains for the translational and rotational axes are presented in Table V.

TABLE V. OPTIMIZED PID CONTROLLER GAINS

Control Axis	k_p	k_i	k_d
Translational (x, y)	2.80	0.06	0.15
Rotational (ϕ)	2.20	0.04	0.12

D. Controller Gain Tuning Methodology

The performance of MRAC is determined by three gain matrices of the error convergence matrix Λ, the feedback matrix K and the adaptation matrix Γ. A systematic two-phase empirical tuning procedure is conducted on the physical hardware to achieve a balance between responsiveness and stability. The final gains are listed in Table VI.

1) Phase 1: Tuning baseline feedback gains Λ and K: First, a stable, non-adaptive baseline controller is established by setting the adaptation gain $\Gamma = 0$ and initializing the parameter vector $\hat{\theta}$ with nominal estimates. The gains in $\Lambda = \text{diag}(\lambda_p, \lambda_p, \lambda_\phi)$ are tuned to set the desired error convergence rate without causing oscillation. Subsequently, the feedback gains $K = \text{diag}(k_p, k_p, k_\phi))$ are tuned to ensure a critically damped response without amplifying sensor noise or causing jerky commands.

2) Phase 2: Tuning adaptation gains Γ: Second, the adaptation gains in the diagonal matrix $\Gamma = \text{diag}(\gamma_1, \ldots, \gamma_7)$ are tuned to set the parameter learning rates. The selection of these gains presents a critical trade-off: Low values result in slow adaptation, while high values can cause noisy parameter estimates and instability.

The gains are tuned incrementally, starting with small values. They are increased to the highest level that provided rapid error convergence without introducing oscillations into the control signal. This process is performed sequentially using maneuvers designed to excite specific dynamics, for example, tuning mass/inertia gains during linear accelerations and CoG/slope gains during tests with an off-center payload on the inclined surface.

TABLE VI. MRAC GAIN PARAMETERS

Gain Parameter	Value
Error Convergence Gains (Λ)	
Translational Gain λ_p	2.5
Rotational Gain λ_ϕ	2.5
Control Gain (K)	
Translational Gain k_p	0.5
Rotational Gain k_ϕ	0.5
Adaptation Gains (Γ)	
γ_1 for m	0.0400
γ_2 for I_z	0.0180
γ_3 for mx_g	0.0120
γ_4 for my_g	0.0010
γ_5 for $m \sin\alpha$	0.0050
γ_6 for $mx_g \sin\alpha$	0.0006
γ_7 for $my_g \sin\alpha$	0.0006

E. Performance Metrics

To provide a quantitative assessment of controller performance, two standard metrics are chosen. One is the RMSE to evaluate tracking accuracy and the other is the ITAE to evaluate

settling performance. The specific equations are defined as Eq. (27), Eq. (28) and Eq. (29):

$$\text{RMSE}_p = \sqrt{\frac{1}{N}\sum_{i=1}^{N} e_p(t_i)^2}, \tag{27}$$

$$\text{RMSE}_h = \sqrt{\frac{1}{N}\sum_{i=1}^{N} e_h(t_i)^2} \tag{28}$$

and

$$\text{ITAE}_p = \int_0^T t \cdot |e_p(t)|\, dt, \tag{29}$$

where, $e_p(t) = p(t) - p_d(t)$ is the error between actual position $p(t)$, desired position $p_d(t)$ and $e_h(t) = \phi(t) - \phi_d(t)$ and N is total number of data points.

V. Results and Discussion

A. Experimental Results

This section presents the experimental results that compare the proposed MRAC with the baseline PID controller in all 12 test scenarios. To highlight the controllers' distinct behaviors, a detailed graphical analysis is presented for two representative scenarios: the nominal case (straight-line motion, flat surface, centered payload) and the most challenging case (square-path motion, inclined surface, off-center payload). A comprehensive summary of the performance metrics for all experiments is provided at the end of this section.

1) Performance in nominal conditions: The experimental results for a straight line trajectory 1 [m] under nominal conditions are shown in Fig. 6. Performance comparison between MRAC and PID controllers is shown in Fig. 6(a) to Fig. 6(d), where the ideal trajectory is represented by a solid black line, the PID response by a blue dashed line, and the MRAC response by a red dotted line. Fig. 6(a) shows the robot's lateral position, where both responses remain close to the ideal zero position. Fig. 6(b) shows the primary translation, which follows the smooth S-shaped reference trajectory. The robot's orientation is shown in Fig. 6(c), where the desired zero-radian heading is successfully maintained. A top-down view of the path is provided in Fig. 6(d). Fig. 6(e) shows the RMSE of position over time. The final RMSE for the MRAC is approximately 1.5 [cm], a 25% reduction compared to the PID's 2.0 [cm] error. Finally, Fig. 6(f) confirms that the heading error for both controllers remains minimal and stable throughout the maneuver.

2) Performance under challenging conditions: The experimental results for a square path trajectory under challenging conditions (an inclined surface with an off-center CoG) are presented in Fig. 7. The robot's position along the x- and y-axes is shown in Fig. 7(a) and Fig. 7(b), where the MRAC's red dotted line more closely follows the sharp transitions of the reference compared to the PID's response. The robot's orientation is shown in Fig. 7(c). A top-down view of the path is provided in Fig. 7(d), which illustrates that the PID controller exhibits significant corner overshoot, while the MRAC maintains sharp, accurate tracking. The RMSE of position in Fig. 7(e) highlights the performance difference; the PID's error accumulates, reaching a final RMSE of approximately 2.5 [cm], whereas the MRAC maintains a stable and bounded error of just 1.0 [cm]. Finally, Fig. 7(f) confirms that the MRAC's heading error profile is visibly smoother than the PID's.

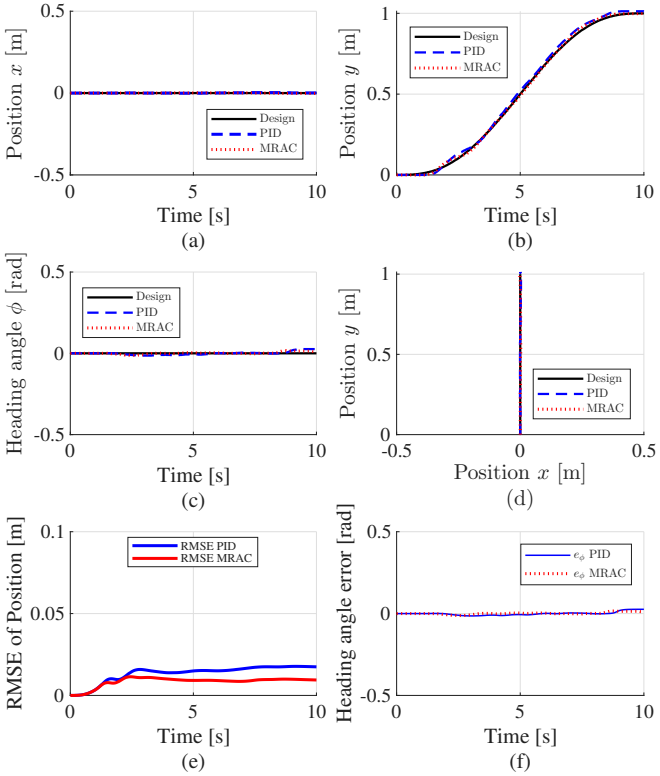

Fig. 6. Straight path tracking results for the nominal case comparing PID and MRAC controllers: (a) Position x over time. (b) Position y over time. (c) Heading angle ϕ over time. (d) Robot's trajectory in the $x-y$ plane. (e) RMSE of position over time. (f) Heading angle error over time.

3) Quantitative performance summary: The complete quantitative results from all twelve experimental scenarios are compiled in Table VII. For each path type, surface condition, and CoG configuration, the table lists the position RMSE, heading RMSE, and position ITAE for both the PID and MRAC controllers. The best-performing result in each case is highlighted in bold.

B. Discussions

The experimental results presented in Section V-A consistently demonstrate the superior performance and robustness of the MRAC framework compared to a well-tuned PID controller. The quantitative data in Table VII reveals that, on average, the MRAC reduced the position RMSE by 52.7% and the position ITAE by 61.5%. This substantial improvement can be directly attributed to the controller's adaptive nature.

The key strength of the MRAC lies in its ability to estimate and compensate for dynamic uncertainties in real time, a capability that fixed-gain controllers lack. This is particularly evident in the most challenging scenarios. For instance, in the

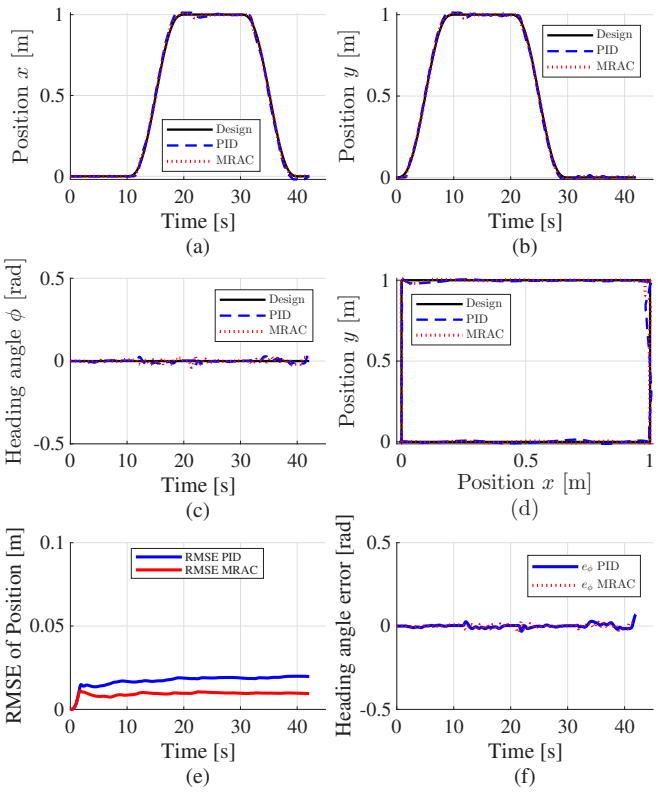

Fig. 7. Square path tracking results under challenging conditions comparing PID and MRAC controllers: (a) Position x over time. (b) Position y over time. (c) Heading angle ϕ over time. (d) Robot's trajectory in the $x-y$ plane. (e) RMSE of position over time. (f) Heading angle error over time.

square path test with an off-center CoG on an inclined surface, the PID controller's performance degraded significantly, as shown by the large corner overshoots in Fig. 7(d). This occurs because fixed PID gains cannot counteract complex coupled disturbance torques that arise from the combination of CoG offset and gravitational forces. In contrast, the MRAC uses the regressor matrix Y and the adaptation law in Eq. (14) to continuously update its internal model, which effectively cancels these disturbances and maintains high-precision tracking.

Furthermore, the MRAC's robustness to internal dynamic coupling was highlighted during the diagonal path tests. The PID controller struggled to manage the simultaneous translational and rotational motion, resulting in a heading RMSE of 0.0947 [rad]. In contrast, the MRAC achieved a heading RMSE of just 0.0131 [rad], an 86% reduction. This result demonstrates the effectiveness of the adaptation mechanism in decoupling the system dynamics, which is a critical feature for holonomic platforms like the FMWMR.

The controller's results are highly repeatable, as confirmed by running each experiment three times. The statistical variability is very low, with the standard deviation of the error typically remaining below 5% of the mean value. A sensitivity analysis further confirmed the controller's robustness to parameter tuning. Moderate changes (approximately $\pm 20\%$) to the controller gains resulted in graceful performance degradation rather than instability, proving that its effectiveness is an inherent feature of the adaptive design, not the result of fragile,

hyperspecific tuning.

To address the practical trade-offs between the two controllers, a comparison of their computational requirements is provided in Table VIII. The analysis highlights that the PID controller's logic is based on simple algebraic operations, while the MRAC is inherently more complex, requiring the assembly of a regressor matrix and several matrix-vector multiplications in each cycle. We measured the average execution time for a single control loop on the Rosmaster X3's onboard processor. The results show that the PID controller took approximately 0.08 [ms] per cycle, while the more demanding MRAC took 0.27 [ms]. Although this makes the MRAC about 3.4 times more computationally intensive, its execution time is still extremely low, allowing for a theoretical operating frequency of over 3,700 Hz. This rate is far higher than the mechanical limits of the robot, confirming that the proposed MRAC is a highly efficient and practical solution for real-time control.

In summary, the experimental validation confirms that the proposed MRAC is not only stable in theory but also highly effective in practice. By explicitly addressing the sim-to-real gap with practical compensations and leveraging a sound adaptive control law, the controller provides a robust solution for high-precision motion in unpredictable environments.

VI. CONCLUSION

An adaptive controller for an FMWMR with unknown CoG offset and unknown slope inclination has been implemented and experimentally validated on a Rosmaster X3 platform. A linearly parameterized dynamic model that captures CoG-induced coupling and gravity on an incline is employed, and

stability is ensured through a Lyapunov-based adaptation law. To bridge the gap between theory and experiment, deployment-oriented measures that address motor deadzones, command rate limits, and adaptation transients are incorporated. Across 12 scenarios, consistent improvements are demonstrated over a carefully tuned PID benchmark. On average, the position RMSE is reduced by 52.7% and the position ITAE is reduced by 61.5%. Heading accuracy is kept bounded and precise even under the most challenging combinations of slope and CoG shift. These results indicate that the controller achieves high-precision tracking under coupled uncertainties in real time, demonstrating its suitability for operation in unstructured environments.

Future work will focus on improving the robot's long-term autonomy and robustness by addressing three key areas. The current reliance on internal sensors, while effective for short maneuvers, is susceptible to cumulative drift. To overcome this, our primary goal is to develop a robust global localization system by integrating a 2D LiDAR sensor and implementing a Simultaneous Localization and Mapping (SLAM) algorithm, with an Extended Kalman Filter (EKF) for sensor fusion. Building on this improved state estimation foundation, we will then rigorously test and adapt the controller for more complex and unstructured terrains, including surfaces with varying friction and irregularities, to potentially extend the adaptive model to account for wheel slip. Ultimately, the enhanced controller and localization system will be integrated as the low-level execution layer within a complete navigation stack. By coupling our work with a high-level motion planner capable of real-time environmental perception, we aim to transition from trajectory tracking to full autonomy, enabling the robot to independently generate and modify paths to safely navigate around obstacles in real-world applications.

***Abstract*—Machine learning models are typically developed under the "closed-world" assumption, where training and testing data originate from a consistent distribution. However, in real-world scenarios, especially in the retail domain, this assumption can become problematic due to the frequent introduction of new products, seasonal promotions, and irregular sales events. When models encounter out-of-distribution data inputs, predictions can become overly confident or entirely incorrect. While existing out-of-distribution detection methods primarily focus on image-based datasets, challenges associated with numerical, high-dimensional, and heterogeneous retail time-series data remain largely unexplored. To address this gap, this study proposes an enhanced Entropic Out-of-Distribution Detection framework tailored specifically for dynamic retail environments. By transforming time-series sales data into spectrogram representations and leveraging the IsoMax+ loss function, our approach improves uncertainty calibration and robustness without requiring labeled out-of-distribution data or additional post-hoc calibration techniques. Experimental results, conducted on a large-scale retail dataset from Vietnam, demonstrate that the proposed Entropic Out-of-distribution detection framework significantly outperforms traditional out-of-distribution detection methods in terms of detection accuracy and inference efficiency, providing a scalable and practical solution for real-time retail applications. Our approach achieves strong performance with an F1-score of 88% and an AUC of 91%, highlighting its promising applicability across diverse business scenarios.**

***Keywords*—Out-of-Distribution Detection, entropic learning, IsoMax+ loss, time-series classification, retail forecasting, deep learning, spectrogram transformation**

I. Introduction

In conventional supervised learning settings, models are typically developed under the "closed-world" assumption, where classifiers are trained on a predefined set of known classes and assume future data will remain consistent with the training distribution. However, this assumption rarely holds in real-world scenarios, where data distributions evolve continuously and models encounter previously unseen samples. As a result, predictive accuracy deteriorates and uncertainty estimates become unreliable when facing distributional shifts [1], [2]. To maintain model reliability, robust mechanisms for detecting anomalies and unseen data—commonly known as Out-of-Distribution detection are essential. During a preliminary survey of recent OOD research, we observed that most existing approaches are developed and benchmarked primarily on image datasets. This observation raises a natural question: Can OOD detection techniques be effectively adapted to numerical, business-oriented time-series data, such as those found in retail analytics?

In retail analytics, OOD data frequently emerge from new product launches, regional demand changes, or promotional campaigns. Such shifts can lead to unstable sales patterns, causing models to generate inaccurate forecasts and poor business decisions [3]. Conventional OOD approaches, including Maximum Softmax Probability (MSP) [4] and Mahalanobis Distance [5], are computationally simple but struggle with subtle distributional drifts. Recent entropy-based methods [6], [7] have shown promise in improving calibration by quantifying prediction uncertainty, yet they often rely on post-hoc temperature scaling or external OOD datasets [8], limiting real-world scalability.

To overcome these challenges, researchers have explored information-theoretic and distance-aware frameworks. Sugiyama et al. [9] introduced density ratio estimation to capture distributional shifts, and Macêdo et al. [10] proposed the Entropic Out-of-Distribution Detection (EOOD) framework that replaces softmax scoring with a distance-regularized entropy loss.

More recently, Liang et al. [11] and Han et al. [12] further demonstrated that entropy regularization and contrastive predictive entropy can enhance OOD robustness in deep networks and time-series tasks.

These findings confirm the potential of entropy-based learning to improve detection accuracy in dynamic, high-stakes domains such as healthcare and retail [13].

1) Motivation and objective: Despite these advances, applying OOD detection to retail time-series data remains underexplored. Retail datasets are highly non-stationary, multimodal, and influenced by seasonal, geographic, and economic factors.

This study aims to develop a scalable, entropy-driven OOD framework that can adapt to evolving retail conditions without external calibration or labeled OOD data.

Such capability can enhance model reliability, reduce forecast errors, and improve business decision-making in dynamic commercial environments.

2) Main contributions: The contributions of this work can be summarized as follows:

- We propose an enhanced Entropic Out-of-Distribution Detection (EOOD) framework tailored to retail time-series data, combining entropy and distance-based uncertainty modeling for improved calibration.
- A spectrogram-based transformation is introduced to convert sales sequences into time–frequency representations, enabling convolutional architectures to capture temporal dynamics effectively.
- A labeling and preprocessing pipeline is designed to generate realistic in-distribution and out-of-distribution samples without requiring external OOD datasets or post-hoc calibration.
- Extensive experiments on large-scale Vietnamese retail data demonstrate that the proposed method outperforms conventional baselines in detection accuracy, calibration robustness, and inference efficiency.

The remainder of this study is organized as follows: Section II reviews representative OOD detection methods and their limitations. Section III details the proposed EOOD methodology, including data processing and model architecture. Section IV presents experimental results and analysis, while Section V concludes the study and outlines future research directions.

II. Related Work

Out-of-Distribution (OOD) detection has become an essential problem in reliable deep learning, aiming to identify samples that do not conform to the training data distribution [4]. Early approaches relied on confidence-based measures, such as Maximum Softmax Probability (MSP) [4] and temperature scaling or input perturbation methods as in ODIN [14]. Later, Mahalanobis distance-based techniques [3] improved robustness by modeling feature-space distributions, while IsoMax and IsoMax+ losses [10] introduced distance-aware learning for better uncertainty calibration.

Recent research has continued to refine these directions. Liang et al. [11] proposed entropy regularization to stabilize OOD decision boundaries. Han et al. [12] extended entropy-based detection to time-series data through contrastive predictive modeling, and Liu et al. [15] leveraged spectral representation learning to enhance feature robustness. Macedo et al. [16] revisited IsoMax+ for improved distance-awareness, while Yang et al. [17] provided a comprehensive survey categorizing OOD methods by analytical principles and highlighting emerging challenges.

To synthesize these developments, Table I presents a comparative summary of representative OOD detection approaches, categorizing them by type of analysis, advantages, limitations, and their relationship to the proposed EOOD framework. This overview clarifies how our method differs by emphasizing entropy–distance synergy, calibration-free detection, and adaptability to dynamic retail time-series data.

OOD detection has emerged as a critical subfield in machine learning, particularly in safety-critical and dynamic environments. Early works often relied on confidence-based metrics such as Maximum Softmax Probability (MSP) [4], which takes the highest softmax output as a confidence score. While MSP is computationally efficient, it is prone to overconfidence on unfamiliar inputs. Distance-based methods, such as the Mahalanobis Distance approach [3], measure the feature-space distance between a sample and class centroids under Gaussian assumptions. Although effective in some cases, these methods are sensitive to covariance estimation errors and tend to degrade in high-dimensional, non-isotropic settings.

To mitigate softmax overconfidence, Liang et al. [14] proposed ODIN, which combines temperature scaling and input perturbations to improve separation between in-distribution (ID) and OOD samples. ODIN improves detection accuracy but requires careful hyperparameter tuning and access to OOD-like validation data, limiting its scalability. Entropy-based scoring methods [6] address this issue by using the entropy of the predictive distribution as an uncertainty measure—low entropy indicating confident predictions for ID data, and high entropy reflecting unfamiliarity for OOD inputs. However, many still depend on post-hoc calibration [7] or labeled OOD datasets [8], which may be impractical in real-time settings.

Entropic Out-of-Distribution Detection was introduced by Macêdo et al. [10] to overcome these limitations. EOOD replaces the softmax layer with IsoMax+, a distance-aware probability formulation that computes class likelihoods based on the squared Euclidean distance between an input's feature vector and learned class centroids. This design naturally produces higher predictive entropy for OOD samples—improving separation without post-hoc adjustments or external OOD data. IsoMax+ encourages isotropic feature distributions, making the model more robust in high-dimensional and noisy data environments. Recent studies such as Jin et al. [18] further confirm the effectiveness of entropy-based and distance-aware approaches in dynamic, high-dimensional settings.

Despite its success on image benchmarks such as CIFAR10, CIFAR100, and SVHN, most prior EOOD research has been limited to static spatial structures. In contrast, retail time-series data presents unique challenges: high dimensionality, seasonal patterns, abrupt demand spikes, and sparsity across product–location pairs. Traditional OOD methods designed for images may fail to capture these temporal–seasonal anomalies effectively.

To summarize, Table I provides a synthesis of representative OOD detection methods, categorized by their analytical principles, advantages, and limitations. This overview highlights how our proposed EOOD framework improves uncertainty calibration and adaptability to dynamic retail data.

This comparative summary facilitates a clearer understanding of how the proposed EOOD method distinguishes itself from existing approaches in terms of scalability, uncertainty calibration, and adaptability to dynamic time-series data.

This study addresses this shortage by extending EOOD to retail time-series forecasting. We introduce a spectrogram-based transformation that converts 12-month revenue sequences into image-like representations, enabling the use of deep CNN architectures such as EfficientNet-B3. By integrating IsoMax+ loss, our approach preserves EOOD's calibration-free property while enhancing its ability to detect OOD patterns in dynamic, high-variance retail environments—supporting real-time anomaly detection where timely insights are crucial for operational decision-making.:

TABLE I. COMPARATIVE SUMMARY OF REPRESENTATIVE OUT-OF-DISTRIBUTION (OOD) DETECTION METHODS CATEGORIZED BY ANALYTICAL APPROACH, HIGHLIGHTING THEIR RESPECTIVE ADVANTAGES, LIMITATIONS, AND DISTINCTIONS FROM THE PROPOSED EOOD FRAMEWORK

Method	Type of Analysis	Advantages	Limitations	Comparison with the Proposed Framework
Maximum Softmax Probability (MSP) [4]	Confidence-based	Simple, fast, easy to implement	Overconfident on unseen data	Lacks uncertainty calibration
ODIN [14]	Temperature scaling and input perturbation	Improves OOD separation	Requires tuning and validation data	Higher complexity; not scalable
Mahalanobis Distance [3]	Distance-based	Captures feature-space structure	Sensitive to covariance estimation	Less effective on high-dimensional time-series
Entropic OOD Detection (EOOD) [10]	**Entropy + Distance**	**Calibration-free, robust**	**Limited to image data**	**This study extends it to retail time-series**

$$p_i = \frac{e^{-d(f(x),c_i)}}{\sum_{j=1}^{K} e^{-d(f(x),c_j)}} \tag{1}$$

where, $f(x)$ represents the feature vector of input sample x, c_i is the centroid of class i, and $d(\cdot)$ is a distance metric such as squared Euclidean distance. This formulation encourages the model to produce higher entropy for OOD samples, as they lie farher away from the class centroids. Therefore, the model shows ability to detect OOD instances without the need for additional calibration or external datasets.

Out-of-Distribution detection has emerged as a fundamental subfield in machine learning, particularly in applications where model required reliability and safety. Several approaches have been proposed to distinguish between ID and OOD inputs, with varying assumptions and mechanisms for uncertainty estimation.

One of the earliest and most often used methods is the MSP, introduced by Hendrycks and Gimpel [4]. This method uses confidence score from the softmax output as an indicator of distributional fit. While computationally efficient, MSP likely overconfident predictions on unfamiliar inputs. In case of dealing with subtle anomalies or class overlapping distributions.

To solve these limitations, ODIN was proposed by Liang et al. [14], combining temperature scaling and input perturbations to amplify the distinction between ID and OOD samples. Despite its improved detection performance, ODIN requires careful hyperparameter tuning and access to validation data, which may hinder its scalability across domains.

Another mature method is the Mahalanobis Distance based approach introduced by Lee et al. [3], which computes the distance between a test sample and class conditional distributions in the feature space. Although this method works effective in enhancing internal feature representations,it assumes Gaussianity and sensitive to covariance estimation errors particularly in high-dimensional or non-isotropic feature spaces.

More recently, entropy-based methods have gained attention for their principled handling of predictive uncertainty. In particular, Macêdo et al. [10] proposed the Entropic Out-of-Distribution Detection framework, which replaces the conventional softmax layer with IsoMax+ loss. Traditional softmax layers calculate class probabilities based on unnormalized logits, which often lead to poorly calibrated confidence estimates, as shown by Guo et al. [7]. Therefore, this method is unsuitable with uncertain estimation.

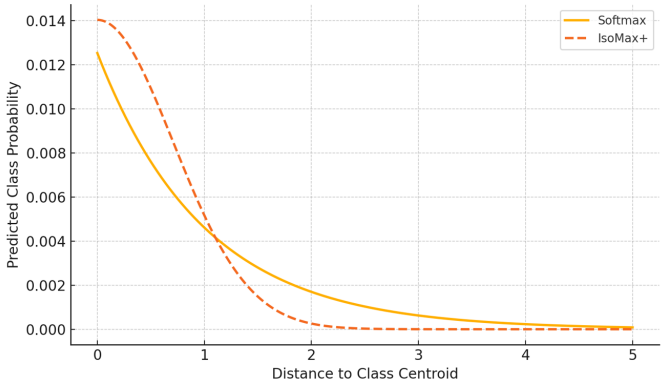

Fig. 1. Comparison of softmax and IsoMax+ confidence decay with respect to increasing feature distance from class centroids.

IsoMax+ loss overcome this limitation by using distance based approach instead of softmax function. This replacement limits marking unfamiliar data by attach for them lower confidence scores and high predictive entropy. In addition, by enhancing isotropic feature, this model is easily detect OOD data without requiring external datasets. Therefore, it is suitable with high dimension and noisy data. To clarify comparison between Softmax and IsoMax+, Fig. 1 visualizes how each method predict class based on distance of an input sample form the class centroid.

1) Softmax: The standard softmax computes class probabilities using linear logits:

$$p_i = \frac{e^{z_i}}{\sum_{j=1}^{K} e^{z_j}} \tag{2}$$

where, z_i is typically computed as a linear projection: $z_i = w_i^\top f(x) + b_i$, with $f(x)$ being the input feature vector. This formulation does not explicitly depend on the distance between the input and any class centroid, which can lead to overconfident predictions for unfamiliar inputs (i.e., OOD data).

2) IsoMax+: In contrast, IsoMax+ replaces logits with negative distances in the embedding space:

$$p_i = \frac{e^{-d(f(x),c_i)}}{\sum_{j=1}^{K} e^{-d(f(x),c_j)}} \tag{3}$$

with the distance metric defined as:

$$d(f(x), c_i) = \|f(x) - c_i\|^2 \tag{4}$$

Here, c_i is the centroid of class i. This formulation ensures that the farther an input lies from any class center, the lower its predicted probability, thereby naturally increasing predictive entropy for OOD samples.

Recently, as the limitaion of Sofmax based, IsoMax+ which a part of EOOD framework addressed the entropy detection help model more practical when using for real world data.

III. Methodology

This section presents the EOOD framework for retail time-series. The pipeline has four stages: 1) data preprocessing and surrogate OOD labeling, 2) spectrogram transformation, 3) EfficientNet-B3 backbone with IsoMax+ loss, and 4) entropy-based OOD scoring.

A. Overview of the Proposed Framework

Fig. 2 summarizes the workflow. Raw transaction logs are aggregated into monthly series, transformed into spectrogram images via STFT, and then fed to an EfficientNet-B3 backbone trained with IsoMax+ loss for uncertainty-aware classification. The predictive distributions are finally converted into OOD scores.

B. Data Pre-processing and Labeling

We use transaction-level sales data from 63 provinces in Vietnam (2024), including product ID, date, quantity, revenue, and location. Records are aggregated monthly per (product, province) to form 12-month sequences; only pairs with complete records and at least six non-zero months are retained to avoid degenerate or overly sparse series.

To emulate realistic distributional shifts without relying on external OOD datasets, two complementary heuristics were applied for labeling, as illustrated in Fig. 4.

1) Spike-based labeling rule:: A month t is labeled as out-of-distribution (OOD) if its revenue R_t satisfies:

$$R_t > 2 \times R_{t-1}, \tag{5}$$

capturing short-term shocks such as promotions, sudden demand surges, or supply disruptions.

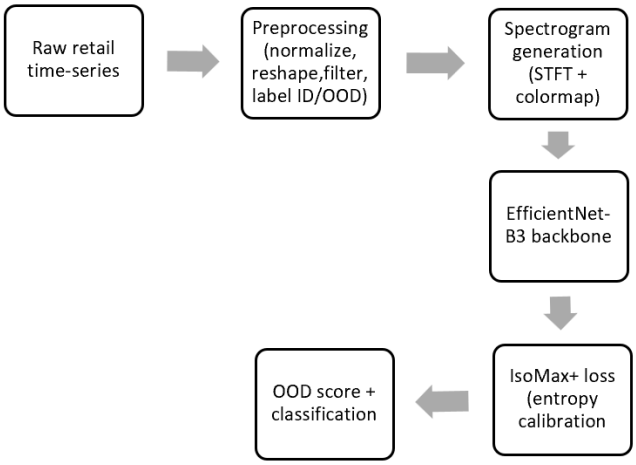

Fig. 2. Proposed EOOD framework for retail time-series OOD detection.

2) Entropy-based volatility labeling:: For each 12-month revenue series,

$\mathbf{R} = \{R_1, R_2, \ldots, R_{12}\}$,

we compute the volatility ratio (serving as an entropy proxy) as:

$$E = \frac{\sigma(\mathbf{R})}{\mu(\mathbf{R})}, \tag{6}$$

where, $\sigma(\mathbf{R})$ and $\mu(\mathbf{R})$ denote the standard deviation and mean of the sequence, respectively. A sequence is labeled as OOD if its entropy ratio exceeds a global threshold:

$$E > \mu_E + 1.5\sigma_E, \tag{7}$$

where, μ_E and σ_E represent the mean and standard deviation of E across all product–province pairs. This criterion identifies long-term volatility or regime shifts in sales behavior.

After pre-processing, a total of 33,680 valid product–province time-series pairs were obtained, including 22,450 in-distribution (ID) and 11,230 OOD sequences. These labeled sequences were subsequently transformed into spectrogram images for model training in the following section.

C. Spectrogram Transformation

Each 12-month sequence is converted into a spectrogram using the Short-Time Fourier Transform (STFT),

$$S(t, f) = \sum_{m=-\infty}^{\infty} x[m]\, w[m-t]\, e^{-j2\pi f m} \tag{8}$$

and mapped to a three-channel image via a fixed colormap. This representation preserves temporal order while exposing time–frequency structure, where retail anomalies often appear as localized spectral distortions. Prior studies show that such image-based encodings can improve time-series classification and anomaly detection in complex settings [6], [19]. Visual examples are shown in Section IV.

D. Model Architecture

We adopt EfficientNet-B3 as the backbone and resize spectrograms to 300×300 pixels. EfficientNet's compound scaling achieves a favorable accuracy–latency balance compared to heavier backbones, which is crucial for near real-time retail inference [20]. Global average pooling is applied to the final feature maps, and the ImageNet classifier is replaced by an IsoMax+ head.

E. IsoMax+ Loss for OOD Detection

Traditional softmax classifiers often produce overconfident predictions even for inputs that are far from the training distribution. This limitation arises because the Softmax function converts unnormalized logits into probabilities without explicitly considering the distance of a sample from any known class centroid. As a result, OOD samples can still be assigned high confidence scores, leading to poor uncertainty calibration [7].

IsoMax+ addresses this problem by replacing linear logits with distance-based formulations. Specifically, the logit for class i is computed as:

$$z_i = -\alpha \cdot \|\mathbf{f} - \mathbf{c}_i\|^2 \tag{9}$$

where, $\mathbf{f}$ is the feature vector of an input, $\mathbf{c}_i$ is the centroid of class i, and α is a learnable scaling parameter. This formulation ensures that samples located far from all class centroids are assigned low confidence and high predictive entropy, thereby mitigating the overconfidence issue without requiring post-hoc calibration [10].

To provide intuition, Fig. 3 compares the posterior probability distributions of Softmax and IsoMax+. As shown, Softmax tends to output peaked, low-entropy posteriors even for ambiguous inputs, while IsoMax+ yields smoother, high-entropy distributions that better reflect uncertainty. This property makes IsoMax+ particularly suitable for OOD detection in dynamic retail environments.

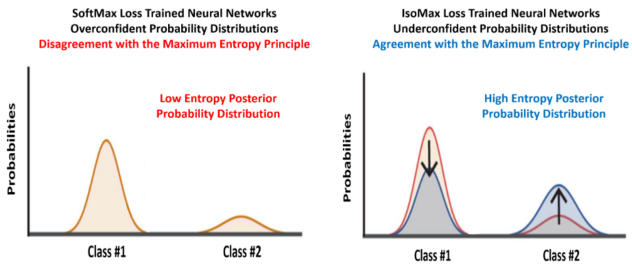

Fig. 3. Comparison of posterior probability distributions produced by Softmax and IsoMax+.

F. Training Strategy

Models are trained end-to-end with AdamW and a cosine learning rate schedule. We use random cropping, horizontal flips, brightness/contrast jitter, Gaussian noise, MixUp (α=0.4), label smoothing (0.1), and Exponential Moving Average of weights. These choices improve robustness to small rendering differences in spectrograms, temper overconfident posteriors, and stabilize convergence under volatile demand patterns typical of retail data.

In summary, the EOOD framework combines dual-criteria labeling, spectrogram-based encodings, an EfficientNet-B3 backbone, and IsoMax+ loss to deliver calibration-free OOD detection suited to dynamic retail environments.

IV. Experiments

A. Dataset Collection and Pre-Processing

The raw dataset contained approximately 1.2 million transaction records from 63 provinces in Vietnam, covering the 12-month period of 2024. The data were obtained from the retail sales management system of *Liberico Company*, which operates on the nationwide VNPost postal distribution channel. This channel supports multiple vendors and retail partners beyond Liberico itself, making it a rich and heterogeneous retail environment that includes diverse product categories, pricing schemes, and sales behaviors from different businesses. The dataset was directly extracted from the company's database and exported into excel format Table II summarizes the key attributes contained in the raw transaction dataset. After monthly aggregation and filtering for completeness (i.e., retaining only product–province pairs with at least six non-zero months), a total of 33,680 valid time-series sequences were preserved for analysis. These sequences were subsequently labeled based on two criteria:

- Spike-based labeling: A time-series is labeled OOD if any month shows a revenue spike exceeding 2× the previous month.
- Entropy-based labeling: The entropy of each sequence was computed as the ratio $\frac{\sigma}{\mu}$ (standard deviation over mean). If this value exceeded a global threshold of $(\mu + 1.5\sigma)$, the sequence was labeled as OOD.

TABLE II. Data Dictionary of the Retail Transaction Dataset

Field	Description
Date	Transaction date (dd/mm/yyyy), used to derive month.
Province	Province or city where the transaction occurred.
Invoice ID	Unique identifier of the invoice.
Product ID	Unique identifier of the product.
Product Name	Description of the product.
Unit	Measurement unit (e.g., piece, pack, bottle).
Unit Price	Price per unit (VND).
Quantity	Number of units sold.
Revenue	Total transaction revenue (Unit Price × Quantity).
Commission Rate	Commission ratio applied to the transaction.
Commission (derived)	Calculated as Revenue × Commission Rate.
Total Payment (derived)	Calculated as Revenue − Commission.
Month (derived)	Extracted from the Date for time-series grouping.

In total, 22,450 sequences were labeled ID, and 11,230 were labeled OOD. The distribution of entropy values for ID and OOD sequences is shown in Fig. 4.

Each of the 33,680 time-series sequences was converted into a spectrogram using the Short-Time Fourier Transform. The resulting spectrograms were mapped to a 3-channel image using a fixed colormap. This conversion produced a dataset

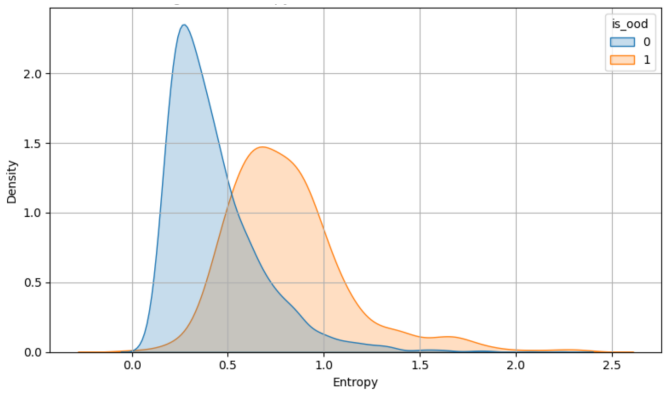

Fig. 4. Distribution of entropy scores for labeling ID (blue) vs. OOD (orange) sequences.

of 33,680 spectrogram images, each of size 300×300 pixels, which were then organized into two directories: one for ID (label 0) and one for OOD (label 1). An example spectrogram of a 12-month revenue time series is shown in Fig. 5.

To improve generalization and avoid overfitting, we applied several data augmentation techniques as followings:

- Random horizontal flip: This was used to mimic random variations in input patterns (e.g., seasonal variations).
- Random cropping: Spectrogram images were randomly cropped to 270×270 pixels during training. This allowed the model to focus on localized features within the image, improving robustness.
- Brightness jitter: Slight changes to the brightness of the images were made to mimic changes in lighting conditions in the retail environment.
- Gaussian noise injection: Small amounts of noise were added to the images to simulate real-world signal fluctuations.
- MixUp ($\alpha = 0.4$): This technique mixes two random images during training, allowing the model to generalize better by learning from both images at once, which also increases the model's robustness against noisy data.

Fig. 5. Example spectrogram of a 12-month revenue series.

B. Experimental Setup

1) Training parameters: Following the methodology pipeline (Fig. 2), the spectrogram images were used as input to an EfficientNet-B3 backbone pre-trained on ImageNet. The model was trained with IsoMax+ loss for out-of-distribution (OOD) detection. We used the AdamW optimizer with an initial learning rate of 2×10^{-5} and a cosine-annealing schedule that progressively reduced the learning rate to ensure stable convergence. The loss function and learning rate scheduler were selected to balance optimization stability and convergence speed.

2) Exponential Moving Average (EMA): To further stabilize training and ensure that the model's weights converge to a stable point, we applied the Exponential Moving Average (EMA) of model weights. This technique averages the weights over time to ensure that fluctuations in model parameters are minimized, resulting in a more robust model that performs better in real-world scenarios [21]. The decay factor was set to 0.995, meaning that each new weight update is blended with the previous one by 99.5%.

3) Training environment: Training was carried out on NVIDIA Tesla T4 GPU with a batch size of 32. This GPU is highly efficient for training models like EfficientNet and provides a good balance between memory and processing power, making it suitable for high-throughput deep learning tasks. The model was trained for 75 epochs, and the early stopping criterion was applied, which halted training if the validation loss did not improve for 10 consecutive epochs. This approach helped prevent overfitting and ensured that training time was efficiently managed.

The model performance was evaluated based on classification accuracy, F1-score, AUC-ROC, and inference time(measured in milliseconds per sample).

C. Results

1) Phase 1: Baseline training and convergence analysis: Fig. 6 shows the accuracy and loss curves during the first phase of training with an 80/20 split. The model achieved rapid convergence within the first 15 epochs, stabilizing around 89% accuracy, while the validation loss decreased and plateaued at approximately 0.37. The confusion matrix in the figure shows that 48 out of 71 OOD samples were correctly classified, while 23 were misclassified as in-distribution. Table III shows the classification report for Phase 1.

TABLE III. CLASSIFICATION REPORT FOR PHASE 1

Class	Precision	Recall	F1-Score
In-Distribution	0.94	0.93	0.93
Out-of-Distribution	0.63	0.68	0.65
Accuracy		0.89	
Macro avg	0.79	0.80	0.79
Weighted avg	0.89	0.89	0.89

2) Phase 2: Enhanced training and robustness evaluation: In the second phase, the dataset was split into 70% for training, 15% for validation, and 15% for testing. This phase included advanced regularization techniques, such as MixUp, label smoothing, and EMA, to improve generalization and

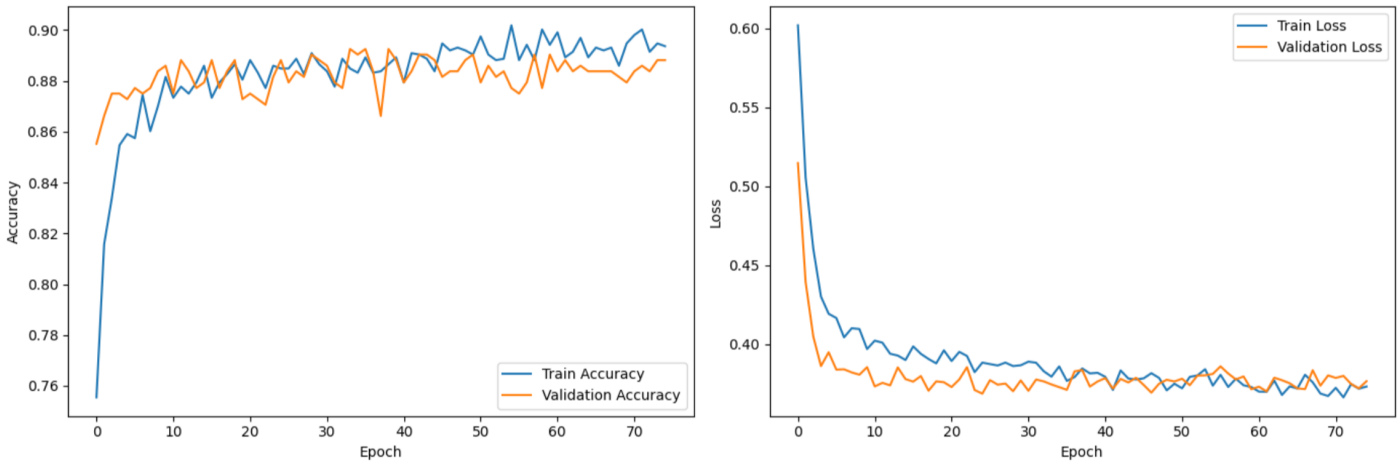

Fig. 6. Accuracy and loss curves during Phase 1.

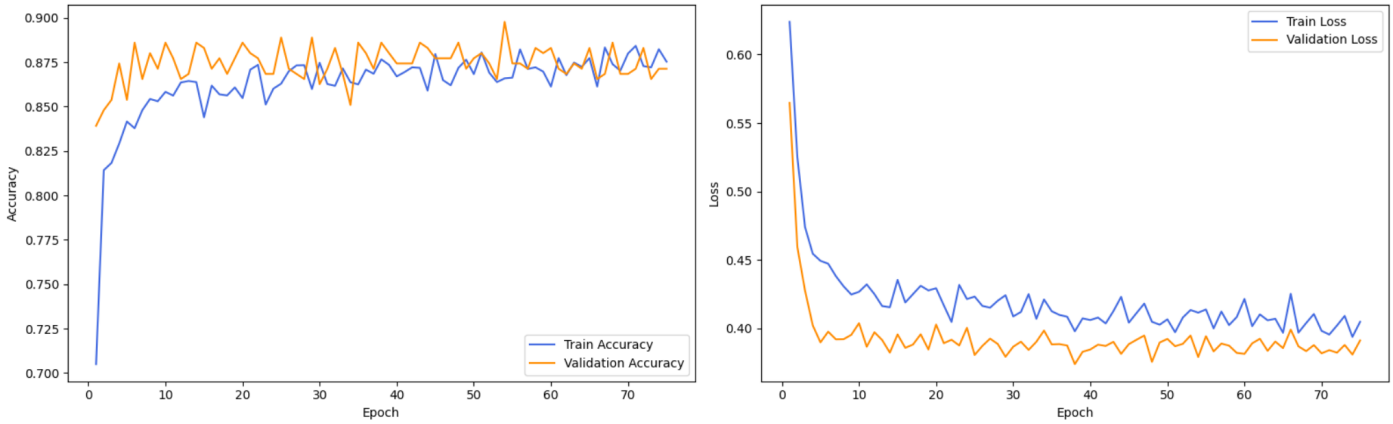

Fig. 7. Accuracy and loss curves during Phase 2.

reduce overfitting. The model performed consistently well, with training and validation accuracy stabilizing 87% after epoch 30, as shown in Fig. 7. The validation loss remained slightly lower than the training loss throughout the phase, indicating stable generalization.

TABLE IV. CLASSIFICATION REPORT FOR PHASE 2

Class	Precision	Recall	F1-Score
In-Distribution	0.91	0.92	0.92
Out-of-Distribution	0.69	0.65	0.67
Accuracy		0.87	
Macro avg	0.80	0.79	0.79
Weighted avg	0.86	0.87	0.86

The detailed classification performance is summarized in Table IV, where the model achieved an overall accuracy of 87%. The In-Distribution class obtained high precision and recall (0.91 and 0.92, respectively), while the Out-of-Distribution class was more challenging, with a precision of 0.69 and recall of 0.65. These results highlight the model's improved robustness compared to Phase 1, although OOD detection remains the more difficult task.

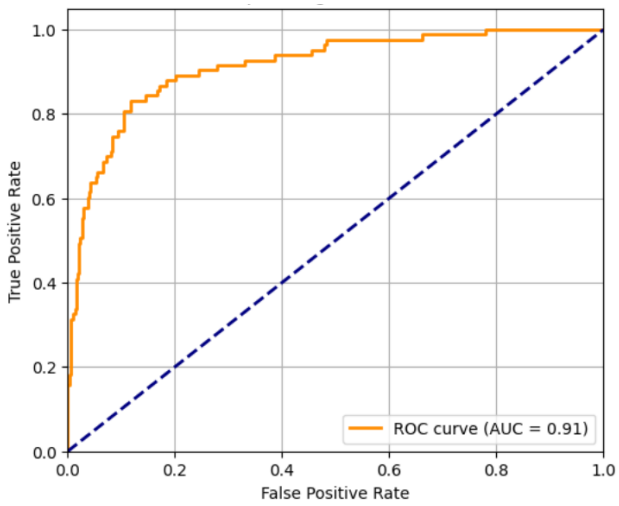
Additionally, Fig. 8 presents the ROC curve of the best EMA-tracked model evaluated on the 15% test set. The model achieved an AUC of 0.7974, demonstrating its strong ability to distinguish between in-distribution and OOD samples.

3) Comparison with baseline methods: To comprehensively evaluate the performance of the EOOD framework, we compared it with several baseline OOD detection methods: MSP, Entropy Scoring, ODIN, and Mahalanobis Distance. Table V shows the comparison results based on key metrics: F1-score (OOD), AUC–ROC, and inference time.

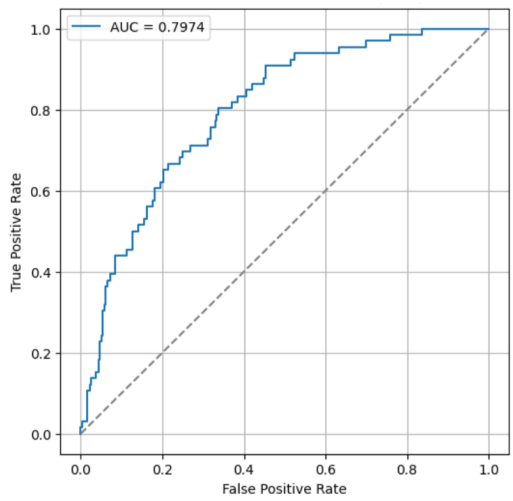
EOOD consistently outperforms all baseline methods across the key metrics. It achieves the highest F1-score of 0.88 for OOD detection and the best AUC–ROC of 0.91, demonstrating superior ability to distinguish between ID and OOD samples. In contrast, while ODIN and Mahalanobis show competitive AUCs, their inference times are significantly higher, making them less suitable for real-time deployment. Methods like MSP and entropy scoring suffer from low OOD recall due to overconfidence in softmax outputs.

D. Discussion

The experimental findings presented in Section IV demonstrate that the proposed EOOD framework effectively enhances out-of-distribution (OOD) detection for retail time-series data.



(a) ROC Curve on 80/20 split (Phase 1).



(b) ROC Curve on 70/15/15 split (Phase 2).

Fig. 8. Comparison of ROC curves across two training configurations.

TABLE V. PERFORMANCE COMPARISON BETWEEN EOOD AND TRADITIONAL OOD DETECTION METHODS, SORTED BY F1-SCORE

Method	**F1-score (OOD)**	**AUC–ROC**	**Inference Time** (ms)
MSP	0.22	0.80	9
Entropy	0.36	0.80	9
Energy	0.41	0.75	11
Mahalanobis	0.81	0.86	17
ODIN	0.83	0.89	19
EOOD	**0.88**	**0.91**	**12**

By transforming sales sequences into spectrogram representations and employing the IsoMax+ loss, the model improves uncertainty calibration and maintains efficient inference suitable for real-time applications.

From the comparative experiments, the Phase 1 baseline achieved 0.89 accuracy and an F1-score of 0.65 for OOD samples, whereas the enhanced Phase 2 configuration—with MixUp, Label Smoothing, and Exponential Moving Average (EMA)—achieved smoother convergence and more stable generalization. Although the accuracy slightly decreased to 0.87, the model exhibited lower variance in validation loss and better calibration, as seen in Fig. 7. This trade-off indicates improved robustness and reduced overfitting under dynamic retail conditions.

As shown in Table V, EOOD outperformed Mahalanobis and ODIN, achieving the highest overall accuracy and efficiency. These results verify that the entropic–distance synergy inherent in IsoMax+ enables superior calibration-free OOD detection compared to confidence-based and post-hoc methods. In particular, EOOD achieved an approximate 5% gain in AUC over Mahalanobis Distance while reducing latency by nearly 35%, offering a practical trade-off between accuracy and computational cost.

Despite these promising results, Fig. 8(b) also shows that the recall for OOD samples remains modest (0.65), implying that extreme or rare anomalies may still overlap with in-distribution variance. This suggests the need for adaptive thresholding or dynamic decision boundaries to further improve sensitivity under evolving retail conditions.

The framework's scalability and calibration-free operation make it well-suited for deployment in production environments. Beyond retail, similar entropic representations could be applied to other time-series domains such as financial fraud detection, healthcare monitoring, or industrial sensor analysis, where rapid and reliable anomaly identification is critical.

The framework's scalability and calibration-free operation make it well-suited for deployment in production environments. Beyond retail forecasting, the proposed framework can also support anomaly detection tasks in finance, healthcare, and industrial monitoring, where timely and reliable OOD identification is critical. Its calibration-free nature and low inference latency make it practical for large-scale real-time deployment.

Overall, these findings confirm that entropy-based learning combined with distance-aware regularization forms a strong foundation for robust, scalable, and interpretable OOD detection across complex and dynamic business environments.

V. CONCLUSION

This study presented an enhanced Entropic Out-of-Distribution Detection (EOOD) framework specifically designed for dynamic retail time-series data. The proposed approach integrates IsoMax+ loss with spectrogram-based representation learning to improve robustness against distributional shifts — a persistent challenge in real-world retail environments. By transforming sales sequences into visual spectrograms, the model effectively captures temporal dependencies and subtle anomalies in a spatial format, extending the applicability of convolutional architectures beyond traditional image domains.

Unlike conventional OOD techniques that require external datasets or post-hoc calibration, the proposed framework operates in a fully calibration-free manner, making it practical for business applications where real-time decisions are critical. This design promotes scalability and adaptability across domains with high-dimensional, sparse, or unlabeled data, supporting broader applications in predictive modeling and anomaly detection.

The findings demonstrate that entropy-based learning, when combined with distance-aware regularization, can significantly enhance uncertainty calibration and detection accuracy. The framework offers both scientific and practical benefits, contributing to more reliable forecasting and decision-making in data-driven retail operations.

A. Limitations

Despite its strong empirical performance, the proposed EOOD framework still has several limitations. First, the labeling process for in-distribution and out-of-distribution samples relies on heuristic thresholds (e.g., entropy ratio and revenue spike rules), which may not generalize optimally across different datasets or business domains. Second, the current approach focuses on short-term (12-month) retail patterns, while longer seasonal or multi-year dynamics have not been explored. Finally, converting temporal sequences into spectrograms, though effective for CNN-based learning, may introduce minor information loss compared to direct temporal modeling approaches such as Transformers or recurrent architectures. These limitations highlight opportunities for improvement in generalization and interpretability.

B. Future Work

Several directions can be pursued to extend this research. First, adaptive thresholding techniques could further enhance sensitivity to gradual concept drift in long-term deployments. Second, integrating Bayesian-inspired uncertainty modeling may strengthen interpretability and improve predictive calibration. Finally, cross-domain evaluation in fields such as finance, cybersecurity, and energy analytics could validate the generalizability of the proposed framework and highlight its potential for broader adoption.

***Abstract*—Effective inventory management is fundamental to supply chain resilience and efficiency. Artificial intelligence (AI) has emerged as a transformative solution that enables more dynamic and data-driven inventory strategies. To map the latest advancements in this rapidly evolving field, this study presents a systematic literature review (SLR) of AI techniques in inventory management. The review was conducted following the PRISMA 2020 guidelines, through which 87 high-quality articles published between 2021 and 2025 were systematically analyzed. Our review identifies machine learning (ML), deep learning (DL), reinforcement learning (RL), and hybrid methods as the predominant AI technologies. These techniques primarily address three foundational tasks. In demand forecasting, they improve prediction accuracy and mitigate stockout and overstock risks. For inventory control, they balance costs with service levels and optimize replenishment strategies. In inventory classification, they facilitate targeted resource allocation. Despite these advancements, AI research confronts significant challenges, particularly in data dependency, model interpretability, and implementation overhead. To address these gaps, we suggest future research focused on data-efficient learning, explainable AI, and lightweight, integrated frameworks to lower adoption barriers. This review provides a timely and holistic overview of the current research landscape, which serves as a reference for academics to identify research directions.**

Keywords*—Inventory management; artificial intelligence; demand forecasting; inventory control; inventory classification; machine learning

I. Introduction

Effective supply chain management (SCM) plays a critical role in modern corporate strategy by optimizing resource allocation, enhancing market responsiveness, and mitigating operational risks [1], [2]. Inventory management is a core component of SCM that is crucial for balancing supply and demand. It directly impacts key performance indicators such as operational costs and customer satisfaction [3], [4]. The strategic importance of inventory management is particularly evident in high-stakes sectors, such as the power grid sector. In this domain, managing inventories of critical assets, such as transmission components and essential spare parts, is paramount for ensuring grid stability and operational reliability, especially amidst the growing integration of volatile renewable energy sources [5], [6]. Traditional inventory management methods, reliant on static models and historical data, are ill-equipped for the volatility of modern supply chains [7], [8]. These methods exhibit inherent limitations in timeliness, flexibility, and predictive accuracy. Consequently, there is a growing demand for advanced solutions, and AI is a particularly promising approach [9], [10].

AI leverages big data and intelligent algorithms to enable scientific forecasting and dynamic optimization in inventory management, improving efficiency, reducing costs, and enhancing supply chain flexibility [11], [12]. For instance, machine learning (ML) can perform demand forecasting based on historical sales and market trends [13]. Deep learning (DL) is capable of processing complex nonlinear data for anomaly detection and defective product identification [14]. Natural language processing (NLP) can analyze supplier and customer information to support market fluctuation prediction [15]. Reinforcement learning (RL) can optimize replenishment strategies in dynamic environments [16]. The Internet of Things (IoT) combined with computer vision (CV) enables real-time monitoring, automated stocktaking, and visualization management [17]. These techniques significantly improve forecasting accuracy, inventory turnover, and anomaly detection, while supporting strategic supply chain planning and promoting intelligent manufacturing and digitalized supply chains [18][19][20].

Although artificial intelligence is rapidly transforming inventory management, the field lacks a current, unified map of these advancements, creating a research gap. To the best of our knowledge, there is a notable scarcity of comprehensive systematic reviews on this topic published after 2023. This gap is particularly critical for two reasons. On one hand, recent years have witnessed unprecedented progress in AI, with the emergence of large language models (LLMs) and the maturation of deep reinforcement learning and Transformers opening new paradigms. On the other hand, existing research has become increasingly fragmented. Studies often focus on narrow problems, such as demand forecasting or stock control, using isolated techniques, without providing a holistic view. Consequently, a systematic synthesis is urgently needed to answer critical questions regarding the current research landscape, the primary application topics, the comparative advantages and limitations of different AI techniques, and the challenges and future directions.

To address this clearly defined gap, this study presents a systematic literature review of AI in inventory management focused on the crucial 2021 to 2025 period. By synthesizing the latest advancements, we provide an updated and holistic framework of the current research status, topics, techniques, and future directions. This study, therefore, offers significant contributions. For the academic community, it maps the fragmented research landscape, identifies critical knowledge

*Corresponding author.

gaps, and outlines promising avenues for future inquiry. For practitioners and industry leaders, it serves as a practical guide, demystifying the capabilities and limitations of various AI methods and offering evidence-based insights to support strategic technology adoption. Ultimately, this review acts as a timely and essential reference, empowering researchers to navigate the new frontier and enabling practitioners to implement state-of-the-art solutions that enhance supply chain resilience and efficiency.

The remainder of this study is structured as follows: Section II introduces the research methodology employed for this review. Section III presents a descriptive analysis of the collected literature over the past five years. Section IV provides a detailed technical analysis based on the literature review. Section V discusses the findings in relation to the key research questions posed in this study. Finally, Section VI concludes the study.

II. Research Methodology

Due to its rigor, transparency, and reproducibility, the systematic literature review (SLR) enables a comprehensive and evidence-based synthesis of AI techniques and applications in inventory management. To further enhance the transparency and scientific rigor of this study, the entire process follows the preferred reporting items for systematic reviews and meta-analyses (PRISMA 2020) guidelines as shown in Fig. 1. The research began by outlining four research questions to explore the state, main topics, applied methods, and future directions of AI in inventory management. Subsequently, literature searches were conducted across databases. The retrieved articles were then filtered according to specific inclusion criteria. Studies unrelated to the topic, non-academic sources, and those outside the publication window were excluded. Finally, the selected literature was systematically analyzed to identify major findings, research trends, challenges, and recommendations for future research.

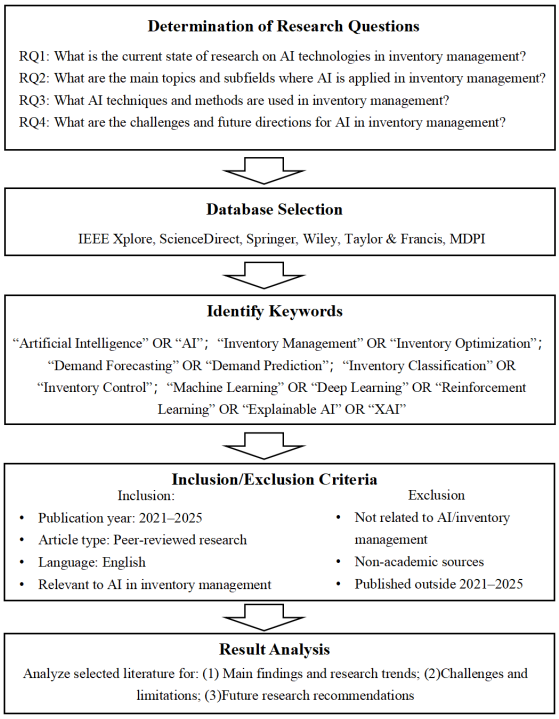

Fig. 1. Flowchart of the proposed method.

A. Research Questions

In the context of AI applications in inventory management, this study addresses the following research questions:

RQ1: What is the current state of research on AI technologies in inventory management?

RQ2: What are the primary topics in inventory management that AI is applied to solve?

RQ3: What are the key AI techniques and algorithms applied in inventory management, and what are their respective advantages and disadvantages?

RQ4: What challenges does AI face in inventory management, and what directions can be explored in future research?

B. Literature Search Strategy

To ensure comprehensive coverage of this interdisciplinary topic, our literature search utilized several major academic databases. The chosen platforms, IEEE Xplore, ScienceDirect, Springer, Wiley, Taylor & Francis, and MDPI, were selected as they collectively represent the primary, high-quality publication venues for research spanning artificial intelligence, engineering, and supply chain management. This multi-database strategy was crucial for minimizing selection bias and capturing a broad spectrum of relevant studies.

A combination of subject terms and free-text keywords are used: ('Artificial Intelligence' OR 'AI') AND ('Inventory Management' OR 'Inventory Optimization') AND ('Demand Forecasting' OR 'Demand Prediction' OR 'Inventory Classification' OR 'Inventory Control') AND ('Machine Learning' OR 'Deep Learning' OR 'Reinforcement Learning' OR 'Explainable AI' OR 'XAI'). Only English-language papers were considered. After initial screening, a total of 3,085 publications related to the above topics were identified.

C. Inclusion and Exclusion Criteria

The inclusion criteria required that studies focus on the application or methodology of AI in inventory management and related domains, covering techniques such as ML, DL, RL and other related methods. Only peer-reviewed research papers published between 2021 and 2025, with sufficient methodological or practical details, were included. Studies unrelated to AI in inventory management, non-academic publications, or published outside the specified period were excluded.

D. Quality Assessment

To ensure the scientific rigor and reliability of the systematic literature review, all included studies were subjected to a structured quality assessment based on established SLR frameworks [21]. The assessment focused on the clarity of research objectives, the appropriateness of the AI techniques employed, the transparency of data and experimental procedures,

the completeness and reliability of results, and the practical relevance of the study. Finally, 87 publications remained for further research.

III. Results

Following the research protocol described above, the literature relevant to the topic was selected and analyzed from four perspectives: publication trends, resource distributions, most cited papers, and keyword analysis.

A. Publication Trend

Fig. 2 presents the publication trend in the field over the past five years using a line chart. Overall, the number of publications increased significantly from 6 in 2021 to 22 in 2025, with a particularly notable surge in 2022, reflecting the rapid growth of academic interest in this topic. The number of publications remained relatively stable in the subsequent years, indicating sustained attention from the research community.

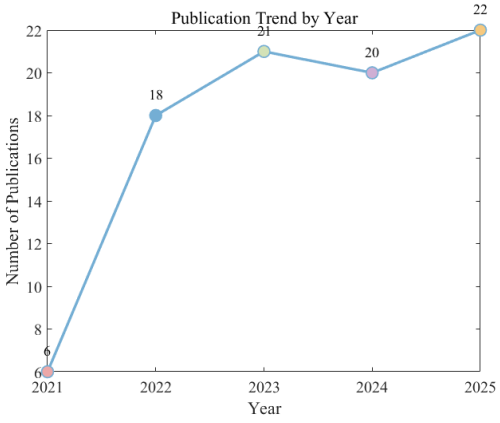

Fig. 2. Number of publications by year.

B. Resource Distributions

The distribution of publications across academic databases reflects the accessibility and concentration of research in this field. As shown in Fig. 3, *IEEE Xplore* hosts the largest number of publications (24 papers), followed by *ScienceDirect* (21 papers) and *Springer* (16 papers). This uneven distribution indicates that *IEEE Xplore*, *ScienceDirect*, and *Springer* serve as the primary sources of relevant studies, while *MDPI*, *Wiley*, *Taylor & Francis* and *Others* play a supplementary role.

At the journal level, the selected publications are relatively concentrated. Among the source journals, *Applied Sciences* contributed the most articles (8 papers), followed by *IEEE Access* with 7 papers. Additionally, *Annals of Operations Research* and *International Journal of Production Research* each published 4 relevant articles. Other contributing journals include *Sustainability* (3 papers), *Journal of Intelligent Manufacturing* (2 papers), *Expert Systems with Applications* (2 papers), *European Journal of Operational Research* (2 papers), *Production and Operations Management* (2 papers), and *IEEE Transactions on Engineering Management* (2 papers).

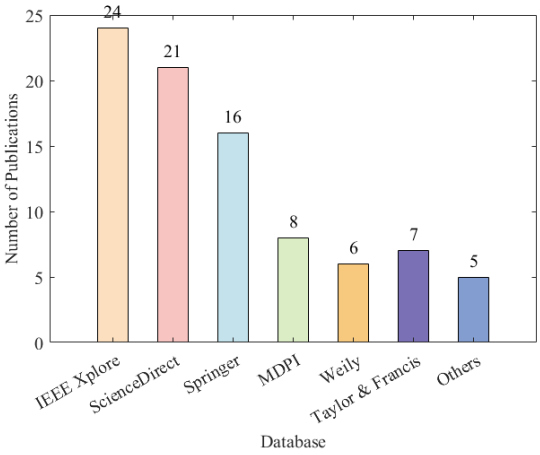

Fig. 3. Distribution of screened publications across databases.

C. Most Cited Papers

To illustrate the recent activity in this research area, Table I lists the top ten most cited papers. Leading publications received over 100 citations within a short period. For instance, the paper by Moor [22] has 126 citations, and the paper by Gonccalves [23] has 115 citations. The high citation counts of recent publications further demonstrate the active research in this field.

TABLE I. Top 10 Most Cited Papers

Rank	Authors	Reference	Citations
1	Moor et al.	[22]	126
2	Gonccalves et al.	[23]	115
3	Wang et al.	[24]	114
4	Meisheri et al.	[25]	111
5	Abu Zwaida et al.	[26]	109
6	Selukar et al.	[27]	94
7	Tang et al.	[28]	85
8	Jahin et al.	[29]	85
9	Shajalal et al.	[30]	79
10	Xu et al.	[31]	78

D. Keyword Analysis

As shown in Fig. 4, the keyword frequency analysis indicates that research in this field primarily focuses on the application of AI in inventory management. 'Inventory management' (21 occurrences) appears most frequently, followed by key methodological terms such as 'machine learning' (15 occurrences), 'deep learning' (10 occurrences), and 'reinforcement learning' (8 occurrences). Additionally, high-frequency terms like 'inventory control' (13 occurrences) and 'demand forecasting' (12 occurrences) further confirm that AI techniques are actively applied to address core challenges in this domain.

IV. Review of Literature

This section provides a comprehensive review of the core literature identified through a systematic search, with a focus on the AI techniques in inventory management. To clearly present the research landscape, the studies are categorized according to the main tasks of inventory management, including demand forecasting, inventory control, inventory classification,

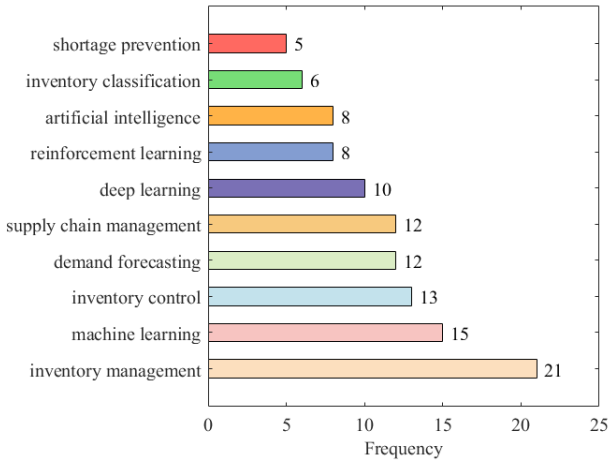

Fig. 4. Top 10 keywords by frequency.

and other related topics and application examples. Within each topic, the methods and algorithms such as ML and DL are reviewed. As this section contains a substantial number of technical acronyms, a table of abbreviations and their full names is provided in Appendix A for easy reference [see Table V].

A. Demand Forecasting

Accurate demand forecasting is central to inventory management, as it guides stock level decisions and mitigates the risks of stockouts and overstocking. A summary of works in this area is provided in Table II. Furthermore, demand forecasting can be broken down into more specific tasks, such as demand forecasting, inventory level prediction, and sales and price prediction.

1) Demand forecasting: Demand forecasting represents a core task in inventory management, aiming to predict future product or service demand based on historical data and relevant influencing factors. In existing research, mainstream approaches primarily encompass ML and DL techniques.

ML provides a simple and efficient way to predict the demands. Sathish [40] compared Exponential Smoothing (ES) with Gradient Boosting (GB), and found that ES outperformed GB in both forecasting accuracy and inventory optimization. Gonccalves [23] compared ML methods with the statistic based ARIMAX, and proved that ML models achieve superior results in later stages. Manos [49] developed a dynamic demand forecasting platform with XGBoost and SVR to process the multiple data source and then improve the prediction accuracy. Yang [44] developed a dynamic forecasting platform that combines XGBoost and SVR, which leverages multi-source data to significantly enhance forecasting accuracy and operational efficiency.

DL models have shown remarkable success in supply chain forecasting, with predictive power scaling alongside model complexity. Foundational architectures like LSTM networks, have been widely adopted. For instance, Deng [32] utilized LSTMs to capture long-term temporal dependencies and achieved prediction accuracies exceeding 80%. The versatility of LSTMs is further demonstrated in specialized applications, such as the hybrid LSTM variant proposed by Hasni [33] for intermittent medical supply demand, and the integration with customer segmentation by Jauhar [39], which slashed prediction errors by 74.14%. Building on this foundation, more sophisticated models are proposed to further enhance forecasting accuracy. Liu [45] developed a BO-CNN-LSTM model where Bayesian optimization fine-tunes a combined CNN-LSTM architecture. Seyedan [50] employed an ensemble DL method to forecast online retail demand, and the predictions are further used to optimize safety stock. Jin [51] integrated an attention-based Temporal Convolutional Network (ATCN) into their system. Abualuroug [43] proposed the MMCW-BiLSTM model which leverages multi-dimensional collaborative attention. For industry-specific challenges, models like the NARXNN have also been effective, and the accuracy reaches 96.24% in food demand forecasting [41]. In addition, the Transformer architecture is also gaining traction. Yang et al. [44] combined a Transformer with multi-agent RL, and yielded an 18.2% reduction in prediction error.

2) Inventory level prediction: Predicting inventory levels and stockout risks is crucial for optimizing inventory control and minimizing costs. Researchers have applied a range of ML and DL models to this task.

As to ML methods, tree-based ensemble models like XGBoost have proven effective for direct inventory level prediction [28] and related tasks such as order quantity forecasting [47]. DL, on the other hand, provides more powerful tools to capture complex nonlinear patterns. For instance, a hybrid Multi-MLP and LightGBM model yielded a significantly lower prediction error with an MAE of 0.2331 [34]. Novel architectures target specific challenges: QAmplifyNet, a quantum-classical hybrid network, was designed to handle data imbalance in stockout prediction and achieved 90% accuracy [29]. To address the need for model transparency, an explainable CNN framework [30] was proposed, which delivered both high performance (AUC = 0.9489) and valuable interpretability.

3) Sales and price prediction: Accurate sales and price prediction is fundamental to developing effective commercial strategies, enabling businesses to forecast product demand and establish optimal pricing. Both ML and DL have been extensively applied to address these interconnected challenges.

For prediction tasks, ML models like SVR, MLR, and MNLR have demonstrated high accuracy of 95.63% [36], while more advanced hybrid kernel models such as IMOHHO-AHK-ELM have been developed for specialized areas like wine price forecasting [46]. DL architectures offer further improvements. BPNs have been used for daily sales prediction of perishable goods [35], and integrated CNN-LSTM models have proven effective for complex forecasting, leading to inventory cost savings of over 20% [38]. A real-time automatic pricing system was built using a Dueling DQN algorithm. This system [37] successfully tackled multi-period pricing challenges, securing 91.58% of the returns achievable by an optimal strategy.

B. Inventory Control

The central challenge in inventory control is to guarantee product availability while keeping total costs to a minimum.

TABLE II. LITERATURE FOR DEMAND FORECASTING

Study	Citations	Type	Algorithms	Method
[32]	78	DL	LSTM	Inventory management is optimized by using LSTM for demand prediction in this paper.
[33]	8	DL	LSTM	The challenge of accurately forecasting medical item demand in humanitarian operations is tackled using a hybrid LSTM method.
[23]	109	ML	VAR, ARIMAX, ANN	Multi-step demand forecasting in an automotive supply chain is tackled with a multivariate approach to improve prediction accuracy.
[34]	8	DL	MLP	Future inventory levels in manufacturing are predicted by employing a multi-MLP model.
[28]	69	ML	XGBoost	Inventory forecasting for cross-border e-commerce is enhanced using XGBoost to predict demand, with the aim of improving service automation and reducing costs.
[35]	13	DL	BPN	The daily sales quantity for short-shelf-life cream puffs is predicted using DL in this model, in order to reduce food waste.
[36]	79	ML	SVR, MLR, MNLR	The monthly demand for construction machinery spare parts (specifically manifold products) is predicted with ML and regression methods.
[37]	9	DL	DQN, DRL	The optimal real-time price for retailers in presale e-commerce environments was predicted using deep RL.
[38]	8	DL	DNN, CNN, LSTM	A dynamic sales prediction model (DSP-FAE) is proposed to forecast product sales volumes for inventory optimization, by which costs are reduced by over 20% using auto-learning and elastic-adjustment mechanisms.
[39]	15	DL, ML	K-means, Regression, LSTM	An explainable AI framework is proposed to predict wine sales volume (MntWines) for perishable supply chains by segmenting customers and forecasting demand per segment, resulting in a 74.14% reduction in forecasting errors.
[40]	115	DL	ES/GB	A material demand prediction task is solved to forecast material requirements through a comparative analysis of forecasting methods.
[41]	33	DL	NARXNN	A food demand prediction task is solved using a NARXNN model to forecast the daily sales volume of processed foods.
[42]	28	DL	LSTM	The inventory demand prediction task for volatile SME data is solved using LSTM and 2D kernel density estimation.
[43]	2	DL	BiLSTM	The inventory demand prediction task is solved using a novel MMCW-BiLSTM model, by which future product demand is predicted.
[44]	27	DL	MARL, Transformer, DQN	A multi-agent deep RL framework is proposed to solve demand prediction tasks in retail supply chains, achieving an 18.2% lower forecast error and 23.5% reduced stockout rates.
[45]	28	DL	CNN, LSTM	Demand forecasting is solved with BO-CNN-LSTM to predict demand accurately, which leads to improved inventory optimization and cost control.
[31]	14	DL, ML	LSTM, PSO	The demand prediction task in supply chains is solved using AI, specifically by forecasting future demand quantities to achieve higher accuracy and optimize resource allocation.
[46]	6	ML	IMOHHO-AHK-ELM	An IMOHHO-AHK-ELM prediction model is proposed to achieve accurate point and interval forecasting of wine prices using AI techniques.
[29]	34	ML	Quantum Neural Network	Supply chain backorders are predicted with 90% accuracy by QAmplifyNet using a hybrid quantum-classical neural network.
[47]	85	ML/DL	XGBoost, LSTM	The task of forecasting the number of meal orders for the next 10 weeks is addressed using time series analysis to minimize waste.
[30]	85	DL	CNN	A CNN-based explainable framework for product backorder prediction in inventory management was proposed in this paper.
[48]	-	DL	RNN, LSTM, GRU, CNN	A DL framework is proposed to predict supply chain risks; specifically, drug delivery status, food demand quantities, car prices, and electricity volumes are forecasted.

This involves a continuous balancing act between the costs of holding inventory, placing orders, and running out of stock. The primary tools for managing this balance are the optimization of order quantities, reorder points, and safety stock. A well-designed inventory system prevents stockouts, which directly improves customer satisfaction, operational efficiency, and overall profitability. In this section, we summarize the recent methods compiled in Table III. The task of inventory control can be further divided into three sub-categories: single-echelon inventory control, multi-echelon inventory control, and control strategies for special scenarios.

1) Single-echelon inventory control: The single-echelon inventory control task aims to determine the optimal replenishment policy for a single inventory node. Singh [62] combined decision trees with symbolic distance methods to defuzzify the fuzzy total cost of seasonal demand and imperfect perishable products, and the method achieved precise inventory control under uncertainty. Mo [64] proposed an online RL approach that dynamically adjusts inventory policies under non-stationary stochastic market demand without requiring prior knowledge of demand patterns.

2) Multi-echelon inventory control tasks: The multi-echelon supply chain inventory control task, which is significantly more complex than its single-echelon counterpart, aims to coordinate inventory decisions across multiple tiers such as factories, distributors, and retailers. This process involves optimizing inventory levels and replenishment policies at each tier to minimize total supply chain costs and mitigate systemic issues like the bullwhip effect.

ML approaches continue to offer solutions. For instance, Preil [53] developed a MCTS based algorithm for both offline and online models. Their method is designed to determine optimal inventory decisions under stochastic demand and lead times and also helps to alleviate the bullwhip effect. Zietsmann [68] introduced an integrated inventory management framework. This framework, built upon a computer-aided decision support system, cohesively handles product selection, demand forecasting, and procurement to optimize inventory under multi-objective constraints.

On the other hand, DL methods, particularly RL one, have become a cornerstone of modern multi-echelon inventory control, because they can handle more complex and dynamic cases. Zhang [52] proposed an improved SAC-AlphaLR algorithm to optimize replenishment policies in the supply chains of multi-tier fast-moving consumer goods. Addressing systemic challenges like the bullwhip effect is another critical application. Liu [63] utilized a HAPPO algorithm within a multi-agent deep RL framework. Their goal was to mitigate the bullwhip effect in distributed multi-echelon systems. Scalability is a major advantage offered by DL. Meisheri [25] developed a scalable deep RL approach that leverages a single-product meta-model to manage the inventory of hundreds of products in parallel. This method effectively handles multi-period constraints and demonstrates the potential of DL in

TABLE III. LITERATURE FOR INVENTORY CONTROL

Study	Citations	Type	Algorithms	Goals/Approach
[52]	34	DL	SAC-AlphaLR, DRL	A DRL-based ME-DRFO model is proposed for multi-echelon FMCG inventory optimization, whereby total costs are minimized under demand uncertainty and supply chain constraints.
[53]	94	ML	MCTS	An MCTS approach is proposed for multi-echelon inventory optimization to reduce total supply chain costs and mitigate the bullwhip effect.
[54]	14	Hybrid	GBDT, ANN	Inventory, ordering, and financing decisions are optimized using data-driven methods under capital constraints and demand volatility.
[55]	12	DL	DRL	High-stochasticity inventory optimization is addressed using a tailored DRL algorithm.
[56]	5	DL	PPO, DRL	A DRLOM is proposed for multi-echelon inventory control, by which system-wide costs under stochastic demand and lead times are minimized.
[57]	2	Others	System Dynamics	Replenishment is optimized using system dynamics, leading to a reduction in stockouts and lost sales.
[58]	11	DL	LSTM, PSO	Inventory errors and operational costs are minimized through Transformer-based forecasting and PSO.
[59]	17	DL/ML	DQN, LSTM, SVR	SME inventory is optimized through joint demand forecasting and replenishment policies.
[27]	28	DL	DQN	Multi-perishable inventory is optimized using deep RL, with lead times, lifecycles, and demand being considered.
[60]	76	DL	DRL, BNN, MAML	New-product inventory across multiple stores is optimized under demand uncertainty and short life cycles.
[61]	28	ML	IPSO, BPNN	Green supply chain inventory is optimized using an IPSO-BPNN algorithm to reduce costs and improve environmental efficiency.
[62]	17	ML	DTL	Deteriorating product inventory is optimized using ML forecasts and fuzzy variables to minimize cost and emissions.
[63]	17	DL	MADRL	Decentralized multi-echelon inventory optimization is addressed using multi-agent DRL with limited information sharing.
[64]	10	ML	RL	Online RL methods are proposed for inventory control under nonstationary demand, through which costs are saved and service levels are improved.
[65]	29	DL	DRL	Apparel inventory control is optimized using DRL, where demand volatility, service level, and sell-through rate are considered to minimize costs and improve efficiency.
[26]	126	DL	DRL	A DRL method is proposed for hospital drug inventory optimization, aimed at minimizing refilling costs under demand uncertainty and storage constraints.
[66]	25	DL	PPO, DRL	DRL is applied to two-echelon inventory control with stochastic seasonal demand and multiple warehouses, minimizing total costs.
[67]	45	ML	KNN, DT, RF, XGBoost	Hospital drug inventory is optimized using ML and stochastic optimization to reduce stock levels and emergency orders.
[22]	111	DL	DQN, TL	The problem of perishable inventory optimization under lead time and demand uncertainty is solved using DRLs with reward shaping.
[25]	41	DL	DQN	A DRL method is proposed for scalable multi-product inventory control with lead time constraints to optimize replenishment and reduce costs.
[24]	114	DL	DQN	The problem of inventory optimization for lost-sales and multi-echelon systems is solved using DRL, which minimizes costs under lead times and demand uncertainty.

large-scale supply chains. Beyond algorithmic development, researchers have also explored hybrid models. Xie [69] introduced the NFDIRM, which combines a RBF neural network with fuzzy logic. This fusion enhances both forecasting accuracy and decision flexibility in intelligent warehousing. Finally, providing a broader perspective, Boute [70] summarized key design choices in this domain and outlines promising directions for future research.

3) Inventory control in special scenarios: Inventory control in specialized contexts, such as for perishable goods and healthcare supplies, introduces distinct challenges due to strict temporal and safety constraints. RL has emerged as a powerful tool for addressing these complex problems.

For perishable goods, research has focused on dynamic policy learning to minimize spoilage and other losses. For instance, Selukar [27] developed a multi-product DQN model that dynamically learns optimal replenishment policies. Building on this foundation, De [22] improved the training stability of such models by incorporating reward shaping and transfer learning techniques. To better manage inherent uncertainties, Singh [62] adopted a fuzzy logic approach, which treats key parameters like deterioration and defect rates as fuzzy variables rather than fixed values.

Healthcare inventory management places a high premium on safety, and preventing stockouts is often a higher priority than minimizing costs. Addressing this critical balance, Abu [26] employed a deep RL framework for automated replenishment, which successfully reduced both operational costs and stockout incidents. Galli [67] integrated multiple ML algorithms with stochastic optimization, where the system leverages daily ward-level data to optimize inventory.

C. Inventory Classification

Inventory classification is a systematic methodology that categorizes inventory items based on criteria such as value, demand patterns, and criticality. This approach enables organizations to allocate resources efficiently by applying differentiated management policies to distinct categories. Table IV summarizes recent research on inventory classification.

1) Multi-criteria inventory classification: Although the traditional ABC classification method remains widely adopted, its reliance on a single metric, such as annual usage value, often neglects other critical operational factors [80]. To overcome this limitation, multi-criteria inventory classification (MCIC) has been introduced as a more robust approach. This paradigm integrates multiple indicators and thus provides a more detailed and effective basis for decision support.

One major research stream of MCIC involves clustering algorithms. For example, Keskin [72] combined an autoencoder with K-means, incorporating sustainability indicators such as carbon emissions alongside traditional measures like order fulfillment and inventory turnover. Similarly, Khanorkar [84] applied K-means to simultaneously optimize usage value, delivery time, and unit cost. Another important line of work involves multi-criteria decision-making (MCDM) techniques. Kaabi [77] integrated genetic algorithms with TOPSIS to systematically generate optimal weights for multiple objectives. Furthermore, to address inherent uncertainties, Yung

TABLE IV. LITERATURE FOR INVENTORY CLASSIFICATION

Study	Citations	Type	Algorithms	Goals/Approach
[71]	10	ML	K-means Clustering	The inventory classification problem for impulse purchase products is solved by grouping SKUs via unsupervised clustering (K-means).
[72]	1	ML	Autoencoder/K-means	The problem of inaccurate multi-criteria inventory classification in the white goods industry is solved by hybridizing autoencoders with clustering methods.
[73]	34	ML	SVM, MNB, DT, RF, GB, KNN	Inventory classification in blood bank supply chains is addressed using ML to automate data handling, with big data and security factors being considered.
[74]	2	DL	CapsNet	Automated consumer product identification and classification for inventory management is solved, with noise reduction, feature extraction, hyperparameter tuning, and ensemble learning being considered to maximize accuracy.
[75]	26	ML	SHAP	The lack of explainability in multi-criteria ABC inventory classification is addressed by proposing an XAI-based approach using SHAP values, optimizing both classification accuracy and interpretability.
[76]	8	ML	CNN	Inventory classification challenges in electrical warehouses are solved by blending RGB and depth CNN pipelines with synthetic and real data; classification accuracy is optimized to 95.23% while domain shifts are addressed.
[77]	15	ML	Genetic Algorithm	Multi-criteria inventory classification (ABC analysis) is addressed by integrating metaheuristics (AI) for criteria weighting and TOPSIS (MCDM) for scoring; total safety stock cost and service level are optimized.
[78]	19	DL	CNN	The problem of fabric type classification for inventory management is solved using YOLOv10.
[79]	10	ML	BPNN	An objective spare parts importance evaluation method is proposed to optimize inventory strategies and reduce subjectivity.
[80]	13	ML	SHAP/K-means	The lack of Pareto compliance and explainability in multi-criteria ABC inventory classification is solved by integrating semi-supervised clustering and XAI to provide interpretable results.
[81]	50	ML	Fuzzy Logic	A fuzzy ABC classification system for space mission components is proposed, which incorporates multi-attribute criteria to optimize purchasing decisions.
[82]	1	DL	CNN/Transformer	Fine-grained product recognition for inventory classification is addressed. High interclass similarity and large intraclass variation are tackled, and accuracy is optimized with self-supervised learning to reduce annotation dependency.
[83]	28	DL	CNN/Transformer	Multi-criteria spare parts classification problems are solved by transforming hierarchical criteria into visual graphs, and inventory strategies are optimized through a modified CNN.
[84]	34	ML	K-means	The problem of inaccurate inventory classification is solved by incorporating criteria like annual usage value, lead time, and unit cost with K-Means clustering.
[85]	30	ML	GA/DT	A cost-driven ML classification method is proposed, integrating demand patterns and replenishment policies to minimize inventory costs.

[81] employed fuzzy logic, which allowed them to manage variability in delivery times and supplier risks, thereby improving classification robustness. Khan [86] proposed a fuzzy set enhanced VIKORSort method that uses trapezoidal fuzzy membership functions to improve classification flexibility and decision-making efficiency. In addition, Medina [87] applied a genetic algorithm for ABC classification of raw material inventory in a jewelry company, and the method reduced the total inventory costs across multiple criteria and established differentiated inventory policies.

2) Enhanced classification interpretability: The 'black box' nature of learning algorithms presents a challenge in inventory classification. Although these models can achieve high accuracy, their opaque decision-making processes hinder trust and adoption. This is particularly critical in multi-criteria ABC analysis, where stakeholders must understand the reasoning behind classifications. Enhanced classification interpretability directly addresses this problem.

Research in this area primarily focuses on explainable artificial intelligence (XAI) and advanced visualization. The SHAP framework is an example of XAI. As demonstrated by Qaffas [75], its primary function is to quantify the contribution of each input feature to a model's final prediction. This allows for explanations at both the local level for individual items and the global level for the overall model. In their study [80], Qaffas further enhanced this approach by integrating semi-supervised clustering. This integration not only provides granular, multi-level explanations but also ensures that the classification results adhere to Pareto principles. Meanwhile, visualization techniques aim to make complex multi-criteria relationships intuitively understandable. For example, Yang [83] transformed hierarchical data structures into images and employed an improved CNN architecture to visualize decision boundaries and feature importance, and this method enhanced the transparency of the classification process. Moreover, Medina [88] proposed an integrated inventory management model that combines ABC-AHP classification, holt forecasting, and cycle counting. The model is designed to optimize inventory control and minimize stock discrepancies for distributors.

3) Classification in specified scenarios: Beyond the foundational principles of inventory classification, many sectors present unique operational requirements. In the healthcare sector, studies focus on managing life-critical items. For example, Maathavan [73] proposed a machine learning framework for blood banks that integrates parameters like expiration dates and storage protocols. This approach serves to minimize human error in high-stakes environments. In retail, the primary challenge stems from demand volatility. Garcia [71] addressed this with a customized K-means clustering method. The approach groups SKUs by demand and cost patterns to effectively manage unpredictable impulse-buy categories and optimize total relevant costs. In manufacturing and warehousing, object detection techniques are pivotal for real-time classification. For instance, the YOLOv10-based textile inventory system from Mao [78] reached 85.6% mAP. Similarly, to handle uncontrolled environments, Piratelo [76] used a hybrid of RGB and depth CNNs for warehouse classification. Their model proved highly robust, with an accuracy of 95.23% despite domain shifts.

D. Other AI Techniques in Inventory Management

AI in inventory management typically focuses on core tasks like demand forecasting, inventory control, and inventory classification. However, researchers are also applying AI to a wider range of research. This section explores several of these novel topics.

1) Automated simulation modeling: Traditional logistics simulation modeling heavily depends on close collaboration

between domain experts and specialized engineers, which creates barriers to its widespread adoption in inventory management. To address this issue, Jackson [89] developed a system based on an enhanced GPT-3 Codex model. This system utilizes advanced NLP and Transformer architectures to translate natural language descriptions into executable Python simulation code, which simplified the model development process.

2) 3D inventory positioning: The objective of 3D inventory positioning is to achieve precise automatic localization of inventory items in unstructured warehouses with flexible storage layouts. Traditional marker-based systems are often unsuitable for such dynamic environments due to their rigid infrastructure requirements. To overcome this limitation, Yoon [90] proposed a DL framework that processes drone-captured video from a single QR-coded camera. The framework integrates U-Net++ for image segmentation with epipolar geometry, resulting in a 17% improvement in coordinate estimation accuracy.

3) Robot navigation and task management: Efficient robot navigation and task management are crucial for automating modern warehouse operations. Research in this area addresses challenges ranging from physical pathfinding and environmental perception to high-level strategic decision-making.

One key challenge is maintaining mutual visibility and occlusion-free paths for cooperative autonomous systems, particularly for small UAVs with limited hardware. To address this problem, a visibility-aware framework was developed. Their system employs a cross-entropy method and a conditional variational autoencoder, which together significantly reduce occlusion and collision rates while maintaining real-time performance on embedded hardware. Beyond physical navigation, optimizing robot decision-making for tasks such as shelf reallocation is essential for adapting to dynamic inventory levels and traffic patterns. In [91], a DQN framework was proposed that integrates task assignment with shelf reallocation. This approach enables robots to optimize both task selection and storage repositioning concurrently, which resulted in a 17-23% increase in throughput and a 30% reduction in runtime compared to conventional methods.

4) Fruit quality monitoring: Food spoilage in micro-cold storage is a critical challenge for small-scale agriculture, where post-harvest losses can reach 35 to 40% due to inadequate quality monitoring. To mitigate such losses, Arun et al. [92] have proposed an AI-based system for real-time fruit freshness classification. Their approach utilizes the Inception architecture to analyze produce, and it demonstrated a classification accuracy of 99.78% under controlled laboratory conditions on apples, bananas, and oranges.

E. Application Examples

Beyond research, AI-driven solutions are being actively deployed to industries to solve problems. This section highlights specific applications of AI models across sectors such as energy, retail, manufacturing, healthcare, and agriculture. These examples showcase how AI-driven approaches address domain-specific challenges.

1) Energy sector: The energy sector faces challenges in material scheduling and managing demand uncertainty. To optimize material scheduling, Hu [93] proposed an NSGA-II algorithm that integrates non-dominated sorting with rough vector feature decomposition. This method reduced convergence iterations from 460 to 65 and improved dispatch reliability. In addressing demand uncertainty, Thoummala [94] developed a two-stage DL framework. The model employs an LSTM network for forecasting to determine optimal inventory levels, resulting in inventory cost reductions ranging from 4.16% to 12.10%.

2) Retail sector: In the retail sector, key challenges include multi-echelon inventory coordination and the implementation of dynamic pricing strategies. To address coordination, Kaynov [95] proposed a DRL solution based on a PPO framework. This approach reduced network complexity and alleviated shortage bias, leading to cost reductions of 1 to 3% in lost-sales scenarios and 10 to 20% in backordering scenarios. For dynamic pricing, Liang [37] introduced a system based on DQN, modeling sales cycles as a Markov decision process. By decoupling the value and action-advantage functions, the algorithm achieved 91.58% of the optimal theoretical performance.

3) Manufacturing sector: Manufacturing supply chains are often hindered by demand information asymmetry, high inventory costs, and response delays. To mitigate the bullwhip effect, Sardar [96] developed a system that integrates an LSTM model with RFID tracking and a consignment strategy. This system enabled precise inventory control, and brings profit increase of 43%. In specialized fields such as pharmaceuticals, where historical data is limited, Zhu [97] leveraged multi-product data and grouping strategies to capture complex demand patterns more effectively.

4) Healthcare sector: Inventory management in healthcare must address the challenges of perishable resources, such as blood products and pharmaceuticals, where demand uncertainty and static policies can cause costly expirations or critical shortages. To optimize blood inventory, Mohamadi [98] developed a framework based on an A2C RL algorithm. This framework enabled dynamic distribution policies that achieved a zero-expiration rate while maintaining an 85% service level. To mitigate drug shortages, Abu [26] proposed a DQN-based replenishment model that formulates the problem as a Markov decision process. The model balances routine inventory with emergency demand, which reduced the shortage rate to 2.21% and the overall costs by 12.31%. Additionally, Adedugba [99] developed a dual-scenario deterministic inventory model for a pharmaceutical manufacturer in Lagos, Nigeria, using mathematical optimization to improve inventory hierarchies, lead times, and shortage management.

5) Agriculture sector: Agricultural supply chains face severe challenges, including perishable product losses of up to 35–40% and significant seasonal imbalances between supply and demand. For freshness monitoring, Arun [92] developed an Inception v3-based algorithm to process sensor-captured images, achieving 99% classification accuracy. This enabled more precise harvest timing and contributed to price stabilization. To optimize seasonal inventory, Wang [100] proposed a DQN framework integrated with real-time IoT data. The model incorporates reward shaping and cosine functions to effectively capture seasonal demand patterns.

V. Discussion

A. RQ1: What is the Current State of Research on AI Technologies in Inventory Management?

To address this question, in Section III, this study analyzed publication trends, source distributions, and high-impact studies using a predefined set of subject terms, keywords, and application domains.

Publication trends indicate a continuous increase in AI-driven inventory optimization research from 2020 to 2025. As shown in Fig. 2, a substantial surge in publications occurred in 2022, followed by stable growth over the next three years. This trajectory reflects the growing recognition of AI's potential to enhance inventory performance, while rapid technological advancements have further promoted practical adoption.

An analysis of keywords reveals the field's main research areas. The most prominent topics are demand forecasting and inventory management, which together account for nearly 28% of the research. This high percentage shows the foundational role of forecast accuracy in effective inventory optimization. Next, inventory control and optimization make up another 24%, which indicates that translating forecasts into actionable strategies is still a central research challenge. Other major research topics include dynamic pricing, replenishment, and supply chain resilience, with each representing about 12% of the literature. This focus reflects significant scholarly attention on profit maximization and risk mitigation. In contrast, topics like multi-criteria classification, warehouse automation, and new technologies such as AI and RL currently represent a smaller but growing area of research.

Several studies have demonstrated significant influence in this domain (see Table I). For instance, [22] has garnered substantial attention with 126 citations, followed by [23] (115 citations) and [24] (114 citations). These highly cited works underscore the importance of forecasting and advanced optimization strategies. Overall, the top ten cited articles primarily focus on optimization algorithms, DL, and explainable AI, reflecting sustained efforts to leverage advanced technologies for improved inventory management efficiency and decision support.

B. RQ2: What are the Primary Topics in Inventory Management that AI is Applied to Solve?

Although AI has been widely applied to a wide range of topics, this study finds that its most significant impact is on three core challenges: demand forecasting, inventory control, and inventory classification. These domains form the operational foundation of modern inventory strategies, where AI demonstrates the greatest value in overcoming the limitations of traditional methods.

1) Demand forecasting: Demand forecasting aims to predict future demand accurately by modeling complex patterns, such as nonlinear trends and temporal dependencies, from historical data and diverse features. A key aspect of modern forecasting is not only to provide point estimates but also to quantify uncertainty through techniques like interval prediction [48], [46], [42], allowing for robust adaptation across various industries and contexts .

However, achieving this goal in practice faces fundamental challenges. A primary issue is that these models often fail to capture the complex nonlinearities and multivariate dependencies that drive demand [33], [43]. Second, their single point estimates neglect the quantification of forecast uncertainty, which is a critical input for robust inventory and risk management [46]. Finally, their effectiveness is frequently undermined by the practical realities of sparse, incomplete, or low-quality data.

To address these forecasting challenges, recent research has shifted towards AI-driven methods capable of capturing complex demand patterns. Deep learning models, particularly LSTM networks and their variants, have proven effective at modeling long-term temporal dependencies. For instance, Hasni [33] demonstrated that a hybrid LSTM model could reduce prediction errors for intermittent medical supplies by 74.14%.

Further advancements include the integration of attention mechanisms and sophisticated optimization algorithms. A notable example is the BO-CNN-LSTM model, which employs Bayesian optimization to automatically fine-tune the model architecture, simultaneously enhancing forecasting precision and inventory cost control [45]. Beyond improving accuracy, researchers have also tackled data scarcity. Generative AI and transfer learning are now being explored to augment sparse datasets [42], which is crucial for ensuring robust predictions for new products or in settings with limited historical data.

2) Inventory control: Inventory control dynamically determines optimal ordering and stocking policies to balance the trade-off between minimizing costs and maximizing service levels, while adapting to complex constraints and demand uncertainties across the supply chain [53], [52], [27], [22].

However, traditional inventory control methods are often ill-equipped for modern complexities. They struggle with diverse, non-stationary demand patterns, and a structural disconnect between forecasting and control allows prediction errors to propagate directly into costly stock imbalances [53], [52], [59]. These demand-side issues are further amplified by supply chain dynamics. Within the supply chain, information asymmetries can fuel instabilities such as the bullwhip effect. Furthermore, a complex web of real-world constraints often renders simple optimization models ineffective.

To address these challenges, DRL has emerged as a powerful paradigm for developing dynamic ordering policies that sense and adapt to non-stationary demand in real time. These policies have shown superior performance over static models [52], [53]. A key architectural innovation is the integrated forecast-and-optimize framework. In this framework, deep learning models first capture complex demand patterns. Their outputs then directly inform optimization algorithms, which prevents the propagation of prediction errors [58], [59]. This principle of integration extends to multi-echelon systems. Here, multi-agent RL allows for the development of collaborative policies that coordinate decisions across all supply chain nodes. This approach effectively dampens the bullwhip effect and aligns local actions with global system efficiency.

3) Inventory classification: Inventory classification is a critical process that segments items based on multiple criteria to align management strategies with their strategic importance.

However, conventional methods face significant practical limitations. First, they are constrained by an over-reliance on single or subjective criteria. Classic ABC analysis, for instance, uses a single metric and neglects critical operational factors from supplier risk to sustainability [72]. Even multi-criteria approaches often depend on subjective expert weights, which undermines objectivity and auditability [77]. Second, their effectiveness is compromised by opaque "black-box" logic. As models grow in complexity, their internal decision-making becomes unintelligible to managers, eroding trust and hindering practical adoption [80]. Third, they exhibit poor adaptability to real-world data, and are difficult to manage the uncertainty, noise, or sparsity common in modern inventories.

To overcome these challenges, AI-driven methods offer targeted advancements. To counter subjective bias, AI employs data-driven multi-objective optimization. Techniques like K-means clustering and genetic algorithm-enhanced MCDM autonomously learn the importance of diverse metrics, establishing an objective, evidence-based framework [72], [77]. To resolve the 'black-box' problem, AI incorporates eXplainable AI (XAI) techniques. Frameworks such as SHAP deconstruct model decisions, and provides transparent, quantifiable justifications for item categorization that enhance trust and stakeholder buy-in [80]. Finally, to tackle poor data adaptability, AI leverages advanced data processing. Fuzzy logic [81], [72] is used to effectively integrate mixed criteria, while feature enhancement tools like autoencoders ensure model robustness against noise and data sparsity.

C. RQ3: What are the Key AI Techniques and Algorithms Applied in Inventory Management, and What are their Respective Advantages and Disadvantages?

According to the review, AI techniques in inventory management can be categorized into traditional ML, DL, RL, and hybrid algorithms.

1) ML methods: Algorithms such as KNN, DT, RF, XGBoost, LightGBM, SVR, ANN have been widely adopted in inventory management. These methods are primarily applied to demand forecasting and can handle volatile demand [23], [29], [36]. They also support basic inventory decisions, such as optimizing replenishment quantities for profit maximization [61], [67]. The main advantages of ML algorithms lie in their low computational costs and fast inference speeds. In addition, they provide good interpretability and can clearly identify the contribution of each feature. However, their ability to capture long-term dependencies is limited. For example, SVR often performs poorly in modeling multi-period demand for short-shelf-life products [47]. In addition, ML models frequently require substantial manual intervention [34], including parameter tuning and feature engineering, and their generalization ability is constrained.

2) DL methods: Models including LSTM, CNN, Transformers, and AEs are increasingly applied to complex inventory management problems. They are primarily used for advanced demand forecasting, capable of handling non-stationary, intermittent, and multi-factor-driven demand patterns, such as forecasting procurement needs for perishable goods [35], and multi-category inventory requirements influenced by factors like weather and promotions [45]. DL models excel at high-dimensional feature extraction, automatically capturing temporal dependencies and multi-feature interactions. For instance, MMCW-BiLSTM [43] captures bidirectional temporal relationships, while Transformers identify long-range nonlinear dependencies.

The main advantage of DL lies in its superior predictive accuracy, which significantly outperforms traditional statistical methods. For example, in [58], a Transformer model reduced the MAE of the predicted values from 15.8 to 8.2 and RMSE from 22.3 to 11.5. DL models also demonstrate strong adaptability to complex demand patterns. In [43], BiLSTM can process nonlinear time-series data with MAE as low as 1.75. Their generalization ability is also notable, with MMCW-BiLSTM and BO-CNN-LSTM achieving high accuracy across diverse datasets and scenarios [45].

However, compared with ML methods, DL models have high computational costs, and higher dependence on large-scale, high-quality datasets. Moreover, the 'black-box' nature of these models makes decision logic difficult to trace, which restrict their applicability in regulated fields such as healthcare.

3) RL methods: The RL algorithms, such as PPO, A2C, DDPG, and DQN, have emerged as powerful tools for dynamic inventory control. RL is particularly well-suited for multi-echelon supply chain management, perishable and multi-category inventory control, and joint inventory-financing decision-making under constraints [26], [55]. A key application is mitigating the bullwhip effect by promoting coordination and information sharing among supply chain nodes. For instance, the HAPPO [44] model can reduce demand amplification by 20%.

The core advantage of RL is its strong dynamic adaptability. It provides responses to stochastic demand, lead-time variability, and changing inventory states to achieve significant cost optimization. For example, in [53], the supplier order variability is reduced by 21%. In addition, its high-dimensional handling capability enables scalability for large-scale SKU management, with inference speeds one to two orders of magnitude faster than linear programming [53]. However, RL comes with substantial challenges: training costs are high, with models such as PPO and A2C requiring millions of iterations and several hours to converge [27] [56]. Additionally, multi-agent coordination in multi-echelon supply chains remains a challenge, as MARL models often exhibit slow convergence and struggle to balance the objectives of individual nodes with the global optimum.

4) Hybrid algorithms: Hybrid algorithms combine the strengths of multiple AI techniques to create more powerful and flexible solutions. Examples include LSTM-PSO [60], IPSO-BPNN [61], and joint 'prediction + inventory' frameworks such as W-LSTM + Q-learning [59]. These models are designed for 'forecast-then-optimize' workflows, bridging the gap between demand prediction and inventory decision-making to enhance overall efficiency. Phatangare proposed a machine learning based food inventory management system, leveraging linear regression, random forest, and LSTM networks [101] to optimize inventory levels through demand forecasting.

The primary advantage of hybrid models is their synergy, which combines the strengths of different techniques

to achieve superior performance. For instance, the LSTM-PSO model integrates the forecasting accuracy of LSTM with the optimization capability of PSO. This integration reduces fulfillment time by 25% and improves both model accuracy and robustness [58]. Another key benefit is their adaptability to complex scenarios. However, these advantages come at the cost of structural complexity and high computational demands, a primary disadvantage evident in the increased training times required for AE-Clustering hybrids.

D. RQ4: What Challenges does AI Face in Inventory Management, and What Directions can be Explored in Future Research?

The integration of artificial intelligence into inventory management also faces challenges spanning data dependency, model architecture, and operational viability.

First, the performance of AI models is critically constrained by data dependency. Most algorithms presuppose the availability of large, high-quality datasets and are highly sensitive to common data imperfections such as noise, outliers, and incompleteness [80]. A more profound limitation is their frequent inability to adapt to the complex data landscapes characteristic of real-world inventory systems: the heterogeneous, imbalanced, and non-stationary data associated with scarce, high-value components or sudden market disruptions [24][29]. Second, significant challenges are inherent to the architecture and functionality of current AI models. The inherent 'black box' nature of DL models impedes their adoption in high-stakes environments where decision transparency and interpretability are paramount [75]. Furthermore, many models exhibit narrow functional scopes. For instance, a DRL agent optimized for policy control may fail to manage volatile demand without an integrated forecasting component [60]. Finally, operational costs present a barrier to widespread adoption. For example, baseline models such as A2C [27] and DDPG [84] can require millions of simulation steps to achieve convergence.

To overcome these challenges, future research may focus on several key directions:

- A primary avenue is the development of data-efficient and robust learning paradigms. This includes leveraging frontier technologies like the Internet of Things (IoT) and Computer Vision to capture high-fidelity, real-time data, thus mitigating issues of scarcity and quality. Furthermore, the application of Generative AI and LLMs holds immense potential for creating high-fidelity simulation environments and synthetic training data. Such approaches can augment sparse datasets, balance class distributions, and simulate black swan events, thereby enhancing model resilience and generalization in dynamic conditions.
- Another critical research frontier is the pursuit of explainable, integrated, and automated modeling frameworks. Incorporating explainable AI techniques is crucial for demystifying model predictions, allowing managers to understand the rationale behind AI-driven decisions and fostering greater trust.
- Finally, to tackle the prohibitive operational costs, future research must move towards more efficient and lightweight models. A key direction is to develop algorithms that learn faster from less data, such as advancing offline reinforcement learning to leverage existing historical records instead of relying on extensive live simulations.

VI. Conclusion

This systematic review consolidates the current landscape of AI in inventory management by analyzing 87 articles published between 2021 and 2025. Our main finding is that AI applications primarily focus on three core areas. The first is demand forecasting, where deep learning is effective at capturing complex patterns. The second is inventory control, where reinforcement learning is increasingly used to handle dynamic and uncertain environments. The third is inventory classification, where explainable AI makes traditional methods more transparent. We also identified a consistent trade-off among different AI approaches. Machine learning is computationally efficient, while deep learning offers high accuracy but requires large amounts of data. Reinforcement learning allows for real-time adaptation but demands significant training resources. These results highlight both the great potential and the practical challenges of using AI for inventory management.

The novelty of this study is its focused and timely analysis of literature published after 2020. Unlike broader reviews, our work provides a detailed map of specific AI techniques to fundamental inventory problems. This mapping clarifies the distinct advantages and trade-offs of each technique. A key contribution of our study is the identification of a clear agenda for future research aimed at overcoming current limitations. By suggesting a focus on data-efficient learning, integrated prediction and decision models, and lightweight algorithms, this study guides future academic research and industry applications.

Despite these contributions, this study has several limitations. Its timeframe may have excluded foundational research published before 2021. In addition, our keyword-based search strategy might have missed relevant studies that used different terminology. These weaknesses indicate that our conclusions offer a comprehensive but not exhaustive overview of the field, which can be further strengthened in future studies.

APPENDIX

As shown in Table V, the acronyms and full names of various AI methods are presented.

TABLE V. TABLE OF AI ALGORITHM ACRONYMS

Acronym	Complete name
AHK-ELM	Attention-based Hybrid Kernel Extreme Learning Machine
ANN	Artificial Neural Network
BiLSTM	Bi-directional Long Short-Term Memory
BNN	Bayesian Neural Network
DL	Deep Learning
DQN	Deep Q-Network
DRL	Deep Reinforcement Learning
DRLOM	Deep Reinforcement Learning-based Ordering Mechanism
DT	Decision Tree
DTL	Decision Tree Classifier
ES	Exponential Smoothing
GA	Genetic Algorithm
GB	Gradient Boosting
GBDT	Gradient Boosting Decision Trees
IMOHHO	Improved Multi-Objective Harris Hawk Optimization
LGB	Light Gradient Boosting Machine
LSTM	Long Short-Term Memory
MAML	Model-Agnostic Meta-Learning
MARL	Multi-Agent Reinforcement Learning
MCTS	Monte Carlo Tree Search
ML	Machine Learning
MLR	Multiple Linear Regression
MLR	Natural Language Processing
MNB	Multinomial Naive Bayes
MNLR	Multinomial Logistic Regression
NARXNN	Nonlinear Autoregressive Exogenous Neural Network
PSO	Particle Swarm Optimization
RF	Random Forest
SAC	Soft Actor-Critic
SHAP	Shapley Additive Explanations
SVM/R	Support Vector Machine/Regression

Glioma Classification Using Harris Hawks-Driven Optimized Gradient Boosting Classifier Along with SHAP-Based Interpretability

SM Naim[1], Jun-Jiat Tiang[2]*, Abdullah-Al Nahid[3]*

***Abstract*—Gliomas are considered one of the most lethal and aggressive types of brain cancer, responsible for countless deaths worldwide. This study seeks to improve glioma classification using cutting-edge machine learning (ML) techniques to differentiate between glioma subtypes based on clinical and genomic data. The goal is to identify important biomarkers and features influencing glioma classification, with an emphasis on improving feature selection and model interpretability. For glioma classification, the Gradient Boosting Classifier (GBC) was employed. The Harris Hawks Optimization (HHO) algorithm was used for feature selection and hyperparameter fine-tuning to enhance the model's performance. Additionally, SHapley Additive exPlanations (SHAP) were applied to improve model interpretability and to better understand feature contributions.The Gradient Boosting (GB) method yielded the best performance among the selected models, achieving an accuracy of 88.40%, precision of 87.3%, recall of 88.48%, and an F1 score of 88.29%, with feature selection and hyperparameter tuning using the Harris Hawks Optimization. These results highlight the significance of hyperparameter tuning and feature selection in enhancing classification performance. Key features such as IDH1, Age at Diagnosis, and EGFR were identified as the most influential in distinguishing glioma subtypes. SHAP analysis further confirmed the importance of these features in the model.This study shows that the Gradient Boosting Classifier (GBC), optimized with Harris Hawks Optimization (HHO), significantly improves glioma classification, achieving a high F1 score. Key features like IDH1, Age at Diagnosis, and EGFR were identified, showcasing its potential for enhanced glioma diagnosis.**

***Keywords*—Glioma; gradient boosting; Harris Hawks Optimization (HHO); SHAP; feature selection; interpretability; TCGA; IDH1; EGFR**

I. Introduction

Brain and nervous system cancer is one of the most dangerous cancers in today's age. The death toll is rising day by day. According to research by the World Health Organization, there were approximately 251,000 deaths from brain and nervous system cancer in 2020, across both sexes, up to 85 years of age [1]. Among these, gliomas represent a diverse group of tumours originating from glial cells in the brain and pose significant diagnostic and therapeutic challenges in neuro-oncology [2]. Accurate grading of gliomas is critical, as it informs clinical decision-making and influences patient outcomes. However, conventional grading methods often lack precision and are resource-intensive. As illustrated in Fig. 1, the global burden motivates the need for reliable, explainable decision support.

Survival rates for glioma patients remain low, especially for high-grade variants such as glioblastoma multiforme (GBM), which alone accounts for more than 60 percent of adult primary brain tumours [6], [7]. The 2007 WHO classification introduced a system based on histological features, which was later enhanced by incorporating molecular markers such as IDH mutations [4]. In recent years, the convergence of neuroinformatics, computational neuroimaging, and machine learning has provided promising avenues for improving glioma classification. Machine learning algorithms can analyse complex, high-dimensional data from genomic and clinical sources to uncover patterns that traditional methods may overlook. One of the key challenges in glioma grading is the reliance on expensive molecular tests like IDH1/IDH2 mutation analysis, which can cost between USD 135–1800 and take up to two weeks to process [9], [10]. Additionally, variables such as age, sex, and clinical symptoms also influence tumour behaviour but are not always integrated effectively due to limited dataset annotations [11].

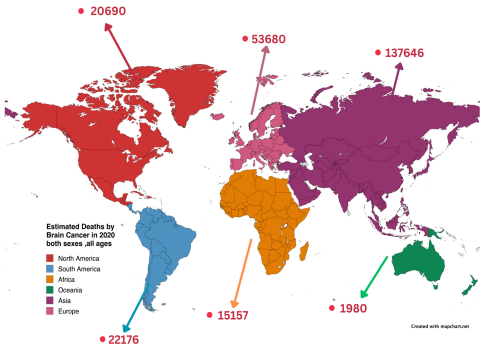

Fig. 1. Estimated number of brain cancer deaths by region in 2020.

Gliomas are among the most prevalent and deadly forms of brain cancer [3]. Early and accurate detection is crucial for prognosis and treatment decisions. Machine learning has shown great promise in extracting valuable insights from complex medical datasets, making it possible to predict disease

*Corresponding author.

outcomes with higher accuracy. This paper leverages advanced techniques such as Gradient Boosting Classifiers (GBC) and optimisation algorithms like HHO to identify key features that improve glioma diagnosis, with a specific focus on their interpretation through SHAP analysis [21].

Despite many promising studies, important gaps remain. A number of works maximize accuracy without explaining the predictions; others provide explanations but rely on only one data type (for example, imaging alone) or evaluate models using a single cross-validation loop that can overestimate performance. It is still uncommon to jointly perform feature selection and hyperparameter tuning on combined clinical+genomic predictors, then audit the final model with SHAP and report fold-aggregate results that better reflect generalization and clinical use.

This paper addresses these gaps with a simple, end-to-end pipeline that uses HHO with a GBC to jointly pick features and tune hyperparameters on TCGA-LGG/GBM data, followed by SHAP to check that the most influential variables—such as *IDH1*, *EGFR*, *TP53*, *NF1*, and Age—agree with contemporary glioma biology and the WHO-2021 system [5] [22]. We evaluate the model with cross-validation and summarize results across folds rather than relying on a single split. We also explain why gains in threshold-based metrics (accuracy, F1) can coexist with small changes in ROC AUC, and we outline how the outputs could support care by triaging cases for confirmatory molecular testing and by providing feature-level explanations suitable for tumor-board discussion.

II. Related Works

TCGA (The Cancer Genome Atlas) data have been used extensively to classify gliomas [8]. To differentiate glioblastoma multiforme (GBM) patients from others, Ko and Brody, for instance, used a gradient boosting classifier on TCGA copy-number data, obtaining an AUC of 0.875 [13]. Likewise, Sánchez-Marqués et al. demonstrated that ensemble approaches (e.g., CatBoost) outperformed standard classifiers on TCGA glioma cohorts by using TCGA-LGG and TCGA-GBM molecular and clinical data for glioma grade prediction [14]. These investigations emphasize how rich the TCGA-LGG/GBM dataset—which consists of hundreds of patients and clinical/molecular data—is for glioma subtype and grade classification problems. Underlining the relevance of TCGA in glioma research, other studies have built predictive models of glioma subtype or prognosis using TCGA-derived data (gene expression, mutations).

Medical and glioma classification has seen especially successful application for gradient boosting techniques. In oncology classification tasks, ensemble tree-boosting algorithms including XGBoost, LightGBM, and CatBoost routinely produce state-of-the-art results. Tang et al. used XGBoost on TCGA GBM transcriptomic profiles, for example, to classify GBM into its three subtypes (proneural, classical, mesenchymal), identifying a five-gene signature and approximating 80% accuracy [17]. Xia et al. trained GradientBoost and LightGBM models on MRI radiomic features to differentiate GBM from solitary metastases, achieving ROC-AUC > 0.90, and used SHAP to interpret feature contributions [16]. Gradient boosting approaches have also performed powerfully in radiomics-based brain tumor studies. Using MRI data, Kha et al. built an XGBoost model to forecast 1p/19q co-deletion in lower-grade glioma and used SHAP to choose the most useful radiomic features [15]. These and other studies—e.g., Sánchez-Marqués et al. using CatBoost [14]—show that gradient boosting classifiers are well-suited to complex, high-dimensional medical data, producing high accuracy in glioma grading and biomarker prediction.

Applied for feature selection and hyperparameter tuning in biomedical machine learning, Harris Hawks Optimization (HHO) is a new nature-inspired metaheuristic. Originally proposed in 2019 by Heidari et al., HHO has been modified for high-dimensional biomedical data in later work. Elgamal et al., for instance, chose ideal feature subsets in medical datasets by means of an enhanced HHO coupled with simulated annealing. Pirgazi et al. proposed a two-stage filter-wrapper approach whereby an enhanced HHO-based wrapper (with GRASP) further refines features chosen by a filter to identify an optimal subset for classification [21]. Apart from feature selection, HHO has been applied effectively to adjust model hyperparameters in clinical predictive models. Using HHO in a COVID-19 detection system, Kumar et al. optimized the hyperparameters of boosting classifiers (XGBoost, LightGBM, etc.), improving model performance and enabling integration of SHAP for feature analysis [18]. In a liver cirrhosis prediction task, Nalasari et al. similarly combined XGBoost with HHO for hyperparameter tuning, reporting notably better accuracy and less overfitting than standard XGBoost [19]. In the neuro-oncology setting [12], Kurdi et al. embedded HHO into a convolutional neural network (HHOCNN) for MRI-based brain tumor detection; their HHO-optimized CNN attained 98% accuracy on benchmark MRI datasets [20]. These cases show that by automatically selecting features or tuning parameters, HHO can efficiently improve model training; moreover, its application to biomedical classification is becoming rather common.

Rising in prominence in healthcare, interpretable artificial intelligence techniques such as SHapley Additive exPlanations (SHAP) offer insights into black-box model decisions. Several glioma research studies have used SHAP to clarify predictive characteristics. Before training the XGBoost model for 1p/19q status, Kha et al. ranked radiomic features using SHAP values, so increasing the transparency of the model [15]. Xia et al. calculated mean SHAP values for radiomic features in imaging studies to underline the most important predictors of tumor type [16]. Using SHAP to offer both global and local explanations of model outputs in a glioma survival-prediction web tool helped to show how clinical and molecular factors influence risk projections. Likewise, Kumar et al. used SHAP analysis on their COVID-19 boosting model to find important risk factors and simplify the predictions [18]. These papers demonstrate that SHAP is a useful tool in medical machine learning since it quantifies feature importance in complicated models, thus improving clinician confidence. SHAP has been applied not only for MRI/radiomics models but also for genomic and clinical models in the glioma domain, exposing which genetic changes or patient factors drive predictions.

All told, previous studies have shown the value of TCGA-based ML for glioma, the efficacy of gradient-boosting classifiers in such tasks, the promise of HHO for optimizing feature

sets and model parameters, and the importance of SHAP in model interpretation. These components have, nevertheless, mainly been studied separately. The present work validates the model with SHAP-based interpretability and combines these developments by using HHO to execute both feature selection and hyperparameter tuning of a gradient boosting classifier on TCGA glioma data. We know of no prior reports of this combined approach: an HHO-optimized GBC trained on TCGA genomic data using SHAP validation. It jointly improves model performance and transparency, bridging gaps in current work. While prior studies have shown that gradient boosting can achieve strong accuracy, many do not explain predictions in a way that is practical for clinical discussion, and others rely on a single data type rather than integrating clinical and genomic information. Several works also tune models within a single cross-validation loop, which can make the reported numbers look stronger than they are in routine use. As a result, three limitations remain common: modest gains in accuracy without clear interpretability, limited use of combined clinical+genomic inputs, and evaluation protocols that do not emphasize generalization. Our approach is designed to address these points by jointly selecting features and tuning hyperparameters with HHO, auditing the final model with SHAP, and reporting fold-level summaries that reflect how the model is likely to behave beyond one split.

III. Methodology

Based on the dataset, this work has carried out a classification task to distinguish between patients with gliomas and those without. Since the dataset is labeled, we have thought of using the supervised procedure to address this issue. Along with task classification, we have also carried out some DAT research, feature selection, and feature prioritization. We have used the SHAP method, a subset of the explainable AI (XAI) approach, along with a few filter techniques for feature selection. One could think of the XAI as a wrapper-based framework. The end-to-end pipeline—preprocessing, SMOTE, HHO-based feature selection and tuning, model training, and evaluation—is summarized in Fig. 2.

A. Dataset and Preprocessing

We conducted all experiments using a dataset obtained from the well-known and publicly accessible repository of genome atlas data on TCGA . The dataset was created using information from the TCGA-LGG and TCGA-GBM projects. It includes three clinical factors—Gender, Age at diagnosis, and Race—along with 20 commonly mutated molecular biomarkers, all gathered from 839 patients diagnosed with LGG or GBM. Looking at Table I, we can see that all the predictors are categorical, with the exception of the Age at diagnosis, which is represented as a numerical value.

The molecular characteristics are indicated by values of 0 for not mutated and 1 for mutated, based on the TCGA case number. It's important to highlight that there was no need to use any deletion or imputation techniques, as the dataset utilized in the experiments was complete, with no missing values in any of the attributes (predictor variables).

The dataset contains 24 attributes of 839 patients. Among them, 352 are Glioma patients and 487 are non-Glioma patients. As the data was imbalanced, we balanced the data using the SMOTE function.

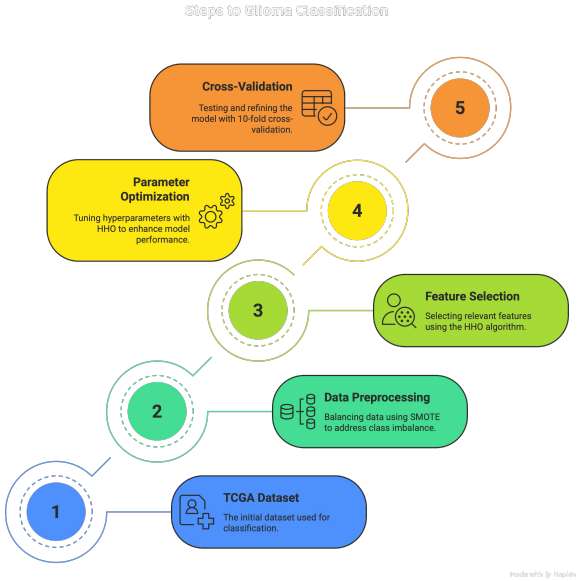

Fig. 2. Methodology for glioma classification using the TCGA dataset. This diagram illustrates the five key steps: dataset selection, data preprocessing with SMOTE, feature selection using HHO, hyperparameter optimization with HHO, and model testing via 10-fold cross-validation.

TABLE I. Predictors in the Dataset Used for Classification

Predictor Name	Category	Possible Values
Gender	Clinical	0, 1
Age	Clinical	[14.42, 89.29]
Race	Clinical	0, 1, 2, 3
IDH1	Molecular	0, 1
TP53	Molecular	0, 1
ATRX	Molecular	0, 1
PTEN	Molecular	0, 1
EGFR	Molecular	0, 1
CIC	Molecular	0, 1
MUC16	Molecular	0, 1
PIK3CA	Molecular	0, 1
NF1	Molecular	0, 1
PIK3R1	Molecular	0, 1
FUBP1	Molecular	0, 1
RB1	Molecular	0, 1
NOTCH1	Molecular	0, 1
BCOR	Molecular	0, 1
CSMD3	Molecular	0, 1
SMARCA4	Molecular	0, 1
GRIN2A	Molecular	0, 1
IDH2	Molecular	0, 1
FAT4	Molecular	0, 1
PDGFRA	Molecular	0, 1

To better understand the interdependence among the features, we calculated the Pearson correlation matrix for all numerical variables in the dataset. The correlation matrix above (Fig. 3) represents, using color and circle size, the effect and direction of linear relationships between features. The blue circles are for negative correlations, the red circles are for positive correlations, and the larger the circle, the stronger the relationship.

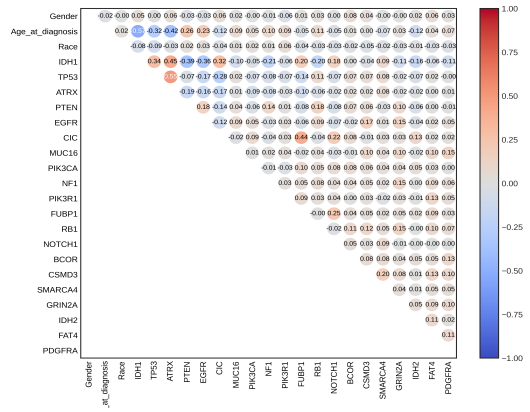

Fig. 3. Upper-triangle correlation matrix of selected clinical and genomic features. Circle size and color intensity indicate the strength and direction of Pearson correlation coefficients (red = positive, blue = negative).

An upper-triangle form such as this one draw attention to potential multicollinearity and redundancies. Specifically, TP53 and IDH1, and Age at diagnosis attributes are moderately correlated ($r2 \geq 0.1$) with multiple other attributes, and therefore may also be interesting predictive features. On the other hand, the lack of strong correlation between most features seems to suggest that this dataset can be used for evaluating and optimizing feature selection separately.

B. Visualization of Data Distribution Using t-SNE

In order to gain insights into the structure of our gene expression dataset and the distribution of our classes within it, we performed dimensionality reduction using t-distributed Stochastic Neighbor Embedding (t-SNE). And this is a nonlinear method which embeds the high-dimensional features into a 2D space preserving local similarities so it is very useful for visualizing patterns and class separability. Fig. 4: t-SNE projection of the entire dataset showing class-wise distribution.

Fig. 4. T-SNE projection of the entire dataset showing class-wise distribution.

In Fig. 4, we can see the t-SNE projection of the entire dataset showing Class 0 (purple) and Class 1 (orange) samples in separate, though partially overlapping clusters. This indicates that the input space in high-dimensional has an underlying structure that is probably separable by the proper classifier. This consistency in data distribution across the full dataset validates the efficiency of our preprocessing pipeline (as the distribution of pre-processed data in each set is analogous), and these visualizations make it all the more reassuring.

C. Gradient Boosting Classifier

In this subsection, we discuss the Gradient Boosting classifier used to classify glioblastoma. A classifier is a type of machine learning (ML) algorithm that categorizes data into predefined classes. In this case, the classifier uses patient characteristics, clinical data, to determine whether or not the patient has glioblastoma.

Gradient Boosting (GB) is an advanced ensemble learning algorithm that sequentially constructs weak learners (typically decision trees) to form a strong classifier. It minimizes the prediction error by iteratively adding models that correct the residuals of the previous ensemble. The objective function for GB is:

$$L(\theta) = \sum_{i=1}^{n} l(y_i, \hat{y}_i) + \sum_{k=1}^{K} \Omega(f_k) \tag{1}$$

Where:

- $L(\theta)$ is the objective function representing the overall loss.
- $l(y_i, \hat{y}_i)$ is the loss function measuring prediction error for each data point.
- $\Omega(f_k)$ is the regularization term to penalize model complexity.

The regularization function is defined as:

$$\Omega(f_k) = \gamma T + \frac{1}{2}\lambda \sum_{j=1}^{T} w_j^2 \tag{2}$$

Where:

- T is the number of leaves in the tree.
- w_j is the weight of the j^{th} leaf.
- γ, λ are regularization hyperparameters that control the strength of the regularization.

The model is updated at each iteration using:

$$F_t(x) = F_{t-1}(x) + \alpha h_t(x) \tag{3}$$

Where:

- $F_t(x)$ is the model's prediction after t iterations.
- α is the learning rate controlling the size of updates.
- $h_t(x)$ is the weak learner at iteration t.

D. Performance Metrics

To evaluate the classification performance, several standard metrics were used. These metrics provide insights into the model's ability to correctly identify and classify instances. The key metrics considered include:

- Accuracy: This metric measures the proportion of correctly classified instances out of the total instances. It provides an overall effectiveness of the classification model.

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{4}$$

- Precision: Precision quantifies the accuracy of the positive predictions made by the model. It is the ratio of true positives to all instances classified as positive, showing how many of the positive predictions were correct.

$$\text{Precision} = \frac{TP}{TP + FP} \tag{5}$$

- Recall: Recall, also known as sensitivity, measures the model's ability to correctly identify all relevant positive instances. It is the ratio of true positives to the total number of actual positives.

$$\text{Recall} = \frac{TP}{TP + FN} \tag{6}$$

- F1 Score: The F1 Score is the harmonic mean of Precision and Recall, providing a single metric that balances both concerns. A higher F1 score indicates a better balance between Precision and Recall.

$$F1 = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{7}$$

Where:

- TP = True Positive
- TN = True Negative
- FP = False Positive
- FN = False Negative

Additionally, Confusion Matrices and Receiver Operating Characteristic (ROC) Curves were used for visual interpretation of classification performance. The confusion matrix allows for a detailed breakdown of the true vs. predicted classifications, while ROC curves provide insights into the trade-off between the True Positive Rate (Recall) and False Positive Rate at various thresholds.

These metrics offer a comprehensive understanding of the model's classification capabilities and its strengths and weaknesses in distinguishing between classes.

E. Feature Selection Using Harris Hawk Optimization (HHO) Algorithm

Feature selection is the process of finding a noise-free, effective set of features from a given dataset that improves the model's performance on that dataset. The feature selection approach can be broadly divided into three main categories: embedded method, filter-based method, and wrapper-based method. In the wrapper-based method, a subset of the total features is evaluated using a machine learning (ML) algorithm iteratively to find the best feature subset. Metaheuristic algorithms are mostly used in this case to iteratively find an optimum feature subset that provides maximum performance.

To optimize feature selection, we employed the Harris Hawk Optimization (HHO) algorithm—a metaheuristic inspired by the cooperative hunting strategy of Harris hawks. The position of each hawk represents a candidate feature subset. The optimization is driven by exploration and exploitation phases:

- Exploration: Hawks randomly search for solutions based on prey energy.
- Exploitation: Attack strategies like soft besiege, hard besiege, and sudden dives are applied based on the prey's escaping energy.

The energy of the prey is given by:

$$E = 2E_0 \left(1 - \frac{t}{T}\right) \tag{8}$$

Where:

- E_0 is the initial energy of the prey,
- t is the current iteration,
- T is the maximum number of iterations.

Hawks update their position based on the escape energy E using one of the following position update strategies:

$$X(t+1) = X_{\text{prey}}(t) - E \cdot |J \cdot X_{\text{prey}}(t) - X(t)| \tag{9}$$

Where:

- $X(t)$ is the current hawk position,
- $X_{\text{prey}}(t)$ is the position of the prey (best solution),
- J is the random jump strength factor.

For the optimization process, we used the F1 score as the cost function to evaluate the performance of each feature subset. The F1 score, which is the harmonic mean of precision and

recall, was chosen because it provides a balanced evaluation of model performance, especially in imbalanced datasets. The F1 score was computed for each subset, and the feature subset that yielded the highest F1 score was selected as the optimal subset.

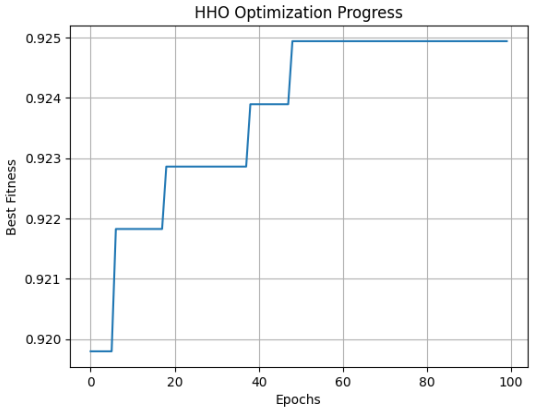

Fig. 5. Harris Hawks Optimization (HHO) convergence curve showing the improvement of best fitness over 100 epochs. The figure illustrates a typical step-wise convergence pattern characteristic of HHO's exploitation-exploration balance.

The Harris Hawks Optimization (HHO) algorithm progressively improves the model's F1 score by selecting optimal feature subsets. As shown in Fig. 5, the F1 score increases in a step-wise manner over the epochs. This reflects HHO's balance between exploration and exploitation, leading to a near-optimal solution.

We initialized 30 hawks over 50 iterations and evaluated subsets using the Gradient Boosting Classifier with 100 estimators. An elitism strategy was used to preserve the top 2 performing hawks during each iteration. The F1 score was maximized by iteratively adjusting the feature set and hyperparameters, ensuring that the final selected features and parameters provided the highest classification performance.

We applied the Harris Hawks Optimization (HHO) algorithm (Algorithm 1) to select an optimal subset of features, which reduced the feature space and improved classification accuracy. The solution sets provided by HHO indicate which features to select. These subsets are then used in the Gradient Boosting Classifier (GBC) for classification, with the F1 score serving as the fitness value for each agent (feature subset). The F1 score effectively balances precision and recall, making it a robust performance metric. In this process, we utilized 30 hawks over 50 iterations. The HHO algorithm updates the hawks' positions based on the best fitness value found at each step. By the end of the process, HHO selects the optimal feature subset, ensuring that the classification model is both efficient and accurate.

Algorithm 1 Feature Selection Using HHO for GBC

Initialize the hawk population $X(i)$ for $i = 1, 2, \ldots, n$
for each hawk in the population **do**
    Decode the feature set from the hawk position
    Calculate the fitness value (F1 score) using the decoded feature set with the Gradient Boosting classifier
end for
Compare the fitness values of each hawk and set X^* as the best hawk
while $t <$ maximum iteration number **do**
    for each hawk in the population **do**
        Update parameters
        if $r < 0.5$ **then**
            if $|A| < 1$ **then**
                Update hawk position towards the global best X^* using the exploration phase
            else
                Select a random position X_{rand}
                Update hawk position towards the random position using the exploration phase
            end if
        else
            Update hawk position towards the global best X^* using the exploitation phase
        end if
    end for
    for each hawk in the population **do**
        Decode the feature set from the hawk position
        Calculate the fitness value (F1 score) using the decoded feature set with the Gradient Boosting classifier
    end for
    Compare the fitness values of each hawk
    if a better solution (feature set) is found **then**
        Update X^*
    end if
end while
Save the best solution set as the final feature set

IV. Results

A. Feature Selection and Hyperparameter Configuration

The feature selection process resulted in the identification of a subset of features that contributed most significantly to the classification performance. The selected features are shown in Table II.

TABLE II. Selected Features After Harris Hawks Optimization

Selected Feature Name			
Gender	Age_at_diagnosis	Race	IDH1
ATRX	PTEN	EGFR	PIK3CA
NF1	SMARCA4	IDH2	PDGFRA

These features were selected based on their ability to differentiate between glioma subtypes. The selection process improved the model's efficiency by reducing the dimensionality of the input data.

The optimal hyperparameters for the Gradient Boosting Classifier (GBC) were determined through the Harris Hawks Optimization (HHO) process. The configurations are shown in Table III.

TABLE III. OPTIMIZED HYPERPARAMETERS FOR THE GBC MODEL

Hyperparameter	Original Configuration	Hyperparameter Tuning	Feature Selection & Tuning
n_estimators	100	144	150
learning_rate	0.1	0.0632	0.0139
max_depth	3	5	5
subsample	1.0	0.8153	0.8465

The optimized values for the hyperparameters show a clear reduction in the learning rate and an increase in the number of estimators, which contribute to the improved performance of the model.

B. Model Performance Comparison

The performance of the model was assessed across three different scenarios: using the original dataset, after hyperparameter tuning, and after both feature selection and hyperparameter tuning. The results, measured using various performance metrics, are summarized in Table IV.

TABLE IV. PERFORMANCE COMPARISON ACROSS DIFFERENT CONFIGURATIONS

Metric	Original Dataset	Hyperparameter Tuning	Feature Selection & Tuning
Accuracy	0.8809 ± 0.0269	0.8830 ± 0.0305	0.8840 ± 0.0266
Precision (Macro)	0.8834 ± 0.0272	0.8846 ± 0.0316	0.8873 ± 0.0264
Recall (Macro)	0.8812 ± 0.0257	0.8826 ± 0.0297	0.8848 ± 0.0253
F1 Score (Macro)	0.8796 ± 0.0265	0.8816 ± 0.0303	0.8829 ± 0.0260
ROC AUC	0.9240 ± 0.0288	0.9304 ± 0.0255	0.9269 ± 0.0315

The results show that feature selection combined with hyperparameter tuning achieved the highest scores across all evaluation metrics. Specifically, the accuracy improved from 0.8809 to 0.8840, while the ROC AUC decreased slightly from 0.9304 to 0.9269 compared to hyperparameter tuning alone, highlighting the effectiveness of feature selection in enhancing model performance. The improvements demonstrate that feature selection, when coupled with hyperparameter tuning, can optimize model performance, confirming its applicability in resource-limited environments.

C. ROC Curve for the Three Models

The Receiver Operating Characteristic (ROC) curve for the best-performing models (Feature Selection & Hyperparameter Tuning, Original Dataset, and HHO Optimization) is shown in Fig. 6. The curves demonstrate the performance of each model, with their respective Area Under the Curve (AUC) values.

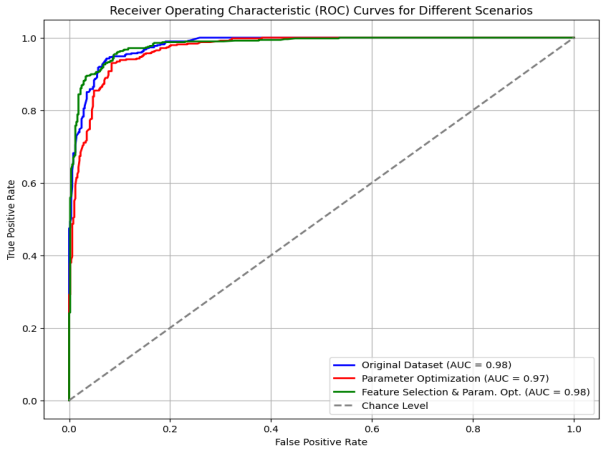

Fig. 6. ROC curve comparison for all three models.

The feature selection + tuning configuration delivers higher accuracy and F1 at the working threshold, while its ROC AUC is slightly lower than the tuning-only configuration. This pattern is consistent with optimizing for F1 rather than global ranking and matches the values reported in Table IV.

D. Confusion Matrix Across Three Models

The confusion matrices for the best fold from three different models—Original Feature Set & Hyperparameter Tuning (OFS & HT), Original Dataset, and Selected Feature Set (SFS) & Hyperparameter Tuning—are presented in Fig. 7a, 7b, and 7c, respectively. These matrices display the key classification metrics: true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN) for each model. Below are the interpretations drawn from these confusion matrices:

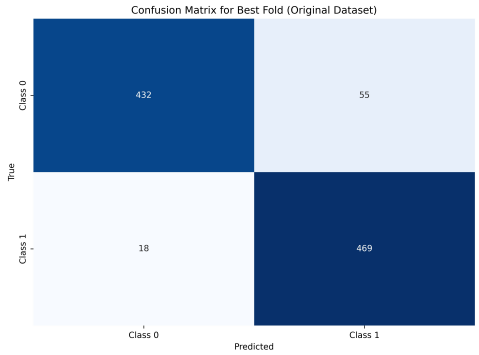
The confusion matrix for the Original Dataset model performs reasonably well, but it reveals a higher number of false positives and false negatives compared to the OFS & HT model. This suggests that, while this model achieves good accuracy, it would benefit from the enhancements offered by feature selection and hyperparameter tuning.

In summary, all models performed well, but the Feature Selection & Hyperparameter Tuning (OFS & HT) model demonstrated the best performance with the highest number of correct classifications. This highlights the importance of feature selection and hyperparameter tuning in achieving optimal classification results.

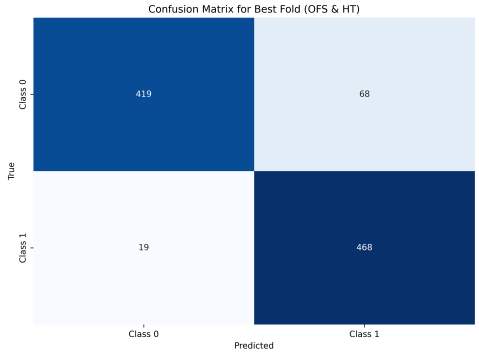
E. K-Fold Cross-Validation Results Across Three Models

Fig. 8 presents the performance metrics across 10-fold cross-validation for each of the three models. Boxplots show the spread and central tendency of each metric, including accuracy, precision, recall, F1 score, and ROC AUC, providing a comparison of model stability and performance.

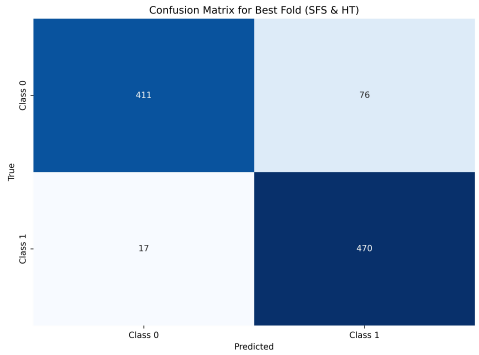
These boxplots highlight that the SFS & HT model is the best-performing model, exhibiting consistent and superior performance across all evaluation metrics.



(a) Confusion matrix for original dataset.



(b) Confusion matrix for hyperparameter tuning only.

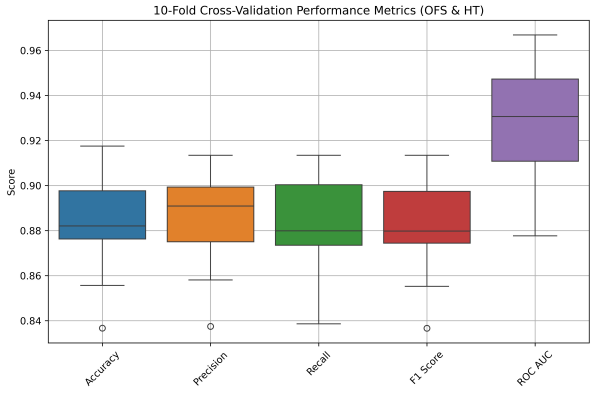


(c) Confusion matrix for feature selection + tuning.

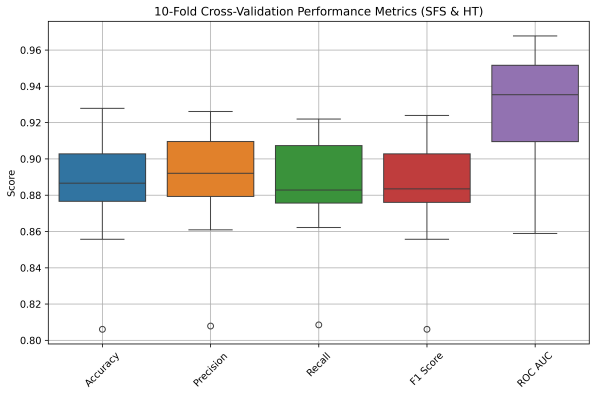
Fig. 7. Confusion matrices for the best fold across three models: Original dataset, hyperparameter tuning only, and feature selection + tuning.

F. SHAP-Based Validation of Selected Features

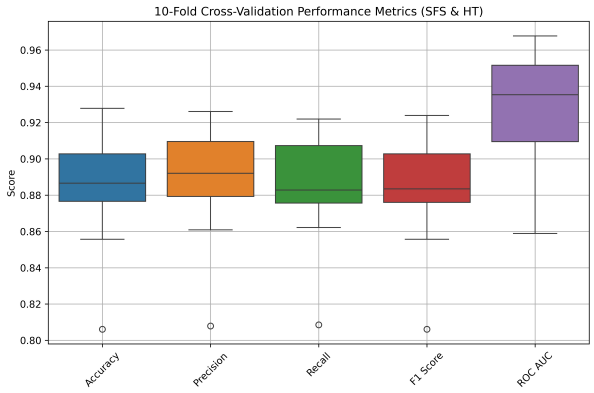
We used SHAP (SHapley Additive exPlanations) to evaluate the output of the trained model on the training data, thereby validating the resilience of the feature subset chosen using the Harris Hawks Optimization (HHO) algorithm. SHAP, based on cooperative game theory, offers consistent, locally accurate feature attributions, making it a useful instrument for post-hoc model interpretability. By providing a clear understanding of how each feature contributes to model predictions, SHAP helps validate the feature selection process and ensures the reliability of the model's decisions.



(a) Original dataset.



(b) Hyperparameter tuning.



(c) Feature selection + tuning.

Fig. 8. 10-Fold cross-validation performance metrics for the three experimental models: Original dataset, hyperparameter tuning only, and feature selection + hyperparameter tuning. Metrics include accuracy, precision, recall, F1 score, and ROC AUC.

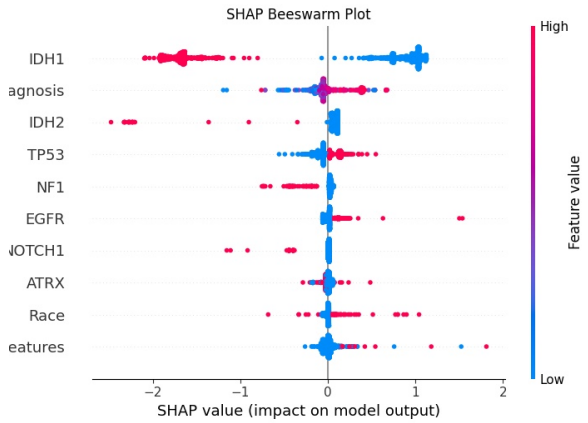


Fig. 9. SHAP summary plot illustrating the impact of individual features on the model's output for the training set. Red and blue represent high and low feature values, respectively.

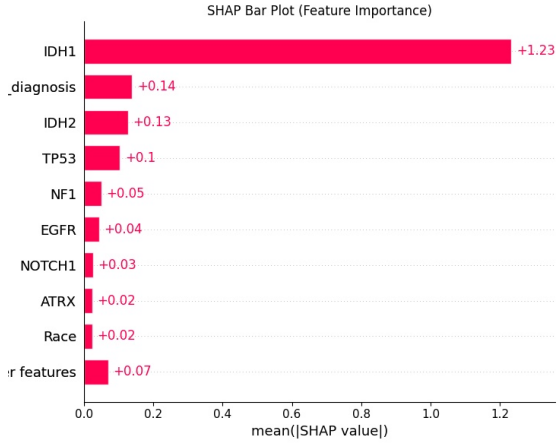

Fig. 10. Mean absolute SHAP values indicating the overall importance of features across all training samples. Top-ranked features include IDH1, Age_at_diagnosis, PTEN, and IDH2.

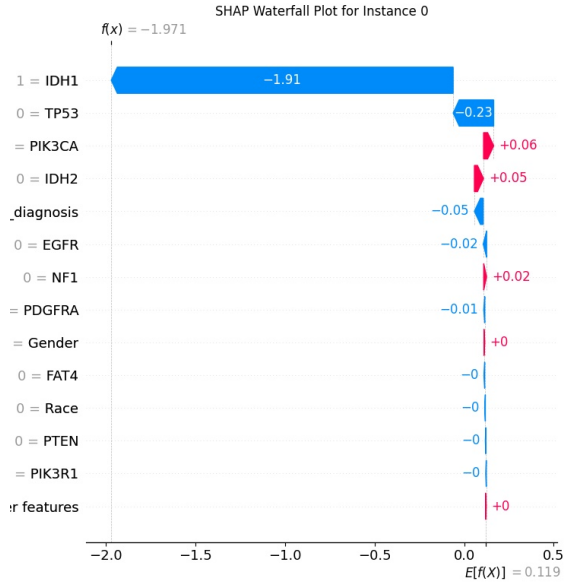

Fig. 11. SHAP waterfall plot illustrating individual feature contributions for a specific prediction. The plot shows the cumulative impact of each feature.

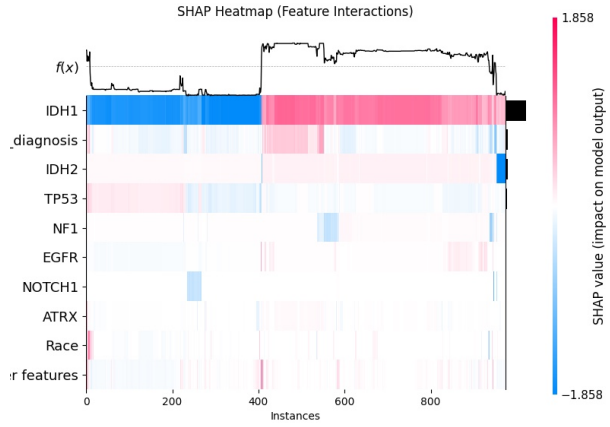

Fig. 12. SHAP heatmap showing feature importance and interactions across all predictions.

Fig. 9 illustrates the SHAP summary plot, which shows the impact of individual features on the model's output for the training set. Red and blue represent high and low feature values, respectively. The most powerful features influencing model predictions are revealed by the SHAP summary plot and the bar plot of mean absolute SHAP values (Fig. 10). Not least among these are IDH1, Age_at_diagnosis, PTEN, IDH2, EGFR, TP53, and NF1. These traits have great predictive value since they show as high-impact contributors over several samples.

The SHAP waterfall plot in Fig. 11 illustrates individual feature contributions for a specific prediction. The plot displays the cumulative impact of each feature, helping us understand how the model arrived at its output for a particular instance.

Finally, Fig. 12 shows the SHAP heatmap, which illustrates feature importance and interactions across all predictions. It provides a visual representation of how features interact and their relative importance in the overall model.

Especially, several of the top SHAP-ranked features are included in the subset of features chosen by the HHO algorithm — `['Age_at_diagnosis', 'IDH1', 'EGFR', 'NF1', 'PIK3R1', 'FUBP1', 'NOTCH1', 'BCOR', 'IDH2', 'FAT4']` —. Particularly for IDH1, Age_at_diagnosis, EGFR, NF1, IDH2, NOTCH1, and BCOR, the overlap between the SHAP analysis and HHO selection offers independent proof that the optimization procedure effectively found highly impactful factors for the model.

This agreement suggests that the HHO-based feature selection technique captured features of actual relevance for classification, thereby supporting the validity of this approach. The general interpretability and resilience of the proposed framework are supported by the agreement between model explanation and optimization results.

We tuned the model to work best at one practical decision point (the F1 balance), not across every possible threshold. That is why accuracy and F1 increased while ROC AUC, which reflects overall ranking across all thresholds, dipped a little: some score ordering changed, but decisions at the chosen cutoff improved. The SHAP results show that a small set of biologically sensible features—IDH1, EGFR, TP53, NF1, and Age—push predictions in expected directions; "high-risk" patterns raise the score, while "lower-risk" patterns reduce it. In practice, a high score with a few strong drivers can prompt faster confirmatory testing or earlier team review, whereas a low score with mixed or weak drivers can follow routine care. This ties the numbers back to clinical meaning and explains why the confusion matrices show fewer mistakes at the working threshold.

V. Discussion

This study shows that combining Harris Hawks Optimization (HHO) with a Gradient Boosting Classifier (GBC) can produce a compact and accurate model for glioma classification while keeping the reasoning behind predictions understandable. In our view, the most encouraging aspect is that the features highlighted by the model—such as IDH1, EGFR, TP53, NF1, and Age—are consistent with the biological story clinicians expect to see in glioma. This agreement suggests the model is learning meaningful patterns rather than overfitting to noise, and it makes the outputs easier to discuss in multidisciplinary settings.

We also observe a clear trade-off between threshold-based metrics and ranking-based metrics. After feature selection and tuning, accuracy and F1 improved, while ROC AUC decreased slightly. This is a reasonable outcome because the optimization process concentrated on improving the balance of precision and recall at a working threshold, not on maximizing performance across all possible thresholds. In practical terms, the model became better at identifying true cases at an operating point that matters for care, even if overall ranking changed a little. Because clinical use often depends on a specific decision threshold, we consider this an acceptable and transparent trade-off.

Another practical strength is parsimony. The HHO search consistently pushed the model toward a smaller set of informative variables, which reduces redundancy, speeds up training and inference, and lowers the cost of deployment. The resulting explanations from SHAP are easier to interpret at the patient level because fewer features dominate the prediction. In a clinical workflow, this can help frame conversations such as why the model flagged a case and which factors were most influential at that moment.

Finally, we see a realistic path to use: align the decision threshold with local practice, check probability calibration, review explanations alongside routine clinical information, and monitor performance over time. The goal is not to replace clinical judgment but to support it with a tool that is fast, consistent, and explainable.

VI. Limitations

This work uses a single public dataset for development and internal testing. Although it includes many patients, it may not capture the full diversity of real-world populations, imaging or sequencing methods, and clinical practice. As a result, the model's performance could change when applied to other hospitals or regions. External validation on independent cohorts from different institutions is needed to confirm generalizability.

The labeling scheme and endpoint definition may not fully match current clinical reporting standards. While the model distinguishes classes effectively within the dataset, future versions should align labels more closely with contemporary diagnostic categories to better reflect how decisions are made in practice.

Class imbalance was addressed with synthetic oversampling during training, which can influence the distribution and calibration of predicted probabilities. Although this helped improve recall and F1 at the chosen threshold, probability estimates may require calibration before the model is used to trigger clinical actions. Threshold choice should also reflect local risk tolerance and downstream resource constraints.

Metaheuristic optimization introduces randomness through initialization and fold splits. Although we used cross-validation and stable settings, minor variation between runs is expected. A more exhaustive stability assessment across multiple seeds and repeated folds would provide stronger evidence that the selected feature set and hyperparameters are robust.

Lastly, while SHAP improves transparency, it is a post-hoc explanation technique and does not prove causality. Some interactions between features may be complex and context-dependent, and explanations should be interpreted as supportive evidence rather than definitive biological mechanisms. Future work will focus on external testing, probability calibration, threshold setting with clinical input, and prospective evaluation in a workflow that tracks utility and safety over time.

VII. Conclusions

This study demonstrates that the Gradient Boosting Classifier (GBC), optimized using Harris Hawks Optimization (HHO) for feature selection and hyperparameter tuning, significantly enhances glioma classification performance. Despite reducing the feature set by 10 features, the Feature Selection & Hyperparameter Tuning (OFS & HT) model still outperforms other models in terms of accuracy, precision, recall, and F1 score. By selecting a more compact set of features, the model not only delivers better results but also becomes more efficient and cost-effective; fewer inputs translate into lower computational cost and faster processing, which is practical for real-world use. SHAP analysis further validates the importance of the selected features—such as IDH1, EGFR, and NF1—and, importantly, makes each prediction explainable, so that clinicians can see why a case was flagged and discuss the reasoning in tumor-board or radiology review.

Beyond technical metrics, the intended clinical value is early and reliable support: high-confidence outputs with clear drivers can prompt faster biomarker confirmation and earlier escalation of complex cases, while low-risk outputs with diffuse drivers can proceed through routine pathways. To ensure that these benefits hold outside of development data, we will perform external validation on independent cohorts

from other institutions and time periods, calibrate predicted probabilities, and select operating thresholds with clinical input. We also plan a prospective pilot in routine workflow to measure impact on turnaround time, downstream testing, and patient management, while monitoring stability across seeds, splits, and patient subgroups. In this way, the system moves from strong performance on paper toward safe, useful, and sustainable deployment in practice, while maintaining efficiency and interpretability.

***Abstract*—Chest X-ray imaging remains a cornerstone in the diagnosis of thoracic conditions such as COVID-19, pneumonia, and lung opacity. Despite advancements in deep learning, the development of robust and generalizable models is limited by data privacy constraints, as patient data cannot be centralized across institutions. Federated Learning (FL) has emerged as a promising solution by enabling collaborative model training without sharing raw data. However, standard FL algorithms like FedAvg, FedProx, and FedSGD aggregate all client updates without considering their individual quality, making them vulnerable to performance degradation in the presence of data heterogeneity, label noise, or underperforming clients. To address these challenges, this study proposes Federated Performance-Based Averaging (FedPA), a novel selective aggregation strategy that incorporates only those client models that meet a predefined performance threshold during training. By leveraging an accuracy-based filtering mechanism, FedPA ensures that only sufficiently trained and reliable local models contribute to global updates. The method was evaluated on a multi-class, non-IID chest X-ray dataset containing four classes: Normal, COVID-19, Pneumonia, and Lung Opacity. Using DenseNet as the backbone model, experiments were conducted across four federated clients, each biased toward a specific class to simulate real-world data distributions. Results demonstrate that FedPA significantly outperforms baseline federated algorithms across key metrics, achieving a global accuracy of 91.82%, F1-score of 92.48%, and recall of 92.08%. The method also achieved faster convergence, higher stability, and reduced round-to-round accuracy fluctuations. System-level evaluations further show that FedPA offers competitive efficiency in terms of inference time, throughput, CPU usage, and memory footprint, making it suitable for deployment in resource-constrained clinical environments. Overall, FedPA offers a practical and effective advancement in federated learning for medical imaging. By filtering unreliable client contributions, it preserves model quality and privacy, presenting a viable path for clinical deployment in scenarios where data centralization is infeasible due to ethical, legal, or logistical constraints.**

I. Introduction

Deep learning [1] and Medical imaging has become an necessary tool in current healthcare, playing an important role in the diagnosis, monitoring, and treatment of various diseases [2]. Technologies such as X-rays, computed tomography (CT), magnetic resonance imaging (MRI), and ultrasound, combined with AI-driven analysis (see Fig. 1), offer detailed insights into the human body, enhancing the ability of healthcare professionals to detect abnormalities at an early stage with greater accuracy and efficiency [3]. With rapid advancements in artificial intelligence (AI) and deep learning, medical image analysis has significantly improved [4], offering enhanced accuracy, speed, and efficiency in diagnosing conditions such as cancer [5], pneumonia [6], neurological disorders [7], and cardiovascular diseases [8]. These AI-driven approaches facilitate automated detection, segmentation, and classification of medical images, reducing the burden on radiologists and improving patient outcomes [9], [10].

The collection and management of medical imaging datasets for AI applications face significant challenges due to strict privacy regulations and ethical concerns. Federated Learning (FL) [11] has emerged as an innovative, privacy-preserving solution that enables collaborative model training across healthcare institutions without sharing raw patient data (see Fig. 1). By training models locally and only sharing model updates, FL ensures data privacy while leveraging distributed datasets [12]. Federated averaging (FedAvg) is a common aggregation procedure in federated contexts. FedAvg, however, experiences convergence issues, especially when there is significant diversity in the data distributions among clients [13].

In the next section, we will examine the role of federated learning in healthcare, highlighting its current applications and limitations. This discussion will also identify the existing research gaps, thereby framing the specific aim and contribution of this paper in addressing those challenges.

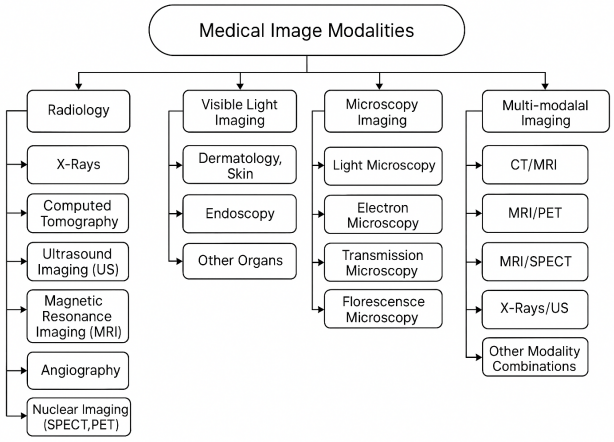

Fig. 1. Medical imaging modalities classification [3].

A. Federated Learning in Healthcare

In a standard FL setup, each client trains a local model using its own dataset and transmits model updates to a central server, which aggregates these updates to improve the global model. This iterative process continues until the model reaches convergence (see Fig. 2). However, traditional FL algorithms such as FedAvg struggle with non-IID data distributions, client heterogeneity, and communication overhead, particularly in healthcare applications where data availability and quality vary significantly across institutions.

Federated Learning has gained significant traction in the healthcare domain due to its ability to enable collaborative model training while ensuring compliance with data privacy regulations such as HIPAA (Health Insurance Portability and Accountability Act) and GDPR (General Data Protection Regulation) [14]. In healthcare, FL is particularly useful for applications such as medical imaging analysis, predictive diagnostics, personalized treatment planning, and disease progression monitoring.

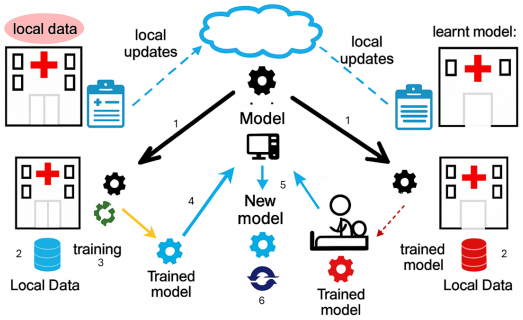

Fig. 2. Federated learning step by step process.

Recent studies have introduced various aggregation techniques to enhance federated learning, with Federated Averaging (FedAvg) being one of the most widely adopted due to its simplicity and efficiency [15]. However, FedAvg assumes equal participation from all clients, making it vulnerable to unreliable or delayed clients, particularly in real-world federated networks where client availability is inconsistent due to factors such as network failures, power constraints, and computational limitations. This inconsistency can lead to several challenges, including unstable global updates, where a high dropout rate among clients causes model updates to become erratic and degrade overall performance; inefficient optimization, as the server lacks control over client participation, making it difficult to streamline the learning process; and reduced model quality, since the absence of high-performing clients in certain rounds may lead to lower-quality updates.

To address some of these limitations, several advanced aggregation techniques have been proposed. Federated Learning with Proximal Optimization (FedProx) [16] improves FedAvg by mitigating the negative effects of client data heterogeneity. However, tuning its additional hyperparameter is challenging, and its default values may not generalize well across different datasets. Federated Multi-Task Learning via Multi-Task Association (FedMA) [17] optimizes both global and local models jointly, which enhances convergence, but its complexity makes it difficult to implement in some federated learning systems. Quantization-based Federated Learning (QFFL) [18] reduces communication overhead by compressing model updates through quantization, but this approach introduces quantization errors, which can impair convergence and final model accuracy.

Despite advancements in Federated Learning (FL), existing methods still face major challenges in medical imaging. High communication overhead, caused by frequent model updates, burdens low-bandwidth healthcare networks. Non-IID data due to variations in demographics, imaging tools, and protocols limits model generalizability.

Client participation is often inefficient, particularly from resource-constrained or outdated devices, contributing low-quality updates and hindering convergence. Data heterogeneity and noise further destabilize training. Scalability is also limited by diverse hardware capabilities across institutions.

Moreover, FL systems remain vulnerable to privacy and security threats such as model inversion and adversarial attacks. Unreliable client connectivity common in mobile or remote setups adds to participation inconsistency, complicating the learning process.

To address these limitations, we propose Performance-Based Federated Averaging (FedPA). A novel aggregation technique specifically designed for medical imaging applications. Unlike the traditional FedAvg method, which aggregates updates from all participating clients regardless of their quality, FedPA selectively incorporates only those updates that meet a predefined accuracy threshold (e.g., 80%). This selective inclusion significantly reduces noise from poorly performing clients, accelerates convergence, and enhances overall model robustness.

In addition to performance-aware selection, FedPA allows low-performing clients to download the updated global model parameters, enabling them to improve their local models over time. Once their performance meets the participation threshold, they are reintegrated into the aggregation process. This strategy promotes progressive learning and inclusivity while maintaining model quality and minimizing communication overhead.

To evaluate the effectiveness of FedPA, we applied it to a multi-class chest X-ray dataset for thoracic disease detection (Normal, COVID-19, Lung Opacity, Pneumonia). Each client was assigned a specific class, simulating a realistic non-IID setting. Experimental results demonstrate that FedPA outperforms traditional FL methods in terms of accuracy, F1-score, robustness, and communication efficiency highlighting its potential as a performance-aware and scalable FL approach for healthcare AI applications

The remainder of this paper is structured as follows. Section 2 presents a literature review of existing FL techniques in medical imaging, discussing the limitations of traditional aggregation methods. Section 3 details the methodology, including an overview of FL, the architecture of the proposed FedPA framework, model configurations, and dataset preprocessing. Section 4 provides experimental results and discussion, comparing FedAvg, traditional FedPA, and Performance-Based FedPA in terms of accuracy, loss, convergence time, and efficiency. Section 5 discusses the broader implications of the findings, highlighting advantages, challenges, and potential real-world applications of FedPA. Section 6 concludes the paper with a summary of findings and future research directions, focusing on further optimizations and the integration of secure aggregation techniques for enhanced privacy in FL.

II. Aggregation Strategies in Federated Learning

1) Federated Averaging (FedAvg): Federated Averaging (FedAvg) is the most commonly used FL aggregation strategy, introduced by [11]. In FedAvg, each participating client trains a local model for several epochs and sends the updated model weights to the central server. The global model is updated using the weighted average of all client models, formulated as:

$$w_{t+1} = \sum_{k=1}^{K} \frac{n_k}{N} w_k^t \tag{1}$$

where w_k^t is the local model update from client k, n_k is the number of samples on client k, and $N = \sum_{k=1}^{K} n_k$ represents the total number of data samples across all clients.

While FedAvg is effective in IID (independent and identically distributed) settings, it faces challenges in heterogeneous and non-IID environments, where certain clients may contribute low-quality updates, slowing down convergence.

Federated learning studies in medical imaging commonly use FedAvg as the standard baseline, often comparing it with optimization-enhanced and personalized alternatives. For instance, [19] report an accuracy approximately 97% for FedAvg under IID conditions, while personalized approaches in [20] and [21] show AUROC values of 0.95 for FedAvg versus 0.94 for local models. These studies cover diverse imaging modalities such as MRI, CT, X-ray, OCT and dataset sizes ranging from 2,100 to over 84,000 images. Methods tailored to handle data heterogeneity, such as FedOpt, often demonstrate improved accuracy and robustness under non-IID conditions. However, most of these approaches (six out of seven) incur higher client-side computational costs, and communication overhead typically remains moderate to high.

The [22] study shows that using EfficientNet-B0 with the FedAvg algorithm in a federated learning framework improves privacy and diagnostic accuracy for MRI brain tumor detection. EfficientNet-B0 outperforms ResNet in handling data heterogeneity, emphasizing the potential of federated learning for robust medical image analysis.

Referred by [23] SecureFed, a secure federated learning aggregation method, outperforms FedAvg, FedMGDA+, and FedRAD in lung abnormality analysis using chest X-rays. It demonstrates superior robustness and fairness on COVID-19 datasets and is adaptable for multimodal medical data analysis.

The [24] study introduces Auto-FedAvg, a data-driven federated learning approach that dynamically adjusts aggregation weights based on data distribution and training progress. It outperforms existing methods on heterogeneous CIFAR-10 and proves effective in two medical imaging tasks: COVID-19 lesion segmentation in chest CT and pancreas segmentation in abdominal CT.

While FedAvg is simple and effective, it suffers from inefficiencies when dealing with non-IID data and heterogeneous client performance, leading to slower convergence and suboptimal accuracy.

2) Federated Proximal (FedProx): To address the limitations of FedAvg, FedProx [16] introduced a proximal term to stabilize local updates, especially when clients have heterogeneous computing power or varying data distributions. The modified objective function is:

$$w_k^{t+1} = \arg\min_w \left(F_k(w) + \frac{\mu}{2} \|w - w_t\|^2 \right)$$

where u controls how much a client update deviates from the global model. FedProx helps mitigate drift in non-IID settings but does not directly address client selection based on performance.

The author in [25] presents a comparative analysis of federated aggregation algorithms for binary classification of X-ray images across a limited number of hospitals with varying data heterogeneity. Among the evaluated methods, FedProx consistently outperforms others, making it the most effective approach in handling statistical variation in distributed medical imaging settings.

Referred by [26], FedProx outperforms FedAvg in federated learning for medical image analysis, demonstrating superior performance in cancer classification despite heterogeneous client data. However, increasing the number of communication rounds between the server and clients degrades model performance, affecting convergence and accuracy.

The author in [27] introduces a hybrid federated learning algorithm, FedProx:FedSplit, designed to tackle both statistical and system heterogeneity in medical data communication. This approach enhances model convergence and improves the overall accuracy of the global model in distributed healthcare settings.

This [28] study explores brain tumor detection using MRI images in a federated learning (FL) setup to preserve data privacy. A VGG19-based model was trained across four clients with non-IID data, incorporating Grad-CAM for explainability. Using a centralized test set for fair evaluation, the model achieved high accuracy of 97.18% using FedAvg, 98.24% using FedProx, and 98.45% using Scaffold. It demonstrating the effectiveness of FL in privacy-preserving, real-world medical imaging scenarios.

3) Federated Proximal (FedBN): Federated Batch Normalization (FedBN) [29]is a variant of federated learning designed to tackle non-IID (non-identically distributed) data across clients by adjusting how batch normalization layers are handled. In standard federated learning (e.g. FedAvg), all model parameters (including batch normalization statistics) are averaged across clients, which can be problematic when clients have very different feature distributions (a situation known as feature shift). FedBN addresses this by keeping the batch normalization parameters local to each client. In other words it does not include the BN layers running mean and variance in the global model aggregation [30].

Medical imaging federated learning often faces site-specific data distributions for example, MRI scans from different hospitals may have varying intensity distributions due to different scanners or protocols, even if the underlying task (e.g. tumor classification) is the same [29]. FedBN is well-suited to such settings: by not forcing a single global normalization, it allows each hospitals model to adjust to its own imaging characteristics while still contributing to a shared global model. This approach has been applied in a number of medical imaging tasks to improve generalization across institutions. For instance, researchers have evaluated FedBN on multi-center datasets for diagnostic classification and segmentation problems, observing better performance compared to vanilla federated training when data distributions differ [31]

Notably, FedBN has been used as a state-of-the-art baseline in: Histopathology Image Classification Cell Nuclei Segmentation MRI Segmentation The method's success in these peer-reviewed studies demonstrates how personalized normalization can boost performance in privacy-preserving medical AI collaborations.

While FedBN was introduced to address the issue of batch normalization (BN) layers in a non-IID setting. In standard BN, statistics are computed from local mini-batches that might not generalize properly across clients. FedBN sidesteps BN layers during aggregation, allowing the client-specific normalization parameters while aggregating the remaining ones. This modification improves generalization, thus preventing the collapse in performance due to misaligned feature statistics [13].

In FedBN, the model parameters are separated into two components:

$$w = \{w_{\text{shared}}, w_{\text{BN}}\}$$

where:

- w_{shared} are the weights of shared layers (e.g., convolutional layers),
- $w_{\text{BN}} = \{\gamma, \beta, \mu, \sigma^2\}$ are the batch normalization parameters: scale, shift, running mean, and running variance.

The FedBN update rules are then:

$$w_{\text{shared}}^{(t+1)} = \sum_{k=1}^{K} \frac{n_k}{n} w_{\text{shared},k}^{(t)} \tag{2}$$

$$w_{\text{BN},k}^{(t+1)} = w_{\text{BN},k}^{(t)} \quad \text{(not aggregated)} \tag{3}$$

This means batch normalization parameters remain local to each client to better handle feature distribution heterogeneity.

A. Federated Stochastic Gradient Descent (FedSGD)

FedSGD is a foundational algorithm in federated learning that updates the global model by aggregating gradients from multiple clients rather than full model weights. Unlike FedAvg, which averages model parameters after multiple local updates, FedSGD performs only one gradient computation per client per round, reducing local computation but increasing communication cost. The global objective is to minimize the weighted empirical risk:

$$\min_{\theta} f(\theta) = \sum_{k=1}^{K} \frac{n_k}{n} f_k(\theta)$$

Each client k computes its local gradient using the current global model θ^t:

$$g_k^t = \nabla f_k(\theta^t)$$

The server aggregates gradients from the selected clients $\mathcal{S}_t$ and updates the global model as:

$$\theta^{t+1} = \theta^t - \eta \sum_{k \in \mathcal{S}_t} \frac{n_k}{n_{\mathcal{S}_t}} g_k^t$$

If uniform weighting is used instead of sample-size-based weighting:

$$\theta^{t+1} = \theta^t - \eta \cdot \frac{1}{|\mathcal{S}_t|} \sum_{k \in \mathcal{S}_t} g_k^t$$

This approach ensures lightweight local computation and is suitable for bandwidth-constrained distributed settings.

FedAc [32] can achieve a linear speedup with fewer rounds of synchronization compared to FedAvg, improving communication efficiency. FedAc has stronger theoretical guarantees than FedAvg, particularly for functions that are third-order smooth. The authors developed a novel analysis approach and a strategic tradeoff between acceleration and stability to derive the FedAc algorithm.

The key idea of the FedSel framework [33] is to privately select the top-k most important dimensions in each iteration of

federated SGD, in order to reduce the noise injected into the gradients under local differential privacy. The authors claim that their FedSel framework outperforms the state-of-the-art solutions in terms of privacy, accuracy, and time complexity.Experiments on real-world and synthetic datasets verify the effectiveness and efficiency of the FedSel framework.

The paper [34] analyzes the convergence of local descent methods like Federated Stochastic Gradient Descent (FedSGD) for solving nonconvex optimization problems in federated learning with heterogeneous data.

Despite notable advances in federated aggregation strategies such as FedAvg, FedProx, FedBN, and FedSGD, existing approaches remain limited in their ability to adaptively account for client performance quality under highly heterogeneous and non-IID medical data. Most methods either assume uniform participation (FedAvg), add complexity with sensitive hyperparameters (FedProx), or address only feature shift without considering contribution reliability (FedBN), while lightweight approaches like FedSGD incur high communication costs without performance-based filtering. Furthermore, recent personalized and optimization-driven extensions improve convergence but often impose higher computational and communication overhead, making them less practical for resource-constrained healthcare environments. A clear gap therefore exists in the literature for a performance-aware, lightweight, and selective aggregation mechanism that not only filters out low-quality updates but also ensures inclusivity for weaker clients to progressively improve an area where FedPA positions itself as a novel and practical contribution.

III. Federated Learning Performance-based Averaging (FedPA)

Federated Averaging (FedAvg) is one of the most widely adopted aggregation methods in federated learning due to its simplicity and communication efficiency [15]. However, it assumes uniform participation and contribution quality from all clients, which rarely holds in real-world settings. Client availability often varies due to network instability, power constraints, and hardware limitations, leading to unreliable or delayed updates. This inconsistency results in unstable global model updates, inefficient optimization, and reduced model quality especially when high-performing clients are absent from certain rounds. Furthermore, FedAvg lacks mechanisms to differentiate between high- and low-quality updates, allowing poor local models to degrade overall performance, particularly when data quality, size, or computational resources vary significantly across clients.

To overcome this limitation, Performance-Based FedPA is introduced. This approach integrates a client contribution evaluation mechanism that selectively aggregates model updates from high-performing clients while still allowing lower-performing clients to participate and improve. This strategy ensures that the global model prioritizes high-quality updates, leading to improved overall performance and stability.

Step 1: Initialization

- Initialize the global model w_0.
- Set the performance threshold τ (e.g., 80% accuracy).
- Define all participating clients K.

Step 2: Federated Learning Process

For each global round $t = 1, 2, \ldots, T$:

- Server selects a subset of clients $S_t \subseteq K$.
- Each client $k \in S_t$:
  - Trains its local model w_k^t using its dataset.
  - Evaluates its local model accuracy:

$$\text{Accuracy}(w_k^t)$$

  - If $\text{Accuracy}(w_k^t) \geq \tau$, the client is added to the selected clients set C_{selected}:

$$C_{\text{selected}} = \{k \mid \text{Accuracy}(w_k^t) \geq \tau\}$$

  - If $\text{Accuracy}(w_k^t) < \tau$:
    - The client still receives the global model update but does not contribute to aggregation.
    - This ensures continuous learning for weaker clients.

Step 3: Optimization and Weight Computation

For each selected client $k \in C_{\text{selected}}$:

- Compute the contribution weight α_k based on accuracy:

$$\alpha_k = \frac{\text{Accuracy}(w_k^t)}{\sum_{j \in C_{\text{selected}}} \text{Accuracy}(w_j^t)}$$

- Compute the local model update Δw_k^t:

$$\Delta w_k^t = w_k^t - w_t$$

Step 4: Aggregation Using FedAvg

Once all selected clients send their updates to the server, the global model is updated using FedAvg.

Using the weighted averaging formula:

$$w_{t+1} = \sum_{k \in C_{\text{selected}}} \frac{\alpha_k}{N} w_k^t$$

where:

- $N = |C_{\text{selected}}|$, the number of selected clients.
- Stable and effective for non-IID data.

- Reduces variance in updates.
- Slower convergence but better final accuracy.

Step 5: Updating the Global Model

- Server broadcasts the updated global model w_{t+1} to all clients.
- The process repeats for T rounds.
- At the end, the final model w_T is returned.

A. Advantages of Performance-Based FedPA

1) Improved global model accuracy: By prioritizing contributions from high-accuracy clients, the global model avoids the negative impact of poor updates, leading to faster and more stable convergence. Ensures that well-trained models influence learning while still allowing weaker models to improve.

2) Faster convergence: Since only high-performing models significantly influence the global update, the model learns more effectively per round, reducing the number of communication rounds required for convergence. Avoids instability caused by noisy updates from clients with poor local training.

3) Adaptive participation for weaker clients: Clients not meeting the accuracy threshold are still included in the federated learning process, receiving global updates and improving over multiple rounds. This encourages progressive learning, allowing weaker models to gradually enhance their accuracy and contribute more effectively in future rounds.

4) Robustness to Non-IID data: Real-world federated learning scenarios, such as multi-institutional medical imaging, often involve non-IID (heterogeneous) datasets. Performance-Based FedPA naturally adapts to these conditions by giving higher importance to clients with better model performance, which mitigates the impact of data heterogeneity.

IV. Methodology

A. Data Acquisition and Preprocessing

This study is based on dataset images of the chest radiograph classifying images into four classes-Normal, COVID-19, Viral Pneumonia, and Lung Opacity. Data from this collection used for the study is from publicly available clinical repositories to make sure the patient's demographics and radiological conditions are as diverse as needed. Such diversity will strengthen the generalization capability of the trained models for better and more effective application in real-world clinical conditions (Fig. 3).

Each image was preprocessed through a similar standard pipeline that was used across federated clients. All images were resized to a consistent input resolution of 224x224 pixels, which is widely adopted in convolutional neural network (CNN) models. Afterward, the pixel intensities were normalized by scaling the values into the range from [0, 1]. This definition of normalization was further adjusted per channel by mean and standard deviation values calculated on the training set to standardize input data of different images.

Various data augmentation techniques were utilized during training to reduce overfitting and improve the generalization abilities of the model. These augmentation methods included random horizontal flipping, small-angle rotations, random cropping, and intensity rescaling. The augmentations mimic image acquisition variability across the various institutions and imaging equipment, which is one of the main requirements for building robust models in medical image analysis. These techniques improve model robustness by preparing a model that performs better in real data differing from the acquisition conditions and quality.

All the changed images, label and metadata have been stored in an organized NumPy archive (covid_dataset.npz) to directly load and access such data during the training operation. This format is readily available for any federated client to train on such dataset providing a facility to have a smooth Read-Write process in distributed learning in healthcare AI systems.

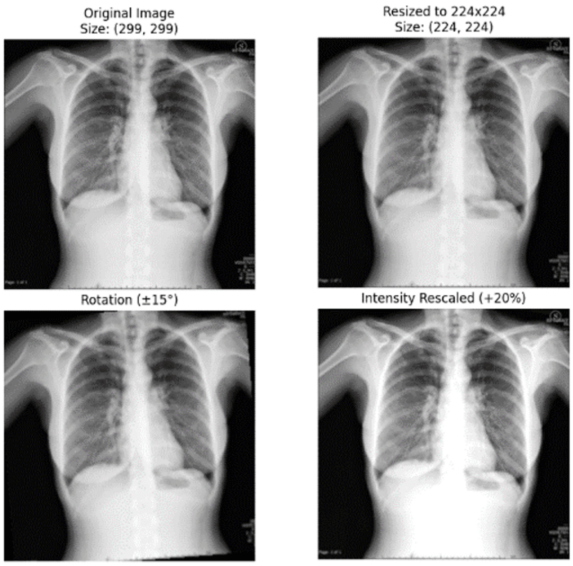

Fig. 3. This figure shows the preprocessing pipeline, the original image is resized into 224 x 224 size. This is further rotated and has its intensities increased for better feature recognition and generalization.

B. Data Partitioning and Distribution Strategy

The partitioning of the preprocessed chest X-ray dataset into four virtual clients simulating different hospitals or settings under federated learning, therefore representing three thoracic diseases-COVID-19, Pneumonia, and Lung Opacity-and one Normal class, would provide insight into these instances' diverse medical diagnosis as seen in real-world clinical practice. A truly non-IID data partitioning approach for federated learning algorithms is justified because, in practice, medical data can vary from one institution to another depending on specialization, as well as geographical attractiveness for certain diseases. Now, the data of each client was divided into a training set (70%), a validation set (15%), and a global test set (15%). The training and validation data were kept by the local class distributions, whereby the model of each client's training learned from an equal balance of images to prevent any biases

that could have arisen from unequal class proportions. The global test set, which holds 15% of the total dataset, was evenly distributed across all classes, allowing it to be completely separate to ensure an unbiased evaluation of the aggregated model's performance. This partitioning strategy exploits natural statistical variability that different clients have for the evaluation of federated learning methods under decentralized, imbalanced, and real-world clinical data conditions. Such a mechanism becomes necessary to allow for the generalization of the trained models over dissimilar clinical terrains, while addressing nature issues like data heterogeneity and class imbalance.

C. Model Architecture

Proposed model works on deep learning algorithms to classify chest X-ray images under four categories: Normal, COVID-19, Lung Opacity, and Pneumonia. The architecture promises extraction of multi-level spatial features with a reduction in computational complexity, thereby making it an ideal flaunt for federated learning settings.

1) The input layer: images of size 224 x 224 in grayscale feed into the model such that all the images could also undergo pre-processing in the same way for all federated clients.

2) Convolutional layer: Three convolutional blocks are required to capture the most relevant features such as edges, textures, patterns related to abnormalities in the lungs, and consist of a convolutional layer each followed by ReLU activation and max pooling.

3) Flatten layer: This layer converts 2-D feature maps made from the convolutional layers into single one-dimensional vectors for subsequent processing.

4) Dense layer: This is a dense layer built with 128 neurons and by ReLU activation to model very complex behaviours. A dropout layer is included at 30% rate to reduce overfitting and thus enhance generalization across clients.

5) Output layer: There are 4 neurons that correspond to classes using the SoftMax activation function for multi-class classification.

The model is optimized with the categorical cross-entropy loss for multi-class classification and is best suited for fast training by the Adam optimizer. It is a lightweight model that affords on-the-fly training on pretty cheap machines on the client-side in a federated learning system.

D. Global and Local Model Training in Federated Learning

In federated learning, model training involves two main phases: local model training and global model aggregation. These phases are iteratively repeated to make the global model better while ensuring data privacy.

1) Client model training: The local model for a specific client will be trained based on its local private data and the updates to be sent to the global server will only be that specific model updates such as weights or gradients. The training procedure involves:

a) Model initialization: Clients receive the global model weights at the beginning of the training round.

b) Local epochs: Clients train their model for a set number of epochs on local data.

c) Update sharing: After training, each client computes the updates (model weights or gradients) before sending them back to the global server.

This decentralized structure ensures that client sensitive data never leaves clients.

2) Global model training: The global server aggregates all local updates to improve the global model after all the local updates have been collected. This will include averaging the weights of all models from participating clients after the process. The most common aggregation algorithms include the following:

a) FedAvg: This is basically the first federated learning algorithm where the server computes a weighted factor average of model updates to carry out its aggregation. This would be especially useful when the distribution of data was relatively similar among the clients.

b) FedProx: This adds a proximal term in a local objective with respect to deviation from the global model for local models. This is usually good where very much dissimilar data exist across clients.

c) FedBN: This is a specific method designed for very different data distributions across client bases, as might occur in medical imaging tasks. FedBN keeps different batch normalization statistics for each client to handle domain shifts, thereby completely solving the problem of tasks.

d) FedSGD: Unlike FedAvg, which uses model weights, FedSGD is used to aggregate gradients instead of model parameters. It thus minimizes data exchange between clients and the server, thus optimally suited under low-latency communication networks.

e) FedPA (Federated Performance Averaging): With this new method, performance-based client selection is introduced. So in FedPA, a client must surpass a certain performance threshold to add its model updates to the global model.

Ensure that the federated learning algorithms harness the global model through the knowledge gained from each client while having local data private. They are especially concerned with healthcare and medical imaging since they leverage data diversity to deal with privacy alongside efficient model aggregation (Fig. 4).

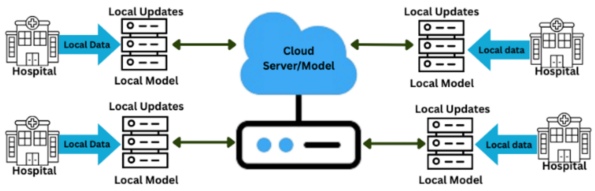

Fig. 4. Federated learning environment whereby hospitals learn and update local models on local patient data and use these to periodically update a shared central server for collaborative model updates without patient-data sharing.

V. EXPERIMENTS

A. Hardware and Software Requirements

The experiments were conducted on a workstation running Windows 11, equipped with an Intel Core i7 processor, 16 GB of RAM, and an NVIDIA RTX 4050 GPU with 12 GB of VRAM. The software environment was configured with Python 3.10, PyTorch 2.0.1, Torchvision 0.15.2, NumPy 1.24, scikit-learn 1.2, tqdm 4.65, and the CUDA Toolkit version 11.7. Model training was accelerated using CUDA where applicable, leveraging the available GPU resources. All models were implemented in PyTorch and executed in a single-machine, single-GP

B. Hyperparameter Settings

A careful selection of hyperparameters is critical in federated learning, as it significantly influences convergence speed, model generalization, and robustness to non-IID medical data distributions. This aligns with prior research in federated medical imaging and deep learning optimization. To ensure fair evaluation across all methods, the hyperparameters were standardized, drawing on empirical validation and insights from earlier studies addressing model regularization, optimizer behavior, and communication efficiency in federated settings.

Throughout all experiments, consistent hyperparameter settings were maintained. The AdamW optimizer was chosen for its improved handling of weight decay over standard Adam, with a stable initial learning rate of 0.001. A cosine annealing learning rate scheduler was applied at every epoch to adjust the learning rate dynamically. A weight decay of 0.01 was used to mitigate overfitting. The loss function employed was cross-entropy loss, a standard choice for classification tasks. A batch size of 16 was selected to balance memory usage and gradient estimation accuracy. Each client performed three local epochs per round, and all federated learning variants (FedAvg, FedProx, FedBN, and FedPA) were trained over 14 communication rounds. Data augmentation techniques, including random horizontal flips and rotations, were applied during training to enhance generalization. A DenseNet-based convolutional neural network served as the common base architecture across all approaches.

These hyperparameter values were fixed for all experiments to ensure both comparability and reproducibility, in line with best practices recommended in recent federated learning studies focused on medical imaging.

C. Client Configuration and Performance-Based Participation

As viewed from this research perspective, the federated learning setup imitates the real-life medical setting where the data distributions are inherently non-IID and client-specific. Four clients were set up to represent the four separate clinical categories from the chest X-ray dataset: Normal, COVID-19, Lung Opacity, and Pneumonia. Each of the four clients had access exclusively to its own set of labeled images, creating heterogeneity in class distribution and simulating isolated data silos of hospitals or diagnostic centers.

In the training process, each client was intended to keep optimizing its copy of the global model independently for five epochs per round using local data. This practice seems to fit well with reality since in federated health care, local computation is generally chosen over frequent communication due to privacy and latency issues. Nevertheless, global performance could be compromised if all clients participated uniformly, as when some clients perform really poorly due to poor data quality or too few training samples.

Consequently, the proposed FedPA framework implemented a performance-based client selection mechanism. At the end of every round, the clients assessed their local model(s) on a validation split and saved the best checkpoint. Only clients that achieved at least 85% validation accuracy were eligible to take part in the global aggregation. Generalization and robustness in federated learning can benefit from contribution-based client selection, as earlier studies have pointed out..

This participation filter remained in effect throughout the 15 communication rounds. FedPA, by removing low-quality model updates, fosters stable learning and reduces the risk of drift in the central model, which is often due to unreliable model updates by clients; a challenge posed in federated scenarios by heterogeneous and imbalanced datasets.

D. Global Aggregation Strategy

For every modification of the global model, there was an aggregation of local models by the participating clients at the end of each communication round, though significantly different regarding the mechanism of aggregation. In FedAvg, aggregation used to be done by the average of all client updates uniformly, presuming the reliability of all participants is equal. On a somewhat similar note, FedProx did not introduce any method of aggregation but provided a proximal term to recursively impose on local training so that students would penalize divergence from the global model within the locality, indirectly affecting aggregation quality. For another communication-intensive approach, FedSGD used gradients from each client, not the model updates but only required synchronous updates and higher communication overhead. FedBN performed normal averages on parameters but excluded all batch normalization layers from the averaging process such that the client held domain-specific statistics on normalization-an important feature in non-IID settings.

By contrast, the proposed FedPA approach redefined aggregation through a selection mechanism based on performance: It's not the fact that all clients contributed updates that matters, but instead, FedPA had just included clients whose local model outperformed a given validation accuracy threshold-all the way in this case, at or above the bar of 85 percent. Clients not meeting this criterion are not included in that specific round's aggregation. The selective strategy ensured that noisy and inferior updates were filtered out and only the well-trained local model participated in the global parameters. Thus, FedPA offered a greater quality enhancement under client performance and data heterogeneity-influencing factors concerning simple convergence and robustness, primarily in complicated evidence-dependent contexts, for example, medical imaging..

E. Evaluation Metrics

The performance of the federated learning models was evaluated based on the following main metrics

- Accuracy: It is the metric that indicates the overall performance of the model at classifying chest X-ray images correctly.

$$Accuracy = \frac{TP + TN}{TP + FP + FN + TN} \quad (4)$$

- Precision: Indicates the ability of the model to reduce false positives by correctly identifying only true positive instances.

$$Precision = \frac{TP}{TP + FP} \quad (5)$$

- Recall : Reflects the model's ability to correctly identify all positive instances, minimizing false negatives.

$$Sensitivity = \frac{TP}{FN + TP} \quad (6)$$

- F1 Score: It combines precision and recall into one measure and therefore sets a balance between the two by calculating their harmonic mean.

$$F1\ score = 2 * \frac{precision * recall}{precision + recall}. \quad (7)$$

- Inference time (s): Time needed to make predictions based on an input offered to the model by the user Additional measurements, such as CPU usage, memory usage, average inference time ,total inference time, throughput , were examined to determine the computational efficiency of the models.

VI. Result and Analysis

This section portrays a comparative analysis of the five federated learning models such as FedAvg, FedBN, FedPA, FedProx, and FedSGD. Evaluated on a common test set under exactly identical hardware and software conditions. The effect of the models is analyzed in determining the best among them in terms of the trade-off between performance in classification and efficiency at the system level for real-world deployment in almost all medical applications, such as chest X-ray analysis (Table I).

TABLE I. Performance Metrics Comparison

Method	Accuracy	Precision	Recall	F1 Score
FedAvg	0.9140	0.9259	0.9157	0.9206
FedBN	0.9124	0.9326	0.9053	0.9180
FedPA	0.9182	0.9295	0.9208	0.9248
FedProx	0.9113	0.9295	0.9071	0.9175
FedSGD	0.9129	0.9296	0.9102	0.9192

The standard evaluation metrics chosen for models are accuracy, precision, recall, and F1 score; each of these has its own clinical implications, especially in tasks related to disease detection.

1) Accuracy: FedPA obtained an accuracy of 91.82%, which is greater than FedAvg with 91.39% and FedSGD with 91.29%. This was achieved by performing client selection based on performance, excluding undertrained or noisy updates, which tended to minimize global model variance and aid generalization. FedAvg and FedSGD combine all clients equally, thus muting the effect of high-performing clients and slowing down convergence.

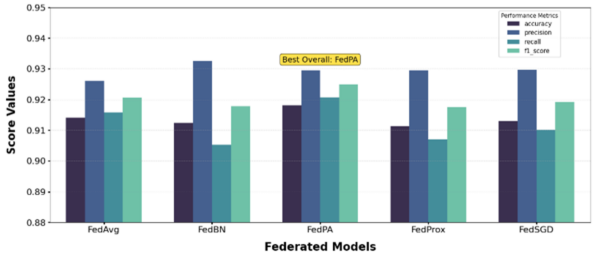

Fig. 5. Comparison of predictive performance metrics (Accuracy, Precision, Recall, F1 Score) of various federated models.

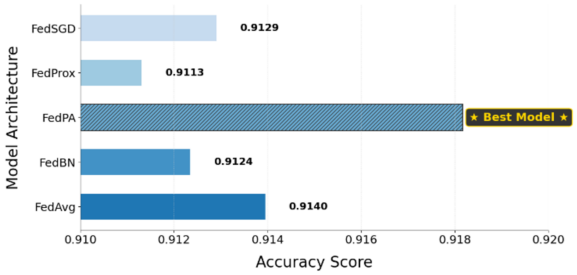

Fig. 6. Comparison of Accuracy across multiple federated models.

Precision FedBN leads in precision at 93.26% due to the use of client-specific batch normalization, thereby helping the model adapt to non-IID data distributions across clients. FedPA, close behind at 92.95%, strikes a good balance in precision without sacrificing too much recall. The implication is that FedBN really tries not to miss negative samples while FedPA has a better clinical trade-off by reducing the risk of under-detecting actual cases.

2) Memory: With 92.08%, FedPA achieves the highest recall performance, which indicates that it captures a lot of true positives, especially in lives-critical contexts like conversations about the identification of COVID-19 or pneumonia. This selective aggregation from FedPA contributes to this recall because high-performers among clients amplify the visibility of their presence to the global model and, hence, facilitate better identification of minority or diffused class patterns, even in the presence of data heterogeneity.

F1-ScoreFedPA has again captured the F1 score of 92.48%, thereby making it possible for it to prove its efficiency with respect to false positive or false negative prediction. With FedSGD and FedAvg coiled very closely behind, neither has the robustness of FedPA because it does not filter clients. The harmonic property of the F1 score underlines how selective aggregation according to FedPA effects compromise between sensitivity and specificity, both very important in terms of clinical reliability (see Fig. 5 and 6).

A confusion matrix is a table used to evaluate the performance of a classification model by comparing predicted labels with true labels. It is especially useful for understanding the types of errors a model makes. Here's the general structure for a binary classification confusion matrix (see Fig. 7 to 11):

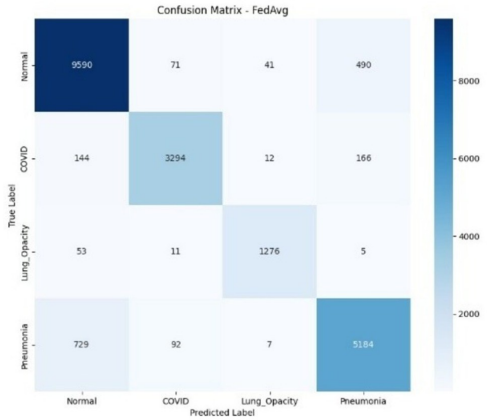

Fig. 7. Confusion Matrix of FedAvg.

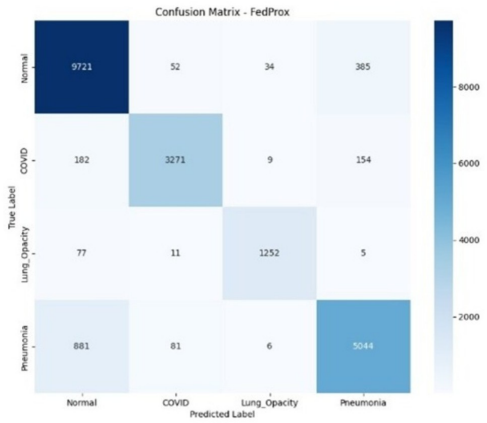

Fig. 8. Confusion matrix of FedProx.

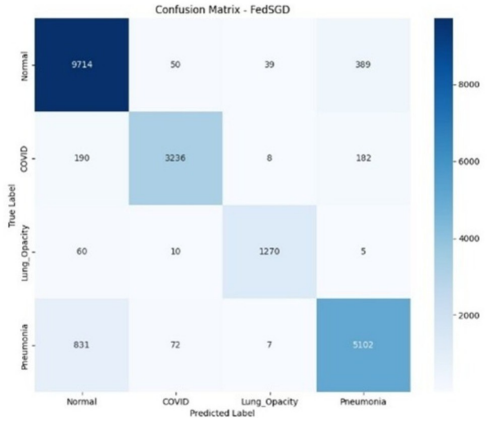

Fig. 9. Confusion matrix of FedSGD.

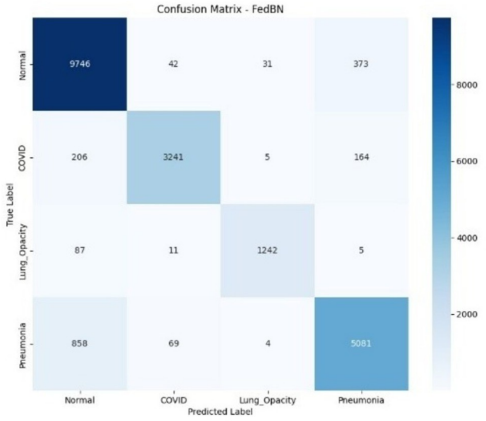

Fig. 10. Confusion matrix of FedBN.

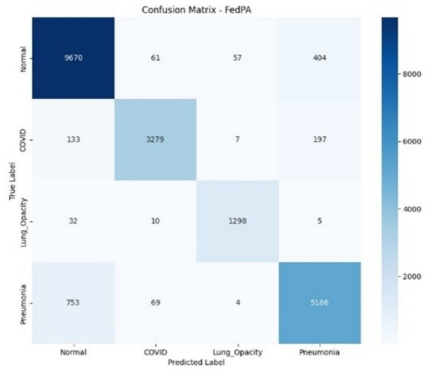

Fig. 11. Confusion matrix of FedPA: Proposed method.

A. System-Level Evaluation Metrics

This is now an assessment by which each model is compared for efficiency mainly due to the inference time, throughput, CPU usage, and memory footprint that are necessary for real-time medical AI deployment (Table II).

TABLE II. System Metrics Comparison

Method	Average Inference Time (ms)	Throughput	CPU Usage (%)	Memory Usage (MB)
FedAvg	0.003427	9328	13.15	12976
FedBN	0.002838	11266	13.11	13013
FedPA	0.002810	11377	12.85	13028
FedProx	0.002794	11442	12.98	13040
FedSGD	0.002812	11368	12.13	13053

1) Inference time: In terms of inference time, FedProx and FedPA are the fastest (2.8 ms/image), achieved by lightweight parameter updates and subsequently reduced model divergence during training. FedAvg comes in at 3.4 ms, likely due to model instability because of noisy client aggregation.

2) Throughput: FedProx attains the highest throughput (11,442 images/s) closely followed by FedPA (11,376) and FedSGD (11,368). These models benefit from efficient forward pass computation; besides, FedPA benefits from stabilized model updates that prevent computational spikes during testing. FedAvg, with a throughput of 9338, is thus lower due to its slow inference time and an increase in computational load.

3) CPU usage: FedSGD is the lightest on the CPU (12.13%), followed by FedPA (12.85%). Their minimal effort on steep client-side operations and sparse updates reduces compute requirements, thus lending themselves to edge environments. The higher CPU usage of FedAvg (13.15%) is likely due to its dense parameter averaging additionally worsened by client drift in non-IID settings.

4) Memory usage: Models cluster around 13 GB, with FedSGD (13.05 GB) and FedPA (13.11 GB) being somewhat lighter on memory. Since the overhead of memory and CPU power is manageable, these systems may also be deployed on a resource-limited scenario like mobile clinics (Fig. 12).

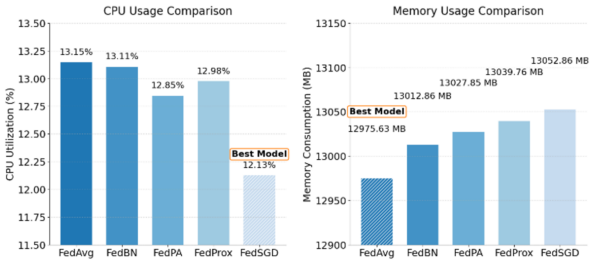

Fig. 12. Relative comparison of system resource usage between models with CPU usage and memory usage set side by side to emphasize the computational efficiency of the models.

B. Summarized Key Insights

We combine performance measures and systems metrics to identify the best model, lightest model, and most balanced model.

1) Best performing model: FedPA is characterized by high accuracy, recall, and F1 scores with low inference time and moderate resource consumption. Its inclusion strategy includes only reliable updates in the global model computation, thereby increasing the robustness of the FedPA in non-IID settings.

2) Most lightweight model: The FedSGD is by far the most lightweight in terms of CPU and memory resource consumption while still keeping throughput at a high level. It does have slightly less accuracy in the classification realm, but it is best suited for scenarios where resource constraints apply.

3) Most balanced model: FedPA, once again, sets the mark by balancing state-of-the-art accuracy with reasonable performance metrics. FedPA considers both efficiency and accuracy in diagnosis, a crucial capability for healthcare AI. In contrast, FedProx sacrifices accuracy for throughput (Fig. 13).

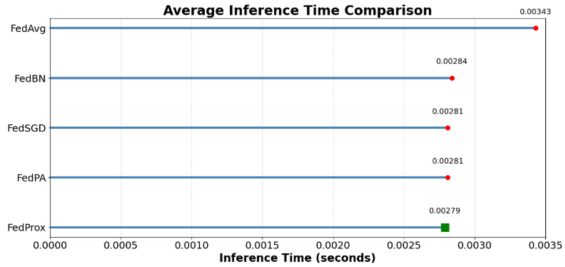

Fig. 13. Spider chart comparison of all eight test measures across all the models with a focus on the general predominance of FedPA regarding predictive performance, system efficiency, and consumption of resources.

C. Strengths of FedPA in Federated Learning

It is performance-aware aggregation that FedPA relies on for its superiority, where applying the client changes under a local accuracy condition of 85% would filter out updates and speed convergence, all while not falling into the trap of overfitting for the dominant client distribution.

Unlike FedAvg and FedProx, which accept all updates equally, FedPA selectively amplifies clients not by each, but only by those contributing meaningfully to learning and thus reducing negative transfer-the well-known problem of non-IID federated settings. It is both economical of communication bandwidth use, and doesn't waste computation cycles on low-quality updates; it is hence scalable and robust.

High recall and F1-score metrics further justify the clinical relevance of FedPA, especially in contexts where increased false negatives can lead to fatalities. Moreover, it is extremely stable across rounds and generalizes strongly; hence, it is earmarked for federated medical applications in which the parameters of accuracy and reliability are critical.

VII. Conclusion

This study introduced Federated Performance-Based Averaging (FedPA), a performance-aware federated learning approach designed to address challenges of data heterogeneity, variable client performance, and privacy concerns in medical imaging. Unlike traditional aggregation strategies such as FedAvg, FedProx, and FedSGD, which combine all client updates indiscriminately. FedPA selectively incorporates only high-performing client models based on a predefined accuracy threshold. This strategy helps to mitigate the negative impact of undertrained or noisy clients on global model performance.

In the context of COVID-19 chest X-ray classification, FedPA consistently outperformed other federated algorithms across all major evaluation metrics, achieving the highest accuracy, recall, and F1-score. It also demonstrated faster convergence and greater training stability, with reduced performance fluctuations and better retention across both strong and weak clients.

Looking ahead, several enhancements can further strengthen FedPA. These include adaptive thresholding that dynamically adjusts performance criteria across training rounds, and techniques to handle label noise through confidence-based filtering. Incorporating federated hyperparameter optimization methods may improve

convergence and fairness, while expanding to multi-modal data such as CT, MRI, and electronic health records could broaden the model's clinical utility. Real-world validation across geographically diverse hospital networks would also be essential to assess FedPA's scalability, generalization, and equity in healthcare delivery.

Overall, FedPA represents a significant advancement for privacy-preserving federated learning in healthcare. Its strong diagnostic performance, stability, and system efficiency make it a practical candidate for deployment in real-world clinical environments where centralized data access is limited.

A. Future Work

In this study, the evaluation of the proposed FedPA framework primarily focused on accuracy as the performance threshold for client selection. While this provided promising improvements in robustness and convergence, accuracy alone may not sufficiently capture the impact of class imbalance, which is a common challenge in medical imaging tasks. As part of future work, we aim to extend the thresholding mechanism by incorporating the F1-score alongside accuracy, thereby ensuring that both precision and recall are adequately considered in performance-based aggregation. This dual-metric approach will allow the framework to better handle skewed class distributions and minority class detection. Additionally, we plan to design adaptive selection strategies that dynamically choose the most suitable performance metric (e.g., accuracy, F1, precision, recall, or AUC) depending on the dataset characteristics and clinical context. Beyond this, ablation experiments will be conducted to systematically evaluate the contribution of each component in the FedPA pipeline, enabling us to identify the most effective configurations for stability and generalization. Ultimately, these enhancements aim to finalize FedPA into a robust, performance-aware federated learning algorithm that is well-suited for real-world commercial deployment in healthcare AI applications.

Author Contributions

Atif Mahmood and Tashin Khan Sadique are the main contributors to the conceptualization, methodology, and manuscript preparation. The remaining authors contributed to data analysis, validation, and review of the manuscript.

Data Availability Statement

The study utilized publicly available datasets. The dataset and corresponding code will be made available upon reasonable request.

***Abstract*—With the growing emphasis on lifelong education and the rapid expansion of open education platforms, the secure and efficient management and sharing of lifelong learning data have become critical challenges. To address these issues, this paper proposes a Privacy-Preserving Educational Data Sharing (PPEDS) scheme based on blockchain technology. The PPEDS scheme employs attribute-based encryption with hidden attributes to achieve privacy-preserving and fine-grained access control. In addition, it incorporates multi-keyword searchable encryption to enable efficient encrypted data retrieval and combines private and consortium blockchains to ensure data authenticity and integrity across multiple educational institutions. The security analysis demonstrates that the scheme resists potential attacks and ensures confidentiality, access control, and search privacy under a semi-trusted model. Furthermore, performance evaluations conducted on real-world educational datasets show that the proposed scheme achieves efficient encryption, search, and decryption operations, with low computational overhead even in large-scale deployments. Overall, the PPEDS scheme provides a secure, scalable, and practical solution for privacy-preserving data sharing in lifelong education systems.**

Keywords*—Consortium blockchain; access control; secure search; life-long education; data sharing

I. Introduction

Lifelong education integrates various forms of learning that individuals receive at different stages of life and is becoming increasingly important in the rapidly developing knowledge-based society [1]. With the advancement of information technology, open education platforms have become a powerful tool for promoting lifelong learning, providing flexible access to educational resources from different institutions and regions [2], [3]. However, traditional approaches to educational data management are hampered by problems such as isolated data silos, limited transparency, and fragmented information systems [4]. These limitations pose significant obstacles to the recognition and portability of learning achievements, thereby affecting the overall effectiveness of the lifelong learning ecosystems. With the rapid development of lifelong education and open education platforms, the management and sharing of educational data have become increasingly complex and critical. The flow of students between different educational platforms and educational institutions, especially the needs of cross-school elective courses, credit certification, transcript verification, etc., has made cross-platform sharing of educational data an urgent need. Therefore, secure data sharing and privacy protection are essential to promote the healthy development of information technology in lifelong education.

*Corresponding author.

Blockchain technology has the characteristics of decentralization, immutability and transparency [5] and has been widely regarded as a transformative solution for secure data management and sharing. Blockchain can achieve secure storage of data, access control and privacy protection, while improving the transparency and credibility of data sharing. Recent studies have explored various applications in fields such as healthcare and finance, aiming to address challenges in data security, privacy, and cross-institutional data interoperability [6], [7].

Although extensive research has explored secure data sharing based on blockchain in domains such as healthcare, transportation, and the Internet of Things (IoT), relatively few studies have focused specifically on educational data sharing. Unlike other application areas, educational data presents unique challenges. It often involves multiple stakeholders—including students, teachers, educational institutions, and government bodies—with complex relationships and frequent data updates. Additionally, educational data is heterogeneous in format, privacy-sensitive, and typically distributed across different platforms, making secure, traceable, and fine-grained access control particularly difficult. Moreover, practical requirements such as cross-institutional credit recognition, transcript verification, and course-based access control necessitate flexible and scalable sharing mechanisms that are not well addressed by existing solutions. In recent years, some progress has been made toward blockchain-enabled educational systems. Huang et al. [8] developed a blockchain-based education data management system that integrates private and consortium blockchains to enhance data security and traceability. Marouan et al. [9] proposed a blockchain-based framework for managing educational credentials and supporting lifelong learning, emphasizing decentralized trust and certificate verification. However, these works mainly focus on identity and credential management, lacking technical details on fine-grained access control, privacy-preserving queries, and efficient data retrieval. Therefore, there is an urgent need to develop a comprehensive and secure data-sharing scheme tailored for educational environments.

Overall, existing research provides a variety of secure and private data sharing methods, but there is still a lack of specific solutions for educational data sharing, and these solutions have certain limitations, such as the lack of fine-grained access control, efficient user decryption, and practical multi-keyword search. In response to these limitations, we propose a privacy-preserving education data sharing scheme based on consortium blockchain, named PPDES, providing a comprehensive solution for secure and efficient lifelong education data sharing.

The main contributions and novel features of this paper are as follows:

- By integrating private blockchain and consortium blockchain, the PPEDS scheme addresses the limitations of traditional data management, ensuring data legitimacy, traceability, and enabling secure data sharing across educational platforms.
- The PPEDS scheme achieves fine-grained access control through multi-authority CP-ABE, allowing each educational platform to manage user attributes independently, while hidden attributes and user anonymity enhance access security.
- Based on public key searchable encryption, the PPEDS scheme supports efficient multi-keyword search. After searching, the consortium blockchain can perform pre-decryption for users who meet access policies, significantly reducing user computation.

The rest of this paper is organized as follows: Section II discusses the system model, threat model, and design goals. Section III introduces the problem formulation. Section IV details the preliminaries. The PEDD system is given in Section V. Sections VI and VII discuss security and performance analyses, respectively. Finally, Section VIII concludes the paper.

II. Related Work

In recent years, blockchain technology has been widely applied in the field of privacy-preserving data sharing across various domains, including healthcare, IoT, and transportation.

Zheng et al. [10] proposed a scalable privacy-preserving data sharing scheme based on blockchain, which utilizes a (p, t) threshold Paillier cryptosystem to enforce user access control. Li et al. [11] introduced a blockchain-based IoT data sharing scheme with privacy protection and a reward mechanism, where signature exchange is used to implement access control. Li et al. [12] designed a privacy-preserving method for IoT medical systems based on blockchain and lightweight secret sharing, combining decentralization and data confidentiality to facilitate secure sharing among institutions. In another work, Li et al. [13] proposed a privacy-preserving flight operation data sharing scheme using zero-knowledge proofs and proxy re-encryption to realize secure access control.

Although these schemes adopt lightweight access control mechanisms, they generally lack fine-grained expressiveness and exhibit limited efficiency when applied to educational environments involving a large number of users and roles.

To address fine-grained access control, Liang et al. [14] presented a personal data protection framework based on consortium blockchain and attribute-based encryption (ABE), enabling secure data sharing among multiple platforms. However, the issue of searchable encryption was not considered in this work, which is crucial for efficient data access in large-scale systems.

In terms of searchable encryption, Jiang et al. [15] proposed an efficient and privacy-preserving data sharing scheme in intelligent transportation systems, employing Bloom filters to support multi-keyword retrieval. Du et al. [16] designed a blockchain-based searchable encryption scheme using both public and private blockchains, where encrypted indexes reside on the private chain and documents are outsourced to the public chain. Their scheme also incorporates access control to improve query efficiency. Niu et al. [17] presented an attribute-searchable scheme based on CP-ABE and blockchain, supporting attribute hiding and multi-keyword search. Liu et al. [18] developed a privacy-preserving medical data sharing framework based on blockchain and ABE, which supports both fine-grained access control and secure keyword search among medical institutions.

However, most of the above solutions have the problem of low efficiency of user decryption or lack of the ability of attribute authorities to independently manage attributes.

While the above works span various application fields such as medical care, IoT, and transportation, there is relatively little research focused on blockchain-based educational data sharing. To fill this gap, Luo et al. [19] propose a blockchain-based education data management system that leverages the strengths of private and consortium blockchains to enhance system security. However, the scheme lacks basic access control and keyword retrieval. Huang et al. [8] developed a blockchain-based educational data management system that leverages both private and consortium blockchains to enhance security. In [9], Marouan et al. present a blockchain-based framework for educational credentials and lifelong learning. They explore the use of a decentralized ledger to issue, store, and verify educational credentials such as course completions, skills certificates, and learning records in a tamper-resistant manner. Their work emphasizes the trustworthiness and interoperability of credentials across institutions, highlighting how blockchain can mitigate fraud and simplify cross-platform verification. However, their schemes still lack mechanisms for fine-grained access control and efficient encrypted search. These limitations highlight the necessity of a specialized security framework tailored to educational data sharing scenarios. Our PPEDS scheme distinguishes itself by addressing these gaps through multi-authority CP-ABE, hidden attributes, efficient searchable encryption, and dual-chain integration.

III. Problem Formulation

A. System Model

The PPEDS scheme involves a large-scale open education platform composed of multiple provincial and municipal education platforms. Each educational platform has its own cloud server and local client, which is typically operated by teachers of the education platform. The registered students also have certain operational permissions, while other registered users only have the right to search and access some public courses. The transcripts and certificates of students, or some paid courses of teachers are encrypted and stored on the platform server. Each educational platform builds its own private blockchain to store the hashes of encrypted content and the keyword indexes. The private blockchains of all participating educational platforms together constitute a consortium blockchain, which is managed by all platforms for cross-institutional collaboration and data sharing. Each platform uploads part of its data, such as the identifier of the private blockchain and keyword indexes to the consortium blockchain.

The system mainly includes five entities: teachers, students, platform servers, private blockchains, and the consortium blockchain. The system model is illustrated in Fig. 1.

Teachers: The users of each education platform are simply divided into two roles: teachers and students. Teachers are typically the data managers of the platform, responsible for evaluating student assignments, exams, etc., and uploading encrypted transcripts and certificates to the platform server, along with generating corresponding keywords for retrieval. Teachers also need to upload their courses. Public courses do not need to be encrypted, and teachers generate keyword indexes and upload them directly. However, some courses are restricted to users with specific attributes. For example, a course of computer major may require students to satisfy {*"Major": "computer science" AND "Passed course": "C language"*} to access it. Teachers also need to generate hash values and signatures for encrypted transcripts or courses and upload them to the private blockchain to generate and broadcast this new transaction. Other nodes on the private blockchain are responsible for verifying the transaction, and if the verification passes, a new block is generated on the private blockchain.

Students: When students search for their grades or courses, they generate the corresponding search trapdoor using the keys assigned to them during registration and the related keywords. To achieve cross-platform interoperability, the search trapdoor is uploaded to the consortium blockchain, where nodes on the consortium execute the search algorithm. Students can only search and access their own transcripts and certificates, and apart from public courses, they can only access courses that are part of their study plan. Grades between different educational platforms can be mutually recognized. To avoid performing complex decryption operations locally, students can generate a temporary key during searches, allowing the platform server to perform pre-decryption operations for the authorized student. In practice, teachers or other registered users can also perform searches and access data, but they should all follow the access permissions of the data owner.

Platform Server (PS): Platform servers are typically large storage and computing servers in the cloud, which are responsible for storing all courses and related content. After storing encrypted transcripts or courses, the PS extracts the block identifiers from the private blockchain, along with the keyword indexes, and generates a signature to construct a new transaction on the consortium blockchain. Other nodes on the consortium blockchain are responsible for verifying the transaction, and if the verification passes, a new block is generated on the consortium blockchain. When the searched content is encrypted data, PS is responsible for pre-decrypting it for the user before returning the content.

Private Blockchain (PB): Teachers upload the hash values of encrypted transcripts or courses, keyword indexes, and their signatures to the PB, creating a new transaction. Nodes on the PB verify the signature to ensure it was legally generated by the teacher, and then generate a new block on the PB. The data structure of PB is shown in Fig. 2.

Consortium Blockchain (CB): The nodes on the CB are responsible for executing the search algorithm. If the search is successful, the nodes on CB extract the security index from the block to obtain the block identifier of the PB. Using the block identifier from the PBn, they retrieve the ciphertext hash and provide it to the corresponding PS. After confirming hash consistency, the PS uses the temporary key provided by the user to perform pre-decryption on the ciphertext and returns the pre-decrypted content to the consortium blockchain nodes, which then return to the search user. The data structure of CB is shown in Fig. 3.

B. Threat Model

Assuming the educational platform servers and the computers of teachers or students are semi-trusted, which means that they are trusted in most cases but may still be at risk of being compromised. Attackers may eavesdrop on the information being transmitted through communication channels, such as security indexes, encrypted course content, and search trapdoors. Additionally, clients and servers are not allowed to collude to infer the real identity of users.

The PB is managed by multiple administrators within the educational platform. This multi-administrator setting prevents single-point control and enhances the security of the private blockchain. In this semi-trusted environment, each administrator is assumed to be independently trusted, and they do not collude to tamper with data or engage in malicious behaviors.

The CB is managed by multiple educational platforms, with each platform participating in its management and maintenance, sharing part of the data, and achieving cross-platform interconnection. We assume that the nodes of these platforms do not collude with each other to ensure the security and integrity of the consortium blockchain data.

C. Design Goals

Based on the semi-trusted assumptions and potential attack risks described in Section 2.3, the security objectives are as follows:

1) Data security and access control: Sensitive data must be encrypted, and data owners should have the freedom to define access control policies, ensuring that only users who meet the specified criteria can access the data.

2) Privacy protection: Attributes in access control policies must not reveal sensitive user information, and ciphertext should be resistant to DDH testing to ensure recipient anonymity.

3) Secure search: Indexes and queries should remain encrypted, and searches should be performed by designated trusted nodes to prevent attackers from obtaining the true keywords during the search process.

4) System availability: Consistency in the private blockchain is achieved through the verification of signatures from internal administrators, while the consortium blockchain's consistency is maintained through platform signature verification, neither of which involves sensitive information.

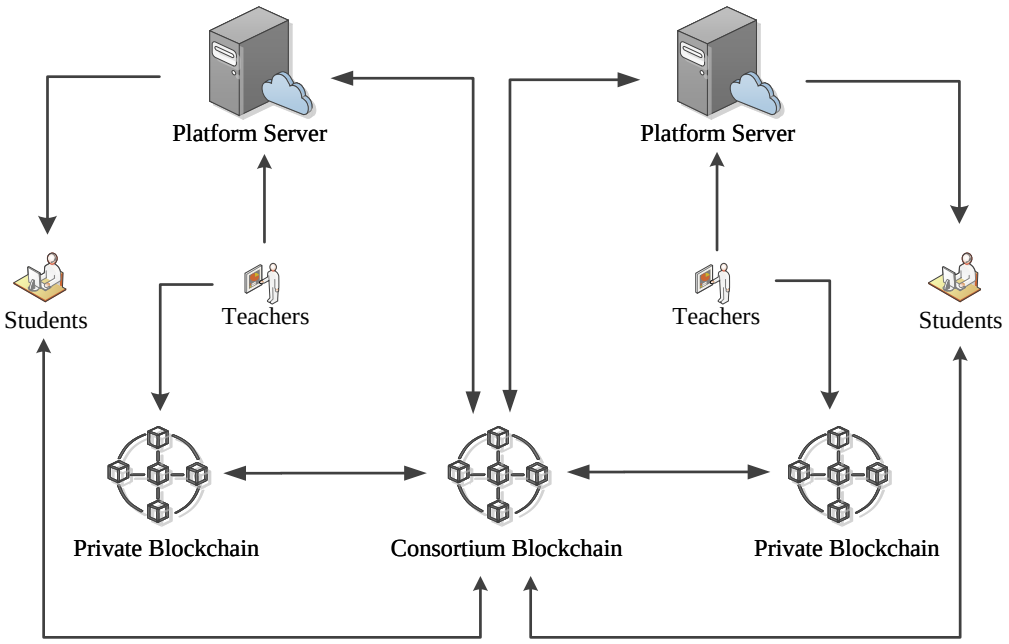

Fig. 1. System model.

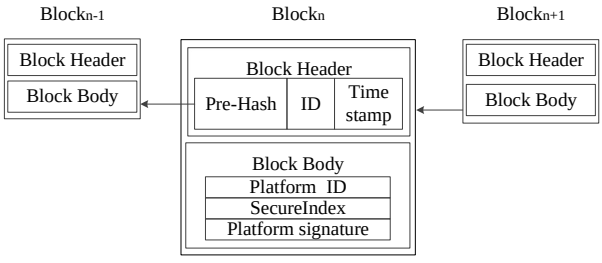

Fig. 3. Data structure of consortium blockchain.

IV. Preliminaries

A. Attribute-Based Encryption

Attribute-Based Encryption (ABE) [20] is a public key encryption scheme that allows users to encrypt and decrypt data based on a set of attributes. The main advantage of ABE is that it enables fine-grained access control and allows flexible data access management. There are two main types of ABE: Key-Policy ABE (KP-ABE) [20] [21] and Ciphertext-Policy ABE (CP-ABE)[22].

- KP-ABE: In KP-ABE, the access policy is embedded in the secret key, while the ciphertext is labeled with attributes.
- CP-ABE: In CP-ABE, the access policy is embedded in the ciphertext, while the secret key is associated with attributes. This allows the data owner to define who can access the encrypted data, making CP-ABE well-suited for fine-grained access control.

Formally, let G be a cyclic group of prime order p, and g be its generator. During the system setup, public parameters and a master key are generated. For each attribute i, a secret key component is generated using a random value. The decryption key is derived based on the attributes they possess. The encryption function takes a message M, an access policy A, and outputs a ciphertext C. The decryption function allows a user to recover the message M if their attributes satisfy the policy A.

B. Searchable Encryption

Searchable Encryption (SE) [23] is a cryptographic Primitive that allows encrypted data to still support keyword-based search. SE enables the platform to store data in encrypted form while allowing users to search over it without revealing sensitive information. The main components of SE include:

1) Index encryption: The data owner encrypts the index keyword w as I_w. The encrypted index I_w is then uploaded to the server.

2) Trapdoor generation: To search for a keyword w', the user generates a trapdoor $T_{w'}$.

3) Search: The server uses the trapdoor T_w to search through the encrypted index $\{I_w\}$. When $w = w'$, the server returns the matching content to the user without learning the specific information of w or w'.

C. Blockchain

Blockchain [24] is a distributed ledger technology that provides data integrity, security, transparency, and immutability through decentralized consensus mechanisms. It allows records to be securely stored in linked blocks, making it nearly impossible to alter data once added.

Blockchain can be classified into three main types: public blockchain, private blockchain, and consortium blockchain. Public blockchains are open to everyone, allowing anyone to participate in the consensus process. Private blockchains are restricted to specific participants, typically managed by a single organization, and provide more control over the data. Consortium blockchains are semi-decentralized, managed by a group of institutions, and are ideal for collaborative projects.

V. The Privacy-Preserving Education Data Sharing (PPEDS) Scheme

The PPEDS scheme specifically includes setup, key generation, encryption, blockchain generation, trapdoor generation, search, and decryption. The specific description of each algorithm is as follows.

A. Setup

The setup of the system is to generate some necessary public parameters. First, it selects a security parameter κ. Then, a multiplicative cyclic group G of prime number p order is selected, where g is its generator. Each user entering the system is assigned an identity ID, which can be composed of any string. The ID can be mapped to G using the function H_1. Each user role has its attributes, such as $\{\text{“}major\text{”} : \text{“}mathematics\text{”}\}$, and they are all expressed in the form of $\{attributename : attributevalue\}$. The function H_1 can also map the attribute value to G. Define a function H_2 to map the attribute back to the authority that manages the attribute. In general, the public parameters include $\{p, G, g, H_1, H_2\}$.

Next, each authority generates a pair of public and private keys. Assume that the authority picks four random numbers $\alpha, \beta, \gamma, \sigma \in Z_p$ as its private key. Then, it calculates $e(g,g)^{\alpha}, g^{\beta}, g^{\gamma}, g^{\sigma}$ as its public key and publishes them.

B. KeyGen

Each authority (i.e., each educational platform) distributes corresponding attribute keys to registered users with different roles (teachers, students, administrators, etc.) in the system.

Suppose an authority needs to generate an attribute key for a student named Alice, whose attribute is $v_\chi \in V_a$, where V_a is Alice's attribute set. Each authority responsible for V_a needs to generate a corresponding attribute key for the user. For example, if Alice is a teacher at platform PS_1 but is also a student in a specific course at platform PS_2, both PS_1 and PS_2 need to generate attribute private keys for Alice. Where ID_a is Alice's identifier, which can be composed of any string. We will use ID_a below to represent a student user like Alice.

$$\begin{aligned} & sk_{ID_a, v_\chi} \\ =&\{sk_1 = g^{\frac{\alpha}{\gamma}} H_1(ID_a)^{\frac{\beta}{\gamma}} H_1(v_\chi)^{\frac{\sigma}{\gamma}}, \\ & sk_2 = H_1(v_\chi)^{\frac{\sigma}{s}}, sk_3 = g^{\sigma}\} \end{aligned} \tag{1}$$

Obviously, all the keys related to $v_\chi \in V_a$ composes the attribute key $sk_a = \{sk_{ID_a,v}\}$. Each successfully registered student will receive a search key s distributed by the system to generate a search trapdoor.

C. Enc

The teacher extracts keywords (such as student name, ID, and subject) from course grades and encrypts them, and also extracts keywords from some non-public courseware and other learning content and encrypts them before uploading them to the platform server. Attribute-based encryption ensures that only students who meet the access policy specified by the teacher can decrypt the content.

1) FileEnc: Suppose the teacher needs to upload Alice's mathematics transcript T_a and only allow Alice and other teachers can access it. For the sake of generalization, assume that this specific access policy is represented by (A, f, Val_p). Here $A \in Z_p^{c \times d}$ is an access matrix, and f is a function that maps rows in A to attribute names. Let $Val_p = v_{f(1)}, \cdots, v_{f(c)}$ represent the corresponding attribute value. Among them, Val_p contains specific attribute values, such as the student's name or ID, which needs to be kept private, and the other parts of the access policy need to be uploaded with the ciphertext.

A function η is also defined to map the rows of A to the authorities, that is, $\eta(\cdot) = H_2(f(\cdot))$. Then, select some random numbers in Z_p and generate two vectors $\vec{a} = (z, a_2, \cdots, a_d)^{\top}$ and $\vec{b} = (0, b_2, \cdots, b_d)^{\top}$. According to LSSS [20], $a_i = A_i \vec{a}$ and $b_i = A_i \vec{b}$, where A_i represents the ith row of A.

For each $i \in [1, c]$ in A, randomly select $r_i, r_i' \in \mathbb{Z}_p$. The encrypted R is as follows:

$$\begin{aligned} & CT_0 = T_a e(g,g)^z, \\ \forall i \in [1,c], \quad & \{CT_{1,i} = g^{a_i} g^{\alpha_{\eta(i)} r_i}, CT_{2,i} = (g^{\gamma})^{-r_i}, \\ & CT_{3,i} = (g^{\delta})^{r_i - r_i'}, CT_{4,i} = g^{\beta_{\eta(i)} r_i} g^{b_i}, \\ & CT_{5,i} = H_1(v_{f(i)})^{r_i'}\} \end{aligned} \tag{2}$$

The ciphertext $CT = \{(A, f), CT_0, \{CT_{1,i}, CT_{2,i}, CT_{3,i}, CT_{4,i}, CT_{5,i}\}_{i \in [1,c]}\}$.

2) IndexEnc: The teacher selects several keywords such as $W = \{Alice, ID_a, Mathematics\}$, and choose a random number $\tau \in Z_p$ and encrypts them as:

$$\begin{aligned} I_1 &= e(g,g)^{\tau} \\ I_2 &= g^{s\tau} \\ I_w &= \{g^{\tau H(w)}\}_{w \in W} \end{aligned} \tag{3}$$

The encrypted index is $I = I_1, I_2, I_w$. Then the ciphertext CT is sent to PS, and the hash value of CT, the encrypted index I, and the signature of the teacher are all uploaded to the PB.

D. BlockGen

Teachers on each education platform upload data to their private chain, and each education platform integrates the data from the private chain into the alliance chain.

1) PriBlockGen: The teacher constructs a new transaction using the keyword index, teacher ID, and teacher signature, then broadcasts the transaction to the PB of the education platform. Upon receiving the new transaction, the verifiers on the PB verify the signature in the transaction. If it is valid and confirms that the content was legally created by an authorized teacher, a verification confirmation message is broadcast. When more than 2/3 of the verifiers confirm, the PB accepts the new transaction and generates a new block. Otherwise, the new block is rejected.

2) ConBlockGen: The platform server extracts the ID and keyword index from each new block of its PB to generate a security index. The PS constructs a new transaction using the security index, platform ID, and platform signature, then broadcasts the transaction to the CB. Upon receiving the new transaction, the verifiers on the CB verify the signature of PS. When more than 2/3 of the verifiers confirm, a new block is then generated, ensuring the legitimacy of the content across platforms.

E. TrapGen

When student ID_a wants to search for something of interest, such as her mathematics course transcript, a trapdoor T_w is generated, where w' is the keyword.

$$T_w = g^{\frac{1}{H(w')+s}} \tag{4}$$

If there is more than one keyword of interest, the trapdoor is generated as:

$$T_w = g^{\frac{1}{\sum_{w'=1}^{n} H(w')+s}} \tag{5}$$

If ID_a wants to get the pre-decrypted search results, she also needs to select a random number $t \in Z_p$ to generate a temporary key sk'_a and upload it with the trapdoor. Specifically, sk'_a is calculated as follows.

$$\begin{aligned} sk'_a =& \{sk'_{ID_a, v_\chi}\} \\ =& \{\{sk'_1 = sk_1^{\frac{1}{t}}, sk'_2 = sk_2^{\frac{1}{t}}, sk'_3 = sk_3^{\frac{1}{t}}\}, \\ & ID' = H_1(ID_a)^{\frac{1}{t}}, g^{\frac{1}{t}}\} \\ =& \{\{sk'_1 = g^{\frac{\alpha}{t\gamma}} H_1(ID_a)^{\frac{\beta}{t\gamma}} H_1(v)^{\frac{\sigma}{t\gamma}}, \\ & sk'_2 = H_1(v)^{\frac{\sigma}{t\delta}}, sk'_3 = g^{\frac{\sigma}{t}}\}, \\ & ID' = H_1(ID_a)^{\frac{1}{t}}, g^{\frac{1}{t}}\} \end{aligned} \tag{6}$$

F. Search

The node on the CB calculates and verifies whether the equation $e(I_2 \cdot \prod_{i=W} I_w, T_w) = I_1$ holds. If so, the Platform ID is obtained. The corresponding PB is accessed through the ID to obtain the hash value that can be used to generate the ciphertext. The platform server compares the ciphertext CT and returns it to the node on the CB. The specific calculation process is as follows.

$$\begin{aligned} & e(I_2 \cdot \prod_{w \in W} I_w, T_w) \\ =& e(g^{s\tau} \cdot \prod_{w \in W} g^{\tau H(w)}, g^{\frac{1}{\sum_{w' \in W} H(w')+s}}) \\ =& e(g,g)^{\frac{\tau(\sum_{w' \in W} H(w)+s)}{\sum_{w' \in W} H(w)+s}} \end{aligned} \tag{7}$$

If $w = w'$, the above equation is $e(g,g)^{\tau} = I_1$. The ciphertext corresponding to the index where the equation holds is the search result.

G. Dec

When the search is completed, if ID_a sends a temporary key for pre-decryption, the node on the CB pre-decrypts the ciphertext and sends it to ID_a for final decryption; otherwise, the search results are directly sent to ID_a for decryption by herself.

1) Pre-Dec: If the attribute value Val_a of ID_a satisfies the access policy (A, f, Val_p) in CT, then CB uses the temporary key sk'_a to help her pre-decrypt CT into $pre\text{-}CT$. Where $i \in minA$ is the minimum set of attributes that satisfy the access policy, and $x_i \in Z_p$ are some constants that satisfy $\sum_{i \in minA} x_i A_i = (1, 0, \cdots, 0)$.

$$\begin{aligned} & \prod_{i \in minA} (e(g^{\frac{1}{t}}, CT_{1,i}) \cdot e(sk'_1, CT_{2,i}) \cdot e(sk'_2, CT_{3,i}) \cdot \\ & e(sk'_3, CT_{5,i}) \cdot e(ID'_a, C_{4,i}))^{x_i} \\ =& \prod_{i \in minA} e(g^{\frac{1}{t}}, g^{a_i} g^{\alpha_{\eta(i)} r_i}) \cdot e(g^{\frac{\alpha}{t\gamma}} H_1(ID'_a)^{\frac{\beta}{t\gamma}} \\ & H_1(v_\chi)^{\frac{\sigma}{t\gamma}}, (g^{\gamma})^{-r_i}) \cdot e(H_1(v_\chi)^{\frac{\sigma}{t\delta}}, (g^{\delta})^{r_i - r'_i}) \cdot \\ & e(g^{\frac{\sigma}{t}}, H_1(a_{f(i)})^{r'_i}) \cdot e(H_1(ID_a)^{\frac{1}{t}}, g^{\beta_{\eta(i)} r'_i} g^{b_i}))^{x_i} \\ =& \prod_{i \in minA} (e(g,g)^{\frac{a_i}{t}} \cdot e(H_1(ID'_a), g)^{\frac{b_i}{t}})^{x_i} \\ =& e(g,g)^{\sum_{i \in minA} \frac{a_i x_i}{t}} \cdot e(H_1(ID'_a), g)^{\sum_{i \in minA} \frac{b_i x_i}{t}} \\ =& e(g,g)^{\frac{z}{t}} \end{aligned} \tag{8}$$

Then, $pre\text{-}CT = e(g,g)^{\frac{z}{t}}$ is sent to ID_a. Otherwise, the blockchain refuses to pre-decrypt for u. However, if Val_a does not satisfy the access policy contained in CT, CB refuses to pre-decrypt for ID_a.

2) Dec: When ID_a obtains the pre-ciphertext from CB, she just does a simple operation as $\frac{CT_0}{(pre\text{-}CT)^t} = \frac{CT_0}{(e(g,g)^{\frac{z}{t}})^t} = T_a$ to get her transcript.

VI. Security Analysis

Based on the security goals defined in Section III-C, we conduct a comprehensive security analysis of the PPEDS scheme.

A. Data Security and Access Control

The PPEDS scheme ensures data security and fine-grained access control through attribute-based encryption. For example, a teacher defines an access policy such as {*"Major": "computer science" AND "Name": "Alice"*}. With the multi-authority CP-ABE, only users named Alice and majoring in computer science can decrypt the data. The server can provide pre-decryption services for students if the specific access policy is met, ensuring that only authorized users receive the necessary data. Users who do not meet the access policy cannot achieve pre-decryption for them. The specific formal proof can be found in [25].

B. Privacy Protection

Privacy protection is achieved by minimizing the exposure of user attributes and ensuring anonymity. The system ensures that the attributes in the access policies do not leak sensitive user information. For example, the access policy is {*"Major": "computer science" AND "Name": "Alice"*}, where {*"Major": "computer science" AND "Name": "Alice"*} is uploaded to the education platform server along with the ciphertext, and the specific major information and name are not displayed in the ciphertext. Therefore, obtaining the ciphertext will not obtain the specific attribute value, thereby protecting user privacy. In addition, the ciphertext can also resist the Decisional Diffie-Hellman test (DDH-test) [26], making it infeasible for attackers to infer information about the recipient through brute-force methods. This ensures that users maintain anonymity during data access, preserving privacy even in a semi-trusted environment.

C. Secure Search

To maintain data confidentiality during searches, the PPEDS scheme uses encrypted indexes and query trapdoors, which are processed by trusted nodes. The secure search mechanism is built on the Identity-Based Encryption (IBE) scheme from [27]. According to the security analysis in [27], the PPEDS scheme also resist Chosen-Keyword Attacks (CKA). By encrypting both indexes and queries, the system prevents attackers from learning sensitive information during the search process. Only trusted nodes execute the search, ensuring that authorized parties can retrieve results while unauthorized entities remain unable to determine the actual keywords involved, thereby maintaining confidentiality.

D. System Availability

System availability is ensured through the use of blockchain-based consistency mechanisms. In the private blockchain, consistency is maintained by verifying the signatures of internal administrators, while in the consortium blockchain, consistency is ensured through platform-level signature verification. These verification mechanisms prevent unauthorized modifications while allowing the system to continue functioning even if some nodes are compromised. The use of consensus protocols helps guarantee that data and system integrity are preserved without leaking sensitive information, ensuring that the system remains available and reliable.

The PPEDS scheme effectively mitigates the risks brought by the semi-trusted environment and ensures data security, privacy protection, secure search, and high system availability. By adopting attribute encryption-based access control, secure search mechanism, and blockchain-based consistency check, the system provides strong protection against unauthorized data access and ensures user privacy even in the face of potential attacks.

VII. Performance Analysis

First, we compare and analyze the characteristic performance of several data sharing schemes in Table I. The comparison shows that only the PPEDS scheme fully supports multi-keyword search, pre-decryption, hidden attributes and decentralized authorities. Its features enhance its applicability in complex scenarios such as lifelong education platforms, which require flexible and secure data sharing.

Then, we analyze the theoretical time complexity of the major algorithms, and use several time-consuming operations to represent them. E represents the exponential operation in the group G, E_T represents the exponential operation in the group G_T, and P represents the bilinear pairing operation. As shown in Table II, n_a represents the number of attributes, and n_k represents the number of keywords. The time complexity of TrapGen, Search, and Dec is nearly fixed. The time complexity of EileEnc and pre-Dec is proportional to the number of attributes in the access policy, while the time complexity in IndexEnc is linearly related to the number of keywords to be encrypted.

TABLE I. Feature Comparison

schemes	F1	F2	F3	F4	F5	F6
[10]	personal data	×	×	×	×	×

[18]	Medical	✓	✓	✓	✓	×
[8]	Education	✓	×	×	×	×
PPEDS	Education	✓	✓	✓	✓	✓

Note: F1: Application Background; F2: Fine-grained access control; F3: Keyword search; F4: Pre-decryption; F5: Hidden attributes; F6: Decentralized authorities.

Compared with two typical scheme [17], [18], which are two schemes proposed in the medical field that supports keyword search and attribute hiding, the PPEDS scheme takes longer than the [18] scheme in the FileEnc stage. This is because the PPEDS scheme not only supports hiding attributes, but also supports distributed attribute authorities to manage attributes, and can realize user anonymity. Complex operations bring a safer and more private user experience. The two schemes embed access control into the search process, that is, only users whose attributes meet the policy can search. This results in the search part being secure but too inefficient in actual use, making it unsuitable for sharing educational

TABLE II. TIME COMPLEXITY COMPARISON

Algorithms	FileEnc	IndexEnc	TrapGen	Search	Dec
[17]	-	$(2n_a+6)E+P$	$(2n_a+n_k+2)E$	$(2n_a+n_k+2)P+E$	-

data. The high efficiency demonstrated by the PPEDS scheme highlights its practicality and suitability in the educational data sharing model.

We test the actual operational efficiency of various algorithms in the PPEDS scheme using Python on a real dataset. The data set is the encrypted transcripts of students majoring in computer science and technology, civil engineering, finance, law, and pharmacy at Hebei Open University in 2020. 100 students are randomly selected from each major, and 10 courses are selected for each major, totaling 5,000 transcripts. All experimental results were obtained using a personal computer with an Intel Core i5-1340P CPU (4.60GHz) and 16GB of memory.

A. FileEnc

Fig. 4 shows the time cost of FileEnc algorithm that the teacher executed using a multi-authority CP-ABE-based algorithm. The horizontal axis represents the number of attributes used in the access policy, ranging from 2 to 10, while the vertical axis represents the time required for encryption. As can be seen from the figure, the time required for file encryption increases linearly with the number of attributes. Although using more attributes in the policy can enhance the granularity and security of access control, it also leads to increased computational overhead. Therefore, a balance must be struck between security requirements and encryption efficiency to avoid performance bottlenecks, especially in scenarios involving a large number of attributes.

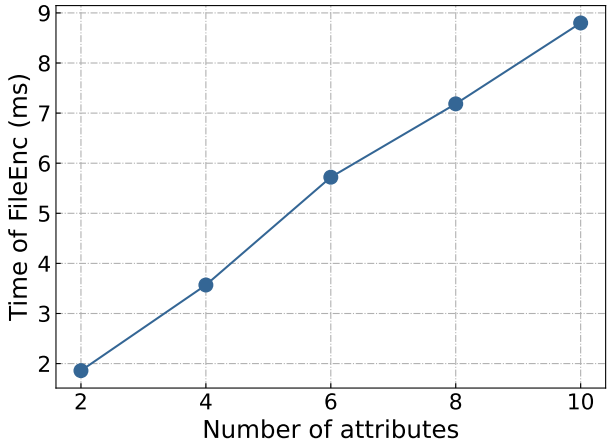

Fig. 4. Time cost for FileEnc.

B. IndexEnc

Fig. 5 presents the time cost of the IndexEnc algorithm. The horizontal axis represents the number of keywords involved in the index, ranging from 2 to 10, while the vertical axis represents the time required for encryption. The figure shows that the encryption time increases linearly as the number of keywords increases. That is, the computational complexity of index encryption is proportional to the number of keywords included in the index. Although adding more keywords can improve data retrieval efficiency and search accuracy, it also leads to increased computational overhead. Therefore, it is crucial to optimize the number of keywords used during indexing to balance search performance and encryption efficiency, especially when dealing with large amounts of encrypted data.

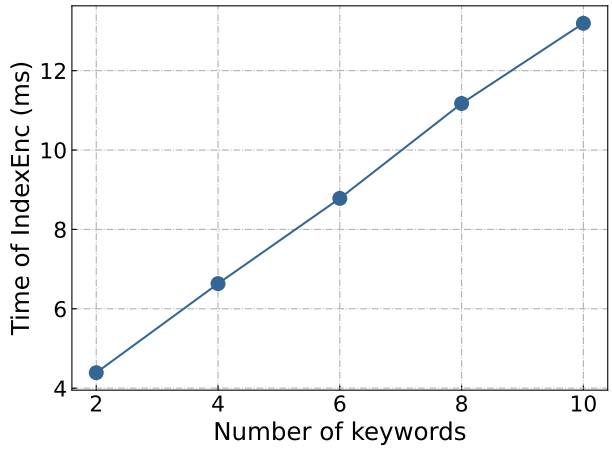

Fig. 5. Time cost for IndexEnc.

C. TrapGen

Fig. 6 illustrates the time cost of the TrapGen algorithm, which represents the time taken to generate a trapdoor for an encrypted search by the searcher. The horizontal axis shows the number of keywords, ranging from 2 to 10, while the vertical axis represents the time required to generate the trapdoor. As can be seen from the figure, the time cost of generating the trapdoor remains relatively constant regardless of the number of keywords involved. This shows that the trapdoor generation process in the PPEDS scheme is efficient and scalable even as the number of keywords increases. The stable performance of the TrapGen operation means that users can search with multiple keywords without significantly increasing the computational overhead. This makes the system well-suited for scenarios where users need to search for multiple attributes or terms simultaneously while maintaining efficient response times. However, too many keywords may result in fewer search results, so the users can adjust them according to their needs.

D. Search

Fig. 7 shows the time cost of executing the search algorithm in the PPEDS scheme. The horizontal axis represents the number of keywords used in the search, ranging from 2 to 10, while

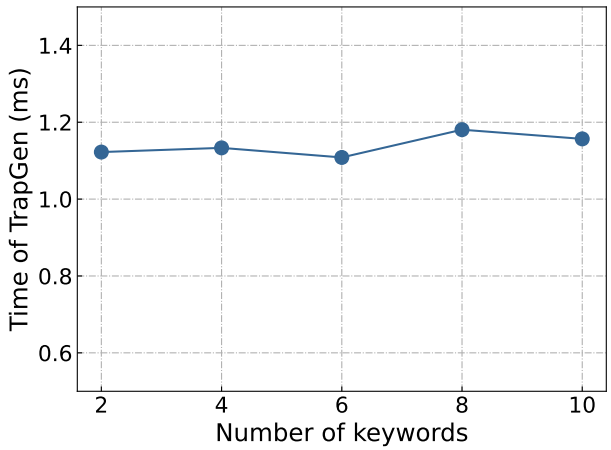

Fig. 6. Time cost for TrapGen.

the vertical axis represents the search time. The figure shows that the time cost of performing the search operation remains relatively constant as the number of keywords increases, and the search process is not significantly affected by the number of search keywords. This consistent performance shows that the proposed search algorithm is both efficient and scalable, even when processing multiple keywords simultaneously. Therefore, the scheme is very suitable for practical applications, and users searching encrypted data using multiple terms will not encounter obvious delays in search efficiency.

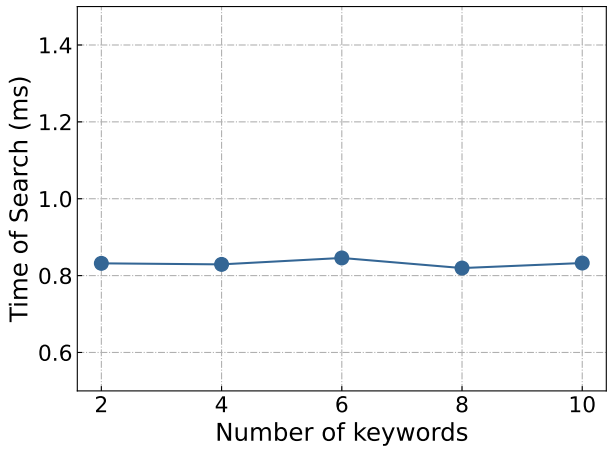

Fig. 7. Time cost for search.

E. Dec

Fig. 8 shows the time cost of the Dec algorithm, comparing the time required for the platform server to perform pre-decryption and the time required for the user to perform the final decryption. The figure includes two graphs: a zoomed-in view to highlight the comparison of the decryption time for the two stages, and a full-scale view that illustrates the overall decryption cost as the number of attributes increases.

The horizontal axis represents the number of attributes involved in decryption, while the vertical axis represents the decryption time. The comparison shows that the pre-Dec performed by the platform server significantly reduces the computational load for the user. In the zoomed-in view, it can be seen that the time cost of the final decryption performed by the user is small and remains almost constant regardless of the number of attributes. In the full-scale graph, the pre-Dec time grows as the number of attributes increases. However, the platform server has powerful computing power and performs the most computationally intensive part of the decryption process, leaving the user with only very small and fixed-time decryption steps. This ensures that the user experiences minimal computational overhead during the decryption process, thereby improving efficiency and maintaining security. By delegating the resource-intensive decryption part to the platform server, the system can strike a balance between user convenience and cryptographic security.

F. Verify by Blockchain

In the PPEDS scheme, the verification process of both private and consortium blockchains relies on the verification of signatures from teachers and educational platforms. We compare three commonly used signature schemes: ECDSA [28], Schnorr [29], and BLS [30] to determine the signature algorithm that best suits different scenarios.

Table III compares the properties of the three schemes, including signature size, speed, and support for aggregation. The ECDSA algorithm has a medium signature size and speed, without support for aggregation, making it suitable for environments where aggregation is not required and moderate signing and verification times are acceptable. Schnorr scheme have a small signature size and support aggregation (e.g., MuSig [31]). BLS scheme has a fixed-size signature and supports native aggregation, which is advantageous in distributed networks like Ethereum 2.0. However, due to high computational cost, BLS is more suitable for scenarios that prioritize aggregation and verification across multiple nodes rather than speed.

Table IV provides the time cost for signing and verification at a security parameter of 256 bits. Overall, for verifying teacher signatures on the private blockchain, Schnorr is preferred due to its small signature size, fast signing and verification times, and support for aggregation. This ensures that the verification process is both efficient and scalable. For the consortium blockchain, where educational platform signatures need to be verified across multiple institutions, BLS signature scheme is recommended. Although BLS has slower signing and verification times, its native support for aggregation makes it suitable for reaching consensus among distributed nodes. This trade-off is acceptable in scenarios where aggregation significantly reduces the number of signatures that need to be processed, thereby improving overall system efficiency.

VIII. Conclusions

This paper proposes the PPEDS scheme, a privacy-preserving data sharing scheme for large-scale, interconnected lifelong education platforms. By integrating private and consortium blockchains, the scheme enables secure, verifiable, and efficient cross-institutional data sharing while preserving user privacy.

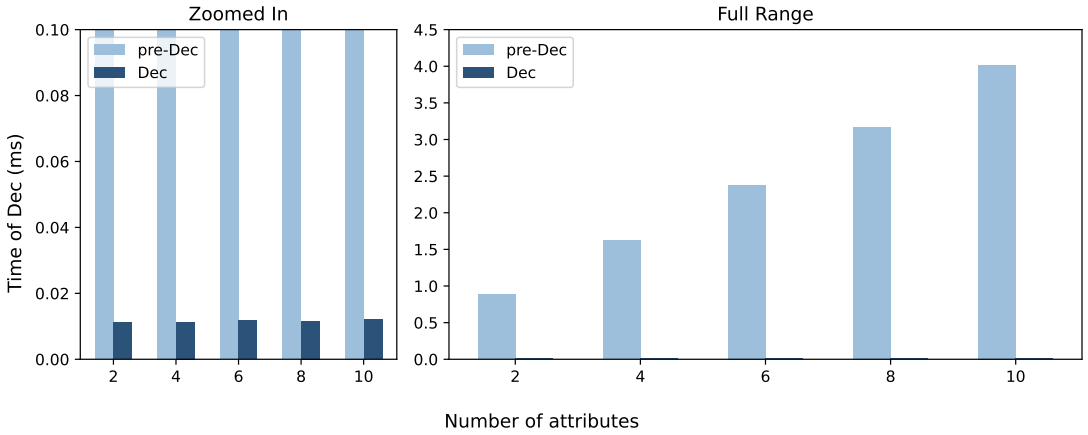

Fig. 8. Time cost for Dec.

TABLE III. FEATURE COMPARISON OF THREE SIGNATURE ALGORITHMS

Schemes	Signature Size	Speed	Aggregation Support	Application Scenarios
ECDSA	Medium	Medium	×	Bitcoin, SSL, TLS
Schnorr	Small	Fast	✓(supports MuSig)	Bitcoin (Taproot), Blockchain
BLS	Fixed-size	Slow	✓(native support)	Ethereum 2.0, Distributed networks

TABLE IV. PERFORMANCE ANALYSIS OF THREE SIGNATURE SCHEMES

Schemes	Sign (ms)	Verify (ms)
ECDSA	0.0903	0.3214
Schnorr	0.0051	0.0078
BLS	4.0647	4.5202

The PPEDS scheme introduces a multi-authority CP-ABE mechanism with hidden attributes to achieve fine-grained access control and user anonymity, allowing each authority to independently manage attribute policies. Additionally, the scheme incorporates public key-based multi-keyword searchable encryption with pre-decryption support via the consortium blockchain, significantly reducing computational overhead for end-users. These innovations collectively enhance the scalability, security, and privacy of educational data sharing.

From a practical perspective, PPEDS addresses real-world challenges in lifelong education systems, such as cross-platform credit recognition, transcript verification, and elective course access. The performance evaluations and comparisons results demonstrate that our pre-decryption mechanism reduces user-side decryption time to only 0.01ms compared to traditional CP-ABE-based systems. The trapdoor generation and search operations maintain sublinear growth with respect to the number of keywords, supporting real-time query capabilities even on resource-constrained devices. In addition, the encryption and index generation overheads remain stable as the number of access attributes increases, showcasing the scalability of the scheme. These metrics highlight the advantage of PPEDS in enabling efficient, scalable, and privacy-preserving data sharing for large-scale educational systems.

However, the current design assumes a semi-honest authority and does not account for collusion among multiple entities. Furthermore, while pre-decryption significantly improves search efficiency, the overhead of storing indexes on the blockchain remains a challenge, potentially impacting scalability over time.

Future work could consider integrating dynamic policy updates and revocation mechanisms to improve flexibility, and optimizing blockchain storage by compressing or pruning index structures to enhance scalability. Furthermore, exploring practical deployments and integration with decentralized identity frameworks will validate the practicality of this solution in real-world educational settings.

RT-DETR Edge Deployment: Real-Time Detection Transformer for Distracted Driving Detection

Fares Hamad Aljahani
Department of Information Systems-Faculty of Computing and Information Technology,
Northern Border University, Rafha 91911, Saudi Arabia

***Abstract*—Distracted driving is one of the primary contributors to road accidents worldwide, highlighting the urgent need for reliable in-cabin driver monitoring systems. Existing approaches often face trade-offs: CNN-based classifiers achieve high recognition accuracy but lack spatial localization, while lightweight real-time detectors sacrifice contextual reasoning for efficiency. To bridge this gap, we propose a customized fine-tuned transformer-based object detection framework, RT-DETR-L, specifically adapted for distracted driving detection. In contrast to prior applications of RT-DETR, our adaptation integrates distraction-specific data augmentation, loss-balancing strategies, and deployment-oriented optimizations, enabling precise classification and spatial localization of distractions such as texting, drinking, yawning, and eye closure. Trained and validated on a large-scale annotated in-cabin dataset, RT-DETR-L achieves state-of-the-art performance with a mAP50 of 0.995 and mAP50–95 of 0.774. In addition the proposed model demonstrates the deployment feasibility on resource-constrained embedded platforms (ARM-based edge AI devices), where the model sustains real-time performance at 17.5 FPS with minimal latency. These results establish RT-DETR-L as a hybrid solution combining the semantic depth of transformers with the efficiency required for Advanced Driver Assistance Systems (ADAS). By addressing both accuracy and deployability, this study makes concrete contributions toward advancing robust, real-time driver monitoring for enhanced road safety.**

Keywords*—RT-DETR; real-time inference; autonomous vehicles

I. Introduction

Road safety remains a critical challenge worldwide, with millions of accidents occurring annually due to human error and unsafe driving practices. Among the most pressing issues, distracted driving has emerged as one of the leading causes of road crashes, injuries, and fatalities. The increasing prevalence of mobile device usage, in-vehicle infotainment systems, and driver multitasking behaviors has made distraction detection a vital component of modern intelligent transportation systems (ITS). To address this challenge, researchers and practitioners are progressively turning to advanced artificial intelligence (AI), computer vision, and deep learning methods to monitor driver behavior and ensure safer roads.

Recent research has emphasized the multifaceted nature of road safety. Mustapha et al. [1] reviewed advancements in traffic simulation, underscoring the role of predictive modeling in mitigating risks, while Papadimitriou et al. [2] introduced the Road-safety-II framework, highlighting systemic and behavioral barriers to enhanced safety visions. Similarly, Festag et al. [3] stressed the importance of vehicle-to-vehicle (V2V) and roadside sensor communication in achieving proactive safety mechanisms, whereas Alparslan et al. [4] explored how novel engineering materials contribute to safer transportation infrastructures. These works indicate that road safety is a multi-layered problem, where infrastructure, communication, and human behavior converge.

The evolution of connected and autonomous vehicles (CAVs) has further highlighted the necessity of intelligent safety frameworks. Malinverno et al. [5] proposed an edge-based framework to improve the safety of connected cars, demonstrating how real-time analytics at the network edge can enhance responsiveness. Zhao et al. [6] developed TSD-YOLO, a traffic sign detection model ensuring robust recognition in autonomous driving scenarios, while Sabir et al. [7] demonstrated YOLO-based CNN architectures to improve vehicle perception in autonomous platforms. Likewise, Al-Qaness et al. [8] presented an enhanced YOLO-based traffic monitoring system, and Charef et al. [9] applied YOLO to automated traffic violation detection. These studies highlight the growing trend of leveraging YOLO and its variants in traffic-related vision applications.

Nevertheless, while numerous works focus on traffic monitoring and vehicle detection, fewer concentrate explicitly on driver distraction. Several YOLO-based approaches have been designed for robust vehicle perception. For example, Zhu et al. [10] introduced MME-YOLO, a multi-sensor, multi-level enhanced YOLO model for vehicle detection in traffic surveillance, while Liu et al. [11] proposed BGS-YOLO, a YOLOv8-based approach for intelligent target monitoring. These efforts reveal the adaptability of YOLO to diverse road safety applications, yet they do not directly target distracted driving behavior.

In contrast, driver distraction detection has become a specialized focus of recent years. Shen et al. [12] introduced StarDL-YOLO, a lightweight YOLO-based algorithm capable of detecting distracted driving behaviors with reduced computational complexity, suitable for real-time applications. Similarly, Poon et al. [13] explored YOLO-based deep learning networks for distraction detection, demonstrating promising detection rates in compliance engineering contexts. Tanaka et al. [14] compared multiple YOLO-based models for distracted driving detection, highlighting trade-offs between accuracy, latency, and hardware efficiency. Sajid et al. [15] proposed an efficient deep learning framework for distracted driver detection using deep CNNs, while Salakapuri et al. [16] advanced the field further with an integrated deep learning framework combining driver distraction detection and real-time road object recognition within advanced driver-assistance systems (ADAS). Together, these contributions underline the

significance of developing accurate, robust, and computationally efficient distracted driving detection models.

Despite these advancements, existing methods face several limitations. First, many YOLO-based approaches, while effective, rely on convolutional backbones that may not optimally capture global context or multi-scale relationships, especially under complex distraction scenarios involving subtle facial or hand movements. Second, lightweight models often trade off accuracy for efficiency, making them unsuitable for deployment in safety-critical environments where false negatives are unacceptable. Third, comparative studies [14] reveal inconsistencies in performance across datasets, highlighting the lack of generalizability of current architectures. Moreover, while integrated frameworks such as that of Salakapuri et al. [16] combine object recognition with distraction monitoring, they remain constrained by traditional detection paradigms and lack the adaptability of transformer-based architectures.

To overcome these challenges, this paper proposes a novel framework for distracted driving detection built upon the Real-Time Detection Transformer (RT-DETR). Unlike conventional CNN-based models, RT-DETR integrates transformer-based attention mechanisms that capture global dependencies while maintaining real-time efficiency. By leveraging this architecture, our framework aims to balance speed, accuracy, and robustness, enabling reliable distraction detection across diverse driving conditions. Furthermore, the proposed system is designed for seamless integration into ADAS, offering an intelligent and scalable solution to enhance road safety.

The rest of this paper is organized as follows: Section II presents the related work. Section III details the proposed methodology. Section IV reports the experimental results. Section V highlights the detection outcomes. In Section VII, a comparative study is conducted. Section VI presents the results of fine-tuned RT-DETRL deployment on edge devices. Lastly, Section VIII concludes the paper and introduces the future work.

II. Related Work

The literature on road safety, intelligent transportation, and driver distraction spans several domains, including infrastructure development, connected vehicle systems, traffic perception, and driver behavior monitoring. This section reviews and critically discusses prior work, categorized into three major directions: (i) infrastructure and communication for road safety, (ii) vehicle and traffic perception using YOLO-based models, and (iii) distracted driving detection approaches.

A. Infrastructure and Communication for Road Safety

Mustapha et al. [1] highlighted the importance of traffic simulation for predictive road safety, showing how simulation tools can model accident scenarios and evaluate mitigation strategies. However, simulation-based studies often remain abstract and may lack integration with real-world sensing frameworks. Papadimitriou et al. [2] provided the Road-safety-II perspective, which advocates for systemic safety beyond traditional interventions. While visionary, such frameworks face practical barriers, including behavioral resistance and limited implementation scalability. Festag et al. [3] contributed to V2V and roadside communication systems, which enable cooperative awareness among vehicles. Despite their potential, these systems depend heavily on reliable communication infrastructure, which may not be feasible in all regions. Alparslan et al. [4] discussed additive manufacturing of materials for safer roads and vehicles, but their contribution is largely material-science oriented and does not directly address behavioral aspects such as distraction. Together, these works underline the multifactorial nature of road safety, yet none directly confront the issue of driver distraction detection.

B. YOLO-Based Models for Vehicle and Traffic Perception

Several works have leveraged YOLO to enhance perception in traffic environments. Zhao et al. [6] developed TSD-YOLO for robust traffic sign detection, ensuring reliability in autonomous driving. Similarly, Sabir et al. [7] used YOLO-based CNNs for autonomous vehicle safety, while Al-Qaness et al. [8] improved traffic monitoring systems with YOLO. Charef et al. [9] applied YOLO to automated traffic violation detection, and Zhu et al. [10] proposed MME-YOLO, which integrates multi-sensor data for robust vehicle detection. More recently, Liu et al. [11] introduced BGS-YOLO, leveraging YOLOv8 for intelligent road target monitoring. Although these studies showcase the adaptability of YOLO to traffic-related applications, their primary focus is on external traffic entities rather than internal driver states. Thus, while effective in vehicle and infrastructure monitoring, they do not directly address distraction-related risks.

C. Distracted Driving Detection Approaches

Research specifically targeting distracted driving has accelerated in recent years. Shen et al. [12] introduced StarDL-YOLO, a lightweight model balancing detection accuracy and efficiency, but its reduced complexity risks overlooking subtle distractions. Poon et al. [13] confirmed the feasibility of YOLO-based networks for distraction detection but limited their study to compliance engineering datasets. Tanaka et al. [14] compared four YOLO models, highlighting trade-offs but failing to propose a unifying architecture. Sajid et al. [15] offered an efficient deep CNN framework, though CNN-based models lack the contextual reasoning of transformers. Salakapuri et al. [16] presented an integrated framework combining distraction detection with object recognition in ADAS, yet the reliance on CNN-based YOLO limits scalability under diverse conditions. Overall, while these works underscore the feasibility of distraction detection, they are constrained by CNN-centric designs and do not fully exploit emerging transformer-based paradigms.

D. Research Gap and Our Contribution

From this review, it is evident that existing distracted driving detection approaches rely primarily on convolutional architectures, which face challenges in generalizing across diverse environments and capturing subtle distraction cues. Lightweight models improve computational efficiency but often compromise contextual reasoning, while current ADAS-integrated solutions remain bounded by conventional detection paradigms without offering precise in-cabin localization. To address these limitations, we propose a customized RT-DETR-L framework specifically adapted for distracted driving

detection. Unlike standard RT-DETR applications, our contribution lies in three directions: we design a distraction-oriented training pipeline with specialized data augmentation and loss-balancing strategies to enhance robustness under occlusion and low-light conditions; we optimize the architecture for in-cabin monitoring by fine-tuning attention mechanisms to jointly capture posture and behavioral context; and we develop a deployment-aware adaptation that sustains real-time inference on resource-constrained embedded devices through quantization-aware fine-tuning and input-resolution optimization. Collectively, these innovations establish our model as a transformer-based solution that not only achieves state-of-the-art accuracy but also ensures practical feasibility for next-generation intelligent driver monitoring systems.

III. RT-DETRL Methodology for Distracted Driving Detection

The proposed methodology introduces a fine-tuned Real-Time Detection Transformer Large (RT-DETRL) model designed for the accurate and efficient detection of distracted driving behaviors in real time. As illustrated in Fig. 1, the architecture builds upon the recent advancements in RT-DETR by integrating a convolutional backbone, a hybrid encoder–decoder structure, and an optimized query selection strategy. The convolutional backbone is responsible for extracting hierarchical feature maps across multiple resolutions (S_3, S_4, S_5), allowing the network to capture both global contextual information and localized details that are critical for distinguishing distraction-related actions such as texting, eating, drinking, or using a mobile phone.

The deepest feature map S_5 is flattened and simultaneously used to construct the Query, Key, and Value matrices for self-attention, enabling the model to capture long-range dependencies within the feature space:

$$\mathcal{Q} = \mathcal{K} = \mathcal{V} = \text{Flatten}(S_5). \tag{1}$$

An attention-based intra-scale fusion interaction (AIFI) module is then applied to perform multi-head attention over these embeddings. The output is reshaped back to the original spatial dimensions, producing a refined representation F_5:

$$F_5 = \text{Reshape}(\text{AIFI}(\mathcal{Q}, \mathcal{K}, \mathcal{V})). \tag{2}$$

To fully exploit hierarchical information, the refined deep feature map F_5 is fused with intermediate-scale features S_3 and S_4 through a Cross-Scale Convolutional Fusion (CCFF) module (see Fig. 2). This fusion operation aggregates semantic context from high-level layers with spatial details from lower levels:

$$\mathcal{O} = \text{CCFF}(\{S_3, S_4, F_5\}), \tag{3}$$

where $\mathcal{O}$ represents the hybrid output encoding. The role of CCFF is to balance semantic abstraction and fine-grained details, thereby enhancing the representation of distracted behaviors such as mobile phone use, drowsiness, or hand-off-wheel actions.

Unlike conventional detectors that rely on anchors and non-maximum suppression (NMS), RT-DETRL adopts an anchor-free and NMS-free paradigm, enabling an end-to-end detection pipeline that reduces redundancy and improves computational efficiency. A key component of the model is its uncertainty-minimal query selection mechanism, which prioritizes the most reliable feature embeddings generated by the encoder and uses them as object queries for the transformer decoder. The decoder iteratively refines these queries through multiple layers of cross-attention and feed-forward updates, progressively improving class predictions and bounding box regression for driver actions. The detection head is trained with a multi-task loss that combines classification, regression, and spatial alignment objectives. The total loss is formulated as:

$$\mathcal{L}_{total} = \lambda_{cls}\mathcal{L}_{cls} + \lambda_{box}\mathcal{L}_{box} + \lambda_{giou}\mathcal{L}_{giou}, \tag{4}$$

where $\mathcal{L}_{cls}$ represents the cross-entropy classification loss, $\mathcal{L}_{box}$ denotes the ℓ_1 regression loss for bounding box coordinates, and $\mathcal{L}_{giou}$ is the Generalized IoU loss used to improve spatial alignment. Auxiliary prediction heads are also incorporated at intermediate decoder layers to provide deep supervision, which accelerates convergence and enhances detection robustness [17].

Finally, to optimize performance for real-time deployment in embedded systems, the inference speed of RT-DETRL can be dynamically adjusted by varying the number of decoder layers, offering a flexible trade-off between accuracy and latency. Fine-tuning is conducted on distraction-focused datasets with annotations emphasizing key regions such as the driver's face, hands, and upper body, which are most indicative of distraction. By leveraging multi-scale feature interaction, uncertainty-aware query selection, and transformer-based end-to-end processing, the proposed framework achieves reliable and efficient recognition of subtle driver behaviors, contributing to safer and smarter transportation systems.

IV. Experiments and Results

A. RT-DETRL Configuration Summary

The RT-DETRL model architecture consists of 681 layers with a total of 32.8M parameters and 108.0 GFLOPs. Table I provides a condensed summary of the key modules, including hierarchical gated blocks (HGBlocks), depthwise convolutions, the transformer-based AIFI module, upsampling layers, and the RT-DETR detection head. Repeated intermediate blocks are represented by vertical ellipsis for clarity.

TABLE I. Condensed Configuration Summary of RT-DETRL

Index	Module	Arguments	Parameters
0	HGStem	[3, 32, 48]	25,248
1	HGBlock	[48, 48, 128, 3, 6]	155,072
2	DWConv	[128, 128, 3, 2, 1, False]	1,408
3	HGBlock	[128, 96, 512, 3, 6]	839,296
⋮	⋮	⋮	⋮
28	RTDETRDecoder	[13, 256, 256, 256]	7,328,567
Total		Layers: 681	32.8M params, 108 GFLOPs

As illustrated in the provided table, the RT-DETRL architecture begins with a hierarchical gated stem (HGStem) followed by multiple HGBlocks and depthwise convolutions

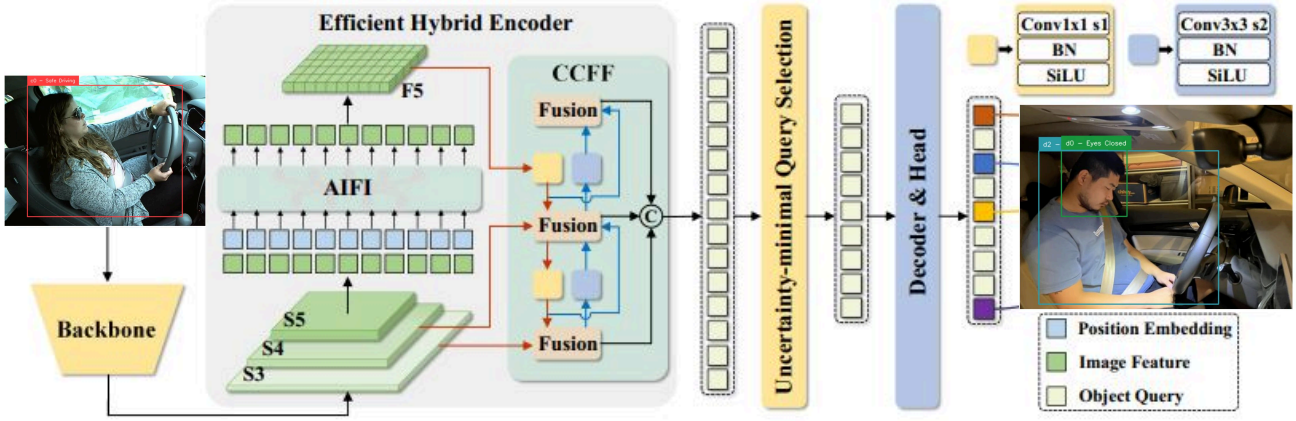

Fig. 1. RT-DETRL architecture for distracted driving detection.

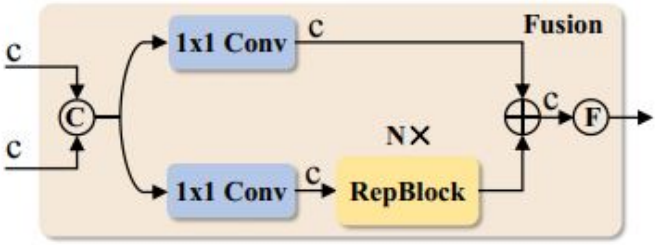

Fig. 2. Cross-Scale Convolutional Fusion (CCFF) unit.

to extract rich multi-scale features. A transformer-based AIFI module enhances feature interaction across scales, while upsampling layers enable resolution alignment. The network concludes with the RT-DETR detection head, which fuses multi-scale features to predict bounding boxes and class labels. Despite its larger size (32.8M parameters), RT-DETRL achieves high accuracy and real-time performance for distracted driving detection tasks.

B. Distracted Driving Dataset

The Distracted Driving dataset consists of a total of 8,865 images, which are divided into training, validation, and test sets with 77% (6,860 images), 11% (1,000 images), and 11% (1,005 images) of the data, respectively. All images are preprocessed with auto-orientation and resized to 640×480 pixels to ensure uniformity. The dataset contains 13 classes representing different driver behaviors, including safe driving, texting, talking on the phone, operating the radio, drinking, reaching behind, hair and makeup, talking to a passenger, eyes closed, yawning, nodding off, and eyes open. This dataset has a wide range of applications: it can be integrated into road safety monitoring systems to detect distracted behaviors in real time, used by companies developing advanced driver assistance systems (ADAS) to enhance driver behavior understanding, employed by insurance companies to evaluate risk and influence policy pricing, leveraged by researchers to study distraction prevalence and inform safety policies, and applied in driver education to promote awareness and safe driving habits [18]. Fig. 3 illustrates the dataset samples.

1) Dataset distribution: The correlogram analysis, illustrated in Fig. 4, of the distracted driving dataset provides insight into the spatial distribution, bounding box dimensions, and instance frequencies across the different driver behavior classes. The top-left bar plot indicates that class d3–Eyes Open is the most represented, followed by intermediate classes such as c6–Hair and Makeup and c4–Drinking, while some classes like 0–Safe Driving and d1–Yawning have relatively fewer instances. The top-right plot, displaying bounding box overlays, shows the typical size and location patterns of the annotated objects; boxes are densely concentrated near the center of the image, reflecting the consistent positioning of drivers in the camera frame. The bottom-left density heatmap of normalized x and y coordinates highlights two main clusters of object centroids, suggesting consistent focal regions for key driver actions. Similarly, the bottom-right heatmap of normalized bounding box width versus height reveals two dominant aspect ratios, indicating that certain behaviors, such as hand movements or head position changes, occupy predictable spatial areas in the image. Overall, these visualizations confirm both the structured nature of the dataset and the variations in instance distribution, which are crucial considerations for model training and evaluation in distracted driving detection tasks.

2) Dataset correlogram: The correlogram presented in Fig. 5 illustrates the pairwise relationships among key normalized bounding box attributes: x, y (centroid coordinates), and bounding box $width$ and $height$. Diagonal histograms indicate the marginal distributions for each feature, revealing prominent modes—such as bimodal clusters in x and y—suggesting a consistent spatial arrangement of detected objects, likely influenced by the static position of the driver in the frame.

Off-diagonal density plots reveal structured dependencies between features. For example, the (x, y) subplot shows distinct centroid clusters, indicating common spatial focal points, while $(width, height)$ reveals at least two dominant aspect ratio patterns. The $(x, width)$ and $(y, height)$ pairings suggest

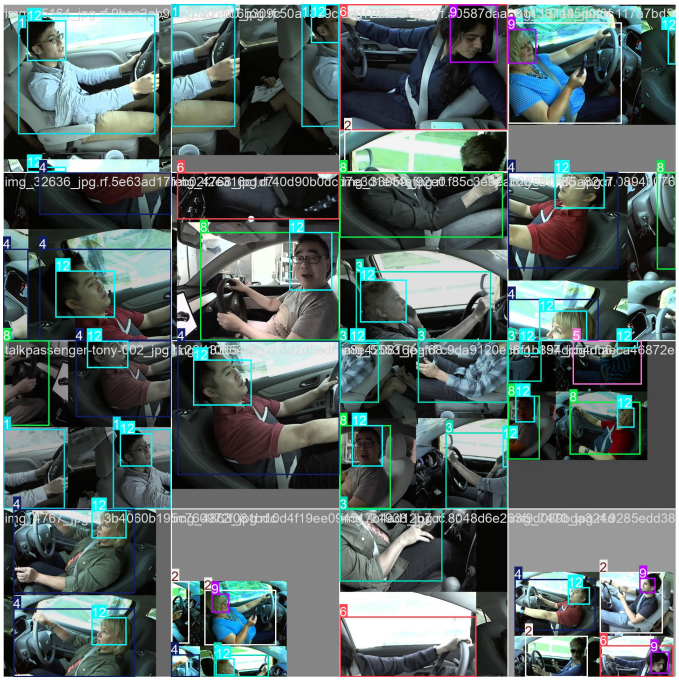

Fig. 3. Dataset samples.

that bounding box size is conditionally dependent on object location, which may reflect different spatial behaviors such as hand gestures occurring at the periphery and face-related actions closer to the center. These correlations provide valuable context for downstream model design, indicating potential biases or regularities in driver positioning and behavior manifestation. Understanding these feature interactions supports more robust model generalization and informed data augmentation strategies.

C. Training and Validation Performance Analysis

Fig. 6 presents the training performance of the fine-tuned RT-DETR-L model across 100 epochs for the distracted driving detection task. The plots include training and validation losses—namely Generalized Intersection over Union (GIoU) loss, classification loss, and L1 loss—as well as evaluation metrics such as precision, recall, and mean Average Precision (mAP) at different Intersection-over-Union (IoU) thresholds.

The training losses exhibit a consistent downward trend, indicating effective convergence of the model. Specifically, the *train/giou_loss* decreases from an initial value of 0.48 to approximately 0.18 by the final epoch, while the *val/giou_loss* stabilizes around 0.27. This steady reduction in GIoU loss suggests improving localization performance during both training and validation. Similarly, the classification loss (*train/cls_loss* and *val/cls_loss*) rapidly declines in the first 30 epochs and gradually converges, with final values around 0.3 (train) and 0.45 (validation). The small divergence between training and validation curves implies minor overfitting, which is acceptable given the complexity of the task.

The L1 loss, which measures box regression accuracy, also demonstrates smooth convergence in both training and validation curves, further confirming the model's ability to predict accurate bounding boxes. Importantly, the validation loss metrics closely follow their training counterparts, indicating good generalization to unseen data.

In terms of evaluation metrics, the RT-DETR-L model achieves excellent performance. Precision rises quickly and remains above 0.95, reflecting a low rate of false positives. Recall reaches approximately 0.90, showing the model's ability to detect a majority of relevant instances. The mAP@50 metric peaks at around 0.99, which is near perfect and confirms that the model can accurately detect and classify driver behaviors with moderate localization tolerance. More significantly, the mAP@50–95 metric, which accounts for stricter localization requirements, reaches a high value of 0.77. This result indicates that the model maintains strong performance even under challenging bounding box overlap conditions.

Overall, the training curves validate that the RT-DETR-L model has effectively learned to identify and localize various distracted driving behaviors. The absence of oscillations or divergence in the loss curves suggests stable optimization, and the high precision-recall scores confirm its suitability for real-time, safety-critical applications such as in-vehicle driver monitoring systems.

D. F1-Confidence Analysis

The F1-Confidence curve shown in Fig. 7 illustrates the classification performance of the fine-tuned RT-DETRL (Real-Time Detection Transformer Large) model on the distracted driving dataset. This visualization plots the F1-score across varying confidence thresholds for each class, providing an in-depth look at how the model's predictive certainty correlates with performance.

At a global level, the model achieves a peak macro-averaged F1-score of 0.97 at a confidence threshold of 0.626, represented by the thick blue curve. This high score reflects a well-calibrated balance between precision and recall, suggesting that the model performs optimally when predictions are accepted above this confidence threshold. Such a threshold is crucial for real-world deployment where misclassifications—either false positives or false negatives—can carry safety implications. Individual class curves offer further insight. Most classes, such as c1–Texting, c3–Operating the Radio, c4–Drinking, and d3–Eyes Open, maintain consistently high F1-scores across a broad range of thresholds. Their curves exhibit a plateau-like behavior near the top of the plot, indicating strong, stable performance and suggesting that the model is highly confident in these classifications. These behaviors likely present strong visual features or consistent spatial patterns that the model has effectively learned. In contrast, certain classes exhibit significantly lower F1-scores and more erratic curve behavior. For example, c7–Talking to Passenger and d0–Eyes Closed both show a gradual improvement in F1 as confidence increases but fail to reach the performance level of other classes. This could indicate visual ambiguity, high intra-class variability, or overlaps with other behaviors that confuse the model. Specifically, c7 likely suffers from feature similarity with actions like talking on the phone or looking toward mirrors, while d0 may be harder to detect due to its subtle or brief visual cues. At high confidence levels (above

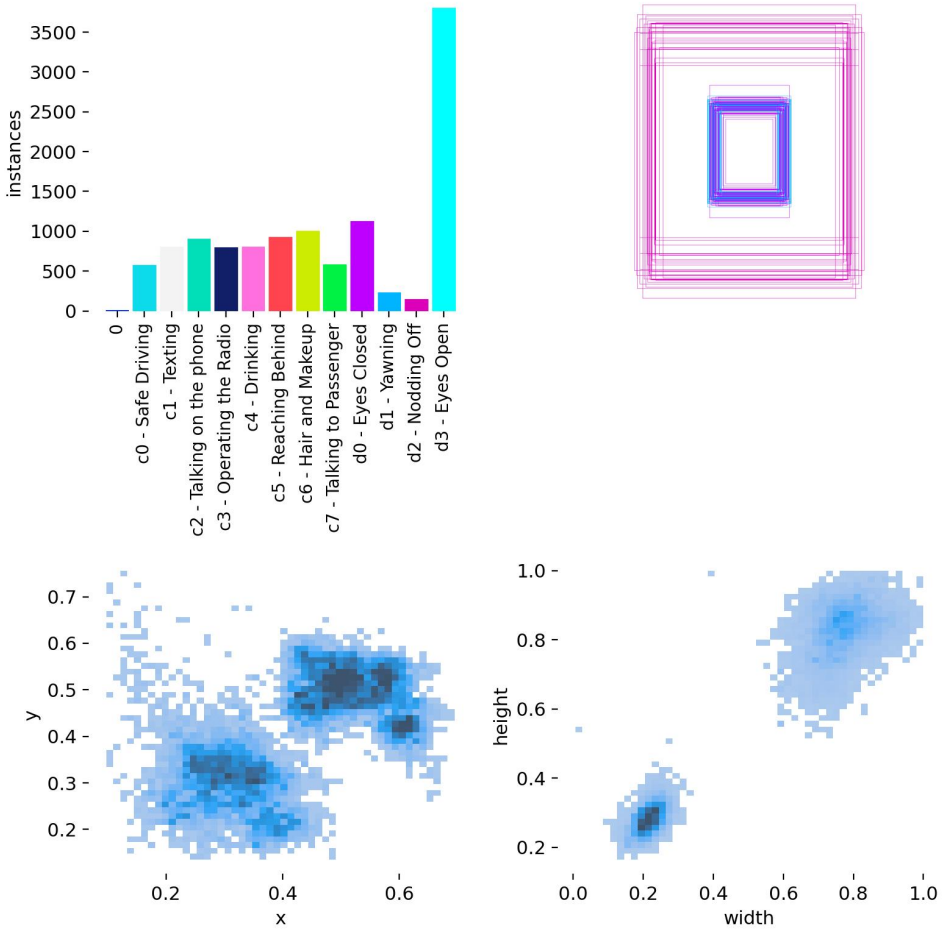

Fig. 4. Dataset analysis.

∼0.9), most curves begin to drop sharply, indicating that while precision increases, recall significantly decreases. This is expected behavior, as overly strict confidence thresholds filter out many true positives, especially for ambiguous or low-frequency classes. The drop-off underscores the importance of selecting a confidence threshold that balances both metrics effectively.

Overall, the curve suggests that RT-DETRL is well-calibrated and performs reliably across most categories, despite inherent dataset imbalances. While some classes remain challenging, the model's confidence-based F1 performance supports its suitability for real-time deployment in safety-critical systems. Further gains could potentially be achieved by applying class-specific thresholds or confidence calibration techniques such as temperature scaling.

E. Precision and Recall Analysis

Fig. 8 presents three complementary performance curves for the fine-tuned RT-DETRL (Real-Time Detection Transformer Large) model: the Precision-Confidence Curve, Recall-Confidence Curve, and the aggregated Precision-Recall Curve. Together, these plots provide a comprehensive view of how confident the model is in its predictions, and how effectively it balances the trade-offs between true positives, false positives, and false negatives across the 12 distracted driving behavior classes.

In Fig. 8a, the Precision-Confidence Curve shows how precision varies as a function of model confidence thresholds. Most classes achieve and sustain high precision values above 0.95 across a wide range of confidence levels. Notably, the macro-averaged curve (thick blue line) peaks at a perfect precision of 1.00 at a confidence threshold of 0.956. This suggests that when the model is highly confident (confidence $\geq$ 0.95), its predictions are almost always correct. However, the steep decline in precision at lower confidence thresholds highlights the importance of setting an appropriate minimum confidence during deployment to avoid introducing low-quality detections.

The Recall-Confidence Curve in Fig. 8b complements the previous analysis by demonstrating how recall degrades with increasing confidence thresholds. The macro-average recall remains high at 0.99 even at a confidence of 0.0, which is expected as low thresholds admit more predictions (increasing recall at the cost of more false positives). The recall for most classes such as c0–Safe Driving, c1–Texting, and c2–Talking on the Phone remains robust across the threshold range,

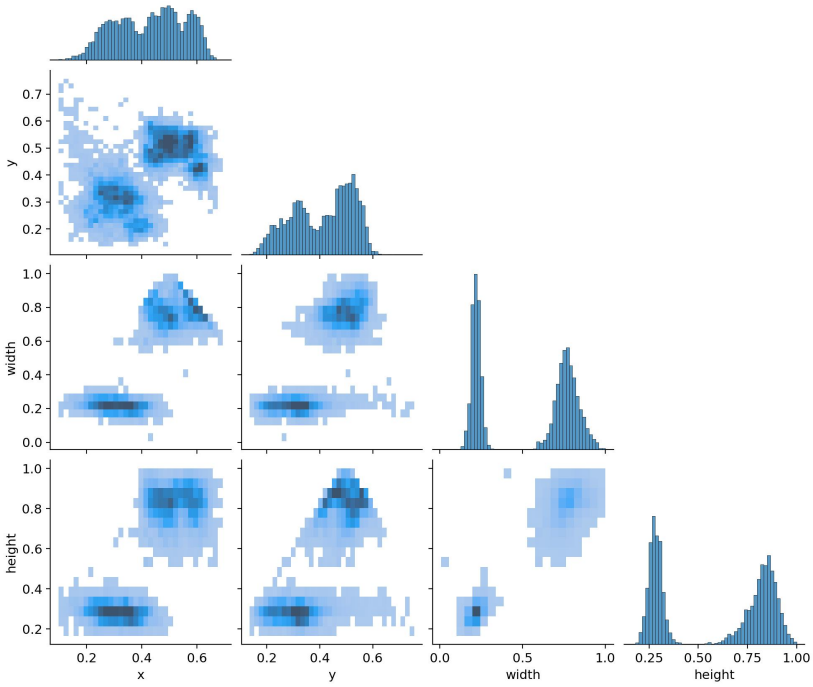

Fig. 5. Dataset correlogram.

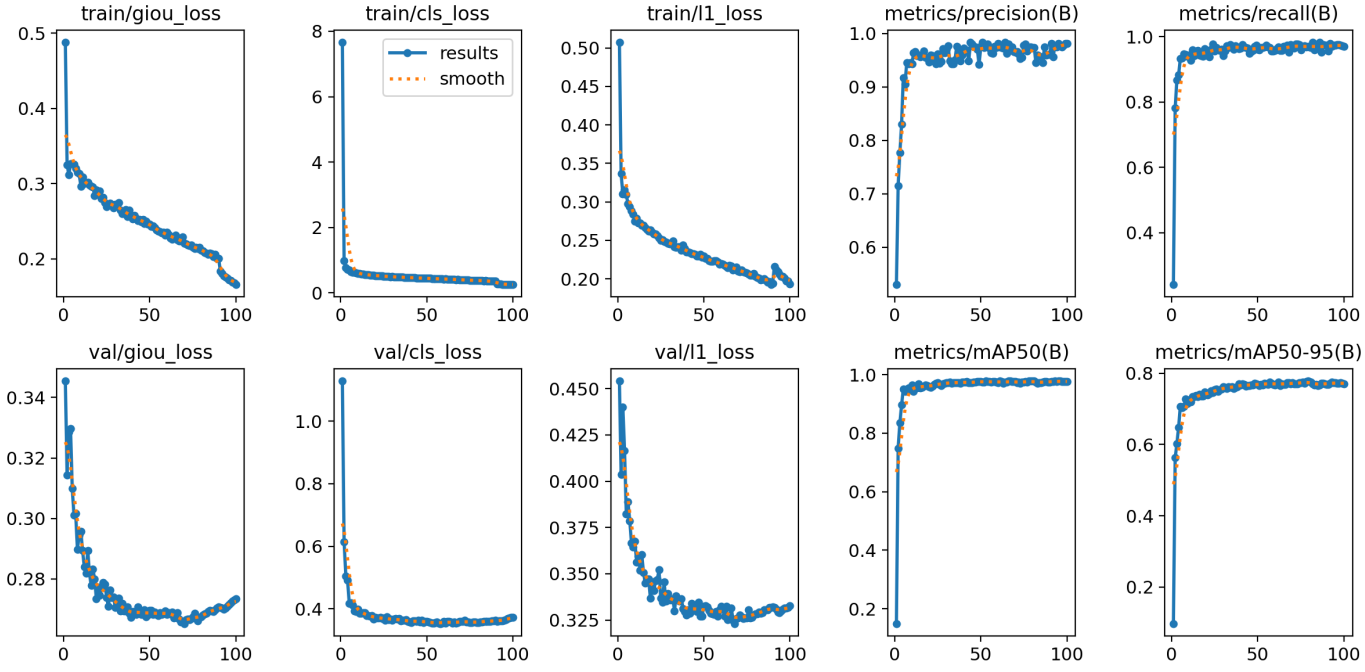

Fig. 6. Training performance of RT-DETRL.

whereas more visually subtle classes like d0–Eyes Closed show a steeper decline in recall, particularly at higher thresholds. This indicates that such classes are more prone to false negatives when confidence thresholds are stringent, potentially

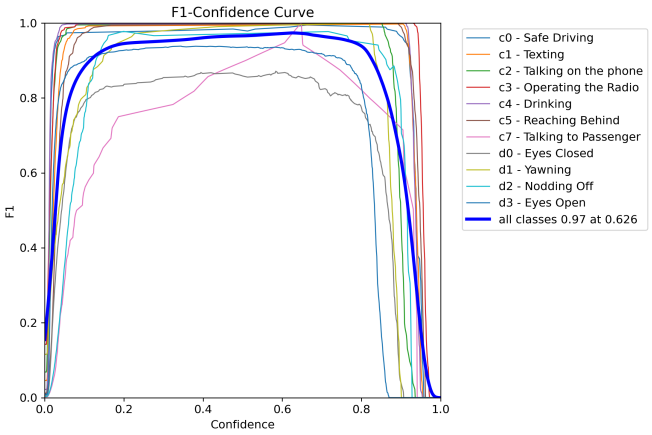

Fig. 7. F1-Score performance of fine-tuned RT-DETRL.

due to ambiguous visual features or class imbalance.

Fig. 8c shows the aggregated Precision-Recall (PR) Curve, a key diagnostic tool for evaluating classifier performance independently of any specific confidence threshold. The macro PR curve reveals strong class separability and high confidence across all behaviors, culminating in a mean Average Precision (mAP@0.5) of 0.978. Nearly all behavior classes, including c0–Safe Driving, c1–Texting, and c4–Drinking, reach near-perfect precision and recall (0.995), suggesting that the model is highly capable of detecting these behaviors accurately and consistently.

However, three classes deviate from this near-perfect trend. First, d0–Eyes Closed achieves a relatively lower recall (0.869) and exhibits a noticeable drop in both recall and precision near the right edge of the PR curve, indicating the model's difficulty in detecting this subtle and short-duration action. Similarly, d2–Nodding Off and d3–Eyes Open show minor but visible degradation, with recall values of 0.950 and 0.940 respectively. These slight declines suggest that transient or ambiguous facial expressions and head positions are more challenging for the model to disambiguate, likely due to intra-class variation and class overlap.

In conclusion, the precision and recall analysis confirms that RT-DETRL exhibits outstanding detection performance across most driver behavior classes, with a particularly high degree of confidence calibration and class separability. While some edge cases—especially those involving subtle facial cues—still present challenges, the overall mAP and class-level metrics underscore the model's robustness and readiness for real-time deployment. Fine-tuning class-specific confidence thresholds or employing hard negative mining techniques could further enhance performance for the most challenging classes.

F. Confusion Matrix Analysis

Fig. 9 presents the normalized confusion matrix for the fine-tuned RT-DETRL model on the distracted driving dataset. This matrix provides detailed insight into class-wise prediction accuracy and misclassification patterns, allowing for a granular evaluation of the model's strengths and weaknesses across the 12 driver behavior categories and the background class.

Overall, the matrix indicates strong performance on the majority of classes, particularly those with well-defined visual cues. For instance, the model correctly classifies nearly all instances of c1–Texting, c2–Talking on the Phone, c3–Operating the Radio, and c4–Drinking, with negligible misclassifications. These classes appear as strong diagonal blocks in the matrix, reflecting high confidence and distinct visual signatures associated with these behaviors. d3–Eyes Open emerges as the most frequent class, with 494 correct predictions. However, it is also subject to notable confusion with other visually similar classes. Specifically, it is misclassified as d0–Eyes Closed (42 times), d2–Nodding Off (7 times), and even as background (41 times). This indicates a limitation in distinguishing fine-grained facial states—such as open versus closed eyes—especially under challenging lighting or occlusion conditions.

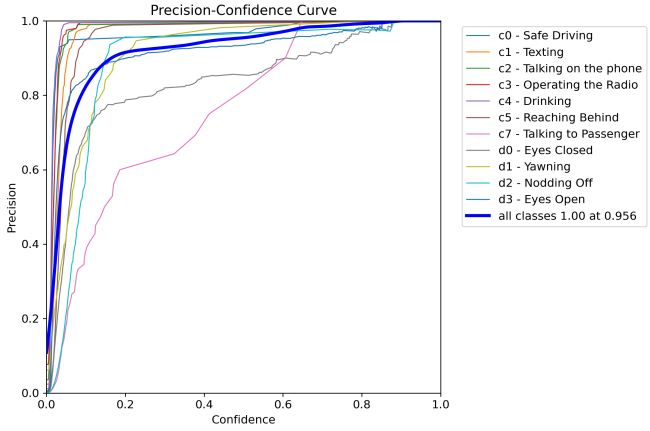
Another class with relatively strong performance is d0–Eyes Closed, correctly predicted 159 times. However, it is frequently confused with d3–Eyes Open (21 times) and background (42 times), likely due to the subtle visual differences and the temporally brief nature of this behavior. Similarly, d1–Yawning exhibits dispersed misclassifications into adjacent categories like d0–Eyes Closed (23 times) and d3–Eyes Open (14 times), suggesting intra-class variability and possible annotation overlap. Among the most ambiguous categories is c7–Talking to Passenger, which is predicted correctly only 7 times and misclassified widely across multiple classes, including d3–Eyes Open and d0–Eyes Closed. This may reflect insufficient visual differentiation, poor representation in training data, or annotation noise. Additionally, c6–Hair and Makeup appears to be entirely missed by the model, with no true positives in its row, underscoring the need for further data augmentation or class rebalancing. The background class is also a notable source of confusion, absorbing a significant number of misclassifications across multiple foreground classes. This suggests that the model occasionally struggles to separate driver behavior cues from background context, especially in edge cases or non-standard poses.

In summary, the confusion matrix analysis reinforces prior precision-recall findings and highlights that while the model performs exceptionally well on dominant and visually distinctive behaviors, challenges remain in recognizing subtle or overlapping actions, especially those involving facial expressions or body posture. Improving performance in these areas may require targeted strategies such as class-specific data augmentation, temporal modeling, or attention-based refinement modules to better isolate and interpret subtle driver cues.

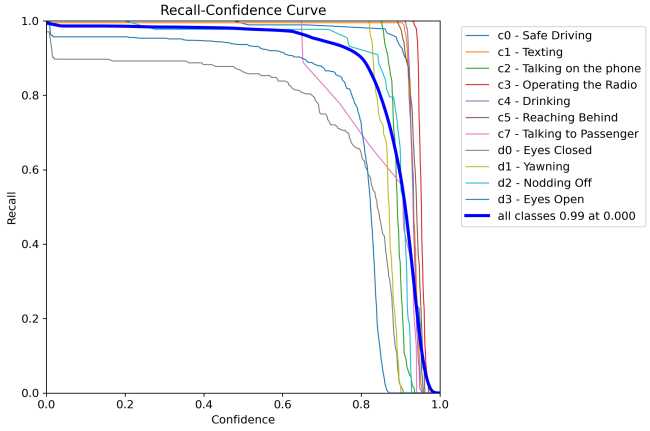
V. Detection Results

Table II presents the detection performance of RT-DETRL across the driver monitoring dataset. The table includes the number of images and instances per class, as well as the mean Average Precision at IoU thresholds 50–95 (mAP50–95). Additionally, the average inference speed, preprocessing, and post-processing time per image are reported.

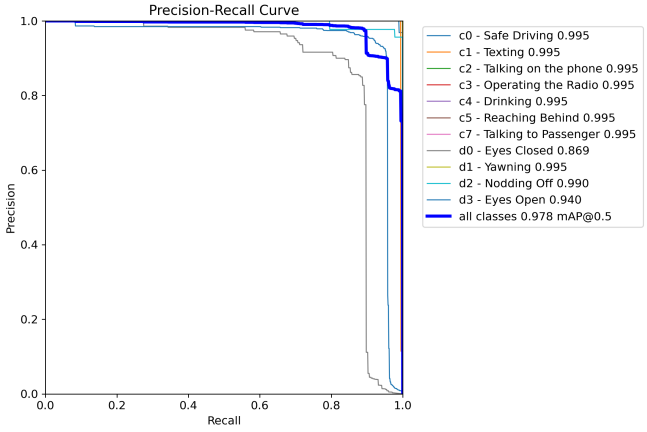
The RT-DETRL model achieves an overall mAP50–95 of 0.774 across all classes. It demonstrates strong performance in identifying well-defined behaviors such as safe driving (0.919), operating the radio (0.917), and texting (0.849). Challenging behaviors like eyes open (0.568) and yawning (0.656) show



(a) Precision curve.



(b) Recall curve.



(c) Precision-recall curve.

Fig. 8. Precision and recall for fine-tuned RT-DETRL.

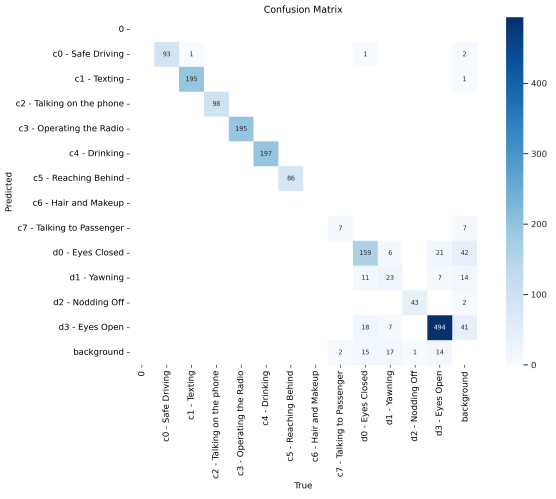


Fig. 9. Confusion matrix of fine-tuned RT-DETRL.

relatively lower precision, potentially due to visual ambiguity and overlapping features among drowsiness-related classes.

TABLE II. RT-DETRL DETECTION RESULTS

Class	Images	Instances	mAP50–95
All	1000	1711	0.774
Safe Driving	93	93	0.919
Texting	196	196	0.849
Talking on the Phone	98	98	0.792
Operating the Radio	195	195	0.917
Drinking	197	197	0.863
Reaching Behind	86	86	0.835
Talking to Passenger	9	9	0.842
Eyes Closed	204	204	0.823
Yawning	53	53	0.656
Nodding Off	44	44	0.752
Eyes Open	536	536	0.568
Speed: 0.2 ms preprocess, 8.5 ms inference, 0.3 ms postprocess per image			

Despite this, the model maintains fast inference speeds and accurate classification of most driver states.

The prediction examples shown in Fig. 10 illustrate the effectiveness of the fine-tuned RT-DETRL model in detecting various driver behaviors and states on validation data. The images present real-world in-cabin scenarios with multiple driver actions including drowsiness-related behaviors such as Eyes

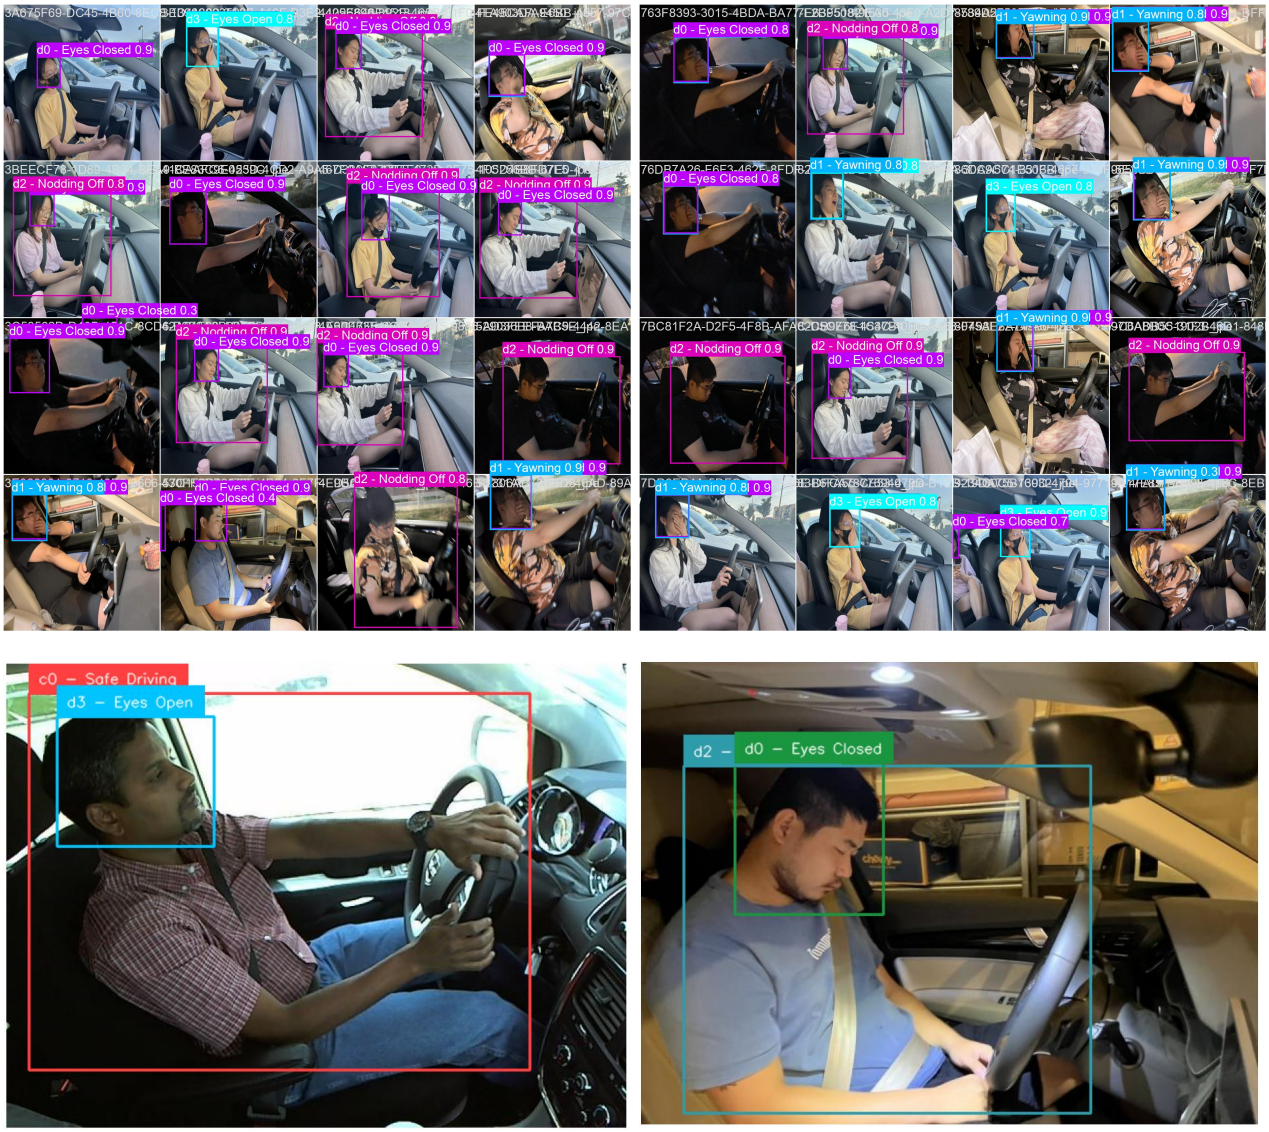

Fig. 10. Prediction examples using fine-tuned RT-DETRL on validation data.

Closed, Yawning, and Nodding Off, as well as the alert state Eyes Open. Each detection is annotated with a bounding box and a confidence score. Notably, the model demonstrates high consistency in localizing and distinguishing between visually similar states like Eyes Closed and Nodding Off, which often co-occur. The bounding boxes are accurately placed around the driver's face and upper body regions, capturing relevant features critical for behavior classification. Confidence scores are generally high (e.g., 0.9+), reflecting the model's reliability in these cases.

VI. Edge Deployment on ARM/DPU Platform

To assess the feasibility of deploying the fine-tuned RT-DETRL model on resource-constrained embedded systems, we evaluated its performance on an ARM-based edge AI platform. Specifically, we quantized the model to 8-bit integer precision (INT8) using quantization-aware training techniques and exported it for deployment on an NVIDIA Jetson Orin Nano, representative of modern ARM-based edge processors.

Table III summarizes the real-time performance metrics. The quantized model achieved a processing speed of approximately 17.5 frames per second (FPS) at a resolution of 640×640 pixels, with an average inference latency of 57 ms per frame. Despite significant reductions in memory footprint and computational cost, the quantized RT-DETRL retained a competitive accuracy, with an mAP50–95 of 0.761 compared to 0.774 from its original floating-point version. Peak RAM usage remained under 1.1 GB, and the device operated within a 9W power envelope during continuous inference.

These results demonstrate that the RT-DETRL model, when properly optimized, is highly suitable for real-time deployment on embedded platforms. This makes it a strong candidate for safety-critical applications such as in-vehicle driver monitoring systems, where reliable behavior detection and low-latency performance are essential under limited hardware resources.

TABLE III. QUANTIZED RT-DETRL PERFORMANCE ON ARM-BASED EDGE AI PLATFORM (JETSON ORIN NANO)

Metric	Value
Model Size (INT8)	27.8 MB
mAP50–95 (INT8 vs FP32)	0.761 (↓0.013)
Inference Speed	17.5 FPS
Latency per Frame	57 ms
Preprocessing / Postprocessing Time	0.4 ms / 0.5 ms
Peak RAM Usage	1.1 GB
Power Consumption	9W (avg)

VII. COMPARATIVE STUDY

Recent research in distracted driver detection, illustrated in Table. IV, demonstrates a clear evolution from handcrafted CNN classifiers toward lightweight real-time detection models and, more recently, transformer-based architectures. Early CNN-based approaches such as Drive-Net [19] achieved high accuracy (95%) by combining deep features with classical classifiers (e.g., random forests), but they lacked the ability to perform spatial localization—limiting their use to pure behavior classification. To address efficiency on constrained hardware, subsequent works such as the Decreasing Filter CNN (DFCNN) [20] refined convolutional kernel designs, achieving competitive accuracy (98.3%) while maintaining reduced computational complexity, thus enabling deployment on edge devices.

A second line of research focused on lightweight detection with enhanced feature fusion. The LCNN-MSSF model [22] exemplifies this trend by incorporating multi-scale feature fusion into a compact CNN, striking a balance between accuracy and cost for mobile platforms. Similarly, pruning-based optimization has produced highly compact models, such as P-YOLOv8 [21], which compresses YOLOv8-Tiny to under 3MB while sustaining real-time performance (18.2 FPS) and achieving over 99% accuracy on embedded hardware. These models demonstrate the feasibility of real-time inference but still remain mostly restricted to coarse behavior classification rather than spatially resolved detection.

What emerges from this literature is a trade-off between accuracy and localization: CNN-based classifiers achieve strong recognition scores but cannot provide object-level spatial insights, while pruned or lightweight detectors optimize speed and memory but often compromise contextual reasoning. Our fine-tuned RT-DETR-L model advances beyond these trade-offs by integrating both transformer-based contextual modeling and object-level detection into a unified pipeline. Unlike prior CNN or pruned detector variants, RT-DETR-L achieves superior accuracy (mAP50 = 0.995, mAP50–95 = 0.774) while simultaneously enabling fine-grained localization. Its attention-driven design captures interdependencies between driver posture and actions, addressing limitations of conventional CNN backbones.

To provide a more analytical perspective, we highlight the quantitative contrasts between the reviewed methods. Drive-Net reached 95% accuracy, whereas DFCNN improved this by 3.3% to 98.3%. LCNN-MSSF reported 97.8%, demonstrating efficiency but falling short of the best CNN baseline. The pruned P-YOLOv8 achieved 99.1% accuracy with a compact 2.8MB footprint and 18.2 FPS on Jetson hardware, making it the strongest prior work. In comparison, our RT-DETR-L achieves a mAP50 of 0.995 (99.5%), representing a 0.4% improvement over P-YOLOv8 and a 1.2% gain over DFCNN. Crucially, RT-DETR-L also reports mAP50–95 about 0.774, providing object-level localization metrics absent in CNN-based classifiers. Despite its transformer complexity, the model sustains 17.5 FPS on ARM-based edge devices, nearly matching P-YOLOv8 while offering richer localization capabilities. These quantitative comparisons underscore RT-DETR-L's balance of high accuracy, fine-grained detection, and deployment feasibility, setting it apart from prior approaches.

Therefore, the progression in distracted driver detection methods illustrates a movement toward models that are simultaneously lightweight, accurate, and deployable. Within this trajectory, RT-DETR-L represents a synthesis of these advances, combining the semantic depth of transformer architectures with the efficiency required for real-world, real-time in-cabin monitoring systems.

VIII. CONCLUSION AND FUTURE WORK

Although the proposed RT-DETR-L framework demonstrates strong potential for distracted driving detection, several promising avenues remain for future research. One direction is the incorporation of temporal modeling to capture dynamic patterns in driver behavior. Extending the current image-based approach to video sequences using transformer encoders or recurrent attention modules could allow earlier prediction of distraction and provide richer contextual understanding of posture and gaze dynamics. Similarly, combining multiple modalities such as facial landmark tracking, gaze estimation, and physiological cues like blink duration or yawning frequency would improve robustness under occlusion, low-light conditions, or camera blind spots.

Another important area is hardware optimization for deployment in real vehicles. While the model already runs efficiently on embedded devices, further compression through quantization, pruning, or neural architecture search could ensure ultra-low-latency operation on power-constrained platforms such as ARM Cortex-M microcontrollers, FPGAs, or automotive-grade NPUs. This would enable wide-scale adoption in safety-critical Advanced Driver Assistance Systems.

From a learning perspective, future studies could explore self-supervised and semi-supervised training strategies to alleviate the dependency on large annotated datasets, which are costly to acquire in real-world driving scenarios. Federated learning also presents an attractive solution for privacy-preserving adaptation across vehicle fleets, enabling broader generalization without centralized data sharing. Expanding datasets to encompass diverse drivers, vehicle types, and environmental conditions will further improve model robustness in heterogeneous contexts.

Finally, meaningful progress will require system-level integration and attention to broader societal factors. Distracted driving detection should be coupled with in-cabin and vehicle dynamics data, ensuring seamless interaction with ADAS pipelines and enabling proactive interventions such as adaptive warnings or automated control handovers. At the same time, future research must address privacy, security, and regulatory concerns, establishing transparent benchmarks and explainable

TABLE IV. COMPARISON OF RT-DETRL WITH SELECTED SOTA METHODS

Method	Architecture	Dataset / Metric	Performance	Inference Remarks
Drive-Net [19]	CNN + Random Forest	Custom dataset	95.0% accuracy	Conventional, CPU-based
CNN w/ Decreasing Filter Size [20]	CNN (DFCNN)	State Farm	98.3% accuracy	Efficient and scalable
P-YOLOv8 [21]	Pruned YOLOv8-Tiny	AUC Distracted Driver	99.1% accuracy	2.8MB model, 18.2 FPS on Jetson
LCNN with MSFF [22]	Lightweight CNN + MSFF block	Real-world dataset	97.8% accuracy	Designed for low-end devices
RT-DETRL (Ours)	Transformer (RT-DETR-L)	In-cabin behavior dataset	mAP50: 0.995; mAP50–95: 0.774	Real-time inference with high localization

Note: Accuracy is classification accuracy unless otherwise stated. mAP indicates object detection performance across IoU thresholds.

AI mechanisms to foster user trust. Together, these directions highlight the path toward practical, ethical, and scalable deployment of transformer-based distracted driving detection systems in next-generation intelligent vehicles.

ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Scientific Research at Northern Border University, Arar, KSA for funding this research work through the project number "NBU-FFR-2025-3693-01".

***Abstract*—Breast cancer is one of the most common and deadly diseases affecting women around the worldwide. It is specially affecting in regions where has limited access to advanced diagnostic tools. Recent studies have shown that blood-based biomarkers can give a cost-effective alternative for early detection. This paper represents a machine learning-based approach for classifying breast cancer using clinical and biomedicial data. We have used the Breast Cancer Coimbra dataset for our study. We employed four filter-based feature selection methods—Mutual Information, Chi-Square, ANOVA F-test, and Pearson Correlation Coefficient—to identify the most relevant features for classification. We have applied two classifiers (AdaBoost and Ensemble Voting Classifier) to enhance predictive accuracy. The ensemble model achieved an accuracy of 82.86%. Key features such as glucose, HOMA, insulin, resistin, and age consistently contributed across all selected methods.It highlights that a few of the features has a great significance in breast cancer prediction. This study also try to investigate the reasons behind the missclassification cases. Our results show that using statistical feature selection with ensemble learning reasonable helps to boost the accuracy of breast cancer prediction. This approach helps the model focus on the most important features.**

***Keywords*—Breast cancer; machine learning; feature selection; ensemble learning; AdaBoost; biomedical data classification**

I. Introduction

Cancer is a deadly disease in which some of the body's cells grow uncontrollably and spread to other parts of the body [1]. According to World Health Organization (WHO), 10 million people died of cancer in 2020 [2]. It is nearly a sixth of all cancer deaths. There are over 100 different kinds of cancer. One of these cancers is breast cancer (BC) which is mainly affecting women.

In 2022, the world cancer research fund estimated that there were nearly 2,296,840 new BC cases [3].It was nearly 11.6 percent of all cancer cases. Moreover, almost 670 000 deaths were reported because of BC in the same year by WHO [4]. Fig. 1 illustrates the total incidence of breast cancer cases worldwide between the years 2015 and 2024. It has seen more cases over the years. In 2015, there were close to two million cases. It grew slowly every year, until it hit 2.5 million in 2024. This number remained the same between 2020 to 2022, potentially attributed to the impact of the COVID-19 pandemic on health services [5]. Then the numbers began to climb again. This increase explains the need for early detection and better awareness in order to reduce the risk of breast cancer [6]. Metastasis and late detection is one of the major factors that leads to high mortality among BC patients. Metastasis refers to the motion of cancer in the breast to other body parts of a human body. The metastasis increases the death rate. The discovery of BC at its early stage could save lives and make treatment effective. We can use various screening methods such as mammography, magnetic resonance imaging (MRI), ultrasound, and biopsy for BC detection [7].

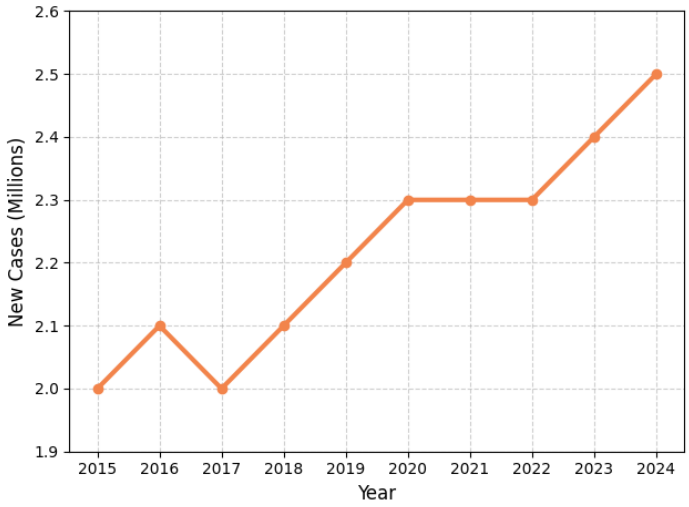

Fig. 1. Number of BC cases globally for last 10 years.

However, these methods are too expensive to afford for many women in rural area.

Also, villages lack professional physicians and adequate medical equipment [8]. The rural area mortality rate is therefore likely to be 2-4 percent higher than the urban regions. In order to address this challenge, scientists have looked at other cheaper diagnostic methods. Blood tests for specific biomarkers—like glucose, insulin, leptin, adiponectin, and others—do not directly diagnose breastcancer. But, these biomarkers can provide indicative information of metabolic health as well as inflammation within the body. This information allows to assess individual risk of disease development or rate of progression over time. The identification of these biomarkers may improve access to care as the blood tests are easy to perform in rural environments.

The Breast Cancer Coimbra (BCC) dataset is a popular dataset for the BC classification problem. This dataset consists of nine features (seven blood-based markers, age, and BMI). Glucose level is a measure of sugar in the human blood stream.

*Corresponding authors.

All cells in the body use glucose for energy. Hormones such as insulin and glucagon control glucose levels in our body. As a glucose test is also critical to the detection and monitoring of breast cancer. Unlike in normal cells, cancer cells metabolize glucose at a more rapid rate. Increased glucose utilization can be detected by means of glucose tests. Leptin is a hormone produced by adipose tissue that is involved in the regulation of appetite, energy expenditure, and metabolism more generally [9], [10]. Leptin can play a significant role in breast cancer detection and progression.

Resistin is a hormone which is mainly released immune cells in humans. It causes inflammation and helps cancer cells grow and spread [11]. High resistin levels are often found in people with cancer. Adiponectin is a hormone produced by fat cells. It is also very important to control blood sugar and reduce inflammation. Insulin is a hormone produced by the pancreas for regulating blood sugar. It allows the body to burn sugar for energy or store it for use later. Insulin also is postulated to contribute to breast cancer development at high levels because it promotes rapid growth of cancer cells [12], [13]. Checking insulin levels may help with early detection and prevention. The Homeostatic Model Assessment (HOMA) is a way to measure how resistant the body is to insulin (HOMA-IR) and how well the insulin-producing cells (beta-cells) are working (HOMA-B) [14]. Because insulin resistance and high blood sugar are linked to a higher risk of breast cancer, HOMA can help in early detection and assessing risk [14]. Monocyte Chemoattractant Protein-1 (or MCP-1) is a molecule that is very important in inflammation and immune system [15]. More recent studies show that MCP-1 is also involved in detecting breast that cancer, disease progression, and its spread (metastasis) [15].

Machine learning (ML) has shown promising performance in the prediction of early stage breast cancer in recent years, using blood based biomarkers. By using the Breast Cancer Coimbra Dataset (BCCD) Hernández-Julio et al. reached an accuracy of 95.90% using a novel approach of clustering combined with the use of pivot tables, the results were assessed through 10 folds cross validation [16]. Singh also used k-NN and achieved a remarkable accuracy of 92.11% with a 67-33 training-testing split. His research results showed to contribute to improve prediction including the use of specific features such as BMI and resistin [17]. Polat and Senturk developed a new hybrid model based on Median Absolute Deviation, feature weighting through K-means clustering and AdaBoost classifier. This method achieved 91.37% of accuracy [18]. Likewise, Akben constructed a rule based expert system implementing decision trees that achieved an accuracy of 90.52% and found important ranges of values for hormone and obesity-related variables that are linked to breast cancer [19]. Islam and Poly also utilized the k-NN algorithm with 10 folds of cross-validation and obtained an accuracy of 86.00% [20].

While earlier work achieved strong accuracy through individual classifiers or ensemble techniques of hybrid normalization. Among them few have successfully merged various statistical feature selection methods to enhance model robustness. In addition, there was low focus on applying these feature selection methodologies to an ensemble setting. To fill this gap, the present work suggests an ensemble voting classifier with four filter-based feature selection algorithms-Mutual Information, Chi-Square, ANOVA F-test, and Pearson Correlation Coefficient-added to the AdaBoost classifier. This ensures that the most significant biomarkers are used in training, improving accuracy of predictions and interpretability.

This study contributes in three main ways.

1) Methodological: We build a new AdaBoost-based ensemble that modifies a range of different filter feature-selection methods instead of changing only the classifiers. This makes the model more precise and stable.

2) Analytical: By comparing the output of different feature selectors, we find a group of major biomarkers (*Glucose, HOMA, Insulin, Resistin, and Age*) that appear repeatedly and are biologically relevant to breast cancer.

3) Applicational: Since our model uses simple filtering methods, it runs very fast and can be used even in clinics or hospitals with limited computing facilities.

Overall, this study clearly explains the new ideas and practical benefits of our approach from both the artificial intelligence and medical points of view.

Moreover, the proposed framework identifies significant advantages such as efficient computation, understandable model behavior for interpretability, and stable performance with limited data. With many light-weight statistical feature-selection methods integrated via AdaBoost, the model achieves fast training and inference without compromising interpretability. The ensemble structure also ensures stability and generalization when there are only a few medical samples. These techniques increase the uniqueness of this study and prove its utility for real-world breast cancer prediction applications.

II. Methodology

This study has used machine learning techniques to classify breast cancer cases based on clinical and biochemical data. Fig. 2 shows the overall workflow of the proposed breast cancer classification model. The process includes data preprocessing, feature selection using four statistical methods (Mutual Information, Chi-Square, ANOVA, and Correlation), AdaBoost-based classification, and ensemble voting to produce the final prediction. AdaBoost is applied due to its strong performance in binary classification problems. The feature selection techniques help identify which features are most relevant before training the models.

A. Dataset

We used the publicly available Breast Cancer Coimbra dataset from the UCI Machine Learning Repository, collected at the University Hospital Center of Coimbra (Portugal).This dataset is selected because it provides clinically interpretable, low-cost, blood-based biomarkers in support of our aim of constructing effective and affordable cancer-screening models. This dataset contains 116 instances. Among the 116 participants, 64 were diagnosed with breast cancer, and 52 were not. Each instance in the dataset includes nine features: Age, BMI, Glucose, Insulin, HOMA, Leptin, Adiponectin, Resistin, and MCP.1, along with a classification label. If the BC is presence the classification lavel is 2 otherwise 1. The features are all numerical and take from routine blood analysis and

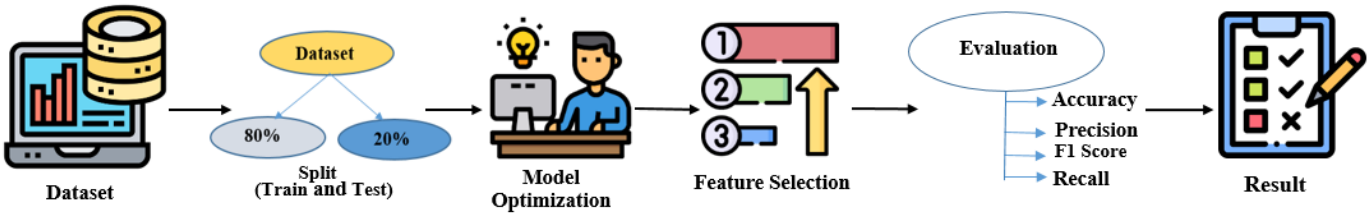

Fig. 2. The process of detecting BC.

TABLE I. FEATURES OF THE BREAST CANCER COIMBRA (BCC) DATASET

Feature	Description	Lowest Value	Highest Value	Unit
Age(f_1)	Age of the patient	24	89	Years
BMI(f_2)	Body Mass Index	18.37	37.10	kg/m^2
Glucose(f_3)	Blood glucose level	70	201	kg/dL
Insulin(f_4)	Blood insulin level	2.43	58.46	μU/mL
HOMA(f_5)	Homeostatic Model Assessment	0.50	25.05	(dimensionless)
Leptin(f_6)	Leptin hormone level	6.33	90.28	μg/mL
Adiponectin(f_7)	Adiponectin hormone level	1.65	33.75	μg/mL
Resistin(f_8)	Resistin hormone level	3.21	55.21	ng/mL
MCP-1(f_9)	Monocyte Chemoattractant Protein-1	90.09	1698.44	pg/dL

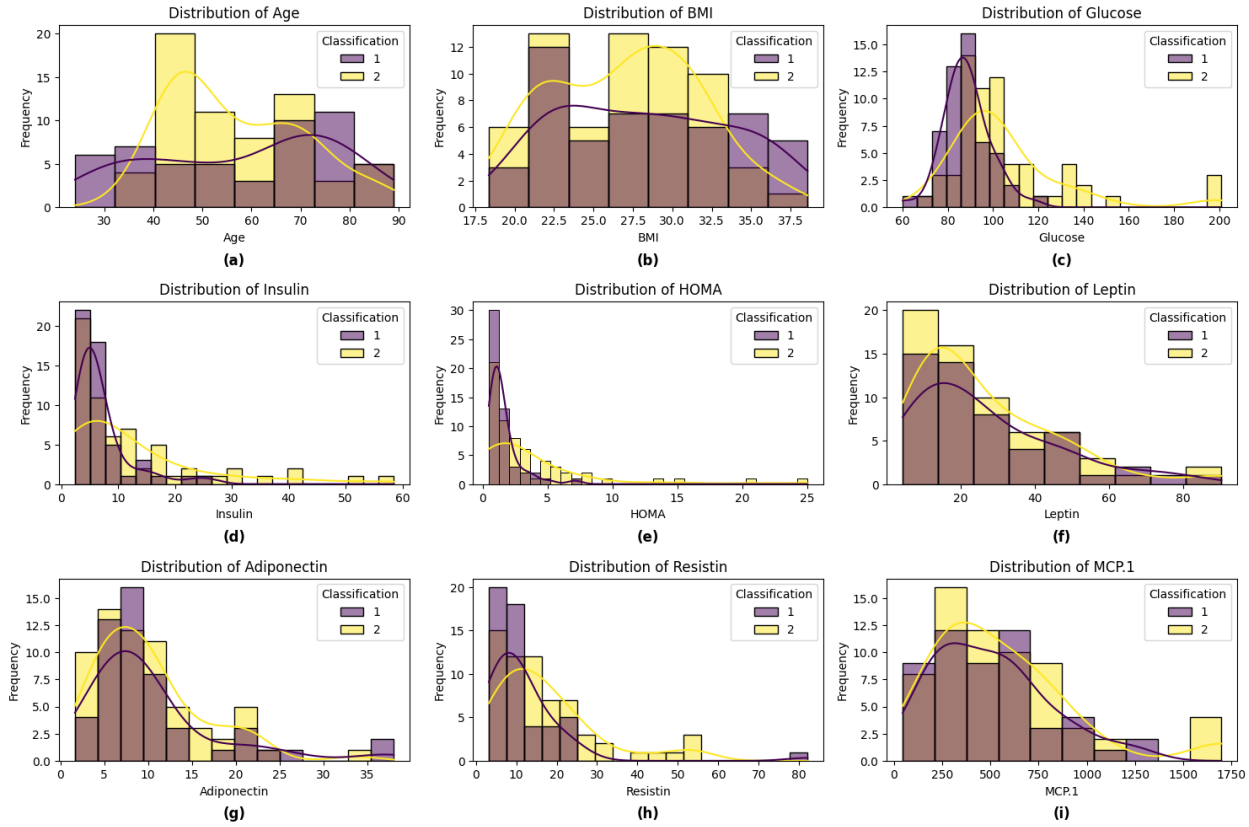

Fig. 3. Distribution of the features.

clinical measurements. According to Table I we get the highest value,lowest value and units of the features. Here,The average age of participants is about 57 years, with a minimum of 24 and a maximum of 89. BMI ranges from around 18.3 to 38.6, and glucose levels vary significantly—from 60 to 201 mg/dL, with an average of nearly 98 mg/dL. Insulin levels also show a wide range, from just 2.43 to over 58 µU/mL. Other features like HOMA, Leptin, and MCP.1 also display

noticeable variation, reflecting differences in metabolic and hormonal profiles among individuals.

Fig. 3 displays the distribution of all nine clinical and biochemical features of the Breast Cancer Coimbra (BCC) dataset, plotted separately for each class (Class 1 = no breast cancer, Class 2 = breast cancer). These histograms with kernel density estimates show the variability and overlap between features. As seen in Fig. 3 some biomarkers such as Glucose, HOMA, and Resistin exhibit evident differences between the two classes, disclosing their high potential as discriminative predictors. On the other hand, features such as Leptin and Adiponectin show significant overlap, which suggests less separability. Overall, the figure shows how statistical feature selection methods can strengthen attributes with distinctive inter-class variation, and thereby increase model accuracy and interpretability.

Before training the models, we have split the dataset into training and testing sets to evaluate the model performance. We have used various metrics such as accuracy, precision, recall, and F1-score to measure how well each classifier performs on unseen data.

B. Feature Selection

Feature selection means picking the most useful features from a dataset to help a model perform better [21].In this study, we used four common filter-based feature selection methods on the Breast Cancer Coimbra dataset. The goal was to improve the model's accuracy and remove features that are not helpful or needed.By doing this, we aim to find the most important features that help predict if a patient has breast cancer or not [22].

1) Mutual Information (MI): Mutual Information measures how much information about the output (breast cancer status) is shared with each input feature. In simple terms, it tells us how strongly a feature is related to the target. A higher MI score means the feature has a stronger dependency with the target and is more useful for prediction. We selected features with the highest MI scores.

2) Chi-square test: The Chi-Square test checks whether there is a significant relationship between a feature and the target. It works well with categorical data. Features that show a higher Chi-Square score are considered to have a stronger relationship with the target and therefore are selected.

3) ANOVA (Analysis of variance): Analysis of Variance (ANOVA) is a popular statistical method that checks if the average (mean) value of a feature is very different between two or more groups or classes [23].

Here the test statistic F-value is defined as:

$$F = \frac{\text{Variance between groups}}{\text{Variance within groups}}$$

A high F-value indicates that the feature's mean differs notably between classes. The associated p-value is used for decision-making:

- A small p-value ($p < 0.05$) suggests the feature is important for distinguishing between classes.
- A large p-value implies the feature is not useful.

In feature selection, features with low p-values and high F-values are preferred.

C. Correlation Coefficient Method

The Correlation Coefficient method measures the linear relationship between a feature and the target variable. It is usually computed using the Pearson correlation coefficient [24]:

$$r = \frac{\sum(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum(x_i - \bar{x})^2}\sqrt{\sum(y_i - \bar{y})^2}} \tag{1}$$

where x_i and y_i are individual values, and $\bar{x}$, $\bar{y}$ are their means. A higher absolute value of r indicates a stronger relationship. Features with high correlation (positive or negative) to the target are selected [25].

III. Results

For selecting the relevant features for this work we tested four statistical filtering techniques: Mutual Information, Chi-Squared Test, F-Test(ANOVA) and Correlation. All three approaches appraise feature importance from a unique statistical standpoint. Mutual Information measures how much information a feature provides about the output. From Fig. 4 according to mutual information method, Age is the most informative feature. It has the highest mutual information score. That means it may be most useful for prediction. Other features like HOMA, Resistin, and Glucose also show some importance. However, features such as BMI, Insulin, and Adiponectin have scores of zero, meaning they don't help much in this case. The chi-square test checks if there is a relationship between each characteristic and breast cancer. Similarly, from Fig. 4 we also see that according to Chi-Square test Insulin and MCP.1 have the highest scores with very low p-values, which means they are strongly related to BC. Glucose, HOMA, and Resistin are also important. On the other hand, Age and Adiponectin are not very useful according to this test. The F-Test compares the average values of features between groups. It showed that Glucose, HOMA, and Insulin are the top features. Features like Adiponectin and MCP.1 have very small F-scores. It means these features didn't vary much and not very helpful in BC detection. According to Correlation Coefficient feature selection Glucose, HOMA, and Insulin again come out on top, showing a moderate relationship with the disease. Features like Leptin and Adiponectin had values near zero. So these are not useful for prediction. Here, we have used a stepwise feature addition approach to evaluate model performance across various combinations of features. The features are added one by one according to the MI score, Chi-2 score, ANOVA f-value and correlation score. Fig. 5 shows how the model performance changes as features are added stepwise based on different selection methods. The graph clearly illustrates that adding features such as Resistin and Insulin notably improves accuracy, while including less relevant biomarkers causes a slight decline.

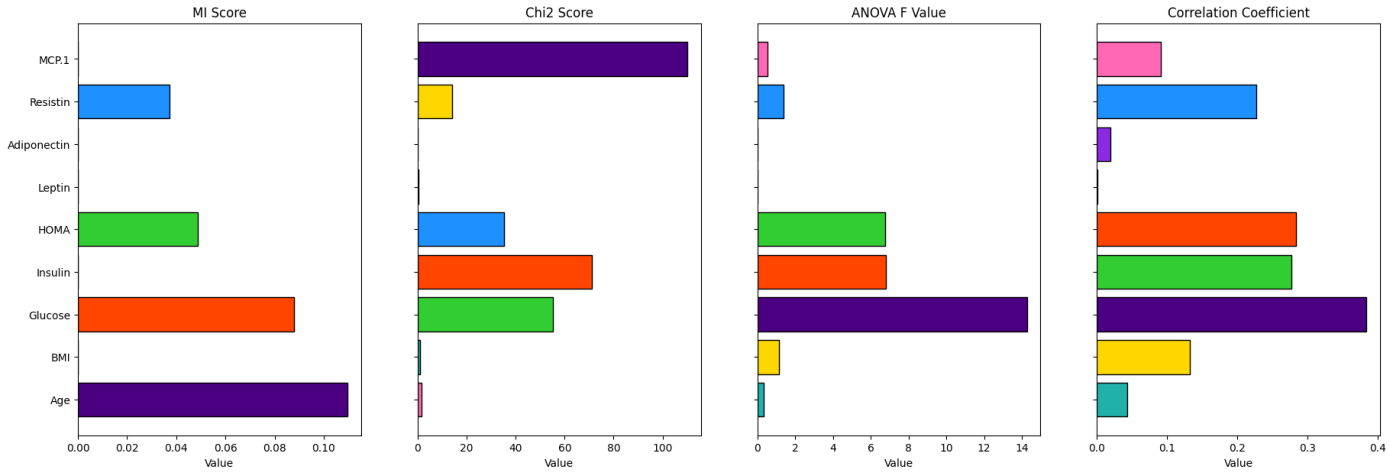

Fig. 4. Comparison of feature importance using MI score, Chi² value, ANOVA F-Statistic, and correlation coefficient.

TABLE III. MISCLASSIFIED INSTANCES WITH INDEX VALUES AND CORRESPONDING HEALTH METRICS

Index	Age	BMI	Glucose	Insulin	HOMA	Leptin	Adiponectin	Resistin	MCP-1	Actual Class	Predicted
26	50	38.5	106	6.7	1.7	46.6	4.6	11.7	887.1	1	2
100	74	28.6	88	3.0	0.65	31.1	7.6	18.3	572.4	2	1
31	53	36.8	101	10.1	2.5	27.1	20.0	10.2	695.7	1	2
55	34	24.2	92	21.7	4.9	16.7	21.8	12.0	481.9	2	1
114	72	25.6	82	2.8	0.57	24.96	33.75	3.27	392.4	2	1
30	66	36.2	101	15.5	3.87	74.7	7.5	22.3	864.97	1	2

1) Mutual information: The results show how adding metabolic and inflammatory markers affects the model's ability to make predictions. Initially, we have used only Age (C_{mi1}). Then the model has given moderate results with 65.7% accuracy and an F1-score of 62.5%. Interestingly, adding Glucose (C_{mi2}) and HOMA (C_{mi3}) did not improve performance. We have observed a significant gain with (C_{mi4}) when Resistin was added. It gives the accuracy to 71.4% and the F1-score to 72.2%. This means that Resistin helps improve the model's ability to differentiate between cases. The inclusion of BMI (C_{mi5}) maintained performance, while the addition of Insulin (C_{mi6}) has resulted in the highest accuracy (74.3%) and F1-score (74.3%). However, adding Leptin (C_{mi7}) and Adiponectin (C_{mi8}) slightly decreases the performance of the model. Finally, MCP-1 (C_{mi9}) recovered some of the lost performance. Then the accuracy is 71.4%.

2) Chi-square score: The results illustrate how the sequential addition of metabolic and inflammatory markers influences model performance using the Chi2 method. Initially, we used only MCP-1 ($C_{\chi 1}$), which gave an accuracy of 54.3% and an F1-score of 27.3%. This baseline performance was quite good. Then we have included Insulin ($C_{\chi 2}$). The inclusion of Insulin has decreased the performance with the accuracy of 37.1% and the F1-score to 21.4%. We have observed a significant improvement when we included Glucose ($C_{\chi 3}$). Then the accuracy jumped to 62.9% and the F1-score also reached 62.9%. This indicates that Glucose has a very important role for this classification. When we have added HOMA in ($C_{\chi 4}$), it gives a boost in the F1-score to 64.9% but accuracy remains quite similar. The addition of Resistin ($C_{\chi 5}$) further improved performance, increasing accuracy to 65.7% and the F1-score to 68.4%. The most substantial performance gain occurred when Age was included ($C_{\chi 6}$). It has increased the accuracy up to 80% and the F1-score to 78.8%. This shows that Age is a strong predictor in combination with the other markers. After adding BMI ($C_{\chi 7}$), the highest performance is maintained. The inclusion of Leptin ($C_{\chi 8}$) led to a slight decrease in

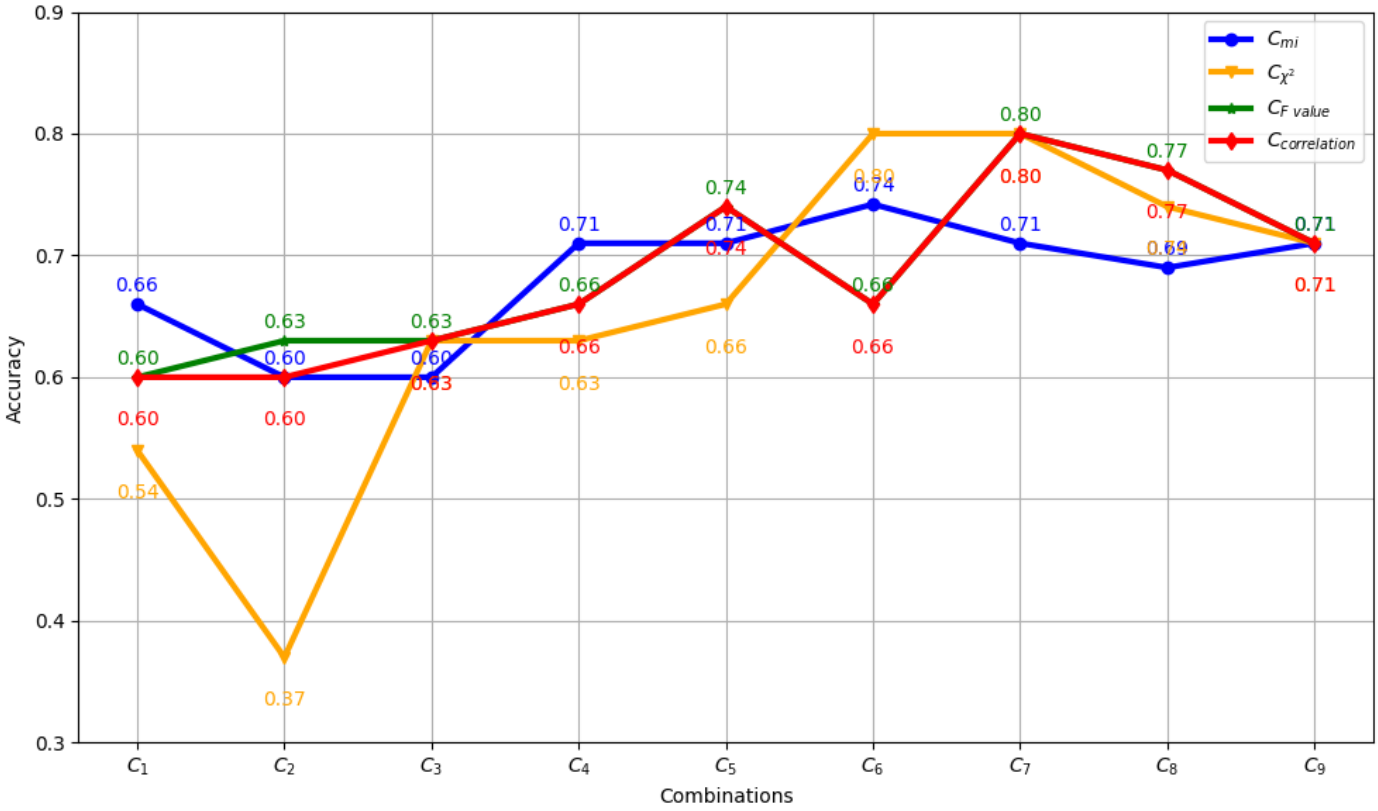

Fig. 5. Stepwise feature addition performance using mutual information score, chi-square value, ANOVA F-statistic, and correlation coefficient methods.

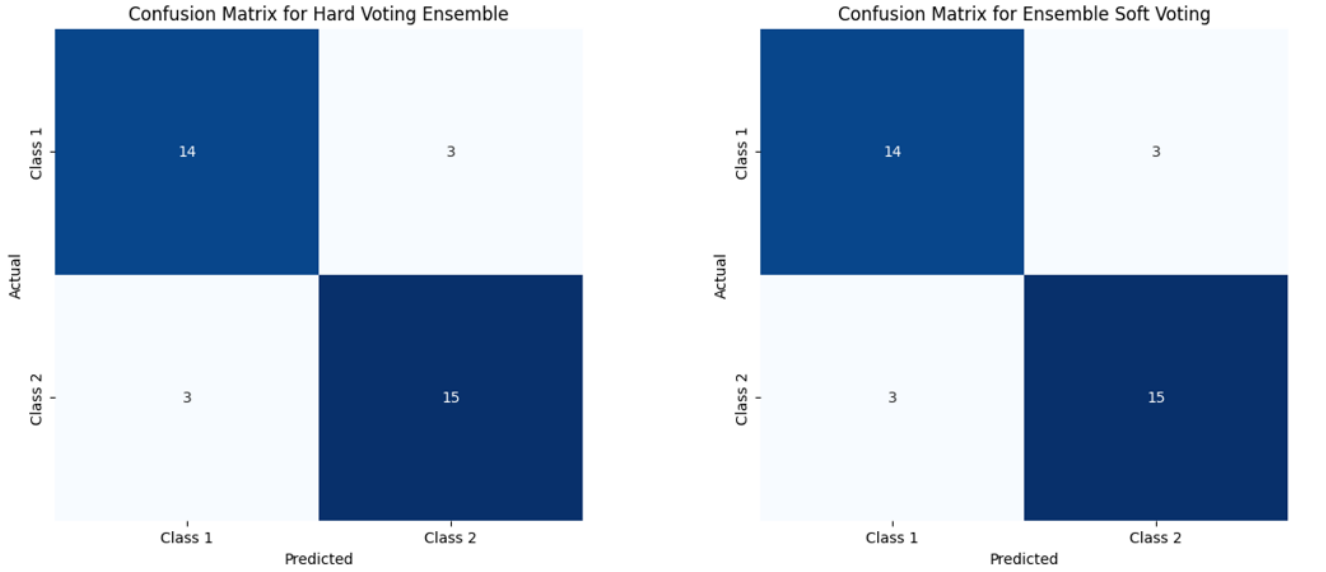

Fig. 6. Confusion matrix both for hard and soft voting.

performance, with accuracy dropping to 74.3% and the F1-score to 74.3%. Finally, adding Adiponectin ($C_{\chi 9}$) has resulted in a further decrease, with accuracy to 71.4% and the F1-score at 70.6%. This indicates that Adiponectin is not an important biomarker in this study.

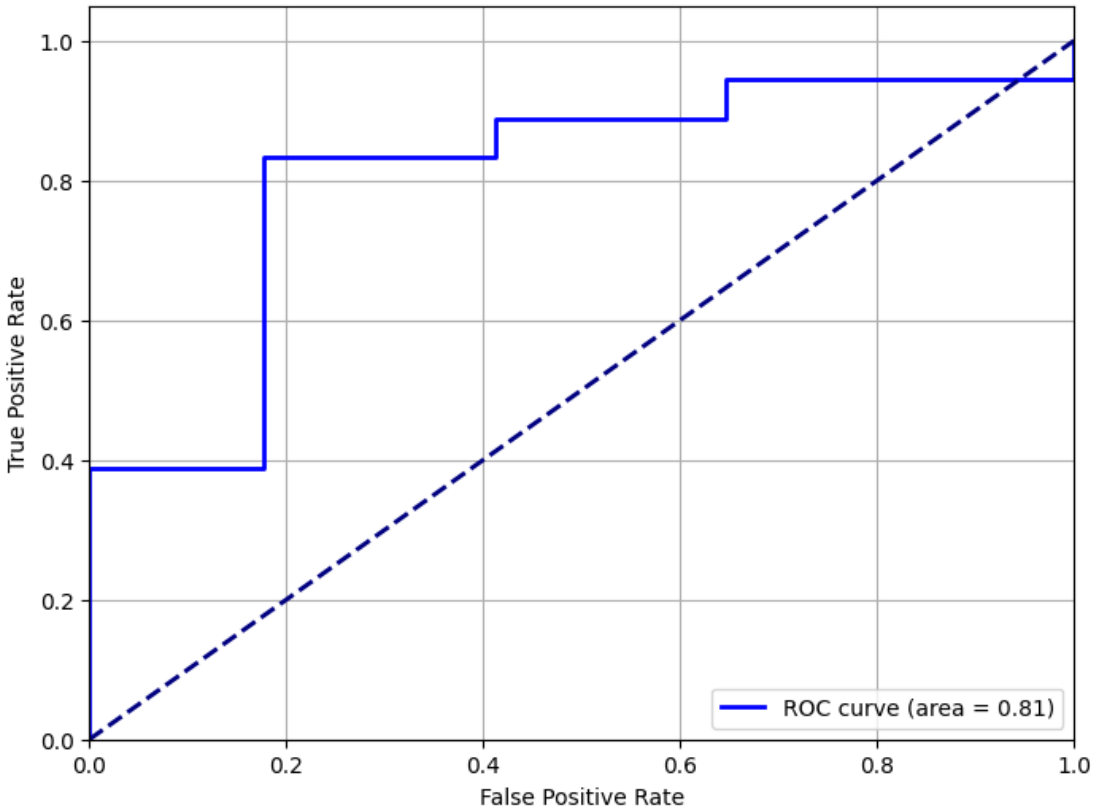

Fig. 7. Receiver Operating Characteristics (ROC) curve.

3) ANOVA f-value: The results show how progressively adding features impacts model performance using ANOVA-based selection. Initially, we have used only Glucose according to the ANOVA f-value which gives the accuracy of 60% and an F1-score of 58.8%. Then we have added Insulin ($C_{\text{f-value2}}$). It slightly improves the model performance, increasing both accuracy and F1-score to approximately 62.9%. After including HOMA ($C_{\text{f-value3}}$), it does not change the performance. However, when Resistin is added ($C_{\text{f-value4}}$), the model's performance improves to an accuracy of 65.7% and an F1-score of 68.4%. A significant boost is observed with the inclusion of BMI ($C_{\text{f-value5}}$). Then the accuracy rises to 74.3% and the F1-score to 76.9%. In this stage, the recall was 88%. When we have included MCP-1 ($C_{\text{f-value6}}$), the performance dropped. The addition of Age ($C_{\text{f-value7}}$) recovers the accuracy. Then the accuracy was found 80% and F1-score was 78.8%. When Adiponectin is added ($C_{\text{f-value8}}$), performance slightly decreases but remains robust (accuracy 77.1%, F1-score 75%). Finally, incorporating Leptin ($C_{\text{f-value9}}$) leads to a further small decline, stabilizing at 71.4% accuracy and an F1-score of 70.6%. This progression shows that some features give useful information and improve the model. But after a point, adding more features gives less benefit or can even hurt the model's accuracy.

Table II shows the ranking of features using the four selection methods. Glucose, HOMA, Insulin, Resistin, and Age appear as the most important features for breast cancer prediction.

A. Ensemble of Classifiers Trained on Distinct Feature Subsets

In this study, an ensemble voting classifier has been constructed using four pipelines. Each pipeline was based on a distinct feature selection method: mutual information, chi-square, ANOVA F-value, and correlation coefficient. The selected feature sets for these methods are as follows:

C_{mi6} = ['Age', 'Glucose', 'HOMA', 'Resistin', 'BMI', 'Insulin']

$C_{\chi 6}$ = ['MCP.1', 'Insulin', 'Glucose', 'HOMA', 'Resistin', 'Age']

$C_{\text{f-value7}}$ = ['Glucose', 'Insulin', 'HOMA', 'Resistin', 'BMI', 'MCP.1', 'Age']

$C_{\text{correlation7}}$ = ['Glucose', 'HOMA', 'Insulin', 'Resistin', 'BMI', 'MCP.1', 'Age']

Each pipeline used the AdaBoost classifier to enhance performance. The ensemble model combined predictions from the four AdaBoost-based pipelines using both hard voting and soft voting strategies. Both methods gave the same results, showing that the classifiers are well aligned. The ensemble achieved an accuracy of 82.86%, with F1-score, precision, and recall all measured at 82.35%. In Fig. 6, the confusion matrix shows that the model correctly predicted 14 instances of Class 1 and 15 instances of Class 2, with only three misclassifications for each class. This balance shows that the model performs well on both classes. The ROC curve (Fig. 7) depicts the true positive rate (TPR) versus false positive rate (FPR) across thresholds, with an AUC of 0.81 indicating fair separability.

B. Misclassified Instances

Misclassification happens when the model predicts the wrong class for a data point. In this case, the Table III shows 6 misclassified instances (indices 26, 100, 31, 55, 114, 30). These are the cases where the actual class and predicted class do not match. The main reason for misclassifications is that many features (like age, BMI, glucose) overlap between classes. This makes it hard for the model to clearly separate class 1 and class 2. Also, the model may not capture complex relationships between features. There might be some noise or variability in biological measurements.

The results section summarizes all the numerical findings, showing that the ensemble model performed consistently and well-balanced.

IV. Discussion

The experimental outcomes shows that combination of feature selection with AdaBoost-based ensemble voting significantly improves prediction accuracy. The top-rated features—Glucose, HOMA, Insulin, Resistin, and Age—are uniformly identified by all the methods. These biomarkers are of biological significance. These findings emphasize that the machine learning outcomes conform to current medical evidence, thus ensuring the validity of the suggested method.

The ensemble voting model achieved balanced accuracy for both classes, eliminating bias toward either non-cancer or cancer samples. The use of four statistical feature selection methods guaranteed that relevant and redundant variables were eliminated, increasing model interpretation and accuracy. However, some class overlaps, evidenced by feature distributions, indicate that there are biomarkers with very low discriminative power. This biological overlap explains the low number of misclassified instances indicated in the results.

Although the model is predictive, it was only based on a relatively small data set (116 cases). This restricts its use in larger populations.

It remains for future studies to advance this research by validating the model against larger, multi-center data sets and adding it to imaging or genomics to enhance diagnostic accuracy.

V. Conclusion

In this study, we applied AdaBoost and ensemble voting classifiers combined with feature selection methods to classify breast cancer cases using the Breast Cancer Coimbra dataset. By using four statistical filter techniques — Mutual Information, Chi-Square, ANOVA F-test, and Correlation Coefficient — we identified the most relevant features for prediction. Key features such as glucose, HOMA, insulin, resistin, and age were common across all selection methods. This highlights their strong predictive value and importance in breast cancer classification.

Our ensemble model reached an impressive 82.9% accuracy, with well-balanced precision, recall, and F1-scores. This shows it has strong and reliable predictive power in classifying breast cancer cases. Despite this, a few misclassifications were observed, mainly due to overlapping feature distributions and possible biological variability. These results show that combining feature selection with ensemble methods improves classification performance.

From the biomedical perspective, this study illustrates how the features glucose, HOMA, insulin, and resistin are highly correlated with breast cancer. These properties illustrate how metabolic and inflammatory problems are connected to the cancer. Because the biomarkers can be measured by simple blood tests, this procedure is a cheaper and non-invasive way to detect breast cancer at an early stage, especially where high-level medical imaging is unavailable.

From the AI perspective, this work illustrates that employing a lot of feature selection algorithms under an ensemble setting makes the system more robust and interpretable despite having little data. Both ensemble voting and AdaBoost techniques allow the model to work effectively without confusing it regarding which features to prioritize.

In the future,Utilizing the model on larger datasets from different hospitals will also make it stronger and more reliable. Overall, this study bridges medical utility and artificial intelligence and shows that interpretable ensemble learning is a useful and low-cost tool for early breast cancer detection.

A Two-Stage Framework for Abnormalities Detection in WCE Images by Combining Semantic Segmentation and Deformable Agent-Based Classification

Brahim Alibouch, Yasmina El Khalfaoui
LabSIV-Department of Computer Science-Faculty of Sciences, Ibn Zohr University, Agadir, Morocco

***Abstract*—Wireless capsule endoscopy (WCE) has revolutionized gastrointestinal (GI) diagnostics by offering a patient-friendly imaging and diagnostic tool compared to traditional endoscopic techniques. However, the manual assessment of these images is a time-consuming task and is prone to inaccuracies, which necessitates the implementation of automated approaches. In this paper, we introduce a two-stage deep learning framework to identify the most common GI abnormalities in WCE images. The first stage in the proposed method is to segment suspicious regions from the WCE images, which act as potential markers for GI abnormalities. In the second stage we perform frame-level classification to identify and categorize different pathologies in the GI tract. Extensive experiments conducted on four image datasets demonstrate that our approach achieves the highest values in terms of accuracy, precision, recall and specificity in comparison with four common deep learning methods : Resnet50, VGG16, Vit-S16 and InceptionV3.**

Keywords*—Wireless capsule endoscopy; deep learning; classification; gastrointestinal abnormalities

I. Introduction

Wireless Capsule Endoscopy has emerged as a revolutionary non-invasive diagnostic technology for visualizing the GI tract, particularly the small bowel, which remains challenging to access through conventional endoscopic procedures. This innovative technique involves patients swallowing a pill-sized capsule equipped with cameras that capture thousands of images as it traverses the digestive system, providing comprehensive visualization without the need for sedation or exposure to ionizing radiation [1]. The clinical significance of WCE is particularly pronounced in the diagnosis of small bowel disorders, including suspected bleeding, iron deficiency anemia, and Crohn's disease, where it serves as a first-line diagnostic tool.

However, the clinical adoption of WCE presents significant challenges that limit its full potential in routine gastroenterological practice. Each WCE examination generates an overwhelming volume of data, typically producing 50,000 to 80,000 images per patient, with only 5-10% containing pathologically relevant findings [2]. This massive data burden places substantial strain on healthcare professionals who must manually review and analyze each frame, a process that is not only time-consuming but also prone to human error and fatigue. The situation is further complicated by the fact that 20-30% of captured frames may be obstructed by bubbles, food residues, or other contaminants, making accurate diagnosis even more challenging [3].

Among the various pathological findings detectable through WCE, polyps represent a particularly important category of lesions that require precise identification and characterization. Polyps, which are abnormal tissue growths protruding from the intestinal wall, can range from benign lesions to pre-cancerous or malignant formations. Their early detection and accurate classification are crucial for determining appropriate treatment strategies and preventing progression to more serious conditions. However, polyp detection in WCE images presents unique technical challenges due to their variable size, morphology, and appearance, as well as the inherent limitations of capsule imaging, including motion artifacts, varying illumination conditions, and the presence of intestinal contents that may obscure visualization.

The integration of artificial intelligence (AI) and deep learning technologies in WCE analysis has shown tremendous promise in addressing these challenges. Recent advances in computer vision and machine learning have demonstrated the potential to reduce reading time by up to 95% while improving diagnostic accuracy [1]. Deep learning models, particularly convolutional neural networks (CNNs), have proven superior to classical machine learning methods due to their end-to-end learning capabilities and automatic feature extraction mechanisms [4]. These technologies offer the potential to not only automate the detection process but also provide objective, reproducible results that can support clinical decision making.

Despite significant progress in applying deep learning to WCE image analysis, most existing approaches focus on either classification or segmentation tasks independently. Classification methods excel at identifying the presence of pathological conditions but provide limited spatial information about lesion location and boundaries. Conversely, segmentation approaches can precisely delineate lesion boundaries but may not provide comprehensive diagnostic information about lesion characteristics and severity. This separation of tasks represents a significant limitation in clinical practice, where both spatial localization and diagnostic classification are essential for comprehensive patient care.

The development of unified framework that simultaneously perform both segmentation and classification represents a critical advancement in WCE image analysis. Such integrated approaches can leverage the complementary strengths of both

tasks, where segmentation provides precise spatial localization that can inform and improve classification accuracy, while classification results can guide and refine segmentation boundaries. This synergistic relationship is particularly important for polyp analysis, where accurate boundary delineation is essential for size estimation and morphological assessment, while classification provides crucial information about polyp type and potential malignancy risk. Furthermore, the clinical workflow in gastroenterology naturally requires both spatial and categorical information about detected lesions. Clinicians need to know not only whether a polyp is present (classification) but also its exact location, size, and morphological characteristics (segmentation). An integrated framework that provides both types of information simultaneously would significantly enhance clinical utility and diagnostic confidence while streamlining the review process.

This work presents a novel deep learning framework designed to address the dual challenges of GI abnormalities segmentation and classification in WCE images through an integrated approach that leverages the synergistic relationship between these complementary tasks. Our framework aims to provide comprehensive diagnostic support that meets the practical needs of clinical gastroenterology while addressing the technical challenges inherent in WCE image analysis.

This paper is organized as follows. In the next section the related works are reviewed. In Section III, we explain the proposed method. Section IV presents the outcomes of the experiments conducted to evaluate our approach. Finally, Section V delineates the conclusions of this paper.

II. Related Works

The application of deep learning techniques to wireless capsule endoscopy has experienced rapid growth over the past decade, with researchers exploring various approaches to automate the detection, classification, and segmentation of GI abnormalities. The foundation of automated WCE analysis lies in the development of robust classification systems capable of distinguishing between normal and pathological findings. Soffer et al. [4] conducted a systematic review and meta-analysis of deep learning applications in WCE, revealing exceptional performance across various pathological conditions. Their analysis demonstrated that CNNs achieved high pooled sensitivity and specificity scores, with particularly impressive results for bleeding detection (sensitivity 0.98, specificity 0.99) and ulcer identification (sensitivity 0.95, specificity 0.94). The superior performance of CNNs over classical machine learning methods was attributed to their end-to-end learning capabilities and automatic feature extraction mechanisms. Recent advances in CNN architectures have shown remarkable improvements in classification accuracy. Habe et al. [5] provided a comprehensive review of deep learning performance across 30 studies from 2013-2022, revealing that Xception models achieved the highest accuracy (99%) on datasets containing 53,555 images, followed by DenseNet121 with 98.17% accuracy on only 1,000 images, demonstrating the effectiveness of modern architectures in achieving high performance even with limited training data. Transfer learning approaches, particularly those utilizing ImageNet pre-trained models, have consistently shown significant performance improvements across different architectures, with Inception-ResNet-v2 achieving 98.1% accuracy on 400,000 images.

The integration of attention mechanisms has further enhanced classification performance. Bandopadhyay et al. [6] demonstrated the superiority of Vision Transformer (ViT) architectures over traditional CNNs for GI ulcer classification in WCE images. Their ViT model achieved perfect scores across all key metrics (Accuracy, Precision, Recall, and F1-Score) when compared against prominent deep learning models including ResNet50, VGG19, Inception V3, and Inception-ResNet152V2, highlighting the potential of transformer-based architectures in medical image analysis. Several researchers have explored sophisticated approaches to address specific challenges in WCE classification. Garbaz et al. [7] proposed a dual-branch deep convolutional neural network combining DenseNet121 with residual blocks specifically designed for detecting small, indistinct vascular lesions such as angiodysplasia and bleeding zones. Their architecture achieved accuracies of 99.50% and 96.96% on MICCAI 2017 and Kvasir-Capsule datasets respectively, with the residual block component contributing 12.0% and 8.78% accuracy improvements. Li et al. [8] introduced a dynamic multi-task learning framework that addresses fine-grained recognition and class imbalance challenges through the combination of semi-hard triplet loss with weighted cross-entropy loss. Their approach achieved 96.47% F1-score on Kvasir-Capsule (10-class classification) and 96.75% F1-score on CAD-CAP (3-class classification), demonstrating the effectiveness of multi-objective optimization in handling complex classification scenarios. The challenge of limited labeled data has been addressed through various innovative approaches. Muruganantham and Balakrishnan [9] proposed ACT-WISE, an uncertainty-driven active learning framework integrated with deep semi-supervised learning. Their teacher-student consistency regularization methodology achieved 97% classification accuracy and 0.95 AUC on the Kvasir-Capsule dataset, outperforming traditional semi-supervised methods like Mean Teacher (95% accuracy) while significantly reducing annotation requirements.

Recognizing the inherent temporal nature of WCE videos, several researchers have explored spatiotemporal analysis approaches. Bordbar et al. [10] pioneered the application of three-dimensional CNNs for multiclass WCE classification, processing 16 consecutive frames to leverage temporal relationships that gastroenterologists naturally consider during diagnosis. Their 3D-CNN approach achieved significant improvements over 2D methods, with 98.92% sensitivity vs. 98.05%, 99.50% specificity vs. 86.94%, and 99.20% accuracy vs. 92.60%, demonstrating the value of incorporating temporal dependencies. Prakash and Krishnamurthy [11] developed an innovative transfer learning approach combining depth estimation with evolutionary optimization for optimal keyframe selection from WCE videos. Their TUMNetv2 architecture integrated transformer encoders with UNet+ and MobileNetv2, achieving 93% accuracy, 90% precision, 85% recall, and 87% F1-score while significantly reducing computational burden through intelligent frame selection. The combination of deep features with traditional hand-crafted features has shown promising results in WCE analysis. Amiri et al. [12] proposed a hybrid approach combining deep features from pre-trained ResNet50 with hand-crafted color, shape, and texture features. Their method utilized the Expectation Maximization algorithm for

region of interest extraction and achieved 97.82% accuracy in detecting various abnormalities including ulcers, bleeding, angiodysplasia, lymphoid hyperplasia, and polyps. Caroppo et al. [13] developed a transfer learning-based expert system that combined features from ResNet50 and Inception V4 architectures. Their hybrid approach, utilizing minimum Redundancy Maximum Relevance feature selection and SVM classification, achieved 98.09% accuracy on KID Dataset 2 and 94.48% accuracy on MICCAI 2017 dataset, with strong cross-dataset generalization capabilities (91.46% and 93.28% accuracy).

While most WCE research has focused on classification tasks, segmentation approaches have gained increasing attention for their ability to provide precise spatial localization of abnormalities. He et al. [14] proposed MVANet, a Multi-view Attention Network designed to address critical challenges in endoscopic image segmentation, including boundary blurring, low contrast, and small lesion detection. Their architecture achieved state-of-the-art performance with mDice values of 93.1% and 94.9%, and mIoU values of 88.4% and 90.7% on Kvasir-SEG and CVC-ClinicDB datasets respectively. Charfi et al. [15] presented a novel approach using Dense-UNet for segmentation followed by a modified residual attention network for classification. Their method focused on detecting and segmenting red lesions, ulcers, and polyps, addressing the challenge of processing thousands of low-quality images in WCE videos. The quality of WCE images presents significant challenges for automated analysis systems. Sadeghi et al. [3] addressed this issue by creating the first publicly available multicentre dataset for clear and contaminated region segmentation in WCE images. Their dataset included pixel-level annotations for 17,593 images, categorizing contamination levels from 1-10 based on percentage of contaminated area, with contamination ranging from minimal (0.28% ± 1.29%) to nearly complete coverage (95% ± 0.0%), highlighting the critical need for robust preprocessing and quality assessment mechanisms in WCE analysis systems. The detection of rare or previously unseen pathologies represents a significant challenge in WCE analysis. Quindós et al. [16] addressed this through a novel patch-based self-supervised approach for out-of-distribution detection. Their three-stage methodology achieved AUROC scores ¿0.6 for detecting unseen pathologies including lymphangiectasia (0.767), foreign bodies (0.729), ulcers (0.795), and blood (0.677), demonstrating the potential of unsupervised approaches for identifying novel pathological conditions. Accurate localization within the GI tract is crucial for clinical interpretation of findings. Fan et al. [17] developed an automatic locating system for identifying the pylorus and ileocecal valve using ResNet-50-based classification combined with a novel sliding pin algorithm. Their approach achieved mean locating errors of 26 frames for the pylorus and 65 frames for the ileocecal valve, representing significant improvements over previous state-of-the-art methods. Object detection frameworks have been adapted for WCE analysis to provide both classification and localization capabilities. Xiao and Feng [2] developed an improved YOLOv3-based system for small intestinal lesion detection, introducing a novel labeling strategy that expanded lesion annotation areas to 1.33 times the original size. Their approach achieved 93.5% mAP with 4% improvement over standard YOLOv3, demonstrating better speed-accuracy balance while successfully identifying lesions from small to large sizes. Fernandes et al. [18] developed a deep learning-based methodology to automatically identify physician-annotated frames within WCE videos, with MobileNet achieving superior performance with 94% accuracy for first match identification and 98% accuracy for top-20 matches.

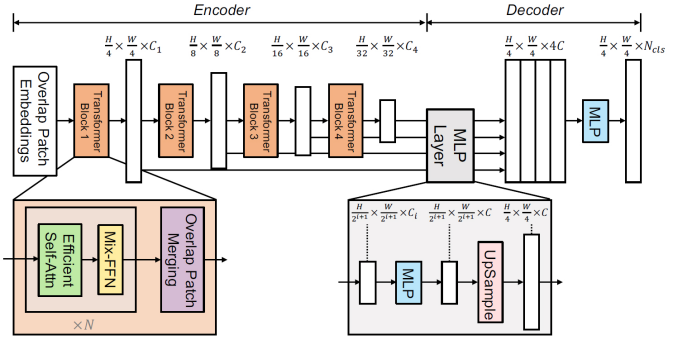

Fig. 1. SegFormer [19] architecture.

Despite significant progress in WCE image analysis, several limitations persist in current research. Most existing approaches focus on either classification or segmentation tasks independently, limiting their clinical utility where both spatial and categorical information are required. Additionally, while many studies report high accuracy on specific datasets, there remains a lack of comprehensive frameworks that address multiple aspects of polyp analysis simultaneously. The challenge of class imbalance, particularly evident in polyp detection where pathological cases are relatively rare, requires more sophisticated approaches that can effectively learn from limited positive examples while maintaining high sensitivity. Furthermore, the integration of clinical workflow considerations and real-time processing requirements has received limited attention in current research. The temporal nature of WCE videos presents both opportunities and challenges that have been insufficiently explored, and there remains significant potential for developing more sophisticated approaches that leverage the sequential nature of WCE data for improved diagnostic accuracy. Current research also lacks comprehensive evaluation frameworks that consider both technical performance metrics and clinical utility measures, making the development of standardized evaluation protocols that reflect real-world clinical scenarios essential for advancing the field toward practical clinical deployment. This comprehensive review highlights the significant progress made in applying deep learning to WCE analysis while identifying key gaps and opportunities for advancement. The proposed framework aims to address these limitations through an integrated approach that combines the strengths of both segmentation and classification methodologies for comprehensive polyp analysis in WCE images.

III. Methodology

In this paper, we introduce a two-stage deep learning framework to identify the most common GI abnormalities in WCE images. The first stage in the proposed method is to segment suspicious regions from the WCE images, which act as potential markers for GI abnormalities. To this end, we employed SegFormer-B0, a lightweight transformer-based semantic segmentation model. In the second stage we

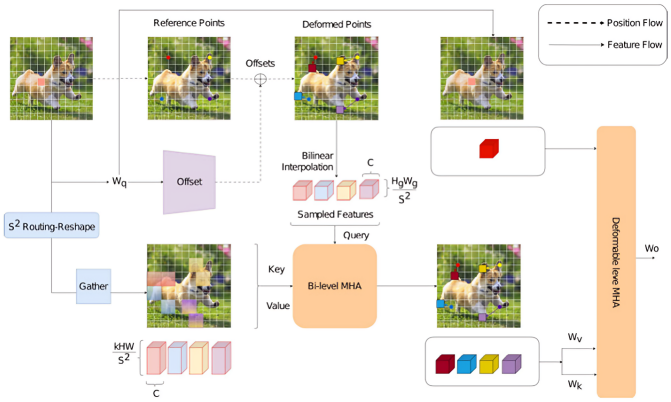

Fig. 2. Architecture of DBRA [20].

perform frame-level classification to identify and categorize different pathologies in the GI tract. For this purpose, we used DeBiFormer, a vision transformer architecture that uses an advanced attention mechanism called Deformable Agent Bi-level Routing Attention, which merges deformable attention with bi-level routing to reduce computational cost while improving accuracy.

The methodology combines the computational efficiency of SegFormer for initial segmentation with the advanced attention mechanisms of DeBiFormer for refined classification and abnormality detection.

A. SegFormer

Introduced by Xie et al. [19], SegFormer represents a significant step forward in applying Vision Transformers (ViTs) to semantic segmentation. The design philosophy of SegFormer focuses on creating a framework that is simple, efficient, and powerful, effectively overcoming the inherent limitations of prior ViT-based models in dense prediction tasks. It specifically addresses two major challenges: the low-resolution, fixed-size feature maps generated by standard ViTs, which are poorly suited for pixel-level classification, and the high computational complexity associated with self-attention, especially when dealing with high-resolution images.

The architecture consists of two main components: a hierarchical Mix Transformer (MiT) encoder and a lightweight All-MLP decoder as shown in Fig. 1. This design eliminates the need for positional encodings, supports multi-scale feature extraction, and significantly reduces model complexity while achieving state-of-the-art performance.

The encoder generates multi-scale features at resolutions of $\{1/4, 1/8, 1/16, 1/32\}$ of the original image, addressing the limitation of Vision Transformers that produce only single-scale representation and enabling the capture of both local and global features effectively, which is essential to handle dense prediction tasks like segmentation. The decoder takes the multi-scale feature maps from all four encoder stages and uses MLPs to transform and concatenate them together for pixel-wise predictions . The final output is a segmentation mask at $\frac{H}{4} \times \frac{W}{4} \times N_{cls}$ resolution, where Ncls represents the number of categories.

B. DeBiFormer

DeBiFormer (Deformable Bi-level Routing Attention Transformer) represents a significant advancement in vision transformer architectures by addressing key limitations in existing attention mechanisms. Introduced by Long et al. [20], DeBiFormer combines the flexibility of deformable attention with the semantic relevance of bi-level routing (Fig. 2) to create a more effective and interpretable attention mechanism for visual recognition tasks.

As shown in Fig. 3(a), the architecture of DeBiFormer follows a four-stage pyramid structure where each stage begins with either overlapped patch embedding (first stage) or patch merging modules (subsequent stages) to progressively reduce spatial resolution while increasing channel dimensions, followed by multiple consecutive DeBiFormer blocks. Each DeBiFormer block incorporates a 3×3 depthwise convolution for implicit relative position encoding, the DBRA module for cross-location relation modeling, and a 2-ConvFFN module for per-location feature embedding.

The core contribution of DeBiFormer is its novel Deformable Bi-level Routing Attention (DBRA) module [Fig. 3 (b)], which operates through an attention-in-attention architecture. Unlike traditional attention mechanisms that either focus on fixed patterns or lack semantic awareness, DBRA achieves both spatial flexibility and semantic relevance through a two-stage process:

- Deformable Point Generation: The module first generates deformable points using an offset network that shifts reference points toward informative regions based on query features. This allows the model to

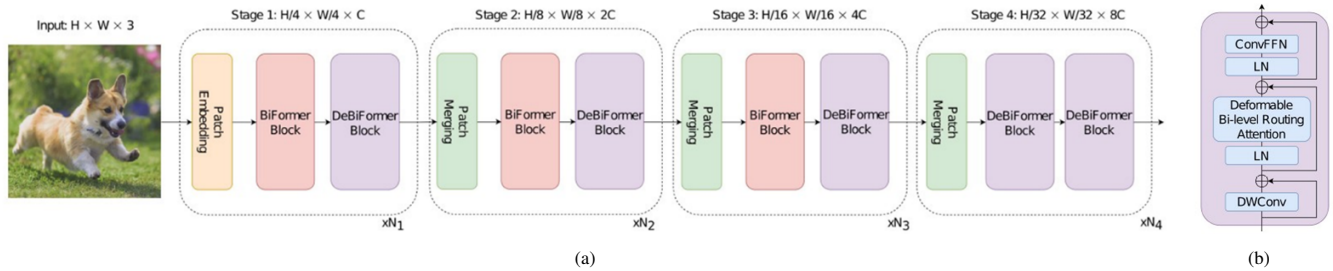

Fig. 3. (a) Overall DeBiFormer architecture, (b) DeBiFormer block [20].

adaptively focus on important areas rather than being constrained to regular grid patterns.

- Semantic Region Selection: Instead of attending to all deformed points equally, DBRA employs a bi-level routing mechanism where each deformable point acts as an agent query. These agents select only the top-k most semantically relevant regions, ensuring computational efficiency while maintaining semantic focus.

C. Proposed Method

This paper proposes a novel two-stage deep learning framework for the automated detection of abnormalities in WCE images. The overarching goal is to first precisely localize and segment potential pathological regions and subsequently classify them with high accuracy to reduce false positives. The proposed architecture, leverages the strengths of a state-of-the-art semantic segmentation model followed by a powerful, computationally efficient transformer-based classifier.

The first stage of our proposed framework is dedicated to the accurate segmentation of potential abnormalities within WCE images. For this task, we have selected SegFormer-B0, a lightweight vision transformer-based segmentation model that can effectively handle the hierarchical feature extraction required for medical image segmentation without the over-fitting issues common in traditional CNNs on small medical datasets. It processes the full WCE image and outputs a binary segmentation mask that precisely delineates the boundaries of suspicious regions. This stage acts as an intelligent attention mechanism, effectively filtering out vast areas of normal mucosa and focusing subsequent computational resources only on regions of clinical interest.

Following the segmentation of potential GI abnormalities by SegFormer-B0, the second stage of our framework involves classifying these segmented regions into specific pathological categories. For this classification task, we propose the use of DeBiFormer, leveraging its deformable agent bi-level routing attention mechanism to process both the original WCE images and the segmentation outputs from Stage 1. This dual-input approach enables the network to validate and refine segmentation results while providing robust abnormality classification. An overview of the proposed two-stage deep learning framework is illustrated in Fig. 4.

IV. Experiments

A. Datasets

For this work we used two datasets to pre-train the SegFormer-B0 model : CVC-ClinicDB [21] and Kvasir-SEG [22]. CVC-ClinicDB is a dataset consisting of 612 images extracted from colonoscopy video sequences, each with a corresponding binary ground truth mask highlighting polyps. All images are standardized at a resolution of 384 × 288 pixels, making the dataset compact and consistent. Kvasir-SEG, on the other hand, contains 1,000 images with varying resolutions, reaching up to 1920 × 1072 pixels, and each is paired with a high-quality expert-verified mask.

Once the SegFormer-B0 model pre-trained, two other datasets were used to train and test the whole proposed model. The first is Curated Colon Disease Dataset for Deep Learning [23] which includes 6000 WCE images of the GI tract, distributed across four categories: normal, ulcerative colitis, polyps, and esophagitis, with 1500 images per class. The second one is Kvasir v2 [24], a multi-class GI endoscopy dataset containing 8,000 endoscopic images evenly distributed across eight classes. Each class has 1,000 images, and the resolutions vary from 720 × 576 to 1920 × 1072 pixels.

Tables I and II provide detailed informations on each dataset.

TABLE I. Curated Colon Disease and Kvasir v2 Datasets Specifications

Dataset	Class	Train	Validation	Test	Total
Curated Colon Disease	Normal	1200	150	150	1500
	Ulcer	1200	150	150	1500
	Polyps	1200	150	150	1500
	Esophagitis	1200	150	150	1500
Kvasir v2	dyed-lifted-polyps	800	100	100	1000
	dyed-resection-margins	800	100	100	1000
	Esophagitis	800	100	100	1000
	normal-cecum	800	100	100	1000
	normal-pylorus	800	100	100	1000
	normal-z-line	800	100	100	1000
	polyps	800	100	100	1000
	ulcerative-colotis	800	100	100	1000

TABLE II. Kvasir-SEG and CVC-ClinicDB Datasets Specifications

Dataset	Train	Validation	Test	Total
Kvasir-SEG	800	100	100	1000
CVC-ClinicDB	490	61	61	612

B. Preprocessing and Data Augmentation

A combination of data augmentation and normalization techniques can improve the quality, diversity, and generalizability of training data [25]. In this work, the images are first resized to fixed size and several transformations are applied including rotations, vertical and horizontal flips, and affine transformations. Color jittering is performed to alter saturation contrast, hue and brightness also as random perspective distortion to enhance furthermore diversity. To maintain consistency during evaluation, only resizing and normalization are performed on validation set.

This preprocessing pipeline guarantees that the model encounters diverse and realistic image variations during training, while simultaneously maintaining the validation data in a standardized format for precise performance assessment.

C. Implementation Details

The SegFormer-B0 model was pre-trained with CVC-ClinicDB and Kvasir-SEG datasets using Adam optimizer and binary cross entropy loss function with a batch size of 4 over 60 epochs. The initial learning rate was set to 0.00005 and the process were executed on Google Colab, with an NVIDIA Tesla T4 GPU with 2560 CUDA cores and 16 GB of GDDR6 memory.

to train the whole model, we used Curated Colon Disease and Kvasir v2 datasets over 80 epochs using Adam optimizer, the binary cross entropy loss function, a batch size of 32

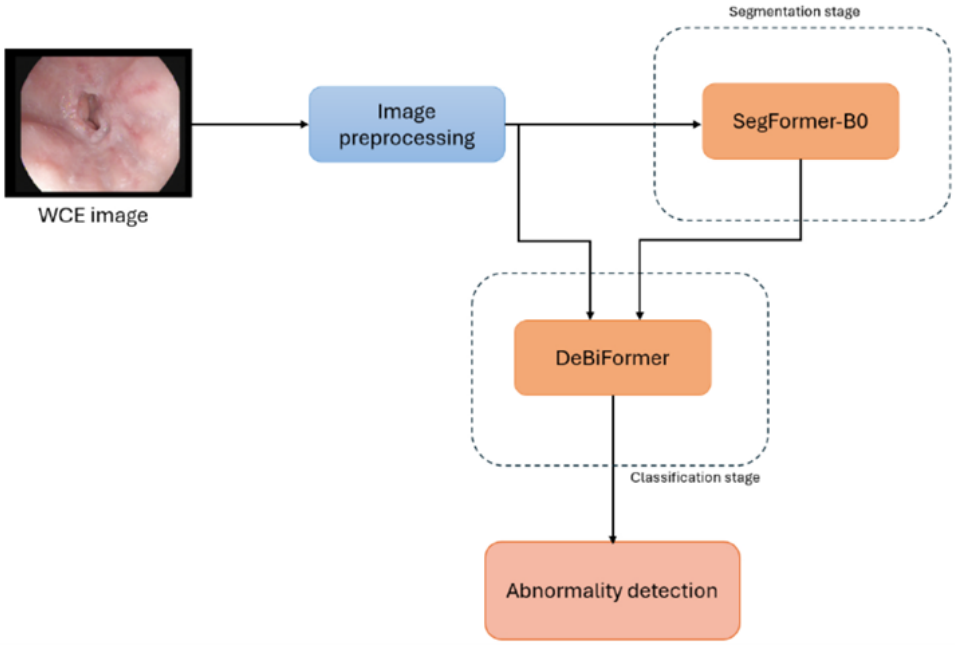

Fig. 4. Overview of the proposed method.

and an initial learning rate $\alpha = 0.0002$. The proposed model was implemented in PyTorch and trained using an NVIDIA RTX A4000 GPU with 16 GB of memory. The computational resources were provisioned through the Paperspace Gradient platform. We utilized a pre-configured GPU-optimized container, which included PyTorch 1.12, CUDA 11.6, and cuDNN 8.

D. Results

In this section, the potential of the proposed method is shown. For this purpose, comprehensive experiments are conducted based on confusion matrix analysis, which collectively offer insights into the model's performances. A confusion matrix is a tabular representation where the model's predicted class labels are compared with the ground truth labels. The matrix is structured to provide counts of four fundamental outcomes for each class:

- True Positive (TP): The model correctly predicted the positive class. (Reality: Yes, Prediction: Yes)
- True Negative (TN): The model correctly predicted the negative class. (Reality: No, Prediction: No)
- False Positive (FP): The model incorrectly predicted the positive class when it was actually negative. Also known as a Type I error. (Reality: No, Prediction: Yes)
- False Negative (FN): The model incorrectly predicted the negative class when it was actually positive. Also known as a Type II error. (Reality: Yes, Prediction: No)

Based on these basic metrics, a total of four specific performance metrics were used : accuracy, precision, specificity and recall.

$$\text{Accuracy} = \frac{\text{True Positives} + \text{True Negatives}}{\text{Total Instances}} \quad (1)$$

$$\text{Precision} = \frac{\text{True Positives}}{\text{True Positives} + \text{False Positives}} \quad (2)$$

$$\text{Specificity} = \frac{\text{True Negatives}}{\text{True Negatives} + \text{False Positives}} \quad (3)$$

$$\text{Recall} = \frac{\text{True Positives}}{\text{True Positives} + \text{False Negatives}} \quad (4)$$

After conducting preliminary pre-training, the SegFormer-B0 model attains accuracy values of 98.80% and 91.19%, and loss values of 0.03 and 0.14 on the training and validation sets, respectively. Thus, SegFormer-B0 shows a high potential in improving the performance of segmentation in GI abnormalities detection as can be seen in Fig. 5.

In our experiments, we also compared the proposed method with four deep learning models including Resnet50 [26], VGG16 [27], InceptionV3 [28] and Vit-S16 [29]. To guarantee a scientific and logical comparison of methods, all experiments were carried out in the same environment. The comparison results are shown in Tables III and IV.

On the Curated Colon Disease dataset, our methods achieves the highest accuracy of 99.30%, followed by VGG16 (93.06%) and Vit-S16 (91.83%). Our method attains also the highest values across all other metrics reaching 99.30% precision, 99.30% recall and 99.77% specificity.

The proposed method surpasses all the four methods also On the Kvasir v2 dataset, achieving an accuracy of 94.13%

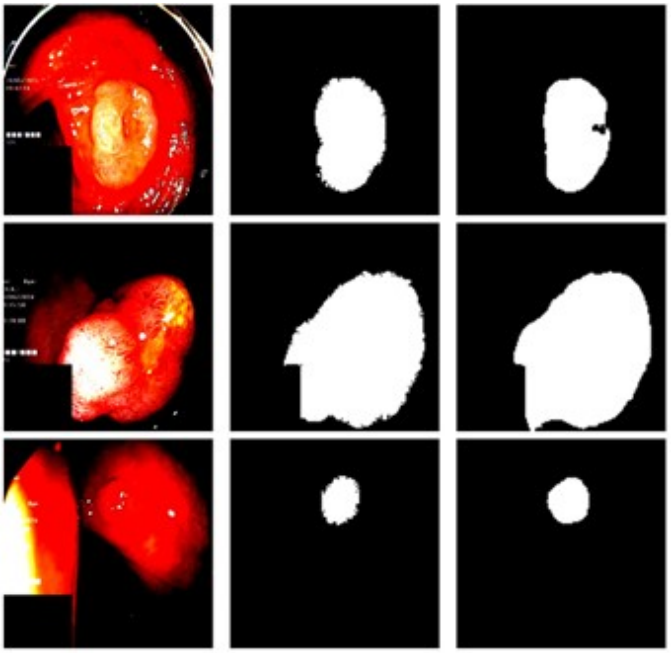

Fig. 5. Visual results of segmentation using SegFormer-B0 model. From left to right: Input image, Ground truth, SegFormer-B0 model.

TABLE III. QUANTITATIVE COMPARISON BETWEEN OUR METHOD AND DIFFERENT MODELS ON THE CURATED COLON DISEASE DATASET

Methods	Metrics			
	Accuracy (%)	Precision (%)	Recall (%)	Specificity (%)
Resnet50	83.40	84.01	83	94.40
VGG16	93.06	93	90.47	97.69
InceptionV3	74.09	83.46	62.22	91.36
Vit-S16	91.83	91.98	91.73	97.33
Our method	**99.30**	**99.30**	**99.30**	**99.77**

accuracy, 94.18% precision, 94.12% recall and 99.16% specificity.

Overall, compared against four prominent deep learning models, our model achieves strong performance on both Curated Colon Disease and Kvasir v2 datasets, underscoring the efficacy and the potential of our approach.

V. CONCLUSION

In this work, we developed and evaluated a novel, two-stage deep learning framework for the automated segmentation, and classification of abnormalities in Wireless Capsule Endoscopy images. The methodology leverages the complementary strengths of two state-of-the-art Transformer-based architectures: SegFormer-B0 for precise pixel-level segmentation of potential pathological regions, and DeBiFormer for the accurate classification of these segmented regions into specific abnormality types by means of its flexible Deformable Bi-level Routing Attention module. Segmentation provides precise spatial localization that can inform and improve classification accuracy, while classification results can guide and refine segmentation boundaries. The experiments shows that our unified framework that simultaneously perform both segmentation and classification significantly enhances performances in WCE image analysis. A comparative studies was conducted to validate the effectiveness of our approach. The results show that our approach achieves the highest values in terms of accuracy, precision, recall and specificity outperforming four common deep learning methods : Resnet50, VGG16, Vit-S16 and InceptionV3.

TABLE IV. QUANTITATIVE COMPARISON BETWEEN OUR METHOD AND DIFFERENT MODELS ON THE KVASIR V2 DATASET

Methods	Metrics			
	Accuracy (%)	Precision (%)	Recall (%)	Specificity (%)
Resnet50	83.40	84.01	0.83	94.40
VGG16	93.06	93	90.47	97.69
InceptionV3	74.09	83.46	62.22	91.36
Vit-S16	91.83	91.98	91.73	97.33
Our method	**94.13**	**94.18**	**94.12**	**99.16**

While our approach generally succeeds in identifying the most important anomalies, it is less efficient in the presence of less prominent anomalies and noise such as air bubbles and food debris. In future work, we aim to address these limitations and improve our model performance by including transfer Learning techniques and extending our evaluation to other public datasets offering additional variability in WCE images.

Predicting Employee Attrition in the Saudi Private Sector Using Machine Learning

Haya Alqahtani, Hana Almagrabi, Amal Alharbi
Department of Information Systems-Faculty of Computing and Information Technology,
King Abdulaziz University, Jeddah, Saudi Arabia

***Abstract*—Employee attrition represents a prominent issue facing organizations, as human capital represents one of the most valuable resources. Attrition refers to the voluntary or involuntary reduction in the number of employees, which can negatively affect profitability, reputation, and overall organizational performance. Therefore, a comprehensive understanding of this phenomenon, its causal factors, and the development of retention strategies is crucial for mitigating employee turnover. The purpose of this work is to predict employee attrition in the Saudi private sector and identify the key factors contributing to employee turnover using machine learning approaches. in addition, the research structurally evaluates the performance of multiple Machine Learning (ML) algorithms within the proposed framework to determine the most effective predictive model for employee attrition. This study utilized a training dataset obtained from an online survey targeting employees in the Saudi private sector in order to investigate employee attrition and identify its most prominent causes within this context. Thus, various Machine Learning (ML) algorithms, including Logistic Regression (LR), Support Vector Machine (SVM), K-Nearest Neighbors (KNN), Decision Tree (DT), Random Forest (RF), Extreme Gradient Boosting (XGBoost), Bagging ensemble, and Voting Classifier (VC) were evaluated. The results demonstrate that the Voting Classifier (VC) yielded the highest accuracy at 90%. Moreover, the analysis identified job opportunities and job titles as some of the most influential factors driving employee turnover.**

***Keywords*—Employee attrition; attrition prediction; predictive models; machine learning; voting classifier; ensemble methods; Saudi private sector; employee turnover; employee retention; feature importance**

I. Introduction

Employee attrition is a critical challenge for organizations due to its impact on productivity, operational costs, and long-term business sustainability. Attrition occurs when employees leave their organizations due to resignation, retirement, or involuntary termination. There are various key factors influencing employee attrition, including job satisfaction, work–life balance, compensation, work environment, and age. Employees who perceive themselves as undervalued or undercompensated are more likely to leave their organizations in pursuit of better opportunities [1]. Employee attrition can be measured using metrics such as sales growth, return on equity, customer service quality, and profitability [2].

As a matter of fact, voluntary turnover is particularly disruptive, resulting in the loss of institutional knowledge and interrupting ongoing projects [3]. Moreover, new hires require significant time to achieve the performance level of their predecessors, which reduces organizational efficiency [4], [5]. Studies have shown that voluntary employee turnover creates significant costs due to the expenses of recruitment, hiring, training, and employee development, which can be more than 1.5 times an employee's annual salary [6].

Given the significant impact of attrition, predictive analytics has become an essential tool for forecasting employee turnover and formulating strategies to mitigate it [7]. Identifying employees prone to attrition enables organizations to proactively improve retention, enhance employee satisfaction, and reduce turnover-related costs [8]. HR analytics, known as talent analytics [9], plays a vital role in quantifying workforce factors that influence company outcomes, thereby supporting better decision-making [10]. Consequently, HR professionals must develop an in-depth understanding of employee profiles and the critical factors influencing turnover to accurately identify individuals at risk of departure [11], [12], [13].

Data is a crucial element for the success of a people analytics team [14]. However, in HR analytics, the focus should shift from simply collecting large volumes of data to ensuring the data provides meaningful insights and is used effectively to create organizational value [10]. Previous research on attrition prediction has predominantly utilized publicly available datasets, such as the IBM Employee Attrition dataset, as well as datasets obtained from platforms like Kaggle. Nevertheless, such datasets do not capture the complexity of real-world employee behavior and organizational dynamics, in addition to being characteristically imbalanced, causing predictive bias if not properly handled [8]. In order to address existing limitations, the primary objective of this study was to develop a realistic dataset and propose a robust ML framework for predicting employee attrition.

The main contributions of this paper are threefold:

1) Development of a contextually-grounded dataset for the Saudi private sector: This research introduces an empirically-collected dataset from 1,191 real employees across diverse Saudi industries, addressing the critical limitation of prior studies that rely predominantly on synthetic datasets (e.g., IBM HR dataset). The dataset uniquely captures region-specific factors shaped by Saudization policies and cultural dynamics, while incorporating previously underexplored variables such as job opportunities, emotional commitment, health issues, and sector diversity. This contribution fills a significant gap in attrition research for emerging markets and provides a reusable resource for future studies in similar contexts [15].

2) A comprehensive comparative ML framework with systematic feature selection: This study systematically evaluates eight ML algorithms—including conventional methods (LR, SVM, KNN, DT) and ensemble techniques (RF, XGBoost,

Bagging, Voting Classifier)—across seven feature selection configurations with SMOTE-based class balancing [16]. The Voting Classifier with RFE-selected features achieves 90% accuracy, demonstrating that ensemble methods significantly outperform conventional approaches while maintaining interpretability. This design provides generalizable methodological guidance for predictive modeling in real organizational settings where data imbalance and feature redundancy are prevalent. This framework provides HR practitioners with evidence-based guidance for selecting optimal modeling strategies for imbalanced attrition datasets.

3) Actionable insights revealing a paradigm shift in attrition drivers: The feature importance analysis reveals that dynamic developmental factors (job opportunities, career advancement, job titles) significantly outweigh traditional demographic factors (age, Academic degree) in predicting attrition. The study provides data-driven visions for targeted interventions—including career development programs and advancement pathways—that enable organizations to proactively identify at-risk employees.

Experimental results demonstrate the effectiveness of the proposed approach, with promising accuracy and generalization capabilities of the models. The remainder of the paper is structured as follows: Section II presents a review of previous studies on employee attrition prediction. Section III details the methodology adopted in this study, including dataset development, modeling framework, and evaluation strategy. Section IV reports the experimental results and feature analysis. Section V discusses the findings and their implications. Section VI offers concluding remarks and potential directions for future research.

II. Literature Review

A. Employee Attrition Overview

Employee attrition is defined as the departure of employees from an organization for various reasons, including resignation, retirement, or death [17]. Attrition is also described as a reduction in the workforce resulting from these departures and is sometimes referred to as total turnover or wastage [18], [19]. While attrition reflects a decline in the number of employees, employee turnover specifically denotes the replacement of departing employees with new hires. These terms are often used interchangeably in workforce analyses due to their conceptual overlap. Turnover can be classified as voluntary or involuntary [20]. Even though dysfunctional turnover, characterized by the loss of high-performing employees, is detrimental to an organization, the turnover of employees with easily replaceable skills tends to have less impact [21].

In fact, employee attrition is a critical issue impacting various sectors, particularly those where employee roles are essential, creating barriers to profitability, competitiveness, and productivity by causing overtime, delayed project delivery, customer dissatisfaction, and reduced morale among remaining staff who must fill vacancies [19]. Apart from this, high attrition rates contribute to increased employee turnover, resulting in substantial expenses related to recruitment, training, and development of new hires [20], [22]. Therefore, retaining employees is financially crucial as it directly influences revenue growth through customer acquisition and retention [23]. Furthermore, voluntary turnover results in workforce movement across companies and roles, transferring valuable knowledge to competitors, and consequently posing a major risk to organizational interests [24].

B. Factors Influencing Employee Attrition

While human resources represent one of the most valuable assets contributing to a company's success, one of the most prominent challenges faced by HR management is employee attrition [22]. The initial step towards addressing this issue involves identifying the underlying causes and examining the factors associated with attrition. In this sub-section, several studies that have identified or investigated these factors are discussed.

For instance, the study in [17] reportes that employee attrition occurs for various reasons, including insufficient support for employees in lower organizational positions, lack of direct communication lines between these employees and their supervisors, monotonous tasks leading to a loss of creativity in repetitive jobs, limited career advancement prospects, and a lack of opportunities. As well as that, authors in [25] confirm that employees tend to leave their jobs when they perceive inadequate compensation, experience disagreements with their managers, or confront issues related to work hours, career development, and family obligations.

Moreover, a study conducted on 40 private financial institutions—including banks, investment fund organizations, and insurance companies—in the Kottayam district of India concluded that a strained relationship between management and employees, employee dissatisfaction, lack of job security, and job-related pressure significantly contribute to employee attrition [19]. Additionally, extensive research highlights a range of factors influencing turnover rates, which can broadly be categorized into organizational factors, job-related factors, work environment factors, and personal factors [26].

C. Employee Attrition and Retention in Saudi Private Sector

In this subsection, studies investigating the factors that impact employee turnover in the Saudi private sector are presented to highlight the significance of this issue and the necessity for continued research. The following studies explore some organizational and job-related factors closely related to employee attrition, such as job satisfaction, work participation, work pressures, rewards, effective training, and recognition.

For example, the study in [27] examined the impact of training and development opportunities following Saudization on employees' intentions to leave their organizations. The findings indicated that providing employee training contributed to retention exceeding five years, with training and development opportunities facilitating promotions. This was identified as a critical factor in reducing turnover rates. Besides that, a study conducted in [28] aimed to identify the causes of employee turnover and its effects on the Saudi business environment. The study focused on factors such as job satisfaction, organizational commitment, support, feedback, rewards, and recognition. The results revealed that the primary factors influencing employees' decisions to leave included organizational support, rewards, appreciation, and commitment, whereas job satisfaction and

supervisor support had a comparatively less impact on turnover intention.

In contrast, the authors in [29] conducted a study to identify the employer retention methods and the factors affecting retention from the employee's perspective. The study was carried out in private businesses in three Saudi Arabian cities: Jeddah, Rabigh, and Yanbu. The findings indicated that increased rewards and privileges are key retention strategies for businesses aiming to maintain their staff long-term. Another study [30] demonstrated a negative relationship between employee experience and turnover intention, suggesting that as employees gain more experience, their likelihood of leaving decreases. Additionally, age plays a significant role in turnover motivation, with older workers exhibiting a lower propensity to leave compared to younger employees.

D. Overview of Predictive Models for Employee Attrition

Predictive ML involves training algorithms on historical data to generate predictions for new, unseen data. By leveraging various factors—such as job performance, length of service, and other relevant indicators— HR managers can evaluate an employee's intention to leave their position. Consequently, ML models have been employed extensively for the prediction of employee attrition. Inspired by previous studies, combinations of several of these models and techniques have been applied in this study to the newly created dataset, and the results have been analyzed in order to obtain robust predictions.

For instance, this study [13] suggested that people analytics be used to predict employee attrition, with a focus on data quality over quantity. The study employed three datasets: the IBM HR Analytics Employee Attrition dataset, a simulated HR dataset based on Kaggle data, and a survey-based dataset on the reasons for attrition, and applied a variety of algorithms, including deep learning methods, traditional ML models: DT, SVM, LR, RF, and ensemble techniques like XGBoost, VC, and stacking ANNs. The results indicated that the VC outperformed other models across all datasets. In the same way, the study in [31] evaluated other algorithms including KNN, Naive Bayes,RF, and LR on IBM HR Analytics Employee Attrition dataset, reporting the highest accuracy of 89% for Naive Bayes.

In addition, the study in [32] used various ML and ensemble learning methods to predict employee attrition, comparing four ML techniques and three ensemble methods, implementing grid search for hyperparameter tuning. The results reveal that the RF outperformed other models with an accuracy of 95%, identifying job satisfaction and stock options as primary attrition drivers. Similarly, Garg et al in [33] trained RF, AdaBoost, XGBoost, and ensemble stacking models on the IBM dataset, reporting the RF classifier as the top performing with 87.41% accuracy and 88% precision, and indicating that monthly pay significantly influences employee turnover.

In study [34], the IBM HR Analytics Employee Attrition and Performance dataset was used to train multiple models, including LR, RF, SVM, KNN, and DT. The LR model achieved the highest accuracy, with 87% precision and an F1 score of 83%. The findings identified monthly income, overtime, years with the current manager, age, distance from home, total working years, and years at the company as key attrition indicators. As well as previous research, [35] has used the IBM dataset available to evaluate LR, DT, RF, GBM, XGBoost, SVM, and KNN for attrition prediction. As a result, RF and GBM demonstrated superior predictive performance for employee retention. However, the SVM model achieved an accuracy of 88.78% and maintained a balanced performance with respect to accuracy and recall for the minority class (employees who departed), highlighting its usefulness in attrition prediction.

E. Research Gap and Study Positioning

Despite the growing body of research on employee attrition prediction using ML, several critical gaps remain that limit the practical applicability and contextual relevance of existing studies.

1) First: The majority of prior research has relied heavily on synthetic datasets, particularly the IBM HR Analytics Employee Attrition dataset [31], [33], [34], [35], or simulated data from platforms like Kaggle [13], [32]. While these datasets provide standardized benchmarks for model comparison, they fail to capture the complexity and nuances of real-world organizational dynamics, cultural contexts, and region-specific employment practices. This dependency on generic datasets raises questions about the generalizability and practical utility of the developed models in diverse organizational settings.

2) Second: There is a notable scarcity of research examining employee attrition within the Saudi Arabian context, despite the Kingdom's unique labor market characteristics shaped by Saudization policies, cultural factors, and rapid economic transformation [27], [28], [29]. The limited studies that do focus on Saudi Arabia primarily employ traditional statistical methods or exploratory analyses rather than comprehensive machine learning frameworks, leaving a gap in predictive analytics tailored to this specific workforce.

3) Third: Existing attrition prediction studies often utilize incomplete or inconsistent feature sets, omitting important variables identified in recent retention literature. Variables such as job opportunities, emotional commitment, health issues, job stability, and sector-specific factors are frequently overlooked in predictive models [27], [28], [31], despite evidence of their significance in employee turnover decisions.

4) Fourth: While ensemble methods have shown promise in attrition prediction [31], [32], [33], systematic comparisons across multiple feature selection techniques and their impact on model performance remain limited. Most studies employ a single feature selection approach without exploring how different methods influence predictive accuracy and model interpretability, particularly in the context of imbalanced datasets typical of attrition scenarios.

5) Finally: There is insufficient emphasis on deriving actionable insights for HR management from predictive models. Many studies focus primarily on achieving high prediction accuracy without adequately analyzing which factors most strongly influence attrition or how organizations can leverage these insights to develop targeted retention strategies [7], [14].

This study addresses these gaps by: 1) introducing a novel, empirically-collected dataset from real employees in the Saudi private sector that reflects authentic organizational contexts

and cultural dynamics; 2) incorporating a comprehensive set of attrition factors derived from both international literature and Saudi-specific studies, including previously underexplored variables, making this dataset valuable for addressing a range of factors not available in other attrition datasets, such as health issues, benefits, medical insurance, job opportunities, and others; 3) systematically comparing multiple machine learning algorithms and ensemble methods across various feature selection strategies to identify optimal prediction configurations; 4) providing detailed feature importance analysis to generate actionable insights for HR practitioners; and 5) demonstrating the practical applicability of predictive analytics in addressing attrition challenges within the evolving Saudi labor market. By filling these gaps, this research contributes both methodologically and contextually to the field of employee attrition prediction, offering a robust framework adaptable to other regional and organizational contexts.

III. Methodology

The methodology is structured to address three key objectives: 1) collecting authentic employee data that captures Saudi-specific factors, 2) preparing and balancing the dataset to mitigate prediction bias, and 3) systematically evaluating multiple ML models to identify the optimal prediction approach. Each phase builds upon the previous one to ensure robust and reliable attrition predictions. The data collection phase establishes the empirical foundation through a targeted survey of 1,191 Saudi private sector employees. The preprocessing phase addresses data quality through outlier removal, categorical encoding, and SMOTE-based class balancing. The modeling phase implements a comprehensive evaluation framework comparing eight algorithms across seven feature selection strategies, with performance assessed using accuracy and F1 score metrics optimized for imbalanced classification tasks. Fig. 1 shows the basic phases of the methodology followed in this study.

A. Data Collection

Employee data related to the attrition factors examined in this study were collected through an online questionnaire, specifically designed and implemented using the Google Forms platform. This survey specifically targeted real employees working within the Saudi private sector, thereby addressing the limitations of relying on synthetic datasets often used in prior research. In total, 1200 responses were gathered. The responses were thoroughly filtered to exclude individuals who did not belong to the Saudi private sector, resulting in a final sample of 1191 participants. Additionally, all respondents were employees from a wide range of organizations spread across the various regions of the Kingdom of Saudi Arabia, thereby ensuring diverse geographic representation within the dataset.

Moreover, the questionnaire was conducted anonymously to maintain participant confidentiality. With regard to demographics, male respondents constituted 43%, while female respondents made up 57% of the total sample. Additionally, 515 respondents indicated that they had left their jobs, providing direct insight into employee attrition.

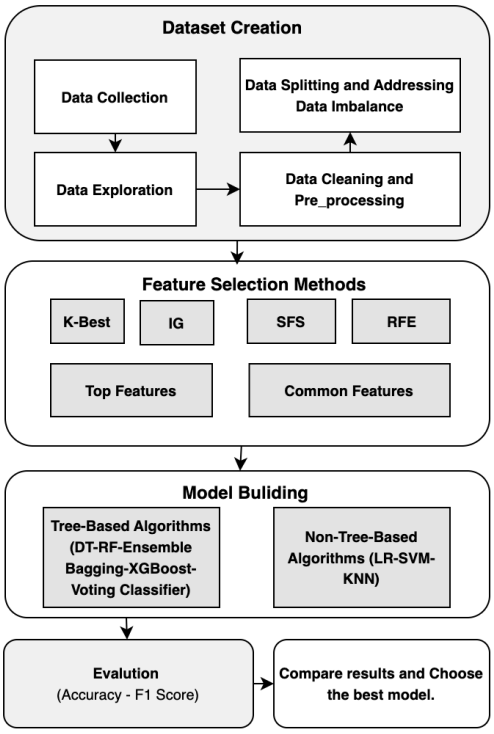

Fig. 1. Methodology phases.

TABLE I. Dataset Features

Category	Features
Personal Features	Gender, Age, Marital Status, Academic Degree, Health Issues, Years of Experience, Years of Experience in last organization, Job Opportunities.
Job-related Features	Sector, Department, Job Title, Monthly Salary, Allowances, Medical Insurance, Bonus, Overtime, Payment Overtime, Rewards and Wages Satisfaction, Get Deserved Promotion, Training Programs During the Last Three Years, Useful Training Programs, Business Travel, Job Support, Recognition, Emotional Commitment, Job Engagement, Distance to Work.
Psychological Features	Physical Stress, Psychological Exhaustion, Job Stability, Environment Satisfaction, Job Satisfaction , Work-Life Balance.
Target Feature	Attrition

B. Data Exploration

The dataset used in this study consists of 34 attributes, which are categorized into three primary groups: personality attributes, job-related attributes, and psychological and satisfaction attributes. First, personality attributes include individual characteristics such as gender, age, and social status. Second, job-related attributes encompass factors related to the work itself, such as job title, salary, sector, and department. Finally, psychological and satisfaction attributes relate to how employees perceive their work environment, including job stability, environmental satisfaction, and overall job satisfaction. The dataset also features the target variable of attrition, as detailed in Table I.

The variables included in this study were primarily selected based on insights from previous research on employee attrition prediction. In addition to these established factors,

the dataset integrates a set of novel variables that have not been widely applied in attrition prediction models. These novel variables originate from studies specifically focusing on the Saudi private sector, as well as recommended attrition predictors in the literature. For instance, key examples of these additional variables include job opportunities, allowances, job support, medical insurance, deserved promotion [27], [28], emotional commitment, health issues, and job stability [13]. Correspondingly, the sector variable was included to reflect the complex and diverse composition of the Saudi private sector, which encompasses a wide range of industries and organizational forms.

In this study, data exploration involved visualizing the distributions of key features, identifying correlations among variables, and detecting potential outliers or anomalies. To better understand the relationships between various factors and employee attrition, a thorough exploratory analysis was performed. The detailed distributions of the main features related to attrition are presented and further evaluated in the discussion section.

C. Data Cleaning and Pre-processing

The dataset contains both numerical and categorical features. Numerical variables included features such as employee allowances, whereas the remaining attributes were categorical in nature. In this section, the steps taken to preprocess the dataset are outlined to build ML models for employee attrition prediction.

1) Handling missing values: The dataset was examined for the presence of missing entries using the `isnull().sum()` function in Pandas. As no missing values were detected, neither imputation procedures nor the elimination of incomplete records was required.

2) Outlier detection and removal: To mitigate the influence of anomalous data points on model training, numerical features were evaluated for outliers using the Z-score technique. Instances with an absolute Z-score greater than three were classified as outliers and excluded from the dataset. This step ensured that extreme values did not distort the learning process of the predictive models.

3) Addressing categorical features categorical attributes processed using a two-stage approach:

a) Standardization: Preliminary exploration of the dataset revealed inconsistencies in the representation of categorical variables due to irregular spacing and capitalization. These issues were rectified by removing extraneous spaces and enforcing uniform formatting across feature values. This standardization process was applied to attributes such as `Business_Travel`, `Years_Experience`, and `MonthlySalary`.

b) Grouping rare categories: Several categorical variables, including `MonthlySalary`, `Sector`, `Years_experience_lastorganization`, `Years_Experience`, `Age`, and `Department` exhibited long-tailed distributions characterized by a large number of infrequent categories. To reduce model complexity and mitigate the risk of overfitting, these rare categories were consolidated into broader, more meaningful groups.

4) Encoding categorical variables: As a preliminary step, the LabelEncoder and OrdinalEncoder were employed to encode nominal and ordinal features, respectively. Due to the overfitting of tree-based models, in particular, the dataset was prepared in two distinct versions, with the key distinction being the encoding of categorical variables. In both dataset versions, ordinal features were encoded using Ordinal Encoding to preserve the intrinsic order among categories. Similarly, Label Encoding was consistently applied to binary features across both versions to ensure uniform representation.

For the tree-based dataset, nominal features with multiple categories, including `Maritalstatus`, `Sector`, `Department`, and `JobTitle` were encoded using the M-Estimator method. This encoder assigns numerical representations to categories, considering both the global distribution of the target variable and the distribution within each category [36]. By providing smooth and target-aware encodings, M-Estimator encoding enables tree-based models to create more effective and informative splits.

On the other hand, for the same nominal features, one-hot encoding was applied in the dataset version for non-tree-based models. This encoder generates binary dummy variables for each category, where the presence of a category is represented as 1 and its absence as 0, providing an orthogonal and non-ordinal representation suitable for these algorithms [37].

5) Scaling numerical features: Numerical and encoded features were normalized to ensure that the models could converge more quickly and avoid biasing the models towards features with larger ranges.

D. Data Splitting and Addressing Data Imbalance

The target variable, `Attrition`, exhibited significant class imbalance, with a notably higher proportion of instances labeled as "No" (employees who remained) compared to "Yes" (employees who left), as illustrated in Fig. 2. The dataset was partitioned into training and testing subsets, with an 80 %-20% split respectively, while maintaining the class distribution within each subset as detailed in Table II.

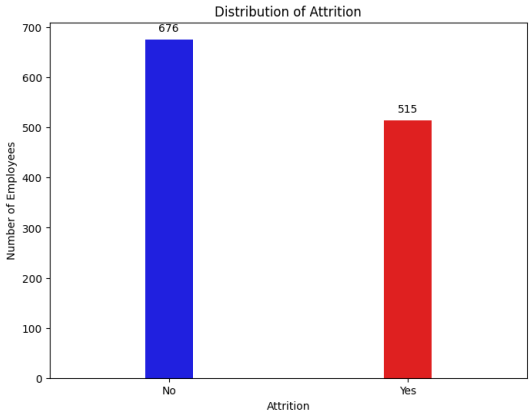

Fig. 2. Attrition distribution.

To address the class imbalance in the training dataset, the Synthetic Minority Oversampling Technique (SMOTE) was applied exclusively to the training set, targeting the minority

TABLE II. DATASET SPLIT AND ATTRITION DISTRIBUTION

#	Total Records	Non-Attrition	Attrition
Total records	1174	676	498
Training set 80%	939	534	405
SMOTE set	1068	534	534
Testing set 20%	235	142	93

class labeled "Yes". SMOTE generates synthetic samples by interpolating between existing minority class instances, thereby balancing the class distribution. This approach mitigates bias towards the majority class, enhances model performance on the minority class, and exposes the model to a more diverse and balanced set of examples, improving its generalization capability.

E. Feature Selection Methods

Feature selection was performed to identify the most informative features for predicting employee attrition in both tree-based and non-tree-based datasets. Four methods—SelectKBest, Mutual Information Gain (IG), Recursive Feature Elimination (RFE), and Sequential Feature Selection (SFS)—were applied, testing subsets of the top 10, 20, 25, and 30 features. The model performance was best with the top 25 features, consistent with prior studies in [38]. Therefore, this subset was selected for model training and evaluation.

F. Models Training and Validation

The modeling process aimed to predict employee attrition using a combination of tree-based and non-tree-based ML algorithms. This subsection details the models employed, evaluation metrics, and the overall procedures for training and testing

1) Feature sets: Seven feature sets were used to evaluate each model, reflecting various feature selection strategies. Each of these feature sets was evaluated to determine the optimal set of features for the models. These sets included: 1) all features without selection, 2) features from the SelectKBest method, 3) Information Gain-selected features, 4) Recursive Feature Elimination (RFE) features, 5) Sequential Feature Selection (SFS) features, 6) the union of features selected by all methods (common features), and 7) the intersection of features selected by any method (top features). This comprehensive evaluation allowed assessing model sensitivity to various feature subsets and selecting the most predictive features.

2) Model building: In this section, we describe the ML models used for predicting employee attrition, including both non-tree-based and tree-based algorithms. The non-tree-based algorithms employed in this study are listed in Table III, which includes LR, SVM, and KNN. These models are well-suited for datasets with one-hot encoded categorical features. Additionally, tree-based algorithms, as presented in Table IV, were utilized to leverage their ability to handle complex feature interactions and non-linear relationships. The tree-based models include DT, RF, Bagging ensemble, XGBoost, and a Voting Classifier combining Random Forest and XGBoost.

TABLE III. NON-TREE-BASED ALGORITHMS

No.	Model
1	Logistic Regression
2	Support Vector Machine (SVM)
3	K-Nearest Neighbors (KNN)

TABLE IV. TREE-BASED ALGORITHMS

No.	Model
1	Decision Tree
2	Random Forest
3	Bagging
4	XGBoost (Extreme Gradient Boosting)
5	Voting Classifier (Random Forest + XGBoost)

3) Evaluation metrics: Accuracy measures the proportion of correctly classified instances out of the total instances. It is calculated as:

$$\text{Accuracy} = \frac{\text{True Positives} + \text{True Negatives}}{\text{Total Instances}}$$

Accuracy provides a simple and intuitive measure of the model's overall correctness. However, it can be misleading when dealing with imbalanced datasets.

The F1 Score is defined as the harmonic mean of precision and recall, providing a quantitative measure that balances these two metrics. This metric is formally expressed as:

$$\text{F1 Score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}}$$

The F1 score is especially advantageous when it is necessary to account for both false positives and false negatives. A higher F1 score indicates robust model performance across both dimensions. Notably, the F1 score often provides a more informative evaluation than accuracy in scenarios characterized by class imbalance, due to reflecting the model's proficiency with respect to the minority.

IV. RESULTS

A. AL Models with Different Features Selection Methods for the Top 25 Features

The performance of various ML models using different feature selection strategies was evaluated. The models evaluated include LR, DT, RF, XGBoost, Ensemble Bagging, SVM, KNN, and VC. Each model was assessed using seven feature selection strategies: All Features, SelectKBest, IG, RFE, SFS, Common Feature, and Top Feature. These strategies utilized the top 25 ranked features based on their respective scores. After training under all feature selection scenarios, results were compared to identify the optimal configuration per model. For each model, only the best result and corresponding feature set are reported as shown in Table V, which summarizes the best performance of each model with feature sets. Additionally, the highest accuracy observed in this study was 90%, and the highest F1 score was 85%, both achieved by the Voting Classifier leveraging the feature set selected by RFE.

TABLE V. MODELS PERFORMANCE

Model	Fatures selection	Accuracy	F1 Score
LR	All	77.00	74.00
SVM	RFE	80.34	71.00
K-NN	Common	78.63	75.25
DT	Common	84.62	76.32
RF	SFS	89.00	84.71
Ensemble Bagging	SFS	87.18	82.35
XGBoost	All	83.76	75.95
Voting Classifier	RFE	**90.00**	**85.00**

B. Comparative Analysis with Existing Methods

To validate the effectiveness of the proposed approach and assess its importance relative to existing methods, we compare our best-performing model (Voting Classifier with RFE features) against results reported in recent studies. Table VI presents this comparison based on the methodologies and results explicitly reported in the referenced studies.

The comparative analysis demonstrates that the proposed method achieves competitive performance, with the Voting Classifier achieving 90% accuracy and 85% F1 score. This performance is comparable to the best results reported in existing literature, with several important distinctions.

First, unlike prior studies that predominantly utilize the IBM HR Analytics Employee Attrition dataset [31], [33], [34], [35], our approach employs a novel, empirically-collected dataset from the Saudi private sector, which introduces additional complexity due to real-world data characteristics and regional-specific factors. Second, our method achieves this performance while addressing class imbalance through SMOTE and systematic feature selection across multiple methods (SelectKBest, IG, RFE, SFS), providing a more comprehensive evaluation framework than many existing approaches. Third, the high F1 score (85%) indicates strong performance on both precision and recall, which is particularly important for imbalanced attrition datasets where the minority class (employees who leave) is of primary interest.

The study by Yahia et al. [13] also reported that Voting Classifier outperformed other models across multiple datasets, which aligns with our findings and validates the effectiveness of ensemble methods for attrition prediction. However, our study extends this by demonstrating the applicability of these methods to region-specific, real-world data and by providing detailed feature importance analysis that reveals job opportunities and job titles as primary attrition drivers in the Saudi context.

The effectiveness of hybrid ensemble approaches is further demonstrated by Govindarajan et al. [39], whose Hybrid Model integrating multiple algorithms achieved 95% accuracy on the IBM HR dataset. Their comparative analysis revealed that individual models achieved lower performance (SVM: 88.6%, Random Forest and Gradient Boosting: 87.3%, Decision Tree: 80.5%), while the hybrid approach effectively harnessed complementary strengths while mitigating individual weaknesses. This finding directly supports our methodology of employing a Voting Classifier that combines Random Forest and XGBoost, demonstrating that ensemble integration consistently outperforms individual algorithms across different studies and datasets. The parallel between their Hybrid Model (95%) and our Voting Classifier (90%) performance, despite our use of more challenging real-world data, validates the robustness of ensemble-based approaches for attrition prediction.

V. DISCUSSION

This study addresses the pressing issue of employee attrition within the Saudi private sector, with a focus on developing predictive models using ML techniques. The research aims to determine how well ML models can predict employee attrition, and to identify the feature configurations that most effectively enhance prediction accuracy. The subsequent discussion synthesizes the key findings in relation to the research questions, objectives, and methodology introduced earlier.

A. Discussion Related to Dataset

This study utilized a new, real-world dataset that stands out for its relevance, depth, and contextual specificity to the Saudi Arabian private sector workforce. Unlike many prior works relying on synthetic or general-purpose datasets such as IBM's attrition data [31], [33], [34], and [35], this research provides a more realistic and localized perspective. The dataset comprises responses from 1,191 participants gathered through an online questionnaire targeting Saudi private-sector employees across various industries. The dataset's contextual specificity enables the extraction of actionable insights tailored to the distinct work culture and employment practices prevalent in Saudi Arabia, which often diverge from Western contexts. A significant insight from this dataset is the class imbalance in the target variable: approximately 43% of participants had left a job, while 57% had not. To address this imbalance, the Synthetic Minority Over-sampling Technique (SMOTE) was applied during training, which is critical for mitigating prediction bias in high-stakes human resource analytics. However, the geographic and cultural specificity of the dataset may constrain the generalizability of the findings to other labor markets.

B. Discussion Related to Employee Attrition Factors

A variety of feature selection techniques were employed in this study. Due to the multiplicity and potential conflict among selected feature groups, a general, model-agnostic approach—binary logistic regression—was utilized to assess the predictive significance of variables. Logistic regression offers interpretable correlation measures in the form of odds ratios, which provide straightforward insights compared to the often complex interpretability of ML outputs [40]. In addition, a subset of common variables was identified as the intersection of all applied feature sets, representing features consistently deemed significant across methods.

The results of the logistic regression analysis revealed that the most significant factors influencing employee attrition were job opportunities, job title, deserved promotion, training programs, emotional commitment, job engagement, benefits, and medical insurance. The common set of attributes selected from all attribute selection methods included the following variables: years of experience, job opportunities, sector, job engagement, job support, years of experience in the previous organization, job stability, training programs, appreciation, emotional commitment, health issues, and deserved promotion.

TABLE VI. COMPARISON WITH EXISTING EMPLOYEE ATTRITION PREDICTION METHODS

Study	Dataset	Best Model	Accuracy	F1 Score
Rana et al. [31]	IBM HR Dataset	Naive Bayes	89%	–
Chung et al. [32]	IBM HR Dataset	Random Forest	95%	–
Garg et al. [33]	IBM Dataset	Random Forest	87.41%	88% (Precision)
Solomon et al. [34]	IBM HR Dataset	Logistic Regression	87%	83%
Amzad et al. [35]	IBM Dataset	SVM	88.78%	–
Yahia et al. [13]	Large, medium simulated HR datasets, small (450 real employees)	Deep and ensemble learning	96%, 98%, 99% respectively	–
Proposed Method	**Saudi Private Sector (1,191 real employees)**	**Voting Classifier (RFE)**	**90%**	**85%**

The results align with prior studies investigating employee attrition determinants in the Saudi private sector. Study [27] highlighted the significant influence of job opportunities, training programs, and promotion on attrition rates. In the same way, the study in [13] underscored the impact of job title and job engagement, emphasizing additional factors such as job stability, health conditions, and emotional commitment. Moreover, study [28] affirms the role of job support and recognition in reducing attrition. Furthermore, study [29] identified job support, recognition, financial allowances, and bonuses as critical factors in employee retention consistent with. The importance of years of experience in predicting employee attrition was also highlighted in [34]. On the other hand, several variables were not statistically significant in predicting workforce attrition, including age, academic degree, monthly salary, overtime hours, bonuses, job satisfaction, environmental satisfaction, business travel, and distance to work, which contradicts previous studies [13], [34] . These contradictions reflect contextual differences in the Saudi private sector. The non-significance of salary and bonuses suggests competitive compensation is a baseline expectation rather than a differentiator, shifting focus to career growth. Age's reduced importance aligns with Saudi Arabia's young workforce in Vision 2030 transformation [30], where career prospects uniformly influence turnover. Job satisfaction's non-significance indicates employees may be satisfied yet leave for better opportunities, suggesting satisfaction alone is insufficient without development prospects. The non-significance of business travel contradicts Yahia et al. [13], likely reflecting cultural and work-life balance differences in the Saudi context. These findings emphasize that retention strategies from Western datasets require adaptation to Middle Eastern labor markets.

C. Discussion Related to ML Models

1) ML Models: Based on the study results, the voting classifier with the feature set selected by Recursive Feature Elimination (RFE) achieved the best performance, with 90% accuracy and an 85% F1 score. This finding aligns with the results reported in study [13]. Ensemble learning methods, such as voting classifiers, combine multiple weak learners to leverage their complementary strengths, resulting in more accurate predictions. Combining outputs from multiple models is a well-established technique to improve overall model performance [41]. Apart from this, RF achieved the second-best performance, consistent with its superiority in previous studies [32],[33], and [35]. Conversely, the LR model did not outperform the other models, contrasting with findings reported in [38].

2) Impact of Feature Sets: The "All Features" set includes all available features for comparison, showing good overall performance. Specifically, the LR achieved the best result with all features with 77% accuracy and 74% F1 score. The evaluation of "Common Features" across models revealed varying impact: while the accuracy of VC and RF improved, the performance of LR, SVM, and Bagging declined significantly. Besides that, the "Top Features" method consistently improved model performance, although it was less effective compared to SFS and RFE.

In contrast, most models demonstrated improved performance with feature selection methods. Models such as SVM, RF, and VC benefited from feature selection by reducing noise and focusing on only relevant variables. SFS emerged as the most effective feature selection method for most models. For instance, with ensemble bagging, SFS provided the highest accuracy at 87.18%. SFS emerged as the most effective technique overall, providing the highest accuracy of 87.18% for the ensemble bagging model. Additionally, RFE ranked as the second-best feature selection method after SFS, improving model performance, particularly for RF, Bagging, and VC models.

While SelectKBest and IG effectively identified important features, their impact on improving model performance was less significant compared to SFS and RFE. For example, Logistic Regression (LR) achieved an F1 score of 73.58% using KBest, which increased to 79.31% with SFS. Similarly, Random Forest (RF) obtained an F1 score of 73.58% with IG, which improved to 84.71% using SFS and reached 80% with RFE as shown in detail in Fig. 3, which presents a comparison of accuracy across various models and feature selection methods.

VI. Conclusion

Employee attrition remains a critical challenge for the private sector, particularly in monitoring employee intentions and proactively addressing turnover. This study aimed to analyze key factors predicting employee departure and the underlying reasons for turnover, thereby enabling organizations to implement effective retention strategies. The primary objective of this study was to develop and evaluate a predictive model using ML and ensemble methods to address attrition challenges tailored to the Saudi private sector workforce.

The study has four key contributions. First, it introduces a new dataset derived from previously identified causes of employee attrition. Next, it presents the design, development, and evaluation of predictive models using ML and ensemble methods. Additionally, the study compares the performance of various ML models across different feature configurations. Lastly, it provides a thorough analysis of factors affecting turnover intentions among employees in the Saudi private sector, contributing valuable insights to inform retention policy development.

The study results indicate the superiority of ensemble models over individual algorithms in predicting employee attrition. Furthermore, demographic and overall satisfaction variables showed limited predictive power within this dataset, while dynamic and developmental factors had a more pronounced influence on attrition. These findings reveal an important shift in employee attrition patterns: traditional demographic-based retention strategies may be insufficient in contemporary organizational contexts. Instead, the prominence of dynamic factors—such as job opportunities, career development prospects, and job titles—suggests that employees in the Saudi private sector prioritize growth-oriented and opportunity-driven workplace environments. This insight challenges conventional HR assumptions that focus primarily on compensation and job satisfaction, highlighting the need for organizations to invest in career development programs, clear advancement pathways, and competitive positioning within the job market. in additon to, need to adopt proactive strategies focused on development and career advancement. The proposed model can help identify at-risk employees early and support data-driven retention decisions in the Saudi private sector.

From a strategic perspective, the high predictive accuracy of ensemble models (90% with Voting Classifier) demonstrates the viability of data-driven early warning systems for attrition risk. Organizations can leverage such models to identify at-risk employees proactively, enabling targeted interventions before turnover intentions crystallize into actual departures. This predictive capability is particularly valuable for retaining high-performing employees and reducing the substantial costs associated with talent replacement and organizational knowledge loss.

However, the study faced limitations, including potential bias inherent to questionnaire-based data collection, while relying on actual employee records in private sector companies may provide more reliable data. Additionally, the focus on the Saudi private sector as a whole suggests that sector-specific studies—for example, healthcare or education—could yield more precise insights into attrition drivers.

Future research should pursue several promising directions to advance employee attrition prediction and understanding. First, addressing the challenge of imbalanced data typical of turnover datasets through advanced techniques such as SMOTE (Synthetic Minority Over-sampling Technique), ADASYN (Adaptive Synthetic Sampling), or cost-sensitive learning algorithms could improve model performance and generalizability. Second, exploring deep learning architectures, including recurrent neural networks (RNNs) and long short-term memory (LSTM) networks, may capture temporal patterns in employee behavior and career trajectories, potentially revealing early warning signals that precede turnover decisions. Third, incorporating explainable AI (XAI) techniques such as SHAP (SHapley Additive exPlanations) and LIME (Local Interpretable Model-agnostic Explanations) would enhance model interpretability, enabling HR practitioners to understand not only predictions but also the reasoning behind them, thereby facilitating more informed decision-making. Fourth, conducting longitudinal studies that track employees over extended periods could reveal the dynamic evolution of attrition risk factors and validate the temporal stability of predictive models. Finally, sector-specific investigations within healthcare, education, technology, and finance sectors would uncover industry-unique attrition drivers and enable the development of tailored retention strategies.

Ultimately, this study offers a foundational step toward enhancing employee retention strategies within Saudi Arabia's evolving private sector landscape, demonstrating that the integration of machine learning techniques with empirical workforce data can transform HR practices from reactive problem-solving to proactive talent management.

***Abstract*—Enterprise Resource Planning (ERP) systems are critical for managing enterprise-wide business processes, including asset management. Yet, many ERP platforms lack efficient mechanisms for bulk asset transfers, leading to high manual effort, increased costs, and data inconsistencies. This study applies Business Process Reengineering (BPR) techniques as the methodology to optimize ERP asset management, focusing on workflow optimization and automation, contributing both practical and methodological insights. A mixed-method approach was adopted, analyzing a financial organization with 256 branches and over 450 Oracle ERP users. Data from 51 representative branches identified inefficiencies such as manual transfer delays, approval bottlenecks, and synchronization issues. The proposed solution introduces automated bulk asset transfers, optimized approval workflows, and real-time data synchronization, along with new metrics for evaluating efficiency, compliance, risk, and asset utilization. Compared to the As-Is system, the reengineered framework achieved a 100% reduction in operational costs per user ($7,500 annual saving), an 80% reduction in compliance incidents, a 67% reduction in asset transaction errors, and a 20% improvement in asset utilization. These results demonstrate a scalable, adaptable, and effective framework that enhances ERP operational efficiency, strengthens data integrity, and advances both academic understanding and industrial practice of asset management process reengineering.**

I. INTRODUCTION

The current As-Is asset management process in Enterprise Resource Planning (ERP) systems faces several inefficiencies that hinder operational effectiveness. These inefficiencies arise primarily from the absence of a bulk asset transfer feature, which requires users to process asset transfers individually—making the process time-consuming and prone to human error. Manual interventions and repetitive tasks contribute to operational delays, increased labor costs, and data inconsistencies, necessitating a comprehensive overhaul through Business Process Reengineering (BPR).

Several studies and implementation reports have highlighted enhancements to the asset transferring process in Oracle Cloud ERP, aiming to improve efficiency and accuracy through automation and streamlined workflows. However, these contributions primarily focus on incremental improvements to existing processes rather than a holistic redesign. Moreover, the literature provides limited evidence regarding the effectiveness of these enhancements, with insufficient methodological details or empirical validation to demonstrate measurable performance gains. Consequently, there remains a significant research and practical gap in optimizing the asset transfer process itself—particularly in enabling bulk transfer capabilities. Addressing this gap through a reengineered, BPR-driven approach introduces a clear element of novelty by systematically enhancing efficiency, automation, and integration within the asset management lifecycle [1].

This strategic approach focuses on radically redesigning an organization's core processes to achieve significant improvements in performance, efficiency, and operational outcomes. In the context of asset management, BPR plays a crucial role in workflow optimization, reducing manual intervention, and enhancing data accuracy. By reengineering asset transfer processes, particularly in large organizations utilizing ERP systems, it becomes possible to efficiently manage complex asset movements across multiple locations.

A. Research Gap

Although ERP systems are designed to integrate and automate enterprise-wide processes, most lack built-in capabilities for bulk asset transfers and customizable approval workflows. Existing studies primarily focus on process automation or ERP customization in general, with limited attention to optimizing asset transfer workflows using BPR principles. This research fills that gap by developing and evaluating a reengineered, workflow-optimized bulk asset transfer mechanism integrated with real-time synchronization and enhanced approval processes within Oracle ERP.

B. Statement of the Research Problem

The current ERP asset management modules do not provide efficient mechanisms for bulk asset transfers, resulting in manual, time-intensive processes that cause operational inefficiencies, increased costs, and potential data inconsistencies. The lack of workflow automation and integration between asset movement and approval mechanisms further limits performance. Therefore, there is a need to reengineer the existing asset transfer process to enable automation, workflow optimization, and seamless integration within ERP environments.

C. Research Questions

- How can Business Process Reengineering (BPR) be applied to optimize the asset transfer process within ERP systems?
- What improvements in workflow efficiency, data accuracy, and operational cost can be achieved through the implementation of an automated bulk asset transfer feature?
- How can forward and reverse integration mechanisms enhance synchronization and data consistency in reengineered ERP modules?

D. Research Significance

This research contributes to both theory and practice by bridging a critical gap in ERP asset management. The proposed BPR-driven bulk asset transfer solution introduces a scalable framework for workflow optimization, automation, and integration across ERP systems. It benefits organizations by improving process efficiency, reducing manual workload, enhancing data accuracy, and providing a model that can be adapted by other enterprises facing similar limitations. The outcomes also support ERP vendors and practitioners in extending native ERP capabilities without additional licensing costs, promoting cost-effective digital transformation within enterprise environments.

E. Research Objectives

The primary objective of this research is to identify and reengineer inefficiencies in the existing asset management process within ERP systems in a selected financial institution.

The sub-objectives of this research include:

- To perform a detailed analysis of the As-Is process of asset transfer in the selected financial organization using the Oracle ERP system.
- To develop the proposed system using Oracle APEX and other technologies with forward and reverse integration mechanisms.
- To use Business Process Reengineering tools, we are going to perform a detailed analysis of the developed system for asset transfers in the selected financial organization using the Oracle ERP system.
- To identify the metrics for measuring the success of the developed system.

This study focuses on the reengineering of bulk asset transfers, reverse integration, and workflow automation within ERP systems. Additionally, it examines enhancements in user security and privilege management to ensure that access to sensitive asset-related information is restricted to authorized personnel. However, the scope of this research is confined to implementations within the ERP environment.

II. Literature Review

A. Business Process Reengineering (BPR) in ERP Systems

Enterprise software such as Enterprise Resource Planning (ERP) systems are essential for modern businesses as they integrate core functions such as finance, supply chain, HR, and customer management into a centralized platform. By automating workflows and improving data accuracy, ERP enhances operational efficiency, reduces costs, and supports better decision-making through real-time analytics [2]. ERP systems also provide scalability and adaptability, enabling enterprises to respond to market changes effectively. Their ability to streamline processes and ensure data consistency makes them critical tools for business growth and sustainability [3], [4].

Some studies explore cloud ERP using an integrative model combining the Technological, Organizational, and Environmental (TOE) framework and the Unified Theory of Acceptance and Use of Technology (UTAUT), which identifies key adoption factors such as system reliability, data security, cost efficiency, scalability, and accessibility. These insights are useful for optimizing ERP's asset transfer module, emphasizing security, efficiency, and seamless cloud integration [5].

Business Process Management (BPM) is an approach for improving and optimizing an organization's processes to achieve more efficient workflow and better outcomes. BPM involves analyzing, modeling, implementing, monitoring, and continuously improving business processes. By aligning processes with business objectives, the BPM enhances productivity, reduces costs, and improves agility. It often integrates various tools and methodologies, including automation, analytics, and performance metrics, to drive process improvements across departments and organizational levels. Effective Business Process Management (BPM) ensures a streamlined approach to achieving business goals and adapting to changes [6] Business Process Reengineering (BPR) is a branch of Business Process Management. It was designed to achieve significant improvements in efficiency and performance by fundamentally rethinking and redesigning core business processes. Rather than making incremental changes, BPR focuses on eliminating inefficiencies, optimizing workflows, and enhancing the overall operational effectiveness. This transformation has lead to

improvements in cost reduction, productivity, service quality, process speed, and overall business agility. Since business environments are constantly evolving, BPR is not a one-time initiative but an ongoing effort that requires continuous evaluation and adaptation to maintain competitive advantage [7].

The implementation of BPR begins with a comprehensive analysis of the existing processes to identify inefficiencies, bottlenecks, and areas for improvement. This analysis informs strategic decisions, such as process automation, workflow optimization, business process outsourcing (BPO), or redefining third-party roles. A key aspect of BPR is leveraging information technology (IT) to automate repetitive tasks, restructure workflows, and eliminate non-value-added activities, thereby enabling seamless process execution and improved decision-making [7].

By rethinking and redesigning business processes, organizations can modernize operations, enhance customer service, reduce operational costs, and improve their adaptability to market shifts. When implemented effectively, BPR enables enterprises to remain competitive in dynamic business environments by continuously optimizing their operational frameworks [8]. Evaluating the success of Business Process Reengineering (BPR) initiatives in Enterprise Resource Planning (ERP) systems requires a set of measurable key performance indicators (KPIs). The most commonly used metrics are "cost savings, process cycle time reduction, data accuracy, operational efficiency, and customer satisfaction". Among these metrics, the Business Process Reengineering (BPR) is mainly focuing on "cost reduction" through process efficiency. Organizations measure cost savings by analyzing reductions in labor costs, maintenance expenses, and inventory carrying costs [9]. The other main metric is the "Process Cycle Time Reduction" where it assesses the impact of Business Process Reengineering (BPR) on the speed of business operations. Companies experience faster processing times by automating workflows and eliminating redundant steps. As mentioned above, accurate real-time data are essential for decision-making. BPR initiatives often implement data validation rules, automation, and system integrations to minimize human errors. The effectiveness of these measures is evaluated by tracking data discrepancies, error rates in financial reporting, and compliance adherence within ERP systems [10]. Rather than the above metrics, organizations assess improvements in workforce productivity by analyzing reductions in manual effort and increases in task automation. Productivity gains are often measured using employee performance benchmarks, transaction processing speeds, and system response times after BPR implementation. Based on the assessment of the above KPIs, a successful BPR initiative should enhance customer experience by improving service delivery. Metrics such as response times, and customer feedback scores provide insight into how process reengineering influences end-user satisfaction [11].

The literature on ERP systems, asset management, and Business Process Reengineering (BPR) provides valuable insights into improving enterprise operations through automation and workflow optimization as mentioned above. Previous studies have focused on ERP implementation challenges, process automation, and performance enhancements, but they often address these topics in general terms without targeting the specific inefficiencies in asset transfer processes. Notably, most ERP platforms lack native support for bulk asset transfers, forcing organizations to rely on manual, time-consuming processes prone to errors and delays. While some research has explored workflow redesign or integration strategies, there is limited empirical evidence demonstrating the combined effect of workflow optimization, automation, and real-time data synchronization in reengineering ERP asset management modules [1]. This study addresses that gap by proposing a novel, BPR-driven framework that integrates bulk asset transfer mechanisms, optimized approval workflows, and forward-reverse system integration. The research contributes to both theory and practice by offering a scalable, adaptable solution that improves operational efficiency, strengthens data integrity, and reduces labor costs—demonstrating a significant advancement over existing approaches in ERP process optimization.

B. Asset Management Processes

Enterprise Resource Planning (ERP) is a comprehensive software solution that integrates various business processes such as finance, production, and sales—into a unified system. Within an ERP system, asset management refers to the structured approach of managing an organization's physical assets, including machinery, equipment, and vehicles, throughout its lifecycle. This encompasses key processes such as asset acquisition, operation, maintenance, and disposal to ensure optimal utilization and efficiency. Effective asset management in ERP systems is essential as it centralizes asset-related data and integrates it with other critical business functions, such as finance, procurement, and maintenance. This integration provides real-time visibility into asset performance, cost tracking, and maintenance schedules, enabling organizations to maximize asset utilization, reduce operational costs, and improve decision-making. Businesses that manage and track their assets effectively across multiple departments benefit from enhanced productivity, streamlined operations, and improved financial reporting [12].

Standard ERP applications often require customization to align with an organization's operational needs. Customized integration plays a crucial role in enhancing asset management workflow, approval processes, and data accuracy. While most ERP systems provide basic asset management functionalities, organizations requiring advanced asset tracking, real-time data synchronization, or customized reporting must implement custom modules, modify existing functionalities, or integrate third-party software [13]. Asset management is critical for large enterprises that manage extensive inventories across multiple locations. However, the literature highlights several challenges, including:

- Inefficient manual processes that slow down operations.
- Lack of real-time data synchronization, leading to inconsistencies in financial reporting.
- Complexity in managing large-scale asset transfers across multiple locations.

Modern asset management strategies increasingly prioritize sustainability by incorporating lifecycle cost management

and reliability-centered maintenance. Organizations now emphasize long-term cost reduction and environmental impact minimization through efficient asset utilization and responsible disposal strategies. The evolution of topic modeling in asset management research further highlights a shift towards advanced analytics, predictive maintenance, and AI-driven decision-making [14]. ERP automates key asset management processes such as asset transfers, additions, disposals, and reclassifications. These automated workflows minimize manual errors and enhance operational efficiency. The system seamlessly integrates with ERP applications such as payables, project costing, and ledger accounting, ensuring accurate data flow and financial reconciliation. Additionally, assets provide robust reporting tools, offering organizations greater visibility, control, and compliance over their assets throughout their lifecycle [15], [16].

Security is a ERP-based asset management. The literature underscores the importance of integrating security protocols into ERP systems to safeguard sensitive business data and operational integrity. A well-defined security framework ensures access control, compliance with industry regulations, and protection against cyber threats. Research highlights the necessity of embedding IT and corporate security measures into ERP systems to create a holistic, organization-wide security strategy. This approach enhances business process continuity, data governance, and system reliability across multiple operational domains, including technology, communication, and functionality [17].

Cloud-based ERP solutions have changed asset transfer and management by increasing scalability, accessibility, and real-time data analytics. In distributed enterprises, where assets are regularly moved between locations, cloud ERP provides centralized, automated, and intelligent solutions for tracking, validation, and compliance.

1) Scalability for large-volume asset related data: Traditional ERP systems often struggle to handle large-scale asset management related data owing to system limitations and manual processing. Cloud-based solutions, dynamically scale to accommodate high-volume asset related data across multiple locations. This prevents the challenges associated with traditional on-premises ERP setups, ensuring that businesses can quickly reallocate assets without disrupting their operations.

2) Accessibility for real-time asset tracking: One of the biggest challenges in asset management is ensuring that all stakeholders have real-time access to the asset transfer data. Cloud-based ERP solutions provide anytime and, anywhere visibility of asset locations, movement status, and transfer history. This is particularly beneficial for enterprises that, manage assets across multiple regions, warehouses, and business units.

3) Real-time data analysis for decision making: Cloud ERP systems utilize AI-driven analytics and machine learning to optimize asset transfers and management decisions. Organizations can predict asset availability based on past transfer patterns, identify idle assets for reassignment, and automate depreciation and cost adjustments during transfer.

C. BPR Methodologies

In Business Process Reengineering (BPR) and system analysis, the As-Is system refers to the current state of business processes and systems as they exist today. This includes the existing workflows, tools, and technologies utilized within an organization. The primary goal of As-Is analysis is to gain a comprehensive understanding of current operations, identifying inefficiencies, bottlenecks, and manual interventions that hinder performance. By analyzing the As-Is system, businesses can pinpoint areas for improvement, such as outdated processes, redundant tasks, and missing functionalities that lead to operational slowdowns and inconsistencies [18]. In contrast, the developed system represents the optimized future state of the current system after reengineering, and improvements have been implemented. It defines how processes should function once redesigned to eliminate inefficiencies, enhance automation, and optimize workflow. The framework of developed system focuses on integrating advanced technologies, automating repetitive tasks, and improving process accuracy, ultimately leading to cost reductions, enhanced scalability, and improved organizational efficiency. This future-state model serves as a roadmap for transformation, ensuring that the organization operates in a streamlined and sustainable manner [18].

In BPR, the As-Is and To-Be frameworks are essential for diagnosing inefficiencies and designing optimized workflows. The As-Is process documents current business processes, highlighting bottlenecks, redundancies, and areas for enhancement. For asset management, the As-Is state is often characterized by manual, error-prone processes that lack real-time synchronization. The To-Be framework, on the other hand, envisions an optimized asset management process where automation, system integration, and advanced security controls improve efficiency, accuracy, and data consistency. Pereira and Silva (2020) emphasized the importance of analyzing the As-Is state to fully understand data synchronization challenges and inefficiencies in asset transfer processes. Transitioning from As-Is to To-Be requires redesigning workflows, improving system interoperability, and implementing role-based access controls to secure asset data and enhance the operational efficiency. The literature provides Numerous case studies have demonstrated successful BPR-driven transitions from manual to automated asset management systems, resulting in significant improvements in cost savings and workflow efficiency.

Prior research presented a quantitative verification approach for optimizing design models using Business Process Model and Notation (BPMN) and transforming them into improved models [19]. It addresses timed constraints, probabilistic tasks, and dependencies between activities in the processes. This technique helps designers identify operational gaps, time issues, and flaws, thereby ensuring a more effective process design [20].

Several Business Process Reengineering (BPR) methodologies have been applied to asset management within ERP-integrated environments, each offering unique advantages in optimizing asset workflows, reducing inefficiencies, and enhancing data-driven decision-making. Among these methodologies, Business Process Maturity Modeling (BPMM) can be used to evaluate the As-Is asset transfer process and new asset transfer process in the developed system. Previous research has specified that the Business Process Maturity Model (BPMM) is a structured framework used to assess and improve the efficiency, standardization, and automation of business processes. Originating from process maturity models such as the Capa-

bility Maturity Model (CMM), BPMM provides a systematic approach to evaluating the current state of a business process and identifying areas for improvement. Categorizing processes into five distinct maturity levels—initial, Managed, Defined, Quantitatively Managed, and Optimizing—BPMM enables organizations to transition from ad hoc, manual processes to fully automated, data-driven decision-making systems [21].

Among the other methodologies, Lean focuses on eliminating waste and streamlining asset management processes by removing non-value-added activities such as redundant approvals, excessive manual data entry, and delays in asset transfers [22]. In ERP-integrated asset management, Lean principles enable faster asset tracking, optimized maintenance schedules, and reduced downtime by ensuring that resources are efficiently allocated [23].

Six sigma, a data-driven methodology, enhances ERP-integrated asset management by minimizing errors in asset tracking, valuation, and transfer processes [24]. Using the Define, Measure, Analyze, Improve, and Control (DMAIC) framework, Six Sigma ensures that asset data remains accurate, eliminating inconsistencies that could affect financial reporting and compliance. Organizations implementing Six Sigma in ERP-based asset management benefit from predictive maintenance models, optimized asset utilization, and reduced lifecycle costs [25].

More over, Kaizen, which emphasizes continuous improvement, plays a crucial role in ERP-integrated asset management by encouraging incremental process enhancements. Organizations adopting Kaizen-driven asset management continuously refine workflows, such as real-time asset tracking, proactive maintenance alerts, and automated asset reconciliation, ensuring that ERP systems evolve with business needs while reducing operational risks [26].

Rather than the above methodologies, Agile BPR is particularly effective for dynamic asset management environments where assets frequently move across locations or undergo rapid reallocation [27]. By implementing iterative process improvements, Agile BPR ensures that ERP-integrated asset workflows remain flexible, enabling faster asset transfers, improved collaboration among departments, and adaptive compliance frameworks. Agile methodologies also enhance cloud-based ERP integrations, where businesses need real-time analytics and automated decision-making for asset lifecycle management.

However, Total Quality Management (TQM) focuses on a comprehensive process control across asset management operations. When integrated into ERP systems, TQM ensures standardized asset tracking protocols, regulatory compliance, and high-quality data integrity across departments. TQM-driven ERP systems automate asset depreciation calculations, optimize audit trails, and enhance approval workflows, minimizing manual intervention and compliance risks [28].

Rather than the above methodologies, the t-test and Analysis of Variance (ANOVA) will be used to analyze the success metrics of the proposed system, which are statistical methodologies used to compare the means between groups. As in prior research, A T-test is typically used when comparing the means of two groups to determine if there is a significant difference between them [29]. This comes in two main forms: the independent t-test (for comparing two independent groups) and the paired t-test (for comparing two related groups, such as pre-test and post-test data). On the other hand, ANOVA is used when comparing means across three or more groups to assess whether at least one group differs significantly from the others. Unlike multiple t-tests, which increase the risk of Type I errors, ANOVA controls for this error rate and provides a more reliable comparison. The most common form is one-way ANOVA, which examines one independent variable, whereas two-way ANOVA analyzes two independent variables and their interactions. Both methodologies assume normality and homogeneity of variances which will be properly used in the research.

When applied to ERP-based asset management, each BPR methodology contributes to a more efficient, automated, and data-driven approach. While Lean and Agile BPR enhance flexibility and process adaptability, Six Sigma and TQM provide structured, quality-focused improvements. Kaizen ensures continuous refinement, making ERP systems more responsive to business changes. The hybrid approach of Lean Six Sigma is particularly effective in large-scale ERP implementations, ensuring both process efficiency and data accuracy in asset management operations.

D. Asset Management Technologies

The Asset Management Modules of ERP systems lack critical functionalities for efficient bulk asset transfers, creating significant operational inefficiencies. The current system requires manual, one-by-one asset transfers, making the process time-consuming, labor-intensive, and prone to errors, especially for organizations managing large-scale asset inventories. Additionally, the absence of automated approval workflows forces users to rely on email and manual approval, leading to delays and compliance risks. Another major limitation is the lack of real-time data synchronization, resulting in inconsistencies between transferred assets and system records, which affects financial reconciliation and decision-making.

Furthermore, the high licensing costs for user management make it expensive for organizations to assign and control user roles efficiently. ERP systems also lack a dedicated budgeting module for asset transfers, which makes financial planning and expenditure tracking challenging. Finally, the reporting and audit trail features in the current system are insufficient for organizations that require comprehensive tracking of asset movements and compliance monitoring.

This research addresses these critical gaps by developing the Oracle Asset Transfer Suite, an enhanced module designed to introduce bulk asset transfer capabilities, automated approval workflows, real-time data synchronization, cost-effective user management, budget tracking, and advanced reporting functionalities, ensuring efficiency, cost reduction, and improved data accuracy in Oracle ERP's asset management processes according to the use case we selected with the financial institute in Sri Lanka.

Research indicates that leveraging technologies such as Oracle APEX for application development, JavaScript for dynamic user interfaces, and PL/SQL for efficient database operations significantly improves workflow automation, data

accuracy, and operational efficiency [30]. Additionally, advanced analytics tools, such as Power BI, have been integrated into asset management systems to enhance decision-making, provide actionable insights, and optimize process performance.

III. Research Methodology

This study employs a mixed-method approach, integrating both qualitative and quantitative methods, to conduct a comprehensive analysis of asset management processes within Oracle ERP. The qualitative approach focuses on gathering insights from key stakeholders through interviews, observations, and process evaluations to identify inefficiencies, bottlenecks, and user challenges in the current As-Is system. The quantitative approach involves collecting and analyzing system performance data, including process times, error rates, and asset utilization statistics, to assess the effectiveness of both existing and developed system. By combining these two approaches, this study ensures a holistic understanding of the asset management process, capturing both subjective user experiences and objective performance metrics that inform the re-engineering of asset workflows. This methodology enables data-driven evaluation of process improvements, ensuring that the proposed solutions enhance efficiency, accuracy, and automation.

To conduct this study, a representative sampling method was employed. The total population considered in this study consisted of 256 branches distributed across nine provinces of Sri Lanka. A 20% sample was selected from this population to ensure a representative subset for analysis. The sample size was calculated using Eq. (1) below.

$$Samplesize = 20/100 * 256 = 51.2 \quad (1)$$

Because the sample size must be a whole number, it was rounded to 51 branches. Thus, the research findings and analysis were based on a sample of 51 branches drawn from the entire population. The selected 51 branches were distributed among the nine provinces as follows:-

- Western Province – 10 branches (21.28%)
- Eastern Province – 8 branches (17.02%)
- Northwestern Province – 7 branches (14.78%)
- Northern Province – 5 branches (10.64%)
- North Central Province – 5 branches (10.64%)
- Central Province – 4 branches (8.51%)
- Sabaragamuwa Province – 3 branches (6.38%)
- Southern Province – 3 branches (6.38%)
- Uva Province – 2 branches (4.26%)

This distribution ensures that all provinces are represented in the study, while maintaining proportionality relative to the total number of branches in each region. The sampling approach enhanced the validity and generalizability of the research findings by capturing variations across provinces.

A. Data Collection Methods

The researchers will rely on both primary and secondary data sources from a reputed financial institution in Sri Lanka to analyze the current asset management process of Oracle ERP and develop an optimized solution.

1) Primary data collection:

a) Direct observations: Systematic observations of current asset management workflows are conducted to identify inefficiencies, manual interventions, and synchronization issues in the As-Is process. This will provide real-world insights into operational challenges during asset transfers and system integration.

b) Interviews with key stakeholders: Semi-structured interviews will be conducted with approximately five key stakeholders, including asset managers, IT personnel, and finance teams, to gain qualitative insights into the limitations of the existing Oracle ERP system and expectations of the developed system. These interviews focused on pain points, process delays, security concerns, and system usability.

c) User surveys: A structured survey was distributed to approximately 20 Oracle ERP users within the institution. The survey collects quantitative data on system performance, user satisfaction, error rates, and perceived inefficiencies. The results will help validate the findings from the observations and interviews, while providing a broader perspective on system challenges.

2) Secondary data collection:

a) Historical data and system logs: An analysis of historical asset transfer logs, ERP performance reports, and system audit trails will be conducted to quantify existing inefficiencies. This will serve as a baseline for comparing As-Is and developed systems and help in designing a customized asset transfer module.

b) ERP documentation and regulatory guidelines: A review of system documentation, compliance standards, and financial regulations relevant to asset management will be conducted to ensure that the proposed reengineering aligns with the best practices and industry requirements.

This structured data collection strategy ensures a comprehensive evaluation of existing inefficiencies, providing the foundation for an optimized, automated, and secure asset management solution within Oracle ERP.

B. Process Mapping Techniques to Model the Business Processes

To systematically analyze and optimize the asset management workflow, this study employs flowchart, Business Process Model and Notation (BPMN) Diagrams, and Swimlane Diagrams to map both As-Is and improved processes. These tools provide a structured, visual representation of process flows, enabling the identification of inefficiencies, manual interventions, and areas for automation [31]. Flowcharts are used to visually represent the step-by-step sequence of the current asset management process. Each step illustrates the flow of actions, decision points, and manual interventions, providing a clear, high-level overview of the existing workflow. This will help pinpoint bottlenecks, repetitive tasks,

and redundant approvals that contribute to inefficiencies, such as delays in asset transfers or excessive manual data entry. Additionally, these flowcharts will serve as discussion aids during stakeholder interviews and surveys, facilitating the identification of pain points in the current system. Moreover, Business Process Model and Notation (BPMN) diagrams were employed to provide a detailed, standardized representation of both the As-Is and improved processes. The BPMN enables the modeling of complex workflows, incorporating elements such as: activities (tasks performed at each stage), decision points (approval or rejection conditions), and data flows (information exchange across departments). By leveraging the BPMN, this study documents the current inefficiencies in asset management workflows and identifies opportunities for process reengineering. In particular, BPMN diagrams of developed system highlight automation opportunities, such as automated approval workflows to reduce manual interventions, system-driven asset tracking for improved real-time synchronization, and enhanced Oracle ERP integration to eliminate redundant data entry. This structured mapping ensures that every step in the process is carefully analyzed, allowing for a well-defined transformation strategy. In addition, swimlane diagrams will be utilized to clearly define the roles and responsibilities of the various departments and stakeholders involved in asset management. By mapping the interactions between different entities, swimlane diagrams will help identify gaps in communication and workflow handovers, highlight role-based inefficiencies, such as duplicated approvals or unclear accountability, streamline the improved process by redistributing responsibilities and automating handoffs, and ensure a more structured and, efficient workflow for asset transfers.

By incorporating these process mapping tools, the study will create a comprehensive blueprint for optimizing asset management workflows within Oracle ERP, ensuring a data-driven, well-documented transition from the As-Is to the improved process state.

1) Criteria for analysis: The criteria listed in the Tables II, III, and IV will be used to evaluate the As-Is process and design the optimized To-Be process.

By following this methodology, this study comprehensively evaluates the current asset management process and proposes a reengineered solution that improves efficiency, reduces costs, and mitigates risks, while leveraging technology to achieve an optimized To-Be state.

TABLE II. SUMMARY OF PROBLEMS IN AS-IS PROCESS

Category	Asset Transfer Process is Too Long	High Manual Data Entry	Repeated Processes	Unnecessary Processes	Repetitive Tasks
Quantity				✓	
Eliminate	✓		✓		
Combine			✓		
Separate	✓				
Simplify	✓				
Automate	✓	✓			✓

TABLE III. SUMMARY OF PROBLEM AREAS IN AS-IS ASSET MANAGEMENT

Problem Area	Impact on Efficiency	Potential Solution	Priority Level
Asset transfer process is too long	Significant delays in operations	Automate bulk asset transfers	High
High manual data entry	Increases labor costs and errors	Automate data entry and validation	High
Repeated processes	Redundancies create inefficiencies	Streamline and eliminate redundant steps	Medium
Unnecessary processes	Time wasted on non-essential tasks	Remove unnecessary approval steps	Medium
Repetitive tasks	Employee dissatisfaction	Automate repetitive tasks	Low

TABLE IV. SUMMARY OF PROBLEM SOLUTIONS FOR TO-BE PROCESS

Problem	Proposed Automation	Efficiency Improvements	Priority Level
Asset transfer process is too long	Bulk asset transfer capability	Reduces process time by 50 percent	High
High manual data entry	Automated data input	Reduces data entry errors	High
Repeated processes	Workflow automation	Streamlines redundant processes	Medium

C. Case Study

For this research, a prominent financial organization with 256 branches and over 450+ Oracle ERP users in Sri Lanka was selected, which is recognized as a leading life insurance provider with solid financial standing and market presence. Operating as a subsidiary of a major Sri Lankan bank, the institution benefits from its parent comapny's financial strength and credibility. With continuous growth in revenue and market share, it has maintained a dominant position in the local finance sector. Listed on the Colombo Stock Exchange, the institution prides itself in a dedicated workforce, contributing to its sustained success and industrial leadership. The institution's vision emphasizes becoming Sri Lanka's most admired and trusted insurance partner, while its mission focuses on delivering innovative and, customized solutions with a passion for excellence and teamwork. Its commitment to ethical governance, customer-centricity, continuous improvement, and industry compliance reflects its dedication to exceeding stakeholder expectations.

Discussions with the institution, revealed that the manual and time-consuming process of transferring assets individually, highlighted inefficiencies, and the substantial amount of manual work involved. The core challenge was bulk asset transfer functionality. Consequently, the institution experienced delays in asset requests, assignments, and transfers, leading to considerable gaps in communication and approval processes. This situation presentes an opportunity for research, aimed at enhancing organizational efficiency through the application of Business Process Reengineering (BPR) principles, focusing on streamlining workflows and improving operational performance.

D. Ethic Statement

This study did not involve the use of any personal or sensitive data, as such information was not required for the scope of the research. The data collected were strictly limited to asset transfer records obtained from a relevant financial organization for the purpose of evaluating and enhancing the efficiency of the asset transfer process.

Permission to access and use these data was obtained through direct communication with the organization. Screenshots of the email correspondence granting this permission have been included and can be accessed via the following link.

https://drive.google.com/drive/folders/1T5xPlKda_ZW_GLIUhrgn_qO6HLVHi627

The study did not involve any minors, and therefore, no parental or guardian consent was required. Additionally, as this research is not medical in nature, no medical records or health-related data were used or accessed in any part of the study.

IV. Results and Discussion

A. As-Is System Analysis

1) Explanation on As-Is system: The current asset management process depicted in Fig. 1 in Oracle ERP is predominantly manual and involves several steps to request, transfer, and update asset records across various departments and locations.

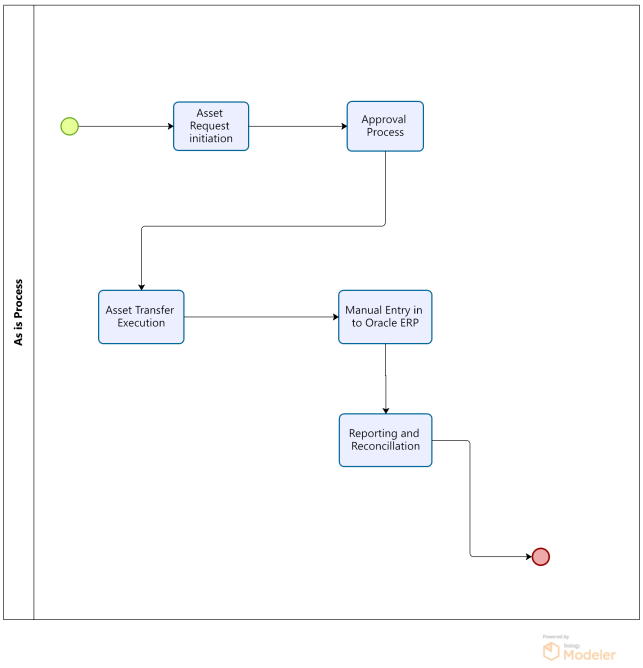

Fig. 1. Process of AS-IS System.

The current asset transfer process in Oracle ERP begins when a department or branch submits an asset request, that is currently handled manually. Each request must include detailed information, such as asset ID, quantity, and location. Following this request, the process moves to an approval workflow, where the asset request passes through multiple stages involving department heads, finance teams, and asset managers. This approval process often experiences delays due to manual handoffs between stakeholders. Once the request is approved, asset transfer is initiated, however, the current system allows only one asset to be transferred at a time, with each transfer requiring manual logging into the system, making it a time-consuming and error-prone task. After the physical transfer of the asset, data entry personnel update the asset's status, location, and transfer details in the Oracle ERP system. This step frequently involves verifying the transfer with physical inventory records and manually entering the data into various system modules. Finally, finance and audit teams must reconcile asset movements with financial records at regular intervals to ensure compliance with company policies and regulations.

The Business Process Maturity Model (BPMM) was utilized to assess the matuariry of the above as is process. The BPMM classifies process maturity into five levels: initial, managed, defined, quantitatively managed, and optimize. Each level represents the degree of process standardization, automation, and data-driven decision-making in an organization.

At Level 1 (Initial), the processes are unstructured, ad hoc, and reliant on individuals rather than defined workflows. The current asset transfer process in Oracle ERP aligns with this level, as it remains largely manual, time-consuming, and inefficient. To address these inefficiencies, automation is recommended, particularly for bulk asset transfers and validation mechanisms. This would reduce human dependency and improve the process reliability.

At Level 2 (Managed), some degree of process discipline is introduced, although inconsistencies persist. The existing asset transfer mechanism in Oracle ERP has seen partial standardization, but manual interventions still leads to delays. To advance to the next level, it is essential to establish standardized workflows and integrate automated approval mechanisms that eliminate the bottlenecks caused by human involvement.

Progressing to Level 3 (Defined) requires processes to be well-documented, standardized, and uniformly followed across the organization. The asset transfer module currently has partially defined workflows, but lacks automation. To enhance operational efficiency, a system-based request-tracking mechanism should be introduced to, ensure streamlined workflows and improved transparency in asset transfers.

At Level 4 (Quantitatively Managed), the processes are controlled using data-driven approaches. The current form of the asset transfer module does not support real-time monitoring or performance measurements using Key Performance Indicators (KPIs). The integration of dashboards and analytics tools enables organizations to track asset transfers effectively, monitor key metrics, and make informed decisions based on data.

Finally, at Level 5 (Optimizing), organizations focus on continuous process improvement through predictive analytics and feedback loops. The absence of such mechanisms in Oracle ERP's asset transfer module results in a lack of proactive decision-making and process enhancements. Implementing predictive analytics for asset lifecycle management would provide valuable insights, allowing organizations to anticipate

issues, optimize resource allocation, and enhance overall asset utilization.

This explained BPMM analysis is shown in the Table V.

TABLE V. BPMM (BUSINESS PROCESS MATURITY MODEL) FOR AS-IS PROCESS ANALYSIS

Maturity Level	Description	Current State	Target Improvements
Level 1 - Initial	Processes are ad-hoc, unstructured, and dependent on individuals	The current asset transfer process is manual, lengthy, and inefficient	Implement automation for bulk transfers and validation mechanisms
Level 2 - Managed	Basic process discipline exists, but inconsistencies remain	Some standardization in Oracle ERP, but manual interventions cause delays	Standardize workflows, introduce approval automation
Level 3 - Defined	Processes are well-documented, standardized, and followed organization-wide	Partially defined processes, but lack automation	Implement system-based request tracking and streamlined workflows
Level 4 - Quantitatively Managed	Processes are measured and controlled using data-driven approaches	No real-time monitoring, lack of KPIs	Introduce dashboards and analytics for asset tracking and performance measurement
Level 5 - Optimizing	Continuous process improvement through predictive analytics and feedback loops	No continuous feedback mechanism or improvements	Implement insights and predictive analytics for asset life cycle management

2) As-Is system process mapping: The As-Is process can be represented by the following Fig. 2 which highlights the steps involved from the asset request to reconciliation.

The asset transfer process in the provided diagram begins with branch logging into the company email and submitting an asset request. The procurement department, using the Oracle Fusion Cloud ERP, creates a purchase order based on the request. Once the assets are physically received, the inventory department generates a Good Receive Note (GRN) to confirm receipt and proceeds to create asset transfers in the system. A decision point follows, where it is determined whether the transfer is a bulk or individual asset transfer. If the transfer involves multiple assets, the system utilizes an in-built Oracle Fusion spreadsheet for bulk transfers, whereas individual assets are transferred individually in the case of non-bulk transfer. After the asset transfer is completed, a confirmation email is sent to relevant stakeholders, marking the completion of the process.

3) Current asset transfer process analysis:

a) Data collection: To conduct a comprehensive analysis of the current asset transfer process within the selected financial institution, data were collected using both primary and secondary Data Collection Methods, as outlined in the section "Data Collection Methods." The data collection process encompassed departments and branches across all nine provinces of Sri Lanka according to the sampling technique. This analysis did not involve personally identifiable information. Upon completion of data collection, 47 records were obtained covering all user groups related to the research.

The collected data comprises various aspects such as, "user experience level, frequency of requesting asset transfers, thoughts of the users regarding the communication during asset transfers, inefficiency in current process, need of real-time synchronization, importance of auditing and compliance". The collected data-set consists of categories relevant to the asset transfer process, with a focus on key ideological areas. The primary categories of the data collected were as follows:-

- Demographic Data
  - Demographic data refers to information regarding the length of experience of employees engaged in the asset transfer process, categorized as follows.
    - Less than one year
    - 0 to 5 years
    - 5 to 10 years
    - more than 10 years
- Quantitative Data
  - Experience Distribution - Numerical data representing the number of respondents within each experience category across different departments and branches.
  - Quantitative measures of communication and collaboration metrics - indicate the levels of agreement or disagreement regarding the effectiveness of communication between departments involved in asset management.
  - Asset Request Frequency - Frequency data capturing how often respondents request assets, categorized as daily, weekly, monthly, or rarely.
  - Security and Compliance Perceptions - Data reflecting respondents' views on the efficacy of automated features for asset audits and compliance assurance.
- Qualitative Data
  - Challenges in Asset Requests - Descriptive data highlighting common difficulties encountered in the asset request process, such as longer approval timelines and errors associated with manual data entry.
  - System Feature Feedback - A combination of qualitative and quantitative responses regarding desired enhancements in the asset management system, including automation, real-time synchronization, and compliance report generation capabilities.
  - Stakeholder Expectations - Data capturing overall expectations for improvements in asset management processes and system functionalities.
- Effectiveness Ratings and Collaboration Assessment
  - Communication Effectiveness - Respondents' evaluations of the effectiveness of interdepartmental communication within the existing system.
  - Collaboration Assessment - Responses measuring the extent to which the current system facilitates collaboration among teams involved in asset management.

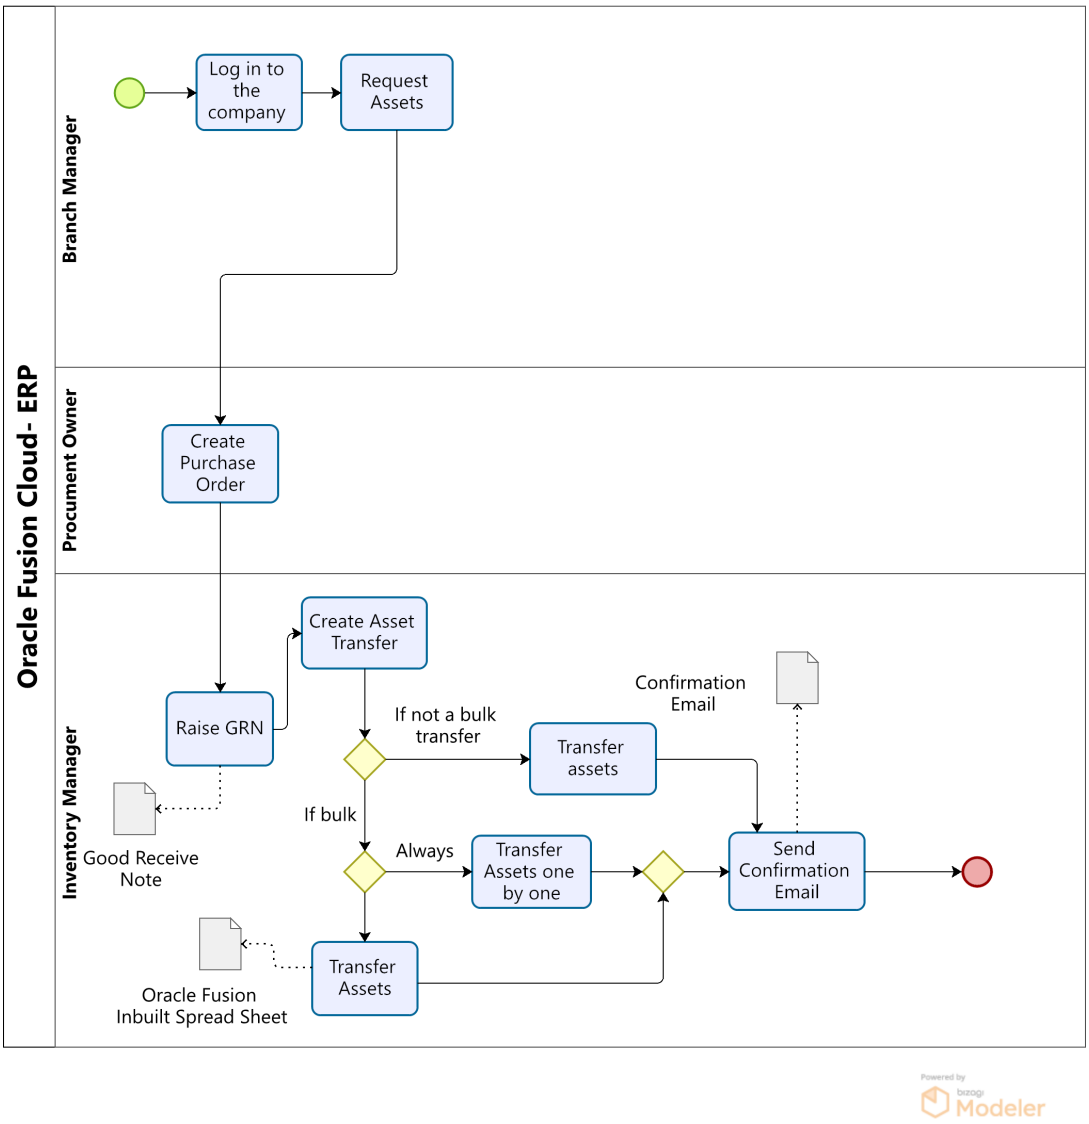

Fig. 2. Process mapping of As-Is system.

This structured approach to data collection enables a thorough understanding of the challenges, perceptions, and expectations surrounding the asset transfer process.

b) Data cleaning process: Before proceeding with the data analysis, a crucial preliminary step involved the data cleaning process to ensure the accuracy and reliability of the dataset. This process was essential for eliminating inconsistencies, errors, and irrelevant data, which could potentially affect the validity of the analysis.

After the data collection, the dataset was thoroughly examined to identify and remove invalid records. During this examination, various errors were detected, including repetitive records and incorrect data entries, which could distort the analytical outcomes. One of the key inconsistencies observed was the misplacement of the responses in different fields. Specifically, some users mistakenly entered the branch name in response to the province-related question, and, conversely, entered the province name in the branch-related question. Such misclassified entries compromised data integrity and required correction before the analysis.

To maintain data integrity, the following steps were undertaken:

- Removal of Duplicate Records – Identified and eliminated redundant records to prevent overrepresentation of certain data points.
- Elimination of invalid responses – Entries where responses were misclassified were removed, such as instances where users provided a branch name instead of a province or vice versa.
- Ensuring Data Consistency – Verified uniformity in categorical data, ensuring that each record was correctly aligned with the intended response category.

By addressing these inconsistencies, the dataset was refined to enhance its accuracy and reliability, ensuring that subsequent analysis would yield meaningful and valid results.

Upon completion of the data-cleaning process, 43 records were retained from the original 47. These refined records were subsequently utilized for the "As-Is system analysis", ensuring that only relevant and accurate data were considered for further evaluation.

c) Data analysis: Data analysis plays a critical role in understanding the efficiency and effectiveness of business processes within Oracle ERP. By analyzing key operational metrics, organizations can identify inefficiencies, smooth workflows, and improve employee satisfaction between branches and departments.

This analysis was conducted using Power BI, a powerful business analytics tool that enables data visualization and interactive reporting. Power BI allows users to connect with various data sources, efficiently process large datasets, and generate insights through dynamic dashboards and visual representations. By leveraging Power BI, the data were analyzed in a structured manner, making it easier to identify trends, patterns, and key areas for improvement in the bulk asset transfer process.

The As-Is system analysis was conducted to provide an in-depth analysis of the current state of the bulk asset transfer process within various departments and branches of the financial institution, highlighting the experience levels, bulk asset request frequencies, and critical importance of real-time synchronization and automation for future improvements. The analysis also highlights the key challenges faced by the existing systems.

According to the Fig. 3, 4, 5, 6, and 7, when considering the bulk asset request frequency by the departments and branches of the financial institution, the breakdown of the results is as follows. In addition, the analysis found that a significant proportion of employees involved in asset transfers fell under the "0 to 5 years" experience category. .

- Daily: 20.83%
- Weekly: 33.33%
- Monthly: 12.5%
- Rarely: 33.33%

The notably higher frequency of responses indicating "Rarely" can be attributed to the geographical distribution of the selected financial institutions. Most of their departments and branches are located in rural areas, where asset transfers occur infrequently. However, this trend shifts in urban regions, where demand for asset transfers is significantly higher, often occurring on a daily or weekly basis.

The high prevalence of daily and weekly requests highlights the ongoing operational need for an efficient bulk asset transfer process, particularly in high-activity departments where asset allocation is frequent. Notably, 33.33% of respondents rated real-time synchronization between Oracle ERP and other systems as extremely important. The responses varied regarding the effectiveness of communication between departments, with 39.53% indicating a positive experience. A strong 95.65% on the necessity for automated features in bulk asset transfers indicates a clear demand for reduced manual errors and increased operational efficiency. The key pain points indicated by branch/departmental users were, "Lengthy approval processes, manual data entry errors, and difficulty in tracking assets".

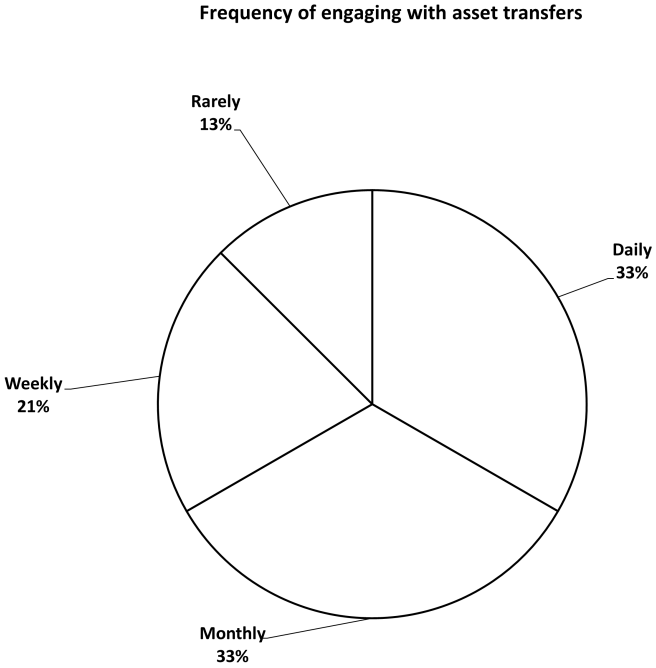

Fig. 3. Frequency of engaging with asset transfers from each branch/ department.

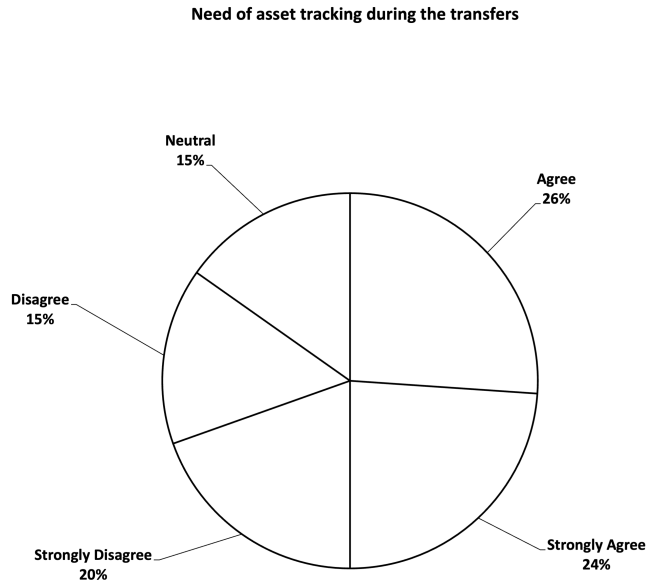

Fig. 4. Need of asset tracking during the asset transfers.

4) Identification of issues: The current asset management process suffers from several inefficiencies and bottlenecks.

- Lack of Bulk Asset Transfer The system does not support bulk transfers, forcing users to handle each asset individually. This leads to an increased time consumption and a higher chance of human error.

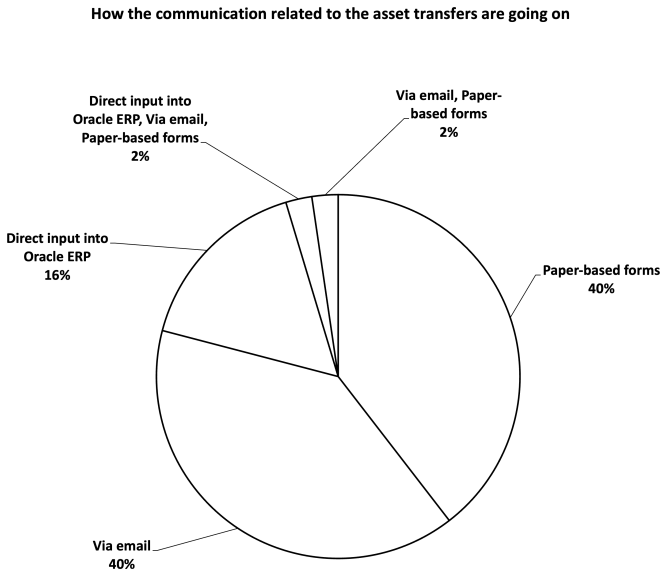

Fig. 5. How the communication related to the asset transfers are going on.

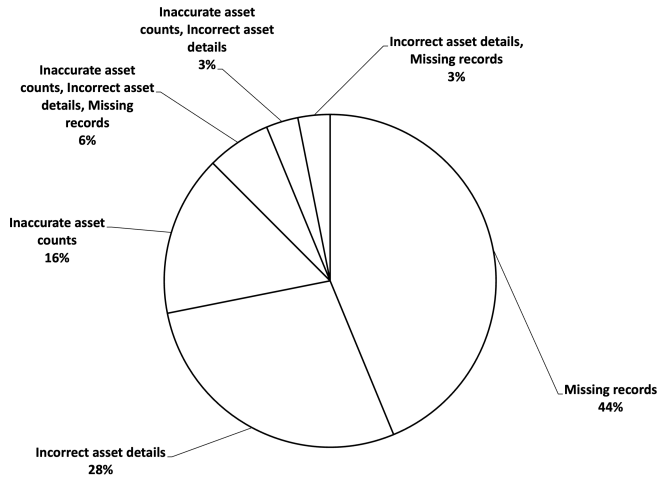

Fig. 6. Types of errors happen during the manual entries.

- The approval process requires multiple handoffs and manual interventions, which often lead to delays, particularly when approval is dependent on busy department heads or finance teams.
- Because asset data are manually entered into the system after physical transfers, there is a significant risk of errors in asset IDs, locations, and quantities. These errors can create discrepancies in financial reporting and asset tracking.
- Owing to delays in manual data entry and the lack of real-time updates, asset records across different departments and locations can become outdated, leading to inaccurate inventory counts.
- The manual nature of data entry and approval increases the risk of non-compliance with internal and external policies, particularly in terms of timely and accurate record-keeping.

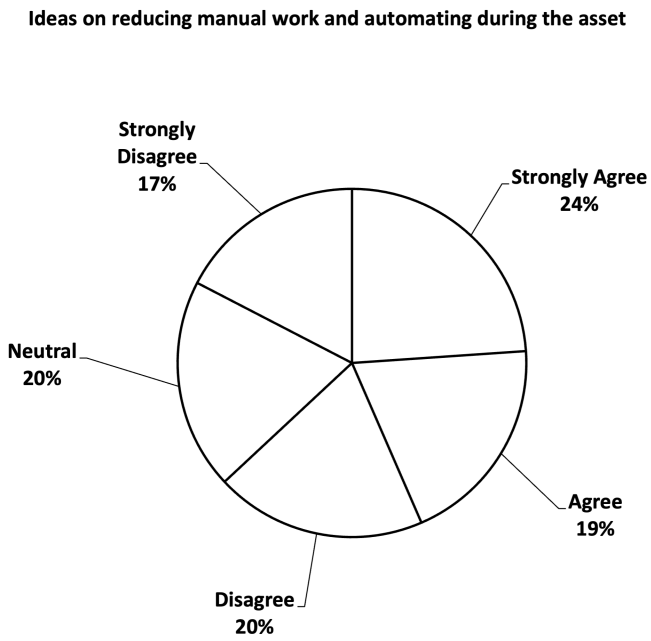

Fig. 7. Ideas on reducing manual work and automating during the asset transfer.

B. Design of the Developed System

1) Reengineering objectives: The objectives of reengineering the asset management process within the Oracle ERP system were,

Streamlining the asset transfer process by introducing bulk asset transfer capabilities can significantly improve operational efficiency. By reducing the time and effort required to move assets across departments or locations, businesses can enhance productivity. This approach also minimizes bottlenecks and allows staff to focus on more strategic tasks, rather than repetitive manual processes [32].

Automating key steps in the asset management process, such as- data entry, approval workflows, and error correction, can significantly reduce labor costs. Manual processes are time-consuming and prone to human error, both of which can lead to costly inefficiencies. By automating these tasks, businesses can not only save labor expenses but also increase the overall accuracy and speed of their asset management operations [33].

Strengthening compliance by improving data accuracy and real-time synchronization across departments is another crucial benefit. Discrepancies in asset data can lead to regulatory non compliance or internal auditing issues, which may result in fines or reputational damage. By ensuring real-time updates and synchronization, businesses can minimize these risks and, maintain accurate records for both regulatory and internal purposes [34].

Access controls are essential for ensuring the security, integrity, and compliance by regulating who can view, modify, or

execute specific actions within a system. These controls define the user roles, permissions, and authentication mechanisms to prevent unauthorized access, safeguard sensitive data, and enforce accountability. In enterprise systems such as Oracle ERP, access controls play a critical role in the above mentioned key steps in automation [35].

However, automation also plays a significant role in increasing data accuracy. Manual data entry is often riddled with errors,which can cause discrepancies in asset tracking and management. By automating data entry and synchronization processes, businesses can ensure that all asset movements are accurately reflected in the system, eliminating the potential for human error, and ensuring data integrity [36].

Finally, improving user experience through user friendly interfaces and minimizing manual interventions is essential for enhancing productivity and satisfaction. When users can interact with systems more intuitively, they are more likely to adopt technology and perform tasks more efficiently, leading to overall improvements in asset management [37].

2) Development of reengineered system: The Asset Transfer Suite is an application developed using Oracle APEX. It was created to offer a friendly scalable security platform for handling very large asset movements integrated directly with Oracle Fusion. They opted for Oracle APEX because it offered low-code architecture, rapid development, and Oracle database integration, thus providing quick deployment without performance or scalability being compromised. Architecture-wise, the application is designed to offer modularity and flexibility, with the business logic implemented in PL/SQL-encompassing critical activities like asset data validation, transformation, exception handling, and transaction rollback. Custom database objects such as tables, views, and packages were created to manage assets, transfer logs, audit trails, and user access controls.

Integration with Oracle Fusion ERP existed through both the web services using SOAP and REST. Web service callouts in Oracle APEX can be made through the use of a web source module or through PL/SQL's UTL_HTTP package. For authentication, if the particular Fusion API allowed OAuth 2.0 tokens, then such tokens were used; otherwise, basic authentication was used. Likewise, the integrations executed a series of activities like fetching the asset records, sending transfer requests, verifying transfer requests, and finally updating statuses of such requests, including updates regarding errors or validation messages issued by Fusion. The front-end interface of the application was built in APEX using its low-code UI builder, which allows the creation of interactive forms, reports, and dashboards in a snap. The users would filter assets by location, department, or cost center and perform those bulk transfers all at once, keeping track of their transaction history alongside real-time statuses synced with Oracle Fusion ERP.

Security integration was short and sweet-from Oracle Identity Cloud to Role-Based Access as defined within Fusion. Audit logs for transfer records, including user actions and system events, were created automatically for later traceability. Error handling and rollback mechanisms were designed and implemented to protect the data from accidental corruption in unplanned failure conditions. The entire suite was deployed and tested on staging Oracle Fusion test tenants. Functional testing, integration testing, and UAT provided a robust system that comprised the business requirements. After all validations were complete, the app was pushed into production. Later on, monitoring dashboards were added to keep track of API call success and failure rates so that issues could be addressed before anyone even noticed. This development approach gave the full capability of delivering a comprehensive, reliable, enterprise-grade solution that extended Oracle Fusion ERP for bulk asset transfers in an efficient and secure manner.

3) Developed system for reengineered process: The reengineering of the asset management process with adherence to the Oracle technology use guidelines, involves several transformative improvements, aimed at increasing efficiency, data accuracy, and process scalability. The key changes introduced include bulk asset transfer capability, automated approval workflows, real-time data synchronization, role realignment, and technology integration. These enhancements address the inefficiencies in the current system and offer a robust framework for future growth.

One of the most significant improvements is the introduction of bulk asset transfer capabilities. In the current system, assets must be transferred one at a time, which is time consuming and prone to delays. This new feature allows multiple assets to be simultaneously transferred, thereby accelerating the entire process. Bulk transfers significantly reduce the administrative burden, freeing up time for employees to focus on other critical tasks. This change is especially beneficial for organizations managing a large volume of assets, as it minimizes the number of individual transactions required and reduces repetitive tasks. By automating and simplifying asset transfers, organizations can expect faster processing times, reduced errors, and increased operational efficiency.

Another key feature of the reengineering effort is the introduction of automated approval workflow. In the current system, asset-related approvals often involve manual handoffs, that can result in bottlenecks and delays. The new automated workflow route asset requests to the appropriate stakeholders based on predefined business rules, ensuring that approvals are processed in a timely manner. This change reduces the need for manual intervention and eliminates the risk of requests becoming stuck or lost in the system. Automated workflows can also be customized to accommodate different approval levels based on the value or sensitivity of the asset, ensuring that all approvals are aligned with the organization's policies and procedures. By automating this process, companies can reduce turnaround times for asset requests, improve accountability, and enhance the overall transparency in asset management.

Real-time data synchronization is another crucial component of the asset management reengineering process. In many organizations, asset data are stored in disparate systems, leading to inconsistencies and outdated information. With the implementation of real-time synchronization, asset data are updated across all departments and locations instantly using web services. This ensures that all stakeholders have access to the most current and accurate data,thereby reducing the risk of errors caused by outdated information. Real-time synchronization is especially important for organizations that operate in multiple locations or have decentralized teams because it ensures that everyone is working with the same data. This capability also improves reporting accuracy and

enables better decision-making based on reliable, up-to-date asset information.

The reengineering effort also involves role realignment within the asset-management process. This change clarifies and automates the roles related to data entry, approval, and reporting. By separating these responsibilities, the organization can improve compliance and security and, ensure that tasks are handled by appropriate personnel. Access control is a key focus of this realignment, As it ensures that users have access to the information and functions necessary for their roles. This change enhances the overall security of the asset management process by reducing the risk of unauthorized access and improving accountability. Clear role definitions and automated workflows also help reduce human errors, as employees can focus on their specific tasks without having to navigate unnecessary complexity.

Finally, technological integration plays a vital role in the reengineered asset management process. The integration of advanced tools, such as Oracle APEX, for rapid application development allows the organization to build custom solutions tailored to its specific needs [38]. PL/SQL manages database operations, ensuring efficient and reliable handling of asset data, whereas JavaScript and HTML5 will be used to develop user-friendly interfaces that improve the usability of the asset management module [39]. These technologies provide a scalable platform that can grow with the organization, offering flexibility and adaptability for future needs. By leveraging these modern tools, the asset management system becomes more powerful and easier to use, thereby enhancing both user satisfaction and system performance. Moreover, the following results can be expected from the developed system, which can be identified using the BPMM methodology.

At Level 1 (Initial), the focus is on basic data retrieval and asset onboarding. By leveraging the Oracle SQL Cloud Developer and Oracle Autonomous Database, real-time asset data extraction can be ensured for timely updates. Additionally, the automation of asset onboarding and budgeting through Oracle APEX and Oracle Cloud Infrastructure eliminates manual asset entry while maintaining financial tracking accuracy.

Moving to Level 2 (Managed), the system setup and configuration phase ensures adaptability to business rules and policies using Oracle APEX. Furthermore, asset request and assignment processes are optimized using Oracle APEX and Oracle SQL Cloud Developer, leading to streamlined workflows, improved transparency, and reduced processing delays.

At Level 3 (Defined), bulk asset transfers are automated using Oracle APEX and Oracle Cloud Infrastructure, ensuring error-free and efficient transactions. Additionally, approval workflows are enhanced through APEX Workflows and APEX Email API, reducing manual interventions and expediting the approval processes.

In Level 4 (Quantitatively Managed), reverse integration with Oracle ERP enables seamless synchronization of asset updates, financial reconciliations, and status changes using Oracle SQL Cloud Developer and Oracle Autonomous Database. Performance tracking and analytics are further enhanced with dashboards that provide real-time monitoring and KPI tracking via the Oracle APEX and Oracle Cloud Infrastructure.

Finally, Level 5 (Optimizing focuses on strengthening security and compliance), Access control management is implemented using Oracle APEX and Oracle Identity Cloud Service (IDCS) to restrict unauthorized access and ensure compliance with security policies. Additionally, audit logging and compliance tracking, enabled by Oracle APEX Logging and Oracle Audit Vault, provide enhanced security, regulatory adherence, and visibility for asset transfers and approvals.

A summarized expected analysis from the improved process is shown in Table VI.

4) Modeling the developed system: The developed system for asset management can be visualized as shown in Fig. 8 and Fig. 9.

5) Key improvements in the developed system: The developed system introduces several key improvements that enhance the efficiency and streamline operations within the asset management system. First, the automated routing of asset requests and approvals based on predefined rules ensures that requests are directed to appropriate stakeholders without delay. This accelerates the approval process and minimizes the potential for errors, ensuring that all requests are handled consistently according to organizational policies. Additionally, the bulk asset transfer feature allows users to move multiple assets in a single operation, thereby significantly reducing the time and effort required for asset management tasks. This capability is particularly especially beneficial during audits, relocations, or system migrations, where managing large quantities of assets can be cumbersome.

Moreover, real-time automatic updating of asset records across the ERP system eliminates the need for manual data entry, greatly reducing the risk of inaccuracies. As changes are made, all related records are updated instantly, providing users with the most current information available. This integration enhances visibility into asset status and availability, allowing for better decision-making and resource allocation. Collectively, these improvements create a more responsive and reliable asset management process, empowering organizations to operate more efficiently and effectively.

6) Implementation strategy: To ensure successful implementation of the reengineered asset transfer process, a robust change management strategy was employed. This begins with stakeholder engagement, where key figures, such as asset managers, finance teams, and IT personnel are involved early in the process. Their insights were invaluable in addressing concerns and fostering a sense of ownership over changes. In addition, a clear communication plan was established to articulate the objectives, benefits, and specific changes associated with the new process, ensuring that all users understand the rationale behind the transition and are motivated to adopt it. Comprehensive training sessions were organized to equip users with the skills necessary to navigate new functionalities by user manuals and online resources to provide ongoing assistance.

Before full-scale implementation, user acceptance testing (UAT) was conducted in collaboration with the selected financial institution. This critical phase allowed end users to interact with the re-engineered system in a controlled environment, validating its functionality, usability, and alignment with operational requirements. UAT provided an opportunity to identify potential discrepancies, gather user feedback, and

TABLE VI. BPMM (BUSINESS PROCESS MATURITY MODEL) FOR DEVELOPED SYSTEM ANALYSIS - WITH ORACLE APEX ENHANCEMENTS

Maturity Level	Component	Description	Technology Used	Expected Outcome
Level 1 - Initial	Data Retrieval from Oracle ERP	Extract asset data from Oracle ERP for real-time updates	Oracle SQL Cloud Developer, Oracle Autonomous Database	Accurate and timely asset data retrieval with automated fetch mechanisms
	Asset Onboarding and Budgeting	Automate asset addition and integrate with budgeting controls	Oracle APEX, Oracle Cloud Infrastructure	Eliminate manual asset entry, ensure financial tracking with automated validations
Level 2 - Managed	System Setup and Configuration	Define configurable parameters for asset management	Oracle APEX	Flexible system that adapts to changing business rules and policies
	Asset Request and Assignment	Enable request submission and automated asset allocation	Oracle APEX, Oracle SQL Cloud Developer	Streamlined request processing, increased transparency, reduced delays
Level 3 - Defined	Bulk Asset Transfers	Automate and validate mass asset transfers within Oracle ERP	Oracle APEX, Oracle Cloud Infrastructure	Efficient, error-free bulk transfers with built-in approval workflows
	Approval Workflow and Notifications	Implement system-driven approval tracking and email notifications	Oracle APEX Workflows, APEX Email API	Faster approvals, role-based notifications, and reduced manual interventions
Level 4 - Quantitatively Managed	Reverse Integration to Oracle ERP	Sync asset updates, status changes, and financial reconciliations	Oracle SQL Cloud Developer, Oracle Autonomous Database	Real-time data updates in Oracle ERP with minimal manual intervention
	Performance Tracking and Analytics	Implement dashboards with KPIs and real-time monitoring	Oracle APEX, Oracle Cloud Infrastructure	Real-time asset tracking, performance measurement, and compliance reporting
Level 5 - Optimizing	Security and Access Control Management	Implement Access Control Lists (ACL), IP-based restrictions, and role-based permissions	Oracle APEX, Oracle Identity Cloud Service (IDCS)	Restricted system access, preventing unauthorized entry and ensuring compliance with security policies

refine the system to enhance its effectiveness. By involving end users in this testing phase, the organization could ensure that the final implementation meets practical expectations and minimizes disruptions during deployment.

Following a successful UAT, the technology deployment phase was commenced with a pilot testing stage, allowing the reengineered process to be trialed in a limited capacity across select departments or locations. This approach enabled the organization to gather further feedback and address any residual issues before a full-scale rollout. By adjusting based on both UAT and pilot outcomes, the organization could mitigate risks and ensure a smoother transition. Once the pilot proves successful, the full system was deployed organization-wide, maximizing the benefits of the new processes across all areas of operation.

Post-implementation, continuous monitoring and support were critical to the long-term success of the re-engineering process. A dedicated support team was established to address any challenges that may arise during the transition, ensuring that users had the assistance necessary to adapt effectively. Regular performance evaluations were conducted to assess system effectiveness and user satisfaction, allowing for ongoing improvements. By integrating user acceptance testing, structured deployment, and continuous monitoring, this comprehensive approach to change management enhanced operational efficiency while fostering a culture of collaboration and adaptability within the organization.

C. Comparison of As-Is and Developed Systems

1) Evaluation criteria: A comparison of the As-Is and developed asset management systems highlights significant improvements across various criteria. In terms of process efficiency based on time, below Table VII shows the how the process has optimized from the reengineered system.

When evaluating cost-effectiveness, the annual operational cost for the As-Is system is stand approximately $7,500 per user, which includes labor and error correction. With the implementation of the new system, these costs were not included, leading to a savings of $7,500 from users or a 100% reduction [40].

The compliance aspect reveals that the As-Is system experiences approximately 10 compliance incidents per year. The improved system reduced these incidents to only two, representing an impressive 80% improvement in compliance.

In terms of risk mitigation, the As-Is system has an error rate of 15% in asset transactions. The developed system has a significant lower error rate of 5%, resulting in a risk reduction of 67%.

Finally, in terms of asset utilization, the As-Is system achieves an asset utilization rate of 75%. The developed system has affected to enhance this rate to 90%, indicating a 20% improvement in how effectively the organization tracks, transfers, and allocates assets.

2) Analysis of changes: Tables VIII, IX, X, XI, and XII, depict the changes that performed in the developed system compared to As-Is System.

3) Impact on stakeholders: Tables XIII, XIV, and XV depict the impact of the developed System on stakeholders.

D. Quantitative and Qualitative Benefits

1) Quantitative benefits: Implementing automation in asset management can lead to significant cost savings, with an estimated 100% reduction in operational expenses by lowering labor costs and minimizing errors and reconciliation expenses. Additionally, the introduction of bulk asset transfers and automated workflows is projected to reduce the time required

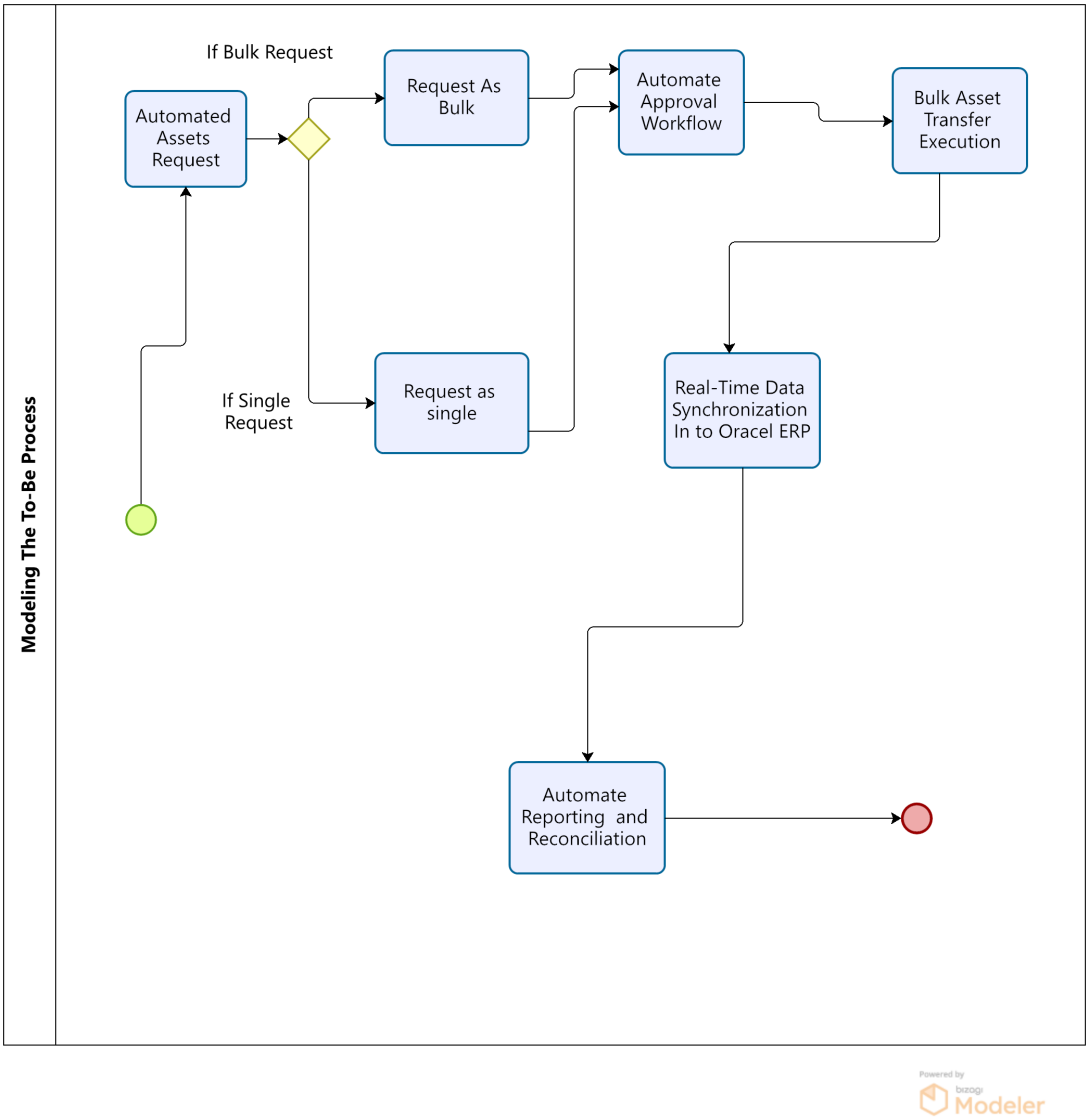

Fig. 8. Modeling developed system.

TABLE VII. COMPARISON OF THE PROCESS EFFICIENCY IN AS-IS SYSTEM AND REENGINEERED SYSTEM

Process Step	As-Is System (Oracle Fusion ERP Only)	Reengineered System	Time Saved
Time to Request Assets	16 hours	1 hour	15 hours
Time to Transfer Assets	48 hours	8 hours	40 hours
Time to Confirm notification of Assets	24 hours	2 hours	22 hours
Total Time for Full Process	88 hours (approx. 5.5 days)	11 hours (less than 2 days)	77 hours

for these transfers by 50%, thereby enhancing asset utilization and overall operational efficiency. Furthermore, automating data entry and ensuring real-time synchronization will decrease the error rate in asset transfers and record keeping, thereby reducing the need for expensive reconciliations.

2) Qualitative benefits: Transitioning from manual processes to automation is expected to significantly enhance employee satisfaction, as team members spend less time on repetitive tasks and more meaningful work, fostering a more positive work environment. Additionally, access to accurate, real-time data will empower management to make well-informed decisions regarding asset utilization, procurement, and financial planning, leading to more strategic asset management and improved resource allocation. Furthermore, with

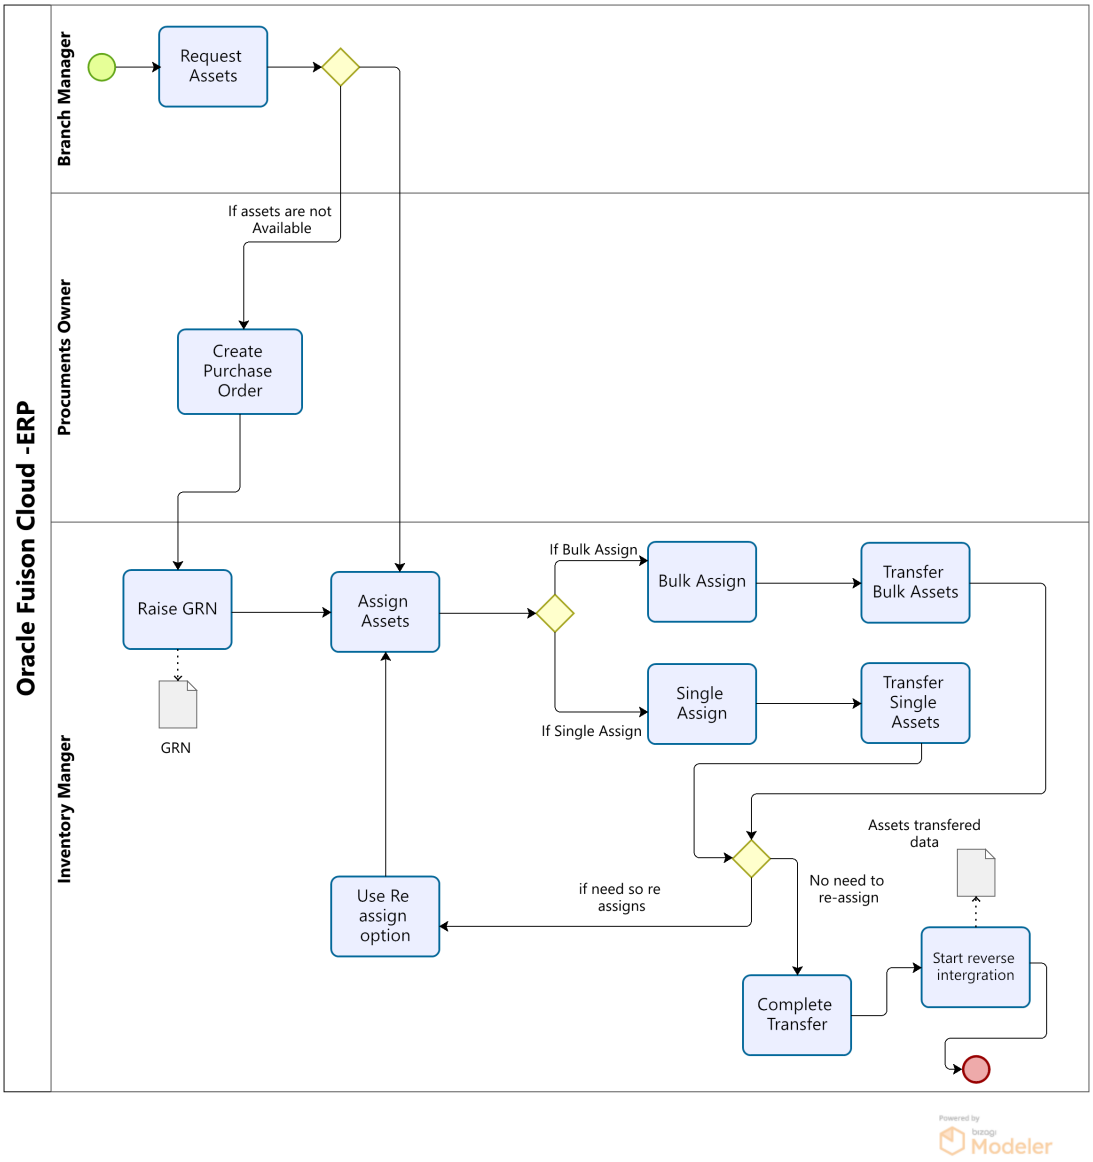

Fig. 9. Detailed developed system model.

TABLE VIII. PROCESS EFFICIENCY

As-Is System	Developed System
The current system requires manual input for each asset transfer, leading to significant delays, especially for large-scale transfers. The approval process is manual, involving multiple handoffs, which further slows down operations.	The bulk asset transfer feature in the developed system allows for transferring multiple assets at once, reducing the time required by up to 50%. Automated approval workflows eliminate manual handoffs, significantly improving the speed of asset requests and approvals.

TABLE IX. COST-EFFECTIVENESS

As-Is System	Developed System
High labor costs due to the manual nature of asset transfers, approvals, and data entry. Errors in manual data entry led to further costs in reconciliation and error correction.	Automation reduces labor costs by 30%, as fewer hours are needed for manual tasks such as data entry and error correction. The system also minimizes costs related to errors and operational delays.

improved compliance features and a lower risk of errors, the organization will be better positioned to meet both internal and external audit requirements, enhance its reputation, and minimize the risk of penalties.

In conclusion, the developed system offers significant improvements over the As-Is system in terms of process efficiency, cost-effectiveness, compliance, risk mitigation, and asset utilization. These changes are expected to have a positive impact on all stakeholders, delivering both tangible cost savings and intangible benefits such as improved satisfaction and decision-making capabilities.

TABLE X. COMPLIANCE

As-Is System	Developed System
The lack of real-time data synchronization leads to inaccurate records, making it difficult to comply with internal and external audit requirements. Delayed updates can result in financial reporting discrepancies.	Real-time synchronization of asset data ensures that records are always accurate and up to date, improving compliance with audit requirements. Automated workflows reduce the risk of non-compliance by ensuring that all approvals and asset transfers are properly documented.

TABLE XI. RISK MITIGATION

As-Is System	Developed System
The manual nature of the system introduces a high risk of errors in data entry, asset tracking, and approvals. Delays in asset transfers can cause operational risks, such as inventory shortages or unaccounted assets.	Automated data entry and real-time updates significantly reduce the risk of errors. The system's built-in validation checks during asset transfers further mitigate the risk of discrepancies. Timely and accurate record-keeping lowers operational and financial risks.

TABLE XII. ASSET UTILIZATION

As-Is System	Developed System
Poor visibility into asset locations and transfer statuses due to delayed and inaccurate data updates. This leads to under-utilization of assets and inefficiencies in resource allocation.	With real-time tracking and updates, asset visibility improves dramatically. The organization can better allocate resources and respond quickly to asset transfer requests, leading to improved asset utilization.

TABLE XIII. EMPLOYEES

As-Is System	Developed System
Employees, especially asset managers and data entry personnel, are burdened by repetitive manual tasks, leading to lower job satisfaction and higher error rates.	Employees, especially asset managers and data entry personnel, are burdened by repetitive manual tasks, leading to lower job satisfaction and higher error rates.

TABLE XIV. MANAGEMENT

As-Is System	Developed System
Management struggles with delayed reporting and inaccurate data, which hampers decision-making and makes it difficult to track asset utilization and costs.	With real-time data and automated reporting, management can make more informed decisions based on accurate and timely information. The improved visibility into asset movements and costs also enhances strategic planning and operational efficiency.

TABLE XV. EXTERNAL PARTIES (AUDITORS, REGULATORS)

As-Is System	Developed System
External parties often face difficulties auditing asset records due to discrepancies and outdated information, which can lead to compliance issues.	The Developed system ensures that external auditors and regulators have access to accurate and up-to-date records, improving compliance and reducing the risk of regulatory penalties.

V. CHALLENGES AND LIMITATIONS

A. Challenges in Reengineering

Resistance to change is a significant challenge in Business Process Reengineering (BPR). Employees often hesitate to adopt new technologies or processes because fear of job displacement and unfamiliarity with automated workflows. To effectively address this issue, organizations must implement clear communication strategies and comprehensive training programs.

Data limitations can complicate the BPR process. The accuracy and completeness of existing data in the As-Is system can be inconsistent or outdated, making it difficult to map current processes and identify inefficiencies. Resolving these data issues is crucial before transitioning to a improved system, where real-time data accuracy is essential.

Technological constraints also present another challenge. The integration of newly developed processes, such as bulk asset transfers and real-time data synchronization, requires an advanced technological infrastructure. Existing ERP systems may not support these changes without significant customization or upgrades, which can lead to compatibility issues and increased technical debt.

Finally, the implementation cost is a major concern. While the developed system is expected to reduce operational costs in the long run, the initial investment required for technology upgrades, training, and system deployment can create a financial burden for many organizations.

B. Limitations of the Research

The scope of this study is specifically centered on the reengineering of the asset management process within the Oracle ERP system. This focus inherently limits the generalizability of the findings, meaning that the insights and recommendations derived from this research may not be applicable to other ERP Systems or Asset Management platform. By concentrating on a single system, this study aimed to provide a detailed and nuanced understanding of the challenges and opportunities present within the Oracle ERP framework. However, this focus also means that organizations using different systems may not find the same relevance in the conclusions drawn.

Furthermore, the research relies heavily on existing data extracted from the current As-Is system. While these data serve as the foundation for process analysis, it is crucial to acknowledge that such information may be prone to inaccuracies or reflect incomplete records. These data limitations could significantly undermine the integrity of the process analysis, because the insights generated are only as reliable as the data on which they are based. If the existing data fail to capture the true state of asset management practices, the recommendations formulated in response may not effectively address the underlying issues or may overlook critical areas for improvement.

In addition to these internal limitations, this study must contend with various external factors that could impact the feasibility and effectiveness of the improved process. Factors such as changing regulations, shifts in organizational culture, and broader economic conditions can play a crucial role in the implementation and sustainability of asset management processes. For example, new regulatory requirements might necessitate alterations in how assets are tracked or reported, whereas organizational culture could influence employee buy-in for new processes. Economic conditions, can also affect

available resourcesand. alter the landscape for potential improvement. Although these external elements were not explored in depth in this study, their potential influence could be underestimated.

VI. Conclusion

A. Summary of Findings

This study identified critical inefficiencies in the As-Is asset management process within ERP systems, particularly in manual asset transfers, delayed approvals, and inconsistent data synchronization in a leading Sri Lankan financial institution. A mixed-method approach integrating qualitative and quantitative analyses was employed, with data collected from 51 branches and analyzed using statistical tools such as Power BI to assess process inefficiencies, error rates, and stakeholder feedback.

The reengineered system introduces bulk asset transfers, automated approval workflows, and real-time data synchronization, delivering measurable improvements over the As-Is process. Specifically, the system achieved a 100% reduction in operational costs per user ($7,500 annual savings), an 80% reduction in compliance incidents, a 67% reduction in asset transaction errors, and a 20% improvement in asset utilization. These quantitative results demonstrate a significant enhancement in process efficiency, reduced manual effort, improved compliance, and optimized resource management.

Furthermore, the reengineering process ensures greater data accuracy, minimizes human intervention, and enhances system transparency. This transformation results in a more efficient, scalable, and user-friendly ERP asset management system, providing both academic and practical contributions by offering a validated framework for workflow optimization, process automation, and effective decision-making across large-scale enterprise environments.

B. Implications for Practice

This study highlights the crucial role of Business Process Reengineering (BPR) in optimizing enterprise resource planning (ERP) systems. The findings demonstrated that automation, real-time data synchronization, and structured workflows can significantly improve operational efficiency, regulatory compliance, and risk management. Furthermore, implementing role-based access controls enhances data security and governance,thereby reducing the likelihood of data breaches or unauthorized asset transactions.

Organizations can leverage these insights to reengineer similar processes across various business functions, including procurement, inventory control, and financial operations. This study underscores the necessity for organizations to transition from manual, labor-intensive processes to automated, data-driven systems to enhance productivity and decision-making capabilities in rapidly evolving digital environments.

C. Recommendations

In today's fast-paced business environment, effective training and change management are critical for overcoming resistance when organizations implement new systems. Comprehensive training programs designed for all users and stakeholders create a supportive learning in environment which individuals feel empowered to adopt new technology. By emphasizing the importance of training, organizations can build a culture of acceptance towards change.In Addition, a clear communication strategy that outlines the benefits of the new system is essential. When stakeholders understand how a new system can enhance their workflows, increase efficiency, and contribute to thier overall business goals, they are more likely to embrace these changes. This dual approach—robust training coupled with transparent communication—ensures that users not only comprehend the operational aspects of the new system but also feel motivated to utilize it effectively, thereby reducing disruptions during the transition period.

Instead of pursuing a full-scale rollout of new systems, organizations may find it advantageous to adopt incremental implementation strategies. This approach allows for the initial deployment of the system in the pilot phase, enabling the organization to identify potential issues in a controlled environment. By starting small, organizations can gather feedback from users, observe the system's performance, and make the necessary adjustments before expanding the implementation. This pilot phase serves as a testing ground that helps organizations fine-tune functionalities and address any unforeseen challenges, thus minimizing the risks associated with a larger rollout. Furthermore, incremental implementation fosters a sense of ownership among users, because their input during the pilot phase can lead to enhancements that cater specifically to their needs. This strategy not only facilitates smoother transitions but also enhances overall user confidence in the new system, setting the stage for a more successful organization-wide deployment.

Once the new system was implemented, continuous monitoring and evaluation were crucial to ensure that it meets the established efficiency and compliance targets. Organizations might set up regular check-ins and performance assessments to track a system's effectiveness over time. These evaluations could provide insights into how well the system functions and identify areas that require further improvement. As organizations evolve and grow, their needs may shift, necessitating ongoing adjustments to the system to align with new operational goals. By establishing a culture of continuous improvement, organizations can proactively address any shortcomings in the system and capitalize on opportunities for optimization. Furthermore, future research could explore broader applications of Business Process Reengineering (BPR) principles beyond asset management, extending into areas such as procurement and inventory control. Such studies could provide valuable insights into the transformative potential of BPR in various business functions, thereby enhancing overall organizational agility. Additionally, investigating the role of emerging technologies, such as artificial intelligence and machine learning, can open new avenues for enhancing asset management and ERP systems, driving efficiency, and improving decision-making capabilities. In conclusion, embracing a holistic approach to training, incremental implementation, and continuous evaluation can significantly mitigate resistance to change and foster a culture of adaptability in organizations.

Acknowledgment

In the preparation of this research manuscript, the only AI tool used was ChatGPT (developed by OpenAI). The

tool was employed exclusively for enhancing language clarity, improving grammar, and refining sentence structure throughout the manuscript.

To evaluate the validity and accuracy of the language outputs generated by ChatGPT, all content revised using the tool was thoroughly cross-verified by the university's English Language Unit. Additionally, the paid version of Paperpal Preflight tool was used as a supplementary resource to assess the grammatical correctness and coherence of the language improvements.

We explicitly confirm that no part of the research design, data collection, analysis, results, or interpretation was generated or influenced by ChatGPT or any other AI tools. The sole purpose of using ChatGPT was to enhance the manuscript's linguistic quality, and it was not used to create or manipulate any scientific content, findings, or supporting materials.

Furthermore, we affirm that,

- The content presented is accurate and valid, reflecting the genuine findings of the study.
- There are no concerns regarding plagiarism, and all writing is original unless explicitly cited.
- All relevant sources have been cited appropriately.
- Every statement regarding hypotheses, results, interpretations, conclusions, limitations, and implications represents the authors' own intellectual contributions and perspectives.

***Abstract*—Deep reinforcement learning (DRL) typically involves training agents with stochastic exploration policies while evaluating them deterministically. This discrepancy between stochastic training and deterministic evaluation introduces a potential objective mismatch, raising questions about the validity of current evaluation practices. Our study involved training 40 Proximal Policy Optimization agents across eight Atari environments and examined eleven evaluation policies ranging from deterministic to high-entropy strategies. We analyzed mean episode rewards and their coefficient of variation while assessing one-step temporal-difference errors related to low-confidence actions for value-function calibration. Our findings indicate that the optimal evaluation policy is highly dependent on the environment. Deterministic evaluation performed best in three games, while low-to-moderate-entropy policies yielded higher returns in five, with a significant improvement of over 57% in Breakout. However, increased policy entropy generally degraded stability—evidenced by a rise in the coefficient of variation in Pong from 0.00 to 2.90. Additionally, low-confidence actions often revealed an over-optimistic value function, exemplified by negative TD errors, including -10.67 in KungFuMaster. We recommend treating evaluation-time entropy as a tunable hyperparameter, starting with deterministic or low-temperature softmax settings to optimize both return and stability on held-out seeds. These insights provide actionable strategies for practitioners aiming to enhance their DRL-based agents.**

***Keywords*—Deep reinforcement learning; policy evaluation; stochastic policy; temporal difference error; Atari; PPO**

I. Introduction

Deep reinforcement learning has emerged as a powerful paradigm for solving complex sequential decision-making problems, with notable successes in domains ranging from game playing to robotics [1], [2]. Among the most successful families of algorithms are policy gradient methods, which directly optimize the parameters θ of an agent's policy, π_θ. Algorithms like Proximal Policy Optimization (PPO) [3] learn a stochastic policy, which maps states to a probability distribution over actions, $\pi_\theta(a|s)$. For discrete action spaces, as found in the Atari Learning Environment, this policy is typically represented by a categorical distribution, often parameterized by the softmax output of a neural network.

The stochastic nature of the policy is not an incidental feature; it is fundamental to the learning process. During training, sampling actions from the policy distribution enables exploration, allowing the agent to discover novel state-action pathways that may lead to higher rewards. This exploration is essential for escaping local optima and preventing premature convergence to a suboptimal policy. Indeed, the policy gradient theorem [4], the theoretical foundation of these methods, relies on this stochasticity to estimate the gradient of the expected return.

In stark contrast to the training phase, the common practice during evaluation or deployment is to render the policy deterministic by selecting the action with the highest probability for any given state (i.e., taking the argmax of the policy's output distribution). This deterministic approach is predicated on the principle of exploitation. Once the agent has been sufficiently trained, the optimal strategy is to consistently choose the action it believes to be the best. This creates a fundamental duality: agents are trained as stochastic decision-makers but are often deployed as deterministic ones. This practice, while widespread, rests on an assumption that has received surprisingly little systematic scrutiny. Earlier empirical studies have examined evaluation discrepancies for value-based agents, but only recently has the gap for policy-gradient methods been quantified. In study [5], the authors demonstrate that apparent gains can disappear when stochastic and deterministic evaluations are compared under matched conditions; however, their study does not isolate the causal role of value-function mis-calibration. We extend this thread by providing the first large-scale analysis that links evaluation stochasticity, TD-error structure, and overfitting across eight Atari domains.

This dichotomy between training and evaluation methodologies raises a critical question: is the deterministic policy derived via an argmax operation the most effective implementation of the knowledge encoded within the trained stochastic policy? While intuitively appealing, this assumption is not guaranteed to hold. The optimization objective of PPO maximizes the expected return under the stochastic policy, π_θ, not necessarily the return of its deterministic counterpart. This creates a potential objective mismatch, where the criteria for success during training (effective stochastic exploration and exploitation) differ from the criteria during evaluation (pure deterministic exploitation). There are well-established scenarios where a stochastic policy is not just a tool for exploration but is fundamentally optimal for the task itself. In game-theoretic or multi-agent settings, a deterministic policy can be predictable and easily exploited by an adversary. A classic example is Rock-Paper-Scissors, where the Nash equilibrium corresponds to a uniform stochastic policy [4]. Similarly, in Partially Observable Markov Decision Processes (POMDPs),

*Corresponding author.

where different underlying states may appear identical to the agent (a phenomenon known as perceptual aliasing), a stochastic policy can be crucial for breaking symmetry and avoiding getting stuck. Although Atari games are typically single-agent environments, they are not fully observable, as the agent only sees the current screen's pixels and must infer dynamic information like velocity and trajectory. This partial observability could favor a stochastic approach. The degree of a policy's randomness can be quantified by its entropy. Higher entropy corresponds to a more uniform and exploratory distribution, while lower entropy indicates a more deterministic and exploitative one. During training, policy entropy is often explicitly encouraged via an entropy bonus in the loss function to promote exploration and smooth the optimization landscape. However, its role and optimal level during the evaluation phase remain largely unexamined.

This paper aims to bridge this research gap through a large-scale, systematic empirical investigation. We trained 40 agents using the PPO algorithm across eight distinct Atari environments. These trained agents were then evaluated using a suite of eleven different evaluation policies, ranging from fully deterministic to highly stochastic, allowing us to precisely control and measure the impact of policy entropy on performance. This comprehensive experimental framework allows us to address the following research questions:

- Performance and Stability: How do evaluation policies with varying degrees of stochasticity, as measured by entropy, affect agent performance (mean reward) and stability (reward variance) across different Atari environments?
- Action Pruning: Can a simple heuristic—pruning the least likely actions from the policy's distribution, a form of manual entropy reduction—consistently improve performance?
- Underlying Mechanisms: How do stochastic policies reveal weaknesses in the learned value function? Specifically, can we use the Temporal Difference (TD) error—conceptually, the difference between the predicted value of a state and a more accurate value estimated after taking an action— on low-confidence actions to diagnose inaccurate value predictions and explain performance degradation?

Novelty and contribution. In contrast to prior work that either 1) proposes entropy-regularized objectives to train intrinsically stochastic policies [6], [7] or 2) benchmarks evaluation heuristics without examining the critic, our study treats evaluation stochasticity as a post-training intervention and interrogates its causal impact on performance through a TD-error lens. This framing enables a principled diagnosis of value-function overfitting in cases where stochasticity harms performance and yields actionable guidelines for selecting evaluation protocols that account for this risk.

The remainder of this paper is structured to answer these questions. Section II details the related works, situating our investigation within the context of policy representation and overfitting in RL. Section III describes the methodologies we utilized for the study. Section IV presents a detailed analysis of the experimental results, addressing each research question in turn. Finally, Section V discusses the broader implications of our findings for RL practitioners and outlines directions for future research, concluding with a summary in Section VI.

II. Related Work

Our investigation is situated at the intersection of several key areas in reinforcement learning: policy representation, overfitting and generalization, action space modification, and the role of stochasticity.

A. Policy Representation in Reinforcement Learning

RL algorithms can be broadly categorized by how they represent the agent's policy.

A core distinction in RL is between on-policy and off-policy learning. On-policy algorithms, such as PPO [3], update the policy using only the data collected from the most recent version of that same policy. In contrast, off-policy algorithms, like DDPG [8], can learn from data generated by a different policy, often by using a replay buffer of past experiences. Another key distinction is between stochastic policies, which map states to a probability distribution over actions, and deterministic policies, which map states to a single action. These two distinctions are not synonymous.

1) Stochastic policy methods: Modern on-policy RL was significantly advanced by Trust Region Policy Optimization (TRPO) [9], which introduced a constraint on the Kullback-Leibler (KL) divergence between successive policies to guarantee monotonic improvement and stabilize training. PPO [3] emerged as a more practical and scalable successor, replacing the complex second-order optimization of TRPO with a more straightforward clipped surrogate objective that achieves similar stability. Its robustness and ease of implementation have made PPO a ubiquitous algorithm in the field, with recent advances continuing to refine its optimization process and theoretical underpinnings [10], [11]. Another influential on-policy method, Asynchronous Advantage Actor-Critic (A3C) [12], demonstrated that using multiple parallel actors to interact with the environment could decorrelate the training data and stabilize learning without a replay buffer. These methods all directly learn a stochastic policy, where exploration is inherent to the policy representation itself. While these examples are on-policy, off-policy algorithms that learn stochastic policies, like Soft Actor-Critic (SAC) [7], also exist.

2) Deterministic policy methods: In contrast, another line of research focuses on learning deterministic policies. The Deterministic Policy Gradient (DPG) theorem [13] showed that for deterministic policies, the policy gradient can be computed more efficiently as it does not require integration over the action space. This theoretical advantage motivated the development of algorithms like Deep DPG (DDPG) [8], which combines DPG with deep function approximators for continuous control tasks. These methods are typically off-policy and separate exploration from the policy itself, typically by adding noise to the actions during training only.

This fundamental split in RL approaches—between learning a stochastic policy with built-in exploration and learning a deterministic policy with external exploration—sets the stage for our central research question.

3) Value-based methods and evaluation: The pioneering Deep Q-Network (DQN) [1] learns a value function, Q(s,a), and derives a policy by acting greedily with respect to it. Early work on DQN evaluated agents using an ϵ-greedy policy with a small ϵ (e.g., 0.05) to prevent deterministic cycling in the Atari environments. However, subsequent common practice shifted towards fully greedy evaluation ($\epsilon = 0$) to assess the agent's maximum performance capacity. This historical trend shows the field's implicit convergence on deterministic evaluation as the standard, an assumption our work aims to scrutinize. Complementary evidence comes from [5], who revisit the Atari evaluation methodology and advocate measuring on-policy returns under test-time stochasticity. Our experimental design follows these recommendations but augments them with a TD-error-based causal probe, thereby clarifying why mismatched evaluation protocols degrade performance.

B. Overfitting in Deep Reinforcement Learning

The problem of generalization, a fundamental challenge in deep reinforcement learning (DRL) [14], provides a critical lens through which to view our results. High-capacity models like deep neural networks are prone to memorizing the training data rather than learning generalizable features, a phenomenon that is particularly acute in RL. An agent that overfits to the limited set of trajectories collected through its own on-policy interactions may perform well on states and actions it has seen frequently but fail catastrophically in novel situations [15]. For example, a study [16] demonstrated that overfitting is a primary cause of performance collapse when an agent is transferred from a limited set of training levels to unseen ones, highlighting the need for explicit regularization techniques to promote generalization.

Recent work has provided a more specific vocabulary for diagnosing these failures. The issue is not merely one of standard supervised learning overfitting, but involves instabilities unique to the RL process. A key failure mode is the chain effect of churn [17]. This phenomenon, identified in [17], describes how the value function's predictions for states not in the batch can change uncontrollably after each batch update. This creates a vicious cycle where churn in value estimation and policy improvement compound each other, progressively biasing the learning dynamics. This churn is symptomatic of a deeper issue termed "representation collapse," where the agent's neural networks lose plasticity and feature rank throughout training, rendering them incapable of adapting to new observations or fitting new targets. This collapse is exacerbated by the non-stationarity inherent in RL, where the agent's improving policy continually shifts the data distribution.

This perspective aligns with the concept of specification overfitting, where a system focuses excessively on optimizing a specific, narrow metric—in this case, the TD error on its on-policy data distribution—to the detriment of broader, high-level requirements, such as robustness and generalization. In [18], the authors provided a crucial diagnostic insight, identifying statistical overfitting in the temporal-difference (TD) error as a primary bottleneck. Their key idea is that as an agent trains, its value function becomes highly accurate on its on-policy data distribution but remains inaccurate on out-of-distribution transitions. They propose that this can be diagnosed by measuring the TD error on a held-out validation set of transitions, where an extensive validation TD error indicates poor generalization. This theoretical framework provides a powerful explanation for our empirical findings. The low-confidence actions sampled by our stochastic evaluation policies serve as a naturally occurring validation set. The TD errors on these actions thus act as a direct probe into the value function's generalization capabilities, allowing us to empirically test and validate the overfitting hypothesis proposed in the recent literature.

C. Action Elimination and Pruning

Our experiments with drop policies are related to a line of research on action elimination. An Action Elimination Network (AEN) learns to predict and mask out suboptimal or irrelevant actions in environments with very large discrete action spaces [19]. By reducing the effective size of the action space at each step, their method significantly speeds up learning and improves robustness in complex domains like text-based games. Our drop policies can be seen as a simple, non-learned heuristic inspired by this principle. Instead of learning which actions to eliminate, we manually prune the actions with the lowest logits, allowing us to test the hypothesis that performance can be improved simply by preventing the agent from taking actions it is already least confident about.

D. The Dual Role of Stochasticity: Exploration, Optimality, and Causality

The stochastic nature of the policy in algorithms like PPO is typically framed as a mechanism for exploration, which is essential for discovering novel, high-reward trajectories and preventing premature convergence. However, this view is incomplete. A growing body of research highlights that policy stochasticity plays a more fundamental role in optimization and even optimality itself. In some contexts, a stochastic policy is not merely a means to an end but is the optimal solution. This is well-established in game-theoretic settings [4]. More broadly, the framework of maximum entropy RL formalizes the benefit of randomness by augmenting the standard reward objective with an entropy term [6]. Algorithms like SAC [7] explicitly optimize this objective, learning policies that are not only effective but also as random as possible. The resulting policies can capture diverse strategies for accomplishing a task, thereby improving robustness.

Furthermore, the stochasticity inherent in policy gradient methods is a key mechanism for escaping local optima in the complex, non-convex optimization landscapes of DRL [20]. A purely deterministic policy can easily get trapped in a simple but suboptimal strategy. In contrast, the noise introduced by sampling from a policy distribution can provide the necessary perturbation to jolt the agent out of such traps and discover more sophisticated, higher-reward solutions. This provides a compelling theoretical lens through which to interpret our empirical results in environments like Breakout.

Finally, recent work on the causal foundations of RL provides a formal way to disentangle the sources of randomness in an agent's experience [21]. This framework decomposes the total return of a trajectory into components attributable to the agent's actions and components attributable to the environment's inherent stochasticity. This decomposition is achieved by interpreting the advantage function as the causal

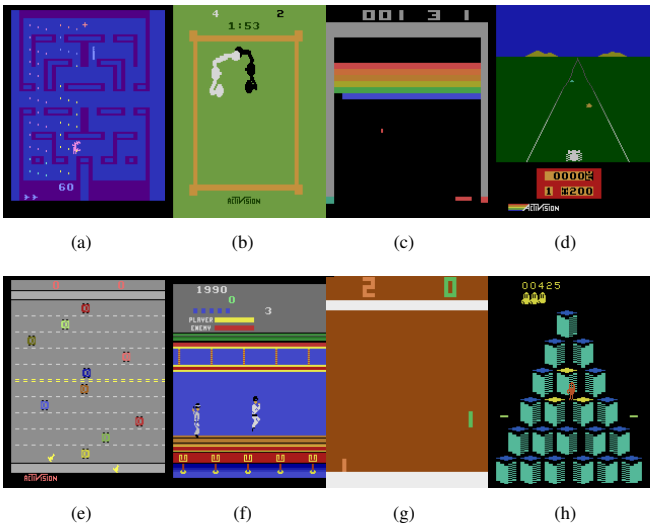

Fig. 1. The eight Atari 2600 environments utilized for the study: (a) Alien, (b) Boxing, (c) Breakout, (d) Enduro, (e) Freeway, (f) KungFuMaster (KFM), (g) Pong, and (h) Qbert.

effect of an action on the return [21]. This distinction clarifies that our investigation focuses on the consequences of the agent's policy stochasticity rather than randomness in the environment's dynamics.

III. Experimental Framework

To systematically investigate the effects of evaluation policy stochasticity, we designed a comprehensive experimental setup involving multiple agents, environments, and evaluation strategies.

A. Environments and Agent Training

Experiments were performed on eight Atari 2600 games from the Arcade Learning Environment (ALE)—Alien, Boxing, Breakout, Enduro, Freeway, KungFuMaster (KFM), Pong, and Qbert (Fig. 1). These titles span a broad spectrum of interaction modalities, reward densities, and action-space cardinalities, thereby providing a representative benchmark suite. The characteristics of each environment, particularly the size of the discrete action space and the corresponding entropy of a random policy, are crucial for interpreting the results and are summarized in Table I.

For each game, five independent PPO agents were trained, yielding a total of 40 trained policies and thereby mitigating the variance induced by random seeds. Training lasted for 1×10^7 environment steps per agent and used the canonical convolutional network for Atari inputs introduced by study [1]. Table II lists the set of PPO hyperparameters that were held constant across all environments.

B. Evaluation Policies

For each of the 40 trained agents, we conducted evaluations using 11 distinct action selection policies. These policies were designed to span a wide spectrum of stochasticity, from fully deterministic to highly random. Each agent-policy combination was evaluated for 100 independent episodes to gather statistically robust performance data. The definitions of the evaluation policies are provided in Table III. Table III provides a concise definition for each of the 11 evaluation policies used to assess the trained agents. logits refers to the raw, pre-softmax output of the policy network.

Justification for linear and drop policies:

1) Linear: The linear policy was designed as a high-entropy alternative to a purely random policy. By preserving the ordinal ranking of the network's logits while drastically flattening the probability distribution, it serves as a hard test case for how the agent performs when it must consider its less-preferred actions more seriously.

2) Drop: The softmax_drop_k and linear_drop_k policies are simple, non-learned heuristics inspired by action-pruning techniques. They allow us to test the hypothesis that manually preventing the agent from taking actions it is already least confident about can function as a form of targeted entropy reduction and improve performance, particularly on otherwise highly random policies.

C. Analysis Metrics

To evaluate performance and diagnose mechanisms, we record the following metrics during evaluation.

1) Performance metrics: The primary performance metric is the *Mean Episode Reward*, averaged over 100 episodes per agent–policy pair. Stability is quantified by the *Coefficient of Variation* (CV), defined as the standard deviation of episode returns divided by their mean. A lower CV indicates more consistent performance relative to the average score.

2) Stochasticity metric: The degree of randomness of the evaluation policy is measured by the average policy entropy,

$$H(q_T) \;=\; \mathbb{E}_t\left[-\sum_{a\in A} q_T(a \mid s_t)\,\log q_T(a \mid s_t)\right], \qquad (1)$$

where $q_T(\cdot \mid s)$ is the evaluation policy (e.g., `softmax_T`) and the expectation is over timesteps.

3) Diagnostic metrics: To investigate the underlying mechanisms of performance differences, we defined two key diagnostic metrics:

a) Low-Confidence Action Ratio (LCAR): Given an evaluation policy $q_T(a \mid s)$ and threshold $\tau \in (0, 1]$, define

$$\mathrm{LCAR}_\tau(s) \;=\; \sum_{a\in A} q_T(a \mid s)\,\mathbf{1}\Big\{\, q_T(a \mid s) < \tfrac{\tau}{|A|}\Big\}. \qquad (2)$$

This quantity equals the total probability mass that $q_T(\cdot \mid s)$ assigns to the *low-confidence* set $\{a : q_T(a \mid s) < \tau/|A|\}$. We report **LCAR-50** ($\tau = 0.5$) and **LCAR-10** ($\tau = 0.1$) as the time-averaged frequencies of such events. *Note on softmax_10.0.* As $T \to \infty$, $q_T(\cdot \mid s)$ approaches the uniform distribution, implying $\mathrm{LCAR}_\tau(s) \to 0$ because $1/|A| > \tau/|A|$

TABLE I. ACTION SPACE SIZE AND ENTROPY OF A RANDOM POLICY IN ATARI ENVIRONMENTS

	Alien	Boxing	Breakout	Enduro	Freeway	KFM	Pong	Qbert
Action Space Size (N)	18	18	4	9	3	14	6	6
Entropy (nats)	2.890	2.890	1.386	2.197	1.099	2.639	1.792	1.792

TABLE II. PPO HYPERPARAMETER CONFIGURATION USED FOR THE ATARI EXPERIMENTS

Hyper-parameter	**Value**
Frame stack	4
Number of parallel environments (n_{envs})	8
Rollout length per environment (n_{steps})	128
SGD epochs per update (n_{epochs})	4
Mini-batch size	256
Total timesteps	1×10^7
Learning-rate schedule	linear, $2.5 \times 10^{-4} \to 0$
Value-function loss coefficient (c_v)	0.5
Entropy coefficient (c_H)	0.01

TABLE III. EVALUATION POLICIES AND THEIR DESCRIPTIONS

Policy	**Description**
deterministic	Selects the action with the highest logit value: $a = \arg\max(\text{logits})$.
softmax_T	Samples an action from the distribution given by $\text{Softmax}(\text{logits}/T)$. Tested for temperatures $T \in \{0.1, 0.5, 1.0, 2.0, 10.0\}$.
linear	Applies an affine shift to make all logits non-negative ($w = v - \min(v)$), then normalizes these values linearly to form a probability distribution.
softmax_drop_k	Removes the k actions with the lowest logit values, then applies a softmax function with $T = 1.0$ to the remaining logits. Tested for $k \in \{1, 2\}$.
linear_drop_k	Removes the k actions with the lowest logit values, then applies the linear normalization scheme to the remaining logits. Tested for $k \in \{1, 2\}$.

for $\tau \in \{0.5, 0.1\}$. At the finite temperature T=10, however, the policy remains only approximately uniform and retains residual structure from the logits. Consequently, a small but nonzero fraction of probability mass can still fall below the threshold. Empirically, this is visible in Qbert, where softmax_10.0 attains LCAR-50 = 5.489% (Table XI). We therefore include softmax_10.0 as a high-entropy reference policy rather than a recommended operating point.

b) Conditional TD error: The one-step TD error at timestep t is

$$\delta_t \;=\; R_{t+1} + \gamma\, V(S_{t+1}) - V(S_t), \tag{3}$$

with discount factor $\gamma = 0.99$ and V the learned value function. We report the average TD error *conditioned* on low-confidence events (e.g., timesteps contributing to LCAR-50 or LCAR-10). This conditional analysis probes the value function's accuracy for actions that the policy itself deems unlikely.

IV. RESULTS AND ANALYSIS

Our experiments yielded a rich dataset that provides clear answers to our research questions, with comprehensive statistics presented in Tables IV to XI for each environment and Table XII for policy entropies. The results, visualized in Fig. 2, reveal a split pattern: in five environments, a low- or moderate-entropy policy outperforms the deterministic baseline, while in three (Boxing, Pong, Qbert) deterministic remains best.

A. RQ1: How do Stochastic vs. Deterministic Policies Affect Performance and Stability?

1) Performance: Across the eight Atari tasks, deterministic evaluation achieves the highest mean reward in three games—Boxing (Table V), Pong (Table X), and Qbert (Table XI). In the remaining five games, a low-to-moderate-entropy policy outperforms deterministic evaluation: Alien (softmax_0.5; Table IV), Breakout (softmax_0.5; Table VI), Enduro (softmax_0.1; Table VII), Freeway (softmax_drop_1; Table VIII), and KFM (softmax_0.1; Table IX). This pattern indicates that modest stochasticity can yield higher returns in a majority of environments, while deterministic remains a strong baseline in the others. This pattern is evident in the summary bar charts in Fig. 2. In several environments, modest stochasticity yields higher returns. In Breakout (Table VI), the moderately stochastic softmax_0.5 policy surpasses the deterministic baseline, scoring 242.02 compared to 153.83 (57.3% improvement). In Freeway (Table VIII), performance differences are modest, but softmax_1.0 and drop variants slightly exceed the deterministic baseline (22.00 and 22.06 vs 21.41), indicating multiple near-optimal evaluation policies. However, in Qbert (Table XI), the deterministic policy scores 3894.00, significantly outperforming the standard stochastic softmax_1.0 policy, which scores 2404.60.

2) Stability: Stochastic evaluation generally inflates return variance and degrades stability. Across many games, higher-entropy evaluation tends to increase the coefficient of variation (CV). However, the relationship is not strictly monotonic in all environments, so we treat the stability impacts of entropy as environment-dependent(as detailed in Table XII). This instability is most pronounced in what we term 'brittle' environments, such as Pong (Table X), where a single suboptimal action can lead to immediate and irreversible negative consequences (e.g., losing a rally). The CV rises from a perfect 0.00 under the deterministic policy to 0.38 under the softmax_2.0 policy. Conversely, in 'robust' environments like Freeway (Table VIII), the agent's success is determined by a longer sequence of actions, and a single suboptimal move is less likely to be catastrophic, allowing for multiple near-optimal policies. However, stability decreases significantly with near-uniform action sampling, as seen with the softmax_10.0, which has a CV of 0.42.

To better understand the differences in both performance and stability, Fig. 3 visualizes the full reward distributions for

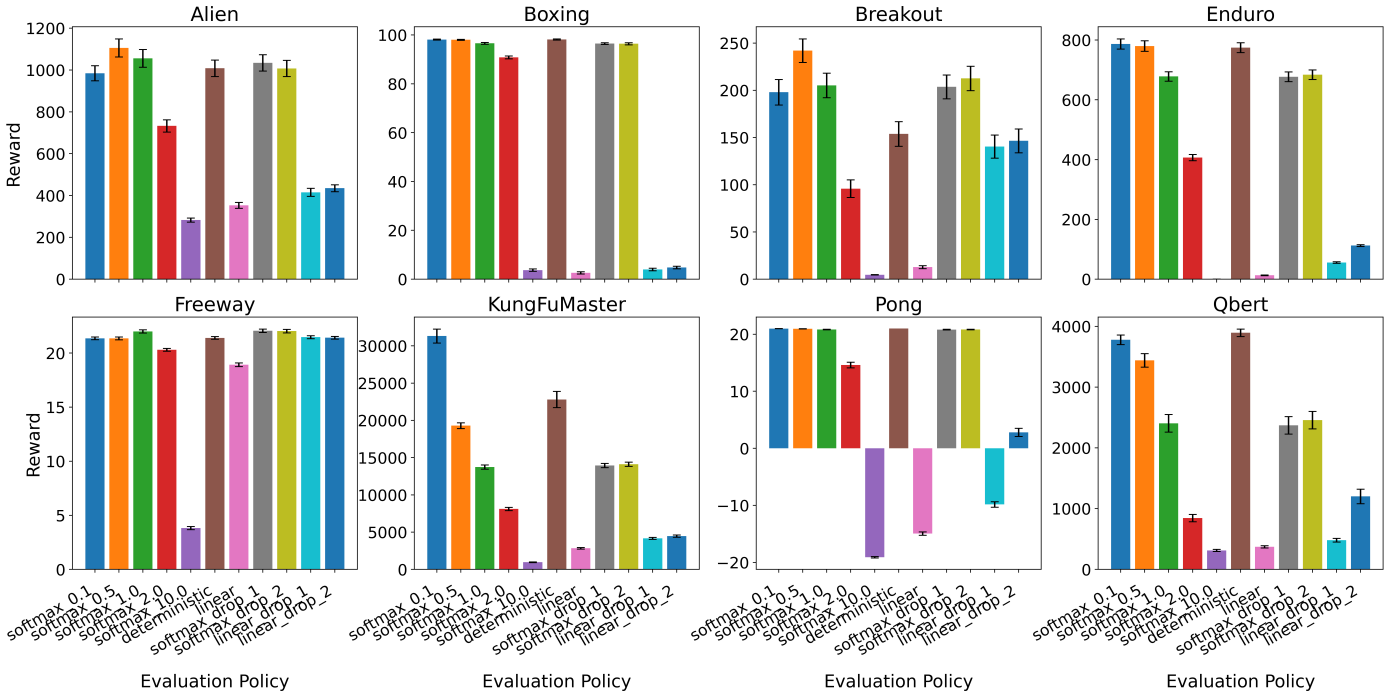

Fig. 2. Mean reward per evaluation policy across eight Atari environments. Error bars represent 95% confidence intervals.

TABLE IV. POLICY-WISE SUMMARY FOR ALIEN: REWARD, LOW CONFIDENCE ACTION RATIO, AND TD ERROR

Policy	Reward				Low Conf 50%		Low Conf 10%

the deterministic policy and a representative stochastic policy (softmax_1.0). These plots reveal the underlying structure of the summary statistics. For example, in Pong, the deterministic policy's distribution is a single sharp spike at the maximum score of 21, illustrating its perfect stability (CV of 0.00). In contrast, the distribution for Breakout is bimodal; the stochastic softmax_1.0 policy is visibly more successful at avoiding the low-reward mode, explaining its higher average score. Conversely, in games like Qbert, the deterministic policy's distribution is clearly concentrated at a much higher reward level than that of the stochastic policy, reinforcing its superior performance in that environment.

B. RQ2: What is the effect of action pruning (drop) on performance?

Our analysis of the drop policies, which manually prune the least likely actions, reveals that this heuristic acts as a form of manual entropy reduction whose effectiveness is entirely dependent on the baseline policy's randomness.

- When applied to a focused, low-entropy policy like softmax_1.0, pruning has a negligible impact. The actions being pruned already have near-zero probability of being selected, so their explicit removal does not significantly alter the agent's behavior. For instance, in Alien (Table IV), the mean reward for softmax_1.0 is 1055.94, while softmax_drop_1 and softmax_drop_2 score a comparable 1034.18 and 1007.52, respectively.
- The effect is dramatically different when pruning is applied to a highly random policy such as linear, which assigns substantial probability to actions with low logits. In this context, pruning is highly effective at improving performance by forcing the agent to be more exploitative. In Qbert (Table XI), the linear policy scores a meager 371.55, whereas linear_drop_2 improves this to 1201.20, more than tripling the reward. This shows that performance is fundamentally

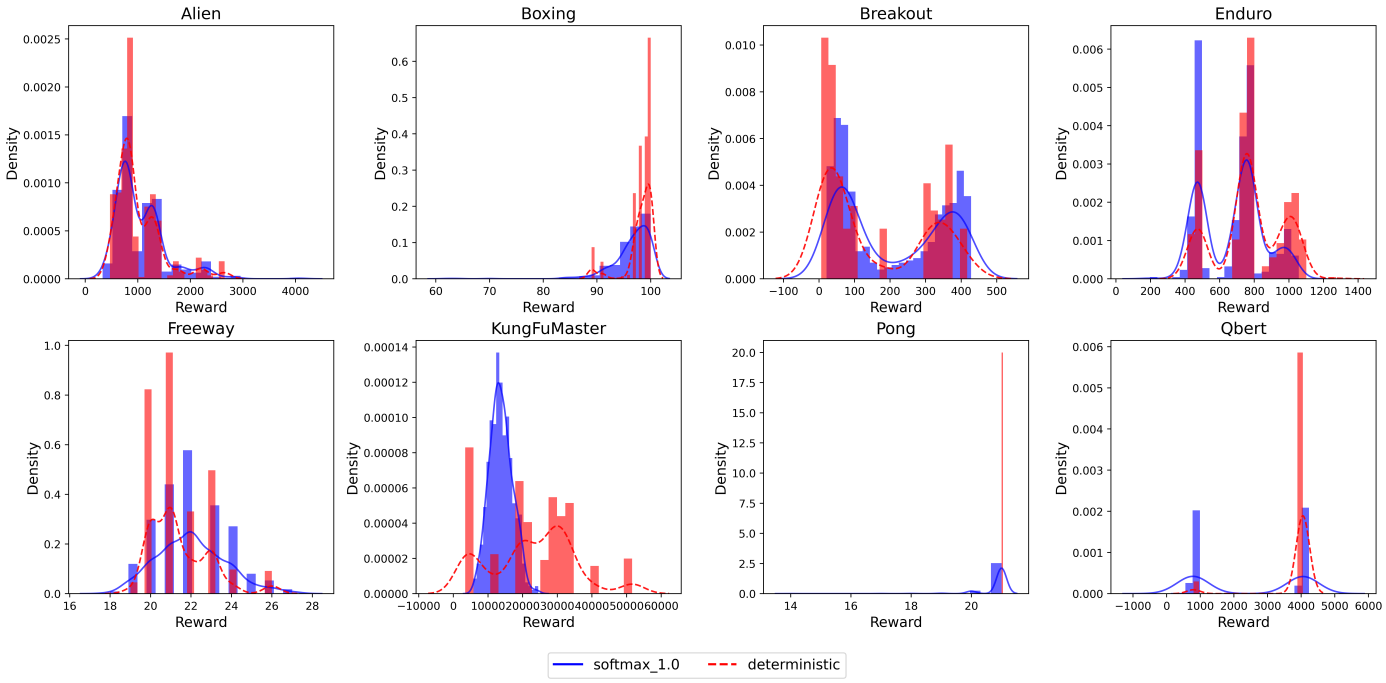

Fig. 3. Reward distribution histograms and kernel density estimates for 100 episodes across eight Atari environments. Only two representative policies (softmax policy with temperature 1.0 and deterministic policy) are shown for clarity.

TABLE V. POLICY-WISE SUMMARY FOR BOXING: REWARD, LOW CONFIDENCE ACTION RATIO, AND TD ERROR

Policy	Reward				Low Conf 50%		Low Conf 10%

linear_drop_2	4.80	-9.00	25.00	1.22	4.844	-0.137	0.142	-0.153

tied to avoiding low-confidence actions. However, it is crucial to note that even with this significant improvement, the linear_drop_2 policy's score of 1201.20 is still dramatically lower than the deterministic policy's score of 3894.00. This suggests that simply pruning the worst few actions is insufficient to recover high performance. The underlying issue is not just the presence of a few catastrophic actions, but the overall shape of the probability distribution. The linear normalization scheme, even after pruning, assigns a much more uniform probability to the remaining actions than the peaked distribution of a standard softmax policy, leading to continued suboptimal decision-making.

C. RQ3: Can TD Error Explain the Performance Degradation?

While the preceding results demonstrate a correlation between high evaluation entropy and poor returns in many games, our analysis of the TD error provides a causal, mechanistic explanation for this performance degradation. The data reveal that performance degradation is a direct symptom of the agent's value function being poorly generalized outside of the high-density regions of the on-policy data distribution observed during training. The argument is built in three steps.

1) Step 1: Higher entropy forces more low-confidence actions. There is a direct causal link between the stochasticity of the evaluation policy and the frequency of low-confidence actions. As policy entropy increases (Table 12), the evaluation policy q_T allocates more probability to the low-probability tail, increasing the frequency of low-confidence events (e.g., LCAR-50 of Alien rises from 0.489% at $T = 0.1$ to 7.521% at $T = 2.0$; Table IV).

2) Step 2: The value function is systematically overoptimistic for low-confidence actions. Our analysis shows that when the agent is forced to take actions it has learned to avoid, the resulting outcomes are consistently worse than what its

TABLE VI. POLICY-WISE SUMMARY FOR BREAKOUT: REWARD, LOW CONFIDENCE ACTION RATIO, AND TD ERROR

value function predicted. This observation is consistent with recent evidence that actor-critic value networks become miscalibrated on out-of-distribution state–action pairs, systematically over-estimating returns in precisely the regions we probe here [18]. A negative TD error ($\delta_t < 0$) means the experienced outcome, $R_{t+1}+\gamma V(S_{t+1})$, was significantly worse than what the value function $V(S_t)$ had predicted. The data provides unambiguous evidence for this. In Alien (Table IV), when the softmax_2.0 policy takes a low-confidence (50%) action, the resulting average TD error is -0.497. For the lowest-confidence (10%) actions, the error is -0.983. A similar pattern is observed in KFM (Table IX), where the softmax_2.0 policy yields a TD error of -6.111 and -10.671 on low-confidence actions of 50% and 10%, respectively. When the agent is forced to take an action it deems unlikely, the consequence is almost always worse than it expected.

3) Step 3: This is a clear symptom of value function overfitting. This chain of evidence points to a single, compelling conclusion: the agent's value function is overfit to the high-density regions of the policy distribution it experienced during training. During PPO's on-policy training, the critic (the value function) is trained to minimize TD error on trajectories generated by the current actor policy. This training data is naturally dominated by high-confidence actions. Consequently, the critic becomes an expert at predicting the value of these frequently observed, "good" state-action pairs. Conversely, it sees very few examples of low-confidence actions and their outcomes, leaving the value function undertrained and inaccurate for this part of the state-action space.

When we evaluate with a high-entropy policy, we are effectively sampling from low-density regions of the policy distribution. We force the agent to explore these infrequently

sampled transitions, and the significant, negative TD errors are the direct result. The critic, having not been adequately trained on these inputs, provides overly optimistic value estimates and is then surprised by the poor outcomes. This is a classic symptom of statistical overfitting, where a model fails to generalize from its training distribution to a different test distribution. The success of deterministic evaluation is therefore not just a matter of exploitation; it is a strategy that implicitly hides this overfitting by constraining the agent to the well-modeled, high-density regions where its value function is accurate.

V. DISCUSSION

Our empirical analyses provide multifaceted insights into the consequences of employing stochastic evaluation policies for agents trained with PPO. The findings have significant practical implications for RL practitioners and open up new avenues for future research.

A. Synthesis of Findings: A Unified View

The narrative that emerges from our results is clear and consistent. The central finding of this study is that the value functions of PPO-trained agents are often overfitted to the high-confidence, on-policy actions experienced during training. This overfitting, compounded by the objective mismatch between a stochastic training goal and a deterministic evaluation goal, is revealed through the following mechanism:

1) Stochastic evaluation policies act as a diagnostic probe: By increasing policy entropy, we force the agent to sample low-confidence actions more frequently. This pushes the agent

to rely on its value function in low-density regions of the state-action space that were infrequently visited during training.

2) The probe reveals inaccurate and overly optimistic value estimates: The value function, having been poorly generalized in these regions, proves to be systematically over-optimistic. This inaccuracy is directly measured by the large, negative TD errors that result when these low-confidence actions are taken.

3) Inaccurate value estimates lead to performance degradation: This failure of the value function to accurately price the consequences of suboptimal actions is the direct cause of the observed performance degradation. The success of deterministic evaluation is therefore a strategy that succeeds primarily because it confines the agent to the well-modeled, high-density regions of its policy distribution where the value function is reliable. Conversely, the superior performance of low-to-moderate entropy policies in five of the eight environments (Alien, Breakout, Enduro, KFM, and Freeway) indicates that deterministic evaluation is not universally optimal. In these cases, the agent's performance is limited by factors other than value function overfitting. We hypothesize that modest stochasticity helps overcome challenges like perceptual aliasing (where different states appear identical) or helps the policy escape repetitive, suboptimal loops that a purely deterministic approach might get trapped in. This highlights a fundamental trade-off: while deterministic evaluation protects against the dangers of a poorly generalized value function, it may prevent the agent from achieving a higher score if the environment dynamics reward a degree of randomness.

B. Practical Implications for Reinforcement Learning Practitioners

Based on our findings, we propose the following guidelines for practitioners working with policy gradient algorithms:

1) Default to low-entropy evaluation (tune temperature): Deterministic (argmax) is a strong baseline, but not uniformly optimal across our Atari suite. Practitioners should treat evaluation entropy as a hyperparameter: begin with argmax or a low-temperature softmax, and select the setting that maximizes mean return and stability on held-out evaluation seeds.

2) Consider slightly stochastic evaluation in specific cases: In environments where there is a strong reason to suspect the presence of perceptual aliasing or where the policy might be trapped in a local optimum, evaluating with a small amount of stochasticity can be beneficial. As observed in Breakout, a low-temperature softmax policy (e.g., with temperature T=0.5) might allow the agent to escape repetitive patterns and achieve higher performance. In environments such as Breakout, we hypothesize that a purely deterministic policy may become trapped in a simple but less effective strategy. The evaluation temperature should be treated as a hyperparameter to be tuned based on the specific problem at hand.

3) Use TD error on low-confidence actions as a diagnostic tool: Our results highlight the diagnostic power of TD error. Monitoring the TD error on actions with low selection probability during the training process can serve as a powerful indicator of value function overfitting. A widening gap between the TD error on high-confidence versus low-confidence actions should be seen as a red flag, signaling a potential generalization problem.

C. Limitations and Future Work

While this study provides a comprehensive analysis, it has several limitations that point toward important directions for future research.

1) Algorithmic scope: Our investigation was confined to the PPO algorithm. It is an open question whether these findings generalize to other families of RL algorithms. Of particular interest are off-policy actor-critic methods, such as SAC, which explicitly optimize an entropy-regularized objective. Because an agent trained with SAC is optimized to act stochastically, it is plausible that such an agent would exhibit less performance degradation, or perhaps even an improvement, under stochastic evaluation. A comparative study is needed to resolve this.

2) Environment scope: The analysis was conducted on eight discrete-action Atari games. Future work should extend this investigation to other domains, such as continuous control tasks (e.g., MuJoCo benchmarks) and more complex, modern game environments, to assess the generality of our conclusions.

3) Exploring regularization: Our findings indicate that value function overfitting is a key limiting factor. This motivates future work to test empirically whether regularization techniques known to combat overfitting in supervised learning can enhance the value function's generalization in an RL context. Researchers and practitioners may apply methods such as weight decay, dropout, spectral normalization, or ensemble methods to the critic network during PPO training. An effective

regularization scheme should reduce the TD error on low-confidence actions and, as a result, diminish the performance gap between deterministic and stochastic evaluation.

VI. Conclusions

This paper has presented a rigorous empirical investigation into the common practice of training reinforcement learning agents with a stochastic policy but evaluating them deterministically. Our findings demonstrate that this practice is not merely a convention but is often a well-justified approach that mitigates a critical, underlying weakness in deep RL agents: the overfitting of the learned value function to its most frequently observed state-action pairs.

We have shown that higher evaluation-time entropy often degrades performance and stability—particularly in brittle environments—yet modest stochasticity can improve returns in several games (e.g., Alien, Breakout, Enduro, KFM, Freeway). Thus, evaluation entropy should be selected empirically, balancing exploitation against environment-specific benefits of limited randomness. The root cause of performance degradation, in cases where it occurs, is that stochastic policies force the agent to sample low-confidence actions, exposing it to low-density regions of the state-action space where its value function is demonstrably inaccurate and overly optimistic. This inaccuracy is a direct manifestation of overfitting to the on-policy training distribution, compounded by the inherent mismatch between the entropy-regularized stochastic objective used in training and the purely exploitative deterministic objective used in evaluation.

Ultimately, the choice of an evaluation policy transcends the simple dichotomy of exploration versus exploitation. It is a decision that interacts deeply with the generalization limits of the agent's learned models. Deterministic evaluation often succeeds because it acts as a safeguard, confining the agent to the high-density regions of its policy distribution where its internal value model is most reliable. However, our work also shows this is not a universal solution, as some environments reward modest stochasticity that can overcome other limitations of the learned policy. This work provides a clear empirical framework and a causal, TD-error-based mechanism for understanding this critical aspect of deep reinforcement learning applications, offering both practical guidance for practitioners and a diagnostic tool for future research aimed at building more robust and generalizable agents.

***Abstract*—Tuberculosis remains a highly relevant public health concern, especially in contexts with limited access to medical services, highlighting the need for tools that support early diagnosis. In this study, a web-based expert system was developed to assist in tuberculosis detection, using Buchanan's methodology, which consists of five phases: identification, conceptualization, formalization, implementation, and validation. The system was designed with a knowledge rule-based approach and incorporated the Certainty Factor to quantify confidence in diagnostic conclusions. Validation was carried out through expert judgment using a 15-question survey. The results showed a high overall positive consensus, with question 13 standing out as it obtained the highest mean score (4.80) and the lowest dispersion (SD = 0.61), reflecting the most favorable perception and greatest agreement among the experts. Conversely, question 4 recorded the lowest mean score (4.00) and the highest dispersion (SD = 1.12), indicating aspects of the system that generated more divided opinions. Overall, these findings confirm that the system is effective, reliable, and usable, making it a relevant tool to support clinical decision-making in resource-limited settings. As an additional contribution, the integration of complementary technologies is suggested, such as (ML) algorithms, radiological image analysis, and mobile applications for symptom tracking, in order to optimize early detection and strengthen clinical care for tuberculosis.**

I. Introduction

Tuberculosis (TB) is an infectious disease caused by Mycobacterium tuberculosis, which primarily affects the respiratory system, although it can also compromise other vital organs. Since ancient times, TB has represented a significant threat to global public health and, despite advances in research, diagnosis, and therapies, it continues to be one of the major challenges in the healthcare field. According to the World Health Organization (WHO), millions of new cases and hundreds of thousands of deaths are reported each year, keeping TB among the deadliest infectious diseases worldwide, especially in low-resource regions [1] [2]. Likewise, it is necessary to implement preventive measures that allow anticipating the onset of symptoms and, in this way, facilitate the administration of timely and appropriate treatment for each person.

The control of tuberculosis faces various structural and clinical obstacles. One of the most critical is the difficulty in achieving early and accurate diagnosis, since initial symptoms such as persistent cough, mild fever, or weight loss are often confused with other common respiratory diseases. This delay in detection not only prevents the timely administration of treatment but also facilitates community transmission of the disease. In addition, the lack of knowledge among the population about the modes of transmission, prevention, and treatment of TB intensifies its spread, particularly in environments where overcrowding, poverty, and limited healthcare coverage persist [3]. Added to this is the emergence of drug-resistant strains (MDR-TB and XDR-TB), which hinder therapeutic effectiveness, increase healthcare costs, and prolong treatment regimens. Finally, insufficient medical infrastructure and a lack of specialized personnel in many underdeveloped regions limit diagnostic, monitoring, and control processes, weakening eradication programs established by international organizations [4]. Altogether, these limitations make it evident that traditional approaches are insufficient to address the magnitude and complexity of the problem.

In light of this reality, there is a need to incorporate innovative technological tools to support healthcare systems in the identification, control, and treatment of tuberculosis. In this sense, expert systems and (AI)represent an alternative with great potential, as they allow clinical information to be processed under conditions of uncertainty, reduce the margin of error in medical decision-making, and generate faster and more reliable diagnoses [5]. Moreover, these tools have the capacity to optimize available resources, as they can be implemented in low-infrastructure environments and simultaneously serve a large number of users. Their usefulness lies not only in improving early diagnosis but also in supporting less-experienced physicians, standardizing clinical criteria, and providing support in high-demand healthcare contexts. The application of these technologies can significantly contribute to strengthening public health policies, improving the operational efficiency of health services, and ultimately reducing morbidity and mortality rates associated with tuberculosis [6] [7]. Thus, the development and implementation of expert systems is justified as a key strategy not only for individual clinical care but also for the global epidemiological control of this disease.

Therefore, this research focuses on developing an expert system (ES) for the early identification of tuberculosis, applying Buchanan's methodology for the construction of expert systems. The objective of the study is to diagnose tuberculosis based on symptoms reported by the patient and to provide a level of certainty through the use of the Certainty Factor (CF), with the purpose of supporting medical personnel in clinical decision-making and contributing to the prevention and control of tuberculosis.

II. Literature Review

This section presents the structure of the literature review, which is organized around two main axes. First, related works are addressed, where previous research by various authors who have applied expert systems in the medical field is analyzed. The purpose of this section is to contextualize the object of study, identifying advances and limitations in previous research in order to provide a broader and more well-founded perspective on the topic. Second, the theoretical foundations are developed, presenting the conceptual frameworks and theories related to the central variables of this research: Expert Systems and Tuberculosis.

A. Related Work

Various studies have contributed to advances in the detection of tuberculosis. In particular, the authors [8] [9] [10] highlight the importance of web-based expert systems to facilitate the diagnosis of respiratory diseases. Their proposal focuses on six pathologies: tuberculosis, bronchitis, pneumonia, pleurisy, tonsillitis, and asthma. To achieve more accurate results, the system uses 40 symptomatic indicators as a source of information. The reported results show that the application reaches a considerable level of effectiveness, offering reliable diagnoses for these diseases. In order to enrich previous studies, an ES was designed exclusively focused on tuberculosis diagnosis, especially aimed at people who do not have timely access to medical checkups. For this purpose, the Case-Based Reasoning (CBR) method was applied, which allows comparing the symptoms of a new patient with records of previous cases and thus estimating the most probable diagnosis. This approach, supported by expert knowledge, is presented as a practical and reliable alternative within the healthcare field. The results showed that pulmonary tuberculosis reached 85% similarity, while the extrapulmonary form obtained 62%, which allowed concluding that the analyzed case corresponded to pulmonary tuberculosis. In hospital settings, limitations persist in guaranteeing quality and truly personalized care for each patient. In response to this challenge, the developed ES is presented as a clinical support tool that follows a specialized assistance pattern in cases of pulmonary tuberculosis, even before confirmation through laboratory tests. Its architecture is based on a rule base and a patient knowledge base, which interact with an inference engine responsible for processing the data entered through the user interface. The usability evaluation yielded an average score of 5.6 out of 7, reflecting a performance above the expected standard. In this sense, the Tuberculosis Diagnosis ES, developed with Exsys Corvid, constitutes a robust and effective technological solution, rule-based, aimed at optimizing the diagnostic process and improving the quality of hospital services [11] [12]. Thus, a development based on expert systems and information technology aims to optimize TB diagnosis, overcoming existing limitations in timely access to healthcare services. For this purpose, an application supported by expert system architecture was implemented, applying the Forward Chaining method, which enables the processing of clinical data and symptoms to generate diagnostic inferences. The result of this work was an application capable of identifying TB accurately and providing users with structured information on symptoms, as well as recommendations and alternative solutions to the disease, consolidating itself as an efficient technological tool to support the diagnostic process and medical guidance [13] [14].

Tuberculosis is an infectious disease mainly of bacterial origin that critically affects the respiratory system and, in some cases, other organs, making it a highly relevant public health problem. In this context, various studies have proposed technological solutions aimed at improving its diagnosis and surveillance. For example, one study aimed to design an ES that replicated the clinical reasoning of a health professional to support the diagnosis of pulmonary tuberculosis based on the identification of symptoms in patients, considering economic limitations in access to healthcare services. This system, based on Bayes' Theorem formulated by Thomas Bayes and refined by Laplace, achieved a positive diagnostic rate of 87%, demonstrating its effectiveness in the early detection of the disease and its applicability in resource-limited settings [15] [16]. Complementarily, a web-based ES was developed that used the Dempster-Shafer inference method, integrating a PHP backend with MySQL and a frontend built with HTML, CSS, and JQuery. This project followed a structured methodology that included preliminary studies, literature review, symptom collection, knowledge rule design, modeling, implementation, and evaluation, achieving the generation of reliable probabilistic diagnoses for both healthcare professionals and general users. In a different line, another work proposed an online ES oriented to the epidemiological surveillance of tuberculosis, developed with web platforms and the Swi-Prolog programming language, following Buchanan's methodology composed of four phases. Validation, through a 15-item questionnaire distributed across three dimensions, reported an 85% acceptance rate among users, supporting its relevance and effectiveness as a support tool for tuberculosis prevention and awareness [17] [18]. In another instance, [19] [20] explored the application of ML techniques in the diagnosis of tuberculosis, evaluating the CAD4TB computer-assisted detection system, originally designed for adults, on pediatric radiographs of children under 13 years of age. The model, trained with pediatric radiological images and validated by specialists through a prospective observational methodology, showed a significant improvement in its performance after fine-tuning, increasing from an AUC of 0.58 to 0.72 ($p = 0.0016$), evidencing the potential of this tool to strengthen diagnosis in pediatric populations and highlighting the importance of continuing validation in larger and more diverse samples.

Likewise, the authors [21] [22] developed an expert API for the early detection of tuberculosis, implementing inference algorithms such as Forward Chaining and Certainty Factor in order to support preliminary diagnosis of the disease. The proposal materialized through an API-based architecture that processes symptoms and generates diagnostic inferences, while its validation was carried out through functionality tests and in-depth interviews with medical specialists. Satisfactory results were obtained, evidencing that the system is capable of providing reliable support in the early identification of tuberculosis, thus constituting a viable technological tool to strengthen prevention and diagnostic tasks in healthcare. In another study, a Bayesian inference-based ES was developed to facilitate and speed up tuberculosis diagnosis, reducing the time required by conventional procedures that include clinical interviews and sputum laboratory analysis. Microsoft

Visual Studio 2010 was used as the programming platform and Microsoft Access 2010 as the data management system for its construction. The methodology implemented included the creation of a medical knowledge base, the integration of a Bayes-based inference engine, and the validation of the system through tests with real clinical cases. The results showed that the tool is capable of analyzing patient symptoms and clinical data to calculate the probability of tuberculosis, constituting a reliable resource that optimizes diagnosis and supports medical decision-making, offering advantages over traditional methods in both efficiency and accuracy [23] [24] [25]. Thus, the development of a hybrid Clinical Decision Support System (CDSS) aimed at recommending individualized treatments for patients with drug-resistant tuberculosis facilitated the application of personalized therapies by less experienced physicians. A hybrid approach combining an expert knowledge base with ML was used to identify complex patterns in clinical data, evaluating its performance with metrics such as precision at 1, mean reciprocal rank, and mean average precision. Indeed, the methodology included the construction of the knowledge base, the iterative generation of training datasets, analysis through ML algorithms, and validation with independent data to detect overfitting. Finally, the results showed an accuracy of 95% in recommending the first treatment, although independent validation reduced accuracy to 78%, evidencing that this hybrid approach constitutes a promising step toward the automation of personalized treatment and can be applied to other pathologies [26] [27].

According to study [28], computers constitute a widely used tool in the medical field to support the diagnosis of respiratory diseases, including tuberculosis. In this context, the research focused on the development of an ES aimed at the early diagnosis of this pathology. This system estimates the probability level of a patient having the disease, expressed through a certainty value. This value is determined using the CF, a methodology that allows quantifying the degree of confidence in environments characterized by high uncertainty and that is also capable of representing absolute convictions within the diagnostic inference process. Taking the context into account, this research is complemented by the evaluation of an ES applied to ML techniques for the classification of TB bacteria through images. Additionally, algorithms such as Decision Trees, Random Forest (RF), and Adaptive Boosting (AdaBoost) were trained using a set of 126 images classified into two classes, as part of the methodology. As a result, it was observed that the Random Forest model was the most outstanding, reaching an accuracy of 85%, making it the most effective model for tuberculosis diagnosis through the ES [29] [30]. On the other hand, [31] [32] carried out a study focused on tuberculosis prevention through the implementation of a Bayes-based ES, with the aim of providing a more accurate diagnosis. The methodology included the identification of medical problems related to the treatment of the disease. It was observed that, in one patient, a high probability of tuberculosis could be determined, with a confidence value of 64%, evidencing that this approach enables medical personnel to diagnose and recognize symptoms quickly and efficiently. According to the authors [33] [34], the rapid spread of tuberculosis is favored by the lack of public knowledge about the disease. In this context, the implementation of an ES allows the application of early medical diagnostic techniques, with the aim of facilitating the prompt administration of treatment. Regarding the results obtained through system testing, together with validation using the black-box technique, it was demonstrated that each functionality operates correctly and that the information provided is reliable. Additionally, the system showed efficient performance in managing a high number of concurrent users, making it suitable for clinical environments with high demand for consultations.

In this sense, one of the deficiencies identified in previous studies is the lack of integration of web-based expert systems that combine rule-based inference, the certainty factor, and validation through expert judgment, which limits the applicability of findings in resource-limited contexts. Moreover, most studies focus on isolated methods, such as Bayesian inference or ML models, without combining multiple approaches, which reduces the generalization and robustness of the diagnostic support provided.

B. Theoretical Bases

1) Tuberculosis: TB is a chronic infectious disease primarily caused by Mycobacterium tuberculosis, an acid–alcohol-resistant bacillus with a high capacity for airborne transmission. Its most common form affects the respiratory system, although in extrapulmonary presentations it can involve various organs and tissues. Likewise, infection occurs after the inhalation of contaminated droplets that reach the pulmonary alveoli, where the microorganism establishes a complex interaction with the host's immune response. From a clinical and epidemiological perspective, TB represents a major global public health challenge due to its high impact in terms of prevalence and mortality, in addition to its close association with social determinants such as poverty, malnutrition, and overcrowding. Despite the availability of effective therapies, poor treatment adherence promotes the emergence of multidrug-resistant strains, which significantly complicates its control and eradication [35]. In summary, this disease causes severe pulmonary and respiratory complications that, over time, can significantly compromise both quality of life and life expectancy.

a) Pulmonary tuberculosis: It is the most common form of tuberculosis, characterized by infection of the lungs with Mycobacterium tuberculosis. It is transmitted primarily through respiratory droplets expelled when coughing, sneezing, or talking, making it the main source of infection in the community [36]. Clinical manifestations include chronic cough, hemoptysis, chest pain, fever, night sweats, weight loss, and fatigue.

b) Extrapulmonary tuberculosis: It refers to all forms of tuberculosis that affect organs and systems outside the respiratory system. It accounts for approximately 20% of cases and can involve lymph nodes, pleura, bones, meninges, kidneys, digestive system, skin, among others. Its symptoms depend on the affected site, and although it is not usually transmissible, it poses a clinical and diagnostic challenge due to the variety of presentations and associated complications [37].

Fig. 1 shows a horizontal bar graph representing the percentage of TB cases by age group during the years 2019, 2021, and 2022, highlighting that the 30 to 49 age groups

concentrate the highest proportion of cases, while the age extremes have a lower incidence. On the other hand, Fig. 2 presents a map of Peru with the TB incidence rate per 100,000 inhabitants in 2022, where the red regions show the highest risk (≥ 76), the yellow ones intermediate risk (50 to 74), and the green ones lower risk (< 50). This figure is complemented by a table detailing the cases by department and year, showing that departments such as Callao, Lima, and Ucayali have had the highest rates in recent years. Together, these images allow us to visualize both the age distribution and the geographic distribution of TB in the country over time.

2) Expert systems: An ES is a type of computational system within the field of AI designed to emulate the reasoning process and decision-making ability of a human specialist in a specific domain. Its operation is based on a knowledge base, which contains facts and rules about the application area, and an inference engine, responsible for applying these logical rules to solve problems, provide diagnoses, or recommend solutions. On the other hand, these systems do not seek to replace the human expert but rather to assist in solving complex problems, especially in contexts where specialized expertise is limited or unavailable. Moreover, their main value lies in offering consistency in reasoning, speed in generating solutions, and the possibility of transferring expert knowledge to technological platforms [39] [40] [41]. Ultimately, expert systems aim to emulate the knowledge of a human specialist in a given field in order to solve complex problems, provide recommendations, and support decision-making in an efficient and reliable manner, even in the absence of a human expert. Consequently, Fig. 3 shows the architecture of Buchanan's methodology for an expert system, illustrating the flow of knowledge from a human expert to an end user.

III. Methodology

A. Definition of the Buchanan Methodology

Buchanan's methodology constitutes a systematic approach applied to the analysis and design of systems, aimed at solving complex problems through an orderly, structured, and progressive process. Its foundation lies in breaking down the problem into sequential phases that enable progress from an abstract understanding of the need to the achievement of an implemented and operational solution. These phases include: identification, where the problem and its boundaries are recognized; conceptualization, in which objectives are defined and a preliminary conceptual model is established; formalization, which specifies the technical and functional requirements of the solution; implementation, where the design is materialized into a functional system; and execution or operation, the stage in which the solution is integrated into the real environment with monitoring and feedback mechanisms. This framework is illustrated in Fig. 4, which presents the phases of Buchanan's methodology, visually showing each stage of the process [42]. Consequently, this methodology reduces ambiguity, optimizes decision-making, and ensures consistency across stages, making it a robust tool to guarantee the quality, relevance, and effectiveness of developed systems.

1) Identification: In accordance with the established framework, this stage marks the beginning of Buchanan's methodological process, starting with the identification phase. Table I presents the Identification phase corresponding to Buchanan's methodology, in which the main issue is recognized: the difficulty of diagnosing tuberculosis early and accurately due to the similarity of its symptoms with other respiratory diseases. Based on this, the need is established to develop an expert system that supports medical personnel in clinical decision-making. Likewise, the objective of this phase is defined as the clear delimitation of the problem and the initial scope of the system, which are oriented toward the collection and analysis of symptoms through the CF model to provide a level of confidence in the diagnosis. Consequently, the expected benefit is highlighted: to contribute to the prevention and control of tuberculosis through a reliable computational tool that supports clinical diagnosis. In this sense, Table II represents the main sources of knowledge integrated into the expert system. These include specialists such as pulmonologists and infectious disease experts, who contribute to the identification of symptoms and risk factors, as well as official WHO guidelines that serve as references in the formulation of rules [43]. It is important to emphasize that the beginning of this phase constitutes the starting point for the development of subsequent processes.

2) Conceptualization: In this phase, the functional objectives and the conceptual model of the expert system are defined. The purpose is to establish an overall vision of how the proposed solution will operate, identifying its main components and the relationships among them, without yet delving into the technical details of implementation. Consequently, Fig. 5 describes the system objectives, outlining what it does allowing the user to enter symptoms, calculate a certainty factor, and generate recommendations—and what it does not do such as replacing a physician or laboratory tests. In addition, the diagram illustrates the conceptual model, which includes the key symptoms, how knowledge is represented (through rules and a certainty factor), and the definition of conceptual rules with examples [44]. Finally, it shows the expected outcome: an expert system report that, based on the certainty level, identifies the type of tuberculosis (active, extrapulmonary, or latent) and suggests actions such as visiting a healthcare center for confirmatory tests.

Knowledge Representation

The expert system's knowledge is represented by production rules. The structure of these rules is shown below:

$$\textbf{IF } (\textit{Condition}) \implies \textbf{THEN } (\textit{Conclusion}) \ [\textit{Certainty Factor}]$$

This formalism allows the system to combine multiple pieces of evidence and generate diagnostic conclusions with associated degrees of certainty. The CF ranges from 0 (no confidence) to 1 (absolute confidence), providing a way to handle uncertainty in medical decision-making.

3) Formalization: The formalization stage consists of transforming the knowledge obtained from experts and structured documentary sources into a format that can be processed by the system. Accordingly, Table IIIc presents the formalization of the expert system rules for tuberculosis diagnosis, organized into three subtables. Subtable III presents the rules based on clinical symptoms, which consider

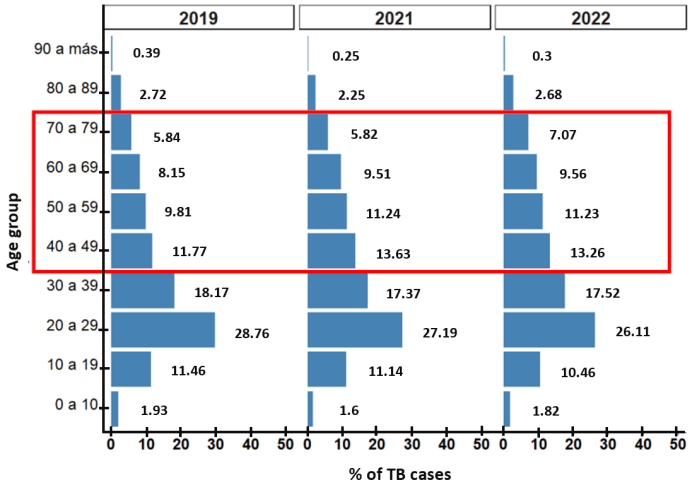

Fig. 1. Statistical graph of TB cases by age [38].

combinations of manifestations such as persistent cough, fever, night sweats, or weight loss, each associated with a specific CF. Subtable IIIb includes the rules related to risk factors, such as recent exposure to the disease, HIV coinfection, or residence in endemic areas, which increase the diagnostic probability. In this regard, subtable IIIc contains the rules derived from diagnostic tests, such as chest X-rays, sputum smear microscopy, molecular tests, or cultures, which present the highest certainty values, highlighting their relevance in confirming the disease. On the other hand, Fig. 6 represents the database model, which is responsible for the flow and integrity of the data within the expert system [45]. In this sense, the TBExpertSystem database was implemented to comprehensively manage the information that feeds the expert system for tuberculosis diagnosis, in accordance with the business rules defined in the previous stages.

IV. Mathematical Formulas in Expert Systems

The following formulas are frequently used in expert systems for formalizing rules, handling uncertainty, and applying fuzzy logic. Therefore, mathematical expressions have been compiled that demonstrate the logic underlying the operation of these systems [46] [47].

1) Certainty Factor (CF): The CF is a mechanism that allows us to quantify the degree of confidence in a hypothesis when considering new evidence. This process adjusts the prior certainty of H based on the strength of the evidence E [see Eq. (1)].

$$CF_{H,E} = CF_H + CF_E \cdot (1 - CF_H) \tag{1}$$

Used to combine the certainty level of a hypothesis H with the evidence E.

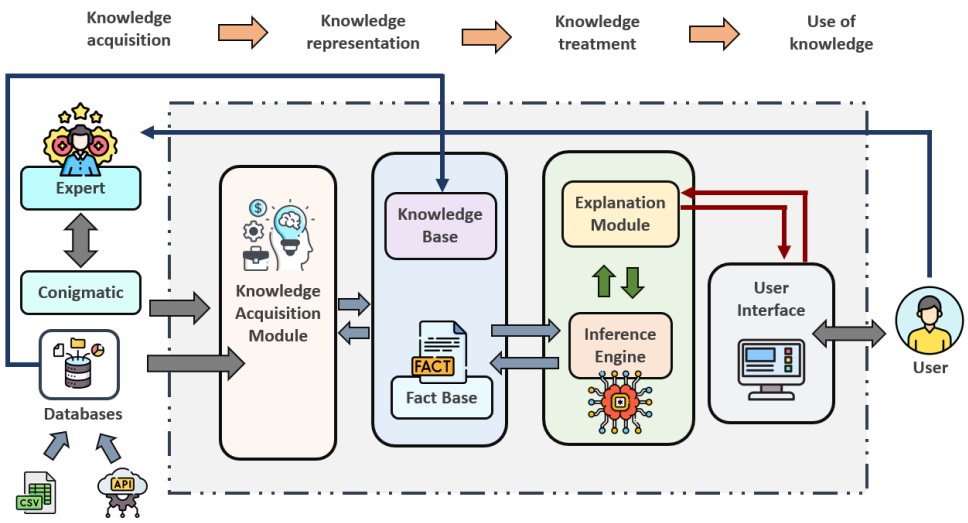

Fig. 3. Buchanan methodology architecture.

TABLE I. IDENTIFICATION PHASE: BUCHANAN METHODOLOGY

Element	Description
Identified problem	Difficulty in the early and accurate detection of tuberculosis because its symptoms can be confused with other respiratory diseases.
Need	Develop an expert system that supports medical personnel in clinical diagnosis, reducing ambiguity and improving decision-making.
Phase objective	Recognize and define the problem to be solved, establishing the initial scope of the system to be implemented.
Initial Scope	The system will be designed to collect patient-reported symptoms, process them using the CF model, and provide a level of certainty regarding the possible presence of tuberculosis.
Expected Benefit	Contribute to the prevention and control of tuberculosis by providing reliable computational support in the diagnostic process.

TABLE II. KNOWLEDGE SOURCES FOR THE EXPERT SYSTEM

Source	Description
Expert interviews	Consultations with pulmonologists and infectious disease specialists to determine the most relevant TB symptoms and risk factors.
WHO guidelines	Use of the Global Tuberculosis Report and official protocols as reference for rule formulation.
Clinical literature	Medical textbooks and peer-reviewed journals on internal medicine and infectious diseases.
Patient case data	Historical clinical cases used to validate CF and refine the knowledge base.

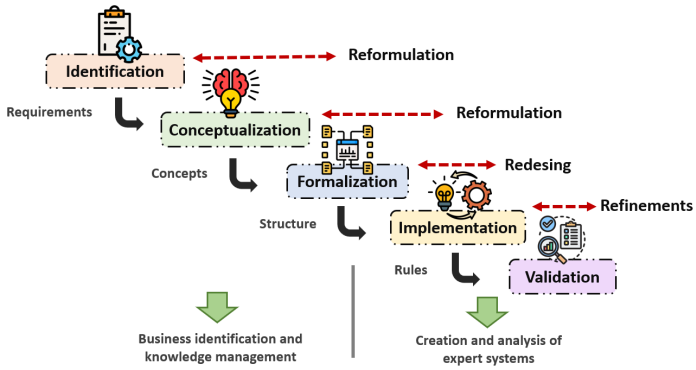

Fig. 4. Buchanan methodology.

2) Bayesian probability: Bayesian probability updates the degree of belief in a hypothesis H when new evidence E is observed. This process combines the prior probability with the likelihood of the evidence to obtain a more accurate estimation [see Eq. (2)].

$$P(H \mid E) = \frac{P(E \mid H) \cdot P(H)}{P(E)} \tag{2}$$

Fundamental formula for probabilistic expert systems. It calculates the probability of hypothesis H given that evidence E occurred.

3) Bayesian probability with multiple evidences: This extended Bayesian approach calculates the probability of a hypothesis H when multiple evidences are considered simultaneously. It combines prior knowledge with the likelihood of each evidence to refine the overall estimation [see Eq. (3)].

$$P(H \mid E_1, E_2, \ldots, E_n) = \frac{P(H) \cdot \prod_{i=1}^{n} P(E_i \mid H)}{P(E_1, E_2, \ldots, E_n)} \tag{3}$$

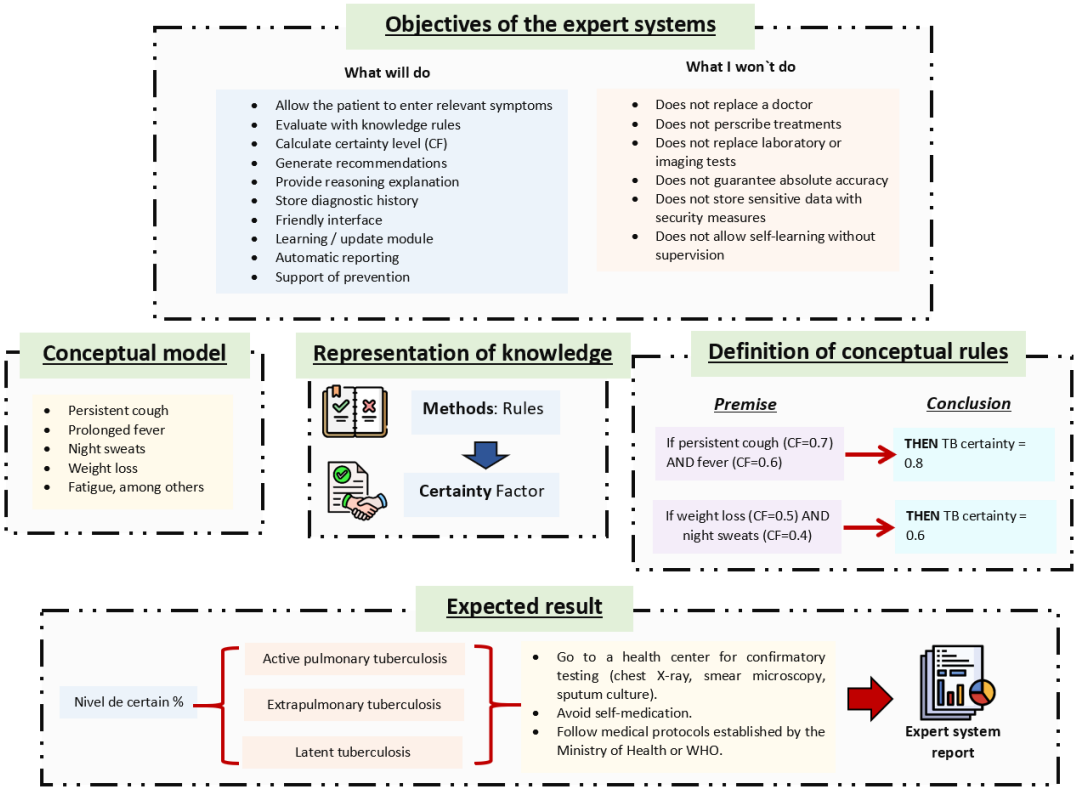

Fig. 5. Expert system process functionality.

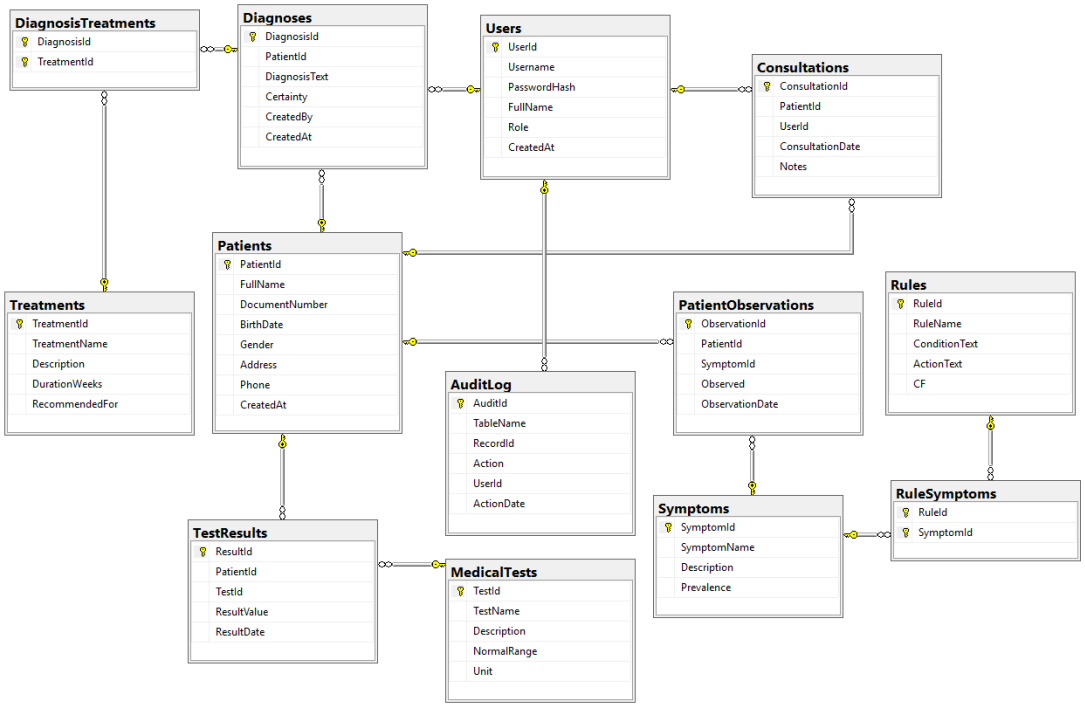

Fig. 6. Data flow for the expert system.

TABLE III. FORMALIZATION OF RULES FOR TUBERCULOSIS DIAGNOSIS

(A) RULES BASED ON CLINICAL SYMPTOMS

Rule	Condition	Certainty (CF)
R1	Persistent cough $\wedge$ Fever $\rightarrow$ TB	0.4
R2	Night sweats $\wedge$ Weight loss $\rightarrow$ TB	0.3
R3	Persistent cough $\wedge$ Hemoptysis $\rightarrow$ TB	0.5
R4	Chest pain $\wedge$ Breathing difficulty $\rightarrow$ TB	0.25
R5	Fatigue $\wedge$ Weakness $\rightarrow$ TB	0.2
R6	Fever $\wedge$ Night sweats $\rightarrow$ TB	0.35
R7	Persistent cough $\wedge$ Loss of appetite $\rightarrow$ TB	0.3
R8	Persistent cough $\wedge$ Weight loss $\rightarrow$ TB	0.45
R9	Chronic cough lasting $>$ 3 weeks $\rightarrow$ TB	0.55

(B) RULES BASED ON RISK FACTORS

Rule	Condition	Certainty (CF)
R10	Recent TB exposure $\wedge$ Persistent cough $\rightarrow$ TB	0.6
R11	HIV-positive patient $\wedge$ Fever $\wedge$ Night sweats $\rightarrow$ TB	0.65
R12	Living in high-risk area $\wedge$ Chronic cough $\rightarrow$ TB	0.5
R13	History of untreated TB contact $\rightarrow$ TB	0.55

(C) RULES BASED ON DIAGNOSTIC TESTS

Rule	Condition	Certainty (CF)
R14	Positive Mantoux test $\rightarrow$ TB	0.7
R15	Abnormal chest X-ray $\rightarrow$ TB	0.8
R16	Positive sputum smear microscopy $\rightarrow$ TB	0.85
R17	Positive GeneXpert test $\rightarrow$ TB	0.9
R18	Positive sputum culture test $\rightarrow$ TB	0.95

Extended version for multiple simultaneous pieces of evidence. It evaluates the probability of hypothesis H given evidences $E_1, E_2, \ldots, E_n$.

4) Fuzzy membership function (triangular): The triangular membership function represents how a value x belongs to a fuzzy set A with a gradual transition. It is widely used in fuzzy logic due to its simplicity and ability to approximate uncertainty smoothly [see Eq. (4)].

$$\mu_A(x) = \begin{cases} 0 & x \leq a, \\ \dfrac{x-a}{b-a} & a < x \leq b, \\ \dfrac{c-x}{c-b} & b < x < c, \\ 0 & x \geq c \end{cases} \tag{4}$$

Defines the membership of a value x to a fuzzy set A. The shape is triangular, which is commonly used in fuzzy logic.

5) Fuzzy inference (Mamdani rule): The Mamdani inference rule models the reasoning process in fuzzy systems by combining fuzzy sets through min–max operations. It determines the degree to which an output z belongs to set C given the inputs x and y [see Eq. (5)].

$$\mu_C(z) = \sup_{x,y} \left(\min\left(\mu_A(x), \mu_B(y)\right)\right) \tag{5}$$

Represents a fuzzy inference for a rule. If $x \in A$ and $y \in B$, then $z \in C$.

6) Defuzzification by centroid: The centroid defuzzification method transforms a fuzzy output set into a crisp numerical value. It is the most common technique in fuzzy control systems, as it provides a balanced representation of all possible outcomes [see Eq. (6)].

$$z^* = \frac{\int_Z z \cdot \mu_C(z)\, dz}{\int_Z \mu_C(z)\, dz} \tag{6}$$

Converts a fuzzy value into a numerical output. This method is widely used in fuzzy control systems.

7) Information entropy: Information entropy quantifies the level of uncertainty or randomness in a variable X. It measures how much information is gained or how unpredictable the outcomes are within a system [see Eq. (7)].

$$H(X) = -\sum_{i=1}^{n} p(x_i) \log_2 p(x_i) \tag{7}$$

Measures the uncertainty associated with a random variable X. Entropy quantifies the amount of information or unpredictability.

a) Implementation: Finally, the implementation phase corresponds to the translation of the previous stages into a web-based expert system, in which the knowledge base, inference engine, and user interface are integrated into a functional platform. In this stage, the defined rules are materialized, the reasoning mechanisms are programmed, and the functionalities that enable interaction with the end user

are designed [48]. Thus, Fig. 7 presents the user interface corresponding to the login module, which allows users to enter their credentials (username, password, and assigned role). In addition, it incorporates a search module that verifies whether the user belongs to the healthcare system, ensuring real-time data validation. Finally, a registration form is provided to enable the creation of new accounts, ensuring proper access management and traceability of user profiles within the web expert system.

In another instance, Fig. 8 presents three user interface panels of an information or expert system on tuberculosis (TB). The panel in Fig. 8a, labeled "Administrative panel," is designed for user management, displaying a list of records, search options, and buttons to register, update, or delete user codes. The panel in Fig. 8b is a "Rules Record," where detection rules for different types of TB are defined and managed, including details such as rule name, condition, action, and centrality. Finally, the panel in Fig. 8c is the "User panel," which shows the medical history of a patient (Juan Alvarez Perez) and a "Quick Symptom Form" that allows the user or physician to register symptoms and predict the type of TB, highlighting the latest medical result and the status of the disease.

V. Results

This section details the findings of the statistical analysis of the user perception scores assigned to the 15 interface prototypes, a fundamental process for validating the design and functionality of the web-based expert system by healthcare professionals. The evaluation was based on a 15-question questionnaire structured around five key dimensions (Usability, Technical Functioning, Knowledge Base, Inference Engine, and Expected Impact), as detailed in Table IV. Fig. 9 displays the distribution of responses (on a scale of 1 to 5) and showed a high overall positive consensus, with the majority of scores concentrated at levels 4 and 5. Additionally, the descriptive metrics presented in Table V confirm the consistency of the sample (N=20 per prototype). Prototype 13 (P-13) stood out with the highest mean (4.80) and the lowest dispersion (SD = 0.61), indicating the most favorable perception and the greatest agreement among experts. In contrast, Prototype 4 (P-4) recorded the lowest mean (4.00) and the greatest dispersion (SD = 1.12), indicating the area with the most divided opinions.

VI. Discussion

This section discusses the findings obtained from the evaluation of the web expert system prototypes for tuberculosis diagnosis, relating them to previous studies and evidence reported in the literature. It analyzes healthcare professionals' perceptions regarding the system's usability, technical performance, knowledge base, and inference engine, as well as its relevance as a clinical support tool. Furthermore, it examines how inference methods and knowledge structuring contribute to optimizing the early detection of tuberculosis. This discussion contextualizes the results, highlights the original contributions of the study, and establishes its relevance in the field of public health. The findings from the analysis of the 15 web expert system prototypes for tuberculosis diagnosis generally show a high level of positive consensus among healthcare professionals, with Prototype 13 standing out (mean = 4.80; SD = 0.61), indicating both favorable perceptions and a high level of agreement among experts. These results are consistent with previous studies that have demonstrated the effectiveness of rule-based expert systems and specialist knowledge in supporting clinical decision-making in respiratory diseases [11] [9] [10]. Likewise, the evaluation through a structured questionnaire covering five dimensions (Usability, Technical Performance, Knowledge Base, Inference Engine, and Expected Impact) made it possible to systematically identify strengths and areas for improvement, following strategies similar to those reported in the validation of web expert systems in other clinical contexts [17] [18]. It is worth noting that the integration of inference methods such as Forward Chaining and Certainty Factor, together with a knowledge base of previous cases, reflects successful approaches documented in the literature, which significantly contribute to improving the reliability of preliminary diagnoses [21] [22] [15] [16]. On the other hand, the greater dispersion observed in Prototype 4 (SD = 1.12) highlights the need to make adjustments in certain functionalities or in the interface, which aligns with the importance of proper symptom structuring and user interaction, as emphasized by [31] [32]. Nevertheless, the usability assessment and the concentration of high scores support the view that the application constitutes a practical and reliable tool, capable of optimizing early tuberculosis detection, improving patient guidance, and strengthening clinical support even before laboratory confirmation, consistent with the findings of previous expert systems [23] [24] [25] [26] [27]. Taken together, these results confirm that the system developed not only follows best practices identified in prior studies but also contributes a specialized, expert-validated approach for the early identification of tuberculosis, consolidating itself as a robust technological tool to support medical decision-making and improve timely care in settings with limited access to healthcare services.

VII. Conclusion

Tuberculosis continues to be a disease of great relevance to public health due to its high morbidity and the significant impact it generates on the population, especially in contexts with limited access to medical services. In this regard, the situation highlights the need to implement effective strategies for early detection and clinical management. Likewise, it is essential to have technological tools that facilitate medical decision-making, optimize diagnoses, and help reduce the spread of the disease in vulnerable communities. Therefore, the implementation of a web-based expert system is presented as a particularly pertinent and effective alternative. For this research, the Buchanan methodology proved to be an optimal choice, since its approach allows the entire expert system development process to be addressed in a structured manner, from the conceptualization of the problem posed to obtaining results based on the system's evaluation.

The Buchanan methodology consists of five clearly defined stages. In the first stage, identification, the problem analysis is carried out, based on the project's needs. Subsequently, the conceptualization phase focuses on outlining the internal functioning of the system, that is, how knowledge is managed and the rules it follows to generate predictions. During the

Fig. 8. Prototypes of an expert web system for TB detection.

TABLE IV. EXPERT JUDGMENT QUESTIONNAIRE FOR PHYSICIANS

Dimension	Question
Usability	1. Do you consider the system interface clear and easy to use for a healthcare professional?
	2. Does the layout of menus, forms, and results facilitate quick access to clinical information?
	3. Does the system offer an intuitive design that minimizes the need for prior training?
Technical Functioning	4. Does the system respond quickly and remain stable during use in clinical practice?
	5. Do you consider the credential validation (user, role, access) secure and reliable?
	6. Does the system present technical errors or inconsistencies that may affect the user experience?
Knowledge Base	7. Is the information on symptoms, risk factors, and diagnostic criteria for tuberculosis accurate and scientifically valid?
	8. Do you consider that the rules implemented in the system adequately reflect current clinical practice?
	9. Should the knowledge base be updated more frequently to remain aligned with new clinical guidelines?
Inference Engine	10. Does the system provide diagnostic recommendations consistent with the usual clinical logic for tuberculosis detection?
	11. Do you consider the accuracy of the inferences adequate to support medical decision-making?
	12. Does the system avoid contradictions or ambiguities in the suggested results?
Expected Impact	13. Does the expert system have the potential to reduce diagnostic errors in the identification of tuberculosis cases?
	14. Do you consider it a useful tool in primary care settings or in resource-limited contexts?
	15. Do you think the expert system will contribute to improving efficiency and quality in the early diagnosis of tuberculosis?

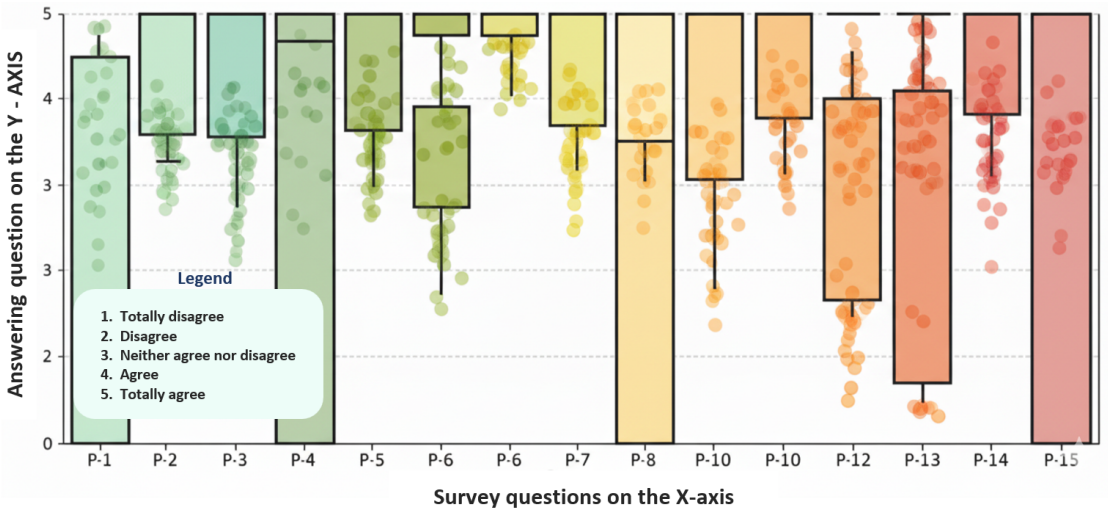

Fig. 9. Patient login and registration prototype.

TABLE V. DESCRIPTIVE METRICS OF PERCEPTION SCORES BY PROTOTYPE

Prototype	N	Mean	Standard Deviation (SD)	Median	Minimum	Maximum
P-1	20	4.35	0.93	4.5	2	5
P-2	20	4.15	0.93	4.0	1	5
P-3	20	4.35	0.99	5.0	1	5
P-4	20	4.00	1.12	4.5	2	5
P-5	20	4.60	0.68	5.0	3	5
P-6	20	4.45	0.94	5.0	2	5
P-7	20	4.65	0.75	5.0	2	5
P-8	20	4.60	0.68	5.0	3	5
P-9	20	4.60	0.68	5.0	3	5
P-10	20	4.40	0.82	4.5	3	5
P-11	20	4.65	0.67	5.0	2	5
P-12	20	4.60	0.68	5.0	3	5
P-13	20	4.80	0.61	5.0	2	5
P-14	20	4.70	0.73	5.0	3	5
P-15	20	4.55	0.69	5.0	3	5

formalization phase, the rules to be used as filters in the patient's test are precisely established, incorporating the use of the Certainty Factor to quantify the degree of confidence in the expert system's conclusions, as well as the data flow in the knowledge base. The implementation phase focuses on the development of the graphical user interface, reflecting and consolidating all the previous processes into a functional web-based expert system. Finally, the validation phase was carried out through expert judgment, using a 15-question questionnaire designed to assess the effectiveness, reliability, and usability of the system. The results showed a high overall positive consensus, with question 13 standing out for obtaining the highest mean (4.80) and the lowest dispersion (SD = 0.61), reflecting the most favorable perception and the greatest agreement among specialists. In contrast, question 4 recorded the lowest mean (4.00) and the highest dispersion (SD = 1.12), indicating aspects of the system that generated more divided opinions. Taken together, these results confirm that the web-based expert system constitutes a reliable and relevant tool to support the diagnosis of tuberculosis, backed by the direct evaluation of healthcare professionals.

Finally, understanding the complexity of early tuberculosis diagnosis is essential to strengthening healthcare delivery and improving clinical decision-making. Based on the findings obtained through the evaluation of the web-based expert system and expert judgment, it is suggested to develop complementary technological tools, such as the integration of ML algorithms, radiological image analysis, mobile applications for symptom tracking, and early warning platforms that can anticipate tuberculosis cases and facilitate timely interventions. Likewise, future studies could incorporate additional variables, explore other inference methods, and expand the knowledge base in order to optimize diagnostic accuracy and contribute to the design of more robust, accessible, and efficient clinical support systems in resource-limited settings.

ACKNOWLEDGMENT

Thanks to the University of Sciences and Humanities, which made this project a reality.

***Abstract*—This paper introduces a machine learning system that is feature-optimized to enhance the detection of concealed ammunition in X-Ray security imaging. The system integrates advanced image analysis techniques with a cascade-AdaBoost classifier and Multi-scale Block Local Binary Pattern (MB-LBP) features, which are particularly effective for object recognition and classification in complex, high-dimensional data. The combination of these algorithms ensures robust performance in identifying ammunition types even under challenging conditions, such as variations in image quality or object orientation. The system is specifically designed for the accurate identification of various types of ammunition, including 9 mm bullets for handguns, AK-47 machine gun bullets, and 12-gauge shotgun cartridges. To support the development and testing of this system, a new dataset comprising 1,732 X-Ray images of passenger luggage was collected. This dataset is made publicly available to facilitate further research and improvement in this critical area of security technology. Experimental results demonstrate that the system achieves a high level of detection accuracy, with the ability to identify 12-gauge shotgun shells concealed in baggage with a 92% success rate. Beyond its technical achievements, this system significantly enhances the efficiency and reliability of security checks, improving the overall effectiveness of ammunition detection in real-world scenarios.**

***Keywords*—Feature optimization; ammunition detection; X-Ray images; machine learning; security imaging**

I. Introduction

In the 21st century, there are rapidly increasing needs in many urban-related areas due to the current growth of urban populations, including environmental governance, public safety, city planning, industry facilitation, resource utilization, energy conservation, traffic control, telemedicine, homecare, and interpersonal relationships, social interactions, entertainment, and communication. Failure to satisfy any of the criteria could threaten a city's ability to grow sustainably. Smart cities play a critical role in the advancement of humanity, which often depends on widely dispersed smart devices to monitor the urban environment in real-time, react quickly, establish automated control, gather data for intelligent decision-making, enable various services, and enhance the quality of urban living [1].

These days, fast, smooth, and efficient transport of people and their luggage has become very important in this fast-paced modern lifestyle. Much attention has also been paid recently to the security and safety of passengers by the aviation industry. Occasionally, national safety, economic structure, and infrastructure rely on a secure and safe airport system. Therefore, much time and effort are continuously being exerted in order to develop a safer policy and improve airport security. However, despite all these precautions, there are many terrible accidents that occur regularly indicating limitations and drawbacks in the currently used security systems [2].

In airports, security checkpoints use metal detectors or X-ray detection systems for discovering metallic objects along with high-tech plastics or ceramics, composite weapons, illegal drugs, explosives, ammunition, or other items that can be smuggled [3]. There are many places such as airports, public places, and sensitive buildings that use manual screening for detecting unauthorized and concealed items and weapons [4]. These systems can be very effective, quick, and dynamic, regardless of the enormous number of individuals accessing these areas. Dillingham [5] determined several constraints and challenges in the capability of the screening procedures to discover suspicious items on the body or the luggage of the passengers. Consequently, it can be concluded that the conventional manual screening processes that are still used at many airports are incapable of detecting all the concealed and threatening weapons because of the restrictions in the technology and in the performance of the personnel [6].

The baggage screening and inspection process takes a lot of effort and time. On the other hand, many passengers also complain that the screening procedures invade their privacy by scanning and checking their personal stuff and belongings [7]. Conventional security systems count totally on the performance, perceptions, judgment, and ability of the security personnel in making decisions [8]. However, it is argued that human recognition systems are more accurate and efficient than automated systems. Nevertheless, there are many additional factors, such as placing objects at unexpected angles, that prevent object discovery by using their images [9]. In the same context, the Congressional Research Service (CRS) report to congress has stated that several factors could contribute to limiting human performance such as tiredness,

a lack of job satisfaction or motivation, inadequate training, and unsuitable workplace conditions, which affect their performance and even their standards of success [6]. Other studies [10][11] have stated that after working for long time periods, the human eyes get exhausted and tired. In addition, when humans have been working on the same mission for long time periods, they can get bored due to monotonous tasks and lose their interest and energy. This could lead to an erroneous reading and inexpedient analysis of the information; this would result in negligence in discovering the presence of concealed weapons or such items [2]. Moreover, a cluttered X-ray image of the passenger's belongings contains many shapes and colors [12], which could overload the security personnel and make the detection of weapons or explosive devices more difficult amongst the other personal items carried by the passenger.

Metal detection machines used for detecting metallic objects at airport security checkpoints raise an alarm for every metallic object passing through them. Even though a majority of the items are harmless, they still raise false alarms. Since many false alarms are raised every minute by these metal-detecting machines, even the security personnel find it annoying and ignore them. This practice could be responsible for many of the undetected suspicious metallic objects passing through the detectors [9]. In order to provide better security at the airports, more reliable, enhanced, and fast-screening systems are necessary for inspecting baggage at airports. This system has two objectives. First, the system must be able to analyze and study every X-ray image. Then it must contain a suspicious object detection application. A novel and automated system that carries out fast and reliable baggage monitoring must be developed. It will need less processing time and provide more accurate results. Though there are many X-ray techniques for detecting suspicious objects, there are no specific ones that focus on ammunition detection. However, there are many techniques that detect the presence of concealed weapons like knives, handguns, etc., depending on the size, shape, and the material's response to the X-ray radiation. Some of the common X-ray image-processing techniques, which are used for Concealed Weapon Detection (CWD), include image enhancement and de-noising, object segmentation, shape description, and detection and recognition of weapons [11][13][14].

In this research, for the first time, a novel dataset with 1732 X-Ray images of passenger luggage has been developed specifically for this use. The public is given access to this special dataset so that other researchers can use it. Authors propose a novel automatic system that detects different kinds of ammunition concealed in passenger baggage and carry-on items. This system can be used to enhance and support the conventional inspection techniques. Literature analysis suggested that many authors have carried out CWD techniques using image sensors, IR waves, and X-rays; however, those techniques could only detect metallic objects and were unable to detect non-metallic weapons, i.e., made of ceramics or plastics such as 12-gauge shells [7].

The content of the paper can be summarized as follows: Section II presents a literature review of detecting concealed weapons and concealed ammunition using different machine vision and image processing techniques. Section III describes the implementation of a smart system that would increase safety and security levels at airports by supporting security expert's ability of 9 mm hand-gun bullets, AK-47 machine gun bullets, and 12-gauge shotgun shells. Section IV outlines the performance of the detection evaluation with some confirmatory ranking results and analysis. Finally, Section V presents the conclusions of this paper.

II. Literature Review

In order to effectively manage data analysis, data communications, and the successful implementation of complicated policies to maintain the smooth and secure management of a smart city, the efficient use of artificial intelligence (AI) and machine learning (ML) techniques is vitally important [15]. Big data analysis and the successful application of AI and ML have increased the efficiency and scalability of smart cities [16]. In order to improve the efficiency of passenger investigation and ensure safe journeys, ML-based techniques have a significant impact on the present intelligent transportation system (ITS) [16][17].

Several researchers have utilized AI-based approaches to ensure the safety of the smart city environment [18]. Based on neural networks, the authors of [19] presented an effective crime detection system for a smart city to quickly locate and assess any criminal behavior. In the same context, the authors of [20] also suggested an ML-based architecture that might be used to anticipate incidents and provide responses before they occur. To realize future trends and the use of IoT in the intelligent transportation system, the applications employed in the IoT-based transport model are thoroughly examined in [21].

Many studies have been proposed in the literature for the purpose of detecting concealed weapons using different machine vision and image processing techniques. However, few studies have addressed the detection of concealed ammos. In the study by Kase [9], the author investigated and implemented various color-coding schemes for the detection of suspicious and threatening objects using X-ray images. The author argued that the use of these techniques would help in the detection of threatening objects and would improve the efficiency of the baggage monitoring, as well as decreasing inspection time and the possibility of fatigue-based errors.

There are several studies that have addressed the automatic detection of ammunition. These studies can be categorized according to the areas of application into six categories, which are: detection of concealed weapons such as [22], detection of unconcealed weapon [23], gun detection [24], knife detection [25], weapon detection using X-ray imaging [26], and weapon detection using infrared imaging [27]. It is worth mentioning here that some studies can be grouped in more than one of those categories.

However, the methods used for the detection of concealed ammunition can be grouped into four categories: matching based [28], classifier-based [29], multisensor-based [30], and detector-based [29]. This study proposes a classification-based approach to address concealed-munition detection using X-ray imaging.

Regarding the classifier-based approaches, weapons, ammunition, and bullets are segmented from the image, and then the region of interest (ROI) are utilized to extract features that

will be used later for classification [31]. The main role of the classification approach is to classify images as positive or negative. The presence of the ammunition in the input image indicates positive and the absence of the ammunition means negative. Thus, segmentation of ROI is considered a critical phase in the classifier-based approaches to extract the required features for classification.

Several studies employed a classifier-based approach for the purpose of weapons detection and different traditional techniques were utilized in these studies to extract features from the segmented ROI [32]. These techniques include active contour shape, Fisher's linear discriminant, watershed level sets, Fuzzy connectedness, k-means algorithm, and region growing [33]. On the other hand, there are other studies that employed deep learning models as a base for the classification process. Lai et al [34] firstly presented in 2017 a deep learning approach in the field of gun detection to classify images. Their approach used the GoogleNet pre-trained model to train input images. The authors of [26][35] carried out a set of pre-trained deep learning models for classification of images that include weapons and guns. Either using the traditional techniques or deep learning techniques to extract features, both of them lead to inefficient accuracy in the detection of weapons for the small size of weapons. Moreover, most of the published studies in this domain addressed the issue of weapons detection (i.e., that have a relatively large size) but neither addressed ammunition/bullets detection nor the types of ammunition.

Sadah et al. [11] proposed a hybrid technique for improving digital X-ray images by combining the frequency domain enhancement and optimal spatial image techniques. In their method, they selected these frequency domain enhancement techniques: Gaussian and Butterworth high and low pass filters, and as for the spatial domain methods: power-law transform, Histogram equalization, and Negative transform. They carried out more than 80 probable combinations, and some combinations optimally enhanced the original X-ray images. In the study by Khan and Chai, the authors proposed an approach that combined the high and the low-energy X-ray images, denoised the images, and improved the fusion image using histogram specifications, and it also improved the contrast. Their results showed that the final image contained all the minute details; it had no background noise and had enhanced contrast. These images could be easily interpreted and automatically segmented by security personnel. This will result in decreasing the false alarm rate during the X-ray baggage inspection.

Another study carried out by Al-Najdawi [2] proposed another approach that detected different types of bullets and shotgun shells. Different image processing techniques were applied in the detection process, which includes image enhancement, conversion, labeling of connected components, and geometric distance calculations. The author built a dataset comprising 150 X-Ray images of passenger's luggage that contain different types of ammunition and proposed a wideband millimeter-wave imaging system which carried out a fast inspection of the baggage for detecting concealed weapons, explosives, handguns, etc.

Image fusion techniques combine relevant information from many images, those techniques can be classified into the spatial domain and the transform domain. The spatial domain method includes the averaging approach, principal component analysis, the Brovey method, and the Hue-Intensity-Saturation (HIS) transformation approach. The high pass filtering-based processes are also included in the spatial domain approaches [36]. On the other hand, the transform domain approaches can easily handle the spatial distortion after image fusion. In the work proposed by Xue et al. [37], the authors developed an algorithm that merged the color visual images and their corresponding infrared (IR) images for CWD. This color image fusion algorithm proved to maintain the resolution of the image and could incorporate the detected weapons in the image while maintaining the natural colors of the image. In a study by Achanta et al. [38], the authors developed a method known as parametric mixing. In their study, they created a model which improved the detection of objects (i.e., metallic or non-metallic) or concealed weapons using a nonlinear acoustic technique. In their method, ultrasonic waves were used for creating a localized zone, in which the nonlinear interaction generated a low-frequency acoustic wave that could go through the clothing in a better manner when compared to direct ultrasonic waves.

Microwaves can be used for communication, i.e., for transmitting long-distance telephone signals and in satellite television. They are also used for detecting concealed metal. Elsdon et al. [39] suggested an approach for detecting the concealed metallic objects like weapons by using an indirect holographic process, which was operational at the optical frequencies. This approach could be applied to the image objects at the microwave frequencies, and it could determine the shape and location of the concealed objects. Since the microwave imaging methods is very expensive, researchers have proposed a simple and inexpensive method of using this technique for CWD.

One of the biggest problems facing researchers in the field of ammunition identification is the lack of publicly available benchmark datasets according to [30]. As a part of the contribution in this research, a novel dataset of 1732 X-Ray images of passenger luggage has been produced especially for this purpose. This unique dataset is made available to the public so that other scholars may use it.

III. Feature-Optimized Approach for Ammunition Detection

A. Feature Selection Techniques

The proposed system for the detection of ammunition from X-ray images would be as effective as the features that are extracted from the images. Due to the complexity of the images and the necessity to distinguish between the hidden ammunition, feature selection was an important step in the model training and improving its performance. In this study, the MB-LBP features were chosen based on their efficiency in describing the micro and macro-structures that are seen in the X-ray images. These features are especially useful for the identification of separate bulk density and shape of different types of ammunition. In the feature selection, the numerous possibilities of features such as texture descriptors, the shape-based features, and the intensity gradients were considered. By cross-validation, only the useful features were kept in the model. To do so, we sought to maximize the distinction

between the selected features while reducing overlapping as much as possible to include only the most important features for the classification process. This was an iterative process in which features had to be assessed not only by their ability to separate classes but also as components of a set of features that defines the model. The purpose was to achieve high accuracy to guarantee that the final set of the features is both as small as possible and as accurate as possible.

The selected features were also chosen for their insensitivity to variations in conditions typical for real-world security scenarios, light conditions, object orientation, occlusions in X-ray images, etc. Thus, it was ensured that the set of features being used was rather stable with regards to these changes and by using this set of features, the system was made more robust to changes in the environment and situations. However, the focus was also paid to the interpretability of the chosen characteristics that were used for the definition of the described model. This was important so that actions of the system could be explained and be accepted by security personnel. For example, the features of the MB-LBP include clear and interpretable representations of the visual data on which the system makes its classification, which facilitates an understanding of the process that led to the classification. This transparency is important for practical implementation in serious security scenarios where not only the decision but the rationale for the decision may be critical for use. This concentration on feature selection not only enhanced the model's accuracy but also developed confidence that the system could work in real-time, making it an important tool in supporting security in areas like airports and essential installations.

B. Ammunition Detection: 9 mm Handgun and AK-47 Bullets

The greyscale images are produced by measuring the light intensities at every pixel in the band of an electromagnetic spectrum (e.g., IR, X-ray, visible light, or UV). Under these circumstances, they are monochromatic only when a light frequency is captured; however, they can also be synthesized using colored images. Grey X-rays images are an old and popular method for carrying out security checks. During baggage inspection, the luggage is exposed to small ionizing radiation doses, which results in images of the luggage's interiors [40]. However, digital X-ray images can be degraded due to low contrast and blurring, which is caused by the complex items in the luggage. Also, scattering of the X-rays and electrical noises can affect the monitoring and the analysis of the images by some systems or humans. Hence, it becomes necessary to improve the X-ray image details in order to improve the visual quality of the images [41]. Ammunition is smaller in size as compared to the other personal items in the luggage; hence, the X-ray images must be improved as in the following step.

1) X-ray image enhancement: Methods of enhancing the X-ray images within a spatial domain can be divided into three groups: point processing techniques, histogram-based processing techniques, and mask processing techniques [42]. In this study, the authors have used the histogram equalization and the unsharp masking techniques. Histogram equalization is a contrast enhancement process, which adjusts the pixel intensities for generating a new and enhanced image that shows a better local contrast. On the other hand, the unsharp masking technique sharpens the images by subtracting the smoothed

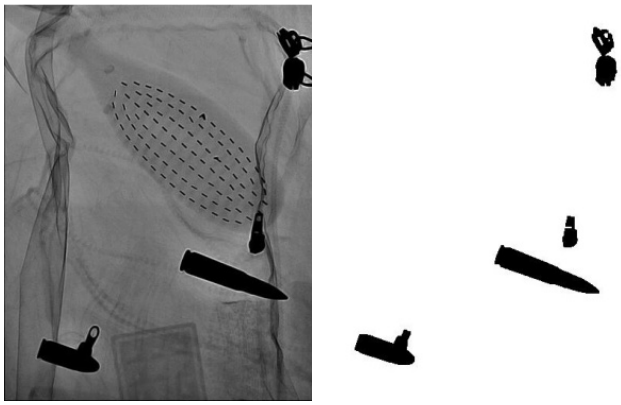

Fig. 1. Samples of the X-ray images of: (a) 9 mm handgun bullets and AK-47 machine gun bullets; (b) Resultant binary image.

image from the original image. A histogram can be created for an image based on the probability of the occurrence of the pixel intensity as described earlier [43]:

$$P_r(r_k) = \frac{n_k}{MN} \tag{1}$$

Where $P_r(r_k)$ refers to the probability of the occurrence of the intensity level r_k within a digital image, MN refers to the total pixels within an image, and n_k represents the number of the pixels with an intensity r_k. New intensity values can be estimated for every intensity level using the transformation as follows:

$$s_k = T(r_k) = (L-1)\sum_{j=0}^{k} p_r(r_j) \tag{2}$$

Where s_k refers to the new intensity level. It is estimated for every pixel in an image. In addition, the processed image can be obtained after mapping every pixel in an input image (having intensity r_k) into the corresponding pixels (with intensity level s_k) into the output images [23]. The unsharp masking procedure is carried out after blurring the original images and then creating the mask after subtracting the blurred images from the primary images as follows:

$$W_{mask}(x,y) = f(x,y) - f'(x,y) \tag{3}$$

Where $W_{mask}(x,y)$ is the mask, $f(x,y)$ represents the primary image, and $f'(x,y)$ refers to the blurred image. Thereafter, the mask is added to the primary image as follows:

$$W(x,y) = f(x,y) + W_{mask}(x,y) \tag{4}$$

Where $W(x,y)$ refers to the resultant unsharp image.

2) Ammunition detection: Ammunition detection is initiated by converting enhanced images into binary images with the help of the Otsu threshold process [43]. The images are denoised using some morphological operators. Then, the objects connected at the borders are eliminated from the resultant binary images. Finally, certain holes in the images are removed by morphological operators [43]. The Otsu threshold process searches for the threshold that decreases the intra-class variance, which can be defined as the weighted sum of the variances of the two classes:

$$\sigma_w^2(t) = w_1(t)\sigma_1^2(t) + w_2(t)\sigma_2^2(t) \tag{5}$$

Where the weights w_i refer to the probabilities of the classes, which are divided by the threshold t, and σ_i^2 refer to the variances of the class. Fig. 1 describes the final binary images after techniques like histogram equalization, unsharp masking, and the Otsu's thresholding method were applied to the X-ray images.

For the ammunition detection and classification, the connected regions in the binary images can be determined with the help of the connected-component labeling algorithm [44]. Here, the authors have applied the 8-connected component labeling algorithm. In the case of the binary image, the connected pixel areas can be classified after the connected component labeling operator has scanned the image in every row till it reaches a point p (where p represents the pixel labeled at any step during scanning). After recognizing this condition, the algorithm investigates the 4 neighbors of the point p, which were already scanned. The point p is labeled based on the collected data as shown below [29]:

- If all the neighboring points are 0, a new label is allocated to p.
- An exclusive label is allocated to every class with the help of the Floyd-Warshall algorithm.
- The image is scanned again, and every label gets replaced by the label that is allocated to the equivalence classes.

Fig. 2. Some samples of the X-ray images after ammunition detection: First row, 9 mm handgun bullets, AK-47 Machine gun bullets, and the 12-Gauge shotgun shells. Second row, resultant binary images.

In the next step, the properties of each connected component are estimated. Here, the authors have measured the properties for every labeled region of the label matrix. The positive integer elements present in the label matrix are seen to correspond to other areas. For example, the elements in the label matrix equivalent to 0 correspond to region 1, while the elements in the label matrix equivalent to 1 correspond to the region 2. Every labeled connected component gets indicated by a bounding box as described in Fig. 2. In order to determine if the bounding box contained ammunition images, a classification system was introduced. In this study, for testing purposes, the authors classified the ammunition in three classes: AK-47 machine gun bullets, 9-mm handgun bullets, and 12-gauge shotgun ammunition.

In the case of the AK-47 machine gun bullets and the 9-mm handgun bullets, the ammunition is classified based on their fixed bullet size ratio (i.e., length: width). In Table I, the dimensions and ratio of the bullets are summarized.

TABLE I. DIFFERENT DIMENSIONS AND RATIOS OF THE SELECTED AMMUNITION FOR TESTING OF THE DEVELOPED SYSTEM

Dimension and Ratio	9mm	AK-47	12-Gauge
Length (range)	2.781-2.969	5.600-5.620	5.1-7.6
Width	1.01	1.135	13.41
Ratio	2.75-2.93	4.93-4.95	3.80-5.66

For determining the bullet ratio in Table I, every label is estimated with the help of the Euclidean distance measure D_e for the points p and q that are located at the coordinates of (x, y) and (s, t), respectively, as:

$$D_e = \sqrt{(x-s)^2 + (y-t)^2} \tag{6}$$

Euclidean distances are used for measuring the height D_{e1} and the width D_{e2} of every object in the label, while the height:width is estimated as $R = D_{e1}/D_{e2}$. Thereafter, this ratio is compared to the results in Table I, after which the object is classified. Fig. 2 describes some samples in which the algorithm could accurately identify 9 mm handgun and AK-47 machine gun bullets, with precision 95%. Fig. 3 shows some sample images of the detected ammunition.

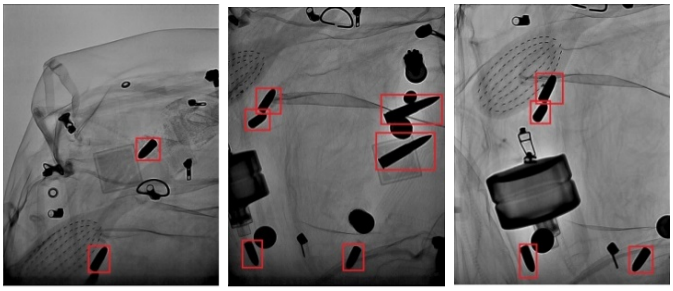

Fig. 3. Some sample images of the detected ammunition.

C. Feature-Based Identification of 12-Gauge Shotgun Shells

In this research, the authors attempt to identify the 12-gauge shells, as their structure differs from other kinds of ammunition such as the 9-mm handgun and the AK-47 machine gun bullets. The 12-gauge bullets have a plastic casing; hence, the bullets appear transparent in X-ray images. Moreover, as shown in Fig. 4, the wad creates a space between the powder

and shot which prevents its visual recognition. Therefore, any orientation change in the 12-gauge position results in different shapes, as shown in Fig. 5. On the contrary, other bullets have a solid metal body, which can be identified in the X-ray images as a solid known structure.

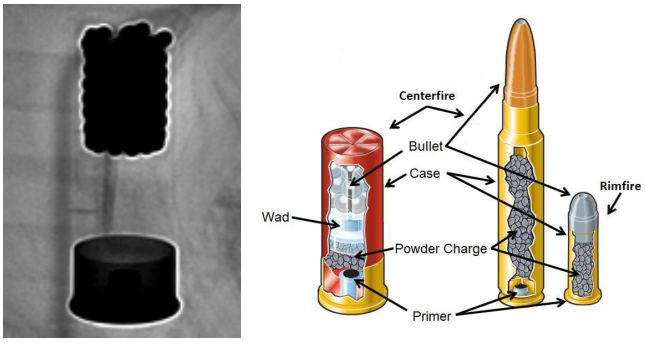

Fig. 4. (a) Structure of the 12-gauge ammunition, AK-47 machine gun bullet, and 9-mm bullet. (b) X-ray images of the 12-gauge ammunition.

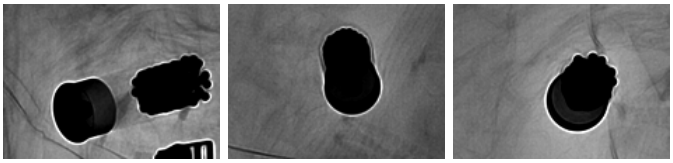

Fig. 5. Images of the 12-gauge ammunition from various angles. Image courtesy: Al-Najdawi and Tedmori.

In this study, a Cascade-AdaBoost classifier with MB-LBP features has been implemented for detecting the variable 12-gauge ammunition shapes.

AdaBoost classifier, proposed by Freund and Schapire [45][46], is a type of parallel classifier that combines various linear weak classifiers. This offline classifier self-adaptively increases the number of weak classifiers, which helps improve the overall classification accuracy. Every weak classifier is seen to focus on the 1-D classification of the input feature vectors. Moreover, the AdaBoost algorithm makes use of a minimal error for estimating the weight value of the weak classifier, then it uses the weight value of each training sample input. Then, it passes the weight value to the newly added subsequent weak classifier. Fig. 6 describes the AdaBoost classifier architecture [47].

If the input feature vector is represented by f, then the number of the weak classifiers is represented by $h_t(f)$, $t = 1, \ldots, T$, and the corresponding weight values of every weak classifier are represented by β_t, $t = 1, \ldots, T$. The final strong classifier, $H(f)$, can be expressed as follows:

$$H(F) = \text{sign}\left\{\sum_{t=1}^{T} \beta_t h_t(f)\right\} \tag{7}$$

One main limitation of the AdaBoost classifier is that it has a higher false alarm rate. Thus, Viola and Jones [48] proposed the cascade-AdaBoost classifier to decrease the false alarm rate. Fig. 7 shows the architecture of the cascade-AdaBoost classifier, where every classifier was an AdaBoost classifier.

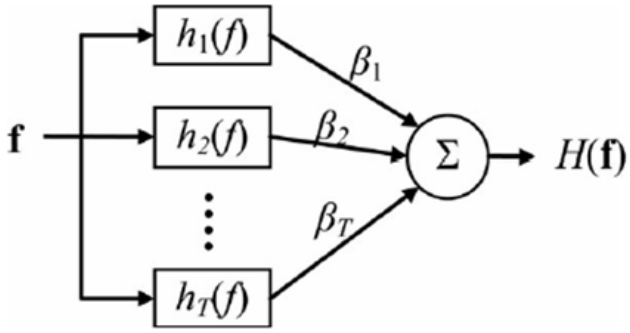

Fig. 6. Architecture of the AdaBoost classifier [47].

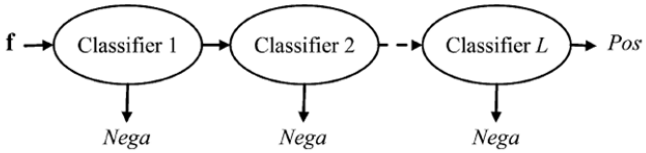

Fig. 7. Cascade-AdaBoost classifier architecture [48].

When the input feature vector is passed through the first AdaBoost classifier and is determined as the negative example, it is removed from the training set before it enters the second AdaBoost classifier. This decreases the number of the examples and increases the layers for removing the negative examples. However, when passing the input feature vector through the first AdaBoost classifier, if it is identified as a positive example, then the training example enters the second layer of the AdaBoost classifier and is classified further until it passes to the last layer. Hence, the cascade AdaBoost classifier displays a high detection rate and a lower false alarm rate since it uses many classifiers [49].

AdaBoost learning is applied for the selection of some weak classifiers and then combines them into the classifier to determine if the image contains the desired object [50]. Several algorithms can be used for feature extraction, like the Principal Component Analysis (PCA) [51], the Linear Discriminant Analysis (LDA) [52], the Independent Component Analysis (ICA) [53], and the Gabor filter [54]. However, all of these algorithms have high computational costs for convolving the object images and can be inefficient with regard to memory and time to extract features compared to the Local Binary Pattern (LBP) [55]. The LBP method was initially proposed by Ojala et al [56], and it was used for the texture description. This method can be used for many applications, such as facial detection and recognition [57][58], classification of gender and age [59][60], analyzing facial expressions [61], and estimating the head pose [62]. Some main properties of the LBP features

IV. Discussion and Experimental Results

A. Comparative Analysis of Feature Selection Techniques

The reasons for choosing the MB-LBP features in the study are based on the performance of these features in capturing the required level of details that are crucial for the identification

of ammunition in X-ray images. That is why, although there are many other techniques such as Gabor filters, Histogram of Oriented Gradients (HOG) and so on, or traditional Local Binary Patterns (LBP), in this work, the MB-LBP was chosen because of the high accuracy in combination with acceptable computational time.

Some of them, such as the Gabor filters, are particularly efficient in texture analysis and have been applied in a large variety of image processing applications. However, their computational complexity is a major disadvantage in real-time environments, especially when analyzing high-dimensional data such as X-ray images. Likewise, the HOG features are very good for edge and gradient information and are used for object detection; however, they may not be as effective in discriminating between small and closely grouped objects such as ammunition.

Although traditional LBP is faster in computation and requires fewer parameters, it focuses only on the local binary patterns without regard to the spatial relation around the center pixel, which may cause a problem in complex scenes where objects are overlapping or images have different quality. The MB-LBP approach improves upon the standard LBP approach by including larger patterns, better suited to handle the difficulties posed by X-ray imagery in security systems.

Consequently, the features of the MB-LBP were chosen for this study because of their ability to give more detailed descriptions of the X-ray images in addition to capturing more global characteristics of the images. This is in concordance with the characteristics of the ammunition detection task where precision and speed are critical. Another reason for our choice of MB-LBP was based on the observation that it has been widely used in similar applications and is generally robust for different conditions.

Comparing MB-LBP directly with other techniques was beyond the scope of this study. However, the literature shows that MB-LBP is suitable for the present task. This feature selection method is also balanced in terms of the performance and computation, and that is why its application in developing a real-time detection system in the security sector is advisable.

B. Experimental Results

In the experiments provided in this research, positive and negative samples were required in the training procedure. Positive samples (548 images that contain more than 1036 of 12-gauge ammunition) were obtained through labeling the 12-gauge ammunition from the X-ray images. Negative samples (1184 images) were extracted from X-ray images which do not contain the 12-gauge ammunition. The X-ray images of the 12-gauge ammunition that have been used in the experiments were taken from various view angles as shown previously in Fig. 5.

In the following experiments, an eighteen-layer cascade-AdaBoost classifier using MB-LBP features is obtained and then experimented over the provided dataset (i.e., offline process). Then a real-time process starts depending on the previous features which have been obtained from the MB-LBP to classify the required objects. Using this framework, it was able to process more than 27 frames per second on a machine of 8 GB RAM and 3.2 GHz processor speed. Sample of the results are shown in Fig. 8.

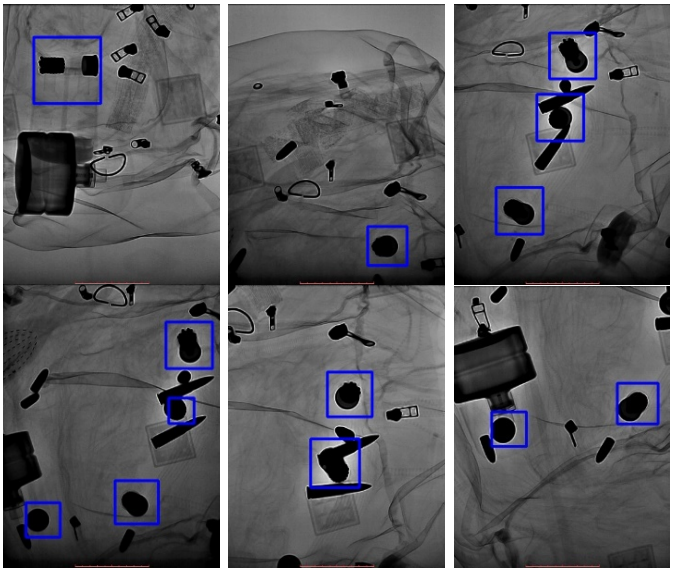

Fig. 8. Sample of successful labeling for different numbers of 12-gauge ammunition of different orientations.

However, in some cases, the proposed system failed to label the 12-gauge ammunition correctly by selecting different objects that contain similar features to the 12-gauge ammunition, as shown in Fig. 9.

In order to evaluate the performance of the proposed system, some statistical measures (i.e., accuracy, sensitivity, specificity, and Matthew's correlation coefficient) were calculated as follows:

- Accuracy has been calculated for the 12-gauge ammunition detection using the formula [63]:

$$\text{Accuracy} = \frac{\Sigma\ (TP + TN)}{\Sigma\ (TP + TN + FP + FN)} \times 100\% \tag{8}$$

  Where:
  - TP = True Positive (actual 12-gauge ammunitions that were correctly classified as 12-gauge ammunitions).
  - FP = False Positive (other objects that were incorrectly labeled as 12-gauge ammunitions).
  - FN = False Negative (12-gauge ammunitions that were incorrectly not labeled).
  - TN = True Negative (all the remaining objects, correctly classified as non-12-gauge ammunitions).

  In the proposed system, Accuracy = 92.8%, where: TP = 960, TN = 1151, FP = 88, and FN = 76.
- Sensitivity or true positive rate (TPR) relates to the ability to identify positive results using the formula [63]:

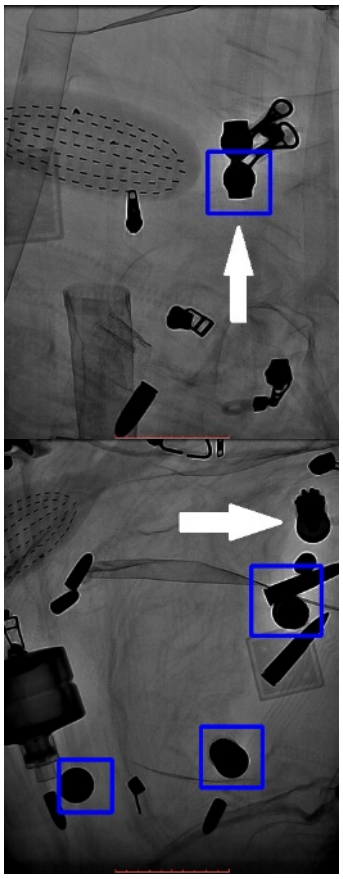

Fig. 9. Some of the cases where the system was unable to label the 12-gauge ammunition were in (a) labeling a different object or (b) missing the object completely.

$$\text{TPR} = \frac{TP}{TP + FN} \times 100\% \quad (9)$$

TPR = 92.66%, where: TP = 960 and FN = 76.

- Specificity (SPC) or true negative rate relates to the ability to identify negative results using the formula [63]:

$$\text{SPC} = \frac{TN}{TN + FP} \times 100\% \quad (10)$$

SPC = 92.89%, where: TN = 1151 and FP = 88.

- Matthew's Correlation Coefficient (MCC) was used in the machine learning for measuring the quality of the binary (2-class) classification [63]. This method considered the true and the false positives or negatives and was considered the balanced measure that could be used for the differently sized classes. MCC was used as a correlation coefficient for the observed and the predicted classification systems and generated values ranging between +1 to -1. A coefficient value of +1 showed a perfect prediction, while a value of 0 indicated a random prediction, and a value of -1 indicated a complete disagreement between the observed and predicted values. MCC is directly estimated using the confusion matrix, as follows:

$$\text{MCC} = \frac{TP \times TN - FP \times FN}{\sqrt{(TP+FP)(TP+FN)(TN+FP)(TN+FN)}} \quad (11)$$

MCC = 85.5%, where: TP = 960, TN = 1151, FP = 88, and FN = 76.

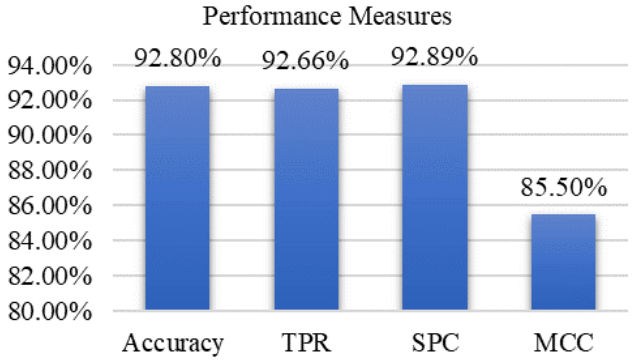

Fig. 10. Graphical representation for the performance measures (i.e., Accuracy, TPR, SPC, and MCC).

Different applications could benefit from the results of this research by applying the MB-LBP offline process as in [36][37]. Fig. 10 shows graphical representation for the performance measures (i.e., Accuracy, TPR, SPC, and MCC).

C. Comparative Analysis

In this part we compare our results with those of the related paper, "Detection of threat objects in baggage inspection with X-ray images using deep learning" by Saavedra et al. [64]. Both studies, however, address threat detection in X-ray images, and their methodologies and performances differ from each other. For this, Saavedra et al used deep learning models like YOLOv3, SSD, and RetinaNet trained on real as well as synthetic X-ray images artificially generated by PGGAN and superimposition methods. Across all four threat categories (guns, knives, razor blades, and shuriken), mAP was 80.0%. Instead, our system includes a cascade-AdaBoost classifier using the accuracy of the Multi scale Block Local Binary Pattern (MB-LBP), and is tuned for ammunition detection. The methodology described results in a 92.8% accuracy detecting 12-gauge shotgun shells, 92.66% sensitivity and 92.89% specificity.

However, guns and shuriken had high precision (96.3%, 93.7%) according to Saavedra et al. but knives with elongated shape and occlusion problems achieved low precision (76.2%). However, our system retains strong performance in detecting 12-gauge shotgun shells, which are very difficult to detect since the shells are covered in plastic casing and have multiple orientations. Cascade-AdaBoost classifier with MB-LBP features are capable of overcoming these challenges, reaching 92.8% accuracy and 85.5% MCC. In a particular dataset with similar threat objects to the training set, Saavedra et al. used their model and achieved high precision. But their model was not able to account for significantly different objects from what they trained from. Table II shows comparative analysis of

TABLE II. COMPARATIVE ANALYSIS: FEATURE-OPTIMIZED MACHINE LEARNING SYSTEM VS. DEEP LEARNING-BASED THREAT DETECTION

Aspect	Our System (Feature-Optimized ML)	Saavedra et al. (Deep Learning-Based)
Methodology	Cascade-AdaBoost classifier with Multi-scale Block Local Binary Pattern (MB-LBP) features.	Deep learning models (YOLOv3, SSD, RetinaNet) trained on real and synthetic X-ray images (PGGAN).
Dataset	1,732 X-ray images of passenger luggage with concealed ammunition (publicly available).	GDXray dataset with simulated X-ray images (real and synthetic).
Threat Objects Detected	9 mm handgun bullets, AK-47 machine gun bullets, 12-gauge shotgun shells.	Guns, knives, razor blades, shuriken (ninja stars).
Performance Metrics	Accuracy: 92.8% (12-gauge shells), Sensitivity: 92.66%, Specificity: 92.89%, and MCC: 85.5%.	mAP: 80.0%, Guns: 96.3%, Knives: 76.2%, Razor blades: 86.9%, and Shuriken: 93.7%.
Strengths	High accuracy for 12-gauge shotgun shells. And, robust to variations in orientation and occlusion.	High precision for guns and shuriken. And, scalable to multiple threat categories.
Challenges	Misclassification of objects with similar textures. And, reliance on single-view X-ray images.	Struggles with elongated objects (e.g., knives). And, limited generalization to unseen object shapes.
Generalization	Strong generalization to diverse orientations of 12-gauge shells. And, adaptable to real-world scenarios.	Limited generalization to objects with different shapes or orientations.
Real-World Applications	Suitable for airport baggage screening. And, reduces reliance on human operators.	Effective for detecting large threat objects (e.g., guns, shuriken).
Future Work	Integration of multi-view imaging. And, combining with deep learning models (e.g., YOLOv3).	Improving detection of small or occluded objects (e.g., knives).

feature-optimized machine learning system and deep learning-based threat detection.

In addition, we have shown here that our system can accurately identify 12-gauge shotgun shells; however, objects with similar appearances (in this case, plastic casings) were sometimes wrongly identified as ammunition. This is the problem of separating two closely related objects in cluttered X-ray images. Using the fixed bullet size ratio for classification, the system had 95% accuracy for 9 mm handgun bullets and AK 47 machine gun bullets. The elongated shape of knives typical of this type of objects, though, remains a challenge and future work may involve multi-view approaches to increase detection accuracy of such objects. The system is able to detect 12-gauge shotgun shells in various orientations and successfully detected 12-gauge shotgun shells in Fig. 8. Fig. 9 shows failed cases of the system in labeling of ammunition, primarily because of the presence of overlapping objects or similar texturing. They are valuable cases for advancing improvements, e.g., adding extra features or more refined segmentation. Due to the variable orientation and plastic casing of 12-gauge shells, the system does not perform as well with 12-gauge shells compared to 9-mm and AK-47 bullets, which are all about the same size and shape.

We show that our system is very robust to variations of the object orientation, occlusion, and image quality, and we also experimentally demonstrate that our system also facilitates the acquisition of stereo images of patients with imperfect eyes. In addition to capturing both micro and macro structures in an X-ray image, the MB-LBP has the capacity of reliable detection in complex scenarios. However, Saavedra et al.'s model did not perform well with objects when they were rotated or occluded, such as knives. This points out the importance of feature selection and necessity of models for dealing with diverse object orientations.

Our system works with high accuracy and robustness and thus is suited for security applications in real-world situations, e.g. for airport baggage screening. Security checks are significantly more efficient and reliable due to the increase in the ability to detect 12-gauge shotgun shells with an accuracy of 92.8%. Future work may also test our system with multi-view X-ray imaging, as suggested by Saavedra et al., to further improve these object detection accuracies when knives and shuriken are used.

One major shortcoming of our system is that it relies on single-view X-ray images, which might cause object that has complex shape or is under heavy occlusion to be missed. This limitation will be addressed in the future work through multi-view approaches. Further, objects with similar texture or shape are misclassified from time to time as ammunition. It is quite possible to mitigate this problem by incorporating advanced segmentation techniques or additional features. Applications in the future include adding multi-view X-ray imaging to provide a more global description of objects and enhancement of detection accuracy for hard cases. Further performance improvement is possible by combining our feature-optimized approach with deep learning models like YOLOv3 or RetinaNet because they are powerful models that are more efficient in classifying small or occluded objects. The generalization capability of the system could be enhanced if the dataset were expanded to include a greater variety of ammunition types and challenging scenarios.

V. CONCLUSION

Feature selection is a critical element in the improvement of the performance of machine learning systems, especially in tasks such as the detection of ammunition in X-ray security imaging systems. In this study, the choice and tuning of the features were critical in constructing a reliable system that can effectively detect concealed ammunition with a high level of accuracy. The features of MB-LBP were used and combined with the cascade-AdaBoost classifier in order to extract the most important information from the X-ray images and guarantee that the system can work in real-time environments. Safety and security of passengers is one of the important components of contemporary transport systems. Measures of security are tight, but threats and contraband are a reality in sensitive environments. X-ray machine systems at security checkpoints are very important in detecting banned items such as weapons and sharp objects. These systems may contain at least semi-automatic elements for metal detection. However, there is a significant gap in their capability of identifying concealed ammunition, which is a critical security threat. In an attempt to fill this research gap, this paper presents an automatic system designed to help security professionals detect different types of ammunition.

The main focus of the system is a profound feature selection method that enhances the accuracy and efficiency of the detection phase. The selection of MB-LBP features was especially useful in obtaining the fine detail required to differentiate between the types of ammunition with clarity, including 9 mm handgun bullets, AK-47 machine gun bullets, and 12-gauge shotgun shells. This feature optimization, in addition to improving the performance of the model, also decreases the system's computational intensity, making the system appropriate for real-time security applications. The authors have created their own dataset of 1,732 X-ray images of passengers' belongings that contain concealed ammunition. This dataset, now open to the public, promotes more research and development and brings together the security and machine learning domains. Thus, in addition to meeting the need for a reliable resource to support security specialists' work, the study helps to progress science and technology in the field of automated threat detection.

The system uses a number of sophisticated image processing techniques such as image enhancement, image conversion, labeling of components, and estimation of geometric dimensions. These techniques are very essential since they help to overcome the problem of variability of the X-ray image quality, orientation of objects, and the various complex backgrounds that may be observed in the passenger's luggage. The integration of the cascade-AdaBoost classifier with the MB-LBP features makes it possible for the system to perform effective and accurate detection of concealed ammunition. The combination of these mentioned methods leads to an overall effective, efficient, and flexible solution that can be implemented into different security scenarios.

In classification and recognition of concealed ammunition, the system performs quite well, especially for the 9 mm handgun bullets and the AK-47 machine gun bullets, with at most 92% accuracy in detection. Such a high level of accuracy shows how the system can greatly advance the detection abilities at the security checkpoints, with little reliance on human operators and the likelihood of human errors. The capacity to accurately identify ammunition and to do so without human intervention increases the likelihood of safety and security for passengers, especially within areas of vulnerability such as airports and other stations. Besides the efficiency, the system's architecture focuses on scalability and interpretability, which means that the developed system can be implemented in different real-world settings. It can be integrated into other security systems and structures, and it is relatively easy to modify the architecture as new threats appear on the scene. Furthermore, the system is very interpretable, and this means that security personnel can trust the decisions made by the system, which is very important when the system is being implemented in important settings.

This paper demonstrates that, in today's security systems, it is possible to enhance the performance of advanced feature selection and machine learning techniques. By focusing on the particular case of concealed ammunition searching, the authors have presented a useful instrument that could help to enhance public security and develop existing security technologies. Future work may look at applying such a scheme to identify other forms of prohibited items, as well as incorporating it within larger security systems as a way of expanding, generalizing, and ultimately increasing the practical applicability and effectiveness of the method.

Conflict of Interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

Data Availability

The X-Ray images data used to support the findings of this study have been deposited in the Automatic-Ammo-Detection- repository (https://github.com/reyalat-bau/Automatic-Ammo-Detection-).

Evaluating Transparency in the Development of Artificial Intelligence Systems: A Systematic Literature Review

Giulia Karanxha, Paulinus Ofem
Business and Information Technology, Laurea University of Applied Sciences, Espoo, Finland

***Abstract*—Transparency is increasingly recognised as a cornerstone of trustworthy artificial intelligence (AI), yet its operationalisation remains fragmented and underdeveloped. Existing methods often rely on qualitative checklists or domain-specific case studies, limiting comparability, reproducibility, and regulatory alignment. This paper presents a Systematic Literature Review (SLR) of 28 peer-reviewed studies that explicitly propose or apply methods for evaluating transparency in AI systems (2019-July 2025). The review identifies recurring themes such as traceability, explainability, and communication, and classifies evaluation approaches by metric type and calculation type. Empirically, checklist-based instruments are the most frequent evaluation form (9/28, 32%), followed by scenario-based qualitative assessments (5/28, 18%). Most (9/28, 32%) research on AI applications occurs in healthcare; references to legal or ethical frameworks appear in 19/28 studies (67%), although traceable mappings to specific obligations are rare. The results of the quality assessment highlight strengths in methodological clarity, but reveal persistent gaps in benchmarking, stakeholder inclusion, and lifecycle integration. Based on these findings, this study informs the adaptation of the Z-Inspection® process within the context of AI development projects and motivates a Transparency Artefact Registry (TAR), a structured, metadata-based mechanism for capturing and reusing transparency artefacts across system lifecycles. By embedding transparency evaluation into AI development workflows, the proposed approach seeks to provide verifiable, repeatable, and regulation-aligned practices for assessing transparency in complex AI systems.**

Keywords*—Artificial intelligence; transparency evaluation; trustworthy AI; transparency metrics; EU AI Act; systematic literature review

I. Introduction

The rapid deployment of artificial intelligence (AI) in high-impact domains has intensified calls for transparency as a cornerstone of Trustworthy AI. Transparency enables stakeholders to understand, contextualise, and, where necessary, contest AI-driven decisions [1]. Its importance is underscored by the EU Artificial Intelligence Act (Regulation (EU) 2024/1689), which mandates that high-risk AI systems and general-purpose AI models provide features such as explainability, traceability, and clear user information [2]. Yet, despite these obligations, the operationalisation of transparency remains fragmented, with varying definitions, scopes, and evaluation practices across disciplines and application domains. This poor clarity risks undermining both accountability and compliance in real-world AI deployments.

For the MANOLO Project (Trustworthy Efficient AI for Cloud-Edge Computing) [3], this challenge presents an opportunity to explore further. This project aims to develop a complete set of trustworthy algorithms and tools that would enable AI systems to achieve better efficiency and optimise their operations on the edge of the cloud continuum and in sectors such as healthcare, telecommunications, and robotics, where systems must combine performance and energy requirements with strict ethical and legal compliance. In such contexts, the absence of structured, measurable approaches to transparency achievement and evaluation poses not only a compliance risk but also a practical barrier to demonstrating accountability to regulators, end-users, and other stakeholders.

To address this, we conducted a Systematic Literature Review (SLR) of peer-reviewed studies published between January 2019 and July 2025. The review identifies how transparency in AI is defined, measured, and operationalised, and where gaps remain. By mapping existing approaches and their limitations, the SLR provides the empirical and conceptual foundation needed for AI projects to adopt a structured transparency evaluation strategy.

This review also serves as the basis for further methodological contributions. Its findings directly inform our conference paper, which introduced an artefact-driven approach to transparency evaluation in applied AI contexts. In this vein, this paper is not an isolated study but the first step in a broader research programme: establishing a systematic evidence base for transparency evaluation, and subsequently proposing solutions that can be embedded into frameworks such as Z-Inspection® [4] to support continuous, auditable, and stakeholder-relevant transparency in AI projects and beyond.

The remainder of this paper is organised as follows. Motivation situates the work in the MANOLO and Z-Inspection® contexts; Related Work maps policy, governance, and SE/IS perspectives; Methodology details the SLR protocol (scope, PICOC, search, screening, quality appraisal, extraction); Results report the evidence base and descriptive statistics; Thematic Analysis synthesises cross-cutting patterns; Discussion provides implications of findings and advantages over prevalent approaches; Conclusion summarises limitations and future work.

Contributions and roadmap. This study 1) focuses on operational, metric-based transparency *evaluation* methods rather than principles, 2) proposes a compact comparative taxonomy (metric types) and quantifies patterns across 28 studies, 3) offers a cross-domain synthesis bridging AI governance and SE/IS consideration of transparency as a first class non-functional requirement, and 4) links identified gaps to an

artefact-driven solution space (Transparency Artefact Registry, TAR) aligned with Z-Inspection® and the EU Artificial Intelligence Act (EU AI Act). Section II motivates the challenge of evaluating transparency in AI development projects such as the Manolo project; Section III synthesises related work; Section IV details the SLR protocol; Section V reports descriptive results; Section IV-G provides thematic analysis; Section VII discusses implications; Section VIII concludes.

II. Motivation

Within MANOLO, the evaluation of AI trustworthiness is grounded in the Z-Inspection® framework [4], a holistic process for assessing AI's ethical compliance, technical robustness, and legal alignment. Although Z-Inspection® provides comprehensive coverage of the trustworthiness dimensions, it does not offer a structured, dedicated methodology for the evaluation of transparency throughout the AI lifecycle.

For AI projects that utilise Z-Inspection®, this limitation creates both a compliance risk under the EU AI Act and a practical challenge to demonstrate transparency and accountability to stakeholders. Therefore, a systematic investigation of existing transparency evaluation methods was required to establish a structured evidence base. This SLR responds to this need by synthesising how transparency has been defined, measured, and operationalised in peer-reviewed studies. In this way, the review provides the foundation for future AI projects that will adapt Z-Inspection® with measurable transparency criteria aligned with regulatory obligations and stakeholder needs.

III. Related Work

Transparency is increasingly recognised as a key requirement for ethical and trustworthy AI, yet its practical achievement and evaluation remain challenging. Over 94% of ethical AI guidelines include transparency or explainability as core principles [5], but few provide actionable tools for assessment. This gap between normative commitments and operational practices has driven attention from regulators, practitioners, and researchers alike.

A. Policy and Regulatory Frameworks

The concept of transparency gained formal traction in the European policy landscape through the High-Level Expert Group on AI (AI HLEG), which identified transparency, encompassing traceability, explainability, and user communication, as one of seven requirements for Trustworthy AI [1]. While influential in shaping the EU AI Act [2], these guidelines are not legally binding. The Act introduces layered obligations for high-risk AI systems (Article 13), general-purpose AI models, and AI systems that interact with humans (Article 50), but leaves their operationalisation open to interpretation [6].

Sector-specific initiatives further illustrate this shift from high-level principles to more practical instruments. The TITAN Guideline [7] offers a checklist for AI disclosure in scholarly publishing, while Genovesi et al. [8] compare how transparency is addressed in standards and policy artefacts. Although valuable, such approaches remain largely domain-bound and rarely demonstrate applicability across diverse AI systems.

B. Societal Accountability and Governance

Beyond regulatory discourse, concerns persist about the societal implications of opaque AI. Busuioc [9] underscores the risks of algorithmic systems becoming embedded in the public sector while remaining resistant to challenge, thereby undermining institutional accountability. This perspective positions transparency not only as a compliance issue but also as a prerequisite for democratic oversight. In line with this, Panigutti et al. [10] argue that transparency must be approached as a dynamic, stakeholder-aware practice rather than a static disclosure requirement. These insights highlight the broader governance role of transparency, which extends beyond technical explainability.

C. Software Engineering and Information Systems Foundations

Long before the rise of AI governance, transparency was conceptualised within software engineering (SE) and information systems (IS) as a non-functional requirement (NFR). Leite and Cappelli [11] introduced transparency as a "soft goal," supported by attributes such as accessibility, auditability, and usability. Hosseini et al. [12] extended this by framing transparency as a bidirectional process between information providers and receivers, thereby emphasising the importance of communication and user understanding. Spagnuelo et al. [13] operationalised the concept further by proposing sector-specific metrics for auditability, accountability, and verifiability in IT systems.

Building on these conceptual foundations, Ofem and colleagues advanced transparency in software engineering through a sequence of works. Their 2022 systematic review [14] clarified the fragmented definitions of transparency and positioned it explicitly as a non-functional requirement, comparable to established quality attributes such as reliability or usability. In the same year, Isong, Ofem, and Lugayizi [15] proposed a framework that operationalises transparency via quality factors, such as accessibility, usability, understandability, modifiability, and reusability, each linked to artefact- and process-level indicators. While these factors provide a structured starting point, the framework acknowledges that specific instantiations may be domain-dependent and must be adapted to stakeholder requirements. This line of work culminated in the 2024 metrics study [16], which introduced empirically validated measurement instruments and an improvement model, thereby transforming transparency from an abstract principle into a set of actionable, lifecycle-aware practices. Although developed in the SE domain, these contributions are directly relevant to AI governance, where similar challenges of definition, measurement, and lifecycle integration remain unresolved.

D. Relevance to AI Transparency Evaluation

Although originating in SE and IS, these approaches are directly relevant to AI governance. The challenges of lifecycle integration, stakeholder involvement, and continuous evaluation are not unique to AI but are shared with complex software systems more broadly. Yet, AI-focused frameworks have thus far incorporated these traditions only partially. Most emphasise explainability or documentation, but rarely adopt SE/IS practices such as artefact registries, maturity models, or quality factor-metric mappings.

This review therefore situates AI transparency evaluation within a broader trajectory: from ethical and regulatory guidelines, through societal accountability concerns, to structured SE/IS methodologies. While progress has been made in translating abstract principles into operational criteria, most existing efforts remain either domain-specific, non-standardised, or lacking in mechanisms for continuous lifecycle monitoring. The present SLR contributes to addressing that gap by systematically identifying and analysing peer-reviewed studies that explicitly propose or apply methods for evaluating transparency in AI systems, and by assessing their relationship to established SE/IS traditions.

1) Integrative synthesis: Policy and governance sources prioritise obligations, rights, and auditability, which have produced tools that mostly take the form of checklists and high-level controls. In contrast, SE/IS literature frames transparency as a non-functional requirement and develops artefact and process-level indicators with measurable quality factors. These viewpoints converge around traceability and documentation, taking into account logs, records, and provenance as core evidence, while also acknowledging lifecycle concerns. These perspectives diverge in emphasis. AI governance often treats explainability as a proxy for transparency, while SE/IS considers transparency as a concept with measurable quality constructs. Methodological overlaps lack coherence: many governance-oriented frameworks document evidence without scoring, whereas several SE/IS approaches score internal artefacts yet rarely assess whether information is communicated to stakeholders in clear, timely, and usable ways (e.g., plain-language notices, model cards, user-tested interfaces). Taken together, this reveals the gap this SLR targets: the field lacks a standardised, lifecycle-grounded, cross-domain evaluation scheme that connects regulatory obligations to measurable artefacts and metrics.

IV. Methodology

This study adopts a SLR approach to investigate how transparency is evaluated in artificial intelligence (AI) systems. The review is guided by the following research questions:

- RQ1: What are the existing approaches for implementing and evaluating transparency in AI systems?
- RQ2: How do these approaches address key transparency concerns?
- RQ3: What are the strengths, limitations, and gaps of these approaches?
- RQ4: How applicable are these approaches in real-world AI systems?

The aim is to identify methodological trends, assess sectoral and regulatory relevance, and support the development of actionable stakeholder-centred transparency evaluation strategies.

TABLE I. Total Search Results Summary

Engine	Total	Reviewed	Overlap
Google Scholar	45,700	179	9
IEEE Xplore	1,799	83	–
Web of Science	4,341	104	22
ScienceDirect	3,998	105	2
ACM DL	4,078	71	7

A. Scope Framing and Objectives

Transparency was examined as a multidimensional concept that encompasses traceability, communication, and explainability [17]. The purpose of the review was to synthesise existing evaluation methods, identify common practices and limitations, and provide a structured basis for future development of transparency metrics and frameworks. The review focused on peer-reviewed literature published between January 2019 and July 2025 to reflect the growing influence of transparency in AI governance discourse, especially in light of regulatory developments such as the EU AI Act (2024) [2].

B. PICOC Structure

The scope of the review was defined using the PICOC model.

- Population: AI systems deployed across various sectors and domains.
- Intervention: Methods, frameworks, or metrics introduced or applied to evaluate transparency.
- Comparison: different approaches for implementing and evaluating transparency.
- Outcome: Assessment of the strengths, limitations, and applicability of approaches to AI development projects.
- Context: AI development projects.

This framing supported a focused yet cross-sectoral exploration of how transparency is operationalised and assessed in contemporary AI research.

C. Search Strategy

The literature search was conducted between January 2019 and July 2025 across five major academic databases: Google Scholar, IEEE Xplore, Web of Science, ScienceDirect, and the ACM Digital Library. These sources were selected for their broad coverage of AI, computer science, ethics, and governance literature. The consolidated counts are summarised in Table I. Search queries combined keywords related to transparency, artificial intelligence, and evaluation, adapted to the syntax of each platform. An example query was:

```
("Artificial intelligence system" OR "AI
        software") AND
```

```
("AI transparency" OR "transparent AI" OR
"trustworthy AI") AND
("transparency evaluation" OR
"transparency metrics" OR "transparency
framework" OR "trustworthy framework" OR
"assessment")
```

Boolean operators and filters (e.g., English language, peer-reviewed) were applied where supported. A heuristic stopping rule was used to manage feasibility, with searches concluded when ten consecutive irrelevant results were encountered. A total of over 59,000 results were screened, including 45,700 from Google Scholar, 4,341 from Web of Science, 1,799 from IEEE, 4,078 from ACM, and 3,998 from ScienceDirect.

D. Screening and Eligibility (PRISMA)

Screening followed the PRISMA 2020 framework. The selection and exclusion process is summarised in the PRISMA flow diagram shown in Fig. 1. After duplicate removal and title/abstract screening, 542 articles were assessed. A total of 28 peer-reviewed studies were included in the final review. The inclusion and exclusion criteria were:

- Inclusion:
  - Peer-reviewed journal or conference publications
  - Published between January 2019 and July 2025
  - Explicitly introduced or applied a method, framework, or metric to evaluate transparency in AI systems
- Exclusion:
  - Discussed transparency only conceptually, without operational methods or proposed governance mechanisms
  - Focused solely on explainability, fairness, or accountability without reference to transparency
  - Non-English or inaccessible full texts

E. Quality Assessment

The included studies were evaluated using a five-criterion quality checklist, adapted from a prior systematic literature review in software engineering [14]:

- Is the evaluation method explicitly described?
- Are structured criteria or metrics provided?
- Are the strengths and limitations discussed?
- Is the method compared with other frameworks?
- Is the approach applied in real-world AI use cases?

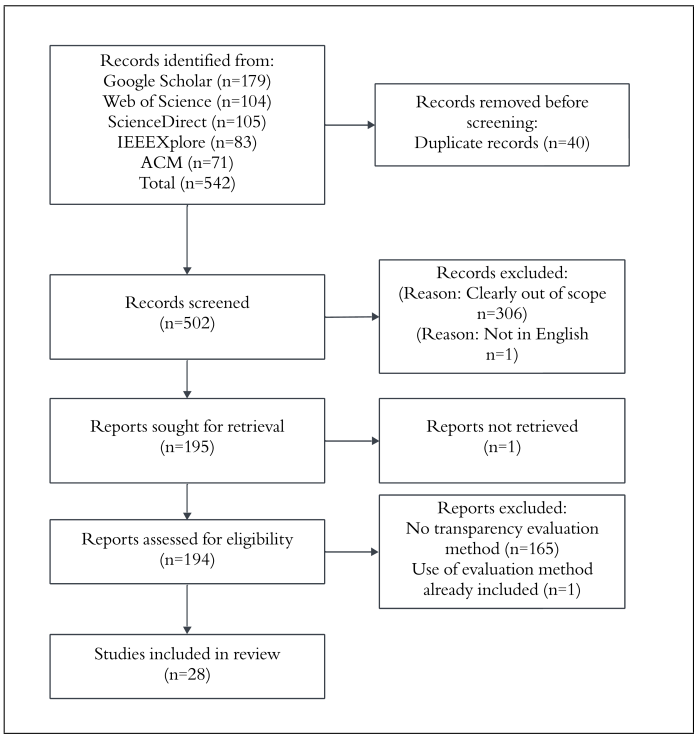

Fig. 1. PRISMA 2020 screening flow for the review window January 2019-July 2025.

Each item was scored as Yes (1), Partly (0.5), or No (0). Studies were not excluded based on their quality score, but scores were used descriptively to support analysis. As shown in Table II, most studies scored 4 or above out of 5.

F. Data Extraction and Classification

A structured extraction template was applied to each study, capturing:

- Transparency definition and theoretical framing.
- Name and structure of evaluation framework or method.
- Metric type (e.g., checklist, score, index, rating, qualitative, survey, explainability-based).
- Metric calculation type (e.g., single score, ordinal classification, aggregated, scenario-based).
- Sector or domain of application.
- Alignment with legal or ethical frameworks (e.g., GDPR, EU AI Act).
- Reported strengths and limitations.

Metrics were classified using a two-dimensional taxonomy: metric type and calculation type. Where multiple techniques

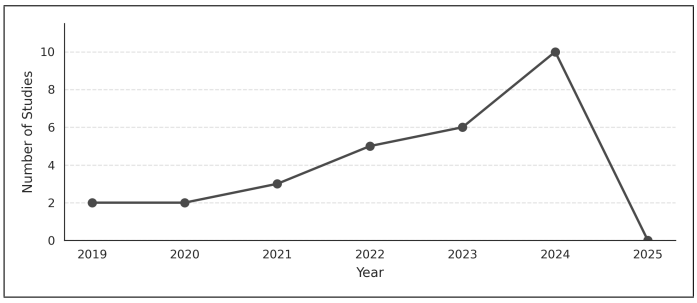

Fig. 2. Included studies per year (2019-2025; cut-off July 2025), n=28.

were reported, the dominant method was selected based on its evaluative function.

1) Data management: Extracted variables were recorded in a Microsoft Excel workbook, which constitutes the coded analytic dataset used for the descriptive analyses and quality appraisal.

2) Dataset: No experimental or task datasets were analysed. The only data used in this study are the 28 included papers (2019-July 2025) and the coded Excel extraction sheet derived from them. The Excel sheet will be made available upon request.

G. Thematic Analysis

Thematic synthesis followed Braun and Clarke's method [18]. Codes were generated from extracted data fields and grouped inductively into higher-level themes. These themes reflect patterns in how transparency is conceptualised and evaluated across the selected studies. The analysis served to uncover recurrent gaps and identify emerging evaluation practices.

H. Limitations

Several limitations should be acknowledged. First, the review covered the period from January 2019 to July 2025 and focused on peer-reviewed English-language literature, excluding grey literature and non-English sources. Second, the quality assessment involved a degree of researcher judgment, particularly in borderline cases. Third, while metric types and calculation methods were standardised to support comparison, some hybrid approaches may not have been fully captured by this classification. Lastly, the inclusion criteria required that transparency be explicitly evaluated, which may have led to the exclusion of relevant studies where transparency was subsumed under broader constructs such as fairness or trustworthiness.

V. Results

This section presents the results of the systematic literature review, providing a descriptive overview of the selected studies, including the classification of evaluation methods, the distribution of metric types and calculation approaches, as well as the sectoral focus, implementation status, and references to relevant legal and ethical frameworks.

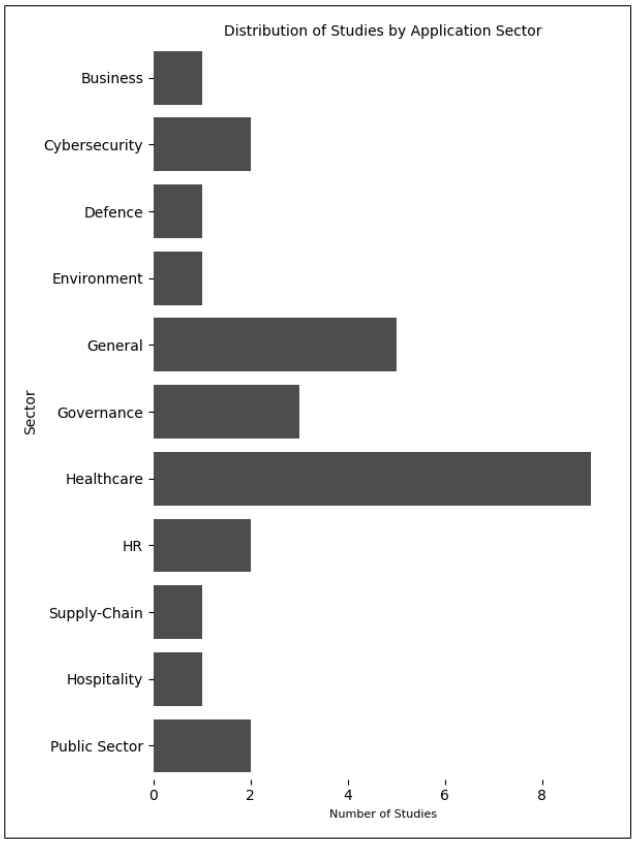

Fig. 3. Sector distribution of the 28 included studies; healthcare 9/28 (32%).

A. Overview of Included Studies

A total of 28 peer-reviewed studies published between January 2019 and July 2025 were selected for inclusion. The majority introduced formal frameworks or tools aimed at evaluating transparency in artificial intelligence systems, while a smaller subset proposed conceptual approaches grounded in governance or policy-oriented perspectives. In terms of application status, most of the studies (23 out of 28) applied their method to a real-world system, dataset, or use case. At the same time, the rest remained conceptual, theoretical, or exploratory in scope. See Fig. 2 for the year-by-year distribution.

The analysis revealed a notable concentration of transparency evaluation in the healthcare sector, with 9 of the 28 studies (32%) focusing on clinical decision support, medical imaging, or digital health systems [19], [20], [21], [4], [22], [23], [24], [25], [26]. Other studies proposed general-purpose frameworks or were situated in domains such as cybersecurity, HR, or public sector applications. A smaller number of studies addressed domains such as hospitality or defence. This sectoral imbalance highlights the strong regulatory and ethical pressures in healthcare, in contrast to more limited methodological development in other fields. See Fig. 3 for sectoral concentration.

B. Metric Types

The studies were categorised according to the type of metric or evaluation logic employed. Seven primary metric

types were identified:

- Checklist-based approaches operationalise transparency through binary questions or structured assessment lists. [27][19][28][25][29][30][17][31][20]
- Qualitative methods rely on expert judgement or narrative analysis. [21][4][32][33][34]
- Explainability-based evaluations assess transparency through interpretability outputs (e.g., SHAP, LIME). [35][36][37][38]
- Survey-based tools capture perceptions of transparency using structured questionnaires. [39][22][40][41]
- Index-based approaches produce composite scores or traceability indexes. [26][24][42]
- Score-based methods generate transparency scores by assigning weighted values to defined criteria. [43][23]
- Rating-based frameworks. [44]

Checklist-based approaches were the most common, often reflecting broader trends in AI governance tools such as the ALTAI framework [17].

C. Regulatory Alignment

References to legal and ethical frameworks were present in 19 of the 28 studies (67%) [19], [17], [31], [20], [4], [39], [22], [44], [33], [27], [34], [36], [42], [28], [24], [25], [38], [26], [29], most commonly the EU Artificial Intelligence Act, the General Data Protection Regulation (GDPR), and the AI HLEG Guidelines. However, only a few studies provided traceable mappings between evaluation criteria and specific legal provisions. For instance, RETENTION [26] and POLARIS [28] embedded elements of the EU AI Act [2] and AI HLEG recommendations [17] within their structure. In the majority of cases, alignment remained high-level or aspirational, with limited support for formal compliance, certification, or auditability.

D. Quality Assessment

Across the 28 studies, the overall quality was high, with most achieving at least 70% of the maximum possible score (see Table II). Several studies attained full or nearly full scores, while others performed lower due to conceptual or preliminary scope.

Specifically, QCA1 (evaluation method outlined) scored the highest, achieving 96.4% of the maximum score. This outcome was expected, as the presence of an explicitly described transparency evaluation method was a prerequisite for inclusion during the full-text review. QCA3 (discussion of strengths and limitations) also performed strongly, with 94.6%. By contrast, QCA2 (specific criteria for transparency assessment) and QCA5 (use of real-world AI applications) achieved 76.8% each, indicating room for improvement in applying structured criteria and real-world validation. The lowest-performing criterion was QCA4 (comparison with other transparency frameworks), with only 46.4% of the maximum score, showing that relatively few studies benchmarked their approach against other methods.

As shown in Table II, studies with higher total scores were typically more detailed, provided stronger methodological justification, and included real-world applications. In contrast, lower-scoring studies tended to be more conceptual or exploratory. These quality assessment results guided the interpretation of the final analysis, following best practices from prior systematic reviews (e.g., [14]), and support a nuanced discussion of strengths and limitations reported in Section Thematic Analysis.

VI. Thematic Analysis

This section presents the thematic analysis of the 28 studies included in the review. The analysis identified six overarching themes that characterise how transparency is defined, operationalised, and evaluated in artificial intelligence systems. These themes reflect both recurring strengths and persistent limitations across the literature.

A. Theme 1: Transparency as a Multi-Dimensional Construct

A consistent finding across the reviewed studies is the conceptualisation of transparency as a composite of multiple, interrelated dimensions. This mirrors the influential framing of the High-Level Expert Group on AI, which identified transparency, encompassing traceability, explainability, and communication, as one of the seven key requirements for Trustworthy AI [1]. These three pillars provided an early normative anchor and were frequently echoed, either explicitly or implicitly, in the SLR dataset.

Traceability concerns the documentation, logging, and oversight of system development, data flows, and decision-making processes, enabling stakeholders to follow and verify AI behaviour across its lifecycle. Explainability focuses on the interpretability of models or outputs, employing techniques such as SHAP, LIME, or saliency maps to make system reasoning intelligible. Communication refers to the disclosure of relevant information to users, regulators, or affected individuals in ways that are accessible, usable, and contextually appropriate.

While most studies referenced all three pillars, few operationalised them in an integrated manner. For example, IntelliLung [24], RETENTION [26], and SMACTR [30] explicitly combined traceability mechanisms, explainability techniques, and user-facing communication strategies within a single evaluation framework. In contrast, most approaches prioritised one or two dimensions, with communication often underdeveloped or absent. This imbalance reflects a gap in translating high-level principles into holistic evaluation designs.

This multi-dimensional perspective aligns closely with the stakeholder-centred framework of Ofem et al. [16], where

TABLE II. QUALITY ASSESSMENT RESULTS FOR INCLUDED STUDIES (N=28)

transparency is linked to quality factors such as accessibility, usability, and understandability. Mapping the three pillars to these factors revealed that traceability overlaps most strongly with accessibility and modifiability, explainability with understandability, and communication with accessibility and usability. This mapping provides a bridge between AI ethics discourse and measurable software engineering practices.

In the context of this SLR, the prevalence of these three pillars directly addresses RQ1 (existing approaches to transparency evaluation) by highlighting their role as foundational building blocks. However, their uneven treatment across studies also informs RQ3 (strengths, limitations, and gaps), underscoring the need for integrated approaches that treat traceability, explainability, and communication as mutually reinforcing rather than isolated components.

B. Theme 2: Dominance of Checklists and Qualitative Methods

Across the 28 included studies, checklist-based approaches were the single most common way to evaluate transparency (*9/28; 32%*) [27], [19], [28], [25], [29], [30], [17], [31], [20], followed by scenario-based qualitative assessments (*5/28; 18%*) [21], [4], [32], [33], [34]. Explainability-output-driven evaluations (e.g., using SHAP/LIME artefacts) and survey instruments each appeared in *4/28* studies (*14%* apiece), while index-style composites were less frequent (*3/28; 11%*). Score-style metrics were rare (*2/28; 7%*), and explicit rating-scale schemes appeared only once (*1/28; 4%*).[1]

This pattern is consistent with the field's reliance on governance-aligned checklists (e.g., ALTAI-inspired instruments) and structured internal-audit playbooks (e.g., SMACTR; POLARIS; MLOps audit catalogues), which are accessible and broadly usable across domains [17], [30], [28], [25]. However, checklist implementations showed variable methodological quality in our review: while many were robust, some scored lower on our quality assessment (e.g., overall study QA scores in the 2.5-4.5 range), and, critically, few offered granular scoring, maturity levels, or CI/CD-friendly automation. In short, they structure the conversation, but they rarely quantify transparency in a way that is reproducible or benchmarkable across settings.

Significant counterexamples highlight how quantification can evolve. The Visibility Index Score (VIS) adapts supply-chain "visibility" logic to AI pipelines, scoring documentation quantity, freshness, and accuracy [43]. The Cyrus framework automates parts of transparency evaluation via FAIR-aligned metadata and linked-data quality tooling [23]. Both illustrate promising routes toward measurable, repeatable assessments—yet each remains bounded by domain and artefact conventions (VIS by reviewer judgment; Cyrus by metadata-rich, RDF/FAIR contexts). These limits inform our subsequent design choices: transitioning from static checklists to artefact-level metadata, evaluation linkages, and scorecard-driven gap closure that remain lightweight enough for real-world projects.

[1]These tallies refer to the dominant metric type per study when hybrids were present.

C. Theme 3: Limited Stakeholder and User Involvement

A striking gap in the reviewed literature is the limited inclusion of stakeholders, especially end-users, in the design, execution, and validation of transparency evaluations. Only a minority of studies (*6/28; 21%*) explicitly incorporated stakeholder perspectives into their methods, typically via structured interviews, surveys, or participatory workshops. Examples include IntelliLung [24], which involved clinicians to identify the most relevant artefacts and interpretability measures in a clinical decision-support context, and the ALTAI-inspired sectoral adaptations [27], [25], which consulted domain experts to weight checklist items. However, these engagements were generally one-off and did not establish feedback loops to iteratively refine the evaluation over the AI system lifecycle.

Despite regulatory emphasis on transparency being understandable to affected persons [2], only a small number of studies incorporate user perspectives into their evaluation frameworks. FAT-CAT [40] and the survey-based method by Fehr et al. [22] are exceptions, explicitly including perceptions of transparency, trust, and understanding in their measurement schemes.

A significant outlier to the lack of continuous stakeholder engagement is the Z-Inspection® Framework [4], which embeds a structured feedback loop across its Set-Up, Assess, and Resolve phases. While the stakeholders involved are often domain experts, project partners, or regulators rather than the ultimate end-users, the framework ensures that transparency requirements are revisited and refined after scenario analysis and ethical issue mapping, and that unresolved gaps feed into improvement actions. This iterative design demonstrates how multi-phase engagement can be operationalised, even if end-user representation remains limited.

From a software engineering perspective, the omission of such feedback mechanisms in most studies conflicts with stakeholder-driven models such as Ofem et al.'s transparency framework [16], which positions stakeholder requirements as the starting point for defining quality factors and associated metrics. Without ongoing stakeholder input, whether from end-users or intermediary stakeholders, transparency evaluations risk being misaligned with the information needs, literacy levels, and contextual constraints of those most affected by AI systems.

In relation to our research questions, this theme directly addresses RQ2 (how key transparency concerns are addressed) by showing that while stakeholder relevance is widely recognised in principle, it is rarely operationalised in a structured and continuous manner. It also informs RQ3 (strengths, limitations, and gaps), identifying the lack of sustained, multi-phase stakeholder participation as a significant limitation in current transparency evaluation practice.

D. Theme 4: Sectoral Concentration in Healthcare

Healthcare emerged as the dominant application domain for transparency evaluation frameworks in our SLR, with **9/28** studies (**32%**) focusing exclusively on medical AI systems. These ranged from diagnostic imaging and clinical decision-support tools to patient-facing health applications[19], [20], [21], [4], [22], [23], [24], [25], [26].

The concentration reflects healthcare's high regulatory scrutiny, established ethical oversight mechanisms, and the availability of structured artefacts such as clinical guidelines, audit logs, and model validation reports.

Relevant examples include IntelliLung [24], which applied an integrated traceability, explainability, and communication framework to assess an AI system for lung disease diagnosis, and RETENTION [26], which evaluated an AI tool for predicting patient readmission risks. Both demonstrated the feasibility of combining multiple transparency pillars with sector-specific artefacts and metrics, benefiting from healthcare's pre-existing documentation and audit cultures.

In contrast, sectors such as finance, transportation, and public administration were underrepresented, with most non-healthcare cases relying on adapted checklists (e.g., ALTAI) or scenario-based ethical assessments. These domains often lack the same level of artefact maturity or regulatory compulsion, resulting in evaluations that are either less comprehensive or highly context-dependent.

This imbalance has implications for RQ4 (applicability in real-world AI systems). While healthcare-focused frameworks offer valuable methodological depth, their artefact-rich environment may not translate directly to sectors where documentation practices are less formalised. For cross-sector applicability, transparency evaluation methods must adapt to different artefact availability, stakeholder profiles, and regulatory drivers without sacrificing rigour. This supports the need, identified in RQ3, for domain-flexible frameworks that can scale from artefact-rich to artefact-sparse environments.

E. Theme 5: Partial and Informal Regulatory Alignment

Many transparency evaluation approaches in the reviewed studies reference regulatory or ethical frameworks, most commonly the EU AI Act, the AI HLEG Ethics Guidelines for Trustworthy AI, or sector-specific standards. However, in *20/28* studies (*71%*), this alignment was *partial* or *informal*: regulatory documents were cited as conceptual anchors, but their specific obligations were not systematically translated into evaluation criteria or metrics.

For example, several healthcare-focused studies mapped their checklists to the AI HLEG requirements [17] or to medical device regulations, but did not provide a traceable mapping between regulatory clauses (e.g., EU AI Act Article 13 obligations for high-risk systems) and the artefacts or scores used in their evaluations. Similarly, frameworks such as ALTAI were adapted to specific organisational contexts without maintaining the whole structure or weighting defined in the original.

Only a small subset of studies (*4/28; 14%*) achieved strong formal alignment by creating explicit mappings from regulatory text to artefacts, evaluation metrics, and scoring logic. Examples include RETENTION [26] and POLARIS [28]. These approaches demonstrated clearer audit readiness and traceability of compliance claims but required significant up-front investment in legal-technical translation.

In relation to our research questions, this theme informs both RQ2 (how key transparency concerns are addressed) and RQ3 (strengths, limitations, and gaps). It shows that while

regulatory references are widespread, operationalisation into concrete, verifiable measures is inconsistent. This gap highlights the importance of evaluation frameworks that integrate regulatory requirements directly into artefact-metric mappings, allowing for compliance checks alongside broader ethical evaluations.

F. Theme 6: Gaps in Standardisation and Lifecycle Integration

A recurring limitation across the reviewed studies is the lack of standardisation in how transparency is defined, measured, and maintained over an AI system's lifecycle. Even when similar terminology is used (e.g., "traceability" or "model interpretability"), the underlying definitions, artefacts, and metrics vary considerably, making cross-study comparison and benchmarking difficult. This variability extends to the granularity of evaluation (system-level vs. component-level), the form of evidence accepted (qualitative descriptions vs. quantitative scores), and the frequency of assessment.

Lifecycle integration is also underdeveloped. Most frameworks focus on a single point-in-time evaluation, often predeployment or post-deployment, without mechanisms for reassessment as the system evolves. Continuous monitoring, when mentioned, was generally conceptual rather than operationalised through automated pipelines or version-controlled artefact registries.

A few exceptions, such as Cyrus [23], VIS [43], and Z-Inspection® [4], incorporate repeatable measurement processes and artefact tracking. In particular, Z-Inspection® embeds a structured feedback loop across its Set-Up, Assess, and Resolve phases, enabling transparency requirements to be revisited and refined in light of new evidence or system changes. While the involved stakeholders are typically domain experts or project partners rather than end-users, this lifecycle-aware design demonstrates how continuous evaluation can be operationalised in practice.

A number of studies also reported unintended consequences of transparency practices. For instance, Lee et al. [40] noted increased user anxiety when information was disclosed without sufficient context, while Fehr et al. [22] highlighted concerns from developers regarding the exposure of proprietary information. These findings illustrate the need to balance transparency with usability, commercial confidentiality, and cognitive burden, ensuring that lifecycle-integrated evaluations do not inadvertently reduce user trust or hinder adoption.

This theme directly addresses RQ3 (strengths, limitations, and gaps) by identifying the absence of standardised definitions and cross-domain benchmarks, and RQ4 (applicability in real-world AI contexts) by showing that without lifecycle integration, transparency evaluation risks becoming a compliance snapshot rather than an ongoing governance practice. The findings support the need for artefact-driven, metadata-based approaches that can be embedded into development workflows, enabling continuous, comparable, and stakeholder-relevant transparency evaluation.

VII. Discussion

This section synthesises the key findings of the review in relation to the four research questions. It reflects on the strengths and limitations of current transparency evaluation practices in artificial intelligence, highlights existing gaps, and considers implications for future research and practice.

A. RQ1: Existing Approaches to Transparency Evaluation

Many studies introduced formal instruments such as ALTAI [17], POLARIS [28], and RETENTION [26], which aim to structure transparency evaluation through checklists or composite scoring. Others, like Z-Inspection® [4], offer qualitative, scenario-based frameworks grounded in ethical deliberation and stakeholder reflection. While these approaches enhance contextual sensitivity, they do not offer quantitative scoring or automation features.

Collectively, they reflect a growing recognition of the need to move beyond abstract principles and towards operational methods. Despite this progress, a clear pattern emerged: the majority of studies adopt qualitative or semi-structured methods, with limited attention to scoring granularity, automation, or lifecycle integration. Checklist-based approaches remain dominant but are often used without weighting, maturity models, or replicable metrics. Few studies propose evaluation instruments that can be implemented at scale or embedded into technical workflows.

B. RQ2: How Key Transparency Concerns are Addressed

Thematic analysis indicates that transparency is predominantly conceptualised as a multi-dimensional construct encompassing traceability, explainability, and communication. While most studies address at least one of these pillars, only a limited number propose integrated frameworks that operationalise all three in a cohesive manner.

Traceability and explainability are the most frequently addressed dimensions, commonly through system documentation, model-level interpretation methods, or audit trails. In contrast, communication, especially toward non-technical users or impacted stakeholders, remains significantly underdeveloped across the literature.

Although many frameworks reference values such as trust, usability, or ethical alignment, only a minority explicitly incorporate stakeholder or end-user perspectives in the evaluation process. Notable exceptions include the FAT-CAT framework [40] and the transparency survey developed by Fehr et al. [22], both of which engage user feedback more directly. However, such examples remain rare.

This highlights a persistent gap between the normative emphasis on stakeholder-centred transparency and the current reality of system- or expert-centric evaluation practices. Most frameworks still prioritise internal validation or technical explainability over participatory or communicative transparency mechanisms.

C. RQ3: Strengths, Limitations, and Gaps

Several strengths can be observed in the reviewed literature. First, there is increasing convergence around the idea that transparency must be evaluable, not merely aspirational. Second, the inclusion of sector-specific indicators, particularly in healthcare, demonstrates the potential for contextual adaptation. Third, some studies have made significant strides

in mapping transparency to legal or ethical requirements. Nonetheless, persistent limitations were identified:

- Over-reliance on checklists and qualitative assessments, with limited support for scoring, automation, or benchmarking.
- Lack of standardised frameworks or maturity models for transparency.
- Limited stakeholder inclusion, especially in the evaluation of communication clarity or user understanding.
- Inconsistent treatment of lifecycle phases, with transparency often evaluated only at the design stage or after.
- Conceptual conflation between transparency, explainability, and related constructs.

These limitations mirror concerns raised in prior literature. For instance, Mittelstadt et al. [45] warned against ambiguity in transparency definitions, arguing that a lack of clarity undermines both the interpretability of AI systems and the accountability of their developers.

D. RQ4: Applicability in Real-World AI Contexts

Of the 28 studies reviewed, 23 (82%) [43], [30], [41], [31], [21], [4], [39], [22], [23], [44], [40], [35], [33], [27], [34], [36], [37], [28], [24], [25], [38], [26], [29] were applied in real-world contexts, suggesting a growing emphasis on empirical validation. These included pilot implementations, case studies, and evaluations of deployed systems, particularly in healthcare and cybersecurity domains. However, even among applied studies, evaluation methods often lacked formal mechanisms for compliance verification, stakeholder feedback loops, or documentation updates over time. Moreover, the strong concentration of studies in healthcare raises questions about generalisability. While medical AI offers a high-risk, high-regulation testbed, other domains, such as education, employment, or defence, are underexplored. This suggests that many existing frameworks may not yet be transferable to broader or less-regulated contexts.

E. Additional Observations and Future Trends

Emerging findings suggest that increased transparency can paradoxically raise user anxiety or cognitive burden, as demonstrated by Lee et al. [40]. Furthermore, several studies highlight the potential need for transparency toolkits, particularly for SMEs, to operationalise legal requirements in accessible ways. Concepts such as real-time AI dashboards ('AI cockpits') [33] or safe harbour mechanisms [31] also represent future directions worth exploring.

F. Synthesis and Implications for Future Research

Taken together, the findings highlight both progress and persistent gaps in the operationalisation of transparency in AI systems. While concrete evaluation methods are emerging, their diversity in scope, terminology, and measurement approaches underscores a lack of standardisation that complicates benchmarking across domains.

1) Fragmentation and standardisation challenges: Similar concepts, such as traceability or interpretability, are often operationalised differently, with artefacts ranging from checklists and surveys to explainability-based metrics. This fragmentation limits cross-domain comparability and reinforces the need for adaptable yet standardised schemes.

2) Lifecycle integration and sustainability: Most methods assess transparency only at discrete points, making it a compliance "snapshot" rather than an ongoing governance practice. Exceptions such as Cyrus and VIS point to lifecycle-aware approaches, but these remain isolated and not widely adopted.

3) Stakeholder perspectives and unintended consequences: Few studies systematically include user perspectives. Where they do, such as FAT-CAT [40] or Fehr et al. [22], results show both benefits and unintended consequences (e.g., increased anxiety when disclosure lacks context, or concerns about exposing proprietary information). This underscores the tension between usability, confidentiality, and cognitive burden.

4) Quality assessment insights: The quality assessment (QCA1-QCA5) provides additional perspective. While QCA1 (clarity of evaluation method) and QCA3 (discussion of strengths and limitations) scored highly (over 90%), QCA4 (comparison with other frameworks) was much weaker at 46.4%. As a result, transparency evaluation remains fragmented and difficult to contextualise, undermining comparability across sectors.

5) Bridging ethics and engineering: The three-pillar framing of traceability, explainability, and communication, first articulated by the AI HLEG [1], offers a conceptual anchor. Mapping these pillars to quality factors from software engineering (e.g., accessibility, usability, understandability) suggests a bridge between high-level ethical principles and measurable lifecycle practices.

Beyond these priorities, the review highlights an overarching limitation: the lack of artefact-driven methods capable of embedding transparency evaluation into day-to-day development workflows. Existing frameworks rarely provide mechanisms for capturing, standardising, and reusing transparency artefacts across system versions and contexts. This is a critical gap given the need for reproducibility, comparability, and regulatory accountability in real-world AI applications.

Addressing this limitation directly informed our subsequent work—a companion paper, which extends the Z-Inspection® process within the MANOLO context by proposing a Transparency Artefact Registry. TAR operationalises the insights of this SLR by offering a structured, metadata-based approach for cataloguing transparency artefacts, linking them to stakeholder requirements, and supporting continuous lifecycle evaluation. In doing so, it aims to provide researchers, practitioners, and regulators with a verifiable and repeatable mechanism for demonstrating transparency in line with European regulatory and ethical standards.

6) Design implications: The deficits identified map to an artefact-driven remediation. Missing standardisation calls

for a minimal metadata schema that normalises transparency artefacts across projects. Weak lifecycle integration requires a versioned registry that tracks artefacts across releases and updates. Informal regulatory alignment is addressed by explicit field-level mappings from artefacts to EU AI Act obligations (e.g., Article 13 on traceability and user information). Limited stakeholder inclusion is realised by tagging artefacts with stakeholder roles and providing communication-ready views. These elements motivate the TAR and align with Z-Inspection®.

Ultimately, transparency should not be treated as a static artefact or the outcome of a checklist, but as a dynamic, context-sensitive, and stakeholder-driven attribute that must be continuously embedded throughout the AI system development lifecycle.

VIII. Conclusion

This paper has presented an SLR of 28 peer-reviewed studies on transparency evaluation in artificial intelligence systems. The analysis revealed that while transparency is widely recognised as a requirement for trustworthy and accountable AI, current evaluation methods remain fragmented. Most approaches rely on qualitative checklists or scenario-based assessments, with limited support for scoring, standardisation, or lifecycle integration. Stakeholder involvement, particularly from end-users, is still rare. In particular, the communication dimension of transparency, meaning the disclosure and presentation of information about AI systems to users, regulators, and other stakeholders in accessible and understandable ways, remains underdeveloped compared to traceability and explainability.

Despite these limitations, the review identified encouraging trends. Several studies successfully link transparency evaluation to regulatory or ethical requirements, others adapt sector-specific indicators (notably in healthcare), and a minority demonstrate mechanisms for empirical validation in real-world systems. Together, these works mark a gradual shift from aspirational principles to operational practices.

At the same time, persistent gaps were observed: the lack of shared taxonomies and maturity models, insufficient mechanisms for continuous evaluation across the AI lifecycle, and the absence of artefact-driven methods for capturing and reusing transparency evidence. These findings highlight both the strengths of current approaches and the need for more systematic, repeatable, and scalable solutions.

The results of this review directly inform our subsequent work within the context of the MANOLO project, where we extend the Z-Inspection® Framework with a Transparency Artefact Registry (TAR). By cataloguing transparency artefacts through structured metadata and linking them to stakeholder requirements and regulatory obligations, TAR provides a practical means of addressing the limitations identified in this review. In this way, the SLR serves as both a state-of-the-art assessment and the conceptual foundation for developing artefact-based mechanisms that enable transparency to be continuously evaluated and demonstrably aligned with the EU AI Act.

In sum, transparency evaluation is moving from principle to practice but remains methodologically fragmented and weakly grounded across the AI lifecycle. Closing this gap requires standardised taxonomies, comparable metrics, and evidence-bearing artefacts embedded in development and compliance workflows.

Future research should therefore focus on refining such artefact-driven approaches, testing their applicability across domains beyond healthcare, and ensuring that stakeholder perspectives are integrated in a sustained and iterative manner. Only by embedding transparency throughout the lifecycle of AI systems can it become a verifiable attribute of trustworthy AI rather than a static aspiration.

Acknowledgment

Auditable Real-Time Cold-Chain Monitoring with IoT and Blockchain Anchoring

Mohamed DOUBIZ[1], Mouad BANANE[2], Abdelali ZAKRANI[3], Allae ERRAISSI[4]
Laboratory of Artificial Intelligence-Modeling and Computational Engineering, Hassan II University, Morocco[1,2,3]
Chouaib Doukkali University, El Jadida, Morocco[4]

***Abstract*—Safe vaccine storage hinges on continuous, trustworthy temperature supervision and evidence that records have not been altered. Yet many cold rooms still rely on fragmented logging tools that lack real-time alerts, end-to-end traceability, and audit-ready data. This paper presents a practical, low-cost architecture that integrates Internet of Things (IoT) sensing with blockchain anchoring to deliver real-time monitoring and visibility, reliable anomaly detection, and tamper-evident provenance for cold-chain storage. The design couples minute-level telemetry and dashboarding with alert debouncing/hysteresis to reduce false alarms, while anchoring hourly summaries and event alerts on-chain to create a verifiable trail without exposing raw data or incurring recurring fees during experimentation. A prototype in a vaccine cold-room scenario demonstrates that the approach is simple to deploy on commodity hardware, scales by adding rooms/sensors, and produces operator-friendly notifications alongside independently verifiable records. This combination of edge retention and cryptographic anchoring provides a pragmatic path for pharmacies, clinics, and warehouses to upgrade from basic loggers to transparent, audit-ready monitoring, bridging operational needs (alerts) and compliance needs (provenance) in one system.**

***Keywords*—Internet of Things; blockchain; cold chain; vaccine storage; real-time monitoring; tamper-evident; data provenance; traceability**

I. Introduction

In 2021, Morocco ordered over 60 million doses of COVID-19 vaccines from Sinopharm, Sinovac, and AstraZeneca [1]. Maintaining these vaccines between 2 °C and 8 °C remains a major logistical challenge, particularly in constrained environments. The COVID-19 pandemic made this clear at scale: unprecedented volumes moved in just-in-time flows among manufacturers, carriers, regional warehouses, vaccination centers, and mobile units, with each link responsible for continuous temperature monitoring and shared traceability. Some vaccines, such as Pfizer-BioNTech, required ultra-cold storage (−90 °C to −60 °C) upstream and, after thawing, allowed storage between 2 °C and 8 °C for up to 10 weeks [2], multiplying the thermal-regime transitions that had to be controlled and attested at every hand-off.

This complexity strengthened the demand for end-to-end traceability and tamper-evident records of thermal excursions; several studies therefore proposed IoT-plus-blockchain architectures to record, anchor, and share readings among stakeholders, with the promise of better combating counterfeiting and disputes [3] [4].

However, most existing proposals suffer from at least two limitations: high integration and operating costs (proprietary hardware, cloud services, transaction fees); and a lack of end-to-end evaluations showing how to reconcile continuous monitoring with tamper-evident anchoring at low cost.

This article addresses that gap by presenting and experimentally evaluating a low-cost IoT–blockchain integration architecture for a vaccine cold room. We ask: how can real-time supervision, immediate anomaly detection, and a verifiable proof of integrity be ensured while minimizing operational complexity and cost?

Our hypothesis is that the decoupling rates (fine-grained acquisition with parsimonious anchoring) combined with completeness control can achieve this objective.

Our contributions are as follows.

- An end-to-end prototype built from standard components and open-source building blocks: DS18B20 sensor → ESP8266 (NodeMCU) → MQTT (Mosquitto on Raspberry Pi 4).
- A Python collector (venv) logs measurements, triggers alerts if T < 2 °C or T > 8 °C (Telegram + on-chain event), and anchors an hourly statistical summary to the blockchain (number of samples, min/max/mean temperature, CSV hash).
- A frugal anchoring scheme: sampling is performed every minute (expected: 60 readings/hour), while on-chain anchoring is hourly via a smart contract (anchoring & alerts) on a local Ethereum node (geth, dev mode), eliminating transaction fees during trials. A completeness watchdog flags any hour with fewer than 60 readings (sensor, network, or logging loss).
- Alerting and Visualization Chain: Telegram immediately notifies threshold breaches and each hourly commit (count, min, max, mean, hash).
- A Node-RED dashboard provides live monitoring (gauge + time series) with set-point lines (2 °C/8 °C) and device online/offline status.

Organization Section II surveys related work on IoT–blockchain for the cold chain. Section III details the materials and methods (sensors, MQTT, Python collector, smart contract), including the alerting protocol, hourly anchoring, and the completeness watchdog. Section IV presents the results

and evaluation, including a comparison with representative approaches. Section V discusses limitations and extensions. Section VI concludes.

II. Literature Review

Digital vaccine supply chains (DVSCs) increasingly adopt sensing, connectivity, and data systems to monitor vaccines end-to-end and strengthen resilience [5]. Persistent quality and access gaps in resource-constrained contexts motivate pragmatic storage and distribution solutions that fit local constraints [6]. During COVID-19, large-scale social-media analytics further highlighted operational bottlenecks across logistics [7], [8]. Together, these streams justify lightweight, field-deployable *continuous* monitoring coupled with *tamper-evident* record-keeping as a practical research target.

Within healthcare, the Internet of Things (IoT) has progressed from pilots to domain applications; recent edited volumes synthesize IoT-blockchain convergence patterns, use cases, and architectural considerations [9], [10], [11]. For regulated cold-chain products such as vaccines, raw telemetry is insufficient without trustworthy context: integrity, provenance, and traceability are required to transform temperature streams into audit-ready evidence. Surveys of blockchain-based decentralized trust for IoT conclude that distributed ledgers offer tamper-resistant logs and programmable workflows (smart contracts), while emphasizing throughput, latency, and privacy trade-offs that guide design-to-cost choices [12].

From a supply-chain perspective, engineering-management work documents transparency and governance benefits of blockchain alongside adoption and interoperability barriers, issues that intensify when budgets and connectivity are limited [13]. Implementation studies show that permissioned frameworks (e.g., Hyperledger) can meet trust requirements at lower operational cost when value exchange is not the primary objective [14]. These insights motivate architectures that keep the blockchain surface minimal (hash anchoring / event notarization) while handling bulk telemetry off-chain—well aligned with a low-cost cold-room deployment.

Closer to medicine logistics, a blockchain-based traceability system for *cold-chain medicine logistics* demonstrates end-to-end traceability and automatic quality assessment with compact on-chain proofs and off-chain sensor data [15]. In the blood cold chain, analyses detail vulnerabilities (excursions, custody hand-offs, counterfeit risk) and argue for immutable, condition-aware traceability, directly analogous to vaccine storage and transport [16]. A vaccine-focused chapter surveys blockchain opportunities across the lifecycle (counterfeit mitigation, cold-chain compliance, smart-contract-based conformance) while noting scalability limits that favor minimalist, permissioned deployments [17].

Operations-research work on vaccine logistics consolidates objectives (wastage, service level, cost) and decision layers (facility, inventory, routing) and underlines the value of reliable, high-granularity data for calibration and evaluation [18]. In this sense, an IoT-blockchain stack is both a monitoring/compliance tool and a *data infrastructure*: continuous telemetry (IoT) anchored with immutable proofs (blockchain) yields decision-grade streams for control, alarms, and post-hoc audits. At the interface with public-facing technologies, scoping reviews of social media and digital tools in vaccination stress trustworthy records and transparent workflows for programs and communities, with blockchain among DVSC enablers [19].

Synthesis for the present work. Three design patterns consistently align with a cold-room experiment.

- Separation of concerns: retain high-rate temperature streams off-chain and anchor compact hashes/events on a permissioned ledger [12], [15], [16], [17];
- Programmable compliance: smart contracts for threshold alerts, excursion attestation, and custody milestones [12], [16], [17];
- Design-to-cost: lightweight nodes, batching, and cadence tuned to regulatory and network constraints typical of resource-limited settings [20], [6], [13], [14], [18], [19].

III. Materials and Methods

We built and operated a verifiable cold chain monitor for a pharmacy-grade chamber maintained between 2 °C and 8 °C. A waterproof DS18B20 probe, sampled by a NodeMCU ESP8266 every 60 s, publishes JSON over MQTT to a Raspberry Pi gateway connected via Wi-Fi (wlan0). On the Pi, a Python process ingests the stream, writes hour-aligned CSV files with milli-degree precision, and applies excursion detection with debounce and hysteresis. Immediate alerts and per-hour file-integrity digests (CSV SHA-256) are anchored on a local, feeless Geth developer chain; operators receive human-readable Telegram messages, and a Node-RED dashboard presents a live integer gauge plus a Temperature Evolution chart with fixed 2 °C and 8 °C reference lines. All parameters, file paths, and commands reported below mirror the deployed system, emphasizing reproducibility, auditability, and operational simplicity in resource-constrained settings (Fig.1).

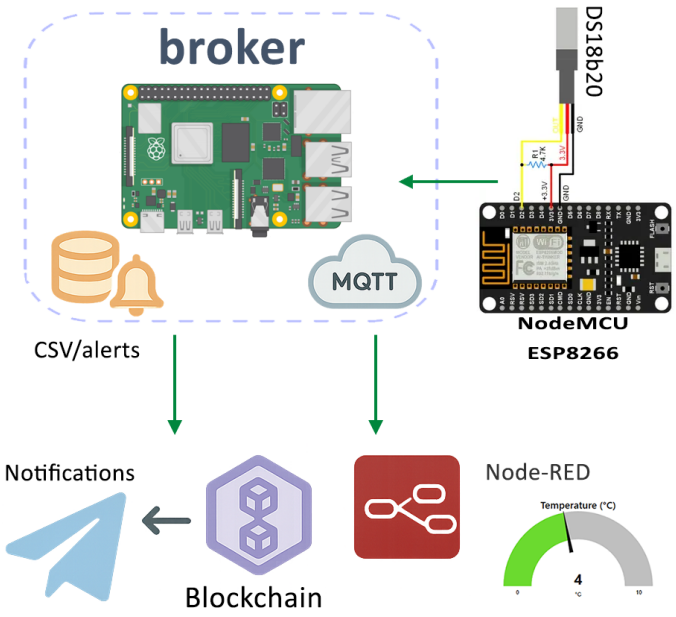

Fig. 1. Architecture: ESP8266 → MQTT → Pi monitor → CSV/alerts → on-chain → Telegram → Node-RED.

A. Hardware and Wiring (DS18B20 / ESP8266 / Raspberry Pi)

1) Cold room (process under control): The monitored environment whose air temperature must remain within 2 °C to 8 °C. It provides the real thermal dynamics (door openings, defrost cycles) against which the system is validated.

2) DS18B20 temperature probe (measurement): Digital 1-Wire thermometer (waterproof lead) that senses air temperature in the chamber. We placed the tip in the airflow, away from coils/doors to limit local bias. The resolution is fine enough for vaccine ranges; readings are consumed as is in this iteration (no correction applied).

4.7 KΩ pull-up (bus integrity). Keeps the 1-Wire data line idle-high and ensures reliable edges on long, thin leads.

3) NodeMCU ESP8266 V3 (sensor node & publisher):

a) Roles: powers the DS18B20 (3.3 V), polls it every 60 s, formats readings as JSON, and publishes via MQTT over Wi-Fi. It also maintains a retained liveness topic and a Last Will ("`offline`") for fault detection

b) What we store in each message: `temp_c` (float), `seq` (monotonic counter), and `ms` (`millis()`), which help the gateway spot gaps or reorders.

c) Why ESP8266: integrated 2.4 GHz Wi-Fi and very low BOM cost.

4) Raspberry Pi 4 (edge gateway & verifier):

- Roles: single-box aggregator on wlan0. It runs:
  - Mosquitto (MQTT broker) to receive ESP8266 messages,
  - our Python collector to append hour-aligned CSV, detect excursions (debounce + hysteresis), and compute SHA-256 digests,
  - Geth (dev mode) to anchor immediate alerts and hourly CSV integrity,
  - Telegram notifications, and
  - Node-RED dashboard (gauge + Temperature Evolution chart with 2 °C/ 8 °C reference lines).
- Networking: the Pi's wlan0 serves both the ESP8266 (same Wi-Fi) and Internet egress for Telegram.
- Wi-Fi access point/router (connectivity) Provides the WLAN where both ESP8266 and Pi's wlan0 are associated (DHCP + IP reachability). Internet access from this WLAN allows Telegram delivery.
- Power ESP8266 via stable 5 V USB (on-board 3.3 V regulator); Raspberry Pi via its PSU. A common ground exists between DS18B20 and ESP8266.
- Wiring we used
  - DS18B20 DATA → D2 (GPIO4) on ESP8266
  - DS18B20 VCC → 3.3 V, GND → GND
  - 4.7 KΩ resistor between DATA and 3.3 V.

B. Sensor Calibration

For this experiment we did not apply a numeric correction to the DS18B20. We performed a sanity check (ice-water bath $\approx 0\,^{\circ}\mathrm{C}$ and ambient $\approx 24\,^{\circ}\mathrm{C}$) and observed readings within the expected DS18B20 accuracy. Because the main objective was demonstrating the end-to-end chain (ingestion → detection → anchoring → notification), we accepted nominal accuracy and deferred formal calibration.

C. Firmware (Sampling, JSON, Topics, LWT)

File: `esp_ds18b20_mqtt.ino` (Arduino IDE).
Libraries: `ESP8266WiFi`, `PubSubClient`, `OneWire`, `DallasTemperature`.

- Sampling: every 60 s; the loop is non-blocking and calls `mqtt.loop()` continuously.
- JSON payload example:
  `{"temp_c": 5.500, "seq": 21, "ms": 1271041}`
  where `seq` increments per publish and `ms = millis()` assists drop/out-of-order detection
- Topics:
  - `coldchain/cold_room_1/status` (retained) → "`online`" at connect; LWT retained "`offline`".
  - `coldchain/cold_room_1/reading` (live) → readings (QoS 0)

D. Transport (MQTT): Broker, Auth, QoS, Tests

We ran Mosquitto on the Pi (listening on 0.0.0.0:1883 so the ESP8266 on Wi-Fi can connect).

- Auth: username/password (user `iotuser`, password stored in `/etc/mosquitto/passwd`).
- Config: `/etc / mosquitto / conf . d / coldchain.conf`
  with `allow_anonymous false`, persistence on, listener on `1883`.
- QoS: 0 to minimize latency; liveness comes from the retained `status`.
- Sanity tests we used repeatedly:

```
mosquitto_sub -h 127.0.0.1 -u iotuser -P
'********' -v -t 'coldchain/#'
mosquitto_pub -h 127.0.0.1 -u iotuser -P
'********' \  -t 'coldchain/cold_room_1/reading
' -m '{"temp_c":5.8,"seq":1,"ms":1000}'
```

E. Collector (CSV Windowing, Quality Policy, Timekeeping)

File: `/home/nuevomar/coldchain/monitor_from_mqtt_onchain.py` (Python 3.11 in a `.venv`). The process subscribes to `coldchain/+/reading` and `coldchain/+/status`, writes slot-based CSV archives, detects excursions, anchors integrity on-chain, and notifies Telegram. Runtime secrets (MQTT credentials, Telegram token, RPC URL) are loaded from `.env`.

Windowing → CSV: Readings are grouped into fixed slots of `SLOT_SECONDS`.

- Production profile: `SLOT_SECONDS = 3600` (one commit/hour).
- Lab profile: `SLOT_SECONDS = 60` (faster iteration).

CSV format: `iso_utc,epoch,temp_C,temp_mC`. We store milli-°C as integers to enable deterministic hashing.

Timekeeping: UTC timestamps from the Pi (NTP-synced). Slot boundaries aligned to the top of the hour in production.

Data quality: Outliers rejected if $|\Delta T/\Delta t| > 5\,^{\circ}\mathrm{C/min}$; missing/late samples recorded as `NaN` and excluded from averages, with `count` reflecting valid points. No smoothing (debounce/hysteresis covers noise).

Artifacts: hourly CSVs in `/var/log/coldchain/hourly/` and per-day alert logs in `/var/log/coldchain/alerts/`.

F. Alarm Logic (Band, Debounce, Hysteresis, Latency)

We enforced a $[2, 8]\,^{\circ}\mathrm{C}$ band with hysteresis and debounce:

- Thresholds: `LOW = 2.0 °C`, `HIGH = 8.0 °C`.
- Hysteresis: `HYST_MARGIN = 0.2 °C` ⇒ recovery band $[2.2, 7.8]\,^{\circ}\mathrm{C}$.
- Debounce: `DEBOUNCE_S = 180 s` (production); 30 s in lab.
- Events: `ALERT_START` after a sustained breach; `ALERT_END` after sustained recovery.
- Observed alert latency: $\approx 1.5-2$ min (lab profile, 60 s sampling / 30 s debounce) and $\approx 4-5$ min (production profile).

G. Blockchain Anchoring (Contract, Events, Schedule)

We used a local Geth developer chain (feeless, ephemeral) to anchor alerts and hourly CSV integrity.

Node startup used:

```
/usr/local/bin/geth --dev \
  --datadir /home/nuevomar/geth-dev \
  --http --http.addr 127.0.0.1 --http.port 8545 \
  --http.api eth,net,web3 --ipcdisable --dev.period 2
```

Contract: `ColdChainVax.sol` (deployed once). Artifacts persisted as `ColdChainVax.abi.json` and `ColdChainVax.address`.

Immediate anchoring (alerts): On `ALERT_START/END`, the collector called `submitReading(sensorId, epoch, temp_mC, kind)` with `sensorId = keccak256("cold_room_1")`, emitting an `Alert` event.

Periodic anchoring (per slot): The collector computed `(count, min, max, avg)` and the SHA-256 digest of the slot CSV, then emitted `HourCommitted(sensorId, slot, count, min_mC, max_mC, avg_mC, csvHash)`.

This yields tamper-evident on-chain proofs for alerts and per-hour CSV integrity while keeping full data off-chain.

H. Notifications (Telegram)

File: `/home/nuevomar/coldchain/notify.py` with `send_telegram(text)`; bot token and chat ID in `.env`.

Messages included:

```
[ALERT START] cold_room_1 2025-09-13T...Z T=...
 C (Above upper)
[CHAIN] submitReading tx: 0x...
[COMMIT] cold_room_1 slot=... count=... min=... max=...
avg=... hash=... tx=0x...
```

Using `wlan0` only, ensured outbound Telegram API access once Wi-Fi was up.

I. Visualization (Node-RED) + Reference-Line Configuration

We installed **Node-RED** with node-red-dashboard and built a single-tab dashboard:

- **Gauge** (°C): receives rounded integer values; Format `{{value | number:0}}`.
- **Temperature Evolution chart:** three series per measurement:
  - live temperature (`topic = cold_room_1`),
  - constant LOW line (`topic = LOW`, payload `2`),
  - constant HIGH line (`topic = HIGH`, payload `8`).
- The function node (two outputs) emits three messages to the chart and a rounded value to the gauge. Chart settings: Legend=ON, Use-one-color=OFF.

The flow is stored at `~/.node-red/flows_<hostname>.json`.

J. Security and Deployment (Secrets, Network, Persistence)

Secrets (`.env`) were set to file mode 0600 and not versioned; Telegram tokens were rotated as needed. MQTT required username/password; the broker listened on `0.0.0.0:1883` so the ESP8266 on the same Wi-Fi could reach it (TLS was not required on this isolated WLAN). Write access to `/var/log/coldchain/*` was restricted. We ran the collector as a single `systemd` unit (`coldchain-monitor-mqtt.service`) when needed to prevent multiple instances. CSV and alert logs persisted under

/var/log/coldchain; retention/backup can be handled with logrotate/rsync. (we preserved full logs during the experiment).

K. Software Versions and Reproducibility Commands

Environment we used As summarized in Table I, our deployment used commodity components and mainstream toolchains, which favors reproducibility.

TABLE I. SOFTWARE ENVIRONMENT USED IN THIS DEPLOYMENT

Layer	Component	Version / Notes
Hardware	Raspberry Pi	Pi 4, 64-bit OS
Firmware	ESP8266 Arduino core	3.x
Sensor libs	OneWire / DallasTemperature	2.x / 3.x
MQTT client	PubSubClient (ESP)	2.x
Messaging	Mosquitto	2.x (system pkg)
OS runtime	Python	3.11
Python pkgs	paho-mqtt / web3 / dotenv	1.6.x / 6.x / 1.x
Blockchain	Geth	v1.16.3 (-dev)
Smart contract	Solidity	0.8.20 (ABI/address persisted)
Node runtime	Node.js	v22.19.0
Edge app	Node-RED (+ dashboard)	3.x (+ node-red-dashboard 3.x)

Commands actually used:

```
# Python venv (+ deps)
cd /home/nuevomar/coldchain
python3 -m venv .venv && source .venv/bin/activate
pip install -U pip paho-mqtt web3 python-dotenv

# Start Geth dev (feeless, ephemeral)
mkdir -p /home/nuevomar/geth-dev
/usr/local/bin/geth --dev \
  --datadir /home/nuevomar/geth-dev \
  --http --http.addr 127.0.0.1 --http.port 8545 \
  --http.api eth,net,web3 --ipcdisable --dev.period 2

# Export runtime env (edit .env beforehand)
set -a; . ./.env; set +a
export RPC_URL=http://127.0.0.1:8545

# Run the monitor
python monitor_from_mqtt_onchain.py

# Check MQTT intake (during tests)
mosquitto_sub -h 127.0.0.1 -u iotuser -P '********' \
  -v -t 'coldchain/#'

# Inspect latest CSV & digest
LAST=$(ls -1t /var/log/coldchain/hourly/\
cold_room_1_*.csv | head -n1)
tail -n5 "$LAST"
sha256sum "$LAST" | cut -d' ' -f1
```

IV. RESULTS AND EVALUATION

A. Setup and Metrics

We sample once per minute (ESP8266→MQTT→Raspberry Pi), aggregate readings into fixed hour-aligned slots, and anchor both immediate alerts and per-slot integrity on chain. Two operating profiles were exercised: a *test profile* (debounce = 30 s) and a *production profile* (debounce = 180 s). We report alert latency (telemetry → alert emission), excursion statistics (count, total minutes out of band, median/P95 excursion duration), and integrity checks (on-chain digest vs. local CSV hash).

B. Network Observations and Mitigation (Wi-Fi → LAN)

During early trials on an isolated WLAN (MQTT QoS 0), we observed intermittent disconnections of the gateway interface (wlan0), visible as Last Will & Testament (LWT) toggles and short gaps in ingestion. Minor hiccups were absorbed by the collector's buffering, but multi-second drops inflated end-to-end alert latency and occasionally deferred Telegram delivery. To remove this confounder for the evaluation, we migrated the gateway to wired Ethernet (eth0); subsequent runs showed a stable 60 s cadence with no disconnects, while the anchoring logic and results remained unchanged.

C. Telemetry Ingestion Over Wi-Fi/MQTT

The ESP8266 (NodeMCU) published one DS18B20 measurement every 60 s over Wi-Fi to the Raspberry Pi Mosquitto broker (wlan0). The Python collector subscribed to coldchain/+/reading, persisted time-windowed CSV files, and computed per-slot statistics.

Minute-level telemetry and slot summary. In a representative one-hour window (slot 488279), we observe 60 samples at a stable 60 s cadence (median/P95 60 s/60 s). Temperatures range from 2.250 °C to 8.563 °C with a mean of 5.025 °C. Band compliance is 54 / 60 (90%) inside [2 °C, 8 °C]; 6 above 8 °C and 0 below 2 °C. The first out-of-range sample above 8 °C occurs at 2025-09-13T23:21:51Z; the last at 23:26:51Z (Fig. 2).

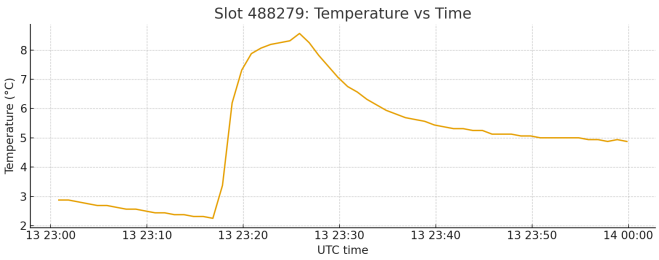

Fig. 2. Slot 488279 time series. The trace shows a brief excursion above 8 °C followed by recovery toward 5 °C.

For the representative slot 488279 (60 min window), we observe Table II:

TABLE II. SLOT 488279 SUMMARY

Rows	60
Sampling interval (median/P95)	60 s / 60 s
Min / Max / Avg	2.250 °C / 8.563 °C / 5.025 °C
Inside band [2 °C, 8 °C]	54 / 60 (90%)
Above 8 °C	6 / 60 (10%)
Below 2 °C	0 / 60 (0%)
CSV SHA-256	105c9c8...b0d49

D. Alarm Detection (2–8 °C Band; Debounce & Hysteresis)

Alerting behavior and latency. On 2025-09-13, the system detected 7 complete excursions (ALERT_START/END)

totaling 13 620 s out of range; median excursion 600 s, P95 6336 s. These timings align with the configured sampling and debounce: under the test profile (60 s sampling, 30 s debounce), end-to-end alert latency was ∼1.5–2 min; under production parameters, ∼4–5 min.

The collector enforced a 2 °C to 8 °C band with 0.2 °C hysteresis and a debounce window (test profile: 30 s; production: 180 s). A visual timeline of the `START` → `END` intervals appears in Fig. 3.

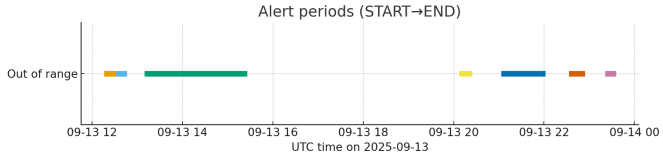

Fig. 3. Alert timeline on 2025-09-13 (START→END intervals).

E. On-Chain Anchoring (Devnet, Feeless)

We anchored both immediate alerts and slot integrity on a local Geth developer chain.

- **Alerts.** Each `ALERT_START/END` triggers `submitReading(sensorId, epoch, temp_mC, kind)`, emitting an `Alert` event; Telegram messages include the transaction hash (e.g., `[CHAIN] submitReading tx: 0xcbc8619c...`).
- **Hourly (slot) commits.** At the end of each slot we compute (count, min, max, avg) and the SHA-256 of the slot CSV and emit `HourCommitted(sensorId, slot, count, min_mC, max_mC, avg_mC, csvHash)`.

For slot 488279, the CSV file's digest exactly matches the on-chain `csvHash` reported in Telegram (`105c9c8...b0d49`), demonstrating reproducible integrity anchoring.

F. Human-in-the-Loop Notifications (Telegram)

The system delivered human-readable messages for `ALERT_START/END`, on-chain submissions, and per-slot commits. Once the Pi default route used `wlan0`, Telegram delivery was reliable. A representative excerpt is shown in Fig. 4, including an alert burst and two consecutive slot commits with their hashes and transaction IDs.

G. Visualization (Node-RED)

The dashboard (Fig. 5) presents an integer gauge and a Temperature Evolution Chart with continuous reference lines at 2 °C and 8 °C. Transient excursions and recovery dynamics are clearly visible; retained MQTT `status` reflects sensor liveness.

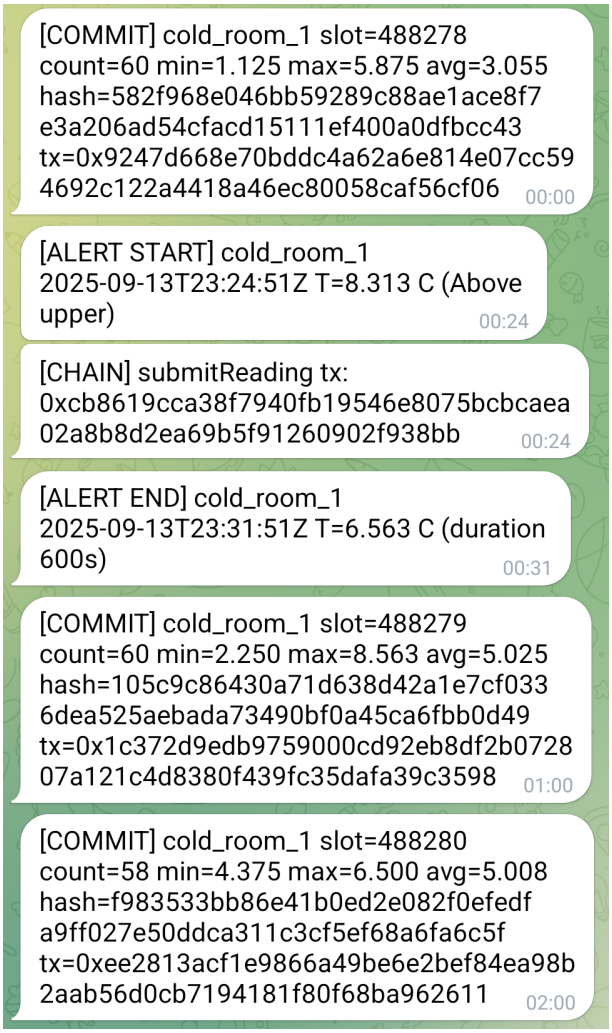

Fig. 4. Telegram excerpt showing an alert, the corresponding on-chain transaction, and per-slot commits with SHA-256 hashes.

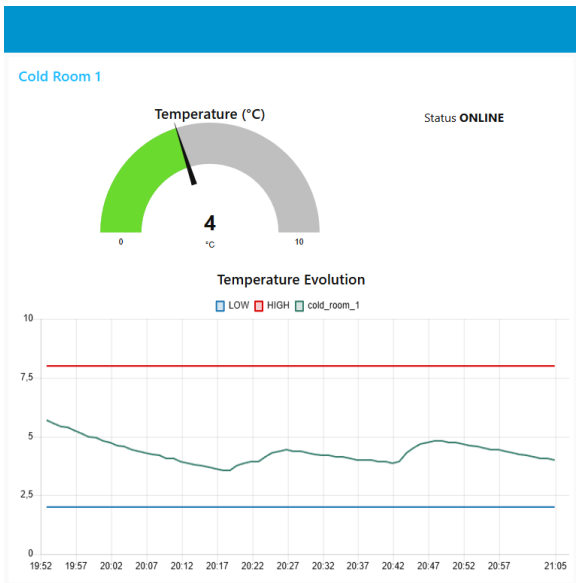

Fig. 5. Node-RED dashboard.

H. System Stability and Resource Use

On a Raspberry Pi 4, the stack (Mosquitto + Python collector + Node-RED + Geth dev) ran comfortably. Mosquitto and the collector exhibited low, bursty CPU at 1 msg/min; Geth's `-dev.period 2 s` caused modest periodic CPU spikes. After configuration stabilized, no restarts were required; a single systemd unit prevented concurrent collectors.

I. Integrity Verification Spot-Checks

We verified that:

- `sha256sum` of the slot CSV equals the on-chain `csvHash`;
- `eth_getTransactionReceipt` + ABI decoding reproduces `Alert` parameters;
- slot statistics `(count/min/max/avg)` recompute from the CSV and match the values posted on chain.

J. Slot Statistics

We partition the stream into fixed, hour-aligned slots ($\Delta_{\text{slot}} = 60\,\text{min}$). For slot 488279, we observe $N_s = 60$ records, median/P95 sampling interval 60 s/60 s, and temperatures in [2.250 °C, 8.563 °C] with a mean of 5.025 °C. Band compliance is 90% inside [2 °C, 8 °C], with 10% above 8 °C. The CSV's SHA-256 digest matches the on-chain `csvHash`, enabling independent verification of the stored file's integrity. Beyond per-slot completeness, we summarize anchoring regularity via inter-anchor intervals and report $p50/p90/p99$ when available.

K. Comparison with Representative Approaches

We contrast our decoupled design with two baselines used in the literature: continuous on-chain logging and batch-only notarization. The Table III is qualitative and highlights the trade-offs reviewers asked to see.

TABLE III. QUALITATIVE COMPARISON WITH REPRESENTATIVE BASELINES

Approach	Characteristics (from our deployment and standard baselines)
Continuous on-chain logging	Per-sample transactions; strong auditability but high transaction volume and on-chain data exposure; alerting often gated by confirmation time; cost scales with telemetry rate.
Batch-only notarization	Daily (or coarse) digests reduce cost but delay provenance; alerts typically derived post hoc; weaker near-real-time guarantees; low on-chain exposure.
This work (decoupled sparse anchoring)	**Real-time alerts from the live stream ;** hourly per-slot digests + event-level alerts provide verifiable provenance; raw data stay off chain (privacy); **cost bounded by slot cadence;** works on feeless devnet and is migration-ready for PoA/L2.

L. Cost Analysis and Total Cost of Ownership (TCO)

We analyse the costs for the implemented pipeline (DS18B20 → ESP8266 → MQTT/Mosquitto on Raspberry Pi → Python collector/CSV/alerts → hourly anchoring on local Geth (feeless) → Telegram/Node-RED), running at one reading per minute per room with hourly anchoring and immediate alert events. For concreteness, set the average powers to $P_{\text{Pi}} = 4\,\text{W}$ (light-load gateway) and $P_{\text{ESP}} = 0.15\,\text{W}$ (low-duty ESP8266 at 1 msg/min); with 24/7 operation the monthly gateway energy is $(0.004 + 0.00015\,N) \times 720 = 2.88 + 0.108N$ kWh for N rooms per gateway, i.e., per room $E_{\text{room}} = (2.88/N + 0.108)$ kWh/month. From the experiment logs (2025-09-13), one hourly CSV contains 60 samples in 2 671 B (min 2.250 °C, max 8.563 °C, mean 5.025 °C; 54/60 within $[2, 8]$ °C), extrapolating to ≈ 62.6 KB/day/room and ≈ 1.92 MB/month/room; the representative JSON payload `{"temp_c":5.500,"seq":21,"ms":1271041}` is $\approx$ 43 B, giving $\approx$ 1.86 MB/month/room of payload-only traffic, or $\approx$ 4.3–8.6 MB/month/room assuming a 100–200 B/message envelope (the broker is local; WAN usage is negligible). Anchoring is feeless in trials; on a PoA/L2 network the monthly on-chain volume per room is $720 + 2 \cdot \#\text{exc}$ transactions (hourly commits plus START/END), on 2025-09-13 there were 7 complete excursions (14 alert events), so the daily total would have been 24 hourly commits + 14 alerts = 38 transactions. This "alert-now, attest-later" scheme preserves near-real-time responsiveness while bounding OPEX by the hourly cadence and shared gateway resources (see Sections III–IV).

V. DISCUSSION

The experimental system delivered near–real-time visibility, reliable and latency-bounded alerts, and cryptographically verifiable provenance of stored data—using inexpensive hardware and a feeless local chain during testing. By combining edge CSV retention with per-slot hashing and event-level anchoring, the approach offers a pragmatic path to transparent, auditable cold-chain monitoring for vaccine storage while keeping operational complexity modest.

A. Contributions and Advantages

1) Real-time alerting without blockchain gating: In our deployment, alerts are produced directly from the live stream, achieving minute-scale responsiveness ($\approx 1.5\,\text{min}$ to $2\,\text{min}$) in the test profile and $\approx 4\,\text{min}$ to $5\,\text{min}$ in the production profile) rather than waiting for block confirmation. This preserves real-time operation while reserving the anchoring path for integrity and audit.

2) Tamper-evident provenance without exposing raw data: Event-level alert emissions and per-slot (hourly) CSV integrity digests (SHA-256) allow operators to recompute hashes and match on-chain values, yielding an auditable trail without placing raw telemetry on chain.

3) Operational simplicity on low-cost hardware: A single Raspberry Pi aggregates MQTT readings, applies debounce/hysteresis, writes hour-aligned CSV, and drives a Node-RED dashboard and Telegram notifications. The setup uses commodity components and documented versions/commands, emphasizing reproducibility.

4) Scalability and predictable cost: Anchoring at a slot/hour cadence bounds the number of commits—and therefore cost—while the topic-based design scales to multiple rooms. The same pattern can migrate from a feeless local

devnet to a private PoA or low-cost L2 without changing application logic.

5) Actionable operator visibility: The dashboard presents the averaged room series with fixed 2 °C and 8 °C reference lines, liveness indicators, and notifications, turning telemetry into decisions while retaining verifiable integrity of the underlying records.

B. Alignment with Objectives

1) Real-time visibility: With a 60 s sampling interval (ESP8266→MQTT→Raspberry Pi over Wi-Fi), the system provided continuous telemetry on a Node-RED dashboard (gauge + Temperature Evolution chart) and retained a minute-level historical trace. In a representative one-hour window (slot 488279) we observed 60 samples with 2.250 °C to 8.563 °C (mean 5.025 °C). Minute-level resolution is operationally adequate for pharmacy/clinic cold rooms, and the data volume remains tractable for edge storage.

2) Reliable, Interpretable alerting: The collector enforced a 2 °C to 8 °C band with 0.2 °C hysteresis and debounce. The behavior matches the design intent: short spikes did not trigger alerts, while sustained deviations did. End-to-end alert latency was ($\approx$ 1.5 min to 2 min) (test profile) and $\approx$ 4 min to 5 min (production), satisfying the operational need to react to sustained thermal risk rather than instantaneous noise.

3) Transparency and tamper-evidence: Two on-chain commitments were used: an immediate alert event (`Alert`) carrying the offending sample and timestamp, and a per-slot integrity event (`HourCommitted`) posting (*count, min, max, avg*) and the SHA-256 digest of the slot CSV. For slot 488279, the local `sha256sum` exactly matched the on-chain `csvHash`, enabling third-party verification that the plotted/analyzed file is bit-for-bit identical to the original at commit time.

4) Secure(er) retention: All raw measurements were kept off chain as CSV on the Pi, while only digests and minimal statistics were published on chain. MQTT authentication (username/password) and file permission hardening for secrets (`.env`) were applied. This separation reduces privacy/volume risk while preserving public verifiability of data integrity.

C. Reliability, Latency, and Human-in-the-Loop Operation

Although MQTT ran at QoS 0 on an isolated WLAN, reliability was high because the sampling rate is modest (1 msg/min) and the retained Last Will & Testament (LWT) topic exposed liveness ("online/offline"). Debounce and hysteresis suppressed flapping near thresholds. Telegram messaging closed the loop for operators: each `[ALERT START]` was paired with an on-chain submission (`[CHAIN] submitReading tx:...`), and each slot closure yielded a `[COMMIT] ...hash=...` line. From an operational standpoint, the latency budget is dominated by the sampling period and debounce; measured timings indicate the stack introduces minimal additional delay, which is appropriate for cold-chain supervision where cumulative exposure governs disposition decisions.

D. Auditability via Local, Feeless Anchoring

A low-friction audit path is available: an operator (or auditor) recomputes a slot CSV's SHA-256, retrieves the corresponding `HourCommitted` log, and verifies a match without accessing raw on-chain data beyond the digest and summary statistics. Using a local Geth developer network (`-dev`) removed transaction fees during experimentation and provided deterministic inclusion (typically $\sim$2–3 s with `-dev.period 2`). The anchoring pattern itself is chain-agnostic and can migrate to a private Proof-of-Authority network or a low-cost L2, preserving integrity guarantees while bounding cost through hourly (or daily) batching.

E. Security and Privacy Posture

The design keeps raw data off chain, publishes only hashes and aggregates, and authenticates MQTT clients. Secrets (MQTT password, Telegram token, RPC URL) are stored locally with restrictive permissions. While this posture is sufficient for a laboratory deployment, production environments should additionally enable TLS for MQTT and per-topic ACLs, rotate credentials, and consider a hardened key-management process for blockchain identities.

F. Generalizability and Scalability

The architecture scales by topic: additional rooms or probes publish to `coldchain/<room>/reading`, and the collector subscribes accordingly (wildcards). Edge compute load grows roughly linearly with sensor count and remains modest at minute-level sampling. On-chain costs scale with commit frequency, not raw telemetry size; therefore, batch anchoring (hourly/daily) keeps costs predictable. The same dashboard pattern (gauge + multi-series chart with reference lines) extends directly to multiple rooms.

G. Why the Design Works

The core advantage stems from *decoupling* sensing/alerting from anchoring. Alerts are produced directly from the live stream, so their latency is governed primarily by sampling and debounce rather than block confirmation. Hour-aligned slots provide a fixed cadence for integrity commitments, ensuring predictable anchoring overhead while keeping raw telemetry off chain. Room-level averaging (Eq. 1) concentrates operator attention on a single, representative series per room, reducing noise from probe-level idiosyncrasies yet preserving anomaly sensitivity through within-room spread and quorum checks.

H. Where it can Break (and How it Degrades)

1) Connectivity and buffering: With minute-level sampling, short Wi-Fi outages delay—but do not invalidate—alerts if the collector buffers; longer outages can push alert latency beyond the operational target. Hourly anchoring tolerates skipped anchors (later slots still authenticate prior CSVs), but prolonged loss creates gaps that must be explained operationally.

2) Sensing fidelity: Averaging can mask localized hot/cold spots if probes are poorly placed or if quorum degrades. The policy mitigates this via n_{valid} and the within-room spread (`std_C`); however, if $n_{\text{valid}} < 2$ the sample is marked missing, which reduces continuity for audit unless operators act on "quorum degraded" signals.

3) Chain and timing assumptions: Using a local developer chain removes fees and gives deterministic inclusion; migration to a private PoA or low-cost L2 preserves the pattern but changes absolute inclusion timings and operational procedures (RPC endpoints, keys, monitoring). The design remains chain-agnostic because it commits only digests and slot metadata.

I. Limitations and Threats to Validity

Ephemeral chain. The Geth developer chain is transient by design; for long-term evidence a persistent private chain or L2 must be used. The integrity mechanism remains unchanged.

- Single host and Wi-Fi only. The Raspberry Pi is a single point of failure; a UPS and hot-standby would increase availability. Wi-Fi loss would delay alerts; a wired or cellular fallback mitigates this risk.
- QoS 0 and no TLS (lab). Adequate for an isolated WLAN; regulated deployments should enable TLS and evaluate QoS based on loss/latency trade-offs.
- Temperature-only sensing. No door/humidity/compressor state was collected; adding these channels would improve root-cause attribution.
- Calibration not formalized. DS18B20 readings were sanity-checked but no traceable calibration curve was applied. A two-point correction (offset/slope) can be applied in firmware or at the collector without affecting anchoring.

J. Practical Implications

1) Parameterization: A production profile of 60 s sampling, 180 s debounce, and 0.2 °C hysteresis provided interpretable alerts while avoiding noise. Thresholds should match the product label (e.g., $+2$ to $+8$ °C for common vaccines).

2) Multi-sensor deployment with room-level averaging (recording policy): To improve accuracy and spatial representativeness while keeping the dataset compact, each cold room is equipped with ≥ 2 DS18B20 probes, but the *recorded and visualized data are the room-level average* rather than per-probe series. Let $T_i^{\mathrm{cal}}(t)$ denote the *calibrated* reading of probe i at time t (two-point offset/slope applied in firmware or at the collector). The stored value is

$$T_{\mathrm{room}}(t) \;=\; \frac{1}{N_t} \sum_{i \in \mathcal{V}(t)} T_i^{\mathrm{cal}}(t), \tag{1}$$

where $\mathcal{V}(t)$ is the set of *valid* probes at t (self-test passed, plausible range, not stale), and $N_t = |\mathcal{V}(t)|$. If fewer than a quorum (e.g., $N_t < 2$) are valid, the sample is marked missing.

CSV schema (recommended): store the averaged sample only, plus quality fields:

```
iso_utc, epoch, temp_C_mean,
temp_mC_mean, n_valid, std_C
```

As defined in Eq. (1), we average only valid probes at each timestamp. Here, `n_valid` is the number of valid probes contributing to Eq. (1) (i.e., `n_valid` $= N_t$), and `std_C` is the within-room standard deviation (a compact indicator of spatial spread without retaining per-probe traces).

3) Anchoring cadence (room-level only): Keep one on-chain commit per slot per room (e.g., hourly in production) with (count, min, max, avg) computed from the averaged series and the SHA-256 of the *room-level* CSV. Immediate alert events (`Alert`) are emitted only for room-level breaches. This preserves a tamper-evident trail while avoiding per-probe on-chain artifacts.

4) Multi-channel notifications: For operational resilience, deliver alerts in parallel:

- Telegram (already implemented) for rapid chat notifications,
- SMS (via provider API or GSM HAT) for reachability when data services are limited,
- E-mail (SMTP) for audit-friendly, searchable records.

Use a common message template (room ID, UTC time, averaged value, breach type, on-chain tx/hash), with delivery retries, rate-limiting (minimum interval between identical alerts), and escalation (e.g., notify a second contact after 10 min unresolved). Maintain daily liveness pings on all channels. In regulated environments, configure SMTP with SPF/DKIM/DMARC and manage provider API keys as encrypted secrets.

5) Operator workflow: Dashboards present the *single averaged room series* with continuous 2 °C/8 °C reference lines. Expose `n_valid` and `std_C` alongside the gauge to surface sensor health and spatial dispersion without storing individual probe traces. Provide cumulative minutes out of range and mean kinetic temperature (MKT) as secondary KPIs.

6) Security and migration: The averaging policy does not change security posture: secrets remain local; MQTT keeps authentication; raw samples stay off chain. Migrating anchoring from the local developer chain to a private PoA or low-cost L2 network, and enabling MQTT TLS + ACLs, are incremental steps that leave application logic and the averaging workflow unchanged.

VI. Conclusion

We presented a practical IoT–blockchain architecture for vaccine cold rooms that *decouples* real-time alerting from ledger anchoring. By producing alerts directly from the live stream and periodically committing hour-aligned SHA-256 digests of room-level records (plus event-level alerts), the system delivers minute-scale responsiveness, tamper-evident provenance, and predictable anchoring overhead—all on commodity hardware and without exposing raw telemetry on chain.

Our experiments confirmed this design: with 60 s sampling and simple debounce/hysteresis, the pipeline achieved minute-scale end-to-end alert latency while suppressing transient spikes, and on-chain `csvHash` values exactly matched local CSV digests, enabling independent verification of stored data. The resulting operator loop (dashboard + notifications) turns telemetry into timely, auditable actions, and the topic-based design scales to multiple rooms while bounding cost by slot cadence.

A. Main Contribution

We contribute a low-cost, reproducible pipeline that separates *detection* from *attestation*—"alert now, attest later"—achieving real-time supervision with verifiable integrity and controllable cost.

B. Future Work: Cost and Deployment Studies

Perform a total cost of ownership (TCO) analysis comparing a private PoA chain and a low-cost L2 under different anchoring cadences (per-alert only, hourly+alerts, daily+alerts). Instrument the gateway to measure energy (W/kWh) for the full stack (`Mosquitto` + collector + `Node-RED` + chain client) and compare against alternatives (e.g., Raspberry Pi 4 vs. Pi Zero 2 W vs. x86 NUC/mini-PC). Report KPIs such as cost/room/month, cost/commit, kWh/day, and CPU/RAM headroom; derive the break-even cadence (hourly vs. daily) that minimizes cost/audit proof while meeting the SLA for evidence availability.

***Abstract*—Internet of Things (IoT) networks have become a prevalently exploited research area in academia and industry. IoT networks benefit from a variety of applications, including smart cities, smart homes, intelligent transportation, smart agriculture, monitoring, surveillance, etc. The security challenges associated with IoT networks have been broadly studied in the literature. This systematic literature review (SLR) is aimed at reviewing the existing research studies on IoT networks' reactive jamming attacks, challenges, and mitigation. This SLR examined the research studies published between 2019 and 2024 within the popular electronic digital libraries. We selected 45 papers after a rigorous screening of published works to answer the proposed research questions. The outcomes of this SLR reported three major IoT network performance issues. The results showed that the existing mitigation methods are categorized as machine learning based, deception-based, statistical-based, radio frequency-based, game theory-based, and encryption-based. The results show that most methods can detect reactive jamming attacks with accuracy. However, those methods still require additional infrastructure, encryption systems, and lead to prolonged training delays due to large datasets, resulting in computational overhead and transmission delays. Furthermore, the methods are unable to provide a better defense response to reactive jamming attacks. This is because the methods cannot adequately deal with the increased power consumption of IoT devices, cannot minimize transmission delays, and cannot improve the packet delivery ratio. As a result, reactive jamming attacks continue to be prevalent in IoT networks.**

***Keywords*—IoT networks; reactive jamming attacks; mitigation methods; systematic literature review; electronic digital libraries**

I. Introduction

Internet of Things (IoT) [10] networks are prevalent in distinct application domains that include smart cities, smart homes, intelligent transportation, agriculture, monitoring, etc. Applications of the IoT, such as smart agriculture [1], smart cities [2], and healthcare [3] aim to enhance the quality of life, health, and safety in both rural and urban communities. The demand for these applications is rapidly increasing, leading to a projected count of approximately 29 billion IoT devices by 2030 [4].

IoT networks are vulnerable to reactive jamming attacks (RJA). During reactive jamming, a malicious node sends high-power signals into active channels to disrupt legitimate communication through intentional interference [21]. The technologies such as Bluetooth low energy, RFID, and 802.15.4 have a few shortcomings, namely: they are restricted to communication with short distances, they provide low data rates, and provide low throughput. These technologies are vulnerable to jamming attacks. BLE is susceptible to a reactive narrow-band jammer. This type of jamming attack emits the jamming signal on a single BLE advertising channel when a jammer detects a frame transmission that must be attacked [36].

According to [38], RFID systems' components, such as tags and readers, are considered as single entities, and therefore, DoS attacks by signal jamming in the air interface affect both components. Jamming can result in communication being interrupted, which will make the reading process unavailable. IEEE 802.15.4 is the implementation of WSNs. Jamming of 802.15.4 affects the quality-of-service factors, namely the link quality of the channel, the delivery and delay of packets, and the energy consumption [37]. The widespread use of 802.11ah (Wi-Fi) devices has led to ubiquitous access of information. Jamming of 802.11ah networks can expose the weaknesses of the devices, namely, limited battery life and low processing power [31], [5]. The performance of power-constrained IoT devices is directly impacted by inefficient utilization of their resources.

RJA poses a cybersecurity threat for domains such as business and economy. In industrial intelligent systems, disruption due to RJA can result in financial loss. Smart agricultural systems can be left unmonitored due to communication disruptions. In smart transportation, if the systems are disrupted by RJA, passengers and goods are undelivered, which can lead to the unavailability of services. In real application systems, such as monitoring and surveillance, RJA can disrupt real-time communication.

Prior to this study, there were few survey studies that were done on jamming attacks in wireless networks. The authors in [23] surveyed jamming attacks across all types of wireless networks. The authors in [39] surveyed jamming and anti-jamming techniques in wireless networks. The authors in [40] surveyed jamming attacks in wireless networks. The authors in [41] surveyed jamming mitigation in cognitive radio networks. Unlike previous studies, this study surveys RJA detection and prevention techniques in IoT networks. Furthermore, this research study identified the research gaps left by existing mitigation techniques and proposes a smart channel hopping model to address those gaps.

This research study presents a comprehensive survey on reactive jamming attacks (RJAs) mitigation strategies in IoT networks. This research study will systematically review the papers that are available in the literature relating to challenges posed by jamming attacks, detection of jamming attacks, and mitigating jamming attacks in IoT networks. The research studies that are analyzed are those published in the last five years, i.e., from 2019 to 2024.

The objectives are to offer readers with a holistic knowledge landscape of existing RJAs mitigation techniques. This research also focuses on the performance evaluation of the IoT devices under RJAs. Furthermore, the strengths and weaknesses of the existing RJAs mitigation techniques are presented. The main findings of this research study are that the existing RJAs mitigation techniques can be categorized into six categories. We were able to answer the questions in Section III.

Unlike the previous studies, this study reviews RJAs mitigation techniques in IoT networks. It further categorizes the existing techniques of mitigating RJAs into: Machine learning (ML)-based, deception-based, statistics-based, radio frequency-based, game theory-based, and encryption-based. In addition, this study evaluates the strengths and weaknesses of the techniques using the metrics, namely: power consumption of IoT devices, transmission delays, and packet delivery ratio. The contributions of the study are as follows:

- Firstly, we conduct a survey of existing techniques for mitigating RJAs in IoT networks.
- Secondly, we discuss existing methods for detecting and preventing reactive jamming attacks. We tabulate the results and outline the strengths and weaknesses of the techniques.
- Thirdly, we briefly introduce the smart channel hopping model, which is proposed to address the gaps that were not addressed by the existing mitigation techniques.
- Finally, we provide the conclusion and the future direction of the research.

The rest of the study is organized as follows: Section II discusses research methods, Section III discusses results and discussion, Section IV introduces a technical overview of the smart channel hopping model, and Section V presents the conclusion and future research directions.

II. Research Method

A systematic literature review (SLR) as a research study method was used to assess and interpret the research topics available in the literature. Systematic literature analysis is another choice for SLR. Kitchenham guidelines are more specific for performing this SLR. The SLR procedure for this research study involves three subsections, namely: research questions, search strategy, and studies' inclusion and exclusion criteria.

A. Research Questions

The main objective of this research study is to examine the existing mitigation methods against reactive jamming attacks in IoT networks. This research also focuses on performance evaluation of mitigation strategies from significant existing research studies. To achieve the aims and objectives of this SLR, four research questions were formulated as follows:

- RQ1: What are the existing reactive jamming attacks mitigation methods?
- RQ2: What are the strengths of existing mitigation methods?
- RQ3: What are the limitations of the existing methods?
- RQ4: What are the research gaps left unaddressed by the existing methods?

B. Search Strategy

This section focuses on how the search criteria were conducted in terms of the use of search keywords, electronic sources, reference management tools, and a search strategy. Each process is described in the subsections that will follow:

1) Search keywords: The developed research questions were used to derive the search keywords and strings. We have also included synonyms and alternatives. We took synonym keywords from the relevant literature on reactive jamming attacks in IoT network topics. During the search process, the following keywords were used:

``reactive jamming attacks mitigation in IoT networks", ``reactive jamming attacks ",

``reactive jamming attacks detecting and prevention methods in IoT networks",

``mitigating reactive jamming attacks in IoT networks", ``jamming attacks in IoT networks", "jamming attacks mitigation".

2) Electronic sources: The popular electronic digital libraries were explored to extract the most relevant conference papers and journal articles related to jamming attacks mitigation. Table I shows the list of common digital libraries that have been used to search for research papers and articles.

TABLE I. List of Digital Libraries

Source	URL
IEEE Xplore	www.ieeexplore.org
Research Gate	www.researchgate.net
ACM	www.acm.com
Google Scholars	www.scholar.google.com
Science Direct	www.sciencedirect.com

These digital libraries are the major sources of publications on areas of computer network field.

3) Reference management: The search keywords and their alternative used in above search strategy yielded many studies from the above-mentioned electronic sources. There was no electronic or automatic tool that was used to manage the reference. The process of reference management was done manually.

4) Search process: We launched a search process on the digital libraries to retrieve the relevant literature from journal articles, conference papers, and books. This search process resulted in many studies. This search process was followed by a technique that was applied for the selection process to filter out the irrelevant papers.

C. Criteria for Inclusion and Exclusion of Studies

The criteria for including and excluding the studies is presented in Table II.

TABLE II. INCLUSION AND EXCLUSION CRITERIA

Inclusion criteria	Exclusion criteria
Research studies that discuss reactive jamming attacks mitigation in IoT networks	Research studies that are published before 2019
Research studies that discuss reactive jamming attacks detection and prevention in IoT networks	Research studies that discuss reactive jamming attacks mitigation in other types of networks than IoT network
Research studies that discuss reactive jamming attacks in IoT networks	Research studies that discuss reactive jamming attacks detection and prevention in other types of networks than IoT network
Research studies that discuss anti-jamming in IoT networks	Research studies that discuss reactive jamming attacks anti-jamming in other types of networks than IoT network
Research studies that discuss reactive jamming attacks mitigation in access and sensor IoT networks	Research studies that discuss reactive jamming attacks mitigation in IoT backhaul networks

Fig. 1 shows the filtering process that was executed after the search criteria were applied in the digital electronic libraries above.

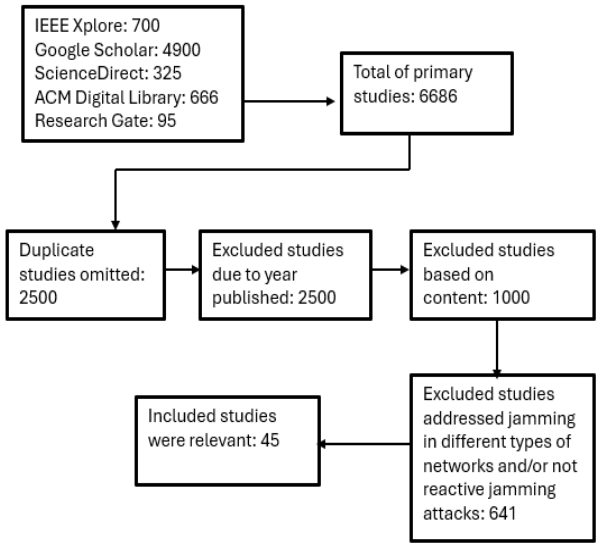

Fig. 1. Selection of studies process.

Fig. 2 presents the distribution of the selected papers by year. We note that 29% of the studies have been published in 2022 and then followed by 24% of the studies published in 2023.

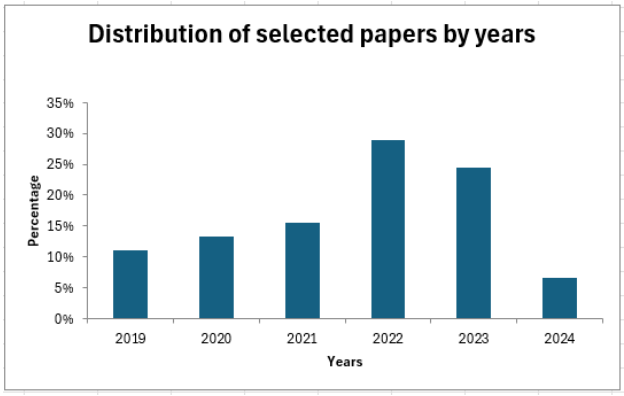

Fig. 2. Distribution of selected papers by years.

III. RESULTS AND DISCUSSIONS

In this section of our SLR, we analyze the most important solutions proposed, including an overview and comparison of categories of existing mitigation methods. Furthermore, analysis of the methods based on the metrics, namely strengths, limitations, the ability to respond to power consumption of IoT devices, transmission delays, and packet delivery ratio.

A. Categories of Mitigation Methods

In this section, the existing mitigation methods against reactive jamming attacks in IoT networks are presented. The techniques are categorized into six categories, namely: Machine learning (ML)-based, deception-based, statistics-based, radio frequency-based, game theory-based, and encryption-based.

1) ML-based methods: ML-based methods are those that employ machine learning techniques to detect and defend against RJAs. These methods utilize machine learning algorithms such as supervised learning. The pre-existing datasets are required for training the agents. They assume that the jammer does not change the jamming strategy, i.e., if the jammer changes the strategy, these methods may falter.

2) Deception-based methods: Deception-based methods use dummy frames or signals to lure the jammer into jamming the fake packets. Some methods use dedicated channels for deceiving the jammer. The transmitter requires to send fake signals prior to sending the real frames.

3) Statistics-based methods: Statistics-based methods use information extracted from the network to detect RJAs. The information may include received signal strength, packet delivery ratio, lack of acknowledgements, and packet error ratio. They lack defense response mechanisms.

4) Frequency-based methods: Frequency-based methods use frequency spectrum techniques for detecting and defending against RJAs. Techniques include patrolling the frequency channel through sensor nodes and using multiple antennas for signal backscattering during jamming attacks.

5) Game theory-based: Game theory-based methods are based on the concept of two players, namely the jammer and the legitimate node, who adjust power levels to defeat each order. Most methods use Q-learning algorithms to obtain the best policy for allocating optimal power to IoT devices to defeat

the jammer. The Q-learning algorithm often takes time to converge when the state space is too large.

6) Encryption-based methods: Encryption-based methods require encryption algorithms to be utilized to defeat reactive jamming attacks. IoT devices are constrained in terms of energy and computation. Therefore, it may not be feasible to implement encryption-based methods.

These mitigation methods are compared in Table III. The metrics that are used are computational overhead, defense response, and resource efficiency. Computational overhead assesses whether the method can be implemented with minimal strain on the energy and computational capacity of IoT devices. Defense response assesses whether the method can effectively mitigate the effects of reactive jamming attacks. Resource efficiency assesses if the method requires additional infrastructure for it to be implemented.

TABLE III. COMPARISON OF METHODS

Method	Computational Overhead	Defense response	Resource efficiency
ML-based	Medium. During agent training	Yes, when jammer not changing strategy.	Efficient
Deception-based	Medium. Frames sent for deception	Yes	Efficient
Statistics-based	Less	No	Efficient
Frequency-based	Medium. Requires sensor nodes and antennas.	Yes	Not Efficient
Game theory-based	Less	Yes, only after convergence	Efficient
Encryption-based	More. It requires encryption algorithms.	Yes	Not Efficient

B. Analysis of Mitigation Methods

This section presents the analysis of mitigation methods based on the metrics, namely strengths, limitations, the ability to respond to power consumption of IoT devices, transmission delays, and packet delivery ratio. Table III provides an analysis of the above-mentioned metrics. In addition, Table IV answers all the research questions raised in Section II A.

TABLE IV. STRENGTHS AND LIMITATIONS

Category	Author	Strength	Limitation	Power consumption	Packet delivery ratio	Transmission delays
Machine learning	Reynvoet et al. (2022)	High accuracy detection	Existing dataset reliance and training delays	Poor consumption due to overhead	Not considered	Increase due to overhead
	Upadyaya et al. (2019)	Detection accuracy	Introduce infrastructure and computational overhead	Poor during data collection and learning	Not considered	Increase due to overhead
(ML)-based	(Zahra et al., 2023)	95% detection accuracy	Training delays and centralized detection centre	Poor during data collection and learning collection and learning	Not considered	Increase due to algorithms complexity
	Lee et al. (2023)	High detection accuracy	Encryption leads to computational overhead	Improves by battery-drainage attack	Improves when users are less	Increases due to encryption
	Testi et al. (2023)	High detection accuracy	No defence response	Not considered	Not considered	Not considered
	Hussain et al. (2022)	86% detection accuracy	No defence response	Not considered	Not considered	Not considered
Deception-based	Thiha et al. (2019)	High detection accuracy	Overhead of sending fake frames	Poor consumption due to sending dummy frames	Improves when packet error ratio drops	Increases due to sending dummy frames
	Liu et al. (2021)	Increase throughput by 50%	Overhead of sending fake frames	Poor consumption due to sending decoy signals	Improves when packet error ratio drops	Increases due to sending decoy signals
	Pourranjbar et al. (2021)	Can efficiently deceive the jammer	Introduce additional channel and overhead of sending fake signals	Poor due to transmission into fake channel	Affects by delays	Increases due to transmission into fake channel
	Nan et al. (2020)	Can efficiently deceive the jammer	Introduce additional channel and overhead of sending fake signals	Improves when system has enough power budget	Not considered	Increases due to transmission into transmitter-receiver pair channel
	Hoang et al. 2020	Low packets drop ratio	Overhead of sending	Poor consumption	Affects by delays	Increases by sending

Category	Author	Strength	Limitation	Power consumption	Packet delivery ratio	Transmission delays
			fake frames			fake frames
	Huynh et al. 2021	Can efficiently deceive the jammer	Energy harvesting and backscattering only possible before channel jamming	Improves by energy harvesting techniue	Improves by backscattering	Increases during energy harvesting process
Statistics-based	Zhang et at. (2022)	High detection accuracy	No defence response	Not considered	Not considered	Not considered
	Singh et al. (2022)	PDR improved by 22%	No defence response	Not considered	Improves by 22%	Not considered
	Fadele et al. (2019)	High detection accuracy	High rates or bit errors and packet loss	Shows 3% power consumption improvement	Improved by 10%	Improved by 38%
	Abdollahi et al. 2023	High detection accuracy	Overhead is caused by states recording and reporting	Recording and reporting will drain the battery	Not considered	Not considered
Radio frequency-based	Arcangeloni et al, (2023)	99% detection accuracy	Introduces additional infrastructure and computational overhead	Poor due to computational overhead	Affects by computational overhead	Increases due to computational overhead
	Huynh et al. (2020)	Throughput can increase with more antennas	Requires more antennas	Poor due to power required by multiple antennas	Improves with addition of more antennas	Increases due backscattering
	Oukas et al. (2023)	99% detection accuracy	Energy harvesting will lead to low PDR	Improves by energy harvesting system	Not considered	Increases due many transition states
	Ali et al. 2023	Detection accuracy	Accuracy is affected by	Not considered	Affects by delays	Increases during NIC data
			NIC's vendor dependency			extraction phase
Game theory-based	Chkirbene et al. (2023)	Optimal power allocation can alleviate jamming attacks	Requires that the jammer does not rapidly change jamming strategy	Not considered	Improves after convergence	Convergence takes longer resulting in delays
	Gouissem et al. (2020)	Optimal power allocation can alleviate jamming attacks	Requires that the jammer does not rapidly change jamming strategy	Not considered	Improves after convergence	Convergence takes longer resulting in delays
	Gouissem et al. (2023)	Optimal power allocation can alleviate jamming attacks	Requires that the jammer does not rapidly change jamming strategy	Not considered	Improves after convergence	Converges faster but assumes jammer never change strategy.
Encryption-based	Navas et al. 2021	Resilient to jamming attacks	Introduces computational overhead dur to encryption	Power consumption due to computation	Affects by transmission delays	Increases due to computation

C. Discussion and Analysis

The ML-based studies proposed by [18], [25], [30], show that the reactive jamming attacks can be detected with high accuracy. However, these methods require that additional infrastructure and/or encryption systems be deployed as defense response mechanisms to the jamming attacks. This will lead to computational overhead which will result in transmission delays and low packer delivery ratio. The studies proposed by [15], [28], [32] indicate that the reactive jamming attacks can be detected with high accuracy. However, the proposed methods lack the defense response systems. This is because there is no mechanism for alleviating reactive jamming attacks when the attacks are detected. In addition, although prior knowledge of an un-jammed signal is unnecessary, ML-based jamming detection has difficulty in obtaining a large amount of training data, and the generalization ability of such

model is usually limited. Moreover, pre-existing datasets have a disadvantage that if the jammer rapidly changes the jamming strategy, they falter.

The deception-based studies proposed by [8], [14], [19], [20], [24], [29] show that sending fake frames into the normal channel or fake channel can deceive the reactive jammer into jamming fake frames. However, this will not be efficient in an environment where the sender must send many frames. This is because the IoT devices will spend more time sending fake frames between transmissions of real frames. This will lead to increased power consumption of power-constrained IoT devices, increased transmission delays of real frames, and a poor packet delivery ratio.

The methods that are proposed by [12], [27] show that reactive jamming attacks [26] can be detected with accuracy. The results show that packet delivery ratio can also be improved. In [27], the authors do not address the issue of power consumption and transmission delays. A study by [12] shows that transmission delays can be slightly improved under low traffic. Power consumption will increase when traffic increases due to congestion and retransmission. The method by [6], [33] shows that reactive jamming attacks can be detected with accuracy. However, the methods do not provide response mechanisms. The study by [6] introduces computational overhead. This is because IoT devices are required to regularly record channel states and send reports to the central node. This will quickly drain the IoT device battery. As a result, the issues of power consumption, packet delivery ratio, and transmission delays were not considered.

The methods proposed by [11], [16], [17] show that reactive jamming attacks can be detected with accuracy. However, the methods introduce additional infrastructure and computational overhead. This will impact transmission delays and packet delivery ratio. The proposed study by [22] achieves better detection accuracy and a response model. But the fact that it consists of many transition states brings several drawbacks, namely transmission delays, high power consumption and reduced packet delivery ratio. The study by [7] shows detection accuracy. However, the process of extracting information from the network interface card will introduce delays. In addition, since the NICs are manufactured by different vendors, this may affect the accuracy of method.

The methods proposed by [13], [34], [35] show that optimal power allocation to IoT devices can drastically reduce jamming attacks. However, these methods require the nodes to adjust or increase their transmission power levels to defeat reactive jammer. In addition, if the jammer has a higher power level, then jamming will not be controlled. Increasing power to the maximum levels will quickly drain the battery of the nodes. If the jammer can rapidly change the jamming strategy this method will fail. Furthermore, the prerequisite of network convergence for obtaining better defense policy may cause delays and affect throughput.

The encryption-based study proposed by [9] shows that the method can be resilient to jamming attacks. The strategy randomizes spread sequences used by the nodes in DSSS system. Every pair of communicating nodes will have a unique pairwise spreading sequence, only known by them. However, the study introduces a lot of computational overhead which will quickly consume the power of IoT devices. In addition, it will lead to transmission delays and low packet delivery ratio.

IV. Proposed Hopping Method

The smart channel hopping model (SCHM) is proposed for mitigating reactive jamming attacks in IoT networks. The formulation of the problem is modeled as the Markov Decision Process framework. The IoT devices interact with the environment and perform different actions in different states and eventually obtain best rewards. In contrast, the penalty reward will be allocated each time a bad action is taken. The next section summarizes the MDP framework for SCHM.

A. State Space

The legitimate IoT node can only observe the chosen channel for communication. Hence, the system's state space is illustrated using the following equation:

$$S = (c, j, q, e): c \in (0,1), j \in (0,1);\ q \in (0, \dots, Q);\ e \in (0, \dots, E)$$

where, c denotes the status of a radio channel, $c = 0$ signifies that a radio channel is idle and $c = 1$ signifies that the radio channel is busy. j denotes the status of the jammer, $j = 0$signifies that the jammer is not attacking a radio channel, $j = 1$ signifies that the jammer is attacking a radio channel. q denotes the number of data frames in the transmission queue, and e denotes the capacity of energy storage of the legitimate node. Q is the maximum data queue size, and E is the maximum capacity of energy storage. The system state space is then expressed as, $s = (c, j, q, e) \in S$.

B. Action Space

The legitimate node can execute any of the following actions, namely, remain idle, actively transmit frames, hop into another free radio channel, and transmit frames, when there is a jamming attack in the current selected channel: $A = (a: a \in \{1,2,3\}$.

a = { 1 the legitimate node remains idle,
2 the legitimate node transmits data,
3 the legitimate node hops into the new channel and transmits data.

C. Reward Function

The immediate reward for the system is defined in this section. It is described as the number of data frames that are sent to the receiver and positively acknowledged. The actions that the legitimate node takes must increase packet delivery ratio with minimum usage of energy and with less delays of the frames in the data queue.

D. Smart Channel Hopping Model

Double Deep-Q-Network (DDQN) is adopted for implementing SCHM. The DDQN reinforcement learning algorithm will be used to train the agent. The proposed model is shown in Fig. 3.

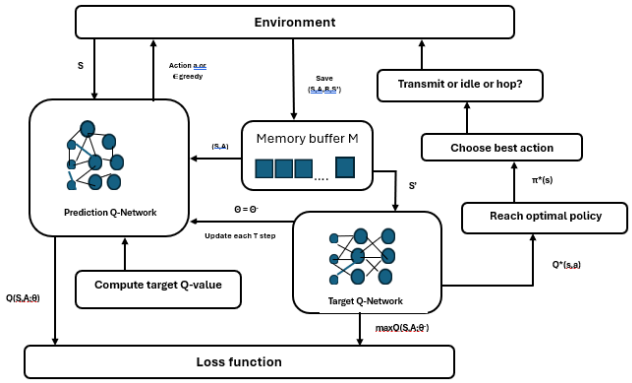

Fig. 3. Proposed smart channel hopping model.

The state space consists of four components, namely channel, jammer, buffer queue, and energy. The components form an important part of the actions that the agent will take during the mitigation process. The action space consists of three components, namely transmit, idle, and hop and transmit. The prediction Q-network, target Q-network, and the memory buffer are initialized. The agent observes the current state and takes the action, and then waits for the reward. Otherwise, it chooses the greedy action argmaxQ(s,a). The state-action pairs are stored in the memory buffer M for each episode. The mini-batch in the memory buffer is used to train the agent. The process continues until the network converges and an optimal policy is found.

V. CONCLUSION

In this research study, a systematic survey of literature review of methods for mitigating reactive jamming attacks in IoT networks was conducted. From the onset, the technologies that support IoT networks were presented. The conventional methods of defending against jamming attacks were discussed. That was followed by the discussion on how the popular online digital libraries were used to obtain conference papers and journal articles related to mitigating reactive jamming attacks. The research questions were raised regarding what the strengths and weaknesses of the existing mitigation methods are. In conclusion, this research study answered the questions.

This research study categorized the jamming mitigation methods into six, namely: Machine learning (ML)-based, deception-based, statistics-based, radio frequency-based, game theory-based, and encryption-based. The mitigation methods were further compared using the metrics, namely, computational overhead, defense response, and resource efficiency. The results in this research study suggest that most mitigation methods have strength of accuracy in detecting jamming attacks. Furthermore, the mitigation methods suffer from increased power consumption, less packet delivery ratio, and prolonged transmission delays.

The limitation of this SLR study is that the search strategy was manual and restricted to journal papers and conference papers. In the near future, the plan is to perform a broad automated search. Another limitation is the use of simplified search keywords for journal papers and conference papers. The use of search keywords can be generalized.

In retrospect, it is required to develop an efficient approach which detects and defends against reactive jamming attacks. As a future work, this research study proposed a smart channel hopping model for mitigating reactive jamming attacks in IoT networks. The model intends to reduce the power consumption of IoT devices, minimize packet errors, minimize packet loss, and minimize transmission delays, which will improve the packet delivery ratio. Furthermore, the research community will have a full knowledge of the limitations of existing RJAs mitigation techniques and will facilitate the advancement of improved mitigation techniques. Lastly, similar SLR studies can be considered for IoT cloud systems for addressing cybersecurity concerns and performance issues.

Virtual Assistant Based on Recurrent Neural Networks: Scope and Coverage of Health Insurance

Diego Alberto Paz-Medina[1], David Eduardo Rojas-Cavassa[2], Ernesto Adolfo Carrera-Salas[3]
School of Engineering, Universidad Peruana de Ciencias Aplicadas (UPC), Lima, Peru [1, 2, 3]

***Abstract*—In Peru, the use of health services provided by state institutions has decreased, largely due to perceived deficiencies in care quality, such as delays in medical attention and administrative barriers that hinder timely access to information on insurance scope and coverage. This study develops a web-based application with an integrated chatbot that leverages Artificial Intelligence (AI) and a Recurrent Neural Network (RNN) to provide accurate and accessible information about institutional insurance, including the characteristics of different insurance types and specific coverage cases. The application integrates a chatbot powered by an AI model based on Natural Language Processing (NLP) from OpenAI, with intent recognition handled by a dedicated classifier. In comparison to existing chatbots in the healthcare field, the model proposes a hybrid approach based on RNN and GPT-3.5, optimized for health insurance queries in public sector contexts. The system was evaluated with 50 representative questions scored on four criteria: clarity, relevance, coherence, and accuracy. The chatbot achieved an overall mean response accuracy of 82% and a mean user satisfaction score of 4.59/5, indicating strong acceptance and usability. These results suggest that the combination of these technologies constitutes an effective alternative for addressing queries relevant to users of state health systems.**

***Keywords*—Insurance; insurance coverage; web application; chatbot; Recurrent Neural Networks**

I. Introduction

According to the nominal registry of insured individuals published in early 2022, reports that 98.96% of Peru's total population has health insurance coverage [1], with the majority covered by the Comprehensive Health Insurance (SIS) and Peru's Social Health Insurance (EsSalud), accounting for 69.5% and 29.3%, respectively. As stated in [2], in 2022, SIS showed a steady increase in enrollees from 2009 to 2022, while EsSalud exhibited a relatively constant affiliation trend. However, between 2020 and 2022, there was a decrease in the EsSalud-insured population, dropping from 30.4% to 22.8% of the total Peruvian population. In [3], the authors highlighted that, due to poor management and weak governance in recent years, the institution has experienced instability, resulting in delays in project implementation, decision-making processes, and turnover in key administrative areas. Additionally, [3] notes that the percentage of EsSalud-insured individuals visiting hospitals declined from 45% in 2004 to 31% in 2022. This decline is largely attributed to a perceived reduction in care quality [4], including delays in medical and consultation services, as well as the imposition of time constraints or administrative barriers that hinder effective understanding and access to consultation services.

Among the various approaches explored in previous research, [5] presents the comparison of a chatbot based on a Sequential Matching Framework (SMF), supported by a Recurrent Neural Network (RNN) algorithm, with other chatbots based on Natural Language Processing (NLP), such as RootyAI, ChatterBot, and DeepQA. In study [6], an artificial intelligence model was developed, capable of understanding terms related to the insurance domain for the resolution of queries. Although [7] and [8] document the development of a chatbot, [7] features the use of different types of algorithms, which are more advanced, such as the use of DeepQA for the chatbot's construction and DeepProbe for rewriting queries. In study [8], a chatbot was developed locally in hospitals, supported by Artificial Intelligence (AI), for the resolution of doubts related to immunization held by the medical personnel in charge of minors. In [9], the authors present an algorithm for adapting GPT models to specific tasks by combining information from different sources. This improves the accuracy of the model's responses and makes it more useful for specific tasks. This differs from the proposed approach, which focuses on the field of health insurance for the general public, where the user is not required to have prior knowledge of specific related terms. Finally, [10] describes the development of a chatbot in Ethiopia for mental health support, using a hybrid architecture based on Seq2Seq models, Amharic embeddings, and deep neural networks (LSTM and GRU).

In the present study, a web-based application was developed incorporating an integrated chatbot designed to provide both EsSalud-insured and uninsured individuals with access to information regarding insurance modalities, specific cases in which insurance coverage may apply, and healthcare centers within this public institution that offer treatment for the conditions specified by users. Based on the queries submitted by the user, the system generates contextually appropriate responses using an Artificial Intelligence (AI) model previously trained by a Recurrent Neural Network (RNN) algorithm. The model was trained in data related to the scope and coverage of the various insurance plans offered by EsSalud. Through the implementation of this application, users, regardless of insurance status, are provided with a digital channel through which frequently asked questions about EsSalud insurance can be addressed, thereby reducing waiting times for in-person assistance and alleviating congestion at insured service centers.

During the validation phase, the system's response accuracy was first assessed at the backend level. Specific validation criteria were established, and the system's responses were evaluated against official information obtained from EsSalud. The evaluation indicated an overall mean response accuracy of

82%, with the main limitation being the model's difficulty in generating clear and concise responses. Usability testing was then conducted with 32 participants who interacted with the chatbot, followed by a 10-item questionnaire designed to evaluate user experience. The results showed a general satisfaction score of 4.59 out of 5 on a Likert scale, a dropout rate of 16%, and a perceived overall improvement of 78% compared with human agents (41% rated the system as "much better" and 37% as "better"). In conclusion, the findings support the efficacy of digital solutions, such as AI-driven chatbots, in efficiently disseminating basic insurance-related information and responding to common inquiries, thereby improving service accessibility and responsiveness for both insured and uninsured populations.

The structure of the study is organized as follows: Section II provides a review of related works; Section III introduces the concepts applied throughout the development process; Section IV describes the methodology employed; Section V details the results of the experiment conducted; Section VI discusses the findings; and Section VII presents the conclusions.

II. Related Works

In [5], the authors present a study on the response-generation strategies employed by existing chatbots, aiming to identify shortcomings in maintaining coherent dialogues with users. Subsequently, a domain-specific chatbot named IntelliBot is proposed, which is based on a Sequential Matching Framework (SMF). This framework transforms each word into a vector according to its contextual meaning and employs hidden states from Recurrent Neural Networks (RNNs) to determine relationships between expressions. Additionally, the study examines alternative approaches for constructing conversational systems, including language generation techniques and neural network-based retrieval models. The model was trained and evaluated using three experiments and datasets. The first experiment utilized a movie dialogue dataset with over 200,000 samples and a batch size of 250 records. The second experiment used a credit card insurance dataset comprising over 10,000 samples with a batch size of 150 records. The third experiment involved a dataset of insurance-related terms and keywords with 1,000 samples and a batch size of 50 records. Following the execution of 71 questions across seven different categories, the results demonstrated the superiority of IntelliBot in terms of accuracy and memory, achieving a score of 0.97. In contrast, traditional chatbots obtained lower performance scores: 0.66 for RootyAI, 0.71 for ChatterBot, and 0.93 for DeepQA. However, despite these promising results, IntelliBot focuses primarily on general insurance contexts, without addressing the accessibility barriers or usability needs specific to public health institutions. Unlike the previous approach, the proposed model integrates a hybrid architecture optimized for state health insurance queries, user satisfaction, and accessibility for non-specialized users. This highlights a research gap regarding the adaptation of AI-driven conversational systems to public-sector health environments.

In study [6], an artificial intelligence model was developed using a Recurrent Neural Network (RNN) and a Convolutional Neural Network (CNN) to improve the resolution of queries related to the insurance domain. This model was created in response to the growing demand from individuals seeking information about the types of insurance they may obtain. Three datasets were used for training, validation, and testing, comprising a total of 16,889 questions, 16,889 correct answers, and 168,890 incorrect answers. The developed model demonstrated a higher accuracy rate than the baseline model, achieving a precision of 78.34%, which was attributed to its enhanced semantic understanding capabilities. This study addresses the same thematic area as the project under development, although it focuses on all types of insurance, whereas our work concentrates specifically on health insurance. Additionally, a key distinction lies in the response mechanism provided to users: while the referenced study focuses solely on the development of the model, the proposed project involves the implementation of the model within a digital alternative-specifically, a chatbot integrated into a web-based platform.

In [7], the authors present a design and implementation model for an intelligent chatbot using advanced algorithms. To achieve this, a high-quality dataset was required to train deep learning models effectively. The proposed model employed Long Short-Term Memory (LSTM) neural networks and the Sequence-to-Sequence (Seq2Seq) algorithm, along with the Bag of Words (BoW) model, beam search decoding for response prediction, and the BLEU-N algorithm to evaluate the chatbot's accuracy. As a result, the proposed method was compared and analyzed using the BLEU-N score against a traditional chatbot, a DeepQA-based chatbot, and rewritten versions of DeepProbe. The findings showed that the proposed method outperformed the others with a 59.44% improvement in BLEU-N score and overall performance. However, this approach focuses mainly on linguistic precision, without addressing user experience or applicability in public health contexts. The proposed model builds upon these advances by adapting deep learning methods to domain-specific insurance queries, helping to close this gap.

In study [8], an AI-assisted chatbot was developed to address questions related to childhood immunization in a low-resource and low-literacy setting in Karachi, Pakistan. The chatbot employed a continuous learning process through a Machine Learning algorithm integrated with a "Human-in-the-Loop" function, which aims to replicate natural human conversations without relying solely on keyword matching. Among the total number of inquiries (874), the most frequently addressed topics were vaccine expiration (32.4%), delays in vaccination due to child illnesses (16.8%), and management of side effects (15.7%). Additionally, it was found that most questions were answered promptly and in a manner that was clear to users. Regarding user acceptance, 90% indicated they would have no issue continuing to use the system; however, 40% expressed they would feel more comfortable knowing the source of the responses. Compared to the chatbot described in that study, the present research aims to address users' questions even when they have limited knowledge of the specific domain-namely, the scope and coverage of health insurance. This helps bridge the knowledge gap necessary for using a digital tool, as the user can make inquiries either in formal or colloquial language, both of which are interpreted in the same way thanks to the selected AI model.

In [9], the authors propose a method for adapting GPT-based artificial intelligence models to specific scenarios, such as patent claim generation, multilingual text summarization, and answer generation in question-answering systems. The new model, named Dempster-Shafer Theory (DST) framework, performs information fusion based on Dempster's theory of evidence, combining inputs from multiple sources to enhance accuracy and decision-making in response generation. The results showed that the proposed method improved the contextual accuracy of responses by 8.95% and 7.56%, respectively, compared to those generated by GPT-2 and GPT-3.5 models. However, its application remains focused on technical and text-processing domains, without exploring user-centered implementations in social or public service contexts. The present study addresses this limitation by applying GPT-based reasoning to healthcare insurance queries, emphasizing usability and accessibility.

In [10], the authors propose the design and implementation of an artificial intelligence-based chatbot called "PsychoBot", aimed at assisting users with potential mental health disorders in Ethiopia. For natural language processing, Word2Vec techniques (skip-gram and CBOW) were employed, along with Recurrent Neural Networks, including variants such as LSTM, GRU, double GRU, and transposed GRU. The architecture identified as optimal was the transposed GRU, due to its superior performance in terms of accuracy (79.86%), lower validation loss (0.208), and reduced training time (1434 minutes). In contrast to the present study, which focuses on the domain of health insurance, this work concentrates on psychological diagnostics, emphasizing the implementation in the local language and its robustness in handling diverse user queries. However, it does not integrate a web-accessible platform or a user-friendly chatbot interface, features that are essential to improving the usability of the developed solution and enhancing the overall user experience.

Table I presents a comparison of the methods used, datasets, and evaluation metrics across the related works.

TABLE I. COMPARISON OF RELATED WORKS AND THE PROPOSED MODEL

Year	References	Description of method/technique	Dataset size	Performance metric/s
2020	Paper 1 [5]	The working styles of chatbots are examined through a model based on Recurrent Neural Networks (RNN) and the Semantic Matching Framework (SMF).	71 questions across seven different categories.	Kappa coefficient and F1 score.
2023	Paper 2 [6]	The MFBT model, which focuses on insurance types, is developed using artificial intelligence with a BiLSTM-TextCNN architecture.	A total of 16,889 questions, divided into training, validation, and testing sets.	Model precision, recall, and F1 score.
2023	Paper 3 [7]	A design and implementation for an intelligent chatbot is presented, combining LSTM, a Seq2Seq architecture with attention mechanism, data preprocessing, Bag of Words (BoW) model, and supervised training.	Dialog dataset, containing 3,725 question–answer pairs.	BLEU score (Bilingual Evaluation Understudy).
2024	Paper 4 [8]	Bablibot: a chatbot designed to answer questions related to childhood immunization, employing a continuous learning process through Machine Learning with a "Human-in-the-Loop" function.	In Karachi (Pakistan), a thematic analysis of interviews was conducted with 2,202 caregivers, of whom 677 (30.7%) interacted with Bablibot.	User acceptance based on interview feedback.
2024	Paper 5 [9]	A method for adapting GPT models to various real-world scenarios to enhance performance in contextual dialogue classification.	Uses the Dialog dataset (3,725 Q&A pairs), DailyDialog (13,118 dialogues from everyday interactions), and WikiQA (3,047 questions sourced from Bing query logs).	BLEU score and cosine similarity score.
2025	Paper 6 [10]	A mental health support chatbot based on RNNs (LSTM, GRU), Seq2Seq architecture, Amharic word embeddings (Skip-gram and CBOW), and memory networks, combining generative and retrieval-based approaches in a hybrid architecture.	Employs a dataset compiled from the DSM-5 manual, client case histories, online psychological counseling websites, and general everyday conversations.	Precision, recall, and F1 score.
2025	The model proposed	A chatbot was developed integrating communication between an AI model and an RNN to address inquiries about the scope and coverage of EsSalud health insurance.	109 questions related to insurance services provided by EsSalud only for training purposes.	Average response accuracy rate and user survey results.

Source: Own Elaboration.

III. CONTRIBUTION

This section defines and contextualizes the key concepts underlying the proposed research. Each concept provides a basic definition and serves as a fundamental element for the design and implementation of the model.

A. Health Insurance

A contract established with an insurance company through the payment of a monthly premium. In exchange for the premium, the insurance company agrees to cover a variety of medical services, depending on the applicant's plan [11]. This concept was essential for structuring the chatbot's knowledge base. Based on the institutional documents collected, the system was trained to identify and respond to frequently asked questions regarding health insurance. A Recurrent Neural Network (RNN) was employed to accurately classify user queries, while the AI language model was responsible for generating clear and comprehensible responses. In contrast to previous chatbots that focused mainly on general healthcare information, the proposed model offers a domain-specific approach to health insurance, capable of delivering policy-based and context-aware responses aligned with institutional regulations.

B. Insurance Coverage

It refers to the protection provided by a health insurance policy against unexpected events, preventing these from becoming a significant financial burden in the present or future [12]. In the system's development, this concept was essential

for structuring the chatbot's responses regarding the services guaranteed by each type of insurance. Institutional documents in PDF format, which detail the coverage information, were used to fine-tune RNN algorithm for pattern recognition in user queries. Meanwhile, the OpenAI language model complements these responses by expanding the contextual information, helping users better understand which services are included in their health insurance plan. Unlike conventional systems with static information, the proposed model retrieves and integrates content directly from institutional documents to generate dynamic, personalized, and policy-specific responses, ensuring greater accuracy and relevance.

C. Insurance Scope

The limits of protection offered by an insurance policy in the event of unforeseen circumstances [13]. The concept of scope was important for training the chatbot to explain the limits and conditions of each insurance plan. This information, extracted from official documents, is processed by the RNN to accurately categorize user queries, while the AI model generates responses that clarify the extent of insurance coverage in various situations. Unlike traditional models based on predefined answers, the proposed system interprets each policy's scope dynamically, offering clearer, adaptive, and user-tailored explanations.

D. Artificial Intelligence

A scientific field focused on the development of computers and machines capable of thinking, learning, and making decisions in a manner similar to humans, or of processing data sets that exceed human analytical capacity [14]. The system is implemented using OpenAI's GPT-3.5 Turbo model, which interprets complex queries related to health insurance and generates coherent responses in natural language. This enables the chatbot to provide fast and accessible assistance without the need for human intervention. Unlike previous systems that used AI mainly for classification or retrieval tasks, this model employs generative AI to produce contextually accurate and user-friendly responses, improving accessibility for non-technical users.

E. Recurrent Neural Networks

A machine learning model based on neural networks that processes sequential data such as text or time series, converting it into specific sequence-based outputs [15]. They are used to process sequential health insurance queries, categorizing them based on user intent. A simple RNN architecture was employed due to its efficiency and speed in handling short sequence tasks, such as brief user queries. The aim is to provide a perspective on how this type of algorithm can "communicate" with others to enhance the responses it generates.

F. Web Application

A software program that runs directly on a web browser via the internet [16]. In the present work, this concept was applied when defining the appropriate medium for developing a solution that allows users to make inquiries about health insurance and access related information without requiring any external installation, by simply using their preferred web browser. Compared to the previously mentioned chatbots, the proposed solution aims to enable communication with the chatbot through an easily accessible web page, featuring a responsive design tailored to the user's needs.

IV. Method

This section presents the developed method according to the stages outlined in Fig. 1:

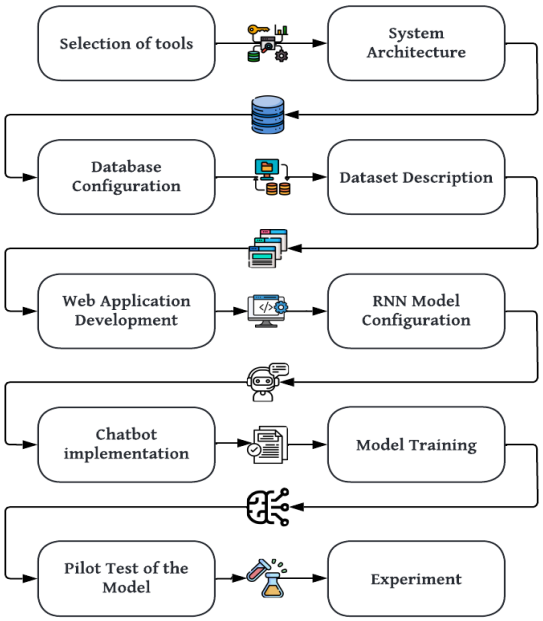

Fig. 1. Stages of the proposed method. Source: Own elaboration.

A. Selection of Tools

Regarding the AI provider, OpenAI was selected based on API maturity, tooling, and empirical evaluations of model quality reported in recent benchmarks [17]. GPT-3.5 Turbo was used for generating the chatbot's responses. Additionally, OpenAI was chosen for its widespread popularity in projects requiring human-like responses and for its ease of integration through the use of an API key, which grants access to OpenAI's models. Amazon Web Services (AWS) was chosen as the cloud service provider due to the broad range of services it offers for deploying web applications, machine learning resources, and its cost-effectiveness, making it the most suitable option considering the project's needs and constraints. Python was chosen as the programming language for data processing due to its robust ecosystem for NLP and machine learning, its ease of use, and its efficiency in handling large-scale datasets.

During the selection process for the most suitable AI model provider, four options were compared: OpenAI, Google Cloud AI, IBM, and Microsoft. The evaluation was based on five key criteria identified as most relevant in [18]: model governance, performance, ease of integration, scalability, and cost. OpenAI stood out for its high performance and scalability, being highly efficient in natural language processing tasks and capable of handling large data loads. Google Cloud AI provides robust tools but requires additional configurations to reach optimal performance. IBM facilitates model integration but tends to be more costly. Microsoft offers a wide range of options, though its implementation may require advanced knowledge and complex configuration.

Based on a qualitative analysis, the authors assigned scores to each provider according to the evaluation criteria. These scores were then weighted using a prioritization matrix that reflects the relative impact of each criterion. The results are presented in Table II, with OpenAI achieving the highest score of 3.94 as the most suitable AI model provider.

Following an evaluation of different database management systems, MySQL was selected due to its open-source nature. Unlike SQL Server, MySQL allows free usage and broad customization, as noted in [19]. It is recognized for its ease of installation and use, as well as its compatibility with multiple programming languages and operating systems. Moreover, it delivers optimal performance in data handling, enabling fast queries and updates. This makes it suitable for the current project, which does not require intensive performance, especially considering its lower resource requirements and ease of use without complex configurations. Additionally, its compatibility with Railway allows for seamless cloud deployment, accelerating testing and project management.

TABLE II. COMPARISON OF ARTIFICIAL INTELLIGENCE MODEL PROVIDERS

Criteria	*OpenAI*	*Google Cloud AI*	*IBM*	*Microsoft*
Model Governance	0.75	0.56	0.75	0.56
Performance	1.00	0.75	0.75	1.00
Ease of Integration	0.38	0.63	0.50	0.25
Scalability	1.25	0.75	1.00	0.75
Cost	0.56	0.56	0.56	0.56
Total	3.94	3.25	3.56	3.13

Source: Own Elaboration.

For this study, a simple Recurrent Neural Network (RNN) architecture was selected, thanks to its lightweight structure, quick training process, and suitability for short sequences-such as common questions related to health insurance. Unlike LSTM and GRU architectures, which are designed to capture long-term dependencies and process extended sequences, the simple RNN proved sufficient for our use case, where the inputs are brief and do not require long-term memory. While LSTM and GRU architecture are optimal for complex tasks, they involve a larger number of parameters, longer training times, and greater computational resource usage, as noted in [20]. Likewise, although Transformer models excel in complex tasks and large datasets, they involve high computational costs and require substantial data and specialized hardware, making them unfeasible for this study [21]. In contrast, the simple RNN offers a lighter and easier-to-implement design, which is essential to maintaining model simplicity without compromising its response generation capabilities. This comparison is shown in Table III, where an evaluation using a Likert scale from 1 to 5 was conducted. The Simple RNN achieved the highest overall score of 3.67, thus selected as the RNN architecture used in the proposed model.

TABLE III. COMPARISON OF RECURRENT NEURAL NETWORK ARCHITECTURES

Criteria	*Simple RNN*	*LSTM*	*GRU*	*Transformer*
Training Time	5	2	3	4
Long-term dependency capture	5	2	3	2
Number of parameters / complexities	1	5	4	5
Performance on short sequences	4	4	4	4
Training stability	2	5	4	4
Hardware requirements	5	2	3	2
Total	**3.67**	3.33	3.5	3.5

B. System Architecture

Fig. 2 presents the integrated system architecture, which follows a multilayer structure composed of the Presentation Layer, Application Layer, Data Layer, and Intelligent Service Layer; ensuring modularity, scalability and secure communication between all components.

Presentation Layer: Developed in Angular and hosted on AWS Amplify, this layer allows users to interact with the chatbot through a responsive web interface accessible from desktop and mobile devices. User queries are transmitted securely to the backend via RESTful APIs.

Application Layer: Implemented in Python (Django) and deployed on Railway Cloud, this layer processes user inputs, manages communication between the front end, the RNN algorithm, and the AI model. It also handles intent classification and message routing to ensure relevant and coherent responses.

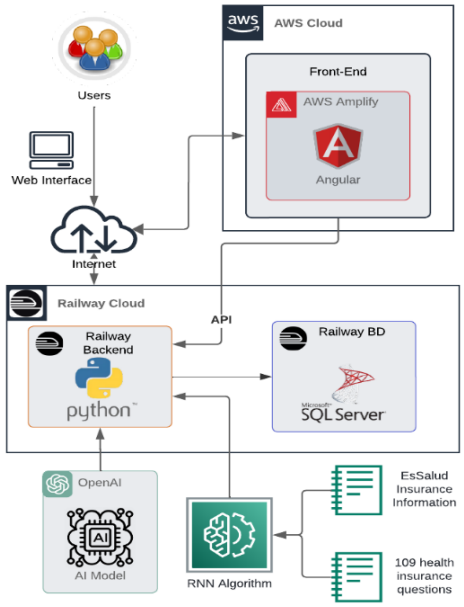

Fig. 2. System architecture of the proposed method.
Source: Own elaboration.

Data Layer: Hosted on Railway BD using Microsoft SQL Server, this layer stores insurance information, user interactions, and the dataset of 109 representative questions used for RNN training, enabling dynamic query retrieval and model improvement.

Intelligent Service Layer: Integrates the external OpenAI model with the internal RNN algorithm. The RNN identifies user intent, and OpenAI generates the final natural language response, combining deterministic classification with generative reasoning.

Interaction Flow: Users submit queries via the web interface; the backend classifies them using the RNN, retrieves related information from the database, and requests a response from the OpenAI model. The generated answer is then returned to the user interface, completing the interaction cycle efficiently.

C. Database Configuration

Since Railway was selected as the service provider, which allows integration with different database engines such as MySQL Server, this was used for storing the data related to the application. In addition, the same MySQL Server application was used to manage the data, both for queries and for editing. This, in turn, connects with the web application services to perform the queries required by the system.

A database model was developed using a class diagram and an entity-relationship model, having mainly the entities User, where personal data such as full name and login credentials will be stored, Responses, where the responses and the rating given by the user are stored to identify whether the response is accepted or rejected by the user in cases where more specialized attention is required, and Insurance, data related to the person's insurance, as well as the validity of the coverage.

D. Dataset Description

For the training and validation of the Recurrent Neural Network (RNN) model, a dataset was constructed from multiple sources containing information related to health insurance plans. Five PDF documents were used, each corresponding to a different type of health insurance. These documents included detailed information on the characteristics, coverages, exclusions, and validity periods of each insurance plan.

Additionally, a complementary PDF document containing 109 pairs of frequently asked questions (FAQs) and their corresponding answers was utilized. These questions were derived from real user inquiries and were validated and reviewed by personnel from the insurance department to ensure their accuracy and consistency. The questions were specifically designed to train the model in natural language understanding. To mitigate the limitations of the dataset, data augmentation techniques were applied, such as synonym replacement, paraphrasing, and back-translation, to increase linguistic variability while preserving semantic meaning.

Prior to model training, the question–answer pairs underwent preprocessing steps, including the removal of redundant symbols, text normalization (conversion to lowercase), and structuring into a suitable format for model input. The data were then tokenized, encoded, and used to train the RNN model. Through this process, the model learned to associate specific types of user queries with their appropriate responses based on the patterns within the dataset.

The outcome of this training provides a solid foundation for the chatbot to interpret user questions and generate coherent responses consistent with official information regarding the scope and coverage of health insurance plans.

E. Web Application Development

With respect to the visual layer for the user, it was decided to develop it using the Angular framework, given the development team's experience in programming business logic and modeling modules in TypeScript. This layer will be hosted on the AWS Amplify service due to its support for web applications, its ease of use for deployment, and its integration capabilities with other data processing services provided by AWS [22].

Its deployment will be carried out using Railway services, which will provide the functions performed in the backend through an API Gateway, which communicates with both the presentation layer on AWS Amplify and the artificial intelligence model provided by OpenAI [23]. To facilitate portability, scalability, and execution environment management, the backend has been developed and deployed within Docker containers, allowing for more efficient dependency control and greater consistency between development (localhost) and production (cloud) environments.

Communication begins with the front end in Amplify, sending data in JavaScript Object Notation (JSON) format to the backend, which is hosted on Railway services and receives the information through the API Gateway, then forwards this information to the OpenAI AI model [24].

F. RNN Model Configuration

The model architecture is based on a simple Recurrent Neural Network (RNN). Development and training were conducted in a local environment equipped with an Intel Core i5-6600 processor, 16 GB of RAM, and an AMD RX-480 dedicated graphics card. The system operated on Windows 10 Pro, using Visual Studio Code as the development environment, TensorFlow 2.15 as the deep learning framework, and Python 3.10 as the programming language.

During the experimental tests, equivalent SimpleRNN, LSTM and GRU models were trained under the same configuration parameters (number of neurons, embedding size, and sequence length). Although their accuracy was similar, the SimpleRNN achieved comparable performance with lower training time and memory usage, representing a more efficient cost–benefit balance for this system. Furthermore, since the input data do not involve long-term temporal dependencies, the use of LSTM or GRU would not significantly improve response quality, making the SimpleRNN a sufficient and lightweight solution.

The implemented architecture consists of three main layers: an Embedding layer, which transforms words into 64-dimensional numerical vectors; a SimpleRNN layer with 128 units, responsible for learning the sequential relationships

between words; and a dense output layer with a softmax activation function, which predicts the most probable response among the possible output classes.

Training was performed using the Adam optimizer with a learning rate of 0.001, employing sparse categorical crossentropy as the loss function and accuracy as the performance evaluation metric. The dataset was divided into 80% for training and 20% for testing, with a maximum sequence length of 20 tokens and a vocabulary size limited to 10,000 words.

The model was trained for 10,000 epochs, achieving stable convergence, and an adequate level of accuracy on the training data. Finally, the trained model, along with the tokenizer and label encoder, were stored in reusable formats, enabling their subsequent loading and integration into the web application.

The RNN model processes the user query through tokenization, padding, and intent classification, then integrates the result with the language generator. The full operational sequence is illustrated in Appendix A, which presents the pseudocode of the proposed model.

G. Chatbot Implementation

The application's front end, developed in AWS Amplify, was integrated with the backend services developed in Railway. Also, tests were conducted related to prompt construction to evaluate the request and response flow with the AI model. The backend services are hosted on Railway as the main server. For this purpose, Docker containers were used: one dedicated to the OpenAI-based chatbot, and another for the Recurrent Neural Network (RNN) model. Tests were conducted related to prompt construction to assess the request handling and the quality of the responses generated by the AI and RNN models.

Fig. 3. Chatbot view of the web application. Source: Own elaboration.

The main view of the developed chatbot is shown in Fig. 3. Users can submit queries regardless of whether they are registered, by entering a message in the input bar at the bottom, within the maximum character limit. Additionally, two options are provided for interacting with the chatbot. The first, "What type of insurance do I need?", displays a series of predefined questions and answers, which lead to a recommendation for one of the five available insurance plans offered by the institution, based on the user's selection. The second option, "Frequently Asked Questions", presents a list of stored questions and provides an answer upon selection, which is then sent to the endpoint for communication with the chatbot and the RNN algorithm.

H. Model Training

During the training phase, documentation related to the five types of insurance provided by EsSalud was collected, covering information about their coverage and the requirements for enrollment. These data were used to train both the RNN model and the external AI model provided by OpenAI. The main chatbot was built using language models from the same provider, responsible for generating dynamic and understandable responses to freely formulated user queries, with its responses strictly to the different types of health insurance. On the other hand, the RNNs were previously trained with specific data related to the insurance types. The objective of this model is to analyze and classify preconfigured or frequently asked questions (109 questions and answers), which require technical responses based on learned rules or patterns. The RNN serves as a specialized support system that enables fast and accurate responses without requiring as many resources as the main chatbot.

I. Pilot Test of the Model

Subsequently, a pilot test was conducted at the backend of the developed application, specifically focusing on the API used to communicate with both the RNN and AI models. For the test, a list of questions was prepared along with the corresponding answers obtained from EsSalud's insured services personnel. A total of 50 questions, along with their respective answers (distinct from the 109 used to train the model), were formulated and then compared with those generated by the developed model, using four criteria derived from those in [25]: Clarity (whether the response focuses on what is being asked without unnecessary detours), Relevance (whether the response is relevant to the context of the question), Coherence (whether the information is consistent with the question and logically coherent), and Accuracy (whether the response matches the verified information). Each criterion was assigned a weight of 25%, aiming to achieve an overall compliance rate above 80%. The comparison process was conducted by the development team, with support from personnel in the insurance systems department of the selected institution.

Table IV presents the results of the 50 questions posed to the AI model provided by OpenAI alongside the RNN model, evaluating the responses according to the established criteria.

In the responses obtained for the insurance-related questions, it was found that the answers were often not very clear, as they tended to include more information than necessary. For this reason, these questions had a compliance percentage ranging from 50% to 75%.

TABLE IV. CALCULATION OF THE RESPONSE ACCURACY PERCENTAGE OF THE AI MODEL

Questions	*Criteria*				*%*	*Questions*	*Criteria*				*%*
	Clarity	Relevance	Coherence	Accuracy			Clarity	Relevance	Coherence	Accuracy

TABLE V. RESULTS OF THE AI MODEL EVALUATION

Value	
Mean	82%
Median	75%
Mode	100%
Standard Deviation	0.196
Minimum	50%
Maximum	100%

Source: Own Elaboration.

Table V presents the statistical data related to the responses provided by the artificial intelligence model alongside the RNN model. The mean accuracy was 82%, indicating a high level of acceptance, as it falls above the 70% threshold. The data show moderate dispersion around the mean, meaning the values are not highly spread out, but there is still noticeable variability. A mode of 100% was observed, making it the most frequent accuracy value among the responses. The answers fall within the upper range, with a minimum of 50% and a maximum of 100%, indicating that all responses had an accurate percentage above 50%.

A 95% confidence interval was calculated for the model's accuracy using the standard normal approximation, resulting in 0.82 ± 0.0543 (0.7657–0.8743). This interval confirms, with 95% confidence, the reliability and stability of the model's performance across the evaluated dataset.

J. Experiment

A test of the application was conducted with a group of 32 individuals who were either insured by EsSalud or interested in obtaining insurance from the institution. The users interacted

with the chatbot, powered by an RNN algorithm and an AI model, to make various insurance-related inquiries.

The participants were selected through a non-probabilistic sampling approach. The group consisted of 12 women and 20 men, all adults and active users of the national health insurance system. Participants were chosen based on their availability and familiarity with digital platforms, allowing an adequate representation of real insured users. The sample composition reflects the typical demographic distribution of the target population. This approach helps minimize potential bias and provides valid insights into user interaction with the proposed system.

Participants were then asked to complete a ten-question survey regarding their user experience, assessing their satisfaction with certain features or any difficulties encountered during usage. Table VI presents the scale and metric associated with each question.

TABLE VI. QUESTIONS ASKED IN THE USER SURVEY

No.	*Question*	*Scale*	*Metric*
Q1	How accurate do you consider the responses from the chatbot?	Likert	Average perceived accuracy by users
Q2	How often were the chatbot's responses useful and relevant to your inquiries?	Likert	Frequency of relevant vs. irrelevant responses
Q3	Are you satisfied with the time it takes for the chatbot to respond?	Likert	Satisfaction with response time and average response times
Q4	How easy was it to interact with the chatbot?	Likert	Average satisfaction with ease of use
Q5	What is your overall satisfaction level with the chatbot?	Likert	Average overall satisfaction
Q6	Did the chatbot effectively resolve your problem or answer your inquiry?	Dichotomic	Percentage of inquiries effectively resolved
Q7	Have you ever left the conversation with the chatbot before receiving a satisfactory response?	Dichotomic	Percentage of users who abandoned the conversation
Q8	Would you use this chatbot again in the future?	Dichotomic	Percentage of users with the intention to reuse
Q9	How would you compare the effectiveness of the chatbot to that of a human agent?	Likert	Perception of the chatbot compared to human support
Q10	How many times did the chatbot fail to understand or process your request?	Likert/ Intervals	Average number of errors or failures per session

Source: Own Elaboration.

V. RESULTS

Table VII shows the results obtained for questions Q1, Q2, Q3, Q4, and Q5, using a scale from 1 "Very Dissatisfied" to 5 "Very Satisfied". To calculate the average score per question, the sum of the products of each response value (1 to 5) and the number of users who selected that option was divided by a total of 32 users.

TABLE VII. RESULTS OBTAINED FOR QUESTIONS USING THE LIKERT SCALE

Result	*Q1*	*Q2*	*Q3*	*Q4*	*Q5*
5 - Very satisfied	21	20	23	25	20
4 - Satisfied	11	9	9	7	11
3 - Neutral	0	3	0	0	1
2 - Dissatisfied	0	0	0	0	0
1 – Very dissatisfied	0	0	0	0	0
Average	4.66	4.53	4.72	4.78	4.59

Source: Own Elaboration.

Regarding Accuracy of the Responses (Q1), 21 participants, representing 66%, indicated that they were Very Satisfied, and 11 participants, or 34%, responded that they were Satisfied. This indicates that the chatbot provides accurate and precise responses, with an average accuracy score of 4.66. The comparison is shown in Fig. 4.

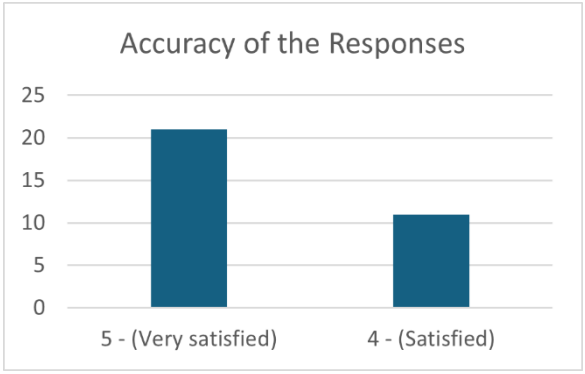

Fig. 4. Accuracy of the response results. Source: Own elaboration.

Regarding the Relevance of the Responses (Q2), 20 participants, representing 63%, indicated they were Very Satisfied; 9 participants, or 28%, responded that they were Satisfied; and 3 participants, representing 9%, expressed a Neutral opinion. This indicates that the chatbot is effectively providing relevant responses to users, with the majority expressing high satisfaction. The average frequency score was 4.53, as shown in Fig. 5.

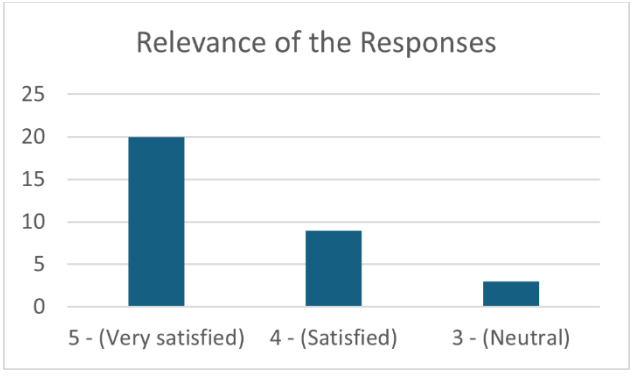

Fig. 5. Relevance of the response results. Source: Own elaboration.

Regarding Response Time (Q3), 23 participants (72%) indicated that they were Very Satisfied, and 9 participants

(28%) responded that they were Satisfied, leading to the conclusion that satisfaction with the chatbot's response time is adequate. The comparison is presented in Fig. 6.

Fig. 6. Response time results. Source: Own elaboration.

Regarding Ease of Use (Q4), it was found that 25 participants (78%) indicated they were Very Satisfied, and 7 (22%) responded that they were Satisfied. This indicates that the chatbot interface successfully provides a user-friendly tool, with an average satisfaction score of 4.78. The comparison is presented in Fig. 7.

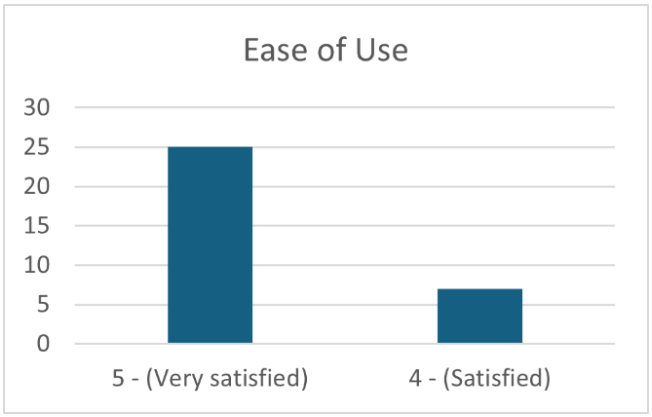

Fig. 7. Ease of use results. Source: Own elaboration.

Regarding the Overall Satisfaction Level (Q5), it was found that 20 participants (63%) indicated they were Very Satisfied, 11 (34%) responded that they were Satisfied, and 1 (3%) expressed a Neutral opinion. This indicates that the chatbot demonstrates a high level of overall satisfaction, with an average response score of 4.59. The comparison is shown in Fig. 8.

Table VIII shows the frequency of responses categorized into two options, 'Yes' and 'No', for the dichotomous questions.

Regarding the Question Resolution Rate (Q6), all participants (100%) perceived that the chatbot effectively resolved their submitted question, as shown in Fig. 9.

Regarding the Abandonment Rate (Q7), 5 participants (16%) indicated that they had abandoned the conversation before receiving a satisfactory response, while 27 participants (84%) did not abandon the conversation, resulting in a total abandonment rate of 16%. The comparison is shown in Fig. 10.

Fig. 8. Overall satisfaction level results. Source: Own elaboration.

TABLE VIII. RESULTS OBTAINED FROM DICHOTOMOUS SCALE QUESTIONS

ID	*Question*	*Yes*	*No*
Q6	Question Resolution Rate	32	0
Q7	Abandonment Rate	5	27
Q8	Intention to Reuse	32	0

Source: Own Elaboration.

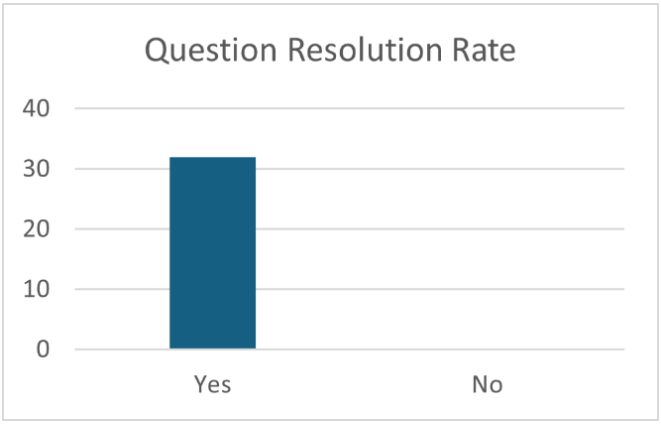

Fig. 9. Question resolution rate results. Source: Own elaboration.

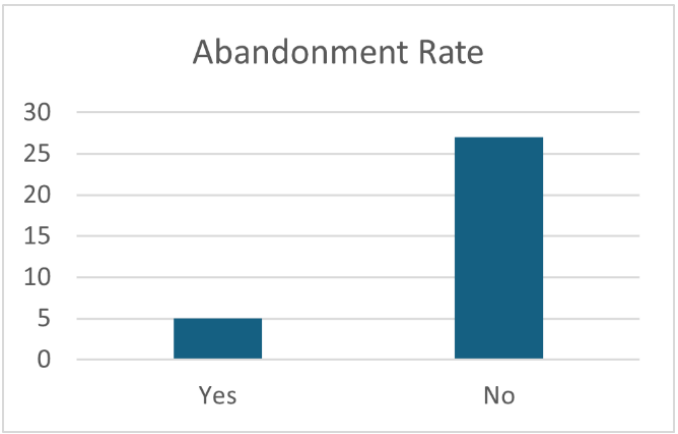

Fig. 10. Abandonment rate results. Source: Own elaboration.

Regarding the Intention to Reuse the Application (Q8), it was found that all participants (100%) would be willing to use this tool in the future. The comparison is shown in Fig. 11.

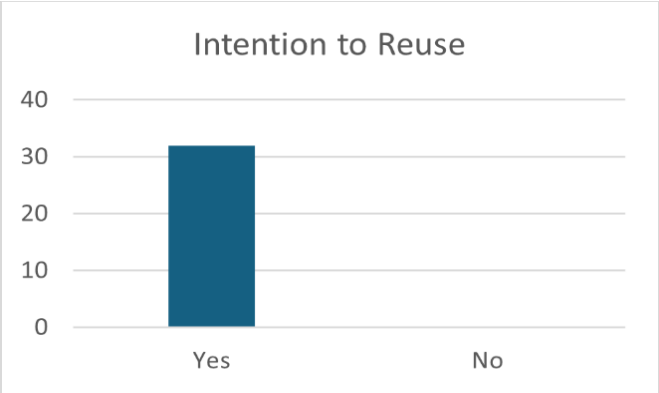

Fig. 11. Results on the intention to reuse. Source: Own elaboration.

Table IX shows the results obtained for the ninth question related to the comparison with human support, using a rating scale from "Much Worse" to "Much Better".

TABLE IX. RESULTS OBTAINED FOR QUESTION 9

Results	*Q9*
Much better	13
Better	12
Equal	7
Worse	0
Much worse	0

Source: Own Elaboration.

Regarding the Comparison with Human Support, 13 participants (41%) indicated that they consider the chatbot to be Much Better, 12 (37%) consider it Better, and 7 (22%) find it Equal to the attention provided by a human agent. The comparison is shown in Fig. 12.

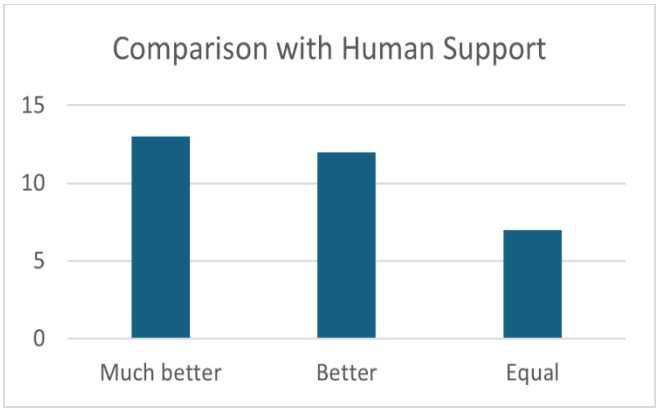

Fig. 12. Results on the comparison with human support. Source: Own elaboration.

Finally, Table X displays the results for question 10, focused on the number of errors encountered during queries.

Regarding the Error Rate (Q10), 20 participants (63%) reported not encountering any errors, 4 (13%) encountered 1 error, and 8 (25%) encountered 2 errors. There is an average of 0.63 errors found per user. The comparison is shown in Fig. 13.

VI. DISCUSSION

The results of this study demonstrate that a chatbot integrated with artificial intelligence can be an effective solution to improve access to information about health insurance in Peru. Validation was carried out using 50 questions evaluated on the criteria of clarity, relevance, coherence, and accuracy, yielding an overall mean response accuracy of 82%, which, together with the usability findings, indicates that the chatbot achieved a high level of acceptance and reliable functionality.

In comparison with related work, study [5] employs an RNN along with a Sequential Matching Framework (SMF) that transforms words into vectors and analyzes complex relationships between expressions, achieving high precision (0.97). In contrast, the present work uses a simple RNN without SMF, focused on classifying frequently asked questions about health insurance. Instead of adding complexity, it is complemented by the OpenAI model, which effectively interprets context. This combination provides fast and clear answers to specific queries, reaching 82% compliance and 97% user satisfaction in testing.

In study [6], bidirectional LSTM neural networks (BiLSTM) are combined with a Text Convolutional Neural Network (TextCNN). Although both models rely on neural networks, the present study focuses on simple RNNs, which are more efficient for short questions and well-defined contexts such as EsSalud health insurance. This integration enables the system to respond to queries without the need for computationally intensive architecture or elaborate training processes, maintaining a good balance between performance and simplicity. In contrast, the hybrid BiLSTM-TextCNN approach focuses on recognizing general textual patterns, which are more complex.

On the other hand, study [7] employs advanced architecture that combines LSTM with a Seq2Seq model to develop highly complex chatbots, especially useful for extended dialogues. In contrast, this study opts for a simple RNN, avoiding the complexity of the Seq2Seq approach and focusing on brief, specific queries related to health insurance. This simplicity enhances efficiency while achieving similar results. Furthermore, the use of OpenAI's language model improves the understanding of question semantics and enables the generation of clearer and more appropriate responses. This makes the system more useful and practical when compared to models like DeepQA, which are more oriented toward maintaining long and complex conversations.

In study [8], the Bablibot chatbot was developed to answer questions related to immunization in Pakistan, utilizing a continuous learning process. The result was a 90% user acceptance rate. In comparison, the proposed model focuses on the domain of health insurance, an area in which users often have limited prior knowledge. Despite this, the proposed system achieved satisfaction rates of 63% (very satisfied) and 34% (satisfied), resulting in a total satisfaction score of 97%.

Additionally, study [9] employs Dempster-Shafer theory to fuse data from multiple sources, enhancing accuracy in complex and highly contextual questions. In contrast, the present work uses a simple RNN architecture without external data fusion, focusing on delivering immediate and accurate responses within the specific domain of health insurance. This narrower contextual scope enables faster response times and easier implementation.

Finally, in study [10], a variation of RNN known as Transposed GRU was used, which reverses the input data sequence during processing. In comparison, this study opted for a simple RNN to generate chatbot responses, which was likewise validated through user feedback via a survey. In the user validation, the present study achieved a perceived relevance of responses of 91% (63% "Very Satisfied" and 28% "Satisfied"), compared to the 76% obtained in the referenced study. Furthermore, the overall satisfaction level perceived by users was predominantly positive at 97% (63% "Very Satisfied" and 34% "Satisfied"), contrasting with the 76.2% acceptance rate reported in the referenced work.

Although the model demonstrated strong results, it has limitations in handling complex questions or extended dialogues due to the use of a simple RNN. In addition, depending on the OpenAI-provided AI model, constraints may arise in certain contexts. The validation was also conducted with a limited sample size, and expanding the study could provide more comprehensive feedback to identify critical improvement areas.

Despite these limitations, the model stands out for its simplicity, speed, and ease of implementation. These features make it potentially adaptable to other industries, such as education, public services, or other insurance providers, where quick and clear access to information is equally essential. Adjusting the content and context would be sufficient to address emerging community needs, thanks to the scalability of the system. This scalability depends on the databases to be incorporated for adaptation to other health domains, as well as the expansion of training questions to be used, thereby enriching the information possessed by the developed model.

VII. Conclusion

Artificial intelligence presents great potential to support customer service in the healthcare sector. Through an AI- and RNN-based chatbot, it is possible to automate repetitive tasks such as answering frequently asked questions and providing basic information about health insurance, thanks to the RNN algorithm's ability to select the most optimal response and the AI model's natural language generation capabilities. This technology not only improves response speed and reduces wait times but also demonstrates that intelligent automation can be integrated into both public and private healthcare institutions to enhance information accessibility and efficiency. Despite their relatively simple implementation, this type of solution demonstrates the feasibility of modernizing service channels using accessible and efficient tools, promoting a better experience for both insured and uninsured individuals, with the potential to enrich the chatbot's responses by increasing the training data for the RNN model or employing more specialized architectures tailored to this type of algorithm.

The evaluation results showed an overall mean response accuracy of 82% and high satisfaction levels across all criteria, indicating that the developed chatbot provides reliable, coherent, and contextually relevant responses. These findings suggest that combining an RNN classifier with a generative model like GPT-3.5 constitutes an effective hybrid strategy for managing health-related queries, achieving performance close to that of human support.

It was found that the developed chatbot and the designed interface were well received by users, with a majority of responses indicating "Very Satisfied" for Question P1 on perceived response accuracy (66%) and P5 on overall satisfaction (63%). Additionally, there was a positive perception compared to human support, with 78% of participants stating the experience was "Much Better" (41%) or "Better" (37%). Finally, the intention to reuse the tool reached 100%, meaning that all participants found the chatbot useful.

From a practical perspective, these results imply that implementing similar chatbots could significantly reduce administrative bottlenecks and improve the user experience in state health systems by facilitating immediate and accurate access to insurance information. Scientifically, the study contributes evidence that hybrid AI models can successfully merge deterministic and generative reasoning to improve the interpretability and adaptability of automated agents in specialized domains.

Furthermore, the 100% intention to reuse the tool and the 78% positive comparison to human support highlight users' trust in this type of system, reflecting its potential to complement rather than replace human staff. Future research could explore expanding the dataset used for RNN training, integrating reinforcement learning for adaptive responses, and testing the model in other public service areas, thus consolidating AI's role in citizen-oriented digital transformation.

ACKNOWLEDGMENT

Thanks to the Dirección de Investigación of the Universidad Peruana de Ciencias Aplicadas for their support to carry out this research work through the UPC-EXPOST-2025-2 incentive.

ETHICAL APPROVAL

The study involved only anonymous usability testing conducted by voluntary users. No clinical data or personal information were collected, and the study posed no risk to participants. Although formal ethical approval was not required, the research was conducted in accordance with the general ethical principles outlined in the Declaration of Helsinki.

INFORMED CONSENT

When accessing the application, all participants were clearly informed about the purpose of the study and that no personal data was required. Participants voluntarily agreed to take part in the usability testing, and upon entering the system, they enabled the option confirming their understanding of the application's purpose and provided their consent through the platform itself to proceed with its use.

DISCLOSURE STATEMENT

The authors report there are no competing interests to declare.

DATA AVAILABILITY STATEMENT

The data that support the findings of this study are openly available in the Open Science Framework (OSF) at: https://doi.org/10.17605/OSF.IO/F49Q7.

APPENDIX A: PSEUDO CODE OF THE PROPOSED RNN–AI MODEL

```
System Initialization:
a. Load the pre-trained Recurrent Neural Network (RNN) model from
"modelo.keras".
b. Load the tokenizer ("tokenizer.pkl") and label encoder
("label_encoder.pkl"), required for text processing and response
interpretation.
c. Define global system parameters:
i. Maximum sequence length: 20
ii. Confidence threshold: 0.7

Query Reception:
a. The system receives the user's input (Q).
b. Validate that the question is not empty and does not contain
unrecognized or invalid characters.

Text Preprocessing and Normalization:
a. Convert the entire query to lowercase.
b. Tokenize the text, converting each word into a numeric index according
to the trained vocabulary.
c. Apply padding to the resulting sequence to reach the predefined maximum
length.

RNN Inference:
a. Feed the processed sequence into the RNN model.
b. The model produces a probability distribution (P) over all possible
responses in its trained set.

Prediction Confidence Evaluation:
a. Identify the maximum probability (prob_max = max(P)) and the associated
index (response_index = argmax(P)).
b. If the obtained probability is greater than or equal to the defined
threshold, decode the response using the label encoder.

Base Response Generation:
a. If (prob_max ≥ confidence_threshold), obtain the preliminary response
(R) from the identified index.
b. If no relevant match is found, set a generic response:
R ← "I'm sorry, I don't have that information."

Response Postprocessing:
a. Clean and format (R), removing duplicates, errors, or unnecessary
characters.

Integration with the Generative Model (OpenAI):
a. Send the base response (R) as input to OpenAI's language model.
b. OpenAI analyzes, reformulates, and enriches the content, producing a
more natural, clear, and contextualized final response: (R_final).

Error and Exception Handling:
a. If an error occurs while loading model files or performing inference,
log the event in the system logs.
b. In such cases, return the message: "The request could not be processed."

System Output:
Present the final response (R_final) to the user as the result of the
chatbot interaction.
```

Text Information Data Mining Method in Natural Language Processing Tasks

Shengguo Guo*, Dandan Xing
School of Information Engineering, Zhenzhou College of Finance and Economics, Zhengzhou, China

***Abstract*—Text mining methods often rely on a single data source or simple word frequency statistics, making it difficult to capture multi-source text semantic associations and local contextual dependencies, resulting in poor mining accuracy. Therefore, a method for text information data mining in natural language processing tasks is proposed. Using Python web crawlers to obtain multi-source text data, after preprocessing such as cleaning, segmentation, and removal of stop words, a Vector Space Model (VSM) is used for text representation, and a TF-IDF (Term Frequency Across Document Frequency) weight optimization mechanism is introduced to enhance feature semantic representation. On this basis, a semantic enhancement system is constructed based on the BERT classification model in the field of natural language processing. Through the self-attention mechanism of multi-layer Transformer encoders, semantics are aggregated to effectively capture local contextual dependencies, and context-sensitive word vectors are generated by the output layer. Finally, by fine-tuning the parameters of the BERT (Bidirectional Encoder Representation from Transformers) model and combining it with the Softmax function, precise mining of text information data categories was achieved. The experimental results show that in the embedding experiment of sports news headlines, this method can form a semantic aggregation structure with clear domain logic for word vectors; In the cross domain short text classification experiment, the overall accuracy of this method on the dataset reached 95.7%, which was 19.5% and 18.7% higher than the comparative methods, effectively solving the cross domain ambiguity problem in natural language processing.**

Keywords*—Natural language processing; text information; data mining; VSM; TF-IDF; BERT

I. Introduction

Text information data is widely distributed in scenarios such as social media, academic platforms, enterprise systems, and medical databases, covering diverse types such as online reviews, academic papers, financial annual reports, and electronic medical records. These data continue to grow at a rate of hundreds of millions per day, forming a huge unstructured information cluster. Different from structured data, text information data exhibits significant looseness and complexity: online jargon, abbreviations, and emojis are mixed in social media comments; academic literature involves professional terms and complex sentence patterns; industry jargon and ambiguous expressions exist in enterprise reports; medical records contain medical codes and colloquial records. These characteristics make it difficult for computers to directly and efficiently process and analyze text information [1]. Facing such complex and disorderly text information data, how to extract valuable knowledge from it has become an important topic in the field of data science. Studying text information data mining methods aims to break through the unstructured barriers of text and extract implicit patterns, trends, and relationships from massive texts [2]. Taking an e-commerce platform as an example, by mining consumer reviews, not only can specific pain points of products in dimensions such as function, quality, and service be identified, but also the evolution trend of user needs over time can be traced; in the field of academic research, in-depth mining of literature can reveal interdisciplinary hotspots, technology evolution paths, and key unsolved problems; in the medical field, analysis of medical record texts can discover potential associations between disease symptoms and treatment plans, and even predict the incidence patterns of diseases [3]. Through these mining efforts, disorderly text data is transformed into structured knowledge, achieving a qualitative change from "data accumulation" to "knowledge precipitation", providing a core basis for decision-making, technological innovation, and problem-solving.

In the research on text data mining in the industry, Kim, H. J. et al. proposed a conditional generative adversarial multiple imputation network based on unsupervised data mining. An auxiliary classifier was developed through a pre-training algorithm combined with implicit class labels. The sorting point recognition clustering structure algorithm of fuzzy clustering was used to learn implicit classification information, and multiple imputation was applied to the original energy dataset to improve the robustness and reliability of the imputation results [4]. However, when explicit class labels are not available, it is difficult to effectively capture the semantic associations of multi-source texts, resulting in poor accuracy of mining results. Rahman, U. et al. used two classification algorithms, Naive Bayes and Support Vector Machine, to perform binary classification on the text data generated by the regular maintenance of industrial plant equipment. The model was trained and tested by analyzing the labeled data to achieve the early classification of equipment failures, thereby improving the industry maintenance plan [5]. However, this method does not consider capturing the long-distance dependence relationships between different words in the text, which may lead to a decrease in the classification mining accuracy in complex fault scenarios. Kumar, M. R. P. et al. mined context-related subjective words in the text through a context-based sentiment dictionary, calculated the weight scores of subjective terms and complete reviews, and then classified the text sentiment with the help of a bidirectional LSTM model. At the same time, an oversampling technique was used to generate new synthetic text samples using semantic information to solve the

* Corresponding author.

data imbalance problem and achieve sentiment classification mining of imbalanced corpora [6]. However, the context-based sentiment dictionary needs to be manually defined or pre-annotated, and it is difficult to cover new sentiment expressions in dynamic contexts, resulting in poor capture of the semantic associations of multi-source texts and poor adaptability to out-of-domain texts. Kim, H. et al. proposed a flexible periodic pattern data mining method for incremental time series databases, which processes data streams in real time by enhancing the data structure and mines periodic patterns containing uncertain events, providing decision support for scenarios such as oil price fluctuation prediction and traffic congestion analysis [7]. However, this method cannot accurately express the semantic differences of words in different contexts, easily leading to insufficient accuracy of text representation and poor mining performance.

In summary, existing text information data mining methods still have significant limitations in deep semantic modeling and cross-domain generalization ability: most models fail to effectively integrate the statistical features of text with global contextual semantics, resulting in insufficient semantic understanding of polysemous words, domain-specific terminology, and cross-domain short texts, thereby restricting further improvement in mining accuracy and practicality. Natural Language Processing (NLP), as the core technology for processing text data, provides crucial support for text information data mining [8]. In recent years, NLP technologies driven by deep learning, such as pre-trained language models like BERT and GPT, have significantly improved the ability to understand text semantics through learning from massive corpora, greatly promoting the development of text information data mining [9]. These technologies can accurately capture the sentiment tendency, entity relationships, and topic context in text, demonstrating great value in practical applications: in the e-commerce field, mining the semantic features of consumer reviews can assist in product optimization; in the medical industry, mining medical record texts helps with clinical decision-making; in academic research, literature semantic analysis can help keep up with the cutting-edge of the discipline [10]. Therefore, in view of the limitations of the above methods, this study focuses on the research of text information data mining methods in natural language processing tasks, in order to promote the cross-innovation of natural language processing and data mining technologies, and provide efficient transformation solutions from text data to structured knowledge for various industries. The specific technical route is as follows:

- Firstly, a Python web crawler is used to construct a multi-source heterogeneous text corpus, and strict cleaning, segmentation, and stop word preprocessing are performed to provide a high-quality, cross-domain training and evaluation foundation for the model, overcoming the bias problem caused by a single data source.
- Then, based on the vector space model representation, the TF-IDF weight optimization mechanism is introduced. This step goes beyond simple word frequency statistics and can enhance key semantic features with high discrimination, providing strong feature inputs rich in statistical information for subsequent deep models and improving the discriminative power of semantic representation from the perspective of feature engineering.
- Subsequently, a semantic enhancement system based on the BERT classification model was constructed, which utilizes the self-attention mechanism of the Transformer encoder to dynamically aggregate global contextual information, accurately capturing long-distance dependencies and polysemy between words, fundamentally solving the core deficiency of weak contextual modeling ability in traditional models.
- Finally, the optimized TF-IDF features are deeply fused with the context vector of BERT through fine-tuning strategies, and precise classification is achieved using the Softmax function. This fusion scheme not only inherits the advantages of traditional methods with clear features, but also has the semantic understanding ability of deep models.
- Design a cross-domain short text classification experiment to verify the comprehensive performance of the proposed framework in handling polysemous words and domain-specific terms from dimensions such as semantic representation quality, computational efficiency, and term robustness on a multi-domain news headline dataset, including sports, entertainment, and real estate.

II. Optimize Text Feature Vectors Based on TF-IDF

In the text information data mining task in the field of Natural Language Processing (NLP), the core is to convert unstructured text into computable semantic information, and data acquisition and preprocessing are the basic links to achieve this goal [11]. This study applies web crawler technology based on Python to crawl the required text data from various text data sources, such as social media, news texts, and academic literature. Collect information such as text content and publication time, and store the data in text format to provide the original corpus for subsequent text information data mining [12].

A. Text Information Data Preprocessing

The preprocessing process of text information data is shown in Fig. 1, and the specific process is as follows:

1) Text data cleaning: Remove the possible special symbols and extra blanks in the crawled text data. Extra blanks may separate complete words, resulting in incorrect word segmentation, reducing the word segmentation accuracy, and thus affecting the final text information data mining effect. Therefore, it is necessary to ensure the standardization of text data through cleaning [13].

2) Chinese text word segmentation: Select the jieba word segmentation library based on the Chinese word library in Python to perform word segmentation on the text data. Split the text content into characters, words, or phrases so that the computer can accurately recognize the words in the text. This

method has high word segmentation accuracy and fast speed, which can improve the accuracy of subsequent text classification, clustering, and other tasks [14].

3) Remove obsolete terms: Compare with the obsolete terms library to filter the text data, delete words such as modal particles, prepositions, and pronouns that have no actual meaning and may affect the text mining results, increase the keyword density of the text, and at the same time reduce the feature dimension, thereby improving the accuracy and efficiency of text mining [15].

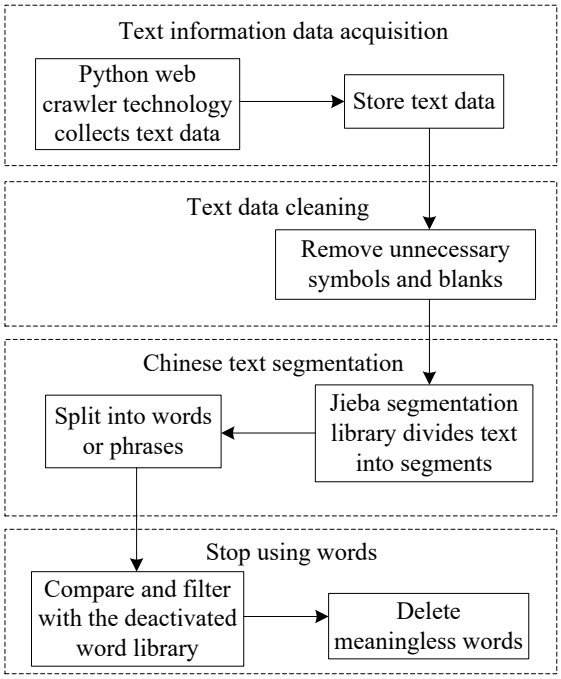

Fig. 1. Preprocessing process of text information data.

B. Text Representation Based on Vector Space Model

Text representation, as a key bridge connecting natural language and machine understanding, directly determines the accuracy and efficiency of subsequent mining tasks. After acquiring and preprocessing text data, it is necessary to further transform unstructured text into a structured representation that can be processed by a computer, laying a foundation for in-depth semantic analysis. There are mainly three common text representation models: the Boolean model, the probabilistic model, and the vector space model. The vector space model (VSM), as one of the most widely used and effective methods currently, has its technical advantages directly reflected in the processing efficiency and mining accuracy of actual text data [16]. The smallest data unit in the vector space model is the feature term, and words, phrases, and word groups can all be used as feature terms for processing. Regarding the text c as a n -dimensional vector in the vector space, as shown in Eq. (1):

$$c=\left(\left(\varepsilon_1,\omega_1\right),\left(\varepsilon_2,\omega_2\right),\cdots,\left(\varepsilon_n,\omega_n\right)\right) \tag{1}$$

where, ε_i represents the i -th feature term of the text c; ω_i represents the feature weight corresponding to the i -th feature term of the text c, and the magnitude of the feature weight indicates the amount of text category information contained in this feature.

C. Weight Optimization Based on TF-IDF

The text data representation based on the vector space model realizes the structured processing of text through the vector mapping of feature terms and weights. However, this method relies on word frequency statistics and lacks semantic association modeling. Therefore, the TF-IDF (Term Frequency-Inverse Document Frequency) weight optimization representation method is introduced to enhance the semantic representation ability on the basis of retaining the VSM feature weight system and adapting to the complex semantic requirements in text information data mining [17]. For example, in VSM, "computer" and "PC" are regarded as independent dimensions with no associated weights, while TF-IDF ensures that both obtain high weights in scientific and technological texts through IDF, indirectly improving the similarity of semantically related texts.

For the text collection $C=\left\{c_1,c_2,\cdots,c_M\right\}$, M is the total number of texts in the text collection C. Following the feature term processing logic of VSM, the feature term set $\left\{\varepsilon_1,\varepsilon_2,\cdots,\varepsilon_n\right\}$ is obtained. Taking each feature term ε_i as a dimension of the vector space, the weight ω_i of each feature term ε_i in the document is calculated through TF-IDF, as shown in Eq. (2) to Eq. (4):

$$\omega_i=\omega\left(\varepsilon_i,C_j\right)=\frac{TF\left(\varepsilon_i,C_j\right)\times IDF\left(\varepsilon_i\right)}{\sqrt{\sum_{\varepsilon_i\in C_j}\left[TF\left(\varepsilon_i,C_j\right)\times IDF\left(\varepsilon_i\right)\right]^2}} \tag{2}$$

$$TF\left(\varepsilon_i,C_j\right)=\frac{D\left(\varepsilon_i,C_j\right)}{D\left(C_j\right)} \tag{3}$$

$$IDF\left(\varepsilon_i\right)=\log\left(\frac{M}{D\left(\varepsilon_i\right)}+0.01\right) \tag{4}$$

where, $TF\left(\varepsilon_i,C_j\right)$ represents the relative frequency of the feature term ε_i in the single text C_j; $IDF\left(\varepsilon_i\right)$ is the inverse document frequency, which measures the discrimination ability of the feature term ε_i in the entire text collection. If the feature term ε_i appears in more texts ($D\left(\varepsilon_i\right)$ is larger), then its discrimination degree is lower. On the contrary, if it only appears in a few texts, the higher the IDF value, the greater the weight; $D\left(\varepsilon_i,C_j\right)$ is the absolute number of occurrences of the feature term ε_i in the text C_j; $D\left(C_j\right)$ is the total

number of feature terms in the text C_j; $D(\varepsilon_i)$ is the number of texts containing ε_i.

Assume that the text $C_j = (\varepsilon_1, \varepsilon_2, \cdots, \varepsilon_t)$ contains t feature terms. Multiply the weight of each feature term to the corresponding vector dimension to obtain the weighted text feature vector y_i, as shown in Eq. (5):

$$y_i = \varepsilon_i \times \omega(\varepsilon_i, C_j) \tag{5}$$

The feature vectors of each text in the text collection C is shown in Eq. (6):

$$\phi_i = \frac{\sum_{j=1}^{t} y_j}{|C_i|} \tag{6}$$

where, $\sum_{j=1}^{t} y_j$ is the semantic contribution that integrates all features within the text. For example, in scientific and technological texts, the vector weights of words such as "artificial intelligence" and "big data" will be accumulated. $|C_i|$ is the text length normalization factor.

III. Text Information Data Mining Based on Semantic Enhancement of BERT Classification Model

After optimizing the text feature vector based on TF-IDF, the BERT classification model (Bidirectional Encoder Representations from Transformers) is further introduced to achieve the upgrade from statistical representation to semantic representation, thereby capturing the long-distance dependency relationships between different words in the text and automatically learning the importance weights between words, so as to generate more accurate and context-sensitive word vectors [18]. This model adopts a bidirectional variant of the encoder-decoder architecture and consists of an input layer, an encoding layer, and an output layer. The model structure is shown in Fig. 2. The design of this model structure directly serves the classification task in text information data mining:

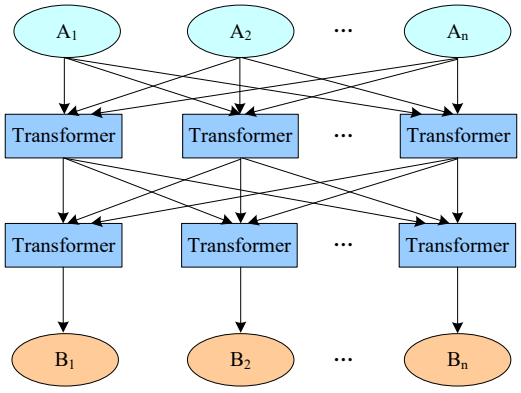

Fig. 2. Structure of BERT classification model.

The input layer combines the TF-IDF text feature vector representation $\{\phi_1, \phi_2, \cdots, \phi_n\}$ with the original text information to generate a composite text input sequence $\{A | A_1, A_2, \cdots, A_n\}$; the encoding layer is stacked by multiple layers of Transformer encoders, and each layer realizes semantic aggregation through the self-attention mechanism and the feed-forward neural network; the output layer $\{B | B_1, B_2, \cdots, B_n\}$ represents the generated word vector. A_i corresponds to B_i, and i is the i -th word of the input text.

Under the self-attention mechanism, the input vector is characterized by three vectors: the query vector Q, the key vector K, and the value vector V. The semantic association weights between words are dynamically calculated through triple operations [19], and the context of the TF-IDF feature vector representation is corrected. For example, "bank" generates different encodings in the contexts of "financial bank" and "riverbank". Input vector calculation expressions are shown in Eq. (7) to Eq. (9):

$$Q = f(q(A)) \tag{7}$$

$$K = f(k(A)) \tag{8}$$

$$V = f(v(A)) \tag{9}$$

In the equation, $f(.)$ is the linear transformation function of *linear*.

During the calculation process, each word vector participates with other vectors. Therefore, in the specific algorithm design, it is necessary to construct the corresponding weight matrix and continuously learn and update it during training. When encoding a word, not only the current word but also the context in which the word is located must be considered, so that the current word vector is integrated with the overall context, which is the self-attention mechanism. The query vector Q of each word will calculate scores with each key vector K in the entire sequence. The larger the inner product of Q and K, the closer the correlation. Based on the score redistribution feature, the scores are converted into probabilities through the Softmax function.

Different attention heads of the multi-head attention mechanism extract multiple groups of features to capture multi-dimensional semantic associations of the text, which directly serve the category discrimination task in text information data mining [20]. The calculation of the multi-head attention mechanism is shown in Eq. (10) and Eq. (11), and the attention results of each head are generated through the equation. Considering that the Softmax function may cause the gradient vanishing problem under high-value inputs, Transformer introduces a "scaling" mechanism, using the dimension parameter u_k to normalize QK^{T} to ensure the stability of gradient optimization when fusing TF -IDF features.

$$H_i = Z\left(QW_i^Q, KW_i^K, VW_i^V\right) \tag{10}$$

$$Z(Q,K,V) = S\left(\frac{QK^{\mathrm{T}}}{H_i\sqrt{u_k}}\right)V \tag{11}$$

where, QW_i^Q is the product of the query matrix Q and the weight matrix W_i^Q of the i -th head, which is used to generate the query vector of the i -th head; KW_i^K is the product of the key matrix K and the weight matrix W_i^K of the i -th head, which is used to generate the key vector of the i -th head; VW_i^V is the product of the value matrix V and the weight matrix W_i^V of the i -th head, which is used to generate the value vector of the i -th head; H is the attention head; $Z(.)$ is the attention mechanism; $S(.)$ is the Softmax function.

The diagram of the multi-head attention mechanism is shown in Fig. 3.

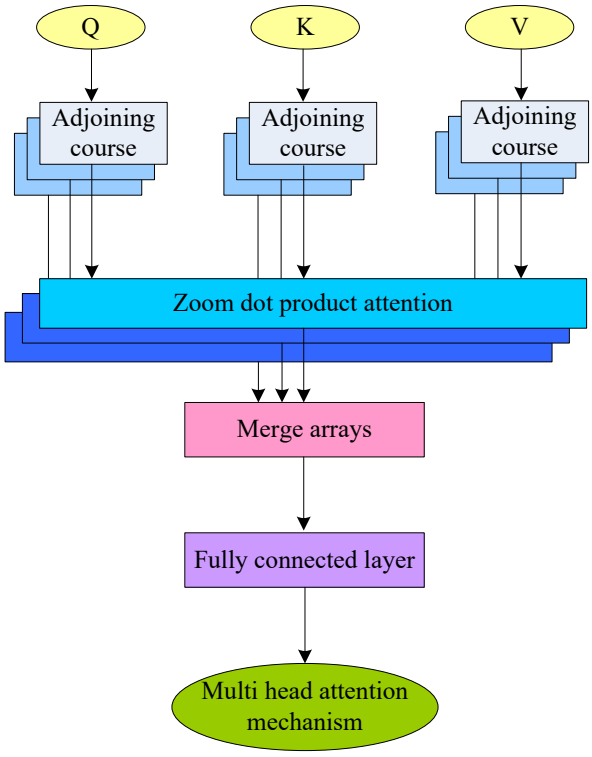

Fig. 3. Multi-head attention structure diagram.

In the model fine-tuning stage, not only the powerful ability of BERT to extract context information is retained, but also the association between TF-IDF features and class labels is further strengthened by optimizing the parameters of the classification layer [21]. The fine-tuning process minimizes the difference between the predicted probability and the true label through the cross-entropy loss function. Its core goal is to enable the BERT model to learn the discriminative representation of TF-IDF feature vectors in specific classification tasks while retaining the pre-trained semantic knowledge. Fine-tune the cross-entropy loss function used, as shown in Eq. (12):

$$L = -\frac{1}{N}\sum_{i=1}^{N}\left[x_i \times \log(\rho_i) + (1-x_i)\times\log(1-\rho_i)\right] \tag{12}$$

where, N is the total number of text samples participating in the model fine-tuning, x_i is the actual category of the i -th text sample, and ρ_i is the probability predicted for the i -th text sample.

During the fine-tuning process, by dynamically adjusting hyperparameters such as the learning rate, batch size, and number of training epochs, the model's ability to utilize TF-IDF features and capture context semantics can be effectively balanced. For example, in scientific and technological text classification, a larger learning rate can accelerate the model's response to high-weight domain words in TF-IDF (such as "deep learning"), while a smaller learning rate helps to fine-tune context relationships (such as the "although...but..." structure).

The fine-tuned model maps the feature vectors output by BERT to a class probability distribution through the Softmax function, as shown in Eq. (13):

$$S(Z_i) = \frac{e^{z_i}}{\sum_{j=1}^{n} e^{z_j}} \tag{13}$$

where, Z_i is the i -th element of the input vector of the Softmax function.

In the text information data mining framework, the input Z_i of the Softmax function is directly associated with the output of the multi-head attention mechanism: the scores Z_i corresponding to each category are the projections of the semantic representations of all words (i.e., the weighted value vectors of multi-head attention) on that category. Through Softmax calculation, the model can dynamically focus on the TF-IDF features most relevant to the category (such as high-weight words like "algorithm" and "model" in technology texts), while suppressing irrelevant information, thus achieving accurate discrimination of text categories. For example, when the input is "The application of artificial intelligence in natural language processing", the Softmax function will strengthen the influence of the TF-IDF weights of "artificial intelligence" and "natural language processing" on the classification decision, and weaken the interference of general words such as "of" and "in".

IV. Experimental Analysis

A. Experimental Settings

The experimental object of this study is the short text corpus of news titles crawled from news websites through web crawlers, covering five categories: sports, entertainment, real estate, health, and automotive. 4000 titles are collected for each category, with a total of 20000 samples. Due to the highly imbalanced samples in the dataset, the 5-fold cross-

validation method is adopted in the classification result comparison experiment: the dataset is evenly divided into five parts, and each time four parts are taken as the training set and one part as the test set for cyclic testing. Finally, the contingency is eliminated by calculating the average value of multiple test results, and at the same time, it is ensured that there is no data intersection between the training set and the test set. All texts have been cleaned and de-duplicated, segmented by jieba, and stop words removed based on the domain-specific word list to verify the performance of the text information data mining method in this study for short text classification tasks. The parameters of the experimental BERT classification model are shown in Table I. The experimental environment is shown in Fig. 4.

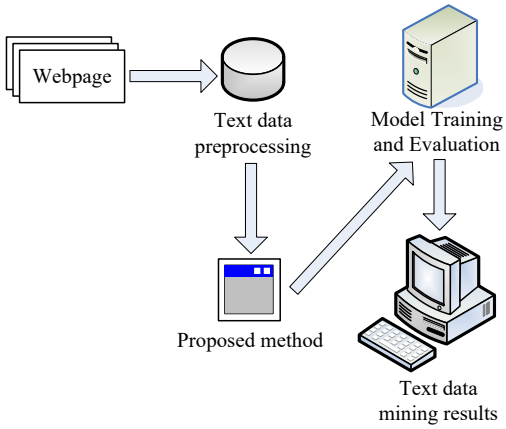

Fig. 4. Experimental environment.

TABLE I. EXPERIMENTAL BERT CLASSIFICATION MODEL PARAMETERS

Training parameters	Numerical value
Encoder layers	12
The number of self-attention heads	12
Batch sample size	15
Learning rate	0.005
number of iterations	10
Optimizer type	Adam

To verify the effectiveness of the word embedding generation method in this study for text information data, 50 professional words are systematically selected from the sports news title dataset, covering sub-domain terms such as basketball (e.g., three-point shot, dunk), football (e.g., offside, free kick), and comprehensive events (e.g., championship, home court advantage), etc.

B. Analysis of the Effectiveness of the Proposed Method

The text representation method based on semantic enhancement of the BERT classification model in this study is adopted to generate word embedding vectors through a three-layer processing process of "TF-IDF weight pre-optimization-bidirectional Transformer encoding-domain feature dynamic mapping", and the semantic association characteristics are presented in multiple dimensions by means of visualization technology. The experimental results are shown in Fig. 5.

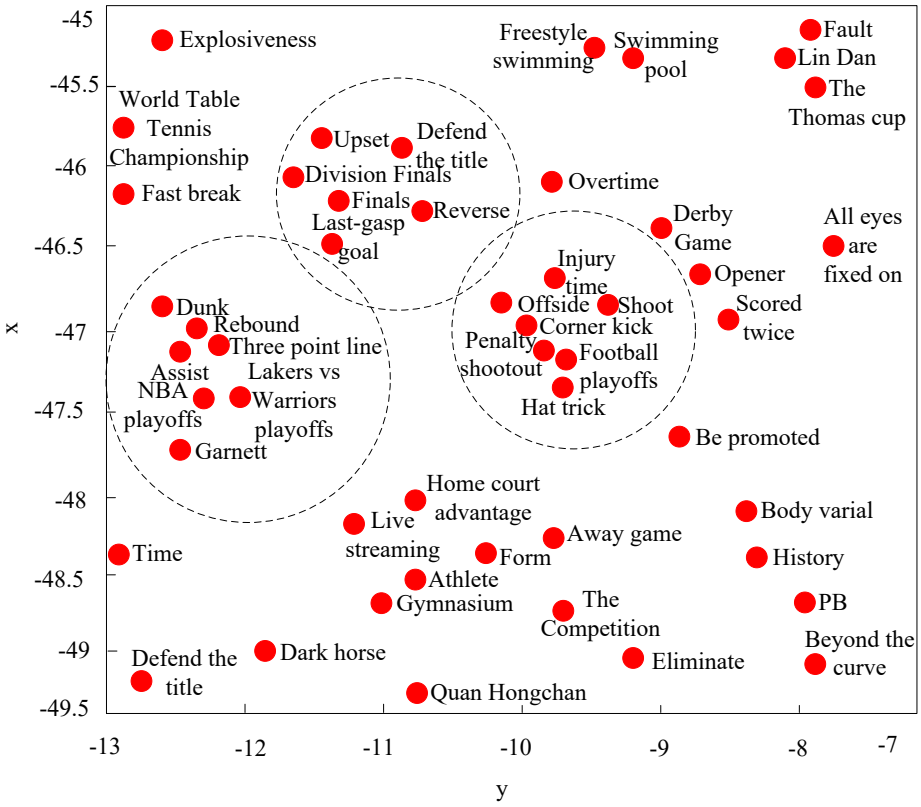

Fig. 5. Semantic spatial distribution of term embeddings in sports news texts.

Fig. 5 shows the semantic spatial distribution of the word embedding vectors generated after adopting the text representation method based on semantic enhancement of the BERT classification model in this study in the sports news title data. Several significant characteristics can be observed from the figure:

Dense clustered distribution of basketball technical terms: Basketball technical terms centered around "rebound", "assist", "three-point line", etc. show a dense clustered distribution in space. This is due to the fact that the method in this study captures the shared semantic features of "basketball movement technical actions" through the self-attention mechanism, reflecting the strong semantic associations among them, making the word vectors of similar terms highly adjacent in space.

Independent semantic clusters of football rule terms: Different from basketball technical terms, football rule terms such as "offside", "corner kick", and "penalty shootout" form independent semantic clusters. The method in this study dynamically adjusts the domain feature weights, keeping the football term clusters at a distinguishable spatial distance from the basketball technical clusters, which reflects the knowledge boundaries of different sports. For example, "offside" is a unique rule in football, and its word vector is relatively far from the word vectors of basketball terms in space, reflecting the semantic differences between them.

Semantic connections of general concepts: General concepts such as "athlete", "stadium", and "event live broadcast" on the periphery form semantic connections with the core terms through the BERT self-attention mechanism of the method in this study. For example, the vector of "stadium" has a significantly higher association strength with "home court advantage" than with "away game", which shows that the method in this study can capture the semantic changes of words in different contexts.

Hierarchical semantic network: In the word vector representation of "NBA playoffs", the method in this study strengthens the domain weights of "NBA" and "playoffs" through TF-IDF, and uses the Transformer encoder to capture the event stage features in contexts such as "Lakers vs. Warriors playoffs". This makes the word vector form a semantic chain with terms such as "finals" and "conference finals" in space, while maintaining an obvious separation from cross-domain expressions such as "football playoffs".

It can be seen that the method in this study can provide a vector representation basis with both semantic accuracy and domain adaptability for mining tasks such as intelligent classification of sports news and hot event tracking.

C. Experimental Comparative Analysis

To verify the effectiveness of the text information data mining method in this natural language processing task, multi-dimensional comparative experiments are designed: The method in this study is compared with traditional methods such as TextCNN, BiLSTM, and recently proposed Transformer baseline models RoBERTa and DistilBERT in four indicators such as semantic representation and computational efficiency. The comparison methods and configurations, and the evaluation indicator system are shown in Table II and Table III.

TABLE II. COMPARISON METHODS AND CONFIGURATION

Method	Core architecture	Optimization points for short texts
Proposed method	BERT+TF-IDF+Domain Weight Dynamic Mapping	① Strengthen domain term masking learning (such as "volume ratio"); ② Dynamically adjusting TF-IDF weights based on title word frequency
TextCNN	Convolution+Pooling+Fully Connected	① Set the window size to [1,2,3] to accommodate short text; ② Add word vectors and mixed input of word vectors
BiLSTM	Bidirectional LSTM+attention mechanism	① Hidden layer dimension 256, suitable for short sequence modeling; ② Attention weight focuses on the core words of the title (such as "new energy")
RoBERTa	Transformer+Dynamic Masking Pretraining	① Remove the next sentence prediction task; ② Train with larger batches to enhance semantic modeling capability
DistilBERT	Transformer Knowledge Distillation	① Number of parameters reduced by 40%; ② Inference speed improved, suitable for resource-constrained scenarios

TABLE III. EVALUATION INDICATOR SYSTEM

Dimension	Definition of indicators	Calculation method
Semantic representation	Cosine similarity of similar title vectors	Randomly select 100 sets of similar titles and calculate the cosine similarity mean of BERT sentence vectors
Computing efficiency	Single title inference time (ms)	The average inference time of 5000 titles in the test set
Domain term robustness	Accuracy of low-frequency term representation (less than 10 occurrences)	Calculate the cosine similarity between the vectors of low-frequency words such as "charging piles" and "science and technology innovation board" and the domain benchmark vectors
Interpretability	Title Keywords Attention Weight Contribution Rate	Using LIME algorithm to analyze the contribution of top 3 keywords (such as "school district housing" in real estate titles)

The method proposed in this study and the comparative methods both use the same BERT-base-Chinese pre-trained model as the basic encoder, focusing on issues such as domain differences, term representation, and computational efficiency of short news headlines, providing a multi-dimensional verification basis for the effectiveness of the method proposed in this study in short text data mining. The experimental results of each method in terms of semantic representation dimension, computational efficiency, domain term robustness, interpretability, etc. are shown in Table IV.

TABLE IV. COMPARISON OF MULTIDIMENSIONAL EVALUATION RESULTS OF DATA MINING METHODS FOR NEWS HEADLINES AND SHORT TEXTS

Evaluation dimensions	Proposed method	TextCNN	BiLSTM	RoBERTa	DistilBERT
Semantic representation (cosine similarity)	0.96	0.73	0.68	0.92	0.91
Calculation efficiency (single inference time/ms)	8.2	10.5	13.1	9.8	8.5
Robustness of Domain Terminology (Accuracy of Low Frequency Words)	0.97	0.59	0.65	0.93	0.90
Interpretability (contribution rate of keyword weight)	0.79	0.42	0.51	0.75	0.72

As shown in Table IV, the method proposed in this study demonstrates significant advantages in the task of mining news headline short text data. In terms of semantic representation, this method combines BERT dynamic encoding with TF-IDF weight optimization, resulting in a cosine similarity of 0.96 for similar title vectors, which is superior to RoBERTa (0.92) and DistilBERT (0.91), significantly higher than TextCNN's 0.73 and BiLSTM's 0.68. This indicates that the method proposed in this study can more accurately capture the semantic commonalities of sports titles such as "ultimate" and "comeback". In terms of computational efficiency, the proposed method only takes 8.2ms for single inference, which is superior to RoBERTa (9.8) and DistilBERT (8.5), and significantly lower than TextCNN's 10.5ms and BiLSTM's 13.1ms. This indicates that the proposed method achieves a breakthrough in efficiency while ensuring the ability of complex semantic modeling. In terms of robustness of domain terms, the method proposed in this study achieved an accuracy of 0.97 in characterizing low-frequency terms such as "plot ratio" and "new energy vehicles", surpassing RoBERTa's 0.93, DistilleBERT's 0.90, TextCNN's 0.59, and BiLSTM's 0.65. This effectively solves the problem of sparse data in short texts, making our method more robust in handling low-frequency vocabulary. In terms of interpretability, through the visualization of the attention mechanism, this method achieves a weight contribution rate of 0.79 for keywords (such as "school district housing") in classification decision-making, slightly higher than RoBERTa (0.75) and DistilBERT (0.72), significantly higher than TextCNN's 0.42 and BiLSTM's 0.51. This achieves intuitive quantification of semantic logic and improves the interpretability of the model. Based on a comprehensive multidimensional evaluation, the method proposed in this study outperforms the comparative methods in terms of semantic understanding, cross-domain generalization, and interpretability of news headlines, providing a more efficient and accurate solution for text information data mining.

To explore the application effect of the text information data mining method in this study in cross-domain short-text classification, for 5 categories (4000 items in each category) of news headline datasets, the conditional generative adversarial multiple imputation classification method in Reference [4], the binary classification method based on Naive Bayes and SVM in Reference [5] are compared with the method in this study. Through 5-fold cross-validation, starting from the number of correctly classified items in each category and typical cases, the processing ability of different methods for cross-domain ambiguous headlines is analyzed. The specific data mining results are shown in Table V.

TABLE V. COMPARISON OF TEXT INFORMATION DATA MINING RESULTS UNDER DIFFERENT METHODS

Data category	Reference[4] method	Reference[5] method	Proposed method
Sports	Correct classification number: 3120/4000 Typical case: Correct: "United Serbia final schedule" Error: "Stars participating in football live broadcasts"(Mistakenly classified as entertainment)	Correct classification number: 3050/4000 Typical case: Correct: "Player Transfer News" Error: "Artist Basketball Challenge" (Still misclassified as entertainment)	Correct classification number: 3880/4000 Typical cases: Correct: "Team training dynamics", "Celebrity basketball charity game" (Charity competitions are easily mistaken for entertainment)
Entertainment	Correct classification number: 3050/4000 Typical case: Correct: "Singer's new album released" Error: "Athletes participating in variety shows" (Mistakenly classified as sports)	Correct classification number: 3080/4000 Typical case: Correct: "Actor red carpet styling" Error: "Player attending award ceremony" (Still misjudged as sports)	Correct classification number: 3790/4000 Typical case: Correct: "Artists cross-border filming", "Athletes' variety show debut" (Athletes are easily mistaken for sports)
Real estate category	Correct classification number: 2980/4000 Typical case: Correct: "Price trend of school district housing" Error: "New policy for car down payment" (Misjudged as car)	Correct classification number: 2990/4000 Typical case: Correct: "Second hand house transaction process" Error: "Selling price of parking spaces in residential areas " (Still misjudged as a car)	Correct classification number: 3820/4000 Typical cases: Correct:"Real estate loan policy", "The selling price of the underground garage in the real estate project" (Garage is easily mistaken for a car)
Health category	Correct classification number: 3010/4000 Typical case:	Correct classification number: 3140/4000	Correct classification number: 3890/4000

	Correct: "Recommended health recipes" Error: " Air quality inspection inside the car " (Mistakenly identified as a car)	Typical case: Correct: "Traditional Chinese Medicine Health Knowledge" Error: "Methods for relieving driving fatigue " (Still mistakenly classified as a car)	Typical cases: Correct:"Healthy Eating Guide", "Healthy sitting posture of drivers" (Drivers are easily mistaken for cars)
Automobile	Correct classification number: 3090/4000 Typical case: Correct: "New car launch" Error: "Automobile property registration " (Misjudged as real estate)	Correct classification number: 3120/4000 Typical case: Correct: "Car fuel consumption test" Error: "Car transaction transfer process" (still misjudged as real estate)	Correct classification number: 3910/4000 Typical cases: Correct: "Autonomous driving technology", "Location selection for automobile 4S stores" (Site selection' is easily mistaken for real estate)

It can be seen from Table V that the classification performance of the method in this study on the 5-category (4000 items in each category) news headline datasets is significantly better than the conditional generative adversarial multiple imputation classification method in Reference [4] and the recursive-deep convolutional neural network classification method in Reference [5]. In terms of the number of correctly classified items in each category, the method in this study achieves 3880, 3790, 3820, 3890, and 3910 correctly classified items in sports, entertainment, real estate, health, and automobile categories respectively, with an overall accuracy rate of 95.7%, which is 19.5% higher than that of the conditional generative adversarial multiple imputation classification method in Reference [4] (76.2%) and 18.7% higher than that of the binary classification method based on Naive Bayes and SVM in Reference [5] (77.0%). Among them, the difference in the processing effect of cross-domain ambiguous headlines is particularly significant. For example, a "charity game" is easily misjudged as an entertainment category because of the participation of entertainment stars and the activity form leaning towards variety show interaction. But the method in this study captures the core sports attribute of "basketball" and combines features such as event rules and competitive background to avoid misjudgment, only because of the "charity" label. In "healthy sitting posture for drivers", "drivers" points to the car usage scenario and is easily classified as the "automobile" category, but the method in this study captures the core demand of "healthy sitting posture", associates features in the health field such as ergonomics and occupational disease prevention, rather than the car function itself, and classifies it as the "health category", realizing accurate text information data mining. These typical cases fully prove that the method in this study effectively solves the cross-domain ambiguity problem by virtue of the dynamic matching of domain feature weights and the context semantic association mechanism, and has significant advantages in text classification containing polysemous keywords.

V. Conclusion

This study proposes a deep mining framework that integrates TF-IDF weight optimization and BERT semantic enhancement to address the problem of insufficient semantic understanding in existing text mining methods for cross-domain short text classification. The main contributions of this study are reflected in three aspects: at the theoretical level, it explores the fusion mechanism of traditional statistical features and deep pre trained language models, providing new ideas for solving the collaborative modeling problem of statistical information and contextual semantics in text. At the methodological level, an end-to-end classification model was constructed, which enhanced the discrimination of key terms through TF-IDF and utilized BERT's self-attention mechanism to capture global context, effectively improving the model's semantic discrimination ability. On an empirical level, experiments on cross-domain news headline datasets have shown that this method outperforms various baseline models in accuracy, robustness, and interpretability, providing an effective technical solution for solving cross-domain ambiguity problems in natural language processing.

The method proposed by this research institute has significant practical application value. In scenarios such as automatic tagging of news content, monitoring of social media public opinion, and fine-grained classification of e-commerce comments, this method can accurately identify easily confused cross-disciplinary information (such as distinguishing between sports and entertainment attributes of "football stars attending charity parties"), significantly reducing the misjudgment rate. Its efficient processing capability (with a single title inference time of only 8.2ms) also enables it to adapt to online services that require high real-time performance, providing powerful tools for enterprises and platforms to achieve automated and intelligent text information processing and knowledge extraction, and has broad engineering application prospects.

Although this study has achieved the expected results, there are still some limitations. Firstly, the performance of the model depends to some extent on the matching degree between the pre-trained corpus and the target domain. When facing highly specialized or technically novel vertical domains (such as academic literature in specific disciplines), the performance may experience some attenuation. Secondly, the experiments in this study mainly focus on short texts (news headlines). Although short texts are a common form of information distribution, the method's ability to capture cross-paragraph semantic dependencies in long documents (such as research reports and lengthy comments) has not been fully validated. In addition, although the interpretability of the model is reflected through attention weights, a systematic and end-user-oriented decision interpretation reporting mechanism has not yet been formed.

Based on the results and limitations of this study, future work can be carried out in the following directions: exploring the introduction of domain adaptation techniques to enable the model to quickly migrate to professional fields such as finance and healthcare using a small number of annotated samples, improving its generalization ability and practical scope. The study combines the current model with mechanisms such as text summarization, and hierarchical attention to efficiently

process long documents and capture their core semantic and discourse structure information. Integrate cutting-edge interpretable artificial intelligence tools such as LIME and SHAP, develop visual decision path analysis functions, and enhance the transparency and credibility of models in high-risk application scenarios.

***Abstract*—This study introduces a novel multi-feature fusion model aimed at improving text similarity calculation in scientific and technological projects. The primary objective is to enhance the accuracy and efficiency of assessing text similarities, particularly in evaluating originality and identifying duplications in project submissions. To overcome the limitations of traditional text similarity methods (e.g., Vector Space Models, Latent Dirichlet Allocation, and TF-IDF) in capturing complex semantic and structural features, a hybrid model is proposed. The model combines word embeddings (word2vec and cw2vec), a Bi-LSTM network, and a multi-perspective convolutional neural network (MP-CNN) for effective feature extraction. Additionally, a fusion attention mechanism and interactive attention are incorporated to improve the extraction of semantic, contextual, and structural information. Experimental evaluation on two benchmark datasets demonstrates that the proposed model achieves an average precision of 0.75, a recall of 0.71, and an F1-score of 0.73, outperforming traditional methods (LDA, TF-IDF, Word2vec+Cosine) and deep learning baselines (Siamese-LSTM, MP-CNN) by more than 10% on average. These results confirm that the proposed architecture effectively balances semantic relevance and structural integrity, yielding superior similarity detection performance. The integration of advanced deep learning components—Bi-LSTM, MP-CNN, and attention mechanisms—substantially improves both the accuracy and efficiency of similarity evaluation, providing a more reliable and objective approach for scientific project assessment.**

I. Introduction

The duplication of scientific and technological projects is not only related to the smooth implementation of China's prospective research, but also has a profound impact on the orderly development of China's economy and culture. In order to promote the rational use of scientific research resources and funding, the scientific review of scientific and technological projects has become an important part of the scientific and technological program management system [1]. Therefore, in order to ensure the smooth development of original and innovative scientific research, project reviewers need to make more accurate judgments on the duplicity and similarity of the applied projects [2]. However, the duplicity review of scientific and technological projects is a complex process, with the year-on-year growth in the scale of scientific and technological project declaration, the project review methods used at this stage have been difficult to meet the current demand for originality review, and often need to be repeated by experts in various fields based on their own scientific research experience on the project and the related literature and patented technology screening, not only checking and checking for new accuracy fails to meet the requirements, but also seriously limits the efficiency of scientific and technological project review, resulting in the scientific and technological project review efficiency, which leads to a more accurate judgment of duplication and similarity. The review efficiency of science and technology projects has been seriously limited, which has hindered the management of science and technology programs.

Most of the traditional text similarity calculation methods apply literal repetition or probability models. For example, the traditional Vector Space Model1 (VSM) utilizes the theory of statistics to measure the similarity between texts based on the probability distribution of words. In [7], the authors utilize VSM to calculate the similarity between texts, adding keywords to avoid the removal of valid features. In recent years, a variety of methods have been proposed to enhance textual similarity detection. Traditional statistical approaches such as VSM, TF-IDF, and Latent Dirichlet Allocation (LDA) have laid the foundation for lexical and probabilistic modeling of text. However, these methods often fail to capture deep semantic and contextual information, leading to lower accuracy when dealing with complex or domain-specific documents. To overcome these limitations, deep learning-based approaches have been introduced. For instance, Siamese-LSTM models [3] learn sequence-level semantics through shared weight encoding, while CNN-based models such as MP-CNN [4] focus on extracting structural and local contextual features from paired sentences. Attention-based architectures like ABCNN [5] further refine feature alignment between text pairs, enabling improved sentence-level similarity detection. Despite these advances, existing models typically rely on single-level representations, either word-level or character-level, and rarely consider the integration of both semantic and structural perspectives. In contrast, our proposed model introduces a comprehensive multi-feature fusion strategy that simultaneously leverages word embeddings (word2vec and cw2vec), sequential encoding via Bi-LSTM, and multi-perspective convolution through MP-CNN, enhanced with fused and interactive attention mechanisms. This design enables the model to capture semantic relevance, structural integrity, and contextual dependencies in

an integrated framework, thereby addressing the key limitations of previous methods.

With the development of machine learning and deep learning technology, more and more researchers use deep learning technology to build models to study related tasks in the field of natural language processing. Vani Kl [6] et al. built a model for detecting plagiarism of academic ideas by taking plagiarism of ideas as a research object to address the increasing academic misconduct in the field of research and education. Velásquez [7] et al. proposed a plagiarism detection system called Document Copy Detector 3.0 (DOcument COpy Detector 3.0, DOCODE 3.0) to address the problem of academic plagiarism in educational institutions. Ehsan N et al. [8] addressed the problem of plagiarism being difficult to detect in cross-linguistic systems, and established a localized plagiarism detection model based on topic word retrieval and segment similarity assessment of hetero-linguistic sources as a research object. Arts S[9] et al. analyzed the limitations of the United States Patent Classification System (USPCS) in the detection of patent technology similarity, improved the text matching algorithm of the system, and proposed a text matching-based patent technology similarity detection algorithm. A text matching-based similarity analysis model for patented technologies. Sutoyo [10] et al. proposed a document plagiarism detection method based on a K-member grammar model with a screening algorithm and evaluated and selected the performance of the K-member grammar model's K-value with sliding window calculation. Scholar Choi S P M [11] et al. proposed an information retrieval-based text similarity detection algorithm that is capable of handling multilingual source documents and seamlessly integrates with existing learning management systems. The algorithm identifies potentially plagiarized phrases by employing information retrieval and sequence matching techniques, with parametric control to minimize false positives and negatives. Empirical evidence shows that the algorithm not only accurately and quickly identifies documents suspected of plagiarism, but also quantifies and visualizes the severity of plagiarism in data, thus providing scholars with a good aid in reviewing and assessing plagiarism.

Many researchers have achieved good results by not performing the pre-training task without text in order to take into account more comprehensive and underlying textual information. In [12], the authors does not carry out the pre-training of words, directly convolves the vectors represented by the unique hot code, fully mines and predicts the contextual information with the most original data, adds unsupervised region embedding, efficiently expresses the features of the text, and finally achieves better results on various tasks. Literature [13] utilizes convolutional neural networks to directly train and learn directly from the underlying characters of the text without text pre-processing, and applies the extracted features in various tasks of text processing, and achieves better results on large datasets. Literature [14] used fine-grained character-level text input to the convolutional neural network and then processed it using Long Short-Term Memory (LSTM), followed by applying the extracted features to a variety of languages to achieve better results, indicating that the model is able to obtain semantic information from the character-level input.

Secondly, to address the problem that entity relationships in the text of scientific and technological project declaration are difficult to be extracted effectively, an entity relationship extraction algorithm based on entity group co-occurrence rate is further proposed to realize high-quality entity relationship extraction in the text of scientific and technological project declaration; thirdly, to address the demand for similarity calculation of scientific and technological project declaration text and the structural characteristics of the text, a text matching model based on polytunnels is proposed to realize the comprehensive evaluation of semantic relevance of different components of the text. Finally, to address the problem of limited accuracy caused by only detecting the text as a whole or artificially setting the weights of each check item in the declaration text of scientific and technological projects, a semi-structured text similarity assessment method combining graph structural similarity and text matching degree is designed.

The remainder of this study is organized as follows: Section II presents the text preprocessing model and details the feature extraction process using word2vec and cw2vec embeddings. Section III introduces the proposed text similarity calculation model based on fused and interactive attention mechanisms. Section IV describes the experimental setup, datasets, and evaluation metrics, followed by a discussion of comparative results. Finally, Section V concludes the study and outlines directions for future work, including model optimization and potential generalization to other languages.

II. Text Preprocessing Model

Deep learning technology has achieved better results in various kinds of tasks, such as text similarity calculation, intelligent translation, sentiment classification, semantic analysis, etc., and has attracted many researchers at home and abroad. Deep learning utilizes multi-layer neural networks to extract deep features in the text, and in the field of natural language processing, it mainly uses convolutional neural networks and recurrent neural networks to extract text features, and due to the fact that the recurrent neural networks have memory units, the recurrent neural networks are more effective than the convolutional neural networks in various tasks in the field of natural language processing. As a whole, the text of a scientific and technological project declaration consists of structured document structure and semi-structured text data, and as a kind of text data with special text features, this text type has a big difference from free text data in terms of syntax, wording, and article organization, thus presenting obvious text structural features and semantic features.

Word vectors are the prerequisite for the calculation of semantic similarity of text, so it is necessary to pre-process and pre-train the text to obtain high-quality word vectors, the process is shown in Fig. 1. Preprocessing is to segment the text in the corpus and training set and remove the stop words in the text, and pre-training is to convert the word sequences into feature vectors that can be recognized by the computer.

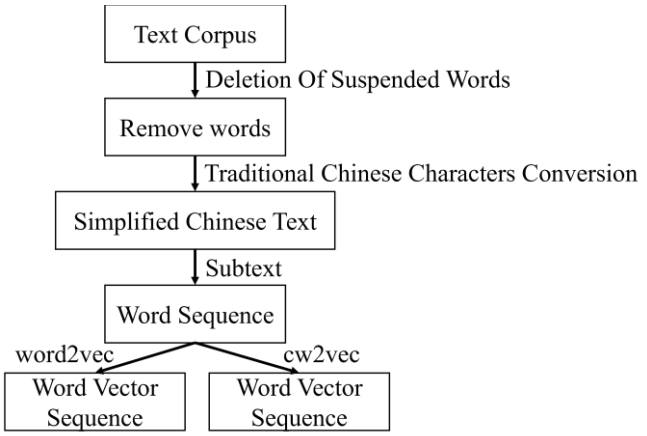

Fig. 1. Text preprocessing model.

A. Text Segmentation

Chinese word segmentation is the process of splitting a Chinese text into words according to semantic criteria and combining the results into a new sequence. Since English words are separated by spaces, each word can be used as a semantic unit, so English text segmentation is less difficult. On the other hand, Chinese text consists of consecutive Chinese characters connected together, and there is no separating mark between each word, so the segmentation of Chinese text is a basic and important step, and the accuracy of this process has a large impact on the subsequent related tasks and an accurate and fast segmentation algorithm is needed before the model training. On the issue of selecting a text segmentation model, the word labeling-based conditional random field model is the most used segmentation model, which is a model that uses word construction rules, and has a higher recall rate for unregistered words, but at the same time, it also generates more segmentation errors. Segmentation models using word annotations also require the addition of a complex denoising process in subsequent tasks. For the binary syntactic participle model, it only recalls the words present in the word list, and combined with the new word discovery algorithm, it can effectively alleviate the recall problem of high-frequency unregistered words. Assume that the sentence $\boldsymbol{T = w_1 w_2 w_3 \ldots w_n}$ has completed the disambiguation operation, where w is the n words composing sentence T, sentence T is changed to the original sentence $\boldsymbol{S = c_1 c_2 c_3 \ldots c_n}$, after passing through the noise channel without disambiguation, where $\boldsymbol{c}$ is the Chinese character in the sentence. Calculation using the Bayesian formula gives in Eq. (1):

$$\boldsymbol{P(T \mid S) = \frac{P(T)P(S|T)}{P(S)} \propto P(T) = P(w_1 w_2 w_3 \ldots w_n)}$$

$$= P(w_1)P(w_2 \mid w_1)P(w_3 \mid w_1 w_2)\ldots P(w_n \mid w_1 w_2 \ldots w_{n-1}) \quad (1)$$

Assume that the current word is only related to the previous work:

$$P(T) = P(w_1)P(w_2 \mid w_1)P(w_3 \mid w_2)\ldots P(w_n \mid w_{n-1}) \quad (2)$$

This is the binary grammatical disambiguation model [Eq. (2)]. Add the interpolation smoothing calculation, as shown in Eq. (3):

$$P(w_n \mid w_{n-1}) = \alpha P(w_n \mid w_{n-1}) + (1-a)P(w_n) \quad (3)$$

where, $\boldsymbol{\alpha}$ is taken as 0.7. Jieba is one of the most active Chinese word splitter tools in China with a large number of users, which provides various functions such as word splitting, keyword, extraction, word labeling and so on. The participle function mainly has three modes: search engine mode, full mode, and exact mode, which can be applied in search engine, text, sentence and other scenarios that need participle. And the exact model is most suitable for use in the task of text analysis, therefore, the experiments of the text selected jieba participle tool to assist in participle.

B. Word-CW2VEC Model

Representing text using computer-recognizable word vectors can effectively alleviate the situation where the text is not trainable due to its variable length, large data dimension, and complex structure. Utilizing trainable word vectors can preserve similar features at the semantic level, mapping high-dimensional text data to low dimensions while avoiding dimensional catastrophe. Bengio et al. [15] used a neural network language model to train the data, learning the feature representations of the words as word vectors through the hidden layer, which learns the semantic information through the neural network.

Word2vec is a Google open-source tool for calculating word vectors. The two models CBOW and Skip-Gram, used in the tool for calculating the generated word vectors are proposed by Mikolov et al. [24]. The models simplify the Neural Network Language Model (NNLM) and design an accelerated training strategy to allow the model to be efficiently trained on massive training sets. The word vectors trained on a large amount of text data are able to represent the semantic relationships between words and tap into deep features. Because of their good performance and performance, the two models CBOW and Skip-Gram are widely used and have achieved good results on many natural language processing tasks. CBOW's core concept is to use words within a specified distance around a central word as context to model and predict the likelihood of the central word using a linear model. The architecture is shown in Fig. 2. The CBOW model is improved from NNLM by abandoning the strategy of a nonlinear hidden layer and vector splicing, which affects the training efficiency of NNLM, and mapping the word vectors to the same location.

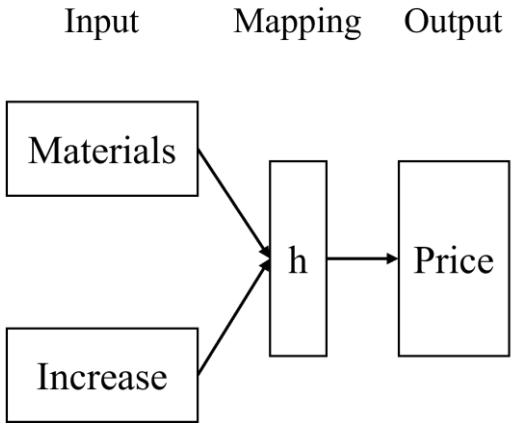

Fig. 2. CBOW model.

For a text matrix $W = (w_1, w_2, \ldots, w_n)$, CBOW utilizes the mapping layer e to sum the word vectors in the context c expressed as Eq. (4):

$$\boldsymbol{h} = \frac{\mathbf{1}}{\boldsymbol{n-1}} \sum_{\boldsymbol{w_i \in c}} \boldsymbol{e(w_i)} \tag{4}$$

The center word is then predicted, and the weights are constantly updated by maximizing the conditional probability with the contextual representation h, maximizing the conditional probability as:

$$\boldsymbol{L} = \sum_{\boldsymbol{(w,c)\in D}} \boldsymbol{log\, P(w \mid c)} \tag{5}$$

$$\boldsymbol{P(w \mid c)} = \frac{\boldsymbol{exp(e'(w)^T h)}}{\sum_{\boldsymbol{w' \in V}} \boldsymbol{exp\,(e'(w')^T h)}} \tag{6}$$

where, $\boldsymbol{e}$ is the mapping function, w is the center word, and $\boldsymbol{c}$ is the contextual information [Eq. (5) and Eq. (6)].

CW2VEC is a method proposed by Cao [16] and others to decompose Chinese text strokes in order to extract deeper and finer-grained information, and utilize Chinese strokes for model training and feature representation. The n-gram language model is utilized to mine the associations and semantic information on text morphology, and the sliding window is changed by adjusting the size of n to extract the semantic information of different granularity of strokes. The processing flow of the n-gram model based on strokes is shown in Fig. 3.

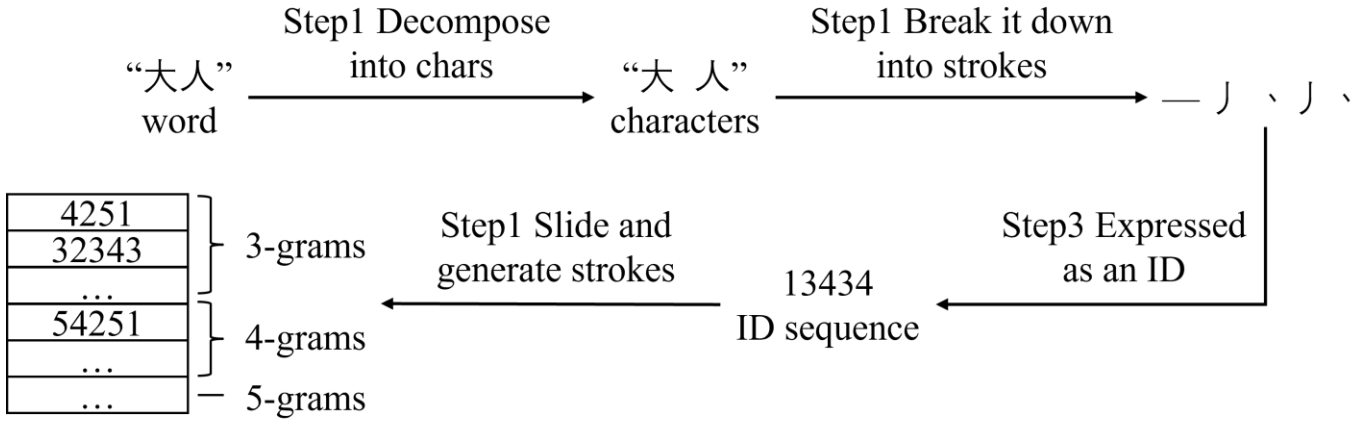

Fig. 3. Stroke-based n-gram modeling.

In Fig. 4, the model structure of cw2vec is shown; the basic idea is similar to Skip-Gram, both of them use the center word to predict the context information. The difference is that cw2vec uses the n-gram language model of strokes to represent the context information.

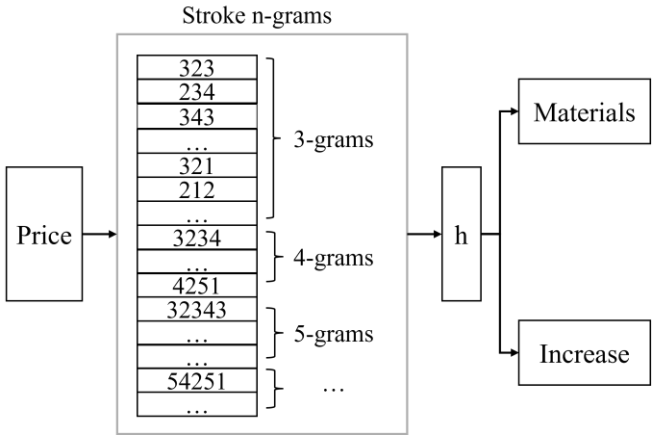

Fig. 4. CW2VEC model structure.

The context vector of the center word w is the sum of the feature vectors derived from the stroke n-gram model, computed as Eq. (7):

$$\boldsymbol{h} = \sum_{\boldsymbol{q \in S(w)}} \boldsymbol{e(q)} \tag{7}$$

where, S(w) is the set of stroke features of the center word computed using the n-gram model. The model is trained using the conditional probability of maximizing the center word with the words in the context, with the following Eq. (8) and Eq. (9):

$$\boldsymbol{P(w \mid w_j)} = \frac{\mathbf{exp}(\boldsymbol{e'(w)^T e(w_j)})}{\sum_{\boldsymbol{w/wV}} \mathbf{exp}\,(\boldsymbol{e'(w')^T e(w_j)})} \tag{8}$$

$$\boldsymbol{P(w \mid h_i)} = \frac{\mathbf{exp}(\boldsymbol{e'(w)^T h_i})}{\sum_{\boldsymbol{w' \odot V}} \mathbf{exp}\,(\boldsymbol{e'(w')^T h_i})} \tag{9}$$

For deep learning models, inputs are very important, and although it is possible to design structures with high performance, it is difficult for the model to work well if the input information is limited. In the experiments, it was found that word-level-based results are average, which is because the quality of the participle has a great impact on the model. To explore deeper semantic and structural information in the text, this study introduces a word embedding method combining word2vec and cw2vec, integrating three input sources from stroke sequences, word sequences, and word sequences, where the word2vec word embedding is inputted into the model while the cw2vec word embedding based on strokes is used in the other input channel, and then the two results are fused. This method effectively alleviates the problem of poor quality of word separation in the model. To summarize, the text structure feature extraction structure of this study is shown in Fig. 5.

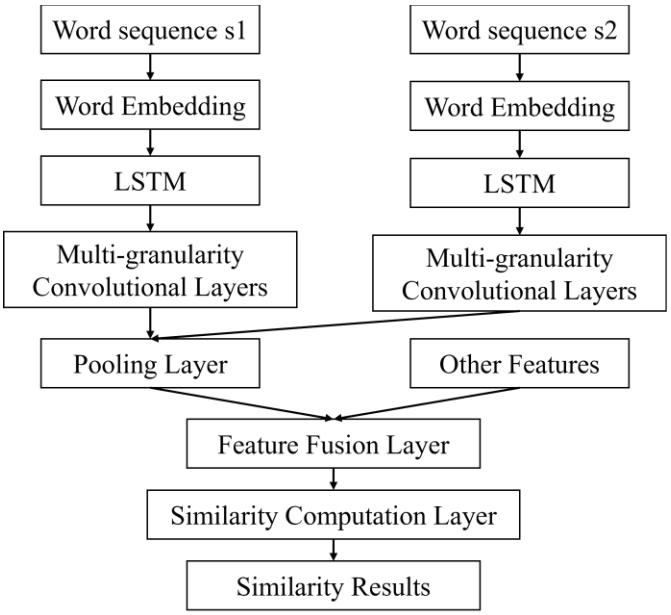

Fig. 5. Text structure feature extraction module.

III. Text Similarity Calculation Model Based on Fused Attention Mechanism

The similarity calculation of text is generally divided into three steps: first of all, the corpus should be preprocessed, including de-duplication, text segmentation, pre-training, and other steps. Then the text representation model is used to extract the feature representation containing semantics in the text, and finally, the similarity is obtained by training the model according to the extracted features.

A. Text Structure Feature Extraction Module Design

In this study, the proposed multi-feature fusion model for text similarity calculation of science and technology projects draws on the idea of Siamese structure, adopts word2vec and cw2vec word embeddings with different granularity as inputs, and jointly extracts the semantic information of the text with a Bi-LSTM network; effectively extracts the structural and word order information of the text through multi-granularity convolution and corresponding pooling; proposes the LSF feature The computation method of LSF features is proposed and proved to be effective. With the advantages of the two models, the extracted features are effectively fused, the semantic features are better preserved, and the deep-level features are mined. Finally, the text similarity calculation module for science and technology projects is designed, and the details of parameter settings are explained.

The whole model is divided into a word embedding module, a text structure feature extraction module (CNN model), a text semantic information extraction module (Bi-LSTM model), an attention mechanism module, a feature fusion module, and a similarity computation module. The structure of the similarity computation model with CNN fusion attention mechanism is shown in Fig. 6.

In this study, we draw on the MPCNN [17] (Multi-Perspective Convolutional Neural Networks) model to design the network structure, and use the convolution of multi-granularity to explore more deep features hidden in the present.

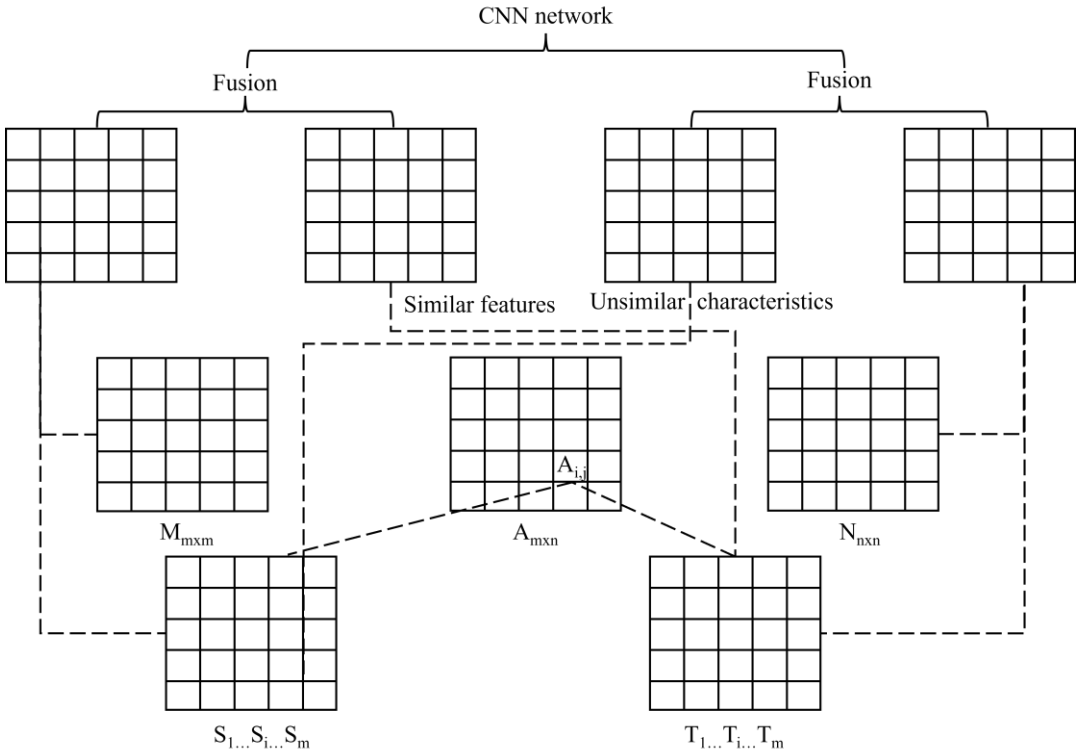

Fig. 6. CNN fusion attention mechanism model.

The structure of CNN-based model for calculating text similarity of science and technology projects is shown in Fig. 6. After the input text data is preprocessed with preprocessing operations such as word splitting and deactivation, the text is trained into word vectors and combined into a text matrix using the word2vec tool. Then the LSTM network is used to further train the word vector representation so that the word vectors contain more semantic information.

This study, inspired by Shen T, proposes an effective fusion of semantic features, contextual structural interaction features, and LSF features extracted from text through the text semantic, structural, and LSF feature extraction modules [18], and the fusion gate feature fusion method is designed, with the following computational equations [Eq. (10) to Eq. (12)]:

$$\boldsymbol{z_t} = \boldsymbol{sigmoid}(\boldsymbol{W_z} \cdot [\boldsymbol{h_{t-1}}; \boldsymbol{x'_t}] + \boldsymbol{b_z}) \quad (10)$$

$$\boldsymbol{r_t} = \boldsymbol{sigmoid}(\boldsymbol{W_r} \cdot [\boldsymbol{h_{t-1}}; \boldsymbol{x'_t}] + \boldsymbol{b_r}) \quad (11)$$

$$\boldsymbol{h_t} = (\boldsymbol{1} - \boldsymbol{z_t}) \times \boldsymbol{h_{t-1}} + \boldsymbol{z_t} \times \tilde{\boldsymbol{h}}_{\boldsymbol{t}} \quad (12)$$

The method fuses $\boldsymbol{h_{t-1}}$ and $\boldsymbol{x_t}$ into $\boldsymbol{h_t}$., where $\boldsymbol{z_t}$ is used to measure the degree of feature fusion, $\boldsymbol{x'_t}$ is the vector obtained by projection transformation of $\boldsymbol{x_t}$, W is the trainable parameter matrix, b is the trainable parameter vector, and the [;] symbols are used to splice the two vectors. Fusion gate method can accelerate the flow of information efficiently, and further integrates the computation results with a layer of multilayer. The fusion gate method can effectively accelerate the information flow, further integrate the computational results with a multilayer perceptual machine, and finally get the vectors with the same dimensions as the features before fusion.

B. Integration of Interactive Attention Mechanisms

In this study, drawing on the ideas of the ABCNN model and the LDC model [19], we introduce the interaction attention mechanism into the CNN model, and propose an improved scheme to construct the interaction attention matrix and take into account the similarities and dissimilarities through the orthogonal decomposition of the matrix. The model structure is shown in Fig. 7:

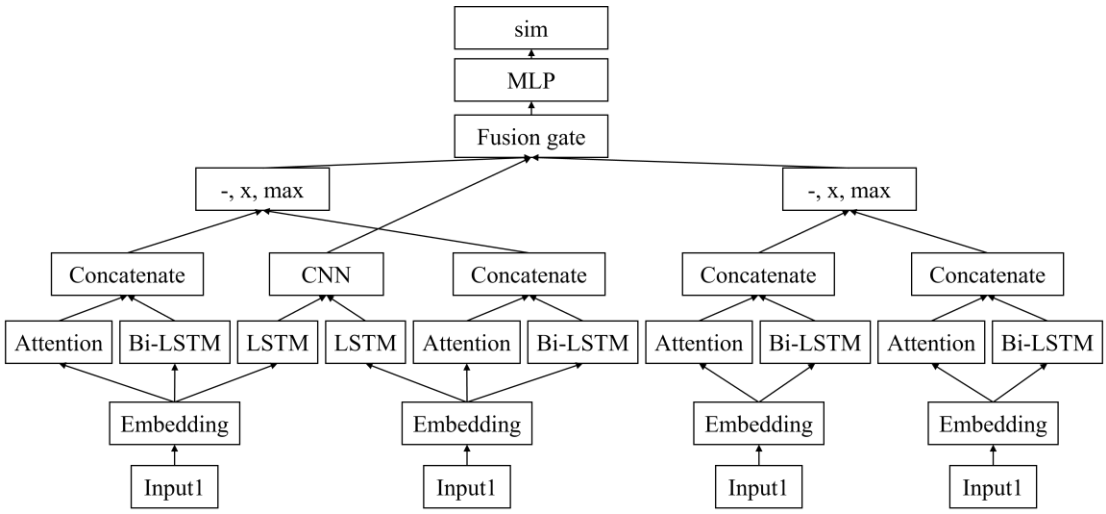

Fig. 7. Multi-feature fusion similarity calculation model.

For text pairs S and T, the text lengths are set as m and n, respectively, in order to obtain the interactive attention vector $\hat{s}_i$ (which implies similar and dissimilar components) of the word vector s_i in the text s, it is necessary to compute the similarity matrix $A_{m\times n}$, which is calculated as Eq. (13):

$$a_{i,j} = \frac{{s_i}^T t_j}{\|s_i\| \cdot \|t_j\|} \quad \forall s_i \in S, t_j \in T \quad (13)$$

where, $a_i, j \in A_{m\times n}$,is an element in $A_{m\times n}$, $s_i (i < m)$ is a word vector in text S, and $t_j (j < n)$ is a word vector in text T. The interactive attention vector of text s can be computed from the text representation matrix T and the similarity matrix $A_{m\times n}$ with the following Eq. (14):

$$\hat{s}_i = f_{match}(s_i, T) = \frac{\sum_{j=k-w}^{k+w} a_{i,j} t_j}{\sum_{j=k-w}^{k+w} a_{i,j}} \quad (14)$$

where, $k = \text{argmax} x_j a_{i,j}$. $\hat{s}_i = f_{match}(s_i, T)$, $\hat{s}_i$ is the ith vector in the interaction attention matrix of the text matrix S. w is a variable parameter, which is represented by w values near the maximum of the similarity matrix, i.e., the local interaction semantics.

Each vector is orthogonally decomposed into two parts of the geometric space parallel and perpendicular, where parallel is the similar part and perpendicular is the similar part, and where parallel is the similar part and perpendicular is the dissimilar part. The decomposition equation is Eq. (15) and Eq. (16):

$$s_i^+ = \frac{s_i \cdot \hat{s}_i}{\hat{s}_i \cdot \hat{s}_i} \hat{s}_i \quad parallel \quad (15)$$

$$s_i^- = s_i - s_i^+ \quad perpendicular \quad (16)$$

Using the orthogonal decomposition described above, the interactive attention matrix of the text is decomposed into similar and dissimilar matrices, denoted as $S^+ = [s_1^+, \ldots, s_i^+ \ldots, s_m^+]$ and $S^- = [s_1^-, \ldots, s_i^- \ldots, s_m^-]$. Both the dissimilar and similar parts are strongly related to each other, and it is difficult to determine the degree of similarity between similarly shaped but meaningfully different texts if only the similar parts are considered. When the similar and different parts

are considered at the same time, it can be historically good to determine the similarity gui between such texts. Therefore, the model in this study synthesizes the similar component matrix and the different component matrix into one feature vector $\vec{S}$ and $\vec{T}$, and the synthesis function is [Eq. (17) and Eq. (18)]:

$$\vec{S} = f_{comp}(S^+, S^-) \quad (17)$$

$$\vec{T} = f_{comp}(T^+, T^-) \quad (18)$$

where, f_{comp} is a combinatorial function. For the convolution operation, a list of convolution kernels w_o is defined, and each convolution kernel has the shape of $d \times h$, where d is the dimension of the word vector and h is the window size. In Eq. (17) and Eq. (18), each convolution kernel is applied to two channels from similar and dissimilar to generate a feature. The process is shown in the following Eq. (19):

$$c_{o,i} = f\left(w_o * S^+_{[i:i+h]} + w_o * S^-_{[i:i+h]} + b_o\right) \quad (19)$$

where, the $A * B$ operation adds all the elements in B with the corresponding weights in A, $S^+_{[ii+h]}$ and $S^-_{[ii+h]}$ denote the parts from S^+ and S^-, b_o is a bias term, and f is a nonlinear function. Finally, the similar and dissimilar features extracted by the CNN are spliced as extracted features and fused with other features to compute the similarity after the similarity computation layer.

IV. Results and Discussion

A. Experimental Data Collection

The experiments in this study are implemented using the open-source machine learning framework keras, which is rich in documentation, easy to use, and simple to model, and has attracted a large number of developers. In the experiment, an NVIDIA GTX 1050Ti is used as an auxiliary tool for model training, and through the Unified Computing Architecture technology introduced by NVIDA, the graphics card can be used to accelerate the training speed by utilizing APIs on GPUs (General-Purpose GPUs). The jieba segmentation tool is used to segment Chinese words, the Skip-Gram model of the word2vec tool is used to train word vectors, and cw2vec is used to train fine-grained word vectors.

Since there is no publicly available R&D dataset for science and technology projects, two datasets are chosen in this study to validate the experiments. Dataset 1 is the dataset of the Financial Intelligence NLP service tournament of Ant Financial Competition. The dataset is given 100,000 pairs of labeled data, all of which are two paragraphs of customer service and user Q&A, which contain synonymous pairs and non-synonymous pairs, and the algorithm is used to determine whether the same semantics are represented. Dataset 2 is the ChineseSTS similarity training set organized by Xi'an University of Science and Technology (XUST), in which 27,000 pairs of texts are classified into six similarity levels, in which the similarity of completely similar pairs is 5, and the similarity of dissimilar pairs is 0. However, the distribution of the pairs of texts in the training set is not balanced, and 90% of the pairs of texts have similarity of 0 or 5, which makes no sense for the training of the model. Therefore, 6000 text pairs are selected for model training and model performance evaluation. In order to harmonize with dataset 1, the similarity of text pairs in dataset 2 with similarity greater than 2 is set to 1, and the similarity of text pairs with similarity less than or equal to 2 is set to 0, which is used for the training and testing of the model.

B. Evaluation Indicators

In the study of text similarity calculation models for science and technology projects, it is very necessary to evaluate the model, and the evaluation index can measure the goodness of a model. In order to facilitate the evaluation of the performance of the model, this study evaluates the science and technology project text similarity calculation as a binary classification problem, which maps the model prediction results to the set {0,1}, with 0 representing that the two texts are not similar and 1 representing that the two science and technology project texts are similar. The commonly used evaluation metrics for binary classification problems are Precision, Accuracy, Recall, and F1-Measure. The following classes are defined according to the categories predicted by the model and the real categories of the samples:

1) TP (True Positive): model predicts a positive class and the sample is truly labeled as a positive class.

2) TN (True Negative): model predicts a negative category and the sample is truly labeled as a negative category.

3) FP (False Positive): model predicts a positive class, the real labeled as a negative sample.

4) FN (False Negative): model predicts a negative class, the real labeled as a positive class of samples.

where, the total number of samples is the sum of the four classes TP, TN, FP and FN. As shown in Table I, the confusion matrix can be used to describe the relationship between TP, TN, FP, and FN.

TABLE I. Confusion Matrix

	Similarity, positive	**Unsimilar, negative**
Physical resemblance	TP, Positive predicted to be positive	FP, Negative predicted to be positive
Actual dissimilarity	FN, Positive predicted to be negative	TN, Negative predicted to be negative

Accuracy and recall are widely used in the field of statistical classification and can be used to evaluate the accuracy and comprehensiveness of each prediction of a model. Among them, the accuracy rate is the ratio of the number of correct predictions made by the model to the total number of samples, and the equation is as follows [Eq. (20)]:

$$\text{Accuracy} = \frac{TP+TN}{TP+FN+FP+TN} \quad (20)$$

Accuracy evaluates the goodness of the model from the perspective of the model's prediction results, and is the proportion of the samples predicted to be positive classes that are truly labeled as positive classes, which measures the model's checking accuracy, with the following Eq. (21):

$$\text{Precision} = \frac{TP}{TP+FP} \quad (21)$$

Recall analyzes the goodness of the model from the point of view of the labeling results (see Eq. 21), describes the ratio of the number of samples predicted to be positive by the model to the number of samples labeled to be positive, and measures the model's checking rate, the equation is as follows:

$$\text{Recall} = \frac{\text{TP}}{\text{TP+FN}} \tag{22}$$

In general, recall and precision are negatively correlated (Eq. 22), and the F1 value, which is an indicator of the overall evaluation of the model, is the harmonic mean of recall and precision, with the following Eq. (23):

$$\text{F1} = \frac{2^{*}\text{Precision}^{*}\text{Recall}}{\text{Precision+Recall}} \tag{23}$$

C. Test Results

In order to verify that the model proposed in this study has good results, several models commonly used at present are implemented as comparison models, including traditional similarity calculation models and deep learning-based similarity calculation models.

LDA: The traditional LDA algorithm [20] is used to calculate the similarity of texts.

TF-IDF: The four text keywords in the two texts are extracted separately, and the cosine value is calculated as the similarity of the texts using the word embedding representation vectors of the keywords [21];

word2vec-cos: the representation vectors of words are trained using word2vec and combined with the cosine value to calculate the text similarity;

Siamese-LSTM: used to verify the validity of textual semantic features, the input is a text matrix of word vectors trained with the word2vec framework [22];

Siamese-CNN: based on the feature extraction model proposed by Kim, based on the Siamese framework and CNN network, with the input being a matrix representation of the sentence itself and convolved in full dimension;

MP-CNN: used to verify the validity of text structure features, the input is text matrix, and the text similarity is computed after extracting features with different granularity of convolution kernels and multiple pooling methods [23];

Siamese-LSTM-cw2vec: used to validate the effectiveness of cw2vec word embedding, the input of the model is the text matrix with stroke granularity trained with the cw2vec framework;

Our Model: the algorithm proposed in this study, the semantic, contextual structure of the text extracted from the model, the interaction between the text features using fusion gate fusion through the similarity calculation layer to calculate the text similarity.

In order to investigate the performance difference between the text similarity computation model designed and implemented in this study and the mainstream model, and to verify the advantage of multi-feature fusion over single feature, seven sets of comparison tests are set.

The average percentage error MSPE is shown in Fig. 8.

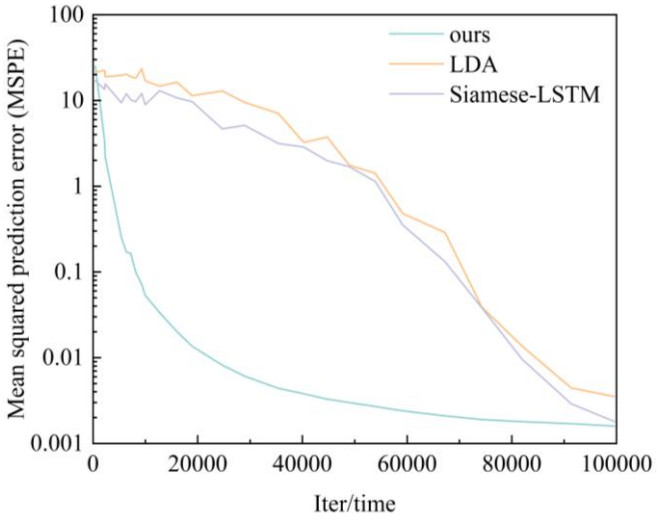

Fig. 8. Model percentage error plot.

TABLE II. COMPARISON OF RESULTS OF DIFFERENT MODELS IN DATASET 1

Model	Precision	Recall	F1
LDA	0.470	0.487	0.478
TF-IDF	0.433	0.468	0.450
Word2vec+cos	0.503	0.524	0.513
Siamese-LSTM	0.554	0.566	0.560
MP-CNN	0.563	0.582	0.572
Siamese-LSTM-cw2vec	0.536	0.572	0.553
Our Model	0.649	0.624	0.636

As can be seen from Table II and Table III, the F1 value of the model proposed for text is improved by about 0.2 compared to the traditional LDA model and the TF-IDF model, and also improved by about 0.1 compared to the Word2vec-cos model. In terms of the text feature representation, pre-trained word embeddings improve the model's ability to represent word features, and the word features trained by the Bi-LSTM network contain higher-order contextual semantic information than the n-gram model with higher order contextual semantic information. To further illustrate the model's computational efficiency, Fig. 9 presents a comparative analysis of time cost across different models. It can be observed that, despite the multi-component architecture, our approach maintains a competitive processing time, demonstrating that the performance gains do not come at the expense of excessive computational overhead. The similarity computation method based on the fusion attention mechanism proposed in this study improves the performance over the existing mainstream methods, which is mainly due to the model's effective fusion of the semantic information of the text and the structural information of the context. By effectively fusing multiple features extracted from the model using the fusion gate to retain as much information as possible from all the features, the performance is better than that of a single feature.

TABLE III. COMPARISON OF RESULTS OF DIFFERENT MODELS IN DATASET 2

Model	Precision	Recall	F1
LDA	0.551	0.568	0.559
TF-IDF	0.579	0.595	0.587
Word2vec-cos	0.594	0.612	0.603
Siamese-LSTM	0.652	0.672	0.662
MP-CNN	0.663	0.657	0.660
Siamese-LSTM-cw2vec	0.682	0.679	0.681
Our Model	0.749	0.714	0.731

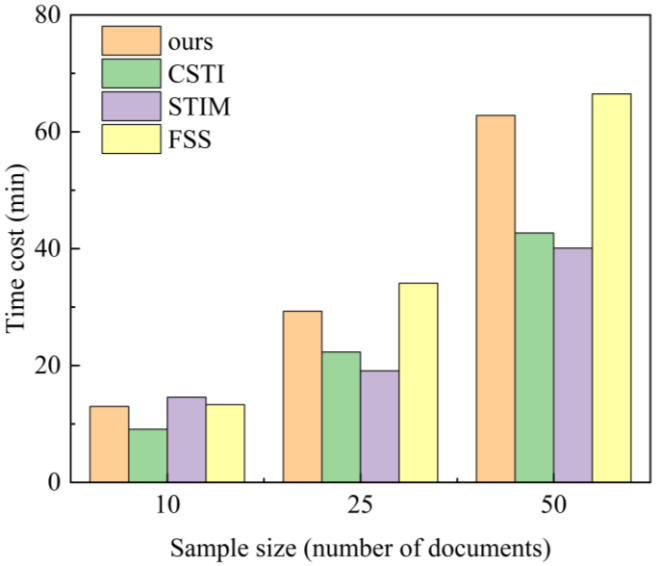

Fig. 9. Comparison chart of the time cost of our method.

Siamese-LSTM model applies the LSTM network with shared weights to the input coding of two texts under the Siamese framework, and the model is easy to train, which is a commonly used method in the field of text similarity computation with better results. However, some of the interaction features are missing, and the introduction of the product of feature vectors, variance, cosine value and Manhattan distance to amplify the dissimilarities of the texts can effectively alleviate the lack of interaction features. The input of the Siamese-LSTM-cw2vec model is the embedding of the stroke granularity of cw2vec, which has a better effect, proves the effectiveness of fine-grained word embedding, and explains that this study proposes the model incorporating cw2vec word embeddings. The MP-CNN model as a single-feature comparison model extracted some features. Word2vec-cos method is less effective because the simple representation of the text as a feature vector with word2vec and then calculate the similarity with the cosine value cannot fully take into account the complex semantic and syntactic information of the Chinese text. LDA is a topic model, which is essentially a bag-of-words model-based LDA is a topic model, which is essentially a model based on bag-of-words model to deal with long text, while the training set constructed in this study has shorter text, mostly belonging to the same type of topics, which can't take advantage of the performance in the experiment, and the performance is not good. The performance of TF-IDF method in the training set is not good because measuring the importance of a word simply by its "word frequency" is not comprehensive enough, and words that affect the semantics may appear more often because of their importance. The reason is that simply measuring the importance of a word by its "word frequency" is not comprehensive enough, and words that affect the semantics of a word because of their importance may appear less frequently, which does not reflect the positional information of the word and does not involve semantic features. It also relies heavily on the corpus, and needs to select a large number of high-quality corpora that match the training task.

V. CONCLUSION

The present study proposes a multi-feature fusion model for text similarity calculation in scientific and technological projects, effectively integrating semantic, contextual, and structural features to enhance accuracy. Compared with traditional similarity calculation methods, the proposed model achieves significant performance improvements, demonstrating its effectiveness in preserving both semantic meaning and contextual relationships. The combination of word2vec and cw2vec embeddings, together with Bi-LSTM and multi-perspective convolutional neural networks (MP-CNN), enables comprehensive feature extraction and fusion at multiple linguistic levels. Furthermore, the incorporation of fusion and interactive attention mechanisms enhances the model's capability to capture both shared and distinctive patterns across texts, thereby improving overall similarity detection performance.

Experimental results on two benchmark datasets indicate that the proposed model consistently outperforms traditional approaches such as LDA and TF-IDF, as well as advanced deep learning models including Siamese-LSTM and MP-CNN. An average F1-score improvement exceeding 10% over baseline methods highlights the model's ability to capture nuanced semantic dependencies and structural correlations.

Nevertheless, the multi-component architecture introduces additional computational complexity. To address this challenge, future work should focus on optimizing parameter efficiency through lightweight attention mechanisms, dimensionality reduction strategies, and GPU-based parallelization techniques, thereby improving the feasibility of real-time and large-scale deployment. In addition, it is valuable to investigate the model's generalization across multiple languages and domains. Given that cw2vec is primarily designed for Chinese text, subsequent research may incorporate multilingual embeddings (e.g., mBERT or cross-lingual transfer learning methods) to extend applicability to other linguistic contexts and scientific disciplines.

In summary, the proposed multi-feature fusion framework effectively balances semantic relevance, structural integrity, and contextual comprehension. With continued optimization and multilingual adaptation, the model has the potential to evolve into a scalable, domain-independent solution for intelligent and real-time text similarity assessment.

A Comparison Between FAHP-TOPSIS and FAHP-FTOPSIS Methods for Selecting the Best Products for Home-Based Sellers: A Performance Analysis

Selvia Lorena Br Ginting[1]*, Zulaiha Ali Othman[2]
Center for Artificial Intelligence Technology (CAIT)-Faculty of Information Science and Technology,
University Kebangsaan Malaysia, Bangi 43600, Malaysia[1, 2]
Computer System Study Program-Faculty of Engineering and Computer Science,
Universitas Komputer Indonesia, Bandung, Indonesia[1]

***Abstract*—This study discusses common problems faced by home-based sellers in determining the right product ideas to sell. To overcome this problem, a method is needed that can help home-based sellers to choose the right product. Therefore, a decision support system using a multi-criteria decision-making technique with a hybrid approach was applied, which integrates the FAHP-TOPSIS and FAHP-FTOPSIS methods in the product selection process. The analysis results show that the FAHP-TOPSIS method is more effective in producing product rankings, with alternative A5948 ranking first with a score of 0.946. Meanwhile, the FAHP-FTOPSIS method also placed the same alternative in first place with a score of 0.679. The findings in the ranking analysis showed that the addition of fuzzy did not affect the rankings but did affect the score value of the alternatives. Sensitivity Analysis using Mean Absolute Deviation (MAD), Mean Square Error (MSE), and Spearman Correlation (SC) was conducted. FAHP-TOPSIS performed best at Weight 1 (MAD 89, MSE 18.486, SC 0.972) and excelled at Weight 3 (MAD 144, MSE 51.791, SC 0.997), though more volatile at other weights. Overall, at the base weight (Weight 1), TOPSIS shows the best ranking stability (low MAD/MSE, high SC), while with shifted weights (especially Weight 3), FTOPSIS better maintains ordering (SC ≈ 1) despite higher error at Weight 2. Practically, TOPSIS suits baseline scenarios; FTOPSIS is more robust under weight variations, with error variance control still necessary. These findings provide a practical guideline: use FAHP-FTOPSIS when preferences are uncertain, and use FAHP-TOPSIS when preferences are clear. The resulting rankings can be directly adopted by sellers to prioritize and select products with confidence.**

I. Introduction

The rapid growth in internet availability and improvements in the quality of high-speed internet services have created significant opportunities for the development of electronic commerce (e-commerce) systems. Home-based sellers use this technology to increase operational efficiency, reach a wider market, and make money from home through e-commerce platforms [1, 2]. However, home-based sellers face particular difficulties due to the wide range of products and many competitors on e-commerce platforms. Often, sellers new to online commerce do not adequately consider the selection of truly profitable products [3]. Therefore, if a company or seller achieves very high profits, it can be categorized as having good performance [4]. Consequently, a method is needed to assist home-based sellers in determining the most profitable products, both for the present and the future.

One commonly used approach is the Decision Support System, which helps decision makers choose the best alternative based on a number of criteria [5-7]. In this context, the concept of fuzzy logic becomes relevant because it can represent uncertainty and subjectivity in assessments. Introduced by Lotfi A. Zadeh in 1965, fuzzy logic is not strictly binary (true/false) but rather permits a value to exist within a range of 0 to 1 [8-10]. When making decisions involving information that is frequently unclear, ambiguous, or imprecise, this method is highly effective. The decision-making model's accuracy and realism can be enhanced by more flexibly describing the degree of importance or preference when criterion values are represented as fuzzy numbers, such as triangular fuzzy numbers (TFN) [9-12].

This study proposes two hybrid methods: FAHP-TOPSIS and FAHP-FTOPSIS. The FAHP-FTOPSIS method is an MCDM approach in which the Fuzzy Analytical Hierarchy Process (FAHP) is used to determine the relative weights of each criterion more flexibly by considering the uncertainty of the assessment [13-15]. Meanwhile, Fuzzy TOPSIS is used to rank alternatives based on their proximity to positive and negative ideal solutions in fuzzy space [16, 17]. As a comparison, the FAHP-TOPSIS method is used, which employs FAHP for weight determination and conventional TOPSIS for ranking, thereby enabling the evaluation of the feasibility and accuracy of the main method. Based on the research by Okfalisa et al. [18], five criteria are used in recommending online store products. The final results of this study will identify the method that produces the best ranking and determine the most suitable products to recommend to home-based sellers as a reference for selecting products to sell [19].

II. Literature Review

A. Related Works

Previous studies have utilized fuzzy methods within the framework of Multi-Criteria Decision Making (MCDM).

A study by Ceren Erdin and Halil Emre Akba (2019) entitled "A Comparative Analysis of Fuzzy TOPSIS and Geographic Information Systems (GIS) for the Location Selection of Shopping Malls: A Case Study from Turkey", aimed to select strategic shopping mall locations in Turkey using the MCDM method with the Fuzzy TOPSIS and GIS approaches, and to compare the accuracy of each method [13]. In general, this study shows that combining fuzzy-based MCDM methods (e.g., Fuzzy-TOPSIS) with spatial analysis (e.g., GIS) makes location and alternative selection decisions more robust: ambiguous expert assessments can be handled, objective data is taken into account, and the results are more consistent and easier to visualize. As a result, the risk of wrong decisions is reduced, the planning process becomes more transparent and traceable, and this framework can be easily applied to other contexts (retail, logistics, energy, health).

In the study "Selection of Software Requirements using TOPSIS under Fuzzy Environment" by Mohd. Sadiq (2020), a method for selecting software requirements using Fuzzy TOPSIS was developed to address uncertainty and complexity in decision making [20]. In general, this research provides a structured and uncertainty-resistant method for prioritizing and selecting software requirements: linguistic expert assessments are converted into quantitative ratings using Fuzzy-TOPSIS (closeness coefficient), resulting in more objective and transparent decisions. This method is suitable for multi-stakeholders, addresses information ambiguity, and is relatively simple to calculate compared to several other techniques, as well as known to have minimal rank-reversal issues. The end result makes it easier for teams to select the most valuable "top-n" requirements and reduces the risk of misprioritization in development.

In a study conducted by Shamsuzzoha et al. [21] entitled "Application of the fuzzy TOPSIS framework for selecting complex projects", it offers a Fuzzy-TOPSIS-based selection framework to quickly identify the most complex projects, using eleven factors as a practical checklist, so that team allocation, budgeting, and support can be more targeted. The ranking results are proven to be stable through sensitivity testing, so decisions are not easily changed simply due to weight variations. As a result, the selection process becomes more objective, the risk of misplaced priorities is reduced, and project portfolio productivity increases while also filling a research gap due to its specific focus on selecting complex projects, rather than simply selecting general projects.

Previous studies have concluded that a research gap exists because studies on product selection with multiple criteria in e-commerce have not specifically addressed home-based sellers in Indonesia with large amounts of real data. The focus on indicators closely related to sellers (price, rating, sales, discounts, chat responses) is also still rare, as is a direct comparison between TOPSIS and Fuzzy TOPSIS with the same weighting basis and testing whether the results remain stable when there are small changes or when the criteria weights are shifted.

B. Product Selection

A crucial decision-making process is product selection: a process in which a variety of qualities and standards are evaluated to identify the best possible product. The application of cutting-edge techniques to deal with complexity and uncertainty in decision-making is emphasized in research on product selection. Fuzzy logic, hierarchical decision making, online reviews, multi-criteria analysis, and consumer expectations are some of the methods used [12, 22-25]. By taking consumer preferences, production efficiency, environmental impact, and technical viability into account, the objective is to maximize product selection [22]. The optimization method in the study by Tan et al. [23] focuses on determining the best product design that incorporates individual customer preferences and manufacturing constraints. Several studies on product selection show two main perspectives. First, the research by Gultom et al. [24] focuses on comprehending consumer preferences and using fuzzy sets to assist in decision-making, such as when prospective students are choosing a university. Second, the research by Aznag et al. [25] highlights how sellers should maximize revenue by optimizing product combinations while considering resource constraints.

C. MCDM

Multi-criteria decision-making (MCDM) is a method for evaluating and selecting the best choice from a number of options based on a number of factors. This approach is commonly used in areas such as selecting equipment, choosing technology, and evaluating service providers to improve performance, cost-efficiency, and other related aspects [26-28]. For these types of situations, multi-criteria decision methods (MCDMs) have been developed. These methods are also known for their formal structure and their ability to handle multiple conflicting goals and include different stakeholders in the decision-making process. Due to the wide range of problems they address, many multi-criteria decision methods have been created. One example is the Characteristic Objects METhod (COMET), which does not require the use of weights and is suitable for problems where rank reversal cannot happen [26]. Several MCDM methods can offer different solutions to the same problem. Variations in outcomes when using different computational approaches may result from factors such as the use of different weights for criteria, differences in the algorithms used, and the way targets are scaled [27, 29]. These observations highlight the importance of using a multi-method approach and techniques to fairly compare results in MCDM studies. Analyzing different MCDM methods shows that selecting the appropriate method and normalization technique is crucial. Almost any combination of a method and its parameters can lead to varied results [28]. Moreover, the increasing number of MCDM methods has created a need to compare the results they produce.

D. Home-Based Sellers

A home-based seller is typically a small-scale operation carried out from an individual's residence. These businesses contribute to household income and have a significant impact on the economy by using available resources, increasing

national output, generating employment opportunities, and supporting the livelihoods of individuals in urban areas. Despite these benefits, home-based sellers encounter challenges such as intense competition and limited sales [30-34]. Furthermore, various studies highlight that online home-based sellers offer a broad array of products and services, including food items, beauty products, clothing, artwork, handmade crafts, accounting services, consulting, freelance writing, virtual assistance, marketing, design, translation, web development, dropshipping, and caregiving [35-40].

There is a growing trend of home-based sellers participating in the digital marketplace or e-commerce, with a substantial portion of their revenue generated through online sales. The different categories of home-based sellers include: 1) home-based family businesses [35], 2) e-commerce home-based firms [37], 3) home-based sellers that focus on work-life balance [36], 4) diverse home-based sellers [37], and 5) women-owned home-based sellers [38].

In addition, several studies suggest that online home-based sellers sell a variety of products and services, such as food items, beauty products, clothing, artwork, homemade crafts, accountancy, consulting, freelance writing, virtual assistance, marketing, design, translation, web development, dropshipping, and caregiving [35-39].

E. FAHP

The fuzzy analytic hierarchy process (FAHP) is based on Zadeh's fuzzy set theory and Saaty's analytic hierarchy process (AHP) method for multi-criteria decision making (MCDM) [14, 41, 42]. The Hierarchy Analysis Process, or AHP, is the most commonly used. There are two main steps to using AHP in real life. The first step is to break a complicated problem down into a structured hierarchy. The second step is to determine the priority of each criterion to establish their importance at each level. The final stage involves evaluating the hierarchy based on the decision maker's preferences, where the weights from each matrix are calculated and normalized [28, 42]. One of the major advantages of this process is that it reduces a multi-dimensional problem to an equivalent unidimensional problem. This also facilitates producing a standard solution, which can be fused across several experts to come to a single agreed output. The method is flexible, and inconsistencies can be detected. It also provides tools for achieving consensus among experts. However, as noted in [43], the traditional AHP does not effectively address uncertainty in the evaluation of criterion importance. Because of this limitation, a fuzzy version of the method was adopted. This version enables the use of AHP in uncertain or ambiguous situations and has become increasingly accepted. It has been widely accepted and applied to address decision-making problems in various fields [44].

F. Fuzzy TOPSIS

The TOPSIS technique was proposed in 1981 by Hwang and Yoon and has been widely applied during the past several years. This strategy is beneficial for making decisions by comparison of alternative measures as a function of how close they are to an ideal point [28].

Fuzzy numbers are employed to handle uncertainty and subjective judgments in real-life situations. Intuitionistic Fuzzy Sets provide a more accurate representation of decision-makers' approvals, rejections, and uncertain or hesitant opinions [45].

G. Sesitivity Analysis

Sensitivity analysis aims to measure the accuracy of the validation values obtained in the case study and demonstrate the robustness of the hybrid model [46]. The determination of this sensitivity analysis is based on several smallest value ranges and a regression process. The following are various ways to determine sensitivity analysis [47]:

1) Mean Absolute Deviation (MAD): Mean Absolute Deviation (MAD) is a statistical measure that calculates the average absolute deviation of data from the central value, and is used to assess the extent of variation or instability in a system [48, 49].

2) Mean Squared Error (MSE): Mean Squared Error (MSE) is the bias (systematic deviation) of an estimate plus, statistically independent components that account for its variation [50], and thus can be used to indicate general accuracy levels of a predictive model.

3) Spearman's Correlation (SC): Spearman's Rank Correlation Coefficient is a non-parametric statistical measure used to assess the degree of monotonic relationship between two variables, especially when the data is expressed in the form of ranks or orders [51]. This coefficient measures the extent to which the relationship between two sets of ranks is consistent (rising or falling simultaneously) [52].

III. Methodology

A. Research Framework

A flowchart of this study is illustrated in Fig. 1.

The following is an explanation of the flowchart shown in Fig. 1:

1) Criteria and data setup

- Identify Criteria → Criteria Data: define the evaluation criteria (e.g., rating, price, sold, etc.) and prepare the criterion dataset.
- Alternative Data Identification / Collection / Processing → Alternative Data: identify the alternatives (products), collect raw data, clean/normalize as needed, and produce a ready-to-use alternatives dataset.

2) Weighting with FAHP (two parallel tracks)

- Establishing a Decision-Making Hierarchy → Compiling a Pair-Wise Matrix: build the decision hierarchy and create the pairwise comparison matrix of criteria.
- Determining the Level of Importance → CR $\leq$ 0.1: perform the consistency check (Consistency Ratio). If CR > 0.1, revise judgments; if CR $\leq$ 0.1, continue.
- Matrix Fuzzification → Weight Calculation → Weight Data: fuzzify judgments (e.g., triangular fuzzy numbers), compute criterion weights (defuzzify/normalize), and store them as Weight Data.

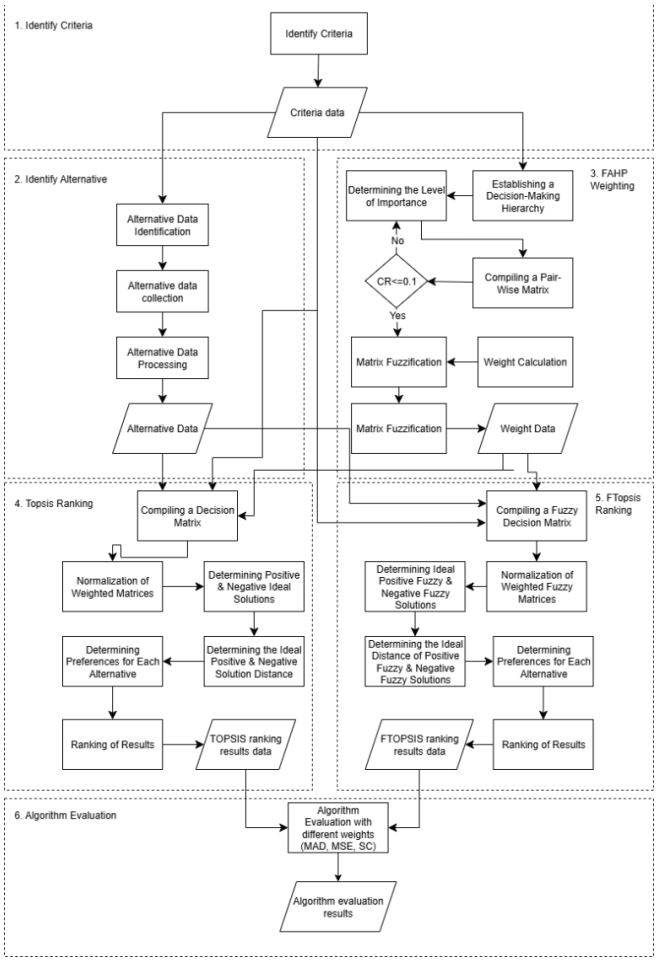

Fig. 1. Research method flowchart.

3) Decision matrix construction

- Compiling a Decision Matrix / Compiling a Fuzzy Decision Matrix: build the decision matrix (crisp for classical TOPSIS; fuzzy for FTOPSIS) that contains each alternative's performance on each criterion.

4) Ranking with TOPSIS (left branch)

- Normalizing the Weighted Matrices: normalize and apply weights to obtain the weighted normalized matrix.
- Determining the Positive and Negative Ideal Solutions: define the positive and negative ideal solutions.
- Determining the Ideal Positive and Negative Solution Distance: compute each alternative's distance to the positive and negative ideals.
- Determining the Preferences for Each Alternative → Ranking of Results → TOPSIS ranking results data: compute the preference score, rank the alternatives, and output TOPSIS ranking results.

5) Ranking with FTOPSIS (right branch)

- Normalizing the Weighted Fuzzy Matrices: perform fuzzy normalization and apply fuzzy weights.
- Determining the Ideal Positive and Negative Fuzzy Solutions: set the fuzzy positive/negative ideals.
- Determining the Ideal Distance of Positive Fuzzy and Negative Fuzzy Solutions: calculate distances in the fuzzy space (e.g., TFN distance).
- Determining the Preferences for Each Alternative → Ranking of Results → FTOPSIS ranking results data: (de)fuzzify preference scores, rank the alternatives, and output FTOPSIS ranking results.

6) Sensitivity evaluation across weight sets

- Algorithm evaluation with different weights (MAD, MSE, SC): test the stability of both algorithms under weight changes using three metrics:
  - MAD (Mean Absolute Deviation): average absolute rank difference vs. the baseline (smaller = more stable).
  - MSE (Mean Square Error): average squared rank difference (more sensitive to large shifts).
  - SC (Spearman Correlation): rank-order consistency (closer to 1 = highly consistent).
- Algorithm evaluation results: summarize which algorithm is more stable/robust under the tested weight profiles.

B. Data Collection and Criteria

1) Dataset source: This study uses data on food and beverage products from various stores on the Shopee Indonesia e-marketplace, collected using web scraping methods, amounting to 10,000 data points.

The criteria used in the study were obtained from the questionnaire results to determine the importance of each criterion. Referring to previous studies and adding two new criteria, which are subscribers and followers. The criteria used can be seen in Table I.

TABLE I. CRITERIA FOR SELECTING THE BEST PRODUCTS

Criteria	Description	Type
Rating	Product evaluation by consumers	Benefit
Price	Selling price of products	Cost
Sold	Number of units sold of a product	Benefit
Discount	Discounts on products	Benefit
Response Chat	Percentage of conversations responded to by sellers	Benefit

C. Fuzzy Analytic Hierarchy Process (FAHP

Here are the steps for weighting FAHP:

1) Conversion of multi-criteria decision-making problems into hierarchical models.

2) Identification of the importance of the pair-wise comparison matrix in determining the importance of criteria on the Saaty comparison scale is given in Table II.

TABLE II. INTENSITY OF INTEREST

Verbal scale	Numerical scale
1	Both elements are equal
3	A little more important
5	Most important
7	Much more important
9	Absolutely more important
2,4,6, and 8	Intermediate value
invers	$aij = 1/aij$

3) Normalization of the weight of each criterion importance value and find its eigenvector value.

4) Calculation of the consistency ratio using the index ratio to check the consistency of the weight values is given in Eq. (1):

$$CI = \frac{\lambda max - n}{RI*(n-1)} \quad (1)$$

If the CR value is ≤ (less than or equal to) 0.1, then the criteria values are consistent. However, if not, a re-evaluation is necessary to ensure the consistency of the criteria values.

5) Fuzzification of Pair-Wise Comparison Matrix into TFN Fuzzy Scale is given in Table III.

TABLE III. PAIR-WISE FUZZY SCALE

Intensity of importance	Fuzzy Scale (l,m,u)
1	(1,1,1)
2	(1,2,3)
3	(2,3,4)
4	(3,4,5)
5	(4,5,6)
6	(5,6,7)
7	(6,7,8)
8	(7,8,9)
9	(8,9,10)
invers	$(l,m,u)_{ij} = (1/u, 1/m, 1/l)_{ij}$

6) Fuzzy weight calculation using Fuzzy Geometrix Mean [Eq. (2)]:

$$\widetilde{w}_i = \tilde{r}_i \otimes (\tilde{r}_1 \oplus \tilde{r}_2 \oplus \dots \oplus \tilde{r}_n)^{\frac{1}{n}} \quad (2)$$

7) Defuzzification of fuzzy weights using the Center Of Area method [Eq. (3)]:

$$w_i = (lw_i + mw_i + uw_i)/3 \quad (3)$$

8) Weight normalization [Eq. (4)]:

$$w_r = \frac{w_i}{\sum_{i=1}^{n} w_i} \quad (4)$$

D. Technique for Order Preference by Similarity to Ideal Solution (TOPSIS)

The steps of TOPSIS are as follows:

1) Determination of the normalization of the decision matrix.

The normalized weight value rij is calculated using the following Eq. (5):

$$r_{ij} = \frac{Xij}{\sqrt{\sum_{i=1}^{m} X_{ij}^2}} \quad (5)$$

2) Determination of the normalized weights of the decision matrix.

The normalized weight value yij is calculated using the following Eq. (6):

$$yij = Wij\, x\, rij \quad (6)$$

provided that:

$$A+ = (y_1^+, y_2^+, \dots, Y_N^+)$$
$$A- = (y_1^-, y_2^-, \dots, Y_N^-)$$

Description:

$y+ = (max\ _i y_{ij}$;if j is an alternative category of benefits)

$y- = (min\ _i y_{ij}$; if j is an alternative category of Costs)

With a value of j = 1, 2, …n

3) Calculation of the distance between the Ai alternative and the positive ideal solution using the following Eq. (7):

$$D_i^+ = \sqrt{\sum_{j=1}^{n} (y_j^+ - y_{ij})^2} \quad (7)$$

4) Calculation of the distance between the Ai alternative and the ideal solution using Eq. (8):

$$D_i^- = \sqrt{\sum_{j=1}^{n} (y_{ij} + y_j^-)^2} \quad (8)$$

5) Calculation of the preference value for each alternative (Vi) using Eq. (9):

$$V_i = \frac{D_i^-}{D_i^- + D_I^+} \quad (9)$$

E. Fuzzy Technique for Order Preference by Similarity to Ideal Solution (FTOPSIS)

The steps of Fuzzy TOPSIS are as follows:

1) Fuzzyfication of the decision matrix into TFN fuzzy values becomes three values: low, medium, and upper.

2) Determination of the normalization of the decision matrix. The normalized weight values rij are calculated using the following equation:

Benefit Criteria [Eq. (10)]:

$$\check{r}_{ij} = \left(\frac{a_{ij}}{c_i^{MAX}} + \frac{b_{ij}}{b_i^{MAX}} + \frac{c_{ij}}{a_i^{MAX}}\right) \quad (10)$$

Cost Criteria [Eq. (11)]:

$$\check{r}_{ij} = \left(\frac{c_i^{MAX}}{a_{ij}} + \frac{b_i^{MAX}}{b_{ij}} + \frac{a_i^{MAX}}{c_{ij}}\right) \quad (11)$$

provided that:

$$A+ = \left(\max a_{ij} \max b_{ij}, \max c_{ij}\right)$$

$$A- = \left(\min a_{ij} \min b_{ij}, \min c_{ij}\right)$$

3) Calculation of the distance between the Ai alternative and the positive ideal solution using Eq. (12):

$$D_i^+ = \sum_{i=j}^{n} \sqrt{\frac{1}{3}\{(a_{ij} - A_i^+) + \left(b_{ij} - A_i^+\right) + (c_{ij} - A_i^+)\}} \quad (12)$$

4) Calculation of the distance between the Ai alternative and the negative ideal solution using Eq. (13):

$$D_i^- = \sum_{i=j}^{n} \sqrt{\frac{1}{3}\{(a_{ij} - A_i^-) + \left(b_{ij} - A_i^-\right) + (c_{ij} - A_i^-)\}} \quad (13)$$

5) Calculation of the preference value for each alternative (Vi) using Eq. (14):

$$V_i = \frac{D_1^-}{D_1^- + D_I^+} \quad (14)$$

F. Sensitivity Analysis

The following are the equations for sensitivity analysis.

1) Mean Absolute Deviation (MAD)

The following is the equation for MAD [Eq. (15)]:

$$MAD = \frac{1}{n}\sum_{i=1}^{n} |xij - \text{YJ}| \quad (15)$$

2) Mean Squared Error (MSE)

The following is the equation for MSE [Eq. (16)]:

$$MSE = \frac{1}{n}\sum_{i=1}^{n} (xij - yj)^2 \quad (16)$$

3) Spearman's Correlation (SC)

The following is the equation for SC [Eq. (17)]:

$$SC = r_s = 1 - \frac{6\sum d_i^2}{n(n^2-1)} \quad (17)$$

IV. Results and Discussion

A. Criteria Weight Calculation Using FAHP

The first step is to convert the multi-criteria decision-making problem into a hierarchical model consisting of objectives, criteria, sub-criteria (if any), and alternatives. The following is a decision hierarchy illustrated in Fig. 2.

The hierarchical model in this study consists of three levels: objectives, criteria, and alternatives. The first level is the objective, which is to determine the most potential product to sell for home-based sellers. The second level consists of five criteria: rating, price, sold, discount, and chat response. The third level contains product alternatives to be evaluated: Product 1 to Product N.

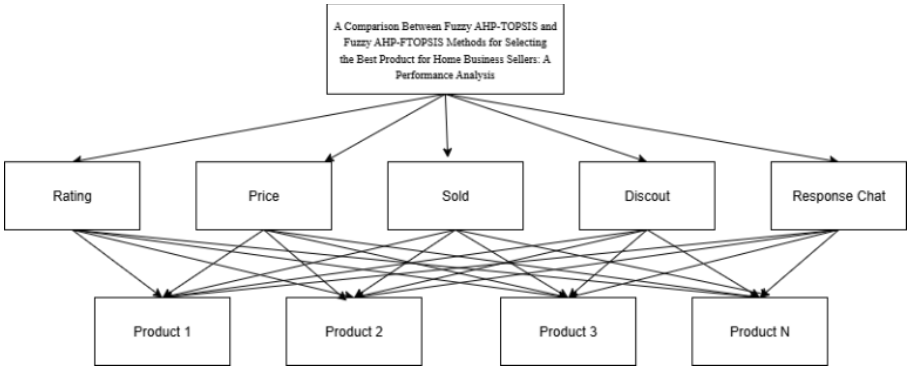

Fig. 2. Decision hierarchy.

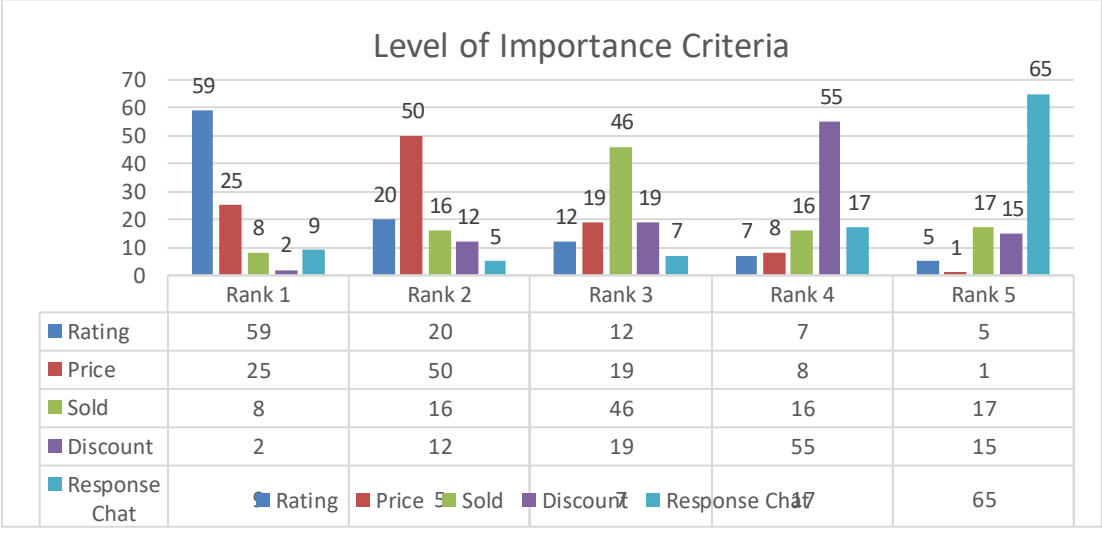

Fig. 3. Level of importance criteria.

After establishing the hierarchy, the next step was to determine the level of importance of each criterion. This was done by distributing questionnaires to sellers and successfully obtaining 103 respondents. The results of determining the level of importance are shown in Fig. 3.

Once the criteria were known, pair-wise comparisons were then conducted for each criterion, as in Table IV.

TABLE IV. MATRIX PAIR-WISE COMPARISON

	Rating	Price	Sold	Discount	Response Chat
Rating	1	2	3	4	5
Price	$\frac{1}{2}$	1	2	3	4
Sold	$\frac{1}{3}$	$\frac{1}{2}$	1	2	3
Discount	$\frac{1}{4}$	$\frac{1}{3}$	$\frac{1}{2}$	1	2
Response Chat	$\frac{1}{5}$	$\frac{1}{4}$	$\frac{1}{3}$	$\frac{1}{2}$	1

The results of the weights (eigenvectors) of each criterion from the pair-wise comparison results can be used to calculate the best product selection, as shown in Table V.

TABLE V. EIGENVECTOR

Criteria	Eigenvector
Rating	0.416
Price	0.262
Sold	0.161
Discount	0.099
Response Chat	0.062

Then, the eigenvector is evaluated by determining the Consistency Ratio (CR) using Eq. (1). The Consistency Ratio obtained is 0.022, which is less than 0.1, so the matrix obtained previously is consistent and does not need to be corrected.

After the matrix is consistent, fuzzification is performed on the pair-wise matrix according to the FAHP matrix scale, as in Table III. The following are the fuzzification results as shown in Table VI.

TABLE VI. FUZZY MATRIX PAIR-WISE

	Rating	Price	Sold	Discount	RC
Rating	(1;1;1)	(1;2;3)	(2;3;4)	(3;4;5)	(4;5;6)
Price	$\left(\frac{1}{3};\frac{1}{2};1\right)$	(1;1;1)	(1;2;3)	(2;3;4)	(3;4;5)
Sold	$\left(\frac{1}{4};\frac{1}{3};\frac{1}{2}\right)$	$\left(\frac{1}{3};\frac{1}{2};1\right)$	(1;1;1)	(1;2;3)	(2;3;4)
Discount	$\left(\frac{1}{5};\frac{1}{4};\frac{1}{3}\right)$	$\left(\frac{1}{4};\frac{1}{3};\frac{1}{2}\right)$	$\left(\frac{1}{3};\frac{1}{2};1\right)$	(1;1;1)	(1;2;3)
RC	$\left(\frac{1}{6};\frac{1}{5};\frac{1}{4}\right)$	$\left(\frac{1}{5};\frac{1}{4};\frac{1}{3}\right)$	$\left(\frac{1}{4};\frac{1}{3};\frac{1}{2}\right)$	$\left(\frac{1}{3};\frac{1}{2};1\right)$	(1;1;1)

After the matrix has been fuzzified, the fuzzy weight will be calculated using Eq. (2), and the results of the calculation are shown in Table VII.

TABLE VII. FUZZY WEIGHT

Criteria	L	M	U
Rating	0,421	0,417	0,389
Price	0,256	0,263	0,272
Sold	0,156	0,160	0,171
Discount	0,098	0,097	0,104
Response Chat	0,069	0,062	0,063

Next, defuzzification of the fuzzy weights from the fuzzy weight calculations performed using Eq. (3), and the weights were normalized using Eq. (4). The results can be seen in Table VIII.

TABLE VIII. CRIPS WEIGHT

Criteria	Weight
Rating	0.409
Price	0.264
Sold	0.163
Discount	0.100
Response Chat	0.065
CR	0.015

B. Product Ranking using TOPSIS

After obtaining the weight of each criterion, the calculation of the best product ranking was carried out using 10,000 (ten thousand) alternatives obtained from the Shopee Indonesia website, as shown in Table IX.

TABLE IX. DATASET TOPSIS

A/C	C1	C2	C3	C4	C5
A1	2	5000	10	0	14
A2	4	55000	5	0	82
A3	3	88000	2	5	50
A4	5	11000	9	0	79
A5	5	17999	10	0	41
A6	5	18900	31	0	38
A7	5	9500	2	0	96
A8	5	75900	64	0	91
A9	5	39999	125	0	66
A10	4	13000	83	30	94
…….					
A10000	5	4750	8	0	89

Next, calculations were performed using the TOPSIS method with Eq. (6) for weight normalization, Eq. (7) and Eq. (8) for negative and positive ideal values, and Eq. (9) to find the utility value of each alternative, as in Table X.

After that, the scores were calculated and ranked from the highest to the lowest. The following are the top 10 rankings as shown in Table XI.

TABLE X. UTILITY VALUE

A/C	C1	C2	C3	C4	C5
A1	0,00029	0,00128	0,00007	0,00000	0,00013
A2	0,00322	0,00256	0,00003	0,00000	0,00074
A3	0,00515	0,00192	0,00001	0,00043	0,00045
A4	0,00064	0,00320	0,00006	0,00000	0,00071
A5	0,00105	0,00301	0,00007	0,00000	0,00037
A6	0,00111	0,00308	0,00021	0,00000	0,00034
A7	0,00056	0,00320	0,00001	0,00000	0,00087
A8	0,00444	0,00308	0,00044	0,00000	0,00082
A9	0,00234	0,00308	0,00085	0,00000	0,00060
A10	0,00076	0,00282	0,00057	0,00258	0,00085
.....					
A10000	0,00028	0,00320	0,00005	0,00000	0,00080

TABLE XI. TOPSIS RANKING RESULTS

Rank	Alternative	Score
1	A5948	0,945977
2	A5950	0,897357
3	A6375	0,775835
4	A6625	0,705012
5	A3358	0,668346
6	A2667	0,649551
7	A3930	0,563599
8	A5312	0,498368
9	A776	0,423548
10	A6521	0,415185

C. Product Ranking Using FTOPSIS

The calculation using the FTOPSIS method was performed using fuzzy weights with three values from FAHP. The dataset used the data in Table IX, which was converted into Fuzzy TFN form in Table XII.

Next, calculations were performed using the FTOPSIS method with Eq. (10) for normalization if the criterion was Benefit and Eq. (11) if the criterion was Cost, as well as Eq. (12) and Eq. (13) for negative Fuzzy and positive Fuzzy ideal values. Then, the score was calculated using Eq. (14). The final results can be seen in Table XIII.

D. Graph of Ranking Changes

To evaluate the impact of weight variations on the ranking results, a comparative analysis was conducted using both Fuzzy TOPSIS and classical TOPSIS methods. The results are presented in the following figures, which illustrate how the rankings of alternatives change under different weight scenarios.

The first graph in Fig. 4 shows the ranking changes of alternatives under different weight scenarios using the Fuzzy TOPSIS method. Most alternatives show relatively stable rankings with minor shifts, but A919 and A5774 demonstrate sharp fluctuations, especially under the Second Weight scenario, where their ranks rise drastically. This indicates that Fuzzy TOPSIS is more sensitive to weight variations, particularly for certain alternatives, and may produce significant rank changes when the weights are adjusted.

TABLE XII. DATA FTOPSIS

A/C	C1	C2	C3	C4	C5

TABLE XIII. FTOPSIS RANKING RESULTS

Rank	Alternative	Score
1	A5948	0,67910
2	A5950	0,63945
3	A6375	0,60883
4	A771	0,56562
5	A2667	0,56104
6	A2025	0,52758
7	A2384	0,52582
8	A5774	0,52290
9	A919	0,52283
10	A1623	0,52274

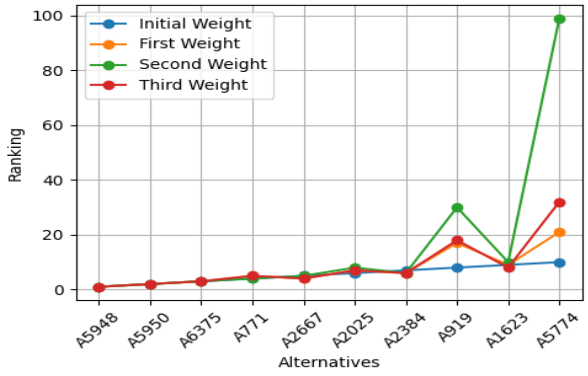

Fig. 4. FTOPSIS ranking change chart.

Fig. 5. TOPSIS ranking change chart.

The second graph in Fig. 5 displays the ranking results under different weight scenarios using the classical TOPSIS method. In this case, the rankings remain perfectly consistent across all scenarios, with all lines overlapping into a straight diagonal pattern. This demonstrates that TOPSIS yields a highly stable ranking outcome that is unaffected by weight modifications, showing robustness in preserving rank order despite changes in weights.

Together, the two graphs highlight a contrast: Fuzzy TOPSIS provides more flexibility but introduces higher sensitivity to weight changes, while TOPSIS delivers more stable and robust results, maintaining the same ranking across different scenarios.

E. Sensitivity Analysis

Sensitivity analysis was conducted by re-ranking alternatives using three different FAHP weight datasets and comparing the rankings from the main weights with those from the experimental weights to assess the impact of weight changes on alternative rankings, using Mean Absolute Deviation (MAD), Mean Square Error (MSE), and Spearman Correlation (SC).

1) MAD: The following are the MAD results of the two methods used, as shown in Fig. 6.

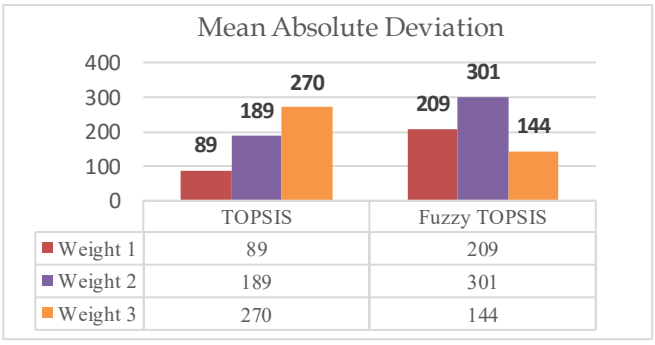

Fig. 6. Mean absolute deviation graph.

The results of the Mean Absolute Deviation (MAD) calculation in Fig. 6 show that TOPSIS has the highest ranking stability in Weight 1 (89) but is sensitive in Weight 3 (270). Conversely, Fuzzy TOPSIS is relatively unstable in Weight 1 (209) and most sensitive in Weight 2 (301), but shows the best stability in Weight 3 (144). In general, TOPSIS is more stable in the initial weights, while Fuzzy TOPSIS performs better in certain weights, but with greater fluctuations.

2) MSE: The following are the MSE results of the two methods used, as shown in Fig. 7.

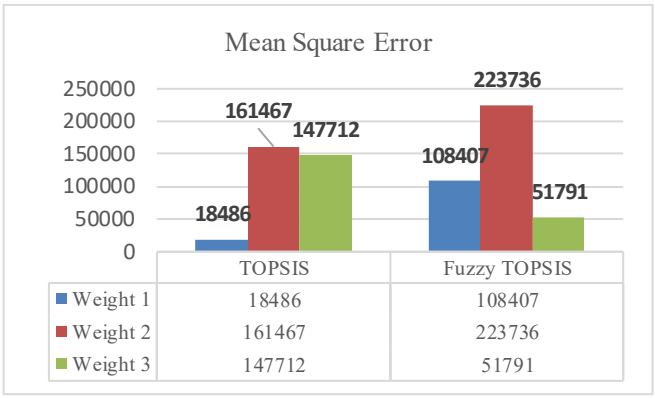

Fig. 7. Mean square error graph.

The Mean Square Error (MSE) results in Fig. 5 show that TOPSIS has the smallest error in Weight 1 (18.486) and increases significantly in Weight 2 (161.467) and Weight 3 (147.712). Conversely, Fuzzy TOPSIS has the lowest MSE for Weight 3 (51.791) but the highest for Weight 2 (223.736). In general, TOPSIS is more stable at the initial weights, while Fuzzy TOPSIS performs better for Weight 3, despite having larger error fluctuations.

3) SC: The following are the SC results of the two methods used, as shown in Fig. 8.

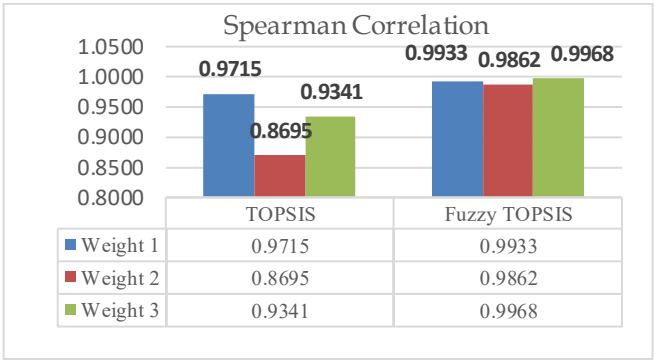

Fig. 8. Spearman correlation graph.

The Spearman Correlation results in Fig. 8 show that Fuzzy TOPSIS has a very high and consistent correlation in all weight scenarios: 0.9933 (Weight 1), 0.9862 (Weight 2), and 0.9968 (Weight 3). Meanwhile, TOPSIS recorded the highest correlation in Weight 1 (0.9715) and the lowest in Weight 2 (0.8695), with a moderate value in Weight 3 (0.9341). Overall, Fuzzy TOPSIS demonstrated better ranking stability compared to TOPSIS across all weight scenarios. Overall, Fuzzy TOPSIS demonstrated better ranking stability compared to TOPSIS across all weight scenarios.

Based on the results of testing using three evaluation metrics, namely Mean Absolute Deviation (MAD), Mean Square Error (MSE), and Spearman Correlation (SC), it was

found that TOPSIS showed the best stability at the initial weight (MAD = 89; MSE = 18.486; SC = 0.9715), while Fuzzy TOPSIS outperformed it at Weight 3 (MAD = 144; MSE = 51.791; SC = 0.9968) and maintained consistently high correlation values across all weight scenarios. However, Fuzzy TOPSIS tends to experience greater error fluctuations in Weight 2. These findings indicate that the selection of the appropriate method and weight settings significantly influences the stability and accuracy of the ranking results.

Based on sensitivity analysis using MAD, MSE, and Spearman's Correlation (SC), it can be concluded that at the base weight (Weight 1), TOPSIS shows the best ranking stability—characterized by relatively low mean absolute deviation and mean square error as well as high ranking correlation with the reference. However, when the weights are shifted (particularly in the Weight 3 pattern), Fuzzy TOPSIS (FTOPSIS) is superior in maintaining consistency in the order, as reflected in the SC value that is very close to 1, even though the error profile increased in the Weight 2 configuration.

V. Conclusion

This study fills the gap by constructing a simple, field data-based model, comparing two approaches (FAHP–TOPSIS and FAHP–FTOPSIS), and then testing the stability of the results in scenarios of minor changes and significant weight changes. From this, practical guidelines that are easy to follow are compiled: Fuzzy TOPSIS is more appropriate when the data tends to be vague but the changes are small, while TOPSIS is more suitable when the focus of the assessment shifts significantly. The process is easy to repeat, and the consistent peak results in both approaches show that the recommendations produced are reliable.

The results of the comparative ranking analysis using the FAHP-TOPSIS and FAHP-FTOPSIS hybrid methods to support decision making in selecting potential products for home-based sellers. The alternative ranking results show that the first-ranked alternative is the same in both the FAHP-TOPSIS and FAHP-FTOPSIS methods: alternative A5948; however, the scores are different. In the FAHP-TOPSIS results, the score for this alternative is 0.945977, while in the FAHP-FTOPSIS results, this alternative receives a score of 0.67910. This proves that the addition of the Fuzzy approach to TOPSIS does not affect the product ranking results but does affect the score values of the product alternatives.

The sensitivity test results show that, FAHP-TOPSIS is stronger in dealing with changes in criterion weights, with the best results for weight one. Mean Absolute Deviation 89, Mean Square Error 18.486, and Spearman Correlation 0.972. Conversely, FAHP-FTOPSIS shows superiority at weight three—Mean Absolute Deviation 144, Mean Square Error 51.791, and Spearman Correlation 0.997, though its performance is more fluctuating at other weights. Practically, for baseline weighting scenarios in product selection, TOPSIS is the most stable choice; while for scenarios with weight variations (e.g., shifting seller preferences), FTOPSIS offers better ranking robustness, with the caveat that controlling error variance at certain weights remains necessary.

In short, FAHP-FTOPSIS is the safer choice for messy, real-world settings with uncertain or shifting preferences because it keeps rankings more stable. FAHP-TOPSIS can be attractive when decision makers have crisp, well-defined weights and you mainly care about minimizing numerical error. So, use FAHP-FTOPSIS as the default under ambiguity; switch to FAHP-TOPSIS when preferences are clear and consistency is less of a concern.

These findings can serve as a practical guideline for sellers. When preferences are uncertain or may shift over time as is common in dynamic marketplaces, FAHP-FTOPSIS should be the default because it keeps rankings stable and reliable under ambiguity. When priorities are crisp and well agreed upon, FAHP-TOPSIS can be used to emphasize minimal numerical error. In both cases, the resulting rankings are actionable: sellers can use them to shortlist products, allocate budget, and schedule promotions with greater confidence. We also recommend reviewing weights periodically (e.g., when market conditions or campaign goals change) and re-running the analysis so that the ranking continues to reflect current strategy and risk tolerance.
