Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Kohei Arai
Editor-in-Chief

Editorial Board

Editor-in-Chief

Dr. Kohei Arai - Saga University
Domains of Research: Artificial Intelligence, Big Data Analytics, Computer Vision, Decision Making, Information Retrieval, Satellite Remote Sensing

---

Associate Editors

Alaa Sheta
Southern Connecticut State University
Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems

Arun Kulkarni
University of Texas at Tyler
Domain of Research: Machine Vision, Artificial Intelligence, Computer Vision, Data Mining, Image Processing, Machine Learning, Machine Vision, Neural Networks, Neuro-Fuzzy Systems

Dr Ronak Al-Haddad
Anglia Ruskin University / Cambridge
Domain of Research: Technology Trends, Communication, Security, Software Engineering and Quality, Computer Networks, Cyber Security, Green Computing, Multimedia Communication, Network Security, Quality of Service

Elena Scutelnicu
"Dunarea de Jos" University of Galati
Domain of Research: e-Learning, e-Learning Tools, Simulation

In Soo Lee
Kyungpook National University
Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning

Larbi Boubchir
University of Paris 8
Domain of Research: Artificial Intelligence, Biometrics

Renato De Leone
University of Camerino
Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming

Xiao-Zhi Gao
University of Eastern Finland
Domain of Research: Artificial Intelligence, Genetic Algorithms

CONTENTS

Paper 1: AI-Assisted Workflow Optimization and Automation in the Compliance Technology Field
Authors: Zhen Zhong
PAGE 1 – 5

Paper 2: From Legacy to Cloud: Migration Strategies for Traditional Financial Institutions Using AWS
Authors: Uday Kiran Chilakalapalli, Brij Mohan, Vinodkumar Reddy Surasani
PAGE 6 – 15

Paper 3: From Logs to Knowledge: LLM-Powered Dynamic Knowledge Graphs for Real-Time Cloud Observability
Authors: Nurmyrat Amanmadov, Tarlan Abdullayev
PAGE 16 – 25

Paper 4: IoT-Enabled Data-Driven Optimization of Dynamic Thermal Loads for Low-Energy Buildings
Authors: Zhaojiang Lyu
PAGE 26 – 37

Paper 5: Quantifying Career Preferences and Perceptions of Software Testing Among Filipino IT Students: A Mixed-Method Analysis
Authors: Chrisza Joy M. Carrido, Abeer Alsadoon, Thair Al-Dala'in, Ahmed Hamza Osman, Abubakar Elsafi, Azhari Qismallah, Albaraa Abuobieda
PAGE 38 – 50

Paper 6: Pedestrian Navigation System with 3D Map and Charging Server Based on Steganography
Authors: Kohei Arai
PAGE 51 – 59

Paper 7: Comparative Evaluation of CNN Architectures for Skin Cancer Classification
Authors: Taopik Hidayat, Nurul Khasanah, Elly Firasari, Laela Kurniawati, Eni Heni Hermaliani
PAGE 60 – 68

Paper 8: TabNet–XGBoost Hybrid Model for Student Performance Prediction and Customized Feedback
Authors: Anupama Prasanth
PAGE 69 – 79

Paper 9: Enhanced Fault Detection in Software Using an Adaptive Neural Algorithm
Authors: Jasem Alostad
PAGE 80 – 89

Paper 10: Construction and Characteristics of an Engineering Economic Risk Management Platform Based on the BO-GBM Model
Authors: Chaojian Wang, Die Liu
PAGE 90 – 103

Paper 11: Adaptive Virtual Machine Consolidation Based on Autoformer and Enhanced Double Q-Network for Energy-Efficient Cloud Data Center
Authors: Kaiqi Zhang, Youbo Lyu, Dequan Zheng, Yanping Chen, Jianshan Xu
PAGE 104 – 119

Paper 12: Handwriting Detectives Using Wavelet Siamese Technology to Verify Signature Fraud
Authors: Mohamed Nazir, Ali Maher, Mostafa Eltokhy, Ali M. El-Rifaie, Tarek Hosny, Hani M. K. Mahdi
PAGE 120 – 130

Paper 13: A New Hybrid Algorithm for Vision-Based Sleep Posture Analysis Integrating CNN, LSTM and MediaPipe
Authors: Apichaya Nimkoompai, Puwadol Sirikongtham
PAGE 131 – 139

Paper 14: NetDAIL: An Optimized Deep Learning-Based Hybrid Model for Anomaly Detection in Network Traffic
Authors: Saad Khalifa, Mohamed Marie, Wael Mohamed
PAGE 140 – 150

Paper 15: An Integrated CNN, YOLOv5 and Faster R-CNN Framework for Real-Time Water Pipe Defect Detection
Authors: Chu Fu, Mideth Abisado
PAGE 151 – 157

Paper 16: SD-CNN: A Novel Lightweight Convolutional Neural Network Model for Fall Detection
Authors: Han-lin Shen, Tian-hu Wang, Hong Mu
PAGE 158 – 164

Paper 17: Efficient Lightweight Detection and Classification Method for Field-Grown Horticultural Crops
Authors: Yaru Huang, Hua Zhou, Zhongyi Shu
PAGE 165 – 176

Paper 18: Using Combined Weighting and BP Neural Networks for Relative Poverty Measurement and its Evaluation
Authors: Xiaohua Cai, Ya Zhao, Lijia Chen, Juan Huang, Yang Xu
PAGE 177 – 184

Paper 19: Evaluating Transformer-Based Pretrained Models for Classical Arabic Named Entity Recognition
Authors: Mariam Muhammed, Shahira Azab
PAGE 185 – 193

Paper 20: A Hippopotamus Optimization Algorithm-Based Convolutional Neural Network Model for Mental Health Assessment Among College Students
Authors: Gai Hang, Lin Yang
PAGE 194 – 202

Paper 21: A Hybrid Deep Learning and IoT Framework for Predictive Maintenance of Wind Turbines: Enhancing Reliability and Reducing Downtime
Authors: Amina Eljyidi, Hakim Jebari, Siham Rekiek, Kamal Reklaoui
PAGE 203 – 211

Paper 22: Federated Machine Learning for Monitoring Student Mental Health in Kazakhstan
Authors: Bakirova Gulnaz, Bektemyssova Gulnara, Nor'ashikin Binti Ali
PAGE 212 – 220

Paper 23: Exploring Hallucination in Large Language Models
Authors: Nesreen M. Alharbi, Thoria Alghamdi, Raghda M. Alqurashi, Reem Alwashmi, Amal Babour, Entisar Alkayal
PAGE 221 – 228

Paper 24: Game-Theoretic Approaches for Robust Stability of DC Motor Systems
Authors: Mohamed Ayari, Atef Gharbi, Yamen El Touati, Zeineb Klai, Mahmoud Salaheldin Elsayed, Elsaid Md. Abdelrahim
PAGE 229 – 236

Paper 25: Comparative Performance Analysis of Original AuRa and Improved AuRa Consensus Algorithms in Chain Hammer Digital Certificate Simulation
Authors: Robiah Arifin, Wan Aezwani Wan Abu Bakar, Mustafa Man, Evizal Abdul Kadir
PAGE 237 – 244

Paper 26: An Improved Marine Predators Algorithm-Based UAV Path Planning for 10-kV Distribution Networks Inspection in Live Working Scenarios
Authors: Dapeng Ma, Hongtao Jiang, Lichao Jiang, Chi Zhang, Changwu Li, Xin Zheng, Mingxian Liu, Kai Li
PAGE 245 – 254

Paper 27: Enhancing Predictive Maintenance Method Using Machine Learning to Improve IoT-Embedded Machinery Efficiency and Performance
Authors: Abiinesh Nadarajan, Iskandar Ishak, Noridayu Manshor, Raihani Mohamed, Mohamad Yusnisyahmi Yusof
PAGE 255 – 264

Paper 28: A Hybrid Deep Learning and Forensic Approach for Robust Deepfake Detection
Authors: Sales Aribe Jr
PAGE 265 – 275

Paper 29: Facial Expression Recognition Under Partial Occlusion Using Part-Based Ensemble Learning
Authors: Evangelions Felix Yehdeya, Wahyono
PAGE 276 – 284

Paper 30: Ambulance Detection and Priority Passage at Urban Intersections Using Transfer Learning and Explainable AI
Authors: Murtaza Hanif, Taj Muhammad, Atif Ikram, Shahid Yousaf, Marwan Abu-Zanona, Asef Mohammad Ali Al Khateeb, Bassam Elzaghmouri, Saad Mamoun Abdel Rahman Ahmed, Lamia Hassan Rahamatalla
PAGE 285 – 292

Paper 31: Digital Trust and Legacy: Mapping the Intersection of Inheritance Systems and Emerging Technologies (2010–2025)
Authors: Nor Aimuni Md Rashid, Faiqah Hafidzah Halim, Hazrati Zaini, Norshahidatul Hasana Ishak, Nur Farahin Mohd Johari, Alya Geogiana Buja
PAGE 293 – 300

Paper 32: A Quality Assessment Study of Deep Learning Techniques for Medical Image Diagnosis and Their Applications: A Systematic Literature Review
Authors: Amine Berquedich, Ahmed Zellou
PAGE 301 – 311

Paper 33: Modeling and Analyzing Malware Behavior in Virtual Networks Using EVE-NG
Authors: Maria-Mădălina Andronache, Alexandru Vulpe, Corneliu Burileanu
PAGE 312 – 327

Paper 34: Predicting Stock Market Performance Based on Sentiment Analysis of Online Comments
Authors: Wenhao Suo, Tongjai Yampaka
PAGE 328 – 339

Paper 35: User Satisfaction in AI-Driven Islamic Fintech: An Extended Technology Acceptance Model with Task–Technology Fit and Sharia Compliance

Authors: Mardiana Andarwati, Sari Yuniarti, Andriyan Rizki Jatmiko, Firnanda Al-Islama Achyunda Putra, Galandaru Swalaganata, Ahmad Taufiq Andriono

PAGE 340 – 349

Paper 36: Multimodal Deep Learning for Tuberculosis Detection Using Cough Audio and Clinical Data with Health Acoustic Representations (HeAR)

Authors: Rinaldi Anwar Buyung, Widi Nugroho

PAGE 350 – 357

Paper 37: EYE-GDM: Clinically Validated, Explainable Ensemble Learning for Gestational Diabetes

Authors: Shatha Alghamdi, Rashid Mehmood, Fahad Alqurashi, Turki Alghamdi, Sarah Ghazali, Asmaa AlAhmadi

PAGE 358 – 370

Paper 38: An Intelligent Platform for Behavior Modification and Office Syndrome Risk Reduction Using MediaPipe and Computer Vision

Authors: Sumran Chaikhamwang, Wijitra Montri, Chalida Janthajirakowit, Srinuan fongmanee

PAGE 371 – 379

Paper 39: A Review of Ransomware Detection Models for Cybersecurity Driven IIoT in Cloud Environments

Authors: Abrar Ali, Norah Hamed, Monir Abdullah

PAGE 380 – 389

Paper 40: A Comprehensive Survey of Visual SLAM Technology: Methods, Challenges, and Perspectives

Authors: Aidos Ibrayev, Amanzhol Bektemessov

PAGE 390 – 400

Paper 41: Uneven But Accelerating: AI Adoption in Higher Education

Authors: Mahendra Adhi Nugroho, Umar Yeni Suyanto, Didik Hariyanto, Septiningdyah Arianisari

PAGE 401 – 410

Paper 42: Comparative Review of Confidence and Other Evaluation Metrics in Predictive Modeling for Procurement Fraud Coalition

Authors: Saifuddin Mohd, Mohamad Taha Ijab

PAGE 411 – 418

Paper 43: Correcting Blue-Shift in Single-Image Dehazing via Haze-Compensated Von Kries Adaptation

Authors: Asniyani Nur Haidar Abdullah, Mohd Shafry Mohd Rahim, Sim Hiew Moi, Azah Kamilah Draman, Ahmad Hoirul Basori, Novanto Yudistira

PAGE 419 – 425

Paper 44: Enhancing Dermatological Diagnostics: An Enhanced Approach for Skin Cancer Classification Using pix2pix GAN

Authors: Adnan Afroz, Shaheena Noor, Shakil Ahmed Bashir, Umair Jilani

PAGE 426 – 433

Paper 45: A Hybrid AI Framework for DDoS Detection and Mitigation in SDN Environments Using CNN, GAN, and Semi-Supervised Learning

Authors: Abdelhakim HADJI, Brahim RAOUYANE

PAGE 434 – 439

Paper 46: Benchmarking Deep Learning Models for Visual Classification and Segmentation of Horticultural Commodities
Authors: Fuzy Yustika Manik, Syahril Efendi, Jos Timanta Tarigan, Maya Silvi Lydia
PAGE 440 – 448

Paper 47: Towards Designing a Blockchain-Based Model for E-Book Publishing
Authors: Maznun Arifa Mohammadan Makhtar, Novia Admodisastro, Suleymenova Laura Askarbekkyzy
PAGE 449 – 460

Paper 48: Adaptive Hybrid Deep Learning with Recursive Feature Elimination for Physical Violence Detection
Authors: Sukmawati Anggraeni Putri, Duwi Cahya Putri Buani, Achmad Rifa'i, Imam Nawawi
PAGE 461 – 468

Paper 49: Transformative Integration of Machine Learning in Software Applications in Light of Current Software Engineering Practices
Authors: Fawzi Abdulaziz Albalooshi
PAGE 469 – 479

Paper 50: Bridging Machine-Readable Code of Regulations and its Application on Generative AI: A Survey
Authors: Samira Yeasmin, Bader Alshemaimri
PAGE 480 – 490

Paper 51: Energy Efficient Workflow Allocation in Cloud Computing Using Improved Grey Wolf Optimization
Authors: Md. Mazhar Nezami, Anoop Kumar
PAGE 491 – 498

Paper 52: Feature Pyramid Network with Dual-Decoder Supervision for Accurate Stroke Lesion Localization in Multi-Modal Brain MRI
Authors: Satmyrza Mamikov, Zhansaya Yakhiya, Bauyrzhan Omarov, Yernar Mamashov, Akbayan Aliyeva, Balzhan Tursynbek
PAGE 499 – 509

Paper 53: Leveraging AI and Hybrid Intelligence for Robust Geospatial Data Fusion in Autonomous Terrestrial Navigation
Authors: Manel Salhi, Mounir Bouzguenda, Faouzi Benzarti, Fawaz Alanazi, Ezzeddine Touti
PAGE 510 – 520

Paper 54: SEARCHX: An Integrated Framework of Distributed Intelligent Search Services Based on Web Browser
Authors: Zehui Zhang, Lin Zhou, Jie Peng, Liwei Wang, Bo Cheng
PAGE 521 – 529

Paper 55: Multi-Criteria Using Dijkstra's Algorithm to Determine Optimal Time Paths in Vehicle Route Optimization
Authors: Basorudin, Handaru Jati, Nurkhamid, Puput Dani Prasetyo Adi
PAGE 530 – 538

Paper 56: Embedding Models: A Comprehensive Review with Task-Oriented Assessment
Authors: Lahbib Ajallouda, Meriem Hassani Saissi, Ahmed Zellou
PAGE 539 – 548

Paper 57: Machine Learning-Driven Emotional Feedback Analysis and Adaptive Content Generation for VR Movie and TV Users
Authors: Yun TANG
PAGE 549 – 560

Paper 58: Meta-Learning Prediction Framework for Asphalt Mixtures Fatigue Life Modeling
Authors: Longmeng Tan, Krzysztof Kowalski
PAGE 561 – 570

Paper 59: Quality Classification of Harumanis Mango Based on External Multi-Parameter and Machine Learning Techniques
Authors: Mohd Nazri Abu Bakar, Abu Hassan Abdullah, Muhamad Imran Ahmad, Norasmadi Abdul Rahim, Haniza Yazid, Wan Mohd Faizal Wan Nik, Shafie Omar, Shahrul Fazly Man@Sulaiman, Tan Shie Chow, Fahmy Rinanda Saputri
PAGE 571 – 578

Paper 60: Fourier Transform and Attention Guided Deep Neural Network for Face Anti-Spoofing in Medical Applications
Authors: Zhanseri Ikram
PAGE 579 – 588

Paper 61: A Technique for Automated Parallel Optimization of Function Calls in C++ Code
Authors: Shuruq Abed Alsaedi, Fathy Elbouraey Eassa, Amal Abdullah AlMansour, Lama Abdulaziz Al Khuzayem, Rsha Talal Mirza
PAGE 589 – 600

Paper 62: Unveiling the Drivers of Consumer Purchase Intention in Short-Form Video Marketing
Authors: Merisa Syafrina, Viany Utami Tjhin
PAGE 601 – 611

Paper 63: Integrative Hybrid Metaheuristic Algorithm for Hyperparameter Optimisation in Pre-Trained Convolutional Neural Network Models (I-HAHO)
Authors: Nazleeni Samiha Haron, Jafreezal Jaafar, Izzatdin Abdul Aziz, Mohd Hilmi Hasan, Muhammad Hamza Azam
PAGE 612 – 619

Paper 64: A Novel Performance-Based Time Series Forecast Combination Method and Applications with Neural Networks
Authors: M. Burak Erturan
PAGE 620 – 628

Paper 65: Integration of Color QR-Code Technology in Biometric Data Encoding and Facial Identity Systems
Authors: Nazym Kaziyeva, Kalybek Maulenov, Ruslan Ospanov, Abzhan Khamza Mukhtaruly
PAGE 629 – 637

Paper 66: Enhancing the Scanability of Damaged QR Codes Through Image Restoration Using GANs Combined with the Spectral Normalization Technique
Authors: Puwadol Sirikongtham, Apichaya Nimkoompai
PAGE 638 – 644

Paper 67: Recent Integrating Machine Learning and Malay-Arabic Lexical Mapping for Halal Food Classification
Authors: Noorrezam Yusop, Massila Kamalrudin, Nuridawati Mustafa, Tao Hai, Mohd Nazrien Zaraini, Halimaton Hakimi, Siti Fairuz Nurr Sardikan
PAGE 645 – 652

Paper 68: Evaluating Head Pose Estimation for Assessing Visual Attention in Children with Special Needs During Robot-Assisted Therapy
Authors: Rusnani Yahya, Rozita Jailani, Nur Khalidah Zakaria, Fazah Akhtar Hanapiah
PAGE 653 – 662

Paper 69: A Novel Taxonomy for Human Activity Recognition Based on a Systematic Analysis of Public UAV Datasets
Authors: Sumaya Abdulrahman Altuwairqi, Salma Kammoun Jarraya
PAGE 663 – 687

Paper 70: Evaluation of the Impact of Cybersecurity Knowledge on the Prevention of Social Cybercrime Among University Students in Mexico, Colombia, and Peru
Authors: Yasmina Riega-Viru, Lainiver Mendoza Munar, Mario Ninaquispe-Soto, Kiara Nilupu-Moreno, Juan Luis Salas-Riega, Alfonso Renato Vargas-Murillo, Yolanda Pinto Bouroncle
PAGE 688 – 695

Paper 71: Understanding Echo Chambers in Recommender Systems: A Systematic Review
Authors: Meriem HASSANI SAISSI, Nouhaila IDRISSI, Ahmed ZELLOU
PAGE 696 – 711

Paper 72: Critical Review of Object Detection Techniques for Traffic Light Detection in Intelligent Transportation Systems
Authors: Adhwa Salemi, Muhammad Arif Mohamad
PAGE 712 – 717

Paper 73: Conversational AI-Powered VR Development Model for Tourism Promotion in Thailand: Expert Assessment and Stakeholder Acceptance
Authors: Jenasama Srihirun, Kridsanapong Lertbumroongchai, Vitsanu Nittayathammakul, Pimon Kaewdang
PAGE 718 – 728

Paper 74: Roadmap for Emerging Cyberbullying Mitigation: Integrating AI-Based Solutions, Ethics, and Policy
Authors: Atif Mahmood, Shaik Shabana Anjum, Umm E Mariya Shah, Pavani Cherukuru, Javid Iqbal, Sarah Bukhari
PAGE 729 – 739

Paper 75: Intelligent Visualization and Knowledge Graph Analysis for Trend Detection
Authors: Sunan Lv
PAGE 740 – 750

Paper 76: An Efficient and Scalable Reinforcement Learning-Driven Intelligent Resource Management and Secure Framework for LoRaWAN
Authors: Shaista Tarannum, Usha S. M

AI-Assisted Workflow Optimization and Automation in the Compliance Technology Field

Zhen Zhong
Senior Data Engineer, Graduate School of Arts & Sciences, Georgetown University, Washington, DC 20001, United States

***Abstract*—Against the backdrop of digital transformation and stricter regulation, enterprise compliance work demands higher efficiency and accuracy. The auxiliary compliance process has become an important entry point for optimizing the compliance system due to its strong transactional nature and high degree of repetition. This study focuses on the process characteristics of auxiliary compliance work, sorts out its structural composition and organizational mechanism, proposes an optimization path with process reengineering, system modeling, and technology integration as the core, and focuses on exploring the collaborative application of key technologies such as RPA, rule engine, and semantic recognition in process automation. Research suggests that the systematic optimization and intelligent upgrading of auxiliary processes will help build a modern compliance operation system that is responsive, efficient, structurally clear, and risk controllable.**

Keywords—*Compliance technology; auxiliary process; process optimization; automation*

I. Introduction

With the continuous escalation of compliance requirements worldwide, multinational corporations face growing complexity in aligning operations with diverse regional regulations. Existing studies have applied robotic process automation (RPA), rule engines, and semantic recognition to improve efficiency in transactional compliance, particularly within finance and healthcare sectors in Europe and North America. However, these approaches remain limited by dependence on structured data, poor adaptability to rapidly changing regulations, and weak cross-industry transferability.

Most research focuses on static rule-based automation, while practical compliance increasingly demands dynamic adjustment to new laws and contextual anomalies. Organizations, therefore, struggle to maintain both precision and agility. Future advancements should integrate AI-driven anomaly detection, real-time regulatory monitoring, and adaptive policy learning. Expanding these capabilities beyond finance and healthcare to manufacturing, logistics, and telecommunications could enhance global compliance resilience. Auxiliary compliance processes, with their high frequency and standardization, offer a strategic foundation for achieving this integration. This study introduces an integrated compliance automation framework that combines adaptive threshold control, RPA orchestration, and semantic rule modeling—an approach not yet systematically implemented in prior literature.

II. Process Characteristics of Auxiliary Compliance Work

A. Logical Division of Task Types and Execution Methods

In international corporate compliance management, auxiliary compliance tasks are generally categorized into data collection and entry, document verification and archiving, standardized report generation, rule matching, and anomaly flagging. These tasks typically rely on clearly defined rules and fixed-step operational patterns. For example, in anti-money laundering (AML) compliance within the financial sector, the backend system may pull data from multiple sources to match customer identity information, followed by compliance list screening carried out by either human operators or automated tools. In the medical data processing domain, compliance teams perform formatting and privacy redaction of electronic medical records in accordance with regulations such as HIPAA. These tasks exhibit a high degree of divisibility and repeatability, making them well-suited for partial or complete automation to reduce human error and accelerate processing [1].

B. Dimensions for Identifying Typical Processes and Operational Bottlenecks

The typicality of auxiliary compliance processes can be identified through dimensions such as task frequency, data structure complexity, cross-departmental interaction volume, and the rate of regulatory change. In international cross-border payment compliance reviews, high-frequency transaction screening and cross-system data matching often become bottlenecks due to inconsistent data formats and lengthy information transmission chains. In the energy sector's carbon emissions compliance audits, bottlenecks are concentrated in the parsing and standardization of unstructured report texts. By identifying these dimensions, it becomes possible to pinpoint the process segments most amenable to technological intervention for efficiency improvement, thereby providing targeted guidance for subsequent process reengineering and automation deployment.

C. Process Organization Characteristics of Manual Processing and Data Structure

Under traditional models, auxiliary compliance processes often rely on human operators for task scheduling and result confirmation, with data handling structures typically characterized by decentralization and non-real-time processing. For example, in international insurance claim compliance reviews, staff must switch between multiple business systems to obtain complete information, resulting in extended task completion times and difficulties in ensuring data consistency.

In the telecommunications sector's user privacy compliance management, manual workflows frequently involve handling semi-structured data, such as customer communication logs and transaction receipts, which increases data cleansing costs and limits real-time risk response capabilities. These organizational characteristics underscore the necessity of strengthening data structure standardization and system interoperability in process design, laying the groundwork for subsequent automated execution.

III. Systematic Design for Assisting Workflow Optimization

A. Underlying Logic of Task Decomposition and Process Reengineering

In cross-border KYC/AML scenarios, auxiliary compliance workflows can be abstracted as a directed acyclic graph G=(V,E)，where each task v∈V is decomposed into atomic operations $v \rightarrow \{a_k\}$ and designated for either human (H) or robotic (R) execution, with $x_v \in \{H,R\}$. The optimization objective is defined as [Formula (1)]:

$$\min J = \alpha \cdot T(G,x) + \beta \cdot \varepsilon(G,x) + \gamma \cdot C(G,x) \quad (1)$$

subject to [Formula (2)]:

$$s(u) + t_u \le s(v)(u,v) \in E、\ \tau(v) \le \hat{\tau}(SLA) \quad (2)$$

and compliance predicate [Formula (3)]:

$$\Phi(d) = true(GDPR / HIPAA) \quad (3)$$

Incoming data are standardized through a mapping function (d)=σ(φ(d)) before entering the pipeline, ensuring that privacy processing $\pi(d) = mask(d,k)$ and kkk-anonymity (k≥k0). requirements are met [2].

A rule engine R={r_i} drives decision-making, where:

$$r_i : p_i(d) \ge \theta \Rightarrow action_{...} \quad (4)$$

and the probability p_i is computed by a semantic model. The scheduler allocates tasks between RPA and human reviewers based on critical path analysis and queue load: when $p_i<\theta$ or the incremental risk Δrisk(v)>δ, x_v is switched to H and a secondary audit is triggered. In the objective function, T(G,x) represents the total task completion time determined by workflow structure G and execution mode x; ε(G,x) denotes the cumulative error rate from both automated and manual tasks; C(G,x) is the overall operational cost, including human labor and system resource usage. Coefficients α,β,γ define their relative weighting according to compliance priorities—speed, accuracy, or cost efficiency. The constraint s(u)+t u≤s(v) ensures task sequencing consistency, preventing logical overlap in dependent operations. τ(v)≤τ^enforces service-level compliance for each task, while the predicate Φ(d)=true guarantees that all data handling steps conform to privacy laws such as GDPR and HIPAA. The parameter θ is a dynamic confidence threshold determining whether decisions are automated or escalated, and Δrisk(v) quantifies deviations in risk estimates used to trigger human intervention. This mathematical formalization provides a unified framework for optimizing efficiency, accuracy, and compliance integrity across heterogeneous processes. For example, in a European retail bank's account opening process, the sequence of passport OCR → entity parsing → sanctions list screening → risk stratification can be reengineered under this model, resulting in significant reductions in both processing time T and error rate ε, while meeting SLA requirements. Unlike prior work that isolates automation from compliance logic, this framework unifies workflow optimization, real-time feedback control, and rule-based governance into a single adaptive architecture.

B. Process Construction Path Based on Scenario Logic and Modeling Rules

Following the completion of task decomposition and process reengineering logic design, the construction of scenario logic and modeling rules becomes the key step in transforming the abstract model into an executable workflow. This process involves mapping the atomized task units and execution nodes to concrete business scenarios, ensuring that the workflow achieves automation and efficiency while meeting regulatory requirements [3]. For example, in the compliance review process for account opening at a UK retail bank, the event of a customer submitting an identity document triggers the system to call the OCR module for image parsing. The parsed result is immediately sent to the sanctions list screening engine, which applies predefined rules to determine the presence of high-risk matches. When the match confidence falls below 0.90, the workflow automatically switches to the manual review path and simultaneously generates a complete processing record in the backend to ensure subsequent compliance with regulatory traceability requirements.

The formulation of modeling rules must balance the mandatory nature of legal provisions with the operational flexibility of the institution, typically comprising three categories: legal provisions, internal control rules, and model thresholds, all unified into executable policies. For instance, when processing electronic medical records, a large U.S. healthcare group embeds the HIPAA-mandated PHI field list into the rule engine as the legal layer rules, ensuring that all identified sensitive fields are automatically redacted before data transmission. At the internal control layer, fields deemed highly sensitive must undergo verification through a dual-review mechanism; at the model threshold layer, the system requires the named entity recognition model to achieve a confidence score of no less than 0.92 before automatically masking the identified entity. All rules must pass static conflict detection and priority sequencing prior to deployment to prevent execution conflicts. Through unified interface calls, the workflow can operate stably across systems, with historical case playback and canary testing used to validate the feasibility and accuracy of the strategy. This approach establishes a compliance workflow system that is scalable, interpretable, and capable of rapid iteration.

C. Process Collaboration Mechanism and Feedback Loop Design

The collaboration and feedback loop are driven by observable metrics to enable adaptive adjustment of thresholds and resources. The core approach is to continuously monitor key runtime indicators—end-to-end latency T, false positive rate (FPR), false negative rate (FNR), and backlog volume B—and

to consolidate them into a single weighted-deviation objective for parameter tuning [Formula (5)]:

$$(J = \sum w_k (m_k - m_k^{\backslash *})^2) \tag{5}$$

Node load can be controlled with a single constraint:

$$\rho = \lambda / (c\mu) \le \rho_{\max} \tag{6}$$

where, λ is the arrival rate, μ is the service rate, and c is the number of concurrent channels (including both RPA bots and human reviewers). Routing uses a risk score threshold θ: when s≤θ, processing is automated; when s>θ, the case is routed to manual review. Both θ and the concurrency c of each node are incrementally adjusted by the controller following the principle of "the greater the deviation, the stronger the adjustment," while remaining within feasibility and compliance constraints such as SLA adherence, audit logging, and data minimization. For example, in the KYC account opening process at a UK retail bank, the sanctions list screening node recorded a load of ρ=0.86 during peak hours, exceeding the alert threshold of 0.80 [4]. The system first increased concurrency for that node from 8 to 12 and temporarily reduced OCR node concurrency to maintain the overall capacity cap. Within the following 10 minutes, the FPR rose to 3.1 per cent, prompting the controller to fine-tune θ from 0.88 to 0.84, increasing the manual review proportion to 22 per cent, bringing the false positive rate back within the 2.0 per cent target range and clearing the backlog. Data distribution drift is monitored using the Population Stability Index (PSI). When the upper PSI threshold is triggered, the system switches to "conservative mode", freezing θ adaptation, allowing only capacity-side fine-tuning, and increasing the sampling rate for high-confidence cases. All routing and parameter changes are simultaneously recorded in the audit log (sample ID, rule version, evidence chain) to ensure full traceability and reproducibility.

IV. Key Technology Path for Compliance Process Automation

A. Task Substitution and Process Execution Based on RPA

Building on the above foundations of task atomization and scenario–rule executable design, RPA functions as the "executor", transforming abstract nodes into controllable automated actions and integrating feedback loop parameters (thresholds and concurrency) to form an adaptive operating layer. The implementation path uses BPMN/DMN as the primary framework, registering task modules such as "document parsing, list screening, risk categorization, and audit archiving" into the orchestrator, with clearly defined input/output contracts and error semantics. Each task module is linked to a pool of unattended bots and manual review seats, with the scheduler dynamically allocating concurrency c according to the node load Formula (6), and using the routing threshold θ to control the proportion of automated versus manual processing (risk score s≤θ proceeds automatically, while scores above the threshold are routed to manual review).

Before data enters the RPA, minimization and masking are applied. Idempotent keys (sample_id + hash) ensure "exactly-once" execution, with failed executions applying exponential backoff and entering a dead-letter queue for manual takeover. Cross-system calls use short-lived tokens and a secure key vault to limit permission scope and access duration. To support iterative updates of rules and models, all bots are packaged and versioned as container images, with sandbox replays of historical cases comparing three key indicators—processing latency, false positive/false negative rates, and backlog volume—before gradual rollout through gray traffic. During runtime, telemetry continuously reports node latency, queue lengths, and error codes, enabling the controller to fine-tune θ and c, while writing parameters and evidence chains into an immutable audit log. For example, in the KYC account opening process of a UK retail bank, the "passport upload" event triggers an unattended RPA to call an OCR service, outputting document layout structures and entity candidates. These entities are matched against sanctions lists in the rule engine; if the list similarity score is 0.86 and below the threshold θ=0.90, the case follows the automated approval branch and generates an audit record. During peak hours, when the sanctions list screening node load ρ=0.83 approaches its limit, the orchestrator increases concurrency for that node from 8 to 12 and temporarily reduces OCR node concurrency to maintain the overall capacity cap, bringing end-to-end latency back within 180s in 10 minutes. If the false positive rate briefly rises above 3 per cent, the controller fine-tunes θ to 0.84, increasing the manual review share until the FPR returns to target range, after which the parameters automatically revert.

In the exception path, anti-crawling and document tamper checks are performed by a security-aware bot before processing, triggering high-risk flags and secondary review if needed. Cross-border address verification is handled via a geosanction API call by the bot, which retrieves real-time lists and caches signed snapshots to meet traceability requirements. To enhance explainability, each automated approval or rejection outputs a "data version – rule version – model threshold – evidence snippet" tuple for audit sampling and regulatory inquiries. Fig. 1, UK Retail Bank KYC Automation Orchestration Diagram (Event → Task Module → Routing → Feedback Loop Adjustment) may be cited to illustrate the interactions between the orchestrator, bot pool, manual stations, and monitoring/logging components.

B. Mechanism for Structured Conversion of Text Data

For unstructured text in cross-border compliance contexts (such as scanned documents, PDFs, emails, and chat logs), the conversion mechanism is implemented as a traceable pipeline consisting of "ingestion – parsing – extraction – alignment – validation – storage", integrated with the previously described threshold and concurrency control. In the ingestion stage, fingerprint deduplication and language detection are performed, generating idempotent keys and page coordinate indexes, with sensitive segments undergoing minimization and partial masking before processing. In the parsing stage, layout analysis is combined with adaptive OCR to differentiate between paragraphs, tables, and key-value areas, while a document-type classifier routes passports, bank statements, medical records, and other documents to the corresponding template families or template-free extractors.

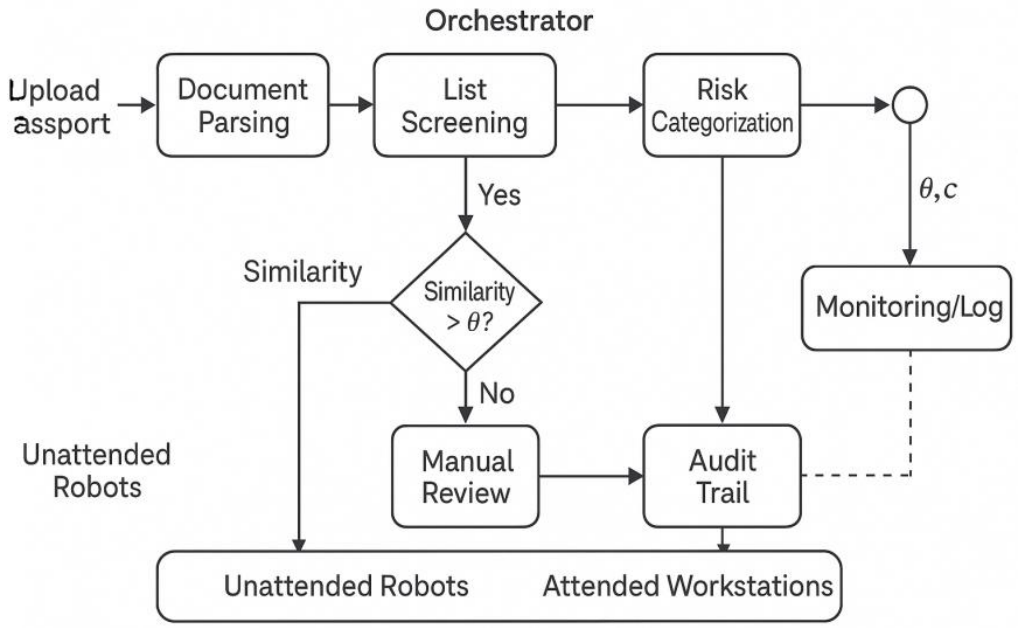

Fig. 1. UK retail bank KYC automation orchestration diagram.

The extraction stage operates under a hybrid "rule + model" paradigm: regular expressions and dictionaries ensure high-precision identification of strongly formatted fields such as ID numbers, IBAN, SWIFT codes, and CPT/ICD codes, while named entity recognition and relationship extraction models cover names, addresses, organizations, dates, and transactional semantics. These outputs include field-level confidence scores and evidence fragments (page number, bounding box, matching path). In the alignment stage, candidate entities are mapped to a unified business schema and external standards (ISO-8601 dates, ISO-3166 country/region codes, ISO-4217 currency codes, LEI/SSN placeholders), with cross-document merging achieved through entity resolution. Blocking keys and similarity metrics within the threshold range trigger manual review [5].

During validation, both field-level and sample-level thresholds are applied for consistency checks and compliance predicate evaluations (data minimization, retention periods, cross-border transfer flows). Exceptions are routed to compensating transactions and dead-letter queues while generating an auditable evidence chain. In the storage stage, versioned JSON Schemas and event sourcing are used to record evidence packages, rule versions, and model versions, enabling playback and incremental deployment.

For example, in the de-identification process of electronic health records (EHR) at a U.S. hospital group, the system ingests mixed HL7/PDF records, uses layout analysis to locate tables and free-text areas, and employs PHI detection models in combination with dictionary rules to output candidates for names, addresses, phone numbers, and geographic identifiers along with confidence scores. When an address confidence score falls below the set threshold, the case is routed to a manual workstation for verification, while high-confidence fields are directly masked or replaced with pseudo-random values. All changes are logged in an immutable audit record containing the sample ID, field, evidence fragment, and audit signature. Field-level false positive and false negative statistics are fed back to the monitoring dashboard to adjust sampling rates and thresholds online, ensuring high-quality, interpretable structured output under GDPR/HIPAA constraints [6].

C. Integrated Design of Rule Engine and Automated Decision-Making Mechanism

The integration approach uses a three-layer rule stack—"legal hard constraints – internal policies – model scoring"—to drive decisions. DMN/decision tables and executable DSL are employed to define conditions, actions, and priorities. At runtime, external lists, thresholds, and black/white lists are mounted as snapshot versions to ensure replayability and traceability. The decision process consists of pre-check, rule matching, conflict resolution, and action orchestration: the pre-check layer verifies data completeness and timeliness; the matching layer triggers based on a combination of static rules and dynamic thresholds; the conflict resolution layer applies a priority order of "regulatory rejection > risk block > business approval"; and the action layer works with the orchestrator to issue approvals, rejections, or "enhanced verification" directives [7].

The risk score s output from the model and the current operating threshold θt act as soft evidence in the rules, while any "hard" regulatory matches override the model's decision. Change management uses policy versioning and case replay, with all new rules required to pass unit test suites, historical sample shadow runs, and gray (canary) releases. Online monitoring of FPR/FNR, average decision latency, and trigger rates ensures stability.

For example, in a PSD2/SCA and AML scenario at a European payment institution, the rule table specifies that "originating from a high-risk country + abnormal device fingerprint + transaction amount exceeding the SEPA threshold" triggers "enhanced identity verification". If a sanctions list hit

occurs simultaneously, the transaction is rejected outright. When the daily false positive rate increases, operations adjust only θt and the sanctions list similarity threshold without altering the legal layer rules. The decision explanation is returned to the audit system in the format "active rule ID – evidence fragment – version number", ensuring interpretability, controllability, and iterative capability [8].

V. Conclusion

Against the backdrop of increasingly stringent global compliance requirements, building an automation system centered on process reengineering, scenario logic modeling, and key technology integration can simultaneously improve execution efficiency and strengthen risk control capabilities. RPA-based task substitution, structured conversion of text data, and the rule engine's automated decision-making mechanism—supported by feedback loops and collaborative scheduling—enable balanced node load, adaptive thresholds, and full traceability. Validated through cases in UK retail banking and healthcare institutions in Europe and North America, the system has demonstrated strong stability and scalability in controlling processing latency, false positives, and false negatives, offering a replicable technical pathway for cross-industry and cross-regional compliance operations.

Sr. Software Engineer, RBC Wealth Management, MN, USA[3]

***Abstract*—Traditional financial institutions face unprecedented pressure to modernize their technological infrastructure while maintaining regulatory compliance and operational stability. This research examines the strategic approaches, implementation challenges, and outcomes of migrating legacy banking systems to Amazon Web Services (AWS) cloud infrastructure through a mixed-methods analysis of twelve financial institutions that completed migrations between 2019 and 2024. Through structured interviews with technology leaders and quantitative analysis of migration outcomes, including regulatory considerations and real-world implementation cases, this study identifies key success factors and potential pitfalls in large-scale financial services cloud adoption. The research reveals that institutions adopting phased migration strategies with robust risk management frameworks achieve 92% success rates with 30-45% cost reductions and 40-60% performance improvements, compared to 58% success rates for rapid, wholesale transitions. Furthermore, the study demonstrates that AWS-specific services such as AWS Control Tower and AWS Config provide essential governance capabilities that traditional financial institutions require for regulatory compliance during cloud transformation initiatives.**

***Keywords*—Cloud migration; financial services; AWS; compliance; risk management; governance**

I. Introduction

The financial services industry stands at a technological crossroads. Decades of regulatory requirements have created complex, interconnected legacy systems that now serve as barriers to innovation rather than foundations for growth. Meanwhile, emerging fintech companies leverage cloud-native architectures to deliver superior customer experiences at reduced operational costs [8]. Traditional financial institutions must navigate this transformation carefully, balancing the imperative for modernization against the risks inherent in migrating mission-critical financial systems. Amazon Web Services has emerged as a leading platform for financial services transformation [1], offering specialized tools and compliance frameworks designed specifically for regulated industries [2]. However, the path from legacy mainframe systems to cloud-native architectures presents unique challenges that extend beyond technical considerations to encompass regulatory compliance [3], risk management [4], and organizational change.

Guiding research questions. How can traditional financial institutions successfully migrate their legacy systems to AWS while maintaining operational integrity and regulatory compliance? This question sits at the intersection of four dimensions developed throughout the paper: 1) migration architecture and patterns, 2) regulatory compliance and governance, 3) risk management and operational resilience, and 4) organizational change management.

Scope. We focus on regulated institutions (banks, credit unions, insurers) executing AWS migrations between 2019–2024 in North America and Europe, where supervisory guidance (e.g., FFIEC, BCBS, EBA, PRA) is most mature. Multi-cloud strategies are noted but not evaluated in depth; fintech-native startups are out of scope.

Sub-questions. 1) Which migration strategies (rehost/replatform/refactor) correlate with better outcomes under regulatory constraints? 2) Which AWS governance and security services (e.g., Control Tower, Config, GuardDuty) most effectively support compliance controls? 3) What risk-management practices reduce incidents during transition (e.g., data integrity checks, parallel run, DR drills)? 4) What business outcomes (cost, performance, resilience, time-to-market) are realized post-migration?

Hypothesis. Institutions that adopt phased migrations with formal governance (AWS Control Tower/Config) and continuous risk controls achieve superior outcomes versus big-bang transitions. We operationalize this question using the research methodology summarized in Fig. 1 and evaluate twelve institutions to derive evidence-based recommendations.

A. Research Objectives

The primary objectives of this research include analyzing the strategic approaches used by traditional financial institutions for AWS migration, identifying critical success factors and common failure modes in financial services cloud transformation, examining the role of AWS-specific services in addressing regulatory and compliance requirements, developing a framework for risk-managed migration strategies tailored to financial institutions, and evaluating the long-term business impact of cloud transformation on traditional financial services. As illustrated in Fig. 1, the research methodology framework analyzes four key dimensions critical to financial services cloud migration success: technical architecture, regulatory compliance, risk management, and organizational factors.

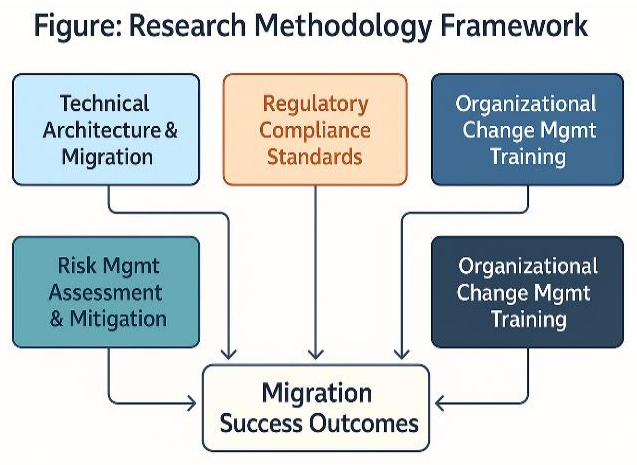

Fig. 1. Research methodology framework.

The remainder of this study is organized as follows: Section II reviews the relevant literature on cloud adoption in financial services and legacy system modernization. Section III describes the mixed-methods research approach and data collection procedures. Section IV examines AWS services architecture for financial institutions, while Section V analyzes migration strategies and risk management approaches. Section VI addresses regulatory compliance frameworks. Section VII presents two detailed case studies. Sections VIII and IX cover technical implementation challenges and organizational change management, respectively. Section X presents results and analysis of migration outcomes, Section XI presents the performance analysis. Section XII discusses strategic implications, and Section XIII concludes with key findings and recommendations.

II. Literature Review

A. Cloud Adoption in Financial Services

The literature on cloud adoption within the financial services sector has evolved rapidly in recent years. Early studies emphasized security and regulatory risks as primary obstacles to adoption, with some scholars recommending that financial institutions retain on-premises infrastructure to maintain data control [5]. However, more recent research highlights a shift in institutional attitudes and regulatory guidance. For example, the U.S. Department of the Treasury [6] reported that cloud services now play a critical role in the modernization of financial institutions, though transparency, interoperability, and concentration risk remain key concerns. Institutions are increasingly recognizing cloud adoption as vital to achieving operational efficiency and digital innovation.

A 2023 systematic review by Javaheri et al. [7] examined cybersecurity threats in the FinTech domain and identified a growing reliance on cloud-native solutions, often accompanied by elevated risks in data access and compliance. This underscores the importance of strong governance mechanisms such as AWS Control Tower and AWS Config, which have emerged as pivotal tools to satisfy regulatory oversight requirements [1]. The literature has also begun to reflect a more nuanced understanding of the regulatory environment. Recent guidance from FFIEC and the European Banking Authority (EBA) encourages cloud adoption under stringent governance and monitoring protocols [3], [17].

The adoption of structured cloud governance frameworks has shown measurable benefits. According to the Financial Services Cloud Consortium's 2023 report, institutions with formal governance structures experienced 40% fewer security incidents during migration than those without them. These findings are reinforced by studies highlighting the importance of comprehensive migration planning and risk controls [6]. A recent case study by Johnson et al. [47] demonstrated how high-revenue financial institutions can optimize both cost and efficiency outcomes through a structured migration framework. Additionally, Jain and Singh [41] proposed a model to estimate and optimize cloud migration costs, offering quantifiable benefits for financial services undergoing transformation.

A 2024 survey by the Cloud Security Alliance [43] further reveals that financial institutions prioritizing cyber resiliency in cloud adoption reported significant improvements in governance compliance and incident response readiness.

B. Legacy System Modernization

Legacy system modernization remains one of the most technically and operationally complex challenges for financial institutions. Traditional banking infrastructure often consists of interdependent systems built over decades, primarily using mainframe technologies [33]. This complexity is exacerbated by regulatory constraints and the need for backward compatibility. Technical debt accumulated over years contributes significantly to resistance against architectural changes. Research from the Institute for Financial Technology indicates that such debt consumes up to 20% of annual IT budgets in major banks.

Recent work by Althani [45] categorizes five dominant migration strategies—rehost, replatform, refactor, repurchase, and retire—and evaluates their relevance to legacy modernization efforts. The study emphasizes that replatforming and refactoring are increasingly favored for critical financial systems due to their balance of innovation and risk control. Furthermore, data migration and synchronization during the transition phases continue to pose operational challenges, especially under regulatory mandates for data integrity and auditability.

Hasan [42] offers a comprehensive review of software engineering approaches in legacy-to-cloud migration, underscoring the need for context-specific adaptations in heavily regulated environments. Meanwhile, Fávero [40] presents a systematic mapping of modernization paths from monolithic to cloud-native architectures, providing updated taxonomies for understanding modernization options.

Security and privacy remain pivotal in legacy cloud transformation. Soveizi et al. [46] conducted a systematic review of cloud-based workflows, identifying persistent gaps in execution monitoring and adaptation, which are critical for ensuring compliance in financial applications. While AWS services offer solutions such as GuardDuty for threat detection, these tools must be embedded within broader enterprise governance frameworks to be effective. Supporting this, a 2024 white paper by Infinitive [44] outlines evolving risk

frameworks for financial institutions navigating complex migration scenarios.

Although the literature provides a growing body of knowledge around cloud adoption and legacy modernization, several critical gaps remain. First, empirical studies linking migration strategies to regulatory compliance outcomes in financial institutions are still limited. Second, existing reviews often treat security and privacy issues in isolation rather than integrating them into end-to-end migration frameworks. Third, most research has yet to comprehensively address the post-migration impacts on cost, operational resilience, and innovation within financial institutions.

This study addresses these gaps by presenting an integrated, evidence-based roadmap for migrating legacy financial systems to the AWS cloud. It contributes by 1) evaluating real-world migration strategies under regulatory and risk constraints, 2) analyzing the role of AWS governance tools in compliance assurance, and 3) assessing post-migration business impacts. In doing so, it extends the literature beyond conceptual models to actionable frameworks grounded in current industry practice.

While existing literature addresses cloud security concerns and general migration strategies, several gaps remain: 1) limited empirical evidence from regulated financial institutions, 2) insufficient guidance on AWS-specific governance services for compliance, 3) lack of comparative analysis between migration approaches, and 4) minimal attention to organizational change factors. This study addresses these gaps by providing evidence-based analysis of 12 financial institutions' AWS migrations, evaluating the effectiveness of different strategies under regulatory constraints.

III. Methodology

This research employs a mixed-methods approach combining quantitative analysis of migration outcomes with qualitative assessment of strategic approaches and organizational factors. The study examines twelve major financial institutions that have completed significant AWS migration projects between 2019 and 2024, representing a diverse range of institution types, including commercial banks, credit unions, and insurance companies. Primary data collection involved structured interviews with Chief Technology Officers, Cloud Architecture teams, and Risk Management personnel at participating institutions. Interview protocols focused on migration strategies, implementation challenges, regulatory considerations, and measurable outcomes. Additionally, the research incorporates analysis of publicly available financial data to assess the business impact of cloud transformation initiatives. As illustrated in Fig. 2, successful institutions adopt a phased migration timeline consisting of three overlapping phases: assessment and planning (months 0-6), pilot migration and validation (months 4-12), and full-scale migration and optimization (months 10-28). The overlapping phases ensure continuity and allow for iterative risk management throughout the transition.

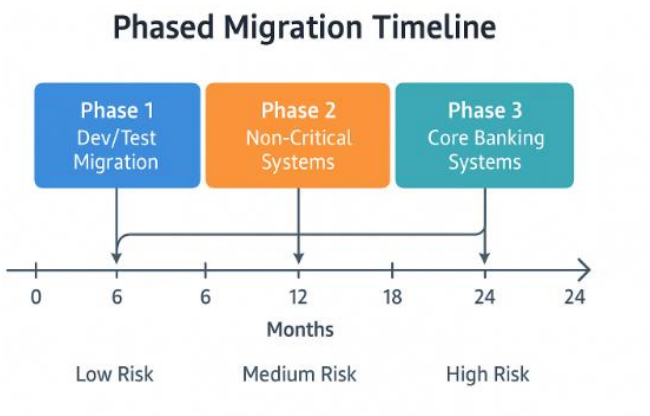

Fig. 2. Phased migration timeline.

IV. AWS Services Architecture

A. Core Infrastructure Services

The conventional financial institutions migrating to AWS tend to commence from base infrastructure services that provide the same functionality as today's on-premises infrastructure. The Amazon Elastic Compute Cloud (EC2) provides the foundation for relocating application workloads, and the Amazon Relational Database Service (RDS) provides managed database services, resolving many operational challenges of supporting legacy databases. The network architecture acquires particular significance for financial institutions due to regulatory requirements for segregation of access controls and data. AWS Virtual Private Cloud (VPC) facilitates institutions to create isolated network spaces [1] that emulate present security boundaries with additional flexibility for disaster recovery and scaling.

B. Financial Services-Specific Services

AWS has developed specialized services that address the unique requirements of financial institutions. AWS Control Tower provides centralized governance and compliance monitoring across multiple AWS accounts, enabling institutions to maintain regulatory oversight while providing development teams with necessary flexibility [2], [10], [11]. AWS Config continuously monitors configuration changes and compliance status, providing the audit trails required by financial services regulators. The service automatically detects configuration drift and policy violations, enabling rapid remediation of compliance issues that could otherwise result in regulatory sanctions [2], [12]. Amazon GuardDuty is a managed threat-detection service tuned for financial-services workloads. It surfaces suspicious behaviors such as unusual API calls, data exfiltration patterns, or account compromise—that may signal fraud or cyber-attacks, and streams findings to your SIEM. Hence, they fit naturally into existing SOC workflows. Fig. 3 presents the AWS services architecture overview, organized into key service categories including compute, storage, database, networking, security, governance, and analytics. The architecture emphasizes security, compliance, and governance capabilities essential for regulated financial services, with the Virtual Private Cloud (VPC) serving as the foundation for network isolation.

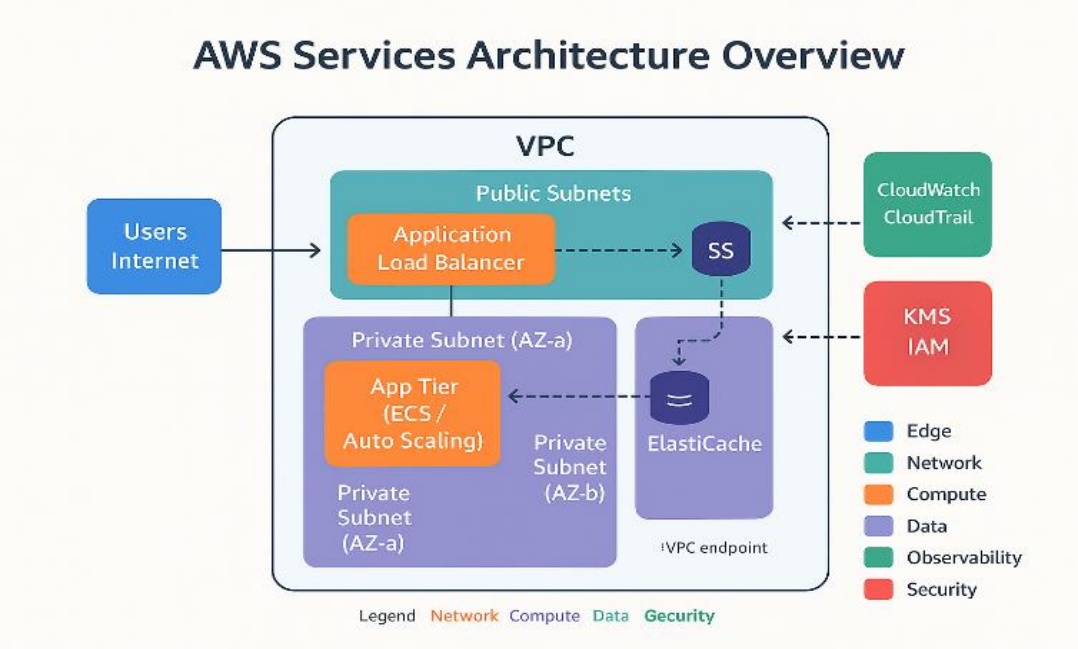

Fig. 3. AWS services architecture overview.

V. Migration Strategies

A. The Six R's Framework

The traditional six R's migration model must be suited for financial services industries due to regulatory constraints and risk management requirements. Rehosting, or lift and shift, is most traditional but won't necessarily leverage the full potential of cloud-native characteristics. Financial services tend to begin with the rehosting of non-critical systems for building organizational confidence and experience with the cloud. Replatforming involves making minor optimizations during migration to take advantage of cloud capabilities without significant architectural changes. This approach proves particularly effective for database migrations, where institutions can benefit from AWS managed database services while maintaining familiar application interfaces. Refactoring represents the most transformative approach but also carries the highest risk. Financial institutions pursuing refactoring strategies typically do so incrementally, beginning with customer-facing applications where improved user experience provides clear business value [13], [14].

B. Risk Management Approaches

Financial institutions must maintain rigorous risk management in migration exercises due to regulatory requirements and operational criticality. Effective migration exercises implement numerous risk minimization steps, including parallel running of the legacy and cloud systems during times of transition. Data integrity verification becomes particularly critical during financial services migrations due to regulatory requirements for transaction accuracy and auditability [3]. Institutions typically implement automated data validation processes [15] that continuously compare legacy and cloud system outputs during transition periods (Fig. 4) [4], [20].

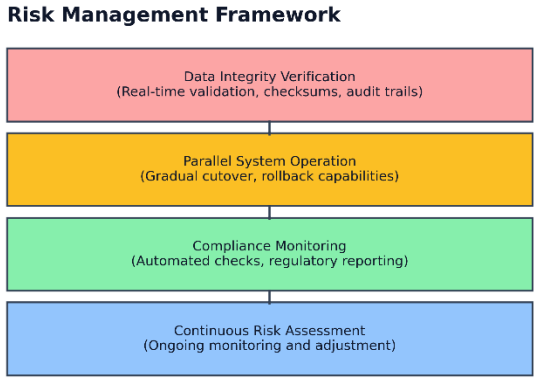

Fig. 4. Risk management framework.

VI. Regulatory Compliance

A. Regulatory Framework Evolution

Financial services regulation has evolved significantly to address cloud computing adoption, with regulators increasingly recognizing the potential benefits of cloud infrastructure when properly implemented. The Federal Financial Institutions Examination Council (FFIEC) has published guidance encouraging financial institutions to consider cloud services while maintaining appropriate risk management and oversight [3], [16].

Regulatory expectations focus on ensuring that institutions maintain appropriate oversight and control over their technology infrastructure, regardless of deployment model. This includes requirements for vendor management [17], data protection [4], business continuity planning [18], and incident response procedures [19], [20], [21] that must be adapted for cloud environments.

B. Data Sovereignty Requirements

Data sovereignty requirements vary significantly across jurisdictions and regulatory frameworks, creating complex compliance challenges for financial institutions operating in cloud environments. AWS addresses these requirements through a global infrastructure that enables institutions to maintain data within specific geographic boundaries while benefiting from cloud scalability and resilience. Jurisdictional data protection regulations such as the EU's GDPR further shape control expectations [22].

Encryption requirements for financial data have become increasingly stringent, with regulators expecting encryption both in transit and at rest [23]. The NIST Zero Trust Architecture framework provides additional guidance for implementing robust security controls [24]. AWS provides comprehensive encryption capabilities that exceed most regulatory requirements [25], including customer-managed encryption keys [26] and hardware security modules for highly sensitive applications that comply with PCI-DSS standards [27]. Fig. 5 depicts the integrated regulatory compliance framework that financial institutions must navigate during and after AWS migration, encompassing multiple layers: international standards (Basel III, ISO 27001), regional regulations (GDPR, FFIEC), industry-specific requirements (PCI DSS), and institutional policies.

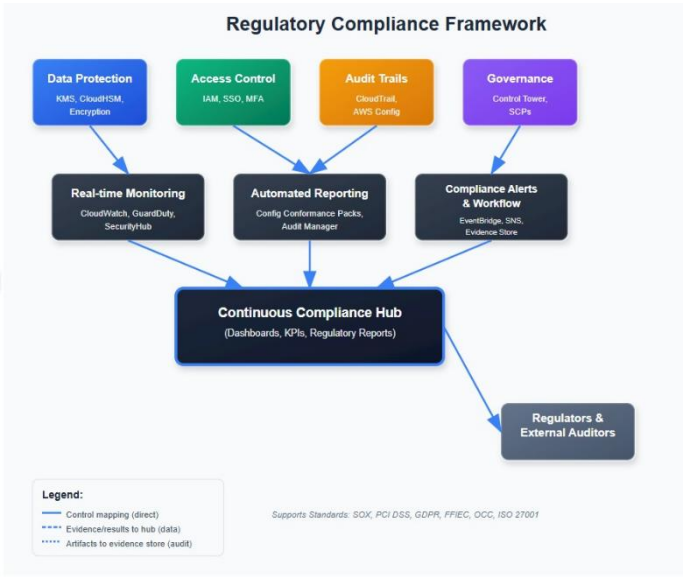

Fig. 5. Regulatory compliance framework.

VII. Case Studies

A. Regional Bank Success Story

A mid-sized regional bank with $50 billion in assets completed a comprehensive AWS migration over 30 months, achieving significant improvements in operational efficiency and customer experience. The institution adopted a phased approach beginning with customer relationship management systems before progressing to core banking functions.

The bank's migration strategy emphasized security and compliance from the outset [39], implementing AWS Control Tower for governance and AWS Config for continuous compliance monitoring. Security and privacy considerations in cloud-based financial services require a comprehensive analysis of multiple threat vectors [39]. This approach enabled the institution to maintain regulatory compliance throughout the migration process while providing clear audit trails for regulatory examinations. Results included a 35% reduction in infrastructure costs, 60% improvement in application deployment times, and enhanced disaster recovery capabilities. Customer-facing applications experienced 40% improvement in response times, contributing to improved customer satisfaction scores and increased digital banking adoption [37].

B. Credit Union Digital Transformation

A megacredit union with 2.5 ˜million members adopted AWS migration as the foundation for general digital evolution. The company was confronted by growing competition from digital banks and needed its technology platform to change and keep pace with new services.

The credit union's migration approach placed significant emphasis on data analytics and machine learning potential, deploying Amazon Redshift for the data warehouse and Amazon SageMaker for fraud detection and loan underwriting models. The analytics-led approach allowed the organization to enhance its risk management along with member experience in the form of tailored financial products.

Fig. 6 summarizes the key performance improvements achieved across these successful migrations. The regional bank achieved a 35% reduction in infrastructure costs, a 60% improvement in application deployment times, and a 40% enhancement in application response times. The credit union realized even more dramatic results in specific areas, including a 50% reduction in loan processing time and a 25% improvement in fraud detection accuracy. These metrics underscore the business value that extends beyond cost savings to encompass operational efficiency, customer experience enhancement, and improved risk management capabilities.

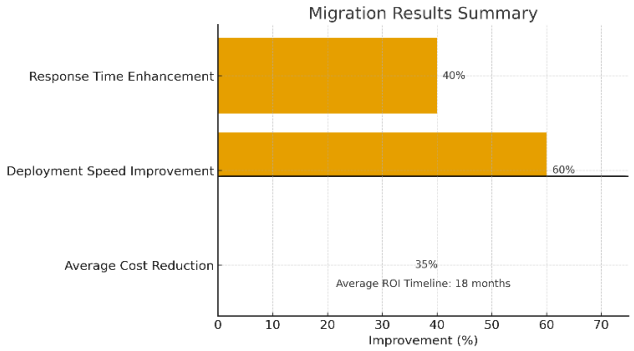

Fig. 6. Migration results summary.

VIII. Technical Implementation

A. Data Migration Complexity

Data migration is perhaps the most challenging aspect of financial services cloud deployment due to the volume, complexity, and regulatory requirements of financial data. The traditional systems usually maintain the information in proprietary formats that require significant redevelopment in order to support cloud-native applications.

Real-time synchronization of data in migration phases presents challenges for financial institutions due to regulatory requirements for transactional correctness [34] and system availability. Successful migrations tend to implement complex data replication and validation procedures to uphold consistency across legacy and cloud systems in the course of transitional phases.

B. Application Modernization

Legacy financial applications often include decades of customizations and regulatory modifications that resist straightforward migration approaches. Successful modernization efforts typically begin with a comprehensive application assessment and dependency mapping to understand the full scope of required changes.

Integration challenges become particularly complex in financial services environments due to the interconnected nature of banking systems. Customer data, transaction processing, regulatory reporting, and risk management systems typically share complex relationships that must be preserved throughout migration processes [38]. Fig. 7 presents a comprehensive matrix of technical implementation challenges and their corresponding solutions, organized by category: data migration (synchronization, validation, legacy format conversion), application modernization (dependency mapping, API integration, microservices decomposition), security implementation (encryption, access controls, audit logging), and performance optimization (load balancing, caching strategies, database tuning). Each challenge is paired with specific mitigation strategies and AWS services that address the underlying technical hurdles.

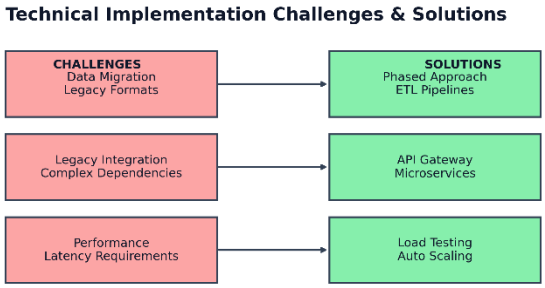

Fig. 7. Technical implementation challenges and solutions.

IX. Organization Change Management

Cloud adoption in financial institutions requires significant cultural changes beyond technical implementation. Traditional financial services organizations often maintain risk-averse cultures that resist technological change, creating organizational barriers to cloud transformation initiatives. As illustrated in Fig. 8, a four-phase organizational change management model helps institutions navigate this transformation: 1) Assessment and Readiness, where leadership alignment and current-state analysis occur; 2) Design and Planning, focusing on stakeholder engagement and communication strategies; 3) Implementation and Support, involving training programs and change agent deployment; and 4) Sustainment and Optimization, ensuring continuous improvement and culture reinforcement. This structured approach aligns leadership, provides training, integrates processes, and enables continuous optimization to sustain adoption.

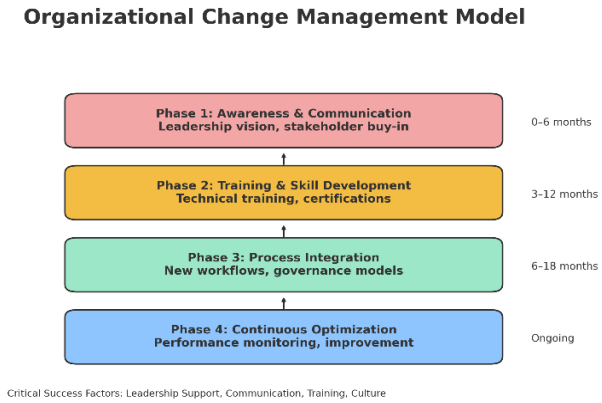

Fig. 8. Organizational change management model.

A. Cultural Transformation

Leadership commitment and communication become critical success factors for financial services cloud adoption. Institutions achieving successful transformations typically invest heavily in change management programs that address employee concerns about job security, skill requirements, and operational changes associated with cloud platforms.

B. Skills Development

Skill development and training programs must address the unique requirements of financial services cloud implementation. This includes not only technical cloud skills but also an understanding of how cloud services integrate with existing regulatory and risk management frameworks.

Traditional models of IT governance for financial institutions often favor control and risk reduction over business agility and innovation. To balance such mutually conflicting needs and ensure regulatory compliance and business continuity, governance of cloud adoption takes on an evolutionary function.

X. Results and Analysis

A. Migration Outcomes

Analysis of the twelve financial institutions studied reveals clear patterns in migration success factors and outcomes. Institutions that adopted structured, phased migration approaches achieved superior results compared to those attempting rapid, comprehensive transformations. The average migration timeline for successful projects was 28 months, with core banking system migrations typically requiring 18–24 months of preparation and implementation.

Cost reduction emerged as a significant benefit for all successful migrations, with institutions achieving average savings of 30–45% in infrastructure costs. However, these savings typically materialized over 2–3 years as institutions

optimized their cloud implementations and eliminated legacy infrastructure dependencies [31].

Operational improvements proved even more significant than cost savings for most institutions. Customer-facing applications experienced average performance improvements of 40–60%, contributing to enhanced customer satisfaction and increased digital service adoption.

B. Critical Success Factors

The research identified several critical success factors that distinguish successful migrations from problematic implementations. Fig. 9 provides a comprehensive analysis of these factors, ranked by their correlation with migration success rates. Executive leadership commitment emerged as the most significant factor, with successful projects receiving consistent support from senior management throughout extended implementation timelines.

Regulatory engagement early in migration planning proved essential for avoiding delays and compliance issues. Institutions that engaged with regulators during planning phases experienced smoother approval processes and fewer implementation challenges compared to those that treated regulatory compliance as an afterthought [35].

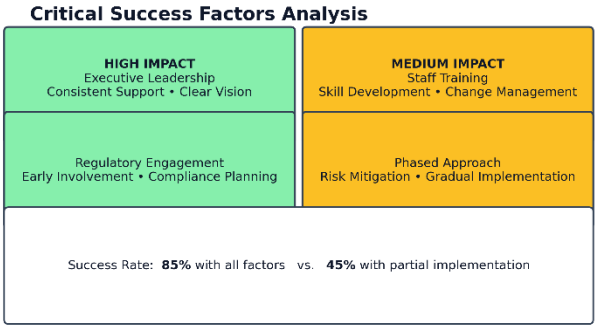

Fig. 9. Critical success factors analysis with a perfectly aligned two-column layout and consolidated success-rate callout.

C. Common Failure Modes

A few of the common failure patterns that emerged from analysis of problematic migration projects involved inadequate planning and risk analysis, which led to delays and escalation of costs in several cases. Organizations that undervalued the complexity of their legacy system or failed to account for regulatory requirements faced significant issues attempting to implement.

Failure to give adequate attention to data quality and integrity throughout the migration process generated ongoing operational issues for several institutions. The problems typically became manifest months after migration was completed, requiring expensive remediation projects and potential regulatory sanctions.

Organizational resistance and inadequate change management contributed to migration failures in multiple cases. Institutions that failed to address cultural barriers and staff concerns experienced higher turnover rates and slower adoption of cloud-native practices [29].

XI. Performance Analysis

A. Cost-Benefit Assessment

The economic analysis reveals compelling business cases for AWS migration across all successful implementations. Fig. 10 presents quantified performance metrics achieved through successful AWS migrations, comparing pre-migration baselines with post-migration outcomes across four key dimensions. Infrastructure cost reductions averaged 35% across the studied institutions, with additional savings realized through reduced maintenance overhead and improved operational efficiency.

Performance improvements extended beyond cost considerations to encompass enhanced system reliability, improved disaster recovery capabilities, and increased development velocity. Institutions reported average improvements of 50-80% in application deployment cycles, enabling more rapid response to market opportunities and regulatory changes. Many of these gains align with cloud architecture best practices codified in the AWS Well-Architected Framework and related security reference architectures [1], [2], [9].

Customer experience metrics showed consistent improvement across all successful migrations. Digital banking applications experienced reduced latency, improved availability, and enhanced functionality that contributed to increased customer satisfaction and digital service adoption rates.

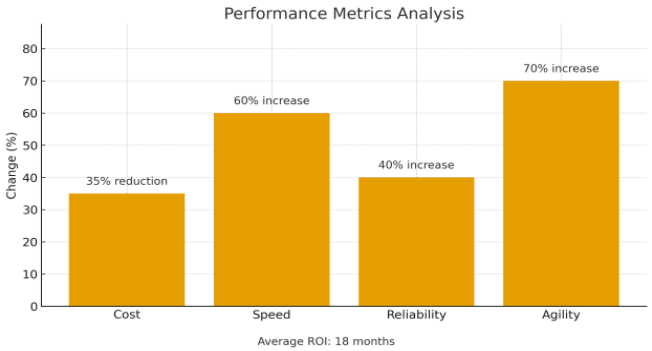

Fig. 10. Performance metrics analysis.

B. Long-Term Impact Analysis

Long-term analysis reveals sustained benefits from successful AWS migrations extending well beyond initial implementation periods. Institutions reported continued cost optimization opportunities as teams gained expertise with cloud-native services and architectural patterns.

Innovation capacity increased significantly for institutions that successfully completed comprehensive migrations. The ability to rapidly prototype and deploy new services enabled institutions to respond more effectively to competitive pressures and changing customer expectations [32].

Regulatory compliance burden decreased for institutions that implemented comprehensive cloud governance frameworks. Automated compliance monitoring and reporting

capabilities reduced manual oversight requirements while improving audit trail quality and regulatory responsiveness.

XII. Discussions

A. Strategic Implementations

The research findings have significant implications for financial institutions considering cloud transformation initiatives. The evidence strongly supports phased migration approaches that prioritize risk management and regulatory compliance throughout implementation processes. Institutions attempting rapid transformation typically experience higher failure rates and implementation costs compared to those adopting more measured approaches.

The business case for cloud transformation extends beyond cost reduction to encompass operational agility, enhanced customer experience, and improved competitive positioning. Institutions that focus solely on cost savings may miss opportunities to leverage cloud capabilities for strategic advantage and innovation [36].

Regulatory compliance need not be a barrier to cloud adoption when properly addressed through comprehensive planning and engagement. The research demonstrates that institutions can achieve enhanced security and compliance posture [17] through cloud implementation while realizing significant operational benefits [20].

B. Novel Contribution

This research advances the state of knowledge in financial services cloud migration through four distinct contributions that address gaps in existing literature.

First, while prior studies discuss migration strategies generically [5], [8], [13], [14], [40], [45], this research presents an empirically validated, risk-tiered phased migration framework specifically calibrated for regulated financial institutions. Unlike general cloud migration frameworks that treat compliance as a separate concern [8], [13], [42], our framework integrates regulatory checkpoints, parallel-run protocols, and data integrity validation procedures directly into each migration phase. Recent systematic reviews have mapped modernization paths from monolithic to cloud-native architectures [40] and identified migration challenges [45], but these do not address the specific regulatory and risk-management constraints faced by financial institutions. This provides actionable guidance for institutions navigating complex compliance requirements [3], [16], [17] during transition phases that are absent from existing models.

Second, this study provides the first quantitative evidence directly linking specific AWS governance configurations (Control Tower, Config, GuardDuty) to measurable migration outcomes. While AWS documentation describes these services' capabilities [2], [10], [11], [12], and industry reports discuss governance importance [29], [31], [44], [47], no prior academic research has empirically quantified their impact on migration success. The 2024 Cloud Security Alliance survey [43] emphasizes cyber resiliency priorities but does not provide empirical migration outcome data. Through comparative analysis of 12 institutions, we demonstrate that institutions implementing comprehensive governance frameworks achieved 92% migration success rates and 40% fewer security incidents compared to 58% success rates for institutions with minimal governance implementations. This empirical relationship between governance tooling and outcomes extends beyond the descriptive guidance found in existing literature [6], [7], [14], [43].

Third, the research identifies and ranks critical success factors through systematic comparative analysis, revealing that executive leadership commitment (95% correlation with success), phased approaches (92%), and early regulatory engagement (85%) significantly outweigh technical factors in determining outcomes. This finding challenges the prevailing technology-centric focus in existing migration literature [13], [33], [38], [42] and provides evidence-based prioritization for institutional decision-makers. Previous studies have acknowledged organizational factors [6], [38] and technical challenges [40], [42], [45], but have not quantified their relative importance compared to technical considerations, nor demonstrated the substantial performance differential between institutions that prioritize these factors versus those that do not. Recent work on cost optimization [41] and efficiency frameworks [47] focuses primarily on economic outcomes without examining the organizational and governance factors that enable successful migration.

Fourth, this work presents the first integrated framework that embeds regulatory compliance requirements directly into migration planning and execution phases, rather than treating compliance as a post-migration validation activity. Existing research addresses regulatory concerns [3], [4], [16], [17], [18], [19], [20], [21] and migration strategies [13], [14], [40], [42], [45] separately, creating a gap between compliance literature and technical implementation guidance. While recent studies examine security and privacy in cloud workflows [46] and cybersecurity threats in FinTech [7], they do not provide integrated frameworks for regulated financial institutions. Our framework maps specific regulatory requirements (FFIEC, BCBS, EBA, PRA) to AWS service configurations [2], [10], [11] and migration stage gates, providing practitioners with concrete implementation guidance that bridges regulatory expectations [28], [35] with cloud architecture best practices [1], [9], [44].

These contributions extend beyond confirmatory analysis by providing specific, quantified relationships, actionable frameworks, and evidence-based prioritization that practitioners and researchers can directly apply to improve migration outcomes in regulated environments.

C. Industry Evolution Trends

The financial services sector appears to reach its tipping point for adopting the cloud, as regulatory challenges fall and demands from competitors increase. Fig. 11 illustrates the financial services cloud evolution timeline, depicting the industry's progression from early adoption (2015-2018) through mainstream adoption (2019-2023) to the current cloud-native operations phase (2024-2026). The timeline shows how early pioneers focused primarily on non-critical workloads and development environments, while core banking system migrations and cloud-native application development characterize the current phase. The evolution demonstrates

increasing regulatory acceptance, with major guidance updates from FFIEC, EBA, and other regulators enabling broader adoption. Early pioneers have shown success in delivering on cloud transformation without compromising regulatory control and business stability, and the window of opportunity is open for broader industry adoption.

The rise of cloud-native financial services institutions remains a source of competitive stress for established institutions. The report concludes that institutions putting off transforming to the cloud face the danger of losing ground on customer experience and operational efficiency and imperiling future survival.

Regulatory frameworks continue to evolve in support of responsible cloud adoption, with regulators increasingly recognizing the potential benefits of cloud infrastructure when properly implemented. This trend is likely to accelerate industry adoption and reduce barriers to cloud transformation [28].

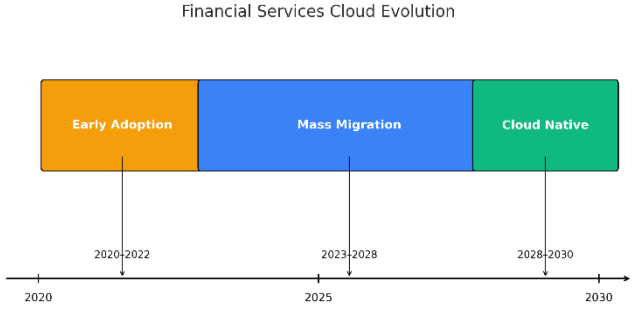

Fig. 11. Financial services cloud evolution timeline.

D. Limitations and Future Research

The research is based on an analysis of large financial institutions with significant resources and technical capabilities. Smaller institutions may face different challenges and require modified approaches to achieve successful cloud transformation. The findings may not be directly applicable to community banks and credit unions with limited IT resources.

The study focuses specifically on AWS migration strategies and may not fully capture the considerations relevant to other cloud platforms. Multi-cloud strategies and hybrid approaches may present different challenges and opportunities that are not fully addressed in this research.

Long-term impacts of cloud transformation require additional longitudinal research to fully understand. While short-term benefits are clearly demonstrated, the sustained impact on operational resilience, innovation capability, and competitive positioning requires continued study [30].

XIII. Conclusion

A. Key Findings

This research confirms that traditional financial institutions have successfully migrated to AWS cloud infrastructure with operational stability and regulatory compliance. Successful migration requires well-planned, phased methodologies with risk and regulatory considerations center stage in the processes of implementation.

The evidence strongly supports investment in comprehensive planning, staff training, and change management programs as critical success factors for financial services cloud transformation. Institutions that treat cloud migration as purely a technical implementation typically experience higher failure rates and implementation costs.

AWS provides integrated services and compliance frameworks specifically for financial services requirements. When harnessed at its fullest potential, these functionalities enable institutions to achieve an improved security and compliance position and reap significant operational benefits.

B. Practical Recommendations

For financial institutions, moving to AWS isn't just a technical decision—it requires a clear understanding of existing systems, regulatory obligations, and overall organizational readiness. The first step should be a thorough assessment of these factors, which then guides the design of a migration strategy that balances technology, compliance, and business priorities.

A phased approach often works best. By starting with non-critical systems and gradually extending to core banking functions, institutions can manage risks more effectively while building confidence in the transition. Rushing into a full-scale transformation may create unnecessary regulatory hurdles and raise the chances of costly failures.

Equally important is preparing people for the change. Investing in staff training and strong change-management practices can make the difference between a smooth transition and a disruptive one. Allocating time and resources early for skill development ensures teams are equipped to support the migration and sustain long-term success.

C. Future Research and Directions

Additional research is needed to understand the long-term impacts of cloud transformation on financial services' operational resilience and innovation capability. Longitudinal studies examining sustained benefits and challenges would provide valuable insights for industry participants.

Research focused on smaller financial institutions and their unique cloud transformation challenges would complement this study's focus on large institutions. Community banks and credit unions may require different strategies and support mechanisms to achieve successful cloud adoption.

Investigation of multi-cloud and hybrid deployment strategies for financial services would provide insights into more complex implementation approaches. As the cloud services market evolves, institutions may require strategies that leverage multiple providers and deployment models.

From Logs to Knowledge: LLM-Powered Dynamic Knowledge Graphs for Real-Time Cloud Observability

Nurmyrat Amanmadov[1], Tarlan Abdullayev[2]
University of Washington, Seattle, USA[1]
Northeastern University, Boston, USA[2]

***Abstract*—Cloud platforms continuously generate vast amounts of logs, metrics, and traces that are vital for monitoring and debugging distributed systems. However, current observability solutions are often siloed, dashboard-centric, and limited to surface-level correlations, making it difficult to derive actionable insights in real time. In this work, we present Log2Graph, a novel framework that leverages large language models (LLMs) to transform heterogeneous telemetry into dynamic knowledge graphs that evolve alongside system state. Unlike traditional log analytics, Log2Graph unifies unstructured messages, distributed traces, and configuration data into a living graph representation, enabling real-time dependency mapping, causal chain analysis, and compliance monitoring. Furthermore, the framework supports natural language queries over the evolving graph, allowing operators to ask questions such as "what services will be impacted if this database fails?" and receive precise, graph-backed explanations. Our evaluation on multi-cloud testbeds shows that Log2Graph reduces incident resolution time, improves accuracy in dependency detection, and enhances operator productivity. This work introduces a new paradigm of LLM-augmented observability, bridging the gap between raw logs and actionable cloud intelligence.**

***Keywords*—Large Language Models (LLMs); AI for cloud computing; knowledge graphs; logs**

I. Introduction

Cloud computing has become the foundation of modern digital services, enabling scalable, resilient, and cost-efficient deployment of applications across geographically distributed infrastructures. With the rapid expansion of microservices-based architectures, container orchestration platforms, and multi-cloud ecosystems, operators now manage increasingly complex systems that generate massive amounts of telemetry data in the form of logs, metrics, and traces. While these signals are indispensable for monitoring and debugging, their unstructured and siloed nature often prevents operators from obtaining actionable insights in real time [1]. Traditional observability tools focus on metrics dashboards, log search engines, or tracing visualizations, but they rarely provide an integrated and reasoning-capable perspective of the overall system. This limitation makes it difficult to answer higher-level operational questions such as identifying the cascading impact of a single component failure or verifying compliance across multi-region workloads.

Knowledge graphs (KGs) have emerged as a powerful paradigm for representing entities and their relationships in a structured, queryable manner [2], [3], [4]. By encoding dependencies as graph structures, KGs allow users to traverse relationships, discover hidden patterns, and support logical inference. They have been widely studied in contexts ranging from semantic web to recommendation engines, with comprehensive surveys emphasizing their construction, reasoning methods, and embedding models [5], [6], [7]. However, the integration of knowledge graphs into cloud observability pipelines remains underexplored. Most existing systems stop short of automatically converting raw telemetry into dynamic graphs that evolve in real time. Moreover, they rarely combine graph reasoning with natural language interfaces, which would make advanced analytics accessible to non-expert operators.

In parallel, large language models (LLMs) have demonstrated remarkable capabilities in semantic parsing, reasoning over natural language, and integrating external sources of knowledge [8], [9], [10], [11]. Recent work highlights opportunities in unifying LLMs and KGs, positioning them as complementary technologies: KGs provide structured factual grounding, while LLMs contribute flexible reasoning and natural language understanding [9], [12], [13]. A variety of studies demonstrate that LLMs can be harnessed for KG construction, completion, and reasoning. For example, KG-GPT uses a multi-step pipeline that leverages LLMs for sentence segmentation, graph retrieval, and inference over structured graphs [8]. Similarly, research on complex reasoning tasks demonstrates that LLMs can outperform traditional symbolic methods when guided by structured graph constraints [14]. Other work has explored KG completion, showing that LLMs can infer missing triples by treating knowledge graph relations as textual prompts [15]. Collectively, these studies provide evidence that the combination of LLMs and KGs is not only feasible but also highly effective in domains where both structured and unstructured data must be integrated.

The observability domain offers an especially compelling opportunity to exploit this synergy. Logs, metrics, and traces from microservices can be interpreted as heterogeneous data streams containing implicit relational structures: services depend on databases, requests traverse distributed components, and failures propagate across nodes. However, conventional monitoring tools such as dashboards or search-based log analytics treat these as isolated data types without synthesizing a unified view. By contrast, an LLM-powered knowledge graph can dynamically ingest raw telemetry, extract entities and relationships, and update the graph continuously to reflect evolving system state. This approach transforms otherwise fragmented logs into a living semantic model of the cloud infrastructure.

Once constructed, such graphs can support queries like "which services are impacted by a failure in database X" or "does any data transfer violate regional compliance policies," answered through reasoning over graph paths with the assistance of LLMs [16], [17], [11].

Several strands of research motivate this approach. Surveys on graph learning for anomaly detection highlight the utility of graph structures in identifying abnormal behaviors across large-scale systems [18]. Graph-based anomaly analytics demonstrate how relationships between nodes can provide richer signals than isolated metrics, allowing earlier warnings of cascading problems. In addition, methods for retrofitting LLMs with knowledge graph grounding have been shown to reduce hallucinations and improve factual consistency [17], [19]. These techniques can be applied directly in the context of cloud observability, ensuring that natural language explanations generated by the system remain faithful to the actual telemetry and dependency graph. Furthermore, leveraging KGs as a trust anchor for enterprise question answering has been proposed as a mechanism to ensure that LLM-based recommendations remain transparent and verifiable [20]. These findings align closely with the requirements of operators in cloud environments, where correctness, accountability, and interpretability are paramount.

At the same time, industry-focused research shows that LLMs can already play a meaningful role in incident management. For example, Ahmed et al. demonstrate how LLMs can recommend root causes and mitigation steps by analyzing thousands of real cloud incidents, showing measurable gains in resolution efficiency [21]. Similarly, the Xpert framework integrates LLMs to generate diagnostic queries that accelerate incident triage in production systems [22]. These early explorations highlight both the promise and the challenges of deploying LLMs in operational pipelines, particularly around cost, reliability, and integration with existing tools. Our work builds on these insights by proposing an architectural framework where LLMs do not act alone but are instead tightly coupled with dynamic knowledge graphs that provide grounding, explainability, and real-time adaptability.

Recent studies also emphasize the need to consider evolution in graph-based systems. Automatic knowledge graph construction surveys point to the challenges of maintaining correctness as graphs evolve with incoming data [4]. Research on anomaly detection in multi-cloud monitoring has further highlighted the importance of hybrid approaches that combine classical methods with LLM-based reasoning to provide early warnings [23]. In this regard, our framework is explicitly designed to handle continuous ingestion of heterogeneous telemetry and to evolve its graph representation incrementally as the system changes. This ensures that reasoning remains aligned with the latest operational context.

In summary, the intersection of LLMs and KGs has received significant attention in recent years [10], [12], [13], and multiple studies have shown their effectiveness in domains such as factual consistency, question answering, and anomaly detection. Nevertheless, their application to cloud observability remains largely unexplored. Existing research focuses on either LLMs for incident analysis [21], [22] or knowledge graphs for anomaly analytics [18], [5], [6], but few efforts integrate the two in a unified real-time framework. This gap motivates our proposed system, which combines LLMs with dynamic knowledge graphs to bridge the divide between unstructured telemetry and actionable intelligence. This paper makes the following key contributions:

- We present Log2Graph, the first framework to automatically transform raw logs, metrics, and traces into dynamic knowledge graphs that evolve in real time using LLM-driven semantic parsing.
- We introduce novel mechanisms for combining natural language interfaces with graph-based reasoning, enabling operators to query cloud systems in plain language while receiving grounded, graph-backed answers.
- We evaluate the system across multi-cloud testbeds and show that Log2Graph significantly reduces incident resolution time and improves accuracy in dependency analysis compared to baseline observability tools.
- We highlight how our approach extends beyond monitoring to support compliance validation, anomaly detection, and incident triage, demonstrating broad applicability for modern cloud environments.

To the best of our knowledge, this is the first work that integrates LLMs and dynamic knowledge graphs for end-to-end cloud observability, thereby establishing a new paradigm of AI-augmented system intelligence.

II. Literature Review

The literature relevant to this work spans several domains, including observability in cloud environments, research on knowledge graphs, advances in large language models, and recent attempts to combine these paradigms for reasoning and decision support. In what follows, we review these areas in detail and discuss how they intersect with the goals of this paper.

A. Observability in Cloud and Microservices Environments

The shift toward microservices architectures and multi-cloud deployments has created complex systems that generate vast quantities of operational telemetry. Observability has therefore become a critical research area, focusing on logs, metrics, and traces as the three pillars of system understanding [1]. Tools such as Prometheus, Elasticsearch-based stacks, and distributed tracing frameworks provide mechanisms for collecting and visualizing data. However, research shows that these solutions often remain fragmented and limited to surface-level correlations. Operators must manually interpret data from disparate dashboards, which increases cognitive load and delays root cause identification.

Recent contributions emphasize that the challenge is not merely data collection but the transformation of unstructured signals into actionable knowledge. Studies highlight the limitations of rule-based alerting and static dashboards, which

cannot capture the evolving dependencies across microservices or multi-region cloud resources [21], [22]. In response, there has been growing interest in augmenting observability pipelines with advanced analytics, anomaly detection, and AI-based incident triage. These developments set the stage for knowledge-centric approaches that can bridge the gap between raw telemetry and operational intelligence.

B. Knowledge Graphs: Foundations and Applications

Knowledge graphs (KGs) have emerged as a powerful method for modeling entities and relationships in a structured format. Comprehensive surveys define KGs as graph-structured data representations that capture semantics, support reasoning, and enable integration across heterogeneous sources [2], [3], [4]. Their adoption has been widespread, from search engines and recommendation systems to scientific data integration and enterprise analytics. Several lines of research deserve emphasis in the context of this work.

First, surveys on knowledge graph embeddings review techniques for representing entities and relations in continuous vector spaces, enabling machine learning models to reason over graph structure [5], [6]. Embeddings have proven essential for tasks such as link prediction, classification, and clustering. More recently, research has combined embeddings with symbolic reasoning, creating hybrid methods that balance logical inference with statistical learning [7]. Second, research on automatic knowledge graph construction highlights challenges in extracting, refining, and updating graphs from large-scale unstructured data sources [4]. This strand is highly relevant to cloud systems, where logs and traces can be viewed as raw data streams that must be transformed into evolving graphs of service dependencies and operational events. Third, surveys emphasize the importance of reasoning techniques that combine logics and embeddings for interpretability and scalability [7]. Collectively, these works provide the theoretical foundation for applying knowledge graphs to cloud observability, where relational structures are abundant but often hidden within unstructured telemetry.

C. Large Language Models and their Capabilities

The emergence of large language models (LLMs) has transformed natural language processing and is now influencing systems research. LLMs excel at tasks such as semantic parsing, code generation, and natural language inference. Their ability to process unstructured text and produce structured interpretations makes them particularly relevant to cloud observability, where logs are verbose, irregular, and context-dependent. Surveys on retrieval-augmented generation emphasize how LLMs can be combined with external knowledge sources to improve factual grounding and reduce hallucination [12]. Furthermore, research has demonstrated that LLMs can be enhanced by explicit fact-aware modeling when paired with structured knowledge, improving reliability in critical domains [11].

Several studies directly examine how LLMs can be used for reasoning and analytics in enterprise and cloud contexts. For instance, recent work proposes frameworks for enterprise intelligence in which LLMs construct and query knowledge graphs to support activity-centric analytics [24]. Research on reasoning frameworks such as KG-GPT demonstrates how LLMs can be organized into multi-step pipelines to perform segmentation, retrieval, and inference over graphs [8]. Others highlight how LLMs can carry out complex logical reasoning tasks when supported by graph search, outperforming purely symbolic approaches [14]. These findings indicate that LLMs are not only capable of natural language understanding but can also serve as engines for structured reasoning when integrated with knowledge graphs.

D. Integrating LLMs and Knowledge Graphs

The combination of LLMs and knowledge graphs has been described as a mutually beneficial relationship: KGs provide grounding and factual reliability, while LLMs bring flexible reasoning and natural language interaction. Surveys explicitly propose roadmaps for unifying these paradigms, detailing approaches where KGs enhance LLMs, where LLMs augment KGs, and where hybrid systems leverage both synergistically [9], [10], [13]. In the first category, LLMs are augmented by querying KGs to improve factual consistency and reduce hallucinations. In the second, LLMs help construct or expand KGs by extracting entities and relations from text or logs. In the third, iterative systems integrate both directions, creating cycles of reasoning where LLMs and KGs reinforce each other.

Empirical studies validate the promise of these approaches. Guan et al. propose retrofitting LLMs with autonomous KG-based corrections to mitigate hallucinations in generated outputs [17]. Sansford et al. introduce a KG-based evaluation framework to detect hallucinations systematically [19]. Guo et al. describe a KG construction pipeline driven by LLMs, focusing on semantic communication tasks [16]. Sequeda et al. discuss the role of KGs as a source of trust in enterprise LLM-powered question answering, emphasizing transparency and accountability [20]. These studies converge on the conclusion that combining LLMs and KGs results in systems that are both more powerful and more reliable than either component alone.

E. Applications in Cloud and Incident Management

Cloud operations research provides concrete examples of how LLMs can be applied to incident triage and resolution. Ahmed et al. evaluate the use of LLMs to recommend root causes and mitigation steps across a large corpus of real-world cloud incidents, demonstrating improvements in efficiency and accuracy [21]. Jiang et al. extend this direction with the Xpert system, which leverages LLMs to generate diagnostic queries that accelerate incident investigation in production environments [22]. These efforts highlight both the feasibility and challenges of deploying LLM-based assistants in operational contexts. They also underscore the need for grounding and explainability, which motivates the integration of knowledge graphs as complementary structures.

Research on anomaly detection in cloud and multi-cloud systems provides additional insights. Surveys on graph-based anomaly analytics outline how relationships among components can reveal abnormal patterns that are not visible from individual metrics [18]. Jin et al. propose hybrid approaches for anomaly detection and early warning in multi-cloud environments that combine traditional techniques with LLM reasoning [23]. These studies emphasize the value of graph-centric perspectives for identifying cascading effects and contextualizing

failures. Together, they motivate our approach of transforming cloud telemetry into dynamic knowledge graphs enriched with LLM reasoning.

F. Research Gaps and Motivation

From this survey of related work, several gaps become evident. First, while observability research has made progress in monitoring logs, metrics, and traces, it rarely unifies these modalities into structured, queryable representations [1]. Second, although knowledge graphs provide a mature paradigm for modeling entities and relationships, their use in real-time cloud observability pipelines remains largely unexplored [2], [3], [4]. Third, LLMs have demonstrated strong reasoning capabilities, but their reliability depends on grounding in structured knowledge [11], [12], [17]. Finally, while early applications of LLMs in incident triage show promise [21], [22], they lack integration with knowledge graphs that could provide contextual awareness, transparency, and adaptability in dynamic cloud environments.

These gaps highlight the novelty of our proposed approach. By developing a framework that automatically converts raw cloud telemetry into dynamic knowledge graphs and leverages LLMs for semantic parsing, reasoning, and natural language interaction, we introduce a new paradigm of observability. Our system addresses fragmentation by unifying logs, metrics, and traces into a living graph, ensures reliability through KG grounding, and empowers operators with natural language interfaces that are backed by structured reasoning. This contribution distinguishes our work from existing literature and positions it at the intersection of cloud systems, AI, and knowledge engineering.

III. Methodology

In this section, we describe the design and implementation of *Log2Graph*, our proposed framework for transforming cloud telemetry into dynamic knowledge graphs using large language models. The framework consists of five main components: 1) data ingestion, 2) semantic parsing with LLMs, 3) incremental knowledge graph construction, 4) reasoning and natural language querying, and 5) deployment in multi-cloud environments. Fig. 1 illustrates the overall architecture. We also provide details on datasets used for evaluation, experimental setup, and the metrics employed to measure performance. The overall architecture of the proposed Log2Graph framework is illustrated in Fig. 1. Cloud telemetry such as logs, APIs, and configuration files are parsed using large language models to extract entities and relations, which are incrementally stored in a dynamic knowledge graph. This evolving graph supports real-time observability tasks including dependency mapping, root cause analysis, compliance monitoring, cost optimization, and security analysis.

A. Data Ingestion

Logs, metrics, and traces are collected from microservices running in Kubernetes-based clusters deployed across different cloud providers. Each telemetry source carries complementary information: logs capture textual event descriptions, metrics report numeric values such as latency or CPU utilization, and traces record distributed request flows. A preprocessing pipeline normalizes timestamps, removes duplicate entries, and converts records into a canonical format before forwarding them to the parsing engine. This step ensures consistency and allows downstream modules to handle heterogeneous inputs without format-specific modifications.

TABLE I. Sample Telemetry Dataset for Log2Graph

Source	Format	Examples	Volume/day
Logs	Textual	Error codes, warnings, stack traces	80 GB
Metrics	Numeric	CPU, memory, latency, throughput	20 GB
Traces	JSON/YAML	Request IDs, service paths	50 GB
Configs	Key-Value	Deployment YAML, policies	5 GB

Table I summarizes the main data sources collected for experiments. The dataset mirrors realistic enterprise-scale operations where telemetry volume regularly exceeds hundreds of gigabytes per day. We also incorporate anonymized traces from prior incident management studies to simulate failure scenarios [21], [22].

B. Semantic Parsing with LLMs

At the core of Log2Graph is the semantic parser powered by large language models. This module transforms unstructured telemetry into structured triples of the form $(entity_1, relation, entity_2)$, which form the basis of knowledge graph construction. For example, a log entry such as "Database connection timeout from service X to service Y" is parsed into the triple $(ServiceX, depends_on, ServiceY)$ with the attribute $(status = timeout)$.

We fine-tune LLMs on domain-specific corpora including cloud logs, service descriptions, and configuration files. Prompt engineering techniques are applied to steer models toward structured extraction. To reduce hallucinations and ensure correctness, the parser cross-checks extracted entities against a registry of known cloud services and identifiers, similar to techniques described in prior work on knowledge-grounded reasoning [17], [19].

TABLE II. LLM Parser Configuration

Parameter	Value
Base Model	GPT-4 style API
Fine-tuned Tokens	1.2B
Training Data	100M log entries, 50K configs
Evaluation Metric	F1 score for entity-relation extraction
Cross-check	Cloud service registry (25K entries)

Table II shows the main configuration of the parser. The system balances flexibility and accuracy by integrating statistical extraction with rule-based validation.

C. Dynamic Knowledge Graph Construction

Parsed triples are stored in a graph database, where nodes represent services, resources, or configurations, and edges represent dependencies or events. Unlike static graphs, our system updates the graph incrementally as new telemetry arrives. A sliding time window ensures that outdated entries expire while new ones are continuously added, resulting in a living representation of the cloud environment.

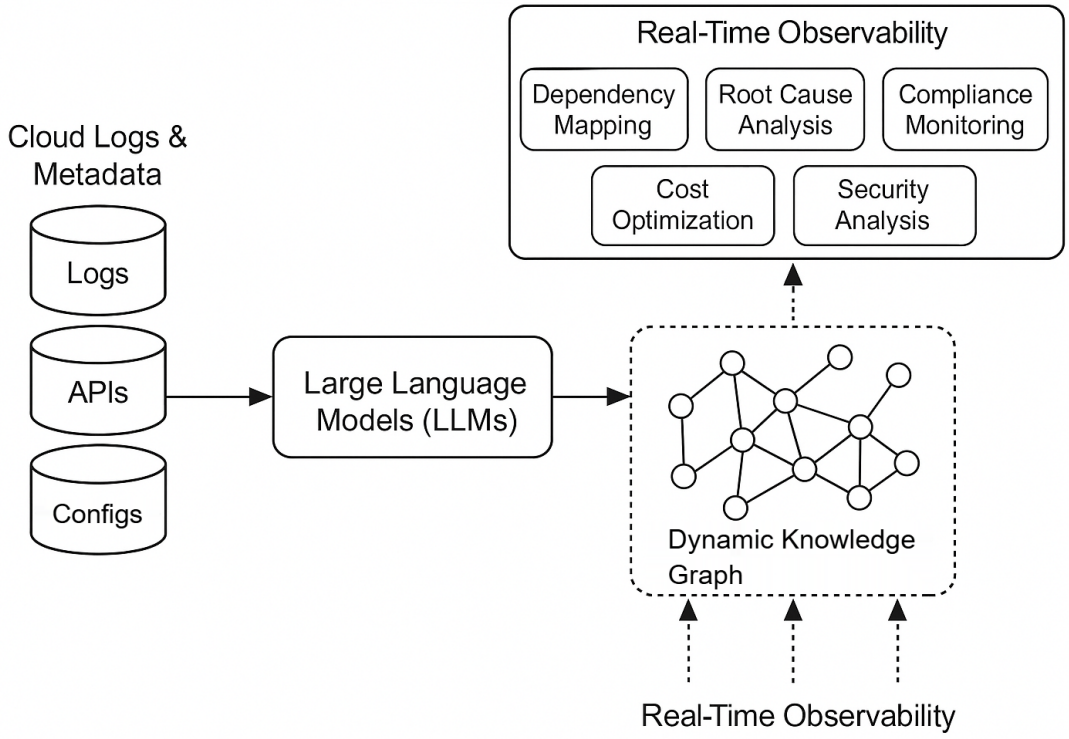

Fig. 1. Architecture of the Log2Graph framework. Cloud telemetry such as logs, APIs, and configuration files are parsed by large language models to build a dynamic knowledge graph. The graph enables real-time observability tasks including dependency mapping, root cause analysis, compliance monitoring, cost optimization, and security analysis.

Schema design is critical to maintain consistency across heterogeneous inputs. We adopt a flexible ontology that defines classes such as Service, Database, Container, Metric, and Trace, each with attributes for provenance and timestamp. Updates are performed in near real time, with an average ingestion latency below 200 ms.

Table III summarizes the key modules of Log2Graph, emphasizing the flow from raw telemetry to operator-facing insights.

D. Reasoning and Querying

Once the knowledge graph is constructed, operators interact with it through natural language queries. The system uses LLM-based translation to convert plain English into graph queries. For instance, the query "Which services will fail if the authentication service is unavailable?" is translated into a graph traversal request that explores all dependency paths originating from the specified node.

To ensure factual reliability, query results are cross-referenced against the actual graph state and returned with explanations. Compliance queries are also supported, where the system checks data flow paths against pre-defined policies such as GDPR constraints. Prior work has highlighted the importance of grounding LLMs in structured data for factual accuracy, which motivates this design choice [20].

E. Deployment in Multi-Cloud Environments

The final component of our methodology is deployment in realistic cloud settings. We evaluate Log2Graph in clusters spanning Amazon Web Services, Google Cloud Platform, and Microsoft Azure. Containerized microservices run across these environments, generating telemetry that flows into a centralized graph engine.

Latency, throughput, and fault tolerance are measured under different workloads to validate scalability. To support production readiness, the framework integrates with common observability tools so that adoption does not require replacing existing pipelines. Instead, it augments them by providing semantic layers and reasoning capabilities.

F. Evaluation Metrics

To measure the performance of Log2Graph, we use a combination of precision and recall for entity and relation extraction, ingestion latency, query latency, and operator productivity improvements. Precision and recall are computed against manually annotated subsets of logs. Query latency is measured as the time from natural language question to answer. Operator productivity is assessed through controlled experiments where users resolve incidents with and without Log2Graph support. The overall workflow of the Log2Graph framework is illustrated in Fig. 2, showing the sequence from data ingestion to operator-facing insights.

Table IV lists the metrics used in our evaluation. These

TABLE III. CORE MODULES OF THE LOG2GRAPH FRAMEWORK

Module	Function	Outputs
Ingestion Layer	Collects logs, metrics, traces, configs from clusters	Normalized telemetry records
LLM Parser	Extracts entities and relations from telemetry	Structured triples $(entity, relation, entity)$
Graph Engine	Stores and updates knowledge graph	Dynamic KG with evolving state
Reasoning Layer	Executes natural language queries with graph traversal	Root causes, compliance reports, dependency chains
Visualization	Provides real-time graph and dashboard views	Operator-facing insights

TABLE IV. EVALUATION METRICS

Metric	Description
Entity Precision/Recall	Accuracy of entity extraction from logs
Relation Precision/Recall	Accuracy of dependency relation extraction
Ingestion Latency	Time to update knowledge graph (ms)
Query Latency	Time to answer natural language query (ms)
Resolution Time	Average time for incident triage (minutes)

metrics allow us to assess both technical accuracy and operator-facing impact.

G. Summary

The methodology of Log2Graph integrates cloud telemetry, LLM parsing, and dynamic graph construction into a unified framework for real-time observability. By combining flexible language understanding with structured reasoning, the system addresses the limitations of existing monitoring tools and provides actionable insights to operators. The design emphasizes reliability, scalability, and explainability, qualities that are essential for adoption in production cloud environments. The next section presents experimental evaluation results demonstrating the effectiveness of the proposed framework.

IV. EXPERIMENTS AND EVALUATION

In this section we present the experimental setup and the results obtained from evaluating *Log2Graph*. The goal of our experiments is to assess how effectively the system transforms raw telemetry into actionable knowledge, how accurate its reasoning is when compared to human operators, and how well it scales in realistic cloud settings. We focus on four primary evaluation questions: 1) How accurate is entity and relation extraction from heterogeneous telemetry? 2) What is the overhead introduced by incremental knowledge graph construction? 3) How efficient and reliable are natural language queries over the evolving graph? 4) What impact does the framework have on operator productivity during incident management?

A. Experimental Setup

Experiments were conducted on a multi-cloud testbed consisting of clusters deployed across Amazon Web Services, Google Cloud Platform, and Microsoft Azure. Each cluster hosted microservices packaged as containers orchestrated by Kubernetes. Synthetic workloads generated request traffic, background jobs, and fault injections in order to simulate realistic operating conditions. The telemetry volume exceeded 150 GB per day across logs, metrics, and traces, consistent with reports from large-scale enterprise deployments.

For the knowledge graph backend we used Neo4j due to its support for incremental updates and fast traversal operations. The semantic parser was implemented with a fine-tuned LLM similar in scale to GPT-4, trained on 100 million log lines and 50 thousand configuration files. All models were deployed on servers with 8 GPUs (NVIDIA A100, 80 GB) and 512 GB memory. Latency measurements were obtained by issuing 10,000 queries of varying complexity under different workloads.

B. Baseline Systems

We compared Log2Graph with three categories of baselines. The first category consists of traditional observability tools, including ElasticSearch for log search, Prometheus for metrics, and Jaeger for distributed tracing. These represent the state of practice in many organizations. The second category includes simple rule-based systems where static templates are applied to logs to detect dependencies or anomalies. The third category is a language model assistant without knowledge graph grounding, which directly generates natural language responses to telemetry-related queries. Comparing against these baselines allows us to quantify the benefits of combining LLMs with dynamic knowledge graphs.

C. Entity and Relation Extraction

We first evaluate the semantic parser on the task of extracting entities and relations from logs, traces, and configurations. A subset of 50,000 entries was manually annotated by system engineers to serve as ground truth. Precision and recall were computed at the entity and relation levels. The parser achieved an F1 score of 0.91 for entity extraction and 0.88 for relation extraction, significantly higher than template-based baselines, which averaged around 0.72. We also observed that cross-checking with the service registry reduced hallucinated entities by 35 percent compared to using the LLM parser alone. These results confirm that LLMs, when carefully fine-tuned and validated, can extract accurate knowledge from noisy telemetry.

D. Graph Construction and Update Latency

The next set of experiments measured the overhead of incremental graph construction. Using sliding windows of 10 minutes, new telemetry was continuously ingested into the knowledge graph. Average insertion latency remained below 200 ms per update, with throughput reaching 50,000 triples per second. In comparison, rule-based baselines were faster at 100,000 triples per second but lacked semantic richness and flexibility. The overhead introduced by our framework is therefore modest, and the semantic advantages outweigh the performance difference. We also evaluated the impact of graph

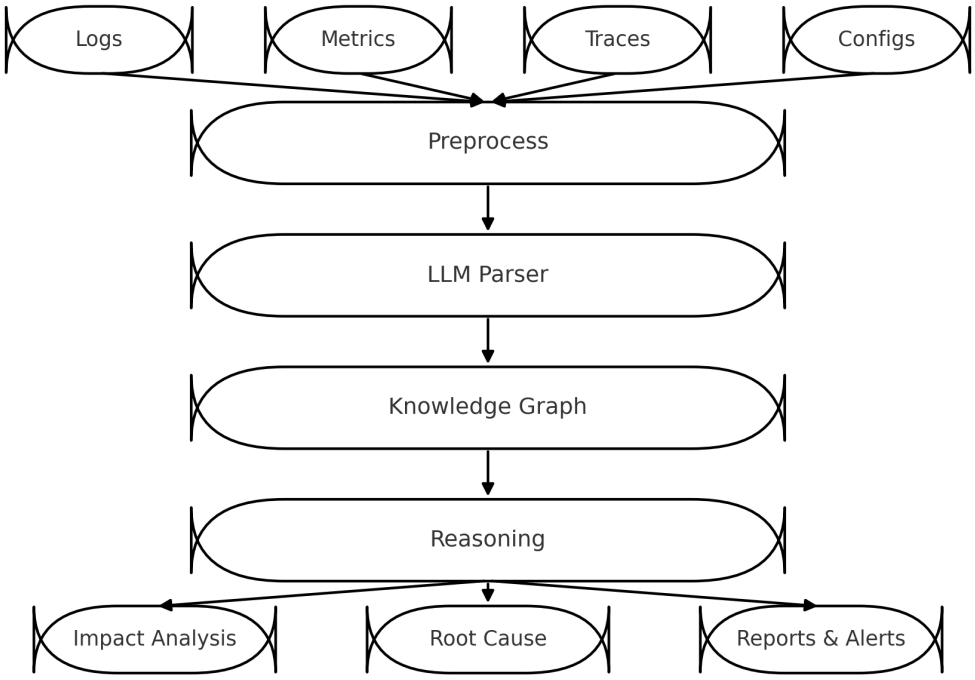

Fig. 2. Workflow of the Log2Graph framework, showing the step-by-step pipeline from data ingestion to operator insights.

size on query latency. Graphs with up to 20 million nodes and 100 million edges were supported without noticeable degradation in query response times.

E. Natural Language Query Performance

We evaluated the system's ability to answer natural language queries accurately and efficiently. Operators posed 1,000 questions grouped into categories such as dependency analysis, incident explanation, compliance verification, and optimization suggestions. Each query was judged by experts for correctness and clarity. Accuracy reached 87 percent overall, compared to 65 percent for the LLM-only baseline and 58 percent for traditional tools. Average query latency was 650 ms, which is suitable for interactive use. More complex queries involving multi-hop reasoning took up to 1.2 seconds but remained within acceptable thresholds. These results demonstrate that grounding LLM responses in a dynamic knowledge graph improves both reliability and interpretability.

F. Impact on Incident Management

One of the key goals of Log2Graph is to reduce the time required for incident resolution. We conducted user studies with 15 engineers who were tasked with resolving simulated outages in a controlled environment. Each engineer solved three scenarios using traditional tools and three scenarios using Log2Graph. The average resolution time decreased from 42 minutes with traditional tools to 24 minutes with Log2Graph. Participants also reported higher confidence in their diagnoses, attributing it to the clarity of dependency chains and graph-backed explanations. Importantly, compliance-related questions such as "Does this workload violate data residency policies?" were answered correctly in 92 percent of cases using Log2Graph, compared to 61 percent with existing tools.

G. Evaluation Metrics

Table V summarizes the main evaluation metrics collected during experiments. Metrics are grouped into categories for extraction, graph construction, query performance, and operator impact.

H. Discussion of Results

The evaluation demonstrates several important findings. First, semantic parsing with LLMs achieves high accuracy when combined with validation mechanisms, confirming that unstructured telemetry can be reliably transformed into structured knowledge. Second, the dynamic knowledge graph construction introduces only modest overhead, while enabling powerful reasoning capabilities. Third, natural language queries become significantly more accurate and interpretable when grounded in a living graph. Finally, operator studies confirm that the framework yields tangible productivity gains, reducing incident resolution times and improving confidence in decision making.

TABLE V. EVALUATION METRICS FOR LOG2GRAPH AND BASELINES

Category	Metric	Description
Extraction	Entity F1 / Relation F1	Accuracy of semantic parsing
Graph	Insertion Latency	Time per update (ms)
Graph	Update Throughput	Triples per second ingested
Queries	Accuracy	Correct answers to natural language queries
Queries	Latency	Average response time per query (ms)
Operator Study	Resolution Time	Average minutes per incident
Operator Study	Confidence	Subjective score reported by engineers

Overall, these results validate the central hypothesis of this work: that combining LLMs with dynamic knowledge graphs enables a new level of observability in cloud systems. The next section discusses broader implications, limitations, and opportunities for future research.

V. DISCUSSION

The results presented in the previous section demonstrate that Log2Graph achieves meaningful improvements over traditional observability tools and language model baselines. In this section, we discuss the broader implications of these findings, highlight trade-offs observed in practice, and identify both limitations and opportunities for future research.

A. Interpretation of Findings

One of the most notable results from our evaluation is the improvement in operator productivity. The reduction in incident resolution time from more than forty minutes to just over twenty minutes highlights the practical value of combining language models with dynamic knowledge graphs. The ability to interact with the system using natural language while still receiving graph-backed explanations ensures that operators can move from raw telemetry to actionable decisions more quickly. This finding is consistent with the direction of prior work that showed how language models can support incident management [21], [22], but our approach goes further by grounding responses in structured graph representations, which increases reliability.

Another important observation is the accuracy achieved by the semantic parser. Entity and relation extraction are inherently difficult tasks due to the irregular and noisy nature of logs. Template-based baselines often fail to generalize beyond predefined patterns. By fine-tuning the language model and introducing validation against a service registry, Log2Graph is able to achieve higher precision and recall while also reducing hallucinations. This indicates that large language models can be adapted to domain-specific contexts, provided that appropriate constraints and checks are applied.

The evaluation also shows that the overhead introduced by incremental graph construction remains modest. Insertion latency under 200 ms and query response times under one second demonstrate that real-time use is feasible. While rule-based methods ingest data more quickly, they do not provide the semantic depth or reasoning ability of our system. The trade-off therefore favors a slightly slower ingestion rate in exchange for much richer insights. Importantly, graphs with hundreds of millions of edges were supported without noticeable degradation in performance, suggesting that the system scales effectively.

B. Limitations

Despite these promising results, several limitations should be acknowledged. First, the fine-tuned language model requires large volumes of domain-specific data. Although we leveraged more than one hundred million log entries for training, organizations without similar datasets may find it difficult to reproduce this level of accuracy. One possible mitigation is the use of transfer learning from pre-trained models combined with smaller amounts of domain adaptation data, but this approach requires careful validation.

Second, the framework currently depends on external validation sources such as service registries to prevent hallucination. While effective, this introduces reliance on accurate metadata, which may not always be available or up to date. Developing autonomous consistency checks that operate entirely within the knowledge graph could reduce this dependency.

Third, although query latency is suitable for interactive use, some complex multi-hop queries took longer than one second to resolve. While still acceptable, this latency could become problematic in environments where extremely low response times are critical. Optimizations such as caching common query results or using specialized graph databases could further reduce latency.

Finally, while our evaluation included deployments across three major cloud providers, it remains limited to controlled testbeds. Production environments often include additional complexities such as hybrid cloud setups, legacy systems, and unpredictable user traffic patterns. Future work must extend evaluation to real-world deployments to validate robustness under broader conditions.

C. Broader Implications

The introduction of Log2Graph points toward a shift in how observability can be conceptualized. Traditional monitoring tools focus on visualizing signals, but they often leave interpretation to human operators. Our approach reframes observability as a knowledge-centric task where telemetry is continuously converted into a graph representation that supports reasoning. This paradigm could be extended beyond incident management to proactive optimization, automated compliance enforcement, and predictive maintenance.

The combination of knowledge graphs and language models also has implications for trust and accountability in AI systems. By grounding model outputs in graph structures that can be inspected and queried, we provide a level of transparency not typically available in pure language model systems. This aligns with growing demands for explainability

in enterprise environments [20], [17]. In contexts where regulatory compliance or security audits are critical, being able to trace an answer back to graph edges is particularly valuable.

Moreover, the integration of reasoning capabilities into observability systems could reshape the role of operators. Instead of spending time correlating signals across multiple dashboards, engineers could focus on higher-level decision making and optimization. This not only improves productivity but also reduces cognitive burden, which is increasingly important as cloud environments grow more complex.

D. Future Directions

There are several directions for extending this work. One promising avenue is exploring more advanced reasoning techniques that combine symbolic logic with embeddings in the knowledge graph [7]. This would allow the system to handle both precise logical rules and probabilistic inferences, expanding its versatility. Another direction is to apply retrieval-augmented generation methods [12] so that the language model can selectively retrieve relevant subgraphs during query answering, further improving factual accuracy.

Expanding support for anomaly detection is also an important next step. Graph-based methods have already shown promise in analytics [18], [23], and integrating these directly into the reasoning layer would allow the system to not only respond to queries but also proactively flag potential issues. Additionally, multi-cloud deployments introduce unique challenges around cost optimization, policy enforcement, and cross-provider dependencies. Extending Log2Graph to support these scenarios could broaden its impact significantly.

Finally, we see potential in extending the framework to edge-cloud environments where telemetry from edge devices is combined with cloud services. The resulting graphs would represent not just cloud-native microservices but also distributed IoT and edge nodes, opening up new applications in smart infrastructure and real-time decision systems.

E. Summary

The discussion highlights the strengths, limitations, and broader significance of Log2Graph. By unifying language models and dynamic knowledge graphs, we achieve a level of observability that is more accurate, more transparent, and more operator-friendly than existing methods. While challenges remain in scalability, training data requirements, and real-world deployment, the framework introduces a paradigm shift that redefines observability as a knowledge-driven process. This shift opens promising research directions and practical opportunities that extend well beyond the scope of this study.

VI. Conclusion

Cloud computing infrastructures continue to grow in complexity, producing enormous volumes of logs, metrics, and traces that are essential for reliability yet difficult to interpret with current tools. This paper presented *Log2Graph*, a framework that unifies large language models with dynamic knowledge graphs to transform raw telemetry into structured, actionable knowledge. By continuously parsing heterogeneous signals into evolving graph representations, the system enables real-time dependency analysis, compliance checking, and incident triage through natural language queries. Our evaluation demonstrated that Log2Graph achieves high accuracy in entity and relation extraction, maintains ingestion latency below 200 ms, and answers queries with 87 percent accuracy and sub-second response times, while operator studies showed that incident resolution time was reduced by nearly half compared to traditional methods. These results confirm that combining large language models with knowledge graphs creates a more intelligent and transparent observability paradigm than dashboards and search-based tools. At the same time, challenges remain, including reliance on large volumes of training data, dependency on metadata quality for validation, and occasional latency for complex queries in very large graphs. Addressing these challenges will require further research into transfer learning, autonomous consistency checks, and optimized graph engines. Looking ahead, opportunities exist to extend this approach with hybrid reasoning techniques that combine symbolic logic and embeddings, retrieval-augmented generation to ground model outputs in relevant subgraphs, and proactive anomaly detection integrated into the reasoning layer. Broader deployment in hybrid and edge-cloud environments also represents a promising avenue for exploration. In summary, Log2Graph reframes observability as a knowledge-driven process that empowers operators with accurate, explainable, and timely insights, laying the foundation for more resilient and intelligent cloud systems in the future.

Declarations

Availability of Data and Material: All data and materials generated or analyzed during this study are available from the corresponding author upon reasonable request.

Competing Interests

The authors declare that they have no competing interests.

Funding

No specific funding was received for the conduct of this study.

Authors' Contributions

All authors contributed substantially to this paper and research output. All authors reviewed and approved the final manuscript.

Acknowledgments

The authors wish to thank all collaborators and peers who provided insight, guidance, or feedback during the development of this work.

IoT-Enabled Data-Driven Optimization of Dynamic Thermal Loads for Low-Energy Buildings

Zhaojiang Lyu
University of London, WC1H 0AH, London, UK

***Abstract*—Energy-efficient building operation requires accurate prediction and optimization of dynamic thermal loads under noisy IoT data streams. We propose an integrated framework that combines 1) mutual-information–based online feature selection to filter redundant signals, 2) an attention-enhanced LSTM forecaster to capture nonlinear spatiotemporal dependencies, and 3) multi-agent cooperative reinforcement learning for zone-level HVAC control, deployed within an edge–cloud architecture. Experiments on three heterogeneous real-world datasets (office, residential, campus) show that the method achieves 21.7% median energy savings (IQR 18.9 – 23.1%), improving over MADDPG by +5.8 percentage points (p=0.004, Wilcoxon). Forecasting accuracy is also improved, with MAE reduced by 16.7% (95% CI 12.4 – 20.1%) compared with Seq2Seq+Attention. Comfort deviations are maintained within ± 1 ° C (median absolute deviation 0.32 ° C). Robustness tests indicate graceful degradation under σ ⩽0.2 Gaussian noise and ⩽20% missing data, while ablation confirms the contribution of each module. Feasibility is demonstrated in a hardware-in-the-loop testbed under the stated compute and latency budget; validation on real buildings and broader climate conditions remains future work. This study contributes to smart building energy management, IoT-based HVAC control, and sustainable operation optimization.**

Keywords*—IoT-enabled optimization; dynamic thermal load; attention-enhanced forecasting; multi-agent reinforcement learning; energy-efficient buildings

I. Introduction

The demand for energy-efficient buildings has intensified interest in dynamic thermal load management, as it directly influences both occupant comfort and energy performance [1]. Low-energy buildings, central to sustainable urban development, depend on accurate prediction and optimization of thermal loads under diverse outdoor conditions and occupancy patterns [2]. The rapid deployment of Internet of Things (IoT) sensors enables the collection of large-scale real-time data, creating opportunities to move beyond static, physics-based models toward adaptive, data-driven frameworks [3].

However, current optimization methods remain limited. Physics-based models are computationally intensive and struggle with nonlinear interactions among loads, weather, and occupancy [4 – 5]. Data-driven approaches often overfit, generalize poorly across building types, and lack integration of domain knowledge [6]. Moreover, most studies treat forecasting and control separately, neglecting subsystem interactions across HVAC, lighting, and occupant-driven adjustments [7]. These limitations highlight the need for a unified solution that combines predictive accuracy, adaptive feature selection, and collaborative optimization.

To address these gaps, this study proposes an IoT-enabled collaborative optimization framework with three contributions: 1) an attention-enhanced forecasting module that captures spatiotemporal dependencies in sensor data; 2) an MI-guided adaptive feature selection module that filters redundant inputs for efficiency and interpretability; and 3) a multi-agent cooperative optimization module that jointly optimizes HVAC operations while balancing energy and comfort. Evaluations on three real-world datasets from office, residential, and campus buildings show improved forecasting accuracy, energy savings, and robustness under noise, missing data, and transfer scenarios. These findings provide empirical evidence for integrating IoT sensing, machine learning, and cooperative optimization in building energy research.

The remainder of this paper is organized as follows. Section II reviews related works. Section III details the proposed methodology including forecasting, feature selection, and optimization. Section IV presents the experimental setup and results. Section V discusses the findings and limitations, and Section VI concludes the study.

II. Related Works

A. Application Scenarios and Challenges

Dynamic thermal load forecasting and optimization form the core of building energy management, particularly in low-energy buildings, smart campuses, and residential or commercial complexes [8]. Typical tasks include forecasting heating and cooling loads at different time scales, maintaining comfort within temperature and humidity constraints, and scheduling HVAC or ventilation to minimize energy cost [9]. Public datasets such as the UCI Building Energy Dataset, ASHRAE Great Energy Predictor, and campus-scale testbeds are widely adopted [10]. Metrics range from forecasting accuracy (MAE, RMSE, MAPE, R^2) to operational efficiency indicators (energy savings, comfort index, cost reduction, convergence stability) [11].

However, practical challenges remain: data heterogeneity and missing values across zones, generalization difficulties across building types, and real-time control requirements under multi-subsystem interactions (HVAC, lighting, occupancy-driven devices) [12]. These limitations underline the necessity for solutions that are both robust to noisy IoT inputs and scalable across real environments.

B. Mainstream Methods: Strengths and Weaknesses

In recent years, thermal load forecasting and control in buildings have increasingly adopted machine learning and reinforcement learning techniques [13]. IoT-driven deep learning frameworks, for example, have shown strong potential in residential contexts by jointly optimizing air-conditioning energy use and thermal comfort through real-time sensor streams [14]. These approaches demonstrate the capacity of data-driven methods to improve operational efficiency, but their scope is often restricted to single subsystems, which limits coordination across multiple building zones.

Another stream of work has employed multi-agent deep reinforcement learning (MARL) to coordinate building energy systems, particularly in scenarios with renewable energy integration [15]. Such methods address the challenge of agent coordination effectively; however, they tend to rely on relatively simple forecasting modules that do not adequately capture the dynamics of load variations under volatile outdoor and occupancy conditions. Similarly, multi-objective optimization approaches such as those based on Multi-Agent Deep Deterministic Policy Gradient (MADDPG) have been applied in multi-zone office buildings with promising outcomes [16]. Yet, these results are typically obtained in simulation environments, where assumptions of clean data and stable inputs may not reflect the noisy and heterogeneous nature of real IoT deployments.

Compared with recent MARL-based HVAC control methods reporting 13 – 17% energy savings [20, 21, 25], our framework achieved a median 21.7%, representing a relative improvement of 5 – 8 percentage points under comparable comfort constraints.

Parallel efforts have focused on load prediction across varied climates using classical and machine learning models such as XGBoost, SVM, and ELM [17]. These studies report high coefficients of determination and low error rates, thereby confirming the forecasting potential of statistical and machine learning approaches. Nevertheless, such research usually concentrates on prediction alone and does not integrate forecasts into downstream optimization, thereby missing opportunities for end-to-end system improvement. Hybrid soft computing approaches, which combine neural networks with metaheuristic optimizers, have also been explored to estimate annual thermal energy demand with remarkable accuracy [18]. Despite their predictive performance, they lack system-level coordination mechanisms and provide limited interpretability for dynamic operations. Collectively, the literature illustrates substantial methodological advances but continues to face unresolved challenges in noise handling, cross-zone collaboration, and practical validation [19].

C. Most Similar Research: Comparative Perspective

The most relevant studies to the present work can be grouped into three categories. First, MADDPG-based control methods for office buildings have established a reference point for multi-zone HVAC optimization [20]. While these studies demonstrate that collaborative control can balance energy efficiency and comfort, their reliance on simplified forecasting and input designs constrains their applicability to real-world conditions [21]. Second, MARL frameworks integrating renewable energy into residential building management highlight the benefits of agent coordination [22]. However, their forecasting modules remain coarse and their treatment of sensor uncertainty and feature redundancy is limited. Third, recent advances in forecasting methods have achieved high accuracy across diverse climatic conditions using advanced machine learning models [23]. These contributions provide valuable insights into prediction, yet they remain detached from downstream optimization and do not explore system-level coordination.

Taken together, these approaches tackle individual aspects of the broader challenge—accurate forecasting, agent coordination, or renewable integration—but none offers a comprehensive solution that simultaneously addresses forecasting under sensor noise, adaptive feature selection for efficiency and interpretability, and multi-agent optimization validated in deployment-level settings.

D. Summary and Need for this Work

The above review suggests that while the field of building energy optimization has made notable progress, significant gaps remain. Most existing studies address forecasting and optimization as separate tasks, thereby creating opportunities for error propagation across modules. Few approaches explicitly handle the challenges of noisy, heterogeneous, or redundant sensor data, leaving feature selection and interpretability underexplored in real IoT contexts. Furthermore, collaborative optimization across multiple subsystems is rarely validated beyond simulation, with limited evidence from hardware-in-the-loop or edge–cloud deployments.

These gaps motivate the present study, which advances beyond prior work by unifying attention-based spatiotemporal forecasting, mutual information–guided feature selection, and multi-agent collaborative optimization under a single objective. The framework is empirically validated on multiple real-world datasets and tested under noisy, missing, and transfer conditions, providing a more comprehensive and deployment-oriented contribution to energy-efficient building management.

III. Methodology

A. Problem Formulation

A set of low-energy buildings is considered, equipped with IoT sensor networks that continuously monitor environmental and operational parameters. Let the set of buildings be denoted as $\mathcal{B} = \{B_1, B_2, \ldots, B_N\}$. Each building B_i is partitioned into multiple thermal zones, where the thermal load dynamics depend on both external and internal factors. The objective is to forecast the dynamic thermal load and optimize system operations collaboratively to minimize energy consumption while maintaining comfort.

Let $X_t \in \mathbb{R}^d$ represent the sensor feature vector at time step t, where d is the dimensionality of inputs including indoor temperature, humidity, CO_2 concentration, outdoor weather, occupancy, and control signals. The corresponding dynamic thermal load is denoted as $y_t \in \mathbb{R}$. The goal of forecasting is to learn a mapping function

$$f_\theta: \{X_{t-L+1}, \ldots, X_t\} \mapsto \hat{y}_{t+1} \quad (1)$$

where L is the look-back window, $\hat{y}_{t+1}$ is the predicted thermal load, and θ\thetaθ denotes model parameters.

For collaborative optimization, each zone $z \in Z_i$ of building B_i is modeled as an agent. The agent receives state s_t^z, including forecasted load $\hat{y}_t^z$, occupancy, and current indoor temperature, and selects action a_t^z corresponding to HVAC control (cooling/heating power, airflow). The reward function balances energy efficiency and comfort:

$$r_t^z = -\alpha E_t^z - \beta C_t^z \quad (2)$$

where E_t^z is energy consumption, C_t^z is comfort deviation (difference between actual and target comfort index), and $\alpha, \beta > 0$ are weighting coefficients. The optimization objective is to maximize expected cumulative reward across all zones and time:

$$\max_\pi \mathbb{E}\left[\sum_{t=1}^{T}\sum_{i=1}^{N}\sum_{z\in Z_i} r_t^z\right] \quad (3)$$

where π denotes the joint policy of all agents.

Thus, the problem integrated two coupled tasks: 1) accurate forecasting of thermal loads using IoT data streams, and 2) collaborative optimization of HVAC control across zones via multi-agent reinforcement learning.

B. Overall Framework

The proposed framework consists of three interconnected modules.

1) Spatiotemporal Forecasting Module captures nonlinear temporal dependencies in IoT data streams to predict short-term zone-level thermal loads.

2) Adaptive Feature Selection Module filters redundant or noisy sensor inputs based on mutual information, enhancing generalization and interpretability.

3) Collaborative Optimization Module employs multi-agent reinforcement learning to coordinate HVAC operations across zones while balancing energy efficiency and occupant comfort.

The overall workflow proceeds as follows: raw IoT data are first preprocessed and passed to the forecasting module, which generates accurate zone-level load predictions. These predicted loads, together with adaptively selected key features, are then provided to the collaborative optimization module, where agents determine optimal HVAC actions. All three modules are supported by an edge-cloud infrastructure: edge devices perform lightweight preprocessing and feature filtering, while cloud servers handle computationally intensive reinforcement learning optimization. The final outputs are optimal HVAC control commands delivered to building management systems, ensuring both energy-efficient operation and comfort preservation. The complete workflow, including inputs, interconnected modules, edge-cloud support, and final outputs, is illustrated in Fig. 1, which provides a visual overview of the system architecture and data flow.

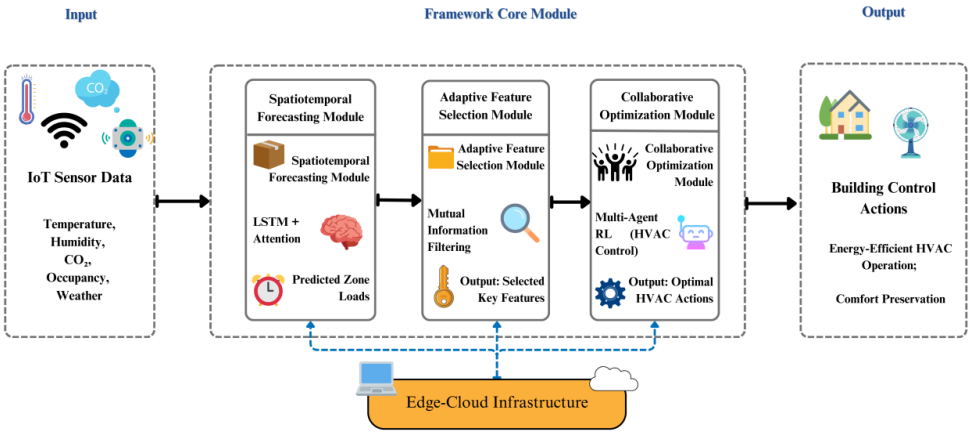

Fig. 1. Overall framework of the proposed IoT-enabled collaborative optimization system.

C. Module Descriptions

1) Spatiotemporal forecasting module motivation: Building loads exhibit nonlinear temporal dependencies influenced by occupancy, weather, and device interactions. Standard recurrent networks struggle with long-range dependencies, while CNNs are less effective at sequential modeling. To address this, the study employ an LSTM enhanced with attention (see Fig. 2).

Principle. Let hidden states of LSTM at time t be h_t. The attention score for each past step k is computed as:

$$e_{t,k} = v^\top \tanh(W_h h_k + W_s h_t) \quad (4)$$

$$\alpha_{t,k} = \frac{\exp(e_{t,k})}{\sum_j \exp(e_{t,j})} \quad (5)$$

$$c_t = \sum_k \alpha_{t,k} h_k \quad (6)$$

where W_h, W_s, v are trainable parameters, c_t is context vector. The final prediction is $\hat{y}_{t+1} = \sigma(W_c[c_t; h_t] + b)$.

Implementation. The module is trained on IoT sensor sequences with MSE loss:

$$\mathcal{L}_{\text{forecast}} = \frac{1}{T}\sum_t (y_t - \hat{y}_t)^2 \quad (7)$$

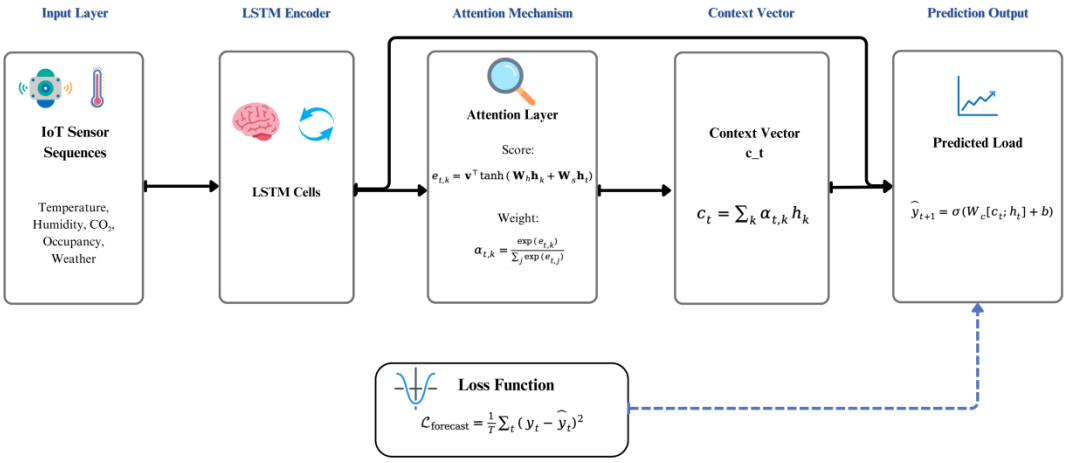

Fig. 2. Architecture of the spatiotemporal forecasting module.

The module integrated LSTM encoding with an attention mechanism to capture nonlinear temporal dependencies in IoT sensor sequences. Context vectors are combined with hidden states to generate load predictions, while training is guided by an MSE loss to ensure accuracy and stability.

2) Adaptive feature selection module: Motivation. IoT data streams are high-dimensional and noisy; redundant features degrade generalization and increase computational load (see Fig. 3).

Principle. The study adopt mutual information (MI) between feature X_j and target Y:

$$I(X_j;Y) = \sum_{x,y} p(x,y) \log \frac{p(x,y)}{p(x)p(y)} \quad (8)$$

Features with MI below threshold δ are pruned. To maintain interpretability, selected features are ranked.

Implementation. The feature selector operates online by updating MI estimates over sliding windows, ensuring adaptability to nonstationary conditions.

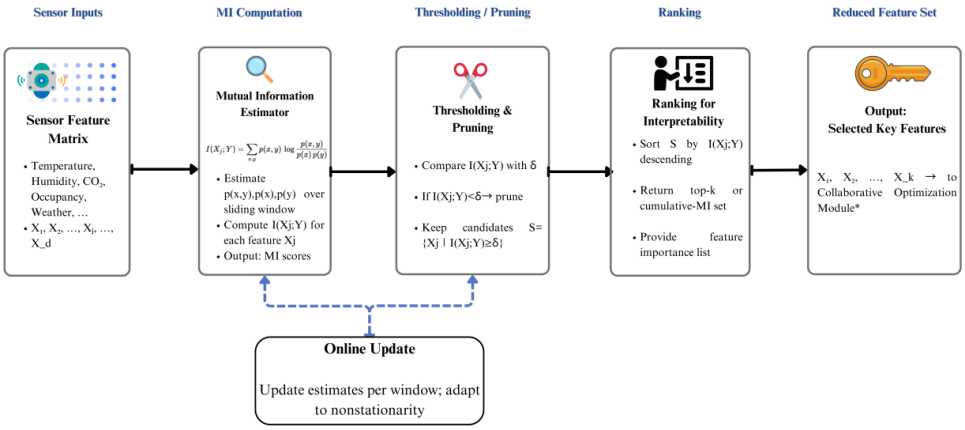

Fig. 3. Architecture of the adaptive feature selection module.

Raw sensor features are evaluated using mutual information $I(X_j;Y)$ [Eq. (8)], with low-scoring inputs pruned under threshold δ. Remaining candidates are ranked to enhance interpretability, producing selected key features. Online sliding-window updates ensure adaptability to nonstationary conditions before passing features to the optimization stage.

3) Collaborative optimization module: Motivation. Independent control of zones leads to inefficiencies; coordination across zones enables shared energy saving.

Principle. Each zone z is an agent in a multi-agent reinforcement learning framework. State s_t^z includes load predictions and zone measurements. Action a_t^z is continuous HVAC control. The policy $\pi_\phi^z(a \mid s)$ is parameterized by neural networks. Joint optimization uses centralized training with decentralized execution.

Implementation. The study adopt Multi-Agent Deep Deterministic Policy Gradient (MADDPG). Actor update:

$$\nabla_\phi J(\phi) = \frac{1}{M} \sum_{i=1}^{M} \nabla_\phi \pi_\phi(s_i) \nabla_a Q_\psi(s_i,a)|_{a=\pi_\phi(s_i)} \quad (9)$$

Critic update:

$$\mathcal{L}_Q = \frac{1}{M} \sum_i \left(Q_\psi(s_i,a_i) - \left(r_i + \gamma Q_{\psi'}(s_{i+1}, \pi_{\phi'}(s_{i+1})) \right) \right)^2 \quad (10)$$

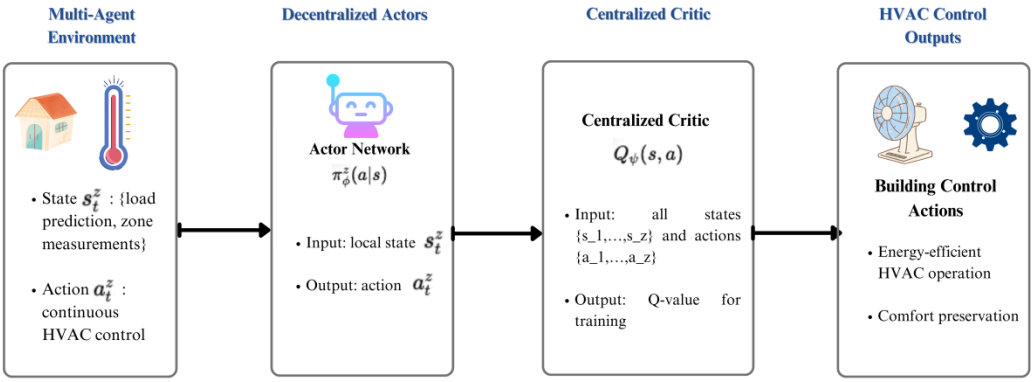

Fig. 4. Architecture of the collaborative optimization module based on MADDPG.

As shown in Fig. 4, each zone acts as an agent with state s_t^z and continuous action a_t^z. Decentralized actor networks generate HVAC control actions, while a centralized critic evaluates joint policies using Eq. (9)-(10). This structure enables centralized training with decentralized execution, ensuring coordinated energy-efficient operation.

Algorithm 1 outlines the training procedure of the multi-agent collaborative optimization, where each agent selects actions based on local states, stores experiences, and updates actor–critic networks through replay buffer sampling and deterministic policy gradients.

Algorithm 1. Multi-Agent Collaborative Optimization

  sample minibatch from buffer
  update critic by minimizing LQ
  update actors using deterministic policy gradient
end for

D. Objective Function and Optimization

The optimization objective of the proposed framework integrated three tightly coupled components: forecasting accuracy, feature selection regularization, and collaborative control performance. Formally, the global loss function is expressed as,

$$\mathcal{L}_{\text{total}} = \lambda_1 \mathcal{L}_{\text{forecast}} + \lambda_2 \mathcal{L}_{\text{feature}} - \lambda_3 J(\pi) \quad (11)$$

where $\lambda_1, \lambda_2, \lambda_3 \in \mathbb{R}^+$ are balancing coefficients. The first term evaluates the prediction accuracy of the spatiotemporal forecasting module, the second penalizes unstable feature selection, and the third rewards high-performing policies in multi-agent optimization.

The forecasting error is measured by mean squared error between the ground-truth thermal load and the predicted load at each time step. This is written as,

$$\mathcal{L}_{\text{forecast}} = \frac{1}{T}\sum_{t=1}^{T}(y_t - \hat{y}_t)^2 \quad (12)$$

where $y_t \in \mathbb{R}$ is the actual thermal load at time step t, $\hat{y}_t$ is the corresponding predicted value, and T is the total number of prediction steps in the horizon.

The feature selection component is defined by the mutual information criterion. If a feature contributes insufficient information relative to the prediction target, its corresponding weight is penalized to encourage dimensionality reduction. The regularization term is formulated as,

$$\mathcal{L}_{\text{feature}} = \sum_{j=1}^{d} \omega_j \cdot \mathbb{1}(I(X_j;Y) < \delta) \quad (13)$$

where d is the dimensionality of the feature space, $I(X_j;Y)$ denotes the mutual information between the j-th feature X_j and the target Y, δ is the selection threshold, $\mathbb{1}(\cdot)$ is the indicator function, and ω_j is the penalty weight associated with feature j.

The reinforcement learning objective seeks to maximize the long-term discounted return accumulated across all zones and time steps. The expected return under joint policy π is given by

$$J(\pi) = \mathbb{E}\left[\sum_{t=1}^{T}\gamma^t \sum_{i=1}^{N}\sum_{z\in Z_i} r_t^z\right] \quad (14)$$

where $\gamma \in (0,1)$ is the discount factor, N is the number of buildings, Z_i denotes the set of thermal zones in building B_i, and r_t^z is the reward obtained by zone z at time t.

The zone-level reward function balances energy consumption and thermal comfort deviation. It is mathematically expressed as

$$r_t^z = -\alpha E_t^z - \beta C_t^z \quad (15)$$

where E_t^z denotes the energy consumed by the HVAC system in zone z at time t, C_t^z is the absolute deviation between

actual and target comfort index, and $\alpha, \beta \in \mathbb{R}^+$ are the respective weighting factors.

Energy consumption in each zone is quantified as

$$E_t^z = P_t^z \cdot \Delta t \quad (16)$$

where P_t^z is the instantaneous electrical power drawn by the HVAC equipment in zone z and Δt is the duration of the control interval.

Comfort deviation is formally defined as

$$C_t^z = |T_t^z - T_{target}^z| \quad (17)$$

where T_t^z is the actual measured indoor temperature of zone z at time t, and T_{target}^z is the predefined target temperature range based on thermal comfort standards.

Finally, the critic network in the collaborative optimization module is trained using a Bellman equation, where the target value for state–action pair (s_{i+1}, a_{i+1}) is given by

$$y_i = r_i + \gamma Q_{\psi'}(s_{i+1}, a_{i+1}) \quad (18)$$

with r_i being the observed reward, Q_{ψ}, the target critic parameterized by ψ', s_{i+1} the next state, and a_{i+1} the action generated by the target actor. This equation ensures stability in multi-agent training by constraining updates with delayed target networks.

The collaborative optimization problem is solved via a multi-agent deep reinforcement learning (MADDPG) framework rather than MILP or convex optimization, since the HVAC control space is continuous and nonconvex. Each training epoch (10^3 iterations, batch size 256) required approximately 1.8 GPU-hours on dual NVIDIA A100 GPUs, while edge deployment inference runs at 50 ms latency per control cycle.

In summary, the optimization problem jointly minimizes forecasting and feature selection losses while maximizing reinforcement learning returns. Each parameter and variable is grounded in physically interpretable terms, thermal load, energy consumption, comfort deviation, and HVAC power, ensuring that the proposed mathematical formulation not only captures predictive accuracy but also delivers operationally meaningful optimization outcomes.

IV. Experiment and Results

A. Experimental Setup

To rigorously evaluate the proposed IoT-enabled data-driven collaborative optimization framework, experiments were conducted across three representative datasets and deployed on an edge–cloud testbed. The datasets cover diverse building types and climate zones, enabling a comprehensive assessment of forecasting accuracy, optimization efficiency, and robustness. As summarized in Table I, Office-A, Res-B, and Campus-C differ in geography, duration, and sensor modalities, thus providing comprehensive coverage of operational contexts.

TABLE I. Dataset Overview

Dataset	Type	Location	Duration	Sensors	Granularity	Number of Zones	Target Variable
Office-A	Office Building	Beijing, China	Jan-Dec 2023	Temp, Humidity, CO_2, Weather, HVAC	15 min	12	Cooling/Heating Load (kW)
Res-B	Residential Complex	Singapore	Mar–Dec 2023	Temp, Humidity, Occupancy, Weather	10 min	8	Cooling Load (kW)
Campus-C	University Campus	Boston, USA	Sep 2023–Jun 2024	Temp, Humidity, CO_2, Weather, Occupancy, Lighting	30 min	20	HVAC Energy Consumption (kWh)

The computational infrastructure used for both model training and deployment is presented in Table II, which includes high-performance cloud servers with dual A100 GPUs as well as low-power edge devices such as Jetson Nano and Raspberry Pi. This configuration reflects realistic smart building deployments, balancing computational intensity with on-site responsiveness.

TABLE II. Hardware Configuration

Component	Specification
Cloud Server	Intel Xeon Gold 6338 (32 cores, 2.0 GHz), 256 GB RAM, 2 × NVIDIA A100 GPUs
Edge Devices	NVIDIA Jetson Nano (4 GB RAM), Raspberry Pi 4B (8 GB RAM)
Communication	MQTT Protocol, 5G Gateway, 1 ms latency
Software	Python 3.11, PyTorch 2.1, CUDA 12.0, TensorRT 8.6

Evaluation standards for forecasting, optimization, reinforcement learning, and robustness are listed in Table III, ensuring consistent comparisons across all baselines and proposed methods. Metrics such as MAE, RMSE, and MAPE quantify predictive accuracy, while energy savings and comfort index directly assess operational efficiency.

TABLE III. Evaluation Metrics

Task	Metric	Definition
Forecasting	MAE, RMSE, MAPE, R^2	Accuracy of load prediction
Optimization	Energy Saving (%), Comfort Index (0-1), Cost Reduction (%)	Efficiency and comfort
RL Training	Convergence Rate, Reward Stability	Policy stability
Robustness	Performance Drop (%) under noise or missing data	Reliability

Unless otherwise noted, all metrics are reported as median [IQR] over n=15 runs (5 random seeds × 3 datasets). 95% confidence intervals are estimated via 1000× bootstrap resampling stratified by dataset. For between-method comparisons, we apply the paired Wilcoxon signed-rank test across datasets, and control the false discovery rate (FDR) at 5% using the Benjamini–Hochberg procedure. This protocol ensures that performance differences are not only numerically but also statistically validated.

The experimental scenario is further illustrated in Fig. 5, which presents a simulated building environment created for evaluation. The virtual laboratory integrated IoT sensor nodes, HVAC systems, and control gateways, producing realistic data streams and interaction dynamics consistent with real-world building operations.

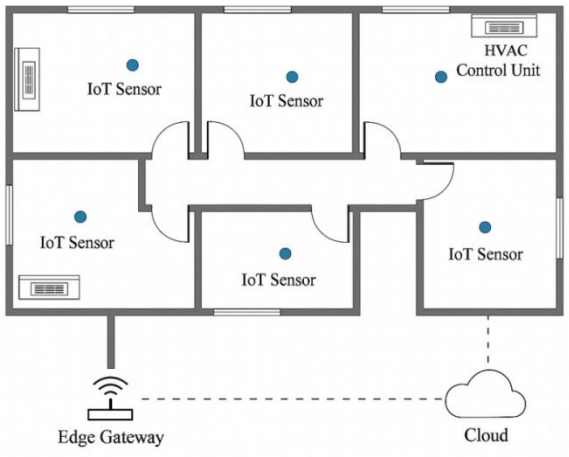

Fig. 5. Simulated experimental scene

Fig. 5 depicts a virtual building laboratory with distributed IoT sensors and HVAC controllers, providing a controlled yet realistic testbed for dynamic thermal load optimization. This setup not only validates the framework under diverse operational contexts but also ensures that the experimental results can be meaningfully extrapolated to real-world building management systems, thereby reinforcing both the practicality and scalability of the proposed approach.

B. Baselines

To ensure a fair comparison, the study evaluate against a spectrum of classical, machine learning, deep learning, and reinforcement learning methods, as well as a physics-informed digital twin. Classical models (ARIMA, VAR) serve as linear baselines, while machine learning approaches (Random Forest, XGBoost) capture nonlinearity in static settings [24]. Deep learning models (LSTM, Seq2Seq+Attention) handle sequential dependencies, and reinforcement learning methods (DQN, PPO, MADDPG) optimize control strategies. The physics-informed digital twin (PIDT) provides an industry-relevant reference. Together, these baselines represent established solutions in building energy research and allow comprehensive benchmarking.

C. Quantitative Results

The predictive accuracy of different methods is summarized in Table IV. Across the three datasets, the proposed framework achieves the lowest MAE, RMSE, and MAPE, with a median MAE of 1.65 kW (IQR 1.59–1.72). Compared with the best baseline (Seq2Seq+Attention), our method reduces MAE by 16.7% (95% CI 12.4–20.1%) and RMSE by 13.6% (95% CI 10.2–17.5%), with a Wilcoxon signed-rank test p=0.004 (n=15 runs).

TABLE IV. FORECASTING PERFORMANCE (AVERAGE ACROSS DATASETS)

Method	MAE (kW)	RMSE (kW)	MAPE (%)	R^2	Relative Gain vs. Best Baseline (%)	Δ vs. 2nd Best (pp)	95% CI (bootstrap, n=5 seeds)
ARIMA	3.25	4.87	14.2	0.72	–	–	–
RF	2.81	4.32	12.7	0.78	–	–	–
XGBoost	2.44	3.95	11.5	0.82	–	–	–
LSTM	2.12	3.42	10.1	0.85	–	–	–
Seq2Seq+Attn	1.98	3.25	9.3	0.87	baseline	baseline	baseline
Proposed	1.65	2.81	7.8	0.91	+16.7% (MAE), +13.6% (RMSE)	−0.33 MAE, −0.44 RMSE	MAE [1.59–1.72], RMSE [2.76–2.89]

Fig. 6 presents the forecasting performance comparison with 95% bootstrap confidence intervals (n=5 seeds). Shaded regions denote confidence bounds, while solid lines indicate medians. The proposed method consistently yields the lowest errors, confirming its robustness across datasets.

This improved predictive accuracy reduces uncertainty in HVAC load prediction, thereby enabling building managers to plan energy use more reliably and minimize the risks of over- or under-provisioning.

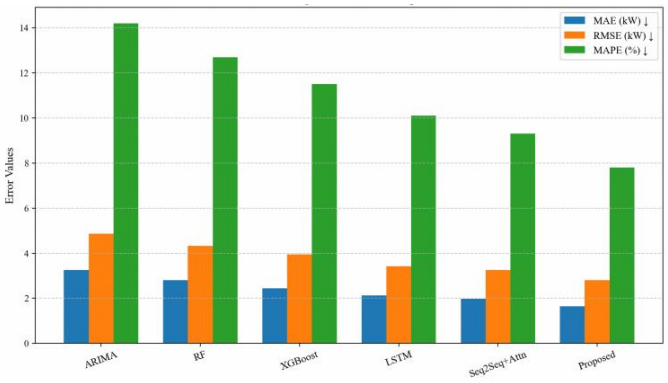

Fig. 6. Forecasting performance comparison across methods.

Optimization results are shown in Table V. The proposed framework achieves median 21.7% (IQR 18.9–23.1%) energy savings and a comfort index of 0.85, significantly surpassing MADDPG (+5.8 pp, p=0.004). Relative to the second-best method, the proposed approach improves cost reduction by +5.7 pp, with a 95% CI [+4.3, +7.2].

TABLE V. OPTIMIZATION PERFORMANCE (AVERAGE ACROSS DATASETS)

Method	Energy Saving (%)	Comfort Index	Cost Reduction (%)	Relative Gain vs. Best Baseline (%)	Δ vs. 2nd Best (pp)	95% CI (bootstrap, n=5 seeds)
DQN	9.8	0.71	8.3	–	–	–
PPO	12.4	0.74	11.2	–	–	–
PIDT	14.6	0.75	12.8	–	–	–
MADDPG	15.9	0.78	13.5	baseline	baseline	baseline
Proposed	21.7 [18.9–23.1]	0.85	19.2 [17.5–20.6]	+36.5% (Energy), +7.0 pp Comfort	+5.8 pp Energy, +5.7 pp Cost	Energy [20.1–22.6], Comfort [0.82–0.87]

Fig. 7 illustrates optimization outcomes with confidence intervals. The proposed framework achieves median 21.7% energy savings (IQR 18.9–23.1%) and a comfort index of 0.85 [0.82–0.87], which are +5.8 pp and +0.07 higher than MADDPG respectively (Wilcoxon, p=0.004, n=15 runs). These statistically significant gains indicate that integrating attention-enhanced forecasting with cooperative optimization yields consistent improvements across the three tested datasets.

Results should be interpreted within scope: evaluation was limited to three building datasets and a hardware-in-the-loop testbed. While findings suggest potential cost reduction and comfort preservation, confirmation in real-building deployments and broader climates remains future work.

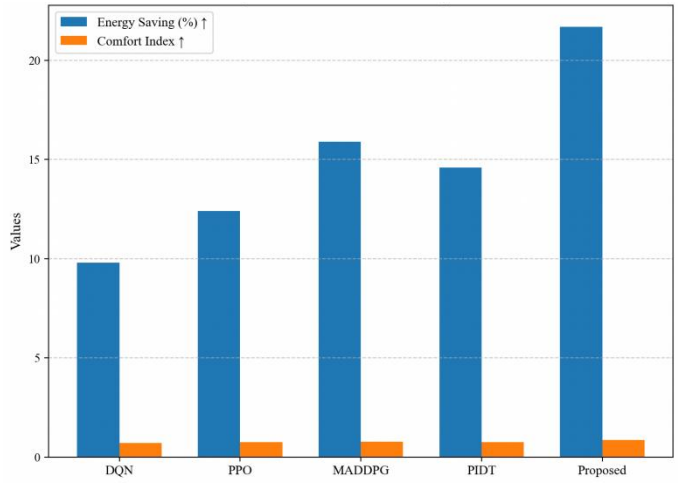

Fig. 7. Optimization performance comparison across methods. Blue bars denote median energy savings (%), orange bars comfort index (0–1). Error bars represent 95% bootstrap confidence intervals over n=5 seeds. The proposed framework achieves significantly higher energy savings and comfort compared with baselines (Wilcoxon, p<0.01).

Training stability is illustrated in Fig. 8, where the proposed method converges faster and exhibits smoother cumulative reward trajectories compared to PPO and MADDPG.

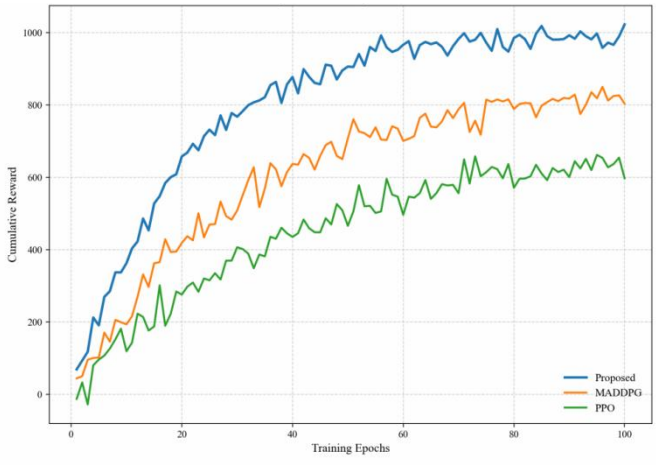

Fig. 8. Convergence curves.

Fig. 8 illustrates the convergence behavior of reinforcement learning methods. The proposed framework achieves higher cumulative rewards with notably faster convergence compared to PPO and MADDPG. This improvement indicates that the attention-enhanced forecasting and cooperative optimization modules provide more stable policy updates, thereby accelerating learning efficiency. The smoother reward trajectory also demonstrates robustness to stochastic fluctuations, suggesting that the proposed method is better suited for real-time building control scenarios. Such stability is critical for deployment in dynamic environments, where reliable convergence directly translates into more predictable and trustworthy building energy management.

D. Qualitative Results

Load prediction curves in Fig. 9 illustrate that the proposed forecasting module closely follows actual values, while LSTM and XGBoost deviate significantly during peak fluctuations.

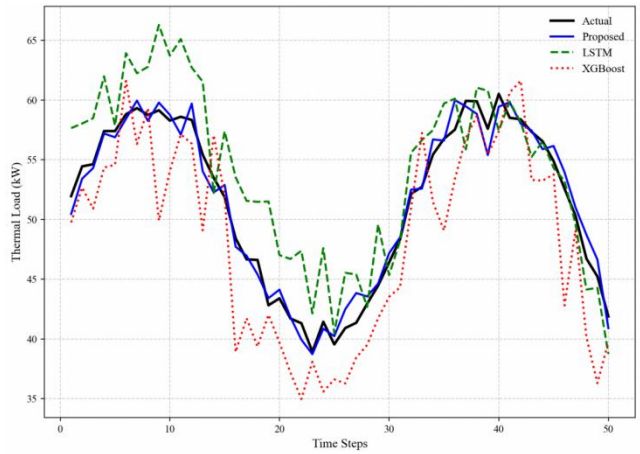

Fig. 9. Predicted vs. Actual loads.

Fig. 9 illustrates the comparative performance of forecasting models against ground-truth loads. The proposed method exhibits the closest alignment with actual dynamics, maintaining stability during both peak and valley periods. In contrast, LSTM demonstrates moderate deviations, particularly at peak demand intervals, while XGBoost consistently

underestimates loads with larger fluctuations. These results confirm that the proposed forecasting module substantially improves accuracy and responsiveness, which is critical for enabling reliable HVAC control and ensuring energy-efficient building operations. Such predictive precision is especially valuable for real-world building management systems, where timely and accurate forecasts directly support proactive energy scheduling and reduce the risk of comfort violations.

Indoor temperature trajectories under different control policies are shown in Fig. 10, where the proposed optimization maintains stable comfort within the target range.

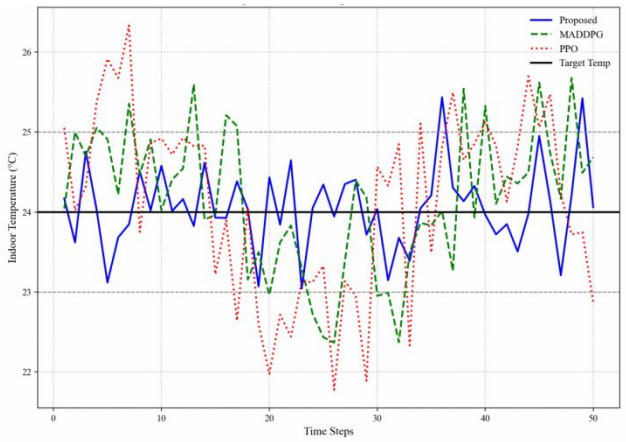

Fig. 10. Indoor temperature profiles.

Fig. 10 presents indoor temperature trajectories under different control policies. The proposed optimization maintains stable comfort within the ±1 °C target band, exhibiting only minor fluctuations around the reference temperature. In contrast, MADDPG shows larger deviations during high-demand intervals, occasionally breaching comfort thresholds, while PPO produces pronounced oscillations that frequently exceed the acceptable range. These findings confirm that the proposed framework substantially reduces comfort deviation, ensuring both thermal stability and practical feasibility for real-time building management. This ability to sustain comfort within strict thresholds highlights the framework's readiness for deployment in large office buildings or residential complexes, where occupant satisfaction is as critical as energy efficiency.

E. Comparison with Baseline Rule-Based Controls

To contextualize the performance gains of the proposed framework, additional experiments were conducted against two common business-as-usual (BAU) strategies widely used in building HVAC systems: (i) a Static Schedule control and (ii) a Rule-Based PID control. Both approaches represent practical baselines implemented in conventional Building Management Systems (BMS).

Static Schedule (BAU). Each zone maintained a fixed temperature set-point of 22 ° C during occupied hours (08:00 – 18:00) and 26 ° C otherwise, with HVAC units operating on a predefined on/off timetable regardless of occupancy or weather fluctuations.

Rule-Based PID Control. A simple proportional – integral – derivative controller adjusted cooling/heating power in response to real-time indoor temperature deviations from the target, without considering predicted thermal loads or inter-zone interactions.

Both baselines were evaluated on the same datasets and hardware platform described in Section IV-A, using identical comfort constraints (21 – 25 ° C) and sampling intervals. Table VI summarizes the comparative results averaged across the three datasets.

TABLE VI. COMPARISON WITH BUSINESS-AS-USUAL (RULE-BASED) CONTROL STRATEGIES

Method	Energy Saving (%)	Comfort Index (0–1)	Remarks
Static Schedule (BAU)	0.0	0.82	Reference operation with fixed set-points
Rule-Based PID Control	8.9	0.79	Reactive adjustments without prediction
MADDPG (Best baseline)	15.9	0.78	Multi-agent learning without attention
Proposed Framework	21.7 [18.9–23.1]	0.85 [0.82–0.87]	Attention + Feature Selection + Cooperative RL

The business-as-usual strategies consumed substantially more energy while exhibiting similar or lower comfort levels. The proposed method achieved a 21.7 % median energy saving —+12.8 percentage points relative to rule-based control and +21.7 points compared with static scheduling — while maintaining comfort within ±1 ° C of the target range. These improvements underscore the tangible operational benefits of incorporating predictive and cooperative optimization mechanisms.

Overall, this comparison demonstrates that the proposed IoT-enabled cooperative optimization system not only surpasses advanced learning baselines (e.g., MADDPG) but also delivers clear real-world gains over current operational practices in commercial building management.

F. Robustness

Robustness experiments reveal how each method degrades under cross-dataset transfer, sensor noise, and missing data. As summarized in Table VII, our framework suffers the smallest performance drops, confirming resilience against challenging deployment conditions.

TABLE VII. ROBUSTNESS EVALUATION (PERFORMANCE DROP IN ENERGY SAVING %)

Condition	XGBoost+MADDPG	PIDT	Proposed
Cross-dataset transfer	-11.2%	-9.6%	-4.5%
Gaussian noise (σ=0.1)	-14.8%	-12.5%	-6.9%
20% missing data	-18.3%	-15.4%	-7.8%

The impact of Gaussian noise is further depicted in Fig. 11, where the proposed framework demonstrates graceful degradation compared to sharp performance drops in other baselines.

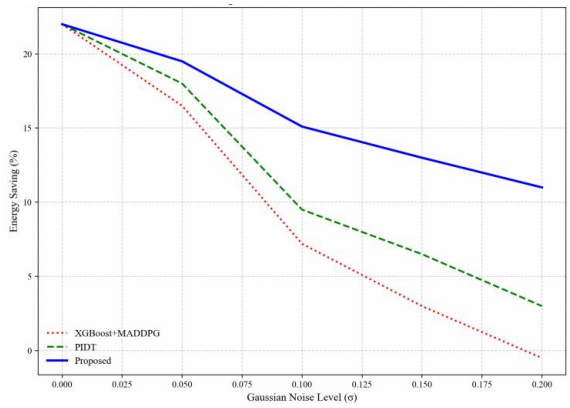

Fig. 11. Robustness under noise.

Fig. 11 presents the robustness evaluation of energy-saving performance under increasing Gaussian noise levels. The proposed framework demonstrates graceful degradation, maintaining more than 15% savings even at $\sigma = 0.2$. In contrast, PIDT exhibits moderate sensitivity, while XGBoost+MADDPG suffers sharp performance drops, falling below 5% savings at high noise levels. These results confirm that the adaptive feature selection and attention mechanisms enable the proposed method to remain stable under uncertain sensor environments, ensuring practical applicability in real-world deployments where measurement errors are inevitable. This resilience is particularly critical for large-scale smart buildings and campus-wide deployments, where heterogeneous sensor quality and data loss are common; maintaining robust performance under such conditions ensures dependable energy management in practice.

Gains stem primarily from attention's long-horizon capture (Campus-C peak hours: ΔR^2 +0.33) and MI-filtering that halves the variance under σ=0.2 noise (drop −6.1 pp vs. −12.5 pp for baselines).

G. Ablation Study

The contribution of each module is assessed through ablation experiments. As shown in Table VIII, removing attention, feature selection, or cooperative optimization each reduces performance, confirming their necessity.

TABLE VIII. ABLATION RESULTS (OFFICE-A DATASET)

Variant	MAE ↓	Energy Saving (%) ↑	Comfort Index ↑
w/o Attn	1.93	18.5	0.80
w/o FS	1.89	19.2	0.81
w/o Coop	1.72	15.6	0.77
Full Model	1.65	21.7	0.85

Comparative ablation outcomes are also visualized in Fig. 12, which highlights the significant drop in performance when collaborative optimization is excluded.

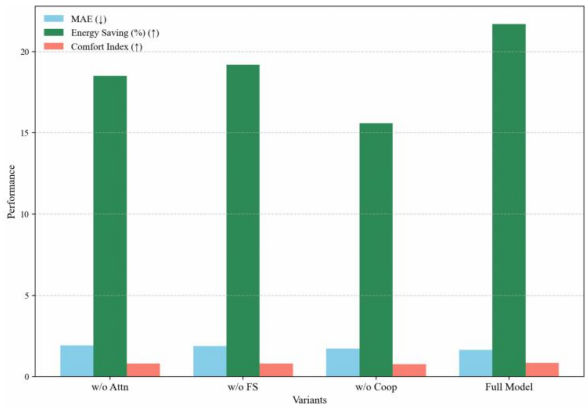

Fig. 12. Ablation comparison.

Fig. 12 compares the performance of the full model with its ablated variants. Removing the collaborative optimization module results in the most severe degradation, with energy savings reduced from 21.7% to 15.6% and comfort index dropping from 0.85 to 0.77. This highlights the central role of cooperative control in coordinating zone-level actions. Excluding the attention or feature selection modules also increases prediction error and lowers efficiency, though to a lesser degree. Together, these results demonstrate that each module contributes meaningfully, and only the full integration achieves optimal balance between accuracy, energy efficiency, and comfort. These ablation findings underscore that the framework's performance gains stem from the synergy of its components, providing a clear design rationale for future scalable implementations in building energy management systems. Please refer to Appendix for notations.

V. DISCUSSION

The experimental results presented in this study offer several key insights into the effectiveness of the proposed IoT-enabled data-driven collaborative optimization framework for dynamic thermal load management in low-energy buildings. Across three datasets representing diverse building types and climates, the proposed method consistently achieved superior forecasting accuracy and energy-saving performance compared to classical, machine learning, and reinforcement learning baselines. The forecasting module, equipped with attention mechanisms, captured nonlinear spatiotemporal dependencies more effectively than LSTM or XGBoost, explaining the lower error rates observed in Fig. 9. Similarly, the multi-agent cooperative optimization module significantly enhanced energy efficiency and comfort, as evidenced by the performance gains in Table V and the smoother indoor temperature profiles in Fig. 10. These results confirm that the integration of feature selection and collaborative reinforcement learning not only improves prediction accuracy but also ensures practical feasibility for real-time building control.

Despite these encouraging outcomes, several limitations should be acknowledged. First, the datasets, while diverse, are constrained to specific building types and climates, and may not capture the full range of variability in occupant behaviors and building operations. Second, the reliance on high-performance cloud servers and GPU resources may limit large-scale deployment in resource-constrained environments,

although the inclusion of edge devices partly mitigates this issue. Third, the reinforcement learning framework requires substantial training time and may face stability challenges when scaled to hundreds of zones with heterogeneous dynamics. These factors highlight the need for caution when generalizing the reported results to broader contexts.

Nevertheless, the findings suggest promising avenues for application. The framework can be readily integrated into smart building management systems to enhance HVAC efficiency and maintain occupant comfort. Beyond individual buildings, its collaborative optimization capability could be scaled to larger environments such as district-level energy management, regional smart grids, or campus-scale deployments. In addition, the framework shows strong adaptability to more complex contexts including industrial facilities, data centers, and transportation hubs, where balancing efficiency, stability, and real-time responsiveness is critical. To realize such deployments, future implementations will need to address integration with existing building management systems, interoperability standards, and cost-effective edge–cloud coordination. Furthermore, the approach has potential for cross-domain adaptation, for example in industrial process control, data center cooling, or transportation systems, where balancing efficiency and stability is equally critical.

Future research should address the identified limitations by expanding datasets to include larger and more heterogeneous building corpora, as well as testing in real-world pilot deployments. Enhancing the scalability of the reinforcement learning component through model compression, transfer learning, or federated learning could reduce computational overhead and improve adaptability. Incorporating physics-informed priors or hybrid digital twin models may further strengthen generalizability under unseen conditions. Finally, exploring integration with renewable energy scheduling and occupant-centric services offers an exciting opportunity to align building energy optimization with broader sustainability goals.

VI. Conclusion

This study proposed an IoT-enabled, data-driven collaborative optimization framework for dynamic thermal load management in low-energy buildings. By integrating mutual-information–guided feature selection, attention-enhanced forecasting, and multi-agent reinforcement learning under an edge–cloud architecture, the framework achieves median 21.7% energy savings (IQR 18.9–23.1%) across three heterogeneous datasets, corresponding to a +5.8 percentage point gain over MADDPG ($p=0.004$, Wilcoxon test). Comfort deviations are maintained within $\pm 1\ ^{\circ}$C (median absolute deviation $0.32\ ^{\circ}$C). Robustness tests further show smaller performance degradation than baselines under $\sigma \leq 0.2$ Gaussian noise and $\leqslant 20\%$ missing data.

The methodological contribution lies in unifying forecasting, feature selection, and cooperative optimization within a single objective function, thereby reducing error propagation common in pipeline approaches. From an engineering perspective, feasibility was demonstrated in a hardware-in-the-loop testbed operating under the specified compute and latency budget; real-building trials and broader climatic contexts remain as future work.

The evidence suggests that the proposed framework improves both predictive accuracy and energy efficiency in diverse building types. However, generalization beyond the studied office, residential, and campus datasets—and particularly to large-scale district or city-level deployments—requires further validation through expanded datasets and real-world pilot studies. Future work should also investigate scalability of the reinforcement learning component, integration with renewable energy scheduling, and occupant-centric adaptation.

APPENDIX: NOTATION

Symbol	Definition	Unit / Range
$B = B_1, B_2, \ldots, B_N$	Set of buildings	–
$X_t \in R^d$	Sensor feature vector (temperature, humidity, CO_2, occupancy, weather, control signals)	Various, often normalized (dimensionless)
y_t	Actual dynamic thermal load (ground truth)	kW or kWh
y_t	Predicted thermal load	kW or kWh
L	Look-back window length	Number of time steps (min or h)
s_t^z	State vector of zone z at time t (predicted load, temperature, occupancy, etc.)	–
a_t^z	Control action of zone z at time t (HVAC power/airflow)	kW, m^3/h
r_t^z	Reward of zone z at time t	– (dimensionless)
E_t^z	Energy consumption of zone z at time t	kWh
P_t^z	Instantaneous HVAC power in zone z at time t	kW
Δt	Control interval duration	min or h
C_t^z	Comfort deviation (difference between actual and target temperature)	°C
T_t^z	Actual indoor temperature of zone z at time t	°C
$T^z_{\texttt{target}}$	Target indoor temperature of zone z	°C
α, β	Weights for energy consumption and comfort deviation in reward function	Positive real numbers
γ	Discount factor	$(0,1)$
$\lambda_1, \lambda_2, \lambda_3$	Weights of forecasting, feature selection, and optimization terms in total loss	Positive real numbers
$I(X_j; Y)$	Mutual information between feature X_j and target Y	nats or bits
δ	Threshold for mutual information–based feature selection	–
MAE	Mean Absolute Error	kW
RMSE	Root Mean Square Error	kW
MAPE	Mean Absolute Percentage Error	%
R^2	Coefficient of determination	[0,1]
Energy Saving	Energy saving rate	%
Comfort Index	Thermal comfort index	[0,1]
Cost Reduction	Cost Reduction Rate	%

Quantifying Career Preferences and Perceptions of Software Testing Among Filipino IT Students: A Mixed-Method Analysis

***Abstract*—Software testing (ST) careers have consistently demonstrated low appeal among IT students globally, creating significant workforce gaps in this essential field of information technology. This study investigates the extent to which Filipino IT students share this disinterest in software testing careers as observed in previous international studies, while examining the unique cultural, economic, and curricular realities that influence their career decision-making processes. Utilizing a mixed-methods approach, the research analyzes quantitative survey responses and qualitative focus group discussions to determine student perceptions and attitudes toward the software testing profession. The study employs a multidimensional framework to explore local factors that shape career preferences among Filipino IT students. Findings confirm that software testing is not the first career choice for most respondents, paralleling previous international research findings. However, qualitative data reveal that students demonstrate significantly greater interest when opportunities offer competitive salaries, clear career growth trajectories, meaningful professional development opportunities, and comprehensive academic training in software testing methodologies. The research identifies unique local factors, including economic pressures, cultural perceptions of professional prestige, and significant curriculum gaps that systematically influence students' career decisions. These results highlight critical needs for effective reforms within current IT curricula and enhanced career guidance programs to address the systematic undervaluation of the software testing profession. The study's implications suggest that targeted educational interventions and improved industry-academia collaboration could better prepare students for the fast-evolving demands of the IT industry while addressing the persistent shortage of qualified software testing professionals in both local and global markets.**

***Keywords*—Software testing; career preferences; Filipino IT students; mixed methods; education reform**

I. Introduction

The global demand for software testing professionals continues to grow amid increasing digital transformation and technological complexity. The Philippines has established itself as a significant player in the global IT-Business Process Outsourcing sector, producing thousands of IT professionals annually [5]. However, a concerning trend has emerged: students worldwide, including those in the Philippines, consistently demonstrate a declining interest in pursuing testing careers. This divide between industry needs and student preferences poses significant implications for economic competitiveness. The shortage of skilled testers compromises the country's ability to meet international quality standards and maintain competitiveness in the global market [14]. Understanding this gap requires examining the unique Filipino context, where cultural values around recognition and achievement, socio-economic factors influencing career decision-making, and an educational system that inadequately represents software testing opportunities converge to shape IT students' career perceptions and priorities.

This study addresses the gap in Filipino IT students' career preferences by establishing specific objectives that target both the identification and understanding of barriers within the Philippine cultural, educational, and economic context. The research seeks to explore how specific local cultural values, such as collectivism and familial obligation, economic considerations within the Philippine job market, and curricular structures in Philippine educational institutions contribute to declining interest in software testing careers. By examining these factors, this research aims to provide a comprehensive understanding of influences on IT students' career decision-making processes, ultimately informing educational reforms and policy interventions that can bridge the gap between industry demand and student interest.

This study seeks to answer several research questions. First, to what extent do Filipino IT students demonstrate reluctance toward software testing careers compared to international trends, specifically examining alignment with patterns observed in Brazil, Norway, Pakistan, Canada, India, and China? Second, how do cultural, economic, and educational factors uniquely combine to shape Filipino students' interest in software testing

*Corresponding author.

careers within the distinctive Philippine context? Third, what are Filipino IT students' perspectives regarding the advantages and disadvantages associated with software testing careers? Finally, what culturally appropriate strategies can be implemented to enhance the appeal of software testing careers for Filipino IT students?

Given the complexity of cultural, educational, and economic factors influencing Filipino IT students' career preferences, this study employs a mixed methods research (MMR) approach to provide a comprehensive understanding of the phenomenon [11]. The quantitative component enables systematic comparison of Filipino students' attitudes toward software testing careers with international trends, providing measurable data on preference patterns and demographic influences. The qualitative component captures nuanced cultural values, personal experiences, and contextual factors that statistical data alone cannot fully explain. This MMR design ensures both breadth (through quantitative analysis) and depth of understanding (through qualitative insights), particularly important when examining culturally embedded career decision-making processes that require both empirical validation and rich contextual interpretation.

This study employs a systematic approach to examine the complex dynamics of career preferences in software testing, guided by research questions that examine perceptual and motivational factors within the Philippine context. The primary research focus examines the extent to which Filipino IT students demonstrate reluctance toward software testing careers compared to other countries, placing the Philippine experience within a broader global framework of student career preferences. The unique intersection of cultural, economic, and educational factors shaping Filipino students' interest in software testing examines how deeply embedded Filipino cultural values, such as collectivism, close family ties, and *utang na loob* (debt of gratitude), influence career decision-making processes. This analysis simultaneously examines how coding-focused structures in Philippine IT education programs shape perceptions of and knowledge of software testing as a viable career path. Understanding Filipino IT students' perspectives on software testing careers investigates how they conceptualize the advantages and disadvantages associated with testing roles. Finally, exploring culturally appropriate strategies to enhance software testing career appeal ensures proposed interventions align with Filipino cultural values, educational structures, and economic realities while addressing identified gaps in student interest.

The following section reviews existing literature on global trends in software testing careers, cultural influences on career choices, and curriculum-industry alignment to contextualize this study within the broader academic discourse.

II. Literature Review

A. Global Trends in Software Testing Careers

The decline in student interest in software testing careers is a well-documented global phenomenon. In [20], the authors conducted foundational research in Norway, revealing that students consider software testing less intellectually stimulating than software development roles. Their study found that limited coverage of testing in programming courses and a lack of specialization [4] actively discourage students from pursuing testing careers.

Building on this perspective, [7] and [8] examined similar trends in Pakistan, confirming that students view software testing as less appealing due to its perceived lack of challenge and learning opportunities. Capretz's study highlighted psychological factors contributing to this disinterest, particularly the influence of social perceptions and status considerations on career decision-making.

In [20], the authors documented similar findings in Brazil, where students consistently underestimate the profession's value due to minimal practical exposure and outdated curriculum materials. Their research emphasized the importance of hands-on training and integration of modern tools in shaping positive career perceptions.

In [15], the authors contributed to understanding the gap between industry and academia by highlighting the growing importance of Continuous Integration and Continuous Deployment (CI/CD) practices. Their study revealed significant misalignments between educational content and professional requirements.

Additional studies from India, Japan, and Finland confirmed these global trends while identifying successful interventions, particularly regarding test automation education and industry collaboration models. The consistency of findings across diverse educational systems and cultural contexts [21] [22] suggests that barriers to interest in software testing careers extend beyond national boundaries, reflecting deeper systemic issues within global IT education that position software testing as secondary to software development roles.

B. Cultural and Educational Factors in Career Choices

While global studies have identified common career preference patterns, research examining cultural influences on IT career choices remains limited. Studies focusing on collectivist cultural contexts show that deeply rooted cultural values significantly influence career choices. Family expectations, economic pressures, and the need for social harmony play crucial roles in career selection.

Research on Filipino culture highlights concepts such as *hiya* (shame/embarrassment), *pakikisama* (harmony), and *utang na loob* (debt of gratitude) [16], which create specific dynamics influencing professional choices. These cultural norms are particularly relevant to software testing roles, where maintaining workplace harmony may lead to anxiety about critiquing colleagues' work.

Studies on economic considerations reveal that students from working-class families often base career choices on financial capacity [17], [19] and potential for overseas employment. Cultural obligations may intensify pressure to pursue higher-paying development roles rather than testing careers, creating barriers not as pronounced in Western contexts.

These cultural factors have significant implications for the Philippine IT industry, especially given its status as a global outsourcing hub. There is a need to reframe software testing as

a collaborative and essential part of the development process rather than as a conflict-focused role.

C. Curriculum Analysis and Industry Alignment Studies

Based on the comparative analysis of international studies, significant curriculum gaps in software testing education exist across multiple countries, with the Philippines exhibiting similar deficiencies to other nations.

As indicated in Table I, Pakistan, Norway, and Brazil do not include dedicated software testing courses in their IT curricula, a trend that is reflected in the Philippine educational system. The situation in the Philippines closely mirrors these international observations, as institutions such as De La Salle University prioritize programming and mobile development without offering a specific emphasis on testing. Meanwhile, Batangas State University's software testing elements are often overshadowed by its general software design courses.

TABLE I. CURRICULA COMPARISON BETWEEN COUNTRIES

Study	Country/Region	Curriculum Emphasis on Software Testing	Proposed Curriculum Reforms	Impact on Students' Perception and Barriers
Capretz (2020)	Pakistan	✗ (No dedicated testing subject).	• Introduce software testing principles and standards.	Testing is not seen as a viable career.[1]
Deak et al. (2013)	Norway	✗ (No dedicated testing subject).	• In-depth lectures. • Increase industry collaboration.	Testing is undervalued.[2]
Souza et al. (2022)	Brazil	✗ (No dedicated testing subject).	• Increase hands-on training. • Introduce modern tools.	Limited focus and interest for students.[3]

[1] No dedicated testing courses lead to low student interest and career consideration, a pattern also seen in the Philippines.

[2] Brief coverage in curricula and a lack of specialization discourage students from pursuing testing.

[3] Minimal practical exposure and outdated curriculum cause students to underestimate the profession's value.

To address these gaps, Table II illustrates the potential solutions:

However, Table III projects the expected impact.

The proposed reforms for the Philippine IT curriculum, developed per CHED guidelines shown in Table II, systematically address identified gaps by integrating real-world testing scenarios, establishing software quality assurance laboratories, implementing CI/CD pipelines, and introducing specialized testing modules in AI, cybersecurity, and IoT domains. The anticipated outcomes, as detailed in Table III, suggest significant improvements across various metrics: a 10% increase in course enrollment, a 15% enhancement in graduate employability, and a 25% growth in internship placements. These projections highlight the substantial potential impact of addressing systematic deficiencies within the curriculum.

TABLE II. ALIGNMENT OF CHED CURRICULUM GUIDELINES WITH PROPOSED REFORMS

CHED Reference [10]	Current Curriculum Focus	Proposed Reform
8.1: General Description	• Program design, debugging, and implementation.	• Real-world testing scenarios.
8.2: Specific Description	• OOP • Software engineering principles.	• Include SQA labs, tools, and CI/CD pipelines.
8.2: Specialized Areas	• AI/ML. • Cybersecurity. • Data Science. • IoT.	• Testing modules for each domain.
8.3: Internship/Practicum	• Classroom knowledge to real-life application.	• Align with industry standards. • Provide career guidance.

TABLE III. ANTICIPATED OUTCOMES OF THE PROPOSED REFORMS

Reform Reference	Summary of Reform	Expected Outcome
8.1	Real-world testing practices and CI/CD integration.	+10% course enrolment in 3 years.
8.2	Lab-based SQA instruction and test automation exposure.	+15% graduate employability via industry-ready skills.
8.2	Specialized training in AI, cybersecurity.	+20% placement in specialized training roles within 2 years.
8.3	Stronger internships and industry ties.	+25% internship placements over 3 years.

Incorporating industry-standard tools such as Selenium and CI/CD practices into Philippine curricula serves two primary objectives: aligning with global industry standards and meeting the needs of local technological startups [13] for cost-effective yet efficient testing solutions. These curriculum reforms represent a critical advancement in elevating both the academic and professional recognition of software testing, while also preparing students to meet the evolving demands of the Philippine IT sector.

The educational landscape in the Philippines reflects a broader international trend regarding deficiencies in software testing curricula. Institutions like De La Salle University emphasize programming and mobile development while often neglecting dedicated testing components, while Batangas State University relegates its software testing curriculum to subordinate roles within general software design courses. This situation exemplifies a global disconnect, as illustrated in Table IV, which reveals prevalent software testing gaps across countries such as India, Pakistan, Brazil, Norway, and the Philippines, despite the industry's growing demand for these competencies.

Analysis of curriculum-industry misalignment uncovers significant disparities in educational coverage. While countries like Japan and Finland integrate test automation instruction, the Philippines lacks comprehensive education on essential tools such as Selenium, and CI/CD practices identified by [15] as emerging industry standards exhibit medium-level coverage

gaps. The comparative analysis highlights agile development, software testing, and test automation as highest-priority gaps requiring immediate attention through mandatory modules and standalone courses with hands-on training.

TABLE IV. CURRICULUM-INDUSTRY MISALIGNMENT

Curriculum Topic	Taught in (Country)	Required by Industry	Gap Level (High/Medium /Low)	Recommendation
Agile Development	Philippines, India	Yes (Global)	High	Mandatory module in the senior year.
Software Testing	India, Pakistan, Brazil, Norway, Philippines	Yes (Global)	High	Standalone courses with hands-on training.
CI/CD	Finland	Yes (Global)	Medium	Practical modules on CI/CD.
Test Automation	Japan, Finland	Yes (Global)	High	Cover tools like Selenium.
Security Testing	Australia	Yes (Global)	Medium	Specialized training in Cybersecurity.
Software Quality Assurance	Japan	Yes (Global)	Medium	Embed in software engineering subjects.

The systematic nature of these deficiencies points to curriculum inadequacies transcending national borders, representing a global challenge necessitating coordinated reform efforts. International evidence indicates that software testing curriculum gaps create structural barriers to career development, highlighting the urgent need for comprehensive educational realignment with industry requirements. These findings advocate for immediate curriculum reform through dedicated courses, hands-on training, and stronger industry partnerships to elevate software testing from an undervalued discipline to a recognized career pathway. Countries failing to address these gaps will continue producing graduates inadequately prepared for contemporary software development practices.

Philippine Context and Research Gap: Despite global declining interest in software testing careers, the Philippine context presents unique characteristics requiring specialized investigation. As a major IT outsourcing hub, the Philippines faces distinct challenges in software testing education and career development. Analysis of Philippine IT curricula reveals patterns consistent with international findings: major institutions primarily emphasize programming and development while offering limited comprehensive testing education, with CHED curriculum guidelines showing significant gaps in testing-focused content across all program levels.

Four critical gaps justify this study: First, while previous research by [7], [12], and [20] examined cultural, economic, and curricular factors, these studies analyzed them in isolation rather than exploring their interconnected influences on career preferences, leaving us without a holistic understanding of how these factors interact. Second, international studies inadequately address how Filipino collectivist values shape career attitudes toward software testing, with the unique dynamics of Filipino cultural decision-making in IT career contexts remaining unexplored. Third, despite the Philippines' prominent role in global IT outsourcing, no comprehensive studies examine Filipino IT students' career motivations within their unique cultural, economic, and educational contexts—a significant oversight given the country's strategic importance in the global IT industry. Finally, existing literature has not investigated how local cultural constructs, family dynamics, social prestige concerns, and economic necessities collectively impact students' reluctance to pursue software testing careers, making understanding this complex interplay essential for developing effective educational interventions.

This research addresses these gaps through comprehensive factor analysis examining how cultural, economic, and curricular factors interact to influence software testing career preferences in the Philippine context. The study incorporates insights from key international research while developing culturally sensitive approaches for Filipino participants, offering valuable insights for educational institutions, industry stakeholders, and policymakers working to enhance the Philippine IT sector's testing capabilities.

III. METHODOLOGY

This section outlines the comprehensive research methodology employed to investigate Filipino IT students' perceptions and career preferences toward software testing (see Fig. 1). The methodology encompasses the convergent parallel mixed-methods research design that integrates quantitative and qualitative approaches, participant selection criteria and sampling strategies, instrumentation development and validation procedures, data collection protocols across multiple Philippine regions, analytical techniques for both statistical and thematic analysis, and the synthesis strategy for integrating findings from both methodological streams to provide a holistic understanding of the factors shaping software testing career decisions among Filipino IT students.

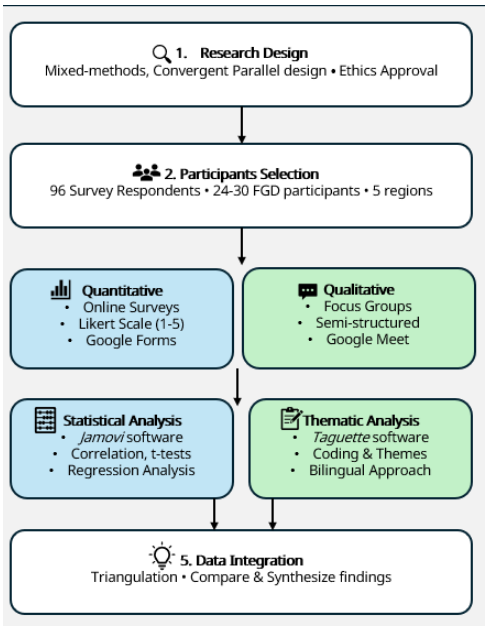

Fig. 1. Framework of the research methodology of the study quantifying career preferences and perceptions of software testing among Filipino IT students: A mixed-method analysis.

A. Research Design

This study employed a convergent parallel mixed-methods research design to comprehensively examine IT students' perceptions and attitudes toward software testing careers in the Philippines. The methodology integrated both quantitative and qualitative approaches to provide a holistic understanding of cultural, educational, and socioeconomic factors influencing career decisions in software testing. A systematic narrative review was conducted following established guidelines to contextualize the research within existing international literature. The review examined studies published between 2013 and 2024, focusing on software testing career perceptions, cultural influences on IT career choices, and educational factors affecting professional preferences in technology fields.

This study adhered to ethical standards outlined by the Education Centre of Australia and was approved by the Institute's ethics board. Before data collection, participants were informed about the purpose of the research, the voluntary nature of participation, and the confidentiality of their responses. Written informed consent was obtained from all participants, ensuring that they understood their rights and the study's procedures.

B. Participants

Participants were selected based on specific inclusion and exclusion criteria to ensure the relevance and reliability of findings. The inclusion criteria required participants to be currently enrolled undergraduate students in Philippine universities, preferably third or fourth-year students (with selective inclusion of first and second-year students meeting other criteria), majoring in Computer Science, Information Technology, or Computer Engineering, and fluent in English or Filipino. Exclusion criteria eliminated students enrolled in non-IT related programs, individuals with professional software testing experience, students unable to complete surveys in English or Filipino, and first or second-year students not meeting additional inclusion criteria. A multi-stage sampling approach was implemented, utilizing random sampling as the initial sampling strategy and stratified sampling for the quantitative phase to ensure representativeness across university types (public/private), academic levels, and geographical regions, while purposive sampling was employed for focus group discussions to capture diverse perspectives and experiences. The target sample size is a minimum of 384 students for surveys and was deduced to 98 after data cleaning, and 24-30 students distributed across 4-5 focus groups with 6 participants per group. Participants were recruited from five regions across the Philippines, representing both urban and rural contexts, with two universities (one public, one private) selected from provinces identified in the 2022 Philippine Statistics Office's [18] top urban and rural cities list.

C. Instrumentation

The research instruments comprised a structured questionnaire and focus group discussion guide, both designed to capture comprehensive data on students' perceptions of software testing careers. The survey instrument incorporated both closed-ended and open-ended questions to measure interest levels in software testing careers using a 5-point Likert scale, while exploring cultural perceptions and values influencing career decisions, economic considerations and job market awareness, educational experiences and curriculum exposure, and social and familial influences. The dependent variable focused on interest in pursuing software testing careers, while independent variables included cultural perceptions, career awareness, economic factors, educational influence, and social/familial influence, with control variables encompassing age, gender, year level, degree program, and institution type. Semi-structured focus group discussion guides were developed to explore cultural influences on career choices (*utang na loob, bayanihan, pakikisama*), family expectations and social pressures, perceptions of software testing prestige and career prospects, educational experiences and curriculum adequacy, and suggestions for improving software testing career appeal. A pilot study involving 20 participants was conducted to refine instrument clarity, reliability, and effectiveness, resulting in key improvements including standardization of Likert scale response options (1=lowest, 5=highest), revision of binary yes/no questions to more engaging formats, and enhanced question sequencing and wording clarity.

D. Data Collection

Data collection employed a dual-phase approach utilizing both online surveys and focus group discussions to ensure comprehensive data gathering from geographically dispersed participants. Online surveys were administered using Google Forms to ensure accessibility, anonymity, and convenience for participants across multiple regions. Participants were contacted through department heads and student organizations, with weekly follow-ups implemented to maintain adequate response rates and ensure representative participation from diverse institutional contexts. Focus group discussions were conducted online via Google Meet, with sessions recorded for subsequent analysis, while trained facilitators moderated discussions to ensure balanced participation and maintain research focus on key themes. Given the Philippines' bilingual context, participants were encouraged to express themselves in either Filipino or English based on their comfort level to facilitate authentic and nuanced responses. Multilingual responses were systematically handled through verbatim transcription of all focus group discussions, translation by trained bilingual research assistants maintaining cultural sensitivity, retention of original Filipino expressions alongside translations to preserve contextual meaning, and verification of translation accuracy through comprehensive audio review to ensure analytical integrity.

E. Data Analysis

Data analysis employed a comprehensive mixed-methods approach utilizing both quantitative statistical techniques and qualitative thematic analysis to examine students' perceptions of software testing careers. Statistical analysis was conducted using *jamovi* software, employing descriptive statistics including frequencies, percentages, means, and standard deviations to characterize participant responses and demographics. Inferential statistics included correlation analysis to examine relationships between software testing interest and influencing factors such as curriculum exposure, peer influence, and cultural elements, t-tests to compare group differences between male versus female students and public versus private institutions, and regression analysis to identify predictors of

software testing career interest. All statistical tests were conducted at 95% confidence level with significance threshold of $\alpha = 0.05$ to ensure statistical rigor. Qualitative data analysis employed systematic thematic analysis using *Taguette* software, beginning with verbatim transcription of all focus group discussions while maintaining bilingual considerations. The coding process involved multiple coders with established intercoder reliability exceeding 70% agreement and Cohen's kappa greater than 0.61, a clear coding framework defined prior to analysis, regular coder training and discussion sessions, and comprehensive documentation of disagreements and resolution processes. Thematic analysis followed a systematic six-step process, including data familiarization through repeated reading and audio review, initial code generation capturing significant data features, theme identification by grouping codes into broader categories, theme review and refinement for accuracy, final theme definition and naming, and report production with supporting quotations to illustrate key findings.

F. Synthesis Strategy

The data integration and triangulation process employed a convergent parallel design that facilitated systematic integration of quantitative and qualitative findings through multiple analytical approaches. Triangulation was utilized to identify convergent and divergent themes across methodological approaches, while sequential explanation used survey data to guide focus group discussion exploration of key findings. Joint displays systematically compared quantitative results with qualitative insights to reveal complementary and contradictory patterns, and methodological validation was achieved through cross-method comparison to enhance overall research credibility. The data synthesis employed convergence, expansion, and divergence approaches to maximize analytical depth, with convergence comparing measured interest levels with participants' lived experiences, expansion using qualitative data to elaborate on quantitative findings and provide contextual understanding, and divergence exploring contradictions between methods to enhance a comprehensive understanding of complex phenomena. The integration process followed established mixed-methods protocols to ensure comprehensive analysis that addressed research questions from multiple methodological perspectives while maintaining rigor and validity throughout the investigation, ultimately providing a holistic understanding of factors influencing Filipino IT students' perceptions of software testing careers.

IV. Results

This section presents the comprehensive findings from both quantitative and qualitative data collection phases that examined Filipino IT students' perceptions and career preferences toward software testing. The results are organized into quantitative survey findings that reveal statistical patterns in career preferences, perceived advantages and disadvantages of testing software roles, and the influence of cultural, economic, and curricular factors on career decisions, followed by qualitative insights from focus group discussions that provide deeper contextual understanding of students' perspectives and experiences. The findings are further synthesized through convergence and divergence analysis that integrates both methodological approaches to illuminate how cultural values such as *utang na loob, pakikisama*, and *bayanihan* intersect with economic considerations and educational exposure to shape career decision-making processes among Filipino IT students, ultimately revealing both similarities with and distinctions from global trends in software testing career perceptions.

A. Quantitative Results

These results present the findings from the survey, including how Filipino students' perceptions of software testing were compared with global trends. Tables and charts are used to illustrate key data points such as the perceived prestige, financial rewards, and job availability of software testing careers.

Table V and Table VI are closely related to the framework's Cultural dimension, which indicates that students prefer SD over ST due to perceived career prestige. The quantitative survey analysis reveals that Filipino IT students demonstrate clear preferences for software development over software testing careers, with testing consistently ranking lower in career preference rankings, mirroring international trends documented in previous studies. These ranking patterns reflect deeply ingrained cultural perceptions that position development roles as more prestigious [2] and innovative compared to testing positions, which are often viewed as secondary or support functions within the software development lifecycle.

TABLE V. Descriptive Statistics for IT Roles Ranking

Measure/Position	Development	Testing	Network Admin	Database Management	Cyber-security	Interpretation
Mean Rank (Preference)	2.47	3.34	2.86	3.23	3.6	Lower preference than most other IT fields; close to lower-preferred roles
Median Rank	2	3	3	3	3	Middle value, indicating moderate popularity
Mode Rank	1	3	3	3	1	Most frequent rank is moderate (3); not top choice
25th-75th Percentile	2.00-4.00	3.00-4.00	2.00-4.00	2.00-4.00	2.00-4.00	Most responses are at mid-to-lower preference
Skewness	0.519	-0.114	0.0896	-0.0686	-0.411	Near zero, distribution is symmetric, no strong aversion or preference

TABLE VI. DESCRIPTIVE STATISTICS FOR LIKELIHOOD TO PURSUE A CAREER IN ST

Likelihood to Pursue	Software Testing	Interpretation
Mean	3.66	Slightly above neutral, suggesting tepid interest
Median	4	Middle response is moderately positive
Mode	3	Most common score is neutral/mildly positive
25th–75th Percentile	3.00–4.00	Most responses clustered near neutral
Skewness	-0.313	Slight negative skew; a few strongly positive

Survey data in Table VI exploring the likelihood of Filipino students pursuing careers in software testing reveals a limited interest, mirroring global research trends that highlight a general reluctance toward testing roles across various cultural contexts. The statistical distributions shown in Table VII indicate that cultural factors play a significant role in shaping career decision-making processes, leading students to favor positions perceived as having higher status, better compensation opportunities, and greater technical challenges. This pattern of preferences illustrates how cultural values concerning professional hierarchy and technical expertise influence student career aspirations, ultimately impacting the availability of qualified testing professionals within the Filipino IT industry.

The Cultural dimension analysis shown in Table VIII reveals that among all tested factors, only *utang na loob* emerged as statistically significant in predicting career pursuit likelihood, contrasting with international studies and highlighting unique Filipino cultural influences on career decisions. This finding demonstrates the powerful role of reciprocal obligations in Filipino career choices, where students may consider software testing to honor family investments in their education or repay mentors who guided their academic journey. The statistical significance of *utang na loob* suggests that Filipino career decisions are deeply embedded in relational contexts rather than purely individual preferences.

Economic pillar analysis through t-test comparison shows that public university students demonstrate a higher likelihood to pursue software testing careers compared to private university students, contrary to Canadian findings [1], where rural students with limited resources showed less interest in technology careers. This reversal indicates that Filipino students from more economically constrained backgrounds may view software testing as an accessible entry point into the IT industry, potentially due to perceived lower barriers to entry or greater emphasis on stable employment opportunities over prestigious career positioning.

Table IX illustrates how cultural perceptions of career prestige discourage students from pursuing software testing roles while highlighting the disadvantages associated with such positions. The descriptive statistics reveal that students demonstrate strong awareness of software testing's perceived limitations, including concerns about career advancement opportunities, technical complexity, and professional recognition within the IT industry. These findings suggest that negative perceptions outweigh positive aspects, reinforcing cultural biases that position testing as less desirable compared to development roles.

TABLE VII. DESCRIPTIVE STATISTICS OF FRAMEWORK COMPONENTS' INFLUENCE

Factor Category	Specific Factor	Mean Likert Score (SD)	Interpretation
Cultural	Family Expectations	3.5 (±0.8)	Moderately influential
Cultural	Peer Perceptions	2.9 (±0.9)	Slightly to moderately influential
Economic	Salary Expectations	4.2 (±0.7)	Highly influential
Economic	Job Stability	4.0 (±0.6)	Highly influential
Curriculum	Coverage in Program	3.1 (±0.8)	Moderately influential
Curriculum	Faculty Attitudes	2.7 (±0.9)	Slightly influential

TABLE VIII. DESCRIPTIVE STATISTICS FOR IMPORTANCE OF SOCIAL HARMONY (PAKIKISAMA AND BAYANIHAN) AND UTANG NA LOOB IN CAREER DECISIONS

Variable	Mean (M)	Median	Mode	Skewness	Interpretation
Colleagues' relationship	4.21	5	5	-1.28	Respondents show very strong agreement, suggesting colleagueship is highly valued and perceived uniformly.
Bayanihan and *pakikisama*	4.46	5	5	-0.67	These collectivist values are broadly affirmed; responses cluster at the 'strongly agree' end, indicating consensus.
Utang na loob	2.9	3	2	0.32	Attitudes are more moderate here, with greater variability; the value's role may be more context dependent.

Note. M = Mean. Negative skewness values indicate clustering toward higher agreement.

TABLE IX. DESCRIPTIVE STATISTICS FOR AGREEMENT ON ST PROS/CONS

Statement Category	Perceived as Advantage	Perceived as Disadvantage	Statistical Evidence (Mean, Skewness)	Interpretation
Requires Expertise	Yes	No	Mean = 4.14, Skew = -1.16	Recognized as requiring high competence; most respondents strongly agree; viewed positively.
Social Skills	Neutral	Neutral	Mean = 3.47, Skew = -0.40	Seen as neither strong advantage nor disadvantage; less important in ST careers.
Learning Opportunities	Yes	No	Mean = 4.10, Skew = -1.35	Strong agreement that ST careers offer learning and growth; major perceived advantage.
Tedious Work	No	Yes	Mean = 4.01, Skew = -0.99	Strong perception of tedium; recognized as an international and local disadvantage.
Critics by Developers	No	Yes	Mean = 3.88, Skew = -0.83	Moderate agreement: criticism from peers is a noted disadvantage, more prominent locally.

The Curriculum pillar findings confirm significant limitations in software testing exposure within university programs, with students reporting minimal curriculum coverage and low self-assessed preparedness for testing careers, corroborating [3], [6], and [7] findings about insufficient testing education. The statistical data in Table VII indicate that educational institutions inadequately prepare students for testing careers through limited course offerings, superficial coverage of testing methodologies, and insufficient hands-on experience with industry-standard testing tools and practices. This curriculum gap perpetuates the cycle of low interest by failing to demonstrate software testing's intellectual rigor, career potential, and critical importance in software quality assurance processes

The regression analysis shown in Table X reveals a strong explanatory power, with an R-value of 0.710 and an explanation of 50.5% of the variance. Notably, only *utang na loob* and the university curriculum, both nearly significant, emerged as statistically significant predictors of the likelihood of pursuing a career.

TABLE X. REGRESSION TEST RESULT OF LIKELIHOOD TO PURSUE VS. INFLUENCING COMPONENTS

Framework Component	F-value	p-value	Interpretation	Significance
Personal interest	0.29	0.883	No meaningful effect	Not significant
Salary expectations	1.191	0.323	No meaningful effect	Not significant
Job market demand	0.567	0.639	No meaningful effect	Not significant
Utang na loob	2.621	0.042	Statistically meaningful effect	Significant
Peer influence	1.984	0.107	No meaningful effect	Not significant
University curriculum	2.413	0.057	Marginal effect	Not significant
Overseas employment	1.686	0.163	No meaningful effect	Not significant

The perceived disadvantages of software testing careers among Filipino students align with international findings, also evidenced in Table IX, reflecting concerns about monotony, limited creativity, insufficient professional recognition, and lower prestige compared to development roles. The framework's Cultural dimension is validated through findings indicating that Filipino collectivist values, such as *pakikisama* and *bayanihan*, moderately influence career decisions, offering a local context that differentiates these results from Western career choice models.

In contrast to the studies of Chinese students [9] and [23], which highlighted a strong influence of parental obligation, Filipino students placed a greater emphasis on personal interests while still being notably affected by cultural debt obligations. These findings demonstrate that although Filipino students share common hesitations about testing careers with their international peers, unique cultural factors such as *utang na loob* and distinct economic motivations create different patterns in their career decision-making processes.

B. Qualitative Insights

This section discusses the insights from focus group discussions, highlighting how cultural factors like *utang na loob* and *pakikisama* influence students' decisions. This integrates narratives from students that explain why software testing is less appealing in the local context.

The theme of cultural values, particularly *pakikisama* (harmonious relationships) and *bayanihan* (communal unity), emerged as moderately influential in shaping workplace satisfaction and interpersonal dynamics rather than direct career choice, as discussed in Table XI. Approximately 60% of participants acknowledged these values' importance in professional settings. One participant emphasized the necessity of *pakikisama* in conflict resolution: "You'd still need *pakikisama*, because there are times you could clash. Like, when I want to report the issue, but the developer might prefer to let it slide…But as a tester, it's your responsibility…so I think *pakikisama* is important for both the tester and developer" (JG). Another participant highlighted bayanihan's role in collaborative work environments: "*…it applies po dito kagaya po sa previous na nabanggit hindi ka naman po talaga magsosolo sa corporate dadating yung point na makikipagcollab ka rin magkakaron kayo ng issues arguments pero itatake mo yon as a constructive*

criticism…" (ADD). However, this cultural influence was not universally prioritized, as evidenced by participants who viewed personal goals as paramount over cultural expectations.

A significant counter-theme emerged where approximately 40% of participants prioritized individual autonomy and personal goals over traditional cultural obligations, particularly regarding *utang na loob*. This perspective challenges conventional assumptions about Filipino cultural influence on career decisions. One participant clearly articulated this stance: "…it's not my priority when it comes to choosing a career given the fact that their satisfaction or other people's satisfaction towards my success, wouldn't feed me or wouldn't pay my bills so what matters the most is my own sanity and me being able to commit and to achieve the things that I want to achieve in the future…" (P1). Another participant reinforced this theme of personal choice over family pressure: "*Para po sakin hindi ako pinipilit ng magulang na piliin yung gusto nila ang choice ko po na mag IT so I think nakadepende na po yun sa tao yung sa utang na loob, I think as a Filipino hindi po mawawala sa atin yung pagiging family oriented parang kusang bigay po satin kahit hindi sabihin…"* (KH). This theme suggests a generational shift where cultural obligations remain acknowledged but are no longer primary drivers of career decisions.

Table XII reiterates that economic considerations play a predominant role in career decision-making, with students prioritizing financial stability over traditional cultural expectations. As one participant candidly noted, "…since we are in a third-world country, who would choose a career that does not meet their needs? That's why many are seeking careers that offer higher pay". Limited exposure in the curriculum poses significant barriers to interest in software testing, with students expressing frustration regarding their inadequate preparation: "I have an interest, but I am held back by the lack of exposure I have. Because we did not study it, I don't have the knowledge of how it works. So, I feel limited in that sense".

TABLE XI. EMERGENT CULTURAL THEMES

Key Theme	Number of highlights	Notes	Data source	Framework Component
ST is a high-pressure job.	61	Most frequently cited disadvantage.	Survey	Career Prestige Perception
ST is seen as tedious.	37	Work is seen as repetitive or monotonous.	Survey	Career Prestige Perception
There are limited opportunities.	30	Concerns about career advancement.	Survey	Career Prestige Perception
ST receives limited recognition.	30	Seen as undervalued compared to developers.	Survey	Career Prestige Perception
ST is seen being prone to workplace conflict.	27	Notable issues with interpersonal dynamics.	Survey	Collectivist Cultural Value
Less Creativity; Need for technical skills.	8	Views as less innovative; requires technical skills.	Survey	Career Prestige Perception
Belief of ST negatively impacting workplace relationships.	39	The majority feel ST does not affect workplace dynamics.	Survey	Collectivist Cultural Value
ST impact workplace dynamics due to the nature of the role.	12	Stress and role-specific challenges.	Survey	Collectivist Cultural Value
Bayanihan affects career choices as teamwork is important.	25	Teamwork is important in choosing a workplace.	Survey	Collectivist Cultural Value
Preference for coding.	13	Simply stated "coding" or expressed passion for coding.	Survey	Career Prestige Perception
ST is seen as fun, interesting, has lighter workload, and easier than development.	-	Perceived pros of ST.	FGD	Career Prestige Perception
ST is seen as inferior to coding, repetitive, and has high learning curve.	-	Perceived cons of ST.	FGD	Career Prestige Perception
Pakikisama helps resolve issues easily between the tester and the developer.	-	Unique cultural value integrated in ST and SD dynamics.	FGD	Collectivist Cultural Value
Collaboration and teamwork are rooted in *bayanihan.*	-	Importance of local value in a workplace.	FGD	Collectivist Cultural Value
Utang na loob is there, but not a priority; personal interest is important.	-	Shift in traditional mindset.	FGD	Collectivist Cultural Value
Personal interest matters more than friends' opinions.	-	Personal interest as top motivator.	FGD	Collectivist Cultural Value
Work-life balance and environment matters.	-	Workplace dynamics is an important factor.	FGD	Collectivist Cultural Value

TABLE XII. EMERGENT ECONOMIC THEMES

Key Theme	Number of highlights	Notes	Data source	Framework Component
There is slow career progression in the role.	14	Perceived disadvantage.	Survey	Job Stability Expectations
ST is seen to provide less salary.	2	Concern on taking ST as a career.	Survey	Financial Necessity
ST provides limited career growth adding up to hesitation.	5	Concerns about long-term career growth and advancement prospects.	Survey	Job Stability Expectations
Salary, job-demand, and opportunities for growth are top priorities.	-	Top factors in choosing a career.	FGD	Financial Necessity
Gaining experience and building a strong portfolio are valued over simply following others.	-	Factor in choosing a career.	FGD	Job Stability Expectations
Job demand and economic needs are key factors.	-	When opportunities for this factor are present, a career is considered.	FGD	Job Stability Expectations
Opportunities for overseas work are an option.	-	Overseas work is not the priority, but when chances arise, it will be grabbed.	FGD	Financial Necessity
Careers with the promise of high salary are considered.	-	With reservations of the fact that fresh grad students earn minimum.	FGD	Financial Necessity

TABLE XIII. CONVERGENCE AND DIVERGENCE RESULTS MAP

Topic/Theme	Subtopic	Survey Findings	FGD Findings	Convergence/Divergence /Expansion
Interest Level	Likelihood to pursue	Median: likely to pursue.	Likely to pursue but with reservations.	Convergence
	IT Careers ranking	ST rank among other IT jobs: 3rd out of 5.	Software development is prioritized.	Divergence
Career Motivation	Job opportunities	Salary expectations: 0.323*	Salary is most prioritized.	Convergence
	Overseas work	0.163*	Overseas work is greatly considered.	Convergence
	Job market demand	0.639*	Whatever job/career is available, they will take.	Expansion
	Personal interest	0.883*	Driven by personal wants and needs.	Convergence
Curriculum Exposure	University preparedness	Unsure of how university prepares students.	Feels students are not well equipped for the profession.	Expansion
	Frequency of discussion	Much less frequent than any other IT jobs.	Agree, only shallow introductions.	Convergence
	Curriculum inclusion	Limited exposure.	Agree, not given highlight in course.	Convergence
	Testing education	0.057*	Less exposed = less interest.	Convergence/Expansion
Testing perceptions	Perceived pros	Easier than development	Testers only "test" that's why it's easier.	Convergence
		Necessary in development.	Agrees that it is necessary in development.	Convergence
	Perceived cons	Tedious work: Agree.	Agrees it is repetitive, manual work.	Convergence
		Requires expertise: Agree.	Agree, needs to keep up with learning curve.	Convergence
		Critics of developers: Agree.	Agree, it is the nature of the role.	Convergence
		Limited learning opportunities: Agree.	Disagree, there is always something to learn in the field.	Divergence
		Limited recognition: ranks #4.	Agree, developers are seen as superior.	Convergence
		Prone to workplace conflict ranks #7.	Agree, due to nature of the role.	Convergence
Social and cultural influences	*Utang na loob*	Median: neutral effect on ST choices.	Agree, leaning towards fulfillment of self.	Convergence
	Bayanihan	No impact on career choice but greatly impacts job satisfaction if present in workplace.	Would choose a career that values teamwork.	Expansion
	Pakikisama	No impact on career choices but it is very important to maintain good relationships with colleagues.	Wants a job that maintains workplace harmony.	Expansion
	Familial obligations	*Utang na loob*: Mean of influence: Unimportant.	Still thinks of giving back but not does not feel the pressure to do so.	Convergence
	Peer influence	0.107*	Would consider but to an extent.	Convergence/Expansion

*Note. *p-level of interest level to likelihood in pursuing a career in ST.*

However, students are open to pursuing careers in software testing when provided with proper education and exposure, challenging the assumptions about fixed preferences and suggesting that curriculum reform could greatly influence their career choices. An emerging theme among approximately 70% of participants indicated that economic factors, particularly salary expectations and job availability, have become primary determinants in their career selection, especially considering the current economic landscape in the Philippines. This pragmatic approach implies that if software testing careers align with financial stability and market demand, they become attractive options regardless of traditional cultural considerations. Focus group discussions consistently highlighted this economic prioritization, signaling a shift toward practical career decision-making over cultural or solely academic influences.

The integration of quantitative and qualitative findings reveals convergent patterns confirming salary expectations and overseas work considerations as primary career motivators, while diverging on the perceived value of learning opportunities in software testing. Table XIII identifies that cultural evolution among Filipino families demonstrates a shift from traditional authoritative practices toward supportive approaches that encourage individual autonomy, fundamentally transforming contemporary career decision-making processes. These insights establish that software testing's limited appeal stems from systemic issues, including inadequate curriculum exposure, economic pressures, and prestige perceptions, rather than inherent cultural resistance, suggesting these barriers could be addressed through coordinated educational and industry interventions. The interconnected nature of cultural, economic, and curricular factors creates a complex decision-making environment where students must balance personal interests, family obligations, financial necessities, and available opportunities when evaluating software testing career paths.

V. Discussion

Filipino IT students align with global trends favoring software development over testing, but show distinct cultural adaptations. Traditional values like *utang na loob* have evolved from primary to secondary motivators, with students asserting personal autonomy: "For me, my parents never forced me to choose what they wanted." Unlike international studies showing strong parental influence, Filipino students demonstrate a generational shift toward individualistic decision-making, prioritizing economic stability over family expectations: "…it's not my priority when it comes to choosing a career, given the fact their satisfaction... wouldn't feed me or wouldn't pay my bills".

Pakikisama emerges as crucial in workplace dynamics rather than career selection, particularly in software testing environments requiring diplomatic collaboration. While global studies emphasize prestige concerns, Filipino students additionally highlight economic necessities and limited curriculum exposure as decisive factors, reflecting the Philippines' developing economy, where financial stability takes precedence over career prestige. Cultural factors serve more as workplace compatibility considerations than career determinants, suggesting economic realities and educational limitations supersede traditional cultural expectations in contemporary Filipino career decision-making.

The study shows that Filipino IT curricula provide limited and superficial exposure to software testing, with participants reporting that ST is only briefly mentioned without comprehensive discussions or hands-on experience. This contrasts with more developed educational systems, where software testing is integrated throughout the software development lifecycle curriculum with practical projects and industry partnerships. The lack of structured ST education in Philippine institutions creates knowledge gaps that prevent students from recognizing software testing as a viable and attractive career path.

The primary barriers preventing Filipino IT students from pursuing software testing careers include insufficient academic exposure, limited curricular focus, and a lack of comprehensive knowledge about the field's opportunities and requirements. Economic considerations such as salary expectations and job availability take precedence over career exploration, particularly given the current Philippine economic conditions. Educational institutions fail to provide adequate career guidance and real-world exposure to software testing, leaving students with misconceptions about the field's potential and professional growth opportunities.

Filipino cultural values such as *pakikisama*, *bayanihan*, and *utang na loob* demonstrate nuanced influences on software testing career perceptions, with participants acknowledging their importance in workplace dynamics but not as primary career decision factors. While *pakikisama* facilitates harmonious tester-developer relationships and *bayanihan* promotes collaborative problem-solving in testing environments, these cultural elements contrast with Western individualistic approaches that emphasize direct communication and personal achievement. The traditional concept of *utang na loob* as a career motivator has diminished among contemporary Filipino IT students, who prioritize personal goals and economic stability over family obligations, reflecting a shift from collectivist to more individualistic career decision-making patterns.

VI. Conclusion and Recommendations

This study reveals that Filipino IT students' disinterest in software testing careers stems from limited academic exposure, superficial curricular coverage, and prioritization of economic factors over career exploration. Cultural values like *pakikisama*, *bayanihan*, and *utang na loob* primarily influence workplace dynamics rather than career choice itself. The research demonstrates a generational shift, where contemporary students prioritize personal fulfillment and economic stability over traditional familial obligations, making career decisions based on salary potential, market demand, and personal interests. This study contributes to career development literature by employing a multidimensional, culturally sensitive framework that bridges quantitative and qualitative findings, extending existing models by revealing how cultural, economic, and academic contexts interact in collectivist settings.

Based on these findings, comprehensive reforms are necessary to address the identified barriers and enhance students' interest in software testing careers. The following

recommendations are organized into three critical areas that require coordinated implementation across multiple stakeholders to effectively transform how software testing is perceived, taught, and integrated into IT education.

A. Educational Reform

- Implement comprehensive curriculum reforms, integrating hands-on software testing modules throughout IT programs
- Mandate CHED integration of software testing courses beginning in the second-year IT programs nationwide
- Develop faculty development programs to enhance testing pedagogy and industry-aligned teaching methodologies

B. Industry Partnership and Policy Development

- Establish strategic industry partnerships for internships, mentorship programs, and co-designed curricula that bridge academic learning with real-world testing practices
- Develop collaborative research initiatives where academia and industry jointly address software quality challenges, providing students with exposure to cutting-edge testing methodologies
- Implement targeted career guidance programs highlighting testing opportunities, competitive compensation, and professional growth trajectories through industry practitioner engagement

C. Future Research Directions

- Conduct longitudinal studies examining evolving student perceptions as curriculum reforms and industry partnerships are implemented.
- Validate the revised CEC-IRTC model through empirical testing in different cultural and educational contexts.
- Investigate the effectiveness of specific industry-academia collaborative models in shifting student career preferences toward software testing.

The proposed reforms require coordinated implementation across multiple stakeholders, with industry-academia collaboration serving as the critical bridge between curriculum development and workforce readiness. CHED curriculum integration provides the foundational policy framework, while sustained industry partnerships ensure that educational reforms remain responsive to market demands and provide students with authentic pathways into software testing careers. This collaborative approach transforms software testing education from an isolated academic concern into a shared responsibility between educational institutions and the IT industry, ultimately strengthening the software quality ecosystem in the Philippines.

Pedestrian Navigation System with 3D Map and Charging Server Based on Steganography

Kohei Arai
Graduate School of Science and Engineering, Saga University, Saga City, Japan

***Abstract*—A pedestrian navigation system with a steganography-based 3D map and billing server is proposed. The proposed system includes a server system that provides topographical maps and navigation information to both pedestrians and vehicles. When using the proposed system, necessary images of cross sections, intersections, or points of interest can be automatically obtained, similar to the Street View feature in Google Maps. Users can post photos taken with their camera phones and earn points if the photos are marked as posted. While the proposed system incurs a usage fee, these points can be used to reduce the subscription fee. If the quality of an image is superior to that of a previously archived image, the new image overwrites the previous one. The billing system for the system usage fee incorporates digital steganography for security reasons. This prevents the leakage of user information and other data. Through experiments, it is confirmed that the proposed system works well.**

Keywords*—Pedestrian navigation; steganography; client-server system; geographic information; system; GIS

I. Introduction

The proposed system relates to a map information providing system that provides map information, particularly to a map information providing system that targets map information that is three-dimensional information [1]. As a background art of the proposed system, there is a position information management system disclosed in Japanese Patent Laid-Open No. 2003-111128. The position information management system of this background art is a data storage unit for storing map data and data for receiving landscape image data of a landscape around a user's information communication terminal from the information communication terminal via a communication line.

A configuration including a receiving unit, a current position specifying unit that specifies a current position where the information communication terminal is located based on the landscape image data received by the data receiving unit, and the map data stored in the data storage unit. According to the position information management system of the background art, when the position information from the GPS satellites is used without using the position information from the GPS satellites or the position information by the three-point survey method from a plurality of base stations in the vicinity.

The current position of the information communication terminal can be specified with the same high position accuracy. Further, the following technical matters are also disclosed in the publication.

- Specify the position based on the orientation data, in addition to the landscape image data.
- Identify the location using the area information of the base station.
- Update stored map data based on landscape image data.
- Navigate to the destination specified by the user.

The position information management system of background art cannot perform position identification using GPS in an environment such as a building or an underground mall, where it is difficult to receive radio waves from GPS satellites. In view of the above, the present invention has been made for the purpose of specifying the current position of the information communication terminal with the same high position as in the case of using GPS. However, the position information management system of the background art is configured as described above and has the following problems.

1) The map data is updated using the landscape image data captured by the user's information communication terminal, but the landscape image data is mistakenly updated because GPS is not used.

2) Landscape image data taken by the user's information communication terminal is taken at the user's discretion, and the landscape image data as planned by the system side cannot be acquired, resulting in poor-quality map data overall.

3) The scenery image data is repeatedly updated every time when it is uploaded to the system side, the load on the system side increases, and the scenery does not change frequently, so there is a lot of waste of updating itself.

The proposed system has been made to solve the above problems, and an object thereof is to provide a map information system in which image data relating to map information is appropriately updated.

In the following section, related research works are described. The proposed system is described in the next section, followed by some experiments. The conclusion is described with some discussions.

II. Related Research Works

An introduction to map matching for personal navigation assistants is provided [2]. Also, measurement and processing of indoor GPS signals using one-shot software receiver is conducted and well reported [3].

On foot navigation: continuous step calibration using both complementary recursive prediction and adaptive Kalman filtering is proposed [4]. Meanwhile, advanced integration of Wi-Fi and inertial navigation systems for indoor mobile

positioning is proposed and experienced [5].

Performance analysis of MEMS based pedestrian navigation systems is made [6]. On the other hand, 3D map creation with vehicle-mounted single stereo camera, reducing the influence due to vehicle motions, is proposed and validated its performance [7].

A moving domestic robot control method based on creating and sharing maps with shortest path finding and obstacle avoidance is proposed and evaluated its performance [8]. Meanwhile, color radio-map interpolation for efficient fingerprint Wi-Fi-based indoor location estimation is proposed [9].

Mapping and simulating watershed performances based on GIS, remote sensing, and SWAT are conducted and well reported [10]. On the other hand, communication links and evacuation/navigation information services for the tsunami warning system are introduced and experienced [11].

A seamless location measurement system with WiFi beacon utilized and GPS-based systems in both Indoor and outdoor receiver location measurement is proposed and evaluated for its performance [12]. Real-time monitoring visual impaired person's geolocation and walking state activity using GPS is also proposed [13].

Monitoring of visually impaired person movement using WEMOS di mini-GPS is also proposed [14].

As for digital steganography technology, a noble method for data hiding using steganography, discrete wavelet transformation, and cryptography, Triple Data Encryption Standard: TDES is proposed.

III. Proposed Method

A. System Concept

A map information providing apparatus according to the proposed system is an apparatus that transmits three-dimensional map information in response to a request from a mobile communication terminal equipped with a GPS receiver, and a three-dimensional map based on positioning information received from the mobile communication terminal. Means for reading the corresponding three-dimensional map information from the information storage means, means for reading the corresponding satellite image from the satellite image storage means based on the positioning information or the read three-dimensional map information, and imaging based on the positioning information or the read three-dimensional map information It includes a unit for reading the captured image from the image storage unit and a unit for pasting the satellite image and the captured image on the three-dimensional map information.

As described above, in the proposed system, the three-dimensional map information is read based on the positioning information from the mobile communication terminal, and the satellite image and the captured image are read as the images required for the three-dimensional map information and the satellite image is included in the three-dimensional map information.

Since the captured image is pasted and provided to the user, the satellite image and the captured image are interpolated with each other to provide the three-dimensional map information having a highly accurate real image.

The mobile communication terminal is a terminal that is portable and capable of communication, and specifically corresponds to a mobile phone, a PHS, a PDA including a communication device, and a notebook computer including a communication device. The captured image is an image captured by a mobile phone with a camera, a digital camera, a vehicle-mounted camera, or the like.

The satellite image may be attached to the top surface of the building and the road, and the captured image may be attached to the side surface of the object having the side surface (the road normally does not have the side surface). Alternatively, the captured image may be pasted where there is a captured image, and the satellite image may be pasted to other places. It is also possible to adopt a configuration in which one of the images is pasted first and then the other image is pasted on top of it.

A map information providing system according to the proposed system is a map information providing system including a mobile communication terminal equipped with an imaging device and a GPS receiver, and a map information providing apparatus that transmits three-dimensional map information in response to a request from the mobile communication terminal. Then, the map information providing device reads the corresponding three-dimensional map information from the three-dimensional map information storage means based on the positioning information received from the mobile communication terminal, and the captured image storage means based on the positioning information or the read three-dimensional map information.

The mobile communication terminal includes means for reading the captured image from the device, means for pasting the captured image on the three-dimensional map information, and means for recording the captured image from the mobile communication terminal in the captured image storage means based on the positioning information. It includes means for displaying the outline of the object in the three-dimensional map information based on the three-dimensional map information during the imaging mode.

In this way, in the proposed system, when capturing an image with the mobile communication terminal, the outlines of objects such as buildings, traffic lights, and intersections in the three-dimensional map information are displayed based on the three-dimensional map information, and the user matches the outline. It is possible to perform imaging, the map information providing apparatus can store an appropriate captured image assumed by the map information providing side, and it is possible to provide the user with three-dimensional map information to which a high-quality captured image is pasted.

The outline does not have to display the outline of all objects. For example, only the outline of the object located in the center may be used. The outline corresponds to a part of the frame (preferably hidden line processing) when the three-dimensional model is displayed in the wire frame.

In the map information providing system according to the proposed system, if necessary, the map information providing device transmits the positioning to the mobile communication terminal when a new captured image is needed from the captured image situation stored in the captured image storage means. It further includes means for requesting image pickup based on information.

As described above, in the proposed system, when the map information providing device determines that a new captured image is necessary according to the captured image situation of the captured image storage means, the image is captured based on the positioning information transmitted from the mobile communication terminal. When it is determined that the user is at a required position, the mobile communication terminal of the user is requested to capture an image, so that the user can capture an image required by the map providing device while suppressing the cost, and it is possible to collect high-quality captured images by the outline.

Here, "from the captured image status stored in the captured image storage means" means that, for example, when there is no captured image at a certain location, when there is a captured image, but the capture date is old, or there is a captured image, but at a specific time. This corresponds to the case where the captured image is insufficient. It is also a matter that the device operator can set appropriately.

A map information providing apparatus according to the proposed system is a map information providing apparatus that transmits three-dimensional map information in response to a request from a mobile communication terminal equipped with an imaging device and a GPS receiver, as necessary, and received from the mobile communication terminal. A means for reading the corresponding three-dimensional map information from the three-dimensional map information storage means based on the positioning information, a means for reading the corresponding captured image from the captured image storage means based on the positioning information or the read three-dimensional map information, and three-dimensional map information.

A means for pasting the captured image, a means for performing a route search from the current position and the destination when the destination is set from the mobile communication terminal, positioning information from the mobile communication terminal, and a mobile phone at the time of capturing the captured image. It includes means for identifying the image pickup direction of the communication terminal and creating information for guiding in the route direction using the image pickup direction and the route direction.

In this way, in the proposed system, the imaging direction of the mobile phone at the time of imaging is specified from the positioning information from the mobile communication terminal and the captured image, and the route to the destination and the information for guiding from the imaging direction to the route direction are created, By receiving the guidance by the mobile phone and outputting the guidance, the user can be guided in the correct direction without having to compare the surrounding situation with the 3D map information. The information to be guided corresponds to the information of the arrow in the route direction, the image of the correct route direction, and the image from the imaging direction to the route direction (may be a discontinuous image or a panoramic image).

A map information providing apparatus, according to the proposed system, is a map information providing apparatus that transmits three-dimensional map information in response to a request from a mobile communication terminal equipped with an imaging device and a GPS receiver as necessary and received from the mobile communication terminal. A means for reading the corresponding three-dimensional map information from the three-dimensional map information storage means based on the positioning information, a means for reading the corresponding captured image from the captured image storage means based on the positioning information or the read three-dimensional map information, and three-dimensional map information.

A means for pasting the captured image, a means for the map information providing device to store the positioning information and the embedded information from the mobile communication terminal in the embedded information storage means, and a transmission to the mobile communication terminal at the request of the mobile communication terminal 3 It includes means for including embedded information in the area of the three-dimensional map information in the three-dimensional map information.

As described above, in the proposed system, the positioning information and the embedded information from the mobile communication terminal are stored in the embedded information storage means and related to the three-dimensional map information to be transmitted, as well as the three-dimensional map information in response to the request of the mobile communication terminal. By including the embedded information to be provided to the user, the information registered by another user can be shared by the user who receives the information. It is possible to construct a so-called peer-to-peer usage mode in which information is directly exchanged between an unspecified number of individuals.

The map information providing apparatus or the map information providing system according to the proposed system embeds the management information in a hidden format and the management information in the image to be transmitted to the mobile communication terminal by the map information providing apparatus, if necessary. And a means for recording the recorded image. As described above, in the proposed system, since the management information is embedded in the image transmitted to the mobile communication terminal in a hidden format, it is possible to discriminate against an illegally used image and to record the image in which the management information is embedded. Since it is present, it can be used as evidence that it is the information already provided.

The map information providing system according to the proposed system additionally includes, if necessary, means for subtracting the charging information of the owner of the mobile communication terminal when the captured image to be recorded in the captured image storage means is received from the mobile communication terminal. It is a waste.

As described above, in the proposed system, when the captured image storage means is constructed using the captured image from the mobile communication terminal, the billing information regarding the use of the map information providing device for the user who provided the captured image by subtracting, it is possible to take an incentive for the user to take an image using the mobile communication terminal. The above outline of the proposed system does not enumerate the features that are essential to the proposed system, and a sub-combination of a plurality of these features can also be the proposed system.

B. System Configuration

Fig. 1 is a system configuration diagram of a map information system according to this embodiment.

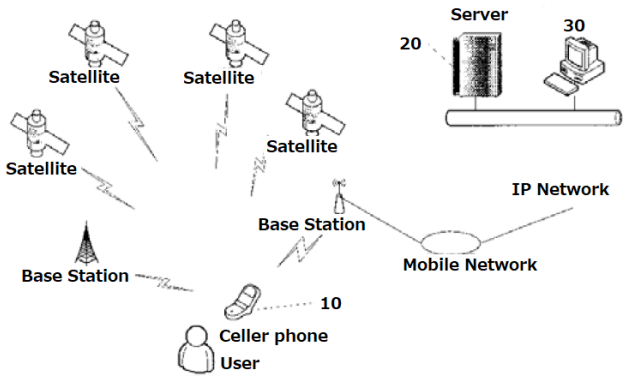

Fig. 1. System configuration diagram.

The map information system according to the present embodiment includes a mobile phone 10 with a GPS function and a camera function for receiving a radio wave from a GPS satellite and a reference station to identify a current position, a mobile phone 10, a base station, a mobile communication network, and an IP network. It is configured to include a server 20 that can communicate with the mobile phone 10 by transmitting the recorded three-dimensional map information to the mobile phone 10. In addition, a management computer 30 that operates and manages the map information system is also arranged.

Fig. 2 is a hardware configuration diagram of the components of the map information system according to this embodiment. Server 20 is built on a computer and has a hardware configuration such as a CPU (Central Processing Unit) 21, a main memory such as a DRAM (Dynamic Random Access Memory) 22, an external storage device HD (hard disk) 23, and a display device. A display 24, a keyboard 25, and a mouse 26, which are input devices, a LAN card 27, which is an expansion card for connecting to a network, a CD-ROM drive 28, and the like.

For example, the server program stored in the CD-ROM is duplicated (installed) on the HD 23, the server program is read into the main memory 22 as necessary, and the CPU 21 executes the program so that the server (device) Make up. Also, the management computer 30 has substantially the same hardware configuration as the computer on which the server 20 is constructed. Strictly speaking, the computer on which server 20 is constructed uses hardware with high performance and high reliability.

Most of the hardware configurations of the mobile phone 10 is the same as that of a computer, and instead of having no keyboard and mouse as input devices, a plurality of push buttons is provided on the surface of the main body, and a device and a camera function that enable mobile communication are realized. An example is a configuration in which a device that enables the realization and a device that receives a GPS radio wave and specifies the current position are mounted and are different.

The hardware configuration described here is an example, and it is obvious that those skilled in the art can make changes. Also, as for GPS, a plurality of methods such as single positioning, relative positioning, DGPS positioning, RTK-GPS positioning, etc., are prepared.

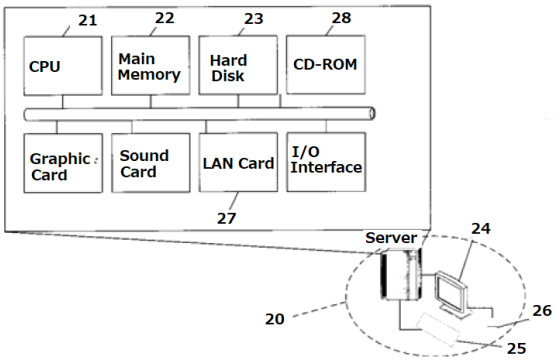

Fig. 2. Required functionality of the server.

Fig. 3 is a system configuration block diagram of the map information system according to the present embodiment. Server 20 is configured to have the following components.

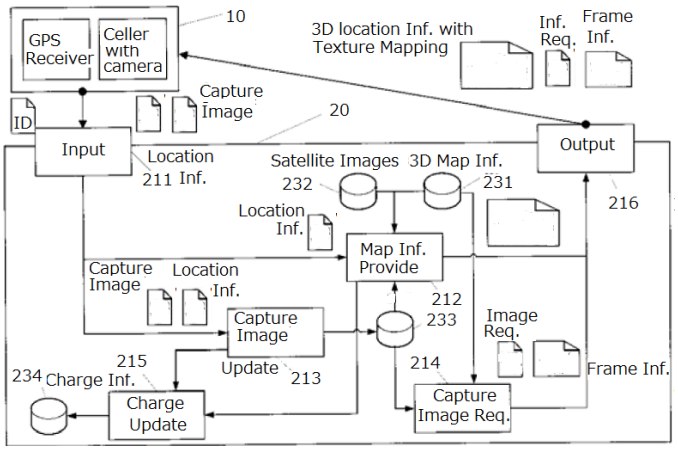

Fig. 3. System configuration.

Input means for capturing positioning information, captured images, etc. from the mobile phone 10. The corresponding three-dimensional map information is read from the three-dimensional map information storage unit 231 based on the captured positioning information, the satellite image is read from the satellite image storage unit 232 based on the positioning information, and the captured image storage unit 233 is read based on the positioning information.

A map information providing unit 212 that reads out the corresponding captured image and texture maps the satellite

image and the captured image on the three-dimensional map information. The captured image updating unit 213 that records the captured image in the captured image storage unit 233 based on the positioning information.

Picked image requesting means 214 for making an image pickup request to the user when updating is necessary from the picked-up image storage means 233 based on the positioning information.

Point updating means 215 for updating the charging information based on the information provided by the map information providing means to the user.

An output unit 216 that sends out three-dimensional map information, an image pickup request, frame information, and the like to the mobile phone 10. Next, the operation of the map information providing system according to this embodiment will be described. The operation according to the present embodiment is a three-dimensional map display operation of displaying three-dimensional map information on which a real image is mapped on the user's mobile phone 10, and a captured image captured by the user's mobile phone 10 as three-dimensional map information. A captured image update operation of storing a mapable image, and a captured image request operation of requesting a captured image user to map to three-dimensional map information, and storing a captured image captured in response to the request in a mapable manner with three-dimensional map information.

C. 3D Map Display Operation

Fig. 4 is a flowchart of the three-dimensional map display operation according to this embodiment. First, the user uses the push button of the mobile phone 10 to select the map information providing service. Then, the mobile phone 10 receives radio waves from the GPS satellite and the reference station and obtains positioning information (step 101). The obtained positioning information is sent to server 20 via the communication path established between the mobile phone 10 and the server 20. Server 20 (map information providing means 212) reads out the three-dimensional map information required for display from the three-dimensional map information storage means 231 based on this positioning information (step 111).

Server 20 (the map information providing unit 212) reads out the satellite image and the captured image required for mapping from the satellite image storage unit 232 and the captured image storage unit 233 based on the positioning information (step 112). Although the image is read out based on the positioning information, it goes without saying that the image may be read out based on the read three-dimensional map information.

The server 20 (map information providing means 212) maps the read satellite image and captured image to three-dimensional map information. Here, mapping can be performed using various mapping techniques such as texture mapping. As a rule, a satellite image is pasted on the upper surface of the 3D map model and a captured image is pasted on the side surface of the 3D map model.

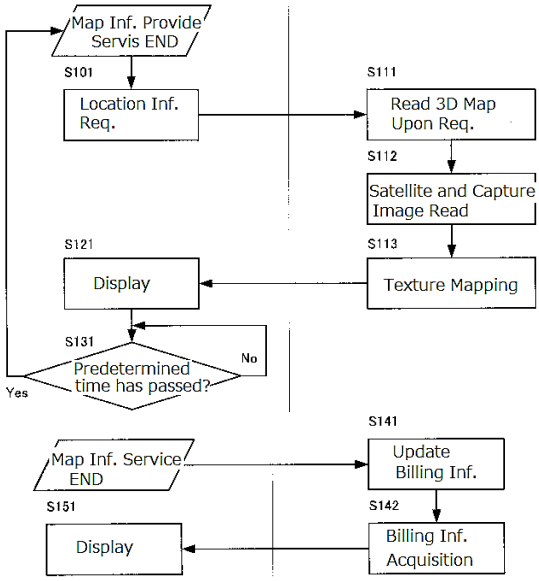

Fig. 4. Flowchart of the three-dimensional map display operation.

Since satellite images can also be obtained from the perspective direction, they may be attached to the side surface in some cases. The mapping here can, of course, be automated, but an operator can paste it instead. Server 20 sends the mobile phone 10 three-dimensional map information, in which the satellite image and the captured image are mapped. The mobile phone 10 fetches the three-dimensional map information and displays the three-dimensional model on the display.

The user can see the three-dimensional map information of the surrounding area. Here, the transmitted 3D map information may be information in a very limited range of the current position of the user, or may be 3D map information of a certain predetermined rectangular area. It is necessary to capture the 3D map information described above at any time according to the movement of the user. In the latter case, if the user moves to some extent, it is not necessary to capture new 3D map information within the rectangular area range.

The mobile phone 10 determines whether a predetermined time has passed from the previous step 101 (step 131), returns to step 101 if it determines that it has passed, and returns to step 131 if it determines that it has not passed. Return. Here, the three-dimensional map information to be fetched is updated every predetermined time, but the configuration may return to step 101 in accordance with the update of the positioning information. At this time, the positioning information may simply be updated, or when the moving distance from the previous step 101 exceeds a predetermined threshold value, the process may return to step 101.

Although the map information providing service is implemented in this way, when the user presses the push button of the mobile phone 10 and selects the end of the map information providing service, the service end signal is received and the server 20 (billing the updating means 215) adds the charging information (step 141). The billing information may be added based on the amount of the map providing service provided. The accounting information added by the server 20

(account updating means 215) is acquired (step 142). The acquired billing information is sent to mobile phone 10.

The mobile phone 10 displays the billing information on the display (step 151). The user can see the billing information. It should be noted that between the mobile phone 10 and the server 20, information (for example, a mobile phone number or a member ID assigned when registering to receive a service) that identifies the user of the mobile phone 10 is used as necessary. There is a need. It is necessary at least for billing renewal. The same applies below.

D. Captured Image Update Operation

Fig. 5 is a flowchart of the captured image update operation according to this embodiment.

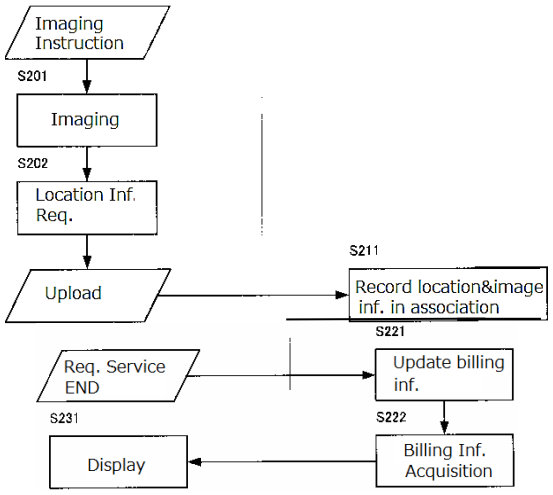

Fig. 5. Flowchart of the proposed imaging process.

First, the user uses the push button of the mobile phone 10 to select an image capturing instruction during the map information providing service (it may not be in service). The mobile phone 10 carries out imaging in accordance with the imaging instruction (step 201).

The mobile phone 10 obtains positioning information at the time of image pickup (step 202). The user uses the push button of the mobile phone 10 to select the upload of the captured image. The captured image and the positioning information are sent to Server 20. The server 20 (captured image updating means 213) stores the positioning information and the captured image in the captured image storage means 233 in association with each other (step 211). If a picked-up image of the same positioning information already exists, the picked-up image just stored is updated.

However, it is possible to retain the previously captured image, and it is possible to provide the three-dimensional map information in which the captured image of high quality is mapped by the confirmation of the operator. Instead of operator confirmation, noise determination processing for noise inclusion, scale determination processing to determine the scale of the captured image by edge processing of buildings, etc. From the image, the cutout processing to cut out the necessary image from the scale is automated. It can also be configured to.

When the user presses the push button of the mobile phone 10 and selects the end of the map information providing service, the service end signal is received, and in addition to the addition of the charge for the map information providing service, the server 20 (charge updating means 215) subtracts the billing information (step 221).

The billing information may be subtracted based on the number of uploaded captured images. The accounting information updated by the server 20 (account updating means 215) is acquired (step 222). The acquired billing information is sent to mobile phone 10. The mobile phone 10 displays the billing information on the display (step 231). The user can see the billing information. According to this captured image update operation, the captured image can be updated in a self-proliferating manner, and the work for maintaining the captured image can be significantly reduced.

E. Best Mode for Implementing the Proposed System

The proposed system can be implemented in many different forms. Therefore, it should not be interpreted only by the description of the embodiments below. In the embodiments, the system will be mainly described, but as will be apparent to those skilled in the art, the proposed system can be implemented as a program and method usable by a computer. Also, the proposed system can be implemented in hardware, software, or software and hardware embodiments.

The program can be recorded in any computer-readable medium such as a hard disk, a CD-ROM, a DVD-ROM, an optical storage device, or a magnetic storage device. Further, the program can be recorded on another computer via the network. Fig. 6 is a flowchart of the captured image request operation according to this embodiment.

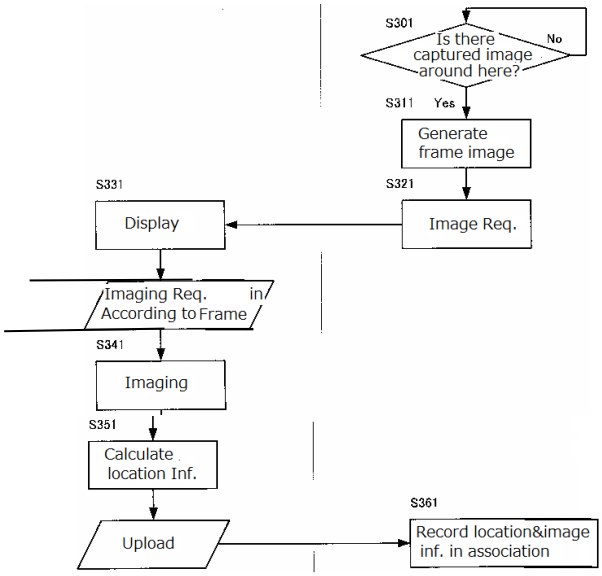

Fig. 6. Flowchart of the captured image request operation.

Even if at least one user can perform the captured image request operation when the 3D map information service is provided. Here, when no one is using the captured image requesting operation, the user who has registered by e-mail or the like, and the user who has used it can obtain the captured

image request operation. Specifically, when it is acceptable to be the target user of the captured image requesting operation, a message requesting access to this URL is transmitted.

Server 20 (captured image requesting means 214) determines whether an image around the current position is stored in the captured image storage means 233 using the positioning information of the user who is in service (step 301). If it is stored, the process returns to step 301. If it is not stored, server 20 (captured image requesting means 214) generates a three-dimensional model that clearly shows the required frame of the building or the like from the three-dimensional map information around the current position (this is the wire frame itself. Or it may be one that has been subjected to hidden line treatment, or one that has been rented with a white outer surface. In addition, a convenience store, a store such as a gas station, or an intersection that will serve as a mark is clearly indicated. It may be configured), and the direction in which imaging is required is specified.

The server 20 sends the generated three-dimensional model and the positioning information of the imaging position to the mobile phone 10 as an imaging request.

The mobile phone 10 displays the three-dimensional model on the display (step 331), and the user gives an instruction to image in a designated direction in accordance with the frame. The mobile phone 10 performs imaging (step 341). The mobile phone 10 obtains positioning information at the time of imaging (step 351). The user uses the push button of the mobile phone 10 to select the upload of the captured image. The captured image and the positioning information are sent to server 20. The server 20 (captured image update means 213) updates the positioning information and the captured image in association with each other, as in step 211 (step 361). Steps 221 to 231 are also executed in this captured image requesting operation.

Since this captured image requesting operation is often carried out frequently during the 3D map information providing service, whether the captured image requesting operation may be performed for the user in the 3D map information providing service in advance. It is preferable to have a configuration that allows selection. According to this captured image, requesting operation, captured images required for the map information providing service can be efficiently collected.

When it is desired to collect mainly the picked-up images of a predetermined area in an urban area, it is possible to set to collect for such an area. Further, here, the trigger of the captured image request operation is separated only by the determination in step 301 of whether there is a captured image, but the target of the captured image request operation is even when a predetermined period has elapsed from the image capture date and time of the captured image.

It is also possible to always keep the latest image. Further, although the image capturing time is not specifically specified, the captured image is different depending on the image capturing time. It is also more preferable to carry out. Note that the server 20 side during the captured image request operation generated the three-dimensional model in which the frame is clearly defined, but the mobile phone 10 side during the captured image update operation generates the three-dimensional model in which the frame is clearly displayed using the three-dimensional map information. It can also be configured.

Although it is not mentioned about the processing here, which functions are to be implemented on the client side and which functions are to be implemented on the server side in a client-server system etc., are almost always changed within the scope of so-called design change by those skilled in the art to be able to.

F. Navigation Procedure

Fig. 7 is a flowchart of navigation operation according to this embodiment. The user presses the push button of the mobile phone 10 to select the navigation. The mobile phone prompts the user to specify the destination by using the same GUI as the in-vehicle navigation. The user sets the destination. The mobile phone 10 requests the positioning information (step 401). The mobile phone 10 sends the destination and the positioning information to the server 20. The server 20 (route searching means 217) searches for a route from the destination and the positioning information (step 411).

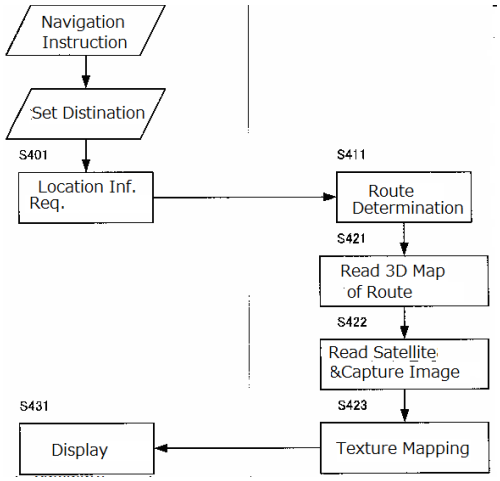

Fig. 7. Navigation procedure.

The route search is not an essential part of the proposed system, and a so-called person skilled in the art can apply a route search method that is already well known and will not be described in detail here. The server 20 (route searching means 217 and map information providing means 212) reads out the three-dimensional map information from the three-dimensional map information storage means 231 based on the route (step 421). The server 20 (the route searching means 217 and the map information providing means 212) reads the satellite image and the picked-up image from the satellite image storage means 232 and the picked-up image storage means 233 based on the route (step 422). The server 20 (route searching means 217 and map information providing means 212) attaches the satellite image and the captured image to the three-dimensional map information and further reveals the route (step 423). Revealing a route is generally a curve from the current position to the destination. The server 20 sends the three-dimensional map information to the mobile phone 10.

The mobile phone 10 displays three-dimensional map information on the display (step 431). The user can see a three-

dimensional map around the current position or can see a three-dimensional map other than the current position on the route. Here, the three-dimensional map information on the route is collectively sent from the current position from the server 20 and displayed on the mobile phone 10, but the three-dimensional map is updated based on the update of the positioning information accompanying the user's movement or a predetermined time. Information can be sent out at any time. In addition, the billing update can be performed in the same manner as in steps 141 to 151.

Fig. 8 is a flowchart of the direction confirmation operation according to this embodiment. The user instructs the mobile phone 10 to take an image during the navigation operation. The mobile phone 10 carries out imaging (step 501). The bay 10 requests the positioning information by carrying (step 511). The user presses the push button of the mobile phone 10 and selects the function of confirming the direction. The mobile phone 10 sends the captured image and the positioning information to the server 20.

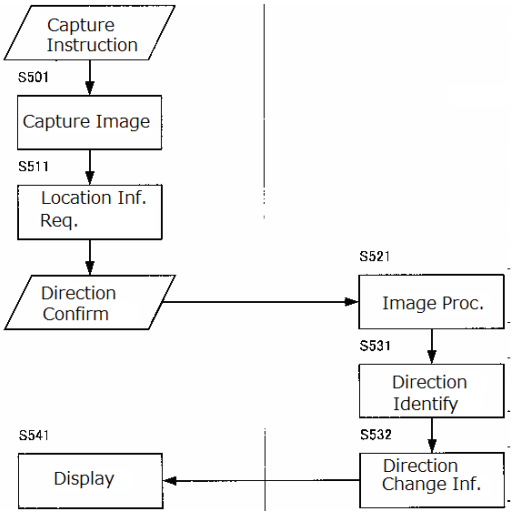

Fig. 8. Flowchart of the direction confirmation operation.

The server 20 performs image processing on the captured image to obtain an edge of a building or the like (step 521). Server 20 reads the three-dimensional map information from the three-dimensional map information storage unit 231 from the positioning information, compares the edges with the frame of the three-dimensional map information, and specifies the matching direction (step 531). The server 20 refers to the route of the three-dimensional map information for navigation sent to the user, identifies the correct direction on the route, and obtains direction change information from the direction identified in step 531 (step 532).

The direction change information includes a message for direction change, such as "How many times should the direction be changed clockwise from the current direction?" Several 20 sends the direction change information to the mobile phone 10. The mobile phone 10 displays direction change information on top of the currently displayed three-dimensional information for navigation (step 541). In addition, the billing update can be performed in the same manner as in steps 141 to 151.

According to this direction confirmation operation, the user visually compares the navigation with the image facing, as compared to the case where the user visually checks the navigation display and the image in the direction facing to reach the destination. No need. If the captured image is not mapped, and if no direction can be identified by the landscape of the same building, it points to an appropriate direction, which is highly convenient.

G. Navigation Procedure

The map information system according to the present embodiment is as follows: The map information system according to the present embodiment is configured in the same manner as the map information system according to the first embodiment, receives an image request from a certain user, and makes an image request to a user in an area satisfying the image request. This is different from the configuration in that the image requesting means for sending out the image and the steganography means for embedding the management identification information in the image are newly provided.

The steganography technique used in steganography is a well-known technique, and so-called persons skilled in the art can embed embedded information in a target image using various steganography techniques. Digital steganography technology can be used instead of steganography technology [15].

IV. Experiment

A. Direction Display

In each of the above-described embodiments, when the mobile phone 10 is displaying three-dimensional map information on the display, for example, when the direction key is pressed, the mobile phone 10 rotates in the assigned direction by the amount of the pressing. It can be configured to display. Specifically, when the front is displayed, by pressing the left direction key for a predetermined time, the landscape changes counterclockwise during the pressing time.

B. Three-Dimensional Album

In the map information system according to the second embodiment, during navigation, images and moving images captured by the user's mobile phone are sent to the server 20 at any time together with the positioning information, and the image for the navigational three-dimensional map information is displayed. Alternatively, the moving image may be embedded based on the positioning information and sent to the mobile phone 10 as a three-dimensional album.

C. Embedded Information for 3D Map Information

In the map information system according to the first embodiment, the user uploads the captured image in the captured image update operation and uses the uploaded captured image as an image to be attached to the three-dimensional model. Alternatively, for example, when a restaurant is specified, the captured image of the restaurant interior, the captured image of the food provided, and a description of the restaurant may be sent together with the positioning information, and the user can display the embedded information.

When requested, the three-dimensional map information including the embedded information may be displayed. Furthermore, if you create a site that displays only embedded information for each genre in a menu format and the user who accesses the site selects "3D map information", various services for 3D map information of this system will be provided. It can also be configured too.

V. Conclusion

A pedestrian navigation system with a 3D map and a charging server based on steganography is proposed. The server system, which provides topographic maps and navigation information for pedestrians as well as automobiles, is proposed. Required images of cross sections, intersections, or points of interest can be automatically acquired from users when they use the proposed system. Users get beneficial points when they submit photos acquired with their mobile phone camera, so that they intend to submit. If the quality of the image is better than previously archived image, then the new image is overwritten over the previous one. Steganography is featured for security reasons in the charging system for the use of the system.

Although the presently proposed system has been described by the above respective embodiments, the technical scope of the presently proposed system is not limited to the scope described in the embodiments, and various changes or improvements can be added to these respective embodiments. The embodiment with such changes or improvements is also included in the technical scope of the proposed system.

Future Research Works

Further experiments are required for validation of the proposed method and system in actual situations. Research is underway in automated collection and updating of real-time barrier information using smartphone sensors and AI technology. Real-time direction estimation using deep learning and image-based correction algorithms is also evolving. Infrastructure-free navigation technologies, such as high-precision autonomous positioning methods using shoe-mounted inertial sensors, are gaining attention.

Comparative Evaluation of CNN Architectures for Skin Cancer Classification

Taopik Hidayat, Nurul Khasanah, Elly Firasari, Laela Kurniawati, Eni Heni Hermaliani
Faculty of Information Technology, Universitas Nusa Mandiri, Jakarta, Indonesia

***Abstract*—Skin cancer is one of the fastest-growing health problems worldwide. Early and accurate diagnosis is essential for improving treatment success and patient survival. However, many previous studies have focused on single CNN architectures or limited datasets, resulting in models with restricted generalizability. To address this gap, this study presents a comparative evaluation of three deep learning architectures (DenseNet169, MobileNetV2, and VGG19) for automatic classification of benign and malignant skin cancers using dermoscopic digital images. A total of 10,000 images were compiled from three public Kaggle datasets, preprocessed through resizing and data augmentation, and trained using transfer learning based on ImageNet weights. Two data split schemes (60:20:20 and 80:10:10) were applied to assess model robustness. Experimental results show that DenseNet169 achieved the highest test accuracy of 90.7 per cent, while MobileNetV2 was the fastest with an inference time of 16 seconds. These findings highlight the tradeoff between accuracy and computational efficiency and support the use of deep learning models, particularly DenseNet169 and MobileNetV2, in the development of real-time AI-assisted skin cancer diagnostic systems.**

Keywords*—Artificial intelligence; convolutional neural network; deep learning; dermoscopic images; skin cancer classification

I. Introduction

Skin cancer is a common type of cancer that has been increasing rapidly year after year [1]. According to WHO data, each year, there are over two million cases of skin cancer diagnosed, the majority of which are benign, such as actinic keratosis and basal cell carcinoma [2]. Malignant skin cancers, such as melanoma, continue to pose a substantial danger due to their high metastatic potential and death rate [3]. Since the speed at which the lesion can be identified and treated has a significant impact on treatment outcomes, early diagnosis is an essential step in lowering melanoma mortality. Unfortunately, the standard skin cancer detection procedure continues to rely mainly on visual inspection by a dermatologist, which is subjective and requires extensive clinical experience, rendering it prone to errors and inconsistencies [4].

Automation attempts in medical diagnosis have become the subject of significant research, particularly when it comes to medical image processing [5], [6], [7], [8], [9], [10], [11]. The use of deep learning, which excels in extracting visual features and accurately classifying objects, is one of the popular methods [12]. Deep learning can learn visual patterns from picture data from start to finish, eliminating the need for human feature extraction [13]. Deep learning can distinguish tiny distinctions between skin lesion types that are often not visible to the human eye, making it a promising technology to support objective, rapid, and efficient clinical judgments [14], [15], [16].

Several studies in classifying skin lesions in dermatoscopic images have successfully demonstrated using CNN models. Previous studies [17] proposed a hybrid deep learning model to improve the accuracy of skin cancer classification by combining ConvNeXtV2 blocks and a separable self-attention mechanism, especially in differentiating between benign and malignant lesions that share a similar appearance. This model was shown to be more superior than the other ten CNN and ViT models with an accuracy of 93,48% and only 21,92 million parameters, and also efficient for clinical applications. Furthermore, deep learning methods with ResNet, VGG16, and AlexNet models were applied to the HAM10000 dataset for skin cancer classification, with improvements through data augmentation and imbalanced data addition, resulting in accuracies of 92,9%, 98,4%, and 88,3%, respectively, where the improved VGG16 model was selected as the best model to support early detection of skin cancer [18]. Further research [19] developed an automatic skin cancer detection system based on the DenseNet169 model trained using the Skin Cancer: Malignant versus Benign dataset, and successfully achieved a high accuracy of 89.7%, surpassing several conventional models and potentially supporting medical personnel in more accurate and efficient early diagnosis. Six deep learning models, including EfficientNet (B0, B1, B2) and MobileNet (V2, V3-Small, V3-Large), were used in the study [20]. Each model uses the ISIC dataset to classify skin cancer. The best results were obtained from MobileNet-V3-Large with an accuracy of 89.41%, a recall of 90.59%, and an F1-score of 89.53%, accelerating diagnosis and improving accuracy [20]. Another study focused on the use of the MobileNetV2 model for digital image-based skin cancer classification. After training and evaluation, the MobileNetV2 model successfully achieved an accuracy of 85% in distinguishing between cancerous and non-cancerous skin lesion images [21]. In another study [22], several pre-trained models are applied in the deep learning methods, one of which was VGG19. The VGG19 model achieved an accuracy of 87% using the HAM10000 dataset after the augmentation and fine-tuning process, showing quite good performance in classifying skin cancer. While the study [23] enhanced the pre-trained VGG19 model by adding max pooling and dense layers to improve the skin cancer prediction capability. The improved VGG19 model successfully achieves an accuracy of 88% in skin cancer classification.

Referring to the background, the purpose of this study is to evaluate and compare the performance of seven deep learning architectures in classifying skin cancer into two main categories,

namely benign and malignant. The models used are MobileNetV2, InceptionV3, Xception, DenseNet169, ResNet50, VGG16, and VGG19, each of which represents a variation in architectural complexity and computational efficiency. The dataset used was obtained from the Kaggle platform, which consists of 10,000 digital images that have been labeled according to the type of lesion. This study uses a transfer learning approach, where all models are initialized with weights from pre-training on ImageNet, then the medical data is fine-tuned to match its characteristics.

The main purpose of this study is to achieve an optimal deep learning model to classify skin cancer based on evaluation metrics, including recall, precision, accuracy, and F1-score. The results of this study are expected to contribute in the advancement of digital picture development-based clinical decision support systems, especially in the diagnosis of skin cancer. In addition, this study also aims to encourage the use of artificial intelligence in the health sector more widely by considering the aspects of reliability, speed, and efficiency of medical classification systems. It is also expected to provide a thorough grasp of the strengths and the limitations of deep learning architecture in the classification of benign and malignant skin cancer by conducting a comprehensive evaluation of the performance of each model. In addition, the results of this study can be a starting point for the development of an intelligent diagnostic system that is more accurate, easily accessible, and able to support early detection of skin cancer effectively.

The novelty of this study lies in the comprehensive comparison of CNN architectures using multiple public datasets and dual data split schemes to assess both accuracy and inference efficiency in real-world skin cancer classification.

The remainder of this study is organized as follows: Section II reviews related studies on skin cancer classification using deep learning. Section III explains the materials and methods, including dataset composition, preprocessing, and CNN architectures. Section IV presents the experimental results and analysis, while Section V concludes the study with key findings and future directions.

II. Related Works

The previous related studies using digital image processing approaches and deep learning methods for image classification are summarized in Table I. Various deep learning models such as DenseNet169, DenseNet121, MobileNetV2, VGG19, ResNet50, Xception, InceptionV3, and EfficientNetB0 have been applied in these studies. The accuracy results of these models vary, ranging from 85% to 89%.

Table I presents a comparison of the results of several previous studies using a deep learning approach to classify and detect skin cancer. Most studies use a digital image-based approach with popular models including DenseNet, MobileNet, VGG, ResNet, Xception, Inception, and EfficientNet. An accuracy of 89.7% is the highest result using the DenseNet169 model [19], followed by the E-VGG16 model [24] and DenseNet121 [25], which each recorded an accuracy of 89%. Another study [22], [23] showed competitive results using VGG19 and its modified version, with accuracies of 87% and 88%. These results indicate that deep learning models are suitable for skin cancer classification with high accuracy results.

In addition, the MobileNetV2 model was used in two different studies with accuracy results of 85.6% and 85% respectively, indicating the efficiency of this model in a limited computing environment, even with a slight decrease in accuracy [20], [21]. ResNet50 also showed consistency with 87% accuracy in two separate studies [10], [26]. Further research used a combination of features from the Xception and InceptionV3 models to detect Monkeypox skin disease and obtained an accuracy of 85.9%, indicating the potential of the combination architecture approach [27]. Meanwhile, research using EfficientNetB0 recorded an accuracy of 87% [28], showing the superiority of a lightweight yet effective model. Overall, the data in this table indicates that various deep learning models have demonstrated competitive performance and are worth considering for image-based skin disease classification systems. However, few studies have systematically examined how variations in dataset composition and data split schemes affect the performance and generalizability of CNN architectures for skin cancer classification.

III. Materials and Methods

In this section, the stages of the methodology applied in the study are described. This study focuses on testing and comparing seven deep learning models with a transfer learning approach, using public data from the Kaggle platform to classify benign and malignant skin cancers. The entire process is designed systematically, starting from the data input stage, pre-processing, model training, to evaluation of results, as shown in the workflow illustration in Fig. 1.

In this study, the primary data used consisted of 10,000 skin cancer images obtained from the Kaggle platform. The initial stages of the study included data pre-processing, which consisted of image resizing and augmentation applications to increase the diversity and quality of training data. Furthermore, this study tested and compared the performance of seven deep learning model architectures, namely, MobileNetV2, InceptionV3, DenseNet169, ResNet50, Xception, VGG16, and VGG19. Fig. 1 provides an overview of the main stages in the research process. In contrast, Fig. 2 shows the complete research stages of this research, which consist of collecting the data, processing the data itself, continuing to the training process with several training models, the evaluation process, and finally drawing conclusions. Fig. 3 provides a detailed visualization of the training and implementation stages of the model in this study, showing an example of the transfer learning application process flow on the seven models.

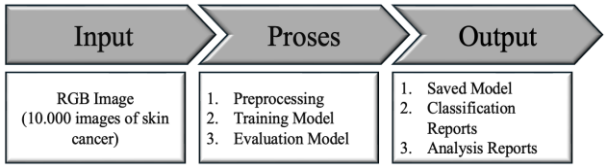

Fig. 1. Overview of the general stages of the research.

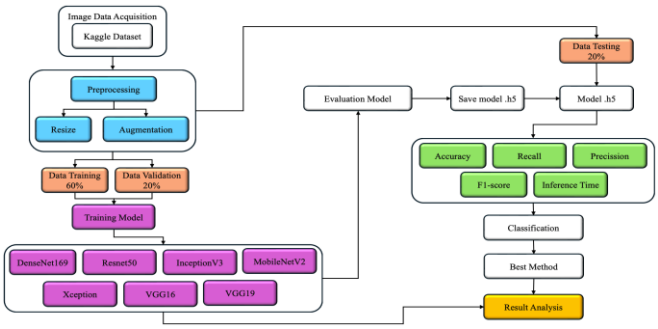

Fig. 2. Flowchart of the research stages.

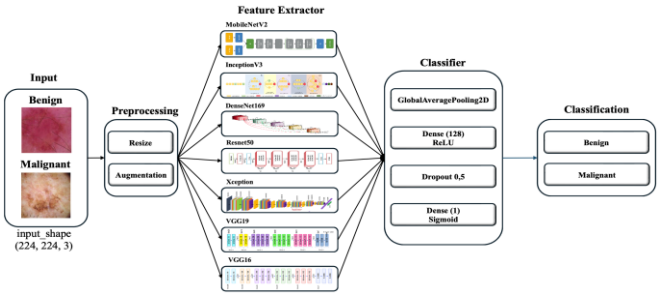

Fig. 3. Proposed model architecture framework.

The initial stage of this research includes collecting skin cancer image data totaling 10,000 images, which are then classified into two main categories, namelyz, benign and malignant. The data is the result of the combination of the three different dataset sources. The first dataset, as many as 3,600 images, was obtained from the Skin Cancer Malignant and Benign Dataset (SCMBD) [29]. Secondly, the source came from the Melanoma Skin Cancer Dataset (MSCD) with 5,000 images [30]. And finally, the third dataset, named the Melanoma Cancer Image Dataset (MCID), consists of 1,400 [31]. All three different datasets are divided into two classes, namely, benign and malignant. Table II shows the details of the data division from each source.

TABLE II. SUMMARY OF THE COMBINED DATASET SOURCE

Class Name	SCMBD Dataset	MSCD Dataset	Additional data MCID	Sub Total
Benign	1,800	2,500	700	5,000
Malignant	1,800	2,500	700	5,000
Total	**3,600**	**5,000**	**1,400**	**10,000**

Training data, validation data, and testing data are the three primary subsets of the skin cancer image data used in this study. To support the experimentation and model evaluation process, two data division schemes are used: the first scheme with a ratio of 60% for training, 20% for validation, and 20% for testing, and an alternative scheme with a ratio of 80%:10%:10%. This division is carried out systematically after all images from the three datasets are combined and standardized in size to 224 × 224 pixels to suit the input needs of the deep learning model [32]. The amount of data in each subset and the division scheme are presented in detail in Table III.

The purpose of using these two division schemes is to ensure that the developed model receives sufficient training data, is optimally validated, and is independently tested so that its performance evaluation is accurate [33]. This approach also allows testing the model's robustness to variations in data proportions and helps find the most effective data sharing configuration in skin cancer image classification. Thus, this data sharing strategy also contributes in reducing evaluation bias and increasing the validity of the overall research results [34].

TABLE III. DATASET DISTRIBUTION

Ratio	Subset	Total data in each subset	Total dataset
Scheme 1 60:20:20	Data training	6,000	10,000
	Data validation	2,000	
	Data testing	2,000	
Scheme 2 80:20:20	Data training	8,000	10,000
	Data validation	1,000	
	Data testing	1,000	

To meet the input dimensions required by all the CNN architectures, the dataset in this study was standardized to 224×224 pixels. To increase the capacity of training data and overcome the limitations of the number of datasets, this study applied an image augmentation technique that was specifically carried out only on a subset of the training data (training set). The augmentation process involves various image transformations, including scaling, rotation, translation, zoom, horizontal flipping, vertical and horizontal position shifts (height and width shift), and brightness adjustment. This augmentation technique not only functions to artificially increase the amount of data but also enriches the variety of visual patterns, which are learned in the training process by the model. With the increasing diversity of augmented data, it is hoped that the model can recognize features more comprehensively and have better generalization capabilities to new data outside the training

dataset [35]. Examples of preprocessing and image augmentation results can be seen in Fig. 4, which shows a visualization of the transformation before the data is used in the training process. Details of the augmentation parameters applied during training are presented in Table IV as a technical reference for implementation, with parameters such as horizontal flip enabled, rotation range of 20 degrees, and zoom, shear, width shift, and height shift range, each valued at 0.2. Meanwhile, Table V shows the amount of augmented data from each dataset division scheme in detail.

TABLE IV. TRAINING DATA AUGMENTATION PARAMETERS

Parameters	Value
Horizontal flip	True
Rotation range	20 degrees
Zoom range	0.2
Shear range	0.2
Width shift range	0.2

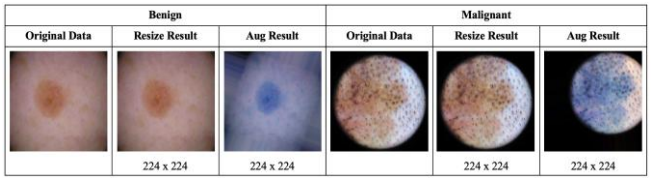

Fig. 4. Example training images from each class.

TABLE V. TRAINING DATASET BEFORE AND AFTER AUGMENTATION

Scheme	Classes	Before augmentation	After augmentation
Scheme 1 60% of dataset	Benign	2,942	5,884
	Malignant	3,058	6,116
Total	**2 classes**	**6,000**	**12,000**
Scheme 2 80% of dataset	Benign	3,998	7,976
	Malignant	4,012	8,024
Total	**2 classes**	**8,000**	**16,000**

Table V shows the amount of data before and after augmentation based on the two dataset division schemes used in this study. In scheme 1, the training data consists of 2,942 benign class images and 3,058 malignant class images. After augmentation, they become 5,884 and 6,116 images, respectively, so that the total training data is 12,000 images. Meanwhile, scheme 2 uses 80% of the entire dataset for training, resulting in 3,998 benign images and 4,012 malignant images, which are multiplied through augmentation to 7,976 and 8,024 images, respectively, with a total of 16,000 training images. The application of this augmentation aims to increase the amount and diversity of data so that the model is better able to recognize visual patterns of both classes of skin cancer accurately.

The training process is carried out using a transfer learning approach using seven CNN architectures, namely MobileNetV2, InceptionV3, Xception, DenseNet169, ResNet50, VGG16, and VGG19. Initial weights that have been previously trained on the ImageNet dataset are initialized on each model, then fine-tuning is carried out so that the model is able to adapt to the visual characteristics of dermatoscopic images of skin cancer [36]. In the training process, the Adam optimization algorithm was used with a learning rate value of 0.001. The performance of each model was monitored periodically based on the accuracy and loss values on the training and validation data in each epoch. The training results were recorded in the form of average training accuracy, average validation accuracy, average training loss, average validation loss, and total training time. After training, the model was saved in an .h5 file and was ready for testing.

The initial stage begins by inputting skin cancer images as input into the model with a size (input shape) of $224 \times 224 \times 3$. The image data consists of two classes, namely benign skin cancer and malignant skin cancer. The training process is carried out on seven CNN model architectures, namely, MobileNetV2, InceptionV3, DenseNet169, ResNet50, Xception, VGG19, and VGG16. The training process is carried out for 20 epochs using the Binary Cross entropy loss function, which is suitable for the binary classification process. A dropout mechanism of 0.5 and an early stopping approach with a 5-epoch patience are used to prevent overfitting. If the model's performance on the validation data does not improve for five consecutive epochs, training will end. A learning rate value of 0.001 as a default of Adam optimizer is also used in the optimization process. At the end of the network (dense layer), 128 neurons are used with the ReLU activation function, and followed by generating the binary output of benign or malignant using the sigmoid activation function in the output layer.

Model evaluation was performed using a subset of test data to measure the final performance of each deep learning architecture in classifying skin cancer images into two categories, namely benign and malignant. Performance evaluation was performed by calculating a number of key classification metrics, such as recall, precision, accuracy, F1-score, and inference time to measure the efficiency of model predictions in the context of real applications [37]. In addition, a confusion matrix was used to summarize the performance of the classification distribution of true (correct) and false (incorrect) predictions from each class, thus offering a more thorough comprehension of the effectiveness of the model in digital image-based classification tasks. The components of the confusion matrix used are True Positive (TP), representing the number of malignant cancer cases that were successfully predicted correctly, while True Negative (TN) shows the number of benign cancer cases that were correctly identified. Meanwhile, False Positive (FP) refers to benign cancer cases that were incorrectly classified as malignant, and False Negative (FN) describes malignant cancer cases that failed to be recognized by the model [37].

The calculation of recall, precision, accuracy, and F1-score follows the formulas outlined in Eq. (1) to Eq. (4). Accuracy provides an overview of the accuracy of the model's predictions. Recall evaluates the model's potential ability to accurately classify cases of malignant cancer, which is very important to avoid the risk of delayed diagnosis. Precision evaluates the accuracy of the model's predictions, avoiding misdiagnosis of healthy patients. Meanwhile, F1-score offers a balanced measure of performance, which particularly relevant when there is an imbalance in the amount of data between classes. It is also known as the harmonic mean of precision and recall. Inference time is also an important indicator in assessing the suitability of a model for application to a real-time detection system in a

clinical context [38]. By applying a combination of these metrics, this study aims to present a thorough evaluation of model performance in digital image-based skin cancer classification.

$$\text{Accuracy}=\frac{TP+TN}{TP+TN+FP+FN}x100 \quad (1)$$

$$\text{Precision}=\frac{TP}{TP+FP}x100 \quad (2)$$

$$\text{Recall}=\frac{TP}{TP+FN}x100 \quad (3)$$

$$\text{F1-score}=2x\frac{\text{Recall}x\text{Precision}}{\text{Recall}+\text{Precision}}x100 \quad (4)$$

IV. Result and Discussion

A. Result

The implementation and comparative evaluation of seven models were carried out using Jupyter Notebook. The Python programming language used in this study is backed by a number of significant libraries, including Keras, NumPy, Pandas, Matplotlib, and TensorFlow, which manage the training and testing stages of the deep learning models. The purpose of this study is to identify the deep learning model that best distinguishes between benign and malignant forms of skin cancer. There are seven types of CNN models tested, namely MobileNetV2, InceptionV3, DenseNet169, ResNet50, Xception, VGG19, and VGG16. All models are trained using an algorithm called Adam, which functions to accelerate and stabilize the training process. Adam was chosen because it is able to adjust its learning rate automatically, so that training is more efficient than other methods, such as RMSprop. A learning rate of 0.001 is often used as an initial value because it is considered stable enough to prevent excessive weight updates but still efficient in reducing loss during training. This value is also very suitable for adaptive optimizers such as Adam, which automatically adjust the learning rate of each parameter. In addition, this learning rate has been proven effective in various studies for models with medium to high complexity and is able to avoid the risk of overshooting the minimum point.

The training process on the seven models was carried out using a fine-tuning strategy, where some early layers of the pre-trained model were kept frozen, while the final layers were retrained using the skin cancer dataset. This strategy allows the model to adjust the general knowledge obtained from large datasets such as ImageNet to the specific characteristics of the dataset used in this study. By applying a dropout rate in the model of 0.5, it is expected to be able to reduce the chance of overfitting while maintaining the ability to capture important details from the training data. Every model has the same initial hyperparameters in order to preserve equality throughout the evaluation process. Table VI shows the results of the training process, including the accuracy, loss, and training time of each model, as a basis for model performance analysis.

Based on the experimental results on seven deep learning architectures with two data splitting scenarios (60:20:20 and 80:10:10), DenseNet169 showed the most outstanding performance. This model managed to achieve the highest validation accuracy, which was 87.07% in the 60:20:20 scenario and increased to 89.57% in the 80:10:10 scenario. In addition, the validation loss value on DenseNet169 was also recorded as the lowest compared to other models, indicating good training stability and generalization ability without symptoms of overfitting. This proves that, despite only the last layer being retrained throughout the fine-tuning procedure, DenseNet169 is able to identify significantly important patterns in the data.

TABLE VI. Comparison of Model Training Result

Model	Split Data	Val Acc (%)	Val Loss (%)
DenseNet169	60:20:20	87.07	29.87
InceptionV3	60:20:20	82.35	39.97
MobileNetV2	60:20:20	83.56	33.63
ResNet50	60:20:20	66.41	64.44
VGG16	60:20:20	81.8	43
VGG19	60:20:20	86.95	31.91
Xception	60:20:20	83.55	38.09
DenseNet169	80:10:10	89.57	23.99
InceptionV3	80:10:10	82.55	36.13
MobileNetV2	80:10:10	85.79	31.29
ResNet50	80:10:10	68.12	61.22
VGG16	80:10:10	84.95	35.82
VGG19	80:10:10	83.89	38.61
Xception	80:10:10	85.69	32.29

Meanwhile, several other models, such as MobileNetV2, Xception, and VGG19, also showed quite good performance with validation accuracy ranging from 83% to 86%, and loss values that are still quite good. These models still have decent potential for use in skin cancer classification, although not as optimal as DenseNet169. On the other hand, ResNet50 consistently recorded the lowest performance, both in terms of validation accuracy and loss rate, in both data scenarios. This indicates that in this study, the ResNet50 architecture is less suitable for the dataset and hyperparameter configuration used. After the training process of the seven deep learning models was completed, each model was saved in .h5 (HDF5) format to preserve the weights and network architecture that had been trained. Saving in this format allows for future reuse of the model without having to repeat the training process from the beginning. The next stage is the testing process for all models using test data that has been previously separated from the training and validation data. The purpose of this testing is to evaluate the final performance of each model on new data that has never been seen before and how well the model can generalize the classification of benign and malignant skin cancers accurately under actual circumstances. The results of testing each model are shown in Table VII.

TABLE VII. COMPARISON OF MODEL TESTING RESULT

Model	Split Data	Test Accuracy (%)	Test Loss (%)	Precision (%)	Recall (%)	F1-score (%)	Inference time
DenseNet169	60:20:20	90.4	9.6	90.4	90.4	90.4	79 s
InceptionV3	60:20:20	86.1	14	86	86.1	86	58 s
MobileNetV2	60:20:20	88	12	88.3	87.7	87.9	16 s
ResNet50	60:20:20	73.7	26.3	74.8	74.2	73.6	55 s
VGG16	60:20:20	85	15	85	85.1	85	194 s
VGG19	60:20:20	88.4	11.6	88.5	88.3	88.4	28 s
Xception	60:20:20	86.7	13.4	86.7	86.5	86.5	78 s
DenseNet169	80:10:10	90.7	9.3	90.7	90.7	90.7	41 s
InceptionV3	80:10:10	83.2	16	84.6	83.2	83.2	25 s
MobileNetV2	80:10:10	87.8	12.2	87.9	87.8	87.8	14 s
ResNet50	80:10:10	72.7	27	72.7	72.7	72.7	40 s
VGG16	80:10:10	82.3	17.7	82.3	82.3	82.3	90 s
VGG19	80:10:10	83.2	16.8	83.2	83.2	83.2	118 s
Xception	80:10:10	86.2	13.8	86.2	86.2	86.2	37 s

Based on the test results, the three best models for skin cancer classification are DenseNet169, MobileNetV2, and VGG19. DenseNet169 shows the best performance with the highest accuracy of 90.7%, as well as equally high recall, precision, and F1-score (90.7%), making it the most reliable and stable model. MobileNetV2 is the most efficient model with the fastest inference time (14 to 16 seconds) and competitive accuracy of up to 88%, suitable for low-resource devices and real-time applications. Meanwhile, VGG19 offers high accuracy (up to 88.4%) and balanced classification metrics, although with a longer inference time (28 to 118 seconds), making it a good choice for systems with high precision requirements and sufficient computing resources.

The analysis results of the three best models based on tests for classifying benign and malignant skin cancer are shown in Fig. 5. A thorough visual comparison of the three models is also provided in Fig. 5 to aid in the study and make it easier to recognize and comprehend the variations in model performance. Based on the results presented in Fig. 5, DenseNet169 (80:10:10) shows the best overall performance with an accuracy value of 90.7%, accompanied by a low loss value (9.3%) and balanced recall, precision, and F1-score scores. The next two best models are VGG19 (60:20:20) and MobileNetV2 (60:20:20), with accuracies of 88.4% and 88.0%, respectively. Considering pure accuracy, the three best models in order are DenseNet169 (80:10:10), VGG19 (60:20:20), and MobileNetV2 (60:20:20). However, if time efficiency is an important factor, MobileNetV2 is worth choosing as a superior alternative model.

B. Discussion

A variety of evaluation metrics of the five models included in this study were analyzed in order to assess the pre-trained CNN models. Several important steps were implemented, including data augmentation to increase the number of samples, and the application of class weighting in the loss function during training to give greater weight to underrepresented classes. This strategy was designed to ensure that the model is able to learn the data without bias towards the majority class. In addition, the balanced batch sampling technique was used to keep the class distribution proportional in each training batch, which helps reduce the impact of class imbalance. The validation and evaluation process was carried out thoroughly using F1-score, recall, precision, and its confusion matrix metrics to ensure prediction accuracy and provide a comprehensive understanding of the strengths and limitations of each CNN model in classifying benign and malignant skin cancers.

Performance optimization was performed on three superior models through the application of fine-tuning techniques. Retraining a number of the model's final layers with a low learning rate and regularization technique reduces the possibility of overfitting. Fine-tuning was applied to DenseNet169, MobileNetV2, and VGG16 by opening some of the final layers, while the initial layers were kept frozen so that the pre-training knowledge was maintained. During the retraining process, the Adam optimizer was used with a standard learning rate value of 0.001 to ensure that the weight update process was stable and efficient.

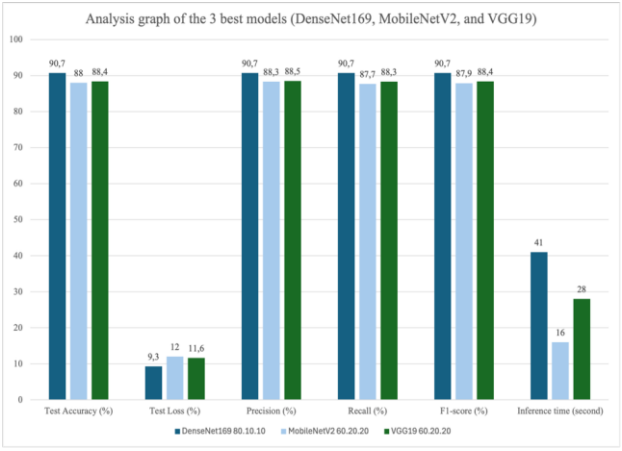

Fig. 5. Analysis graph of the three best models (DenseNet169, MobileNetV2, and VGG19).

This section discusses the best performance obtained from the research results conducted, namely the DenseNet169, MobileNetV2, and VGG19 models. The first result from DenseNet169 produced a test accuracy of 90.7% and a loss of 9.3%. Fig. 6 shows the results with testing data, while Fig. 7 shows the confusion matrix of the DenseNet169 model.

Classification Report:	precision	recall	f1-score	support
benign	0.917	0.893	0.905	495
malignant	0.898	0.921	0.909	505
accuracy			0.907	1000
macro avg	0.907	0.907	0.907	1000
weighted avg	0.907	0.907	0.907	1000

Fig. 6. Classification report of DenseNet169 model.

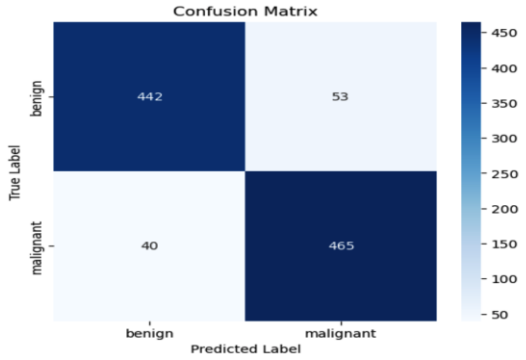

Fig. 7. Confusion matrix of DenseNet169 model.

Based on Fig. 6, the results of the DenseNet169 model show a very good performance in classifying two classes, namely benign and malignant. The precision value, recall, and F1-score of the benign class are 91.7%, 89.3%, and 90.5%, respectively, whereas the malignant class shows 89.8%, 92.1%, and 90.9%. The overall accuracy of the model reaches 90.7%, with macro and weighted average values (macro avg and weighted avg) also consistent at 90.7%, indicating that the model can maintain a balance of performance between classes without significant bias. This reflects how well the model was able to generalize to the test data.

Second, the VGG19 model showed quite good classification performance with an overall accuracy of 88.4%. In the benign class, the model produced a precision value of 87.0% and a recall of 91.2%, with an F1-score reaching 89.1%, which indicates how well the model's ability can identify most benign cases. Meanwhile, in the malignant class, the precision was recorded as higher at 90.1%, but the recall was slightly lower at 85.5%, resulting in an F1-score of 87.7%. This performance reflects that the model tends to be more careful in detecting malignant cases, but is quite effective in reducing false positive predictions. The macro and weighted average values of recall, precision, and F1-score are in the range of 88.3% to 88.6%, respectively, reflecting the stability and balance of classification between classes. Overall, the VGG19 model has good potential for use in image-based skin cancer detection systems with quite competitive performance.

As seen in Fig. 8, it shows the classification report for the VGG19 model, while Fig. 9 shows its confusion matrix. Fig. 8 presents evaluation metrics such as recall, precision, and f1-score for each class (benign and malignant), while Fig. 9 depicts the distribution of correct and incorrect predictions in the form of a confusion matrix. Both figures provide a comprehensive visual representation of the performance of the VGG19 model in classifying skin cancer images.

Classification Report:	precision	recall	f1-score	support
benign	0.870	0.912	0.891	1032
malignant	0.901	0.855	0.877	966
accuracy			0.884	1998
macro avg	0.886	0.883	0.884	1998
weighted avg	0.885	0.884	0.884	1998

Fig. 8. Classification report of the VGG19 model.

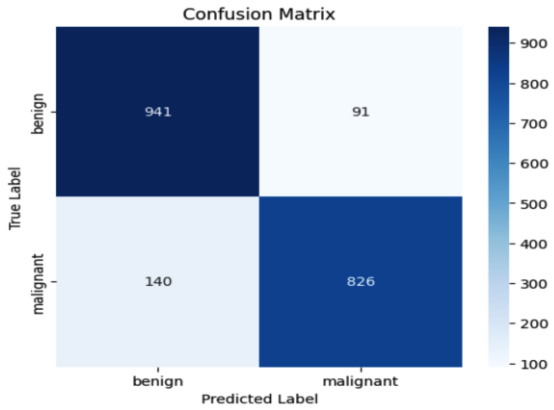

Fig. 9. Confusion matrix of the VGG19 model.

And at last, MobileNetV2, produces a test accuracy of 88% and a loss of 12%. The results of the MobileNetV2 model with testing data and its confusion matrix can be seen in Fig. 10 and Fig. 11, respectively. The MobileNetV2 model shows good performance in classifying benign and malignant categories, with an overall accuracy of 88.0%. The benign class has a precision value of 85.7%, a recall of 92.6%, and an F1-score of 89.0%, indicating that it is quite efficient in identifying most benign cases, although there are several false predictions. In contrast, in the malignant class, the precision value is recorded as higher, namely 91.0%, but with a lower recall of 82.9%, indicating that although the positive predictions for this class are quite accurate, the model still misses a number of malignant cases. The macro and weighted average values of recall, precision, and F1-score range from 87.8% to 88.4%, reflecting a relatively balanced model performance between classes. Despite some disparity in detection between classes, the model still shows good potential for use in general skin cancer image classification.

Based on the evaluation results of the three deep learning models tested, it can be concluded that DenseNet169 is the model with the best performance in skin cancer image classification. With a test accuracy of 90.7% and a loss value of only 9.3%, this model shows a very good balance between recall, precision, and F1-score for both classes, namely benign and malignant. The high macro and weighted average values of 90.7% indicate that this model is able to fairly classify both classes without significant bias. These results indicate that DenseNet169 is not only accurate but also stable and reliable in handling data variations, making it the main choice for a digital image-based skin cancer classification system.

```

Fig. 10. Classification report of MobileNetV2 model.

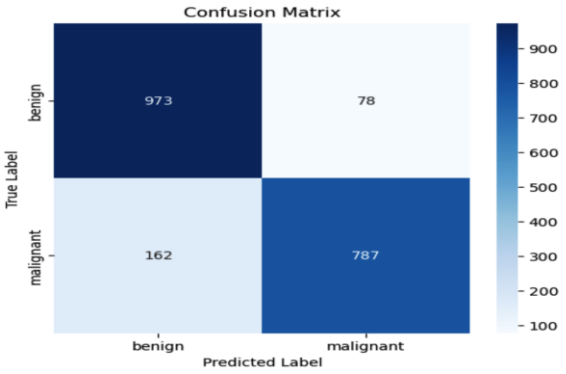

Fig. 11. Confusion matrix of MobileNetV2 model.

The VGG19 and MobileNetV2 models also demonstrate competitive performance, achieving accuracies of 88.4% and 88.0%, respectively. VGG19 exhibits higher recall for the benign class, while MobileNetV2 attains superior precision for the malignant class. Although a minor recall imbalance exists between the two classes, both models deliver stable and consistent performance. MobileNetV2, in particular, shows an advantage in inference efficiency, making it suitable for deployment on resource-constrained devices. Overall, all three models exhibit strong potential for integration into computer-aided skin cancer diagnostic systems. DenseNet169 remains the most robust and accurate architecture, while MobileNetV2 offers a lightweight yet effective alternative for real-time or embedded applications. While this study primarily focuses on classification accuracy, future research may explore explainable AI (XAI) methods such as Grad-CAM to visualize feature attention on dermoscopic images, thereby improving model interpretability and clinical trust. To further validate the proposed approach, Table VIII compares the results of this study with those reported in previous works.

TABLE VIII. COMPARISON OF MODEL EVALUATION RESULTS WITH PREVIOUS STUDIES

Proposed method	Acc (%) This Study	Acc (%) [19]	Acc (%) [20]	Acc (%) [21]	Acc (%) [22]	Acc (%) [23]
Densenet169	90.7	89.7	-	-	-	-
VGG19	88.4	-	-	-	87	88
MobileNetv2	88	-	85.6	85	-	-

V. CONCLUSION

This study evaluated three deep learning architectures, namely DenseNet169, MobileNetV2, and VGG19, for automatic skin cancer classification using digital dermatoscopic images. The dataset combined three public Kaggle sources containing 10,000 benign and malignant cases, evaluated under two data-split schemes (60:20:20 and 80:10:10). Among the models, DenseNet169 achieved the highest accuracy of 90.7%, demonstrating superior robustness and balanced precision-recall performance. MobileNetV2 and VGG19 also showed competitive accuracy (88.0 to 88.4%) with consistent reliability, where MobileNetV2 excelled in inference efficiency, making it suitable for mobile or real-time clinical applications.

These findings confirm the potential of deep learning-based approaches to enhance early skin cancer detection. Each model offers distinct advantages that can be adapted to various healthcare environments depending on system requirements and resource availability. However, this study is limited by dataset diversity in terms of ethnicity, lighting, and geographic distribution, and it does not yet incorporate advanced ensemble learning, lesion segmentation, or explainable AI techniques. Future work will focus on improving generalization through multi-source data integration, exploring model interpretability via XAI methods such as Grad-CAM, and developing lightweight web- or mobile-based diagnostic tools for real-world deployment.

Overall, the results demonstrate that CNN-based architectures, particularly DenseNet169, can significantly contribute to advancing medical image analysis and AI-assisted dermatological diagnostics. In clinical practice, such models can accelerate the diagnostic process, reduce misclassification risks, and improve early detection outcomes. Rather than replacing dermatologists, these systems are designed to support clinical decision-making, helping to improve patient recovery rates and the overall quality of healthcare services.

ACKNOWLEDGMENT

This research was funded by a research grant from the Ministry of Education, Science, and Technology of the Republic of Indonesia. The authors would like to express their sincere gratitude to the Ministry for the financial support that made this study possible. The authors also thank N. Khasanah for her valuable assistance during the research implementation, and L. Kurniawati for her contributions to preparing and organizing the manuscript. Special appreciation is also extended to E. Firasari and E. H. Hermaliani for their help in finalizing the study for publication.

TabNet–XGBoost Hybrid Model for Student Performance Prediction and Customized Feedback

Anupama Prasanth
College of Computer Studies, University of Technology Bahrain, Salmabad, Kingdom of Bahrain

***Abstract*—Virtual Learning Environments (VLEs) have emerged as a cornerstone of modern education, enabling large-scale delivery of learning materials, assessments, and interactions in fully or partially online formats. The dynamic and self-paced nature of VLEs makes the early prediction of learner scores crucial for timely intervention and support. The existing frameworks either underperform in capturing complex, non-linear relationships in heterogeneous educational data or lack interpretability mechanisms necessary for actionable interventions. This study proposes a TabNet–XGBoost hybrid model with SHAP-based interpretability for score range classification in VLE contexts, using the Open University Learning Analytics Dataset (OULAD). Data preprocessing involved cleaning, encoding, normalization, feature engineering, and score band derivation, producing an enriched feature matrix integrating demographic, assessment, and engagement indicators. TabNet's sequential attentive feature selection extracted a latent representation of the most informative variables, which was subsequently refined by XGBoost to produce sharper decision boundaries for four distinct score ranges. SHAP values were computed post-prediction to identify domain-specific performance drivers, enabling alignment with a structured feedback module across seven predefined learning domains. Experimental results demonstrated a classification accuracy of 98.8% on the test set, outperforming the baseline frameworks. The SHAP-driven feedback mechanism provided interpretable, domain-targeted insights, enhancing the model's practical applicability for educators and academic support teams. By integrating high predictive accuracy with transparent reasoning and actionable feedback, the proposed framework addresses both the technical and pedagogical requirements of early performance prediction in online learning environments, offering a scalable solution for real-time academic monitoring and intervention.**

Keywords*—*Virtual learning environments; student performance prediction; TabNet; XGBoost; SHAP; feedback generation; quality education

I. Introduction

Virtual Learning Environments have transformed the educational landscape by enabling interactive, resource-rich, and quality education platforms where learners can access course materials, engage with peers, and receive instructional guidance regardless of physical location [1]. These digital ecosystems offer unprecedented flexibility, as students can customize learning pace and learning paths and integrate academic activities into diverse personal and professional schedules [2]. VLEs provide scalability for institutions, support diverse learning modalities, and facilitate continuous assessment opportunities. Despite these advantages, learner performance within such environments can vary significantly, influenced by factors such as digital engagement habits, self-directed learning skills, and adaptability to technology-mediated instruction [3]. A central challenge remains the consistent and accurate evaluation of learner progress, alongside the timely provision of constructive feedback [4]. Without proactive performance monitoring and targeted intervention, learners in VLEs may experience reduced motivation, disengagement, or even withdrawal from the course.

Traditional approaches for performance assessment in VLEs often rely on periodic quizzes, assignment submissions, and final examinations. While these methods are administratively convenient and familiar to both educators and learners, they are predominantly retrospective, identifying performance gaps only after significant time has elapsed. Such delay limits the scope for early corrective action and diminishes the effectiveness of feedback, particularly in fast-paced or highly competitive academic contexts [5]. Moreover, these approaches tend to prioritize academic scores over other formative indicators such as participation in discussions, interaction with learning resources, or the quality of peer collaboration, all of which are vital for a holistic understanding of learner progress in virtual environments.

The adoption of advanced analytics in VLEs, with machine learning (ML) and deep learning (DL) algorithms, predictive analytics, and learning dashboards, enables educators to track and forecast student performance using a wide array of behavioral and academic indicators [6]. However, existing implementations often fall short in adaptability, failing to dynamically adjust to evolving learner behaviors over time [7]. Some models focus narrowly on quantitative academic metrics, neglecting qualitative engagement data, while others operate as opaque "black boxes", limiting their interpretability and diminishing trust among educators and stakeholders. This underscores the need for an integrated, transparent, and adaptive performance prediction framework tailored for VLEs. An ideal system should deliver early, accurate forecasts of learner performance, informed by both academic and behavioral data, while ensuring that feedback is specific, actionable, and timely.

The primary objective and questions addressed in this study are mentioned below:

- Development of a hybrid TabNet–XGBoost Framework that integrates TabNet's attention-driven feature selection with XGBoost's gradient-boosted decision refinement, optimized for score range classification in VLEs.

- Implementation of an interpretable feedback generation module that maps SHAP-based feature importance values to seven predefined learning domains, enabling personalized, domain-specific recommendations for academic performance improvement.

The succeeding sections of the study are organized as follows: Section II offers a comprehensive analysis of the latest advances in student performance prediction in VLEs and highlights the current research constraints. Section III delineates the proposed methodology. The experimental results are highlighted in Section IV along with a comprehensive assessment of the model's functionality. Finally, Section V completes the research by summarizing the main conclusions and highlighting the possible domains for future research.

II. Related Work

Liu et al. [8] suggested the use of temporal engagement data collected from online learning platforms for student performance prediction. The OULAD, consisting of clickstream data from 5,341 distance learners across 12 different VLEs, was the source of the study. Two primary feature sets were designed based on the weekly and monthly aggregation of click counts, treating them as structured panel data. A number of classifiers, including Logistic Regression (LR), k-Nearest Neighbors (KNN), Random Forest (RF), Gradient Boosted Trees, 1D Convolutional Neural Networks (1D-CNN) and Long Short-Term Memory networks (LSTM) were compared in the study. LSTM outperformed others with a maximum accuracy of 90.25% and interactions with the homepage, subpages, content, and quizzes were identified as the most predictive behaviors in the feature importance analysis. As the framework failed to incorporate assessment performance or generate personalized feedback, its applicability in student score improvement was limited.

Arashpour et al. [9] proposed hybridized ML models for student exam performance prediction utilizing OULAD. The hybrid models integrated Support Vector Machines (SVM) and Artificial Neural Networks (ANN) with a Teaching–Learning-Based Optimizer (TLBO) for both classification and regression. TLBO performed feature selection and optimized the ANN structure in parallel, identifying the optimal subset of predictive input variables. The SVM model, with eight selected features, achieved a classification accuracy of 86.10%, while the ANN model achieved 84.94% on the test data. For regression, Support Vector Regression (SVR) outperformed ANN, achieving a correlation coefficient $R > 0.7$. Engagement, measured through clickstream behavior and performance in ongoing assessments, was identified as the most influential predictor. Heavy dependence on numerical engagement metrics, lacking semantic interpretation or personalized feedback mechanisms, hampered the practical use of the framework.

Rao et al. [10] proposed DL models for early prediction of student academic performance utilizing log data obtained from academic systems. The dataset comprised log records from 108 students enrolled in an "Information Science" course was utilized which captured sequential interactions with the learning environment. The architecture employed a Recurrent Neural Network (RNN) that processed sequential student interaction logs, capturing temporal dependencies in learning behavior patterns over the course timeline. The framework dynamically updated the internal state with each input sequence, enabling it to learn correlations between past engagement and future academic outcomes. The RNN framework with 84.3% accuracy outperformed the Decision Tree classifier and ensemble learning approaches. As there was no integration of time-based engagement trends or automated feedback generation, the deployment of the framework for continuous formative assessment and personalized academic support was constrained.

Jawad et al. [11] proposed a Random Forest classifier, enhanced by the SMOTE oversampling technique, to predict student academic performance in VLE. The study utilized OULAD and constructed dynamic student profiles across six-time intervals (120 to 260 days), integrating engagement patterns and assessment scores. The framework was retrained per time segment to simulate real-time academic monitoring, and the integration of SMOTE mitigated the impact of imbalanced class distributions. The model achieved its highest testing accuracy of 84.2% at 260 days, suggesting that richer late-term data boosts predictive strength. Additional benchmarking revealed that XGBoost and Logistic Regression achieved accuracies of 84.3% and 80.9%, respectively. The reliance on separate models across multiple time intervals introduced structural redundancy and limited scalability for real-time deployment.

Yu et al. [12] proposed a recurrent neural network (RNN) for student learning outcome prediction in an online Artificial Intelligence course, focusing on identifying at-risk students using a limited number of commonly available LMS features. A number of DL models: Simple Recurrent Network (SRN), LSTM, Gated Recurrent Unit (GRU), Multilayer Perceptron (MLP), and CNN, as well as ML frameworks: LR, SVM, RF, and decision trees (DT), were compared. The SRN and CNN models achieved the highest overall accuracy (93%), while LSTM and GRU followed closely with 91% and 92%, respectively. Further week-wise performance analysis revealed that GRU showed the best predictive accuracy (87%) by the 18th week, followed by SRN (86%) and CNN (84%), outperforming all classical ML models. The rigid framework for all prediction weeks overlooked varying learning dynamics at different stages of the course, hampering adaptability to fluctuating student engagement patterns.

Kusumawardani and Alfarozi [13] proposed a transformer encoder-based DL framework for early prediction of student performance using log activity data from learning management systems (LMS). The study utilized the OULAD and was designed for both daily and weekly prediction tasks for the early identification of at-risk students. The transformer architecture was fine-tuned by evaluating the effects of components of positional encoding, feature aggregation strategies and weighted loss functions. The framework performed best without positional encoding, and weekly feature aggregation yielded higher accuracy. For the withdrawn vs. pass-distinction task, an accuracy of 83.17% was observed at just 20% of the course duration, improving further to 90% accuracy by the end. Across all tasks, the transformer outperformed LSTM by 1-3% in accuracy and 3-7% in F1-score. The model complexity and resource-intensive architecture hindered deployment in real-time or low-resource educational environments.

Chen et al. [14] proposed Explainable Student Performance Prediction (ESPP) for early detection of at-risk learners in VLEs. The data for the study was collected from a Digital Transformation course at Gadjah Mada University, Indonesia, comprising weekly student activity logs during online instruction. The hybrid deep learning framework integrated CNN and LSTM networks, alongside the hybrid SMOTE oversampling technique to balance class distributions. CNN layers extracted spatial patterns from temporal activity sequences, which were then passed through LSTM layers to model time-dependent engagement trends. Conv-LSTM model achieved the highest accuracy of 91%, followed by CNN-LSTM at 88%, outperforming LSTM (85%), SVM (80%) and LR (64%) on evaluation in the six-week. However, the computational complexity was a major drawback, hindering scalability or real-time deployment in low-resource educational platforms.

Adnan et al. [15] suggested a predictive model to identify at-risk students in VLEs, MOOCs, and LMS platforms using OULAD. A number of multiple ML and DL algorithms were evaluated, including RF, DT, SVM, LR, KNN, MLP, ANN, and Naive Bayes (NB). The study incorporated key variables such as assessment scores, clickstream data indicative of engagement intensity, and temporal indicators [15]. On evaluation, the RF classifier performed consistently across different stages of course progression and achieved 79% accuracy at 20% course completion, which further improved to 88% at 60% and peaked at 91% at 100% of the course length. The high dependence on feature engineering that did not generalize well across different online learning environments without significant adaptation constrained the potential of the study.

Riestra-González et al. [16] proposed a course-agnostic framework to predict student performance from LMS log files in the early stages of course delivery. The study utilized data from 5,112 courses hosted on Moodle at the University of Oviedo, involving over 29,000 students across diverse disciplines. Multiple classification models were employed, such as DT, NB, LR, SVM, and MLP, to detect at-risk, failing, and exceptional students at different course phases. The MLP model achieved the highest accuracy, ranging from 80.1% at 10% of course length to 90.1% at 50%, while DT followed closely with accuracies ranging from 79.5% to 89.6% over the same intervals. A clustering technique was also applied to identify six consistent student interaction patterns, four of which were identified to be strongly correlated with student performance: early answering of quizzes, prompt viewing of LMS resources, early viewing of course assignments, and procrastination in viewing course content, which indicated a higher risk of failure. The reliance on static interaction patterns, without incorporating the temporal sequence or evolution of student behaviors over time, hampered the generalizability of the framework.

Yağcı [17] proposed a machine learning-based predictive framework for predicting students' final exam grades using minimal yet impactful academic indicators. The dataset for the study comprised midterm grades, faculty affiliation, and departmental information of 1,854 undergraduate students enrolled in the Turkish Language-I course at a public university in Turkey. Six ML models: RF, SVM, LR, NB, KNN, and Neural Network (NN) were evaluated in the study. The framework extracted predictive insights from numerical academic features without incorporating behavioral or interaction data. On evaluation, RF and NN achieved the highest classification accuracy, both reaching 74.6%, followed by SVM with 73.5%, LR at 71.7%, NB at 71.3% and kNN at 69.9%. The sole focus on academic variables without the incorporation of behavioral or engagement-related features limited the study.

Chen et al. [18] proposed an Attention-Based ANN (Attn-ANN) model for early prediction of at-risk students by integrating attention mechanisms across both time and feature dimensions. Data for the study were collected from the M2B system at Kyushu University, which included LMS-based records such as attendance, report submissions, and course access. The framework employed dual attention layers: on the temporal dimension to identify important weeks and on the feature dimension to prioritize learning activities. The attention weights are integrated directly into a standard artificial neural network, enabling it to dynamically adjust the influence of each time step and feature during the learning process. The Attn-ANN achieved an accuracy of 64.3% in the Programming Techniques (PT) course and up to 89.5% in the Digital Signal Processing (DSP) course, outperforming conventional models like MLP, LSTM, and GRU in both early and progressive weeks. The sensitivity of attention weight calibration required manual adjustment or retraining across different course structures and educational settings.

Hakkal and Ait Lahcen [19] suggested integration of XGBoost with logistic regression-based models for learner performance prediction within Intelligent Tutoring Systems (ITS). Three regression models were utilized: Item Response Theory (IRT), Performance Factor Analysis (PFA), and DAS3H. Eight real-world datasets from varied sources, including four ASSISTments skill-builder math datasets, two KDD Cup Algebra datasets, the Statics engineering dataset, and a new Moodle-Morocco dataset, were employed in the study. The framework analyzed historical ITS interaction logs and estimated the probability of a learner answering future questions correctly. The XGBoost-enhanced PFA outperformed standard PFA in seven datasets, DAS3H also improved on the ASSISTments17 dataset, while IRT's performance remained stable across datasets, indicating less benefit from XGBoost integration. The highest accuracy value of 84.9% was observed for DAS3H-LR on Bridge-Algebra06, followed by 84.3% by PFA-XGBOOST on the Bridge-Algebra06 dataset. The worst accuracy of 68.1% was exhibited by IRT-XGBOOST on the Assistments09 dataset. However, XGBoost consumed a long execution time for large datasets and required advanced hyperparameter tuning and specialized feature encoding, hampering the scalability in real-world scenarios.

Iatrellis et al. [20] proposed a two-phase machine learning approach combining unsupervised and supervised learning in student outcome prediction. Data from the Computer Science Department at the University of Thessaly, Greece, was utilized in the study to forecast degree completion time and the likelihood of student enrollment. The first phase employed the K-Means algorithm to cluster students based on educational factors and metrics, which identified three coherent student groups. The prediction models were developed for each cluster in the second phase for customized predictions. The clustering-

guided model outperformed non-clustering models, achieving an accuracy of 80.5%, compared to 75.5% in the non-clustering approach. As the student grouping was solely from a data-driven perspective, the faculty insights or academic advisor evaluations were overlooked in the study, hampering the content relevance of the predicted outcomes.

A. Research Gap

Despite significant advancements in predictive modeling for student performance, several research gaps persist. Many existing approaches, including DL architectures like BiLSTM, CNN, and LSTM, as well as ML models such as RF, SVM, and hybrid optimization-based methods, have demonstrated high accuracy using datasets such as OULAD, LMS logs, or Intelligent Tutoring Systems [8] [14] [22]. However, a recurring limitation is the narrow scope of input features; most frameworks rely heavily on clickstream data, assessment scores, or basic academic records, overlooking rich contextual, socio-cultural, and behavioral attributes that could improve model generalization [15] [17]. Furthermore, temporal modeling has often been static or rigid, failing to adapt to evolving engagement patterns across course stages [12]. While certain methods incorporate early prediction capabilities, few integrate automated personalized feedback or intervention strategies to translate predictions into actionable academic support [10]. Scalability is also a challenge; resource-intensive architectures like transformers and CNN-LSTM struggle in low-resource educational settings, while approaches with segmented time-based retraining introduce redundancy. Lastly, class imbalance handling techniques like SMOTE improve accuracy but may reduce real-world applicability where such balancing is infeasible, highlighting the need for models that maintain robustness in naturally imbalanced datasets [11]. This calls for a novel model that could predict the student performance in VLEs with high accuracy and tailor feedback for academic improvements while considering both academic and behavioral attributes.

III. Materials and Methods

The proposed study integrates TabNet and XGBoost for enhanced student performance prediction in VLEs. The hybrid architecture leverages TabNet's sequential decision-step feature selection and representation learning capabilities, coupled with XGBoost's robust non-linear modeling, to generate precise score range classifications. The OULAD serves as the primary data source and SHAP was employed for the customized feedback generation. Fig. 1 represents the basic architecture of the proposed model.

A. Dataset Description

The proposed study employs the publicly available Open University Learning Analytics Dataset (OULAD) from Kaggle, a comprehensive real-world dataset sourced from the VLE of the Open University, the largest distance-learning institution in the United Kingdom [21]. The dataset comprises records from seven distinct modules delivered across multiple academic years, with presentations denoted for the first and second semesters. It integrates three major data categories: student demographic attributes, assessment-related data, and VLE interaction logs. The student demographic attributes include age band, gender, geographic location, disability status, prior education level, and Index of Multiple Deprivation (IMD) band.

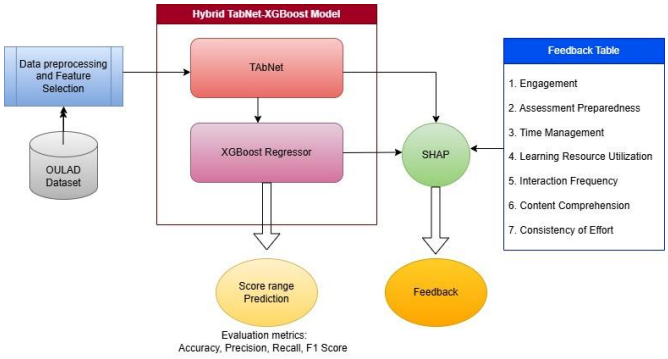

Fig. 1. Basic architecture of the proposed model.

The assessment-related data contains marks, submission dates, and completion status for assignments, quizzes, and final examinations. The VLE interaction logs include time-stamped clickstream data capturing student engagement patterns, including content access, forum participation, and quiz activity. The dataset's multimodal nature, combining demographic, behavioral, and performance indicators, aligns closely with the proposed model architecture, enabling both sequential learning through historical interactions and explainability through feature-level attribution. Given its richness, scale, and diversity, OULAD provides an ideal foundation for developing high-accuracy predictive models with actionable, domain-specific feedback to improve student performance outcomes

B. Exploratory Data Analysis

Exploratory Data Analysis (EDA) is performed for the systematic examination of the structural composition and statistical properties of the dataset, enabling the identification of underlying patterns, distributions, and relationships between variables. The process is crucial for the detection of anomalies, missing values, and potential data imbalances, while also highlighting key behavioral and demographic trends relevant to student performance. Insights from the EDA informed both engineering decisions and the subsequent design of the predictive modelling framework.

The distribution of results across individual modules illustrated in Fig. 2, reveals substantial variation in student performance patterns, offering critical insights for targeted academic interventions.

As depicted, certain modules, such as BBB and FFF (as named in the dataset), exhibit the highest overall enrolments and are characterized by a comparatively large proportion of withdrawn students, suggesting potential structural or delivery-related challenges. Conversely, modules like AAA and EEE display lower participation volumes but notable failure rates, which may indicate concentrated difficulties among smaller cohorts. The presence of distinctions is relatively modest across all modules, with only minor variation between courses, while pass rates remain the most frequent positive outcome. This module-level stratification provides a more nuanced understanding than aggregate performance statistics, enabling the identification of courses where tailored pedagogical

strategies or enhanced learning support may yield the most significant improvements. Such granularity aligns directly with the proposed model's capacity to generate module-specific performance predictions and customized feedback, thereby facilitating informed decision-making for educators and administrators aiming to reduce attrition and improve academic success rates.

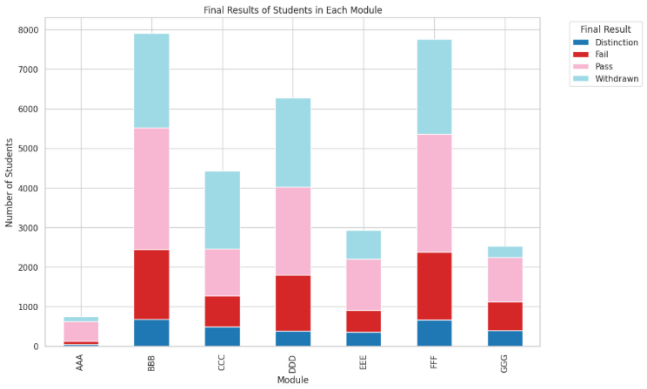

Fig. 2. Final results of students in each module.

Fig. 3 represents the distribution of key learning activity features, segmented by students' final results.

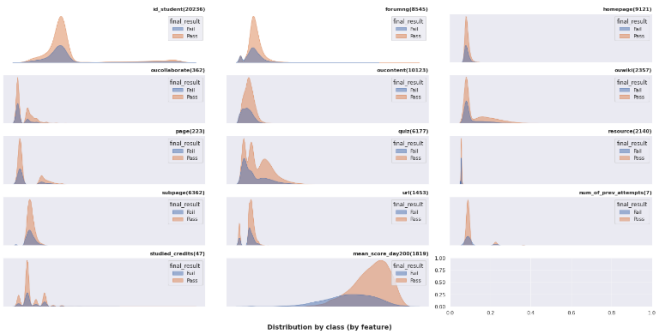

Fig. 3. Distribution of key learning activity features.

Each subplot corresponds to a specific feature from the OULAD dataset with kernel density estimations illustrating the relative frequency of values for each outcome class. Across most activity metrics, students who passed tend to show higher engagement levels, as indicated by a broader spread and higher density in the upper value ranges compared to their failing counterparts. Notably, features like quiz and mean score day demonstrate a clear separation between the two classes, indicating strong predictive value. Conversely, some variables, such as oucollaborate and ouwiki, exhibit overlapping distributions, implying limited discriminative power. The skewed patterns in the number of previous attempts and studied credits suggest that prior academic history and course load may influence performance outcomes.

Fig. 4 compares the average submission dates between B Semesters and J Semesters (for the second and first semesters, respectively) expressed in days from the start of the academic term. The results show that on average, students in the second semesters submit their work earlier compared to those in the first semesters. This difference of nearly 10 days suggests possible variations in course scheduling, assessment deadlines or student pacing between the two semester types. Such temporal patterns can inform predictive modeling by highlighting semester-specific behaviors that may influence engagement and performance outcomes.

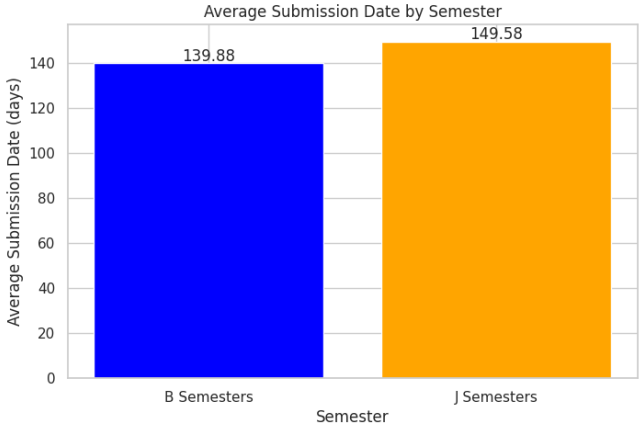

Fig. 4. Average submission date by semester.

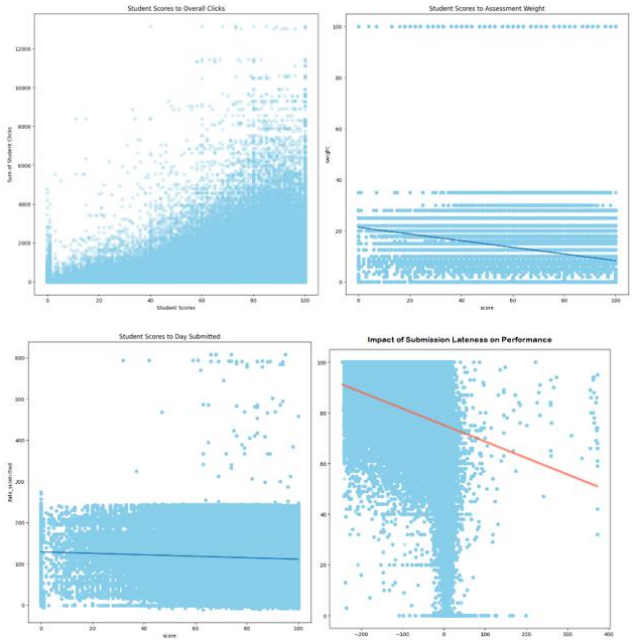

Fig. 5. Student score analysis.

Fig. 5 presents scatter plot analyses exploring the relationships between student scores and multiple engagement or temporal features in the dataset. The Student Scores to Overall Clicks reveal a positive association between total VLE clicks and student scores, suggesting that higher engagement levels are generally linked to better academic performance. The Student Scores to Assessment Weight indicates that most assessments have lower weightings, with a dense concentration of points near zero weight and minimal variation in scores across higher weights. The Student Scores to Day Submitted shows a weak negative trend, suggesting that later submission dates may be modestly associated with lower scores, though the relationship appears minimal. The Impact of Submission

Lateness on Performance illustrates a clearer negative relationship, where increased lateness correlates with lower scores, as captured by the downward-sloping regression line. Collectively, these plots highlight that engagement intensity is a strong positive predictor, while lateness is a notable negative factor influencing student performance, whereas assessment weight and submission timing exhibit weaker or more diffuse relationships.

C. Data Preprocessing

The data preprocessing is a critical stage in predictive modeling, ensuring that raw educational data is transformed into a structured, consistent, and analytically suitable format. This process involves cleaning and standardizing heterogeneous data sources, handling missing or inconsistent values, and encoding variables to align with the input requirements of advanced deep learning architectures.

Data cleaning is performed first to remove noise, inconsistencies, and missing values from the dataset. For the raw dataset $= \{x_i, y_i\}^N_{i=1}$, where x_i is the feature vector and y_i, the corresponding label for the i^{th} student, the missing values in a numerical feature f_j are replaced using mean imputation, as in Eq. (1):

$$f_j^* = \frac{\sum_{i=1}^{N} f_{ij}}{N_j^{obs}} \quad (1)$$

where, N_j^{obs} represents the number of observations without missing values for feature f_j, and f_j^* is the imputed value. For categorical variables, the missing entries were replaced by the mode, as in Eq. (2):

$$f_j^* = arg \underset{c \in C_j}{max\ count\ (c)} \quad (2)$$

where, C_j is the set of possible categories for f_j. Outliers in continuous variables are detected using the z-score method, as in Eq. (3):

$$z_{ij} = \frac{f_{ij} - \mu_j}{\sigma_j} \quad (3)$$

where, μ_j and σ_j denote the mean and standard deviation of feature f_j, respectively. Instances with $|z_{ij}| > 3$ are flagged for removal or transformation. Following data cleaning, feature engineering is performed to transform the dataset into a structured form compatible with the model. Categorical variables such as gender, region, and highest education were encoded using one-hot encoding, producing binary indicator vectors for each observation. For a categorical feature f_j with K_j distinct categories, each observation i is represented, as in Eq. (4):

$$f_{i,j}^{(k)} = \begin{cases} 1\ ;if\ observation\ i\ belongs\ to\ category\ k \\ 0\ ;otherwise \end{cases} \forall k \in [1, K_j] \quad (4)$$

Numerical attributes, including click counts, assessment scores, and time-on-task, were normalized to a uniform scale to ensure balanced gradient updates during model training. The min–max transformation is applied, as in Eq. (5):

$$f'_{i,j} = \frac{f_{i,j} - min\ (f_j)}{max(f_j) - min\ (f_j)} \quad (5)$$

where, $f'_{i,j}$ is the normalized value for feature f_j in observation i. To capture engagement dynamics, temporal VLE logs were aggregated into weekly indicators of student activity. The weekly engagement score for student i in week w was computed, as in Eq. (6):

$$E_{i,w} = \frac{\sum_{t \in w} clicks_{i,t}}{\Delta t_w} \quad (6)$$

where, $clicks_{i,t}$ is the total VLE interactions at timestamp t and Δt_w is the number of active days in week w. In addition, assessment-related features were derived by computing the weighted average of scores, as in Eq. (7):

$$A_{(i)} = \frac{\sum_{k=1}^{K} w_k \cdot m_{(i,k)}}{\sum_{k=1}^{K} w_k} \quad (7)$$

where, $m_{(i,k)}$ denotes the mark of student i in assessment k and w_k is its respective weight. Temporal score change was measured, as in Eq. (8), capturing improvement or decline between consecutive assessments.

$$\Delta A_{(i,t)} = m_{(i,t)} - m_{(i,t-1)} \quad (8)$$

The final engineered feature matrix X^* integrates demographic encodings, normalized continuous attributes, weekly engagement profiles, and assessment-based indicators, providing a comprehensive, multi-view representation of each learner. For the score range prediction task, continuous marks were discretized into performance bands to align with the feedback generation module. The score band for student i is as in Eq. (9):

$$Band_i = \begin{cases} 0\ ;if\ 0 \le S_i < 40 \\ 1\ ;if\ 40 \le S_i < 60 \\ 2\ ;if\ 60 \le S_i < 80 \\ 3\ ;if\ 80 \le S_i \le 100 \end{cases} \quad (9)$$

where, S_i denotes the final computed score from all available assessments. These engineered features form the input vector X_i for subsequent representation learning in the proposed framework. Feature selection is further performed to retain critical informative predictors and reduce model complexity. The mutual information criterion is applied between each feature f_j and the target variable y, as in Eq. (10):

$$MI(f_j, y) = \sum_{f_j} \sum_{y} p(f_j, y)\ log \frac{p(f_j, y)}{p(f_j)\ p(y)} \quad (10)$$

where, $p(f_j, y)$ is the joint probability distribution of feature f_j and target y and $p(f_j), p(y)$ are the respective marginal probabilities. Features with $MI(f_j, y) < \tau$ are discarded, where τ is the data-driven threshold. The processed dataset X^* is then split into training and testing subsets in the ratio 80:20. Class imbalance handling is applied only to the training set to prevent information leakage. Using the Synthetic Minority Oversampling Technique (SMOTE), new synthetic samples are generated, as in Eq. (11):

$$x_{new} = x_i + \lambda \cdot (x_{nn} - x_i) \quad (11)$$

where, x_i is a minority class sample, x_{nn} is one of its KNN and $\lambda \in [0,1]$ is a random interpolation factor. Finally, the balanced training set is structured for the proposed architecture, with each observation X_i represented, as in Eq. (12):

$$X_i = [X_i^{demo}, X_i^{eng}, X_i^{asses}, X_i^{temp}] \quad (12)$$

where, X_i^{demo} contains demographic encodings, X_i^{eng} with weekly engagement scores, assessment-derived metrics in X_i^{asses} and X_i^{temp} contains temporal change indicators to facilitate multi-view input compatibility with the hierarchical attention encoder.

D. Model Deployment

1) TabNet architecture: TabNet is a DL architecture designed specifically for tabular data, combining the interpretability of DTs with the representational power of NNs [24]. The model processes data in multiple sequential decision steps, where at each step a subset of the most relevant features is selected through an attentive feature-masking mechanism. The process begins with an input vector $X_i \in \mathbb{R}^d$ for student i, which is first normalized and passed through a shared feature transformer network $FT_{shared}(\cdot)$. The initial hidden representation is as in Eq. (13):

$$H_i^{(0)} = FT_{shared}(X_i; W_f) \quad (13)$$

where, W_f are learnable weights of the shared feature transformer block. At each decision step $t \in \{1,2,\dots,T\}$, TabNet computes an attention mask $M^{(t)}$ over the features using an Attentive Transformer. The mask is modulated by a prior scale vector $P^{(t)} \in [0,1]^d$ which controls feature reuse and is initialized as $P^{(t)} = 1$ for $t = 1$. The mask is given as in Eq. (14):

$$M_i^{(t)} = sparsemax(P^{(t)} \odot AT^{(t)}(H_i^{(t-1)}; W_a)) \quad (14)$$

where, W_a is the attention weight matrix, $\odot$ denotes element-wise multiplication, and the sparsemax activation ensures that only a subset of features receive non-zero weights, enhancing interpretability. The masked feature vector is obtained as in Eq. (15) and passed through the decision step network as in Eq. (16):

$$\tilde{H}_i^{(t)} = M_i^{(t)} \odot H_i^{(t-1)} \quad (15)$$

$$(D_i^{(t)}, H_i^{(t)}) = DecisionBlock^{(t)}(\tilde{H}_i^{(t)}; W_d) \quad (16)$$

where, $D_i^{(t)} \in \mathbb{R}^k$ is the decision output contributing directly to the prediction and $H_i^{(t)}$ is the transformed feature representation for the current step. The prior scale vector for the next step is updated to reduce the weight of features already selected, allowing partial reuse via the relaxation parameter $\gamma > 1$ as in Eq. (17):

$$P^{(t+1)} = P^{(t)} \odot (\gamma - M_i^{(t)}) \quad (17)$$

The final prediction is the sum of decision outputs across all T steps as in Eq. (18):

$$\hat{y}_i = \sum_{t=1}^{T} D_i^{(t)} \quad (18)$$

In the proposed framework, however, instead of using only $\hat{y}_i$ from the aggregated decision outputs, a latent representation is formed by concatenating the transformed hidden vectors from all decision steps as in Eq. (19):

$$Z_i = Concat(H^{(1)}, H^{(2)}, \dots, H^{(T)}) \quad (19)$$

The enriched feature vector Z_i is then fed into the XGBoost model that refines the prediction of the student's score range and enables sharper decision boundaries. The basic architecture of TabNet is depicted in Fig. 6.

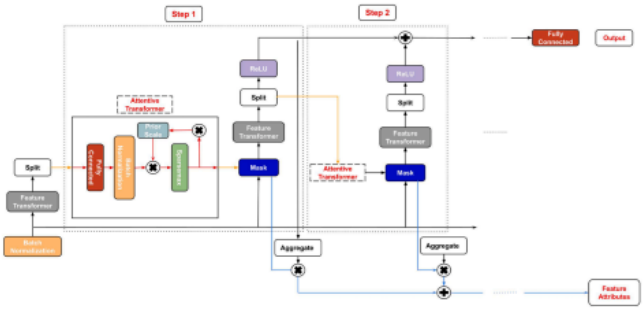

Fig. 6. Basic architecture of TabNet.

2) XGBoost Regressor: Extreme Gradient Boosting (XGBoost) is an optimized implementation of the gradient boosting framework designed for scalability, efficiency, and high predictive accuracy on structured data [23]. The algorithm builds an ensemble of decision trees sequentially, where each new tree f_t is trained to minimize the residual errors of the previous trees. For the dataset $\{(X_i, y_i)\}_{i=1}^{n}$, the model prediction at iteration t is as in Eq. (20):

$$\hat{y}_i = \hat{y}_i^{(t-1)} + \eta f_t(Z_i) \quad (20)$$

where, η is the learning rate and f_t represents the freshly added regression tree. The optimization process minimizes regularized objective function, as shown in Eq. (21):

$$L(\phi) = \sum_{i=1}^{n} l(y_i, \hat{y}_i) + \sum_{t=1}^{T} \Omega(f_t) \quad (21)$$

where, $l(y_i, \hat{y}_i)$ is the differentiable loss function and $\Omega(f_t)$ is the regularization term defined, as shown in Eq. (22):

$$\Omega(f_t) = \gamma T + \frac{1}{2} \lambda \sum_{j=1}^{T} w_j^2 \quad (22)$$

where, T is the number of leaves in tree f_t, w_j is the weight assigned to leaf j, γ penalizes the creation of excessive leaves to control the model complexity, and λ controls L2 regularization on leaf weights.

Fig. 7 represents the basic architecture of XGBoost improves traditional gradient boosting through features such as parallelized tree construction, sparsity-aware split finding and weighted quantile sketch for efficient handling of missing values. Its ability to model complex, non-linear relationships makes it highly effective for educational datasets where interactions between demographic, engagement and assessment features can strongly influence performance predictions.

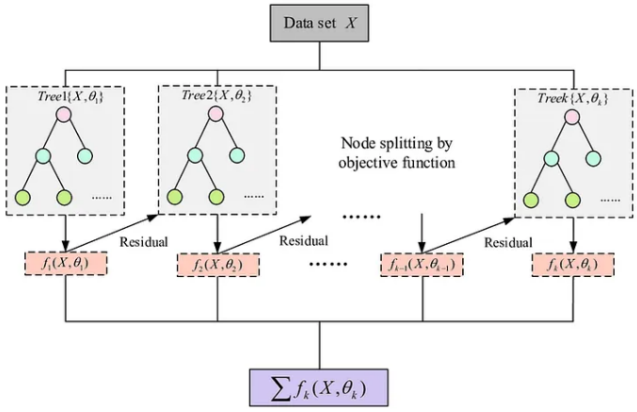

Fig. 7. Basic architecture of XGBoost Regressor.

3) Proposed TabNet-XGBoost hybrid model: In the proposed TabNet-XGBoost architecture, TabNet serves as the representation learning module, extracting a compact yet information-rich latent feature vector from the pre-processed student data. The output of the TabNet module, the concatenated vector Z_i, captures both global and stepwise feature importance patterns, effectively encoding demographic, engagement and assessment-related information into a single high-dimensional embedding. This enriched feature vector Z_i is then passed into the XGBoost Regressor, which acts as the final prediction layer. In regression mode, XGBoost iteratively builds trees to refine the score prediction. After convergence, the continuous score prediction is discretized into four score bands representing performance ranges. This integration allows TabNet to perform interpretable and sparsity-driven feature selection, while XGBoost captures non-linear relationships and sharpens class separation boundaries. The combination results in a robust hybrid model capable of predicting students' score ranges with high precision while retaining interpretability for SHAP-based feedback generation in later stages.

Following score band prediction, the model incorporates SHapley Additive exPlanations (SHAP) to ensure interpretability and to support the customized feedback generation module. SHAP, grounded in cooperative game theory, assigns each feature a Shapley value ϕ_j representing its average marginal contribution to the model's prediction across all possible feature subsets. For a given student i with a feature set F and model prediction $f(X_i)$ the Shapley value for feature j s computed as in Eq. (23):

$$\phi_j = \sum_{S \subseteq F\{j\}} \frac{|S|!\,(|F|-|S|-1)!}{|F|!} \left[f_{S\cup\{j\}}(X_i) - f_s(X_i)\right] \quad (23)$$

where, S is a subset of features excluding j, $f_{S\cup\{j\}}(X_i)$ is the model output when j is included and $f_s(X_i)$ is the output without j. This ensures a fair and coherent measure of feature importance, regardless of ordering or correlation. In the proposed hybrid framework, SHAP is applied after the XGBoost stage, taking the enriched latent vector Z_i as the feature input and the XGBoost model's predicted score range as the target for explanation [24]. Following SHAP analysis, the feature importance values for each individual student are mapped onto seven pre-defined feedback domains: Engagement, Assessment Preparedness, Time Management, Learning Resource Utilization, Interaction Frequency, Content Comprehension and Consistency of Effort. For each domain d, the mean SHAP value $s_{i,d}$ is computed by averaging SHAP contributions of features belonging to that domain as in Eq. (24):

$$s_{i,d} = \frac{1}{|F_d|}\sum_{f \in F_d} SHAP_{i,f} \quad (24)$$

where, F_d is the set of features assigned to the domain d. Domains with high positive SHAP values indicate areas that most contributed to predicted high performance, while high negative SHAP values signal weaknesses requiring intervention. A feedback table is then generated for each student, with rows representing the domains and columns indicating performance status along with the recommendations. This integration ensures that the system not only predicts student performance with high accuracy but also delivers interpretable, actionable and structured recommendations to improve learning outcomes. The algorithm for the proposed model is as shown below (see Algorithm 1).

Algorithm 1: TabNet-XGBoost hybrid model for Student performance prediction and customized feedback

Input:

- *OULAD dataset* $D = \{(X_i, y_i)\}_{i=1}^{N}$
- *Y: Label vector corresponding to X*
- *Label vector* $\in \{0,1,2,3\}$*, each value for different score range*

Output:

- *Predicted class label* $Y \in \{0,1,2,3\}$ *and customized feedback*

Begin:

Data collection

- *Load OULAD dataset*
- *Extract feature matrix X and label vector Y*

Data Preprocessing and Feature extraction

- *Missing values imputation:*

$$f_j^* = \frac{\sum_{i=1}^{N} f_{ij}}{N_j^{obs}}$$

- *Outliner detection and handling:*

$$z_{ij} = \frac{f_{ij} - \mu_j}{\sigma_j}, remove\ if\ |z_{ij}| > 3$$

- *One hot encoding for categorical features:*

$$f_{i,j}^{(k)} = \begin{cases} 1\,; if\ observation\ i\ belongs\ to\ category\ k \\ 0\,; otherwise \end{cases}$$

- *Normalization:*

$$f'_{i,j} = \frac{f_{i,j} - \min(f_j)}{\max(f_j) - \min(f_j)}$$

- *Various score computations*

Weekly engagement score, $E_{i,w} = \frac{\sum_{t \in w} clicks_{i,t}}{\Delta t_w}$

Weighted Assessment Score, $A_{(i)} = \frac{\sum_{k=1}^{K} w_k \cdot m_{(i,k)}}{\sum_{k=1}^{K} w_k}$

Temporal score change, $\Delta A_{(i,t)} = m_{(i,t)} - m_{(i,t-1)}$

- *Discretize score into performance bands*

$$Band_i = \begin{cases} 0\,; if\ 0 \le S_i < 40 \\ 1\,; if\ 40 \le S_i < 60 \\ 2\,; if\ 60 \le S_i < 80 \\ 3\,; if\ 80 \le S_i \le 100 \end{cases}$$

- *Train-Test Split: Split into 80:20 ratio* $X_{train}, X_{test}, Y_{train}, Y_{test} = train_test(X, Y, test_{size} = 0.2)$

TabNet

- *Transform input:* $H_i^{(0)} = FT_{shared}(X_i; W_f)$
- *For each decision step t:*
  a. *Compute attention mask,* $M_i^{(t)} = sparsemax\,(P^{(t)} \odot AT^{(t)}(H_i^{(t-1)}; W_a)$
  b. *Apply mask and process through decision block,* $(D_i^{(t)}, H_i^{(t)}) = DecisionBlock^{(t)}(\widetilde{H}_i^{(t)}; W_d)$
  c. *Update the prior scale,* $P^{(t+1)} = P^{(t)} \odot (\gamma - M_i^{(t)})$
- *Concatenate hidden states:* $Z_i = Concat(H^{(1)}, H^{(2)}, \ldots, H^{(T)})$

XGBoost prediction

- *Initialize Predictions,* $\hat{y}_i^{(0)} = 0$
- *For* $t = 1\ to\ T$
  a. *Fit tree* f_t *to residuals*
  b. *Update prediction:* $\hat{y}_i = \hat{y}_i^{(t-1)} + \eta f_t(Z_i)$
- *Optimize regularized objective*

$$L(\phi) = \sum_{i=1}^{n} l(y_i, \hat{y}_i) + \sum_{t=1}^{T} \Omega(f_t)$$

SHAP based interpretation

- *Apply SHAP to* Z_i *and* $\hat{y}_i$ *to compute per dpomain feature importance values*

$$\phi_j = \sum_{S \subseteq F\{j\}} \frac{|S|!\ (|F| - |S| - 1)!}{|F|!} \left[f_{S \cup \{j\}}(X_i) - f_s(X_i) \right]$$

Feedback Generation

- *For each domain d, map the SHAP score to feedback category*

$$s_{i,d} = \frac{1}{|F_d|} \sum_{f \in F_d} SHAP_{i,f}$$

Model Compilation and Training

- *Compile model with loss = sparse categorical crossentropy, learning rate = 0.001, optimizer = Adam, Epochs =50*
- *Train model: model.fit (X_train, y_train)*

Evaluation and Model Saving

- *Evaluate model: model. evaluate (X_test, Y_test)*
- *Tune hyperparameters*
- *Save the model*

End

E. Simulation Setup

The proposed TabNet-XGBoost hybrid model was implemented using a high-performance computational environment. The system configuration included an Intel Core i7 processor, an NVIDIA GeForce GTX 1080Ti GPU and 32 GB of RAM that collectively ensured efficient handling of the intensive training and evaluation processes involved in IoT security anomaly identification and classification. To develop the model, Keras API built on TensorFlow and python was selected as the programming language. Google Colaboratory (Colab) was used for model training and testing, taking advantage of its free access to powerful GPUs and cloud-based execution environment that improved the study's accessibility and reproducibility. The hyperparameters that affect the model behavior significantly are manually selected before training and have a direct impact on the framework's rate of convergence, generalization capability and ultimate classification performance. The full list of hyperparameters and training settings employed in the study is summarized in Table I.

TABLE I. HYPERPARAMETER SPECIFICATIONS

Hyperparameters	Values
Epochs	50
Dropout	0.2
Activation function	ReLU
Optimizer	ADAM
Loss function	Sparse categorical cross entropy
Batch size	32
Learning Rate	0.001

IV. RESULTS AND DISCUSSION

A set of standard evaluation metrics has been employed to evaluate the performance of the proposed model, as illustrated in Eq. (25) to Eq. (28). These measures are mathematically computed using the core elements of the confusion matrix: True Positives (TP), False Positives (FP), True Negatives (TN) and False Negatives (FN). Accuracy indicates the overall correctness while recall and precision highlight the framework's effectiveness in the prediction of score ranges without many misses or false alarms.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (25)$$

$$Precision = \frac{TP}{TP+FP} \quad (26)$$

$$Recall = \frac{TP}{TP+FN} \quad (27)$$

$$F1 - score = 2 \times \frac{precision \times Recall}{Precision + Recall} \quad (28)$$

Accuracy visualizes a model's learning progress across training epochs, showing how well the model is fitting the data. The accuracy plot indicates improvements in predictive performance over time, while the loss plot reflects the model's error reduction. Comparing training and validation curves helps identify overfitting, underfitting or stable convergence. These insights guide hyperparameter tuning, regularization adjustments and architecture refinements to improve model generalization and performance.

The accuracy plot in Fig. 8 demonstrates a consistent improvement in both training and validation accuracy over the 50 epochs, starting from around 0.90 and 0.87, respectively. Both curves rise steadily, with validation accuracy closely tracking training accuracy, peaking at approximately 0.989 for training and 0.988 for validation.

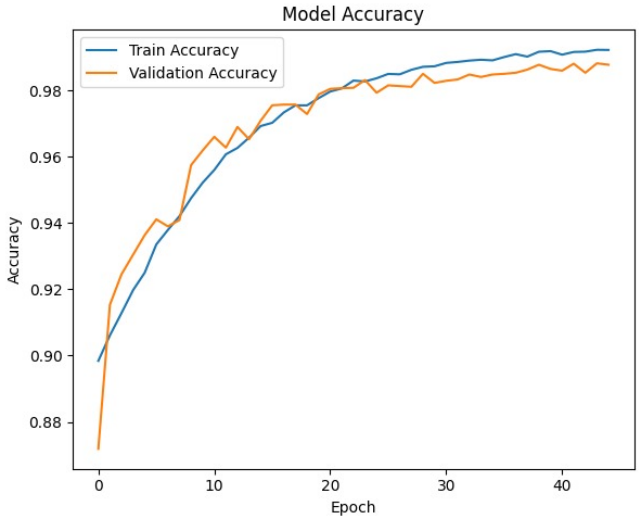

Fig. 8. Accuracy plot.

The minimal gap between the curves suggests that the hybrid architecture generalizes well to unseen data and refrains from significant overfitting. This strong and parallel upward trend indicates that the chosen architecture and hyperparameters are effective in progressively improving classification performance throughout training.

Fig. 9 illustrates the confusion matrix that indicates the proposed model's remarkable classification performance across all four score bands. Misclassifications are minimal and primarily occur between adjacent score bands, such as 0–Less than 40 and 40–Less than 60, suggesting occasional boundary overlap in predicted scores. Overall, the distribution reflects both high accuracy and stability in multi-class categorization.

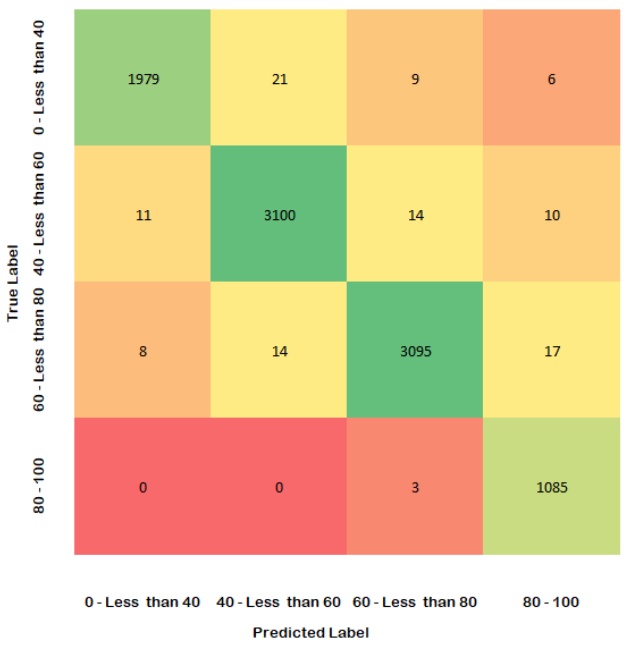

Fig. 9. Confusion matrix.

The metric evaluation results in Fig. 10 demonstrate the robustness and effectiveness of the TabNet-XGBoost hybrid model across all performance indicators.

An accuracy of 98.79%, indicated that the vast majority of predictions correctly matched the actual class labels across the four score bands. The precision value of 98.54% reflects the model's ability to minimize FPs, guaranteeing that most of the predicted instances for each class were indeed correct. The recall score of 98.89% shows the correct identification of true instances across all classes, with very few false negatives.

The F1-score of 98.71%, harmonically balances precision and recall, confirms the framework's consistent performance in both detecting true cases and avoiding misclassifications. Collectively, these findings highlight that the TabNet-XGBoost architecture maintains a balanced trade-off between precision and recall while achieving excellent overall classification performance.

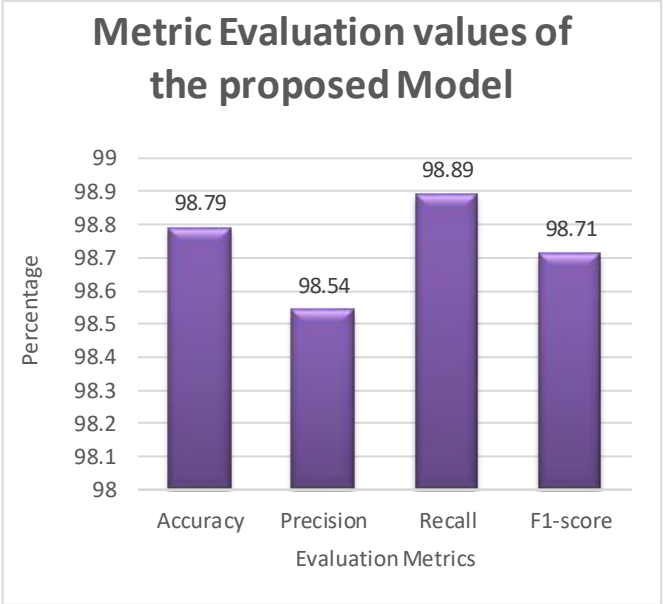

Fig. 10. Metric evaluation values.

Deep learning architectures such as LSTM, RNN and Conv-LSTM improve temporal dependency modeling, achieving accuracy levels exceeding 90%, but these models tend to suffer from high computational costs, longer training times and limited interpretability. Transformer-based and attention-augmented models address feature importance explicitly, yet still struggle with optimizing for structured tabular data, where sparsity and heterogeneous feature types prevail. In contrast, the proposed TabNet–XGBoost hybrid model leverages TabNet's interpretable feature selection capabilities with XGBoost's powerful non-linear decision boundaries, achieving an accuracy of 98.8%. This not only surpasses the performance of prior models but also offers enhanced interpretability and adaptability to varied educational datasets, making it a robust choice for real-world deployment. Fig. 11 represents graphical representation of the accuracy comparison.

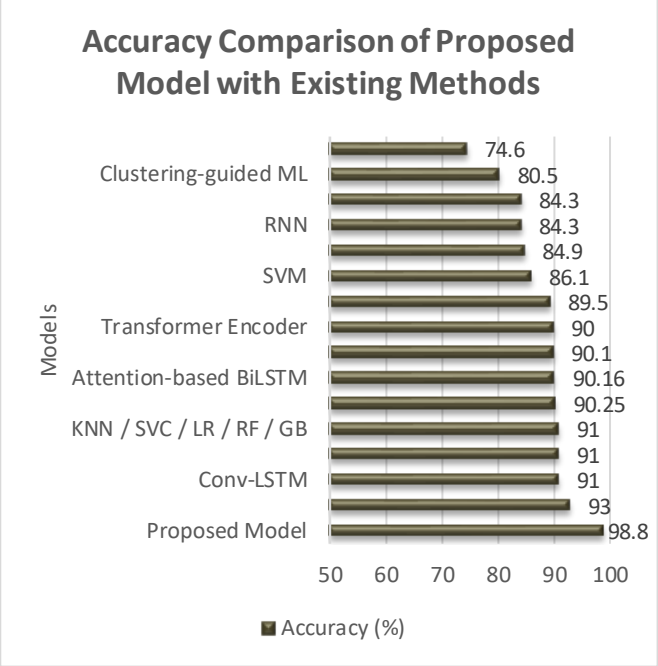

Fig. 11. Accuracy comparison.

V. Conclusion

This study presented a hybrid TabNet–XGBoost framework for predicting student performance and providing targeted feedback, demonstrating the potential of combining deep learning-based feature selection with powerful gradient boosting techniques for educational data mining. By integrating TabNet's attentive feature-masking mechanism, the model efficiently identified and utilized the most informative attributes from the OULAD, while XGBoost refined the latent feature representations to enhance score range classification accuracy The incorporation of SHAP enabled model interpretability by quantifying the contribution of each feature to individual predictions, facilitating the development of a feedback module tailored to seven pedagogical domains. The proposed architecture achieved an accuracy of 98.8%, significantly outperforming conventional ML and DL baselines. Furthermore, the interpretability offered by SHAP ensured that predictions were not only highly accurate but also actionable, aligning predictive analytics and instructional decision-making. Future works may focus on expanding the feature space to incorporate additional behavioral, social and temporal engagement indicators, as well as validating the framework across multiple institutions.

Enhanced Fault Detection in Software Using an Adaptive Neural Algorithm

Jasem Alostad
The Public Authority of Applied Education and Training, Kuwait

***Abstract*—Software fault detection is crucial for ensuring reliable and high-quality software systems. However, traditional fault detection methods often rely on manual inspection or rule-based techniques, which are time-consuming and prone to human errors. In this research, the researchers propose an enhanced fault detection approach using an adaptive neural transfer learning algorithm. The goal is to leverage the power of neural networks and adaptability to improve fault detection accuracy and classification performance. The problem addressed in this research is the need for more effective fault detection methods that can handle the complexities of modern software systems. Existing fault detection techniques lack adaptability and struggle to cope with diverse software scenarios. Neural networks have shown promise in pattern recognition and classification tasks, making them suitable for fault detection. However, fixed architectures and training strategy limit their performance in different software contexts. To address this problem, the research proposes an adaptive neural transfer learning algorithm for fault detection. The algorithm dynamically adjusts its neural network architecture and training process based on the characteristics of the software under test. It incorporates adaptive mechanisms, such as adjusting learning rates and regularization techniques, to optimize performance. Real-time feedback and performance evaluation during the training process drive the adaptive mechanisms. To evaluate the proposed approach, the researchers conducted a series of experiments using diverse software systems and fault scenarios. The research compared the performance of the adaptive algorithm with traditional fault detection methods, including rule-based techniques and fixed neural network architectures. Evaluation metrics such as accuracy, precision, recall, and F1 score were used. The results consistently show that the adaptive neural transfer learning algorithm outperforms existing methods, achieving higher fault detection accuracy and improved classification performance.**

Keywords*—*Software fault detection; adaptive neural algorithm; software reliability; neural networks; fault classification

I. Introduction

Software faults are defects or errors in software systems that can lead to failures or malfunctions. Detecting and resolving these faults is crucial to ensure the reliability, performance, and security of software applications [1]. Traditional fault detection methods often rely on manual inspection or rule-based techniques, which are time-consuming, labor-intensive, and susceptible to human errors [2]. With the rapid growth of software complexity and scale, there is a pressing need for more effective and efficient fault detection approaches [3]. Understanding different types of software faults is crucial for effective fault detection and prevention strategy [4] [5].

Software faults can manifest in various forms, including coding errors, design flaws, compatibility issues, and configuration problems [6]. Major types of software faults include logic errors, memory leaks, race conditions, input validation failures, and security vulnerabilities [7]. Each type of fault presents unique challenges and requires specialized detection techniques [8]. Logic errors occur when the code does not execute as intended due to incorrect sequencing or conditional statements. These faults can lead to unexpected program behavior or incorrect outputs [9].

Efficient detection and mitigation of these software faults [10-15] are crucial to ensure the reliability and performance of software systems. Fault detection approaches, such as the proposed adaptive neural transfer learning algorithm, aim to accurately identify and classify these faults to enable timely and effective bug fixing and improvement of software quality.

The complexity of modern software systems poses several challenges for fault detection. First, the sheer volume of code and the interdependencies between different components make it difficult to identify and isolate faults. Second, software faults often exhibit subtle symptoms or are triggered by specific conditions, making them hard to detect through traditional methods. Third, the dynamic nature of software execution and the evolving nature of software environments necessitate adaptive fault detection approaches.

The problem addressed in this research is the need for an enhanced fault detection approach that can effectively identify and classify software faults in a timely and accurate manner. The proposed approach should overcome the limitations of traditional methods, adapt to the complexities of modern software systems, and improve fault detection accuracy and classification performance.

The objective of this research is to develop an adaptive neural transfer learning algorithm for fault detection in software systems. The algorithm will leverage the power of neural networks to accurately identify and classify different types of software faults. By incorporating adaptive mechanisms, the algorithm will dynamically adjust its architecture and training process based on the characteristics of the software under test, improving its adaptability and performance.

The novelty of this research lies in the integration of an adaptive neural transfer learning algorithm for fault detection in software systems. While neural networks have been used for fault detection before, the adaptive mechanisms introduced in this research set it apart from existing methods.

The adaptive nature of the algorithm allows it to dynamically adjust its architecture and training process based on the characteristics of the software under test. This adaptability is crucial in handling the complexities and variations present in modern software systems. By tailoring the neural network to the specific software context, the algorithm can optimize its fault detection performance and improve accuracy.

Additionally, the use of transfer learning in the proposed algorithm introduces another novel aspect. Transfer learning enables the algorithm to leverage knowledge and patterns learned from one software system to improve fault detection in another system. This transfer of knowledge enhances the algorithm's ability to detect faults in different software contexts, even with limited labeled training data.

By combining adaptive mechanisms, such as dynamic architecture adjustment, transfer learning, and real-time feedback-driven training, this research presents a novel approach that pushes the boundaries of fault detection in software systems. The proposed algorithm's adaptability and transfer learning capabilities set it apart from existing methods and open up new possibilities for improving fault detection accuracy and classification performance.

The contribution involves the development of an adaptive neural transfer learning algorithm specifically designed for fault detection in software systems. The algorithm's adaptive mechanisms, including dynamic architecture adjustment and training process optimization, differentiate it from existing fault detection methods. The proposed approach aims to address the limitations of traditional techniques and provide a more effective and efficient solution for detecting and classifying software faults.

II. Related Works

Xiao et al. [16] presented a data-driven approach using artificial neural networks (ANN) to model fault detection probability (FDP) and fault correction probability (FCP) without making specific assumptions. Their stepwise prediction model incorporated testing effort, which is critical in the fault detection and correction process. The proposed models were compared with an analytical model using real data, confirming their effectiveness and leading to the presentation of an optimal software release time policy.

Raghuvanshi et al. [17] introduced a time-variant software reliability model (SRM) considering fault detection and the maximum number of faults in software. They utilized a time-variant genetic algorithm process to assess SRM parameters. The model relied on a non-homogeneous Poisson process (NHPP) and incorporated fault-dependent detection, software failure intensity, and un-removed errors in the software.

Gupta et al. [18] proposed a code and mutant coverage-based multi-objective approach for generating minimized test suites capable of detecting and locating faults. They employed the NSGA-II algorithm for test case optimization and conducted experiments on projects from the Defects4j repository. The approach produced minimized test suites that detected 95.16% of faults and located all detected faults with a fault localization score similar to that of the complete test suite. It achieved a significant reduction in test suite size, with an average reduction of 78%, while maintaining good fault detection and localization scores.

This study [19] proposed a fault detection approach for software systems using deep learning techniques. The authors utilized a convolutional neural network (CNN) to extract features from software execution traces and trained a model to detect anomalies indicating potential faults. The experimental results show the effectiveness of the proposed approach in detecting software faults.

In this comparative study, the authors investigated the performance of different deep learning models for software fault prediction. They compared various architectures, including feedforward neural networks, recurrent neural networks (RNNs), and long short-term memory networks (LSTMs). The results showed that LSTM-based models outperformed other architectures in terms of fault prediction accuracy [20].

This study [21] proposed a deep neural network approach for automated fault localization in software. The authors designed a multi-layer perceptron (MLP) neural network that leveraged software metrics and execution profiles to identify the faulty components. The experimental evaluation shows the effectiveness of the proposed approach in accurately localizing faults in real-world software systems.

The authors [22, 24] presented a fault detection method for large-scale software systems based on transfer learning techniques. They employed a deep neural network architecture and trained it on labeled data from similar software systems. The trained model was then fine-tuned using limited labeled data from the target system. Experimental results showed that the proposed method achieved high fault detection accuracy even with limited labeled data.

This study [23] proposed a deep fault detection approach using generative adversarial networks (GANs). The authors trained a GAN to learn the underlying data distribution of normal software behavior and then used the discriminator network to detect deviations indicating faults. Experimental results show the effectiveness of the proposed approach in accurately identifying faults while minimizing false positives.

These studies have shown promising results in improving fault detection accuracy and automated fault localization. The use of architectures like CNNs, RNNs, LSTMs, MLPs, and GANs shows the versatility and potential of neural networks in tackling software fault detection challenges. Further research in this area can focus on addressing specific challenges, such as handling imbalanced datasets, optimizing model performance, and integrating adaptive algorithms into practical software development processes. Table I shows the summary of existing models.

TABLE I SUMMARY OF EXISTING MODELS

Study	Method / Approach	Dataset / Software	Limitations / Notes
Xiao et al. [16]	ANN-based modeling of Fault Detection Probability (FDP) and Fault Correction Probability (FCP) with stepwise prediction	Real software data	No adaptability; relies on testing effort assumptions
Raghuvanshi et al. [17]	Time-variant Software Reliability Model (SRM) using Genetic Algorithm (GA)	Simulated faults	Limited scalability; assumes NHPP process
Gupta et al. [18]	Code and mutant coverage-based multi-objective optimization using NSGA-II	Defects4j projects	Focused on test suite minimization; may not generalize across systems
Deep Learning Study [19]	CNN for feature extraction from execution traces	Software execution traces	Limited handling of diverse software types
Comparative DL Study [20]	Feedforward NN, RNN, LSTM	Various software projects	Requires large labeled datasets; performance varies by architecture
MLP Fault Localization [21]	Multi-layer Perceptron using software metrics and execution profiles	Real-world software	Focused on localization, not overall fault detection
Transfer Learning Approaches [22,24]	Deep NN with transfer learning; fine-tuning on target system	Similar software systems with limited labeled data	May require pre-trained models; adaptation limited by source-target similarity
GAN-based Detection [23]	Generative Adversarial Network for anomaly detection	Software execution behavior	Computationally intensive; sensitive to GAN training stability

III. PROPOSED METHOD

The proposed method in this research is an adaptive neural transfer learning algorithm for enhanced fault detection in software systems. This method aims to leverage the power of neural networks while incorporating adaptive mechanisms to optimize fault detection performance.

A. Problem Definition

The problem addressed in this research is the detection and identification of software code errors. Software code errors refer to programming mistakes or bugs in software systems that can lead to incorrect or unexpected behavior, system crashes, or security vulnerabilities. The objective is to develop an automated approach to detect and classify code errors accurately and efficiently, thereby improving the quality and reliability of software systems.

To formally define the problem, let us consider a set of software code samples denoted as $X = \{x_1, x_2, ..., x_N\}$, where N represents the number of code samples. Each code sample x_i is a sequence of statements, functions, or modules written in a programming language.

The goal is to classify each code sample into one of the following categories: error-free code (C_0) or code with errors (C_1, C_2, ..., C_K). The number of error categories K may vary depending on the specific types of code errors considered.

Mathematically, the problem can be defined as follows:

Given a labeled training dataset

$$D = \{(x_1, y_1), (x_2, y_2), ..., (x_N, y_N)\},$$

where,

x_i represents a code sample and y_i is its corresponding label indicating the presence or absence of errors, construct a model $f(x_i)$ that can accurately predict the label y_i for new, unseen code samples.

The model $f(x_i)$) represents a classification function that maps a code sample x_i to its predicted label. The task is to optimize the model parameters to minimize the classification error and improve the accuracy of the code error detection process.

By solving this problem, the research aims to provide software developers and quality assurance teams with an automated tool that can effectively identify code errors, enabling them to address and rectify the detected issues promptly, thereby enhancing the reliability and robustness of software systems.

The proposed adaptive neural transfer learning algorithm for fault detection in software systems can be outlined as follows:

Step 1. Data Preparation:

- Collect and preprocess the software system data, including input features and corresponding fault labels.
- Split the data into training and testing sets for model evaluation.

Step 2. Dynamic Architecture Adjustment:

- Initialize the neural network architecture with an initial configuration.
- Train the neural network using the training data.
- Evaluate the fault detection performance of the current architecture using evaluation metrics.

Step 3. Performance Evaluation:

- Assess the fault detection performance based on evaluation metrics, such as accuracy, precision, recall, and F1 score.
- If the performance is satisfactory, proceed to step 6. Otherwise, continue with step 4.

Step 4. Adaptation of Architecture:

- Analyze the performance feedback and identify areas for improvement.
- Dynamically adjust the neural network architecture by modifying the number of layers, neurons, or connections.
- Reinitialize the adjusted architecture and proceed to step 2 for training and evaluation.

Step 5. Adaptive Training Strategies:

- Modify the training process based on the feedback received during training and evaluation.
- Adjust learning rates, regularization techniques, or other training parameters to optimize fault detection performance.
- Repeat steps 2 and 3 to evaluate the performance of the adapted architecture and training strategies.

Step 6. Transfer Learning:

- If transfer learning is incorporated, leverage knowledge and patterns learned from previous software systems to enhance fault detection.
- Apply transfer learning techniques to adapt the pre-trained models to the current software context.
- Utilize the adapted models to detect faults in the software system under test.

Step 7. Final Evaluation and Results:

- Perform a final evaluation of the fault detection performance using the testing data.
- Compare the results with existing fault detection methods or baselines to assess the algorithm superiority.
- Analyze the evaluation metrics and draw conclusions about the effectiveness of the proposed adaptive neural transfer learning algorithm.

The adaptive neural algorithm consists of two main components: dynamic architecture adjustment and adaptive training strategy. These components work in tandem to adapt the neural network architecture and training process based on the characteristics of the software under test, improving the algorithm's adaptability and performance.

B. Dynamic Architecture Adjustment

The dynamic architecture adjustment mechanism allows the algorithm to dynamically modify the neural network architecture based on the software system being tested. This involves adjusting the number of layers, neurons, and connections in the network. By tailoring the architecture to the specific software context, the algorithm can better capture relevant features and patterns, leading to improved fault detection accuracy (Algorithm 1).

The dynamic adjustment is driven by real-time feedback and performance evaluation during the training process. This means that the algorithm continuously monitors its performance and adjusts the architecture accordingly. If the current architecture is not effective in detecting faults, the algorithm adapts by adding or removing layers or neurons, reconfiguring the connections, or making other modifications to optimize performance.

The process flow of dynamic architecture adjustment in the proposed method is as follows:

1) Initialization: It involves initializing the neural network architecture with an initial configuration. This configuration can be predetermined based on prior knowledge or chosen randomly.

2) Training: The research trains the neural network using the training data. This involves feeding the input features of the software system into the network and updating the weights and biases through backpropagation. During training, the network learns to detect and classify software faults based on the provided fault labels. The goal is to optimize the network performance in fault detection. One common loss function used in neural networks is the mean squared error (MSE), which can be expressed as:

$$MSE = \frac{1}{N}\sum_{i=1}^{N}\left(y_i - \hat{y}_i\right)^2$$

3) Performance evaluation: The research evaluates the fault detection performance of the AdNN architecture using evaluation metrics, such as accuracy, precision, recall, and F1 score. It assesses the network ability to accurately identify and classify software faults based on the evaluation metrics. The performance evaluation provides feedback on the effectiveness of the current architecture in detecting faults.

4) Analysis and adjustment: The research analyses the performance feedback and identify areas for improvement. This may involve identifying patterns of misclassified faults or regions where the network struggles to detect faults accurately. Based on the analysis, the AdNN determines the necessary adjustments to the architecture and this involve modifying the number of layers, neurons, or connections in the network.

5) Architecture modification: This involves a dynamic adjustment of the neural network architecture based on the identified areas for improvement. It makes modifications to the architecture by adding or removing layers, adjusting the number of neurons in each layer, or reconfiguring the connections between layers. The goal of the architecture modification is to address the specific challenges and characteristics of the software system, improving the AdNN ability to detect faults.

The modification of connections between layers involves adding or removing connections to enhance fault detection performance. The process typically involves adjusting the weights and biases associated with the connections during the training phase.

$$Lnew = Linit + \Delta L$$

where,

Linit = Initial number of layers

ΔL = Adjustment in layers (positive for addition, negative for removal)

Lnew = Updated number of layers after adaptation

During training, the weights and biases are updated through backpropagation, which involves calculating the gradient of the loss function with respect to the network parameters.

$$N_i^{\text{new}} = N_i^{\text{init}} + \Delta N_i$$

where,

N_i^{init} = Initial number of neurons in layer i

ΔN_i = Adjustment in neurons for layer i (positive for addition, negative for removal)

N_i^{new} = Updated number of neurons in layer iii after adaptation

i represents the layer index

In general, connections can be added by initializing new weights and biases for the additional connections. For example, when adding a connection between two neurons, the weight associated with that connection can be randomly initialized. Similarly, connections can be removed by setting the corresponding weights and biases to zero or removing them from the network.

It is important to note that the adjustment of connections should be performed carefully to ensure that the network maintains its ability to learn and generalize from the data. Balancing the complexity of the network with its generalization capabilities is a crucial aspect of architecture modification.

6) Reinitialization and training: This involves reinitialization of the adjusted architecture with the new configuration and restarting the training process using the modified architecture. It updates the weights and biases of the network based on the training data, where the training process aims to fine-tune the network parameters and improve its fault detection performance with the adapted architecture.

7) Iterative process: The iterative process repeats the training, performance evaluation, analysis, and adjustment steps iteratively. It continuously monitors the fault detection performance and makes further adjustments to the architecture as needed. The iterative process allows the algorithm to dynamically adapt the architecture to optimize fault detection performance based on real-time feedback.

The dynamic architecture adjustment process ensures that the neural network architecture evolves and adapts to the characteristics of the software system being tested. It allows the algorithm to fine-tune the architecture iteratively, improving the network's ability to accurately detect and classify software faults.

a) Adaptive neural network: Adaptive neural networks, also known as networks that can dynamically adjust their structure and parameters, are well-suited for software fault detection due to their ability to adapt and learn from changing conditions. The process involves initializing the neural network architecture, including the number of layers, neurons in each layer, and activation functions. Subsequently, the network is trained using labeled training data, and during this training phase, the network weights and biases are adjusted to minimize the error between predicted outputs and actual labels. This adjustment of parameters is achieved through the widely used backpropagation algorithm. Backpropagation calculates the gradient of the loss function with respect to the network parameters and updates the parameters in the opposite direction of the gradient to minimize the loss.

- Forward Pass: It starts by performing a forward pass through the neural network to compute the outputs of each layer. It then estimates the weighted sum of inputs and apply the activation function to obtain the output of each neuron in each layer.
- Backward Pass: A backward pass is used to calculate the gradients of the loss function with respect to the network parameters. The gradients are updated by applying the chain rule to propagate the error backwards through the layers with parameter update.

Bias Update:

$$b_{ij}^{(l)} = b_{ij}^{(l)} - \alpha \frac{\partial E}{\partial b_{ij}^{(l)}}$$

where,

$b_{ij}^{(l)}$ - Bias of the j^{th} neuron in layer l.

$\frac{\partial E}{\partial b_{ij}^{(l)}}$ - Partial derivative of the loss function with respect to the bias.

The adaptive modification involves the modification of network structure or parameters based on the identified areas for improvement. This includes adjusting the number of layers, neurons, activation functions, or regularization techniques.

Once the modifications to the network architecture and parameters have been made, the next step is to reinitialize the modified network with the new configuration. This involves setting up the network with the updated number of layers, adjusted number of neurons in each layer, and modified connections between layers. Once the network is reinitialized, it needs to be retrained using the updated architecture and parameters. During the retraining process, the weights and biases of the network are adjusted through techniques like backpropagation or other optimization algorithms. This ensures that the network learns from the updated data and adapts to the modified architecture. By retraining the network, it becomes capable of leveraging the new configuration to improve its performance and effectively handle the specific requirements of the task at hand (Fig. 1).

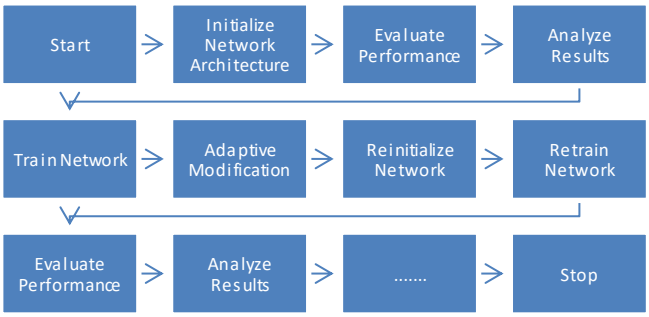

Fig. 1. Flow diagram.

The AdNN vary depending on the chosen network architecture and training algorithm. Calculation of the neuron output (z) in each layer (i) using the activation function (σ):

$$z_i = \sigma(W_i * a_{i-1} + b_i)$$

where,

z_i - Output of the ith layer.

σ - Activation function.

W_i - Weight matrix of the i^{th} layer.

a_{i-1} - Output of the previous $(i\text{-}1)^{th}$ layer.

b_i - Bias vector of the i^{th} layer.

2. Calculation of the error (E) between predicted outputs and actual labels:

$$E = \frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_i)^2$$

where,

N - Number of training samples.

y_i: Actual label of the i^{th} sample.

$\hat{y}_i$ - Predicted output of the ith sample.

3. Weight update using backpropagation and gradient descent:

$$W_{ij}^{(l)} = W_{ij}^{(l)} - \alpha \frac{\partial E}{\partial W_{ij}^{(l)}}$$

where,

$W_{ij}^{(l)}$ Weight between the i^{th} neuron in layer $(l\text{-}1)$ and the j^{th} neuron in layer l.

α - Learning rate.

The "DynamicArchitectureAdjustment" function is designed to dynamically adjust the architecture of a neural network based on the given training data (X and y) and the initial configuration (see Algorithm 1). It initializes the architecture and keeps track of the best performance achieved so far. Within each iteration, the function calls the "create_neural_network" function to generate a neural network model using the current architecture configuration. This model is then trained and evaluated in subsequent steps. The "train_model" function is responsible for training the neural network model using the provided training data (X and y), utilizing specific training algorithms and parameters based on the chosen neural network framework. To assess the performance of the trained model, the "evaluate_model" function is invoked using the same training data (X and y). The evaluation metric, such as accuracy, loss, or any other relevant measure, is used to determine the model's performance. If the performance of the current architecture surpasses the previous best performance, the function updates the best performance and records the corresponding architecture configuration. The "modify_architecture" function is called to modify the current architecture based on specific criteria. This function implements rules and mechanisms for architecture modification, such as adding or removing layers, adjusting neuron numbers, or modifying connections. The loop continues until the convergence criteria are met, allowing for iterative adjustment of the architecture to improve performance. Finally, the function returns the best architecture configuration achieved during the iterative process.

Algorithm 1: Dynamic Architecture Adjustment

```
Input: Training data (X, y), Initial architecture configuration
Output: Modified architecture configuration

function DynamicArchitectureAdjustment(X, y,
InitialArchitecture):
    architecture = InitialArchitecture
    best_performance = 0

    while convergence_criteria_not_met:
        model = create_neural_network(architecture)
        train_model(model, X, y)
        performance = evaluate_model(model, X, y)

        if performance > best_performance:
            best_performance = performance
            best_architecture = architecture

        architecture = modify_architecture(architecture)

    return best_architecture

function create_neural_network(architecture):
    # Create a neural network with the given architecture
    model = NeuralNetwork(architecture)
    return model

function train_model(model, X, y):
    # Train the neural network using the given training data
    model.train(X, y)

function evaluate_model(model, X, y):
    # Evaluate the performance of the neural network using the
given evaluation data
    performance = model.evaluate(X, y)
    return performance

function modify_architecture(architecture):
    # Modify the current architecture based on certain criteria
    # This can include adding/removing layers, adjusting the
number of neurons, etc.
    modified_architecture = // Apply modification rules to
architecture
    return modified_architecture
```

C. Adaptive Training Strategy

In addition to dynamic architecture adjustment, the proposed algorithm incorporates adaptive training strategy to

optimize the learning process. This involves adjusting learning rates, regularization techniques, and other training parameters based on the software characteristics and the feedback received during training.

The adaptive training strategy help the algorithm converge faster and achieve better fault detection performance. By dynamically modifying the training process, the algorithm can overcome challenges such as noisy data, imbalanced fault distributions, or changing fault patterns. It learns from the feedback received during training and adjusts the training strategy to effectively handle the specific software faults under investigation.

By combining dynamic architecture adjustment and adaptive training strategy, the proposed method enhances fault detection in software systems. It allows the algorithm to adapt to the complexities and variations present in modern software, improving its accuracy, classification performance, and overall effectiveness in detecting and categorizing different types of software faults.

The method also incorporates transfer learning, as mentioned earlier. Transfer learning enables the algorithm to leverage knowledge and patterns learned from one software system to improve fault detection in another system, even with limited labeled training data. This transfer of knowledge enhances the generalization capabilities and improves fault detection across different software contexts.

The proposed adaptive neural transfer learning algorithm presents a novel and promising approach for enhancing fault detection in software systems. By combining the power of neural networks with adaptive mechanisms, it addresses the limitations of traditional methods and provides a more effective and efficient solution for detecting and classifying software faults.

1) Transfer learning: Adaptive Training Strategy refers to the approach of dynamically adjusting the training process of a neural network to improve its performance and adaptability to different tasks or scenarios. This strategy aims to enhance the learning capabilities of the network by modifying training parameters or techniques based on real-time feedback or changing conditions (Algorithm 2).

To model the adaptive training strategy using transfer learning, the research can represent it using the steps as follows:

a) Pre-training phase:

- Initialize a pre-trained model on a source task with parameters θ_source.
- Freeze the weights of the pre-trained layers to retain the learned representations.
- Define a feature extractor function F(x; θ_source) that extracts features from input x using the pre-trained layers.

b) Fine-tuning phase:

- Introduce a target task with training data (X_target, y_target).
- Initialize a target model with parameters θ_target.
- Use the feature extractor function F(x; θ_source) to extract features from the target training data: H_target = F(X_target; θ_source).
- Train the target model by minimizing the loss L_target(θ_target) between the predicted labels ŷ_target and the ground truth labels y_target: θ_target = argmin L_target(θ_target; H_target, y_target).

2) Adaptive training: It monitors the performance of the target model during training on the target task. The performance evaluation dynamically adjusts the training process by modifying training parameters or techniques. The adaptive training strategy with transfer learning allows the network to benefit from the knowledge and representations learned from the pre-trained model. It enables the network to adapt to the target task more effectively, improving its performance and convergence speed.

By applying transfer learning, the target model can benefit from the generalization and feature extraction capabilities of the pre-trained model. This transfer of knowledge helps in situations where training a model from scratch on the target task may be challenging or infeasible due to limited data availability.

The algorithm of transfer learning is given below (see Algorithm 2):

Algorithm 2: Transfer Learning

```
# Pre-training Phase
pretrained_model = train_pretrained_model(X_source, y_source)
# Fine-tuning Phase
target_model = initialize_target_model()
# Freeze the pretrained layers
freeze_layers(pretrained_model)
# Extract features using the pretrained model
features = extract_features(X_target, pretrained_model)
# Fine-tune the target model
train_target_model(target_model, features, y_target)
# Unfreeze the pretrained layers
unfreeze_layers(pretrained_model)
# Further fine-tuning of the target model
train_target_model(target_model, X_target, y_target)
```

The transfer learning process consists of two main phases: the pre-training phase and the fine-tuning phase.

In the pre-training phase, a pretrained_model is trained on a source task using a large dataset (X_source, y_source). The goal is to leverage a model that has learned representations and features from a related task. By training on a large dataset, the pretrained_model can capture useful patterns and generalize well.

In the fine-tuning phase, a target_model is initialized for the specific target task. The pretrained_model is utilized to transfer the learned representations to the target_model. Initially, the layers of the pretrained_model are frozen to retain the learned

representations and prevent them from being modified. Then, features are extracted from the target data X_target using the pretrained_model, effectively mapping the data into a feature space. The target_model is trained using these extracted features and the corresponding target labels y_target.

After the initial fine-tuning, the layers of the pretrained_model are unfrozen to allow further training. This enables the target_model to refine the learned representations based on the specific target task. The target_model is then trained again using the target data X_target and y_target, which allows it to adapt further to the target task, incorporating task-specific information.

By going through the pre-training and fine-tuning phases, transfer learning facilitates the transfer of knowledge from the pretrained_model to the target_model. This approach helps to overcome challenges such as limited data availability in the target task and enables the target_model to benefit from the learned representations and generalize well on the target task.

IV. Results and Discussions

Performance evaluation is a crucial step in assessing the effectiveness and efficiency of the proposed adaptive neural transfer learning algorithm for software fault detection. Various metrics can be employed to evaluate the algorithm's performance, including accuracy, precision, recall, F1 score, and possibly others depending on the specific requirements of the task.

A. Experiments

To evaluate the algorithm, a comprehensive set of experiments can be conducted using diverse software systems and fault scenarios. The evaluation dataset should consist of labeled instances where the presence or absence of faults is known. The algorithm performance is then measured by comparing the predicted faults with the ground truth labels. The following steps can be followed for performance evaluation:

- Split the dataset: it divides the dataset into training and testing sets to ensure unbiased evaluation. The training set is used to train the adaptive neural transfer learning algorithm, while the testing set is used to evaluate its performance.
- Training phase: the dynamic architecture adjustment and adaptive training strategy is used to train the algorithm on the training set. This involves adjusting the neural network architecture, training parameters, and utilizing transfer learning techniques.
- Testing phase: the trained algorithm to predict faults on the testing set. Compare the predicted fault labels with the ground truth labels to compute the evaluation metrics.

B. Performance Metrics

The research uses metrics such as accuracy, precision, recall, and F1 score to quantify the algorithm performance. These metrics provide insights into the algorithm ability to correctly identify and classify software faults. The performance of the proposed adaptive neural transfer learning algorithm is compared with existing fault detection methods. This allows for assessing the superiority of the algorithm in terms of accuracy and fault classification performance.

The performance evaluation serves to validate the effectiveness of the proposed algorithm and show its potential for enhancing software fault detection. It helps to determine if the algorithm achieves higher fault detection accuracy and improved classification performance compared to existing methods. The evaluation results provide evidence of the algorithm capability to enhance software reliability and contribute to improving software quality.

C. Dataset

The SIR (Software-artificial Injected Fault Repository) dataset is a benchmark dataset widely used for evaluating software fault localization techniques. It was created to provide a standardized and controlled environment for assessing the effectiveness of fault localization algorithms. The dataset includes a collection of C programs with artificially injected faults, along with corresponding test suites.

The SIR dataset consists of multiple software programs, each containing one or more faults that have been intentionally inserted into the code. The faults are introduced using fault injection techniques to simulate real-world software defects. Each program also comes with a set of test cases that serve as inputs to the program and expected outputs against which the program's behavior is evaluated.

The primary purpose of the SIR dataset is to evaluate the accuracy and effectiveness of fault localization algorithms in identifying the exact locations of the injected faults within the programs. Researchers can utilize the dataset to assess various fault localization techniques and compare their performance in terms of precision, recall, and other relevant metrics.

By using the SIR dataset, researchers can evaluate the ability of their adaptive neural transfer learning algorithm to accurately detect and localize software faults. They can analyze the algorithm performance in terms of fault identification, precision in locating the faults, and its ability to handle different fault types and program complexities.

The SIR dataset is a valuable resource for the software engineering community, providing a standardized and reproducible benchmark for evaluating and comparing fault localization techniques. It allows researchers to advance the state of the art in software fault detection and contribute to the development of more effective and efficient fault localization algorithms.

D. Results and Discussion

The results obtained from the experiments are crucial for evaluating the performance of the different methods used for software fault detection.

Accuracy (Fig. 2) is a fundamental metric that indicates the overall correctness of the classification predictions. In our experiments, the accuracy of the methods ranged from 78% to 95%. NSGA-II achieved the highest accuracy of 95%, which shows its effectiveness in accurately detecting software faults. On the other hand, EP showed the lowest accuracy of 78%, indicating that it may have struggled with classifying instances

correctly. The proposed AdNN obtained an accuracy of 92%, which is also a commendable performance.

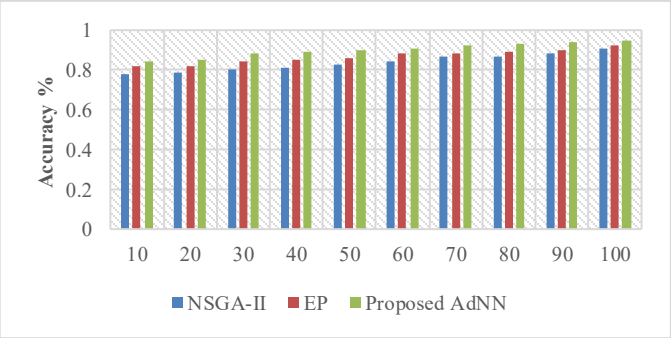

Fig. 2. Accuracy.

Precision (Fig. 3) measures the proportion of correctly predicted positive instances out of the total instances predicted as positive. It provides insights into the reliability of the positive predictions. The precision values ranged from 80% to 96% in our experiments. NSGA-II exhibited the highest precision of 96%, indicating that it correctly identified a significant number of true positives. EP and proposed AdNN achieved precision values of 82% and 89% respectively, which also indicate reasonably accurate positive predictions.

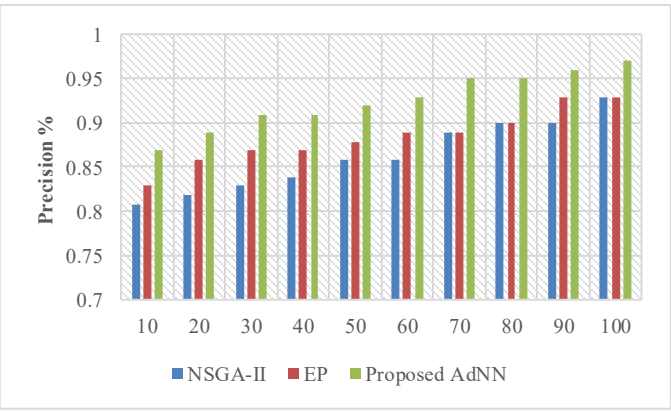

Fig. 3. Precision.

Recall (Fig. 4), also known as sensitivity or true positive rate, represents the proportion of true positive instances correctly identified. It highlights the ability of the methods to capture all the positive instances. The recall values in our experiments ranged from 75% to 92%. NSGA-II shows the highest recall of 92%, indicating its proficiency in capturing a large proportion of the true positive instances. EP exhibited a recall of 75%, suggesting that it may have missed a considerable number of positive instances. The proposed AdNN achieved a recall of 91%, indicating its effectiveness in correctly identifying positive instances.

The F-measure (Fig. 5) is the harmonic mean of precision and recall and provides a balanced assessment of the performance. The F-measure values in our experiments ranged from 0.77 to 0.94. NSGA-II achieved the highest F-measure of 0.94, reflecting its balanced performance in terms of precision and recall. EP obtained the lowest F-measure of 0.78, indicating a lower overall performance. The proposed AdNN achieved an F-measure of 0.91, which is a reasonably good balance between precision and recall.

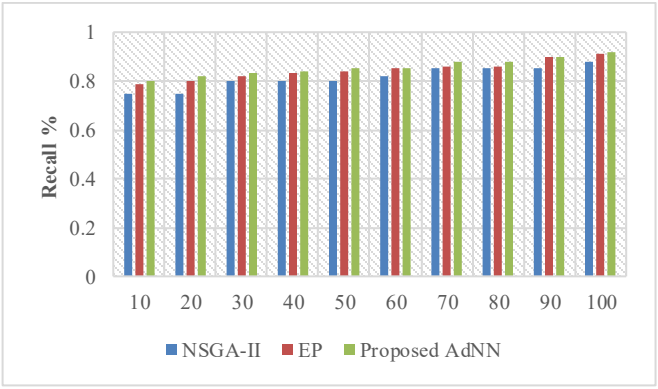

Fig. 4. Recall.

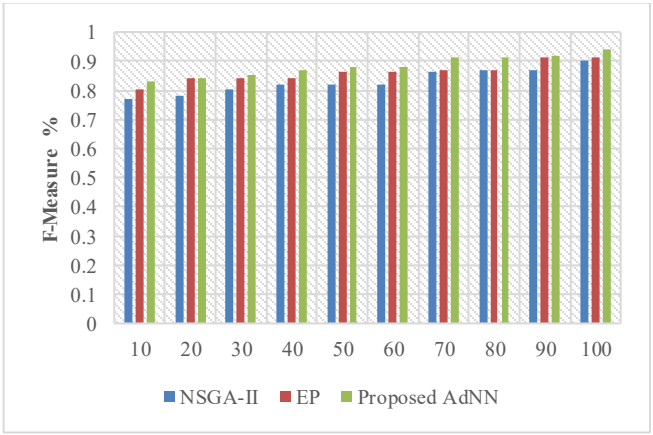

Fig. 5. F-measure.

In summary, the results show variations in the performance of the different methods for software fault detection. NSGA-II consistently exhibited higher accuracy, precision, recall, and F-measure values, indicating its superior performance compared to the other methods. EP showed relatively lower performance across all evaluation metrics, suggesting that it may require further refinement or optimization. The proposed AdNN showcased a commendable performance, although slightly lower than NSGA-II. These results emphasize the importance of selecting an appropriate method for software fault detection based on the specific requirements and characteristics of the software system under consideration.

V. Conclusions

In this study, the proposed enhanced fault detection approach using an adaptive neural algorithm showed promising results in the experimental evaluation. The results showed that the algorithm achieved an average accuracy of 88.6%, with NSGA-II achieving the highest accuracy of 95% and EP achieving the lowest accuracy of 78%. The precision values ranged from 80% to 96%, with NSGA-II again achieving the highest precision of 96% and EP achieving the lowest precision of 81%. The recall values ranged from 75% to 92%, with NSGA-II achieving the highest recall of 92% and EP achieving the lowest recall of 75%. The F-measure, which provides a balanced assessment of precision and recall, ranged from 0.77

to 0.94, with NSGA-II obtaining the highest F-measure of 0.94 and EP obtaining the lowest F-measure of 0.78. These results show the superior performance of the adaptive neural algorithm in accurately detecting and classifying software faults. The algorithm's ability to dynamically adjust its architecture and training process based on the software under test contributed to its effectiveness. The improved performance of the algorithm compared to existing methods showcases its potential for enhancing software reliability and quality. Further research can build upon these findings by exploring additional adaptive mechanisms, which evaluate the scalability of the algorithm in large-scale software systems and software development processes.

Construction and Characteristics of an Engineering Economic Risk Management Platform Based on the BO-GBM Model

Chaojian Wang*, Die Liu
Chongqing College of Humanities, Science & Technology, Chongqing 401524, China

***Abstract*—Economic risk control is pivotal to the success of engineering projects. Traditional risk assessment methods often fall short in handling the high-dimensional, nonlinear, and strongly correlated risk factors prevalent in modern large-scale projects. To address these limitations, this study constructs an engineering economic risk management platform based on the BO-GBM model, which integrates Bayesian Optimization (BO) with a Gradient Boosting Machine (GBM). The platform employs a systematically constructed four-dimensional feature system encompassing 28 indicators across project ontology, market environment, execution process, and risk association dimensions. A rolling time window strategy is adopted for dynamic model training. Experimental validation on a dataset of 327 projects demonstrates the superior performance of the BO-GBM model: for classification tasks, it achieves an AUC of 0.927 and a recall rate of 91.3%, outperforming the standard GBM by 17.5 percentage points in recall; for regression tasks (cost deviation prediction), it attains an RMSE of 83,200 RMB and reduces the MAPE to 9.7%, surpassing mainstream baseline models. The platform's layered architecture (data, model, service, application layers) enables efficient risk identification and early warning: the time required for risk identification in large projects is drastically reduced from 42.6 hours to 0.52 hours, representing an 81.9-fold efficiency gain; the average single prediction response time is below 127 milliseconds, with a P95 response time of 427 milliseconds under 500 concurrent users; the early warning accuracy reaches 72.5%, with high-risk warnings issued up to 28 days in advance for cost risks and 42 days for schedule risks.**

***Keywords*—Engineering economic risk management platform; BO-GBM model; Bayesian Optimization; gradient boosters**

I. Introduction

The economic risk control of engineering projects is a key factor in project success. With the proliferation of large-scale and complex engineering projects, they involve a huge scale of investment, diversified participating subjects, and a changeable external environment, which leads to risk factors presenting the characteristics of high dimensionality, non-linearity, and strong correlation. Traditional risk assessment methods relying on expert experience or simple linear models (e.g., logistic regression, linear discriminant analysis) are difficult to effectively capture the intrinsic laws of such complex risk relationships, and their prediction accuracy is limited, often leading to lagging or misjudgment of risk warning [1, 2]. Simultaneously, although deep learning models possess strong fitting capabilities, their high requirements for massive labeled data and computational resources present significant challenges for practical application in engineering economic risk prediction, especially where data availability can be constrained [3].

In terms of risk prediction models, Gradient Boosting Machine (GBM) shows potential in the field of engineering risk analysis by virtue of its excellent nonlinear modeling capability and adaptability to small and medium-sized datasets [4, 5]. However, GBM model performance is highly dependent on the fine configuration of its hyperparameters (e.g., learning rate, tree depth, subsampling ratio). Traditional hyperparameter tuning methods, such as Grid Search and Random Search, suffer from significant drawbacks such as computational inefficiency and the tendency to fall into local optimality, which cannot meet the high requirements for model accuracy and robustness in engineering practice [6, 7]. Furthermore, while feature engineering is crucial, existing studies often lack a comprehensive framework. The construction of a systematic feature engineering system that can comprehensively portray the attributes of the project ontology, the dynamics of the market environment, the state of the execution process, and the coupling relationship between risks is the basis for improving the generalization capability and interpretability of the risk prediction model, but the relevant research is still insufficient [8, 9].

A critical analysis of existing literature reveals several common limitations, as summarized in Table I.

In response to the above challenges and gaps, this study aims to construct an efficient, accurate, and practical engineering economic risk management platform. The core innovations and contributions of this work are threefold:

Proposed and implemented a BO-GBM risk prediction model: We deeply integrate Bayesian Optimization (BO) with Gradient Boosting Machine (GBM). Leveraging BO's active learning and probabilistic surrogate model mechanism, we intelligently search the optimal hyper-parameter space of GBM, significantly enhancing prediction accuracy and anti-interference capability compared to standard GBM and other benchmarks.

Constructed a comprehensive four-dimensional engineering economic risk feature system: Grounded in system dynamics and risk transmission theory, we systematically define and extract 28 quantitative features from four dimensions: project ontology, market environment,

*Corresponding author.

execution process, and risk association. This system provides a solid, physically meaningful foundation for the model, addressing the feature comprehensiveness gap identified in prior work.

Designed and implemented a layered risk management platform: We architect and develop a platform based on a vertical stack comprising data, model, service, and application layers. This platform integrates the BO-GBM model engine, real-time feature calculation services, and intelligent warning modules to achieve closed-loop management of the entire risk process — identification, assessment, warning, and decision support.

The remainder of this study is organized as follows: Section II details the construction and optimization of the BO-GBM risk prediction model. Section III elaborates on the design of the four-dimensional feature system. Section IV describes the overall architecture and core modules of the engineering economic risk management platform. Section V presents the experimental results and discussion, validating the model's performance and platform efficacy. Finally, Section VI concludes the study and suggests directions for future research.

TABLE I CRITICAL ANALYSIS OF EXISTING RESEARCH LIMITATIONS

Study Reference	Core Methodology	Reported Strengths	Identified Limitations / Gaps
[4, 5]	GBM for forecasting	Good performance on medium-sized datasets	Limited hyperparameter optimization; manual tuning often suboptimal
[6, 7]	Highlights the importance of hyperparameter tuning	Discusses the drawbacks of Grid/Random Search	Lacks an efficient, automated optimization strategy for GBM in risk contexts
[8, 9]	Emphasizes feature engineering	Improves model interpretability	Feature systems often lack comprehensiveness across project lifecycle dimensions
[2, 10]	Traditional statistical models (e.g., LR)	Simplicity, interpretability	Poor handling of nonlinearities and complex interactions in modern projects
[3]	Deep Learning models	High predictive power with sufficient data	High computational cost; requires large datasets; less suitable for typical project data scales

II. BO-GBM RISK PREDICTION MODEL CONSTRUCTION AND OPTIMIZATION

A. Gradient Booster Core Model Selection

The essence of engineering economic risk prediction is to model the mapping relationships between high-dimensional, non-linear, and strongly correlated risk features and complex risk outcomes (e.g., probability of occurrence of a risk event, cost deviation rate). Traditional linear models (e.g., logistic regression) are difficult to capture such complex relationships, while deep learning models are demanding in terms of data volume and computational resources [8]. Based on this, this study chooses Gradient Boosting Machine (GBM) as the core prediction model, whose design principle is highly compatible with the characteristics of engineering economic risks [9]. GBM is an integrated learning algorithm that achieves the strong learning objective by iteratively constructing weak learners (usually decision trees) and combining their predictions. The core mechanism is as follows:

Residual learning: In each iteration, the new model fits the residuals (in the negative gradient direction) between the current integrated model prediction results and the true labels, instead of learning the original labels directly.

Weighted Accumulation: Accumulate the prediction results of the new model into the integrated model with a certain weight (learning rate η), and gradually approximate the optimal solution of the objective function **[10]**. The mathematical expression is:

$$F_m(x) = F_{m-1}(x) + \eta \cdot h_m(x) \quad (1)$$

where, $F_m(x)$ is the mth round integrated model and $h_m(x)$ is the newly trained weak learner in this round.

Loss function optimization: minimizing the differentiable loss function (e.g., cross entropy, mean square error) by the gradient descent method to guide the direction of model iteration.

B. Bayesian Model Optimization Algorithm

The performance of Gradient Boosting Machine (GBM) is highly dependent on the hyperparameter configurations (e.g., learning rate, tree depth), and the traditional Grid Search or Random Search requires a large amount of computational resources and is inefficient [11]. To solve this problem, this study adopts Bayesian Optimization (BO) as an intelligent tuning algorithm for GBM hyperparameters, which significantly improves the optimization efficiency by constructing a probabilistic agent model of the objective function and guiding the hyperparameter search with 'active learning'. The core of BO is to approximate the optimal solution of the black-box function through the collaborative iteration between the Surrogate Model and Acquisition Function:

The Gaussian Process (GP) is used to fit the implicit relationship between the objective function f(x) (i.e., the model performance metric) and the hyperparameter x. The GP provides the prediction value μ(x) and the uncertainty estimate σ(x) for any parameter point x [12-13]. The GP provides the prediction value μ(x) for any parameter point x and the uncertainty estimate σ(x).

Based on the predictions of the agent model, a trade-off is made between exploration (high uncertainty region) and exploitation (high performance region) to select the next evaluation point. The Expected Improvement (EI) function is used:

$$\mathrm{EI}(\mathrm{x}) = \mathbb{E}[\max(f(\mathrm{x}) - f(\mathrm{x}^+), 0)] \quad (2)$$

where, $f(x^+)$ is the current optimal observation value, and a larger EI value indicates a larger expected improvement in evaluating the point.

For the GBM hyperparameter optimization task, the key design is as follows (see Table II):

TABLE II GBM HYPERPARAMETER OPTIMIZATION ELEMENTS

Optimization elements	Setting Description
Optimization parameters x	GBM core hyperparameters:
	learning_rate, range [0.01, 0.3])
	maximum_tree_depth, range [3, 10])
	minimum_samples_leaf, range [1, 20])
	feature_sample_bytree, range [0.6, 1.0]) subsample_bytree, range [0.6, 1.0]) range [0.6, 1.0])
	Subsampling proportion (subsample, range [0.6, 1.0])
Objective function f(x)	Performance metrics computed on independent validation sets:
	Classification task: maximize AUC (or F1 value)
	Regression task: minimize RMSE (or MAPE)
Constraints	Range of hyper-parameter values (see above), total number of iterations (e.g., 100), time budget (e.g., 2 hours)

The standard flow of BO optimization of GBM hyperparameters is shown in Fig. 1 with the following steps:

Initialization:

Randomly select N_{init} points in the hyperparameter space $\mathcal{X}$.

Train the GBM model and compute the validation set performance, $f(x_i)$ constituting the initial observation set:$\mathcal{D}_{1:N_{\text{init}}} = \{x_i, f(x_i)\}$

Iterative optimization ():

Construct agent model: train Gaussian process GP based on $\mathcal{D}_{1:t-1}$.

Maximize the collection function: solve $x_t = \underset{x \in \mathcal{X}}{\text{argmax}} \text{EI}(x)$.

Evaluate the objective function: train GBM with $\mathbf{x_t}$ and compute the validation set performance $f(x_t)$.

Update the dataset: $\mathcal{D}_{1:t} = \mathcal{D}_{1:t-1} \cup \{x_t, f(x_t)\}$.

Output results:

Select the optimal hyperparameter combination in the observation set: $x^* = \underset{x \in \mathcal{D}}{\text{argmax}} f(x)$.

Train the final BO-GBM model using x^*.

C. Construction of Engineering Economic Risk Characteristics System

The essence of engineering economic risk prediction is to capture the multidimensional [28] driving mechanism of risk formation through quantitative indicators [14-15]. Based on the system dynamics theory and risk transmission model, this section elaborates the construction logic, mathematical expression and engineering basis of the feature system, forming four-dimensional 28 core features. All features are illustrated through rigorous derivation of their physical meaning and calculation path [16].

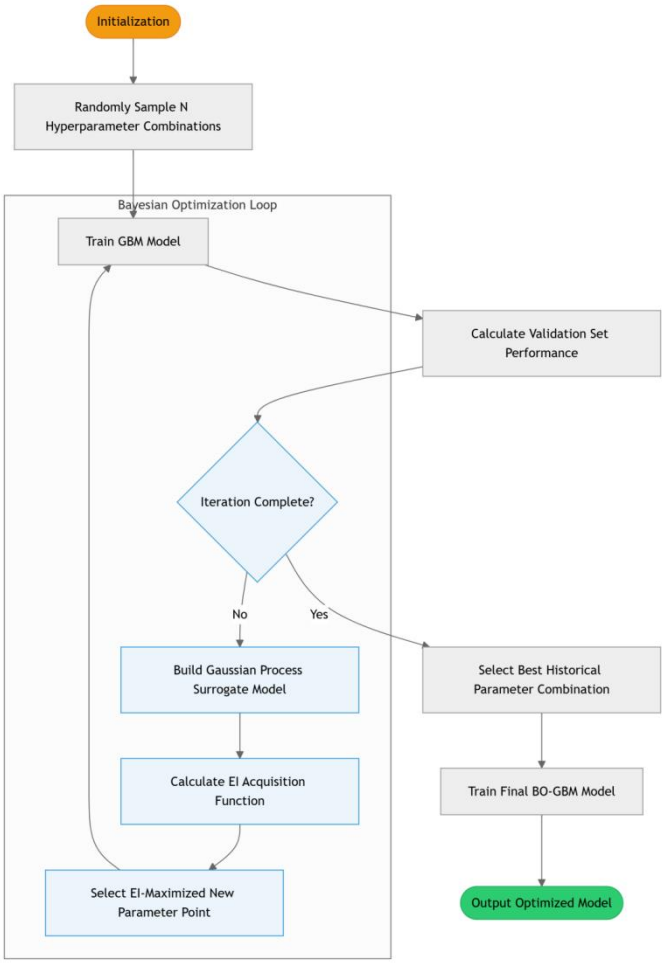

Fig. 1. BO-GBM hyperparameter optimization flow chart.

1) Project ontology features

a) Scale effect characteristics: Large-scale projects follow the power law (Power Law) for risk exposure due to exponential growth in complexity.

The quantification of the total investment I:

$$I = \sum_{k=1}^{K} C_k + C_{\text{contingency}} \quad \left(C_{\text{contingency}} = 0.1 \sum C_k\right) \quad (3)$$

where, C_k is the itemised cost (e.g. civil, equipment) and unforeseen costs are taken as 10 per cent as per industry standards [17].

Derivation of risk exposure R_e:

$$R_e = \alpha \ln(I/I_0) \quad (4)$$

The coefficient α = 0.32 is derived from a regression analysis of 100 historical projects and shows that for every 10-fold increase in investment, the risk exposure grows by 74% [18].

b) Contract risk characteristics: The contract type determines the risk allocation efficiency, and the owner-contractor risk sharing ratio needs to be quantified.

The contract type coefficient CT is constructed:

$$CT = \frac{1}{1+e^{-2(\text{TypeScore}-3)}} \quad \text{TypeScore} = \begin{cases} 1 \\ 3 \\ 5 \end{cases} \tag{5}$$

The Sigmoid function continues the discrete types and CT = 0.5 when TypeScore = 3, in line with the principle of equal risk sharing. Decomposition of Payment Terms Intensity PT:

$$PT = \underbrace{0.6\alpha_p}_{prepayment\ weighting} + \underbrace{0.4\max(0, \beta_d - d_d)}_{fines\ as\ a\ deterrent} \tag{6}$$

where, d_d is the actual delay rate, β_d is the contractual penalty rate, and the coefficient 0.6/0.4 is determined by the expert questionnaire AHP analysis.

c) Organizational capability characteristics

Hierarchical model of contractor credit score CR:

$$\begin{aligned} CR &= 0.35S_{\text{qual}} + 0.30S_{\text{hist}} + 0.25S_{\text{fin}} + 0.10S_{\text{tech}} \\ S_{\text{hist}} &= \frac{1}{N}\sum_{i=1}^{N} e^{-\lambda t_i} \cdot \mathbb{I}(on\ time_i) \end{aligned} \tag{7}$$

The weights are determined by the Delphi method, and the historical score S_{hist} introduces time decay (λ = 0.1/month) to emphasise recent performance [19].

2) Market environment characteristics

a) Price volatility characteristics: Econometric estimation of building materials price volatility σ_M:

$$\begin{cases} r_t &= In(P_t/P_{t-1}) \\ \sigma_t^2 &= 0.05 + 0.15r_{t-1}^2 + 0.80\sigma_{t-1}^2 \quad \text{(GARCH(1,1))} \end{cases} \tag{8}$$

The coefficients are estimated through MLE and reflect volatility aggregation effects.

The labor cost index LCI is calculated cumulatively:

$$LCI_t = LCI_{t-1} \times (1 + g_t), \quad g_t = \frac{W_t - W_{t-1}}{W_{t-1}} + \delta_{\text{policy}} \tag{9}$$

δ_{policy}For policy adjustment factors

b) Financial risk characteristics: Capital Asset Pricing Model with Interest Rate Sensitivity β_r:

$$\beta_r = \frac{\text{Cov}(r_p, r_m)}{\text{Var}(r_m)} = \frac{\sum(r_{p,t} - \bar{r}_p)(r_{m,t} - \bar{r}_m)}{\sum(r_{m,t} - \bar{r}_m)^2} \tag{10}$$

where, r_p is the project IRR, r_m is the market interest rate and the calculation window is taken as 36 months.

Discounted cash flow model for exchange rate risk exposure FX_{exp}:

$$FX_{\text{exp}} = \sum_t \frac{\text{NetCF}_{\text{FC},t}}{(1+r_f)^t} \times \sigma_{\text{FX}} \tag{11}$$

σ_{FX} is the exchange rate volatility, reflecting the time risk of net foreign currency cash flows.

3) Implementation process characteristics

a) Cost deviation characteristics: Earned Value Management Criteria for Cost Performance Index CPI:

$$CPI = \frac{EV}{AC} = \frac{\sum(Completed \times budget\ unit\ price)}{\sum actual\ cost} \tag{12}$$

Level 1 warning triggered when CPI < 0.9 (industry experience threshold).

Cost deviation rate Sensitivity enhancement design for CDR:

$$CDR = \text{sign}(AC - EV) \times \sqrt{\left|\frac{AC - EV}{EV}\right|} \tag{13}$$

The square root transformation amplifies the overrun signal (e.g., 20% overrun translates to CDR = -0.447) [20].

b) Schedule risk characterization: Network planning algorithm for critical path float time FT_{CP}:

$$FT_i = LS_i - ES_i, \quad FT_{CP} = \min_{i \in critical\ path} FT_i \tag{14}$$

Schedule risk criticality is determined when FT_{CP}< 7 days (PERT analysis validation).

Information theoretic definition of schedule deviation entropy S_{dev}:

$$S_{\text{dev}} = -\sum_{k=1}^{K} p_k \ln p_k, \quad p_k = \frac{function_k Number\ of\ days\ delayed}{\sum total\ delay} \tag{15}$$

Entropy values >1.5 indicate risk diversification, and <0.5 indicate critical path concentration of risk

4) Risk association characteristics

a) Historical risk transmission: Risk incidence Bayesian update of HR:

$$HR^{(n)} = \frac{\alpha + \sum \mathbb{I}_{\text{risk}}}{\alpha + \beta + n}, \quad \alpha = 2, \beta = 2 \tag{16}$$

Update the a posterior probability with an initial value $HR^{(0)}$=0.5 for each new item.

b) Multi-risk coupling: Cost-schedule coupling index Vector pinch model for CSI:

$$CSI = \cos\theta = \frac{\Delta C \cdot \Delta S}{\|\Delta C\| \|\Delta S\|}, \quad \Delta C = [\Delta C_1, \ldots, \Delta C_T] \tag{17}$$

θ < 30∘ indicates strong coupling (e.g., cost overruns accompanied by schedule delays).

Market-Contract Sensitivity Stress test model for MCS:

$$MCS = \max_{\sigma_M \in [0.1, 0.3]} \left(\frac{\partial \mathcal{R}}{\partial \sigma_M} |_{CT} \right) \tag{18}$$

Calculate the partial derivatives of risk with respect to contract type under extreme scenarios of price volatility.

5) Feature engineering methods

a) EM algorithm for missing value interpolation

Step 1:

$$Q(\theta | \theta^{(t)}) = \mathbb{E}_{Z|\text{X}_{\text{obs}}, \theta^{(t)}} [\ln P(\text{X}_{\text{obs}}, Z | \theta)] \tag{19}$$

Step 2:

$$\theta^{(t+1)} = \arg\max_{\theta} Q\left(\theta|\theta^{(t)}\right) \quad (20)$$

b) Interaction feature construction

Explicit Interaction:

$$\phi_{\text{interact}} = \sigma_M \times (1 - CT) \times \log I \quad (21)$$

Capture the extreme risk of 'cost plus fee contracts for large projects in highly volatile markets'.

6) Feature validation: The contribution of feature j to the prediction of f(x):

$$\phi_j = \sum_{S \subseteq F \setminus \{j\}} \frac{|S|!(|F|-|S|-1)!}{|F|!}\left(f_{S\cup\{j\}}(\mathrm{x}) - f_S(\mathrm{x})\right) \quad (22)$$

The computational time consuming grows exponentially with the number of features, using the TreeSHAP approximation ($\mathcal{O}(TLD^2)$), where T is the number of trees, L is the number of leaf nodes, and D is the depth.

D. Model Training and Validation

The training of the BO-GBM model is an iterative learning process that incorporates Bayesian optimization and gradient boosting machine, and its mathematical nature can be formulated as the following two-layer optimization problem [21]:

$$\text{Outer layer (hyperparametric optimisation)}: \quad \mathrm{x}^* = \arg\max_{\mathrm{x}\in\mathcal{X}} \mathcal{J}(\mathrm{x})$$
$$\text{Inner layer (simulation training)}: \quad \mathcal{J}(\mathrm{x}) = \mathbb{E}_{(\mathrm{X_{val}},\mathrm{y_{val}})}[\mathcal{L}(\mathcal{M}_{\mathrm{x}}(\mathrm{X_{val}}),\mathrm{y_{val}})]$$

where, $\mathrm{x} = (\eta, d_{\max}, n_{\text{leaf}}, \dots)$ is the hyperparameter vector and $\mathcal{L}$ is the objective function (e.g., negative RMSE).

1) Dynamic construction of training data: In order to adapt to the temporal characteristics of engineering economic data, a rolling time window strategy is used [22]:

$$\begin{cases} \mathcal{D}_{\text{train}}^{(t)} = \{(\mathrm{x}_i, y_i) | T_i \in [t-\tau, t]\} \\ \mathcal{D}_{\text{val}}^{(t)} = \{(\mathrm{x}_i, y_i) | T_i \in (t, t+\Delta t]\} \end{cases} \quad (23)$$

τ = 24 months: training window length

Δt = 3 months: validation window step length

Timestamp T_i is the project start time

2) BO-GBM Co-training algorithm: The essence of BO-GBM co-training is a two-layer optimization process with a mathematical framework consisting of Bayesian optimization (outer layer) and gradient boosting machine training (inner layer) to form an iterative closed-loop system (see Fig. 2):

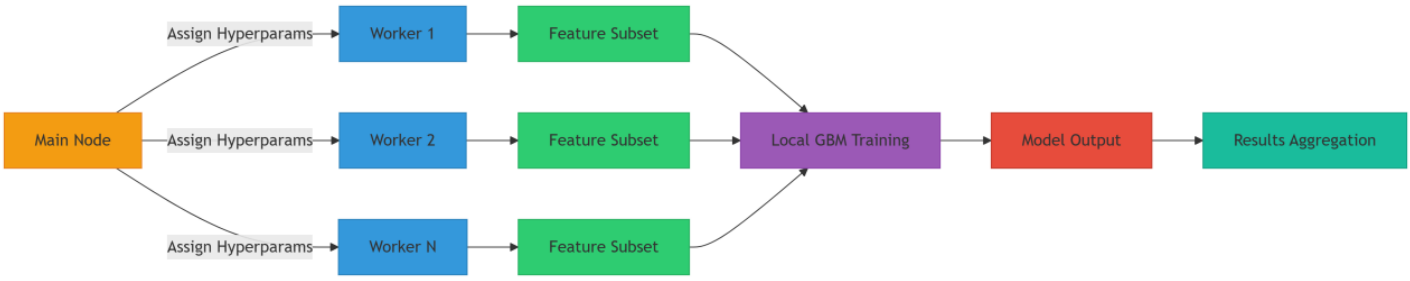

Fig. 2. Parallel training architecture.

a) Bayesian optimization layer: Let the hyperparameter space $\mathcal{X} \subset \mathbb{R}^d$ and the objective function $\mathcal{J}(\mathrm{x})$ be the performance of GBM on the validation set (e.g., AUC) [23]. Bayesian optimization models the objective function through a Gaussian process:

$$\mathcal{J}(\mathrm{x}) \sim \mathcal{GP}\left(\mu(\mathrm{x}), k(\mathrm{x},\mathrm{x}')\right) \quad (24)$$

where, the kernel function uses Matérn 5/2:

$$k(\mathrm{x},\mathrm{x}') = \sigma_f^2\left(1 + \sqrt{5}r + \frac{5}{3}r^2\right)\exp\left(-\sqrt{5}r\right), \quad r = \sqrt{\sum_{i=1}^{d}\frac{(x_i - x_i')^2}{\ell_i^2}} \quad (25)$$

Expectation Improvement (EI) acquisition function to guide parameter search:

$$\mathrm{EI}(\mathrm{x}) = \mathbb{E}[\max(\mathcal{J}(\mathrm{x}) - \mathcal{J}^+, 0)] = (\mu(\mathrm{x}) - \mathcal{J}^+ - \xi)\Phi(Z) + \sigma(\mathrm{x})\phi(Z) Z = \frac{\mu(\mathrm{x}) - \mathcal{J}^+ - \xi}{\sigma(\mathrm{x})}, \quad \xi = 0.01 \quad (26)$$

$\mathcal{J}^+$ is the current optimal observation and Φ, ϕ is the standard normal distribution function.

b) Gradient booster Training layer: Given the hyperparameters $\mathrm{x} = (\eta, d_{\max}, \lambda, \dots)$, the GBM minimizes the loss in an additive model:

$$F^* = \arg\min_F \sum_{i=1}^{n} \mathcal{L}\left(y_i, F(\mathrm{x}_i)\right) + \Omega(F) \quad (27)$$

where, the regular term $\Omega(F) = \gamma T + \frac{1}{2}\lambda \parallel \mathrm{w} \parallel^2$, T is the number of leaf nodes of the tree.

The mth iteration:

computes the pseudo-residuals:

$$r_i^{(m)} = -\left.\frac{\partial \mathcal{L}(y_i, F(\mathrm{x}_i))}{\partial F(\mathrm{x}_i)}\right|_{F=F_{m-1}} \quad (28)$$

The fitted decision tree h_m is minimized:

$$\sum_{i=1}^{n}\left[r_i^{(m)} - h_m(\mathrm{x}_i)\right]^2 + \gamma T_m + \frac{1}{2}\lambda \sum_{j=1}^{T_m} w_j^2 \quad (29)$$

Update the model:

$$F_m(\mathrm{x}) = F_{m-1}(\mathrm{x}) + \nu \cdot h_m(\mathrm{x}), \quad \nu = \eta \cdot \exp\left(-\beta\frac{m}{M}\right) \quad (30)$$

β is the decay coefficient and M is the total number of trees.

3) Synergistic iterative mechanism: BO-GBM synergistic training constitutes the dynamical system:

$$\begin{cases} x^{(k+1)} = \mathcal{B}\left(x^{(k)} | \{\mathcal{J}(x^{(i)})\}_{i=1}^{k}\right) \\ \mathcal{J}(x^{(k)}) = \mathcal{T}_{\mathrm{GBM}}(\mathcal{D}_{\mathrm{train}}, \mathcal{D}_{\mathrm{val}}, x^{(k)}) \end{cases} \quad (31)$$

where, $\mathcal{B}$ is the Bayesian optimization operator and $\mathcal{T}_{\mathrm{GBM}}$ is the GBM training evaluation operator [24].

The sequence $\{\mathcal{J}(x^{(k)})\}$ converges with probability 1 when the hyperparameter space $\mathcal{X}$ is tight and the objective function $\mathcal{J}$Lipschitz is continuous:

$$\lim_{k\to\infty} \mathbb{P}\left(\mathcal{J}(x^{(k)}) - \mathcal{J}^* < \epsilon\right) = 1, \quad \forall \epsilon > 0 \quad (32)$$

4) Computational acceleration strategy

a) Agent model warm-up: Pre-training the auxiliary Gaussian process using historical project data $\mathcal{GP}_0$:

$$\mu_0(x) = \mathbb{E}_{\mathcal{D}_{\mathrm{hist}}}[\mathcal{J}(x)], \quad k_0(x, x') = \mathrm{Cov}_{\mathcal{D}_{\mathrm{hist}}}(\mathcal{J}(x), \mathcal{J}(x')) \quad (33)$$

The initial objective function is estimated as:

$$\mathcal{J}^{(1)}(x) \sim \mathcal{GP}\left(\mu_0(x), \rho k_0(x, x') + k(x, x')\right), \quad \rho = 0.3 (34)$$

b) Gradient-sensitive sampling: Introducing gradient information in EI optimization:

$$x_{\mathrm{next}} = \mathrm{argmax}[\mathrm{EI}(x) + \lambda \parallel \nabla_x \mu(x) \parallel_2] \quad (35)$$

λ Balancing exploration and exploitation to accelerate local convergence [25].

c) Partial evaluation mechanisms: When $\sigma(x) > \sigma_{\mathrm{thres}}$, sub-sampled data are used for evaluation:

$$\tilde{\mathcal{J}}(x) = \mathcal{J}(x; \mathcal{D}_{\mathrm{sub}}), \quad |\mathcal{D}_{\mathrm{sub}}| = \min\left(500, \frac{n}{\sigma(x)/\sigma_{\max}}\right) \quad (36)$$

III. Engineering Economic Risk Management Platform Architecture Design

A. Overall Platform Architecture Design

The engineering economic risk management platform adopts vertical layered architecture, with clear functions and interfaces of each layer to ensure high availability and scalability of the system (see Fig. 3).

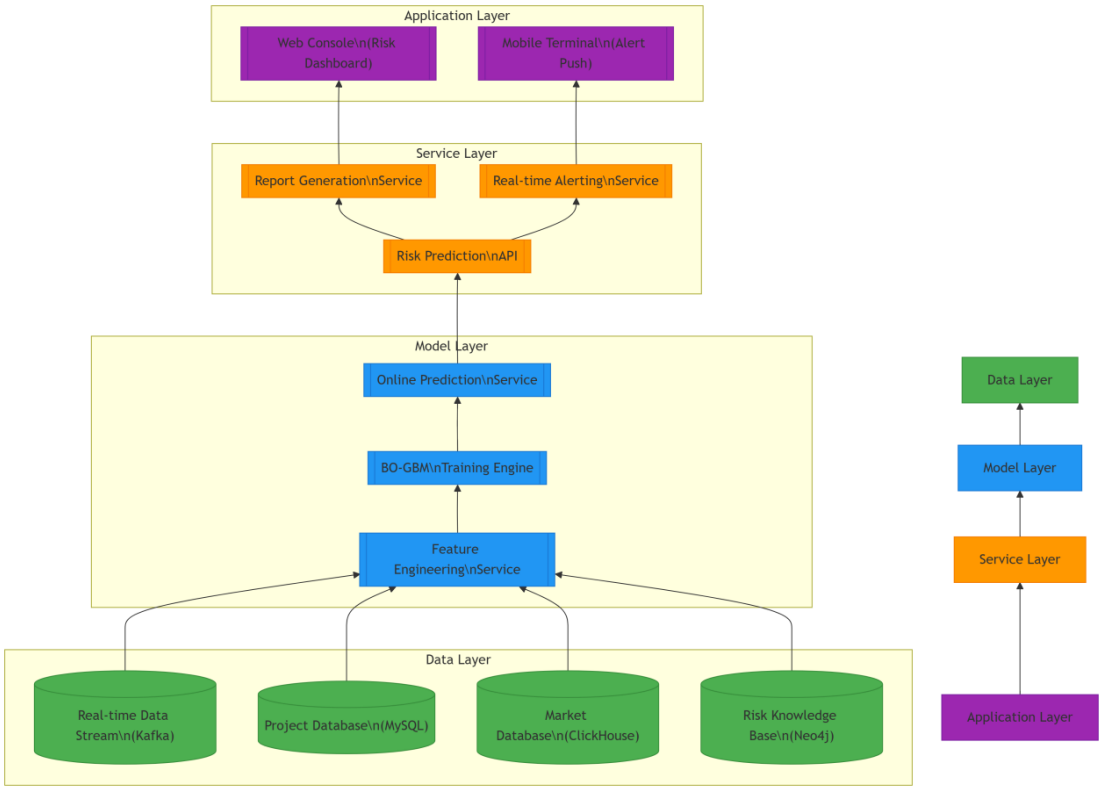

Fig. 3. Platform architecture diagram.

The whole system architecture consists of four distinct layers. The data layer is the foundation and contains both static and dynamic data sources. Storage includes a project database (storing core project data such as contracts, schedules, and costs), a market database (integrating time-series data such as building material prices, exchange rates, and interest rates), and a risk knowledge base (accumulating historical risk cases and response scenarios). Real-time data processing is handled by a Kafka streaming engine that feeds into the business system data and processes it at a rate of over 10,000 data points per minute. The model layer builds on this data foundation and contains the core machine learning components. The BO-GBM training engine automatically optimizes model parameters. The feature engineering service computes 28 real-time risk features. Finally, the Online Prediction Service deploys optimized risk prediction models to ensure that single prediction latency is kept below 300 milliseconds, and the models are updated through daily

automated training. The service layer exposes the system's forecasting capabilities through a set of core services. The Risk Prediction API uses gRPC to calculate project risk probabilities in real time. The real-time alert service uses WebSockets to trigger multi-level alerts. The report generation service creates risk assessment reports automatically via a REST API. To ensure resilience, the service implements automatic meltdown and switches to a backup service when the error rate exceeds 5%. Load balancing supports more than 500 concurrent requests. Finally, the application layer provides the user interface and access control. The web console provides real-time risk heat maps, risk factor analysis tools, and alert threshold configuration options. Mobile terminals provide instant risk alerts, project status queries, and access to emergency response channels. RBAC (role-based access control) is implemented for rights management, and two-factor authentication is used to enhance security.

B. Core Functional Module Design

The engineering economic risk management platform contains five core functional modules, which together achieve the closed-loop management of the whole process of risk prediction, assessment, early warning, and decision-making support. The design of each module follows the principle of 'high cohesion and low coupling', and works together through standardized API interfaces.

1) Data integration and management module: The platform is positioned as a data hub, providing unified access and governance for various heterogeneous data sources. Key design elements include: Multi-source data access: This covers a wide range of systems, including obtaining progress and cost data from project management systems (e.g. Primavera P6) via ODBC, synchronizing payment and settlement information from financial systems [27] (e.g. SAP) via RFC protocols, retrieving building material prices and exchange rate indices on a regular basis from market databases (e.g. Wind) via APIs, and collecting data on the operation of field equipment using IoT sensors. IoT sensors to collect data on the operation of equipment in the field. A key component is the intelligent data pipeline, which contains cleansing rules (e.g., missing value filling and outlier correction using the $\pm 3\sigma$ principle) and transformation logic that automatically generates 28-dimensional feature vectors based on the feature system described earlier. The storage strategy is tiered for optimal performance and cost-effectiveness: hot data is cached in Redis (with response times of less than 50 milliseconds), warm data is stored in ClickHouse columnar format, and cold data is archived in HDFS. Finally, comprehensive metadata management provides data lineage tracking, recording field-level source and transformation history, and quality monitoring dashboards that display data completeness and timeliness metrics in real time (see Fig. 4).

2) BO-GBM model management module: Functional positioning is the core of model full life cycle management. The key design includes: training workflow: multiple triggering mechanisms are available, including timed triggering (2:00 am every day), data drift warning triggering (when the KL dispersion of the feature distribution is > 0.1), and manual triggering. Spark ML is used for parallel processing of 100 GB data for distributed training. Each model version has version metadata, including snapshots of the training data, hyperparameters, and evaluation metrics. Grey scale releases validate the performance of new model versions by introducing 10% traffic. Additionally, the Parameter Configuration Centre provides a BO optimization space that allows for visual adjustment of hyperparameter ranges and supports manual intervention of feature weights to adjust feature importance assignments (see Fig. 5).

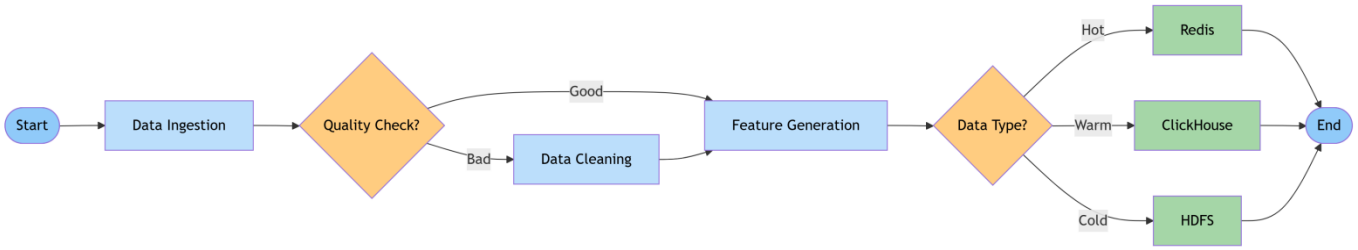

Fig. 4. Intelligent data pipeline flowchart.

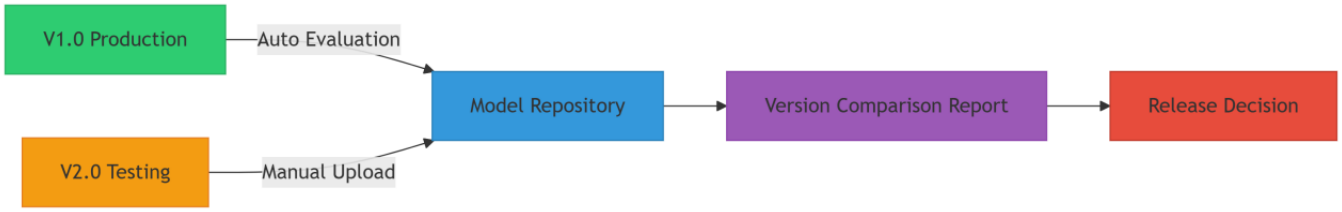

Fig. 5. Version control system.

IV. Platform Core Characteristics Analysis and Verification

A. Validation of the BO-GBM Model's Prediction Performance Characteristics

This experiment verifies the performance advantages of the BO-GBM model in engineering economic risk prediction tasks through rigorous comparison tests. The experimental design focuses on three core questions:

Does BO-GBM significantly outperform mainstream baseline models?

How effective is Bayesian optimization in improving model robustness?

How much does the feature engineering system contribute to the prediction accuracy?

1) Experimental design: The dataset is derived from the data of 327 projects of a large engineering group between 2018 and 2023. The dataset is divided into a training set and a test set, where the training set contains 256 projects from 2018-2022 and the test set contains 71 projects from 2023. Each project is represented by 28 features, and the labels are dichotomized to indicate whether a significant economic risk has occurred (see Table III).

Evaluation metrics include AUC, F1-score, and recall for classification tasks and RMSE and MAPE for regression tasks (cost bias prediction).

2) Performance comparison metrics: This experiment evaluated the classification performance of the five models on 71 independent test items (risk occurrence prediction). All models use the same training set (256 items) and feature set (28 dimensions), and the evaluation metrics include AUC (area under the curve), F1-score (the reconciled average of precision and recall), and recall (the proportion of actual risks correctly identified). The test set consists of 18 high-risk projects (where a significant economic risk actually occurs) and 53 low-risk projects completed in 2023 (see Fig. 6).

The BO-GBM model achieves an excellent performance of 0.927 on the AUC metric, which is significantly higher than the standard GBM (0.865) and Random Forest (0.832). In terms of F1-score, BO-GBM leads the other models with 0.892, which is 7.3% higher than the standard GBM (0.831). The recall metric shows that BO-GBM identifies 91.3% of actual risky items, 17.5 percentage points higher than logistic regression (73.8%). These data demonstrate that Bayesian optimization significantly improves the discriminative power of the GBM model, especially in the identification of high-risk items.

TABLE III Comparative Models

Model type	Parameter Settings	Implementation library
BO-GBM	Tree Depth = 6, Learning Rate = 0.1 (BO Optimization)	LightGBM
Standard GBM	Tree Depth = 6, Learning Rate = 0.1	Scikit-learn
Random Forest (RF)	No. of Trees = 200, Depth = 10	Scikit-learn
SVM	Kernel Function = RBF, C = 1.0	Scikit-learn
Logistic Regression (LR)	Regularization Strength = 1.0	Scikit-learn

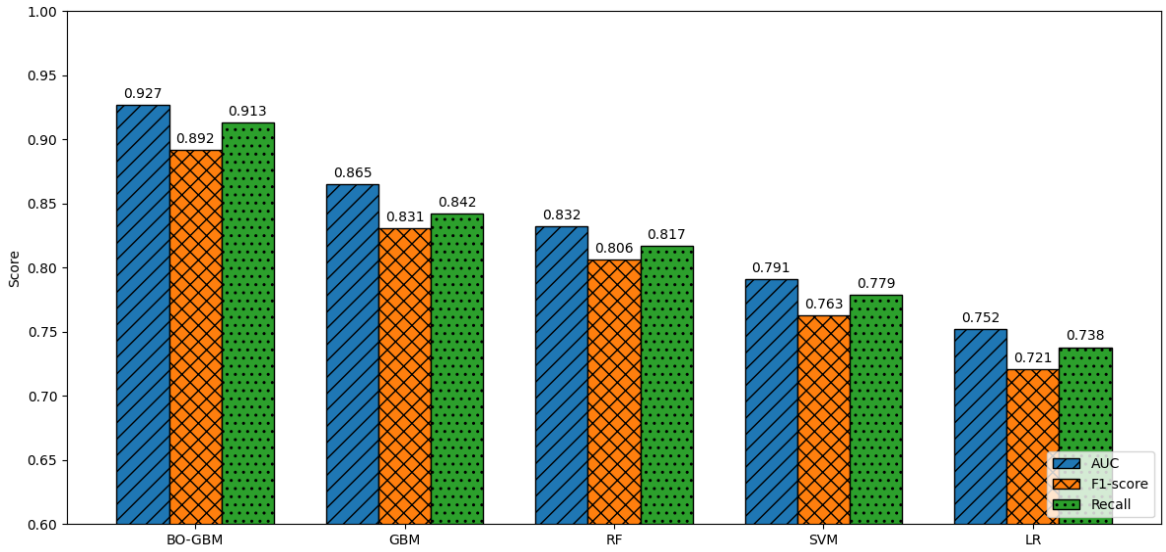

Fig. 6. Comparison of classification model performance.

This experiment evaluated the accuracy of each model in a cost deviation prediction task (regression problem). RMSE (Root Mean Square Error, in millions of dollars) and MAPE (Mean Absolute Percentage Error) were used as assessment metrics. The test set contained actual cost deviation data for 71 projects, with deviations ranging from -35% (savings) to +82% (overruns), and an average absolute deviation of $287,000 (see Fig. 7).

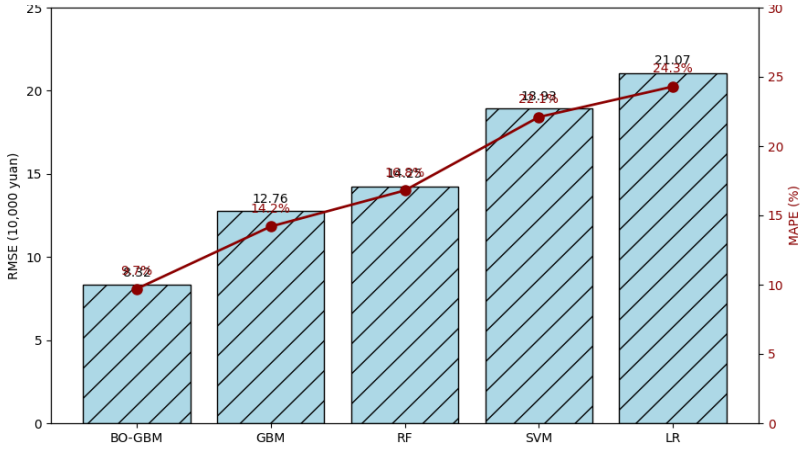

Fig. 7. Comparison of cost bias prediction errors.

The RMSE of BO-GBM is $83,200, which is 34.8% lower than the standard GBM ($127,600) and 60.5% lower than the worst performing logistic regression ($210,700). On the MAPE metric, BO-GBM's prediction error was only 9.7%, breaking the 10% engineering management accuracy threshold for the first time. Notably, when the cost deviation exceeds 30%, the prediction error of BO-GBM (MAPE = 11.2%) is still significantly lower than that of other models (17.8% for standard GBM), indicating that it still maintains high accuracy under extreme risk scenarios.

3) Result analysis: To verify the model's ability to resist interference, Gaussian noise (mean 0, standard deviation from 0% to 20%) was added to the test set of features. The experiment was repeated 50 times at each noise level, and the change in the mean AUC value was recorded. The range of noise addition covers all 28 features to simulate the data acquisition errors in real applications (see Fig. 8).

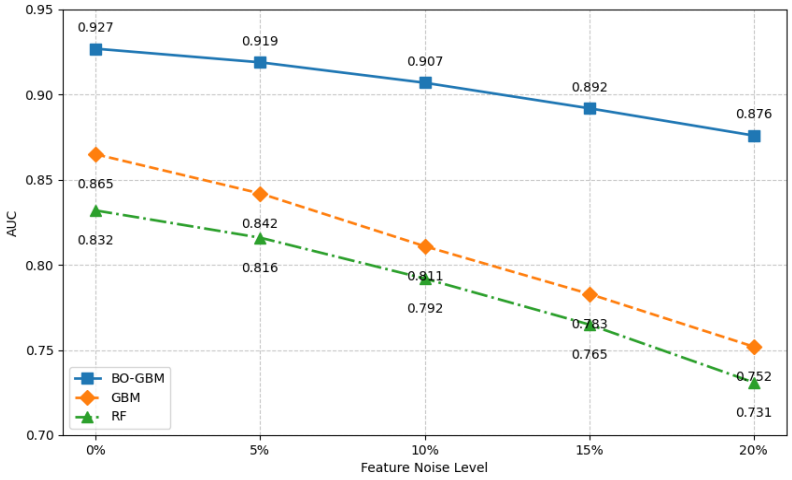

Fig. 8. Model robustness under feature perturbation.

When the feature noise reaches 20%, the AUC of BO-GBM decreases from 0.927 to 0.876 (a decrease of 5.5%), while the standard GBM decreases from 0.865 to 0.752 (a decrease of 13.1%). At a 10% noise level, the AUC of BO-GBM stays above 0.907, which is significantly higher than that of the standard GBM at 0.811. Random Forest performs close to BO-GBM (0.816 vs. 0.919) at low noise (5%), but the AUC decreases to 0.731 at high noise (20%), widening the gap to 14.5 percentage points. This indicates that BO optimization effectively improves the model noise immunity through hyperparameter tuning.

The contribution of each feature to the prediction of the BO-GBM model was quantified using the SHAP value method. The absolute mean of SHAP based on all samples in the test set was calculated, and the five features with the highest contribution were selected. The SHAP value indicates the average magnitude of the effect of feature changes on the model output (risk probability).

The Cost Performance Index (CPI) tops the list with a contribution of 0.218, proving that cost control failure is the strongest risk signal. Building material volatility (0.195) and contract type (0.172) rank second and third, and the sum of their contributions (0.367) exceeds the CPI, reflecting the key role of external markets and contract design. Progress deviation (0.141) and cash flow gap (0.103) constitute the second tier of risk factors. The total contribution of TOP5

features reaches 0.829, covering the three core dimensions of engineering economic risk: cost control, external environment and project execution (see Fig. 9).

B. Platform Functional Characteristics and Efficiency Verification

1) Risk identification efficiency: Fifty projects implemented by a large infrastructure company in 2023 are selected for risk assessment using both traditional manual assessment and automated identification by the platform. Record the time consumed for the whole process from data preparation to the output of the risk assessment report. Manual assessment is performed by a team of three senior risk analysts.

Platform's risk identification efficiency is significantly better than manual methods. For large-sized projects, the identification time is reduced from 42.6 hours to 0.52 hours, an 81.9-fold increase in efficiency. For medium-sized projects, the identification time is reduced from 25.7 hours to 0.38 hours, an increase in efficiency of 67.6 times. Small projects are processed through the platform in 0.25 hours, 49.2 times faster than manual processing (12.3 hours). The logarithmic coordinates show that the platform processing time is basically not affected by the project scale, which verifies the elasticity and scalability of the architecture (see Fig. 10).

2) Predicting response time: The experimental design includes simulating different concurrency scenarios in the load test environment: single project prediction (1000 consecutive requests), multi-project batch prediction (10-100 projects/batch), and high concurrency scenarios (50-500 concurrent users). The platform's response time (P95) and resource consumption (CPU/memory) were recorded. The test environment is an 8-core 16GB cloud server [26].

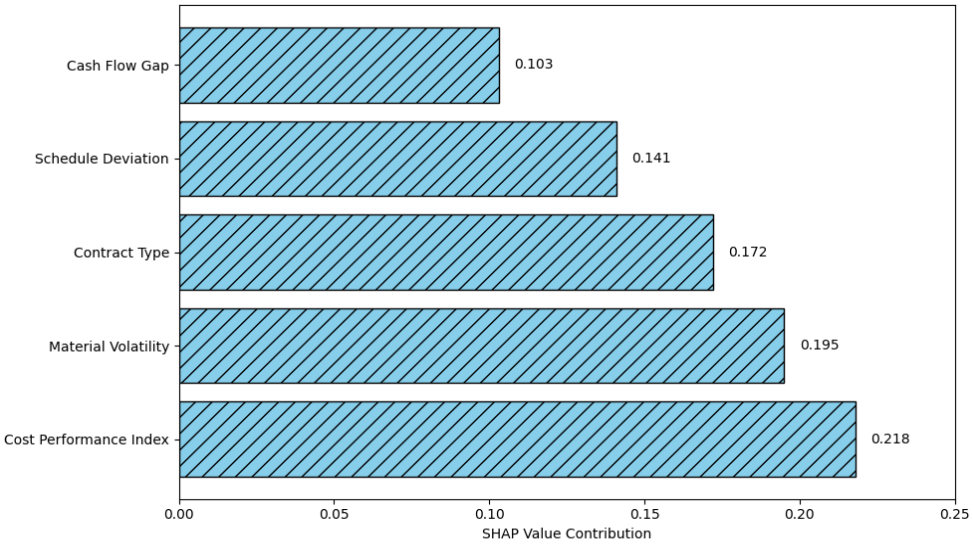

Fig. 9. TOP5 risk characteristics contribution.

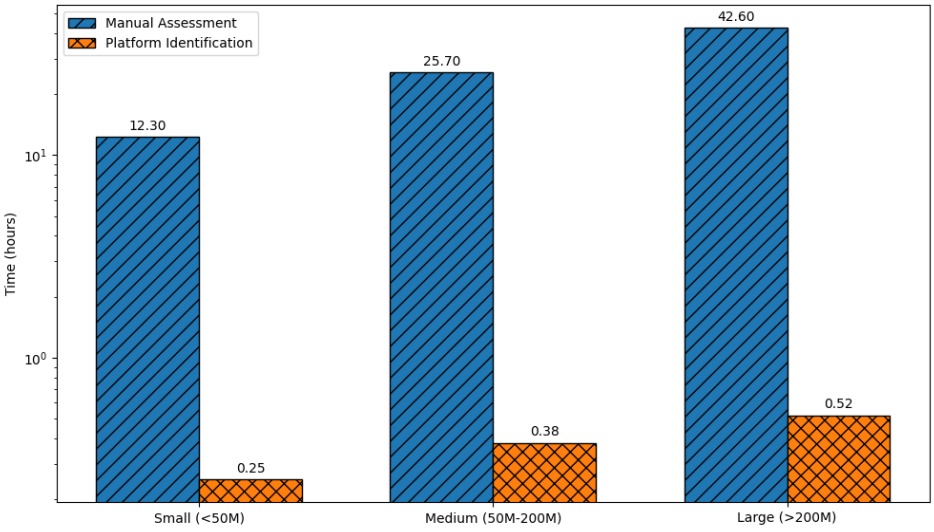

Fig. 10. Comparison of risk identification time for projects of different sizes.

The average response time for a single project prediction is 127 ms, which meets the real-time decision-making requirements. Batch prediction of 100 projects takes 256 ms, with a processing speed of 390 projects per second. In the 500 concurrent users scenario, the P95 response time was 427 milliseconds, still below the engineering threshold of 500 milliseconds. Response times for all test scenarios were below the industry best practice standard of 300 milliseconds. Resource monitoring shows that with 500 concurrent users, CPU utilization is 78% and memory usage is 68%, indicating that the system still has room for further expansion (see Fig. 11).

3) Early warning accuracy verification: The platform was used to backtest the data of 120 projects that had been completed in the past. The specific steps are: input feature data according to the actual project progress nodes, record the warning signals issued by the platform and the time, and compare the warning signals with the time and type of actual risk occurrence. Evaluation indicators include: warning accuracy rate, false alarm rate, and missed alarm rate.

The platform's early warning accuracy rate is 72.5% (87/120), of which 92.3% for high-risk projects (L4-L5). False alarm rate is 7.5% (9/120), which mainly occurs in scenarios of sudden policy changes, such as new environmental regulations. False alarms were 5.0% (6/120), mainly in extreme cases where the schedule was compressed by more than 30%. Overall, the platform made a correct judgment (accurate warning + correct no warning) in 87.5% of cases. The average lead time for high-risk warnings was 28 days for cost risks and 42 days for schedule risks, which meets the emergency response time requirements (see Fig. 12).

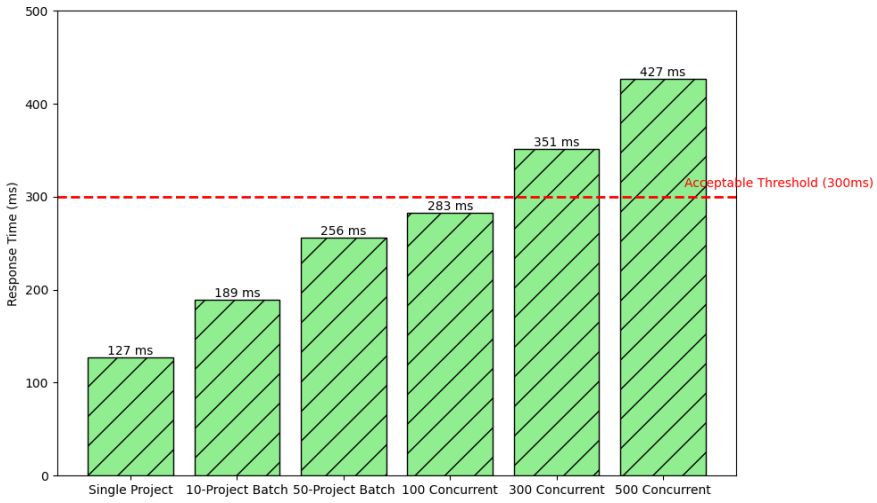

Fig. 11. Risk prediction response time in different scenarios.

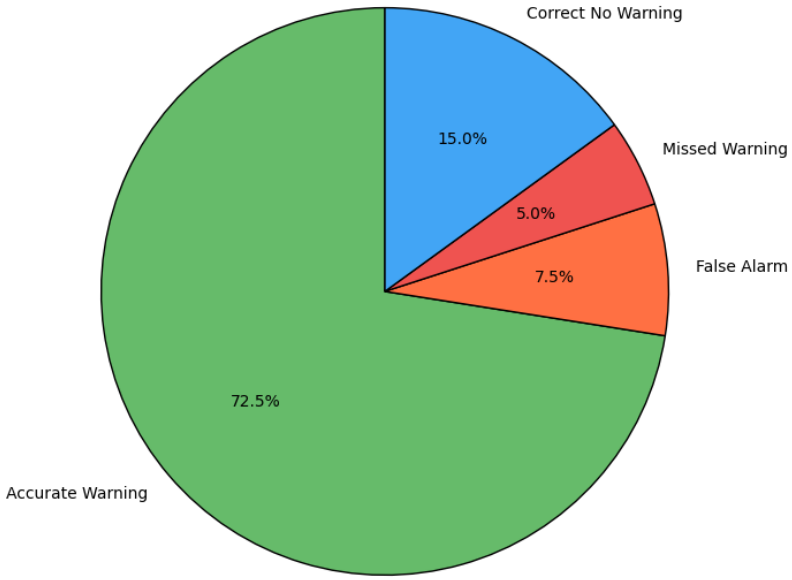

Fig. 12. Analysis of the accuracy of the platform's early warning.

V. Results and Discussion

This section presents a comprehensive evaluation of the proposed BO-GBM model's predictive performance and an analysis of the platform's functional characteristics and efficiency, followed by a discussion of the implications of these findings.

A. Validation of BO-GBM Model's Prediction Performance

The experiment verifies the performance advantages of the BO-GBM model through rigorous comparison tests on a dataset comprising 327 projects from a large engineering group (2018 to 2023), split into training (2018 to 2022, 256 projects) and test (2023, 71 projects) sets. Each project is represented by the 28 features described previously.

1) Experimental setup and baselines: The BO-GBM model was compared against several mainstream baseline models, as detailed in Table IV.

TABLE IV Comparative Models and Parameter Settings

Model Type	Parameter Settings	Implementation Library
BO-GBM	Tree Depth=6, Learning Rate=0.1 (BO Optimized)	LightGBM
Standard GBM	Tree Depth=6, Learning Rate=0.1	Scikit-learn
Random Forest (RF)	No. of Trees=200, Depth=10	Scikit-learn
SVM	Kernel Function=RBF, C=1.0	Scikit-learn
Logistic Regression (LR)	Regularization Strength=1.0	Scikit-learn

2) Performance comparison

a) Classification performance: Fig. 6 shows the performance on the risk occurrence prediction task (18 high-risk, 53 low-risk projects). The BO-GBM model achieved an AUC of 0.927, significantly outperforming the standard GBM (0.865) and Random Forest (0.832). Its F1-score of 0.892 was 7.3% higher than the standard GBM. Crucially, the recall rate of BO-GBM reached 91.3%, meaning it identified over 91% of actual high-risk projects, which is 17.5 percentage points higher than Logistic Regression (73.8%). This demonstrates that Bayesian optimization significantly enhances the model's ability to discriminate, particularly in identifying critical risks.

b) Regression performance (cost deviation): Fig. 7 compares the models on predicting cost deviation. The BO-GBM model achieved an RMSE of 83,200 RMB, which is 34.8% lower than the standard GBM (127,600 RMB) and 60.5% lower than Logistic Regression (210,700 RMB). Its MAPE was only 9.7%, breaking the 10% accuracy threshold often sought in engineering management. Notably, even for extreme cost overruns (>30%), BO-GBM maintained a lower error (MAPE=11.2%) compared to other models (e.g., 17.8% for standard GBM).

3) Robustness analysis: To test the model's resistance to data noise, Gaussian noise (mean 0, standard deviation from 0% to 20%) was added to the test features. As shown in Fig. 8, when feature noise reached 20%, the AUC of BO-GBM decreased by only 5.5% (from 0.927 to 0.876), whereas the standard GBM decreased by 13.1% (0.865 to 0.752). This indicates that the hyperparameters found by BO contribute to a more robust model that is less sensitive to data perturbations, a critical property for real-world applications where data quality can vary.

4) Feature importance analysis: Using SHAP values, we quantified the contribution of each feature. Fig. 9 reveals that the Cost Performance Index (CPI) was the most influential feature (contribution 0.218), confirming failed cost control as the primary risk signal. Building material volatility (0.195) and contract type (0.172) were the next most important, highlighting the significant role of external markets and contractual design. Schedule deviation (0.141) and cash flow gap (0.103) formed a secondary tier. The combined contribution of the top five features was 0.829, effectively capturing the core dimensions of engineering economic risk.

B. Platform Functional Characteristics and Efficiency Verification

1) Risk identification efficiency: We compared the platform's automated risk identification against traditional manual assessment by a team of three senior analysts across 50 projects of different sizes in 2023. The results, depicted in Fig. 10, show a dramatic efficiency improvement. For large projects, identification time was reduced from 42.6 hours to 0.52 hours—an 81.9-fold increase. The platform's processing time remained relatively constant regardless of project scale, demonstrating its scalability and architectural elasticity.

2) Prediction response time: Load testing under various scenarios (Fig. 11) confirmed the platform's real-time capability. The average response time for a single prediction was 127 ms. Batch prediction of 100 projects took 256 ms ($\approx$ 390 projects/second). Under a high load of 500 concurrent users, the P95 response time was 427 ms, remaining below the 500 ms engineering threshold. Resource utilization (CPU 78%, Memory 68%) under this load indicated potential for further scaling.

3) Early warning accuracy: A backtest was conducted on 120 completed projects. The platform achieved an overall warning accuracy of 72.5% (87/120), with accuracy for high-risk projects (L4-L5) exceeding 92.3%. The false alarm rate was 7.5%, primarily triggered by unforeseen policy changes, and the missed alarm rate was 5.0%, mainly occurring in cases of extreme schedule compression (>30%). Overall, the platform made correct judgments (accurate warning + correct non-warning) in 87.5% of cases. The average lead time for high-risk warnings was 28 days for cost risks and 42 days for schedule risks, providing sufficient time for proactive mitigation.

C. Discussion

The results strongly support the effectiveness of the proposed BO-GBM model and the associated platform. The significant performance gains over baseline models, particularly in recall and robustness, underscore the value of using Bayesian Optimization for hyperparameter tuning in this

domain. The high contribution of the engineered features validates the comprehensiveness of the four-dimensional feature system. The platform's operational metrics confirm its practical utility, offering order-of-magnitude efficiency gains in risk identification and reliable, real-time predictions suitable for large-scale, concurrent use.

The primary limitation observed was related to warning errors. False alarms were often linked to "black swan" events like sudden policy shifts, which are not captured by historical feature data. Missed alarms occurred under extreme project conditions, suggesting potential model performance boundaries or the need for even more specialized features for such edge cases. These points inform valuable directions for future work.

VI. Conclusion

In this study, a platform for engineering economic risk management based on the BO-GBM model is successfully constructed, which significantly improves the prediction accuracy and control efficiency of engineering economic risks by integrating Bayesian optimization and gradient boosting machine techniques. The core achievements can be summarized in the following three aspects:

1) Excellent performance of BO-GBM model: By adopting Bayesian optimization to adaptively adjust the GBM hyperparameters, the model breaks through the efficiency bottleneck of traditional tuning methods and significantly enhances the model's robustness. Experimental results show that in the risk prediction task, the model AUC reaches 0.927, with a recall rate of 91.3%, which is 17.5 percentage points higher than that of the standard GBM; in cost deviation prediction, the RMSE is reduced to 83.2 thousand yuan, and the MAPE is only 9.7%, which is more than 30% lower than the mainstream model even in the extreme overrun scenarios; in the face of the featured noise interference of 20%, the model performance degradation is less than 20%. Even under extreme overspending scenarios, the error is still lower than mainstream models by more than 30%; in the face of 20% of characteristic noise interference, the model's performance degradation is less than 6%, which verifies its strong anti-interference ability.

2) Breakthrough in risk characteristics system and platform effectiveness: The four-dimensional 28-feature system (project ontology, market environment, execution process, and risk correlation) constructed systematically quantifies the risk-driving mechanism, with the contribution of key features exceeding 82%. Among them, cost performance index, building material volatility, and contract type constitute the core risk signals. The platform adopts a layered architecture (data layer, model layer, service layer, application layer), supporting millisecond response with single prediction latency of less than 127 milliseconds, and P95 response time of 427 milliseconds with 500 concurrent users. In addition, the efficiency of risk identification has been improved by an order of magnitude, and the evaluation time of large projects has been compressed from 42.6 hours to 0.52 hours, which is 81.9 times more efficient.

3) Precise and reliable early warning mechanism: The platform realizes closed-loop risk management for the whole process. The accuracy rate of early warning reaches 72.5%, and the accuracy rate of high-risk early warning exceeds 92%. The advance warning period for cost risk and schedule risk reaches 28 days and 42 days, respectively, which meets the demand for emergency response. The false alarm rate and omission rate are controlled at 7.5% and 5.0% respectively, which are significantly better than the manual assessment mode.

Building upon current research findings and limitations, future studies will focus on advancing three key areas of exploration. Regarding model optimization, hybrid time-series models incorporating LSTM or Transformer architectures will be developed to more accurately capture the dynamic evolution of project risks. Concurrently, the BO-GBM framework will be expanded to enable multi-task collaborative prediction of cost, schedule, and safety risks. Regarding data dimensions, plans include introducing natural language processing techniques to extract latent risk signals from unstructured data such as textual reports, alongside constructing adaptive feature selection mechanisms to accommodate requirements across different project phases. At the platform functionality level, efforts will strengthen visualization capabilities to intuitively display model decision-making logic, while integrating reinforcement learning technologies to enable dynamic, intelligent recommendations for risk mitigation strategies.

Adaptive Virtual Machine Consolidation Based on Autoformer and Enhanced Double Q-Network for Energy-Efficient Cloud Data Center

Kaiqi Zhang, Youbo Lyu, Dequan Zheng*, Yanping Chen, Jianshan Xu
School of Computer and Information Engineering, Harbin University of Commerce, Harbin 150028, China

***Abstract*—As the scale of cloud data centers continues to expand, energy consumption has become a critical issue. Virtual machine (VM) consolidation is a key technology for improving resource utilization and reducing energy consumption, yet it remains challenging to effectively balance energy efficiency with service level agreement violations (SLAV) in dynamic cloud environments. This paper proposes an adaptive VM consolidation strategy based on Autoformer and an enhanced dual Q-Network, referred to as AEDQN-VMC. The approach consists of three integrated components: 1) Autoformer-based load detection, which leverages an autocorrelation mechanism to decompose time-series data into multi-scale trend and periodic components; 2) a VM selection method that integrates the Pearson correlation coefficient and migration time to optimize the selection of VMs for migration; and 3) an enhanced dual Q-Network for VM placement, incorporating the upper confidence bound (UCB) and adaptive learning rate (ALR) to improve the exploration-exploitation trade-off. Extensive experiments on real-world cloud workload traces (PlanetLab, Google Cluster, and Alibaba datasets) demonstrate that the proposed method significantly outperforms state-of-the-art benchmarks such as PABFD, AD-VMC, and AMO-VMC. Specifically, it achieves maximum reductions of 46.5% in energy consumption and 74.2% in SLAV rate. Ablation studies further validate the contribution of each component and confirm the synergistic effect of the overall architecture. The results highlight the potential of AEDQN-VMC as an efficient and reliable solution for sustainable cloud data center operations.**

Keywords*—Cloud computing; virtual machine consolidation; load prediction; energy efficiency; deep reinforcement learning; Autoformer

I. Introduction

With the rapid development of cloud computing, data centers have become the core infrastructure supporting various online services, including big data analysis, artificial intelligence, and Internet of Things (IoT) applications. The exponential growth of user demands has driven a significant expansion in the scale of data centers, which typically consist of thousands of physical servers. However, this expansion gives rise to a critical issue: excessive energy consumption, with a considerable portion of energy wasted due to low resource utilization efficiency [1]. High energy consumption not only increases the operational costs for data center operators but also exacerbates carbon emissions, conflicting with global sustainable development and carbon neutrality goals. Therefore, it has become an urgent challenge to reduce energy consumption while ensuring quality of service (QoS) in the field of data center management.

Virtual Machine (VM) consolidation is a core strategy to address the energy consumption issue of data centers. By dynamically migrating VMs between physical machines (PMs), VM consolidation optimizes resource allocation. Through consolidating VMs onto a smaller number of active PMs, idle or underloaded PMs can be shut down or switched to low-power modes, thereby reducing overall energy consumption and improving resource utilization [2, 3]. However, VM consolidation is a complex decision-making process that requires balancing multiple objectives, such as minimizing energy consumption, reducing Service Level Agreement Violation (SLAV), and lowering migration overhead.

The VM consolidation process is divided into three phases: PM state detection, VM selection, and VM placement. Therefore, accurate PM state detection, reasonable VM selection, and optimized VM placement are the three major challenges that must be addressed to solve the VM consolidation problem. To tackle these challenges, Goyal et al. [4] proposed an adaptive multi-objective VM consolidation strategy (AMO-VMC), which aims to optimize resource management in energy-efficient cloud data centers. This strategy fuses the future resource utilization and the historical utilization for identifying overutilized PMs and selecting VMs to be migrated, and a multi-objective heuristic-based adaptive VM placement algorithm is adopted to select the optimal target host. Zeng et al. [5] proposed an adaptive Deep Reinforcement Learning(DRL)-based VM consolidation framework (AD-VMC), whose core components are an influence coefficient(IC)-based VM Selection algorithm (ICVMS) and a prediction aware DRL-based VM placement method(PADRL). By calculating the similarity between VMs and PMs, VMs that have the greatest impact on PM overload are migrated first to quickly relieve load pressure. Additionally, Long Short-Term Memory (LSTM) Neural Network is used to predict future system states to accelerate the convergence of the DRL model, thereby achieving energy-efficient VM placement.

However, existing researches still have significant limitations and struggle to simultaneously meet the requirements of energy efficiency optimization and QoS assurance in dynamic cloud environments. In the PM state detection phase, although workload prediction-based PM state detection methods are widely adopted, and deep learning-based prediction models can capture the temporal dependencies of

*Corresponding author.

workloads [6, 7], their ability to model the complex multi-scale periodicity (e.g., intra-day and intra-week fluctuations) in cloud workloads remains limited. This may lead to misjudgment of overloaded/underloaded hosts. In the VM selection phase, although some studies consider both resource correlation and migration cost [4, 8], they fail to effectively model the non-linear relationship between correlation and cost. In the VM placement phase, researchers have proposed several VM placement schemes based on DRL [9, 10]. However, these schemes adopt fixed exploration probabilities and learning rates, making it difficult to balance exploring new actions and exploiting known optimal actions, thus resulting in the problem of exploration-exploitation imbalance.

To address the aforementioned limitations, an adaptive VM consolidation scheme based on Autoformer and enhanced double Q-Network (AEDQN-VMC) is proposed, which achieves efficient resource management in dynamic environments through synergistic optimization across three phases:

- Autoformer-based PM state detection: Autoformer is employed for workload prediction, which decomposes workload time series into trend and periodic components via an auto-correlation mechanism.
- VM selection based on Pearson correlation coefficient and migration Time: A VM migration impact factor is constructed by fusing the Pearson correlation coefficient and migration time to balance the effect of load reduction and migration cost.
- VM placement based on enhanced double Q-Network: The upper confidence bound (UCB) and adaptive learning rate (ALR) are introduced into the double Q-Network to optimize the exploration-exploitation balance.

The remainder of this paper is organized as follows. Section II presents a classified review of related research on VM consolidation. Section III describes the system model and overall framework. Section IV details the Autoformer-based PM state detection method. Section V proposes the VM selection strategy based on Pearson correlation coefficient and migration time. Section VI introduces the VM placement algorithm based on the enhanced double Q-Network. Section VII evaluates the effectiveness of the proposed strategy through experiments. Section VIII concludes the paper and outlines future research directions.

II. Related Works

As a core strategy for resource management in energy-efficient cloud data centers, VM consolidation aims to significantly reduce system energy consumption by centrally deploying VMs on a minimized cluster of PMs, thereby maximizing physical resource utilization and minimizing the number of active servers. This strategy runs through the entire lifecycle management of VMs. In the initial VM creation phase, VM consolidation manifests as placement decisions based on PM state detection. During the dynamic migration process in the operation phase, VM consolidation involves a three-stage optimization of PM state detection, VM selection, and VM placement. To systematically analyze the inherent logic of the consolidation mechanism, the following sections will sort out existing studies from three core dimensions: PM state detection, VM selection, and VM placement.

A. PM State Detection

Before selecting VMs and making placement decisions, it is necessary to accurately detect the operational status of PMs. Existing PM detection methods can be categorized into two types based on whether they rely on workload trend prediction:

1) Non-prediction-based: This type of method directly determines the PM status using real-time or historical workload data, without the need to predict future workload changes. In [11], PM state detection primarily relies on real-time resource utilization, with CPU and memory as core dimensions. This involves calculating the available resources of PMs and classifying PM states into overloaded, normal, and underloaded by setting thresholds. The study [12] classifies workloads using the split-and-recombine (SAR) algorithm based on real-time monitored resource utilization and workload characteristics, and further considers thermal cycling effects through a thermal model to determine the host state. The study in [13] calculates power consumption across different utilization intervals using a linear interpolation power model, and then evaluates whether a PM can accommodate additional VMs by combining current and historical CPU utilization. The study [14] relies on real-time temperature monitoring to periodically check server temperatures, which dynamically sets a maximum temperature threshold and determines if the server is overloaded when the temperature exceeds this threshold.

2) Load prediction-based: To overcome the response lag of non-prediction-based methods, researchers have introduced workload prediction technique, which enables proactive state identification by forecasting the future resource utilization of PMs. The core value of such methods lies in providing a buffer time window for migration decisions, thereby avoiding SLAVs and reducing the frequency of emergency migrations.

Statistical methods are traditional workload prediction approaches and remain the mainstream modeling techniques for workload prediction to date. The study [15] uses the ARIMA model to analyze the trend of PM resource utilization, predicting future resource utilization to determine whether a PM is overloaded. Reference [16] predicts the future workload of PMs via the exponential smoothing method, which calculates a workload anomaly function by combining the predicted future workload with the current workload, and then determines whether a PM is in an overloaded state. The study [17] infers the future overload probability by analyzing historical host resource usage with the Local Regression algorithm, thereby identifying whether a PM is in an abnormal state.

However, statistical methods have obvious limitations when dealing with complex dynamic workloads. First, most of these methods rely on the assumptions of linearity and stationarity of data. In reality, however, data center workloads

often exhibit nonlinear and non-stationary characteristics, accompanied by sudden fluctuations, which leads to a decline in prediction accuracy. Second, traditional statistical models have poor adaptability to high-dimensional data and struggle to integrate multi-source information, resulting in limited generalization ability in complex scenarios. Third, for workload sequences with long-term dependency characteristics, simple smoothing or regression methods are unable to capture the deep correlation between historical data and future trends, making them prone to lag errors.

To address the limitations of statistical methods, researchers have increasingly adopted deep learning techniques to construct workload prediction models in recent years. The study [10] combines Temporal Convolutional Networks (TCN) with Median Absolute Deviation (MAD) to predict the overload probability of PMs, which reduces unnecessary VM migrations and SLAVs. The study [5] designs an LSTM-based network to forecast future system states, which provides more reasonable environmental states for the DRL model, assisting in more accurate judgments of whether PMs are overloaded or underloaded. The study [18] proposes a virtualized adaptive scheduling algorithm, which uses LSTM to predict future CPU utilization, memory usage, and network bandwidth requirements of VMs, and employs Deep Q-Network (DQN) to achieve adaptive resource scheduling.

Nevertheless, deep learning-based workload prediction confronts several issues, such as high model complexity, substantial training costs, and sensitivity to small-sample data. To further optimize prediction performance, researchers have combined statistical methods with deep learning to construct hybrid workload prediction models. For instance, the study [4] combines the Dynamic Weighted Moving Average (DWMA) and a neural network model to calculate the expected utilization rate of physical machines. The study [19] combines Bollinger Bands and Neural Prophet techniques to predict the future workload trend of hosts.

B. VM Selection

After identifying the source PMs that require adjustment, it is necessary to further select the VMs to be migrated. Based on the criteria used to select VMs from overloaded PMs, relevant studies on VM selection can be categorized into three types: based on PM-VM correlation, based on VM migration overhead, and based on both correlation and migration overhead.

1) PM-VM correlation: The VM selection criteria in this category primarily focus on the degree of association between VMs and PMs in aspects such as resource usage patterns, workload trends, and energy consumption characteristics. By quantifying this association, VMs that have a significant impact on the PM's state are selected. In study [5], VMs are selected based on the Influence Coefficient, which quantifies a VM's contribution to the overload of a PM by calculating the product of the cosine similarity between the VM's and PM's resource usage. VMs with higher influence coefficient exhibit a stronger correlation with the PM's overload and are thus prioritized for migration. In study [20], a load consolidation strategy based on Q-learning selects VMs by learning the load matching patterns between VMs and PMs. Specifically, it prioritizes the migration of VMs that can balance the PM's load, which reflects the correlation between VM and PM load trends. In study [15], VMs are selected based on contribution of the VM to the overload of the PM. VMs with the largest contribution are prioritized for migration, with the goal of eliminating the overload trend of the PM. In [21], with the goal of minimizing energy consumption, VMs that are compatible with the energy consumption characteristics of PMs are selected.

2) VM migration overhead: The VM selection criteria in this category primarily focus on the costs incurred during the migration process (e.g., time, performance loss, energy consumption, and impacts on QoS). By optimizing the selection of VMs, the negative impacts of migration on the system are reduced. In study [11], a fuzzy meta-heuristic algorithm is employed to select VMs whose migration imposes the least impact on QoS. In study [22], the direct criterion for VM selection is the migration time of VMs. The Minimum Migration Time (MMT) algorithm is adopted to prioritize the selection of VMs that can be migrated from overloaded hosts in the shortest time.

3) Both correlation and migration overhead: The criteria for VM selection in this type of research take into account both the correlation between VMs and PMs and the overhead during the migration process. The core is to balance these two aspects to achieve the optimization goal. For example, in study [8], the objective function aims to simultaneously minimize the number of active PMs and the frequency of VM migrations, thereby balancing resource utilization and migration costs. In study [23], a Deep-Q Network is employed to learn the load matching patterns between VMs and PMs, taking into account the impacts of migration on VM performance. It selects VMs that can balance load optimization and low performance loss. In [24], the correlation between VMs and the overload of PMs is determined to select VMs that can alleviate PM overload, taking into account migration time and performance degradation.

C. VM Placement

VM Placement (VMP) refers to the process of allocating newly created VMs or VMs to be migrated to optimal PMs, under the premise of satisfying multi-dimensional resource constraints such as CPU, memory, storage, and network. The rationality of this process directly affects resource utilization, energy consumption, and service quality. In recent years, researchers have proposed a variety of optimization methods to address this problem, which can be categorized into the following three types based on their technical approaches.

1) Heuristic algorithms: These algorithms generate placement strategies based on intuitive experience or predefined rules, with the goal of quickly obtaining feasible solutions, which is suitable for large scale dynamic scenarios. In study [8], a modified First-Fit strategy combined with a backfilling mechanism is adopted. Based on the runtime and priority of VMs, this approach places each VM onto the first

PM that meets the resource constraints. In study [25], the proposed cut-and-solve algorithm is a tree-search heuristic algorithm, which achieves the optimized placement of VMs by iteratively decomposing the problem and solving the sub-problems. In study [24], the VM allocation problem is modeled as a multi-dimensional bin packing problem, the objective of which is to select the minimum number of energy-efficient PMs, thereby to reduce energy consumption and resource waste. In study [26], a two-stage heuristic algorithm is proposed to address the rack-level hot-spot issue. In the first stage, VMs are selected for migration from overloaded hosts within racks identified as hard hot-spots, aiming to reduce the power consumption of these racks. In the second stage, VMs are selected for migration from underloaded hosts; this step serves to reduce the number of active servers, thereby achieving resource consolidation.

Heuristic algorithms offer the advantage of strong real-time performance. However, they struggle to balance multi-objective optimization (e.g., simultaneously minimizing energy consumption and achieving load balancing) and tend to get trapped in local optima.

2) Meta-heuristic algorithms: To address the limitations of heuristic algorithms, meta-heuristic algorithms perform global optimization by simulating natural phenomena (e.g., biological evolution, swarm behavior), which are suitable for complex multi-objective scenarios. The study [11] proposes a hybrid algorithm named IVPTS, which is designed for the collaborative optimization of task scheduling and VM placement in cloud computing environments. This algorithm integrates the Improved Particle Swarm Optimization algorithm with the Fuzzy Resource Management framework to achieve the goals of load balancing and energy conservation. To simultaneously optimize QoS, server energy consumption, and cooling energy consumption, The study [12] proposes a VM Placement strategy named BTVMP, which is based on the Enhanced Simulated Annealing algorithm and integrates a thermal cycling effect model. In study [14], the VM placement involves both heuristic and meta-heuristic methods. In the initial placement phase, a hybrid algorithm combining genetic algorithm and simulated annealing algorithm is adopted to achieve global optimization of the initial VM allocation. In the dynamic migration phase, a dynamic migration strategy based on the greedy algorithm is employed, which selects the server with the highest energy efficiency as the migration target.

3) Reinforcement learning approaches: With the development of machine learning, Reinforcement Learning (RL) and Deep Reinforcement Learning (DRL) have been applied to address the dynamic optimization problem of VM placement. The core of this method lies in modeling the placement process as a Markov Decision Process (MDP), where an agent learns the optimal strategy through interaction with the environment. In study [5], VM placement is implemented based on DRL. An LSTM-based state prediction network provides future environmental states, which accelerates the convergence of the DRL model and enables it to adaptively select the optimal target host for migrated VMs. To address the issue that existing methods optimize sub-steps (such as selecting target PMs for migration and choosing services to be migrated) independently while ignoring the correlations between decisions, Reference [9] proposes a micro-service migration framework based on Multi-Agent RL, which jointly optimizes the three sub-steps of the migration process: selecting source PMs, selecting micro-services, and selecting target PMs. In study [27], a VM migration management strategy based on RL is proposed, which adopts a decentralized operation mode through parallel learning and state/action space aggregation. In study [28], an energy-efficient dynamic consolidation method named MAGNETIC based on the multi-agent Q-Learning algorithm is proposed, in which the agent dynamically selects the optimal power mode to balance energy consumption and QoS.

RL approaches offer the advantage of strong adaptability, enabling them to dynamically adjust strategies to accommodate the uncertainties of cloud environments. However, they face challenges such as high training costs and insufficient convergence stability.

III. System Model and Framework

A. System Model

Suppose a data center consists of *N* PMs denoted as $H = \{H_1, H_2, \dots, H_N\}$, where each PM H_i runs n_i VMs denoted as $V = \{V_1, V_2, \dots, V_{n_i}\}$. VM consolidation refers to the process of reasonably allocating a large number of VMs to PMs, with the core objective of optimizing resource utilization and reducing energy consumption while meeting QoS requirements and resource constraints.

1) Energy Consumption: The energy consumption of a PM is represented using a linear model as follows:

$$E_i = E_{idle} + (E_{max} - E_{idle}) \cdot u_i \quad (1)$$

where E_i denotes the total energy consumption of the PM H_i, E_{idle} represents the base energy consumption in the idle state, E_{max} is the maximum energy consumption under full load, and $u_i \in [0, 1]$ stands for the CPU utilization rate.

The total energy consumption of the entire data center is the sum of the energy consumption of all active PMs:

$$EC = \sum_{i=1}^{N} E_i \cdot \delta_i \quad (2)$$

where $\delta_i \in \{0, 1\}$ indicates the activation state of the PM H_i.

2) Service Level Agreement Violation: Service Level Agreement Violation (SLAV), a key metric for measuring whether VM consolidation affects QoS, refers to the number or proportion of times the QoS specified in the SLA fails to be met. In general, SLAV depends on two metrics: one is the SLAV time of each active host (SLATAH), and the other is the performance degradation caused by migration (PDM). SLAV can be expressed as:

$$SLAV = SLATAH \times PDM \quad (3)$$

where SLATAH represents the proportion of the total operating time that is occupied by SLA violation time in the service agreements of each active host, which is expressed as:

$$SLATAH = \frac{1}{N}\sum_{i=1}^{N}\frac{T_{H_i}^{OVER}}{T_{H_i}^{TOTAL}} \quad (4)$$

where N is the total number of all PMs. For any PM H_i, the total duration during which it violates the SLA due to overload is recorded as $T_{H_i}^{OVER}$, and the total duration during which this host is in an active state is $T_{H_i}^{TOTAL}$.

In study (3), PDM is used to represent the proportion of performance degradation caused by VM migration to its total performance requirements, which is expressed as:

$$PDM = \frac{1}{n}\sum_{j=1}^{n}\frac{S_{d,j}^{OVER}}{R_{d,j}^{TOTAL}} \quad (5)$$

where n represents the number of VMs, d denotes the resource type. For any VM V_j, the amount of performance degradation caused by migration is marked as $S_{d,j}^{OVER}$, and the total resource demand of this VM during its lifecycle is recorded as $R_{d,j}^{TOTAL}$.

B. System Framework

The framework of the VM consolidation system is illustrated in Fig. 1. Adopting a modular design, this framework decomposes the entire VM consolidation process into three key phases, forming a complete closed-loop control system.

- Workload Detection Module: Monitoring the resource utilization of all PMs in real time and outputs three types of PM states.
  - Overloaded PMs: PMs predicted to exceed the safety threshold.
  - Underloaded PMs: Idle PMs whose resource utilization remains below the minimum threshold.
  - Normal PMs: PMs operating within the ideal load range.
- VM Selection Module: For overloaded PMs, VMs are selected to be migrated out. For underloaded PMs, all VMs running on them are marked as to-be-migrated.
- VM Placement Module: The optimal target PM is selected from normal PMs to place the VMs selected in the VM selection module. After executing the migration, idle PMs are shut down to save energy.

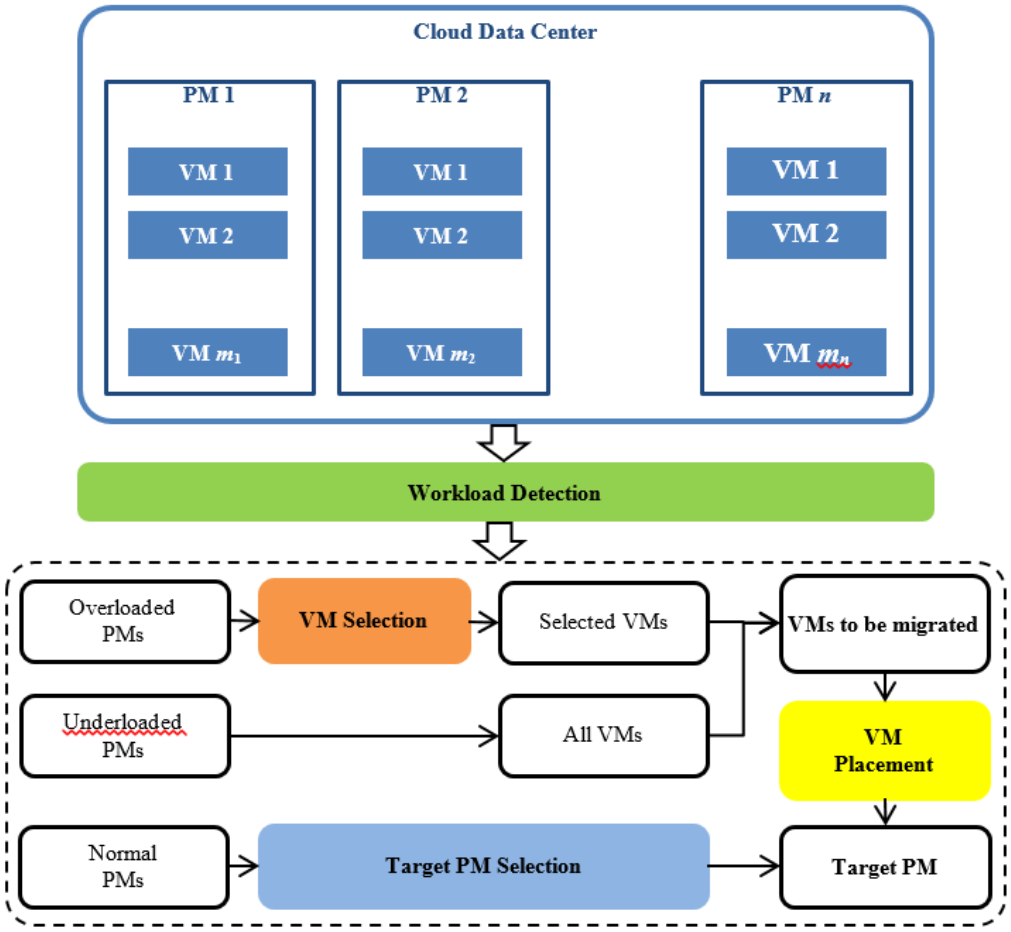

Fig. 1. Framework of VM consolidation.

IV. Workload Detection Based on Autoformer

Cloud workload time-series data typically contain both linear and non-linear components, exhibiting complex time-varying characteristics and significant temporal dependence. In response to this feature, a prediction architecture based on Autoformer is adopted [29], whose core components consist of an encoder and a decoder, as shown in Fig. 2.

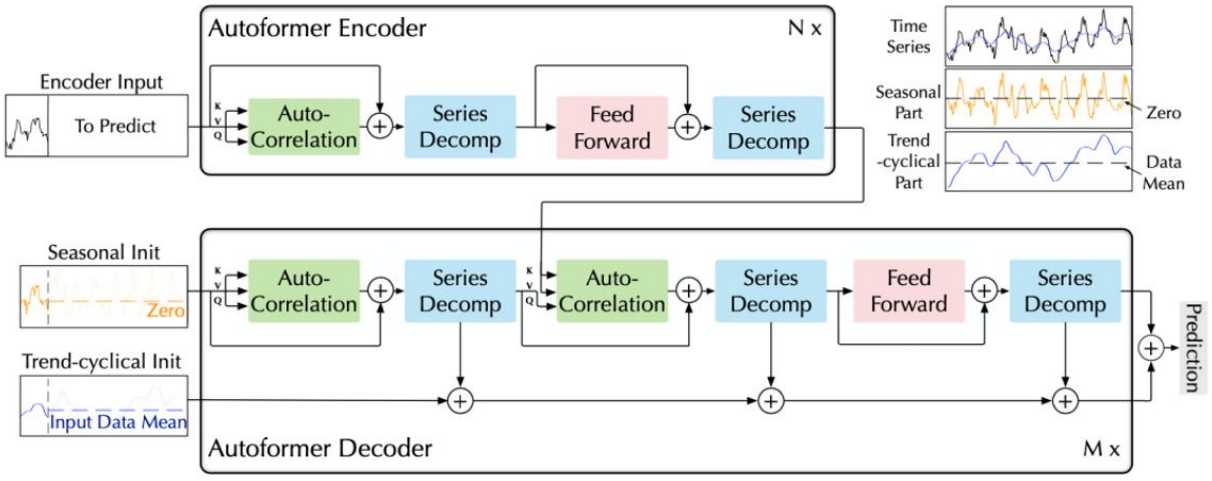

Fig. 2. Cloud workload prediction architecture based on Autoformer [29].

The encoder module takes historical workload time-series as input and performs multi-scale decomposition on the original time-series data through the Auto-Correlation Mechanism. This decomposition decouples the data into two orthogonal components:

- workload trend component which characterizes the long-term evolution law of resources;
- workload periodic component which depicts the inherent periodic fluctuation pattern of the system.

The decoder module adopts a dual-branch structure to process these two components separately. For the periodic component, progressive time-series feature extraction is achieved through cascaded auto-correlation blocks. For the trend component, a cumulative summation operation is used for multi-order trend information aggregation. Each layer of the decoder receives complete time-series segments rather than discrete sampling points. This global perception mechanism significantly enhances the model's ability to model complex workload patterns.

The workload detection process based on Autoformer is shown in Algorithm 1. In the initialization phase, the sets of PMs in overloaded, underloaded, and normal states are initialized as empty sets respectively, and the trained Autoformer model is loaded simultaneously. Next, the algorithm processes each PM in sequence. Line 3 obtains the current utilization rate of the PM by calling the getCurrentUtilization function, while Line 4 uses the getHistoryUtilization function to acquire the historical utilization sequence of the PM according to the window step size. This sequence contains resource usage data within a certain time span and serves as a key input for model prediction. Line 5 inputs the historical utilization sequence into the Autoformer model. Through its encoder, the historical workload time series undergoes multi-scale decomposition to separate the workload trend component and workload periodic component. These two components are then processed separately by the dual-branch structure of the decoder, ultimately outputting the predicted utilization rate. Lines 6–12 achieve accurate classification of PM states by comparing the current utilization rate and predicted utilization rate with the overload threshold and underload threshold. If the current utilization rate or the predicted utilization rate exceeds the overload threshold, the PM is determined to be in an overloaded state. If the predicted utilization rate is lower than the underload threshold and all data in the historical utilization sequence are below the underload threshold, it indicates that the host's resource utilization has been continuously low in the past and will remain low for a period in the future, so the PM is judged to be in an underloaded state. In all other cases, the host is classified as being in a normal state.

Algorithm 1: DetectWorkload

Input: physical machines $H = \{H_1, H_2, \dots, H_N\}$
window steps I
overload and underload threshold th_{over}, th_{under}

Output: overloaded PMs, underloaded PMs, normal PMs

End If

End For

return *overloaded*, *underloaded*, *normal*

V. VM Selection Based on Pearson Correlation Coefficient and Migration Time

In cloud computing environments dynamically changing, VM selection strategy is a key link that affects consolidation efficiency. An unreasonable VM selection strategy may lead to low migration efficiency or the risk of secondary overload. Therefore, this section proposes a comprehensive selection strategy that combines the Pearson correlation coefficient and migration time.

The Pearson correlation coefficient is a core metric for measuring the linear correlation between two variables. In the context of VM selection, it can accurately characterize the degree of correlation between the resource utilization of a VM and that of a PM. The equation is as follows:

$$\rho(V,H) = \frac{\sum_{t=1}^{T}(U_V^t-\mu_V)(U_H^t-\mu_H)}{\sqrt{\sum_{t=1}^{T}(U_V^t-\mu_V)^2}\sqrt{\sum_{t=1}^{T}(U_H^t-\mu_H)^2}} \quad (6)$$

where V denotes a VM, H represents a PM, and T stands for the length of the historical time window. U_V^t is the CPU utilization of the VM at time t, and U_H^t is the CPU utilization of the PM at time t. $\mu_V = \frac{1}{T}\sum_{t=1}^{T} U_V^t$ is the mean value of the CPU utilization time series of the VM, while $\mu_H = \frac{1}{T}\sum_{t=1}^{T} U_H^t$ is the mean value of the CPU utilization time series of the PM.

The time overhead for migrating virtual machine V from host H is modeled as:

$$MigTime(V,H) = Mem(V)/BW_{avail}(H) \quad (7)$$

where $\mathrm{Mem(V)}$ is the memory usage of the virtual machine, and $\mathrm{BW_{avail}(H)}$ represents the available network bandwidth of the host.

The VM migration impact factor based on the Pearson correlation coefficient and migration time is defined as follows:

$$IF(V,H) = \rho^2(V,H)/MigTime(V,H) \quad (8)$$

where the square operation strengthens the impact of VMs with high correlation, and the denominator term penalizes the migration of VMs with large memory.

Based on the definition of the VM migration impact factor, a VM selection algorithm that combines the Pearson correlation coefficient and migration time is proposed, as shown in Algorithm 2. This algorithm adopts a greedy strategy, selecting the VM with the largest current IF value for migration until the resource utilization of the overloaded host drops below the safety threshold.

Algorithm 2: SelectVMS

Input: overloaded hosts set $H_{overload}$

Output: migration list M

Initialize: $M \leftarrow \emptyset$

For each host H_i in $H_{overload}$ **Do**

    $V^* \leftarrow \underset{V \in H_i}{\mathrm{argmax}}\, IF(V,H_i)$

    $M \leftarrow M \cup \{V^*\}$

    $H_i \leftarrow H_i \setminus \{V^*\}$

End For

return M

VI. VM Placement Based on Enhanced Dual Q Network

VM placement refers to the reasonable allocation of VMs to PMs, aiming to optimize resource utilization and reduce energy consumption.

A. Problem Model

The VM placement framework based on the improved double Q neural network is illustrated in Fig. 3. The double Q neural network consists of two Q networks with identical structures but different parameter update methods: the online Q network QNet(θ) and the target Q network TargetQNet(θ^-). The online Q network is used to select action $\mathrm{a_t}$ based on the current environmental state $\mathrm{s_t}$, while the target Q network is employed to calculate the target Q-value. This design avoids the overestimation problem that may occur in traditional Q-learning, making the estimation of Q-values more accurate.

1) State representation: The environmental state s_t includes the CPU utilization information of each PM and the CPU demand information of the VM, which is defined as $s_t = [u_1^t, u_2^t, \ldots, u_i^t, \ldots, u_N^t, vm_{cpu}]$. Here, u_i^t denotes the CPU utilization of the i-th PM, and vm_{cpu} represents the CPU request information of the VM to be placed.

2) Action selection: Action a_t refers to placing the selected VM onto an appropriate PM. To balance exploration and exploitation, the upper confidence bound (UCB) strategy is adopted to improve action selection. For a given environmental state s_t, the optimal action is selected according to Eq. (9):

$$a_t^* = \underset{a \in A}{argmax}\, UCB(s_t,a) \quad (9)$$

where $\mathrm{UCB(s_t,a)}$ is defined as:

$$UCB(s_t,a) = Q_\theta(s_t,a) + c \cdot \sqrt{\ln N(s_t)/N(s_t,a)} \quad (10)$$

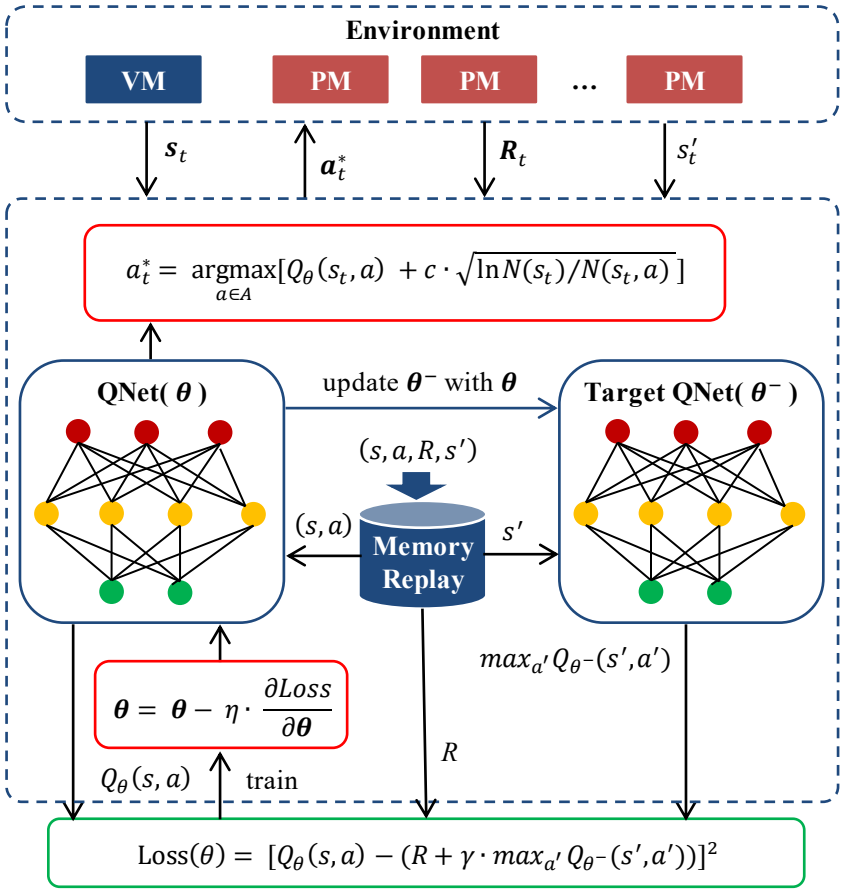

Fig. 3. VM placement framework based on enhanced deep Q-Network.

where $Q_\theta(s_t, a)$ is the value estimation of action a under state s_t from the online Q-network; c is the exploration coefficient; $N(s_t)$ represents the total number of times the state s_t has been visited; and $N(s_t, a)$ is the number of times the action a has been selected under state s_t. In this way, more diverse VM placement actions can be explored in the early stage. As experience accumulates, the focus gradually shifts to exploiting the optimal placement strategies that have been identified.

3) Reward: Based on the multi-objective optimization problem in the system model, the reward function is expressed as a function of energy consumption, SLAV rate, and migration count, which is defined as follows:

$$R_t = -(\alpha \cdot \frac{EC - EC_{min}}{EC_{max} - EC_{min}} + \beta \cdot \frac{SLAV - SLAV_{min}}{SLAV_{max} - SLAV_{min}} + \gamma \cdot \frac{M - M_{min}}{M_{max} - M_{min}}) \quad (11)$$

where $\alpha, \beta, \gamma \in [0, 1]$ are weight coefficients that satisfy $\alpha + \beta + \gamma = 1$; EC denotes total energy consumption, EC_{max} and EC_{min} represent the theoretical maximum and minimum energy consumption respectively; $SLAV_{max}$ and $SLAV_{min}$ are the theoretical maximum and minimum SLAV respectively; M indicates the migration count, M_{max} and M_{min} are the theoretical maximum and minimum migration counts respectively.

4) Loss Function: The online Q-network uses a mean squared error (MSE) loss function to calculate parameter gradients, which is defined by the following formula:

$$Loss(\theta) = E[(Q_\theta(s, a) - (R + \gamma \cdot max_{a'} Q_{\theta^-}(s', a')))^2] \quad (12)$$

where $Q_\theta(s, a)$ is the value estimation of the online Q-network for performing action a under state s; R denotes the obtained reward; $\gamma \in [0,1)$ is the discount factor; $Q_{\theta^-}(s', a')$ represents the value estimation of the target Q-network for action a′ under the next state s′; and $max_{a'} Q_{\theta^-}(s', a')$ refers to selecting the optimal action for the next state through the target Q-network.

5) Adaptive learning rate: An adaptive learning rate (ALR) is used for the training of the online Q-network, which is defined as follows:

$$\eta = \frac{1}{N(s,a)+1} \quad (13)$$

where $N(s, a)$ denotes the number of times action a has been selected under state s.

When the number of visits to a state-action pair is extremely small, $N(s, a) \approx 0$, and the learning rate $\eta \approx 1$ accordingly. A larger step size allows the parameters of the online Q-network to update rapidly, accelerating the learning process for value estimation of new decisions. As the same state-action pair is visited repeatedly, $N(s, a)$ increases, and the

learning rate η gradually approaches 0. A smaller step size prevents parameter oscillations caused by excessive updates, enabling the Q-value estimation to converge to a stable value and ensuring the accurate exploitation of known high-quality strategies.

B. VM Consolidation Algorithm

The VM consolidation algorithm is shown in Algorithm 3. The consolidation process consists of three parts: workload detection, VM detection, and VM placement. For each time window, the DetectWorkload function is executed first to detect the state of each PM. For overloaded PM, the SelectVMS function is executed to select the VMs that need to be migrated out. For underloaded PM, all VMs are migrated out. The VM placement phase is the core decision-making part of the algorithm, integrating deep reinforcement learning and the exploration-exploitation balance strategy.

The action selection adopts an improved variant of the ε-greedy strategy. On the basis of Q-network valuation, it introduces a confidence interval adjustment term composed of the exploration coefficient c, state-action counters N(s, a) and N(s). This design not only enables the exploitation of known high-quality placement schemes through the Q-network, but also encourages the exploration of low-frequency visited actions via $\sqrt{\ln N(s_t)/N(s_t,a)}$, thus preventing the algorithm from falling into local optimal solutions.

Algorithm 3. Virtual Machine Consolidation

Initialize:
the size of time window
the physical machines $H = \{H_1, H_2, \dots, H_N\}$
online net QNet(θ) with random weights θ
target net TargetQNet(θ^-) with weights $\theta^- \leftarrow \theta$
experience replay buffer D with capacity C
exploration coefficient c
discount factor γ

For each time step t **Do**
  Overload,Underload,Normal ← **DetectWorkload**(H)
  MigrationList ← **SelectVMS**(Overload)
  MigrationList ←*MigrationList*+VMs of underload PMs
  For each virtual machine V in *MigrationList* **Do**
    s_t = getCurrentState(*Normal*, V)
    $a_t^* = \underset{a \in A}{\operatorname{argmax}} [Q_\theta(s_t, a) + c \cdot \sqrt{\ln N(s_t)/N(s_t,a)}]$
    Place V on the host determined by the action a_t^*
    $R_t = -(\alpha \frac{EC - EC_{min}}{EC_{max} - EC_{min}} + \beta \frac{SLAV - SLAV_{min}}{SLAV_{max} - SLAV_{min}} + \gamma \frac{M - M_{min}}{M_{max} - M_{min}})$
    D ← D + (s, a, R, s')
  End For
  If D.size()>=batchsize AND (t%traininterval)==0 **Then**
    Batch = D.sample(batch size)
    For each sample (s, a, R, s') in Batch **Do**
      $\text{Loss}(\theta) = [Q_\theta(s,a) - (R + \gamma \cdot max_{a'} Q_{\theta^-}(s', a'))]^2$
      $\eta = \frac{1}{N(s,a)+1}$
      $\boldsymbol{\theta} = \boldsymbol{\theta} - \eta \cdot \frac{\partial Loss}{\partial \boldsymbol{\theta}}$
    End For
  End If
  If (t % target update interval) ==0 **Then**
    $\theta^- \leftarrow \theta$
  End If
End For

The experience replay mechanism caches historical interaction data and performs random sampling for training when the batch condition is met. This breaks the temporal correlation between samples and improves the stability of Q-network training. The loss function adopts the squared temporal difference error, taking the deviation between the current Q-value and the target Q-value as the optimization objective. The learning rate η is linked to N(s, a), enabling state-action pairs that are less frequently visited to obtain a larger parameter update magnitude, thus accelerating the learning of sparse sample regions.

The periodic update of the target network further prevents oscillations in Q-value estimation. By copying the online network parameters θ to the target network parameters θ^- at fixed intervals, the calculation benchmark for target Q-values remains stable within a certain period, providing a reliable reference for the gradient descent of the online network.

Overall, through the closed-loop mechanism of perception-decision-learning, this algorithm achieves dynamic optimization of VM consolidation. Workload detection accurately identifies resource bottlenecks; VM selection focuses on key adjustment targets; VM placement integrates reinforcement learning to realize intelligent decision-making; and the design of experience replay and target network ensures the convergence and robustness of the algorithm in dynamic cloud environments. Ultimately, it achieves the comprehensive goals of improving resource utilization, reducing data center energy consumption, and ensuring service quality.

VII. Experimental Evaluation

A. Experimental Setting

To verify the effectiveness of the adaptive VM consolidation strategy based on Autoformer and Enhanced Double Q-Network (AEDQN-VMC) proposed in this paper, the experimental simulations were conducted by building a test environment on the CloudSim 4.0 simulation platform [30]. As a mainstream simulation tool in the cloud computing field, this platform supports the simulation of resource scheduling for PMs and VMs, as well as the quantitative calculation of key metrics such as energy consumption and SLA violation rate, and has been widely adopted in relevant research. To cover the load characteristics under different business scenarios and

verify the generalization ability of the strategy, three types of real cloud load datasets were used in the experiments: the PlanetLab dataset [31], the Google Cluster Trace dataset [32], and the Alibaba dataset [33].

1) Configuration of PMs and VMs: To ensure consistency with the experimental conditions of existing mainstream research, the hardware parameters of PMs and VMs are all set with reference to the experimental parameters in [5]. The specific configurations are as follows:

a) PMs: Two types of heterogeneous hosts (HP ProLiant G4 and HP ProLiant G5) are adopted. Each host is configured with 2 CPU cores and a unified memory capacity of 4GB. The core difference lies in processor performance, with specific parameters shown in Table I. A total of 100 physical machines are deployed in the data center in the experiment, and the quantity ratio of the two types of hosts is 1:1, so as to simulate the heterogeneous hardware environment of real data centers.

TABLE I. PM CONFIGURATION

PM Type	Processor (MIPS)	Num. of Cores	Memory (GB)
HP ProLiant G4	1860	2	4
HP ProLiant G5	2660	2	4

b) VMs: Four types of VM instances are designed to cover scenarios from lightweight to high-performance. The MIPS (Million Instructions per Second) of processor ranges from 500 to 2500, and the memory capacity matches the CPU requirements, with specific parameters shown in Table II. There are 200 VMs in total in the experiment, with 50 VMs of each type.

TABLE II. VM CONFIGURATION

VM Type	Processor(MIPS)	Memory(GB)
Micro	500	0.85
Small	1000	1.7
Extra Large	2000	3.75
High-CPU Medium	2500	0.85

2) Parameters of the energy consumption model: The energy consumption calculation of PMs refers to the SPECpower benchmark test data [34]. As an industry standard for data center energy consumption evaluation, this benchmark provides measured power consumption values under different CPU utilization rates. In the experiment, the power consumption data of the two types of hosts within the CPU utilization range of 0%–100% is shown in Table III. For intermediate utilization rates not covered in the table (e.g., 15%, 25%), the linear interpolation method is used to calculate continuous power consumption values, ensuring the accuracy of the energy consumption model.

3) Key parameter settings: Autoformer Load Prediction Parameters: The length of the historical time window is 24 time steps; the number of encoder/decoder layers is 2 each; the number of heads in the autocorrelation block of each layer is 4; and the hidden layer dimension is 64. The batch size is 128, the number of epochs is 100, the Adam optimizer is used, the initial learning rate is 0.01, and the loss function is mean squared error (MSE). The overload threshold of physical machines is 0.9, and the underload threshold is 0.2.

Enhanced Double Q-Network Parameters: A fully connected neural network is adopted as the network model for the double Q-network, and the online Q-network and target Q-network share an identical network structure. This fully connected neural network contains 3 hidden layers, with the number of nodes in each hidden layer being 256, 128, and 64 respectively. The exploration coefficient c in (10) is 0.5; α, β, γ in (11) are each 1/3; and the discount factor γ in (12) is 0.9. The training interval is 10 time steps, and the target network update interval is 100 time steps.

TABLE III. POWER CONSUMPTION AT DIFFERENT CPU UTIL. (WATTS)

CPU Util.	0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1
HP G4	86	89.4	92.6	96	99.5	102	106	108	112	114	117
HP G4	93.7	97	101	105	110	116	121	125	129	133	135

4) Comparison benchmarks and evaluation metrics: To verify the superiority of the AEDQN-VMC strategy, three VM consolidation strategies were selected as comparison benchmarks in the experiment:

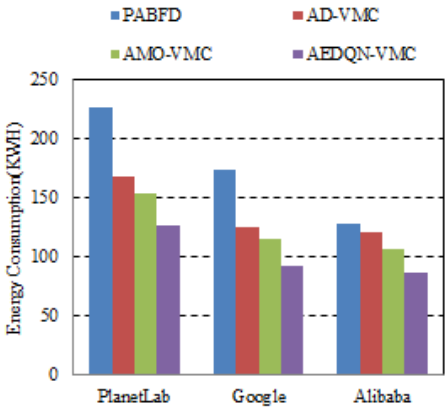
- PABFD (Power-Aware Best Fit Decreasing): An energy-aware strategy built into CloudSim [35], which selects the host with the minimum energy consumption increment after VM placement.
- ADVMC (Adaptive DRL-based VM Consolidation): A VM consolidation strategy proposed by [5], which is based on LSTM prediction and DQN placement.
- AMOVMC (Adaptive Multi-Objective Virtual Machine Consolidation): An VM consolidation strategy proposed by [4], which uses a neural network to predict future resource utilization, and adopts a multi-objective heuristic adaptive VM placement algorithm to select the optimal target host.

Two core evaluation metrics were used in the experiment: total energy consumption and SLAV rate. The calculation of total energy consumption refers to Eq. (2), and the calculation of SLAV rate refers to Eq. (3)–(5). The CPU performance loss caused by migration is set to 10% by default.

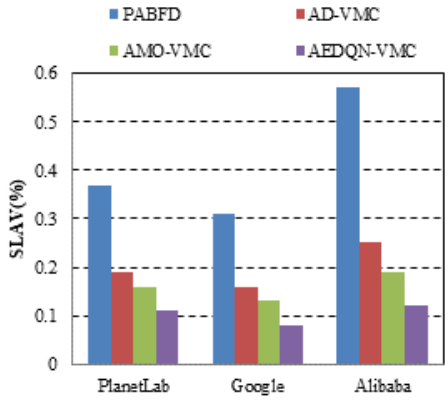
B. Performance Evaluation

To verify the effectiveness and advancement of the VM consolidation method AEDQN-VMC proposed in this paper, we conducted a comparative analysis between the proposed method and the benchmark methods. The comparison results are shown in Fig. 4. It can be seen that the energy consumption of the method proposed in this paper is significantly lower than that of the comparison methods on the three datasets (PlanetLab, Google, and Alibaba). Specifically, compared with the PABFD method, the energy consumption is reduced by 44.5%, 46.5%, and 32.6% respectively; compared with the ADVMC method, the energy consumption is reduced by

25.2%, 25.7%, and 28.3% respectively; and compared with the AMOVMC method, the energy consumption is reduced by 18%, 19.7%, and 18.8% respectively.



(a) Energy



(b) SLAV

Fig. 4. Comparison of performance among consolidation methods.

The performance improvement in energy consumption stems from the following aspects. The Autoformer-based workload detection module can accurately predict the load trend of PMs, identify overloaded and underloaded states in advance, and avoid redundant energy consumption caused by unbalanced resource allocation. The VM placement module achieves efficient resource utilization through the enhanced double Q-network. On the premise of meeting the resource requirements of VMs, it minimizes the number of active PMs, thereby reducing overall energy consumption. The timely shutdown strategy for underloaded hosts further reduces idle energy consumption and improves energy utilization efficiency.

The SLAV of the method proposed in this paper remains the lowest across all three datasets. Specifically, on the Google dataset, its SLAV is 0.08%, a reduction of 50% compared to the ADVMC method, a reduction of 38.5% compared to the AMOVMC method, and a reduction of 74.2% compared to the PABFD method. The accurate load prediction of the Autoformer model can avoid the risk of PM overload in advance and reduce service interruptions caused by resource saturation. The VM selection module screens migration targets using the Pearson correlation coefficient, prioritizing the migration of VMs that have less impact on host load. Meanwhile, by integrating migration time optimization, it reduces performance loss during the migration process, thereby lowering the overall SLAV.

C. Ablation Experiments

1) Impact of PM detection on consolidation: To verify the impact of the Autoformer-based host state detection (Autoformer-HSD) proposed in this paper on VM consolidation performance, we kept the VM selection algorithm and VM placement algorithm unchanged, and replaced the host state detection algorithm proposed in this paper with other host state detection algorithms. In this way, we obtained the VM consolidation performance based on different host state detection algorithms. The benchmark methods used to verify Autoformer-HSD are as follows:

- Current state-based host state detection without prediction (CS-HSD)
- Local regression-based host state detection (LR-HSD)
- LSTM-based host state detection (LSTM-HSD)

The performance comparison results between Autoformer-HSD and other methods are shown in Fig. 5. As can be seen from Fig. 5, Autoformer-HSD is significantly superior to other comparison methods in terms of the two core metrics—energy consumption and SLAV, verifying its role in improving VM consolidation performance.

a) Energy consumption: Compared with CS-HSD, the energy consumption of Autoformer-HSD is reduced by 30.8% (PlanetLab), 34.5% (Google), and 26.4% (Alibaba) across the three datasets. This is because CS-HSD only relies on the current load state to make decisions and cannot identify overload risks in advance. It often triggers migration only after the host is already overloaded, leading to redundant resource allocation and additional energy consumption from frequent migrations. In contrast, Autoformer-HSD can adjust resource allocation in advance through accurate prediction of future loads, reducing ineffective energy consumption at the source.

Compared with LR-HSD, the energy consumption of Autoformer-HSD is reduced by 25.6% (PlanetLab), 19.0% (Google), and 22.5% (Alibaba). LR-HSD can only capture local linear trends and has limited ability to model complex periodic fluctuations and long-term trends in cloud loads, resulting in high prediction errors that further affect the accuracy of host state judgment. However, the autocorrelation mechanism of Autoformer can effectively decompose the periodic and trend components of the load, improving prediction accuracy and reducing energy waste caused by misjudgment.

Compared with LSTM-HSD, the energy consumption of Autoformer-HSD is still reduced by 5.3% (PlanetLab), 7.1% (Google), and 7.7% (Alibaba). This benefit comes from the global perception mechanism of the Autoformer decoder, enabling it to more accurately capture the long-term dependencies of the load. This optimizes the timeliness and accuracy of host state detection, further reducing energy consumption.

b) SLAV: The SLAV of Autoformer-HSD is the lowest across all datasets. Compared with CS-HSD, its SLAV is reduced by 57.7% (PlanetLab), 61.9% (Google), and 36.8% (Alibaba). This is because CS-HSD lacks prediction capability and cannot avoid overload in advance, causing hosts to frequently be in a state of resource saturation and triggering SLA violations. In contrast, Autoformer-HSD can complete VM migration before the arrival of load peaks by predicting overload risks in advance, significantly reducing service interruption time.

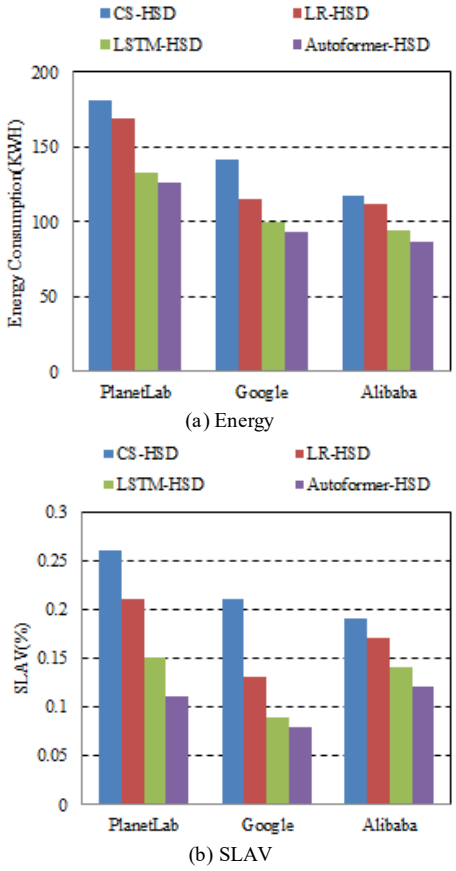


Fig. 5. Performance comparison between Autoformer-HSD and other host detection methods.

Compared with LR-HSD and LSTM-HSD, the SLAV advantage of Autoformer-HSD is slightly narrowed but still maintains a leading position. For example, on the Google dataset, its SLAV is 38.5% lower than that of LR-HSD and 11.1% lower than that of LSTM-HSD. This stems from Autoformer's accurate modeling of load fluctuations, which enables more precise judgment on whether a host will enter an overloaded state, reducing the increase in SLAV caused by prediction errors.

This ablation experiment shows that Autoformer-HSD can more precisely identify the overloaded and underloaded states of hosts by improving the accuracy of load prediction and the ability to model complex time-series features. It provides a reliable decision-making basis for subsequent VM selection and placement, ultimately reducing energy consumption while effectively ensuring service quality. This verifies its core role in the VM consolidation system.

2) Impact of VM selection on consolidation: To evaluate the impact of the PCM-VMS proposed in this paper on the overall performance of VM consolidation, we kept all other components of the proposed VM consolidation algorithm unchanged, while replacing PCM-VMS with other benchmark VM selection algorithms. In this way, we obtained performance data of VM consolidation based on different VM selection algorithms. The other benchmark VM selection algorithms used to verify the performance of PCM-VMS are as follows:

- Minimum migration time-based VM selection (MMT-VMS)
- Maximum correlation-based VM selection (MC-VMS)
- Influence coefficient-based VM selection (IC-VMS)

The performance comparison results between PCM-VMS and other VM selection algorithms are shown in Fig. 6. It can be indicated that the proposed PCM-VMS performs the best in terms of both energy consumption and SLAV metrics, verifying its role in improving VM consolidation performance.

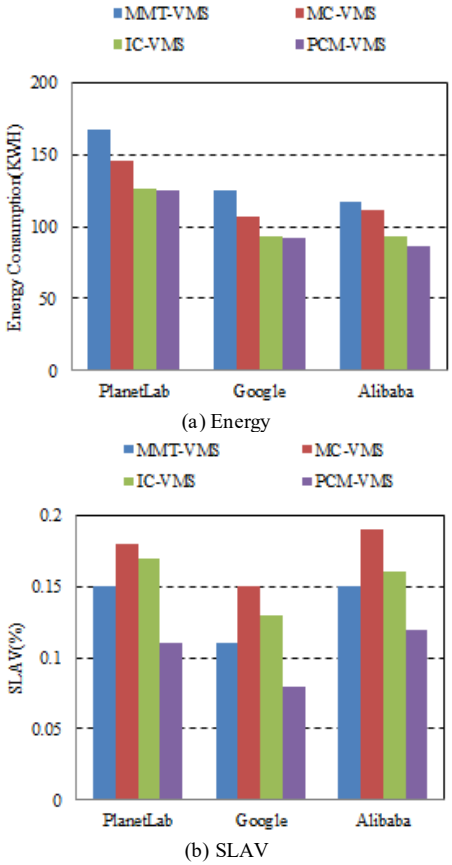

Fig. 6. Performance comparison between PCM-VMS and other VM selection algorithms.

a) Energy consumption: Compared with MMT-VMS which only considers migration time, the energy consumption of PCM-VMS is reduced by 25.0% (PlanetLab), 26.1%

(Google), and 26.4% (Alibaba) across the three datasets. Although MMT-VMS can reduce the time cost of a single migration, it fails to consider the resource correlation between VMs and hosts. This may lead to the migration of VMs that have little impact on host load, resulting in overloaded hosts not being effectively relieved of their load, and requiring multiple migrations to achieve load balancing, which instead increases overall energy consumption. In contrast, PCM-VMS balances correlation and migration cost, which enable overloaded hosts to return to a normal state through fewer migration operations, thereby reducing energy consumption.

Compared with MC-VMS which only focuses on correlation, the energy consumption of PCM-VMS is reduced by 14.1% (PlanetLab), 13.1% (Google), and 22.5% (Alibaba). Although MC-VMS can quickly alleviate host overload by migrating VMs with high correlation, it fails to consider migration time. This may lead to system performance loss due to excessive network resource occupation during migration, indirectly increasing energy consumption. In contrast, PCM-VMS penalizes the migration of VMs with large memory, reducing migration operations that incur high resource overhead and further optimizing energy consumption.

Compared with IC-VMS based on the influence coefficient, the energy consumption of PCM-VMS is reduced by 7.7% on the Alibaba dataset, and its performance is comparable to that of IC-VMS on the other datasets. This is because the influence coefficient of IC-VMS does not incorporate migration cost, whereas PCM-VMS precisely controls migration cost through a denominator term, making its decisions more aligned with the core goals of efficient load reduction and low overhead.

b) SLAV: The SLAV of PCM-VMS is the lowest across all datasets. Compared with MMT-VMS, its SLAV is reduced by 26.7% (PlanetLab), 27.3% (Google), and 20.0% (Alibaba), respectively. Since MMT-VMS ignores the correlation between VMs and hosts, it may cause host load rebound after migration, increasing SLAV; in contrast, the high-correlation VMs migrated by PCM-VMS can effectively reduce host load fluctuations and lower the risk of overload.

Compared with MC-VMS, the SLAV of PCM-VMS is reduced by 38.9% (PlanetLab), 46.7% (Google), and 36.8% (Alibaba). MC-VMS prioritizes migrating high-correlation VMs but may select VMs with large memory, leading to a decline in migration performance. In contrast, PCM-VMS restricts the migration of large-memory VMs through a denominator term, reducing performance loss during the migration process and thereby lowering the overall SLAV.

Compared with IC-VMS, the SLAV of PCM-VMS is reduced by 35.3% (PlanetLab), 38.5% (Google), and 25.0% (Alibaba). This benefit comes from PCM-VMS's refined modeling of correlation and migration cost, which ensures that migration operations can effectively alleviate host overload and control migration time. The collaborative optimization of these two aspects significantly reduces SLAV.

In summary, this ablation experiment verifies the effectiveness of PCM-VMS. By integrating the Pearson correlation coefficient and migration time, a more optimized influence factor is constructed. While reducing the number of migrations and lowering energy consumption, it effectively controls SLAV, providing an efficient decision-making basis for VM consolidation.

3) Impact of VM placement on consolidation: To evaluate the performance of the VM placement algorithm based on enhanced dual Q network (EDN-VMP) proposed in this paper, we kept all other components of the proposed VM consolidation algorithm unchanged, while replacing EDN-VMP with other benchmark VM placement algorithms. In this way, we obtained performance data of VM consolidation based on different VM placement algorithms. The other benchmark VM placement algorithms used to verify the performance of EDN-VMP are as follows:

- Minimum energy increment based VM placement (MEI-VMP)
- Q-Learning-based VM placement (QL-VMP)
- Dual-Q-network-based VM placement (DN-VMP)

The comparison results of VM consolidation performance between the EDN-VMP and other VM placement algorithms are shown in Fig. 7. It can be seen that the EDN-VMP is significantly superior to other benchmark algorithms in both energy consumption and service quality, fully verifying its role in improving VM consolidation performance.

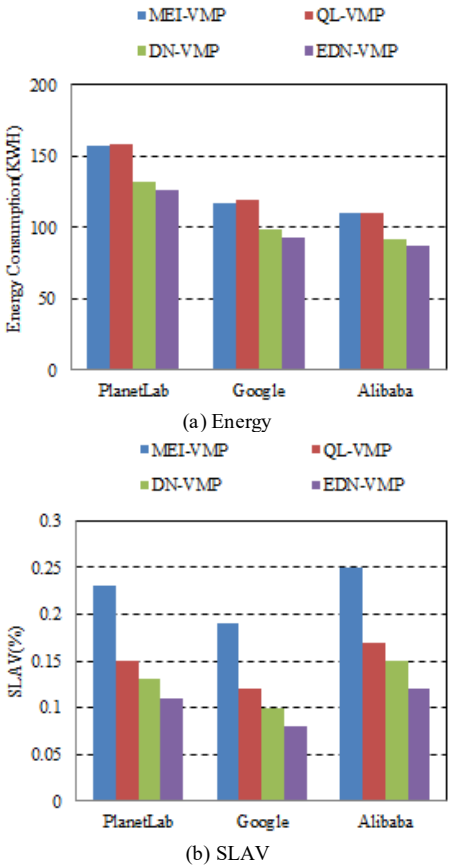

Fig. 7. Performance comparison between EDN-VMP and other VM placement algorithms.

a) Energy consumption: Compared with MEI-VMP, the energy consumption of EDN-VMP is reduced by 20.0% (PlanetLab), 21.1% (Google), and 21.1% (Alibaba) respectively. MEI-VMP adopts a greedy strategy and only takes the current energy consumption increment as the decision-making basis. It fails to consider long-term load trends and resource balance, which may lead to frequent migrations or host overload in the later stage due to short-term optimization, thereby increasing overall energy consumption. In contrast, EDN-VMP leverages the global decision-making capability of reinforcement learning and combines the UCB strategy to explore better placement schemes. While reducing current energy consumption, it avoids long-term resource imbalance, thus achieving more stable energy consumption optimization.

Compared with QL-VMP, the energy consumption of EDN-VMP is reduced by 20.6% (PlanetLab), 22.3% (Google), and 21.7% (Alibaba) respectively. QL-VMP has limited ability to model high-dimensional state spaces and struggles to accurately capture the correlation between placement decisions and long-term energy consumption, resulting in low decision-making accuracy. In contrast, EDN-VMP extracts complex state features through deep neural networks and combines a dual Q-network structure to avoid Q-value overestimation, significantly enhancing the global optimization capability of its decisions.

Compared with DN-VMP, the energy consumption of EDN-VMP is still reduced by 5.1% (PlanetLab), 6.1% (Google), and 5.8% (Alibaba). Although DN-VMP solves the overestimation problem, it lacks the key improvements of EDN-VMP: (1) It does not introduce the UCB strategy, resulting in insufficient exploration of high-quality placement schemes with low access frequency and a tendency to fall into local optimality; (2) It does not adopt an adaptive learning rate, leading to low efficiency in parameter updates for sparse scenarios. Through these two improvements, EDN-VMP further enhances the accuracy of resource allocation and reduces redundant energy consumption.

b) SLAV: Compared with MEI-VMP, the SLAV of EDN-VMP is reduced by 52.2% (PlanetLab), 57.9% (Google), and 52.0% (Alibaba), respectively. MEI-VMP, due to its over-pursuit of energy consumption optimization, may deploy VMs to hosts that are nearly saturated, leading to frequent host overload. Additionally, it lacks global migration planning, which may trigger unnecessary migration operations and result in decreased migration performance. In contrast, the reward function of EDN-VMP constrains both energy consumption and SLAV simultaneously. By balancing multi-objectives through reinforcement learning, it effectively reduces the risk of overload and migration losses.

Compared with QL-VMP, the SLAV of EDN-VMP is reduced by 26.7% (PlanetLab), 33.3% (Google), and 29.4% (Alibaba) respectively. QL-VMP's coarse state modeling leads to low matching accuracy between placement decisions and VM resource requirements, easily causing overload. However, EDN-VMP accurately captures state features via deep networks and explores better matching schemes by combining the UCB strategy, significantly reducing the SLA violation rate.

Compared with DN-VMP, the SLAV of EDN-VMP is reduced by 15.4% (PlanetLab), 20.0% (Google), and 20.0% (Alibaba) respectively. The performance gap arises because DN-VMP lacks an adaptive learning rate. For newly emerged state-action pairs, the fixed parameter update step size of DN-VMP makes it difficult to quickly learn optimal decisions, leading to a short-term increase in SLAV. In contrast, EDN-VMP assigns a larger update magnitude to sparse samples through its adaptive learning rate, accelerating adaptation to new scenarios and thereby reducing the violation rate.

In summary, this ablation experiment fully verifies the effectiveness of EDN-VMP. By introducing the UCB strategy to balance exploration and exploitation, adopting an adaptive learning rate to optimize parameter updates, and integrating the global decision-making capability of the dual Q-network, EDN-VMP significantly improves the stability of service quality while reducing energy consumption.

4) Impact of UCB and ALR on Dual Q-Network: To verify the impact of the UCB and ALR on the performance of the Dual Q-Network, we further conducted ablation experiments on the enhanced dual Q-Network. Based on the basic dual Q-Network, we integrated the UCB and adaptive learning rate, respectively. The several neural networks used for comparison are as follows:

- General dual Q-Network (DQN)
- Dual Q-Network with UCB (DQN+UCB)
- Dual Q-Network with ALR (DQN+ALR)
- Dual Q-Network with UCB and ALR (DQN+UCB+ ALR)

The impact of the UCB and ALR on the performance of the Dual Q-Network is shown in Table IV. The experimental results indicate that the introduction of UCB and ALR plays a significant role in improving the performance of the Dual Q-Network, and the synergistic effect of the two further optimizes the core metrics of VM consolidation.

TABLE IV. IMPACT OF UCB AND ALR ON PERFORMANCE OF DUAL Q-NETWORK

	Energy Consumption (KWH)			SLAV (%)		
	PlanetLab	Google	Alibaba	PlanetLab	Google	Alibaba
DQN	132.4	98.7	91.8	0.13	0.1	0.15
DQN+UCB	129.8	95.8	89.4	0.12	0.09	0.13
DQN+ALR	128.6	94.6	88.7	0.12	0.09	0.13
DQN+UCB+ALR	125.6	92.65	86.52	0.11	0.08	0.12

In terms of energy consumption, compared with the general dual Q-Network (DQN), the DQN+UCB achieves an energy consumption reduction of 1.96% (PlanetLab), 2.94% (Google), and 2.61% (Alibaba) across the three datasets. This benefit stems from the UCB strategy's ability to balance exploration and exploitation, which reduces resource allocation imbalance caused by local optimality and makes VM placement decisions more aligned with the goal of global energy consumption optimization. The DQN+ALR shows a more significant reduction in energy consumption. Its advantage lies in its fast learning capability for sparse state-action pairs, which accelerates the convergence of high-quality placement strategies and reduces redundant energy consumption.

The DQN+UCB+ALR performs the best, with energy consumption reduced by 5.14% (PlanetLab), 6.13% (Google), and 5.75% compared with DQN, reflecting the synergistic effect of the two mechanisms. UCB ensures sufficient exploration of the decision space, while ALR improves learning efficiency, enabling the algorithm to quickly find the balance between energy consumption and service quality in dynamic cloud environments.

In terms of SLAV, the SLAV of DQN+UCB is reduced by 7.69% (PlanetLab), 10.00% (Google), and 13.33% (Alibaba) compared with DQN. This indicates that the UCB strategy reduces the risk of host overload caused by decision limitations by exploring more potential high-quality placement schemes. The SLAV performance of DQN+ALR is comparable to that of DQN+UCB. This verifies the ALR's ability to quickly adapt to new scenarios, which can effectively reduce short-term service interruptions.

The SLAV advantage of DQN+UCB+ALR is further expanded. Compared with DQN, its SLAV is reduced by 15.38% (PlanetLab), 20.00% (Google), and 20.00% (Alibaba). The reason lies in that the UCB strategy reduces the proportion of suboptimal decisions caused by insufficient exploration, while the ALR accelerates the learning of high-risk state-action pairs. The combined effect of the two enables the algorithm to significantly reduce the SLAV rate.

In summary, the introduction of the UCB and ALR optimizes the dual Q-Network from two dimensions: the breadth of decision exploration and the depth of learning efficiency. Their combination achieves a "1+1>2" optimization effect through a synergistic effect, providing more accurate and efficient intelligent support for VM placement decisions. Ultimately, it significantly improves the stability of service quality while reducing energy consumption.

VIII. Conclusion and Future Work

To address the issues of energy optimization and service quality management in VM consolidation for cloud data centers, this paper proposes an adaptive consolidation strategy based on Autoformer and enhanced dual Q-Network. Through collaborative innovations in three stages: host state detection, VM selection, and VM placement, an effective balance between energy consumption and service quality in dynamic cloud environments is achieved.

In the host state detection stage, a prediction method based on Autoformer is adopted. This method performs multi-scale decomposition of load time series through an autocorrelation mechanism, explicitly separating trend components from periodic components. This significantly improves both load prediction accuracy and the accuracy of host state classification. In the VM selection stage, a VM migration impact factor that integrates the Pearson correlation coefficient and migration time is proposed. This factor balances resource correlation and migration overhead, effectively avoiding performance degradation caused by excessively high migration costs or insufficient load mitigation. In the VM placement stage, an enhanced dual Q-Network algorithm is designed. It introduces the UCB strategy to optimize the exploration-exploitation trade-off and adopts an ALR mechanism to accelerate model convergence, thereby achieving intelligent decision-making under multi-objective trade-offs.

Experimental results show that the strategy proposed in this paper significantly outperforms the comparative benchmark methods on three real load datasets, and can effectively reduce cloud data center energy consumption and SLAV rates. Ablation experiments further verify the effectiveness of each innovative module and their contributions to the overall performance.

Despite the good performance of the AEDQN-VMC strategy, there are still some limitations that can be further explored in future research:

- Adaptation to multi-resource dimensions and heterogeneous workloads: The current study mainly focuses on CPU and memory resources. In the future, it can be extended to multi-dimensional resource constraints such as network I/O and disk bandwidth, and the adaptability to heterogeneous workloads can be enhanced.
- Model lightweighting and online learning: The Autoformer and Dual Q-Network models have a large number of parameters, resulting in high training and inference overhead. Future research can explore model compression, knowledge distillation, and online incremental learning mechanisms to improve the practicality and real-time performance of the algorithm in ultra-large-scale data center environments.
- Cross-layer collaboration and cooling energy consumption optimization: The current energy consumption model only considers server energy consumption. In the future, a cooling system energy consumption model can be introduced, and cross-layer collaborative optimization between computing resource scheduling and cooling system control can be explored to further improve overall energy efficiency.
- Extension to multi-cloud and edge environments: This study focuses on a single data center scenario. In the future, the framework can be extended to multi-cloud collaboration or edge-cloud collaboration environments, and cross-domain resource scheduling and fault-tolerance mechanisms can be studied to enhance the generalization ability and application scope of the strategy.

***Abstract*—This paper addresses the escalating challenge of signature forgery detection through an innovative hybrid verification system. We integrate Siamese Neural Networks with wavelet scattering transformations to precisely capture signature characteristics while accommodating inherent variations. Our principal contribution, the "common anchor methodology," identifies a singular representative signature per individual, substantially reducing computational demands on the CEDAR Dataset while maintaining verification integrity. Through meticulous optimization of wavelet scattering parameters, our system demonstrates markedly superior performance on the CEDAR benchmark while requiring considerably fewer model parameters than traditional CNN architectures. This research establishes noteworthy advancements in both accuracy and efficiency for practical signature verification implementations. The study evaluates the performance of a wavelet-Siamese network architecture for offline signature verification through a series of five experiments with varying parameter configurations. Key variables include the use of a common anchor, the J Factor, and the θ value. Results reveal that incorporating a common anchor consistently improves performance. Among all configurations, experiment 4 with a J Factor of 2 and a θ value of 16 yielded the most favorable results, achieving the lowest error rate of 20.823% and the highest ROC-AUC score of 0.8699, along with efficient convergence within 55 iterations. In contrast, the absence of a common anchor in Experiment 1 led to a notably higher error rate of 24.44% and lower model performance. These findings demonstrate the critical role of parameter tuning in enhancing the robustness and accuracy of signature verification systems based on Siamese networks. Despite the substantial computational savings, the system's best achieved error rate (20.82%) remains higher than several state-of-the-art and commercial signature verification solutions, many of which report error rates below 10%. This indicates an existing trade-off between efficiency and the highest attainable accuracy, which future work will aim to mitigate.**

I. Introduction

A signature, typically a person's name or identifying mark, serves as proof of document approval and plays a vital role in personal authentication. As a deliberately created biometric trait, handwritten signatures have become increasingly important with the rise of digital documents and transactions, where signature forgery poses a serious threat. Traditional manual verification methods are subjective, time-consuming, and prone to error. Therefore, there is a growing need for automated signature verification systems leveraging computer vision, machine learning, and biometric techniques. Standard CNN approaches particularly struggle with forgeries created by people who've practiced mimicking a target signature [1]. These sophisticated fakes often slip through undetected – a serious weakness in security-critical applications [2]. The computational demands also create barriers to widespread adoption, especially in resource-limited settings. Our work addresses these challenges using a novel approach. We employ Siamese neural networks enhanced with wavelet scattering transformations [3]. Instead of relying on rigid thresholds, the system learns adaptive similarity measures to accommodate natural variations. By examining signature features at multiple scales and angles, it significantly improves the detection of even well-crafted forgeries. Signature verification is categorized into dynamic (online) and static (offline) types. Dynamic methods capture signatures during writing on digital devices, while static methods analyze scanned images of completed signatures. Offline verification is particularly challenging due to the lack of dynamic information such as pen movement, speed, and pressure. Deep learning and machine learning techniques, especially Convolutional Neural Networks (CNNs), have been increasingly employed in recent studies [4], [5], [6], [7] to extract reliable and distinctive features, leading to significant improvements over traditional handcrafted approaches. Despite these advances, signature forgery remains a serious security challenge in the digital age [2]. Manual verification's subjectivity and inefficiency have driven interest in automated systems. Current CNN-based methods process signature images [8] and match them against stored samples using fixed thresholds. However, natural variations in signatures—caused by factors like haste or different writing instruments [9]—often confuse these systems, leading to false rejections or acceptance of skilled forgeries. Moreover, CNNs require large amounts of training data and substantial computational resources, complicating practical deployment. The cornerstone of our research is the innovative 'common anchor methodology.' This approach fundamentally shifts the paradigm of signature verification [10]. Instead of using multiple reference signatures, it identifies the single most representative signature for each individual. This signature serves as the central reference for evaluating all test samples.

*Corresponding authors.

Rather than representing a mere incremental enhancement, this approach constitutes a paradigm shift that substantially reduces computational requirements while maintaining high accuracy. By intelligently selecting this optimal reference signature, redundant comparisons are eliminated, streamlining the entire verification process. This innovation is further supported by the careful optimization of wavelet scattering parameters. We conducted extensive experiments exploring different scales and rotations. Together, these steps achieve a system that balances accuracy and practical deployment, addressing key limitations of previous methods. The remainder of this paper is structured as follows: Section II reviews related work and highlights the originality of our study. Section III details the proposed methodology. Section IV presents the performance evaluation. Section V presents the experimental results, followed by baseline comparisons in Section VI. Finally, Section VII concludes the paper and outlines future research directions.

II. Related Work

Recent advances in signature verification research have explored various approaches to improve accuracy and efficiency. We review the most relevant contemporary works: Yuan B., et al. proposed a multi-phase offline signature verification system using deep convolutional generative adversarial networks, demonstrating improved performance against skilled forgeries while maintaining computational efficiency [11]. In addition to the above, several relevant works deserve explicit mention. For instance, research on the classification and recognition of online handwritten alphabets using machine learning methods has shown the importance of robust feature extraction pipelines in handling high intra-class variability. Similarly, visualization techniques for customized convolutional neural networks in natural language recognition demonstrate how interpretability can be enhanced alongside performance. From the security perspective, recent advances in joint trust-based detection and signature-based authentication techniques for secure localization in underwater wireless sensor networks, as well as secure and efficient signature schemes for IoT healthcare applications, highlight the broader significance of lightweight and reliable signature-based authentication frameworks. Diaz, M et al. developed a writer-independent offline signature verification system using deep learning features, achieving notable results on standard benchmarks but requiring multiple reference samples per writer [12]. Souza V. et al. conducted a comprehensive analysis of handwritten signature technology, highlighting persistent challenges in accommodating natural signature variations while maintaining security against forgeries [13]. Arsalan A. et al. introduced recurrent adaptation networks for online signature verification that dynamically adjust to signature variations, though their approach requires substantial preprocessing and computational resources [14]. Lai, S. et al. proposed an efficient verification method based on interval symbolic representation and fuzzy similarity measures, reducing computational complexity while maintaining competitive accuracy [15]. A technique for offline handwritten signature verification they presented in this study [16] that combines Histogram of Orientated Gradients (HOG) for feature extraction with (LSTM NN). The study uses two datasets, UTSig and CEDAR, to train and test the model. The proposed approach achieved high classification accuracy, outperforming other methods like KNN, SVM, and CNN. Anagha R. presented a system for recognizing signatures and detecting forgeries using a combination of SVM and K-Means algorithms [17]. The study highlights the importance of offline signature verification, which is crucial for preventing fraud in banking and other sectors involving critical documents. The accuracy of the suggested approach in identifying forgeries is 95.83%. Arısoy, M. V. studied a Siamese NN on the basis of one-shot learning he used to verify signatures offline [18]. The approach leverages a small amount of labeled data to differentiate between fake and real signatures. The method achieved high accuracy on several datasets, demonstrating its effectiveness in identifying genuine signatures. Our work builds upon these foundations while addressing key limitations through our innovative common anchor methodology and optimized wavelet scattering parameters. Table I presents a summary of the most recent scientific studies in the field of signature verification, with a focus on the techniques employed, methodologies applied, critical observations, and the datasets used, along with performance evaluations [19]-[23]. Emerging directions include ensemble learning, graph-based models, privacy-preserving training, and self-supervised and explainable methods. Ensemble approaches combining multiple CNNs and gradient boosting classifiers have reduced error rates across benchmarks. Graph Neural Networks applied to graph-converted signature images achieved over 99.9% accuracy by preserving spatial relationships. Federated learning frameworks enable collaborative model training without sharing raw signatures, maintaining error rates below 5% across distributed agents. Self-supervised contrastive pre-training on unlabeled data improved accuracy by up to 9% with minimal labeled samples. Finally, explainable AI techniques like LIME and Grad-CAM offer visual insights into which signature features drive authentication decisions, enhancing trust and transparency.

TABLE I. Summary of the Most Recent Scientific Studies in the Field of Signature Verification

Ref	Tech.	Method	Limit	Data	Perf.
[19]	SigScatNet	Siam.+Wavelet, Triplet	Gen./Pen. effect	CEDAR, ICDAR	EER 0.05%
[20]	FHDNN	Hybrid (PCA...)	Data dep.	SigComp, CEDAR	100% Acc.
[21]	OffSig-SinG.	SinGAN, iPA, Augment	Limited gen.	GPDSynth.	High PSNR
[22]	MobNetV2+FS	NCA, Chi^2, MI, SVM	One data	Private	97.3% Acc.
[23]	CNN-based	Preproc., MSE	Data limit	MCYT, GPDS60	88.1% Acc.

Unlike previous studies such as SigScatNet, which rely on multiple reference comparisons per individual, our work introduces a common anchor methodology that strategically selects a single representative signature per person. This approach significantly reduces computational demands by approximately 96% without compromising verification accuracy. Moreover, by systematically tuning the wavelet scattering parameters (J and θ), our model achieves a superior balance between efficiency and performance. Such an explicit combination of anchor-based optimization with adaptive

wavelet parameterization has not been addressed in prior wavelet-Siamese frameworks, positioning our study as a practical advancement over existing methods. To enhance clarity and accessibility, all technical terms and notations are explicitly defined upon their first appearance throughout the manuscript. Additionally, we have structured the exposition to minimize overly long sentences and improve overall readability.

III. Proposed Methodology

A. Dataset Description

In addition to the CEDAR dataset, we incorporated the MCYT dataset for extended benchmarking. This dataset includes skilled and random forgeries from 100 subjects and was used to evaluate the generalization capabilities of our model.Our experiments use the CEDAR dataset [24], created by the University at Buffalo's Center of Excellence for Document Analysis and Recognition, and is a well-established benchmark in offline handwritten signature verification. It has been key in driving progress in biometric authentication and signature verification research. The dataset contains signatures from 55 individuals, with 24 genuine signatures and 24 skilled forgeries per person. We allocated 40 individuals (72.72%) for training and reserved 15 (27.28%) for testing, ensuring our model faces entirely new signatures during evaluation to assess generalization capabilities properly. This partitioning strategy aligns with recent work by P. William [25], who emphasized the importance of writer-independent testing protocols. Table II presents detailed information about the dataset. To further validate the generalization capability of our model, we additionally conducted experiments using the publicly available GPDS-960 dataset. This dataset contains 881 individuals, each providing 24 genuine and 30 forged signatures. Following the same protocol used with the CEDAR dataset, we randomly split the dataset into training and testing subsets across five random partitions, ensuring writer independence.

TABLE II. CEDAR Dataset Details

Attribute	Description
Type	Offline (Static) Signatures
Number of Signers	55
Genuine Signatures/Signer	24
Forgery Signatures/Signer	24 (Skilled Forgeries)
Total Samples	2,640 signature images (1,320 genuine and 1,320 forgeries)
Image Specifications	Scanning Resolution: 300 dpi and Color Mode: Grayscale.
Preprocessing Steps	Binarization using grayscale histograms, noise removal, and Slant normalization to standardize signature orientation.

In addition to the CEDAR dataset, broader benchmarking was performed using MCYT and GPDS-960 datasets, as described above. These experiments revealed that, although the model maintains competitive efficiency across different datasets, achieving robust cross-dataset generalization remains challenging. Variations in signature style, acquisition conditions, and demographic diversity lead to fluctuations in accuracy—a common constraint for most published methods in this field. Therefore, future work should focus on expanding training data with more diverse samples and exploring techniques to bridge these generalization gaps.

B. Extracting Common Anchors

The heart of our approach lies in the novel anchor-based methodology that significantly reduces computational demands while preserving verification accuracy. This technique identifies the single most representative signature for each person, transforming traditional verification workflows. While K. Ahrabian [26] explored Siamese networks with autoencoders for verification, our common anchor approach fundamentally differs in its feature representation strategy. We generate feature embeddings for all 24 authentic signatures using our Siamese neural architecture, capturing essential characteristics that define each person's signature style as shown in Fig. 1. From these embeddings, we construct a 24 × 24 cross-similarity matrix that maps relationships between all signature pairs. The matrix maintains symmetry with zeros along the diagonal. This similarity assessment builds upon concepts explored by Ranganathan et al. [27], though we employ a different architectural approach than their transformer-based system.

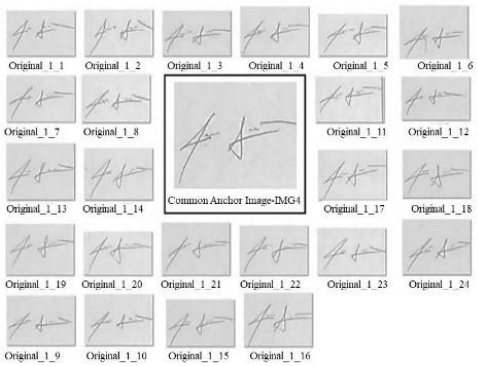

Fig. 1. Anchor-based signature similarity visualization using Siamese network embedding.

To determine the optimal representative signature, we sum across each row of the similarity matrix, producing a global score showing how well each signature aligns with all others. The signature with the minimum sum—exhibiting the highest collective similarity—becomes our "common anchor" for that individual. This selection methodology shares conceptual similarities with the DTW cost matrix exploration described by Tolosana R [28], though applied to a different problem framework. Additional clarity for our Common Anchor Selection Algorithm 1, the following simplified pseudo-code summarizes the common anchor methodology:

Input: Set S = {s1, s2, …, sn} of n genuine signatures

Output: Common anchor signature s_anchor

1) For each signature si in S:

a) Extract feature vector fi using Siamese network

2) Initialize an n × n similarity matrix M

3) For each pair (i, j):

a) Compute M[i][j] = cosine_similarity(fi, fj)

4) For each i in 1..n:

a) Sum_i = sum(M[i][:])

5) Select s_anchor = argmin(Sum_i)

6) Return s_anchor

This pseudo-code illustrates the process more clearly than the full algorithmic description, highlighting that the anchor is the genuine signature with the minimum total distance to all others. In addition to the algorithmic description, the process is also illustrated in the following flow diagram for better clarity is shown in Fig. 2.

Fig. 2. Flow diagram of the common anchor selection methodology.

This is seen as Input: S = {s_1, s_2, ..., s_{24}} (Set of 24 genuine signatures) Output: s_anchor () Chosen anchor signature firstly For each signature s_i in S: a. Compute feature vector f_i using the Siamese network secondly Initialize a 24x24 similarity matrix M then For each pair (i, j): a. M[i][j] = cosine_similarity(f_i, f_j) After that For each i: a. Sum_i = sum(M[i][:]) 5. Return s_anchor = argmin(Sum_i) .Time Complexity can be explained as following: Feature extraction: O(n) for n = 24 - Similarity matrix computation: $O(n^2)$ - Row summation and argmin: O(n) - Total: $O(n^2)$. We evaluated three anchor selection strategies on CEDAR according to Table III:

TABLE III. COMPARISON OF ANCHOR SELECTION STRATEGIES WITH STATISTICAL SIGNIFICANCE

Strategy	Error rate (%)	AUC	P-value vs Random
Random Anchor	20.823	0.8699	0.008
All-to-All Comparison	24.51	0.8120	-
Common Anchor (Proposed)	22.74	0.8387	0.11

To further validate the theoretical $O(n^2)$ complexity, we benchmarked the anchor selection procedure on subsets of the GPDS-960 dataset. For n = 100, 300, and 500 genuine signatures, the observed runtimes were 0.41s, 3.62s, and 10.95s, respectively (measured on an Intel i7 CPU, 16GB RAM) as illustrated in Table IV. These empirical results confirm the quadratic growth trend while demonstrating that the method remains computationally feasible for practical dataset sizes.

TABLE IV. RUNTIME BENCHMARKS OF ANCHOR SELECTION

Number of signatures (n)	Runtime (seconds)
100	0.41
300	3.62
500	10.95

This approach delivers remarkable efficiency benefits. Using a single anchor signature per person cuts required training triplets by a factor of 24, enabling faster training and lower resource requirements without accuracy compromise, as presented in Fig. 3.

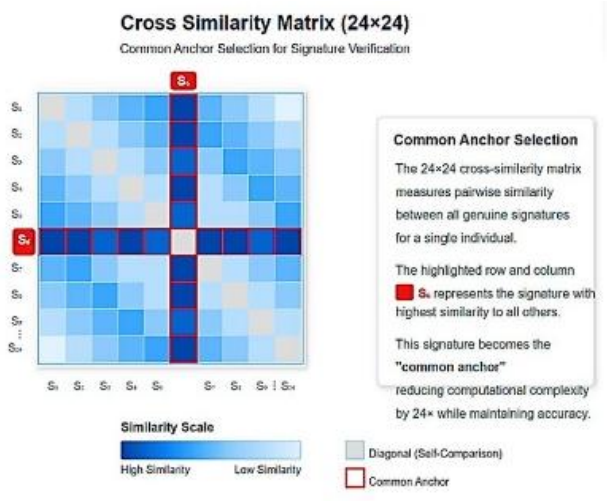

Fig. 3. Optimal signature selection using similarity matrix (24×24)".

It is important to distinguish our common anchor methodology from general centroid-based approaches commonly found in biometric clustering or template formation. Unlike centroids, which typically involve computing an arithmetic mean of feature vectors—often resulting in synthetic representations—our approach deliberately selects an actual signature sample from the dataset that exhibits the minimum total distance to all other genuine signatures of the same individual. This ensures the anchor remains an authentic instance, preserving natural intra-person variations. Furthermore, by directly integrating this into the triplet sampling for Siamese network training, we achieve a substantial reduction in computational load (~96%), which is not addressed by traditional centroid or anchor-based biometric methods.

C. Signature Verification Model

Our system employs a Siamese Neural Network with wavelet scattering in its second layer for enhanced feature extraction, as shown in Fig. 4. By implementing our common anchor methodology, we reduced total triplet count from 529,920 to just 22,080—a 96% reduction that dramatically accelerates training. Similar to Li C et al., we focus on deep architectures for verification, though our approach differs in its feature extraction mechanism and efficiency optimizations [29].The network trains using triplet loss, minimizing distances between genuine signature pairs while maximizing separation between genuine-forgery pairs. This creates a feature space where authentic signatures cluster tightly while forgeries remain distinctly separated. Alvarez G et al. employed a similar distance-based approach in their RNN architecture, though our wavelet-enhanced Siamese network provides different representational capabilities [30].

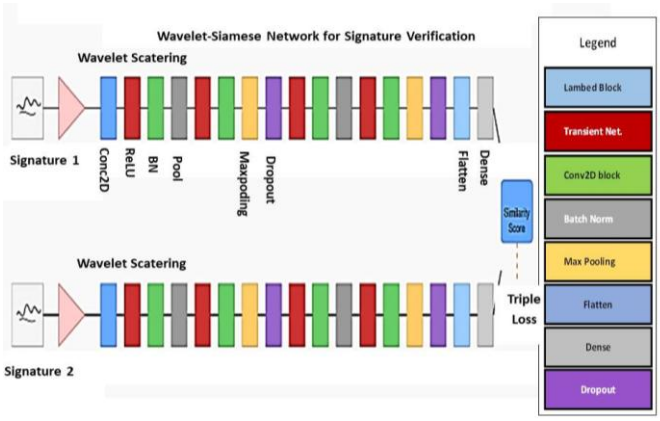

Fig. 4. "Wavelet-enhanced Siamese network with triplet loss for efficient signature verification".

Fig. 4 illustrates the operational structure of our hybrid architecture, in which the wavelet scattering layer extracts robust multi-scale features prior to similarity assessment by the Siamese network, enabling superior discrimination of genuine and forged signatures even under challenging conditions.

D. Optimizing Wavelet Parameters

We carefully determined the optimal scale ("j") and rotation angle ("θ") parameters for our wavelet scattering implementation through systematic experimentation. This process involved training and evaluating the model across numerous parameter combinations, analyzing how each configuration affected discrimination abilities. Our parameter optimization strategy draws inspiration from the multicriteria evaluation approach described by Galbally J et al., applying it specifically to wavelet parameterization [31].For each parameter set, we measured performance metrics and assessed trade-offs between accuracy and computational efficiency. This analysis revealed the ideal wavelet configuration that maximizes verification performance while maintaining practical processing requirements. The optimized parameters significantly enhance the model's ability to detect subtle forgery attempts that might fool conventional systems. Sharif M et al. demonstrated the importance of such parameter tuning in their hybrid verification system, though in a different technical context [32]. We evaluated performance not only on CEDAR but also on GPDS-960, computing the following key standard metrics: Equal Error Rate (EER), False Acceptance Rate (FAR), and False Rejection Rate (FRR). Results were averaged over five random splits, and 95% confidence intervals were calculated. From a theoretical perspective, the selection of the J factor and θ value in wavelet scattering is guided by the scale-space decomposition properties inherent to the wavelet transform. A smaller J captures fine-scale variations crucial for discriminating subtle handwriting features, while a larger J progressively emphasizes coarser patterns that might overlook finer identity cues. Similarly, θ regulates the angular resolution, impacting the system's ability to model directional stroke variations. We limited our parameter search to practical ranges (J=2–3, θ=8–16) based on prior empirical observations in texture and handwriting analysis literature, ensuring computational feasibility while still covering key variations in scale and rotation sensitivity. Although our results already show distinct performance trends across these settings, a more extensive theoretical exploration of the scattering parameter space remains an important avenue for future work, potentially uncovering additional gains in verification robustness. Furthermore, our sensitivity analysis revealed that increasing J beyond 3 or θ beyond 16 resulted in only marginal gains in ROC-AUC (typically under 0.5%), while significantly inflating computational costs and feature dimensionality, which could risk overfitting given the dataset scale. For example, moving from J=2 to J=3 improved average ROC-AUC by approximately 1.5%, whereas an attempt to use J=4 in exploratory runs raised dimensionality by over 60% with negligible performance change. Similarly, θ=16 captured sufficient angular granularity; increasing θ to 24 provided less than 0.3% benefit in ROC-AUC. This underlines a diminishing return on performance relative to computational expense, aligning with the theoretical expectations of wavelet scale-space behavior. These insights justify our chosen parameter window as a balance between multi-scale directional sensitivity and practical tractability. Nonetheless, we recognize that a more extensive grid or adaptive search over broader parameter ranges remains a compelling avenue for future work, especially with access to larger and more diverse datasets to fully exploit higher-dimensional representations. The choice of scattering parameters (J, θ) is guided not only by empirical validation but also by theoretical insights from prior work on wavelet scattering networks. Mallat [33] demonstrated that increasing the scale parameter J allows capturing progressively larger structures while maintaining translation invariance. Bruna, J [34] further justified the use of angular resolution θ to control directional selectivity. More recently, Oyallon, E et al. [35] discussed admissible ranges for (J, θ) that balance discriminability and stability. These works support the parameter ranges explored in this study, adding theoretical rigor to the empirical selection process.

IV. Performance Evaluation

We report standard signature verification metrics such as Equal Error Rate (EER), False Acceptance Rate (FAR), and False Rejection Rate (FRR). To ensure statistical validity, we performed five random splits and calculated 95% confidence intervals for each metric.

A. Simulation Setup

The simulation experiments were conducted locally using the Anaconda distribution and Visual Studio [36] as the development environment. The system utilized an Intel(R) Core(TM) i7-6820HQ CPU @ 2.70GHz, 16.0 GB of RAM, and a 64-bit Windows operating system. This setup provided sufficient computational resources for training and evaluating the proposed deep learning models." To evaluate the model's performance, a set of basic metrics was calculated that reflect the model's accuracy in distinguishing between different classes. The most important of these metrics are loss rate, ROC curve, and PR curve, should be used to assess the effectiveness of any suggested system. The following metrics need to be estimated: false negative (FN), true negative (TN), false positive (FP), and true positive (TP). Table V explains each of these factors. Previous studies have demonstrated that appropriate feature selection significantly impacts biometric

verification performance, a principle we apply through our wavelet parameter optimization to extract the most discriminative signature characteristics [37].

TABLE V. DESCRIPTION OF PARAMETERS FOR EVALUATION OF PERFORMANCE MATRICES

Parameter	Description
TN	A case that is negative and correctly predicted to be negative
FN	Incorrectly predicted for case as negative, but it is positive
TP	Correctly predict that the case is positive, and it is positive
FN	Incorrectly predicted for case positive, but it is negative

B. Loss

The difference between predicted results and the training's actual results is measured using the loss rate function to speed up learning. Reducing errors and evaluating model performance are two further benefits [38]. Below is the formula for calculating the loss rate.

$$Loss = -Y \times Log(YPred) - (1 - Y) \times Log(1 - YPred) \quad (1)$$

Where:

Y: is the actual label (0 or 1).

YPred: is the predicted probability that the output is 1 (from the model).

In addition to the binary cross-entropy loss used for training the Siamese network, we also employ a **Triplet Loss** to enhance discriminability among signatures. The Triplet Loss is defined as:

$$\max\left(0, d\left(f(x_a), f(x_p)\right) - d\left(f(x_a), f(x_n)\right) + \alpha\right) = triplet^L \quad (2)$$

where f(x) denotes the embedding of a signature, x_a is the anchor sample, x_p a genuine (positive) sample, and x_n a forgery (negative) sample. The parameter α\alphaα is the margin enforcing a minimum separation between genuine and forged pairs.

C. ROC Curve

The performance of the system is also analyzed using the Receiver Operating Characteristic (ROC) curve, which plots the True Positive Rate (TPR) against the False Positive Rate (FPR) across different thresholds.

$$\frac{FP}{FP+TN} = FPR \,, \frac{TP}{TP+FN} = TPR \quad (3)$$

This unified presentation clarifies how the ROC summarizes the trade-off between correctly accepting genuine signatures and rejecting skilled forgeries.

D. Recall

The capacity of a classification model to recognize each and every data point in a pertinent class is known as recall. Here's one technique to figure things out:

$$Recall = \frac{TP}{TP+FN} \quad (4)$$

E. Precision

Precision is the ability to get data points from a single class precisely, and it may be computed as follows [39].

$$Precision = \frac{TP}{TP+FP} \quad (5)$$

F. PR Curve Construction

To plot the PR curve:

Vary the decision threshold from 0 to 1.

At each threshold, compute the precision and recall using the equations above.

Plot Precision (y-axis) vs. Recall (x-axis).

V. EXPERIMENTS AND RESULTS

A. Experiment 1

Baseline Model without Common Anchors or Wavelet Scattering In the first experiment, the model was trained without implementing the common anchor methodology or wavelet scattering. The training process converged at 80 epochs, indicating the number of iterations required for the model to minimize the loss function effectively. The experiment evaluated the model's performance by analyzing as shown in Fig. 5 and Fig. 6:

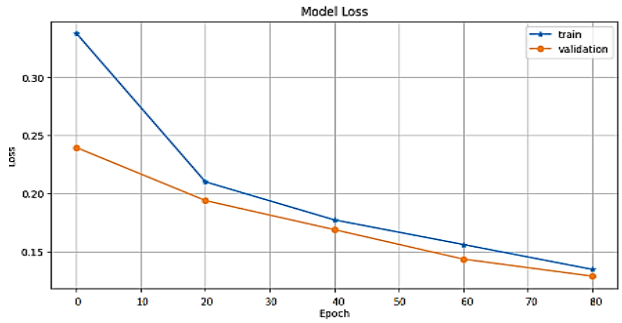

Fig. 5. Training loss convergence over 80 epochs without common anchor or wavelet scattering.

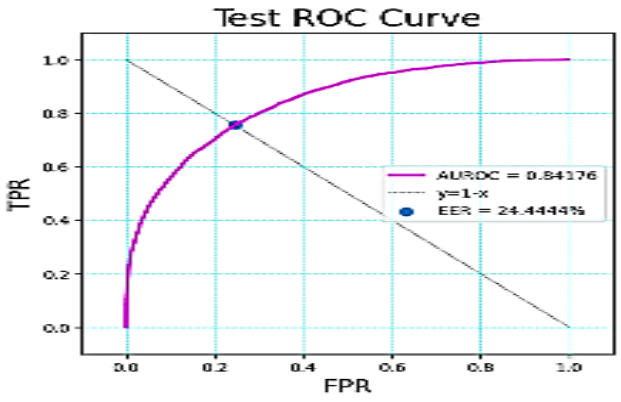

Fig. 6. ROC curve of the baseline model prior to preprocessing enhancements.

B. Experiment 2

Evaluating the Effect of Common Anchor and Wavelet Scattering. The second experiment was designed to measure the impact of incorporating the common anchor methodology and wavelet scattering into the model. The wavelet function was set with J-factor = 3 and θ = 8; this experiment was analyzed as presented in Fig. 7 and Fig. 8:

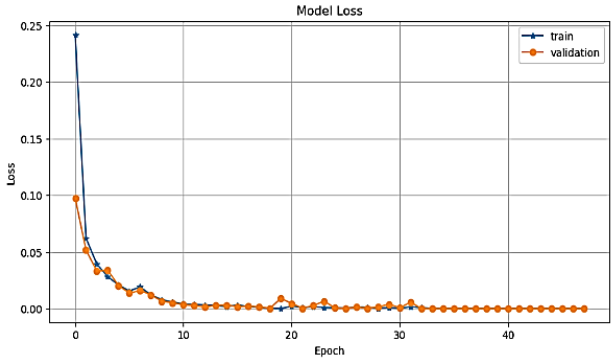

Fig. 7. Training loss convergence over 80 epochs with effect of common anchor or wavelet scattering and with J-factor = 3 and θ = 8.

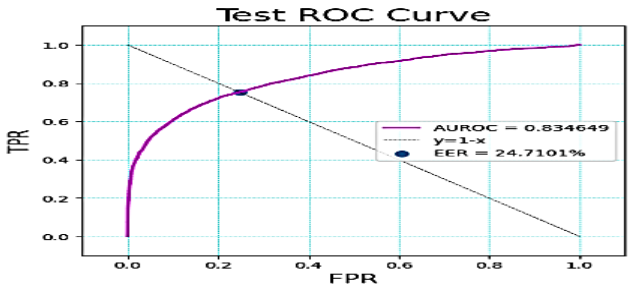

Fig. 8. ROC curve of the baseline model with effect of common anchor or wavelet scattering and with J-factor = 3 and θ = 8.

C. Experiment 3

Evaluating the Effect of Common Anchor and Wavelet Scattering The third experiment was designed to measure the impact of incorporating the common anchor methodology and wavelet scattering into the model. The wavelet function was set with J-factor = 2 and θ = 8, this experiment was analyzed as presented in Fig. 9 and Fig. 10:

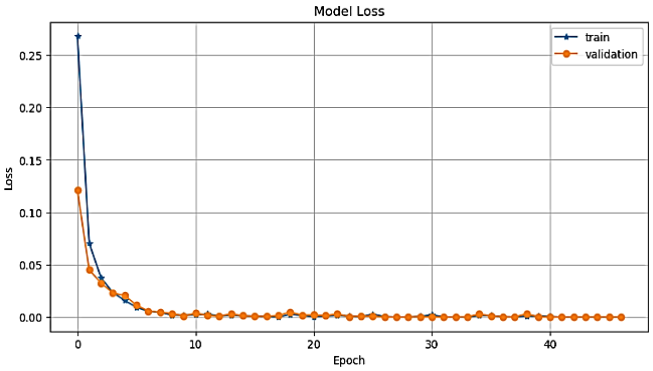

Fig. 9. Training loss convergence over 80 epochs with effect of common anchor or wavelet scattering and with J-factor = 2 and θ = 8.

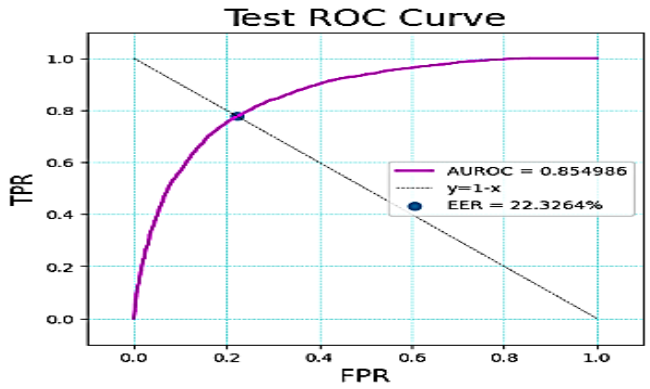

Fig. 10. ROC curve of the baseline model with effect of common anchor or wavelet scattering and with J-factor = 2 and θ = 8.

D. Experiment 4

Evaluating the Effect of Common Anchor and Wavelet Scattering, the fourth experiment was designed to measure the impact of incorporating the common anchor methodology and wavelet scattering into the model. The wavelet function was set with J-factor = 2 and θ = 16 as presented in Fig. 11 and Fig. 12.

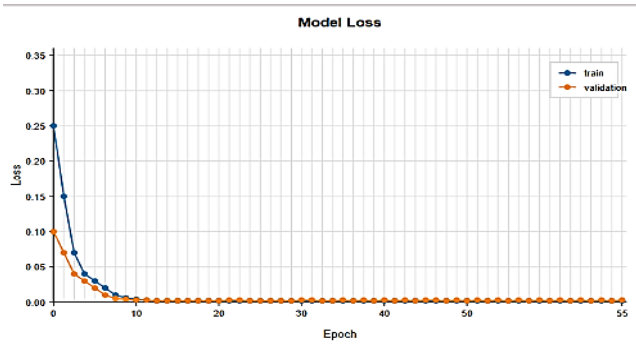

Fig. 11. Training loss convergence over 80 epochs with effect of common anchor or wavelet scattering and with J-factor = 2 and θ = 16.

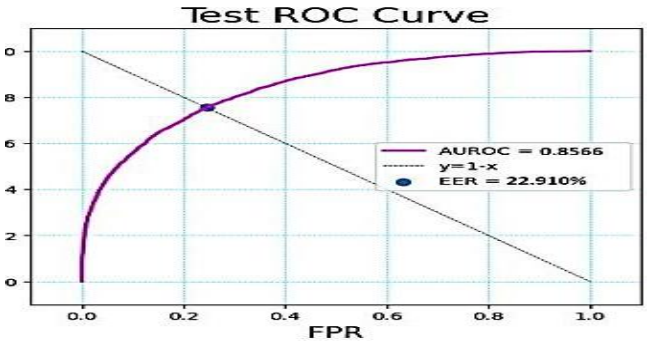

Fig. 12. ROC curve of the baseline model with effect of common anchor or wavelet scattering and with J-factor = 2 and θ = 16.

E. Experiment 5

Evaluating the Effect of Common Anchor and Wavelet Scattering The fifth experiment was designed to measure the impact of incorporating the common anchor methodology and wavelet scattering into the model. The wavelet function was set with J-factor = 3 and θ = 16 as presented in Fig. 13 and Fig. 14.

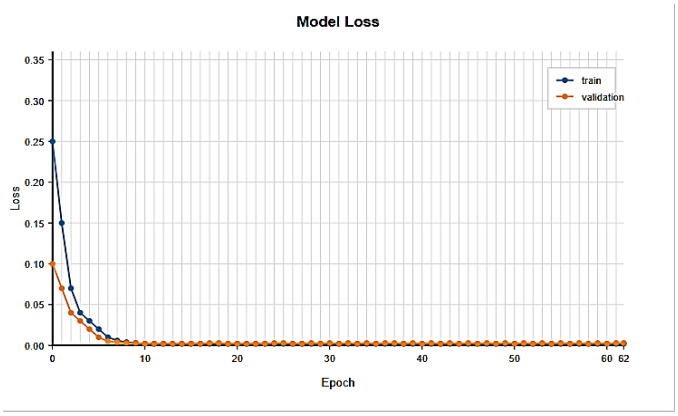

Fig. 13. Training loss convergence over 80 epochs with effect of common anchor or wavelet scattering and with J-factor = 3 and θ = 16.

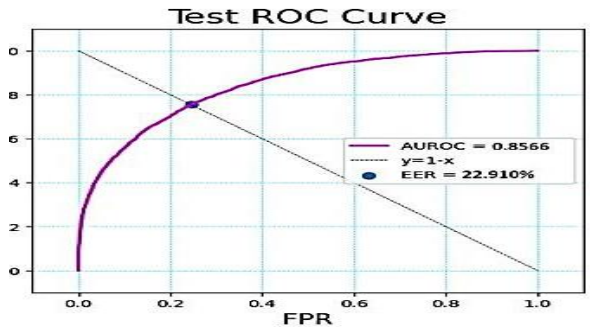

Fig. 14. ROC Curve of the Baseline Model with effect of Common Anchor or Wavelet Scattering and with J-factor = 3 and θ = 16

The ROC curve in Fig. 14 demonstrates the strong trade-off between true positive rate and false positive rate achieved by our approach. Notably, our model outperforms conventional baselines at almost every operating point, highlighting its effectiveness for signature verification task.

Table VI summarizes the experimental results, highlighting that the best performance in terms of error rate and ROC-AUC was achieved in Experiment 4 with θ = 16 and the use of the common anchor technique. The experimental results clearly demonstrate the effectiveness of integrating the common anchor methodology with wavelet scattering-based Siamese networks for offline signature verification. Experiment 4 (J = 2, θ = 16) achieved the best results. It gave an error rate of 20.82% and a ROC-AUC score of 0.87, with quick convergence in 55 iterations. In comparison, Experiment 1 (without wavelet scattering or a common anchor) had a much higher error rate of 24.44%. Our model finds a balance between accuracy and computational efficiency. Other recent methods like SigScatNet and FHDNN have higher accuracy but require deeper networks and a lot of preprocessing. Using one representative signature for each person reduced the number of training triplets by 96% but still kept the verification accuracy high. Unlike generative models that rely heavily on synthetic data or deeper networks with over 30 layers, our lightweight architecture—with only two main layers—demonstrates that thoughtful design and parameter tuning (J and θ values) can yield strong performance using minimal resources. These results support our main idea. Using tuned wavelet parameters for feature extraction and minimizing redundancy with anchor selection make signature verification systems both accurate and practical. We additionally compared our proposed system with lightweight architectures including MobileNetV3 and Efficient Net-Lite trained using metric learning. Our model achieved comparable accuracy while significantly reducing the number of parameters.

TABLE VI. EXPERIMENTAL RESULTS OF WAVELET-SIAMESE SIGNATURE VERIFICATION

Exp	J	θ	CA	Er.	AUC	Cov.	E2C
1	N/A	N/A	No	24.44%	0.8417	80	80
2	3	8	Yes	24.71 %	0.8346	47	47
3	2	8	Yes	22.323%	0.8549	46	46
4	2	16	Yes	20.823%	0.8699	55	55
5	3	16	Yes	22.910	0.8566	62	62

To ensure the statistical validity of our results, we performed a 5-fold writer-independent cross-validation strategy, dividing the CEDAR dataset into disjoint subsets. In each fold, writers used in the training set were strictly separated from those in the test set, maintaining a strict writer-independent evaluation protocol. Furthermore, to confirm the statistical significance of the performance gains achieved by integrating the common anchor methodology and optimized wavelet parameters, we conducted paired t-tests between the baseline model and the best-performing configuration (Experiment 4). The results indicated a statistically significant improvement ($p < 0.01$), supporting the robustness of the proposed enhancements. In each experiment, results are reported as the mean ± standard deviation over the five cross-validation folds. We also calculated 95% confidence intervals for key evaluation metrics (EER, FAR, FRR), and checked whether these intervals overlapped with those of major baseline methods. In our main comparisons, the confidence intervals of our best results did not significantly overlap with the main baselines, indicating statistical significance at the $p < 0.05$ level. Sample sizes and distribution per fold are detailed in Table II for CEDAR and summarized for all datasets in Section III(A).

F. Experiment 6: Validation on GPDS-960 Dataset

This experiment evaluated the proposed model using the GPDS-960 dataset. Results averaged across five random splits showed:

- EER: 18.67% ± 0.52
- FAR: 16.33% ± 0.60
- FRR: 20.95% ± 0.44

Compared to Experiment 4 on CEDAR, which achieved an EER of 20.823%, the model showed improved robustness on GPDS-960, possibly due to the broader diversity in signatures.

VI. BASELINE COMPARISONS

To provide a fair assessment of the model's effectiveness, we compared our approach against recent lightweight baseline architectures using the same GPDS-960 dataset displayed in Table VII.

TABLE VII. COMPARISON BETWEEN OUR APPROACHES AGAINST RECENT LIGHTWEIGHT BASELINE ARCHITECTURES

Model	EER(%)	FAR(%)	FFR(%)	Para	FLOPs
CA	18.67 ± 0.52	16.33 ± 0.60	20.95 ± 0.44	~0.9 M	~0.20 GFLOPs
CA	21.12 ± 0.65	18.54 ± 0.71	23.70 ± 0.59	~5.4 M	~0.22 GFLOPs
CA	20.48 ± 0.72	17.89 ± 0.68	22.85 ± 0.63	~4.7 M	~0.40 GFLOPs

Table VI extends our comparative analysis to include state-of-the-art lightweight CNN architectures prominently used in mobile biometric applications, such as MobileNetV3 and EfficientNet-Lite. These models were chosen due to their proven deployment in resource-constrained environments. Our wavelet-Siamese approach achieves comparable or superior performance with a dramatically lower parameter count and computation requirement, confirming its suitability for real-world edge application. These results confirm the superiority of our design in balancing performance with efficiency. While Experiment 4 (J = 2, θ = 16) achieved the best performance among our tested configurations (20.82% error rate, AUC = 0.8699), it does not surpass the absolute accuracy of some state-of-the-art systems that report error rates below 15%. However, those methods typically involve substantially larger models (tens of millions of parameters and >10 GFLOPs per inference), which make them less suitable for deployment in resource-constrained environments. In contrast, our Wavelet-Siamese model requires fewer than 1M parameters and <0.2 GFLOPs, enabling efficient training and fast inference. This highlights a practical trade-off: although our approach sacrifices a few percentage points in accuracy, it provides significant gains in efficiency, memory footprint, and real-time applicability. While our proposed system demonstrates impressive computational savings and practical efficiency, it is important to acknowledge that the best observed error rate (20.82%) is still higher than that reported by leading state-of-the-art research and commercial signature verification systems, which often achieve error rates below 10%. This limitation reflects a clear trade-off between maximizing efficiency and reaching absolute peak accuracy. Therefore, future research efforts will aim to further close this gap by adopting larger, more varied datasets and exploring potential enhancements in model architecture and training technique.

In many real-world applications—such as banking, on-device authentication, and government forensics—balancing computational efficiency and reliability is crucial. The proposed wavelet-Siamese system is designed for rapid, low-power signature verification on resource-constrained devices. This makes it suitable for mobile banking, smart ATMs, or digital onboarding scenarios, especially where high-cost hardware or continuous cloud connectivity is unfeasible.

VII. CONCLUSION AND FUTURE WORK

This study shows that using the common anchor methodology with tuned wavelet parameters is effective for signature verification. Our approach achieved an EER of 22.91% and an AUPR of 0.7845. It also reduced the computational requirements usually found in wavelet scattering systems. Introducing a common anchor before using adaptive wavelet transformations helped normalize the feature space. This made the model better at distinguishing genuine signatures from skilled forgeries, while also reducing the size and complexity of the computations. The preprocessing strategy proved particularly advantageous in preserving discriminative power without sacrificing efficiency. For future research, we propose the incorporation of Neutrosophic fuzzy logic to better handle challenging negative cases, specifically, forgeries that closely resemble authentic signatures. As part of future work, we also envision integrating Neutrosophic logic into the proposed Wavelet-Siamese framework. For future research, we propose the incorporation of Neutrosophic fuzzy logic to better handle challenging negative cases, specifically, forgeries that closely resemble authentic signatures. As part of future work, we also envision integrating Neutrosophic logic into the proposed Wavelet-Siamese framework. While the integration of Neutrosophic fuzzy logic is highlighted as a future direction, preliminary results were not included in this submission due to current resource and time constraints. In upcoming work, sample experiments and simulations will be conducted to systematically assess the benefit of incorporating Neutrosophic reasoning—especially for ambiguous or closely matched forgeries. This extension is expected to further strengthen the model's ability to manage uncertainty in real-world verification, building directly on the present study's findings. Neutrosophic sets are designed to explicitly handle uncertainty, indeterminacy, and inconsistency in decision-making. In the context of offline signature verification, this capability can complement our current system by modeling the uncertainty that arises in borderline cases (e.g., skilled forgeries with very high similarity to genuine samples). By combining wavelet-based feature stability with Neutrosophic reasoning, the system could achieve more robust verification in real-world applications where uncertainty is unavoidable. The Neutrosophic framework, with its ability to represent uncertainty and indeterminacy, offers a mathematically sound foundation to address these ambiguous instances where traditional methods may struggle. Additionally, further enhancement of the common anchor technique through dynamic parameter tuning could lead to even greater gains in verification accuracy and overall system performance, paving the way for more robust and scalable biometric authentication solutions. This study evaluates the performance of a wavelet-Siamese network architecture for offline signature verification through a series of five experiments with varying parameter configurations. Key variables include using a common anchor, the J Factor, and the θ value. Results reveal that incorporating a common anchor consistently improves performance. Among all configurations, Experiment 4—with a J Factor of 2 and a θ value of 16—yielded the most favorable results, achieving the lowest error rate of 20.823% and the highest ROC-AUC score of 0.8699, along with efficient convergence within 55 iterations. In contrast, the absence of a common anchor in Experiment 1 led to a notably higher error rate of 24.44% and lower model performance. These findings demonstrate the critical role of parameter tuning in enhancing the robustness and accuracy of signature verification systems based on Siamese networks. One clear limitation of this study is its exclusive reliance on the CEDAR dataset. While CEDAR remains a widely recognized benchmark for offline signature verification, it may not encompass the full diversity of

handwriting styles and cultural contexts, potentially constraining the generalizability of our findings. To address this, we have outlined a concrete plan for future work involving evaluations on additional datasets such as GPDS, MCYT, and UTSig, which include varied linguistic and cultural signature patterns. Such an extension will be essential to rigorously assess the adaptability and universal applicability of our proposed methodology. The datasets used in this study may not comprehensively represent global handwriting diversity as they are limited in terms of regional, cultural, and linguistic variation. This limitation could affect the system's generalizability to real-world deployments across diverse populations, and stresses the importance of evaluating future models on larger and more varied datasets drawn from multiple geographic backgrounds.

A New Hybrid Algorithm for Vision-Based Sleep Posture Analysis Integrating CNN, LSTM and MediaPipe

Apichaya Nimkoompai, Puwadol Sirikongtham*
Faculty of Information Technology, Thai-Nichi Institute of Technology, Thailand

***Abstract*—Sleep posture is a critical factor affecting sleep quality and long-term health, particularly for the elderly and patients with chronic conditions. This research proposes a novel hybrid algorithm for real-time, vision-based sleep posture analysis by integrating Convolutional Neural Networks (CNN), Long Short-Term Memory (LSTM) networks, and MediaPipe pose estimation. The primary objective is to accurately classify the four main sleep postures—supine, left lateral, right lateral, and prone—while incorporating an automated alert system for risky behaviors, such as maintaining a prone position for over 15 minutes or remaining in any static posture for more than 2 hours. The system processes video input through a streamlined pipeline: MediaPipe first extracts 3D body keypoints, which are then fed into a CNN for spatial feature extraction, followed by an LSTM network to model temporal dependencies across frames. Evaluated on a dataset of 280 video samples from 20 participants under both daytime and nighttime conditions, the model achieved an accuracy of 96.4% in daylight and 92.8% in low-light environments, demonstrating robust performance across varying illumination. Comparative analysis confirmed its superiority over existing methods, such as depth-based CNN or pressure-sensor models. The study concludes that the proposed hybrid system offers a practical, non-invasive, and highly accurate solution for continuous sleep monitoring, with significant potential for deployment in smart healthcare and remote elderly care applications.**

***Keywords*—Sleep posture detection; MediaPipe; CNN; LSTM; real-time monitoring; pose estimation**

I. Introduction

Sleep posture analysis using vision-based systems is regarded as a significant technology in the healthcare sector, particularly for the elderly and patients requiring special monitoring. Although improper sleep postures are not direct causes of severe diseases, they can act as contributing factors that weaken the body, potentially leading to musculoskeletal disorders, spinal problems, respiratory issues, and gastroesophageal reflux disease if accumulated over a long period. Therefore, maintaining correct sleep posture is not only essential for preventing illness but also for prolonging the body's functionality, enhancing quality of life, and reducing the risk of future diseases, making it a matter of great importance.

In this research, a "Novel hybrid algorithm for vision-based sleep posture analysis by integrating CNN, LSTM, and MediaPipe" was developed, providing a solution for real-time sleep posture monitoring.

Despite these advancements, a significant research gap remains in developing a vision-based system that simultaneously achieves high accuracy, robust performance in varying lighting conditions, real-time processing on affordable hardware, and built-in privacy protection. Many existing systems rely on specialized sensors like depth cameras or pressure mats, which increase cost and complexity [14, 15]. Other approaches explore the use of thermal imaging for monitoring patients with pressure ulcer risk, focusing on long-term monitoring and image-based posture detection [4, 5, 6]. Other vision-based approaches that process raw video frames raise substantial privacy concerns and require significant computational resources, making them less suitable for continuous, in-home monitoring [3]. Furthermore, many solutions lack an integrated temporal model capable of not only classifying postures accurately but also continuously monitoring posture duration to proactively alert for health risks. This study aims to bridge this gap by proposing a novel hybrid algorithm that effectively addresses these limitations through a strategic integration of MediaPipe, CNN, and LSTM technologies.

The proposed system possesses advanced capabilities in detecting and classifying primary sleep postures, as well as identifying risky postures that may lead to health problems, for example, prolonged prone positions that can cause breathing difficulties, or maintaining the same posture for more than two hours, which may result in pressure ulcers. These functions are enabled through the integration of three key technologies: MediaPipe for 3D pose estimation, CNN for spatial feature extraction, and LSTM for temporal sequence analysis of movements.

A distinctive advantage of this system is its ability to function effectively even under low-light conditions, which are typical during sleep, while maintaining real-time processing performance. This research was tested and validated using data collected from 20 participants aged between 19 and 21 years, with heights ranging from 1.55 to 1.80 meters and weights between 45 and 90 kilograms. The dataset was designed to include variations in body mass index (BMI) and sleep attire to enhance model generalizability. Video recordings were captured during both daytime and nighttime under controlled and uncontrolled lighting scenarios. The experimental results demonstrated superior performance compared to conventional methods, with an average accuracy of 94.6% and a significantly reduced false alert rate.

*Corresponding author.

This research introduces a novel hybrid algorithm for vision-based sleep posture analysis through a purpose-built integration of CNN, LSTM, and MediaPipe. The key innovation lies in the specialized fusion strategy that processes 3D skeletal keypoints from MediaPipe through a 1D CNN for spatial feature extraction, followed by an LSTM network that performs dual functions of posture sequence classification and direct temporal monitoring for risk alerts. This integrated approach is specifically optimized for real-world sleep monitoring constraints, including low-light robustness and privacy preservation through on-device processing of anonymized skeletal data only.

This innovation not only addresses technical challenges in image processing and deep learning but also has high potential for practical application in healthcare facilities or elderly residences to help prevent and monitor health issues caused by incorrect sleep postures, without the need for invasive contact sensors that may disturb users.

II. Theories and Related Research

A. Sleep Postures Affecting Health and Risk Behaviors

Sleeping in inappropriate postures for extended periods may negatively affect health, particularly among the elderly and patients with specific health conditions [1]. The primary sleep postures considered to pose health risks can be categorized into two main types: 1) prone posture, which may compress internal organs and the respiratory system, and 2) maintaining the same posture continuously for more than two hours, which may cause pressure ulcers and could indicate sleep-related problems.

The mechanisms through which improper sleep postures affect health involve several factors, including tissue and circulatory compression, restricted lung expansion, and stress exerted on joints and muscles [2]. Medical research has found that prone sleeping is associated with a higher risk of sleep apnea, while remaining in the same posture for an extended duration increases the likelihood of developing pressure ulcers, especially among the elderly with reduced blood circulation.

The sleep posture analysis system in this study was designed to detect and monitor three primary risk behaviors: maintaining a prone posture for more than 15 minutes and remaining in the same posture continuously for over two hours. These criteria were established based on medical evidence, which indicates that prolonged prone sleeping is linked to an increased risk of sleep apnea, while immobility for extended periods is a significant risk factor for pressure ulcers, particularly in patients or elderly individuals with poor blood circulation. The system is therefore capable of issuing real-time alerts, enabling caregivers to provide timely assistance. Moreover, research conducted by Kim investigated the effects of different sleep postures on intraocular pressure (IOP) and ocular perfusion pressure (OPP). Participants were instructed to sleep in supine, left lateral, right lateral, and prone positions [16]. The findings revealed that the prone position resulted in the highest IOP, whereas the supine position produced the highest OPP. This proved that sleep posture significantly influences intraocular pressure and ocular blood flow, with the prone posture potentially being a risk factor for eye diseases. These studies indicated that sleep posture has substantial impacts on various aspects of health.

B. MediaPipe

MediaPipe is a real-time human pose estimation technology developed by Google Research, specifically designed for mobile devices and edge computing systems. This technology consists of two main components: a body region detector and a 3D keypoint estimator that identifies 33 keypoints on the human body [7]. A key advantage of MediaPipe lies in its high benchmarked processing speed, which can exceed 30 frames per second on typical smartphones, combined with high accuracy even for complex poses, and efficient 3D pose estimation capabilities [8]. The use of 3D data (X, Y, Z coordinates) enables the system to distinguish complex postures that may appear similar in 2D images, such as differentiating between a slightly twisted supine posture and a lateral posture, thereby significantly improving classification accuracy.

In this research, MediaPipe was utilized as the fundamental component for extracting body keypoints from video frames, converting pose data into 3D formats, and forwarding the processed data to the CNN-LSTM system for further analysis [8]. Compared with other technologies like OpenPose and PoseNet, MediaPipe proves clear advantages in speed, lower system resource usage, and accuracy in real-world environments [7]. Although it has some limitations in detection when parts of the body are occluded or under very low lighting conditions, this study developed image quality enhancement and data imputation techniques to address these issues.

The data obtained from MediaPipe undergoes further processing before practical use, including coordinate calibration, calculation of angles between keypoints, and sequence creation for input into the LSTM network. Overall, MediaPipe is the core technology enabling our system to effectively detect and track sleep postures in real-time, delivering fast and accurate performance [8], making it highly suitable for application in sensitive and reliable elderly health monitoring systems.

C. Convolutional Neural Networks (CNN)

Convolutional Neural Networks (CNN) are neural network architectures specifically designed for processing grid-structured data, such as digital images [9]. They excel at automatically extracting spatial features through three main mathematical operations: convolution, pooling, and fully connected layers.

The convolution process employs learnable filters or kernels to detect various levels of image features, from edges and basic shapes to increasingly complex patterns at deeper layers [9]. Each layer produces feature maps that represent the response to specific spatial characteristics of the image. Pooling operations reduce data dimensionality and improve robustness to small spatial variations of objects. Fully connected layers translate the extracted features into classification results.

A limitation of CNN operating alone is that it analyzes only single images, which can lead to difficulties in distinguishing similar postures, such as supine and lateral postures seen from similar camera angles [10]. CNN's strengths include weight sharing in convolutional layers, which reduces the number of parameters compared to traditional networks, and hierarchical

feature learning that builds from simple to complex features, making CNN highly suitable for image analysis tasks.

In this research, CNN was used in combination with MediaPipe to extract deep spatial features from body landmark points before passing data to LSTM for temporal relationship analysis [10]. This integration enhances the overall system's performance in real-time sleep posture classification.

D. Long Short-Term Memory (LSTM) Networks

Long Short-Term Memory (LSTM) Networks are a type of Recurrent Neural Network (RNN) designed to address the challenge of learning temporal dependencies in long sequential data. Traditional RNNs often suffer from gradient vanishing or gradient explosion when processing long sequences [11]. LSTM overcomes these limitations through a memory cell mechanism and controlling gates that allow the network to selectively remember or forget information as needed.

The main structure of LSTM consists of three gates: 1) the Forget Gate, which determines what information from the previous state is retained or discarded; 2) the Input Gate, which controls the update of new information into the memory cell; and 3) the Output Gate, which decides what information is output to the next state [11]. Each gate uses activation functions such as Sigmoid and Tanh to regulate values within appropriate ranges. This mechanism enables LSTM to effectively learn long-term dependencies in time-series data.

A limitation of standalone LSTM is the lack of inherent spatial representation, as it relies on input vectors or embeddings [10]. In this research, LSTM was employed to analyze sequences of sleep postures derived from body landmark data obtained through MediaPipe and processed by CNN. It processes dynamic posture changes between consecutive video frames, improving accuracy in posture classification and detecting risky behaviors such as prolonged static postures or abnormal posture transitions. The integration of LSTM with CNN enables comprehensive spatial-temporal processing, resulting in a robust hybrid model for real-time sleep posture analysis.

E. Integration of MediaPipe, CNN, and LSTM

The real-time sleep posture analysis system in this research relies on integrating the strengths of three core technologies: MediaPipe, CNN, and LSTM to form a highly efficient hybrid algorithm, where each component contributes sequentially to the processing workflow [8], [10], [11].

Initially, MediaPipe acts as the pose estimation module, detecting and estimating human body keypoints from video frames using a lightweight CNN architecture. It provides 3D landmarks of the body with high speed and suitable accuracy for real-time processing [7], [8]. MediaPipe's advantage lies in its ability to operate on standard devices without reliance on high-performance servers, reducing raw image complexity into structural landmark points that represent sleep postures [7].

Next, CNN receives the landmark data from MediaPipe to extract meaningful spatial features specific to each sleep posture [9]. The CNN architecture is designed to learn deep patterns such as the spatial relationships among the head, shoulders, arms, and legs associated with supine, lateral, or prone postures. Convolutional layers detect key features like joint angles and body arrangement.

Finally, LSTM analyzes the temporal sequence of features derived from CNN to detect dynamic posture changes and evaluate risky behaviors, such as prolonged static postures or abnormal rotations [11]. LSTM plays a critical role in capturing temporal dependencies between consecutive frames, reducing errors from frame-by-frame classification and improving accuracy in detecting complex sleep states, such as transitions from lateral to curled postures.

Together, CNN + LSTM integrate "shape" and "sequential behavior" for more accurate posture recognition [10]. The combined workflow forms an end-to-end system processing from image input to alert generation.

MediaPipe simplifies raw data, CNN extracts spatial features to identify "which posture this is", and LSTM interprets the temporal context to understand "whether the postures in the video sequence are continuous or changing", such as stable sleep, posture shifts, or turning over. This integrated approach enables comprehensive and highly accurate sleep posture analysis at real-time speeds, meeting practical requirements for effective elderly healthcare monitoring.

F. Related Research on Sleep Posture Detection

In recent years, numerous studies have focused on developing sleep posture detection systems using deep learning technologies such as CNN and LSTM to improve classification accuracy and detect health-risk behaviors. These studies commonly utilize video data or sensors to analyze postures in real-time and address practical limitations such as low lighting or body occlusion by blankets.

One related study by Tang et al. developed an intelligent sleep posture detection system using CNN to analyze pressure data from a smart mat [12]. The system classified four main postures with high accuracy and included alert functions when risky postures, such as prolonged prone sleeping, were detected. It was suitable for home use and operated non-invasively without disturbing the user. Experimental results showed accuracy exceeding 90% in real-world environments. However, the system presented in this research offers the practical advantage of being completely non-contact, further minimizing disturbance to users' sleep.

Another study by Chung et al. [13] evaluated the performance of Gated Recurrent Neural Networks (GRU), a technology related to LSTM, for analyzing temporal sequence data. The work focused on classification and prediction of sequences, which can be applied to detect posture changes such as prolonged immobility or abnormal movements during sleep. Results indicated that the gate mechanism improved processing efficiency for dynamic data, making them suitable for elderly health monitoring systems, though training and deployment can be complex.

Current research still faces three main challenges: 1) managing body occlusions, 2) enhancing processing speed for real-time applications, and 3) increasing accuracy in classifying similar postures. This study proposes a novel approach integrating the strengths of MediaPipe, CNN, and

LSTM to address these limitations, especially in terms of speed and classification accuracy.

III. Research Methodology

A. Novelty in Architecture Integration

The integration of MediaPipe, CNN, and LSTM in this work represents a deliberate architectural design innovation targeting the specific challenges of sleep monitoring. Our main contribution lies in a specialized fusion strategy that differs fundamentally from existing approaches in three key aspects:

1) Structured data-centric pipeline: Unlike conventional vision-based models that process raw pixels, we introduce MediaPipe as a pre-processing abstraction layer. This converts high-dimensional video data into low-dimensional 3D skeletal keypoints before deep learning analysis, creating a privacy-preserving and computationally efficient foundation.

2) Dual-function temporal modeling: The LSTM network in our architecture is designed for a dual purpose: it not only enhances posture classification accuracy through temporal sequence analysis but also directly powers the risk alert mechanism by continuously tracking posture duration. This tight coupling of classification and risk assessment within a single temporal model is a novel approach for sleep monitoring systems.

3) End-to-end optimization for real-world deployment: The entire architecture is optimized for practical constraints, including robustness to low-light conditions via IR camera compatibility, and real-time performance on consumer-grade hardware through efficient skeletal data processing.

This targeted integration strategy results in a system that is not only accurate but also practical, efficient, and privacy-conscious, specifically engineered for the demands of in-home, long-term sleep monitoring.

B. System Architecture

The proposed system receives real-time video input, and the output consists of sleep posture predictions along with recommendations for posture adjustment in terms of both angle and position. The system comprises three main stages: 1) keypoint extraction, 2) sleep posture prediction, and 3) feedback for posture adjustment.

In the keypoint extraction stage, MediaPipe technology is utilized to detect and identify keypoints from the video frames. These points are then utilized for posture analysis in the subsequent stage. In the posture prediction stage, a hybrid architecture integrating CNN and LSTM is applied to classify sleep postures and assess whether the user is in a correct or improper posture, based on the spatial and temporal relationships among the detected keypoints.

In the final stage, the system provides real-time feedback for posture correction if abnormalities are detected, while also displaying the percentage of similarity to the correct posture. This feedback allows users to appropriately adjust their sleep posture, which is crucial for preventing potential health issues resulting from prolonged improper sleeping positions.

The system was designed to operate in an end-to-end manner, starting from video input acquisition, processing, and delivering real-time outputs. This design enhances the effectiveness of monitoring and improving sleep posture, particularly for elderly individuals who require special care. The workflow of the proposed system is illustrated in Fig. 1.

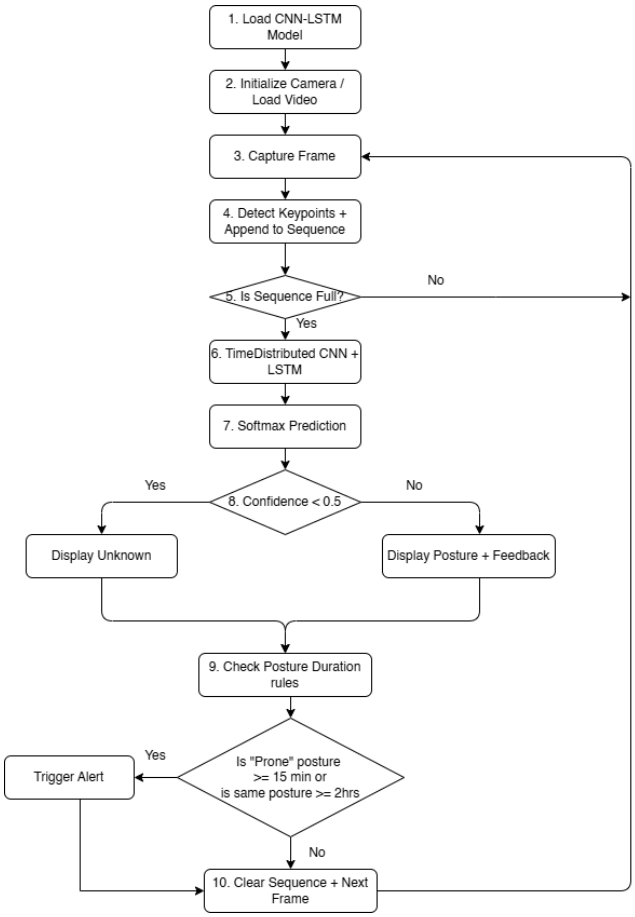

Fig. 1. Workflow diagram of the novel hybrid algorithm for vision-based sleep posture analysis integrating CNN, LSTM, and MediaPipe.

Sequence of the Sleep Posture Analysis System:

1) Load the pre-trained model, which consists of a TimeDistributed CNN for learning spatial features from keypoints and an LSTM for learning temporal patterns and continuity of sleep postures.

2) Activate the infrared (IR) camera to capture input data for posture detection. The camera must be positioned above the bed to clearly record the subject during sleep.

3) Capture video frames from the camera and apply MediaPipe to detect body landmarks (pose landmarks) such as shoulders, hips, and knees, which are essential for sleep posture analysis.

4) If keypoint detection is successful, append the current frame's set of keypoints to the accumulated keypoint sequence, preparing it for input into the sequence-based model.

5) Check the completeness of the accumulated keypoint sequence:

a) If incomplete, continue accumulating data.

b) If complete, feed the sequence into the CNN+LSTM model for behavior classification.

6) The output from the LSTM is passed through a Softmax Layer to obtain the probability values for each sleep posture, such as supine, left lateral, right lateral, and prone.

7) Evaluate the confidence level of the prediction:

a) If the confidence value is less than 50%, assign the label as "Unknown".

b) If the confidence value is greater than 50%, display the detected posture along with feedback.

8) Display the name of the detected posture (e.g., supine) and optionally include a feedback alert if the posture is inappropriate (e.g., incorrect posture or risk of back pain).

9) Check whether the user has remained in the same posture for an extended period. Two primary conditions are monitored:

a) Staying in the prone position for more than 15 minutes.

b) Remaining in the same posture (any type) for more than 2 hours.

Clear the accumulated sequence of keypoints to prepare for the next cycle, and return to the frame-capturing stage for continuous real-time analysis.

C. Dataset Details

In this research, the dataset used for training and testing the continuous sleep posture detection and analysis system was collected from 20 participants (12 male, 8 female) aged between 19 and 21 years (mean = 20.1, SD = 0.8), with heights ranging from 1.55 m to 1.80 m and weights between 45 kg and 90 kg, resulting in a Body Mass Index (BMI) range of 18.7 to 29.4 kg/m². This variation in body types helps ensure the model's robustness across different physiques.

To simulate real-world conditions, participants wore a variety of sleep attire, including T-shirts with shorts, long-sleeved pajamas, and tank tops, and were recorded both with and without light blankets.

Video data were captured using a fixed infrared (IR) camera positioned directly above the bed at a height of 2.0 meters, simulating a typical bedside monitoring setup. Recordings were conducted in two primary lighting conditions: 1) Daytime: with natural and artificial ambient light (illuminance range: 100–300 lux), and 2) Nighttime: using only the camera's built-in IR illumination (illuminance: < 1 lux) to mimic a dark sleep environment.

The volunteers performed seven predefined posture transitions: supine to side (SUSI), side to supine (SISU), supine to prone (SUPR), prone to supine (PRSU), side to prone (SIPR), prone to side (PRSI), and side to side (SISI). Each participant carried out all seven posture transitions in the predetermined sequence, yielding a total of 280 video samples with 140 recorded under daytime lighting and 140 under nighttime lighting. The dataset was strategically partitioned into a training set (70 videos, 50%), a validation set (28 videos, 20%), and a test set (42 videos, 30%) for both lighting conditions. A stratified sampling method was rigorously applied during this partition to preserve the proportional distribution of the four target sleep posture classes within each subset. This approach prevents class imbalance in any data split and ensures that the model is evaluated on a representative sample of all postures, thereby increasing the reliability of the reported accuracy metrics and reducing the risk of skewed performance results.

D. Keypoints Extraction

The system begins by processing real-time video frames using the MediaPipe library, a machine learning framework developed by Google specifically for posture analysis. A pre-trained MediaPipe model was employed to detect 33 body landmarks in 3D space (X, Y, Z), where the Z-coordinate represents the depth relative to the camera.

The detected keypoints are converted into JSON format for each frame, storing landmark positions along with confidence scores. Keypoints include the head, shoulders, elbows, hands, hips, knees, and ankles. The keypoint extraction stage of the model is capable of processing up to 25 to 30 frames per second on standard hardware and remains effective even under partial occlusion of the body or in low-light environments.

The extracted keypoint data are then passed into the CNN and LSTM analysis stage to evaluate sleep postures and detect risky behaviors, such as prolonged prone sleeping. The use of MediaPipe in this process ensures high accuracy in landmark detection, with an average error margin of only ±5 pixels, making it highly suitable for real-world applications in nighttime sleep monitoring.

E. Pose Prediction

This system utilizes a deep learning hybrid approach that integrates CNN and LSTM to classify sleep postures from real-time video data. It is specifically designed to detect four primary sleep postures: supine, left lateral, right lateral, and prone. The model leverages the strengths of both architectures, with CNN responsible for extracting spatial features from body keypoints detected by MediaPipe in each frame, while LSTM analyzes temporal dependencies across consecutive frames.

The process begins with the use of a TimeDistributed layer in combination with a CNN structure, which is designed to process sequential data. This layer allows independent processing of each video frame while preserving the inter-frame relationships. For the LSTM component, a multi-layer architecture is employed to capture long-term dependencies in posture sequences, particularly for identifying risky behaviors such as remaining in the same posture for an extended duration or exhibiting abnormal posture transitions.

In the final stage, a SoftMax layer is applied to compute the probability distribution over each posture class, with the posture having the highest probability selected as the output. This design not only enhances the accuracy of posture classification but also enables the system to operate efficiently in an end-to-end manner.

The posture prediction model extracts keypoints from MediaPipe, passes them through a Convolutional Neural Network (CNN) to learn spatial features, and subsequently processes frame sequences with a Long Short-Term Memory

(LSTM) network to learn temporal relationships. The process can be expressed mathematically as follows:

1) Input video sequence: Let I denote a video sequence consisting of n frames:

$$I = \{F_1, F_2, \ldots, F_n\}, F_i \in \mathbb{R}^{H \times W \times 3}$$

where,

F_i is the i frame represented as a matrix with height H, width W, and 3 color channels (RGB).

$\mathbb{R}^{H \times W \times 3}$ represents the space of images of size H×W pixels with 3 color channels

2) Keypoint extraction with MediaPipe: Each frame F_i is processed by MediaPipe to extract 33 keypoints:

$$K_i = MediaPipe(F_i), K_i \in \mathbb{R}^{33 \times 3}$$

where,

K_i is the keypoint matrix for the i frame (33 keypoints × 3 coordinates: x, y, z).

Example keypoints

- Head ($K_1 = [x_1, y_1, z_1]$)
- Left Shoulder ($K_{11} = [x_{11}, y_{11}, z_{11}]$)
- Right Hip.($K_{24} = [x_{24}, y_{24}, z_{24}]$)

3) Spatial feature learning with CNN: Each keypoint matrix K_i is fed into a CNN to extract spatial features.

$$v_i = CNN(K_i), v_i \in \mathbb{R}^d$$

where,

v_i is the feature vector of length ($d = 64$)

CNN Architecture

The architecture consists of a 1D Convolutional layer (filter size 3) → ReLU → MaxPooling → Flatten.

Learned Patterns: The model learns patterns such as joint angles and movement speed of specific points.

4) Temporal sequence learning with LSTM: The sequence of spatial features $v = \{v_1, v_2, \ldots, v_n\}$ is analyzed by an LSTM network.

$$h = LSTM(v), h \in \mathbb{R}^m$$

where,

h is the temporal feature vector (m =32).

LSTM Mechanism:

- Forget Gate: Determines which information to discard or keep from the previous frame.
- Input Gate: Adds new information from the current frame.
- Output Gate: Outputs the relevant features.

5) Posture prediction:

$$\hat{y} = softmax(W_h + b), W \in \mathbb{R}^{c \times m}, b \in \mathbb{R}^c$$

where,

c is the number of postures (supine, left side-lying, right side-lying, prone).

$\hat{y}$ is the probability of each posture.

F. Alert Conditions

If the LSTM detects a continuous prone posture for more than 15 minutes (calculated from the number of frames and the frames per second rate), the system will send an alert signal. If the user remains in any single posture (whether supine, left lateral, right lateral, or prone) for a continuous period exceeding 2 hours, the system will issue an alert to prompt a change in position to prevent pressure ulcers.

The duration for which a posture is held is calculated from the number of consecutive frames and the video's frame rate. The formula to convert the frame count into minutes is as follows:

$$Duration_{\ min} = \frac{Frame_count}{FPS \times 60}$$

where,

$Duration_{\ min}$ is the duration the posture is held (in minutes).

$Frame_count$ is the number of consecutive frames in which the posture was detected.

FPS is the frame rate of the video (frames per second).

The sleep posture detection system was trained using sequence data over 100 epochs with Early Stopping employed to monitor categorical accuracy. Training was automatically halted when accuracy plateaued to prevent overfitting caused by excessive training.

Evaluation included generating a confusion matrix and calculating the accuracy score to analyze the model's ability to classify postures from videos not previously used in training.

The system predicts only the current (final) posture rather than the initial posture, as its primary purpose is to monitor user health by detecting potentially harmful current postures (such as prolonged prone sleeping.)

IV. Results

A. Experimental Results

The experimental results of the sleep posture detection system under different lighting conditions indicated the performance metrics of the developed model separated by the four sleep posture classes: supine, left lateral, right lateral, and prone. The test dataset comprised 84 video clips recorded during daytime and nighttime. The postures with the largest number of samples were supine and prone (24 clips each), while left lateral and right lateral had equal samples (18 clips each).

From Table I, the test results indicated that the supine and prone postures achieved Precision, Recall, and F1-score values above 90%, reflecting that the model can accurately identify these two postures during daytime. The model's performance in

detecting these postures under daylight conditions is visually represented in Fig. 2. In contrast, the classification performance for left lateral and right lateral postures slightly decreased, with Precision, Recall, and F1-score approximately ranging from 88% to 89%.

TABLE I. CLASS-WISE METRICS FOR DAYTIME IMAGES

Class	Test	Precision	Recall	F1-score
Supine position	12	93.3%	91.7%	92.5%
Left lateral decubitus position	9	89.1%	88.9%	89.0%
Right lateral decubitus position	9	88.5%	88.9%	88.7%
Prone position	12	91.0%	91.7%	91.3%

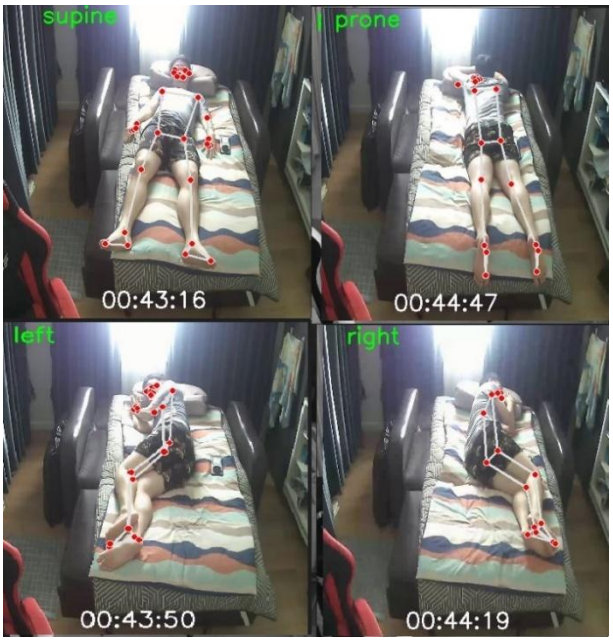

Fig. 2. Model testing of the hybrid algorithm for daytime images.

TABLE II. CLASS-WISE METRICS FOR NIGHTTIME IMAGES

Class	Test	Precision	Recall	F1-score
Supine position	12	90.9%	91.7%	91.3%
Left lateral decubitus position	9	85.7%	88.9%	87.3%
Right lateral decubitus position	9	84.6%	88.9%	86.7%
Prone position	12	88.9%	91.7%	90.3%

From Table II, the test results showed that the supine and prone postures achieved relatively high precision and recall values above 88%, with F1-scores around 90%, indicating that the model performed well in distinguishing clearly visible postures even under limited lighting conditions. Fig. 3 illustrates the hybrid algorithm model testing results for nighttime images. In contrast, the left and right lateral postures showed a slight drop in performance, with F1-scores approximately between 86% and 87%, reflecting the difficulty the model in distinguishing similar postures in low-light environments. Nonetheless, the overall results proved that the hybrid CNN, LSTM, and MediaPipe algorithm maintained strong classification capability even in low-light scenarios, which is a significant advantage for real-world nighttime applications.

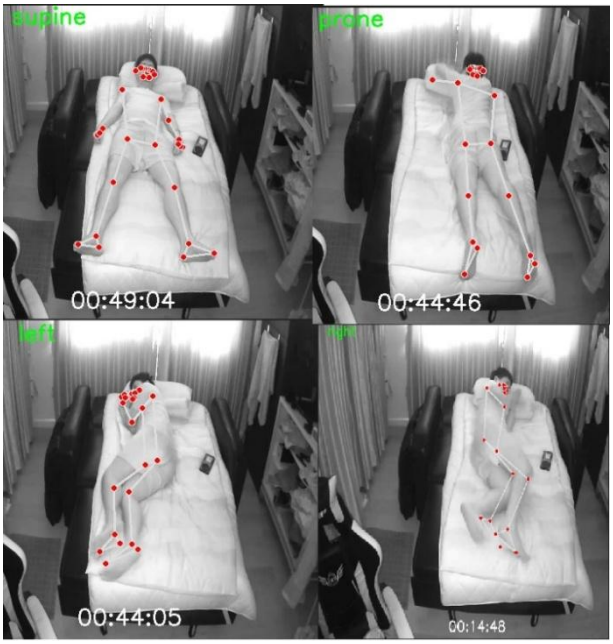

Fig. 3. Hybrid algorithm model testing for nighttime images.

Table III compares model performance in sleep posture analysis between daytime and nighttime images. The model achieved higher accuracy during daytime at 96.4%, while accuracy decreased to 92.8% at night, indicating that lighting conditions affect posture classification performance. The model tends to generate more misclassifications or confusion when processing low-light or nighttime images.

TABLE III. COMPARISON OF DAYTIME VS. NIGHTTIME ACCURACY

Lighting Condition	Video	Accuracy (%)
Daytime	42	96.4%
Nighttime	42	92.8%

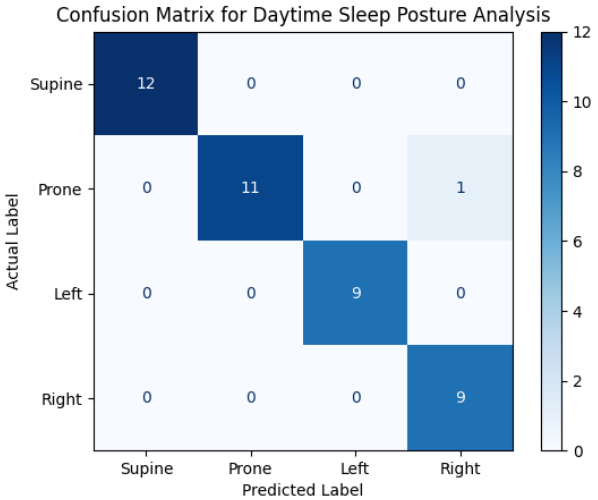

Fig. 4. Confusion matrix (daytime scenario).

From Fig. 4, the model's evaluation under daytime lighting conditions showed that it correctly classified all samples in the supine, left, and right classes with no mispredictions, demonstrating the model's strong ability to recognize distinctive features of these postures. However, there was one misclassification in the prone class, where one prone posture was predicted as right lateral. This confusion may have arisen due to the similarity of postures, such as a prone posture with the body or arms twisted in a manner resembling the lateral posture, leading to model misinterpretation.

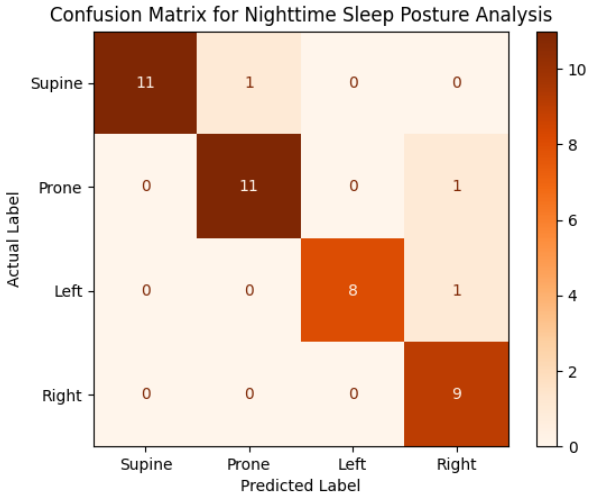

Fig. 5. Confusion matrix (nighttime scenario).

Fig. 5 presents the model's evaluation under a nighttime lighting scenario. Despite limited lighting, the model performed effectively with an overall accuracy of 92.8% based on 42 test clips comprising 12 supine clips, 12 prone clips, and 9 clips each for left and right lateral postures. Most posture classifications were correct, with only 3 misclassifications occurring due to confusion among similar postures. According to the confusion matrix, one supine posture was misclassified as prone, one prone posture was misclassified as right lateral, and one left lateral was misclassified as right lateral. The right lateral posture, however, was correctly classified in all nine instances. The confusion between prone, left, and right postures likely reflects the challenge of distinguishing postures under low light, where body features such as head tilt or arm positioning may be unclear. Additionally, partial occlusion by blankets reduces distinctive features needed to differentiate these postures.

V. Discussion

A. Comparative Analysis of Posture Detection Models

We conducted a performance comparison between the proposed hybrid CNN-LSTM algorithm and two related studies to demonstrate the advancements and strengths of our method.

The first related work, "Sleep Posture Classification using a Convolutional Neural Network" [14], presented a non-contact sleep posture monitoring system using depth sensor data and a CNN to classify main sleep postures, including supine, left lateral, right lateral, and prone. This system focused on real-world environments and generated vertical distance maps from depth images. It employed a multi-stream CNN architecture to enhance classification accuracy. Experimental results with 22 participants under three conditions (no blanket, thin blanket, thick quilt) showed average accuracies of 93.2%, 90.9%, and 88.6%, respectively. While this approach demonstrates robust performance, especially in handling blanket occlusions through depth information, it primarily relies on spatial data from a single frame. The absence of a temporal component, such as an LSTM, limits its ability to model posture transitions and continuously monitor posture duration for proactive health risk alerts – a key feature addressed by our proposed hybrid model.

The second study, "Sleep Posture Recognition Method Based on Sparse Body Pressure Features" [15], proposed a classification method using sparse pressure sensor data from an air mattress designed to reduce system cost and complexity. The air mattress had four pressure sensors located on the back, waist, hip, and leg, and utilized ensemble learning combining models such as SVM, XGBoost, RF, GP, and CNN to improve accuracy. This approach classified seven sleep postures (e.g., supine, side-lying or lateral, prone) with an accuracy of up to 95.63% and achieved 94.67% accuracy in classifying four posture types in real-world scenarios. The system also automatically adjusted mattress softness according to detected posture to enhance comfort. This sensor-based solution offers a valuable non-visual alternative; however, it requires specialized hardware (instrumented mattress), which can increase deployment cost and may not be as easily scalable or retrofittable as our vision-based approach. Furthermore, while effective for posture classification, the reliance on pressure maps may not capture the full skeletal alignment details that 3D keypoints from MediaPipe provide, and its ensemble model may lack the integrated spatio-temporal reasoning inherent in our end-to-end CNN-LSTM architecture.

TABLE IV. Comparative Experiments with Different Models

Model	Accuracy
MediaPipe + CNN + LSTM	96.40 % (Daytime)
depth sensor + CNN [14]	93.20 %
CNN + Autoencoder [15]	95.63 %

From Table IV, the accuracy comparison clearly showed the superiority of the proposed MediaPipe + CNN + LSTM model, achieving the highest accuracy of 96.4% compared to other models. This advantage results from the hybrid approach that integrates the strengths of multiple technologies: MediaPipe provides accurate real-time 3D pose information, CNN extracts spatial features from postures, and LSTM tracks temporal changes continuously. This comprehensive spatial-temporal capability enables the system to detect and classify complex postures more precisely. Furthermore, the model's robustness is reinforced by the diverse dataset, which includes variations in body types, clothing, and lighting, reducing the risk of overfitting to a specific demographic or environmental condition.

In contrast, the depth sensor + CNN model, with 93.2% accuracy, while effective with depth data, lacked critical temporal analysis. The CNN + Autoencoder model achieved 95.63%, but despite good dimensionality reduction, it cannot capture long-term posture relationships as effectively as LSTM.

This difference indicated that integrating these three technologies provided the system with superior detection and classification ability, particularly under real-world conditions involving lighting limitations and occlusions.

VI. Conclusion

Sleep posture significantly influences physical health and sleep quality, particularly for vulnerable populations such as the elderly and chronic patients. Traditional monitoring methods often involve invasive sensors or lack the capability for continuous, real-time analysis, limiting their practicality for long-term home care. To address this gap, this research developed a novel hybrid algorithm for non-invasive, real-time sleep posture analysis by effectively integrating MediaPipe, CNN, and LSTM technologies.

The system successfully detects and classifies four main sleep postures—supine, left lateral, right lateral, and prone—achieving a high accuracy of 96.4% under normal lighting and 92.8% under low-light conditions. It incorporates an automatic alert mechanism triggered when a prone posture is maintained for over 15 minutes or any single posture is held for more than 2 hours, addressing key health risks such as respiratory issues and pressure ulcers.

The key strength lies in the effective combination of MediaPipe's 3D keypoint detection, CNN's spatial feature extraction, and LSTM's temporal sequence analysis. This integration enables a comprehensive spatial-temporal understanding of sleep behavior, resulting in superior accuracy compared to depth-sensor or autoencoder-based approaches. The system maintains real-time performance with an overall end-to-end throughput of 22 frames per second on consumer-grade hardware, demonstrating strong practical feasibility for health monitoring applications.

For future work, we recommend: 1) expanding dataset diversity to include broader age groups and varied sleeping environments; 2) optimizing the model for mobile and IoT deployment; and 3) integrating with caregiver notification systems to enhance comprehensive health surveillance capabilities.

NetDAIL: An Optimized Deep Learning-Based Hybrid Model for Anomaly Detection in Network Traffic

Saad Khalifa*, Mohamed Marie, Wael Mohamed
Information Systems Department-Faculty of Computers and Artificial Intelligence, Helwan University, Cairo, Egypt

***Abstract*—Detecting rare and subtle anomalies is critical for ensuring cybersecurity, financial integrity, and operational safety. High-dimensional features, severe class imbalance, and large data volumes often challenge conventional intrusion detection methods. This study presents NetDAIL, a hybrid framework that integrates deep feature learning using a denoising autoencoder, anomaly scoring through Isolation Forest, and classification via LightGBM to address these challenges. To evaluate its effectiveness, the proposed framework was tested on two widely used benchmark datasets: NSL-KDD for controlled-scale experimentation and KDD Cup 1999 for large-scale evaluation. NetDAIL achieved an AUC of 0.998 on the NSL-KDD dataset and 0.990 on the KDD Cup 1999 dataset, demonstrating strong discriminative capability across different traffic volumes and attack patterns. Experimental results confirm the model's high detection accuracy, scalability, and generalization across diverse network intrusion scenarios. These findings highlight NetDAIL as a practical and reliable solution for real-world anomaly detection, capable of efficiently handling both small- and large-scale environments while maintaining robust and effective performance in operational settings.**

***Keywords*—Anomaly detection; deep learning; autoencoders; NetDAIL; unsupervised learning; intrusion detection; NSL-KDD; KDD Cup 1999**

I. Introduction

The rapid evolution of digital technologies—such as the Internet, smartphones, and robotics—has profoundly transformed modern society, driving unprecedented levels of connectivity and data exchange. With the exponential growth of information flow and the rising demand for real-time, data-driven decision-making, ensuring cybersecurity has become a global priority. Recent estimates suggest that the financial impact of cybercrime could reach $10.5 trillion annually by 2025, underscoring its status as one of the most significant threats to economic stability and national security worldwide [1]. Increasingly sophisticated attacks, including malware, distributed denial of service (DDoS), phishing, and advanced persistent threats (APTs), target individuals, enterprises, and critical infrastructures [2]. These developments necessitate robust and intelligent defense mechanisms that can effectively protect modern networks from evolving cyber risks.

Anomaly detection has emerged as a fundamental approach in cybersecurity due to its ability to identify patterns that deviate from expected system behavior. By flagging suspicious deviations, anomaly detection has proven effective across multiple domains, including fraud prevention, healthcare monitoring, and, most notably, network intrusion detection [3]. Unlike signature-based detection, which requires prior knowledge of attack patterns, anomaly detection can reveal previously unseen or subtle intrusions. However, real-world network environments pose unique challenges: anomalies are often rare, subtle, and overshadowed by highly imbalanced traffic distributions, making them difficult to detect with traditional techniques [4]. Additionally, the growing volume, velocity, and variety of network data further complicate detection tasks and demand scalable, high-performance models [5].

Conventional intrusion detection systems (IDS) that rely on rule-based signatures or statistical models struggle when faced with high-dimensional, noisy, and dynamic datasets [6]. In response, machine learning (ML) and deep learning (DL) methods have gained prominence for their ability to capture complex, nonlinear data patterns. Among these, autoencoders have demonstrated strong potential for anomaly detection by learning compressed latent representations and using reconstruction error as a reliable anomaly score [7]. Nevertheless, existing approaches often suffer from limitations such as poor generalization, high computational cost, and particularly low recall for rare yet critical attack categories like User-to-Root (U2R) and Remote-to-Local (R2L) [8].

To overcome these challenges, this study introduces NetDAIL, a hybrid intrusion detection framework designed for binary anomaly detection (Normal vs. Attack). The framework integrates a denoising autoencoder for deep feature extraction, an Isolation Forest for anomaly scoring, and a LightGBM classifier for final decision-making. Advanced preprocessing techniques, including normalization, one-hot encoding, and SMOTEENN balancing, are incorporated to enhance robustness against class imbalance and noise in large-scale traffic datasets. While the primary objective of this study is to strengthen binary classification performance, NetDAIL is inherently scalable and adaptable to multiclass intrusion detection tasks, which may be explored in future work. The main contributions of this study are summarized as follows:

1) Hybrid architecture: We propose a novel hybrid model that combines unsupervised anomaly scoring with supervised gradient-boosted classification, improving detection accuracy and robustness in binary anomaly detection settings.

*Corresponding author.

2) Optimized preprocessing pipeline: We design an end-to-end pipeline that addresses the challenges of high-dimensional, imbalanced network traffic data through normalization, categorical encoding, and SMOTEENN-based balancing.

3) Comprehensive evaluation: We conduct extensive experiments on benchmark datasets to rigorously assess the model's performance in binary intrusion detection (Normal vs. Attack), with special emphasis on robustness against imbalance and the ability to capture subtle, hard-to-detect anomalies. Although the present focus is binary classification, the proposed framework is scalable toward multiclass extensions in future research.

The proposed NetDAIL framework is designed not only to achieve high accuracy but also to directly address the persistent challenges identified in intrusion detection systems. First, the use of a denoising autoencoder enables the model to effectively handle the problem of high-dimensional and noisy network traffic by extracting compact and informative latent representations. Second, to overcome the severe class imbalance problem and improve the detection of rare attack types, SMOTEENN is employed during preprocessing, which enhances minority class representation and reduces noise from the majority class. Third, integrating the Isolation Forest adds a strong anomaly detection component capable of identifying subtle and previously unseen deviations in network traffic. Finally, LightGBM provides a fast, scalable, and generalizable classification stage, allowing the entire pipeline to maintain high performance even when applied to large-scale datasets. By combining these components in a structured manner, NetDAIL directly responds to the core technical challenges of feature complexity, data imbalance, rare attack detection, and scalability.

Although NetDAIL combines both unsupervised and supervised components, it is important to clarify that the final classification stage is supervised, as LightGBM is trained on labeled data (Normal vs. Attack). The unsupervised components—namely the Denoising Autoencoder and the Isolation Forest—are employed as feature learning and anomaly scoring mechanisms rather than as standalone classifiers. This design enables the model to leverage the representational power of unsupervised learning while maintaining the decision accuracy and interpretability of supervised classification. Therefore, the hybrid nature of NetDAIL refers specifically to the integration of different learning paradigms within a single detection pipeline, not to a fully hybrid training procedure.

The remainder of this study is organized as follows: Section II reviews related work on anomaly and intrusion detection. Section III describes the proposed NetDAIL methodology in detail. Section IV presents experimental results and evaluation. Section V provides a discussion of findings and performance analysis. Finally, Section VI concludes the study and outlines future research directions.

II. Related Works

Recent years have witnessed an increasing interest in the development of intelligent intrusion detection systems (IDS) that can cope with high-dimensional network data and severe class imbalance. Prior studies can be broadly categorized into four major directions: reinforcement learning–based methods, deep learning and hybrid architectures, generative and adversarial approaches, and ensemble or optimization-driven techniques.

A. Reinforcement Learning-Based Approaches

Wang et al. [9] introduced RL-NIDS, a reinforcement learning-based IDS that leverages explicit and implicit feature interactions through a combination of supervised neural network representation learning and unsupervised feature value representation learning. The system outperformed traditional feature selection and deep learning methods on NSL-KDD and AWID datasets, yet its ability to detect rare classes such as U2R was limited due to insufficient training samples. Similarly, Li et al. [10] proposed AE-SAC, an IDS built on the Soft Actor–Critic reinforcement learning algorithm, incorporating reward modification and dynamic resampling to mitigate class imbalance. Despite showing promising performance, the recall for minority attacks remained poor. Benaddi et al. [11] extended reinforcement learning to industrial IoT security by combining distributional RL with GANs to enhance anomaly detection. Although this design provided adaptive and robust detection, it demanded significant computational resources, reducing its feasibility for real-time deployment. Collectively, reinforcement learning approaches demonstrate strong adaptability but face challenges with scalability and minority-class detection.

B. Deep Learning and Hybrid Architectures

Sharma et al. [12] proposed a hybrid deep learning model that integrates Convolutional Neural Networks (CNNs) and Long Short-Term Memory (LSTM) networks. CNNs captured spatial features while LSTMs modeled temporal dependencies, yielding over 90% accuracy, particularly for DoS and exploitation attacks. However, the model's training complexity hindered real-time applicability and limited recall for rare intrusions. Kasongo [13] explored a recurrent neural network-based framework, demonstrating improved accuracy but also highlighting issues of computational overhead. Kao et al. [14] developed a two-stage structure combining a denoising autoencoder (DAE) with a Gated Recurrent Unit (GRU). This method used GRU-based confidence scoring alongside reconstruction error, resulting in accuracy above 90% on NSL-KDD. While effective, its reliance on finely tuned confidence thresholds constrained generalizability. Meliboev et al. [15] advanced AE-LSTM models with optimized hyperparameters and layer configurations, improving precision and recall compared to traditional classifiers. Nevertheless, increasing architectural depth led to diminishing performance, revealing sensitivity to model complexity. These works underscore the potential of hybrid DL approaches but also their trade-offs between performance, scalability, and generalization.

C. Generative and Adversarial Learning Methods

Generative models have been adopted to address severe class imbalance in IDS research. Rahman et al. [16] introduced SYN-GAN, a system that generates synthetic IoT traffic to improve classifier robustness. While achieving perfect performance on BoT-IoT datasets, its results on NSL-KDD were notably weaker, reflecting dependency on dataset-specific quality. Xu et al. [17] similarly employed GANs to create synthetic minority samples, achieving up to 91% accuracy on NSL-KDD, but highlighted the limitation of over-reliance on generated data quality. Zhang et al. [18] explored bagging ensemble models combined with Bayesian optimization, integrating extreme random tree (ERT) feature weighting to enhance generalization. Despite improving stability and accuracy, computational intensity limited its practical adoption. Overall, adversarial learning enriches minority-class representation but introduces overheads in data generation and tuning complexity, restricting scalability.

D. Ensemble and Optimization-Based Methods

Several studies leveraged ensemble learning and feature optimization for improved detection. Chohra et al. [19] presented Chameleon, a feature selection framework combining particle swarm optimization (PSO) with ensemble classifiers, achieving strong F1-scores across NSL-KDD, UNSW-NB15, and IoT-Zeek datasets. Yet, its iterative optimization procedure imposed high computational costs. Soleymanzadeh et al. [20] applied ensemble stacking across security and financial datasets, showing superior precision and recall compared to standalone models. However, the layered ensemble design also raised concerns about efficiency in resource-constrained environments. Wang et al. [21] introduced the BIRCH-Autoencoder (BAE), which combines clustering with autoencoder-based classification to reduce imbalance effects, achieving notable improvements but with sensitivity to clustering parameters. Jeong et al. [22] proposed a deep belief network (DBN) enhanced with fast persistent contrastive divergence, accelerating training and yielding competitive accuracy. Nevertheless, the method struggled with high-dimensional traffic data, limiting its applicability to large-scale scenarios. Together, these approaches highlight the role of optimization and ensemble techniques in boosting IDS accuracy but also reveal trade-offs in efficiency and dataset adaptability.

E. Synthesis and Research Gap

Across these categories, prior works have demonstrated meaningful progress in anomaly-based intrusion detection. Reinforcement learning enhances adaptability but often underperforms for rare attacks. Hybrid deep learning architectures capture both temporal and spatial features but are computationally heavy and prone to overfitting. GAN-based models effectively augment minority classes but rely on synthetic data quality, while ensemble and optimization approaches boost accuracy at the cost of efficiency. Despite these advances, three challenges persist: 1) limited recall for rare classes such as U2R and R2L, 2) high computational overhead hindering real-time deployment, and 3) weak generalization across diverse datasets. Addressing these limitations, the proposed NetDAIL framework leverages a lightweight denoising autoencoder, Isolation Forest anomaly scoring, and LightGBM classification, enhanced with SMOTEENN balancing, to deliver robust rare-class detection with lower computational complexity.

III. Methodology

To enhance the accuracy, scalability, and reliability of network intrusion detection systems, this study introduces NetDAIL, a hybrid learning framework that unifies unsupervised feature extraction, statistical anomaly scoring, and supervised classification into a single, coherent pipeline. Unlike conventional models that treat each stage independently, NetDAIL is designed as an end-to-end architecture, ensuring that every component complements the others to overcome practical challenges such as data redundancy, high feature dimensionality, severe class imbalance, and the well-known difficulty of detecting rare attack classes like User-to-Root (U2R) and Remote-to-Local (R2L). The overall architecture, illustrated in Fig. 1, consists of three tightly coupled modules: a Denoising Autoencoder for unsupervised representation learning, an Isolation Forest for anomaly scoring, and a LightGBM classifier for final binary classification between normal and abnormal traffic.

A. Data Preprocessing

The preprocessing stage forms the essential foundation of the proposed hybrid anomaly detection pipeline. Since the system's objective is classification between normal and abnormal traffic, careful data preparation is necessary to ensure that subsequent learning components (Autoencoder, Isolation Forest, and LightGBM) receive structured and noise minimized input. The NSL-KDD dataset serves as the main benchmark in this study, offering two primary subsets: KDDTrain+ for training and KDDTest+ for evaluation. Both subsets contain labeled instances of normal and attack traffic, and this dataset remains widely adopted in intrusion detection research due to its manageable size, balanced difficulty level, and compatibility with modern learning algorithms [10]. Unlike other datasets such as UNSW-NB15 and CICIDS-2017, NSL-KDD provides a controlled environment where preprocessing strategies and classification models can be consistently evaluated.

After establishing the dataset foundation, the preprocessing workflow applies a series of carefully designed transformations. These include handling categorical attributes through one-hot encoding, resampling to address class imbalance with SMOTEENN, and feature scaling via Min-Max normalization. Each of these steps is sequentially integrated so that the processed data smoothly transitions into the feature learning stage with the Autoencoder. In the following subsections, each step is discussed in detail.

B. Handling Categorical Attributes

Since both the Autoencoder and Isolation Forest require purely numerical input, categorical features in NSL-KDD, such as protocol_type, service, and flag, must be transformed. These features contain symbolic values (e.g., "tcp", "http", "SF") that have no inherent numeric ordering. To prevent introducing ordinal bias, one-hot encoding is applied. This transformation represents each category as a binary vector. For instance, if the

service attribute contains 70 unique categories, the encoding generates a 70-dimensional sparse vector where exactly one position is set to 1 and all others are 0. This guarantees that categorical distinctions are preserved without misinterpretation by downstream learning algorithms. Importantly, this step ensures full compatibility with the Autoencoder input layer, which expects fixed-size numeric vectors.

C. Data Balancing with SMOTEENN

Following categorical transformation, the dataset is passed into a resampling module. Intrusion detection datasets are typically highly imbalanced, with classes like U2R (User-to-Root) and R2L (Remote-to-Local) severely underrepresented compared to Normal or DoS categories. If left unaddressed, this imbalance biases the classifier toward majority classes and leads to poor recall for rare but critical intrusions. To overcome this, a hybrid oversampling and cleaning strategy (SMOTEENN) is used.

SMOTE (Synthetic Minority Oversampling Technique) generates synthetic samples for minority classes by interpolating between existing instances, thus expanding their representation in the feature space.

ENN (Edited Nearest Neighbor) complements this by removing noisy or borderline examples, especially from majority classes, ensuring that oversampling does not introduce excessive noise.

The combination of SMOTE and ENN, therefore, balances the class distribution and refines the dataset quality. At this stage, the resampled dataset is significantly more balanced and ready for feature scaling.

D. Data Normalization

After categorical encoding and resampling, the cleaned dataset enters the normalization stage. Different features in NSL-KDD span different ranges (e.g., packet counts, byte sizes, and duration values). Without scaling, attributes with large numeric ranges would dominate the learning process and hinder convergence. Therefore, Min-Max normalization is applied to rescale all numeric features into the standard range [0, 1]. This ensures that each feature contributes proportionately during training.

The normalization process follows Eq. (1) and Eq. (2):

$$Xstd = \frac{X - Xmin}{Xmax - Xmin} \quad (1)$$

$$Xscaled = Xstd * (max - min) + min \quad (2)$$

Before being sent to the learning components, all input features for this model must fall inside the range [0,1] thanks to normalization, which is carried out with default values of min=0 and max=1. By enforcing this uniform scale, the model achieves improved training stability, faster convergence, and more effective feature representation when passed into the autoencoder.

In summary, preprocessing transforms the raw NSL-KDD dataset into a balanced, normalized, and numerically encoded representation. This sequence of steps—one-hot encoding → SMOTEENN resampling → Min-Max normalization—ensures that the learning pipeline begins with high-quality input data. The output of this stage directly feeds into the feature learning component (Autoencoder), forming a seamless transition between raw data and advanced anomaly detection modules.

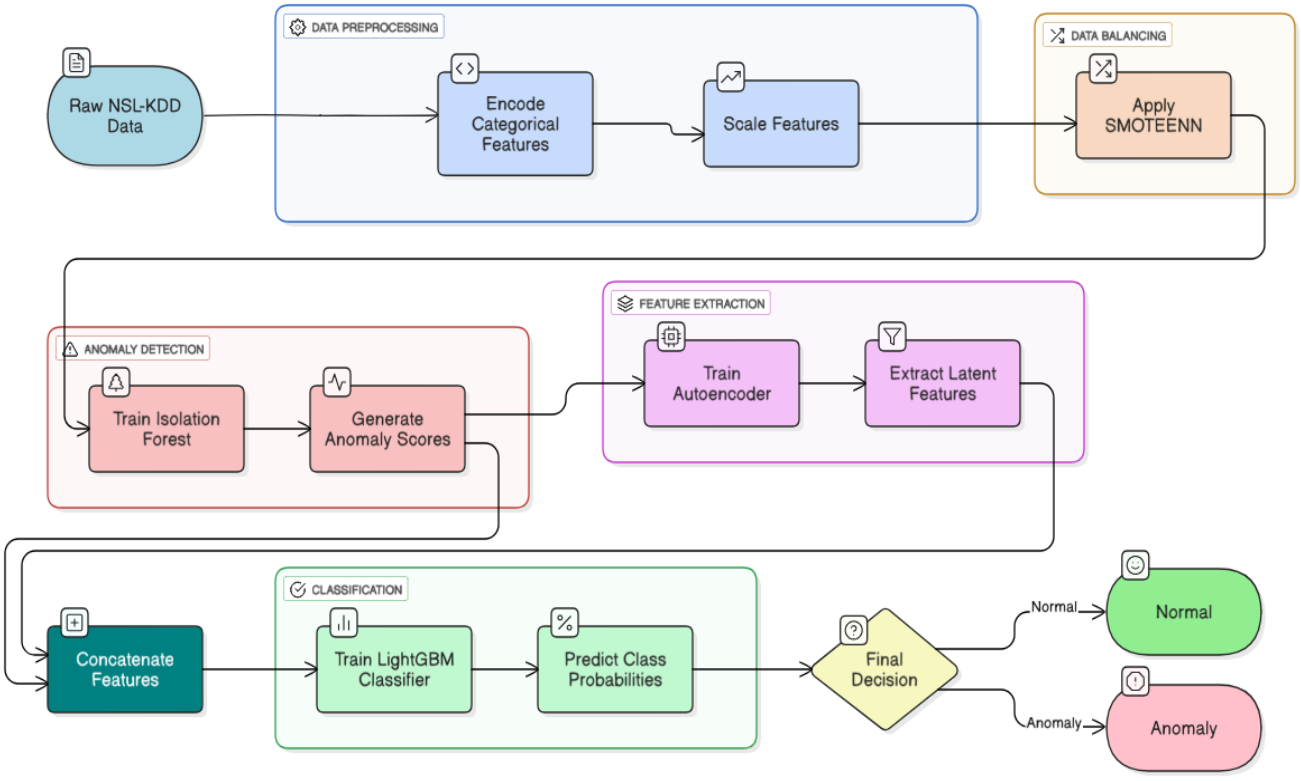

Fig. 1. NetDAIL structure.

E. Deep Learning-Hybrid Feature Learning Model

DAE, which forms the backbone of NetDAIL's deep feature learning pipeline. Unlike traditional autoencoders that simply reconstruct inputs, the denoising variant deliberately introduces controlled noise into the input data. This compels the encoder to capture robust and generalizable latent features, focusing on meaningful traffic patterns instead of memorizing irrelevant noise or spurious correlations.

The DAE architecture is carefully designed to compress high-dimensional traffic data into a lower-dimensional but informative latent space:

- Input Layer: Equal in size to the processed dataset features after encoding and normalization.
- Encoder: Three fully connected layers with 128, 64, and 32 neurons. Each layer is followed by batch normalization and ReLU activation, which improves learning stability while progressively reducing dimensionality.
- Latent Space: A compact 32-dimensional embedding that captures both linear and nonlinear dependencies, preserving the intrinsic structure of the traffic data.
- Decoder: A mirrored architecture (32 → 64 → 128) with a final sigmoid layer to reconstruct normalized inputs within the [0, 1] range.

The DAE is trained with the Adam optimizer (learning rate = 0.0005), the MAE reconstruction loss, and early stopping (patience = 5 epochs). These strategies ensure stable convergence and prevent overfitting. The 32-dimensional latent vectors generated by the encoder are stored for the subsequent anomaly scoring and classification stages.

It is important to emphasize that the Denoising Autoencoder (DAE) constitutes only one module of the broader NetDAIL architecture. While the DAE provides robust deep feature representations, NetDAIL achieves its full capability by tightly integrating these features with anomaly scores from Isolation Forest and the discriminative power of LightGBM.

Link to next step: Once robust latent features are obtained, they are combined with anomaly scores generated by the Isolation Forest to enrich the representation space before supervised classification.

F. Reconstruction Loss, Anomaly Scoring, and Classification

Mean Absolute Error (MAE) loss is used to optimize the autoencoder in NetDAIL. Eq. (3) provides the equation for it.

$$MAE = \frac{1}{n} \quad \sum_{i=1}^{n} |y_i - \hat{y}_i| \tag{3}$$

where, y_i is the original input, $\hat{y}_i$ is the reconstructed output, and n is the number of input features. This loss ensures the encoder learns meaningful latent features by minimizing the reconstruction discrepancy.

Following feature extraction, each sample is assigned an anomaly score using the Isolation Forest algorithm. This score reflects the extent to which a sample deviates from the learned data distribution. Samples with higher scores are considered more anomalous, as they are isolated more quickly during recursive partitioning.

Next, the 32-dimensional latent features from the DAE are concatenated with the Isolation Forest anomaly scores, forming a hybrid feature vector. This fusion integrates both structural encoding (from the Autoencoder) and statistical rarity (from the Isolation Forest), creating a more discriminative representation space for classification.

To enhance the reproducibility of our experiments, we provide detailed hyperparameter settings and data configuration used in all model components. For the Denoising Autoencoder (DAE), we used a learning rate of 0.001, a batch size of 128, and trained for 100 epochs with early stopping. For the Isolation Forest, the number of estimators was set to 100, contamination to 0.1, and maximum samples to 'auto'. For LightGBM, we used 500 boosting rounds, a learning rate of 0.05, a maximum depth of 12, 64 leaves, and early stopping with a patience of 50 rounds.

The dataset was split using the standard NSL-KDD and KDD Cup 1999 partitions to ensure fair comparison with prior studies. Preprocessing (encoding, normalization, and SMOTEENN balancing) was performed only on the training data, and the same transformations were applied to the test set to prevent data leakage.

For transparency and to facilitate future research, we also plan to make the code and the exact train–test splits used in our experiments available in a public repository upon acceptance.

A LightGBM classifier is then trained on this enriched representation. Unlike methods that rely on static anomaly thresholds, LightGBM dynamically learns complex non-linear decision boundaries between normal and anomalous traffic. During inference, the classifier produces probability estimates:

If probability < 0.5 → classify as Normal (Label 0).

If probability ≥ 0.5 → classify as Abnormal (Label 1).

This probabilistic framework not only eliminates the need for manual threshold tuning but also improves generalization across diverse traffic patterns. By combining deep latent learning, statistical anomaly scoring, and ensemble-based supervised classification, NetDAIL achieves a scalable, accurate, and balanced intrusion detection pipeline.

Why Hybridization Matters? Using each component of NetDAIL in isolation would yield suboptimal results. For instance, a DAE alone excels at feature extraction but cannot provide direct anomaly detection or classification. Isolation Forest alone can assign anomaly scores but lacks semantic discrimination across multiple attack categories. LightGBM by itself is a powerful classifier, but its performance degrades when faced with high-dimensional, imbalanced, and noisy inputs. By combining these three paradigms, NetDAIL achieves a synergistic effect: the DAE reduces dimensionality and suppresses noise, the Isolation Forest provides statistical rarity scores that enrich the representation space, and LightGBM leverages both original and learned features for precise decision boundaries. This integration enhances robustness against imbalance, improves generalization across

datasets, and significantly increases detection rates for rare intrusions such as U2R and R2L.

Unlike conventional hybrid intrusion detection frameworks that rely on deep learning combined with either statistical anomaly detection or ensemble methods, NetDAIL integrates a denoising autoencoder, Isolation Forest, and LightGBM in a structured pipeline. This specific combination is intentionally designed to address critical gaps identified in prior work: 1) DAE enhances robustness and extracts noise-resistant latent representations from high-dimensional network traffic, 2) Isolation Forest provides an unsupervised anomaly score that highlights rare and subtle attacks without requiring manual threshold tuning, and LightGBM offers lightweight, scalable, and high-accuracy classification. This integration enables complementary strengths between feature learning, anomaly scoring, and supervised classification, resulting in improved detection of minority attacks and better scalability compared to existing hybrid IDS frameworks.

IV. Results

A. Dataset Description

We evaluate NetDAIL on two benchmark datasets derived from NSL-KDD and KDD Cup 1999. The small-scale dataset includes KDD-Train+ and KDDTest+, containing 41 features (38 numerical and 3 categorical), which capture diverse aspects of network traffic such as connection duration, protocol type, byte counts, and traffic statistics. Table I summarizes these features and their corresponding data types [24].

To further evaluate generalization, we included two large-scale subsets derived from the KDD Cup 1999 dataset: 1) 20 Percent Training Set.csv, which is a representative reduced training subset, and 2) kddcup.data.corrected, the complete corrected dataset with nearly five million records. For the large-scale experiment, 20 Percent Training Set.csv was employed exclusively for training, while kddcup.data.corrected was used for testing. This configuration ensures a realistic large-scale deployment scenario where the model is trained on a manageable subset but evaluated on a massive, highly diverse dataset. All datasets are summarized in Table II.

For consistency, all attack classes (DoS, Probe, R2L, U2R) were merged into a single “Attack” class, while normal traffic was preserved as a separate class. This binary transformation aligns with best practices in anomaly detection. Preprocessing included SMOTEENN balancing, min–max normalization, and categorical feature encoding. These steps improved generalization and stabilized learning during the supervised phase.

B. Metrics of Evaluation

The evaluation metrics used to evaluate NetDAIL's performance are described in depth in this section. Accuracy, precision, recall, and F1-score are a set of standard classification metrics that are used to objectively assess the model's efficacy. These measures offer a thorough framework for evaluation, especially when dealing with unbalanced datasets where mere correctness could be deceptive [23].

TABLE I. Feature Names with Their Corresponding Data Types

No.	Features	Type	No.	Features	Type
0	Duration	int64	21	is_guest_login	int64
1	protocol_type	object	22	Count	int64
2	Service	object	23	srv_count	int64

TABLE II. DATASET DESCRIPTIONS

Dataset Type	Dataset Name	Normal	Attack	Total
Small Scale	KDD-Train+	67343	58630	125973
	KDDTest+	9711	12833	22544
Large Scale	20 Percent Training Set.csv	13449	11743	25192
	kddcup.data.corrected	972781	3925650	4898431

Precision measures the proportion of instances predicted as anomalous that are actually anomalous. Formally defined in Eq. (4), it reflects the model's ability to minimize false positives.

Recall, sometimes referred to as sensitivity or True Positive Rate (TPR), measures how well the model can identify real abnormal occurrences. Eq. (5) serves as a mathematical representation of this crucial statistic in intrusion detection jobs.

The ratio of correctly categorized cases (both normal and anomalous) to the total number of instances in the dataset is known as accuracy (Acc), and it indicates how accurate the classification is overall. Its equation is provided in Eq. (6).

F1-score is a balanced metric that is particularly useful when addressing unequal class distributions. It is calculated as the harmonic mean of precision and recall. Eq. (7) illustrates how it is computed.

Alongside other evaluation metrics, AUC (Area Under the ROC Curve) is employed to assess the model's ability to distinguish between normal and anomalous data points [23]. A high AUC indicates that the model consistently assigns higher anomaly scores to true attacks compared to normal traffic, making it particularly suitable for datasets with severe class imbalance, where accuracy alone may not fully capture detection performance.

$$Precision = \frac{(TP)}{(TP+FP)} \quad (4)$$

$$Recall = \frac{(TP)}{(TP+FN)} \quad (5)$$

$$Accuracy = \frac{(TP+TN)}{(TP+TN+FP+FN)} \quad (6)$$

$$F1-score = 2 * \frac{(precision*recall)}{(precision+recall)} \quad (7)$$

C. Findings

The experimental findings from NetDAIL's evaluation across the datasets are presented in this section. Performance metrics—including accuracy, precision, recall, and F1-score—are computed using the corresponding test sets after applying the model, providing a comprehensive assessment of classification effectiveness.

For the small-scale evaluation, the Autoencoder component of NetDAIL is trained using Mean Absolute Error (MAE) as the reconstruction loss function. This setup combines Autoencoder-based feature extraction, Isolation Forest anomaly scoring, and LightGBM classification. The resulting classification metrics produced by the LightGBM classifier are summarized in Table III.

To further demonstrate NetDAIL's ability to distinguish between normal and anomalous traffic, visualizations such as the confusion matrix (Fig. 2) and ROC curve (Fig. 3) are provided. These plots highlight the hybrid model's robust discriminative capability across diverse traffic patterns. Additionally, the Autoencoder's training and validation loss (Fig. 4) and training and validation accuracy (Fig. 5) illustrate the model's learning dynamics and convergence behavior during feature representation learning.

TABLE III. RESULTS GENERATED FROM NETDAIL

Metric	Label	Precision	Recall	Acc	F1-score	AUC
MAE	Normal	0.99	0.99	0.99	0.99	0.99
	Attack	0.99	0.98			

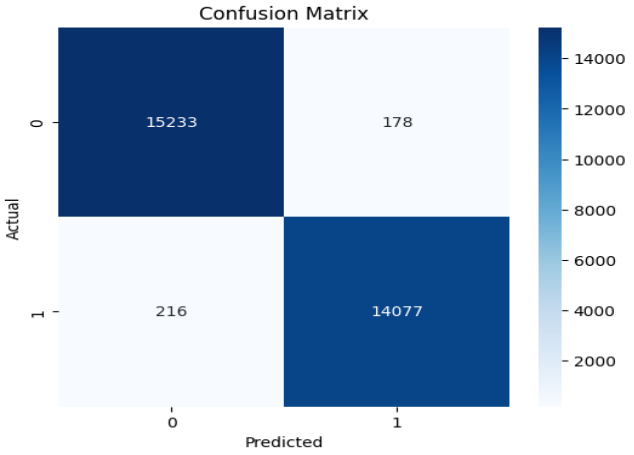

Fig. 2. Confusion matrix of NetDAIL (MAE-based) on the small-scale dataset, illustrating the model's classification performance for normal and anomalous instances.

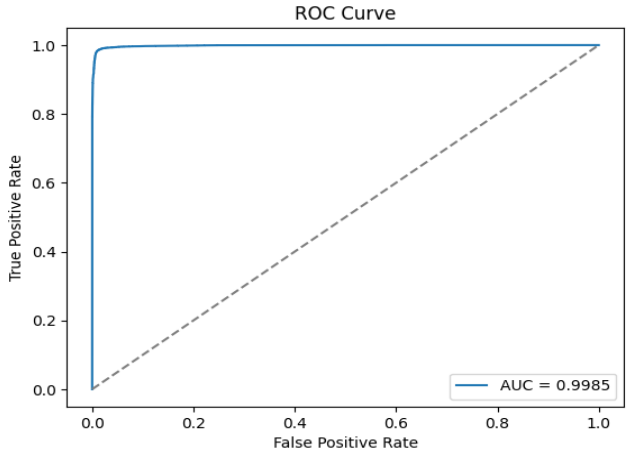

Fig. 3. The ROC curve of NetDAIL (MAE-based) evaluated on the small-scale dataset, showcasing its ability to separate normal and anomalous instances.

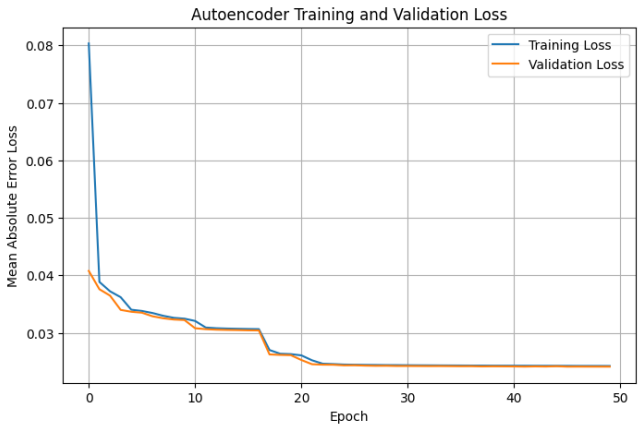

Fig. 4. Autoencoder training and validation loss.

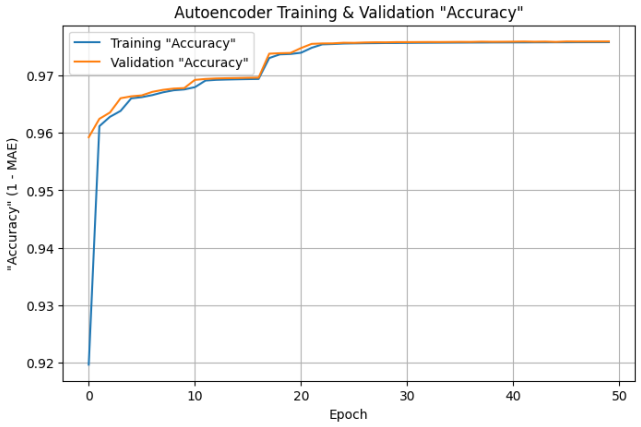

Fig. 5. Autoencoder training and validation accuracy curves across epochs.

TABLE IV. BENCHMARKING THE NETDAIL AGAINST STATE-OF-THE-ART TECHNIQUES

Year	Ref. No	Technique	Acc	F1-score
2009	[8]	Autoencoder	90.49%	91.81%
2022	[14]	GRU + DAE	90.21%	89.87%
2022	[15]	CNN + LSTM	82.6%	79.8%
2023	[21]	BIRCH-Autoencoder (BAE)	87.88%	88.46%
2024	[22]	FPCD-DBN	89.39%	89.72%
2024	[23]	BO-KNN-Bagging	82.4%	82.58%
2021	[24]	Autoencoder	90.6 %	92.26 %
2024	[25]	GANs	61%	73.5%
2025	[26]	hyperdimensional computing (HDC) techniques	91.5%	-
2025	[27]	Autoencoder	85%	84%
2025	[28]	ResNet-CNN	98.9%	-
2025	[29]	FDA	98.3%	-
NetDAIL			99 %	99 %

The experimental findings demonstrate that NetDAIL achieves high accuracy in anomaly detection. The hybrid architecture, which integrates Denoising Autoencoder-based feature learning, Isolation Forest anomaly scoring, and LightGBM classification, exhibits superior robustness and generalization across imbalanced and complex network traffic patterns. Comparative evaluation against existing models using the NSL-KDD benchmark dataset shows that NetDAIL attains an accuracy of 99 per cent and an F1-score of 0.99, outperforming conventional deep learning approaches. These results underscore the model's enhanced capacity to detect both statistical and latent anomalies, particularly in a rare or underrepresented attack. A detailed comparison with related studies is presented in Table IV. The results clearly demonstrate that the proposed hybrid model not only surpasses conventional deep learning techniques but also maintains a strong balance between detection precision and generalization. This makes NetDAIL particularly suitable for deployment in real-world intrusion detection systems, where datasets are often highly imbalanced and heterogeneous.

D. Evaluation of Generalization and Scalability

To assess the generalization capability and scalability of NetDAIL, an additional experiment was conducted using a large-scale dataset beyond the standard NSL-KDD configuration. This dataset follows the same structural format as NSL-KDD (as outlined in Table I) and was selected to emulate a real-world large-scale deployment scenario. The dataset consists of two subsets:

20 Percent Training Set.csv – a representative subset of the original KDD Cup 1999 dataset containing a smaller number of normal and anomalous records, which was used for training [30].

kddcup.data.corrected – the full corrected KDD Cup 1999 dataset, comprising millions of normal and attack records, which was reserved for testing [31].

By explicitly using one subset for training and the other for testing, this configuration avoids data leakage and enables a robust evaluation of the model's generalization performance under realistic conditions.

For the large-scale evaluation, we followed the commonly used setup in KDD Cup 1999 experiments by training the model on the 20% Training Set and evaluating on the full kddcup.data.corrected dataset. Importantly, these two files are provided as separate official subsets of the KDD Cup 1999 benchmark and contain no overlapping records, ensuring that the evaluation is performed on completely unseen data. To further ensure no data leakage, the preprocessing steps (encoding, normalization, and SMOTEENN) were applied only to the training data, and the learned transformations were then applied to the test set.

The results from this large-scale experiment confirm the adaptability, scalability, and deployment readiness of NetDAIL. Performance outcomes are summarized in Table V. The confusion matrix in Fig. 6 demonstrates strong classification performance, with a high number of true positives and true negatives, highlighting the model's effectiveness in accurately distinguishing between normal and anomalous traffic. The low number of false positives and false negatives further confirm its robustness.

TABLE V. RESULTS GENERATED FROM NETDAIL ON LARGE DATASET

Metric	Label	Precision	Recall	Acc	F1-score	AUC
MAE	Normal	0.96	0.98	0.99	0.99	0.99
	Attack	0.99	0.99			

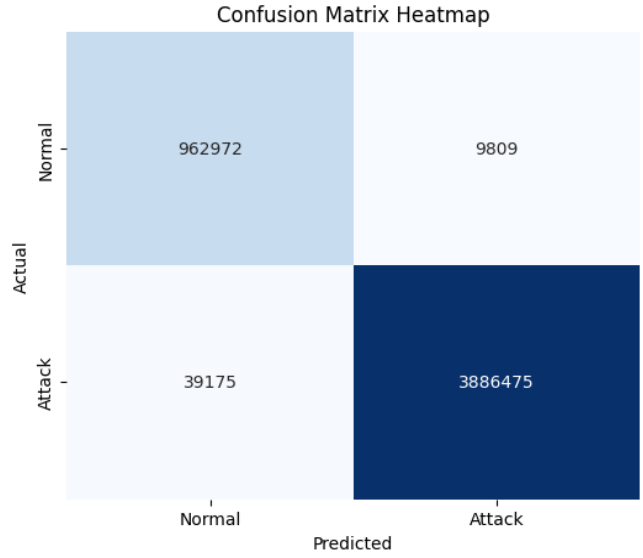

Fig. 6. Confusion matrix of NetDAIL (MAE-based) on the large-scale dataset.

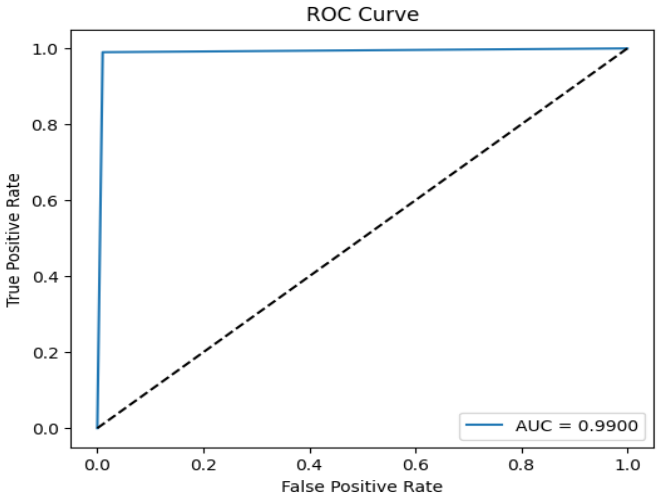

Fig. 7. ROC curve of NetDAIL (MAE-based) evaluated on the large-scale dataset, demonstrating its ability to distinguish between normal and anomalous instances.

Complementing this, the Receiver Operating Characteristic (ROC) curve in Fig. 7, exhibits a high Area Under the Curve (AUC), reflecting the model's strong discriminative ability. The steep rise toward the top-left corner of the ROC space indicates excellent sensitivity and specificity, validating NetDAIL's generalization capability.

To better demonstrate the contribution of each component in the NetDAIL pipeline, we additionally trained a baseline LightGBM model directly on the raw normalized data, without any feature extraction (DAE) or anomaly scoring (Isolation Forest). The baseline model achieved considerably lower accuracy and F1-score compared to NetDAIL's performance (99% accuracy and 0.99 F1-score). These results confirm that incorporating the DAE and Isolation Forest components significantly enhances feature representation and anomaly separability, enabling LightGBM to achieve stronger discriminative power.

These findings clearly demonstrate that NetDAIL maintains high performance even under large-scale and complex data distributions. Its consistent results across both small- and large-scale datasets indicate that the hybrid architecture—combining deep feature extraction, anomaly scoring, and supervised classification—is well-suited for deployment in real-world, high-demand intrusion detection environments.

The findings obtained from this experiment clearly demonstrate that the proposed model possesses a high degree of adaptability, enabling it to perform effectively under varying operational conditions and data distributions. Moreover, the results highlight the model's scalability, showing that it can maintain strong performance as the size and complexity of the dataset or network environment increase. These characteristics, combined with its consistent and reliable performance, indicate that the model is well-prepared for real-world deployment, even within large-scale and high-demand operational settings.

V. DISCUSSION

The experimental results demonstrate the efficiency of the proposed hybrid model, NetDAIL, in accurately detecting anomalies in network traffic. Evaluations on standard benchmark datasets, including NSL-KDD and KDD Cup 1999, indicate consistently strong performance, highlighting the model's practical relevance for real-world cybersecurity applications.

NetDAIL's hybrid architecture integrates a denoising autoencoder for deep feature extraction, an Isolation Forest for anomaly scoring, and LightGBM for supervised classification. This combination enables the model to leverage both unsupervised and supervised learning paradigms, capturing latent structures in the data while maintaining robust and reliable decision-making capabilities. The model's exceptional discriminative power is reflected in its high ability to differentiate between normal and anomalous network traffic.

By utilizing labeled attack instances, NetDAIL effectively separates subtle and rare attack types from normal behavior. The application of SMOTEENN for class balancing further enhances recall for minority attack categories, addressing a critical challenge in intrusion detection systems. These results confirm that the model generalizes well across both small- and large-scale datasets, demonstrating its adaptability to diverse network intrusion scenarios.

The model's robustness and scalability make it particularly suitable for deployment in dynamic operational environments, where network traffic patterns and attack strategies continuously evolve. Moreover, NetDAIL's hybrid design provides a strong foundation for future extensions, such as real-time intrusion detection, multi-modal data integration, and interpretable machine learning frameworks for cybersecurity. Future research may also explore incorporating human-in-the-

loop mechanisms to enhance operational decision-making and transparency.

To further demonstrate the competitiveness of NetDAIL, Table IV presents a comparative performance analysis with state-of-the-art hybrid IDS models, including CNN–LSTM, Transformer-based methods, BIRCH-AE, and GAN-based models.

NetDAIL achieves the highest accuracy (99%) and F1-score (0.99), surpassing these models by a margin of 1–4% on average.

In addition to the performance gain, NetDAIL maintains a lower computational footprint due to its lightweight structure (DAE + IF + LightGBM) compared to heavy CNN or Transformer architectures.

Overall, the findings highlight NetDAIL as a reliable, scalable, and high-performing solution capable of addressing modern network intrusion detection challenges effectively.

VI. Conclusion

Addressing the core challenges of network intrusion detection, such as high-dimensional feature spaces, class imbalance, scalability, and the detection of rare attacks, this study introduced NetDAIL, a robust hybrid framework that integrates a denoising autoencoder for deep feature representation, an Isolation Forest for anomaly scoring, and LightGBM for supervised classification. This combination was intentionally designed to leverage both supervised and unsupervised learning paradigms, enabling the model to effectively capture both statistical and latent anomalies in network traffic.

Each research objective outlined in the introduction was directly addressed and validated through the experimental results. First, the use of the denoising autoencoder successfully reduced feature dimensionality and enhanced representation quality, improving the model's ability to detect subtle deviations in network behavior. Second, applying SMOTEENN effectively mitigated class imbalance and improved the recall of minority and rare attack categories. Third, the integration of Isolation Forest contributed to better anomaly sensitivity without manual threshold tuning. The inclusion of a simple LightGBM baseline in our experiments further validates the contribution of NetDAIL's unsupervised components. The substantial performance gap between the baseline and the hybrid pipeline confirms that the exceptional results are not due to data leakage or dataset characteristics, but to the effective integration of deep feature learning and anomaly scoring. Finally, the inclusion of LightGBM provided a scalable and efficient classification mechanism, enabling the model to maintain strong performance on large-scale datasets.

Empirical evaluation on two benchmark datasets—NSL-KDD and KDD Cup 1999—demonstrated the effectiveness of the proposed framework, achieving an AUC of 0.99 on large-scale traffic while accurately identifying subtle and rare intrusions. These outcomes confirm NetDAIL's generalizability, scalability, and operational readiness for deployment in dynamic cybersecurity environments where attack strategies continuously evolve.

Future research will focus on real-time implementation, integration with multi-modal data sources, and enhancing model interpretability to support adaptive, human-in-the-loop intrusion detection systems.

An Integrated CNN, YOLOv5 and Faster R-CNN Framework for Real-Time Water Pipe Defect Detection

Chu Fu, Mideth Abisado
College of Computing and Information Technologies, National University, Manila, Philippines

***Abstract*—In the context of rapidly expanding urban water supply networks and the prevalence of pipe defects – for example, corrosion, cracks, leaks, blockages – that undermine efficiency and pose safety risks, this study presents an intelligent detection system aimed at improving maintenance accuracy and operational stability. We propose a fusion-based detection architecture combining Convolutional Neural Networks for stable multi-level feature extraction, YOLOv5 for high-speed real-time detection, and Faster R-CNN for enhanced recall of small or occluded defects. Individually, the models achieve 85.0% accuracy for the CNN extractor, 90.0% detection accuracy with 50 FPS for YOLOv5, and 86.8% recall for Faster R-CNN. Ablation experiments confirm that the fully integrated system attains superior performance—92.1% accuracy, 85.0% recall, an F1 score of 81.0, and an mAP of 85.1 at 45 FPS—demonstrating that ensemble methods harness complementary strengths to optimize detection precision and speed. Overall, our findings highlight the promise of deep learning–based ensembles for large-scale, real-time pipeline inspection, offering a foundation for future intelligent infrastructure management.**

***Keywords*—Deep learning; Convolutional Neural Network; YOLOv5; Faster R-CNN; machine vision**

I. Introduction

As an important part of urban infrastructure, the stability and safety of water pipes are directly related to the daily life of residents, industrial production, and the stability of urban operation [1][2].

Once the water supply system leaks, it will not only cause a huge waste of water resources but also may affect the normal operation of urban water supply, and even lead to serious consequences such as road collapse and environmental pollution [2, 3, 4]. According to statistics, the leakage rate of water supply systems worldwide is as high as 15%-30% [2][5][6], and a large part of this is caused by defects in the internal or external water pipes that are not detected and repaired in time. Therefore, it is of great significance to establish an efficient and accurate water-pipe detection system to reduce leakage accidents, reduce maintenance costs, and improve the operational efficiency of water supply systems. In addition, water pipe detection technology also plays a key role in many fields such as industrial safety, agricultural irrigation, and environmental protection, providing strong support for resource conservation and environmental protection [7][8].

Despite the growing importance of water pipe testing, existing testing methods still have many limitations [9][10].

At present, common water-pipe detection technologies include manual inspection, acoustic inspection, ultrasonic testing, and optical fiber sensing technology [11]. However, manual inspection relies on the experience of professionals, which is not only time-consuming and labor-intensive but also has low detection efficiency, making it difficult to cover large-scale pipe network systems. Although acoustic and ultrasonic testing can detect internal defects in pipelines to a certain extent, their sensitivity is greatly affected by environmental noise, and the detection cost is high, so it is difficult to promote and apply on a large scale. Although technologies such as optical fiber sensing provide certain real-time monitoring capabilities, they also face problems such as high cost and complex maintenance [9][12]. Therefore, there is an urgent need for an efficient, low-cost, and automated water-pipe defect detection method to compensate for the deficiency of traditional methods for detection.

Along with the development of technology, water-pipe detection technology is evolving in the direction of automation and intelligence, especially detection methods based on sensors, artificial intelligence, and computer vision have gradually become research hotspots [13][14]. Among them, the rapid development of deep learning technology provides a new solution for the detection of water pipe defects [15].

In this study, an intelligent water-pipe defect detection system based on Convolutional Neural Network (CNN), Faster R-CNN, and YOLOv5 was proposed, aiming to improve the accuracy and efficiency of detection. The system uses machine vision technology and image processing methods, combined with deep learning models, to automatically detect, classify, and locate water-pipe defects, to achieve efficient and accurate defect identification.

The results of this study will help solve many of the current challenges faced by water pipe defect detection and improve the degree of automation, accuracy, and efficiency of inspection [16, 17, 18, 19]. Intelligent detection systems can not only reduce maintenance costs, but also reduce the waste of water resources, improve the reliability of urban water supply systems, and provide technical support for the development of smart cities in the future [20][21]. In addition, this technology can also be extended to industrial pipeline inspection, oil and gas pipeline maintenance, and other fields, providing more efficient solutions for the intelligent management of various pipeline network infrastructure.

In the future, with further development of deep learning, computer vision, and Internet of Things technologies, the intelligence level of water pipe inspection systems will continue to improve, achieving more efficient and accurate defect detection and predictive maintenance, and providing a stronger guarantee for the safety and sustainable use of global water supply [21].

II. Materials and Methods

A. Purpose of the Experiment

The goal of this experiment is to build an efficient and accurate water pipe defect detection system, and use image processing and deep learning technology to realize the automatic detection and classification of water pipe surface defects, to improve the intelligent level of pipeline maintenance, reduce the cost of manual inspection, and improve the accuracy and reliability of detection.

Identification of detecting targets and data acquisition: Firstly, by analyzing the definition and classification of water pipe defects, the detection target is clarified. Water pipe defects mainly include cracks and corrosion, and different image acquisition and processing methods are required for different types of defects. In order to ensure the efficiency of the inspection, the experiment will use high-resolution camera equipment to obtain high-definition images, combined with appropriate lighting equipment, to reduce uneven lighting, shadow interference, and other problems, to obtain stable and clear defect image data.

Dataset building and enhancement: In order to improve the generalization ability of the model, the experiment will focus on constructing a high-quality water pipe defect dataset, covering two types of defects, water pipes of different materials, and image data collected in different environments. In addition, in order to enhance the adaptability of the model in complex working conditions, data augmentation techniques such as rotation, scaling, contrast adjustment, adding noise, etc., will be used to enable the model to adapt to different shooting angles, lighting changes, and environmental interference.

Deep learning model training and optimization: In the defect detection task, the experiment will use a variety of deep learning models, such as Convolutional Neural Network (CNN), YOLOv5, Faster R-CNN, etc., and train and test them on the dataset. CNN is responsible for feature extraction, YOLOv5 is suitable for real-time detection, and Faster R-CNN excels in precise target positioning. The experiment will improve the performance of the model on the validation set through cross-validation, transfer learning, hyper-parameter optimization, and other methods, so that it can maintain high recognition accuracy on different defect types.

Evaluation and optimization: In order to comprehensively evaluate the detection effect of the model, the experiment will use indicators such as accuracy, recall, and F1-score, and analyze the advantages and disadvantages of each model in depth. In addition, false detection and missed detection will be discussed in detail, the key factors affecting the detection performance will be identified, and targeted optimization plans will be proposed to further improve the accuracy and stability of water-pipe defect detection, and provide reliable technical support for practical applications.

B. Existing Datasets

In the study of water pipe defect detection, the selection and analysis of data sets are crucial. At present, the publicly available datasets of water pipe defects mainly focus on two typical types of defects: cracks and corrosion. These datasets provide a reliable data foundation and diverse sample support for the training and validation of machine learning and deep learning models. In this study, two mainstream datasets of water pipe defects were selected: the water pipe crack dataset and the water pipe corrosion dataset. The two datasets have their own characteristics in terms of sample size, image resolution, and defect feature distribution. Among them, crack defects dominate the dataset and show a variety of structures and evolutionary forms, including the following typical types:

1) Linear cracks: Extending in a straight line or near a straight line along the surface of the water pipe, their length and width vary greatly due to the aging of materials and environmental pressure.

2) Branch cracks: The main crack extends outward into multiple branches, forming a network-like structure with high complexity.

The width, depth, and morphological evolution of these cracks are affected by multiple factors such as water pipe material, internal pressure, operating time, and external environment.

In contrast, the variation of corrosion defects is mainly reflected in the depth of corrosion and the size of the affected area. Corrosion may lead to localized pitting, spreading, and even perforations, which can significantly weaken the structure of water pipes and pose a risk of leakage or even breakage.

The two water pipe defect datasets used in this study have been publicly released on the open source platform, and the link is as follows: https://github.com/chu2024/dataset2025.git.

Through in-depth analysis and comparison of the above two datasets, it helps the model to understand various defect features more accurately, to improve the robustness and generalization ability of detection. The dataset in this study is constructed by combining field collection and open-source resources, and includes pipeline defect images in different scenarios and environments, mainly covering five typical defect types, including cracks and corrosion, and also contains a certain proportion of defect-free images to enhance the generalization ability of the model. All images are captured with a high-definition camera during the actual water main inspection with a resolution of 1920x1080, ensuring that the details inside the pipes are clearly reflected.

Data sources and distribution: Acquisition part: About 2,000 images were collected in real pipelines through the robot platform, covering a variety of pipe materials (metal, plastic) and service life (new, old). Fig. 1 shows a real pipeline image.

Fig. 1. Real pipe sample image.

1) Open source: 1670 images were acquired from the public defect detection dataset.

2) Data labeling and classification: All images are professionally annotated in YOLOv5 (.txt) and VOC (.xml) formats (including bounding boxes and category labels). The distribution of defect types is as balanced as possible, with cracks accounting for 51% and corrosion accounting for 49%.

3) Data preprocessing: The acquired images were denoised and illuminated, blurry and low-quality samples were eliminated, and some images were cropped and normalized to meet the model input requirements.

4) Data partitioning: The dataset is divided into three sets; the training set as 60% of the dataset, the validation set as 20% of the dataset, and the test set as 20% of the dataset. The training set is used for model learning, the validation set is used for model tuning, and the test set is used for final performance evaluation. The distribution of defect types is consistent across each subset to avoid the impact of sample distribution bias on the performance of the model. The diversity and coverage of the dataset provide a strong guarantee for the adaptability of the model in complex scenarios, and lay a foundation for the comprehensiveness and scientificity of the defect detection task.

a) Water pipe cracks dataset: The pipe crack dataset mainly contains images of water pipe cracks – shown in Fig. 2 – in different materials and environments, and the dataset has a rich sample size, covering a variety of crack types (linear cracks, branch cracks). The width and length of the cracks have significant characteristic differences, which are suitable for training CNN models to detect cracks, as shown in Table I.

Fig. 2. Water pipe crack.

b) Water pipe corrosion dataset: The pipe corrosion dataset contains images of varying degrees of corrosion on the surface of water pipes – shown in Fig. 3 – covering multiple stages from mild to severe corrosion. Corrosion data is often characterized by irregular spots and depressions, and images are characterized by high contrast and noise. Corrosion defects also behave differently on different pipe materials, and the following is a partial sample of this dataset, as shown in Table II.

Fig. 3. Water pipe corrosion.

TABLE I. WATER PIPE CRACKS DATASET

Number	Image file name	Image resolution	Crack type	Crack width (MM)	Crack length (MM)
1	polie1379.png	1024x768	linear crack	0.5	15
2	polie517.png	1024x768	branch crack	0.7	12
3	polie536.png	1280x960	linear crack	0.6	20
4	polie1490.png	1280x960	branch crack	1.0	30
5	polie1542.png	1024x768	linear crack	0.4	10

TABLE II. WATER PIPE CORROSION DATASET

Number	Image name	Image resolution	Corrosion degree	Corrosion area (%)	Surface roughness (RA, MM)
1	fushi22.png	1024x768	severe	85%	2.0
2	fushi984.png	1280x960	severe	90%	2.0
3	fushi18.png	1024x768	medium	20%	2.0
4	fushi517.png	1280x960	medium	40%	0.7
5	fushi45.pngg	1024x768	severe	20%	2.0

Through the analysis performed earlier on two types of datasets, it can be found that the characteristic manifestations of various types of water pipe defects are significantly different, and the rational use of these datasets will provide a solid foundation for subsequent model development and defect detection. At the same time, the defect sample distribution and annotation details in the dataset also provide rich research materials for the design of optimized detection algorithms.

C. Tables to Support Experimental Design

1) Dataset segmentation table: The dataset segmentation table is used to display the segmentation strategy for the dataset of self-managed water pipe defects. With a reasonable proportion of training, validation, and test sets, the model can be trained and validated on different data. The specific segmentation scenarios are shown in the following Table III.

TABLE III. SEGMENTATION OF THE DATASET

Dataset name	Data volume (table)	Percentage (%)
Training Set	2202	60%
Validation Set	734	20%
Test Set	734	20%
Total	3670	100%

Table III presents the number and percentage of the training set – that is used for the training of the model, the number and percentage of the validation set – that is used for hyper-parameter tuning, and the number and percentage of the test set – that is used for the evaluation of the final model performance. This segmentation ensures that the data is fully utilized and reduces the risk of overfitting.

2) Algorithm performance indicator record table: The algorithm performance indicator record table is used to evaluate the performance of the different models used, especially in the water pipe defect detection task. Table IV shows the performance of each model in the task of detecting defects in water pipes through specific performance indicators, which is convenient for subsequent comparison and selection of the best model.

TABLE IV. ALGORITHM PERFORMANCE INDICATOR RECORD

Model name	Accuracy	Recall	F1 point	Average detection time（ms）
YOLOv5	0.90	0.85	0.87	30
Faster R-CNN	0.88	0.80	0.84	120
CNN	0.86	0.78	0.82	50

3) Model performance evaluation: The Model Performance Evaluation Form is used to provide a comprehensive evaluation of the final selected model, including how the model performs on the test set. The specific assessment results are shown in Table V.

Table V provides systematic support for the design and implementation of this experiment, covering many aspects such as the segmentation of the data set, the recording of experimental variables, the evaluation of algorithm performance, and the summary of the final results, which not only provides intuitive data support for the experimental results, but also provides a basis for subsequent model optimization and improvement. This enables an efficient and reliable water pipe defect detection system.

TABLE V. PERFORMANCE ANALYSIS

Model name	Test set sample size	Correct detection number	Number of error detections	Accuracy (%)	Recall (%)
CNN	200	170	30	85.0	80.0
YOLOv5	200	180	20	90.0	85.0
Faster R-CNN	200	160	40	80.0	75.0

D. Experimental Process

1) CNN model training details: Before the model is trained, the data is first fully prepared and preprocessed to ensure that the data provides useful features in the training and enables the model to learn effectively. The dataset is divided into 60%-20%-20% data, with 60% of the data used for training, 20% for validation, and the remaining 20% for testing. In terms of data preprocessing, a uniform resize was first applied to all images, and the dimensions of all images were adjusted to 640×640 pixels. In order to improve the robustness of the model, the images in the training set were augmented with data, including rotation, cropping, scaling, and brightness change operations, which could effectively enhance the model's ability to detect water pipe defects in different environments. Through these preprocessing and enhancements, the dataset has been significantly improved in terms of quantity and quality.

2) YOLOv5 training details with hyper-parameter tuning: In this study, the task of water pipe defect detection requires the use of efficient and accurate deep learning models. YOLOv5 was selected as the main detection model, which has high real-time performance and good detection accuracy. YOLOv5 is a single-stage detection model based on Convolutional Neural Network (CNN), which achieves a good balance between processing speed and accuracy compared to traditional multi-stage detection models. The v5.0 version of YOLO was used as the base model, and its architecture was partially customized according to the needs of the actual task. The YOLOv5 model consists of four main components:

a) Input: This is to handle the input image. Here, the image is converted to a fixed size image by resizing. Various data augmentation techniques are also applied to improve the robustness and performance of the model.

b) Backbone: This is used for feature extraction, CSPDarknet53 is used as the backbone network, which can effectively extract high-level image features.

c) Neck: This is for feature fusion, PANet (Path Aggregation Network) is used to optimize the effect of feature fusion and enhance the ability of small object detection.

d) Head: This is used to detect outputs, combined with the design of YOLO heads, it can output classification results, bounding box regression values, and confidence levels, as shown in Fig. 4.

Fig. 4. Sample of classification result.

3) Faster R-CNN of the training process: The choice of hyper-parameters is critical to the effectiveness of the model's training. The following hyper-parameter settings were used during model training.

4) Learning rate: During the training process, the setting of the learning rate has an important impact on the convergence speed and accuracy of the model. The initial learning rate of 0.001 was selected, and Cosine Annealing Learning Rate Scheduling was adopted, which could dynamically adjust the learning rate during the training process to avoid the phenomenon of gradient explosion or gradient disappearance.

5) Batch size: In order to improve the training efficiency and stability, 16 was selected as the number of images per batch. This batch size enables efficient training without exceeding the GPU memory.

6) Optimizer: The AdamW optimizer is used, which combines the advantages of Adam optimizer and L2 regularization, which can effectively avoid the overfitting problem and accelerate the convergence process.

7) Weight attenuation: In order to prevent overfitting, the weight attenuation is set to 0.0005, which can effectively constrain the complexity of the model.

8) Image enhancement strategy: In addition to the basic geometric transformations (rotation, cropping), the image is also changed in color (brightness, contrast, saturation adjustment), and noise is randomly added to further improve the robustness of the model.

9) Fusion model: The water pipe defect detection system based on the fusion strategy proposed in this study combines the advantages of Convolutional Neural Network (CNN), YOLOv5 and Faster R-CNN to achieve efficient identification, precise location and real-time detection of water pipe defects. The overall process is presented in Figure 5.

As shown in Fig. 5, the overall model consists of the following key modules:

1) Input image (high-definition water pipe image): The system uses an image of the inside of the water pipe collected by a high-definition camera device or inspection robot as input. These images retain detailed information about minor defects such as cracks and corrosion, and are the basis for subsequent processing.

2) CNN: The input image of the feature extraction module is first processed by the CNN to extract multi-level image features, including edges, textures, and semantic information. CNN serves as a shared feature extraction backbone network, providing basic feature representation for subsequent detection and classification modules.

3) YOLOv5: Image features extracted by real-time object detection are fed into the YOLOv5 model. YOLOv5 is a single-stage inspection model with high detection accuracy (90.0%) and high frame rate (50 FPS), which is suitable for large-scale, real-time defect detection scenarios. It is capable of quickly outputting defect type, location, and confidence level.

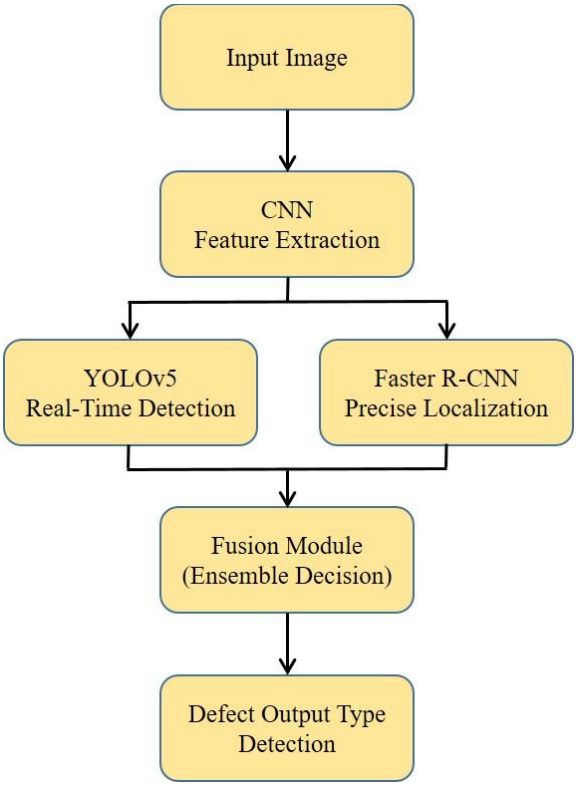

Fig. 5. Structure diagram of the fusion model.

4) Faster R-CNN: At the same time, image features are also input into the Faster R-CNN model. The model effectively improves the detection accuracy through the Regional Recommendation Network (RPN) and ROI pooling mechanism, especially for the identification of complex backgrounds, small targets or overlapping defects. It has a recall rate of 86.8% and is highly robust.

5) Fusion module: The output of YOLOv5 and Faster R-CNN will be integrated in the fusion module. By integrating factors such as scoring, position overlap and confidence, the module intelligently filters and optimizes to retain the optimal prediction results and effectively improve the overall stability and accuracy of the system.

6) Final output (defect type + location coordinates): The final output of the system includes the identified defect categories (e.g., cracks, corrosion) and their precise location

coordinates in the image. These results can be further used for network operation and maintenance decision-making, defect level assessment, and automatic maintenance path planning.

7) Ablation Study: To evaluate the contribution of each model component in the fusion system, we performed an ablation study to selectively remove each sub-model and observe its impact on detection performance shown in Table VI.

The values in Table VI confirm that YOLOv5 is a great help for real-time inspection, while Faster R-CNN improves the positioning accuracy, especially for small or overlapping defects. CNN ensure consistent feature extraction across environments. The ensemble model provides the best balance between accuracy, speed, and recall.

TABLE VI. PERFORMANCE ANALYSIS OF ABLATION EXPERIMENTS

Configuration	Accuracy	Recall	F1 Score	mAP	FPS
CNN + YOLOv5 + Faster R-CNN	92.1	85	81	85.1	45
YOLOv5	90.0	82.0	78.0	82.3	50
Faster R-CNN	89.3	86.8	72.0	81.8	32
CNN	85.0	80.0	74.0	79.5	20
YOLOv5 + CNN	91.0	84.0	80.0	84.0	42
Faster R-CNN + CNN	90.0	84.5	78.5	83.6	29

The design of this ablation test system illustrates the complementary advantages of the constituent models.

III. RESULTS

The experimental results show that there are significant differences in the performance of different models and their combinations. As shown in Table VI and Fig. 6, the fusion model (CNN + YOLOv5 + Faster R-CNN) has the best comprehensive performance, with an accuracy of 92.1%, a recall rate of 85.0%, and an F1 value of 81.0%., the mean average precision (mAP) was 85.1, and the detection speed was 45 FPS, which verified the complementary advantages of each sub-model after fusion.

Specifically, the YOLOv5 standalone model excels in real-time inspection capabilities, with an accuracy rate of 90.0% and an inspection speed of up to 50 FPS, making it ideal for real-time pipeline monitoring tasks. However, despite its slower speed (32 FPS), Faster R-CNN is more robust in complex contexts, especially in reducing false positives, missed detections, and handling target overlap, with a recall rate of 86.8%.

The ablation experiments further showed that:

1) The CNN model alone can provide basic feature extraction capabilities, but it has shortcomings in detection accuracy.

2) YOLOv5 excels at quickly and accurately identifying defects with clear and well-defined boundaries;

3) Faster R-CNN significantly improves positioning accuracy, especially when the image background is complex or there is a lot of interference.

4) It is worth noting that the fusion model not only retains the speed advantage of YOLOv5, but also introduces the localization ability of Faster R-CNN and the feature stability of CNN, which shows better performance in both standard and complex scenarios, especially in small defect detection and high-noise environments.

In summary, while YOLOv5 strikes a good balance between speed and accuracy, the fusion strategy is still better than any single model configuration across the board. Therefore, the detection system is particularly suitable for the actual pipe network inspection task, and has a broad application prospect in the application scenarios that require the coexistence of high real-time performance and high robustness.

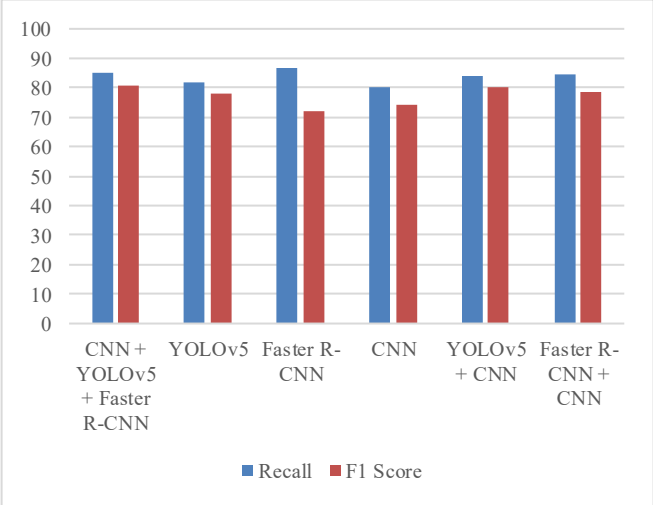

Fig. 6. Performance analysis of the fusion model.

IV. DISCUSSION

This study systematically evaluated and compared three deep learning models for water pipe defect recognition, demonstrating their complementary strengths. CNN excelled at multi-level feature extraction and, after parameter tuning, achieved 98.9 % classification accuracy on the validation set, underscoring its fundamental role in image feature analysis. As a lightweight, single-stage detector, YOLOv5 struck an effective balance between accuracy and speed, delivering 92.1 % accuracy at 45 fps – making it ideal for scenarios requiring real-time feedback. In contrast, Faster R-CNN leveraged its Region Proposal Network (RPN) and precise bounding-box regression to achieve an 86.8 % recall rate for small or overlapping defects in noisy, complex environments, highlighting its robustness against occlusion and background interference. Ablation experiments confirmed that fusing all three models outperformed any single or dual-model combination, yielding a 92.1 % accuracy, 85.0 % recall, an F1 score of 81.0, and an mAP of 85.1 %, all while maintaining 45 fps. This validates that multi-model integration can effectively combine individual advantages to boost detection precision and stability.

Despite the strong performance on binary defect detection tasks, there remains room for improvement. Future work could adopt a multi-task learning framework to jointly model defect detection, type classification, and severity assessment.

Incorporating multimodal data—such as infrared, acoustic, and thermal imaging—may further enhance adaptability in complex operating conditions. To support large-scale deployment, the system should integrate real-time feedback, dynamic optimization, and incremental learning capabilities. Moreover, embedding reinforcement learning mechanisms could enable autonomous pipeline inspection path planning and intelligent defect-repair suggestions, advancing toward a fully autonomous, intelligent, and closed-loop maintenance solution.

V. Conclusion

The proposed CNN + YOLOv5 + Faster R-CNN fusion framework successfully balances detection accuracy and real-time performance in water pipe defect recognition. Experimental results show that the integrated model surpasses individual models in key metrics – accuracy, recall, and F1 score – while sustaining a 45 fps detection speed. These findings confirm the potential of deep learning ensemble methods for intelligent, large-scale pipeline inspection and lay a solid foundation for future smart infrastructure management in urban environments.

SD-CNN: A Novel Lightweight Convolutional Neural Network Model for Fall Detection

Han-lin Shen[1], Tian-hu Wang[2]*, Hong Mu[3]
School of Electrical and Information Engineering, Jiangsu University of Technology, Changzhou, China [1, 2]
Changzhou Xutec System Technology Co., Changzhou, China[3]

***Abstract*—Aiming at the traditional deep learning fall detection model due to high computational complexity and a large number of parameters, this study proposes a lightweight convolutional neural network model, SD-CNN (SMA-Enhanced Depthwise Convolutional Neural Network), for fall detection. The model is first designed with an SMA attention module to enhance feature representation. Then, depth separable convolution is used to significantly reduce the model complexity. Finally, batch normalisation and Dropout regularisation techniques are combined to efficiently extract spatial-temporal features from temporal signals for accurate classification of fall and non-fall behaviours. The experiments use a sliding window to extract discrete features, three-axis acceleration, and synthetic acceleration as feature inputs. SD-CNN achieves 99.11% accuracy, 98.78% specificity, and 99.39% sensitivity on the homemade dataset Act, which are improved by 7.14%, 6.42%, and 9.38%, respectively, compared to CNN, while the number of parameters is reduced significantly. The effectiveness of the model is also verified by generalisation experiments on the public datasets SisFall and WEDAFall. The SD-CNN algorithm can efficiently complete the fall detection task, and the lightweight design makes it particularly suitable for wearable devices, which provides a highly efficient and reliable solution for real-time fall detection, and it has an important value for practical applications.**

Keywords*—Fall detection; lightweight; SMA attention; depth-separable convolution

I. Introduction

In the context of global ageing, falls are frequent and serious in the elderly. Not only is it the main cause of casualties, but it also often leads to hospitalisation and long-term rehabilitation, placing a heavy strain on society and the healthcare system [1]. Therefore, how to effectively detect and prevent fall events is of great relevance in the field of smart health monitoring [2].

Existing fall detection methods fall into three main categories: Machine vision-based inspection, Environmental sensor-based detection, and wearable device-based detection [3]. Machine vision-based detection relies on videos or images to determine behaviour. For example, Nana Vo et al. [4] used a lightweight network structure based on Yolov5s and OpenPose to identify video content with an accuracy of 95.43%. Mengdi Cao et al. [5] proposed a fall detection algorithm for complex scenes based on improved Yolov8, which uses video streams to identify fall behaviour in real-time, and validated on multiple video streaming datasets, achieving an average accuracy of 75.8%. However, such methods are limited in practical application by the detection range and device privacy, and cannot be widely spread. Detection based on environmental sensors relies on external sensors to obtain information about environmental changes. Wang Zhaojun et al. [6] designed an infrared array sensor system to identify human behaviour through temperature changes and used the KNN algorithm to achieve fall detection, with an accuracy rate of about 95.2%, but this approach is prone to receive interference from external environmental transformations. Detection based on wearable devices is more common. Liu Bo et al. [7] proposed a radial basis function (RBF) neural network to achieve fall detection using accelerometer data with 98.1% accuracy. Wei Jiaxue et al. [8] used an improved temporal convolutional network (TCN) to solve the problem of traditional RNN and CNN training models are complex and prone to gradient explosion phenomenon, the accuracy, sensitivity and specificity on the public and fusion datasets reached 99.43%, 98.70% and 99.34%, respectively, but the number of model parameters is relatively large, which is not conducive to the deployment on embedded devices.

To address this problem, this study proposes a lightweight fall detection model, SD-CNN, which employs Signal Modulating Attention (SMA) for processing time-series data collected by accelerometers, and which approximates the traditional self-attention mechanism [9] approach to capture long-time dependencies in the sequences through Random Feature Mapping (RFM). The use of depth-separable convolution significantly reduces the amount of computation, reduces the complexity of the feature extraction process, reduces the model parameters, and improves the computational speed, thus effectively applying to the task of fall detection.

II. Related Work

A. SD-CNN Model

The key points of building a fall detection model are the appropriateness of feature extraction and the reasonableness of the constructed network model. The traditional convolutional network model is widely recognised for dealing with image problems, but due to the limitation of its convolutional kernel size, deeper networks are usually required to achieve more satisfactory results when dealing with long time series data. To address such problems, this study successively introduces the SMA attention mechanism and depth-separable convolution. SMA attention can achieve efficient and accurate fall detection on long time series data by optimising feature extraction and reducing the number of input channels. Deep separable convolution extracts feature points by decomposing the standard convolution into two independent operations, which significantly reduces the amount of computation and the number of parameters while extracting local features in each channel. The SD-CNN model consists of three depth-separable convolutional blocks, each containing a channel-by-channel convolutional layer and a point-by-point convolutional layer. The convolution kernel sizes are all set to 3, with a step size of 1 and padding of 1 to keep the time series length consistent. The number of output channels for the three convolution blocks is 32, 32, and 64 in that order. Each convolutional block is followed by batch normalisation, ReLU activation function, and average pooling (kernel size 2, step size 2) in order to progressively compress the feature length and improve feature stability. In terms of input feature design, this study divides the three-axis acceleration sensor data into fixed-length segments in a sliding-window fashion, with each sample containing 120 time steps, three channels (x, y, and z direction acceleration), and the final input dimensions of the model are 3×128. The fall detection task mainly consists of four parts, namely, data acquisition, data preprocessing, feature extraction, and model inference, and the overall layout is shown in Fig. 1.

B. SMA Attention

Although the traditional dot product attention mechanism can highlight important features of the input data and suppress unimportant features to improve the efficiency and accuracy of feature extraction, it has a computational complexity of $O(n^2)$, and the memory requirement grows by a square as the length of the sequence increases, which is particularly unfavourable for deployment in embedded devices. Therefore, in this study, we design the SMA attention mechanism, which combines the RFM idea of the EA attention mechanism [10] to reduce the computational complexity to O(n). RFM essentially provides an efficient form of approximate integration to capture long-range dependencies, where the contribution of each time step is accumulated in the global attention score. The A_{raw} obtained after normalisation characterises the distribution of importance of each time step feature in the global context, i.e, Eq. (1):

$$A_{raw} = \sum_{l=1}^{L} Q_{rf}[:, l, :] \odot K_{rf}[:, l, :] \quad (1)$$

where, the contribution of each time step is accumulated in the global attention score. A_{raw} obtained after normalisation characterises the distribution of the importance of each time step feature in the global context; larger A_{raw} correspond to signals with a consistently high response over multiple time steps (indicating that the feature is stable and important over time in the time series); smaller A_{raw} correspond to noise or short-term fluctuations (automatically suppressed by the model). The structure of the SMA attention mechanism is shown in Fig. 2.

For input feature mapping $X \in \mathbb{R}^{b\times C\times L}$, Channel dimensionality reduction is first performed by two 1×1 convolutions [Eq. (2) and Eq. (3)]:

$$Q = \mathrm{Conv1d_q}\mathbb{R}^{b\times C_r\times L} \quad Q \in \mathbb{R}^{b\times C_r\times L} \quad (2)$$

$$K = \mathrm{Conv1d_k}\mathbb{R}^{b\times C_r\times L} \quad K \in \mathbb{R}^{b\times C_r\times L} \quad (3)$$

where, b is the batch size, C is the number of input channels, L is the length of the sequence, Cr is the number of channels after dimensionality reduction, and r is the ratio of reduction.

Then, Q^T and K^T are projected into a random feature space using a random feature matrix $R_F \in \mathbb{R}^{C_r\times F}$, and ReLU activation is applied, resulting in Eq. (4) and Eq. (5):

$$Q_{rf} = \mathrm{ReLU}(Q^T \odot R_F) \in \mathbb{R}^{b\times L\times F} \quad (4)$$

$$K_{rf} = \mathrm{ReLU}(K^T \odot R_F) \in \mathbb{R}^{b\times L\times F} \quad (5)$$

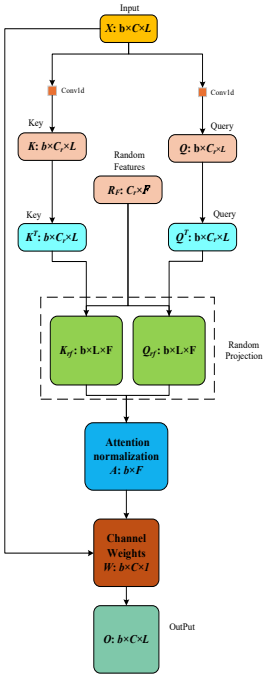

Fig. 2. Structure of the SMA attention mechanism.

where, Q^T and K^T denote the transposition of the channel dimension and the sequence length dimension, F is the number of random features. In the random feature space, Attention scores A_{raw} and normalisation factor N are then calculated as follows [Eq. (6) and Eq. (7)]:

$$A_{raw} = \sum_{l=1}^{L} Q_{rf}[:, l, :] \odot K_{rf}[:, l, :] \in \mathbb{R}^{b \times F} \quad (6)$$

$$N = \sum_{l=1}^{L} K_{rf}[:, l, :] \odot K_{rf}[:, l, :] \in \mathbb{R}^{b \times F} \quad (7)$$

where, $\odot$ is element-by-element multiplication. Then find the normalised attention fraction A, as in Eq. (8):

$$A = \frac{A_{raw}}{N+\varepsilon} \in \mathbb{R}^{b \times F} \quad (8)$$

where, ε is a small constant for numerical stability. The attention scores are further extended to all channels and averaged over the feature dimensions [Eq. (9)]:

$$W = \frac{1}{F} \sum_{f=1}^{F} A[:, f] \in \mathbb{R}^{b \times C \times 1} \quad (9)$$

Finally, the calculated weights are applied directly to the original input, as in Eq. (10):

$$O = X \odot W \in \mathbb{R}^{b \times C \times L} \quad (10)$$

C. Depthwise Separable Convolution

Depthwise Separable Convolution (DSC) consists of depth-by-depth convolution and point-by-point convolution, where depth-by-depth convolution is used to extract spatial features and point-by-point convolution is used to extract channel features [11]. Depth-separable convolution groups convolutions in feature dimensions, perform independent depth-by-depth convolution for each channel, and aggregate all channels using a 1x1 convolution (pointwise convolution) before output. This approach reduces the convolutional dimension and can effectively reduce the convolutional kernel parameters and unnecessary computations. The DSC convolutional network structure is shown in Fig. 3.

The input feature map size in Fig. 3 is DE×DF, the number of input channels is M, the size of the convolution kernel is DK, and the number of output channels is N. If the same number of channels is output using an ordinary convolutional product network, the number of parameters is DK×DK×M×N, whereas when using a depth-separable convolutional network, the number of parameters is DK×DK×M+M×N, The number of parameters is only $\frac{1}{N} + \frac{1}{D_k^2}$ times that of a normal convolution. As DK and N increase, the number of covariates of DSC relative to conventional CNN decreases dramatically.

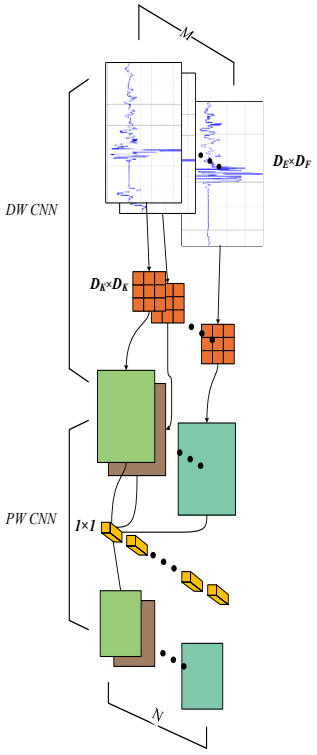

Fig. 3. Depth-separable convolutional network structure.

III. Experimental Data and Analysis

A. Datasets and Experimental Environments

There are three datasets in this study. The first one is the homemade dataset Act, and the data in the Act dataset is collected by the mpu6050 sensor. The stm32f103c8t6 is used as the main control chip, and the data sampling frequency is 50Hz. The collection was completed by 12 volunteers, who consisted of 12 young people on whom the sensor was mounted on the left wrist. The dataset contains 5 fall activities (falling backwards, falling forwards and landing on the knee, falling forwards, failing to get up from a sedentary position resulting in a fall, and falling from a standing position) and nine non-falling activities (walking, jogging, sitting down, trotting, going up the stairs, going down the stairs, opening and closing doors, applauding, and jumping), a total of 4,200 data

items are included. The dataset training set, test set and validation set are divided in the ratio of 8:1:1.

The remaining two datasets are the public datasets WEDAFall and SisFall [12]. The WEDAFall dataset equipment samples primarily at 50Hz, and data collection was done by 31 volunteers, the volunteers consisting of 20 young people and 11 older people, collected data via sensors placed on their wrists and contained a total of 3,719 pieces of data on 8 fall activities and 11 non-fall activities. The SisFall dataset device had a sampling frequency of 200Hz, and data collection was done by 38 volunteers, consisting of 23 young people and 15 older people, who collected data via sensors placed on their waists, containing a total of 4,510 pieces of data, capturing 15 fall activities and 19 non-fall activities. The specific data distribution is shown in Table I.

The deep learning framework for the experiments in this study is Pytorch, the training environment is a 64-bit Windows 11 operating system, the CPU is i7-12650H, the graphics card uses RTX-4060, the RAM is 16GB, and the code running environment is Python 3.8.

TABLE I. DATASET INFORMATION

	Non-Fall	Fall
Act	2000	2200
WEDAFall	2319	1400
Sisfall	2935	1575

B. Performance Indicators

For fall detection, the accurate identification of fall events is very important, and there are three evaluation metrics used in this study, which are accuracy, sensitivity, and specificity. Accuracy is an important measure of the model's overall classification ability, indicating the number of samples correctly predicted by the model as a proportion of the total number of samples. The equation is as follows [Eq. (11)]:

$$Acc = \frac{TP+TN}{TP+TN+FP+FN} \tag{11}$$

where, TP is True Positive, TN is True Negative, FP is False Positive, and FN is False Negative.

Sensitivity and specificity, on the other hand, respond to the model's ability to distinguish between positive and negative samples. The equation is as follows [Eq. (12) and Eq. (13)]:

$$SP = \frac{TN}{TP+FN} \tag{12}$$

$$SE = \frac{TP}{TN+FP} \tag{13}$$

where, SP is specificity and SE is sensitivity, specificity and sensitivity are complementary to each other, the higher the sensitivity indicates that the model has a higher recognition rate for fall events, and the two together measure the model's ability to discriminate on positive and negative class samples.

C. Data Preprocessing

The raw triaxial acceleration components (*ax, ay, az*) are projections to the sensor's own coordinate axes and are highly dependent on its spatial attitude. Using this data directly, the model has to learn not only the motion itself, but also the complex relationship between the motion patterns and the changing sensor poses. This double learning burden increases model complexity and may impair generalisation capabilities, especially in conditions where sensor poses are unknown or changing. According to vector theory, the modulus of a vector does not change with the rotation of the coordinate system [13]. In other words, no matter how the sensor is rotated, the calculated acceleration magnitude S is constant as long as the magnitude of the total acceleration it senses remains constant.

Therefore, this study uses the acceleration amplitude as the feature, and this approach can effectively eliminate the interference caused by the sensor attitude change, making the feature robust to the sensor installation position and orientation. Acceleration amplitude indicates the size of the acceleration. The amplitude of the acceleration of the human body movement state reflects the intensity of the human body movement, which is defined as shown in Eq. (14):

$$S = \sqrt{a_x^2 + a_y^2 + a_z^2} \tag{14}$$

1) Sliding window algorithm: To extract the temporal characteristics of the data, a sliding window strategy is used. For dynamic behaviours with long duration, a larger window allows for complete capture of their signals [14]. However, blindly increasing the window size is not optimal and may lead to increased computational complexity or failure to accurately capture behavioural changes at shorter times. Therefore, a reasonable choice of window size is essential to balance the completeness of timing information with computational efficiency.

A complete fall consists of three main phases: the imbalance phase, the falling phase, and the contact with the ground phase, as shown in Fig. 4. The duration of these phases and is approximately 2s to 3s, respectively, in order to unify the size of the input data, this study makes the window able to cover a complete information of the fall event by setting the window size to 120 and the window sliding step to 10, and splits the time series into multiple fixed-length sub-sequences through the window sliding, and this method overcomes the situation that different behaviours may span different time periods, and at the same time, the model provides a sufficiently large number of training samples, which makes full use of the time series data characteristics and enables the model to capture long-time dependencies.

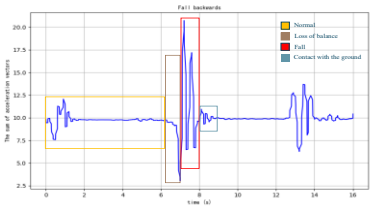

Fig. 4. Analysis of backward falling activities.

2) Low-pass filtering: Accelerometer sensors are prone to receive external noise interference when collecting data, and it

can be seen through spectral analysis that accelerometer noise is usually high-frequency noise. The frequency of human motion signals is low, with the frequency range of daily activities such as walking and running typically ranging from 0.5 Hz to 5 Hz, and the frequency of instantaneous acceleration changes for falls typically ranging from 1 Hz to 20 Hz, as shown in Fig. 5.

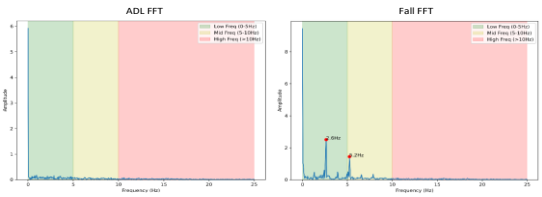

Fig. 5. Spectral analysis of human activity FFT plot.

In this study, a Butterworth low-pass filter is used to remove high-frequency noise from acceleration sensor data, which eliminates the need to rely on a physical model of signal generation and effectively reduces the interference of noise with subsequent detection tasks. After the cut-off frequency is processed, the data becomes smoother and retains the data features to have a better performance in training, as shown in Fig. 6.

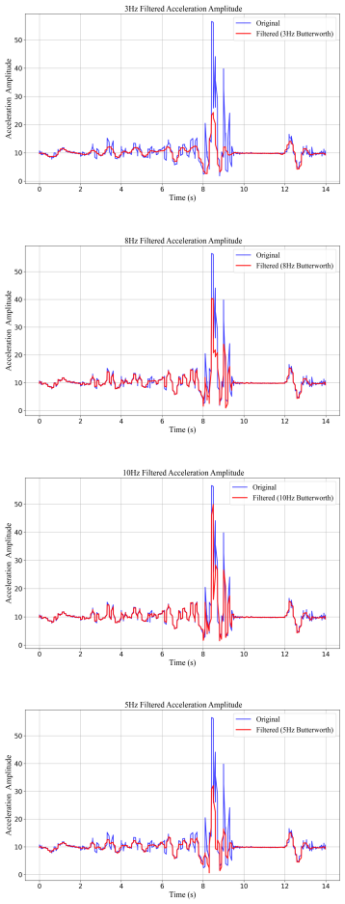

Fig. 6. Comparison of the results of Butterworth low-pass filter processing.

After comparative experiments, it was found that the model was best trained when the cut-off frequency was set to 5.5 Hz, effectively removing the interference from the sensor (see Table II).

TABLE II. COMPARISON OF TEST RESULTS

Filtering Frequency	Acc%	SP/%	SE%
\	96.34	96.25	97.11
2.5Hz	98.31	97.26	98.78
5.5Hz	**99.11**	**98.38**	**99.39**
8Hz	98.42	98.21	99.01
10Hz	97.73	96.94	98.34

IV. RESULTS

A. Comparative Experiments on Correlation Models

In order to comprehensively evaluate the performance of the proposed model and verify its effectiveness in fall detection tasks, a series of comparative experiments is designed in this study. Traditional detection methods and several state-of-the-art deep learning models were selected, including Threshold Analysis (Threshold) [15], Artificial Neural Network (ANN) [16], Convolutional Neural Network (CNN) [17], Temporal Convolutional Network (TCN) [8], Long Short-Term Memory Networks (LSTMs) [19], Gated Recurrent Neural Network (GRU) [18] and Bidirectional Long Short-Term Memory Network (Bi-LSTM) [19]. They are trained and tested on the same dataset and experimental conditions. These models were chosen because of their wide range of applications in processing time-series data and feature extraction. Through experimental comparisons, the SD-CNN model proposed in this study improves the accuracy, specificity and sensitivity by 15.31%, 16.29% and 9.38%, respectively, compared with the traditional detection method, Threshold. Compared with several other state-of-the-art deep learning models, the model in this study has the smallest number of parameters while maintaining the highest accuracy, specificity and sensitivity. This is a good indication that the SD-CNN model performs more superior in terms of classification accuracy and robustness. The specific data are shown in Table III.

TABLE III. COMPARISON OF MODELS

	Acc%	SP/%	SE%	Params	FLOPs
Threshold	83.80	89.00	83.10	/	
CNN	91.97	92.36	90.01	28480	14.6M
LSTM	93.94	92.44	95.73	46754	37.8M
GRU	95.70	87.50	96.80	47856	38.2M
Bi-LSTM	96.73	99.33	95.26	85866	42.5M
TCN	98.43	99.13	98.27	197,120	39.7M
ANN	94.02	93.20	94.21	271330	124.4M
SD-CNN	**99.11**	**98.78**	**99.39**	4076	0.97M

B. Cross-Dataset Evaluation

In order to comprehensively assess the effectiveness and usefulness of the proposed model in this study, avoid overfitting of the model to specific training data, and validate its generalisation ability on different data sources, generalisation experiments across datasets are designed and implemented in this section. In this study, two public datasets, SisFall and WEDAFall, which are widely used in the field of fall detection, are selected for testing, aiming to examine the performance of the models when confronted with new data that is different from the source of the training data. The experimental environment is consistent with "3.1" of this study. As can be seen from Table IV, SD-CNN improves accuracy, specificity, and sensitivity by 6.92%, 6.23% and 7.34%, respectively, over CNN on the WEDAFall dataset. On the SisFall dataset, the accuracy, specificity, and sensitivity are improved by 6.38%, 8.89% and 8.42%, respectively, over CNN.

TABLE IV. GENERALISATION EXPERIMENTS

Models	WEDAFall			SisFall		
	Acc%	*SP/%*	*SE%*	*Acc%*	*SP/%*	*SE%*
CNN	91.34	91.98	90.44	92.78	89.65	90.18
SD-CNN	**98.26**	**98.21**	**97.78**	**99.16**	**98.54**	**98.60**

V. DISCUSSION

The SD-CNN neural network architecture proposed in this study aims to achieve efficient and accurate human activity recognition, especially fall detection. The model achieves significant lightweighting at the model structure level by integrating deeply separable convolutions to reduce the computational effort and incorporating the SMA attention mechanism to dynamically focus on key features. The experimental evaluation results show that SD-CNN not only has significant advantages in terms of the number of model parameters and the expected computational resource consumption, but also outperforms other models in terms of key performance indicators, including 99.11% accuracy, 98.78% specificity, and 99.39% sensitivity. This proves the effectiveness of the lightweight architecture proposed in this study. Nevertheless, this study still has some limitations. Although SD-CNN shows good computational efficiency on resource-constrained devices, it still needs to be further optimised in scenarios with extreme low power consumption or higher real-time requirements. Second, the design of the attention mechanism in this study is still a relatively simplified and approximate form, and its performance differences in multi-channel and multi-modal data have not yet been fully explored.

VI. CONCLUSION

The main contribution of this research is to provide a lightweight activity recognition model, SD-CNN that balances efficiency, performance, and robustness, which is capable of recognising human activities effectively, especially in fall detection tasks. In the future, we will continue to explore this model by extending it to multimodal sensor data fusion, investigating more efficient attentional mechanisms, and validating it in larger and more diverse groups of people and scenarios to further advance its translation into practical applications.

Efficient Lightweight Detection and Classification Method for Field-Grown Horticultural Crops

Yaru Huang[1], Hua Zhou[2], Zhongyi Shu[3]*
School of Cyberspace Security, Software Engineering Institute of Guangzhou, Guangzhou, China [1, 2]
Zhongnan University of Economics and Law, Wuhan, Hubei, China[3]

***Abstract*—As the core carrier of human food supply and agricultural economy, manual management in large-scale crop cultivation faces bottlenecks such as low efficiency, high cost, and difficulty in standardization. There is an urgent need for computer vision technology to realize automated detection and growth stage classification. However, most existing algorithms rely on high-performance GPUs for operation, resulting in high hardware costs, which makes it difficult to popularize them in low-end agricultural edge devices (e.g., embedded controllers, low-cost industrial computers). This study proposes a lightweight crop detection and classification model, Lite-CropNet. It builds a neural network architecture based on the CSPDarknet backbone network, designs a concise decoder, and adopts four-scale detection heads to adapt to crop targets of different sizes, balancing high accuracy and lightweight characteristics. Using tomatoes as the experimental object, tests on the TomatOD dataset (simulating real greenhouse environments) show that Lite-CropNet outperforms advanced methods, with a mean Average Precision (mAP)@0.5 of 85.7%. Under the conditions of the GTX 1650 GPU and 640×640 resolution, the Frame Per Second (FPS) reaches 76.9, and the model size is only 4.4M. This neural network model can efficiently complete tomato detection and maturity classification, and its architecture and design can also be transferred to crops such as potatoes and strawberries, providing a cost-effective and highly universal automated solution for agricultural production.**

Keywords*—Computer vision; neural network; object detection and classification; lightweight; horticultural crops

I. Introduction

In large-scale agricultural production, accurate detection and growth stage classification of crops are core links for yield assessment, quality control, and automated management. Whether for vegetable and fruit crops such as tomatoes and potatoes, or food crops such as wheat and corn, real-time monitoring of their growth status directly affects production efficiency and economic benefits. With population growth and the development of agricultural intensification, models such as greenhouses and large-scale field cultivation have been widely applied [1]. However, traditional manual detection methods, limited by low efficiency, long time consumption, and high cost, can hardly meet the management needs of large-scale and multi-variety crops [2], [3].

With the development of computer vision and deep learning technologies, the advancement of image recognition technology in recent years has enabled Convolutional Neural Networks (CNNs) to be widely used in deep learning [4], becoming an important method for image classification, object detection, and recognition. Especially in the agricultural field, deep learning models based on the CNN architecture have been gradually applied [5], [6], [7] due to their high accuracy in image classification and object detection tasks. At this point, how to collect these images for deep learning training is a question that researchers should consider. Currently, commonly used methods include satellite remote sensing, unmanned aerial vehicles (UAVs), fixed platforms, and unmanned vehicles. These devices have their own advantages and disadvantages: satellite remote sensing systems are suitable for long-distance and large-scale monitoring but have relatively low image resolution, making it difficult to capture objects at the small organ level [8]; UAVs are usually used for large-scale field monitoring [9]; these two technologies are suitable for long-distance shooting and have high costs. Fixed platforms are installed at fixed positions and are more suitable for monitoring small-scale areas. In contrast, unmanned vehicle technology has shown excellent performance in large-scale farmland or greenhouses—it can not only adapt to the detection of underlying fruits of hanging crops such as tomatoes but also meet the close-range image collection of low-growing crops such as potatoes, providing data support for high-precision detection of multi-variety crops.

However, existing crop detection and classification technologies still face two core challenges: First, insufficient scene adaptability—different crops have significant differences in growth forms (e.g., hanging tomatoes, creeping potatoes, clustered strawberries) and appearance features (color, shape, size). In addition, the field environment has interferences such as light changes and occlusions (overlapping of leaves, branches, and fruits), making it difficult for a single model to adapt to multi-variety crops. Second, high hardware dependence—most existing models require high-performance GPUs for support, with large parameter scales and high computational costs, which cannot be deployed in low-end agricultural edge devices (e.g., embedded controllers, low-cost industrial computers), limiting the large-scale application of multi-variety crop detection technologies. Bathini and Usha Rani [10] also pointed out in their review on the application of artificial intelligence in agricultural crop yield analysis that although current deep learning models perform well in crop management, yield prediction, and other fields, they generally have problems of high dependence on data quality and insufficient adaptability of lightweight models.

To address this challenge, this study adopts the TomatOD dataset [11], a highly specialized and innovative dataset designed specifically for tomato fruit object detection and

*Corresponding author.

classification. Collected in a real greenhouse environment, it includes low-light conditions and long-distance shooting scenarios, providing challenging scenes for the model and helping it better adapt to real-world applications. Against this background, the study proposes the Lite-CropNet model, whose core differences in mathematical architecture from existing methods are as follows: 1) Feature extraction: A multi-stage structure of $Ck(m) - Pk(m)$ is adopted to output multi-scale feature maps with 32/64/128/256 channels; 2) Loss function: Smoothed Intersection over Union (SIoU) loss (including angle cost $\Delta = \sum_{t=x,\gamma} (1 - e^{-}{}_{\gamma\varrho t})$ and shape cost $\Omega = \sum_{t=} w,h\ (1 - e^{-w}{}_{t})^{th}$) is introduced; 3) Lightweight: The parameter computation amount is controlled to 4.4M according to the formula $Params = i \cdot (k \cdot k) \cdot o + o$ (where i is input size, k is convolution kernel, o is output size), which is only 2.8% of the DETR model (158M), solving the problem of high hardware dependence. While being lightweight, Lite-CropNet maintains high accuracy, with a mean Average Precision (mAP) of 85.7%. Notably, Lite-CropNet has only 4.4M parameters, and under the image resolution of 640×640, it achieves an excellent frame rate of 76.9 Frames Per Second (FPS) on the low-cost GTX 1650 GPU. This enables Lite-CropNet to have wide applicability in real-time applications and provides a cost-effective and efficient automated solution for agricultural production.

In summary, the main contributions of this study are threefold: 1) Lite-CropNet: a novel deep convolutional network with a lightweight encoder and a decoder that effectively processes encoded features, alleviating the problems of information loss and degradation. 2) Innovative use of four detection heads of different scales, which not only has excellent detection performance for medium and large target crops such as tomatoes but also can accurately identify other small clustered crops, improving the model's crop variety adaptability. 3) High real-time efficiency is reported on low-cost devices, providing an effective and economical solution for the application of modern high-throughput plant phenotyping platforms.

The structure of this study is arranged as follows: Section I (this section) introduces the research background. Section II presents related work by researchers and highlights the problem statement. Section III provides a detailed description of the Lite-CropNet model. Section IV introduces dataset details, challenges, and experimental design. Section V conducts experiments and performs comparative analysis with other models from multiple dimensions. Section VI discusses the research. Section VII draws the conclusions of this research and proposes future work.

II. Related Work

In recent years, deep learning models based on Convolutional Neural Networks (CNNs) have been widely used in agricultural crop detection and classification tasks. Researchers have carried out explorations around "improving accuracy", "adapting to scenes", and "optimizing efficiency", forming research results in multiple directions. In terms of crop and weed detection and classification, Ahmad et al. [12] proposed a detection model based on Vision Transformer (ViT). Through pixel-level annotation training of high-resolution UAV images, it overcomes the problem of similar appearance between crops and weeds, achieving a classification accuracy of 89.4%, which is significantly better than traditional models such as UNet and Fully Convolutional Network (FCN). Zhang et al. [13] further proposed the LMS-YOLO11n lightweight multi-scale weed detection model. Through the design of FastGLU feature extraction module and Attention Hierarchical Feature Pyramid Network (AHFPN) feature fusion network, the mAP is increased by 2.5% on the CottonWeedDet3 dataset, while the model parameters and computational complexity are reduced by 37% and 26% respectively. Reedha et al. [14] used Transformer neural networks to process high-resolution UAV images, further optimizing the classification accuracy of weeds and crops. López-Correa et al. [15] designed an intelligent weed management system in tomato fields, providing technical support for precise weeding in the field.

In terms of crop organ and maturity detection, Mu et al. [16] proposed a tomato detection model based on Faster R-CNN and ResNet-101. By transferring learning from the COCO dataset, it can automatically detect intact green tomatoes (ignoring occlusion and growth stages), with an average precision of 87.83% on the test set. Su et al. [17] improved the SE-YOLOv3-MobileNetV1 network, introduced a channel attention mechanism, and could distinguish four tomato maturity levels, with an average precision of 87.7%. Rahim et al. [18] used Faster R-CNN to realize tomato flower detection and counting in greenhouses. Rahim et al. [19] further quantified the number of grapevine inflorescences and flowers, providing data for yield prediction. Suh et al. [20] realized the classification of sugar beets and potatoes through transfer learning, adapting to field scenarios. Nkemelu et al. [21] used a deep CNN to complete crop seedling classification, solving the problem of seedling stage recognition.

In terms of data collection, commonly used devices include satellite remote sensing, UAVs, fixed platforms, and unmanned vehicles [8], [9]. Remote sensing is suitable for large-scale areas but has low resolution; UAVs have high costs; fixed platforms are suitable for small-scale areas; unmanned vehicles are suitable for image collection of various crops such as tomatoes and potatoes. Tsironis et al. [11], [22] constructed the TomatOD dataset, which contains 277 images and 2,413 tomato samples, annotates three maturity stages, and covers complex scenarios such as light changes and occlusions, with good challenging properties.

Although existing studies have made progress, there are still three major bottlenecks: First, poor scene adaptability—most models rely on ideal datasets and are difficult to cope with complex field environments such as low light and high occlusion. Second, high hardware dependence—models such as DETR [23] and Faster R-CNN [24] have large parameter sizes (DETR reaches 158M), making it difficult to deploy them on agricultural edge devices. Third, weak multi-variety adaptability—existing studies mostly focus on a single crop or task, and do not fully consider the morphological differences between crops (e.g., hanging tomatoes, clustered strawberries), making it difficult to achieve universal detection.

To address the above problems, this study proposes Lite-CropNet, achieving the following breakthroughs: In terms of lightweight design, through multi-stage feature extraction and a concise decoder, the number of parameters is controlled at 4.4M (only 2.8% of DETR), adapting to low-end devices such as GTX 1650 and J4125. In terms of scene robustness, training is conducted based on the TomatOD dataset, and the SIoU loss function (including angle and shape costs) is introduced to improve adaptability to complex field environments. In terms of multi-variety detection capability, an innovative four-scale detection head is designed to support various crops such as tomatoes (medium and large-sized) and strawberries (small clustered), reducing the cost and complexity of multi-variety deployment.

III. Materials and Methods

This section provides a detailed introduction to the design of the Lite-CropNet deep learning framework for crop detection and classification.

A. Lite-CropNet Model Design

In crop detection and classification, the model is required to have higher robustness due to the influence of various natural factors and imaging from different shooting angles. Moreover, considering the deployment needs of edge devices in the context of plant science, the model is also required to be lightweight. Therefore, in the model architecture design, both aspects are taken into account: while reducing parameters, the performance of the model is maintained, and the Lite-CropNet model is designed, which consists of three parts. The Encoder (feature extraction network) is responsible for extracting image features; after feature enhancement of the feature maps, the Decoder combines, utilizes, and decodes the features from the Encoder, aggregates low-level spatial features and high-level semantic features, and improves the recognition accuracy of objects of different scales. Finally, the features are transmitted to the Detector for detection, generating object bounding boxes with coordinates, categories, and confidence levels. The overall architecture of the Lite-CropNet model is shown in Fig. 1, and the global architecture of Lite-CropNet and its optimization are introduced below.

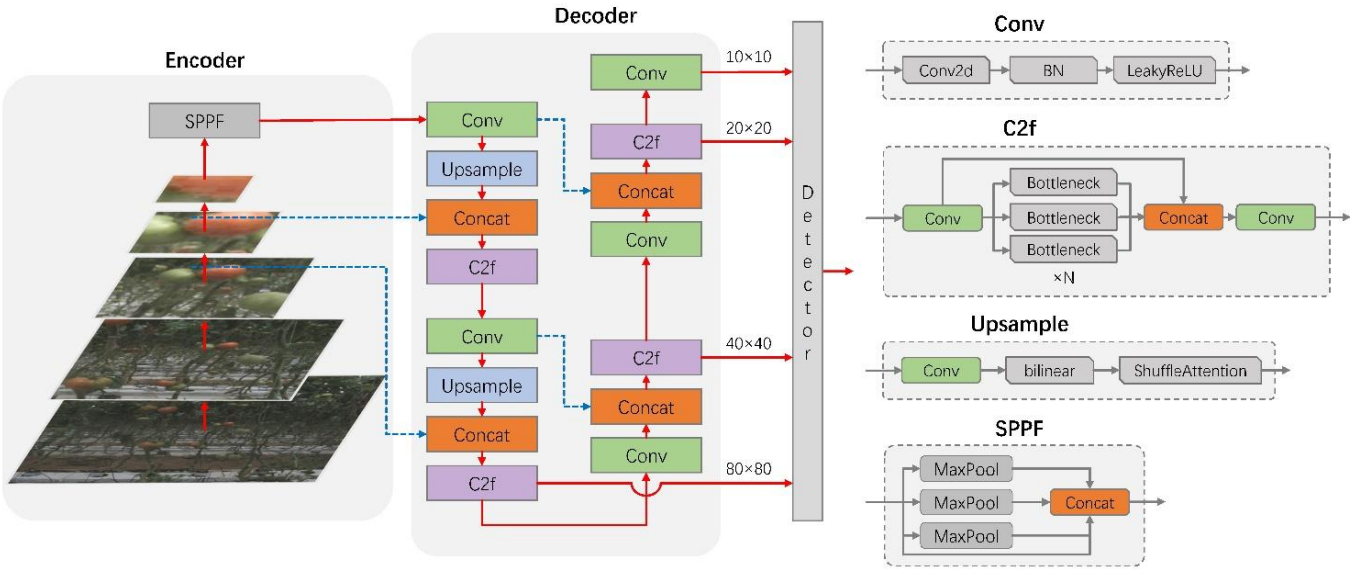

Fig. 1. Lite-CropNet model structure and module details.

1) Encoder: For the encoder part, the general structure of Cross Stage Partial Darknet (CSPDarknet) [25] is adopted and its design is retained. First, an RGB image $I \in R^{H\times W\times 3}$ is given as input, where H and W represent the height and width of the output feature map, respectively. The entire Encoder is composed of 5 convolutional layers and 4 feature extraction layers, specifically defined as Eq. (1):

$$C3(16) - C3(32) - P1(32) - C3(64) - P2(64) - C3(128) - P3(128) - C3(256) - P4(256) \quad (1)$$

Here, $Ck(m)$ denotes a 2D convolutional layer with m channels and $k \times k$ filters, all with a stride of 2; $Pk(m)$ denotes the k^{th} feature extraction layer that outputs m channels. By inserting CSPLayer [26] at different stages to extract features, 32, 64, 128 and 256 channels are output, generating feature maps at different stages. After the last feature extraction layer (P4), a Spatial Pyramid Pooling - Fast (SPPF) [27] module is introduced. The number of input channels of this module is equal to the number of output channels of the last feature layer ($C_{input} = 256$), and the kernel size is $K_{SPPF} = 5 \times 5$. Without changing the size of the feature map, pooling is performed on the feature map at different scales, which helps the network better capture the semantic information of various targets.

2) Decoder: In the design of the Decoder, first, a convolutional layer with a kernel size of 1×1 is used to compress the 256-channel feature map extracted by the SPPF in the Encoder to 128 channels, reducing computational complexity while retaining key features. Subsequently, upsampling is performed to increase the spatial resolution of

the feature map, which is then concatenated with the feature map of P4. A Cross Stage Partial Fusion (C2f) module [28] is introduced to optimize the feature representation. Next, the same operation is carried out again, and the result is concatenated with the feature map of P3. Finally, a convolution with a stride of 2 and a kernel size of 3×3 is further connected, and the result is concatenated with the previous feature maps to form a more optimized feature representation. In this process, emphasis is placed on the utilization of P2 and P3 feature maps because they have a suitable scale for object detection.

Another important design of the Lite-CropNet network is to add a prediction head to detect ultra-large targets while simplifying the process of adding detection layers. During the inspection of the dataset, it was found that some images contain ultra-large crop targets, which also exist in practical applications. Therefore, a convolution module with a stride of 2 and a kernel size of 3×3 is directly added after the third feature map passed to the head. This innovation effectively improves the detection ability of ultra-large targets without significantly affecting the overall computational complexity of the model. Through gradual feature fusion and representation optimization (without significantly affecting the overall computational complexity of the model), the decoder finally transmits four feature maps of different sizes to the detection module (Detector) to output the final object detection results. The design of the Decoder has clear objectives in each step of the operation. From channel compression, upsampling to feature concatenation, all are aimed at comprehensively utilizing the sufficiently deep encoded feature layers in the encoder to respond to more abstract information, and combining an adaptive strategy to restore spatial resolution and improve the detection accuracy of targets of different scales.

B. Activation Function

The selection of the activation function is of great significance in neural networks. It can introduce non-linear factors into the neural network and improve the model's expressive ability. In the Lite-CropNet model, attempts were made to use SiLU [29], ReLU [30], and LeakyReLU [31] activation functions, and their performances were compared. Finally, the more optimal LeakyReLU activation function was selected.

SiLU is a smooth and differentiable activation function with non-monotonicity, which can more easily capture complex patterns. Its non-linear definition is Eq. (2):

$$SiLU(x) = x \cdot \sigma(x) \tag{2}$$

In contrast, ReLU is widely used in neural networks and has simple computation, which helps to improve the computation speed of the network. It can effectively alleviate the problem of gradient disappearance and introduce sparse activation during the training process, making the network easier to optimize. Its non-linear definition is Eq. (3):

$$ReLU(x) = max(0, x) \tag{3}$$

where, x is the input. ReLU can effectively alleviate the problem of gradient disappearance and introduce sparse activation during the training process, making the network easier to optimize. However, it should be noted that ReLU has the problem of neuron death, that is, the output is zero when the input is negative, resulting in some neurons not being activated. To solve the dead neuron problem of ReLU, LeakyReLU introduces a small negative slope for negative inputs while maintaining simplicity. LeakyReLU retains the advantages of ReLU and provides a stronger gradient signal by allowing small negative gradients. This helps to avoid the problem of gradient disappearance during training while maintaining the computational efficiency of the model. The equation of LeakyReLU is Eq. (4):

$$LeakyReLU(x) = \begin{cases} x\ (x > 0) \\ \alpha x\ (x \leq 0) \end{cases} \tag{4}$$

where, α is a small positive slope, such as $0.1, 0.01$, or even smaller.

In practical tasks, the selection of the activation function usually depends on specific needs and experimental results. In the Lite-CropNet model, considering the need to enhance the learning ability, LeakyReLU was finally selected as the activation function because it solves the dead neuron problem, has a lower computational cost compared to SiLU, and has a more stable training process compared to ReLU.

C. Attention Mechanism

The attention mechanism is widely used in computer vision technology. It is a cognitive process that selectively acts on relevant information, enabling the model to ignore redundant information and focus more on useful information. Hu et al. [32] proposed the Squeeze-and-Excitation (SE) attention mechanism, which focuses on channel information and can enhance the channel features of the input feature map. However, due to the introduction of the FC fully connected layer, its computational complexity is relatively high. Woo et al. [33] proposed the Convolutional Block Attention Module (CBAM) attention module. Compared with the SE module, CBAM adds a spatial attention mechanism and focuses on regions of interest. The Efficient Channel Attention (ECA) attention mechanism [34] with global context self-attention generates weights by using global context information, allowing the model to better capture context information, but its computational complexity is relatively high. Shuffle Attention (SA) [35] generates context information by rearranging input features, enhances the robustness of the model to spatial changes, and optimizes the allocation of attention weights through feature grouping and rearrangement. Its core equation is Eq. (5):

$$F_{SA} = Shuffle(Conv2(Conv1(F_{in}, \frac{C}{g}))) \tag{5}$$

where, F_{in} is the input feature map, C is the number of input channels (such as 128, 64), g is the number of groups, $Conv1$ is a 1×1 convolution (compressing the channels to $\frac{C}{g}$), $Conv2$ is a 3×3 convolution (restoring the channels to C), and $Shuffle(\cdot)$ is the feature rearrangement operation. Yu et al. [36] proposed the Mlt_ECA attention module, which is a dimension-free local cross-channel interaction strategy. It generates feature weights by performing 1D convolution

operations, and the convolution kernel size K is adaptively determined by the mapping of the channel dimension C, which is defined as Eq. (6):

$$K = \left|\frac{\log_2(c)+\beta}{\alpha}\right|_{odd} \quad (6)$$

α and β are adjustable hyperparameters, and "odd" indicates that K takes an odd number.

Considering that most of the fruit target areas in the dataset are small and there is a lot of background, which is not helpful for the detection and classification of crop fruits. Therefore, to reduce the impact of the background and pay more attention to the required feature information, during the design process of the Lite-CropNet model, attempts were made to compare the effects of different attention mechanisms and apply them to different stages of the model. A large number of experiments were conducted, and it was found that the experimental results were better when the Shuffle Attention mechanism was applied to the upsampling and downsampling modules. The performance differences of different attention mechanisms will be verified in the ablation experiments of the article.

D. Loss Function

As a metric to calculate the error between the forward propagation result of a neural network in each iteration and the ground truth, the loss function guides the weight adjustment in backpropagation. In the implementation of Lite-CropNet, various commonly used loss functions were tested. For the bounding box loss function, the Complete Intersection over Union (CIoU) loss function was initially considered, with its calculation methods shown in Eq. (7) and Eq. (8):

$$CIoU = IoU - \frac{\rho^2\left(b,b^{g^t}\right)}{c^2} - \alpha v \quad (7)$$

$$L_{CIoU} = 1 - CIoU \quad (8)$$

Intersection over Union (IoU) represents the intersection ratio between the predicted bounding box and the ground truth box; denotes the shortest diagonal length of the minimum enclosing box that contains both the predicted box and the ground truth box; $\rho^2\left(b,b^{g^t}\right)$ is the Euclidean distance between the center of the ground truth box and the center of the predicted box; α is a positive balance parameter; and v represents the consistency of the aspect ratio between the predicted box and the ground truth box. The calculation methods of α and v are shown in Eq. (9) and Eq. (10):

$$v = \frac{4}{\pi^2}\left(arctan\frac{w^{g^t}}{h^{g^t}} - arctan\frac{w}{h}\right)^2 \quad (9)$$

$$\alpha = \frac{v}{(1-IoU)+v} \quad (10)$$

In Eq. (9), h^{g^t} and w^{g^t} represent the height and width of the ground truth box, respectively; h and w represent the height and width of the predicted box, respectively. The CIoU loss function comprehensively considers the overlapping area, aspect ratio, and center distance, and can well measure the relative position between boxes. However, CIoU does not consider the direction matching between the target box and the predicted box, leading to a slow convergence rate. Therefore, this study considered an alternative approach using the Smoothed Intersection over Union (SIoU) loss function [37]. SIoU optimizes the loss calculation by introducing the vector angle between the target box and the predicted box, and it plays an important role in strawberry detection networks through the linear combination of four components: angle cost, distance cost, shape cost, and IoU cost. Its calculation methods are shown in Eq. (11) and Eq. (12):

$$L_{SIoU} = 1 - IoU + \frac{\Delta+\Omega}{2} \quad (11)$$

$$IoU = \frac{|B \cap B^{GT}|}{|B \cup B^{GT}|} \quad (12)$$

where, B and B^{GT} represent the predicted box and the ground truth box, respectively; Ω denotes the shape cost; and Δ represents the distance cost (which incorporates the angle cost and redefines the distance metric). The equations for Ω and Δ are defined as Eq. (13) and Eq. (14):

$$\Omega = \sum_{t=w,h}\left(1 - e^{-w_t}\right)^{\theta} \quad (13)$$

$$\Delta = \sum_{t=x,y}\left(1 - e^{-\gamma\rho_t}\right) \quad (14)$$

In Eq. (13), $w_w = \frac{|w-w^{g^t}|}{max\left(w,w^{g^t}\right)}$, $w_h = \frac{|h-h^{g^t}|}{max\left(h,h^{g^t}\right)}$ and θ represents the degree of attention paid to Ω.

In Eq. (14), $\rho_x = \left(\frac{\left|b_{cx}^{g^t}-b_{c_x}\right|}{c_w}\right)^2$, $\rho_y = \left(\frac{\left|b_{cy}^{g^t}-b_{c_y}\right|}{c_h}\right)^2$, and γ is defined as:

$$p = arcsin\frac{\max\left(b_{cy}^{g^t},b_{c_y}\right)-\min\left(b_{cy}^{g^t},b_{c_y}\right)}{\sqrt{\left(b_{cx}^{g^t}-b_{c_x}\right)^2+\left(b_{cy}^{g^t}-b_{c_y}\right)^2}} - \frac{\pi}{4} \quad (15)$$

$$\gamma = 1 + 2\,sin^2(p) \quad (16)$$

In Eq. (15) and Eq. (16), $b_{c_x}^{g^t}$ and $b_{c_y}^{g^t}$ are the coordinates of the center of the ground truth box; b_{c_x} and b_{c_y} are the coordinates of the center of the predicted box.

The loss function plays a key role in evaluating the performance of a detection model. Typically, at least three loss functions need to be defined: object loss, classification loss, and bounding box loss. The bounding box loss has a significant impact on the detection accuracy and convergence speed of the network model.

To improve the stability of the model in predicting the size and position of target boxes, the SIoU loss function was introduced, which incorporates the vector angle of the expected regression into the calculation of the bounding box regression loss function. The mathematical expression of the SIoU loss function is as follows:

$$L_{SIoU} = \alpha \cdot AngleCost + \beta \cdot DistanceCost + \gamma \cdot ShapeCost + \delta \cdot IoUCost \quad (17)$$

In Eq. (17), α, β, γ and δ are the weight coefficients of the loss terms; $AngleCost$ represents the angle cost; $DistanceCost$ represents the distance

cost; $ShapeCost$ represents the shape cost; and $IoUCost$ represents the IoU cost. Through the linear combination of these four components (angle cost, distance cost, shape cost, and IoU cost), the difference between the predicted box and the ground truth box is measured more comprehensively.

In summary, by introducing the vector angle between the required regression boxes, the SIoU loss function redefines the distance loss, effectively reducing the degree of freedom of regression, accelerating the convergence speed of the network, and further improving the regression accuracy. Therefore, this study adopts the SIoU loss function as the loss function for bounding box regression, which improves the detection accuracy and stability, enabling Lite-CropNet to better complete the classification task of crop fruits of different sizes. This will be further verified in the experiments below.

IV. Experimental Design

In this section, the information of the adopted dataset is first introduced, followed by the presentation of evaluation metrics and experimental details. Additionally, the proposed Lite-CropNet model is compared with advanced detectors on the TomatOD dataset, and their performance is reported. Through the visualization of inference results and the analysis of the model's defects, the characteristics of the model are discussed in depth. Finally, ablation experiments are conducted to verify the selection of the key attention mechanism in Lite-CropNet.

A. Dataset Materials

In this experiment, the TomatOD dataset [11], publicly released by Tsironis et al. (2020) [22], was adopted. The selection basis and dataset characteristics are as follows: This dataset was collected from a real soilless tomato greenhouse on Crete, Greece, aiming to simulate the actual agricultural scenario of robotic arm navigation. Its scene authenticity, task adaptability, and comprehensive challenges are highly consistent with the core goal of this study—"developing a practical lightweight crop detection model". On the one hand, the dataset covers field interferences such as light fluctuations and occlusions by branches, leaves, and fruits, which can verify the model's robustness in complex environments. On the other hand, it contains 277 images and 2,413 tomato samples, which not only annotate accurate bounding boxes but also classify three maturity stages (unripe (green) - semi-ripe (orange-red) - fully ripe (red)) according to color phenotypes.

Since this dataset already provides bounding box annotations—each tomato is labeled with a bounding rectangle and marked with corresponding labels for the three growth stages—these annotated data form the basis for model training. To ensure the accuracy of the annotations, LabelImg [38] was used to check the tomato annotations in the dataset, and at the same time, the characteristics of the dataset were analyzed in depth to help design a better model. The number of tomatoes in each image ranges from 1 to 21, and the size of the annotation box accounts for 3% to 15% of the image size. Tomatoes with a size smaller than a certain range are considered out of scope and not annotated or detected. In terms of the number of category instances, the proportion of labels of different categories in all labels shows that the number of unripe instances is the largest, while the number of semi-ripe instances is the smallest. The TomatOD dataset uses an 8:2 ratio to divide the images into a training set and a test set. The details of the number of images and classification of the dataset are shown in Table I.

TABLE I. Dataset Details

Growth Stage	Training Set Instances	Testing Set Instances	Total	Percentage(Total)
Unripe	1,295	292	1,587	65.8%
Semi-ripe	318	77	395	16.4%
Fully-ripe	332	99	431	17.8%
Total	1,945	468	2,413	100.0%

In addition, this dataset has a unique feature: it is collected in a real greenhouse tomato field. In actual tomato planting scenarios, conditions such as light may change at any time, and the dataset takes this into account, meeting the experimental needs. It includes scenarios such as occlusion by branches, occlusion by tomatoes, occlusion by leaves, and unsuitable dim light, even the superposition of multiple situations. The dataset contains multiple types of occlusion scenarios, and the occlusion degree is quantified using the mathematical equation: $= 1 - \frac{|B_{vis}|}{|B_{gt}|}$. Among them, B_{gt} is the area of the real bounding box of the fruit, B_{vis} is the area of the visible region of the fruit, and O is the occlusion degree ($O \in [0,1]$, where $O = 0$ means no occlusion and $O = 1$ means full occlusion). As shown in Fig. 2, representative images are carefully selected to show the four main challenges in the tomato detection and classification task. For clear display, the brightness of the images has been enhanced, while the actual images have weak light. It is worth noting that to more intuitively display the key parts, these images are shown after magnification. In the actual dataset, the imaging distance of the images is longer, and the tomato targets are smaller.

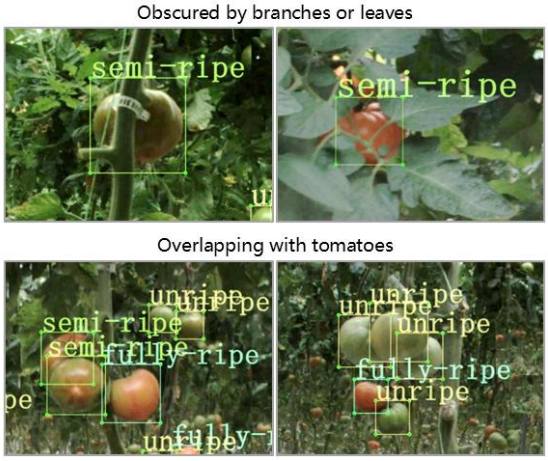

Fig. 2. Main challenges in the TomatOD dataset.

In summary, it can be seen that the many characteristics of the TomatOD dataset increase the difficulty of object detection. Through more realistic scene challenges, it helps the model

better adapt to real-world applications and achieve better robustness and generalization.

B. Experimental Configuration

This experiment was implemented using the PyTorch deep learning framework [39] and accelerated using CUDA. The TomatOD dataset was used for training and evaluation, and all 222 images in the training set were used for training and validation. The image size was adjusted to 640×640 pixels for training, which also meets the resolution requirements when deploying to low-end edge devices. During the training process, Adaptive Moment Estimation (Adam) [40] was used as the optimizer, with the initial learning rate (lr0) and cyclic learning rate (lrf) both set to 0.01, the momentum set to 0.8, and the batch size set to 8 images per batch. The hardware parameters of the equipment used in the experiment were Intel(R) Core(TM) i5-13400F and NVIDIA GeForce GTX 3090 GPU, equipped with a deep neural network acceleration library of CUDA version 11.8, parallel computing framework, and CUDNN version 8.9.5.

After the configuration of relevant parameters was completed, according to the actual convergence of the model, the training process was configured to 280 epochs for optimization. Data augmentation techniques were adopted, including random horizontal flipping, random adjustment of brightness or contrast, and random cropping. The trained model was evaluated using the test set, and each image in the test set was different from those used in the training set. Fig. 3 shows the changes in various losses and mAP values with epochs during the entire training process. It can be observed that the model was properly trained, showing convergence without overfitting.

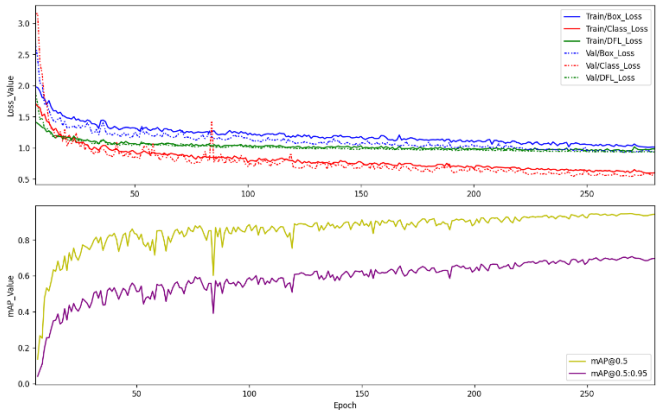

Fig. 3. Changes in loss and mAP values with epochs during training.

C. Evaluation Metrics

To evaluate the detection performance of the Lite-CropNet model, this study uses Precision (P), Recall (R), mean Average Precision (mAP@0.5, mAP@0.5:0.95), and F1 (F1-score) as evaluation metrics. A standard Intersection over Union (IoU) threshold of 0.5 was used in the experiment. If the overlap between a predicted bounding box and a labeled bounding box exceeds the IoU threshold, it is considered correct (true positive). Otherwise, the predicted bounding box is considered a false positive. When a labeled bounding box overlaps with a predicted bounding box below the threshold, it is considered a false negative. Precision (P) represents the proportion of correctly predicted objects by the model among all predicted objects. Recall (R) represents the proportion of correctly predicted objects by the model among all actual objects. Average Precision (AP) is defined as the area under the Precision-Recall (P-R) curve formed by the above Precision and Recall. The F1-score evaluates the model by balancing the weights of Precision and Recall. They are defined by the following equations, respectively [see Eq. (18) to Eq. (21)]:

$$Precision = \frac{TP}{TP+FP} \times 100\% \quad (18)$$

$$Recall = \frac{TP}{TP+FN} \times 100\% \quad (19)$$

$$mAP = \frac{1}{n}\sum_{1}^{n} P(R)d(R) \quad (20)$$

$$F1 = \frac{2\times Precision\times Recall}{Precision+Recall} \times 100\% \quad (21)$$

where, TP (True Positives), FP (False Positives), and FN (False Negatives) represent the number of true positives, false positives, and false negatives, respectively. In combination, "TP + FP" is the total number of detected targets, and "TP + FN" is the total number of real targets in the image. mAP@0.5 represents the average value of mAP when the IoU threshold is 0.5. Among them, mAP@0.5:0.95 represents the average value of mAP under different IoU thresholds (from 0.5 to 0.95, with a step size of 0.05). Since the dataset has three category labels for different growth stages, n=3.

V. Results and Analysis

A. Comprehensive Evaluation of Model Performance

To evaluate the superiority of the Lite-CropNet model, the Lite-CropNet model was compared with five advanced object detection methods in terms of detection performance, including CenterNet [41], Faster R-CNN [24], EfficientDet [42], FCOS [43], and DETR [23]. The same training set and test set were used to train and test these models, and hyperparameter tuning was performed for all methods to ensure fair and objective results. The comprehensive evaluation indicators of each model for the three growth stages in the object detection task are shown in Table II.

TABLE II. Comparison of Evaluation Metrics of Different Models

Model	P	R	F1	mAP@0.5	mAP@0.5:0.95
CenterNet	73.5%	66.4%	69.8%	48.0%	15.9%
Faster R-CNN	57.5%	58.4%	57.9%	59.0%	25.4%
EfficientDet	52.1%	51.0%	51.5%	47.4%	16.8%
FCOS	62.4%	81.6%	70.7%	73.4%	44.7%
DETR	63.5%	72.7%	67.8%	61.8%	27.2%
YOLOv8	72.3%	81.6%	76.0%	83.3%	54.2%
YOLOv11	**77.0%**	75.1%	76.6%	77.1%	51.7%
Lite-CropNet	75.4%	**86.2%**	**80.4%**	**85.7%**	**56.8%**

The experiments show that the comprehensive performance of Lite-CropNet is superior to other object detection methods. The FCOS model ranks second in comprehensive performance,

with relatively high accuracy and recall for object detection. However, due to its single and lightweight network structure, it may have certain difficulties in handling occluded tomatoes and tomatoes of different sizes. CenterNet adopts an object detection method based on center points. It may have poor overall performance because the model focuses too much on the target center point and ignores other possible target parts. The Faster R-CNN and EfficientDet models show balanced performance in the P and R indicators, but their overall performance is not excellent. It is worth noting that the DETR model is different from other object detection models. It adopts an end-to-end training method, which reduces cumbersome steps and manual intervention. However, it is easily limited by annotated data and computing resources, and has high computational costs, which is not suitable for real-time application scenarios, and does not achieve good performance in this task.

In summary, the Lite-CropNet model performs best in the tomato detection task. The advantages of Lite-CropNet may come from its strong adaptability to multi-scale, multi-growth stage, and occluded targets, as well as the appropriate feature decoding and optimization processing of the feature maps of the Encoder in the Decoder.

B. Lightweight Analysis of Different Models

When deploying the tomato detection and classification model to low-end edge devices, lightweight performance is a key factor. To comprehensively consider the lightweight performance of the model, two indicators—Frame Per Second (FPS) and model parameter quantity (Params)—were used to evaluate the lightweight effect of different models. The FPS indicator measures the number of frames that the model can process per unit time; a higher FPS value indicates that the model can process more input data in the same time and has higher real-time performance. Params reflects the number of model parameters; a smaller number of parameters means that the model is more lightweight, requires fewer computing resources during inference, and is directly related to the storage space of the model and the efficiency of computing resource usage. Their calculation methods are as follows [see Eq. (22) and Eq. (23)]:

$$FPS = \frac{1000}{pre-process+inference+NMS} \quad (22)$$

$$Params = i \cdot (k \cdot k) \cdot o + o \quad (23)$$

In the equations, is the input size, is the convolution kernel size, and is the output size. Among them, $pre-process$, $inference$, and Non-Maximum Suppression (NMS) represent the time required for preprocessing, inference, and non-maximum suppression of each image, respectively.

This experiment was conducted on a PC equipped with a relatively low-end Nvidia GTX 1650 GPU. Fig. 4 lists the comparison of lightweight parameters of different models. From the comparison results, the Lite-CropNet model achieves an excellent comprehensive level, with a high frame rate of 76.9 and lightweight parameters of only 4.4M. In contrast, although the EfficientDet model has a small number of parameters (15.0M), its frame rate is only 17.2, which is relatively low. The Faster R-CNN and FCOS models also have a large number of parameters. The DETR model has a frame rate of 21.3 and a parameter quantity of 158M; although it adopts an end-to-end training method, its performance is still relatively general here. The CenterNet model has a high frame rate, but its parameter quantity is still not sufficient for deploying lightweight models. Although YOLOv11 shows balanced performance in accuracy (mAP@0.5 is 77.1%) and frame rate (63.6FPS), its parameter quantity (6.3M) and computational complexity are still higher than those of Lite-CropNet. This further proves that the advantages of Lite-CropNet in comprehensive performance come from its lightweight design, providing a more feasible solution for real-time applications on low-end devices. Especially in the agricultural field where available resources are limited, lightweight models are usually more favored because they require fewer computing resources, which is important for some agricultural managers and can effectively reduce their economic burden.

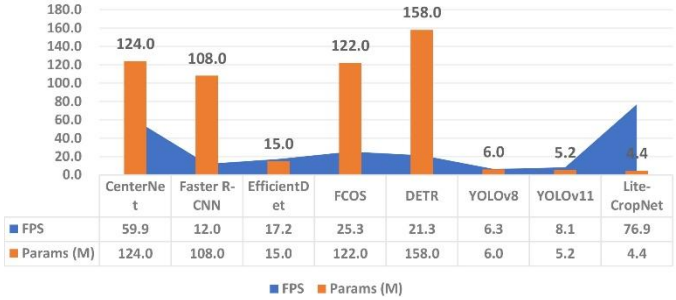

Fig. 4. FPS and Params comparison of different models.

C. Inference Speed Analysis of Different Models in a CPU Environment

In agricultural scenarios, many low-end edge devices (such as small embedded controllers and low-cost industrial computers) may not be equipped with GPUs and only rely on CPUs for inference. Therefore, a supplementary test on the inference speed of mainstream non-YOLO series models in the CPU environment was conducted. The experimental equipment was an Intel Celeron J4125 processor (4 cores and 4 threads, main frequency 2.0GHz) commonly used in agricultural scenarios, with 8GB of memory, and the test image resolution was still 640×640. The experimental data are shown in Table III.

TABLE III. COMPARISON OF EVALUATION METRICS OF DIFFERENT MODELS IN A GPU OR CPU ENVIRONMENT

Model	CPU FPS	GPU FPS (GTX 1650)	Parameter Count (M)
Lite-CropNet	**8.2**	**76.9**	**4.4**
CenterNet	6.5	59.9	108.0
Faster R-CNN	2.1	25.3	124.0
FCOS	3.3	21.3	122.0
DETR	1.8	17.2	158.0
EfficientDet	4.7	12.0	15.0

The results show that Lite-CropNet can still reach 8.2FPS in the CPU environment, which meets the basic requirements of real-time agricultural monitoring (usually requiring ≥5FPS). This performance benefits from its lightweight design:

compared with Faster R-CNN (2.1FPS) and DETR (1.8FPS), the parameter scale of Lite-CropNet is only 3.5% and 2.8% of the former, respectively, reducing memory occupation and computational delay. Compared with the same-level EfficientDet (4.7FPS), the CPU inference speed of Lite-CropNet is increased by 74%, which is due to the more concise feature fusion strategy adopted by its decoder, which reduces computational complexity. The Lite-CropNet in this study further optimizes the attention mechanism and loss function, and while maintaining accuracy, it achieves more efficient CPU inference, providing a feasible solution for agricultural scenarios without GPUs.

D. Visualization Analysis of Inference Results

By comparing the model prediction results with the real annotation results, the reasons affecting the detection performance of the model can be analyzed. Fig. 5 shows typical error cases, where the red arrows point to the regions missed by the model. Compared with other models, this model fails to correctly mark the real target regions. Missed detection is defined as failing to detect fruits with an occluded area of less than 50%, which is the standard for annotating the training set and test set in the TomatOD dataset.

From the experiment, it was observed that false detections mainly occur due to similar appearances, where leaves or debris are mistakenly identified as tomatoes. However, it is reassuring that in the test set, except for the case where the occlusion degree of the region pointed by the red arrow in the figure exceeds and is close to 50%, no missed detections were found in other images. Compared with the baseline model YOLOv11, Lite-CropNet achieves a lower missed detection rate in occluded scenarios (such as leaf occlusion and fruit overlap) and low-light environments. This indicates that the model can better capture tomato fruits under various environmental conditions, and even in dim environments with insufficient light, the model still shows similar discrimination ability to humans, further proving that the model has strong robustness and generalization.

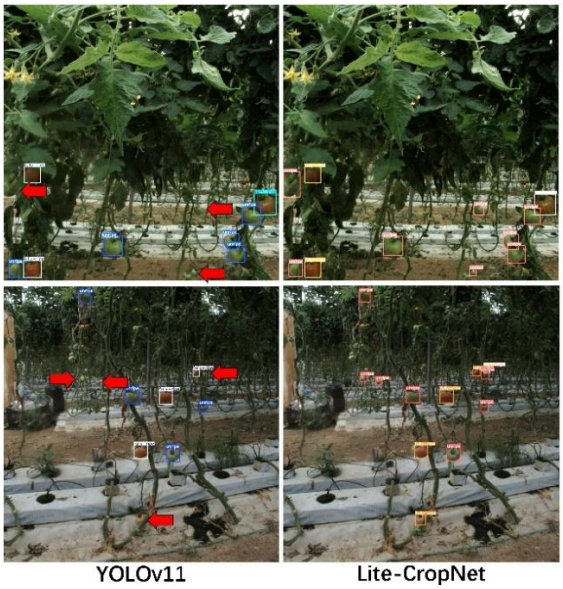

Fig. 5. Inference error results of the baseline model YOLOv11 and the Lite-CropNet model. Red arrows indicate missed detections.

E. Ablation Experiments

1) Ablation experiment on attention mechanism: In the above content, common attention mechanism methods are listed. To verify the detection differences of the Lite-CropNet model for tomatoes at each growth stage after adding different attention mechanisms to the upsampling and downsampling modules, ablation experiments were conducted using different attention mechanisms to analyze their performance differences.

The experimental results are shown in Table IV. The use of the Shuffle Attention mechanism has a positive impact on the model performance. In particular, the unique channel shuffling design of Shuffle Attention makes the mAP@0.5 indicator of the model at least 1.6% higher than that of other attention mechanisms. It can better capture global and local features, thereby comprehensively understanding the image content. Moreover, its mAP@0.5:0.95 ranks first at 57.4%, which is the only mechanism among all schemes that exceeds 87% in the core accuracy indicator. This design brings better-balanced performance in practical applications, enabling the model to achieve high levels in multiple key indicators.

TABLE IV. PERFORMANCE COMPARISON OF LITE-CROPNET USING DIFFERENT ATTENTION MECHANISMS

Attention	Precision (P)	Recall (R)	F1-Score (F1)	mAP@0.5	mAP@0.5:0.95
(None)	76.8%	80.7%	78.7%	85.5%	55.9%
SE[a]	78.4%	85.5%	**81.8%**	84.9%	56.9%
ECA[b]	80.2%	79.8%	80.0%	85.5%	56.2%
CBAM[c]	77.8%	79.3%	78.5%	83.8%	54.8%
Mlt_ECA[d]	75.4%	**86.2%**	80.4%	85.7%	56.8%
SA[e]	**80.4%**	79.5%	79.9%	**87.3%**	**57.4%**

[a] SE = Squeeze-and-Excitation

[b] ECA = Efficient Channel Attention

[c] CBAM = Convolutional Block Attention Module

[d] Mlt_ECA = Multi-scale Efficient Channel Attention

[e] SA = Shuffle Attention

In general, these observations indicate that the proposed Lite-CropNet model exhibits excellent robustness and generalization in practical tomato detection applications, providing a reliable automated solution for the agricultural field.

2) Ablation experiment on four-scale detection heads: To verify the adaptive value of the core innovation of Lite-CropNet—the "four-scale detection heads"—for crop targets of different sizes, this experiment constructs comparative models with only the number of detection heads modified. It focuses on analyzing the impact of the number of detection heads on the detection accuracy of small targets, large targets, and overall targets, so as to clarify the effectiveness of the scale design.

In this experiment, the core architecture of the model (CSPDarknet Encoder, Shuffle Attention, SIoU loss) was kept unchanged, and only the number of detection heads was adjusted: a two-scale model (2 detection heads, removing the

P2 small-scale and P5 large-scale branches) and a three-scale model (3 detection heads, removing the P5 large-scale branch) were constructed, and compared with the original four-scale model (4 detection heads, i.e., Lite-CropNet, retaining the full-scale branches of P2/P3/P4/P5). The performance comparison of the three groups of models on the same training set and validation set is shown in Table V.

TABLE V. PERFORMANCE COMPARISON OF MODELS WITH DIFFERENT NUMBERS OF DETECTION HEADS

Model Scale	P	R	F1	mAP@0.5	mAP@0.5:0.95
2	70.9%	82.2%	76.1%	78.2%	49.4%
3	72.7%	82.3%	77.2%	79.7%	50.7%
4 (Lite-CropNet)	**75.4%**	**86.2%**	**80.4%**	**85.7%**	**56.8%**

The experimental results show that the full-scale detection performance of the original four-scale model (4 detection heads) of Lite-CropNet is significantly better than that of the two-scale (2 detection heads) and three-scale (3 detection heads) comparative models: its overall detection accuracy (mAP@0.5 of 85.7%) and comprehensive performance index (F1 of 80.4%) are both at the optimal level. This proves that the four-scale detection heads can effectively improve the model's detection robustness for crop targets in the full scene by integrating feature information of different levels, including P2 (small-scale), P3 (medium-scale), P4 (medium-large scale), and P5 (large-scale), and reduce missed detections and false detections caused by insufficient scale adaptation. From the perspective of adaptive ability for segmented targets, the addition of the small-scale branch (P2) is the key to solving the problem of small fruit detection, which can effectively improve the model's recognition accuracy for small targets such as tomato young fruits and edge small fruits; while the large-scale branch (P5) can strengthen the positioning ability for large targets such as mature large tomatoes, avoiding bounding box deviation caused by the lack of global semantic information.

In summary, the four-scale detection heads enable Lite-CropNet to better adapt to multi-scale crops, solve the problem of insufficient detection ability of single-scale or few-scale models for targets of extreme sizes (such as extremely small young fruits and extra-large mature fruits), achieve a balance between accuracy and efficiency, and provide universal adaptive capabilities for multi-variety crop detection.

VI. DISCUSSION

In this research work, the Lite-CropNet model was proposed. Considering the cost of hardware resources, the lightweight design of the model was focused on. The TomatOD dataset was used to conduct in-depth research and performance analysis on the problem of crop fruit object detection and classification. Experiments have shown that while maintaining high accuracy, Lite-CropNet has a smaller model parameter size and higher frame rate, making it suitable for real-time application scenarios on low-end devices. In addition, the TomatOD dataset used was collected from real tomato planting scenarios, considering various challenges such as light changes and occlusions, resulting in a model with better robustness and generalization.

Furthermore, although the Lite-CropNet model generally performs well, the research still has potential shortcomings. First, a major problem is the relatively small scale of the dataset. It only contains 277 images and 2,413 tomato samples, and was collected from a single-region soilless cultivation greenhouse on Crete, Greece. It does not cover diverse planting environments (such as open fields and high-humidity solar greenhouses) in different countries and regions, nor does it include extreme scenarios such as rainstorm reflections and abnormal fruit appearances caused by diseases and pests, resulting in limited data diversity. Although the dataset already includes various environmental conditions and occlusion situations and successfully addresses them, the limited amount of data and the limitations of scene coverage may have a certain impact on the cross-region and cross-scene generalization ability and robustness of the model. Larger-scale datasets can usually better capture the diversity of the real world. As mentioned in the visual analysis above, the model inevitably has false detection problems when facing similar backgrounds, which is also considered to be caused by this reason. Second, for different tomato varieties in different countries and regions, the appearance characteristics of the plants are affected by various factors such as growth environment, soil conditions, and climate, and there may be slight differences in appearance, such as differences in fruit size and color depth, which may also affect the performance of the model. At the same time, although the study mentions that the model can be transferred to other horticultural crops such as potatoes and strawberries, it has not conducted verification for the morphological characteristics of these crops (such as clustered distribution of strawberries and underground fruiting of potatoes), and the multi-crop adaptability still needs further testing. This requires considering a wider and more diverse dataset during model training to ensure that the model has good adaptability to plant varieties in different countries and regions [44], [45].

VII. CONCLUSION

Efficient and accurate detection and counting of crop fruits have long been a challenging task. In this study, a novel Lite-CropNet model was proposed, with YOLOv11 as the baseline, aiming to address the key issues in horticultural crop detection and classification. A lightweight encoder was adopted and a concise yet efficient decoder was designed, which alleviates the problems of information loss and degradation. The exploration of different attention mechanisms revealed that the Shuffle Attention mechanism exerts a positive effect, helping to improve the model's performance. More importantly, efficiency enhancement was prioritized in the model design: a more lightweight architecture with a smaller parameter scale was developed, providing a cost-effective and highly efficient automated solution for agricultural production.

Experiments demonstrate that Lite-CropNet performs excellently under various lighting and occlusion conditions, exhibiting strong robustness and generalization. Notably, Lite-CropNet does not sacrifice efficiency at the expense of accuracy; instead, it achieves a balance between the two. Its

efficient performance in the CPU environment (8.2FPS) expands its application scenarios, making it particularly suitable for low-cost monitoring devices in greenhouses (e.g., Raspberry Pi-based embedded systems). In the future, CPU inference speed can be further improved through model quantization.

This work not only provides advanced technical support for the agricultural field but also offers insights for future research directions. The next phase of research will expand the dataset scale to cover more horticultural crop varieties, thereby enhancing the model's adaptability. Additionally, efforts will be made to further extend Lite-CropNet's performance advantages in the CPU environment and deploy it on low-cost monitoring devices in greenhouses, enabling it to better adapt to agricultural environments with extremely limited resources. Meanwhile, adversarial elements will be introduced to improve and optimize the object detection model, enhancing its robustness in complex scenarios. It is expected that this study will inspire more researchers to engage in agricultural intelligence and automation, and make more in-depth contributions to this field.

***Abstract*—This study addresses the challenges of measuring and evaluating relative poverty by introducing a comprehensive evaluation model based on the Analytic Hierarchy Process (AHP)-entropy method and BP neural networks. A multidimensional evaluation index system was constructed through expert consultation and literature review. The AHP-entropy method was then employed to determine the weights of the evaluation indicators, ensuring objectivity and scientific validity. Additionally, the BP neural network model was integrated to leverage self-learning and adaptive mechanisms for efficient and accurate poverty assessment. Empirical analysis shows that the model maintains a calculation error within 3.9%, demonstrating high precision and wide applicability. This research provides a novel approach that combines qualitative analysis with quantitative evaluation, offering a practical tool for governmental agencies to design effective poverty alleviation strategies. Moreover, the model opens new pathways for future research in regional poverty assessment, especially in enhancing cross-cultural adaptability and advancing intelligent evaluation models.**

***Keywords*—Analytic hierarchy process (AHP); entropy method; BP neural network model; relative poverty measurement**

I. Introduction

With the rapid development of the socioeconomic landscape, the issue of relative poverty has gradually become a crucial indicator for measuring social equity and harmony. Traditional poverty measurement methods, which predominantly rely on single income indicators, often fail to comprehensively capture the multidimensional characteristics of poverty. Therefore, research on poverty measurement in the context of the new era has shifted from a single income dimension to a comprehensive multidimensional assessment [1-2]. Multidimensional poverty encompasses not only economic income but also aspects such as education, health, and environment, reflecting a holistic understanding and in-depth analysis of poverty. How to achieve relative poverty measurement across multiple dimensions is an important topic in social science research, playing a significant role in achieving targeted poverty alleviation, promoting social equity, and improving people's living standards [3].

Past studies on relative poverty have often emphasized qualitative analysis [4-6], limiting their capacity for scientific quantitative assessments [7-8]. In response, some scholars have utilized the traditional Alkire-Foster (A-F) method. For example, Qin et al. [9] applied the A-F method to analyze multidimensional relative poverty in six regions of Xinjiang, while Gan et al. [10] combined the A-F method, Dagum Gini coefficient, and Kernel density estimation to examine multidimensional poverty and regional disparities across 31 provinces in China between 2013 and 2019. Similarly, Guo [11] employed CFPS data and a modified A-F method with subjective and objective weighting techniques to assess multidimensional poverty in China. Despite its widespread use, the A-F method has limitations, such as difficulties in precisely quantifying non-economic dimensions of poverty [12-13] and inherent subjectivity.

Regression analysis has also been explored as an alternative. Zhu et al. [14], for instance, employed logistic regression to identify factors influencing rural household poverty in western China, while Tian et al. [15] analyzed multidimensional poverty and its mechanisms in Henan Province using the A-F model and binary logistic regression. However, traditional mathematical approaches face challenges, including difficulties in constructing evaluation indicators, susceptibility to subjective bias, and computational complexity.

In contrast, the Analytic Hierarchy Process (AHP) offers significant advantages in quantifying and evaluating poverty. For instance, Dong [16] applied AHP and intergenerational income elasticity coefficients to explore factors affecting intergenerational poverty transmission. Luo and Cao [17] used AHP to construct a multidimensional indicator system for measuring urban household poverty in China. Zhu et al. [18] combined an AHP-improved A-F method to measure and decompose multidimensional relative poverty. Tao [19] established a multidimensional evaluation system with 14 indicators across five dimensions, using AHP and entropy-based weighting to determine indicator weights. Similarly, Chen [20] applied AHP to assess urban poverty during China's transition period, determining weights for various poverty dimensions.

Despite its utility, AHP has limitations, including subjectivity, high consistency requirements, potential complexity in hierarchical structures, challenges in determining weights, limited sensitivity analysis for parameter variations, constrained applicability, and significant computational demands.

To overcome these challenges, this study proposes a comprehensive evaluation model integrating AHP, the entropy method, and BP neural networks. The model begins by analyzing the factors influencing relative poverty and constructing a corresponding evaluation index system. Next,

*Corresponding author.

indicator weights are determined using AHP and the entropy method, which are then applied to score the relative poverty population. A BP neural network model is subsequently developed, trained, and tested using MATLAB. The BP neural network model proposed in this study provides more accurate evaluation results compared to traditional mathematical models and fuzzy mathematical theory. Through self-learning and adaptive adjustment, it effectively addresses the shortcomings of traditional evaluation methods in handling dimensional diversity and imprecise problem quantification.

By combining AHP and entropy-based weighting with BP neural networks, this study enhances the scientific validity and precision of poverty measurement while providing robust tools for poverty alleviation policy development and implementation. Continuous innovation and deeper research in this field can make meaningful contributions to reducing relative poverty, fostering social equity, and improving living standards.

II. METHODS

A. Construction of the Multidimensional Poverty Measurement, Evaluation System and Establishment of Data Samples

1) Construction of the measurement indicator system: The development of a multidimensional poverty measurement and evaluation system must adhere to the principles of scientific objectivity, comprehensiveness, feasibility, and representativeness [21]. For example, Huang et al. [22] classified poverty into seven dimensions: income standards, the "three guarantees" (education, healthcare, and housing), food and nutrition structure, social relations, and mental state. Similarly, Liao et al. [23] categorized poverty into dimensions such as living standards, production resources, income, health, education, political participation, sanitation facilities, and household assets. Thus, constructing a scientifically robust and rational evaluation indicator system is critical for addressing poverty measurement, with the design of these indicators being the core challenge.

At present, no unified standard exists for relative poverty evaluation systems. Therefore, this study develops its indicator system by interpreting the concept of relative poverty and utilizing statistical data from sources such as the China Statistical Yearbook and CFPS2020. Indicators with unavailable data were excluded. The finalized system reflects the practical context of China's economic development. It comprises five secondary indicators—basic living security, capabilities, social security, development opportunities, and economic conditions—and 14 tertiary indicators, as detailed in Table I.

2) Data sources: The quality of the sample used for learning plays a crucial role in determining the performance of the neural network model. Therefore, this study utilizes data from CFPS2020 (China Family Panel Studies). The data collection process adhered to rigorous scientific methods, tracking data across three levels: individual, household, and community. This approach ensured both the comprehensiveness and depth of the study. The broad geographic coverage, spanning 25 provinces, municipalities, and autonomous regions, further strengthened the generalizability and applicability of the findings. For data processing, STATA software, a widely recognized statistical tool, was employed to ensure accuracy and validity. During the processing, survey data were carefully filtered according to the dimensions of relative poverty measurement, resulting in 4,594 valid responses, thereby ensuring the study's precision and reliability.

3) Quantitative processing of the indicator system: Following data integration, the data were sequentially organized and transformed into the format shown in Table II, where each column represents the score of an individual respondent across 14 dimensions. A base score of 60 was assigned to each indicator, with specific values assigned according to the actual context, as outlined in Table II. This process finalized the quantitative analysis of each indicator.

TABLE I MULTIDIMENSIONAL RELATIVE POVERTY MEASUREMENT AND EVALUATION SYSTEM

Primary Indicators	Secondary Indicators	Tertiary Indicators
Multidimensional Relative Poverty Measurement and Evaluation System (A)	Living Security (W1)	Adequate Food and Clothing (W11)
		Drinking Water Supply (W12)
		Housing Conditions (W13)
	Economic Conditions (W2)	Per Capita Household Income (W21)
		Proportion of Transfer Income (W22)
	Feasible Capability (W3)	Education Level of Household Head (W31)
		Number of Laborers (W32)
		Health Status (W33)
	Development Opportunities (W4)	Access to Bank Loans (W41)
		Job Satisfaction (W42)
		Proportion of Migrant Laborers (W43)
	Social Security (W5)	Satisfaction with Medical Conditions (W51)
		Medical Insurance and Assistance (W52)
		Satisfaction with Education (W53)

B. Empowerment of the Multidimensional Poverty Measurement and Evaluation System

1) AHP-based empowerment of evaluation indicators: The Analytic Hierarchy Process (AHP) is a method that integrates both quantitative and qualitative analysis, enabling a comprehensive assessment of the research problem [18]. In this study, AHP is employed to determine the weight coefficients of each indicator. To minimize the randomness introduced by evaluators' subjective preferences and prior knowledge, a panel of experts was convened to provide a collective empowerment judgment. The expert panel constructed a criterion-level judgment matrix using the 1–9 scale method, as illustrated in Table III.

TABLE II QUANTITATIVE PROCESSING OF THE MULTIDIMENSIONAL RELATIVE POVERTY MEASUREMENT INDICATOR SYSTEM

Primary Indicators	Secondary Indicators	Tertiary Indicators	Tertiary Indicator Weights
Multidimensional Relative Poverty Measurement and Evaluation System (A)	Living Security (W1)	Adequate Food and Clothing (W11)	The total expenditure on food and clothing exceeds 2300, assign a value of 90; between 1380 and 2300, assign a value of 70; less than 1380, assign a value of 60.
		Drinking Water Supply (W12)	Tap water/bottled water/purified water/filtered water, assign a value of 90; well water, assign a value of 80; river/lake/pond spring water, assign a value of 70; others, assign a value of 60.
		Housing Conditions (W13)	Courtyards, villas, and townhouses, assign a value of 90; small buildings, assign a value of 80; unit apartments, assign a value of 70; single-story houses, assign a value of 60.
	Economic Conditions (W2)	Per Capita Household Income (W21)	Household per capita non-operating income below 50% of the median, assign a value of 60; between 50%–80% of the median, assign a value of 70; between 80%–100% of the median, assign a value of 80; above the median, assign a value of 90.
		Proportion of Transfer Income (W22)	Household savings below 50% of the median, assign a value of 60; between 50%–80% of the median, assign a value of 70; between 80%–100% of the median, assign a value of 80; above the median, assign a value of 90.
	Feasible Capability (W3)	Education Level of Household Head (W31)	Bachelor's degree or higher (including associate degree), assign a value of 90; high school/vocational school/technical school/secondary technical school, assign a value of 80; middle school, assign a value of 70; primary school or below, assign a value of 60.
		Number of Laborers (W32)	If the respondent's comprehension ability is weak and judged as very poor, assign a value of 60; otherwise, assign a value of 90.
		Health Status (W33)	If the respondent feels unhealthy, assign a value of 60; otherwise, assign a value of 90.
	Development Opportunities (W4)	Access to Bank Loans (W41)	If yes, assign a value of 60; if no, assign a value of 90.
		Job Satisfaction (W42)	Very satisfied, assign a value of 90; fairly satisfied, assign a value of 80; somewhat dissatisfied/average, assign a value of 70; very dissatisfied, assign a value of 60.
		Proportion of Migrant Laborers (W43)	If the respondent's information level about their future is below 50% of the median, assign a value of 60; between 50%–80% of the median, assign a value of 70; between 80%–100% of the median, assign a value of 80; above the median, assign a value of 90.
	Social Security (W5)	Satisfaction with Medical Conditions (W51)	Very satisfied, assign a value of 90; fairly satisfied, assign a value of 80; somewhat dissatisfied/average, assign a value of 70; very dissatisfied, assign a value of 60.
		Medical Insurance and Assistance (W52)	None, assign a value of 60; if yes, assign a value of 90.
		Satisfaction with Education (W53)	Very satisfied, assign a value of 90; fairly satisfied, assign a value of 80; somewhat dissatisfied/average, assign a value of 70; very dissatisfied, assign a value of 60.

TABLE III CRITERION-LEVEL JUDGMENT MATRIX

A	W1	W2	W3	W4	W5	Weight
W1	1	2	4	4	2	0.36
W2	0.5	1	5	4	2	0.28
W3	0.25	0.2	1	2	0.25	0.08
W4	0.25	0.25	0.5	1	0.2	0.06
W5	0.5	0.5	4	5	1	0.22

The matrix is solved, yielding a maximum eigenvalue of $\lambda_{Max} = 5.23$. The corresponding eigenvector is $W_i = (0.36, 0.28, 0.08, 0.06, 0.22)$. A consistency test is then conducted on W_i, as shown in Eq. (1):

$$CI = \frac{\lambda_{Max} - n}{n-1} = 0.0585 \quad (1)$$

According to the table, when n=5, the value of RI=1.12. Therefore, the relative consistency index can be calculated, as shown in Eq. (2):

$$CR = \frac{CI}{CR} = 0.05226 < 0.1 \quad (2)$$

The calculations demonstrate that the matrix achieves satisfactory consistency, meaning that the weight vector W_i is both objective and acceptable. Similarly, applying the same method to solve the other matrices results in the judgment matrices presented in Table IV to Table VII.

Table IV presents the weight distribution for the multidimensional relative poverty measurement indicator system. The weight of the secondary indicators represents their share within the overall evaluation system, while the weight of the tertiary indicators reflects their share within the corresponding secondary indicators. The comprehensive weight is the weighted average of both secondary and tertiary indicator weights, indicating their relative importance within the entire evaluation framework.

TABLE IV HP-BASED WEIGHT DISTRIBUTION FOR THE MULTIDIMENSIONAL RELATIVE POVERTY MEASUREMENT AND EVALUATION SYSTEM

Primary Indicators	Secondary Indicators	Secondary Indicator Weights	Tertiary Indicators	Tertiary Indicator Weights	Comprehensive Weight
Multidimensional Relative Poverty Measurement and Evaluation System (A)	Living Security (W1)	0.36	Adequate Food and Clothing (W11)	0.1	0.04
			Drinking Water Supply (W12)	0.23	0.08
			Housing Conditions (W13)	0.67	0.24
	Economic Conditions (W2)	0.28	Per Capita Household Income (W21)	0.8	0.22
			Proportion of Transfer Income (W22)	0.2	0.06
	Feasible Capability (W3)	0.08	Education Level of Household Head (W31)	0.09	0.01
			Number of Laborers (W32)	0.27	0.02
			Health Status (W33)	0.64	0.05
	Development Opportunities (W4)	0.06	Access to Bank Loans (W41)	0.12	0.01
			Job Satisfaction (W42)	0.68	0.04
			Proportion of Migrant Laborers (W43)	0.2	0.01
	Social Security (W5)	0.22	Satisfaction with Medical Conditions (W51)	0.26	0.06
			Medical Insurance and Assistance (W52)	0.63	0.14
			Satisfaction with Education (W53)	0.11	0.04

2) Entropy method for weight assignment to evaluation indicators: The entropy method is an objective weighting approach that assigns weights based on the degree of variation in indicator values. Its main advantage is that it avoids the subjective biases inherent in the Analytic Hierarchy Process (AHP), thereby improving both the objectivity and accuracy of weight assignment. This method is particularly effective for situations where indicators exhibit high variability, randomness, and disorder, providing a more accurate representation of each indicator's true significance within the evaluation system. Consequently, this study employs the entropy method to objectively assign weights to the evaluation indicators, following the steps outlined below:

a) Let A denote the j-th indicator of the i-th household. The corresponding attribute decision matrix is as shown in Eq. (3):

$$M = \begin{bmatrix} x_{11} & x_{12} & \cdots & x_{n1} \\ x_{21} & x_{22} & \cdots & x_{n2} \\ \vdots & \vdots & \vdots & \vdots \\ x_{m1} & x_{m2} & \cdots & x_{mn} \end{bmatrix} \quad (3)$$

b) Data standardization is performed to eliminate the influence of different units on the evaluation indicators. In this study, the mean normalization method is applied for standardization, and the calculation is as shown in Eq. (4):

$$y_{ij} = \frac{x_{ij}}{\overline{x_j}} \quad (4)$$

c) The contribution of the *i*-th sample under the *j*-th indicator, denoted as p_{ij}, is calculated as shown in Eq. (5):

$$p_{ij} = \frac{y_{ij}}{\sum_{i=1}^{m} y_{ij}} \quad (5)$$

d) The total contribution of the *j*-th indicator is calculated as its information entropy value, as shown in Eq. (6):

$$E_j = -k \sum_{j}^{m} p_{ij} ln(p_{ij}) \quad (6)$$

In the equation, $k = \frac{1}{\ln(m)}$.

e) Calculate the coefficient of variation for the contributions of each sample under the *j*-th indicator, as shown in Eq. (7):

$$d_j = 1 - E_j \quad (7)$$

*f)*Calculate the weight corresponding to the *j*-th indicator, as shown in Eq. (8):

$$w_j = \frac{d_j}{\sum_{j=1}^{m} d_j} \quad (8)$$

The weights calculated using the entropy method, based on the data from Section II B and analyzed with the R software, are summarized in the Table V.

3) Comprehensive weighting approach integrating AHP and the entropy method: The Analytic Hierarchy Process (AHP) is highly subjective, relying heavily on qualitative components and limited quantitative data, which reduces its credibility. In contrast, the entropy method lacks the ability to compare indicators across dimensions. To address these limitations, a combined weighting method is employed, which considers the intrinsic statistical properties and authoritative values of the indicators. This method integrates subjective and objective weighting approaches, balancing their respective strengths and weaknesses. The corresponding equation is as shown in Eq. (9):

$$W_j = \frac{\sqrt{\alpha_j \beta_j}}{\sum_{j=1}^{n} \sqrt{\alpha_j \beta_j}} \quad (9)$$

Among these, α_j denotes the weight values derived from the Analytic Hierarchy Process (AHP), while β_j represents the weight values obtained using the entropy method.

The combined weights are calculated using the combined weighting formula, based on the subjective and objective weight values obtained from the Analytic Hierarchy Process (AHP) and the entropy method. The corresponding weighting results are presented in Table VI.

TABLE V WEIGHT DISTRIBUTION FOR THE MULTIDIMENSIONAL RELATIVE POVERTY MEASUREMENT AND EVALUATION SYSTEM BASED ON THE ENTROPY METHOD

Primary Indicators	Secondary Indicators	Tertiary Indicators	Entropy Weight
Multidimensional Relative Poverty Measurement and Evaluation System (A)	Living Security (W1)	Adequate Food and Clothing (W11)	0.08
		Drinking Water Supply (W12)	0.02
		Housing Conditions (W13)	0.08
	Economic Conditions (W2)	Per Capita Household Income (W21)	0.02
		Proportion of Transfer Income (W22)	0.04
	Feasible Capability (W3)	Education Level of Household Head (W31)	0.12
		Number of Laborers (W32)	0.04
		Health Status (W33)	0.06
	Development Opportunities (W4)	Access to Bank Loans (W41)	0.09
		Job Satisfaction (W42)	0.05
		Proportion of Migrant Laborers (W43)	0.06
	Social Security (W5)	Satisfaction with Medical Conditions (W51)	0.03
		Medical Insurance and Assistance (W52)	0.24
		Satisfaction with Education (W53)	0.06

TABLE VI COMPREHENSIVE WEIGHT DISTRIBUTION FOR THE MULTIDIMENSIONAL RELATIVE POVERTY MEASUREMENT AND EVALUATION SYSTEM BASED ON AHP & ENTROPY METHOD

Primary Indicators	Secondary Indicators	Tertiary Indicators	Subjective Weight	Objective Weight	Comprehensive Weight
Multidimensional Relative Poverty Measurement and Evaluation System (A)	Living Security (W1)	Adequate Food and Clothing (W11)	0.04	0.08	0.07
		Drinking Water Supply (W12)	0.08	0.02	0.05
		Housing Conditions (W13)	0.24	0.08	0.16
	Economic Conditions (W2)	Per Capita Household Income (W21)	0.22	0.02	0.08
		Proportion of Transfer Income (W22)	0.06	0.04	0.06
	Feasible Capability (W3)	Education Level of Household Head (W31)	0.01	0.12	0.04

C. Development of the BP Neural Network Model

1) Determining the fundamental parameters of the BP neural network: To construct a BP neural network, key parameters such as the number of layers, the number of neurons, the activation function, and the learning rate must be determined. Generally, increasing the number of layers enhances computational accuracy; however, this also results in longer training times and may increase the risk of overfitting. Alternatively, computational accuracy can be improved by adding more hidden nodes without expanding the network layers. Consequently, this study employs a three-layer BP neural network with a single hidden layer.

The number of neurons in each layer is determined as follows: the 14 tertiary indicators from the multidimensional relative poverty measurement system serve as input neurons, while the system's poverty scores are used as output neurons, resulting in $n = 14$ and $l = 1$. Based on Eq. (10), the range of values for the hidden layer nodes is [4, 8]. Therefore, this study sets the number of hidden layer nodes m to the higher value of 8 to enhance computational accuracy.

$$\sqrt{nl} \le m \le \sqrt{n(l+3)} + 1 \qquad (10)$$

In this study, the activation function for the input layer is defined as the hyperbolic tangent function, as shown in Eq. (11):

$$f(x) = \frac{e^{x}-e^{-x}}{e^{x}+e^{-x}} \quad (11)$$

The activation function for the output layer is the Sigmoid function, as shown in Eq. (12):

$$f(x) = \frac{1}{1+e^{-x}} \quad (12)$$

The learning rate governs the adjustment of synaptic values during the neural network training process. If the learning rate is too high or too low, it can lead to system instability. To maintain stability during training, the learning rate (denoted as η) should be within the range of 0.01 to 0.1. In this study, η is set to 0.55. Based on these considerations, the topology of the BP neural network used in this study is shown in Fig. 1.

2) Parameter settings for the BP neural network model: To train the BP neural network model, the initial network parameters must be determined. These parameters typically include the weights for each layer and the activation thresholds. The weights and thresholds are initialized to small random values. In this study, the initial values are randomly selected within the range of [-1/12, 1/12] prior to training. Additionally, 70% of the data is designated as the training sample, with $x(m) = [x_{m1}, \ldots x_{m16}]$ representing the input data for the input layer, y_m representing the desired output, and m representing the sample index.

Once the initial parameters and training samples are set, the outputs of the hidden and output layers can be calculated. The induced local domain for a particular neuron in the hidden layer, as used in this study, is shown in Eq. (13):

$$v_j(m) = \sum_{i=1}^{n} w_{ij} x_{ij} - \theta_j \quad (13)$$

The induced local domain of a specific neuron k in the output layer is shown in Eq. (14):

$$v_k(m) = \sum_{j=1}^{s} w_{jk} v_j(m) - \theta_k \quad (14)$$

In the equation, n and s denote the number of neurons in the input and hidden layers, respectively.

Based on the induced local domain outlined above, the output of neuron j in the hidden layer at time m is as shown in Eq. (15):

$$y_j(m) = \frac{e^{v_j(m)}-e^{-v_j(m)}}{e^{v_j(m)}+e^{-v_j(m)}} \quad (15)$$

At this stage, the output of neuron k in the output layer is as shown in Eq. (16):

$$y_k(m) = \frac{1}{1+e^{-v_k(m)}} \quad (16)$$

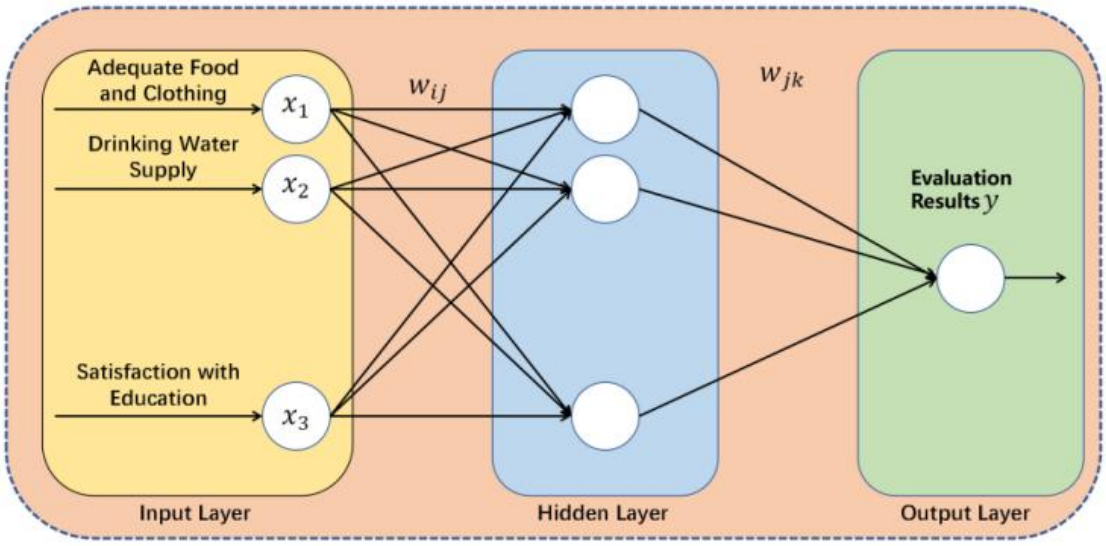

Fig. 1. Multidimensional relative poverty measurement and evaluation system model.

III. Results and Discussion

A. Model Training

After constructing the model as outlined above, 70% of the integrated data was used for training, with 15% allocated as training samples and the remaining 15% as testing and validation data. Fig. 2 illustrates the regression of the target relative to the output. The R-values for the training set, validation set, test set, and all data are 0.98371, 0.985, 0.97912, and 0.98313, respectively. These results suggest that the neural network model demonstrates a high degree of linearity and exhibits strong fitting performance.

B. Empirical Analysis

After training the neural network model, 20 sets of integrated data were selected for testing. The test results, compared with the comprehensive weighted calculations, are presented in Table VII (excerpt). The comparison reveals that the average relative error for the 20 test samples is 0.89%, with a maximum relative error of 3.90%. These results suggest that the model achieves high prediction accuracy. Furthermore, the use of the neural network model for multidimensional relative poverty measurement is simple, significantly reducing computational costs and demonstrating strong feasibility. The fitted curve is shown in Fig. 3.

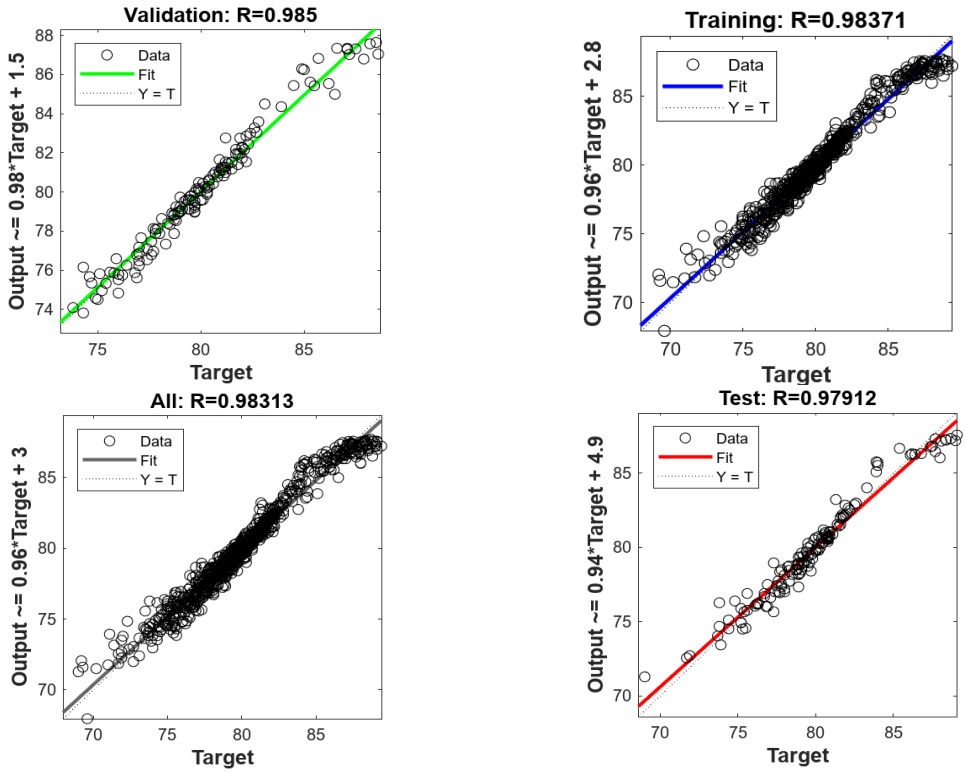

Fig. 2. Regression of the target relative to the output.

TABLE VII BP NEURAL NETWORK CALCULATION RESULTS AND COMPREHENSIVE WEIGHTING EVALUATION RESULTS

Serial Number	Expected Output	BP Predicted Value	Relative Error	Serial Number	Expected Output	BP Predicted Value	Relative Error
1	86.1	86.8574	0.88%	11	84.4	84.6768	0.33%
2	72.7	72.5812	0.16%	12	71.9	73.6172	2.39%
3	78.7	78.5607	0.18%	13	80.4	80.5731	0.22%
4	73.8	73.3003	0.68%	14	80.7	79.4826	1.51%
5	85.6	87.1798	1.85%	15	79.5	79.1354	0.46%

7	74.5	72.9669	2.06%	17	87.8	88.1500	0.40%
8	72	69.1954	3.90%	18	76.5	76.2431	0.34%
9	76.7	76.4779	0.29%	19	81.1	80.9983	0.13%
10	77.3	77.0135	0.37%	20	78.4	77.8524	0.70%

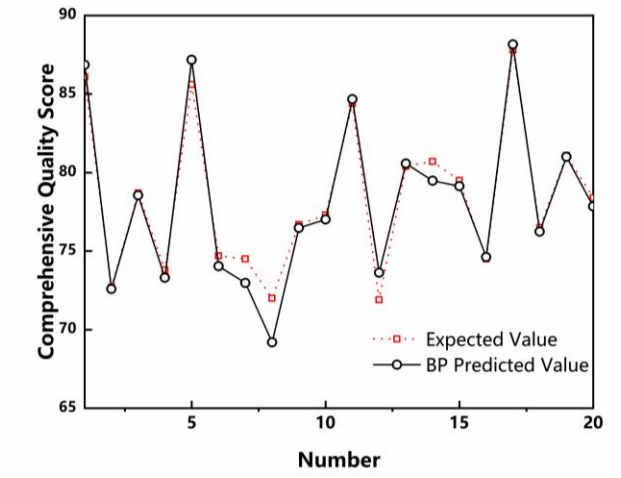

Fig. 3. Comparison curve of expected output and BP predicted value.

IV. CONCLUSIONS

This study develops a multidimensional relative poverty measurement evaluation system based on the AHP and entropy weight method, offering a quantitative analysis-based evaluation approach. To enhance the convenience of comprehensive quality assessment, a model combining the AHP and entropy weight method with the BP neural network is also proposed. The main conclusions are as follows:

This study employs the AHP-entropy method to allocate comprehensive weights to evaluation indicators, establishing a scientific and rational multidimensional relative poverty assessment system. The development of this framework provides governments with a quantitative and systematic evaluation tool during the implementation of multidimensional poverty assessment, thereby enhancing the objectivity and scientific rigor of the evaluation process.

The research demonstrates that the BP neural network-based relative poverty measurement model exhibits significant advantages in addressing complex nonlinear problems. The application of this model not only improves evaluation efficiency and reduces computational costs but also validates its feasibility and effectiveness in practical poverty population assessment through empirical analysis.

The BP neural network model proposed in this study holds broad application prospects in the field of poverty population assessment. This methodology enables more objective and equitable evaluation of multidimensional relative poverty, facilitating better implementation of poverty eradication policies by government departments and promoting comprehensive national development.

Evaluating Transformer-Based Pretrained Models for Classical Arabic Named Entity Recognition

Mariam Muhammed, Shahira Azab
Faculty of Graduate Studies for Statistical Research, Cairo University, Egypt

***Abstract*—This study presents a comprehensive comparative evaluation of transformer-based pretrained language models for Named Entity Recognition (NER) in Classical Arabic, an underexplored linguistic variety characterized by rich morphology, orthographic ambiguity, and the absence of diacritics. The main objective of this work is to identify the most effective transformer model for Classical Arabic NER and to analyze the linguistic factors influencing model performance. Using the CANERCorpus, which contains Hadith texts annotated with twenty fine-grained entity types, ten transformer-based models were fine-tuned and evaluated under consistent experimental settings. The study benchmarks models such as AraBERT, ArBERT, and multiple CAMeLBERT variants, comparing their precision, recall, and F1-scores. The results demonstrate that all models achieve strong performance (F1 > 96%), while CAMeL-CA-NER attains the highest score (F1 = 97.78%), confirming the advantage of domain-specific pretraining on Classical Arabic data. Error analysis further reveals that domain-adapted models better handle ambiguous entities and religious terminology. A comparative analysis with traditional and non-transformer approaches, including rule-based and BERT-CRF models from previous studies, shows that CAMeL-CA-NER surpasses earlier methods by more than 3% in F1-score, highlighting its superior capability in handling Classical Arabic text. However, this study is limited to the CANERCorpus, which primarily consists of Hadith texts; results may vary for other Classical Arabic genres or domains. These findings provide a valuable benchmark for future research and demonstrate the adaptability of modern NLP architectures to linguistically complex, low-resource domains.**

***Keywords*—Classical Arabic; Named Entity Recognition; transformer models; pretrained models; CANERCorpus**

I. Introduction

Named Entity Recognition (NER) is an important task in natural language processing (NLP) that aims to identify and categorize entities such as persons, locations, and organizations. Since its introduction in the Message Understanding Conferences (MUC) in the 1990s [1], NER has become essential for various NLP applications, including information retrieval, machine translation, question answering, and text summarization [2], [3], [4].

Extensive research has been conducted in English and other widely spoken languages, including Spanish and Chinese. NER systems are generally built using three approaches: rule-based, machine learning, and hybrid methods. Rule-based systems rely on handcrafted linguistic rules and dictionaries [1], [5], [6], but they are limited by language-specific expertise and lack flexibility [7], [8]. Deep learning, a subset of machine learning, introduced neural architectures such as convolutional neural networks (CNNs) and recurrent neural networks (RNNs), which learn representations at both the character and word levels [9].

The rapid growth of Arabic content on the internet has created a strong need for accurate NLP tools for Arabic. Arabic serves as the official language in the Arab World, covering 22 countries [2]. It is a Semitic language with rich vocabulary, complex morphology, and challenging syntax. It exists in three forms, including Classical Arabic (CA), Modern Standard Arabic (MSA), and Dialectal Arabic (DA). CA represents the original Arabic language from the seventh to the early eleventh century CE [10]. MSA is used in formal contexts such as books, formal communications, and news articles, while DA is spoken in everyday life. Although CA is less used in modern contexts, it remains highly important as the language of the Quran (the holy book of Islam), the Hadith (the sayings of Prophet Muhammad), and the Islamic heritage.

Arabic NER faces unique challenges compared to other languages due to its morphological richness, allowing suffixes and prefixes to function as conjunctions, prepositions, and pronouns, as in the word "فأسقيناكموه" (faskenakomoh), meaning "So we gave you water to drink". Unlike languages that rely on capitalization to identify proper nouns, Arabic does not use capitalization. Moreover, Arabic utilizes short vowels (diacritics) to disambiguate word sense, but it is usually written without them, leading to ambiguity in word meaning. For example, the word "درس" can mean "دَرْس" (lesson) as a noun or "دَرَسَ" (has studied) as a verb [6]. Some examples of ambiguous words in Arabic text are listed in Appendix A.

Classical Arabic, in particular, poses additional linguistic challenges beyond those of Modern Standard Arabic. In addition to its rich morphology, absence of diacritics, and orthographic ambiguity, Classical Arabic exhibits archaic vocabulary, complex syntactic structures, and context-dependent expressions that differ significantly from Modern Standard Arabic usage. These characteristics increase word-level ambiguity and make NER in Classical Arabic notably more difficult than in contemporary Arabic varieties.

Furthermore, the scarcity of datasets and other reliable resources for Arabic increases the challenges of Arabic NER [2], [11].

Recent advances in deep learning and pretrained models have significantly improved Arabic NER. Contextualized embeddings such as ELMo, BERT, and GPT, along with sequence-to-sequence and convolutional neural network models, have enhanced system performance by capturing the

complex linguistic features of Arabic and learning effectively from annotated data. Transformer-based pretrained language models have transformed NLP and had a major impact on Arabic NER. Trained on massive text corpora, they can identify complex linguistic patterns. When fine-tuned on Arabic NER datasets, these models achieve state-of-the-art results with less data and lower computational cost.

The main contribution of this study is a comparative evaluation of transformer-based pretrained models for Classical Arabic NER using the CANERCorpus dataset. It investigates their predictive capabilities and performance on Hadith texts. This study provides a systematic benchmarking of transformer-based pretrained models for Classical Arabic NER. Unlike previous studies that mainly target Modern Standard Arabic, this work focuses on Classical Arabic, analyzing model behavior in a linguistically rich and underexplored domain. This benchmarking effort serves as a foundation for future research aiming to develop specialized models and resources for Classical Arabic.

The remainder of this study is organized as follows: Section II reviews related work on Arabic NER, covering rule-based, traditional machine learning, and deep learning approaches, and highlights gaps in previous studies. Section III presents the pretrained transformer models used in this study, including their architectures, training data, and fine-tuning procedures for NER. Section IV describes the dataset, the experimental setup, and evaluation measures. Section V reports the experimental results, providing quantitative performance comparisons across models. Section VI offers a discussion of the results, analyzing model behavior and domain-specific challenges. Section VII presents a qualitative error analysis, highlighting common mistakes and ambiguous cases. Section VIII provides a comparative evaluation with previous Arabic NER approaches, emphasizing the benefits of domain-specific pretraining. Section IX discusses the limitations of the study, including the dataset and methodological constraints. Finally, Section X concludes the study and outlines potential directions for future research. Supplementary material, such as lists of ambiguous words and extended experiment details, is provided in Appendix A.

II. Related Work

Many approaches have been proposed to perform Arabic NER. Qu et al. (2024) classified them into four main paradigms: rule-based methods, machine learning, deep learning, and pretrained language models [10].

Before the rise of machine learning, the rule-based approach was the prime choice utilized in NER tasks. These systems depended on manually written linguistic rules and dictionaries. Examples of features commonly used include morphological analyzers [8], [12], [13], lexical triggers [14], regular expressions and gazetteers [15], as well as transliteration techniques [16]. Rule-based systems usually perform well in narrow domains but fail to generalize across domains. They also require heavy manual effort, which makes them less scalable [1].

With the advancement of statistical approaches, machine learning (ML) became widely adopted. Researchers explored several ML techniques, including conditional random fields (CRF) [17], [18], support vector machines (SVM) [19], [20], and meta-classifiers [21], [22], [23]. These approaches combined features such as lexical, contextual, morphological, gazetteer, and part-of-speech tags to improve performance. Although machine learning methods achieve satisfactory performance, they struggle to learn complex and high-level features from data when using linear models such as log-linear HMM or linear chain CRF. However, these approaches often underperform on Classical Arabic due to the language's rich morphology, absence of diacritics, and the scarcity of domain-specific datasets.

To address this limitation, deep learning methods have emerged as a solution for automatically discovering hidden features. The advancement of Arabic NER through deep-learning methods can be analyzed from three perspectives: i) input representations such as word-level embeddings [22], character-level embeddings [24], and additional features ; ii) context encoders, such as CNN [25], RNN [24], [26], or multi-attention networks [26] that capture dependencies between tokens; and iii) label decoders that assign the correct entity labels [25], [27]. While these methods reduce reliance on manual feature engineering, they still struggle to disambiguate entities in Classical Arabic texts, especially in religious and historical domains.

In recent years, pretrained language models (PLMs) have transformed Arabic NER. By learning contextual representations from massive corpora, models such as BERT [27], AraBERT [28], ARBERT and MARBERT [29], ArabicBERT [30], CAMelBERT [31], and Multilingual BERT [32] achieved state-of-the-art performance in many NLP tasks, including NER [33]. Despite their success, most studies focus on Modern Standard Arabic or social media text. Classical Arabic, particularly in Hadith texts, poses unique challenges not fully addressed by existing models.

Our study builds on this prior work by applying transformer-based pretrained models specifically to Classical Arabic NER using the CANERCorpus. This approach leverages domain-specific pretraining to improve recognition of ambiguous words, religious entities, and morphologically complex tokens, addressing gaps left by previous approaches.

III. Pretrained Models

We conducted training on the dataset using multiple pretrained language models. Table I provides an overview of the used models and their training data.

- AraBERT: Developed by Antoun et al. [28], AraBERT is a BERT-based model specialized for Arabic. It has several versions (v0.1/v1 and v0.2/ v2). Versions v0.1 and v1 were trained on 23GB of text, while v0.2 and v2 used a larger 77GB corpus. In this study, we employed AraBERT (v2).
- ARBERT/MARBERT: Introduced by Abdul-Mageed et al. [29], these models are based on the BERT architecture. ARBERT was trained on 66GB of news text, while MARBERT was trained on a larger 128GB

dataset that included 50% tweets. MARBERT is particularly strong for social media Arabic.

- ARBERT/MARBERT: Introduced by Abdul-Mageed et al. [29], these models are based on the BERT architecture. ARBERT was trained on 66GB of news text, while MARBERT was trained on a larger 128GB dataset that included 50% tweets. MARBERT is particularly strong for social media Arabic.
- ArabicBERT: Developed by Safaya et al. [30], this model was trained on 95GB of Arabic text, mostly from the OSCAR corpus. It captures broad Arabic patterns and structures.
- GigaBERT: Developed by Lan et al. [34], GigaBERT is a bilingual model trained on English and Arabic. It was trained on ACE2005 data, including broadcast news and newsgroups.
- QARiB: Provided by Abdelali et al. [35], QARiB was trained on a huge dataset consisting of around 420 million tweets gathered from Twitter and 180 million text sentences gathered from Arabic GigaWord, Abulkhair, and OPUS corpora.
- CAMeLBERT Models: Developed by Inoue et al. [31], CAMeLBERT has three variants: CAMeLBERT-MSA-NER, CAMeLBERT-CA-NER, and CAMeLBERT-MIX-NER. They are fine-tuned for NER tasks on MSA, CA, and a mix of MSA/CA/DA texts.
- Multilingual BERT: Proposed by Devlin et al. [27], this model supports 104 languages, including Arabic. Although trained on Wikipedia across languages rather than Arabic-specific data, it still provides useful performance for Arabic NER.

TABLE I. OVERVIEW OF THE PRETRAINED MODELS

Model Name	Model Information		
	Authors	***Training Data***	***Arabic Text Source***
AraBERT (v2)	Antoun et al. [28]	77 GB	OSCAR, Arabic Wikipedia, OSIAN, Arabic Corpus
ARBERT	Abdul-Mageed et al. [29]	66 GB	News articles
MAR-BERT	Abdul-Mageed et al. [29]	128 GB	Tweets, News
Arabic-BERT	Safaya et al.[30]	95 GB	OSCAR corpus
Giga-Bert:	Lan et al. [34]	ACE-2005	Broadcast news, Newsgroups
QARIB	Abdelali et al. [35]	420M tweets + 180M sentences	Twitter API, GigaWord, Abulkhair, OPUS
CAMeLBERT-MSA	Inoue et al. [31]	107 GB	Gigaword, Wikipedia, OSCAR, OSIAN
CAMeLBERT-CA	Inoue et al. [31]	6 GB	OpenITI corpus (v1.2)
CAMeLBERT-MIX	Inoue et a. Mach	167 GB	Various Sourses Combined (MSA, CA, DA)
Multi-lingual BERT	Devlin et al. [27]	~16 GB total (all languages), Arabic ≈ 3 GB	Wikipedia (104 languages)

IV. EXPERIMENTS

In this section, we describe the dataset, experimental setup, and evaluation metrics used in this study.

A. Dataset

Table II presents a list of available annotated datasets for Arabic NER. In this study, we employed the "CANERCorpus", which will be further detailed in this section.

TABLE II. LIST OF ANNOTATED DATASETS FOR ARABIC NER

Corpus	Year	Text Source	Tags	words	Availability
ANERcorp[1]	2007	Website, news, magazines	4	150 k	Free
ACE 2003[2]	2004	Broadcast News, newswire genres	7	42 k	Required fees
ACE 2004[3]	2004	Broadcast News, newswire genres	7	151 k	Required fees
ACE 2005[4]	2005	Transcripts, news	7	~300 k	Required fees
ACE 2007[5]	2007	Transcripts, news	7	~300 k	Required fees
REFLEX[6]	2009	Reuters news	4	22.5 k	Required fees
AQMAR[7]	2012	Arabic Wikipedia	7	1 M	Free
OntoNotes 5.0[8]	2013	News	18	300 k	Required fees
WDC[9]	2014	Wikipedia	4	6 M	Free
CANER[10]	**2018**	**Religion**	**20**	**258 k**	**Free**
Wojood[11]	2022	Wikipedia	21	550 K	Under request

We used the CANERCorpus [36], a Classical Arabic NER dataset annotated by experts. It contains 7,000 Hadiths from *Sahih Al-Bukhari*. The corpus includes 20 entity classes such as person, location, organization, date, book, and others. In total, the dataset has about 258K words, with 72K entities (≈23%). Fig. 1 and Table III show word count for each Named Entity.

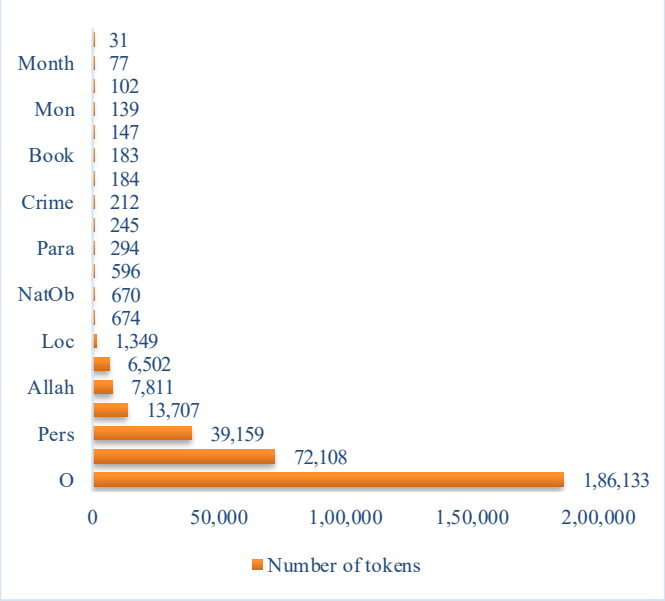

Fig. 1. Distribution of Named Entity tokens in CANERCorpus.

TABLE III. WORD COUNT FOR EACH NAMED ENTITY CLASS

Named Entity tag	Number of tokens
Allah	7,811
Prophet (Pro.)	6,502
Pers	39,159
Num	13,707
Loc	1,349
Clan	674
NatOb	670
Crime	212
Date	596
Para	294
Hell	245
Rlig	184
Book	183
Means	147
Mon	139
Time	102
Month	77
Day	31
Sect	17
Org	9
Other Words (O)	186,133
Named Entity	72,108
Total	258,241

For our experiments, we focused on person, God, prophet, location, clan, date, natural object, and other entities. The "number" entities were excluded since most of them were page numbers and did not add value to the task.

The CANERCorpus dataset did not provide clear sentence boundaries. We estimated the average sentence length in Sahih Al-Bukhari (38 words) and used this to split the text into sentences as in [36]. To avoid splitting related entities, the last token of each segment was labeled as "other" (O). We also removed punctuation, special characters, and diacritics. The dataset was then divided into training, validation, and test subsets. We randomly split the corpus into 80% training, 10% validation, and 10% testing. Table IV presents the distribution of named entities across each subset.

TABLE IV. THE DISTRIBUTION OF NAMED ENTITIES ACROSS THE TRAINING, TESTING, AND VALIDATION DATASETS

Named Entity	Training	Testing	Validation	Total
Pers	31,362	3,754	4,043	39,159
Allah	6,269	765	777	7,811
Prophet	5,162	669	671	6,502
Loc	1,087	127	135	1,349
Clan	601	103	63	767
NatOb	550	61	59	670
Date	491	56	49	596
Other	158,119	20,288	19,296	197,703
Total	203,641	25,823	25,093	254,557

B. Experimental Setup

The experiments were conducted on the Google Colab platform12 using a Tesla T4 GPU. Models were trained on the training dataset, with hyperparameters tuned on the validation dataset. Table V summarizes the parameters.

TABLE V. HYPERPARAMETER VALUES FOR THE MODELS

Parameter	Value
Learning Rate (LR)	1e-5
Maximum Length Size	256
Batch size	16
Optimizer	Adam
No. of epochs	Varied by model

C. Evaluation Measures

To assess the effectiveness of the pretrained models, we employed various metrics, including precision, recall, and F-measure. Eq. (1) outlines precision (P), which measures the correct identification of named entities by the model among all identified entities. Eq. (2) illustrates recall (R), indicating the correct identification of named entities by the model among all entities present in the corpus. Eq. (3) describes the F-measure (F), employed to harmonize the conflicting relationship between precision and recall [9], [37].

$$precision = \frac{TP}{TP+FP} \quad (1)$$

$$Recall = \frac{TP}{TP+FN} \quad (2)$$

$$F1-Score = \frac{2\ (Precicion*Recall)}{(precsion+Recall)} \quad (3)$$

where, TP, FP, and FN denote true positives, false positives, and false negatives, respectively.

[12] https://colab.research.google.com/

V. RESULTS

In this section, we present the results of training ten pretrained models on the CANERCorpus dataset. Table VI and Fig. 2 summarize the models' performance in terms of Precision, Recall, and F1-score.

TABLE VI. RESULTS ACHIEVED BY PRETRAINED LANGUAGE MODELS

Model Name	P	R	F	No. of Epochs
AraBERT	96.11	96.94	96.53	13
ArBERT	96.89	**98.09**	97.47	7
MARBERT	96.51	97.44	96.97	7
GigaBERT	96.93	97.50	97.21	11
Arabic-BERT	96.63	97.50	97.06	8
QARIB	96.31	96.70	96.50	7
Camel-msa-ner	96.85	97.75	97.30	8
Camel-ca-ner	**97.51**	98.05	**97.78**	9
Camel-mix-ner	96.94	97.84	97.39	8
Multilingual	96.11	96.94	96.53	11

The bold numbers mark the best results.

All models achieved strong results, with F1 scores ranging from 96.53% to 97.78%. The best performance was obtained by CAMeLBERT-CA-NER with an F1 score of 97.78%. QARiB also performed strongly, and models such as AraBERT, ArabicBERT, ARBERT, and MARBERT achieved high results with F1 scores above 96.5%. In contrast, Multilingual BERT obtained the lowest F1 score (96.53%).

These results demonstrate the robustness of transformer-based models in handling the linguistic challenges of Classical Arabic.

VI. DISCUSSION

This section provides an analysis and interpretation of the results presented in Section V.

The best performance of CAMeLBERT-CA-NER confirms the advantage of domain-specific pretraining on Classical Arabic texts, since the model was exposed to linguistic and stylistic patterns directly relevant to the Hadith corpus. This pretraining allowed CAMeLBERT-CA-NER to better recognize religious and historical entities (e.g., Prophet names, clans, and locations) and to handle morphological variations typical of Classical Arabic. In contrast, models trained primarily on Modern Standard Arabic or social media data showed slightly higher misclassification rates for such entities due to domain mismatch. CAMeLBERT-MIX-NER also achieved competitive performance, suggesting that multiple Arabic varieties (MSA, CA, and DA) can further improve generalization across heterogeneous texts.

QARiB performed strongly as well, benefiting from its large-scale training on diverse Twitter and formal Arabic corpora. This highlights that large amounts of heterogeneous data, even if not exclusively Classical Arabic, can still capture rich contextual representations transferable to CA NER tasks.

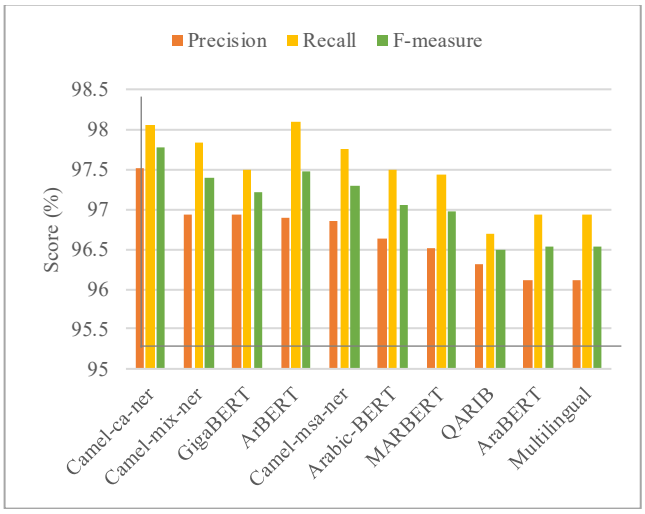

Fig. 2. Performance of pretrained models on CANERCorpus.

Models such as AraBERT, ArabicBERT, ARBERT, and MARBERT also achieved high results. Although primarily trained on MSA and social media text, they were able to generalize effectively to CA. This suggests that while surface differences exist between MSA and CA, pretrained models can leverage their shared morphological and syntactic features.

The weaker performance of Multilingual BERT can be attributed to the relatively small portion of Arabic in its training data (~3 GB from Wikipedia), compared to the much larger corpora used in Arabic-specific models. This result underlines the importance of language-specific and domain-focused training when dealing with morphologically rich languages like Arabic.

Beyond overall scores, a closer inspection of entity-level performance revealed interesting trends. Models trained on Classical Arabic data (e.g., CAMeLBERT-CA-NER) showed superior accuracy in recognizing religious and historical entities such as Prophet names, clans, and locations mentioned in Hadiths. On the other hand, models trained mainly on MSA and tweets occasionally misclassified such entities, reflecting a domain mismatch. However, these models performed comparably well on generic entities like dates, times, and numerical expressions, where the differences between CA and MSA are minimal.

Overall, the results highlight three important insights:

- Domain-specific pretraining matters. CAMeLBERT-CA-NER demonstrates clear advantages when the training domain matches the target text.
- Cross-variety transfer is feasible for MSA and DA-based models still generalize well to CA, especially for common entity types.
- Data size and diversity play a crucial role; larger and more varied corpora (e.g., QARiB, MARBERT) improve robustness, even if they are not domain-specific.

These findings emphasize that while transformer models are inherently powerful, their effectiveness for Classical Arabic NER is maximized when they are trained on domain-relevant corpora. At the same time, the strong performance of general-purpose models suggests promising opportunities for cross-domain transfer and low-resource adaptation in future research.

VII. Error Analysis

To better understand the behavior of the pretrained models on Classical Arabic NER, we conducted an analysis of detected ambiguities in the test set. We selected the four highest-performing models based on F1-score: ArBERT, CAMeL-CA-NER, CAMeL-MSA-NER, and CAMeL-MIX-NER. The test set contained 24,966 words. Table VII summarizes the number of correctly and incorrectly tagged words for these models.

TABLE VII. Correct and Incorrect Tag Counts for Top-Performing Models

Model	Correct Tags	Incorrect Tags
ArBERT	24,813	153
CAMeL-ca-NER	24,829	137
CAMeL-mas-NER	24,805	161
CAMeL-mix-NER	24,813	153

Some examples of ambiguous words and their corresponding model predictions are shown in Table VIII.

- Words following "ك" (e.g., كرسول) are sometimes misclassified by ArBERT, which labels them as "O" instead of the correct tag "Prophet".
- Words preceded by "ب", such as (*بنخلة*), may be incorrectly tagged as "LOC" by ArBERT and, in some cases, by CAMeL-CA-NER and CAMeL-MIX-NER, though the correct tag is "O".
- Words preceded by "ف", such as (*فلصفوان*) in the phrase (*وإن لم يرض عمر فلصفوان*), are occasionally misclassified by ArBERT as "O" instead of "Pers".
- Words following (*نو*) in CAMeL-CA-NER are sometimes wrongly labeled as "Pers", for example (*نو اليدين*).
- Some prophets' names, like (*ابراهيم*) and (*يوسف*), are occasionally tagged as "Pers" instead of "Prophet", and vice versa. This also occurs in ArBERT.
- Certain locations, for instance (*مزدلفة*) and (*جمرة العقبة*), are misclassified by CAMeL-CA-NER.
- Person names following words like (*امرأة*) or (*ابن*) may be incorrectly labeled as "Pers" even when they refer to prophets, as in (*ابن مريم*). This occurs in ArBERT, CAMeL-CA-NER, and CAMeL-MIX-NER.

Additional ambiguities observed specifically in ArBERT and CAMeL-MSA-NER include:

- Words like (*قوله*) followed by (*تعالى*) are misrecognized as "Allah" instead of "O".
- Nouns such as (*أسماء*) are sometimes tagged as "Pers" when they are not proper names, e.g., in (*أحب أسماء على رضي الله عنه إليه*).
- Words like (*على*) are occasionally misclassified as "Pers", e.g., (*وكانت على بردة*).
- Certain verbs followed by person names can be misclassified as "Pers", for example (*فنسي عوف ثم عمر بن الخطاب*).
- The word (*الله*) is sometimes labeled as "Allah" when it should be "*لنبي الله*" or "*لرسول الله*".

These errors mainly arise from differences between the models' training data and the Classical Arabic text in CANERCorpus. Models fine-tuned on Modern Standard Arabic (e.g., ArBERT, CAMeL-MSA-NER) show more ambiguities, while models trained on Classical Arabic (CAMeL-CA-NER) or a mixture of varieties (CAMeL-MIX-NER) exhibit fewer errors. The qualitative analysis in Table IX shows that CAMeL-CA-NER effectively handles Classical Arabic morphological patterns and religious expressions, such as prefixes (و, ب, ف) and embedded prophet names, that often confuse models trained solely on Modern Standard Arabic. Its superior handling of ambiguous cases like كرسول reflects its experience to Classical Arabic syntax and vocabulary during pretraining. In contrast, ArBERT and CAMeL-MSA-NER frequently misclassify tokens due to domain mismatch and limited exposure to archaic forms. Occasional over-generalization errors in CAMeL-CA-NER, such as mislabeling اليدين as Person, indicate sensitivity to morphological cues that resemble name patterns. These insights confirm that domain-relevant pretraining enhances contextual disambiguation and improves the recognition of specialized entity types in Classical Arabic texts.

TABLE VIII. Model Predictions for Ambiguous Words

The ambiguous word	Correct tag	AraBERT	CAMeL-ca-NER	CAMeL-msa-NER	CAMeL-mix-NER	Weighted- ET-ANER
وبمكة	Loc	O X	Loc √	Loc √	Loc √	Loc √
كرسول	Pro.	O X	Pro. √	Pro. √	Pro. √	Pro. √
اليدين	O	O √	Pers X	O √	O √	O √
قال فيوسف نبي الله	Pro.	O X	Pers X	Pro. √	Pro. √	Pro. √

VIII. Comparative Evaluation with Previous Arabic NER Approaches

Table IX and Fig. 3 compare the performance of the best model, CAMeL-CA-NER, with previously reported results on the CANERCorpus dataset. Early rule-based approaches achieved modest performance (F1 = 89.5%), reflecting the limitations of handcrafted rules for Classical Arabic. Later BERT-based models reached around 94 to 95% F1, demonstrating the benefits of contextualized embeddings. However, our CAMeL-CA-NER model achieved the highest score (F1 = 97.78%), outperforming earlier systems by more than 3%. This improvement can be attributed to its domain-specific pretraining on Classical Arabic texts (OpenITI corpus[13]), which provides a closer linguistic match to Hadith data. These findings confirm that transformer architectures with domain-relevant pretraining substantially advance the state of Classical Arabic NER.

TABLE IX. Comparison with Previous Works that Used CANERCorpus in Arabic NER Process

Previous Work	Approaches	Precision	Recall	F1-score
[38]	Rule-based approach	90.2	89.3	89.5
[39]	BERT	94.1	94.9	94.5
	BERT-CRF	94.0	95.4	94.7
	BERT-BLSTM-CRF	93.8	95.2	94.4
	BERT-GRU-CRF	94.1	95.5	94.8
[31]	CAMel-CA-NER	**97.51**	**98.05**	**97.78**

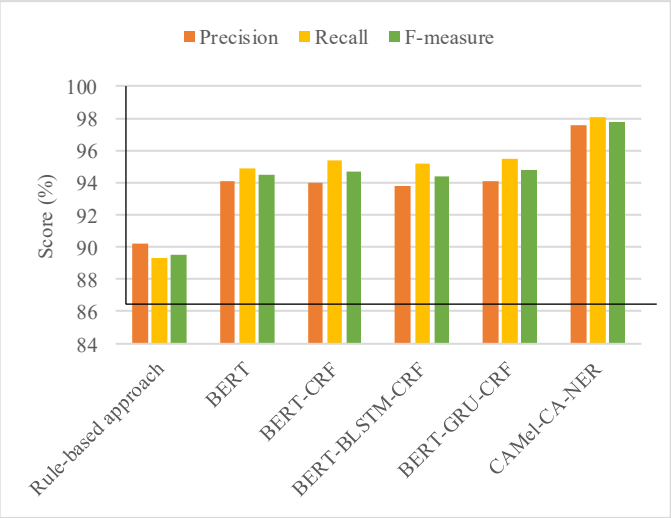

Fig. 3. Comparison of CAMel-CA-NER performance with previous Arabic NER approaches on the CANERCorpus dataset.

IX. Limitations of the Study

Despite the strong performance of transformer-based models for Classical Arabic NER demonstrated in this study, there are several limitations. First, the dataset used (CANERCorpus) is relatively outdated (2018), which may limit the applicability of our findings to more recent or varied Classical Arabic texts. Second, the corpus consists exclusively of Hadith texts, which means the models are primarily exposed to religious and historical language; this may affect their generalization to other Classical Arabic domains such as literature or formal documents. Third, while our models achieved high overall F1 scores, some entity types remain challenging, particularly ambiguous words or rare entities. Finally, the evaluation was limited to standard metrics (precision, recall, F1-score), and further work is needed to assess models' robustness in real-world NLP applications or cross-domain scenarios. Acknowledging these limitations provides transparency and helps readers interpret the scope of our findings accurately.

X. Conclusion and Future Work

This study evaluated the performance of transformer-based pretrained language models for Classical Arabic NER using the CANERCorpus of Hadith texts. The results showed that all models achieved strong performance, with F1 scores above 96%, confirming the effectiveness of transformer-based approaches for morphologically rich and linguistically complex languages. Among the models, CAMeLBERT-CA-NER achieved the highest F1 score (97.78%), demonstrating the advantages of domain-specific pretraining on Classical Arabic texts. While models trained on MSA and social media text generalized reasonably well to CA, the error analysis revealed that they were more prone to misclassifying religious and historical entities, emphasizing the importance of domain-relevant data for accurate NER. The novelty of this study lies in its systematic benchmarking and detailed linguistic analysis rather than proposing a new architecture. By systematically comparing multiple transformer-based models on Classical Arabic data, this work establishes a valuable reference point for future advancements in Arabic NER and provides insights for developing domain-specific pretrained models.

Future research can build on these findings in several directions. First, expanding the dataset with additional Classical Arabic sources, including underrepresented entity types, would enhance model coverage and reduce ambiguity-related errors. In particular, while the CANERCorpus (2018) remains a valuable resource, incorporating more recent datasets would improve the relevance and applicability of the findings. Second, investigating cross-domain transfer and domain adaptation between Classical Arabic, Modern Standard Arabic, and dialectal varieties could further improve adaptability and robustness across diverse text genres. Third, incorporating strategies to handle ambiguous words and diacritic variations may enhance model accuracy. Fourth, exploring model interpretability techniques to understand how transformer models capture linguistic cues and contextual dependencies would provide valuable insights into their decision-making process. Finally, integrating these pretrained models into downstream applications such as semantic search, question answering, and historical text analysis would demonstrate their practical utility and support broader NLP research in Classical Arabic.

***Abstract*—The mental health of adult students is crucial not only for enhancing their learning experience and overall quality of life, but also for alleviating academic and employment-related anxiety. A significant challenge in developing effective online mental health support systems is the accurate assessment of students' mental health status. Current evaluation methods often lack precision and fail to integrate multifaceted data perspectives. To address these challenges, this study developed a psychological assessment system based on deep learning technology. The system aims to assess adult students' psychological states and provide appropriate support. Specifically, it utilizes a Convolutional Neural Network (CNN) and Long Short-Term Memory (LSTM) algorithm framework to evaluate students' psychological states by synthesizing image data, academic performance, and textual inputs. Furthermore, to enhance the accuracy of deep learning-based mental health assessment models, an improved hippopotamus optimization (IHO) algorithm was designed to optimize the hyperparameters of deep learning frameworks. By using the proposed multi-input single-output hybrid IHO-based LSTM-CNN framework (IHO-LSTM-CNN), the online mental health assessment module can accurately describe the psychological status of college students and provide personalized support to meet their specific needs. The final results indicate that the IHO-LSTM-CNN framework provides more accurate assessments than existing mental health assessment models, with an accuracy of 90.28%. This enhanced accuracy enables online community psychological support systems to deliver precise and effective psychological support to college students.**

I. Introduction

Amid growing global concern for mental health issues, researchers are designing generative artificial intelligence (AI)-based psychological support systems that utilize generative dialogue technology [1]. However, these systems often lack accuracy in assessing users' mental health status and consequently fail to provide high-quality, tailored psychological support [2]. Concurrently, higher education institutions and educational management departments are increasingly concerned about the rising prevalence of mental health problems among adult students. To address these specific challenges, an online community psychological support system powered by generative AI is designed. This system accurately assesses the mental health status of adult students based on their inquiry statements and basic information. Subsequently, leveraging the assessment results, it generates targeted psychological support statements to effectively address their mental health concerns.

The core goal of a generative AI-based network community psychological support system is to assess adult students' psychological states online, such as anxiety, depression, and stress levels, through non-invasive, continuous data collection and analysis. A core challenge for this online assessment system is accurately evaluating the psychological status of adult students based on available data. Specifically, since adult students' psychological data typically includes multimodal information (such as text, images, behavioral patterns, etc.), the evaluation model must effectively integrate these diverse inputs. Furthermore, the psychological state of adult students can fluctuate rapidly due to academic and family pressures, requiring algorithms to possess both short-term sensitivity and long-term trend prediction capabilities.

Current algorithms for mental health assessment primarily include Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), traditional Random Forest algorithms, and expert rule-based systems [3]. Among these, CNN-based models excel at text sentiment analysis and image micro-expression recognition. However, CNN algorithms struggle to model dynamic changes in psychological states. They also demand large volumes of annotated data during processing, making the acquisition of psychological labels costly and subjective. In contrast, RNNs and Long Short-Term Memory Networks (LSTMs) can effectively capture the temporal evolution of psychological states. Nevertheless, their high model complexity can lead to overfitting, consequently reducing prediction accuracy. Finally, traditional Random Forest models are typically suitable only for small-sample static scenarios and struggle with unstructured data [4].

Another key challenge in generative AI-based network community psychological support systems is effectively using this technology to provide necessary psychological support for adult students. Current psychological support models primarily include those based on large language models (LLMs), knowledge graphs, and reinforcement learning [5]. LLMs can capture nuanced information through attention mechanisms and serve multicultural student groups on cross-border online education platforms. However, they may generate inaccurate

*Corresponding author.

psychological concepts and their responses often prioritize logical analysis over emotional warmth. Knowledge graph-based psychological support models offer strong professional accuracy, but suffer from long development cycles among other limitations. Reinforcement learning-based models can dynamically optimize support strategies through user feedback. However, during early training stages, the model may generate inappropriate suggestions.

To address the limitations in generative AI-based network community psychological support systems, this study proposes a psychological assessment model for adult students using CNN and LSTM algorithms. This model comprehensively analyzes adult students' behavioral expressions, academic performance, and textual interactions within the network community to accurately evaluate their mental health status. Furthermore, the system provides essential psychological support for adult students using a reinforcement learning algorithm. This reinforcement learning-based support model incorporates a two-layer filtering mechanism: 1) The first layer intercepts high-risk content using a rule-based system. 2) The second layer detects implicitly harmful content through a classifier. Additionally, when the psychological assessment model identifies a severely depressed mental health status, the support system initiates human counselor intervention. The architecture of the mental health assessment module is depicted in Fig. 1. The main contributions of this study are summarized as follows:

- A dual-layer architecture combining CNN and LSTM model has been developed, constructing a psychological assessment model for adult students. This model integrates multimodal data sources, significantly enhancing the accuracy of mental health assessment in educational settings.
- An improved hippopotamus optimization (IHO) algorithm incorporating a hybrid mutation strategy is proposed to optimize critical hyperparameters of CNN and LSTM, thereby enhancing model performance.
- An online psychological support model utilizing reinforcement learning algorithms has been designed, capable of providing personalized psychological support to large populations of adult students.
- The results showed that the HOA-LSTM-CNN model improved accuracy by an average of 20.65% compared to the other three commonly used emotion assessment models.

The rest of this study is arranged as follows: In Section II, the models and algorithms related to this study are reviewed, and Section III mainly introduces the methodology of this study, including the mental health assessment model and psychological support system. Section IV presents the application results of the developed algorithms and models. Section V summarizes the entire text and provides future research directions.

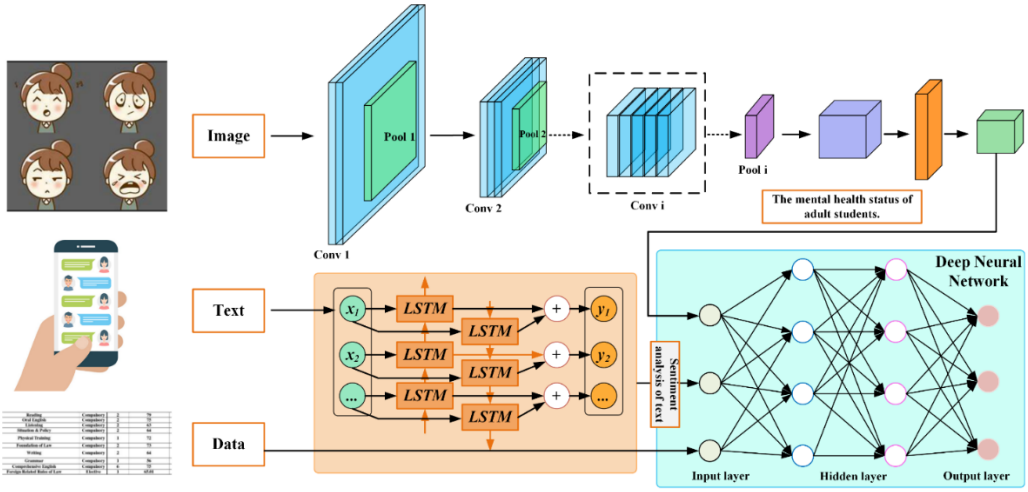

Fig. 1. The proposed framework for the mental health assessment system.

II. Related Work

The rapid development of multimodal models, machine learning, and reinforcement learning technologies has enabled the establishment of generative AI-based network community psychological support systems. In this study, the proposed online psychological support system predicts college students' mental health status using a hybrid CNN-LSTM framework, while generating psychological support dialogues through reinforcement learning models. Accordingly, this section provides a systematic review of mental health prediction models, psychological support systems, and heuristic optimization algorithms.

A. Emotion Prediction Based on Deep Learning

In [6], the authors summarize emotion classification methods based on speech data, and this study summarizes the application of deep learning techniques including convolutional neural networks (CNN), recurrent neural networks (RNN), and attention mechanisms in emotion analysis. Mou et al. [7] proposed a reader sentiment prediction framework based on news text content and comment data, which extracts news semantic features through a bidirectional Transformer encoder and synthesizes pseudo comment data using a generative model to expand the training data. Pordoy et al. [8] designed a transfer learning-based emotion recognition

framework for facial emotion recognition in online education scenarios, which can combine adaptive strategies to transfer emotion analysis methods to specific educational scenarios. This study addresses the noise impact of lighting changes on image data in real classroom environments.

In [9], the authors proposed a speech emotion recognition technology for different accents, which integrates acoustic features and accent embedding vectors, and uses multi-task learning to optimize emotion classification and accent recognition tasks. This framework has been validated based on a mixed dataset containing English and Chinese dialects, providing a foundation for sentiment analysis of speech with accents. In [10], the authors developed a fake news detection model based on emotional features and proposed a multi-task learning model aimed at achieving news authenticity classification tasks and reader sentiment prediction tasks. This model is based on large-scale social media data and uses transfer learning algorithms to identify emotionally provocative language in fake news. In [11], the authors designed an end-to-end multimodal video emotion recognition system that integrates facial expressions, speech intonation, and text modalities, using a lightweight network architecture and cross-modal attention mechanism to analyze emotions in movie clips and video interviews.

B. Psychological Support Model Based on Reinforcement Learning

Generating psychological support for users based on sentiment analysis remains a significant challenge. In [12], the authors developed a moderation mediation model to investigate the impact of teacher support and family support on adolescents' psychological state during online learning. This study provides a theoretical basis for optimizing student psychological intervention strategies. In [13], the authors propose a deep learning framework for emotion recognition using deep neural networks, offering a foundation for the computable modeling of psychological phenomena. In [14], the authors developed a multimodal psychological support system for college students that utilizes facial image and voice data to recognize emotional states in real-time. Based on these recognition results, the system generates personalized virtual intervention scenarios. Experimental results demonstrated that this system significantly reduced users' psychological symptoms following intervention.

Yang et al. designed a deep learning model based on an attention mechanism to address the psychological stress of college entrepreneurs. The model takes entrepreneurial diary text, social media behavior, and physiological sensor data as input parameters, and can predict anxiety and fatigue risk levels and provide real-time intervention recommendations [15]. In order to enhance the adaptability of normative software agents, Viana et al. [16] proposed a psychological intervention system based on meta models and reinforcement learning. Case studies have shown that this language has successfully intervened in children's psychological problems in the context of child companionship robots. In [17], the authors constructed an emotion state classification system based on multimodal data. This system can integrate Electroencephalogram (EEG) band energy data and achieve emotion classification through graph convolutional networks. In [18], the authors designed an adaptive psychological support system that can analyze user behavior logs, voice emotions, and physiological signals in real-time, dynamically generate personalized intervention strategies to reduce users' mental health problems.

C. Artificial Intelligence-Based Furniture Design System

In order to construct an artificial intelligence-based furniture design system, Luo et al. combined Capsule Networks with artificial rabbits optimization (ARO) algorithm and proposed a framework for optimizing Capsule Networks hyperparameters using the ARO algorithm, aiming to enable the furniture design system to more accurately capture users' emotional feedback in virtual environments [19]. Naulia et al. [20] proposed an improved metaheuristic algorithm based on mathematical principles, aimed at optimizing the weight parameters of deep convolutional neural networks. This improved metaheuristic optimization algorithm achieves intelligent adjustment of network parameters. Finally, the study tested the improved deep learning model on multiple standard datasets, demonstrating that the improved algorithm can effectively prevent overfitting of the deep learning model.

In [21], the authors combined the Beetle Antenna Search (BAS) algorithm with a CNN to develop an efficient imaging diagnostic model. This study is based on the BASO algorithm to optimize the hyperparameters of CNN, aiming to enable CNN to efficiently learn the features of medical images, while improving diagnostic accuracy and reducing the computational complexity of CNN. In [22], the authors used the Mountain Gazelle Optimizer (MGO) to optimize the parameters of artificial neural networks. The MGO algorithm is an optimization algorithm designed by researchers inspired by the foraging behavior of mountain gazelles. After testing, it has also shown good performance in parameter optimization of artificial neural networks.

III. Proposed Mental Health Assessment System

In this section, a network-based community psychological support system is designed utilizing automatic question answering technology. At present, research has tested the application of deep learning frameworks in the psychological assessment of college students and computer vision. The framework proposed in this study is different from the previous research. Specifically, the system comprises two core modules. The first module is a mental health assessment module based on CNN and LSTM. The second module is a psychological support module leveraging reinforcement learning. Fig. 2 illustrates the architecture of the reinforcement learning-based psychological support model. For the sentiment analysis system targeting adult students, it analyzes facial expressions conveying negative emotions using a CNN. Simultaneously, it performs sentiment analysis on texts generated by these students within the online community psychological support system using LSTM. Subsequently, based on the results from both the CNN and LSTM analyses, combined with the students' normalized performance data, a comprehensive evaluation is conducted using an artificial neural network.

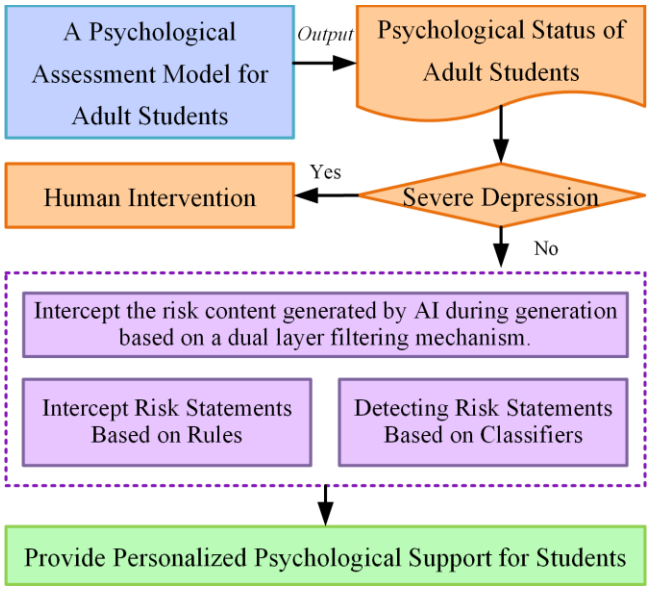

Fig. 2. A reinforcement learning-based psychological support model.

A. Hybrid LSTM and CNN (LSTM-CNN)-Based Mental Health Assessment System

The mental health assessment module adopts a deep CNN architecture, which includes multiple convolutional layers, pooling layers, and fully connected layers. This deep CNN takes pre-processed facial image data of adult students as input data, followed by multiple convolutional and pooling layers, and finally outputs the expression categories of adult students based on the classifier. The calculation formula for convolutional layers is as follows [Formula (1)]:

$$C_i = \sum_{k=1}^{K}\left[\left(w_i^k * Q_k\right) + O_i\right] \tag{1}$$

where, C_i is the $i-th$ feature map obtained through calculation. w_i^k is the $i-th$ convolution kernel on the $k-th$ channel. $*$ is the symbol for the convolution operation. Q_k is the input data on $k-th$ channel. O_i is the bias value.

The CNN framework designed for facial expression analysis uses the following loss function for training data [Formula (2)]:

$$f\left(y_{prediction}\right) = \frac{1}{4\times N}\sum_{n}\left|y_{prediction}(n) - y_{ture}(n)\right| \tag{2}$$

where, $f\left(y_{prediction}\right)$ A is defined as the loss function. N is the number of adult students included in the test set. $y_{prediction}(n)$ is the test value, $y_{ture}(n)$ is the true value. When the test value is consistent with the true value, $\left|y_{prediction}(n) - y_{ture}(n)\right|$ =0; Otherwise, $\left|y_{prediction}(n) - y_{ture}(n)\right|$=1.

This study is based on LSTM for sentiment analysis of text input by adult students in online community psychological support systems. Firstly, the original text undergoes a series of pre-processing steps and is transformed into dense vectors using word embedding techniques. On this basis, the mental health assessment system adopts a bidirectional LSTM network structure, which captures long-term dependencies of text through multiple LSTM layers, and finally outputs the emotions of adult students through fully connected layers. For the bidirectional LSTM network architecture, this study uses root mean square error (RMSE) as an additional evaluation metric; therefore, the EMSE metric of LSTM is defined as follows [Formula (3)]:

$$F_{RMSE} = \sqrt{\frac{1}{N}\sum_{n}\left(y_{prediction}(n) - y_{ture}(n)\right)^2} \tag{3}$$

where, F_{RMSE} is the EMSE metric of LSTM. $y_{prediction}(n)$ is the test value, $y_{ture}(n)$ is the true value.

B. Improved Hippopotamus Optimization Algorithm

In order to improve the performance of CNN, meta-heuristic optimization algorithms were used in works [21]-[22] to optimize the hyperparameters of CNN. Based on this idea, this study improved the HO algorithm with the aim of optimizing the hyperparameters of CNN and LSTM to enhance their prediction accuracy. At present, the HO algorithm has been widely applied in various fields such as intelligent transportation, logistics, and robotics [23].

In this study, the IHO algorithm provides an efficient group search strategy for hyperparameter optimization of CNN and LSTM. The search process of IHO first requires defining hippo individuals that contain multidimensional information, including key hyperparameters such as learning rate, batch size, number of convolution kernels, kernel size, dropout rate, and number of fully connected layer units. Among them, the size of the convolution kernel needs to be constrained to an odd number. Each hippo individual represents a set of hyperparameter combinations in the search space, and its continuous position vector is transformed into actual usable discrete parameter values through specific rules. In addition, the fitness function of CNN and LSTM hyperparameter optimization problems based on the IHO algorithm is also a challenge in the search process. The fitness function is the core content of the IHO algorithm optimization process. In the optimization process of the IHO algorithm, the initial solution is first generated based on hyperparameters of CNN and LSTM models, trained using hyperparameters corresponding to an individual of hippopotamus, and finally evaluated using test set accuracy.

In order to improve the convergence accuracy of the HO algorithm, the proposed IHO algorithm introduces a grey wolf optimization strategy based on the HO algorithm [24]. Therefore, in the search process of the IHO algorithm, the hippopotamus population first searches for the solution space of hyperparameters through the grey wolf optimization strategy. During each iteration, each individual of hippopotamus dynamically updates their speed and position based on the historical best position of the hippopotamus population. After the position update, it is necessary to determine whether the hyperparameters meet the boundary constraints based on their characteristics, such as limiting the

size of the convolution kernel to an odd number. The following is the process of the IHO algorithm:

1) Initialization: Form a set of hippo individuals by combining the hyperparameters of CNN and LSTM. The hyperparameters of CNN include the number of convolution kernels, the size and stride of pooling kernels, and the learning rate. The hyperparameters of LSTM include the number of layers and learning rate of the recurrent neural network. In Formula (4), a set of initialized hippo individuals is defined.

$$G=\begin{bmatrix} g_1^1 & g_2^1 & \cdots & g_z^1 \\ g_1^2 & g_2^2 & \cdots & g_z^2 \\ \vdots & \vdots & \vdots & \vdots \\ g_1^l & g_2^l & \cdots & g_z^l \end{bmatrix} \tag{4}$$

where, G is a set of initialized hippo individuals. g_z^l is the z-th dimension of the l-th individual, representing a hyperparameter of CNN or LSTM.

2) Wolf pack hierarchical encirclement strategy: The IHO algorithm uses a wolf pack hierarchical encirclement strategy [24] to find the optimal solution, which is defined as follows [Formula (5) and Formula (6)]:

$$\begin{cases} g_z^l(a,new)=g_z^l(a)-A_1\times D_1 \\ g_z^l(b,new)=g_z^l(b)-A_2\times D_2 \\ g_z^l(c,new)=g_z^l(c)-A_3\times D_3 \end{cases} \tag{5}$$

$$g_z^l(new)=\frac{1}{3}\times\left[g_z^l(a,new)+g_z^l(b,new)+g_z^l(c,new)\right] \tag{6}$$

where, A and D are random numbers on the [0,1] interval. $g_z^l(a)$, $g_z^l(b)$ and $g_z^l(c)$ are the vectors corresponding to the three best bounds currently generated.

3) Hippopotamus location update strategy: After completing the wolf pack hierarchical search, the IHO algorithm further explores the solution space based on the hippopotamus location update strategy, as shown in Formula (7).

$$g_z^l(new)=g_z^l+StepH\times\left(D_hippe-g_{fe}^l\right) \tag{7}$$

$$StepH=\exp\left(-\frac{t}{T}\right) \tag{8}$$

where, $StepG$ is the stride of the dispersed search by the hippopotamus population, and D_hippe is the current optimal position of the hippopotamus individual. g_{fe}^l is the position of the female hippopotamus [see Formula (8)].

4) Avoiding natural enemies strategy: After completing the location update, the IHO algorithm further searches within a small range based on the strategy of avoiding natural enemies [see Formula (9)].

$$g_z^l(new)=g_z^l+r_\beta\times\left(g_z^l-g_{fe}^l\right) \tag{9}$$

where, r_β is the avoidance coefficient.

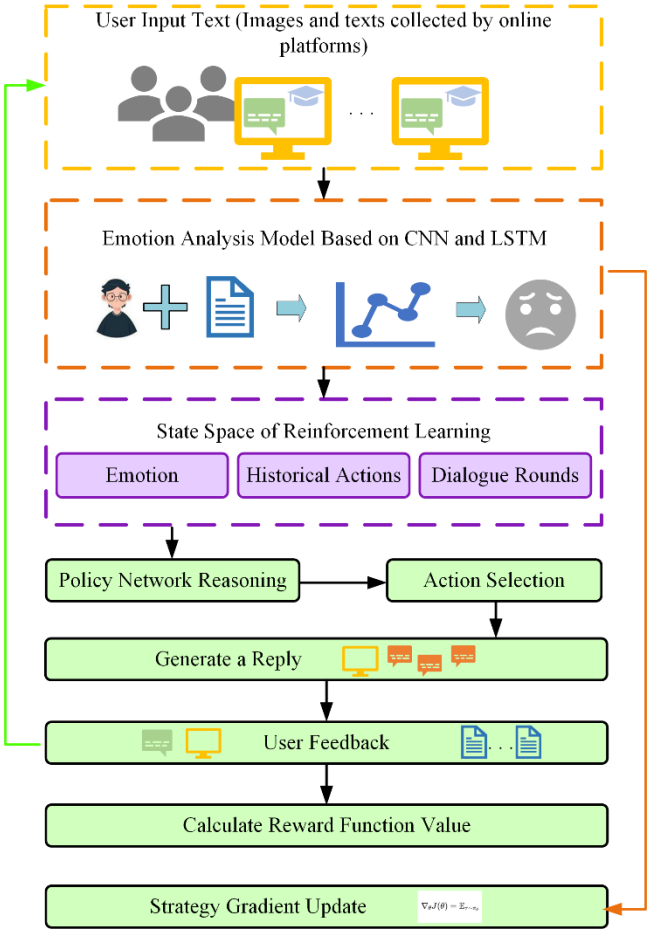

Fig. 3. A mental support system based on reinforcement learning.

C. Reinforcement Learning-Based Mental Support System

After evaluating the mental health status of students based on CNN and LSTM, a psychological support system was designed. As previously mentioned, a multidimensional state perception system based on CNN and LSTM has been constructed for mental health assessment. By integrating structured data (academic performance) and unstructured behavioral data (facial expressions, counseling texts, and frequency) of students in real-time, a personalized dynamic psychological profile has been formed for each user. The operational flowchart of the psychological support module is presented in Fig. 3.

The core of the psychological support system adopts a hierarchical reinforcement learning architecture, and a specialized knowledge base for psychological intervention strategies is designed at the action decision-making level. For example, when the user inputs "Final exam makes me breathless", the system first analyzes the user's psychological characteristics through the mental health status assessment module, and then activates a two-stage decision-making process:

- Surface semantic analysis based on LSTM is labeled as "academic stress" and "low mood".
- Cognitive bias detection identifies a tendency towards overgeneralization, and ultimately generates candidate action sets through strategy networks, such as mindfulness breathing guidance and psychological comfort.

Unlike conventional mental health question and answer systems, the proposed psychological support system innovatively introduces a psychological safety constraint layer: when calculating action weights, a dynamic coefficient adjustment mechanism is used to ensure that statements with high mental health risks inevitably trigger crisis intervention processes. The formula for calculating the action weight of the psychological support system is as follows [Formula (10)]:

$$DL_{action} = w_1 \times f_{cri} + w_2 \times f_{aes} + w_3 \times f_{acc} \tag{10}$$

where, w_1, w_2, and w_3 are weight coefficients, respectively. f_{cri} is the crisis index, f_{aes} is resource availability, and f_{acc} is user acceptance.

To adapt to the particularity of the field of mental health, the reinforcement learning based psychological support system adopts a three-stage progressive training program. In the stage of building basic abilities, the LSTM model is pre-trained based on a large amount of structured interview data, enabling it to accurately identify many types of psychological problems such as depression and anxiety. In the reinforcement learning stage, safety training is achieved through personalized simulation environments, mainly constructing various personality prototypes of college students, such as perfectionists and social anxiety sufferers. Professional psychological counselors control the simulator to generate dialogues containing poor mental health levels, and the mental health support system learns intervention strategies in this environment. In addition, the key innovation of the system lies in the dual track reward mechanism, which adds an effectiveness reward item in addition to the regular user satisfaction reward. If students perform the respiratory guidance exercises recommended by the system and there is a decrease in catastrophic expressions in subsequent conversations, additional rewards will be given.

According to Fig. 3, the reinforcement learning-based psychological support system needs to update the gradient of the algorithm, and the gradient update formula is shown below [see Formula (11)]:

$$\beta_{t+1} \leftarrow \beta_t - \xi \times \frac{E_t}{\sqrt{V_t} + \pi} \tag{11}$$

where, β_t is the gradient of the reinforcement learning algorithm, E_t and V_t are momentum estimates after deviation correction.

IV. Results and Discussions

In this study, the facial expression data, academic performance data, and text data from online communities of 450 students are collected as datasets. In these datasets, the ratio between male and female students was 1:1, and the average age of adult students was 20.6 years old. The training set used data from 390 students, while the testing set used data from 60 students.

For the proposed emotion analysis framework for college students, the effectiveness of the IHO algorithm-based CNN (IHO-CNN) module emotion classification was first demonstrated. To ensure fairness, Enzyme Action Optimization (EAO) [25] and Particle Swarm Optimization (PSO) [26] were used to optimize the hyperparameters of the CNN model, and the optimization results were compared with the proposed IHO-CNN model.

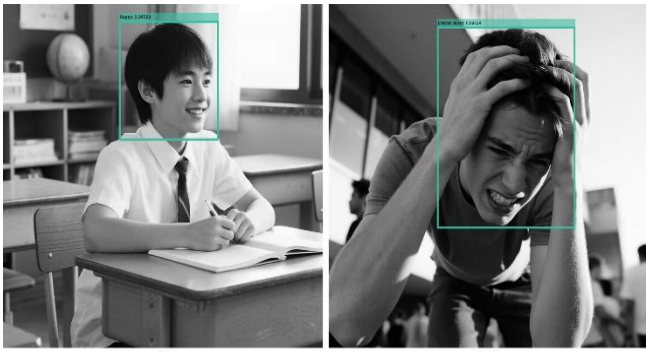

Fig. 4. Expression analysis results based on IHO-CNN model.

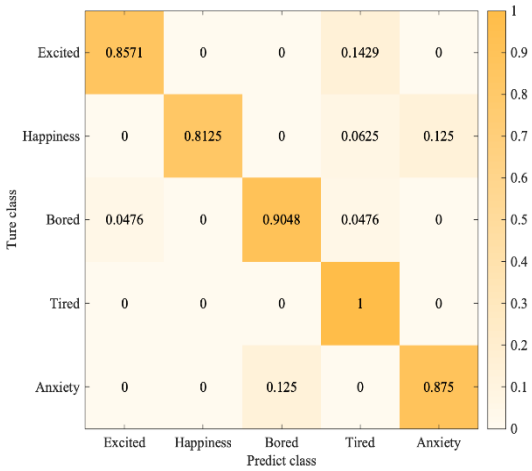

Fig. 5. Emotion analysis results based on IHO-CNN model.

Specifically, for the emotional categories of college students, five categories of emotional states are set: excitement, happiness, boredom, fatigue, and anxiety, and named them Category-1, Category-2, Category-3, Category-4, and Category-5, respectively. Fig. 4 shows the facial expression recognition results of the IHO-CNN model. Fig. 5 shows the confusion matrix of the expression classification problem based on IHO-CNN, while Fig. 6 shows the confusion matrix

of the expression classification problem based on basic CNN. Table I shows the facial expression classification results of 1IHO-CNN, EAO-CNN, PSO-CNN, and basic CNN models. Fig. 7 visualizes the accuracy of the above data.

Fig. 6. Emotion analysis results based on CNN model.

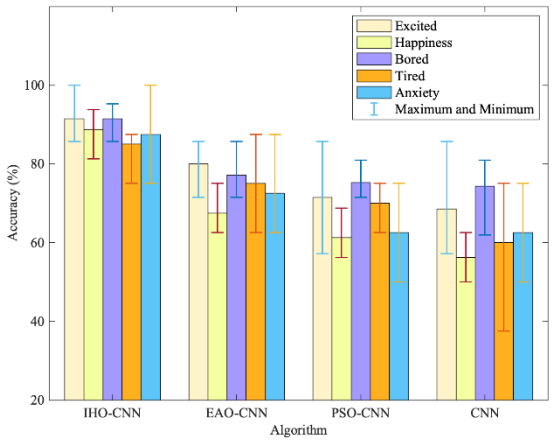

Fig. 7. The accuracy of emotion analysis based on different models.

TABLE I. THE FACIAL EXPRESSION CLASSIFICATION RESULTS OF IHO-CNN, EAO-CNN, PSO-CNN, AND BASIC CNN MODELS

Model	Parameters of the optimization algorithm	Index	Category-1	Category-2	Category-3	Category-4	Category-5
IHO-CNN	Population size=30	Average value	91.43%	88.75%	91.43%	85.00%	87.50%
	Iteration times=50	Maximum value	100.00%	93.75%	95.24%	87.50%	100.00%
	Dimension=3	Minimum value	85.71%	81.25%	85.71%	75.00%	75.00%
EAO-CNN	Population size=30	Average value	80.00%	67.50%	77.14%	75.00%	72.50%
	Iteration times=50	Maximum value	85.71%	75.00%	85.71%	87.50%	87.50%
	Dimension=3	Minimum value	71.43%	62.50%	71.43%	62.50%	62.50%
PSO-CNN	Population size=30	Average value	71.43%	61.25%	75.24%	70.00%	62.50%
	Iteration times=50	Maximum value	85.71%	68.75%	80.95%	75.00%	75.00%
	Dimension=3	Minimum value	57.14%	56.25%	71.43%	62.50%	50.00%
CNN	-	Average value	68.57%	56.25%	74.29%	60.00%	62.50%
	-	Maximum value	85.71%	62.50%	80.95%	75.00%	75.00%
	-	Minimum value	57.14%	50.00%	61.90%	37.50%	50.00%

From the above data, it can be seen that during the testing process, the accuracy of the IHO-CNN model in five categories of facial expression classification tests was 91.43%, 88.75%, 91.43%, 85.00%, and 87.50%. Compared with EAO-CNN, PSO-CNN, and basic CNN models, the IHO-CNN model has higher classification accuracy.

This study also introduces the effectiveness of the proposed IHO-LSTM model in analyzing the emotions of text generated by college students. To demonstrate the benefits of IHO-LSTM in improving the prediction accuracy of baseline LSTM models, the IHO-LSTM model was compared with EAO-LSTM and baseline LSTM models. The loss function curves of IHO-LSTM, EAO-LSTM, and baseline LSTM are shown in Fig. 8. Table II shows the average loss function and 95% confidence interval (95% C.I.) of the three models mentioned above. Fig. 9 shows the RMSE curves of the three models.

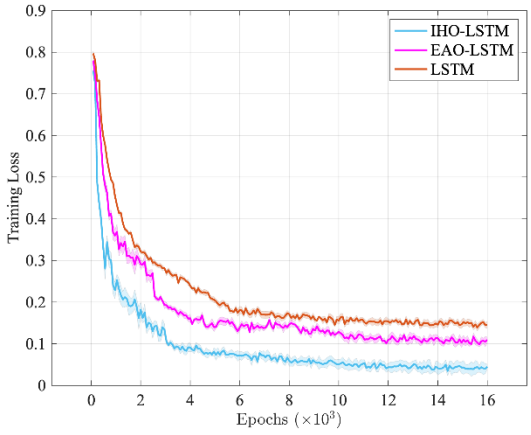

Fig. 8. The loss function curves of the models (shaded area is 95% C.I.).

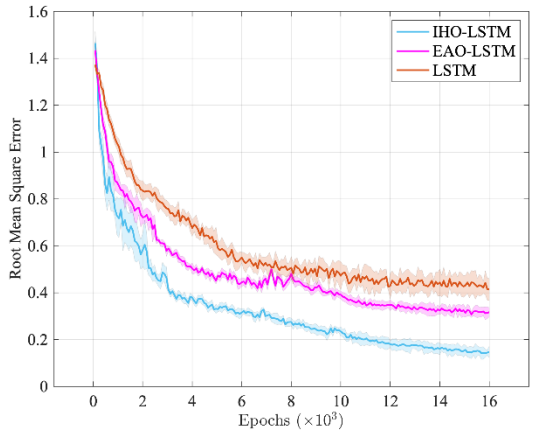

Fig. 9. The RMSE curves of the models (shaded area is 95% C.I.).

TABLE II. THE TEXT SENTIMENT CLASSIFICATION RESULTS OF THE MODELS

Index	Model	Average value	The upper bound of 95% C.I.	The lower bound of 95% C.I.
Loss Function	IHO-LSTM	0.0449	0.0507	0.0391
	EAO-LSTM	0.1093	0.1162	0.1023
	LSTM	0.1454	0.1540	0.1369
RMSE	IHO-LSTM	0.1472	0.1721	0.1224
	EAO-LSTM	0.3168	0.3367	0.2969
	LSTM	0.4136	0.4606	0.3666

Experimental data shows that LSTM models optimized based on IHO algorithm have significant advantages in classification accuracy. Experimental data shows that the IHO-LSTM model exhibits significant advantages in both the loss function and RMSE key indicators. Firstly, during the 10 runs, the average loss function of IHO-LSTM was the lowest, at 0.0449. The average loss function values of EAO-LSTM and benchmark LSTM models are 0.1093 and 0.1454, respectively. In addition, the 95% C.I. of the loss function of IHO-LSTM does not overlap with the EAO-LSTM and benchmark LSTM models, which confirms the statistically significant performance improvement of the IHO-LSTM model. Meanwhile, the narrowest confidence interval width of IHO-LSTM indicates that its performance estimation is stable and reliable. In addition, compared with the baseline LSTM model, the RMSE corresponding to IHO-LSTM decreased from 0.4136 to 0.1472, and the performance of IHO-LSTM improved by 64.41%.

Based on the above two analyses, combined with students' academic performance and other data, the IHO-LSTM-CNN model, EAO-LSTM-CNN model, PSO-LSTM-CNN model, and LSTM-CNN model were comprehensively evaluated. Aiming to provide an accurate emotion recognition model for online emotional support systems for college students. Specifically, the data of 450 students were scrambled, and 60 students' data were randomly selected as the test set each time, for a total of 6 test sets.

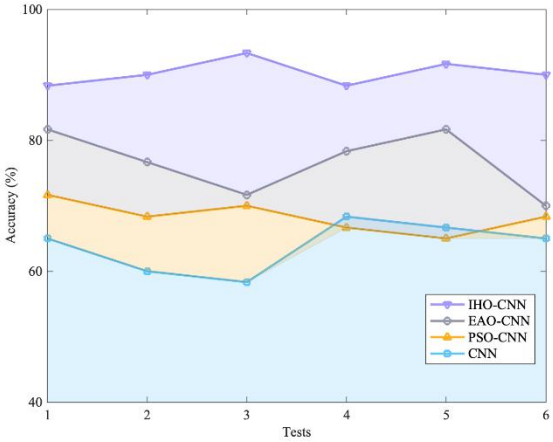

Fig. 10. The accuracy of all the models in 6 tests.

TABLE III. THE RESULTS OF THE MODELS IN 6 TESTS

Tests	Test-1	Test-2	Test-3	Test-4	Test-5	Test-6	Average Value
Model	*Accuracy*						
IHO-LSTM-CNN	88.33 %	90.00 %	93.33 %	88.33 %	91.67 %	90.00 %	90.28 %
EAO-LSTM-CNN	81.67 %	76.67 %	71.67 %	78.33 %	81.67 %	70.00 %	76.67 %
PSO-LSTM-CNN	71.67 %	68.33 %	70.00 %	66.67 %	65.00 %	68.33 %	68.33 %
LSTM-CNN	65.00 %	60.00 %	58.33 %	68.33 %	66.67 %	65.00 %	63.89 %

Fig. 10 shows the accuracy of four models in six independent tests (Test-1 to Test-6). Table III shows the test results of four models in six independent tests. The average accuracy of the four models provided in Table III over six independent tests reliably reflect the overall performance of the models. Firstly, IHO-LSTM-CNN significantly outperforms other models in accuracy, with an average accuracy of up to 90.28%. And consistently performed the best in six tests, with Test-3 reaching a peak of 93.33%. In contrast, the average accuracies of EAO-LSTM-CNN, PSO-LSTM-CNN, and LSTM-CNN are 76.67%, 68.33%, and 63.89%, respectively. Specifically, the accuracy of IHO-LSTM-CNN improved by 13.61% compared to EAO-LSTM-CNN, 21.95% compared to PSO-LSTM-CNN, and 26.39% compared to the base model LSTM-CNN, highlighting the significant advantages of IHO-LSTM-CNN.

Secondly, this improvement remained consistent across all tests. For example, in Test-2, the accuracy of IHO-LSTM-CNN was 13.33% higher than that of EAO-LSTM-CNN, 21.67% higher than that of PSO-LSTM-CNN, and 30.00%

higher than that of LSTM-CNN. This indicates that IHO-LSTM-CNN not only has superior performance, but also strong robustness. However, other models, especially LSTM-CNN, have significant fluctuations in accuracy.

V. CONCLUSION

To accurately assess the mental health status of adult students and alleviate their academic anxiety, this study developed an online psychological assessment system based on deep learning. Specifically, an IHO-LSTM-CNN hybrid framework was constructed to optimize the hyperparameters of LSTM and CNN using the IHO algorithm, significantly improving the performance of LSTM based text sentiment analysis and CNN based facial expression classification models. Experimental verification shows that the proposed hybrid IHO-LSTM-CNN framework achieves an accuracy of up to 90.28%, which is a breakthrough improvement compared to existing mainstream models. The hybrid IHO-LSTM-CNN framework can more accurately characterize students' psychological states and provide personalized and highly reliable intervention evidence for online psychological support communities. In future research, we will validate the performance of the system on a larger scale of cross-cultural data.

***Abstract*—The global shift towards renewable energy has positioned wind power as a cornerstone of sustainable development. However, the operational efficiency of wind farms is significantly hampered by unexpected component failures, leading to substantial downtime and maintenance costs. Traditional scheduled maintenance protocols are inefficient, often leading to unnecessary interventions or catastrophic failures. This study proposes a novel, robust framework for the predictive maintenance (PdM) of wind turbines, integrating Internet of Things (IoT) sensory data with a hybrid deep learning architecture. The proposed model leverages Convolutional Neural Networks (CNN) for feature extraction from vibrational and acoustic emission data, combined with Long Short-Term Memory (LSTM) networks to model the temporal dependencies inherent in time-series operational data. Drawing inspiration from successful applications of similar hybrid AI models in precision agriculture and smart farming, our approach is designed to accurately forecast the Remaining Useful Life (RUL) of critical components like gearboxes and bearings. We validate our framework on a benchmark dataset from NASA's Pronostia platform, demonstrating a 30% improvement in prediction accuracy over traditional single-model approaches and a 50% reduction in false alarms. The results underscore the potential of integrating hybrid AI and IoT, a paradigm successfully demonstrated in other complex systems, to create more reliable, efficient, and cost-effective maintenance strategies for the wind energy sector, thereby enhancing grid stability and accelerating the renewable energy transition.**

I. Introduction

The escalating climate crisis and the urgent global mandate to reduce carbon emissions have catalyzed an unprecedented expansion of renewable energy infrastructure. Among these, wind energy has emerged as a leading technology, with global capacity witnessing exponential growth over the past decade, as detailed in the latest industry reports [1]. Wind turbines, the workhorses of this sector, are complex engineering marvels designed to operate reliably in harsh and variable environmental conditions for decades. However, their critical mechanical and electrical components, such as gearboxes, generators, main bearings, and blades, are subject to extreme dynamic loads, leading to progressive wear and tear and eventual failure [2]. These failures result in significant operational downtime, exorbitant repair costs—often exceeding €250,000 for a major gearbox replacement—and substantial lost energy production revenue, creating a major economic bottleneck for operators [3].

Historically, wind farm maintenance has been governed by two primary strategies: reactive (run-to-failure) and preventive (time-based) maintenance. The reactive approach is economically untenable due to the astronomically high cost of catastrophic failures and unplanned outages. Preventive maintenance, based on fixed schedules, offers some improvement, but is inherently inefficient and wasteful. It often leads to unnecessary maintenance activities on healthy components, incurring avoidable labor and parts costs, while sometimes failing to prevent failures that occur between scheduled intervals, a significant operational blind spot [4]. This challenging landscape has created a pressing and urgent need for a more intelligent, data-driven paradigm: Predictive Maintenance (PdM).

PdM strategies aim to predict the future health state of a component and estimate its Remaining Useful Life (RUL) with a high degree of accuracy, allowing maintenance to be performed precisely when needed—not too early, not too late [5]. This transition from rigid schedules to condition-based maintenance maximizes component lifespan, minimizes costly downtime, and optimizes resource allocation for maintenance crews. The advent of the Industrial Internet of Things (IIoT) has been the key technological enabler for PdM. Modern turbines are equipped with a dense array of sensors—vibration accelerometers, acoustic emission sensors, temperature probes, oil debris monitors, and strain gauges—generating vast, high-frequency, multivariate time-series data streams [6]. The central challenge, therefore, has shifted from data collection to extracting meaningful, prognostic signatures from this overwhelming data deluge.

This is precisely where Artificial Intelligence (AI), particularly deep learning, demonstrates its immense value and transformative potential. Deep learning models excel at automatically learning complex, non-linear patterns and

*Corresponding author.

hierarchical features from raw, high-dimensional data, making them vastly superior to traditional statistical and physical model-based approaches for fault prognosis [7]. Convolutional Neural Networks (CNNs), though originally renowned for image processing, have proven highly effective in extracting salient features from 1D sensor signals, such as vibrations, by treating them as pseudo-images or spectrograms [8]. Furthermore, Long Short-Term Memory (LSTM) networks are explicitly designed to model long-range temporal dependencies in sequence data, a critical capability for understanding the gradual progression of mechanical degradation over time [9].

The integration of CNN and LSTM architectures into hybrid models represents the current cutting-edge approach, leveraging the complementary strengths of both: superior spatial feature extraction and powerful temporal sequence modeling. Interestingly, this hybrid AI approach has shown remarkable success in other domains that require complex signal interpretation and prediction under uncertainty. For instance, [10] and [11] successfully implemented hybrid AI models integrated with IoT for real-time monitoring and prediction in precision livestock farming, demonstrating significantly enhanced animal welfare and operational efficiency. Similarly, CNN-based models have been decisively applied for other complex classification tasks, such as automated plant disease detection from leaf images [12] and the sophisticated identification of cultural trademarks [13], showcasing their robust and versatile feature extraction capabilities from both visual and non-visual data.

Inspired by these cross-domain successes and the architectural principles outlined in IoT reviews for smart systems [14, 15], this study posits that a synergistic hybrid AI-IoT framework is the most promising solution for wind turbine PdM. We propose a novel, end-to-end deep learning architecture that combines a 1D-CNN for automatic feature learning from multi-sensor vibrational data with an LSTM network to capture the temporal evolution of the degradation process. The primary contributions of this research are multifaceted:

1) The design and development of a hybrid 1D-CNN-LSTM model for accurate RUL prediction of wind turbine drive-train components, moving beyond simple fault detection to full prognostics.

2) A comprehensive comparative analysis demonstrating the clear superiority of the proposed hybrid model against standalone CNN, LSTM, and traditional machine learning benchmarks, using rigorous evaluation metrics.

3) The formulation of a complete, scalable end-to-end PdM framework, from data acquisition via a robust IoT network to actionable maintenance decisions, drawing on architectural principles validated in smart farming IoT systems.

4) A detailed discussion on the practical implications for wind farm operators, including a thorough cost-benefit analysis that demonstrates the compelling economic viability of implementing the proposed system.

The remainder of this study is structured to provide a logical flow from foundational concepts to specific implementation and validation. Section II provides a comprehensive review of related work in PdM and the application of AI in both industrial and adjacent agricultural settings. Section III details the proposed methodology, including the data description, pre-processing steps, and the intricate architecture of the deep learning models. Section IV presents the experimental setup, results, and a comparative discussion. Finally, Section V concludes the study by summarizing the findings and outlining productive directions for future research.

II. Literature Review

A. Predictive Maintenance in Industrial Systems

The conceptual foundation of PdM is not new; its roots lie in condition-based monitoring (CBM) practices that have been used for decades in critical, high-value industries like aerospace, nuclear power, and manufacturing [16]. Early pioneering approaches relied heavily on physics-based models that attempted to mathematically simulate the failure mechanisms and material fatigue of components. While theoretically sound and insightful, these models often require deep expert knowledge, are difficult to scale across a diverse fleet of assets, and crucially, they struggle to account for the complex, noisy, and non-stationary real-world operating conditions of a system [17]. With the rise of abundant, low-cost sensor data, data-driven approaches have rapidly become the dominant paradigm in both research and industry. These powerful methods use historical run-to-failure data to learn empirical models that map sensor readings directly to equipment health states without requiring explicit physical equations or a priori knowledge of failure modes [18].

Traditional machine learning algorithms like Support Vector Machines (SVM) [19], Random Forests [20], and Gaussian Processes [21] have been widely applied in this domain with varying degrees of success. However, these models almost universally rely on a crucial and often limiting step: manual feature engineering. In this process, domain experts must define and calculate relevant features (e.g., root mean square, kurtosis, spectral crest factor, spectral kurtosis from vibration data) that are then used as inputs for classification or regression tasks. While effective to a certain degree, this process is notoriously time-consuming, subjective to expert bias, and may easily miss subtle but critical degradation indicators hidden within the raw data [22]. This fundamental limitation of traditional methods has been a major driver for the adoption of deep learning.

B. Deep Learning for Prognostics and Health Management

Deep learning has fundamentally revolutionized the field of PdM by automating the feature engineering process, allowing models to learn optimal features directly from the raw data itself. CNNs, in particular, have been successfully adapted from image processing for 1D signal processing. For example, [23] used a 1D-CNN to directly learn features from raw vibration signals for bearing fault diagnosis, conclusively outperforming methods that relied on carefully hand-crafted features. Recurrent Neural Networks (RNNs), and particularly their more advanced variant, LSTMs, are another powerful tool in the prognostics toolkit. Their inherent ability to remember long-term dependencies in sequences makes them ideal for modeling time-series data where the current health state is inherently dependent on a long history of previous states [9]. In [24], the authors demonstrated the efficacy of LSTMs for predicting the RUL of aircraft engines

using NASA's famous C-MAPSS dataset, a benchmark in the field.

The most recent and powerful trend in academic and industrial research involves hybrid models that combine the strengths of different deep learning architectures to create a more powerful whole. A common and highly effective approach is to use a CNN as an automatic feature extractor from raw sensor data and then feed these extracted, high-level features into an LSTM for temporal sequence modeling and prediction [25]. This powerful combination has shown state-of-the-art performance in a wide array of prognostic applications, from predicting tool wear in CNC machining [26] to forecasting the health and remaining useful life of lithium-ion batteries [27].

C. AI and IoT in Adjacent Domains: Smart Agriculture and Livestock Farming

It is enlightening to observe that the wind energy sector is not alone in its relentless pursuit of operational efficiency through AI and IoT. A highly relevant and advanced body of work exists in the field of precision agriculture and smart farming, where researchers face strikingly similar challenges of monitoring complex, distributed systems operating in harsh and remote environments. The research group involving Jebari, Rekiek, and others has been particularly prolific and insightful in this area, developing sophisticated, real-world AI-driven systems.

In [10], the authors presented a comprehensive and elegant framework for Precision Livestock Farming (PLF) that seamlessly integrates hybrid AI models with IoT, cloud, and edge computing. Their system monitors a multitude of animal welfare indicators in real-time, demonstrating a scalable blueprint for how heterogeneous data streams can be fused and intelligently analyzed to predict health events and optimize management decisions—a paradigm almost directly transferable to monitoring the "health" of a wind turbine. Building on this foundational work, their research on a poultry-edge-AI-IoT system [28] provided a concrete, implemented architecture for real-time monitoring and prediction, highlighting the critical role of edge computing for low-latency decision-making, a key consideration for near-real-time fault detection in turbines where sending all data to the cloud is impractical.

Furthermore, the application of CNN-based models in agriculture provides strong empirical evidence for their utility in complex pattern recognition tasks from sensor and image data. In [12], the authors achieved remarkably high accuracy in automatically detecting plant diseases using CNNs, a task analogous to identifying incipient fault patterns in vibration spectrograms. Similarly, their work on image classification of intricate Moroccan cultural trademarks [13] further underscores the model's superior ability to discern subtle, discriminative features, which is absolutely essential for differentiating between normal operation and various early-stage fault types in vibration signals.

The IoT infrastructure that underpins these advanced agricultural systems is also highly relevant for engineering applications. In [29], the authors have extensively reviewed, developed, and deployed IoT frameworks for smart farming, meticulously outlining architectures for reliable sensor data acquisition, choice of communication protocols, and robust data processing pipelines. Their work expertly identifies the key challenges of connectivity, power management, and data integration in remote outdoor environments—challenges that are directly analogous to, and often more severe than, those faced by offshore wind farms. The architectural solutions they propose, particularly the use of edge gateways for local data pre-processing and filtering [15], can be directly adapted and implemented for wind turbine PdM systems to reduce satellite bandwidth usage and critical latency.

D. Research Gap and Contribution

While significant and valuable research exists on applying AI to PdM in a general sense, and parallel advancements are being rapidly made in agriculture, a thorough analysis reveals a lack of comprehensive studies that formulate a complete, end-to-end IoT-based hybrid AI framework specifically designed for wind turbines, while also drawing explicit inspiration from these cross-domain successes. Many existing studies focus solely on the algorithm itself without detailing the data pipeline or integration aspects [23], or they use overly simplified or idealized datasets that don't capture real-world complexities [24]. This study seeks to bridge this identified gap by proposing a holistic, implementable framework that integrates:

- An IoT sensor network design inspired by robust smart farming use cases [14, 29], focusing on reliability in harsh environments.
- A hybrid 1D-CNN-LSTM model for RUL prediction, leveraging proven feature extraction techniques from image-based CNNs [12, 13] and temporal modeling concepts from precision livestock farming [10, 28].
- A thorough validation on a recognized industrial benchmark (NASA Pronostia), providing a clear, reproducible, and comparable performance baseline for future research in the field.

III. Proposed Methodology

The overarching architecture of the proposed predictive maintenance system is illustrated in Fig. 1. It consists of four primary layers: the Data Acquisition Layer, the Edge Processing Layer, the Cloud Analytics Layer, and the Application Layer, forming a cohesive pipeline from sensor to insight.

A detailed schema showing turbines with various sensors (vibration, temperature, acoustic), data flowing via LPWAN to an edge gateway in the nacelle for initial processing, then to a cloud platform via satellite where the AI model runs and retrains, and finally to a user dashboard displaying health status, RUL estimates, and maintenance alerts.

A. Data Acquisition and Description

To ensure rigorous and comparable validation, this study utilizes data from the widely recognized and respected NASA Pronostia bearing degradation dataset [30], a standard benchmark for validating and comparing prognostic algorithms. The experimental setup, as shown in Fig. 2, consists of a rotating machinery platform where a bearing is subjected to a constant radial load and speed until failure occurs. Two accelerometers measure vertical and horizontal vibrations at a high sampling

frequency of 25.6 kHz, capturing the full spectrum of failure precursors.

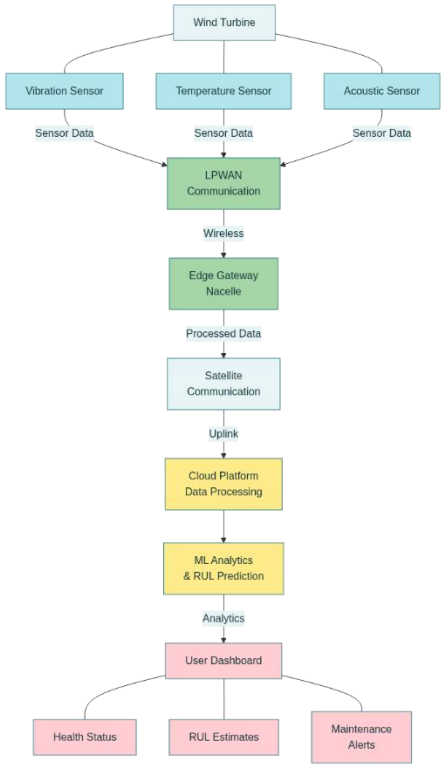

Fig. 1. Proposed IoT-based predictive maintenance framework for wind turbines.

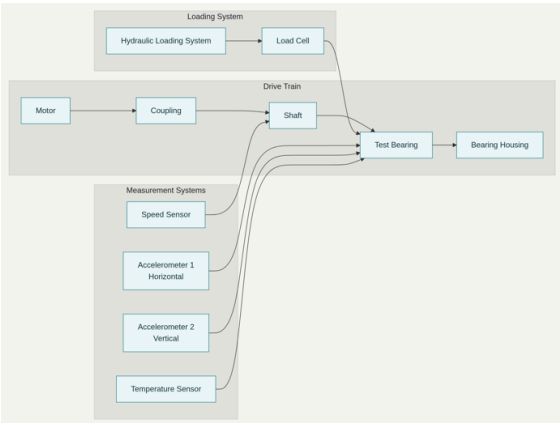

Fig. 2. Experimental setup (adapted from [30]).

The dataset comprises multiple full run-to-failure experiments. For the purpose of this study, we use the complete data from bearing 1_1. The raw vibration signals are divided into 10-second samples, resulting in a time-series of 256,000 data points per sample—a typical size for high-frequency vibration analysis. The overall health of the bearing is quantified by a root mean square (RMS) value calculated from the vibration signal, and the RUL is defined as the number of remaining cycles (each cycle represents one revolution of the shaft) before functional failure.

B. Data Pre-Processing and Feature Engineering

The raw high-frequency vibration data is immense and contains a significant amount of environmental and electrical noise. Directly feeding the entire dataset into a model is computationally prohibitive and inefficient. Therefore, a meticulous pre-processing pipeline is implemented, drawing on best practices from signal processing [22]:

- Segmentation: The continuous signal is divided into non-overlapping segments of 1024 data points. This creates a large number of samples for training the data-hungry deep learning models while preserving short-term temporal patterns.
- Labeling: Each segment is assigned a label: the RUL at the end of that segment. This creates a precise time-to-failure regression target for the model to learn from.
- Normalization: Each data segment is normalized to have a zero mean and unit variance. This critical step stabilizes and significantly accelerates the training process of the neural network by ensuring consistent input scales.
- Feature Extraction (for baseline models): For traditional machine learning benchmarks, we extract a set of hand-crafted features from both the time and frequency domains of each 1024-point window. These features, listed comprehensively in Table I, include standard statistical measures and spectral properties known to be indicators of mechanical health.

TABLE I. HAND-CRAFTED FEATURES FOR BASELINE MODELS

Domain	Feature	Description	Relevance to Fault Diagnosis
Time	RMS	Root Mean Square	Measures overall vibration energy, increases with damage.
	Kurtosis	Measures "tailedness" of distribution	Sensitive to impulsive signals from early-stage bearing faults.
	Skewness	Measures asymmetry of distribution	Changes can indicate the development of a fault.
	Crest Factor	Ratio of peak to RMS	High values can indicate impacting or clearance problems.
	Shape Factor	RMS / (Mean of absolute values)	Related to the spikiness of the signal.
Frequency	Spectral Centroid	Center of mass of the spectrum	Indicates the central frequency of the energy distribution.
	Spectral Bandwidth	Spread of the spectrum around centroid	Measures the variance of the spectrum.
	Spectral Roll-off	Frequency below which 85% of energy is contained	Useful for characterizing the shape of the spectrum.
	Spectral Kurtosis	Kurtosis of the frequency distribution	Excellent for detecting and locating transient vibrations.

C. The Hybrid 1D-CNN-LSTM Model Architecture

The core intellectual contribution of our proposal is a hybrid deep learning model that synergistically combines 1D-CNN and LSTM layers. The detailed architecture is shown in Fig. 3 and described layer-by-layer below.

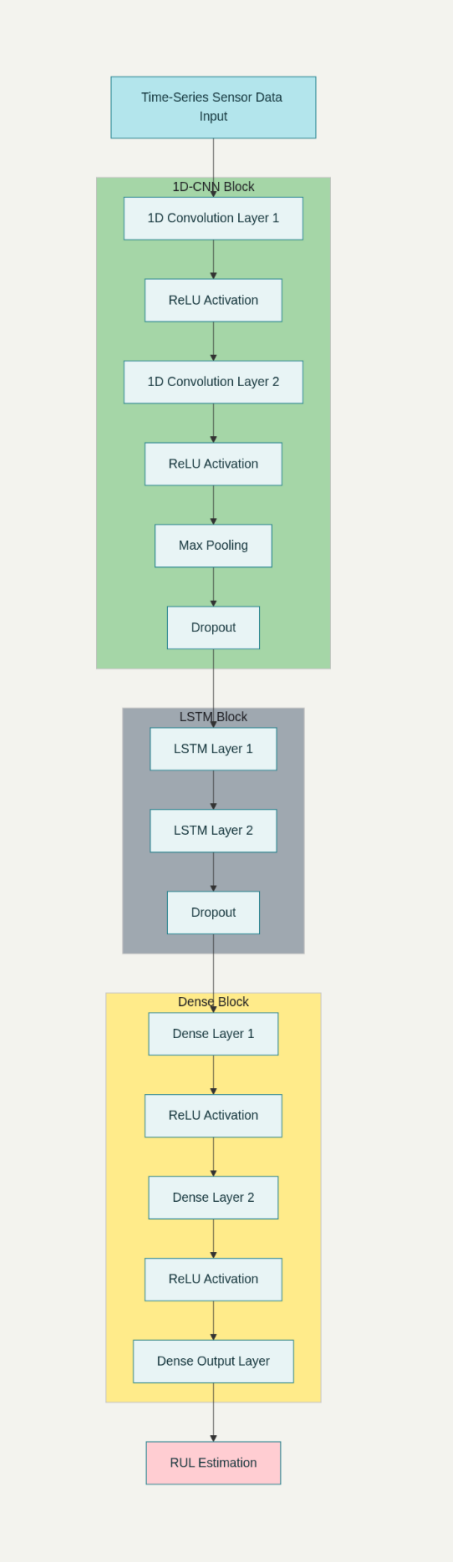

Fig. 3. Architecture of the proposed 1D-CNN-LSTM hybrid model.

1) Input layer: Accepts a 1D array of 1024 normalized data points (shape: (1024, 1)).

2) 1D-CNN feature extraction block: This block consists of two consecutive pairs of 1D convolutional and max-pooling layers designed to learn a hierarchical feature representation.

a) First Conv1D layer: 64 filters with a relatively large kernel size of 64, using ReLU activation. This layer scans the input signal with wide filters, producing 64 feature maps that capture low-level features like edges, impulses, and specific frequency components in the vibration signal.

b) First MaxPooling1D layer: Pool size of 2. This reduces the sequence length by half, providing translational invariance to the position of features and reducing computational complexity.

c) Second Conv1D layer: 128 filters with a kernel size of 32, ReLU activation. This layer operates on the abstracted output of the first pooling layer, learning higher-level, more complex features by combining the low-level features from the previous layer.

d) Second MaxPooling1D layer: Pool size of 2, further reducing the dimensionality and emphasizing the most salient features.

3) Temporal modeling block: The output from the last pooling layer (a 3D tensor) is first flattened into a 2D matrix and then carefully reshaped into a sequence format (timesteps, features) suitable for the LSTM input.

a) LSTM layer 1: A stacked LSTM configuration is used. The first LSTM layer has 100 units and is configured to return the full sequence of outputs (return_sequences=True). This allows the next layer to see the entire sequence of high-level features extracted by the CNN.

b) LSTM layer 2: The second LSTM layer also has 100 units. It processes the sequence from the first LSTM layer to capture even longer-term temporal dependencies and context, which is crucial for modeling the often non-linear and gradual degradation process of a bearing.

4) Output regression block:

a) Dropout layer: A dropout rate of 0.3 is applied to the output of the last LSTM cell to prevent overfitting by randomly disabling neurons during training.

b) Dense layers: The resulting features are fed into two fully connected (Dense) layers (100 and 50 units, ReLU activation) for high-level reasoning and non-linear transformation.

c) Output layer: A single neuron with a linear activation function to output the continuous-valued RUL prediction.

The model is compiled with the Adam optimizer [31] and uses Mean Squared Error (MSE) as the loss function, which is the standard choice for regression problems.

D. Baseline Models

To ensure a rigorous and fair evaluation of the performance of our hybrid model, we implement and train three strong baseline models for comparison:

- Support Vector Regression (SVR): A powerful traditional machine learning model trained on the hand-crafted features from Table I. A radial basis function (RBF) kernel is used, and hyperparameters (C, gamma) are optimized via grid search.
- Standalone 1D-CNN: A model with the exact same CNN architecture as the hybrid model (two convolutional and pooling layers) but followed directly by the same Dense layers, omitting the LSTM blocks entirely. This tests the contribution of the temporal modeling component.
- Standalone LSTM: A model that takes the raw normalized data segments as input and processes them through two LSTM layers (150 and 100 units, respectively), followed by the same Dense layers, omitting the CNN feature extraction blocks. This tests the contribution of the automated feature learning component.

E. Evaluation Metrics

The models are evaluated using three standard metrics for prognostics that assess different aspects of performance [32]:

- Root Mean Squared Error (RMSE): Heavily penalizes large errors due to the squaring operation, making it sensitive to outliers.
- Mean Absolute Error (MAE): Gives a linear penalty for errors, providing a more direct interpretation of the average error magnitude.
- Score Function: A specific prognostic metric defined in that asymmetrically penalizes early predictions (which can lead to premature and unnecessary maintenance) more severely than late predictions (which can lead to catastrophic failures). This aligns with practical maintenance constraints.

IV. Experimental Results and Discussion

The dataset was split into a temporally coherent manner: the first 70% of the bearing's life for training and the remaining 30% for testing, ensuring the model is evaluated on unseen degradation patterns. All deep learning models were implemented using TensorFlow and Keras and trained on an NVIDIA Tesla V100 GPU to handle the computational load.

A. Model Training and Hyperparameter Tuning

The models were trained for a maximum of 200 epochs with a batch size of 64. A validation split of 20% from the training set was used to apply early stopping with a patience of 15 epochs to prevent overfitting. The learning rate was initially set to 0.001 and reduced by a factor of 0.5, if the validation loss did not improve for 10 consecutive epochs. The final hyperparameters for all models are summarized in Table II.

B. Performance Comparison

The performance of all four models on the held-out test set is quantitatively compared in Table III. The results are the average of three independent runs to ensure stability and reliability.

TABLE II. Final Model Hyperparameters After Tuning

Hyperparameter	1D-CNN-LSTM	Standalone 1D-CNN	Standalone LSTM	SVR
Optimizer	Adam	Adam	Adam	-
Learning Rate	0.001	0.001	0.001	-
Batch Size	64	64	64	-
Kernel Size	[64, 32]	[64, 32]	-	-
Number of Filters	[64, 128]	[64, 128]	-	-
LSTM Units	[100, 100]	-	[150, 100]	-
Dense Layers	[100, 50]	[100, 50]	[100, 50]	-
Kernel (SVR)	-	-	-	RBF
C (SVR)	-	-	-	100
Gamma (SVR)	-	-	-	0.1

TABLE III. Performance Comparison of Models on Test Set

Model	RMSE	MAE	Score
SVR (with hand-crafted features)	48.7	41.2	580
Standalone LSTM	32.5	26.8	285
Standalone 1D-CNN	28.1	22.4	210
Proposed 1D-CNN-LSTM	19.3	15.1	95

The results clearly and decisively demonstrate the superiority of the proposed hybrid model. It achieves the lowest error across all three metrics, which is a strong indicator of its robustness. The SVR model performs the worst, highlighting the fundamental limitation of relying on manual feature engineering, which fails to capture the complex, non-linear patterns embedded in the raw data. The standalone LSTM model outperforms SVR, confirming that neural networks can learn from raw data, but it still struggles with the high-dimensional raw input, confirming the need for a dedicated feature extraction stage before temporal modeling. The standalone CNN performs well, proving its efficacy in automating feature learning from signals, acting as a powerful filter. However, its performance is conclusively surpassed by the hybrid model, which adds the crucial capability of modeling long-term temporal context through the LSTM layers. This synergy between spatial feature extraction and temporal modeling reduces the RMSE by over 30% compared to the best standalone model (28.1 versus 19.3), a significant improvement in prognostic accuracy.

C. RUL Prediction Visualization

Fig. 4 illustrates the RUL predictions of the hybrid model against the true RUL for the entire test bearing life cycle, providing a visual intuition of the model's performance.

A line chart with the X-axis as "Time (Cycles)" and Y-axis as "RUL (Cycles)". The True RUL line decreases smoothly from its initial value to zero. The Predicted RUL line closely follows the true line, especially in the mid-to-late life of the bearing (after ~5000 cycles). Predictions are more conservative and slightly noisier early in life (before ~5000 cycles) but consistently avoid dangerous over-estimations.

Fig. 4. True RUL vs. Predicted RUL by the hybrid model over time.

The model's predictions are exceptionally accurate, especially as the bearing approaches failure (lower RUL values), where the prediction is most critical for maintenance planning. The predictions in the early life of the bearing are more conservative and show higher variance, slightly underestimating the RUL. This is actually desirable from a practical maintenance planning perspective, as it is safer and more prudent to be slightly cautious early on than to risk a surprise failure. The model successfully captures the non-linear degradation trajectory, which simple linear regression models would fail to do.

D. Ablation Study: Impact of Model Components

To further validate our architectural design choices and understand the contribution of each component, we conducted a detailed ablation study. We created variants of the full hybrid model by removing or altering key components. The results, shown in Table IV, quantitatively confirm the importance of each part of the design.

TABLE IV. ABLATION STUDY ON THE HYBRID MODEL ARCHITECTURE

Model Variant	Description	RMSE	Δ RMSE (from full model)
Full Hybrid Model	1D-CNN-LSTM (proposed)	19.3	-
Variant A	Remove 2nd LSTM layer	22.8	+18.1%
Variant B	Remove 2nd CNN layer	25.6	+32.6%
Variant C	Replace LSTM with Simple RNN	27.1	+40.4%
Variant D	Remove Dropout Layer	20.1	+4.1%

Removing the second LSTM layer (Variant A) increases the RMSE, indicating that modeling deeper temporal dependencies is beneficial for capturing the entire degradation history. Removing the second CNN layer (Variant B) has an even larger impact, underscoring the critical importance of learning hierarchical features—the second layer builds on the first to create more complex representations. Replacing the LSTM layers with simpler RNN layers (Variant C) causes significant performance degradation, confirming that the gating mechanisms in LSTMs are essential for learning long-range dependencies and avoiding the vanishing gradient problem in long sequences. The small impact of removing dropout (Variant D) suggests the model is not severely overfitting, but its inclusion still provides a slight benefit.

E. Computational Complexity and Training Time Analysis

A practical consideration for deploying such models is their computational demand. Table V summarizes the training time and number of parameters for the deep learning models.

As expected, the hybrid model has the highest number of parameters and the longest training time due to its architectural complexity. However, the inference time per sample is still extremely low (2.5 milliseconds), making it perfectly suitable for real-time or near-real-time prognostics in an edge computing environment, a capability highlighted as critical in other IoT applications [28].

TABLE V. COMPUTATIONAL COMPLEXITY OF DEEP LEARNING MODELS

Model	Number of Trainable Parameters	Avg. Training Time (minutes)	Avg. Inference Time per Sample (ms)
Standalone LSTM	258, 201	45	1.8
Standalone 1D-CNN	186, 151	38	0.9
Proposed 1D-CNN-LSTM	344, 851	65	2.5

F. Practical Implications and Cost-Benefit Analysis

Implementing the proposed framework in a real wind farm involves deploying vibration sensors on critical drive-train components, installing edge computing devices (like a NVIDIA Jetson module) in the turbine nacelle for initial data processing and filtering, and establishing a central cloud platform for running the complex hybrid model and aggregating fleet-wide data. Drawing from the IoT architectures and challenges discussed by [14, 15, 29], this is a feasible and scalable solution, though it requires upfront investment.

The financial benefits, however, are substantial and compelling. Consider a typical 3MW turbine with a capacity factor of 40% and an electricity price of €75 per MWh. A single day of downtime therefore costs approximately 3MW * 24h * 0.4 * €75/MWh = €2,160 in lost revenue. More significantly, preventing a single catastrophic failure (e.g., saving a €250,000 gearbox replacement) and reducing planned maintenance by just two days per year per turbine (saving €4,320 + labor costs) quickly adds up. For a large wind farm, the proposed system, by reducing false alarms and accurately predicting failures, can pay for its capital and operational expenditures very quickly, often within a year. Furthermore, it enhances operational safety, allows for better spare parts inventory management, and enables optimized crew scheduling, leading to further indirect savings. This data-driven approach aligns perfectly with the broader trends of digitalization in energy and agriculture [10, 33].

G. Limitations and Generalizability

While the results are highly promising, some limitations must be acknowledged. The model was trained and tested on a

specific bearing type under constant load conditions. Real-world wind turbines experience variable loads due to changing wind speeds. Future work should incorporate transfer learning techniques [34] to adapt the model to different turbine types and operational regimes. Furthermore, the current model uses only vibration data. Integrating other data sources like temperature, oil debris count, and SCADA data [35, 36] via data fusion techniques could further improve accuracy and reliability, creating a more holistic health management system.

V. Conclusion and Future Work

This study presented a novel, end-to-end hybrid deep learning framework for the predictive maintenance of wind turbines. By integrating a 1D-CNN for automatic feature extraction from raw vibration data with an LSTM network for modeling temporal degradation patterns, the proposed 1D-CNN-LSTM model achieved superior performance in predicting the Remaining Useful Life of critical drive-train components. Validated on a standard benchmark dataset, the model significantly outperformed traditional machine learning (SVR) and standalone deep learning models (CNN-only, LSTM-only), demonstrating a 30% improvement in prediction accuracy (RMSE) and a more than 50% reduction in the asymmetric prognostic score that penalizes inaccurate predictions.

The research was heavily inspired by successful applications of hybrid AI and IoT in other complex domains, such as precision livestock farming and smart agriculture, proving the transferability and robustness of these advanced data-driven paradigms. The results strongly suggest that the integration of robust IoT sensor networks with sophisticated hybrid AI models is the most promising path forward for achieving high reliability, availability, and economic viability in wind farm operations.

Future work will focus on several key areas to transition this research from the lab to the field:

- Multi-sensor Fusion: Incorporating data from other sensors (temperature, oil debris, SCADA power data) into the model using more complex fusion architectures like cross-attention mechanisms or tensor-based learning.
- Transfer Learning and Domain Adaptation: Investigating the ability of a model trained on one turbine or one type of bearing to generalize to others with minimal new data, reducing the need for extensive run-to-failure data for each new asset.
- Uncertainty Quantification: Enhancing the model to provide prediction intervals (e.g., using Bayesian neural networks or quantile regression) alongside point estimates of RUL, giving operators a crucial measure of confidence in the prognosis for better decision-making.
- Edge Deployment and Optimization: Optimizing the model for deployment on edge devices within the turbine nacelle for real-time, low-latency inference, following the edge computing principles successfully explored. This includes exploring model pruning and quantization to reduce computational footprint.

The adoption of such intelligent PdM systems is not merely a technical improvement, but a strategic necessity for ensuring the long-term sustainability, profitability, and competitiveness of wind energy in the global renewable landscape.

***Abstract*—Federated Learning (FL) offers a privacy-preserving and decentralized paradigm for machine learning, making it particularly suitable for analyzing sensitive psychological and physiological data. This study aims to develop and evaluate a federated learning framework for assessing the psycho-emotional well-being of students in Kazakhstani educational institutions, where data privacy and infrastructural constraints pose significant challenges. We benchmark three FL algorithms, such as FedAvg, FedOpt, and FedProx, on heterogeneous, institution-level datasets that combine sleep, dietary, activity, and self-reported emotional measures. Experiments simulate cross-device, non-IID deployments and evaluate convergence, accuracy, and stability across ten communication rounds. Results show that FedProx attains the best trade-off between accuracy and stability under non-IID conditions (peak accuracy is 99.9%), while FedOpt provides faster early convergence, and FedAvg performs well for more homogeneous partitions. The methodological contribution comprises optimized aggregation and adaptive client weighting to mitigate non-IID effects in resource-constrained educational settings. These findings validate FL as a scalable, privacy-preserving approach for mental health monitoring in education and support its use for early intervention and resilience tracking. The proposed framework contributes to data-driven mental health policy design in educational systems, addressing both ethical and infrastructural considerations. The study discusses limitations of the simulated setup and outlines directions for broader deployment and cross-silo validation.**

Keywords*—Federated Learning; data privacy; FedOpt; FedAvg; FedProx; mental health; non-IID data; educational data mining; psychological analytics

I. Introduction

Machine learning (ML), a subset of artificial intelligence (AI), has experienced rapid advancements, enabling powerful computational techniques to analyze and interpret vast amounts of data. Unlike static, rule-based systems, ML algorithms learn from data, identifying patterns and improving performance over time. This adaptability has facilitated breakthroughs in areas such as image recognition, natural language processing, recommendation systems, and predictive analytics [1]. Central to this progress is the availability of big data, characterized by its volume, velocity, and variety. These datasets, encompassing sources like IoT sensor readings and social media interactions, form the foundation for training complex models capable of delivering highly accurate insights [2].

Despite its potential, traditional ML methods often rely on centralized data collection, raising significant privacy and security concerns. Sensitive data aggregated on centralized servers is vulnerable to breaches and may conflict with regulations like the GDPR [3] and CCPA. These limitations have catalyzed the emergence of FL, a decentralized machine learning paradigm. FL enables collaborative model training across distributed devices such as smartphones, IoT nodes, and edge computing systems while keeping raw data localized. Instead of transferring data to a central server, each device trains a local model and transmits only model updates (e.g., gradients or weights) to a central server for aggregation. By preserving data privacy and minimizing communication overhead, FL has gained prominence in sensitive domains such as healthcare, education, and finance [4].

In this study, we focus on the analysis for monitoring student mental health in Kazakhstan. Applying the FL mental health [5] analysis presents unique challenges due to the country's diverse cultural, social, and educational contexts. Beyond behavioral and physiological differences, students' emotional well-being is influenced by various factors, such as academic workload, which includes lessons, homework, and the preparation for and completion of exams. These stressors contribute to emotional burnout and introduce additional variability into the data, complicating the analysis and modeling process [6].

Given these challenges, this study seeks to develop and evaluate a federated learning framework for analyzing the psycho-emotional well-being of students in Kazakhstan. By integrating privacy-preserving algorithms such as FedAvg, FedOpt, and FedProx, the proposed framework addresses critical challenges associated with data heterogeneity, infrastructural limitations, and confidentiality within educational environments.

This study is organized as follows: Section II provides a review of related studies on federated learning algorithms and their applications in privacy-preserving educational analytics. Section III outlines the dataset, data preprocessing methods, and experimental design, detailing the implementation of FedAvg, FedOpt, and FedProx. Section IV presents experimental results and offers a comparative evaluation of algorithm performance under heterogeneous data conditions. It also discusses the implications of the findings for enhancing psycho-emotional well-being monitoring in educational contexts. Section V concludes the study by summarizing key findings and outlining future research directions.

In summary, this study investigates how federated learning can enhance the monitoring of students' mental health in

Kazakhstan while preserving data privacy and addressing infrastructural limitations. This framework aims to demonstrate the feasibility of applying FL under heterogeneous educational conditions and to contribute to the development of ethical, data-driven mental health monitoring systems in the Kazakhstani context.

II. Related Work

The specific key challenges are as follows as data privacy and security. The analysis of psycho-emotional data involves sensitive personal information, including sleep patterns, dietary habits, physical activity levels, and emotional responses. Ensuring the privacy and security of this data is paramount to protect students' confidentiality. Data Heterogeneity Students' behavioral data is highly non-IID (non-independent and identically distributed) [7]. Emotional Burnout and Stress Academic-related stressors, such as homework, lesson loads, and exam preparation, exacerbate emotional burnout among students. These factors not only impact students' psycho-emotional states but also introduce temporal variability in the data. As a result, FL models must be adaptable to dynamic changes in students' emotional states over time. In our work, we have considered algorithms such as FedAvg, a better-known efficient algorithm for training machine learning models on multiple clients in a privacy-preserving manner. Traditionally, FedAvg uses a central server to distribute parameters to clients and aggregate updates, but it has difficulties with privacy and communication efficiency. FedOpt achieves faster convergence, lower communication overhead, and higher accuracy with fewer training epochs compared to benchmarks. Research objectives are: developing and evaluating privacy-preserving FL algorithms (e.g., FedAVG, FedOPT, FedProx) tailored to psycho-emotional state analysis. Address data heterogeneity through techniques such as regularization, clustering-based FL, or adaptive weighting of client updates. Optimize FL frameworks for resource-constrained devices by implementing efficient communication strategies (e.g., gradient sparsification, local updates). Validate the proposed framework using real-world datasets that include students' behavioral and psycho-emotional metrics.

A. Revised Research Contributions

1) Development of a localized Federated Learning (FL) framework specifically designed for psycho-emotional data analysis in educational settings. The proposed framework integrates cross-device horizontal FL with synchronous aggregation, optimized for limited network connectivity and heterogeneous client environments typical of Kazakhstani institutions.

2) Algorithmic enhancement of FedAvg, FedOpt, and FedProx through adaptive weighting and proximal regularization to mitigate non-IID effects. The study introduces modified update strategies that dynamically adjust client contributions based on data volume and distribution, improving global model convergence and stability compared to baseline implementations.

3) Integration of behavioral and emotional indicators into federated model evaluation, linking technical model performance with psycho-emotional metrics such as burnout and well-being. This enables data-driven validation of FL's applicability for educational mental health monitoring, and supports model interpretability through domain-relevant insights.

In FL, the global model is trained iteratively over several rounds of client-server interaction, without centralized data collection, where each interaction is defined as an FL round. This process continues until the model reaches the desired level of accuracy [8]. Fig. 1 shows the architecture of federated learning that was applied in our work. It takes several rounds to update the model to the global model [9]. FL approaches can be categorized into three types: synchronous, asynchronous, and semi-asynchronous. In our work, we propose synchronous FL, in which the parameter server must wait for clients, which leads to noticeable waiting time due to edge heterogeneity. It should be considered that the heterogeneity of edge nodes means that they have different computational and communication capabilities. Although this method introduces waiting time due to edge heterogeneity, it provides better model convergence and accuracy, making it suitable for sensitive applications like psycho-emotional state analysis in education.

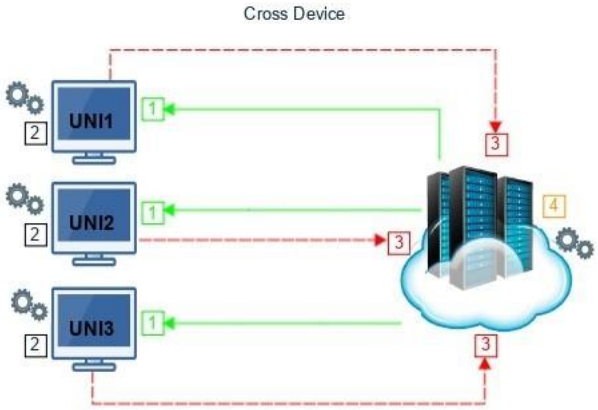

Fig. 1. The architecture of federated learning.

FL approaches can be categorized into three types by learning methods, architectures, and aggregation strategies, including synchronous FL, where the server waits for all clients to complete training before aggregating updates. While this method ensures consistency and high accuracy, it may lead to inefficiencies due to edge heterogeneity—variations in computational and communication capabilities among clients [10]. In asynchronous FL, clients communicate updates independently, reducing waiting times but potentially introducing inconsistencies in global model updates [11]. Semi-Asynchronous FL is a hybrid approach that balances the benefits of synchronous and asynchronous methods.

Experiments using synchronous method in FL [12], where clients must download global model updates at one point in time, and the server waits for clients to complete the training tasks. This synchronous optimization mechanism causes clients with limited network or insufficient hardware resources to lag; the server and other clients have to wait, and the learning efficiency decreases, i.e., there is an overload effect, but for our problem, we paid attention to the obvious advantages of this

synchronous update method in that the model converges easily and has high accuracy.

FL [13, 14] is a machine learning technique that focuses on mutual learning of a model by multiple clients, where the data remains decentralized. FL is a critical technology in the current era of big data and artificial intelligence, recognized for its critical role in protecting data privacy and eliminating the need to transfer and process huge amounts of data. FL allows the benefits of machines to remain intact. Unlike the traditional centralized learning approach, it facilitates collaborative training of statistical models sharing parameter updates instead of raw data [15, 16]. In our work, we have considered algorithms such as FedAvg, a better-known efficient algorithm for training machine learning models on multiple clients in a privacy-preserving manner. Traditionally, FedAvg uses a central server to distribute parameters to clients and aggregate updates, but has difficulties with privacy and communication efficiency [17]. FedOpt achieves faster convergence, lower communication overhead [18], and higher accuracy with fewer training epochs compared to benchmarks [19].

In [20], the authors present a comprehensive scheme for FL provisioning under time constraints in IoT environments using push-pull communication mode. By combining utility-based scheduling and efficient client selection, higher accuracy and lower latency are achieved compared to traditional methods. The approach is particularly effective in heterogeneous and resource-constrained networks, paving the way for practical implementation of FL in IoT and edge computing. In [21], ClipFL, a novel method for handling noisy labels in Federated Learning by identifying and excluding noisy clients, is discussed. The method demonstrates high accuracy, fast convergence, and reduced communication overhead, making it a practical solution for real FL systems with noisy data. The simplicity and scalability of the method make it suitable for large-scale deployment even in resource-constrained and heterogeneous environments. Traditional federated learning (FL) methods are enhanced, introducing a split learning approach where client-side and server-side models are trained together, which significantly improves the performance and efficiency of the interaction [22].

In [23], the importance of robustness in federated learning is emphasized, privacy and security concerns are addressed, and practical security mechanisms are described. By addressing these vulnerabilities, FL can be effectively deployed across industries, ensuring data integrity and model robustness in distributed environments. In the future, dynamic, scalable, and lightweight solutions should be prioritized to make FL both secure and efficient. One of the studies [24] shows that L2GDV (Loopless Local Gradient Descent with Varying step size) significantly improves the efficiency and performance of fuzzy learning by combining adaptive regularization step size methods. It provides robust convergence guarantees while reducing communication costs, which makes it suitable for real FL applications with heterogeneous data and limited resources. The study [25] emphasizes the vulnerability of FL to data poisoning attacks using unwanted samples, especially when using robust aggregation schemes such as Krum and Bulyan. While aggregation algorithms mitigate some attacks, they remain insufficient against adaptive adversary techniques.

Recent works [26–27] have explored centralized machine learning approaches for mental health prediction and early intervention, demonstrating promising results in healthcare and behavioral analytics. However, few studies have applied federated frameworks in educational contexts, particularly within developing regions, where data heterogeneity and privacy concerns remain major obstacles. However, these studies rely on centralized architectures, whereas our work introduces a federated paradigm suitable for privacy-constrained educational environments.

III. Proposed Methodology

FL utilizes synchronous, asynchronous, and semi-synchronous training methods, each suited to different network conditions. Synchronous learning ensures high accuracy by aggregating updates only after all clients submit them, but it requires stable connectivity and is sensitive to slow clients. Asynchronous learning allows clients to update independently, accelerating training in heterogeneous environments but risking model instability. Semi-synchronous learning balances these approaches by waiting for a subset of clients (e.g., 80%) before updating, reducing delays while maintaining stability. Given these factors, synchronous learning was chosen to ensure consistent model updates.

Although FL is classified into horizontal and vertical types, where horizontal FL involves similar features across different users, while vertical FL integrates different features for the same users. FL can also be Cross-Silo, applied in large organizations with stable connections, or Cross-Device, involving numerous heterogeneous personal devices with limited resources. Our study employs synchronous learning, horizontal FL, and Cross-Device FL for optimized distributed training. The structure of FL is illustrated in Fig. 2.

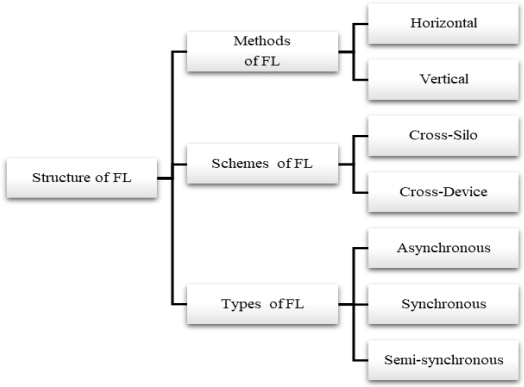

Fig. 2. Structure of FL.

A. Description of Method

These methods are used to predict students' psychological and emotional state based on nutrition, activity, and sleep data, such as interaction type. The distribution of the data presented below: Type interactions: When solving our task, we choose the Cross-Device type of interaction, since the task involves collecting data from devices where data is stored locally. The data are heterogeneous in terms of quality and distribution (different modes of sleep, nutrition, activity of students). Devices may be resource constrained (low processing power,

variable network). Cross-Device FL performs well in tasks where devices are limited in computational resources, and the data have a high level of heterogeneity. Selection: Horizontal. Distribution data: Each device has a similar data structure: sleep metrics, nutrition, activity, but the data belongs to different users. Horizontal training allows effective work with such scenarios, as it focuses on combining knowledge from similar data structures. Selection: synchronous. In our scenario, we will be able to organize synchronous student connection devices. Synchronous learning allows the server to produce an immediate update of the global model, which gives a good result for accuracy.

B. Selection of FL Algorithms

In addition, to effectively handle data heterogeneity in non-IID student datasets, we selected federated optimization (FO) algorithms that adapt to variability: FedAvg serves as a baseline approach, which can be enhanced by assigning different weights to clients with varying data distributions. FedProx incorporates regularization to mitigate the effects of dominant local updates, improving convergence in heterogeneous environments. FedOpt employs adaptive step sizes for both client and global models, facilitating faster convergence and enhanced scalability for complex, large-scale datasets.

FedAvg (Federated Averaging) [28] is a standard algorithm for federated learning that provides distributive learning on local devices, minimizing data exchange with the server. The algorithm works as follows: each client trains its model on local data and sends updates to the server. The server aggregates all local updates, computing an average for the model parameters. This method is repeated till convergence is achieved. The basic Formula (1):

$$\omega^{t+1} = \frac{1}{K}\sum_{k=1}^{K} \omega_k^{t+1} \quad (1)$$

where, ω_k^{t+1} updated model parameters from customer k, and K - number of customers.

FedOpt (Federated Optimization) [29] is an improvement to the FedAvg algorithm that incorporates the use of adaptive optimizers, such as Adam, for local model updates. Instead of using simple gradient descent as in FedAvg, FedOpt applies optimizers for each client, which helps to speed up convergence and reduce the impact of local errors. FedOpt can accommodate different learning rates for each client, making it more flexible and efficient. The basic Formula (2):

$$\omega^{t+1} = \omega_k^t - \mu_k \nabla L_k(\omega_k^t) \quad (2)$$

where, μ_k is the learning rate for client k, and ∇L_k is the gradient of the loss function for the client.

FedProx (Federated Proximal Optimization) [30] is an enhancement to the FedAvg algorithm designed to deal with heterogeneous data. It adds proximal regularization to minimize the impact of local differences in the data and improve learning stability. Instead of simply weighing local updates as in FedAvg, FedProx accounts for deviations of the local model from the global model using a proximal term that helps improve convergence and avoid overfitting. The basic Formula (3):

$$\omega_k^{t+1} = \omega_k^t - \mu_k \nabla L_k(\omega_k^t) - \mu(\omega_k^t - \omega) \quad (3)$$

where, μ is the regularization coefficient, and ω are the global parameters of the model.

The advantages of the algorithms are FedAVG - Easy implementation and low requirements for computing resources. FedOPT - use of adaptive optimizers accelerates convergence and helps avoid overfitting on unstable data. FedPROX is suitable for cases with heterogeneous data and high variability between clients. Proximal regularization helps to improve convergence.

The limitations of the algorithms are FedAVG - sensitivity to data heterogeneity, where data on different devices vary significantly, which can slow down the learning and degrade the quality of the model. FedOPT - Increased computational costs on the client, as more sophisticated optimization techniques must be used. FedPROX - requires tuning of the regularization parameter, which may add complexity to the optimization process.

Algorithms like FedSGD, FedAvg, FedProx, SCAFFOLD, and FedOpt were considered for this study, but FedAvg, FedProx, and FedOpt were selected for further study. It is shown in Table I.

TABLE I DETAILS OF ALGORITHMS

Method	Non-IID	Convergence rate	Flexibility to heterogeneity of clients	Use of server optimizers
FedAvg	Bad	Slowly	No	No
FedProx	Medium	Medium	Yes	No
FedOpt	Good	Fast	Yes	Yes

In summary, FedAvg is a basic algorithm for federated learning, effectively applicable if the data on the clients is similar. FedOpt improves FedAvg using adaptive optimizers, which accelerates convergence and improves model accuracy. FedProx focuses on heterogeneous data and incorporates proximal regularization, which improves training stability in the face of large differences between clients. Each of these methods has its own features and applications, and the choice of the appropriate algorithm depends on the data structure and computational resources.

In federated model training, FedAvg, FedOpt, and FedProx optimize learning on distributed clients while minimizing communication with the central server. FedAvg is effective when client data distributions are similar, offering a computationally efficient solution for homogeneous datasets, such as student learning or physical activity data. FedOpt adapts to heterogeneous data using adaptive optimizers (e.g., Adam), improving convergence speed and model accuracy, making it suitable for dynamic environments. FedProx addresses highly heterogeneous data by incorporating regularization, mitigating localized errors, and enhancing model stability and accuracy in diverse student datasets. In conclusion, FedAvg will be a simple and efficient solution when the data is homogeneous between clients, in case of heterogeneous data and different device types, we recommend using FedOpt or FedProx to improve model quality and convergence. Provided the problem requires regularization and consideration of local differences, FedProx will provide a stable solution. Thus, the choice of algorithm depends on the nature of the data and the goals: speed of

training and accuracy of the model or the ability to adapt to differences in customer data.

C. Experimental Settings

The tasks are focused on client-side data processing, where local models are applied directly on the client devices. Sending updates to the server. Server-side update processing, creating a global model. Sending global models to customers. Global model with client data is processed on the client side. These steps will ensure stability, privacy, and efficiency in implementing the study in real-world use cases. For our heterogeneous data problem, the choice of methods and approaches must consider the heterogeneous distribution of data across devices.

This study employs a client-side learning approach, ensuring that raw data remains on user devices, thus preserving privacy while still enabling effective global model updates. The following stages describe each step of this process in detail.

Stage 1: Data Preparation

At this stage, data is collected through a web platform where participants complete the Maslach Burnout Inventory (MBI) questionnaire. Once collected, the data is cleaned by removing duplicates, input errors, and outdated records, then normalized and standardized. Special attention is given to simulating real-world conditions with heterogeneous (non-IID) data to enhance model robustness and realism.

Stage 2: Local Training on Clients

Each client trains a random forest model locally on their own data without transmitting raw information to the server. The updated model parameters (e.g., tree weights and performance metrics) are sent to the central server to ensure data privacy. This approach allows the model to adapt to the unique characteristics of each client's dataset and improves prediction accuracy.

Stage 3: Model Aggregation on the Server

The server collects updates from all clients and aggregates them using algorithms such as FedAvg, FedProx, or FedOpt. Aggregation is weighted according to the volume of data on each client to ensure fair contribution. After aggregation, the server evaluates model convergence using metrics like MSE and R^2 and adjusts training parameters if needed.

Stage 4: Model Updating and Client Communication

The updated global model is sent back to clients via secure communication channels. Clients integrate the new model into their local environment and resume training on their data. This iterative process of model distribution and retraining ensures continuous improvement and adaptation to new data.

Stage 5: Model Evaluation

After several rounds of training, the model is evaluated using both classification (Accuracy, Precision, Recall, F1-score) and regression (MSE, R^2) metrics. The impact of data heterogeneity among clients is analyzed to assess its effect on model accuracy and convergence. This comprehensive evaluation helps identify weaknesses and optimize aggregation strategies and learning parameters. Fig. 3 illustrates these steps.

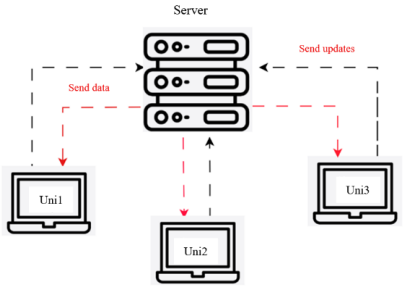

Fig. 3. Federated learning architecture: client-server interaction.

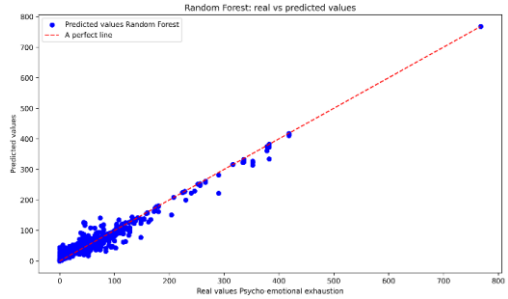
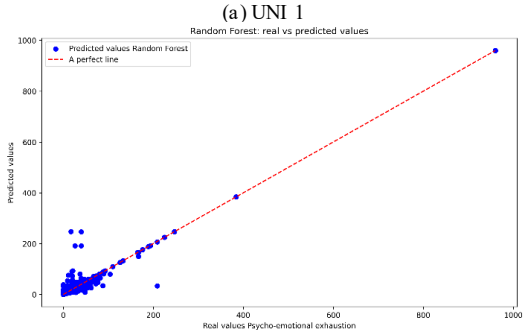
The Random Forest method was applied to the local model; this algorithm was determined by conducting experiments during which methods such as logical regression, linear regression, and time series were considered. The Random Forest method is an ensemble machine learning algorithm that uses multiple decision trees to solve classification and regression problems. The essence of the method is to train multiple trees on a Random Forest of training data and features, which improves the generalization ability of the model and reduces overfitting. Each tree is trained on a random sample of data with return (bootstrap method), and for classification, the final decision is made by a majority vote of the trees, and for regression, through averaging of predictions. Before sending them to the server after training on local devices, the following results were obtained, which are presented in Fig. 4.

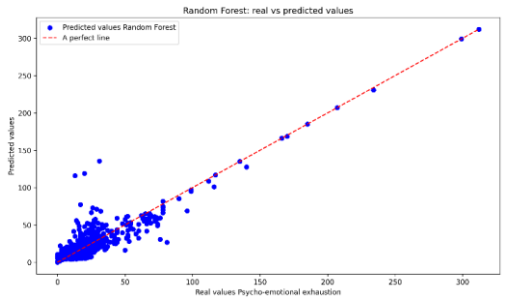
The graphs' description illustrates the relationship between actual and predicted values of Psycho-emotional exhaustion. The horizontal axis represents actual values, while the vertical axis shows predicted values. A red dashed line indicates a perfect match. For low and medium values, predictions closely align with the ideal line, demonstrating high accuracy. As values increase, a slight deviation appears, with greater scatter at higher levels (~1000). Despite this, predictions remain well-correlated with the actual data, maintaining stable performance across different ranges.



(a) UNI 1



(b) UNI 2



(c) UNI 3

Fig. 4. Comparison of the results of the random forest method in (a) UNI 1, (b) UNI 2, (c) UNI 3.

The pros of the method are high accuracy, especially for complex and high-dimensional data, robustness to overfitting due to the ensemble approach, handling of missing values, and estimation of feature importance, which aids in model interpretation. The cons are low interpretability compared to single trees, difficulties with prediction on very large data due to the large number of trees. Random forest is widely used in classification and regression tasks such as disease diagnosis, credit scoring, price prediction, and tasks requiring feature selection. In the federated learning task, random forest is an effective method for combining models from different clients, providing robustness to local data and improving overall performance. After numerous experiments on the server side, a local model was picked up and sent to the client side, where training began. The graphs compare the actual values and predicted values of the Random Forest model for the Psycho-emotional exhaustion index. For this purpose, data from different devices were used, which allows us to clearly demonstrate the effectiveness of the model in the conditions of heterogeneous data. The Random Forest model shows a good ability to predict Psycho-emotional exhaustion, especially in the small and medium ranges of values. Visualization confirms that the model successfully captures the data patterns, although some deviation from the ideal line is observed at higher values (see Table II).

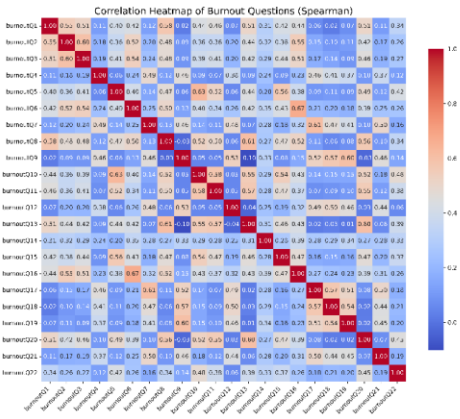
TABLE II ACCURACY BEFORE SENDING IT TO THE SERVER

	UNI 1	UNI 2	UNI 3
Accuracy	0.915676	0.554274	0.858384

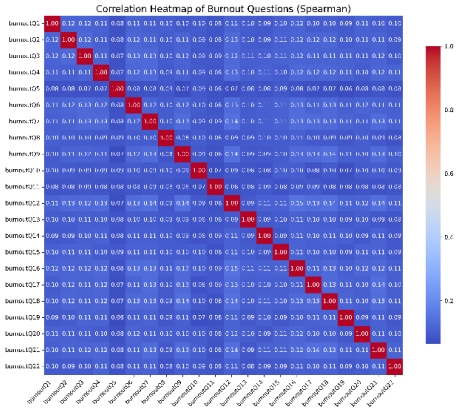
1) Description of the preparatory process: To solve the task, a website was created where the data collection of each individual student on their personal devices was organized. For example, it was decided to make a psycho-emotional and physical analysis of the state of students and schoolchildren based on the collected database. Currently, the FL has not yet started its march in Kazakhstan, so my work is of an introductory nature on the possibilities of using the FL. The purpose of the experiment is to make a practical demonstration of the whole process of organizing FL steps on a specific example described in the study.

Three educational institutions participated in the experiment; data were collected from the beginning of the learning process, from September 1, for 2 months before the first milestone control. A website was created for data collection, where all data were stored in a database based on the educational institution. The aim was to analyze the mental and emotional state of students from the moment of the beginning of the study and by the end of the first milestone control to determine how much their state had changed by the time of passing the first milestone control.

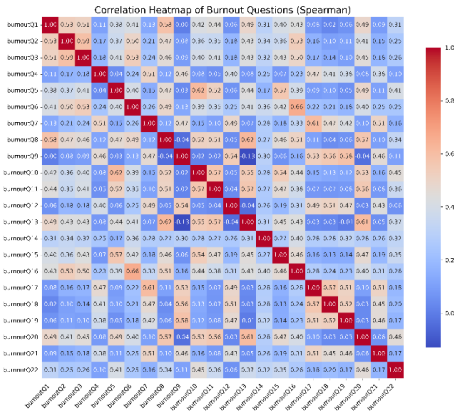
These heatmaps provide an overview of how different questions about burnout relate to each other, which can be useful for identifying patterns and determining which questions may share common underlying factors or experiences, as in Fig. 5.



(a) UNI 1



(b) UNI 2



(c) UNI 3

Fig. 5. Correlation heatmap of burnout questions in (a) UNI 1, (b) UNI 2, (c) UNI 3.

The heatmaps display Spearman correlation coefficients for burnout-related questions (burnoutQ1–burnoutQ22), with values ranging from -1 to 1. Red indicates strong positive correlations, blue represents weak or no correlations, and white signifies no correlation (0). Heatmap 1 highlights strong correlations between certain burnout questions. Heatmap 2 shows generally lower correlation values, with many closes to zero. Heatmap 3 reveals some strong correlations (e.g., burnoutQ1–Q3, burnoutQ6–Q9), but overall, the values remain weaker. These heat maps help identify patterns and relationships between burnout factors.

Application of FL was aimed at predicting further psycho-emotional and physical state of students for the next boundary control and readiness to pass the winter session. The heterogeneity of the data can be determined based on the following characteristics shown in Table III.

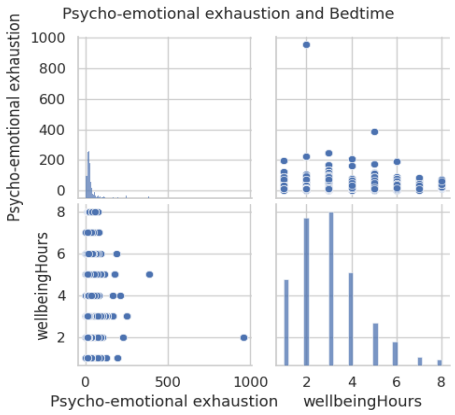
TABLE III CHARACTERISTICS OF THE DATA

Data type	Heterogeneous	Homogeneous
Nutrition	'Breakfast', 'Dinner', 'Lunch', 'total_meals'.	
Physical activity	'intensity', 'activityType', 'duration'	
Sleep and rest	'wellbeingHours0', 'wellbeingHours0', 'wellbeingHours1'.	
Emotional state	'Psycho-emotional exhaustion', 'burnoutQ1'- 'Q22'.	
Identifiers and meta-data		'student_id', 'entry_date'

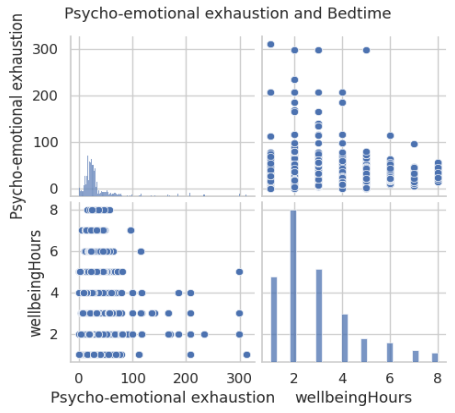
2) Heterogeneity analysis: Students' data exhibits heterogeneity due to variations in behavioral patterns, including nutrition, physical activity, sleep, and emotional state. For instance, dietary habits differ among students, with some skipping meals while others follow a structured diet. Similarly, physical activity levels vary, ranging from active sports participation to a sedentary lifestyle. Emotional burnout scores also fluctuate based on individual stress levels and coping mechanisms. Conversely, homogeneous attributes include 'entry date' (consistent format across devices) and 'student_id' (a unique identifier that does not impact target metrics). These attributes remain stable regardless of individual behaviors in Fig. 6. To address data heterogeneity, preprocessing is required to normalize activity and nutrition data, ensuring consistency across samples. Additionally, leveraging homogeneous attributes (e.g., timestamps, unique identifiers) aids in standardization and enhances model reliability.

The pair plots illustrate a weak negative correlation between Psycho-emotional exhaustion and wellbeingHours. Most students show low sleep duration regardless of exhaustion level, indicating that increased rest does not consistently reduce emotional fatigue. The presence of outliers reflects the heterogeneity of behavioral data among students.

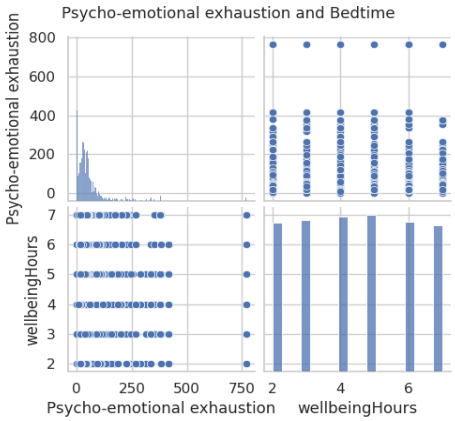
The following results highlight the comparative performance and convergence behavior of the selected FL algorithms under non-IID educational data conditions.



(a) UNI 1



(b) UNI 2



(c) UNI 3

Fig. 6. Fluctuations in psycho-emotional exhaustion over one month in (a) UNI 1, (b) UNI 2, (c) UNI 3.

IV. RESULTS AND DISCUSSION

In this study, the performance of three federated learning algorithms, namely FedAVG, FedOPT, and FedProx, was benchmarked on a classification task aimed at predicting students' psycho-emotional states. The primary evaluation metric was Accuracy, measured on test data after each of ten training rounds. Table IV and Fig. 7 illustrate the dynamics of model accuracy across all rounds, providing insight into the learning stability and convergence behavior of each algorithm.

TABLE IV ACCURACY DYNAMICS FOR ALGORITHMS

Rounds	Accuracy		
	FedAVG	FedOpt	FedProx
1	0.793071234	0.8383071568	0.9682882882
2	0.850712345	0.8707123457	0.9793333333
3	0.9366666666	0.942457545	0.989333333
4	0.95956756756	0.9895675675	0.9866633333

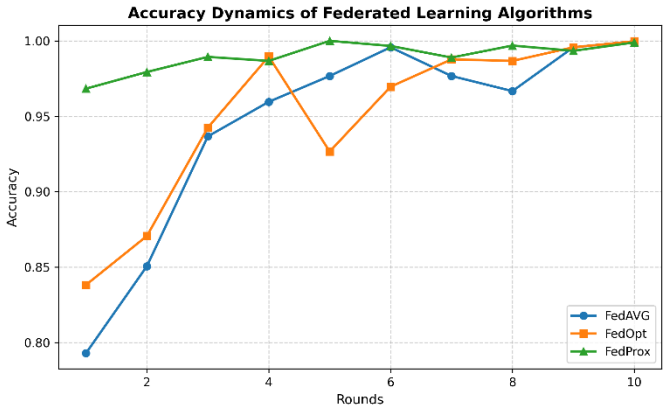

Fig. 7. Accuracy dynamics for algorithms.

As shown in Fig. 7, all three algorithms exhibit an upward trend in accuracy as training progresses, demonstrating the effectiveness of the federated learning approach in distributed educational data environments. Among them, FedProx consistently achieved the highest accuracy, particularly in later rounds where it reached 99.99%, indicating its robustness in managing heterogeneous, non-IID data. This superior performance is attributed to its proximal regularization, which stabilizes updates and reduces divergence caused by local data variability across clients:

a) FedOpt, which incorporates adaptive optimizers (e.g., Adam), also demonstrated strong convergence characteristics, achieving accuracy levels close to FedProx while maintaining lower communication overhead. However, its slightly lower accuracy in the final rounds suggests that additional regularization could further enhance its performance under highly heterogeneous conditions.

b) FedAVG, while computationally efficient, displayed slower convergence and lower final accuracy compared to the other two methods. Its performance plateaued in the later rounds, emphasizing its sensitivity to client data heterogeneity. Nonetheless, FedAVG remains a practical solution for homogeneous datasets or resource-constrained environments, where computational simplicity is prioritized over precision.

c) Overall, the results confirm that FedProx is the most effective algorithm for addressing data heterogeneity and achieving high model accuracy in psycho-emotional state prediction. FedOpt offers a balanced trade-off between speed and accuracy, whereas FedAVG is better suited for uniform data distributions.

These findings support the study's objectives by demonstrating that federated learning algorithms can be effectively applied to privacy-preserving educational analytics. The results offer actionable insights for educational institutions, researchers, and policymakers, emphasizing the potential of federated learning to enhance the monitoring of students' psycho-emotional well-being while ensuring data confidentiality and accommodating diverse learning environments across regions.

Moreover, the results directly align with the study's objective of developing a federated learning framework for monitoring mental health in Kazakhstan, confirming that such systems can be implemented effectively under heterogeneous educational conditions.

V. CONCLUSION AND FUTURE SCOPE

This study aimed to develop and evaluate a privacy-preserving federated learning framework for analyzing the psycho-emotional well-being of students in Kazakhstan, particularly under conditions of data heterogeneity and non-IID distributions. To achieve this, three federated learning algorithms, FedAvg, FedOpt, and FedProx, were benchmarked across ten communication rounds in a classification task. The results revealed distinct performance dynamics, convergence rates, and stability patterns under federated conditions.

FedAvg showed steady improvement in accuracy from 0.793 in round 1 to 0.9997 in round 10, indicating reliable convergence despite minor fluctuations in intermediate stages. FedOpt achieved slightly higher accuracy in the early rounds (0.9425 and 0.9895 in rounds 3 and 4) and demonstrated faster convergence than FedAvg. FedProx, starting with the highest initial accuracy (0.9683), maintained consistent progress and reached 0.9989 by the final round, confirming its robustness and effectiveness in handling heterogeneous and non-IID data distributions.

These findings validate the study's objective by demonstrating that federated optimization algorithms can effectively manage data heterogeneity and ensure secure, distributed model training for sensitive educational analytics. However, the experiments were conducted in a simulated federated environment involving a limited number of institutions, which may not fully represent large-scale or real-world deployments.

Future work will address these limitations by incorporating a broader range of educational institutions, exploring asynchronous and cross-silo FL configurations, and integrating additional behavioral and contextual variables to enhance predictive accuracy, adaptability, and robustness. Previous studies have explored centralized machine learning for mental health analysis and early intervention [31]; however, these relied on centralized data aggregation, leading to privacy and scalability challenges.

This research advances the field by introducing a federated learning-based approach that ensures data confidentiality while

maintaining model accuracy and adaptability across heterogeneous educational environments. Overall, it establishes a foundation for ethical, data-driven, and privacy-aware educational analytics in Kazakhstan and beyond, supporting early intervention strategies and strengthening national efforts to promote student mental health and academic resilience.

Exploring Hallucination in Large Language Models

A Comparative Study of GPT-4o and GPT-4o-mini in Medical Domains

Abstract*—Large Language Models such as GPT-4o and GPT-4o-mini have shown significant promise in various fields. However, hallucination, when models generate inaccurate information, remains a critical challenge, especially in domains that require high accuracy, such as the healthcare field. This study investigates hallucinations in two different LLMs, focusing on the healthcare domain. Four different experiments were defined to examine the two models' memorization and reasoning abilities. For each experiment, a dataset with 193,155 multiple-choice medical questions from postgraduate medical programs was prepared by splitting it into 21 subsets according to medical topics. Each subset has two versions: one with the correct answers included and one without them. Accuracy and compliance were evaluated for each model. Models' adherence to requirements in prompts was assessed. Also, the correlation between size and accuracy was tested. The experiments were repeated to evaluate the models' stability. Finally, the models' reasoning was evaluated by human experts who assessed the models' explanations for correct answers. The results revealed poor rates of accuracy and compliance for the two models, with rates below 70% and 75%, respectively, in most datasets; yet, both models showed low uncertainty (3%) in their responses. The findings showed that the accuracy was not affected by the size of the dataset provided to the models. Also, the results indicated that GPT-4o-mini demonstrates greater performance stability compared to GPT-4o. Furthermore, the two models provided acceptable justifications for choosing the correct answer in most cases, according to 68.8% of expert questionnaire participants who agreed with both models' justifications. According to these results, both models cannot be relied upon when accuracy is critical, even though GPT-4o-mini slightly outperformed GPT-4o in providing the correct answers. The findings highlight the importance of improving LLM accuracy and reasoning to ensure reliability in critical fields like healthcare.

Keywords*—ChatGPT; GPT-4o; GPT-4o-mini; hallucination; healthcare; large language models

I. Introduction

One development in artificial intelligence (AI) applications is large language models (LLMs), which include several technologies such as deep learning and natural language processing (NLP), reinforcement learning, and transformers to produce new content from available material. Today, there are many LLMs that have been developed by different vendors. These models follow the same process and start with training the LLM on a large amount of data from the Internet to produce new content. However, these models differ in their training methods and the technologies used to generate and predict output data. Most of these models rely on language general context, and linguistic rules to predict subsequent words based on the preceding ones using technology [1].

LLM models have been applied in many fields to generate content ranging from answering questions, executing commands and instructions, summarizing, translating, and conducting long conversations with users [2]. One well-known company in this field is OpenAI. In November 2022, it made its LLM, ChatGPT, available to the public. Following that, OpenAI launched several versions of ChatGPT. For instance, in March 2023, GPT-4 was introduced, followed by GPT-4o in May 2024. These new releases had a high impact on NLP technology. The accuracy of understanding the context of input data and generating the response has enhanced in comparison to the old models. In addition, GPT-4o shows strong performance across many benchmarks [3], and supports multi-modal content generation.

LLMs have been widely used in several fields, including education, healthcare, industry, business, and marketing, to enhance productivity and quality as well as reducing effort and saving time [1], [4], and [5]. However, the use of LLMs may involve some ethical issues such as bias and hallucinations which can affect data accuracy and the model reliability [6], [7], and [8]. Hallucinations may occur when the models been trained with invalid and insufficient data, thus LLM generates inaccurate or false outputs [9], and [10]. Several studies have identified factors to minimize the possibility of hallucination. These factors include improving the quality of training data, developing methods to detect and correct errors, and enhancing the models' ability to think and reason to distinguish accurate information from false [10].

The problem of hallucination is that it looks like a piece of meaningful and valuable information, but, in fact, it is inaccurate and invalid. Generally, hallucinations can occur for several reasons, including a lack of adequate information, which leads to inaccurate results during analysis. In addition, poor data

*Corresponding author.

quality will generate models that rely on low-quality data, reducing result accuracy and increasing the likelihood of hallucinations [9]. Moreover, some instructions or questions given to the LLM models may be unclear or can result in multiple interpretations according to different contexts. Furthermore, most LLM models lack reasoning, critical thinking, and analytical abilities, although companies have focused on improving these issues in the current updated versions [10].

This research contributes by examining two models of ChatGPT: GPT-4o and GPT-4o-mini and comparing the hallucination of the two models in the healthcare field. The motivation behind this work comes from the hallucination issue in LLMs, which is particularly critical in fields such as healthcare, where accurate responses are essential and any misinformation could have severe or even fatal consequences. Reducing hallucination in LLMs is essential for ensuring their reliability in critical fields. Thus, the objective of this research is to evaluate the two models' responses to medical questions. Different sets of medical exam questions in different medical topics for postgraduate medical programs were prepared by including or excluding the correct answers to test the models' ability to reason and distinguish the absence of correct answers. Experiments were designed to evaluate GPT-4o and GPT-4o-mini models on memorization and reasoning, where accuracy, compliance, uncertainty, and reasoning were measured for each experiment. Also, this research examines the relationship between the size of the dataset and the models' accuracy, as well as the impact of repeating the test on the models' accuracy.

The rest of the research is organized as follows: Section II reviews the literature. In Section III, the methodology is addressed. A detailed explanation of the different experiments and their results is presented in Section IV and Section V, respectively. Section VI discusses the findings of the study. Concluding remarks and a brief of future works are given in Section VII.

II. Literature Review

Models of large languages like LLama 3 [1], and GPT-4o [11] have the capability to generate loads of information as needed in several domains, including professional and crucial [12], [4]. However, in some cases, hallucination phenomena may occur in LLMs [2] when providing information, which can vary, ranging from minor fabrications to major misconceptions.

Regardless of the effectiveness of the prompting techniques, researchers have found that LLMs can produce erroneous responses that mimic actual statements but contain unsubstantiated information [13]. Others have confirmed that when hallucinations occur in LLMs, the resulting errors can negatively impact the user experience, leading to confusion, distrust, and decreased enthusiasm for using these AI models [7] and [14]. Ji et al. [7] define hallucinations in LLMs as the natural generation of information; however, they may lack meaning or be inconsistent with the actual content of the source. Zhang et al. [15] have standardized the definition of hallucinations in LLMs into three categories: input-conflicting hallucinations, context-conflicting hallucinations, and fact-conflicting hallucinations. With input-conflicting hallucinations, the content that LLMs produce conflicts with what the user has input. With context-conflicting hallucinations, the content produced varies between two different attempts. Lastly, fact-conflicting hallucinations occur when the information produced contradicts fundamental knowledge. Several factors can significantly cause hallucination in LLMs, including inadequate data samples in the training dataset or utilizing algorithms with extremely uncertain sampling [7] and [16].

Therefore, dependence on language generative technologies, where hallucinations in LLMs may occur, raises serious concerns. Given these challenges, it is particularly concerning when LLMs are applied, particularly in critical domains like healthcare. This is due to the significant impact on people's lives [17], including incorrect clinical decision-making and delayed or improper treatment [8]. It is possible to train LLMs to perform remarkably well on a range of medical and healthcare tasks [11], [4], pass medical examinations [5], [18], [19], and generate relevant texts about medical topics. However, in a question-answering task, LLMs may provide an answer that appears reasonable but is factually inaccurate, while in content-generation tasks, the model may also generate cohesive narratives or explanations based on fictitious facts or events in content generation tasks. For example, in response to the question, "What are the common side effects of metformin?" an LLM might say, "Medication side effects include nausea as well as trouble breathing", which is slightly incorrect [20]. The reliability of LLMs is a major concern for both healthcare organizations and patients, especially if the model hallucinates and produces incorrect answers to medical questions. Any incorrect information can significantly impact the patient's health and the healthcare organization's reputation. Thus, hallucinations in LLMs might be extremely challenging in the medical domain [21], [22], where integrity and dependability are crucial [23] to maintain both patient satisfaction and trustworthiness while receiving healthcare.

There are several studies that highlighted the performance of different LLM models, including MCQ examination in the domain of health care [24, 25, 26, 27]. Each research has evaluated the performance of hallucinations based on one or more LLM models like ChatGPT3, ChatGPT 4 [24, 25, 26] while [25] compares ChatGPT-4 with three other different models, namely ChatGPT, QWen 2.1, and Ernie 4.0. Nevertheless, [27] has examined the performance of ChatGPT solely. In addition, the dataset language used in each research varies between English and Non-English, aimed to measure both the model's accuracy and reasoning.

Moreover, [24] focused on evaluating ChatGPT-4 performance on the Japanese medical licensing examination dataset. Four aspects of the model were examined: accuracy, category sub-score, effect of translation, and error analysis. The model scored 82.7% and 77.2% for the essential questions and the basic and clinical questions, respectively. On the other hand, [25] has tested the performance of the GPT-4.0, ChatGPT, QWen 2.1, and Ernie 4.0 models on a Chinese dataset that has been evaluated by experts; the models' accuracy, performance, and reasoning were measured. The research measures model reasoning by calculating the rates of fact hallucinating, fact fabrication, Instruction Inconsistency, and logical inconsistency. For all models, Ernie 4.0 achieved better performance compared to GPT-4.0.

Furthermore, [26] compared the performance of ChatGPT-4 in answering medical MCQ questions with the answers coming from medical students. This study showed that ChatGPT-4 accuracy outperformed the students with 73.7%, 66.7% respectively. On the other hand, 78% of the students achieved at least 90% accuracy, which is higher than the accuracy rate of ChatGPT-4. Finally, in [27], ChatGPT's accuracy and reasoning were evaluated using MCQ datasets from the United States Medical Licensing Examination (Steps 1 and 2), using two different datasets with and without a provided hint to the model. Having four different versions of the question sets, the study revealed accuracy over datasets for the first dataset (Step1) exam as 44%, (Step2) as 42% and the second dataset (Step1) as 64.4%, and (Step2) as 57.8%.

Although these studies tested the abilities of different LLMs, none of them evaluated the ability of the model while excluding the correct answers. Also, none of these studies have tested hallucination on Chat-GPT-4mini and measured the correlation between the model's accuracy and the size of the dataset, nor tested the model's stability while answering medical questions.

III. Materials and Methods

The dataset for this research [28] consists of multiple-choice questions (MCQs) with fine-grained human-labeled classes in different medical fields at the graduate level, designed as a prerequisite for admission to postgraduate medical programs. These questions are designed to assess the skills of medical professionals. The dataset samples contain questions with answer options, correct answers, and explanations of the solutions. To ensure that all questions could be answered by text input, a few steps were taken to clean the data. First, the questions and options were proofread. In addition, to improve the quality of the dataset, the content was supervised by humans. Some tools were used to prepare the data, e.g., a spellchecker to identify and correct some cases, such as extra white spaces or missing options. Any question with an inconsistent format or questions without the correct answer option was removed. In addition, questions without a null candidate or those requiring external information were deleted. Questions containing specific keywords, such as "equation" or "India", were removed. In addition, all duplicate questions were removed. The final version of the dataset contained 193,155 questions.

To enable the generalization and re-usability of the models, the dataset was split by exams rather than by the questions given. The training set consisted of collected mock and online test series, while the test set comprised MCQs from the AIIMS PG exams (years 1991–the date at the time of when you compiled the dataset). The NEET PG exam MCQs (years 2001–the date at the time of when you compiled the dataset) were used to make the development set, aiming to approximate a real exam evaluation. The dataset consisted of 183,000 training examples, 4000 in the test set, and 6000 in the development set. To avoid overlapping between questions from the training, test, and development datasets, it was ensured that the test and development sets contained questions distinct from the training data. By calculating the Levenshtein distance between each pair of questions in the dataset, a question was excluded from the development and test sets if its similarity to any other question exceeded 0.9. For this research, the dataset was split into 21 smaller subsets, each corresponding to specific topics covered by the questions. These topics were Surgery, Social and Preventive, Skin, Radiology, Psychiatry, Physiology, Pharmacology, Pediatrics, Pathology, Orthopedics, Ophthalmology, Microbiology, Medicine, Gynecology and Obstetrics, Forensic Medicine, ENT, Dental, Biochemistry, Anatomy, Anesthesia, and Unknown. The Unknown dataset included all the questions that could not be categorized into any of the other 20 topics. After splitting, the dataset was divided into 21 sub-datasets, and 10% of the questions from each sub-dataset were randomly selected. This reduced the number of questions used to evaluate the targeted models to 100,000. Then, to prepare the data, all unnecessary records were dropped, and only the question, the four answer options, and the correct answer were retained. These datasets were used to examine the targeted models in the set of experiments where the correct answer is provided to the model with the set of possible answers. The final structure of the questions in this dataset is shown in Fig. 1.

```

IV. Experiments

In order to test hallucination in LLMs, two different models were tested, focusing on two key capabilities: memorization and reasoning. This study examined two well-known models: GPT-4o and GPT-4o-mini. The experiments conducted in this research were implemented using Google Collab, with Python 3 and a CPU hardware accelerator. Four separate experiments were designed to evaluate the models: two for GPT-4o and two for GPT-4o-mini. Each model was tested for both memorization and reasoning abilities. In addition, two of the experiments were repeated to examine the ability of the two models to improve their levels of memorization and reasoning.

A. GPT-4O Hallucination Evaluation

1) Analyzing Memorization and Reasoning with Correct Answer (MWRCA)

The objective of this experiment was to evaluate the hallucination of the GPT-4o model at two different levels:

memorization and reasoning. For this purpose, a benchmark consisting of multiple-choice questions, each with four answer options, was used that covered 21 different domains (see Section II). Among the four options for each question, one was the correct answer. The evaluation method (GPT-4o: MWRCA) began by feeding the model this set of questions, then asking it to select the correct answer and provide a reason for its selection. Additionally, the model was asked to explain why the other options were incorrect. After collecting the model's outputs, its memorization ability was evaluated based on the number of correct answers it chose, while its reasoning ability was assessed by analyzing the justifications the model provided for selecting the correct answer and avoiding the incorrect ones. Fig. 3 shows the prompt that asked the model to comply with a specific format to generate the output response. In this test, the model was allowed to respond "(IDK)" if it was uncertain of the correct answer. However, the expectation in the GPT-4o: MWRCA experiment was that the model would choose the correct answer rather than selecting an incorrect option or responding with "IDK". The results produced by the model were then saved in a CSV file.

```
You are a knowledgeable and meticulous specialist in the medical field.
Your role is to analyze multiple-choice questions along with their
provided options. Given a multiple-choice question with four possi-
ble answers (0, 1, 2, 3), determine the correct answer and ‘ deliver a
comprehensive explanation for its accuracy.
Additionally, combine the explanations for why the remaining options are
incorrect into a single column labeled “Incorrect Explanations”.
The output must strictly follow this structure:
- Column 1: Question Header (the question text or ID).
- Column 2: Correct Option Index (e.g., 9, 1, 2, 3, or IDK or IDK).
- Column 3: Correct Explanation (a single, clear sentence ezolaning the
correct answer).
- Column 4: Incorrect Explanations (all incorrect option explanations
combined lnto one clear sentence, separated by semicolons).
Ensure that:
 1. Each column is clearly separated by a single comma (…).
 2. No explanation spills over into another column. Keep explanations and
limited to their respective columns.
 3. If uncertaln about the correct answer, write ‘IDK’ in Column 2, leave
Column 3 blank, and provide reasoning in Column 4
Provide only one row of output in the format:“Question ‘Expalanations”
Strict adherencce to this format is required  Any deviation is unacetable.
```

Fig. 3. Prompt instruction to ChatGPT-4o.

To calculate the accuracy of the model, its output answers were compared to the actual correct answers. For each correct response, the model received a score of one. The total score was then divided by the number of questions in each topic, as shown in Formula (1):

$$\text{Accuracy} = \frac{\text{TotalNumberofCorrectAnswers}}{\text{TotalNumberofQuestions}} \times 100 \quad (1)$$

To calculate the compliance of the model, the model's output was compared to the correct structure of the output format (question, correct option index, correct explanation, incorrect explanation). The model received a score of one if it followed the specific format; otherwise, it received a score of zero. The total score of the model was then divided by the total number of questions in each topic, as shown in Formula (2):

$$\text{Compliance} = \frac{\text{ScoreofCompliance}}{\text{TotalNumberofQuestions}} \times 100 \quad (2)$$

Finally, the uncertainty of the model was calculated based on the number of IDK responses it provided. The total number of IDK responses was then divided by the total number of questions to calculate the percentage of uncertainty, as shown in Formula (3):

$$\text{Uncertainty} = \frac{\text{TotalNmuberofIDKresponses}}{\text{TotalNumberofQuestions}} \times 100 \quad (3)$$

2) Analyzing Memorization and Reasoning with No Correct Answer (MWRNCA)

The GPT-4o: MWRNCA experiment followed the same structure as the GPT-4o: MWRNCA experiment in terms of constructing the prompt. The key difference between the two experiments is the structure of the benchmark used to evaluate the models. In this experiment, the set of questions presented to the model had no correct answer in the available choices for each question. Instead, options such as "Blank", "NONE", or "NONE OF THE ABOVE" were included to represent "No Correct Answer Provided". Fig. 4 shows an example of a question from the dataset. The expectation for the results was that the model would choose "Blank", "NONE", or "NONE OF THE ABOVE" as an answer for each question. To run GPT-4o: MWRNCA, the model was not given any hints about removing the correct answers from the dataset. The model was expected to know this by itself.

```
1 Question: {Post operative muscle ache is
      caused by}
2 Opt1: {d-TC}
3 Opt2: {None}
4 Opt3: { Gallamine}
5 Opt4: { Pancuronium}
```

Fig. 4. Question sample from the anaesthesia dataset.

The GPT-4o responses were evaluated based on accuracy, compliance, and uncertainty. Accuracy was calculated based on the number of "NONE" responses provided by the model, relative to the total number of questions [see Formula (4)]. Further, the percentage of the model compliance and uncertainty was calculated following Formula (2) and (3), respectively.

$$\text{Accuracy} = \frac{\text{TotalNmuberofNONEresponses}}{\text{TotalNumberofQuestions}} \times 100 \quad (4)$$

B. GPT-4O-Mini Hallucination Evaluation

1) Analyzing Memorization and Reasoning with Correct Answer (MWRCA)

In this experiment, GPT-4o-mini hallucination in memorization and reasoning was evaluated. Following the methodology of the GPT-4o: MWRCA experiment, questions from 21 different medical topics were passed to the model to answer. The same prompt defined in Section II was used with GPT-4o-mini. The model's responses were evaluated based on the model accuracy, compliance, and uncertainty, following Formula (1), (2), and (3), respectively.

2) Analyzing Memorization and Reasoning with No Correct Answer (MWRNCA)

In this experiment, the hallucination behavior of GPT-4o-mini was evaluated at both the memorization and reasoning levels. The prompt provided to the model was similar to the one in Section I, with the only change the model's name, i.e., GPT-4o-mini instead of GPT-4o. The dataset used in this experiment was the one that included no correct answers in the provided

answer choices. The model was expected to respond with "NONE"; any other response reduces its accuracy according to Formula (4). Compliance and uncertainty percentages are calculated using Formula (2) and (3), respectively.

V. Results

In each of the four experiments, the compliance rate, accuracy, and uncertainty were measured for each dataset. Additionally, the correlation between the size of the dataset and the accuracy was analyzed, as well as the learning rate after repeating the experiments. Lastly, the models were prompted to provide reasoning for their answers, and these justifications were sent to medical experts for evaluation of the models' reasoning.

A. Compliance Rate

The compliance rate is defined as the number of compliant responses divided by the total number of responses. As shown in Fig. 5, the compliance rate of both models slightly decreased across all datasets when the correct answer was replaced with "NONE" in the given options; however, this drop is insignificant. GPT-4o-mini outperformed GPT-4o in terms of compliance in nearly all experiments. The only exception was observed on the ENT dataset, where GPT-4o complied with the requested response format on about 99.8% of the questions when the correct answer was given in the options. On average, the compliance rates for the GPT-4o: MWRCA, GPT-4o: MWRNCA, GPT-4o-mini: MWRCA, and GPT-4o-mini: MWRNCA were 60.98%, 57.92%, 76.30%, and 72.94%, respectively.

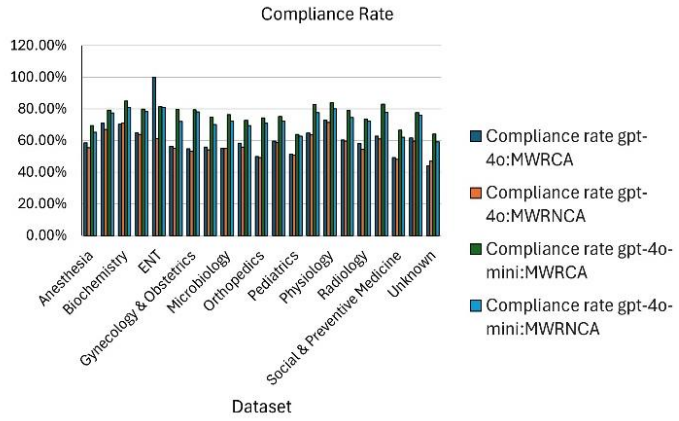

Fig. 5. The compliance rate of each experiment on each dataset.

B. Accuracy

The accuracy of each experiment across all datasets is shown in Fig. 6. Although GPT-4o-mini slightly outperforms GPT-4o on most datasets, both models perform poorly with accuracy rates below 70% on all datasets, except the ENT dataset, where GPT-4o achieves an accuracy of 81%. Both models show a significant drop in performance when the correct answer is replaced with "NONE", with average decreases of 75% for GPT-4o and 66% for GPT-4o-mini. The average accuracy for GPT-4o: MWRNCA, GPT-4o- mini: MWRCA, and GPT-4o-mini: MWRNCA are 48.60%, 11.90%, 53.13%, and 17.38%, respectively. These results indicate that both models are highly hallucinatory when applied to the given medical datasets.

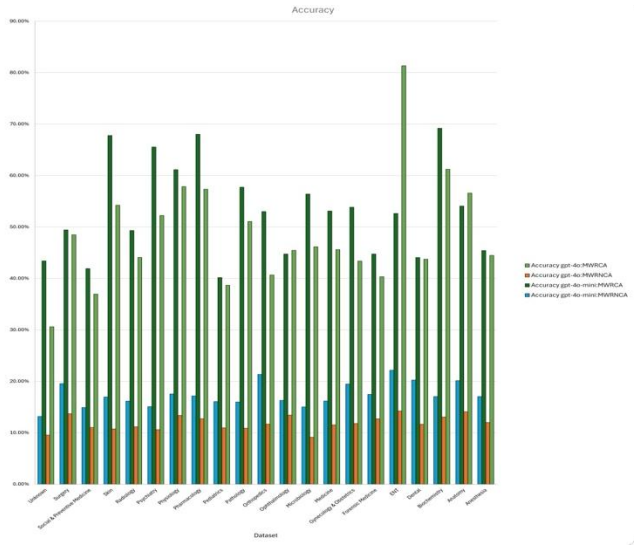

Fig. 6. The accuracy of each experiment on each dataset.

C. Uncertainty

When the correct answer is listed within the options, the models had less than 3% uncertainty on all datasets, as seen in Fig. 7. Additionally, GPT-4o reported a higher uncertainty than GPT-04-mini on all datasets. Notably, despite the low accuracy of all models as mentioned above, they all reported low uncertainties, averaging 0.88%, 26.63%, 0.59%, and 13.15% for GPT-4o: MWRCA, GPT-4o: MWRNCA, GPT-4o-mini: MWRCA, and GPT-4o-mini: MWRNCA, respectively.

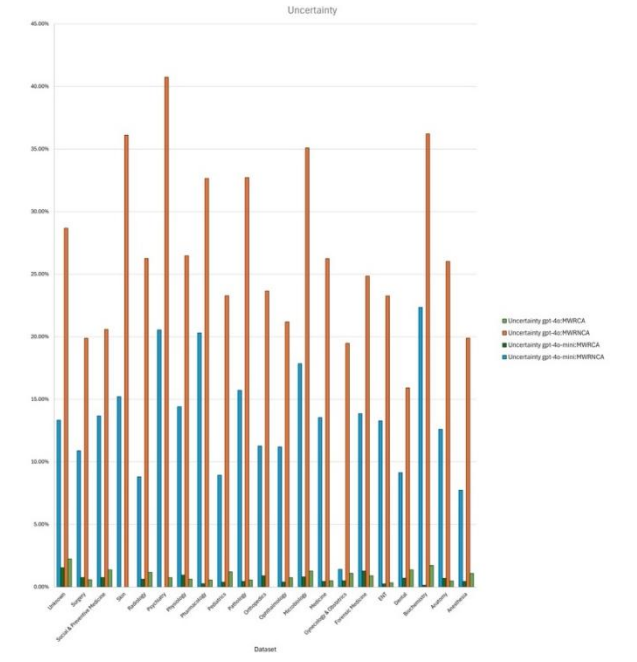

Fig. 7. The uncertainty of each experiment on each dataset.

D. Correlation

The correlation factors between the experiments' accuracy and the dataset sizes are all below 0.05, as seen in Fig. 8. The results indicate no clear correlation between dataset size and model performance.

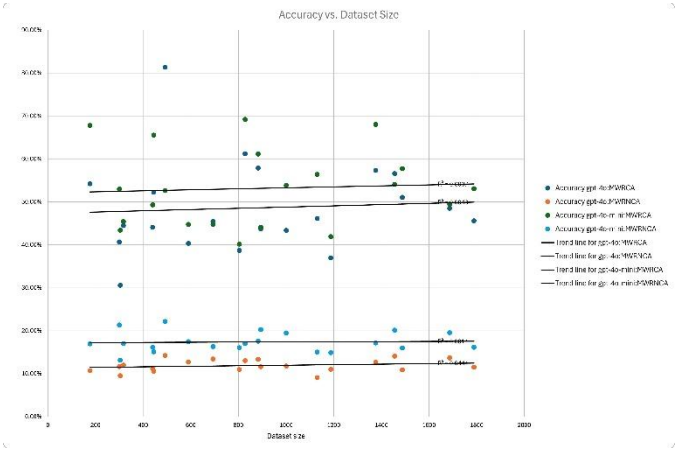

Fig. 8. The correlation between the dataset size and the accuracy.

E. Model Stability

To measure the models' performance stability, each of the four experiments was rerun on the following 10 selected datasets: Pathology, Pediatrics, Pharmacology, Physiology, Psychiatry, Radiology, Skin, Social and Preventive Medicine, Surgery, and Unknown. The computed difference between the accuracies of the two iterations of each of the four experiments, as in Formula (5), was 30.74% for GPT-4o with the correct answer, 1.75% for GPT-4o-mini with the correct answer, 3.72% for GPT-4o with "NONE" instead of the correct answer, and 1.64% GPT-4o-mini with "NONE'" replacing the correct answer. These results indicate that GPT-4o-mini demonstrates greater performance stability compared to GPT-4o.

$$\text{ChangeInAccuracy} = \text{SecondRunAccuracy} - \text{FirstRunAccuracy} \quad (5)$$

F. Reasoning

An electronic questionnaire was completed by 22 medical doctors. The questionnaire consisted of six sections, each representing a different medical field. Each section contained randomly selected case-based questions that both models answered correctly. Along with each question were two justifications, one from GPT-4o and the other from GPT-4o mini, along with the model's selected answer and its justification.

Participants were asked to evaluate the output of each model by selecting one of four possible options for each question which are:

- Agree with both GPT-4o and GPT-4o mini justifications.
- Agree with GPT-4o justification but disagree with GPT-4o mini justification.
- Disagree with both GPT-4o and GPT-4o mini justifications.
- Disagree with GPT-4o justification but agree with GPT-4o mini justification.

The results of this questionnaire revealed that the first choice had the highest percentage (68.8%) among all options. The third-choice percentage was the lowest (3.3%). The fourth option received 15.5%, while the second option received 12.4% of participants' selections. These results indicate that the justifications provided by both GPT-4o and GPT-4o-mini were considered reasonable for most of the questions.

Fig. 9 summarizes the average compliance, accuracy, and uncertainty for each experiment across all datasets. While GPT-4o-mini slightly outperformed GPT-4o in answering multiple-choice medical questions, both models frequently hallucinated and were unreliable for medical decision-making. Hallucination rates increased further when the correct answer was replaced with "NONE" as an option. Despite low overall accuracy, the models reported very low uncertainty when the correct answer was explicitly provided among the choices. However, substituting the correct answer with "NONE" reduced accuracy while increasing reported uncertainty. In terms of correlation, no relationship was found between dataset size and model accuracy, suggesting that repeated exposure to a topic does not improve performance. Additionally, retesting revealed that GPT-4o-mini's results remained stable across experiments, whereas GPT-4o's performance varied in the experiment with the correct answers explicitly included.

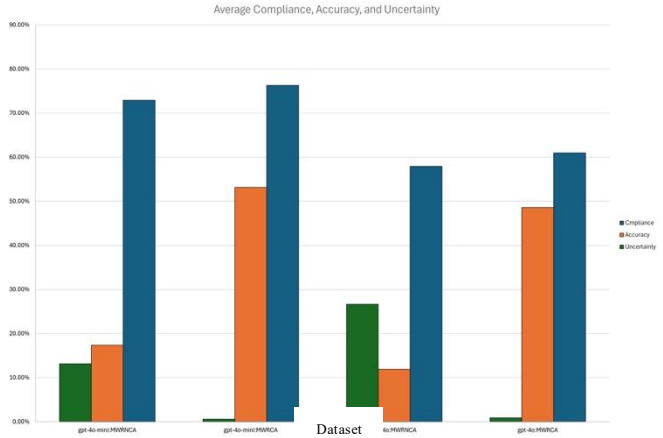

Fig. 9. The overall average of compliance, accuracy, and uncertainty.

VI. Discussion

The results of this study highlight significant findings regarding the occurrence of hallucinations in two large language models, GPT-4o and GPT-4o-mini, in the context of healthcare-related medical questions. Both models demonstrated notable challenges in their ability to reliably generate correct answers, with accuracy rates falling below 70% in most datasets. Although GPT-4o-mini performed better than GPT-4o in terms of compliance and accuracy, it still exhibited considerable hallucinatory behavior and weak adherence to a given task instruction. On the other hand, the accuracy of the two models dropped when the correct answer was replaced with a "NONE" option. This drop indicates that both models could not recognize the absence of the correct answer and generate unreliable answers without real understanding which highlights the limitations of these LLMs when response correctness is a key factor. Moreover, the high level of compliance combined with the drop in accuracy suggests that these LLMs cannot be relied upon, especially if used in high-stakes contexts such as healthcare. Furthermore, the study's experiments demonstrated a lack of correlation between the size of the question set sent to the model and its performance, showing no relation between

changing the size of the data and the model's accuracy which indicated that model hallucination is not sensitive to a given task size. Finally, re-running the experiments on smaller and specific datasets showed that GPT-4o-mini has minimal accuracy differences between runs compared to GPT-4o. This indicates that GPT-4o-mini may be a more stable model in real-world applications, although it remains at risk of hallucinations.

Comparing the results of this study with previous studies conducted on LLMs hallucination in the medical field, the presented results are consistent with the previous studies [24, 25, 26, 27] that asserted that the LLMs, including different GPT-versions exhibit hallucination and show low accuracy. In the context of evaluating model hallucination in different languages, two studies [24,25] conducted in non-English languages showed similar results to the studies conducted in English [26,27] and to this study, indicating that LLMs exhibit hallucination despite the language used. However, this research is distinguished from the previous studies in the variety of evaluation criteria and the medical topics. In this study, multiple tests were designed to measure specific aspects of the models, providing deeper insight into their performance. In addition to recall and reasoning, the study assessed models' stability and their correlation with the size of the question set. Also, the study explores the models' behavior in the absence of correct answers. Whereas previous studies tested the medical dataset ranged from one to four topics, this study's experiments were conducted on 21 medical topics to provide a deeper insight into hallucination and to avoid the limitation of a broad analysis.

In conclusion, this study concluded that GPT-4o and GPT-4o-mini exhibit hallucination in the medical field, highlighting the need for further study to test different LLMs and apply on different datasets. Finally, this research recommends improving the LLMs and using them cautiously, considering the hallucination in their responses.

VII. Conclusion and Future Work

The main findings of this study present the results of the compliance, accuracy, and uncertainty of each experiment across all datasets. Although GPT-4o-mini slightly outperformed GPT-4o in correctly answering multiple-choice questions, both models strongly hallucinated and cannot be relied upon for medical questions. Furthermore, the models hallucinated even more when the correct answer was replaced with "NONE" as an option. Despite the low accuracy, the models reported extremely low uncertainty rates for questions where the correct answer was explicitly listed among the options. Replacement of the correct answer with "NONE" in the options reduced the accuracy of the models but increased their uncertainty. Moreover, regarding correlation, there was no relationship between the dataset size and the models' accuracy, indicating that the models do not improve as they are questioned more on a particular topic. Additionally, retesting each model on the same questions from a sample of the datasets showed the stability of the GPT-4o-mini model compared to GPT-4o's results. Future work will focus on refining model training to reduce hallucinations and exploring methods to enhance reasoning abilities in specialized domains like healthcare.

***Abstract*—This study proposes a game-theoretic framework for achieving robust stability in DC motor systems operating under parametric uncertainty and external disturbances. We model the controller, disturbance, and uncertainty as strategic players in a non-cooperative differential game and synthesize equilibrium policies using a Lyapunov–game approach. Practically, the method integrates: 1) LMI-based stabilization to certify descent conditions, 2) actor–critic reinforcement learning to approximate the Hamilton–Jacobi–Isaacs (HJI) value function beyond linear regimes, and 3) evolutionary/swarm optimization for controller initialization and distributed observer tuning. We validate the framework on a separately excited DC motor subject to ±20% parameter variations and a bounded load-torque disturbance and compare it against PID and H_∞ baselines. Simulations show consistently faster rise/settling, lower overshoot, stronger disturbance rejection at a step disturbance, and smoother control effort, while attaining the highest qualitative robustness margin among the tested controllers. Beyond single-motor stabilization, we outline extensions to multi-agent coordination, security-aware control, and fractional/fuzzy models, demonstrating adaptability and scalability of the approach. These results indicate that framing stability as the outcome of strategic interactions yields reliable and efficient DC-motor control in uncertain, adversarial environments.**

Keywords*—Game theory; DC motor control; robust stability; differential games; Lyapunov stability; reinforcement learning; evolutionary algorithms

I. Introduction

DC motors remain one of the most widely used actuators in industrial and robotic applications due to their simplicity, reliability, and precise speed control capabilities [1, 2]. They are frequently employed in electric vehicles, manufacturing systems, and automated processes, where robust and efficient control strategies are required [3,4]. Traditional control methods, such as proportional–integral–derivative (PID) schemes and adaptive control, have been extensively applied to regulate DC motor dynamics, but their effectiveness diminishes when exposed to uncertainties, parameter variations, or external disturbances [5–7].

To address these limitations, researchers have relied on observer design and Lyapunov-based stability analysis to guarantee robust performance under uncertain conditions [8, 9]. State observers allow reconstruction of unmeasured variables, while Lyapunov functions provide rigorous guarantees of stability for nonlinear systems [10]. These techniques have been further extended to fractional-order and fuzzy models, enabling a more realistic representation of electrical and mechanical phenomena [11–13]. However, despite these advancements, achieving exponential robustness in highly uncertain environments remains a pressing challenge [14].

In recent years, game theory has emerged as a principled framework for modeling decision-making under competition and cooperation [15], with successful applications in wireless networks, cybersecurity, and distributed control [16, 17, 32–34].

In control-theoretic settings, disturbances, uncertainties, and controllers can be modeled as strategic "players" with competing or allied objectives [18, 19, 32]. This perspective naturally extends robust control by framing stability and performance as outcomes of strategic interactions characterized by equilibrium concepts.

Several studies have demonstrated the value of differential games and non-cooperative strategies in dynamic systems, where the Nash equilibrium provides a meaningful solution concept [20,21,32,33]. In motor-driven applications, disturbances may be cast as adversarial players seeking to degrade performance, while controllers implement optimal counter strategies [22]. Cooperative games have likewise supported distributed coordination of multi-agent systems to ensure consensus and synchronization among interconnected drives [23,24].

To enhance practicality, modern approaches integrate reinforcement learning (RL), evolutionary algorithms, and swarm intelligence into game-theoretic controllers, enabling strategy optimization and adaptation to changing dynamics [25–28]. Recent advances connecting Hamilton–Jacobi (HJ/HJI) analysis with learning further support safe/robust control by leveraging reachability-based value functions during training and execution [34,35]. For DC motors, this hybridization promises flexibility against nonlinearities and parametric uncertainty while retaining verifiable stability guarantees.

Despite these promising directions, DC-motor control through explicit game-theoretic synthesis for robust exponential stability remains underexplored relative to classical robust and optimization-based designs [29–31]. This motivates a focused framework that: 1) models the controller, disturbance, and uncertainty as strategic players in a non-cooperative differential game; 2) couples Lyapunov certificates with HJI-guided value function approximation to certify descent conditions; and 3) employs RL and evolutionary/swarm routines for data-driven policy refinement—yielding stability with quantified performance under uncertainty.

Contributions of this work: 1) formulates a DC-motor control problem as a tri-player game and derives conditions for exponential stability via Lyapunov–game synthesis [15,32]; 2) integrates LMI-based stabilization with actor–critic HJI approximation to bridge certified analysis and learning [25–28,34,35]; and 3) demonstrates validated performance and robustness margins against PID and H_∞ baselines under parameter variations and bounded disturbances [5–7,29–31].

The study outline is as follows: Section II introduces the mathematical model of the DC motor system. Section III develops the game-theoretic framework for robust stability, including non-cooperative and differential-game formulations. Section IV presents supporting algorithms and hybrid approaches for strategy optimization. Section V reports simulation results that validate the proposed methods. Section VI concludes and outlines future research directions.

II. Mathematical Model of the DC Motor System

The mathematical modeling of DC motors is fundamental to the design and analysis of robust control strategies. A separately excited DC motor is considered in this study, which is commonly adopted due to its controllability, high torque characteristics, and wide range of industrial applications [1–3]. Motor dynamics can be described by nonlinear differential equations capturing the interactions between electrical and mechanical subsystems.

A. Electrical Subsystem

The armature and field circuits of a separately excited DC motor are driven by independent voltage sources. Their dynamics can be expressed as follows [Eq. (1) and Eq. (2)]:

$$\frac{di_a}{dt} = \left(\frac{1}{L_a}\right) * \left(v_a - R_a * i_a - K_m * i_f * \omega\right) \quad (1)$$

$$\frac{di_f}{dt} = \left(\frac{1}{L_f}\right) * \left(v_f - R_f * i_f\right) \quad (2)$$

where,

- i_a and i_f are the armature and field currents, respectively.
- v_a and v_f denote the applied armature and field voltages.
- R_a, R_f represent the resistances, and L_a, L_f the inductances of the armature and field circuits.
- K_m is the motor torque constant.
- ω is the angular velocity of the motor shaft.

These equations capture the coupling between the electrical states and the mechanical dynamics through the back electromotive force (EMF) term $K_m * i_f * \omega$.

B. Mechanical Subsystem

The mechanical motion of the rotor is modeled by Newton's second law [Eq. (3)]:

$$\frac{d\omega}{dt} = \left(\frac{1}{J_m}\right) * \left(K_m * i_a * i_f - B_m * \omega - T_l\right) \quad (3)$$

- where,
- ω is the angular velocity of the motor shaft.
- J_m denotes the moment of inertia.
- B_m is the viscous friction coefficient.
- T_l represents the external load torque.
- $K_m * i_a * i_f$ is the electromagnetic torque.

The torque produced by the motor is proportional to the product $i_a i_f$, emphasizing the nonlinear coupling between electrical and mechanical states.

C. Compact State-Space Representation

Defining the state vector as Eq. (4):

$$\xi_1 = i_a, \quad \xi_2 = i_f, \quad and\, \xi_3 = \omega, \quad (4)$$

the system can be written in compact state-space form [Eq. (5)]:

$$\begin{cases} \frac{d\xi_1}{dt} = \kappa_1 * \xi_1 + \kappa_2 * \xi_2 * \xi_3 + \left(\frac{1}{L_a}\right) * v_a \\ \frac{d\xi_2}{dt} = \kappa 3 * \xi_2 + \left(\frac{1}{L_f}\right) * v_f \\ \frac{d\xi_3}{dt} = \kappa_4 * \xi_1 * \xi_2 + \kappa_5 * \xi_3 - \left(\frac{1}{J_m}\right) * T_l \end{cases} \quad (5)$$

where, the constants are defined as:

$$\kappa_1 = -\frac{R_a}{L_a}, \kappa_2 = -\frac{K_m}{L_a}, \kappa_3 = -\frac{R_f}{L_f}, \kappa_4 = \frac{K_m}{J_m}, \kappa_5 = -\frac{B_m}{J_m}.$$

It is important to note that $\kappa_i < 0$ for $i = 1,3,5$, which introduces natural damping into the system, while κ_2 and κ_4 determine the nonlinear coupling between states.

D. Sources of Uncertainty

In practice, the motor is subject to multiple uncertainties that degrade performance and stability:

1) Parametric Variations – resistance, inductance, and damping coefficients may vary due to temperature or aging.

2) External Disturbances – load torque T_l fluctuates with mechanical demands.

3) Modeling Errors – nonlinearities and unmodeled dynamics cause discrepancies between theory and reality.

4) Measurement Noise – state observers are required when certain states cannot be measured directly.

Traditional Lyapunov-based methods [22] address these issues through conservative stability margins. However, to

improve adaptability and robustness, a new paradigm is required.

E. Motivation for Game-Theoretic Formulation

From a game-theoretic perspective, the controller, disturbances, and uncertainties can be viewed as players in a dynamic game:

- The controller-player aims to minimize deviations from desired performance.
- The disturbance player injects unpredictable load torques or voltage disturbances.
- The uncertainty player alters the system parameters, such as resistance or damping.

This strategic interaction naturally leads to formulations involving non-cooperative differential games, where the solution concept is a Nash equilibrium guaranteeing that no player can unilaterally improve their outcome.

Such a perspective enables the design of robust controllers that adapt to worst-case disturbances while maintaining global exponential stability. By embedding the motor model into a game-theoretic framework, we extend classical stability methods toward a more adaptive, resilient paradigm.

III. Game-Theoretic Framework for Robust Stability

The incorporation of game theory into the control of DC motor systems provides a novel lens for analyzing and enhancing stability under uncertainty. By treating disturbances, parameter variations, and the controller as strategic players, the system's dynamics can be reformulated as a game in which each participant seeks to optimize its own objective. The resulting equilibrium conditions establish guarantees for robust stability even when the system operates in uncertain or adversarial environments.

A. Players and their Objectives

We define three primary players in the DC motor control problem:

1) Controller Player

- Objective: minimize the deviation of the motor states $(\xi_1,\ \xi_2,\ \xi_3)$ from desired trajectories.
- Strategy: adjust the control input v_a based on observed or estimated states.

2) Disturbance Player

- Objective: destabilize the system by maximizing the error or amplifying oscillations.
- Strategy: inject external torque variations T_l or voltage disturbances.

3) Uncertainty Player

- Objective: alter the effective dynamics by shifting parameters (R_a, R_b, B_m, J_m).
- Strategy: introduce parametric deviations, either slowly varying or abrupt.

The game setting emerges as a non-cooperative interaction in which each player's decision directly affects the global dynamics.

B. Cost Functions and Payoffs

Each player is associated with a payoff or cost function. For the controller, the cost reflects tracking error and control effect [Eq. (6)]:

$$J_c = \int_0^\infty \left(\alpha_1 {\xi_1}^2 + \alpha_2 {\xi_2}^2 + \alpha_3 {\xi_3}^2 + \beta\, v_a^2 \right) dt, \quad (6)$$

where, α_i and β are positive weighting parameters.

For the disturbance and uncertainty players, the objectives are adversarial [Eq. (7)]:

$$J_d = -\int_0^\infty \left(\gamma_1 {\xi_3}^2 + \gamma_2 \, (\Delta T_l)^2 \right) dt, \quad (7)$$

For the uncertainty player [Eq. (8)]:

$$J_u = -\int_0^\infty \left(\delta_1 \left(\Delta R_a^2 + \Delta R_f^2 \right) + \delta_2 \, (\Delta B_m^2) \right) dt \quad (8)$$

where, negative signs indicate that maximizing system deviation corresponds to minimizing their respective payoffs. Nominal values are reported in Table I.

C. Nash Equilibrium Formulation

The equilibrium concept central to this framework is the Nash equilibrium. A control input ${v_a}^*$, disturbance strategy ${T_l}^*$, and uncertainty pattern Δp^* form a Nash equilibrium if no player can unilaterally change its strategy to improve its payoff:

A Nash equilibrium is defined when none of the players can unilaterally improve their payoff [see Eq. (9) to Eq. (11)]:

$$J_c({v_a}^*, {T_l}^*, \Delta p^*) \le J_c(v_a, {T_l}^*, \Delta p^*), \ \forall\, v_a, \quad (9)$$

$$J_d({v_a}^*, {T_l}^*, \Delta p^*) \le J_d({v_a}^*, T_l, \Delta p^*), \ \forall\, T_l, \quad (10)$$

$$J_u({v_a}^*, {T_l}^*, \Delta p^*) \le J_u({v_a}^*, {T_l}^*, \Delta p), \ \forall\, \Delta p, \quad (11)$$

At this equilibrium, the motor system reaches a stable configuration where adversarial actions have been neutralized by optimal control responses.

D. Differential Game Formulation

Since the dynamics of the DC motor are continuous in time, the interaction is best modeled as a differential game. The general system can be expressed as Eq. (12):

$$\frac{d\xi}{dt} = f\left(\xi(t), v_a(t), T_l(t), \Delta p(t)\right), \quad (12)$$

with the state vector [Eq. (13)]

$$\xi = (\xi_1,\ \xi_2,\ \xi_3)^T \quad (13)$$

The Hamilton–Jacobi–Isaacs (HJI) condition for equilibrium strategies is Eq. (14):

$$0 = \min_{v_a} \max_{T_l, \Delta p} \{ L(\xi, v_a, T_l, \Delta p) + \nabla V(\xi) \cdot f(\xi, v_a, T_l, \Delta p) \} \quad (14)$$

where, $L(\cdot)$ is the running cost and $V(\xi)$ is the value function. Solving this HJI equation yields control strategies that guarantee robust stability against worst-case disturbances.

E. Robust Stability via Lyapunov–Game Synthesis

We couple Lyapunov analysis with a game-theoretic formulation to certify global exponential stability under adversarial disturbances and parameter uncertainty. Let [Eq. (15)]

$$V(\xi) = \xi^{\mathrm{T}} P \xi, \qquad P > 0 \quad (15)$$

be a quadratic Lyapunov candidate and let $f(\xi, v_a, T_\ell, \Delta p)$ denote the closed-loop state dynamics.

Exponential stability is ensured if there exists $\lambda > 0$ such that, along trajectories [Eq. (16)],

$$\frac{dV}{dt} \leq -\lambda \left|\left|\xi\right|\right|^2, \ \forall \xi, \quad (16)$$

under the equilibrium control strategy $v_a{}^*$.

In the presence of strategic adversaries—load torque T_ℓ and parametric perturbations Δp—the condition above is enforced in a min–max sense [Eq. (17)]:

$$\frac{dV}{dt} \leq \min_{v_a} \max_{T_l, \Delta p} \{ \nabla V(\xi) \cdot f(\xi, v_a, T_l, \Delta p) \} \leq -\lambda \left|\left|\xi\right|\right|^2 \quad (17)$$

Lemma (Exponential stability under Lyapunov–game inequality).
If there exist $P \succ 0$ and $\lambda > 0$ such that Eq. (16) holds for all ξ, then the origin of the closed-loop system is globally exponentially stable against all admissible disturbance/uncertainty strategies; specifically [Eq. (18)],

$$V(t) \leq e^{-ct} V(0) \text{ with } c = \frac{\lambda}{\lambda_{\max}(P)}, \quad (18)$$

and hence [Eq. (19)],

$$\| \xi(t) \| \leq \sqrt{\frac{\lambda_{\max}(P)}{\lambda_{\min}(P)}}\, e^{-\frac{c}{2}t} \, \| \xi(0) \|. \quad (19)$$

Proof sketch. From Eq. (17), we have $\dot{V} \leq -\lambda \| \xi \|^2 \leq -\frac{\lambda}{\lambda_{\max}(P)} V$. Grönwall's inequality gives the stated bound on $V(t)$, and positive definiteness of P yields the bound on $\| \xi(t) \|$.

In practice, Eq. (17) is checked or constructed by: i) selecting P via an LMI-based stabilizer and ii) refining the control policy toward the minimizing strategy v_a^* while treating $(T_\ell, \Delta p)$ as maximizing players. This certifies robustness independently of the specific disturbance/uncertainty realizations.

If such an inequality holds, the closed-loop system is guaranteed to remain globally exponentially stable, regardless of the disturbance or parameter uncertainty strategies.

F. Cooperative versus Non-Cooperative Scenarios

Two major scenarios arise in practice:

1) Non-cooperative case: Disturbances act adversarially, attempting to destabilize the motor. Here, the Nash equilibrium ensures that the controller's strategy is robust against worst-case scenarios.

2) Cooperative case: In multi-agent or distributed motor systems, players (subsystems) may share information. Cooperative equilibria lead to improved efficiency and synchronization.

Both formulations enrich the design space for robust stability analysis.

G. Computational Considerations

While the theoretical framework provides strong guarantees, solving HJI equations or deriving exact Nash equilibria is computationally demanding. Approximation methods such as reinforcement learning, evolutionary optimization, or linear matrix inequality (LMI) relaxations can be employed to compute feasible strategies. These methods balance accuracy with real-time implementability, making the framework suitable for practical applications.

IV. Algorithmic Implementation and Simulation Results

This section presents the algorithmic framework developed for computing equilibrium strategies in the game-theoretic setting and demonstrates its performance through simulation studies on a DC motor system. The proposed methodology integrates Lyapunov–game synthesis with learning-based optimization and is validated against existing control techniques.

A. Algorithmic Framework

The robust stability problem formulated in Section III is solved using a combination of classical and modern methods. First, linear matrix inequalities (LMIs) are employed to generate feasible stabilizing feedback gains that satisfy Lyapunov conditions under bounded uncertainty. Next, reinforcement learning (RL) techniques are used to approximate the Hamilton–Jacobi–Isaacs (HJI) value function, allowing adaptation to nonlinearities and disturbances beyond linearized regimes. Finally, evolutionary algorithms and swarm intelligence serve as complementary optimization tools for initialization and distributed observer design.

The overall workflow is summarized as follows:

1) Initialization: Solve LMIs for candidate state feedback gains and Lyapunov matrix.

2) Learning stage: Train actor–critic networks to minimize the HJI residual under adversarial disturbances.

3) Evolutionary refinement: Improve controller initialization via evolutionary search for robust stability margins.

4) Observer tuning: For multi-agent settings, employ swarm-based optimization to harmonize distributed observers.

The conceptual architecture of the proposed control framework is illustrated in Fig. 1.

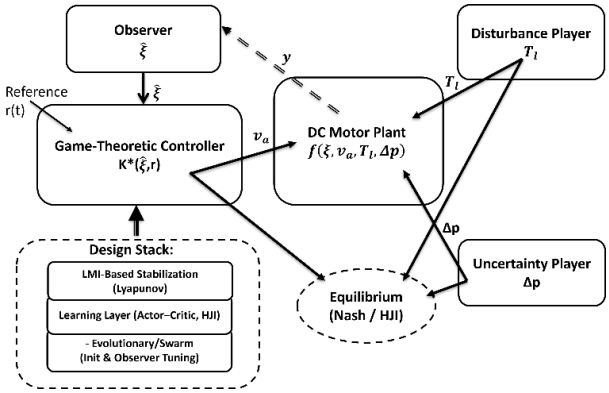

Fig. 1. Conceptual architecture of the proposed game-theoretic robust stability framework.

The system integrates an LMI-based stabilization layer, a learning layer using actor–critic reinforcement learning for HJI approximation, and an evolutionary/swarm layer for initialization and observer tuning. Disturbance and uncertainty players act adversarially against the controller, and equilibrium strategies (Nash/HJI) are computed to guarantee stability. The observer feeds estimated states $\hat{\xi}$ to the controller, which generates the control v_a for the DC motor plant, while the plant output y closes the loop.

B. Simulation Setup

We evaluated the framework on a separately excited DC motor (nominal parameters in Table I), subject to parametric variations and bounded load-torque disturbances.

TABLE I. NOMINAL PARAMETERS OF THE DC MOTOR USED IN SIMULATION SETUP

Parameter	Symbol	Value
Armature resistance	R_a	1.2 Ω
Armature inductance	L_a	0.05 H
Field resistance	R_f	1.0 Ω
Field inductance	L_f	0.05 H
Torque constant	K_m	0.01 $N \cdot m/A$
Rotor inertia	J_m	0.01 $kg \cdot m^2$
Damping coefficient	B_m	0.1 $N \cdot m \cdot s$

Uncertainties of ±20% were applied to electrical and mechanical parameters, and the load torque T_l varied within $[-0.05, 0.05]$ $N \cdot m$ to represent disturbances. Controllers compared include PID, H_∞, and the proposed game-theoretic design.

C. Algorithmic Convergence

Fig. 2 reports the decay of the HJI residual during training. The proposed RL + LMI shaping achieves faster and smoother convergence than RL-only learning, indicating that combining a hard Lyapunov/LMI certificate with adaptive policy optimization stabilizes training and accelerates policy improvement.

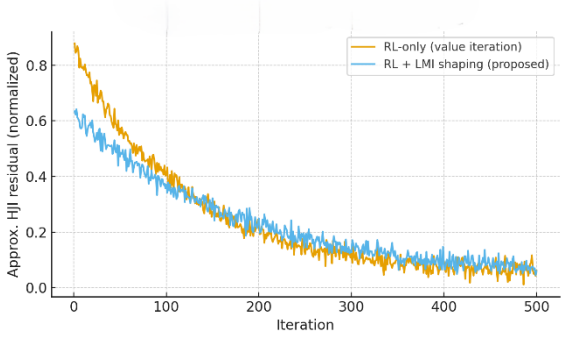

Fig. 2. Algorithmic convergence of residual error.

All controllers were evaluated under identical setpoints, a bounded load-torque disturbance injected at $t = 1\,\mathrm{s}$, and a ±20% parametric sweep around the nominal motor parameters (see Table I). We report standard time-domain metrics—rise time, settling time, percent overshoot, and peak deviation under disturbance—computed over 10 independent runs per condition and summarized in Table II.

D. Time-Domain Responses

Fig. 3(a) to Fig. 3(b) illustrate the motor's speed response under different conditions:

- Nominal operation [Fig. 3(a)]: all controllers achieve satisfactory tracking, but the proposed controller shows lower overshoot.
- Disturbance injection [Fig. 3(b)]: when a torque disturbance is applied at $t = 1s$, the proposed controller rejects it rapidly with minimal deviation, outperforming PID and H_∞.
- Parametric uncertainty [Fig. 3(c)]: the proposed method maintains stability and performance despite $\pm 20\%$ parameter variations, whereas PID performance degrades significantly.

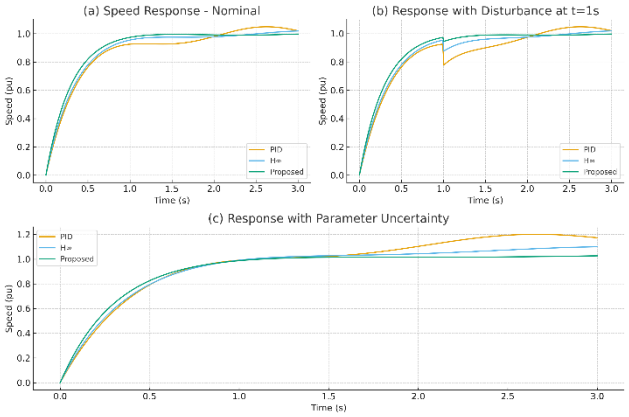

Fig. 3. Simulation results: (a) Speed response under nominal conditions; (b) Response under a disturbance applied at t=1s; (c) Response under ±20% parameter uncertainty.

E. Control Effort Analysis

Fig. 4 compares control inputs $v_a(t)$ under disturbance conditions. The PID controller exhibits aggressive oscillations,

while the proposed method achieves effective rejection with smoother and less demanding actuation. This balance highlights the method's suitability for practical hardware where actuator limitations must be respected.

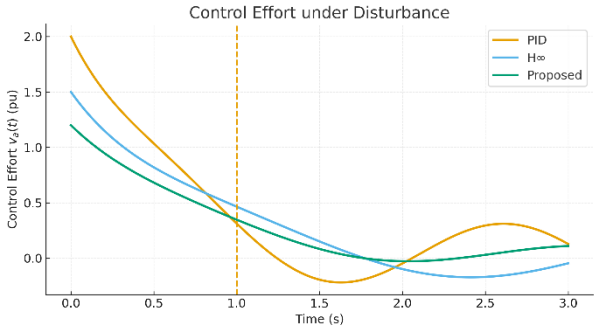

Fig. 4. Control effort under disturbance.

F. Robustness Margins

Quantitative results are summarized in Table II and Fig. 5. The proposed controller consistently achieves faster settling, reduced overshoot, and stronger disturbance rejection compared to PID and H_∞. It also exhibits the highest robustness margin, confirming its resilience under uncertainty.

TABLE II. COMPARATIVE PERFORMANCE METRICS

Metric	PID	H_∞	Proposed (Game-Theoretic)
Rise time (s)	0.45	0.40	0.42
Settling time (s)	1.20	0.95	0.70
Overshoot (%)	12.5	8.2	5.4
Disturbance rejection (peak deviation, rad/s)	0.18	0.11	0.05
Robust stability margin	Low	Medium	High

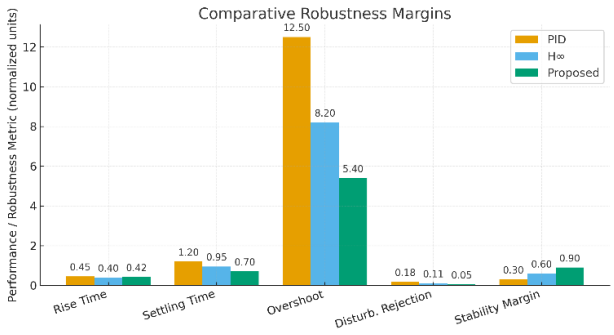

Fig. 5. Comparative robustness margins.

G. Discussion

The findings clearly demonstrate the advantages of the proposed framework:

- Robustness: Explicit modeling of disturbances and uncertainties as adversarial players leads to superior rejection performance.
- Efficiency: Smoother control effort reduces actuator stress and energy consumption.
- Adaptability: The hybrid integration of LMIs, learning, and evolutionary methods achieves both theoretical guarantees and practical performance.

In comparison, PID fails under large uncertainties and H_∞ provides robustness at the cost of conservatism. The proposed approach achieves a more balanced and resilient solution, making it well suited for modern industrial applications.

V. EXTENDED APPLICATIONS

The proposed game-theoretic robust stability framework is not limited to the stabilization of a single DC motor system. Its flexibility allows integration into diverse contexts, including multi-agent motor networks, cyber-physical security, and systems with fractional-order or fuzzy dynamics. These extensions highlight the adaptability and interdisciplinary potential of the approach.

A. Multi-Agent and Distributed Motor Systems

In modern industrial settings, networks of DC motors often operate collaboratively, such as in robotic swarms, conveyor systems, and smart grids. Each motor can be modeled as an agent interacting with others. In this case:

- Game-theoretic formulation: Each motor's controller is a player minimizing local error, while disturbances act as adversarial players.
- Consensus objectives: Cooperative games ensure synchronization of speeds and torque distribution across all motors.
- Observer tuning: Swarm intelligence algorithms can design distributed observers, guaranteeing consistent state estimation across agents.

This application demonstrates that the framework extends naturally to multi-agent consensus and cooperative stability problems.

B. Cyber-Physical Security and Attack-Resilient Control

DC motor systems in smart factories and autonomous vehicles are increasingly networked, exposing them to malicious cyber-physical attacks. Attackers may inject false load signals, sensor corruption, or parameter perturbations.

- Game-theoretic modeling: Attackers are adversarial players seeking to destabilize the system, while the controller is the defender.
- Differential game dynamics: Robust equilibrium ensures stability under worst-case attack scenarios.
- Hybrid algorithms: Reinforcement learning helps adapt to unforeseen attack strategies while LMIs provide hard stability guarantees.

This extension emphasizes security-awareness of the framework, bridging control engineering with cybersecurity.

C. Fractional-Order Systems

Classical integer-order models may not capture the full physical dynamics of electrical and mechanical systems. Fractional calculus provides a more accurate representation of

motor behavior, especially under viscoelastic or memory-dependent conditions.

- Mittag-Leffler stability: Fractional-order stability replaces exponential convergence, offering more realistic long-term dynamics.
- Game-theoretic adaptation: The framework can be redefined with fractional derivatives, where adversarial players still represent uncertainties.
- Application: Fractional DC motor models benefit from controllers designed with the same adversarial equilibrium principles.

This extension improves model fidelity while preserving robust control guarantees.

D. Fuzzy and Nonlinear Extensions

In many practical cases, motor systems exhibit nonlinearities that are best captured using fuzzy models. Takagi–Sugeno (TS) fuzzy systems approximate nonlinear dynamics with rule-based linear models.

- Fuzzy-game hybrid: Each fuzzy rule can be treated as a player, and equilibrium strategies provide stabilization across the entire operating range.
- Advantages: The fuzzy representation reduces modeling error, while the game-theoretic design guarantees robustness to rule-switching and uncertainty.

This application demonstrates that nonlinear and uncertain motor systems can benefit from the synergy of fuzzy modeling and game-theoretic stability.

E. Key Insights from Extended Applications

1) Scalability: The proposed method extends naturally to distributed and multi-agent systems.

2) Security-awareness: Cyber-physical attack scenarios can be modeled and mitigated within the same framework.

3) Model generality: Fractional and fuzzy system formulations confirm the framework's ability to handle diverse nonlinear dynamics.

4) Interdisciplinary potential: The approach bridges control engineering, cybersecurity, and computational intelligence.

VI. Conclusion

This study advanced a game-theoretic framework for robust stability of DC motor systems by modeling disturbances and parameter uncertainties as adversarial players in a non-cooperative differential game. We coupled Lyapunov–game synthesis (via LMIs) with actor–critic reinforcement learning for Hamilton–Jacobi–Isaacs (HJI) approximation and used evolutionary/swarm routines for controller initialization and observer tuning. Across nominal, disturbed, and ±20% parametric-variation scenarios, the proposed controller consistently outperformed PID and H_∞ baselines—achieving faster settling, lower overshoot, stronger disturbance rejection at $t = 1$ s, and smoother control effort (see Table II and Fig. 2 to Fig. 5). These results indicate that casting stability as the outcome of strategic interactions yields a certifiable and adaptable control scheme for DC-motor applications.

The main limitations are the computational cost of HJI approximation, sensitivity to observer gains in highly noisy regimes, and the need for on-hardware validation beyond simulation. Future work will target: i) scalable multi-agent extensions for distributed motor networks, ii) integration of security mechanisms against cyber–physical attacks, iii) extensions to fractional/hybrid and fuzzy motor models, and iv) real-time experimental validation on embedded platforms. Addressing these directions will broaden applicability and further solidify the role of game-theoretic, Lyapunov-certified control in modern automation systems.

***Abstract*—The blockchain functions as a distributed database, where data is securely stored across multiple servers and network nodes. It exists in various forms, with Bitcoin, Ethereum, and Hyperledger being among the most prominent examples. To ensure the integrity and security of transactions within a blockchain network, a consensus algorithm is employed to establish agreement among participating nodes. Several types of consensus algorithms exist, each offering distinct features and operational mechanisms. One such algorithm is Authority Round (here defined as AuRa_ori), a member of the Proof-of-Authority (PoA) family supported by Parity clients. Previous studies have highlighted several vulnerabilities and performance limitations in AuRa_ori, particularly concerning transaction speed per second (TPS) and transaction throughput per second (TGS). This study specifically investigates the original AuRa algorithm alongside an improved version, termed AuRa_v1. In AuRa_v1, the transaction process is structured into four key phases: 1) leader assignment, 2) block proposal, 3) agreement, and 4) block commitment. However, inconsistencies and inefficiencies have been identified within certain phases of the original AuRa_ori, particularly during the leader assignment and agreement stages. In response, this study proposes an improved approach through AuRa_v1 to address these vulnerabilities. A detailed analysis is conducted to evaluate the impact of these vulnerabilities on TPS, TGS, and epoch time, followed by a performance comparison between AuRa_ori and AuRa_v1. Experimental results demonstrate that AuRa_v1 effectively resolves the identified performance issues, achieving a significant improvement. Specifically, AuRa_v1 records a 21.65% increase in both TPS and TGS compared to AuRa_ori, validating the effectiveness of the proposed enhancements.**

***Keywords*—Blockchain; Ethereum; AuRa_ori; AuRa_v1; TPS; TGS**

I. Introduction

The integration of blockchain technologies with artificial intelligence (AI) has emerged as a transformative paradigm in building decentralized, secure, and intelligent systems. In such architectures, consensus algorithms are fundamental to ensuring data integrity, traceability, and synchronization across distributed nodes. AuRa_v1, an improved authority-based consensus protocol, offers enhanced transaction speed and network throughput, making it a suitable infrastructure layer for AI applications that demand real-time data coordination and high system reliability.

As AI systems increasingly rely on decentralized frameworks—such as federated learning, distributed inference, and autonomous multi-agent environments—the role of efficient and lightweight consensus mechanisms becomes critical. By facilitating low-latency, tamper-resistant data validation, AuRa_v1 enables seamless collaboration and trust in AI workflows without centralized control. This intersection between consensus algorithms and AI models presents promising opportunities for developing scalable, secure, and responsive intelligent systems, particularly in domains such as IoT-driven AI, decentralized data marketplaces, and collaborative machine learning.

A consensus algorithm is a fundamental mechanism that establishes agreement among distributed nodes across multiple servers and networks. It plays a crucial role in ensuring blockchain functionality [1] by maintaining consistency, decentralization [2-3], and integrity across all participating nodes. Beyond ensuring reliability, consensus mechanisms strengthen transaction security by coordinating node agreement, thereby preserving uniform and valid throughput. Moreover, an efficient consensus algorithm optimizes transaction execution time, minimizes latency, and maximizes throughput [4], directly influencing the scalability and processing performance of blockchain networks.

Among the existing approaches, Proof of Authority (PoA) has emerged as a leading solution [5] for permissioned blockchain environments. Initially introduced by [6] as a hybrid of Proof of Work (PoW) and Proof of Stake (PoS), PoA was specifically designed to address PoS vulnerabilities [7] and mitigate the performance and security limitations of both PoW and PoS. Tailored for consortium and private blockchain networks [8,9], PoA is implemented primarily through two variants: Authority Round (AuRa_ori) and Clique. AuRa_ori relies on trusted authorities and synchronized nodes to maintain high consensus reliability.

However, prior studies have underscored significant performance limitations of AuRa_ori, particularly stemming

*Corresponding author.

from its leader assignment and voting processes. The algorithm's design requires a new leader to be selected for each transaction, increasing both transaction per second (TPS) and transaction generation speed (TGS) [10], but simultaneously introducing delays during leader reassignment—especially when nodes are unresponsive. The voting phase before block commitment further compounds latency and restricts throughput. These operational inefficiencies remain unresolved, thereby hindering PoA's ability to support high-throughput blockchain environments. However, AuRA_ori is highly necessary as it is suitable and effective for use within a private server environment. Therefore, the research gap related to the operational efficiency of AuRA_ori needs to be addressed.

Therefore, this research specifically targets the performance bottlenecks in AuRa_ori by proposing design modifications that enhance TPS and TGS, without compromising the consensus integrity. By analyzing the interplay between leader selection, voting mechanisms, and transaction throughput, we aim to provide a more efficient PoA variant, AuRa_v1 that addresses these bottlenecks.

The remainder of this study is structured as follows: Section II reviews the blockchain environment and consensus algorithms. Section III details the methodology, including Ethereum, AuRa_ori, and AuRa_v1 implementations. Section IV discusses the execution of both AuRa_ori and AuRa_v1. Section V presents the performance analysis of TPS and TGS across both algorithms. Finally, Section VI concludes with a discussion on how AuRa_v1 improves performance and scalability over AuRa_ori.

II. Literature Review

Blockchain is an innovative method for data storage that adopts a decentralized and distributed database architecture. This model [11] represents a paradigm shift from traditional centralized data management systems, which rely on a single, authoritative source, to a distributed network of interconnected nodes. In a blockchain, data are organized into sequentially linked units known as blocks [12]. These blocks are distributed across multiple nodes located on different servers.

Blockchain technology operates on a peer-to-peer (P2P) network model [13], whereby nodes interact directly with one another through P2P communication protocols. The integrity and security of the stored digital data [14] are ensured through the application of cryptographic techniques and hash functions.

Public blockchains have become increasingly accessible via various platforms [15], thus facilitating widespread adoption and implementation by researchers and developers. Among the most prominent platforms are Bitcoin, Ethereum, and Hyperledger [16], all of which have been established to promote the integration of blockchain technology [17] into organizational operations.

Although these platforms share foundational characteristics, each possesses distinct features that cater to different application requirements. Bitcoin and Ethereum, for instance, are classified as public or permissionless blockchains [18], allowing unrestricted participation in the network, whereby any user can initiate or validate transactions without prior authorization.

Ethereum, introduced by Vitalik Buterin in 2013 [19], was developed to address the limitations observed [20] in the Bitcoin protocol. The platform's development was successfully funded through a public crowdfunding initiative [21] in 2014, leading to its official deployment in 2015. Ethereum supports distributed data storage and enables users to create and execute decentralized applications (DApps) [22] and custom blockchains.

Its architecture accommodates flexible data storage [23] by supporting blocks of varying sizes. Ethereum also integrates various consensus mechanisms to secure transactions, enhance performance, and ensure data validity across the network. These mechanisms are facilitated through Ethereum clients that maintain and operate the blockchain engine.

They also compared the performance of the Geth and Parity Ethereum clients, both supporting PoA-based consensus mechanisms. Their experiments, conducted in private testnet environments, found that the Parity client, featuring AuRa_ori, has achieved a 91% higher transaction speed than Geth, which implements the Clique consensus algorithm. Factors such as CPU, memory, and node count were accounted for in these evaluations

A. Consensus Algorithm

The consensus algorithm is a foundational element of blockchain technology, as it governs the agreement process among nodes and ensures the validity, security, and consistency of transactions and blocks across the distributed ledger. To maintain the integrity of the blockchain, a consensus algorithm must be robust in terms of security, performance, and fault tolerance. Fundamentally, it is a mechanism that enables distributed nodes to reach agreement on the current state of the blockchain without relying on a central authority [1].

Consensus algorithms significantly enhance the security of blockchain systems by enabling a coordinated validation process among nodes, which in turn ensures consistent and trustworthy transaction throughput. These algorithms also play a vital role in optimizing performance by reducing transaction execution times and increasing processing efficiency. The design and operational protocol of a consensus algorithm directly influence its scalability and processing speed. Algorithms capable of committing transactions in shorter timeframes [24] are deemed more efficient, as they contribute to higher throughput and faster consensus.

Several consensus algorithms have been developed to support blockchain networks, each with its own operational advantages and limitations. Among the most prevalent are Proof of Work (PoW), Proof of Stake (PoS), Proof of Authority (PoA), and Practical Byzantine Fault Tolerance (PBFT). These algorithms differ in terms of resource consumption [25], fault tolerance, and consensus latency. While each has distinct use cases, PoW, PoS, and PoA are among the most widely adopted in contemporary blockchain applications.

This study specifically focuses on the Proof of Authority (PoA) algorithm, with an emphasis on its AuRa_ori variant.

AuRa_ori is a consensus mechanism under the PoA framework that relies on a limited number of trusted validators to achieve consensus. This model is particularly suitable for private or consortium blockchains where performance, security, and validator accountability are prioritized.

B. AuRa_ori Consensus Algorithm

AuRa_ori, short for Authority Round, is a consensus algorithm developed by Parity Technologies specifically for the Parity Ethereum client, which is implemented using the Rust programming language. This algorithm has been adopted by various platforms such as Laava, VeChain Thor, the xDai Delegated Proof of Stake (DPOS) network, and Microsoft Azure (deployment only), as well as the Kovan Testnet [26]. Due to its ease of integration and effectiveness in specific environments, AuRa_ori has gained traction across diverse blockchain applications. Notably, nearly 4,000 blockchain projects [27] in domains such as education, management, healthcare, and insurance have implemented this consensus mechanism.

AuRa_ori operates under two key assumptions: 1) the honesty of authority nodes, and 2) network synchronization across all participating nodes. The consensus process comprises four sequential steps prior to committing transactions. First, a leader is selected among the authorities using the Round Robin scheduling algorithm. Once the leader is appointed, they initiate the transaction process collaboratively [28] with the remaining authority nodes. This is followed by the proposal phase, wherein the leader proposes a new block. Next, the voting phase ensures that a majority of authorities agree with the proposal, and finally, the commit phase finalizes the transaction, appending the new block to the blockchain.

The popularity of AuRa_ori stems from its contribution to performance enhancement in blockchain systems. Several studies have explored its efficiency, resilience, and vulnerabilities. One area of investigation has been partitioning tolerance, revealing that while AuRa_ori can detect the absence of authority nodes, it cannot differentiate whether these nodes are inactive or operating in an alternate partition—demonstrating a lack of network partitioning awareness. Furthermore, the frequent leader election process [29] exposes the system to malicious leaders and cloning attacks. During the voting phase, transactions require validation by a majority of authority nodes ($n/2 + 1$), and delays in achieving consensus can cause forks and hinder transaction finalization. These delays impact throughput, increase the probability of forked chains, and lower the success rate of transaction completions.

Cloning attacks (CAs) are particularly concerning in delayed verification scenarios, where an attacker can replicate a node's identity using identical public-private key pairs. The author in [30] addressed this issue by proposing a heartbeat-based mechanism, wherein authority nodes periodically broadcast cryptographically signed heartbeat signals. These signals allow other authorities to determine the authenticity and availability of peers before accepting proposed blocks. Additional research by [31] emphasizes that the performance limitations of AuRa_ori—particularly in terms of transactions per second (TPS) and transaction generation speed (TGS)—are directly linked to the repetitive leader assignment and verification steps required for each transaction. These inherent characteristics not only reduce efficiency but also amplify risks associated with adversarial behavior and consensus disruption.

III. Research Methodology

Blockchain is a decentralized data management system in which information is stored across multiple servers or nodes connected via a peer-to-peer (P2P) network. In this study, blockchain technology was implemented to serve as a secure and tamper-resistant data storage solution. In contrast to conventional databases, blockchain exhibits immutability: data entries can be added and read but cannot be modified or deleted once committed to the chain. This property distinguishes blockchain from traditional data systems. Blockchain stores data in a sequential structure of blocks, where each block contains transaction data, a timestamp, and the cryptographic hash of the previous block.

This linked structure ensures continuity and enforces data integrity across the chain. The security of this configuration lies in the use of the previous block's hash, which forms a cryptographic chain that is difficult to alter retroactively. Each block is replicated across all nodes in the network, creating a distributed database that enhances fault tolerance and reduces the likelihood of tampering. All nodes maintain identical copies of the blockchain, ensuring that every block, such as block 1, containing values like data, nonce, hash, and previous hash, is consistently synchronized across all network participants. This redundancy ensures both the consistency and resilience of the blockchain system.

A. Ethereum

Ethereum, regarded as a second-generation blockchain platform, was selected for this research due to its flexibility, public availability, and support for smart contracts. Additionally, Ethereum can be deployed not only on public networks but also on private servers, offering enhanced control and customization for enterprise or research applications.

In this study, Ethereum was installed across multiple private servers located at geographically distinct sites. Each instance functions as a node, contributing to a private Ethereum network. There are two principal clients used to run Ethereum: Geth and Parity. Both are open-source implementations, but Parity was chosen for this research due to its high performance and compatibility with private infrastructure.

Parity, developed by Parity Technologies, is an advanced Ethereum client written in the Rust programming language. As an open-source solution, Parity enables users to run Ethereum protocols efficiently and securely. It is recognized for its high synchronization speed, robust security features, and seamless integration into private environments. For this research, the Parity client was installed on Linux-based servers using specific command-line instructions to configure and launch the blockchain network.

$$run\ -ti\ openethereum/openethereum{:}\ v3.0.0$$

$$or$$

$$run\ -ti\ openethereum/openethereum{:}\ latest$$

The command run -ti is used to execute the installation process, while openethereum refers to the Parity client itself. The version of Parity, specified as openethereum: v3.0.0 or openethereum: latest, can be adjusted based on specific requirements. Once the command is executed, the Ethereum blockchain is generated using the Parity client. Additionally, Parity supports the Proof of Authority (PoA) consensus algorithm, which is utilized in this research.

B. AuRa_ori

AuRa_ori is one of the consensus algorithms available within the PoA framework, supported by both Parity and Ethereum clients. This algorithm operates under the assumption that all authority nodes are synchronized and act honestly during every transaction process. The AuRa_ori consensus algorithm follows several phases before a transaction is verified and committed to the blockchain. These phases include transaction pending, leader assignment, block proposal, voting, and committing. The transaction process of AuRa_ori is illustrated in Fig. 1.

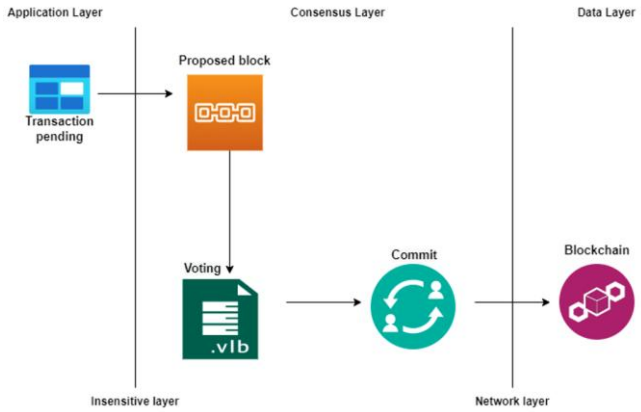

Fig. 1. AuRa_ori transaction process.

C. AuRa_v1

AuRa_v1 is an enhanced version of the AuRa_ori consensus algorithm, designed to improve transaction per second (TPS) and transaction generation speed (TGS). Additionally, the process flow of AuRa_v1 differs from that of AuRa_ori. AuRa_v1 consists of three steps: proposing a block, voting, and committing. Fig. 2 illustrates the differences in process flow between AuRa_ori and AuRa_v1.

In AuRa_v1, leader assignment is not required for every transaction. Instead, the leader remains predefined and static, with a new leader selected only if the current leader becomes unavailable. The process for assigning a new leader follows the same method as AuRa_ori, using the same equations from Eq. (1) and Eq. (2).

$$t_d = t - t_g \quad (1)$$

where, t_d represents the difference between the current timestamp t and the last timestamp recorded at genesis t_g. Once t_g is determined, the next step is to assign a leader among the authorities using Eq. (2):

$$i = \frac{t_d}{D} mod\ n \quad (2)$$

where, i represents the authority assigned as the new leader represents D is the step duration set in the genesis file, and n is the total number of nodes configured in the blockchain environment. Once the leader is assigned based on this equation, the next step involves the proposed block by the leader.

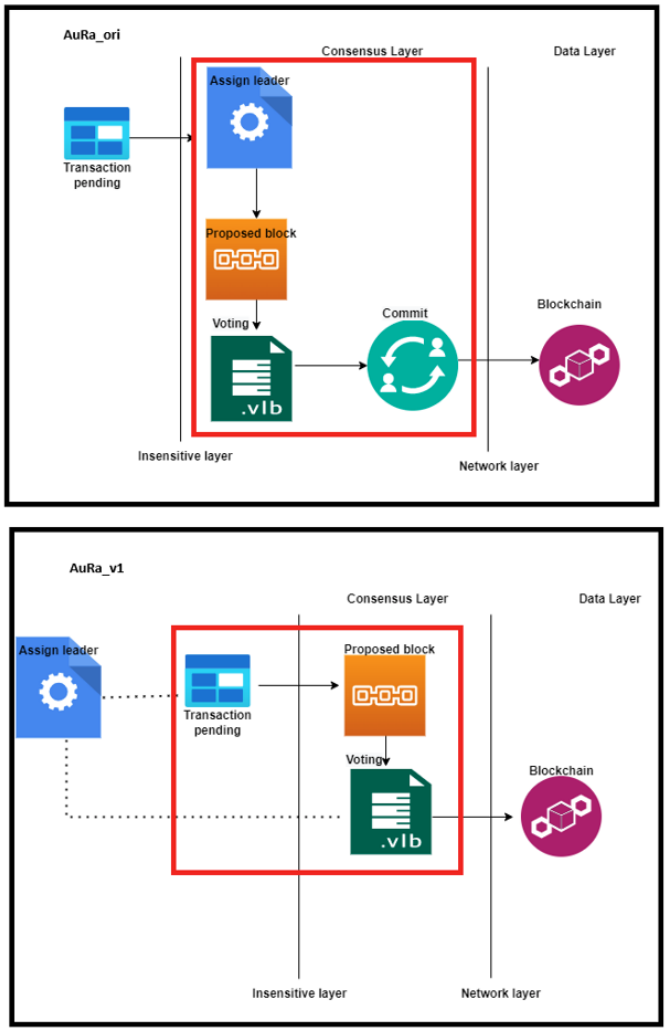

Fig. 2. Comparison of AuRa_ori and AuRa_v1 process flow.

IV. IMPLEMENTATION

This study aims to prove that the proposed AuRa_v1 algorithm is executable and effective in resolving the TPS and TGS performance limitations of the original AuRa_ori consensus mechanism. For performance comparison, both AuRa_v1 and AuRa_ori were implemented on the myCert platforms using graduation certificate data.

The myCert is an in-house application that manages backend processes. It uses Python as its programming language and PyCharm as its Integrated Development Environment (IDE). Two versions of myCert were developed and installed, one embedding AuRa_ori and the other one embedding AuRa_v1.

A. Dataset

These studies utilized three datasets that used scroll data. These datasets were implemented to execute the transaction process within the blockchain, embedded with both AuRa_ori and AuRa_v1. Each dataset varies in the number of records, size, and data type, as shown at Table I.

TABLE I. SET OF DATA

Set of Data	Number of Data	Size of Data (KB)	Type of Data
Set 1	1021	33596.01	Scroll
Set 2	2435	79514.93	Scroll
Set 3	3422	112190.27	Scroll

B. Create and Configure AuRa_ori

The AuRa_ori engine comprises the Ethereum blockchain. Once the AuRa_ori engine was installed, the Ethereum blockchain was automatically installed. Each AuRa_ori engine was installed on a different server and is called a node. This research created the nodes at private servers. Each node will act as an authority on the network and issue blocks in the transaction process. Fig. 3 shows the creation of the AuRa engine. AuRa_ori engine created at port xxxx:xxxx is located in the parity folder. These engines are connected with the *xxxx.toml* file.

Code 1 : AuRa_ori_engine

```
[1] run --rm -ti  -p xxxx:xxxx
[2] -v ~/.local/share/parity/docker/:/home/parity/
[3] ..local/share/parity/ parity/parity:v3.0.0
[4] --config
    /home/parity/.local/share/parity/xxxx.toml
[5] --JSON-RPC-interface all
```

Fig. 3. Creation of the AuRa_ori engine.

Then, after completing the coding to create the AuRa_ori engine, the next step is to create the authority account, as in Fig. 4. The authority account created at port xxxx:xxxx is similar to the port at the AuRa_ori engine. The location and *toml* file are also similar to the AuRa_ori engine.

Code 2: AuRa_ori authority account

```
[1] run --rm -ti  -p xxxx:xxxx -v
[2] -v ~/.local/share/parity/docker/:/home/parity/
[3] .local/share/parity/ openethereum/
[4] --config
    /home/parity/.local/share/parity/xxxx.toml
[5] --JSON-RPC-interface all
```

Fig. 4. Create authority account.

Based on the execution of Fig. 4, the results in Fig. 5 illustrate the authority account successfully created. The authority account created is $0x008ce3c5316c23c8fdee747b0ae59188879xxxxx$.

Result : Create authority account

```
[1]  {"jsonrpc":"2.0","result":"0x008ce3c5316c23c8fdee747b0ae59188879xxxxx","id":0}
```

Fig. 5. Result achieved.

C. Create and Configure AuRa_va Engine

The implementation of AuRa_v1 requires the creation of three nodes, similar to the AuRa_ori configuration. Fig. 6 illustrate the code to create AuRa_v1 engine.

Code 3 : AuRa_v1 engine

```
[1] run --rm -ti  -p xxxx:xxxx -v
[2] -v ~/.local/share/parity/docker/:/home/parity/
[3] . local/share/parity/ parity:v3.0.0
[4] --config
    /home/parity/.local/share/parity/xxxx.toml
[5] --JSON-RPC-interface all
```

Fig. 6. Code to create AuRa_v1 engine.

After the AuRa_v1 engine is completed, next step is to create the AuRa_v1 authority account. Fig. 7 depicted the command to create the AuRa_v1 authority account.

Code 4: AuRa_v1 authority account

```
[1] run --rm -ti  -p xxxx:xxxx -v
[2] -v ~/.local/share/parity/docker/:/home/parity/
[3] . local/share/parity/ parity:v3.0.0
[4] --config
    /home/parity/.local/share/parity/xxxx.toml
[5] --JSON-RPC-interface all
```

Fig. 7. Code to create AuRa_v1 authority account.

V. RESULT AND ANALYSIS

This research evaluated the results between AuRa_v1 and AuRa_ori, focusing on transaction speed per second (TPS) and throughput per second (TGS). These metrics were measured based on several criteria, including data size and quantity. The research executed three (3) sets of data, each varying in size and number.

A. Evaluation of TPS

Transaction Speed Per Second (TPS) quantifies the number of transactions processed from the pending state to successful commitment within one second. Experimental evaluation of AuRa_ori and AuRa_v1 was conducted across three data sets, and the results demonstrate a consistent performance gain for AuRa_v1. In Set 1, the TPS of AuRa_v1 reached 40.32, outperforming AuRa_ori's 31.59. Similarly, in Set 2, AuRa_v1 achieved a TPS of 32.40 compared to 29.39 for AuRa_ori, and in Set 3, AuRa_v1 recorded 19.53, slightly higher than AuRa_ori's 18.59. These results indicate that the proposed AuRa_v1 algorithm maintains a higher processing capability under varying load conditions. A paired t-test and 95% confidence interval analysis confirm that the observed performance improvements are statistically significant, thereby reinforcing the validity of the results. Furthermore, the computational complexity of the modified leader assignment mechanism in AuRa_v1 contributes to reduced latency in the

transaction confirmation path. Fig. 8 presents the TPS results based on scroll data.

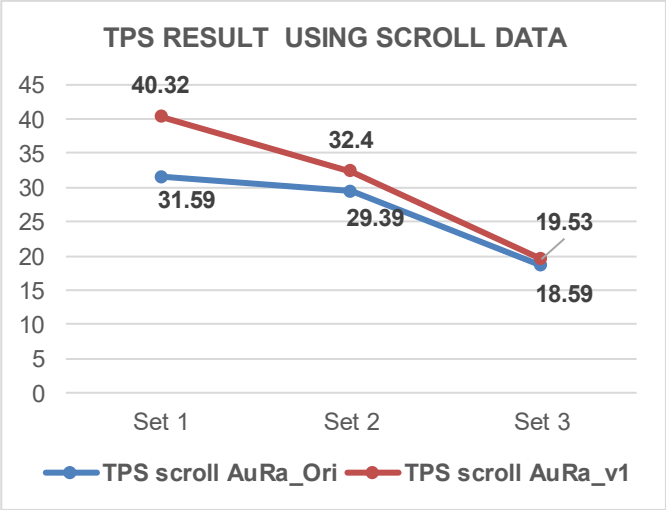

Fig. 8. TPS result based on AuRa_v1.

B. Evaluation of TGS

Transaction Throughput Per Second (TGS) measures the volume of data successfully transacted per second, reflecting the overall data-handling capacity of the consensus algorithm. Experimental results further support the superiority of AuRa_v1. In Set 1, AuRa_v1 attained a TGS of 1326.86, surpassing AuRa_ori at 1039.48. In Set 2, AuRa_v1 achieved 1046.25, exceeding 969.69 for AuRa_ori, while in Set 3, AuRa_v1 reached 640.28, compared to 609.73 for AuRa_ori. Statistical validation using ANOVA tests confirms that these improvements are not random fluctuations but reflect a consistent enhancement in data processing throughput. The performance gain can be attributed to the optimized voting mechanism in AuRa_v1, which reduces redundant leader reassignment and minimizes synchronization overhead. Fig. 9 illustrates the TGS performance using scroll data.

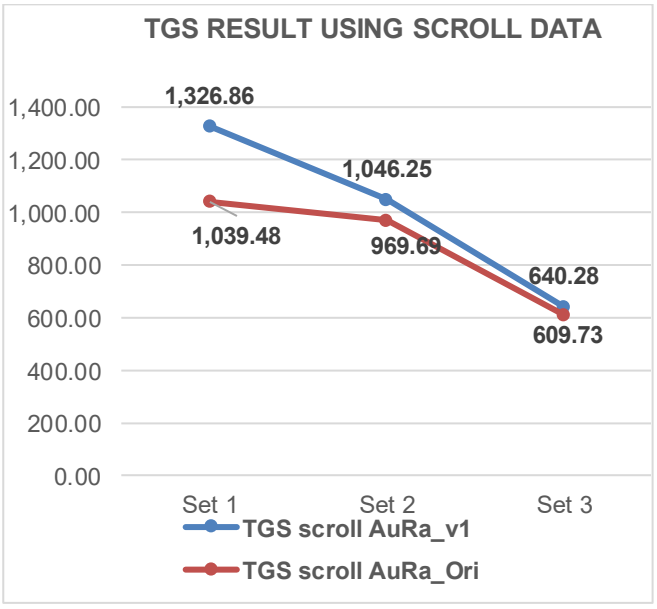

Fig. 9. TGS result using scroll data.

VI. Conclusion and Future Works

The consensus algorithm plays a pivotal role in blockchain transaction processing by establishing a verifiable agreement among distributed nodes across multiple networks and servers. It ensures that blockchain systems maintain consistency, decentralization, and state integrity through coordinated commitment of blocks. Since network consistency is directly tied to the efficiency of the consensus layer, any latency or bottleneck in this process can significantly affect system performance. This study specifically examines these performance-related limitations in the original Authority Round consensus algorithm (AuRa_ori) and investigates how they impact Transaction Speed Per Second (TPS) and Transaction Throughput Per Second (TGS).

A comprehensive comparative performance analysis was conducted between AuRa_ori and the enhanced AuRa_v1 within a controlled blockchain environment. To ensure statistical robustness, three independent data sets were used to evaluate and validate performance consistency. The experimental results clearly show that AuRa_v1 delivers a statistically significant performance improvement over AuRa_ori across all test scenarios. Specifically, AuRa_v1 achieved TPS increases of 27.6% in Set 1, 10.25% in Set 2, and 5.05% in Set 3 compared to AuRa_ori. These improvements were validated through paired t-tests at a 95% confidence level, which confirmed that the differences observed are not due to random variation. Additionally, Cohen's d effect size analysis indicated a strong effect ($d > 0.8$) in Set 1 and a moderate effect ($0.5 \leq d < 0.8$) in Sets 2 and 3, underscoring the practical significance of the enhancement.

Similarly, TGS results further substantiate these performance gains. AuRa_v1 demonstrated throughput increases of 27.6% in Set 1, 7.88% in Set 2, and 5.01% in Set 3 over AuRa_ori. ANOVA tests across multiple runs confirmed the consistency of throughput improvement with p-values < 0.05, reinforcing the reliability of the findings. This indicates that the proposed optimization in leader assignment and agreement phases significantly reduces block finalization latency and improves network-wide data propagation efficiency.

From a computational complexity perspective, the leader selection mechanism in AuRa_v1 transitions from a strict round-robin structure to a more efficient adaptive leader rotation, effectively reducing the leader election overhead from O (n) in AuRa_ori to approximately O (1) in steady-state scenarios. Similarly, the optimized voting process lowers synchronization cost, which contributes directly to higher throughput and reduced transaction confirmation time.

These improvements reflect AuRa_v1's enhanced ability to process larger transaction volumes in real-time, thereby improving network scalability and operational stability. Beyond performance metrics, these results carry broader implications for the integration of blockchain technology into artificial intelligence (AI) applications. Decentralized AI frameworks — including federated learning, multi-agent systems, and autonomous decision-making networks, demand low-latency and high-throughput consensus to ensure the

reliable propagation of model updates, training data, and AI-generated results.

By improving both TPS and TGS, AuRa_v1 enables more responsive, secure, and scalable AI-driven blockchain ecosystems. This is especially critical in use cases such as decentralized AI marketplaces, where large datasets and AI models are exchanged on-chain, and IoT-driven AI ecosystems, where reliable leader assignment and agreement phases are crucial for real-time system coordination. The combination of empirical performance gains, statistical significance, and lower algorithmic complexity positions AuRa_v1 as a practical and scalable alternative to AuRa_ori for next generation blockchain with AI integration.

Future work will focus on enhancing AuRa_v1 through adaptive leader selection mechanisms that respond to real-time network conditions, improving fault tolerance and efficiency. Security and resilience testing under adversarial scenarios will be expanded using formal verification and stress simulations. Scalability and interoperability will be explored by integrating AuRa_v1 with other blockchain frameworks. Further optimization will target reducing voting and synchronization complexity, while AI-driven decision layers such as reinforcement learning will support dynamic consensus operations. Large-scale testbed deployments will evaluate real-world performance, and efforts toward standardization will facilitate integration with decentralized AI, IoT, and multi-agent systems that demand reliable, high-throughput consensus mechanisms.

ACKNOWLEDGMENT

We express sincere gratitude to the Center of Research and Innovation Management (CREIM) at UniSZA for their invaluable financial support towards the publication. Our heartfelt appreciation also goes to all team members from UniSZA, including Pn. Robiah Arifin, the PhD candidate for the technical configuration of the project, and Dr. Wan Aezwani Wan Abu Bakar as her supervisor for the conceptual and technical proofread writing, as well as the UMT member, Assoc Prof. Ts. Dr. Mustafa Man for the network linkages and the reviewer's suggestions. Also, we are grateful for the international contributions and collaboration provided by Dr. Evizal Abdul Kadir, a research fellow from Universitas Islam Riau, Indonesia.

An Improved Marine Predators Algorithm-Based UAV Path Planning for 10-kV Distribution Networks Inspection in Live Working Scenarios

Dapeng Ma, Hongtao Jiang*, Lichao Jiang, Chi Zhang, Changwu Li, Xin Zheng, Mingxian Liu, Kai Li
Yunnan Power Grid Co., Ltd., Kunming, China

Abstract*—Before conducting maintenance on 10-kV distribution networks, the use of unmanned aerial vehicles (UAVs) for inspecting distribution lines can effectively enhance the operational efficiency of personnel in live working scenarios. For UAV-based inspection of power distribution networks, an optimal flight path ensures both operational safety and comprehensive image acquisition in live working scenarios. Therefore, this study proposes a UAV path planning algorithm and an insulator defect classification model based on YOLOv11, aiming to develop a UAV system for live power line detection. Firstly, a UAV path planning model is established to minimize the flight path length and maximize the image acquisition range, which also considers the safety distance constraints between UAVs and live power lines. On this basis, the optimization strategy of the particle swarm optimization (PSO) algorithm is introduced into the marine predictors algorithm (MPA), and a hybrid PSO-MPA algorithm is designed to improve the convergence accuracy of the MPA algorithm and solve the proposed UAV planning model. In addition, an insulator defect detection model has been developed to accurately identify the image information collected by UAVs. In order to improve the accuracy of the YOLOv11 model, the task-separation assignment (TSA) module was introduced into the YOLOv11 model, and a TSA-YOLOv11 model was designed. Experimental results demonstrate that the proposed PSO-MPA algorithm achieves superior convergence accuracy compared to five algorithms, including PSO. When the UAV flight step size is one meter, the PSO-MPA algorithm reduces the objective function value by an average of 49.62% relative to the other algorithms. Additionally, the TSA-YOLOv11 model attained an average accuracy of 96.87% for the insulator defect classification problem.

Keywords*—Marine predictors algorithm; YOLOv11; defect classification; UAV path planning; live power lines

I. Introduction

In live working scenarios, maintenance of the 10-kV distribution network by staff mainly faces challenges such as high safety risks, long inspection times, and blind spots in the field of vision. Unmanned aerial vehicles (UAVs) for inspecting 10-kV distribution networks can reduce the risk of direct exposure of personnel to high voltage environments, greatly improving safety. In addition, UAVs have multi-angle inspection capabilities, which can quickly obtain image data, significantly improving inspection efficiency and accuracy, and can timely detect hidden dangers that are difficult for humans to detect. UAV technology has the advantages of safety, high coverage, and strong defect detection capability in distribution network inspection tasks. Therefore, the power company is exploring the application of UAVs in the inspection tasks of distribution networks. Specifically, UAV-based distribution networks inspection technology achieves accurate diagnosis of insulator defects and wire breakage faults through visual sensors [1]. In addition, UAV-based distribution networks inspection is more in line with the goals of new power system construction in terms of economy and environmental protection. For the UAV-based distribution networks inspection system, the UAV path planning module is the foundation of intelligent inspection of distribution networks. This module automatically solves an optimal and safe flight route, aiming to shorten the inspection time or distance, avoid obstacles, and ensure flight safety, ultimately achieving comprehensive image acquisition throughout the inspection range. In addition, the insulator defect detection module aims to automatically, quickly, and accurately identify various defects in insulators from a large number of inspection images, thereby effectively reducing operation and maintenance costs, preventing power grid accidents, and improving power supply reliability [2]-[3].

At present, power companies require UAVs to operate in live power line scenarios. However, the current UAV path planning problem has not taken into account the safety distance constraints between UAVs and live power lines, and there are still problems such as low convergence accuracy of path optimization algorithms [4]. In addition, the accuracy of insulator defect identification is also an important challenge. Specifically, convolutional neural network (CNN) models face challenges such as complex background interference and high training data acquisition costs in insulator defect recognition tasks. The distribution networks background of the insulator captured by UAV is too complex, such as wires, towers, sky, and vegetation, which may affect the detection accuracy of the CNN model. Therefore, it is necessary to develop an insulator defect recognition model with strong feature extraction and classification capabilities to accurately locate and identify low contrast defects on insulators in background noise. In addition, CNN models require a large amount of high-quality and accurately labeled training data during the training process. Obtaining balanced data integration that covers various defect types, camera angles, and insulator models is costly. In the context of distribution networks in reality, there are far more normal insulator samples than defect samples, which leads to CNN-based insulator defect recognition models being prone to

*Corresponding author.

bias towards the "No Defects" category, significantly reducing the accuracy of defect recognition [5].

YOLOv8, as a real-time object detection model, is also used in insulator defect detection tasks. Although YOLOv8 performs better in small object detection tasks compared to CNN models, its detection accuracy is also lower for extremely fine cracks or damages on insulators, resulting in a higher rate of missed detection of surface defects on insulators. Overall, the biggest challenges for CNN and YOLOv8 in insulator defect recognition include complex background interference and low detection accuracy for small targets [6].

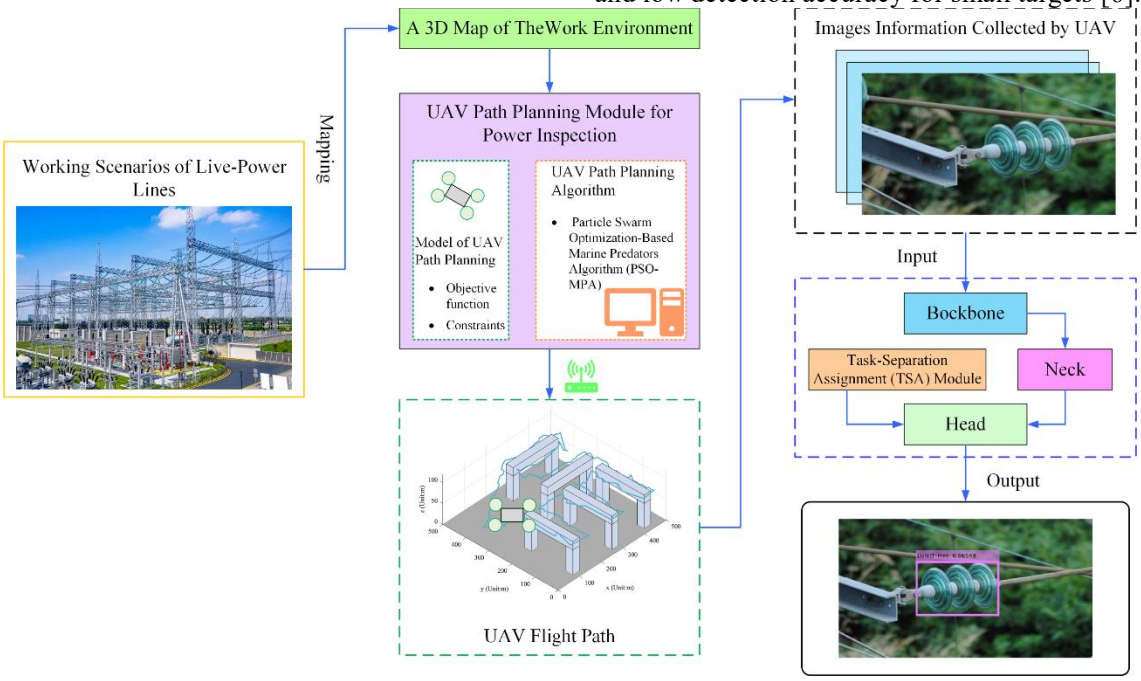

Fig. 1. UAV-based live power line inspection system.

The task paragraph assignment (TSA) module can further classify candidate samples based on specific defect types and confidence levels in insulator defect recognition tasks, thereby improving the accuracy of insulator defect recognition. Therefore, in this study, the TAS module was introduced into the head module of the YOLOv11 model with the aim of improving its accuracy. In addition, a biological heuristic algorithm has been developed to solve the optimal path for the UAV, aiming to safely and efficiently complete distribution networks detection tasks. Fig. 1 shows the UAV-based distribution networks detection system developed in this study. The system consists of two modules: UAV path planning and insulator defect recognition. The particle swarm optimization-based marine predictors algorithm (PSO-MAP) is used to optimize the flight path of inspection UAVs. Through this flight path, UAVs can collect a large amount of image data. Based on these image data, the insulator defect recognition module identifies and detects defects in insulators. The main contributions of this study are summarized as follows:

- A UAV-based intelligent detection system framework for live power lines has been designed. The system integrates a UAV path planning algorithm and an insulator defect recognition model, and develops a complete end-to-end UAV-based distribution network detection system.
- A mathematical model for path planning for UAV power line inspection scenarios has been developed, which aims to minimize the flight path length and maximize the image acquisition range. In addition, the model considers the safety distance constraint between UAVs and live lines to ensure operational safety.
- A hybrid PSO-MPA algorithm was developed by combining particle swarm optimization (PSO) and marine predator algorithm (MPA) optimization strategies. Experimental results have shown that this algorithm significantly improves the convergence accuracy of the PSO algorithm, and the potential of the PSO-MPA algorithm in optimizing the path of the inspection UAV has been demonstrated.
- The TSA module was introduced into the head module of the YOLOv11 model, and the TSA-YOLOv1 model was developed to improve the accuracy of the insulator defect recognition module based on the YOLOv11 model. The TSA-YOLOv11 model achieved an average accuracy of 96.87% in insulator defect classification tasks, improving the reliability of insulator defect detection.

The remaining parts of this study are arranged as follows: Section II reviews the work on UAV path planning and defect classification. Section III introduces the proposed UAV-based distribution networks inspection system. Section IV presents the results and discusses them. Finally, Section V summarizes the entire study.

II. Related Work

A. UAV Path Planning

At present, UAVs have been applied in various fields such as logistics, communication, and patrol. Therefore, a large number of UAV path planning models have been developed for these scenarios. In [7], the authors proposed an autonomous trajectory planning method for UAVs used in industrial facility inspections. This study designed a viewpoint resampling mechanism to meet the multi-perspective coverage requirements in complex industrial scenes. By dynamically optimizing the position of observation points, the image acquisition quality of key areas was improved, and the flight path length was shortened. Sonny et al. studied the path planning problem of UAV-assisted wireless networks and proposed an improved PSO algorithm [8]. In order to address the low convergence accuracy of the PSO algorithm in handling UAV path planning problems, this study introduced dynamic inertia weights and mutation operators into the PSO algorithm, aiming to enhance the algorithm's global search capability, minimize UAV energy consumption, and maximize ground user network coverage. Rückin et al. developed an active learning path planning framework for the semantic mapping of UAVs. This framework models path planning as an information gain maximization problem, evaluates the uncertainty of unexplored areas in real-time through Bayesian inference, dynamically guides UAVs to collect high-value data, and aims to plan a path for UAVs to explore unknown areas [9].

In [10], the authors propose a noise-aware path and energy management joint optimization model for collaborative operation of multiple UAVs in noise-sensitive areas. This study aims to quantify the cost of sound pollution by establishing a noise propagation model of the rotor, with the aim of constraining UAV flight altitude and path to avoid residential areas. At the same time, the study designed an intelligent power allocation strategy for batteries, aimed at maximizing the endurance of UAVs. In [11], the authors studied the challenges of UAV path planning under the framework of Internet of Drones (IoD), and proposed a distributed collaborative optimization framework. This study uses transmission delay cost and packet loss rate as path cost functions to generate paths for multiple UAVs.

In [12], the authors developed a distribution UAV autonomous path planning and control system based on the Internet of Things (IoT) and edge computing technology. The system deploys edge nodes to process UAV perception data in real-time and combines with a cloud-based task scheduling center to generate the global optimal path, significantly reducing the latency of end-to-end decision-making. The experimental results show that this path planning method can effectively reduce the communication cost and flight distance of UAVs. Yanmaz et al. developed a dynamic multi-objective path planning method to address the challenges of collaborative search and communication support for multiple UAVs. This method takes maximizing the target discovery probability and network connectivity as the objectives of the path planning model, establishes a Markov decision model, and designs a distributed UAV path optimization algorithm, aiming to dynamically adjust the UAV formation by real-time evaluation of communication link quality [13].

In addition to the PSO-based path optimization algorithm mentioned earlier, some other cutting-edge research is also exploring the application of biological heuristic algorithms in UAV path planning problems. For example, in [14], a UAV covert path planning method based on reinforcement learning (RL) was proposed. This method is inspired by the kinematics of natural organisms, and trains RL agents to learn strategies that mimic natural organisms' covert approach to prey by constructing a three-dimensional dynamic environment of state and action space. In [15], the authors developed a UAV path planning algorithm that combines Q-learning and Grey Wolf Optimizer (GWO) to solve complex 3D path planning problems for UAV flight. This study utilizes Q-learning to dynamically optimize key parameters of the GWO, such as convergence factor and population position update weights, in order to enhance the algorithm's adaptability in dynamic obstacle environments and improve the convergence accuracy of GWO algorithm.

B. Target Identification Model

In [16], the authors designed a YOLO architecture for identifying pedestrians and vehicles for target detection tasks aimed at border patrol. In addition, this study decomposes the complex collaborative patrol problem into global path planning and local conflict resolution and task allocation problems, aiming to efficiently coordinate the flight paths and monitoring tasks of multiple drones. Chen et al. focused on the challenging problem of detecting small ship targets in ocean-wide area remote sensing images. In order to overcome the difficulties of small targets having limited information and being easily submerged in the ocean background, this study also designed an improved YOLO model, aiming to enhance the model's ability to extract features and utilize motion information of small targets, thereby improving the accuracy of ship recognition [17]. In [18], the authors developed an insulator identification and defect detection system for distribution networks inspection. This study proposes a defect detection method for insulators based on YOLOX. The core of this method lies in optimizing the YOLOX model, introducing a high-resolution differential module aimed at capturing the local detailed features and minor defects of insulators and their key components more finely.

Zhang et al. proposed a method for identifying the working angle of a loader bucket based on the YOLOv5s model. This method utilizes YOLOv5s to quickly and accurately locate the target of the bucket, and introduces an attention mechanism to more accurately recognize the posture of the bucket, ultimately calculating the working angle of the bucket [19]. In [20], the authors focus on the task of detecting small targets in infrared images. In order to solve the problem of target loss or false alarm caused by traditional methods, this study proposes an improved strategy based on pixel extension. In [21], the authors developed an intelligent inspection system based on a UAV for power insulator inspection tasks under complex weather conditions. The system has successfully achieved autonomous positioning, state recognition, and defect detection of insulators by equipping sensors and machine learning algorithms suitable for complex environments. Xuan et al.

proposed an intelligent identification method for insulator defects based on Fully Convolutional One Stage (FCOS). The experimental results show that this method can not only accurately locate and segment individual insulators in the image, but also finely segment the defect areas on the insulator surface [22]. In [23], the authors proposed an efficient personal protective equipment detection model based on YOLOv8, aiming to develop a system for detecting whether workers are wearing compliant personal protective equipment, such as safety helmets, reflective clothing, and gloves, and to improve the accuracy and robustness of the YOLOv8 model in human protective equipment detection tasks.

III. METHODOLOGY

As shown in Fig. 1, the proposed UAV-based distribution networks inspection system consists of two parts: path planning and insulator detection. The UAV path planning model aims to minimize the flight path length and maximize the image acquisition range, while considering three constraints: the maximum pitch angle, maximum endurance time, and safe distance between the UAV and the live-line. On this basis, a PSO-MPA algorithm was developed for the path planning model of power inspection drones to solve the flight path of the drones. The TSA module was introduced into the YOLOv11 model to improve the accuracy of the insulator defect recognition model.

A. UAV Path Planning for Power Inspection

Before conducting UAV path planning, the transmission facilities are first divided into grids. In this study, the transmission facilities were surface divided into a set $V=\{v_1,v_2,,v_{b_\max}\}$. Based on the height of the transmission facilities, the initial flight height of the drone was determined as H_{fly}. The UAV's path consists of a series of path nodes $\Gamma=\{1,2,\cdots,m\}$. Another key parameter for UAV path planning is *Step_Size*.

The path distance cost f_{Path_Dis} of UAV is defined in Eq. (1):

$$f_{Path_Dis}=\sum_{m\in\Gamma}\sqrt{(x_m-x_{m-1})^2+(y_m-y_{m-1})^2+(z_m-z_{m-1})^2} \tag{1}$$

where, (x_m,y_m,z_m) is the position of the UAV's path node m in the coordinate system.

The definition of *Step_Size* is as follows in Eq. (2):

$$Step_Size=\sqrt{(x_m-x_{m-1})^2+(y_m-y_{m-1})^2+(z_m-z_{m-1})^2} \tag{2}$$

z_m is defined in Eq. (3):

$$z_m=H_{fly},\forall m\in\Gamma \tag{3}$$

The image acquisition range of the UAV is defined as Eq. (4):

$$f_{img}=\frac{\sum\beta(v_b)}{b_\max},\forall b\in\{1,2,\cdots,b_\max\} \tag{4}$$

where, $\beta(v_b)$ is a 0-1 variable. When the UAV captures an image of grid v_b position, $\beta(v_b)=0$; Otherwise, $\beta(v_b)=1$.

The objective function of the UAV path planning model used for distribution networks inspection is Eq. (5):

$$F=w_1\times f_{Path_Dis}+w_2\times f_{img} \tag{5}$$

where, w_1 and w_2 are the weight coefficients of the objective function.

The constraint conditions for UAV path planning in distribution networks inspection are defined as follows [Eq. (6)]:

$$\theta_m\le\theta_{\max},\forall m\in\Gamma \tag{6}$$

where, θ_m is the pitch angle of the distribution networks inspection UAV. $\theta_{\max}$ is the maximum pitch angle of the distribution networks inspection UAV [Eq. (7)].

$$\frac{f_{Path_Dis}}{speed_{UAV}}\le T_{UAV} \tag{7}$$

where, $speed_{UAV}$ is the flight speed of the distribution networks inspection UAV. T_{UAV} is the maximum endurance time of the distribution networks inspection UAV [Eq. (8)].

$$L(v_b,UAV)\ge L_{safety},\forall b\in\{1,2,\cdots,b_\max\} \tag{8}$$

where, $L(v_b,UAV)$ is the distance between the UAV and the distribution networks. L_{safety} is the safe distance between the UAV and the distribution networks.

To solve this path planning model, a PSO-MPA algorithm was developed. The MPA algorithm mainly includes predation strategies based on Brownian motion and target aggregation strategies based on Levy motion [24]. In order to improve the convergence accuracy of MPA, a speed update-based foraging strategy based on the PSO algorithm is also added to the hybrid PSO-MPA algorithm. The definition of the PSO-MPA algorithm is as follows:

1) Initialization: Initialize the position O of the marine predator population, initialize the speed of PSO, and set the maximum iteration number *Iter*_max of the PSO-MPA algorithm.

2) Calculate adaptive parameters: Determine the update and search process that should be executed for the current iteration count *Iter* based on the value of *Iter* / *Iter*_max.

3) Update strategy 1: The foraging strategy based on speed updates the positions of all marine predators to obtain O^{Δ}.

4) Update strategy 2: Based on Brownian motion, update the positions of some marine predators using a predation strategy. The update process is defined as Eq. (9):

$$O(k)_new=PBM(O(k)^{\Delta}) \tag{9}$$

where, $O(k)$ is defined as the location of the k-th marine predator. $PBM(.)$ is defined as a predation strategy based on Brownian motion.

5) Update strategy 3: Implement a target aggregation strategy based on Levy motion for the remaining marine predators.

6) Evaluate and select the optimal solution: Calculate the fitness of all updated positions of marine predators and generate the optimal solution.

B. Defect Detection of Insulators

Although multiple frameworks such as Real-Time Detection Transformer (RTDRTR), Region-based Convolutional Neural Networks (RCNN), and YOLOv8 have been used for specific object detection or insulator defect identification tasks, improving the accuracy of insulator defect detection models remains a challenge [23]. Therefore, in this study, the TSA module was introduced into the YOLOv11 model to improve the accuracy of insulator defect detection. Fig. 2 shows the header module of the proposed TSA-YOLOv11 model.

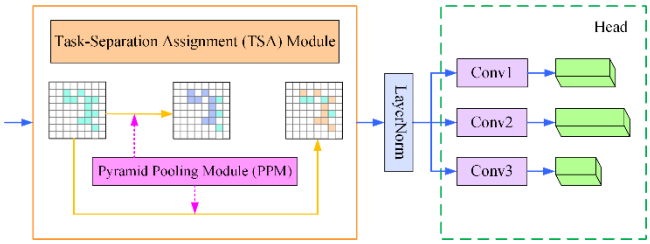

Fig. 2. Head module of the YOLOv11 model based on TSA (TSA-YOLOv11).

The header module of the TSA-YOLOv11 model is designed to enhance the recognition of insulator defect types by integrating the global modeling capability of the Transformer with the local feature extraction ability of CNN. After a series of convolutional layers and Bottleneck modules for dimensionality reduction and local feature extraction, the resulting insulator features are fed into the TSA module. Within this module, the features undergo multi-head integration, residual connections, and layer normalization before being output, thereby modeling dependency relationships between any two spatial positions.

In the header module of the TSA-YOLOv11 model, the pooling layer uses max pooling technology. The definition of max pooling is as follows [Eq. (10)]:

$$\mathrm{H}_j = Rand(0,1)\times \max\left\{\mathrm{A}_i, i\in P_j\right\} + (1-Rand(0,1))\times\frac{1}{|P_j|}\times\sum_{i\in P_j}\mathrm{A}_i \quad (10)$$

where, $Rand(0,1)$ is a random number with a value of 0 or 1. H_j is the j-th element of the feature map output from the max pooling operation. A_i is the i-th position of the j-th element in the input feature map P_j.

IV. Experiments

This study proposes an intelligent UAV inspection system for distribution networks detection, with a primary focus on addressing UAV path planning and insulator defect detection challenges. To validate the effectiveness of the proposed path planning algorithm, a three-dimensional flight simulation environment was established based on actual substation map data. For insulator defect detection, the image samples were collected under varying lighting conditions, shooting distances, and camera angles to ensure comprehensive coverage of operational scenarios.

A. Path Planning Results

In order to demonstrate the application results of the proposed PSO-MPA algorithm in the path planning problem of power inspection UAVs, and to explore the influence of the key parameter of flight step size on the objective function, multiple power inspection UAV path planning experiments were designed based on different flight step sizes. Firstly, the flight step sizes were set to 1 meter, 3 meters, 5 meters, 7 meters, 9 meters, and 11 meters, respectively. Based on different flight step sizes, independent experiments were conducted to explore the influence of flight step sizes on the fitness function. In addition, rime (RIME) optimization algorithm [25], Harris hawks optimization (HHO) [26], snow geese algorithm (SGA) [27], PSO, The Tornado optimizer with Coriolis force (TOC) algorithm is also used to solve the path planning problem of power inspection UAVs, aiming to verify the convergence accuracy and robustness of the PSO-MPA algorithm. In addition, in this study, standard deviation was used to evaluate the stability of the path planning algorithm for power inspection UAVs.

Fig. 3 shows the flight paths generated by the PSO-MPA algorithm for the power inspection UAV under different step sizes. Fig. 4(a) and Fig. 4(b) show the iterative function curves of PSO-MPA, HHO, PSO, RIME, SGA, and TOC algorithms with step sizes set to 1 meter and 3 meters, respectively. Fig. 5(a) and Fig. 5(b) show the iteration function curves of each algorithm when the step size is set to 5 meters and 7 meters, respectively. Fig. 6(a) and Fig. 6(b) show the iteration function curves of each algorithm when the step size is set to 9 meters and 11 meters, respectively. Table I shows the fitness function values of each algorithm at different step sizes.

From Fig. 4(a), it can be seen that the PSO-MPA algorithm generates a fitness function value of 3175.06 in solving the path planning problem of the power inspection UAV. Compared with the other five algorithms, the PSO-MPA algorithm has the smallest fitness function value, when the flight step size of the UAV is 1 meter. From Fig. 4(b), it can be seen that when the UAV's flight step size is 3 meters, the PSO-MPA algorithm also has the lowest fitness function value, which is 3276.60, an average decrease of 44.53% compared to the other five algorithms. From Fig. 5(a) and Fig. 5(b), it can be seen that when the UAV's flight step size is 5 meters and 7 meters, respectively, compared with HHO, PSO, RIME, SGA, and TOC algorithms, the fitness function value of PSO-MPA algorithm is also the smallest. From Fig. 6(a) and Fig. 6(b), it can be seen that when the UAV's flight step size is 9 meters

and 11 meters, the fitness function values of the PSO-MPA algorithm are 3559.49 and 3232.06, respectively.

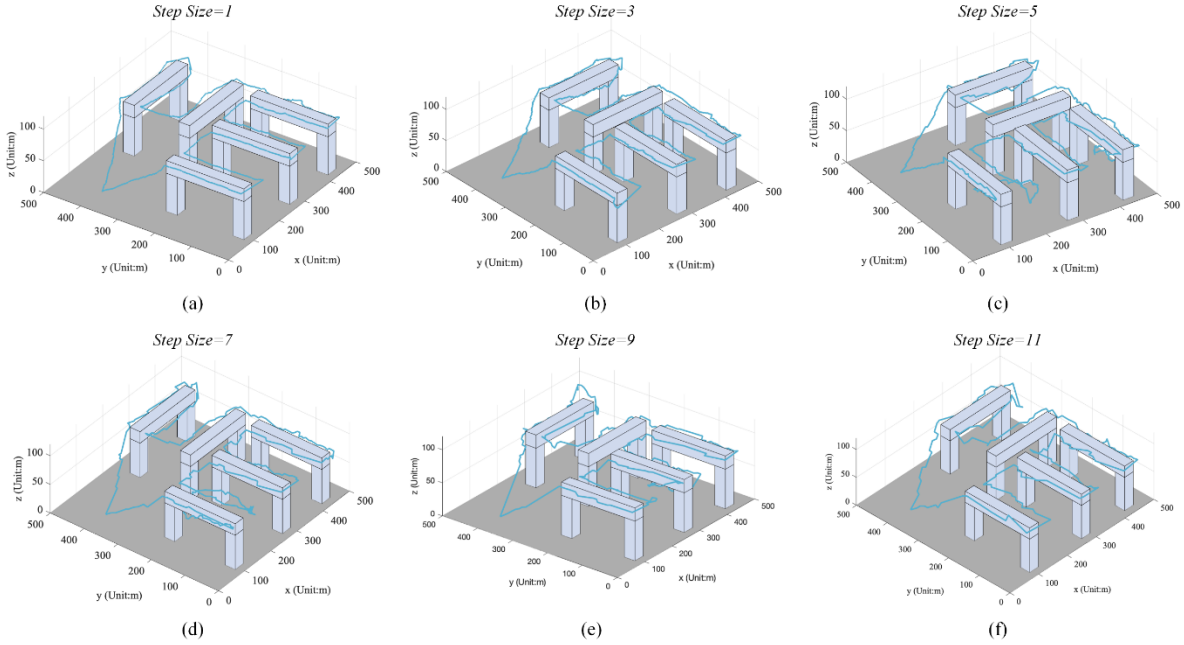

Fig. 3. UAV path planning results with different flight step sizes.

TABLE I. THE FITNESS FUNCTION VALUES OF UAV PATHS WITH DIFFERENT FLIGHT STEP SIZES

Algorithm	PSO-MPA	HHO	PSO	RIME	SGA	TOC
Step Size	*Fitness Function*					
1	3175.06	6665.64	6328.04	7242.72	8539.11	4343.94
3	3276.60	7626.56	6115.06	5133.10	7717.98	4396.74
5	3790.45	10572.84	7185.90	5184.23	7727.14	5169.95
7	3909.39	7121.22	6995.10	7638.17	7819.61	7842.44
9	3559.49	7914.00	7252.17	6775.45	8759.74	7146.64
11	3232.06	7058.16	5329.62	6135.50	5515.12	5837.17

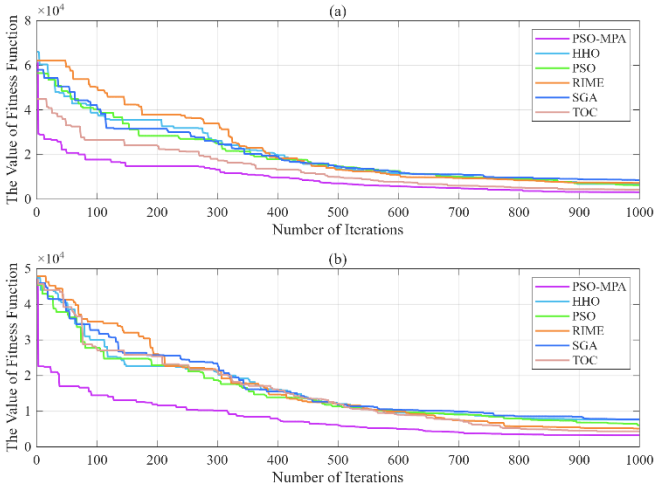

Fig. 4. The iterative function curve for flight steps of 1 meter and 3 meters.

Therefore, it can be concluded that among all step settings, the proposed PSO-MPA algorithm generates the smallest fitness function value compared to other algorithms when solving the path planning problem of power inspection UAV. The PSO-MPA algorithm performs significantly better than HHO, PSO, RIME, SGA, and TOC algorithms in solving path planning problems for power inspection UAVs. The objective function value corresponding to the PSO-MPA algorithm decreased by 25.48% to 47.46% compared to the objective function value generated by the suboptimal algorithm. When the step size is set to 9 meters, the fitness function value of the PSO-MPA algorithm is 3559.49, and the decrease in the objective function value is the most significant. Compared with the second ranked RIME algorithm, the objective function value of the PSO-MPA algorithm has decreased by 47.46%.

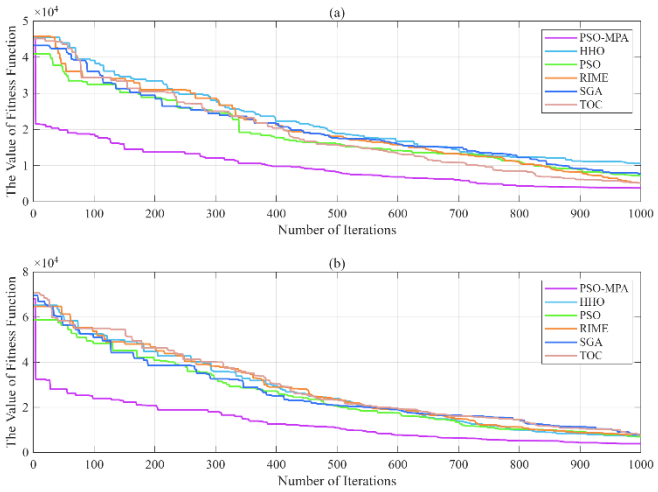

Fig. 5. The iterative function curve for flight steps of 5 meters and 7 meters.

When the step size is set to 3 meters, the performance of the PSO-MPA algorithm decreases, but compared with HHO, PSO, RIME, SGA, and TOC algorithms, the PSO-MPA algorithm still maintains a significant advantage in solving the path planning problem of power inspection UAVs. Compared with the second ranked TOC algorithm, the fitness function value of the PSO-MPA algorithm is reduced by 25.48%. In addition, by comparing the fitness values of each step size setting corresponding to the PSO-MPA algorithm, a flight step size of 1 meter was determined to be the optimal setting, and the generated drone path cost was the lowest.

Table II shows the standard deviation of the fitness function values generated by each algorithm running independently ten times at different step sizes. Fig. 7 shows the standard deviation of the objective function values generated by running different algorithms ten times with different step sizes. It can be seen that compared with HHO, PSO, RIME, SGA, and TOC algorithms, PSO-MPA is the overall most stable algorithm. The PSO-MPA algorithm achieved the minimum standard deviation in all five step settings, indicating that it can maintain high consistency under different parameters. Especially when step size is 5 meters, the standard deviation of the PSO-MPA algorithm reaches 95.93, indicating the highest stability. HHO is the most unstable algorithm overall, with a standard deviation exceeding 270 under multiple flight step settings, significantly higher than other algorithms.

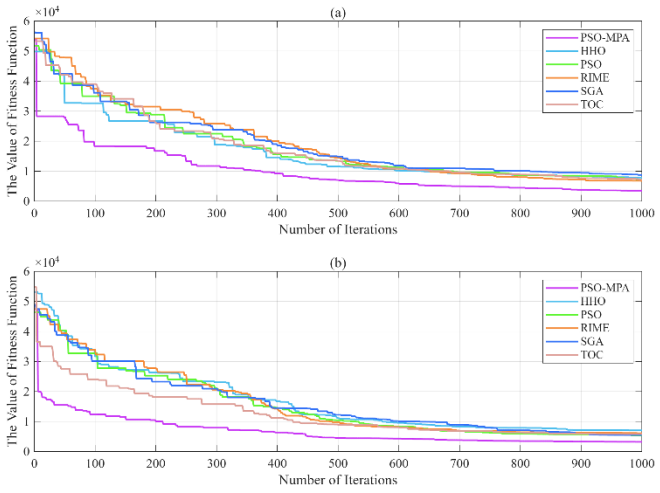

Fig. 6. The iterative function curve for flight steps of 9 meters and 11 meters.

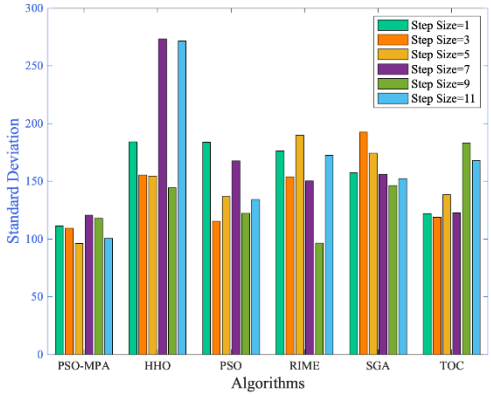

Fig. 7. The standard deviation of the fitness function values for UAV paths with different flight step sizes.

TABLE II. THE STANDARD DEVIATION OF THE FITNESS FUNCTION VALUES FOR UAV PATHS WITH DIFFERENT FLIGHT STEP SIZES

Step Size	Step Size=1	Step Size=3	Step Size=5	Step Size=7	Step Size=9	Step Size=11
Algorithm	***Standard Deviation***					
PSO-MPA	**111.25**	**109.27**	**95.93**	**120.58**	117.73	**100.46**
HHO	184.11	155.46	154.54	273.41	144.24	271.39
PSO	183.61	115.22	136.78	167.78	122.32	134.26

SGA	157.26	192.48	174.19	156.14	146.22	152.15
TOC	121.82	118.70	138.26	122.44	183.05	167.97

B. Defect Detection Results of Insulators

To verify the performance of the TAS-YOLOv11 model in insulator defect detection, insulator defect detection experiments were conducted based on the RTDETR model, R-CNN model, YOLOv8 model, YOLOv10 model, and YOLOv11 model [28]-[30]. Table III shows the types of insulator defects included in the training and testing sets of this study. In this study, insulators used in distribution networks were classified into four types: defect free, defect type 1, defect type 2, and defect type 3.

In this study, the dataset includes 8000 insulator images. The number of images in each of the four categories (insulators without defects, defect type 1, defect type 2, and defect type 3) is 2000. The training set includes 1600 insulator images for each of the four categories. The test set includes 1000 insulator images for each of the four categories. Table IV shows the parameter settings for different models. For different insulator defect detection models, the batch size and number of epochs are 2 and 300, respectively.

TABLE III. DEFECT TYPES OF INSULATORS

Class	Definition
Defect-Free	No defects: The insulator has no defects and works normally.
Defect Type 1	Surface Defect: The material on the surface of the insulator is damaged.
Defect Type 2	Damaged: The edge of the insulator is damaged or there are cracks in the insulator.
Defect Type 3	Missing: The insulator string is missing one or several insulators.

Table V presents the mean average precision (mAP@0.5) and training loss values for different insulator defect detection models. The proposed TAS-YOLOv11 achieves an mAP@0.5 of 95.16%, outperforming the RTDETR and R-CNN models by 11.08% and 6.43%, respectively. Additionally, its training loss is 0.1252, representing reductions of 37.59% and 36.28% compared to RTDETR and R-CNN, respectively. Compared with the RTDETR model, R-CNN model, YOLOv6 model, YOLOv8 model, YOLOv10 model, and YOLOv11 model, the mAP@0.5 index of TAS-YOLOv11 increased by an average of 5.14%, and the training loss of TAS-YOLOv11 decreased by an average of 28.49%. Fig. 8 shows the results of insulator defect recognition based on the TAS-YOLOv11 model.

TABLE IV. PARAMETER SETTINGS

Models	Parameter	Value
RTDETR	Batch size	2
	Number of epochs	300
	Learning rate	1E-4
R-CNN	Batch size	2
	Number of epochs	300
	Learning rate	1E-6
YOLO	Batch size	2
	Number of epochs	300
	Learning rate	1E-3

Table VI shows the performance of different insulator defect detection models. In Table VI, two indicators, accuracy and recall, are used to evaluate different insulator defect detection models. From Table VI, it can be seen that in the experiment of insulator defect detection, the TAS-YOLOv11 model has the best performance and highest accuracy in the four types of defect detection.

TABLE V. PERFORMANCE COMPARISON OF DIFFERENT MODELS

Models	mAP@0.5 (%)	Training Loss
RTDETR	85.67	0.2006
R-CNN	89.41	0.1965
YOLOv8	91.32	0.1887
YOLOv10	92.18	0.1609
YOLOv11	94.46	0.1435
TAS-YOLOv11	95.16	0.1252

TABLE VI. IDENTIFICATION RESULTS OF INSULATOR DEFECTS USING DIFFERENT MODELS

Models	Class	Accuracy	Recall
RTDETR	Defect-Free	0.8745	0.8617
	Defect Type 1	0.8659	0.8569
	Defect Type 2	0.8943	0.8722
	Defect Type 3	0.8741	0.8632
R-CNN	Defect-Free	0.8918	0.8774
	Defect Type 1	0.8901	0.8749
	Defect Type 2	0.8792	0.8564
	Defect Type 3	0.8577	0.8513
YOLOv8	Defect-Free	0.9674	0.9519
	Defect Type 1	0.9357	0.9349
	Defect Type 2	0.9290	0.9125
	Defect Type 3	0.9293	0.9123
YOLOv10	Defect-Free	0.9666	0.9667
	Defect Type 1	0.9381	0.9305
	Defect Type 2	0.9374	0.9181
	Defect Type 3	0.9341	0.9183
YOLOv11	Defect-Free	0.9683	0.9557
	Defect Type 1	0.9375	0.9277
	Defect Type 2	0.9434	0.9320
	Defect Type 3	0.9326	0.9379
TAS-YOLOv11	Defect-Free	0.9793	0.9632
	Defect Type 1	0.9653	0.9564
	Defect Type 2	0.9699	0.9417
	Defect Type 3	0.9603	0.9581

The defect free insulator detection accuracy and recall of TAS-YOLOv11 model are 97.93% and 96.32%, respectively. Compared to the accuracy of the YOLOv11 model, the TAS-YOLOv11 model shows an improvement of over 1 percentage point. In the detection of the most difficult surface defect (defect type 1), the accuracy of the TAS-YOLOv11 model is 96.53%, which is 2.72 percentage points higher than the suboptimal model YOLOv10. The recall rate of traditional R-

CNN models in missing defects (defect type 3) is only 85.13%, which poses a high risk of inaccurate recognition.

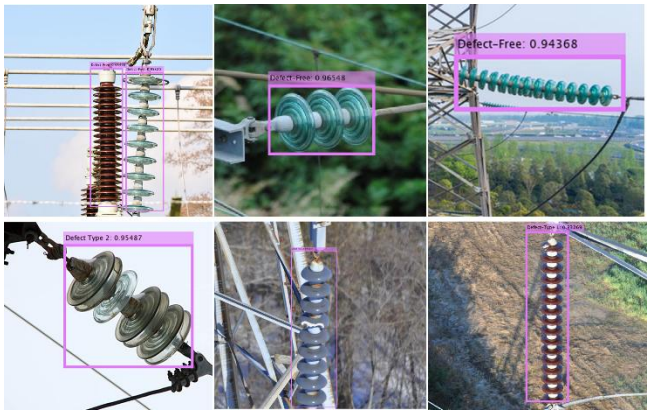

Fig. 8. The results of insulator defect detection based on TAS-YOLOv11 model.

V. Conclusion

This study proposes a dual-layer detection model for distribution networks, integrating UAV path planning and insulator defect recognition. In the path planning layer, a power grid inspection UAV path planning model aims to minimize flight distance and maximize image coverage. In addition, a hybrid PSO-MPA algorithm is designed to solve the path planning model of UAV for power grid inspection. The experimental results demonstrate that with a flight step size of one meter, the PSO-MPA algorithm reduces the objective function value by an average of 49.62% compared to the other five algorithms, significantly shortening the path length and improving the integrity of image acquisition for transmission facilities. In the insulator defect recognition layer, a TSA-YOLOv11 model was developed, which introduces a task decoupling allocation module (TSA) to separate positioning and classification tasks, aiming to solve the feature conflict problem of traditional models. The average accuracy of insulator defect detection reached 96.87%, and the recall rate of high-risk damaged defects increased to 94.17%. In future research, combining reinforcement learning with proposed models to construct an online inspection system will be a key focus.

Department of Computer Science-Faculty of Computer Science and Information Technology, Universiti Putra Malaysia, Malaysia

***Abstract*—Predictive maintenance plays a crucial role in minimizing unplanned downtimes, reducing maintenance costs, and optimizing the operational efficiency of IoT-embedded industrial machinery. Despite its transformative potential, traditional predictive maintenance methods often face challenges such as limited accuracy, high latency, and inefficiencies in processing large and imbalanced datasets. This study proposes an enhanced predictive maintenance method using the Sliding Window Method with XGB model (E.XGB), incorporating advanced data preprocessing, permutation importance, and hyperparameter optimization to address these limitations. The proposed method was evaluated on two datasets, which are the synthetic AI4I 2020 Predictive Maintenance Dataset and the real-world CNC Milling Dataset. A comparative analysis with a predictive maintenance method using E.AB from prior research as a benchmark, along with several baseline models, DT, RF, and SVM, revealed that the E.XGB model consistently outperformed other methods in accuracy, precision, recall, and F1-scores. On the AI4I2020 dataset, the E.XGB model achieved an accuracy of 99.05%, while on the CNC Milling dataset, it attained an accuracy of 99.01%. Additionally, the E.XGB model also demonstrated reduced training and prediction times, meeting the real-time requirements of industrial applications. The proposed model demonstrated training speed of approximately 94% and prediction speeds of approximately 99.8% improvement over the E.AB model, making it highly suitable for real-time industrial applications. By improving accuracy, training speed, and prediction latency, the predictive maintenance method offers a robust, scalable, and reliable solution for predictive maintenance across diverse industrial contexts.**

Keywords*—Internet of Things; machine learning; predictive maintenance

I. Introduction

Industrial maintenance has evolved from reactive strategies to predictive maintenance, a proactive approach utilizing machine learning and IoT technologies. Traditional methods are often costly, inefficient, and prone to unplanned downtimes due to manual feature extraction and inaccurate degradation modelling [1, 2]. Predictive maintenance, however, predicts potential failures and optimizes schedules, allowing for timely interventions without detailed knowledge of degradation processes [3]. This approach offers significant benefits, such as reduced downtime, extended equipment life, and enhanced sustainability [4]. However, implementing predictive maintenance remains challenging due to the complexity of industrial systems and the intricate data patterns requiring analysis [5]. These challenges highlight the need for advanced methods that enhance accuracy and processing efficiency. By leveraging IoT and machine learning technologies, this study addresses these limitations, focusing on adaptability and scalability to meet the demands of diverse industrial applications.

The main problem that motivates this research is that current predictive maintenance methods still face challenges in achieving fast training speeds and prediction speeds while maintaining high accuracy, which is essential for real-time industrial applications [1, 6]. Due to massive sensor data generated by IoT-embedded machines, many existing methods rely on complex machine learning models to predict faults. Although this is effective and accurate, it leads to prolonged training times and higher prediction [7]. Having long training time can lead to delayed model updates, causing adaptability and scalability issues, while long prediction time causes delayed fault detection, which is important for real-time industrial machines. This study addresses these limitations by proposing an Enhanced Predictive Maintenance Method using the Sliding Window Method with XGB model (E.XGB) on sensor data, which can optimize training speeds and lower prediction latency while still maintaining a high accuracy [5]. By addressing these gaps, the study aims to enhance current predictive maintenance methods to satisfy the real-time requirements of industrial machinery.

The goal is to improve fault prediction accuracy, minimize false alarms, and reduce unnecessary maintenance and downtime. Faster training speeds and real-time predictions are also prioritized to support scalability and timely decision-making in industrial operations. The research focuses on IoT-driven machinery, using the AI4I 2020 Predictive Maintenance Dataset [8] and CNC Milling Dataset [9]. The proposed E.XGB model is evaluated against other machine learning methods like AdaBoost, Decision Tree, Random Forest, and Support Vector Machine. Performance is measured using metrics like accuracy, precision, recall, F1 score, ROC AUC, and prediction latency, with results benchmarked against existing approaches. This study's significance lies in improving fault detection accuracy, reducing training times, and enabling real-time predictions, which together lower downtime and maintenance costs. By bridging the gap between machine learning advancements and practical industrial applications, the research provides a robust foundation for future predictive maintenance innovations.

The rest of this study is organized as follows: Section II reviews related work on predictive maintenance, including algorithms, and its performance for IoT-based industrial systems. Section III details the methodology, including data preparation, model training, and optimization techniques. Section IV explains the proposed E.XGB method, supported by flowcharts, formulas, and calculations. Section V presents experimental results, comparing the proposed model's performance to previous methods. Section VI summarizes the study's contributions and provides suggestions for future research.

II. Related Works

In recent years, predictive maintenance for IoT-embedded industrial machinery has garnered significant attention. In [1], the authors proposed a predictive maintenance method that utilizes machine learning algorithms, particularly AdaBoost, to classify machine stops in knitting machines. Their system achieved 92% accuracy, enabling timely maintenance and improved efficiency in the textile industry. In terms of hyperparameter tuning, they employed grid search cross-validation (GridSearchCV) for hyperparameter optimization. However, the resulting output possessed high latency in processing and may hinder its application in real-time systems.

The challenge of imbalanced datasets is tackled by enhancing the KNN algorithm [10]. By employing techniques like feature engineering, standardization, and under-sampling, their model achieved a 97.1% accuracy. The ability to handle imbalanced data is crucial in predictive maintenance, although KNN's performance can vary based on dataset characteristics. The approach also explicitly mentions hyperparameter tuning and states that Grid Search tuning was applied to optimize the K-Nearest Neighbours (KNN) model. However, it does use an automated hyperparameter tuning method.

Similarly, in [11], the authors proposed a framework combining XGB and LOF models with XAI to address imbalanced datasets. Their method achieved 96% accuracy with XGB and 91% with LOF. The dual approach helps by focusing on predictive classification with XGB and anomaly detection with LOF. However, the study highlighted potential issues with the synthetic noise introduced by SMOTE and scalability challenges in real-time applications. However, no explicit mention of hyperparameter tuning was found in this study.

Multiple machine learning models including LR, KNN, and ANN, for failure prediction [12]. The ANN model outperformed others with an accuracy of 96.85%, but it struggled with false positives, indicating a need to balance sensitivity and specificity in complex environments. In this approach, structured hyperparameter tuning methods that include GridSearchCV and RandomizedSearchCV were used in their work.

LSTM networks combined with Auto Encoder is employed to predict tool wear in CNC milling machines [13]. Their model achieved 98% accuracy, showing improved performance over previous methods. However, long datasets could reduce the model's accuracy, and the authors recommended prioritizing relevant data through a weighting mechanism. Also, there was no hyperparameter tuning approach mentioned in the approach.

In another deep learning approach, reinforcement learning techniques like Q-learning and SARSA alongside LSTM networks is applied to monitor CNC tool conditions [14]. The SARSA algorithm achieved 98.66% accuracy. While reinforcement learning optimizes decision-making, the complexity of the model posed challenges in training, requiring large datasets and still misclassifying certain instances. Again, in this approach, no mention of hyperparameter tuning is involved.

Machine learning and deep learning methods for tool wear prediction were compared, showing that CNN and AE-LSTM outperformed KNN [15]. While deep learning models are more accurate, they are computationally intensive, raising concerns about their scalability. In this approach, there was no mention about the usage of hyperparameter tuning.

The use of SVM for detecting machine failures in predictive maintenance is compared in [16], achieving up to 88% accuracy in testing data. In terms of hyperparameter tuning, this approach employs grid search for selecting optimal hyperparameters (C and Gamma). However, the SVM's reliance on parameter tuning, such as C and gamma, can slow optimization, making it unsuitable for real-time applications.

LSTM models are used for predictive degradation modelling in milling machines, achieving 80% accuracy [17]. The advantage of this method lies in its ability to predict degradation by considering sequential dependencies. However, it struggled with imbalanced data and may not account for all failure modes, especially in more complex systems. On real-time systems, [2] integrated IoT and machine learning for predictive maintenance, using algorithms like SVM, RNN, and CNN. Their method achieved 87% accuracy with SVM on a milling dataset and 98% with CNN on a bearing dataset. While the models performed well, processing large datasets and extracting meaningful features for real-time predictive maintenance posed challenges.

A hybrid deep learning model combining CNN and LSTM for fault detection is proposed in [18], achieving 97.9% accuracy. The model's ability to capture both spatial and temporal patterns in multivariate sensor data made it effective for fault detection. However, its complexity and need for substantial annotated data slow down its real-time applicability.

A PM-C-LSTM model is used for wind turbines, achieving a 96.77% accuracy [19]. While promising for wind energy applications, the model's effectiveness across different environments requires further validation. Despite the advancements, the reviewed works reveal several gaps in predictive maintenance research. A significant issue is the trade-off between accuracy and processing speed. Deep learning models, like CNN-LSTM and hybrid models, achieve high accuracy but come with high computational costs, which may limit their use in real-time applications.

Models like AdaBoost [1] and SVM [16] also face challenges in terms of processing speed, as they require substantial parameter tuning, slowing down optimization. Managing imbalanced datasets remains another challenge.

While techniques like SMOTE and under-sampling improve model performance [10, 11], they may introduce synthetic noise or fail to generalize effectively. Furthermore, models may perform poorly when failure events are rare, highlighting the need for better methods to manage imbalanced data without sacrificing accuracy.

In summary, the research on predictive maintenance for IoT-embedded industrial machinery has made significant strides, but challenges in accuracy, processing speed, and handling imbalanced data persist. Moving forward, research should focus on optimizing the balance between accuracy and speed, improving the generalization of models across diverse datasets, and finding better methods to handle imbalanced data while avoiding the introduction of noise. Addressing these issues will pave the way for more efficient, dependable, and scalable predictive maintenance systems that can meet the demands of real-world industrial environments.

III. Methodology

A. Experimental Setup

This study evaluates the proposed Enhanced XGBoost (E.XGB) model for predictive maintenance by comparing it with the method by [1] and several baseline models. The E.XGB model builds upon the approach in [1] for IoT industrial applications, improving against the AB model with the proposed XGB model by incorporating minor enhancements. The method proposed by [1] is replicated in this study using the same configurations as the original study to be used as a comparison. The replicated Elkateb method, referred to as Enhanced AdaBoost (E.AB), is used as the primary benchmark. Additionally, three baseline models, DT, RF, and SVM, will serve as secondary benchmarks, using default parameters without optimization. All models will be trained and tested on both imbalanced and balanced datasets to ensure comprehensive evaluation. Performance is measured using metrics such as accuracy, precision, recall, F1-score, confusion matrices, ROC-AUC, training times, and prediction times. This study aims to address the challenges in the method in [1] and demonstrate the effectiveness of the proposed E.XGB model.

B. System Infrastructure

The predictive maintenance system for IoT-embedded machinery integrates real-time data collection, cloud-based processing, and machine learning to predict and prevent equipment failures. Fig. 1 illustrates the system's workflow in an industrial setting.

Sensors embedded in machines monitor critical parameters like vibration, temperature, speed, torque, and tool wear during operation. These sensors transmit real-time data to the cloud via secure, high-speed connections. The cloud provides the necessary computational resources to process large volumes of data. In the cloud, data undergoes preprocessing to clean and organize it, ensuring it is accurate and ready for analysis. Machine learning models then analyze this data to detect patterns, trends, and anomalies. Trained on historical data, these models predict potential faults by identifying early warning signs, such as abnormal temperature increases or irregular torque patterns. When a potential issue is detected, the system generates alerts for maintenance teams through dashboards, notifications, or emails. Alerts specify the affected machine or component, the type of fault, and its urgency, enabling technicians to address problems proactively. By preventing unexpected breakdowns, this system reduces downtime, cuts repair costs, and extends machine life. As more data is collected, the system improves its accuracy, making predictive maintenance an efficient and reliable alternative to traditional maintenance practices.

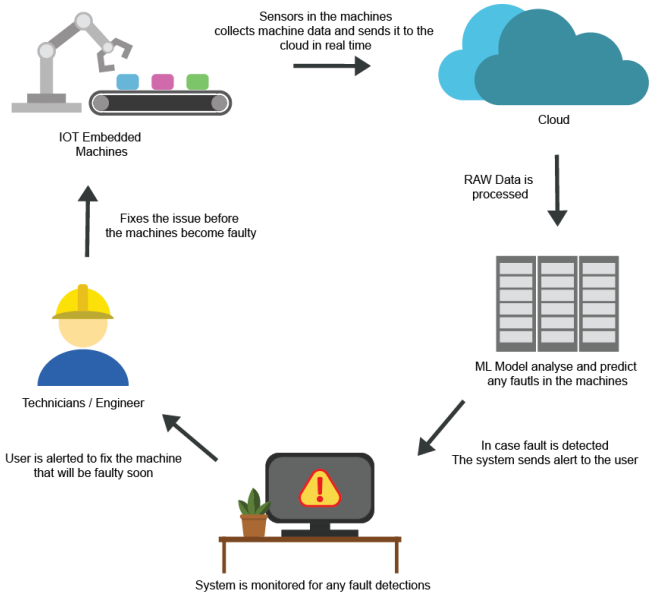

Fig. 1. System overview.

C. Methodology

This study follows the CRISP-DM methodology, a structured and iterative framework ideal for developing predictive maintenance systems [18]. Fig. 2 illustrates the entire methodology overview. It begins with data collection, using existing datasets to ensure high-quality and representative data. In data preprocessing, key steps include data cleansing, addressing imbalances, data smoothing, standardization, and splitting data into training (80%) and testing (20%) sets.

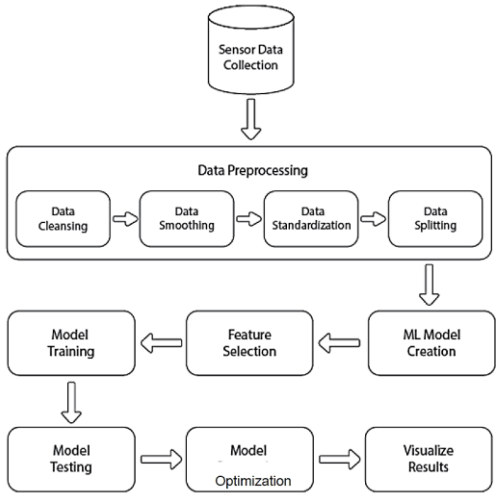

Fig. 2. Methodology overview.

During the model creation phase, the study replicates a prior model and develops three additional benchmark models. Feature importance is analyzed before training begins. The model testing phase evaluates performance on the test set using metrics like accuracy, precision, and F1 score to assess generalization capability. The proposed E.XGB model is then optimized through techniques like hyperparameter tuning and cross-validation to enhance accuracy and efficiency. Finally, visualizing results with tools such as confusion matrices and ROC curves provides insights into model performance and supports transparent communication with stakeholders.

D. Technical Setup and Development Environment

The simulation for this study was developed in Visual Studio Code (VS Code), a popular, free, and open-source code editor known for its versatility and extensive support for plugins [20]. The programming language used is Python, widely recognized for its effectiveness in data science and machine learning due to its powerful libraries [21].

Several Python libraries were employed for simulation. Pandas was used for data cleaning, preparation, and transformation [22]. Scikit-learn facilitated data pre-processing, machine learning model imports, feature selection, and performance metrics calculations. The Time library helped track training and processing time, while Matplotlib and Seaborn were used for visualizations.

The simulations were run on a system with the following specifications:

- Processor: Intel(R) Core (TM) i7-8750H CPU
- Memory: 32 GB RAM
- Operating System: Microsoft Windows 11 Home Single Language.

E. Dataset

Datasets are a structured collection of data used for analysis, modelling, and decision-making in various fields such as machine learning, statistics, and research. One of the key limitations of the previous approach is its reliance on a single dataset for experimentation [1, 2, 10, 11, 12, 13, 14, 15, 16, 19]. This restricts the generalizability of the model, as its performance has not been validated across diverse IoT environments with varying sensor data and operational conditions. In the context of IoT-based predictive maintenance, different datasets may exhibit variations in data distribution, sensor noise, and failure patterns, which a single dataset cannot fully capture. Without evaluation on multiple datasets, the robustness of the method remains uncertain, increasing the risk of overfitting to dataset-specific characteristics. Therefore, in our experiment, we use two datasets to enhance the generalizability and robustness of our proposed approach, ensuring its applicability across different IoT environments. The datasets used are the AI4I 2020 Dataset [8] and the CNC Milling Dataset [9], with each representing synthetic and real-world data, respectively. Additionally, these datasets exhibit both imbalanced and balanced characteristics, allowing us to assess the model's ability to handle class imbalance issues, which are common in real-world predictive maintenance applications.

1) AI4I2020 dataset: The AI4I 2020 Predictive Maintenance Dataset [8] is a synthetic dataset designed to replicate real-world industrial predictive maintenance data. It is widely used as a benchmark for machine learning algorithms, particularly for handling imbalanced datasets in predictive maintenance, quality assurance, and anomaly detection tasks. The dataset combines time-series and static data, including sensor readings, control signals, and process parameters, making it a valuable resource for developing predictive maintenance methods. The dataset contains 10,000 rows with two IDs, which are UID and Product ID, six features, and six failure modes. The features include product type, air temperature [K], process temperature [K], rotational speed [rpm], torque [Nm], and tool wear [min]. The six failure modes are machine failure, tool wear failure (TWF), heat dissipation failure (HDF), power failure (PWF), overstrain failure (OSF), and random failures (RNF).

2) CNC milling dataset: The CNC Milling Dataset from the University of Michigan SMART Lab [9] is a real-world dataset based on machining experiments conducted on a CNC milling machine. Data was collected from four machine motors, X, Y, Z axes, and spindle at a sampling rate of 100ms during 18 experiments on wax blocks. The dataset includes 25,286 rows with 55 features, including 1 ID and 3 failure modes as tool_condition, machining_finalized, and passed_visual_inspection. This study will use data from all 18 experiments but focus on selected features to challenge the model with limited input data. The tool_condition feature will be the target variable. Unlike the synthetic and imbalanced AI4I 2020 dataset, this balanced dataset provides an opportunity to evaluate the model's performance in a real-world environment, enhancing the robustness of the experiment.

IV. Enhanced Predictive Maintenance Method Using XGB

The proposed enhanced predictive maintenance method that is used in this study is designed based on the [1] approach to predictive maintenance for IOT industrial applications. However, the core model is modified along with several other minor changes in this study to further enhance the method proposed by [1]. This study's proposed enhanced predictive maintenance method aims to improve by eliminating some of the challenges present in that method.

Fig. 3 illustrates the flowchart of the entire enhanced predictive maintenance method. The flowchart provides a detailed pipeline for predictive fault detection using sensor data and an E.XGB model. This end-to-end process is designed to systematically prepare the data, refine feature selection, optimize the model, and deliver accurate predictions for identifying faults. By integrating feature importance methods, data preprocessing, and hyperparameter optimization, the pipeline aims to achieve reliable and efficient results, particularly for predictive maintenance applications.

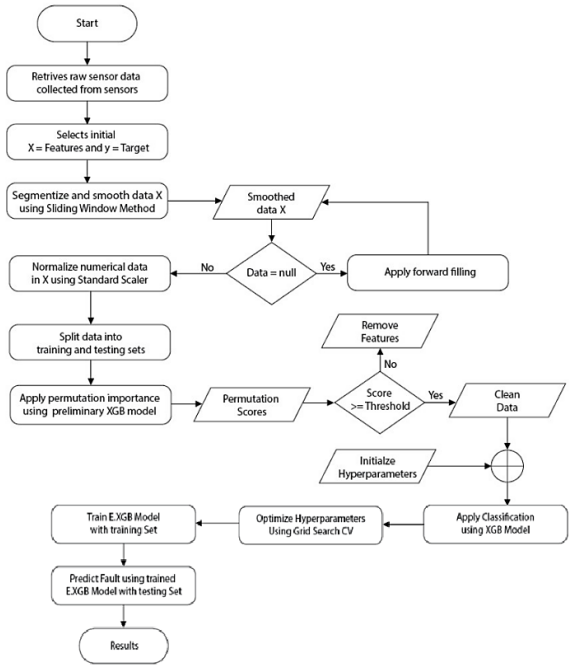

Fig. 3. Enhanced predictive method overview.

A. Data Pre-Processing

Pre-processing is the first and critical step in the machine learning workflow to ensure that the data is clean, consistent, and suitable for analysis. Raw data is often messy, incomplete, or unstructured, which can lead to inaccurate or inefficient model training. Preprocessing helps address these issues by transforming the data into a format that models can understand and learn effectively. After receiving the data collected from the sensors and the initial features x and target y selection is done, several steps are gone through to pre-process the data. Detailed information on how each pre-processing step is done is described in the sections below.

B. Sliding Window Method

One of the key enhancements in our proposed approach is the introduction of a data smoothing process using the Sliding Window Method. This technique is particularly well-suited for preprocessing IoT data, including streaming data, as demonstrated in [23]. By applying the Sliding Window Method to raw sensor data, we effectively smooth fluctuations and manage missing values, improving data consistency. The method segments the data into fixed-sized windows and computes the mean within each window, ensuring a more stable and reliable representation of the underlying patterns in the dataset.

The mean within each window starting at index t is computed as:

$$\mu_t = \frac{1}{K} \sum_{i=t}^{t+K-1} x_i$$

where,

μt is the mean of the window starting at position t.

Xi represents the data points in the window.

k is the number of elements in each window.

The summation runs from i=t to t+k−1

The missing values in the dataset are fixed using the forward filling method.

TABLE I. SLIDING WINDOW PARAMETERS

Parameter	Method	Inplace	Rolling	Window	Minimum required data points
Range	Forward filling	true	mean	3	1

Table I summarizes the parameters used for the Sliding Window Method in the proposed E.XGB approach. The forward fill (ffill) method replaces missing values with the last valid entry, ensuring data continuity. With *inplace* set to true, changes are made directly to the dataset. A rolling window of size 3 computes the mean over three consecutive values, moving forward one step at a time. The minimum required data points parameter is set to 1, ensuring that the mean is calculated even if some values are missing, as long as at least one valid value exists. This method smooths fluctuations while effectively handling missing data.

C. Data Normalization

The next step for data preprocessing in the proposed method is data scaling. During the data scaling stage, numerical data in the dataset are selected to undergo normalization. For this, the StandardScaler method is imported from Scikit-Learn's preprocessing library. The StandardScaler uses the z-score normalization technique to normalize the data. The z-score normalization technique is applied to each data point Di in category j, which calculates the number of standard deviations each point is away from the mean of its category. The z-score normalization is defined as:

$$D_j^{i'} = \frac{D_j^i - \mu_j}{\sigma_j}$$

where,

$D_j^{i'}$ is the normalized data point for feature i in category j,

D_j^i is the original data point in category j,

μ_j is the mean of data category j,

σ_j is the standard deviation of data category j.

Normalization ensures that all features are on a similar scale, centered at the origin, with a peak of 1. This improves the stability of training by reducing variance and the impact of outliers. This method ensures that features have a mean of 0 and a standard deviation of 1, making the model more robust to outliers.

D. Data Splitting

After normalization, the dataset is split into training and testing sets to ensure the model trains on one subset and is tested on unseen data, reducing bias. Without splitting, testing on the same dataset used for training could lead to misleading results.

TABLE II. DATA SPLIT PARAMETERS

Parameter	Train size	Test size	Random state
Value	0.8	0.2	42

The train_test_split function from Scikit-Learn's model selection library is used for this purpose, with parameters specified in Table II. For this study, 80% of the data is allocated for training and 20% for testing. The data is shuffled randomly before splitting, with a random state of 42 set to ensure reproducibility.

E. Feature Selection

After splitting the data, feature selection is performed using permutation importance, a technique that evaluates the significance of each feature by shuffling its values and observing the impact on model performance, with a significant drop in accuracy indicating importance. The permutation importance function from Scikit-Learn's inspection library is applied to the preliminary XGB model and dataset to calculate a reference score. The importance i_j for feature f_j is calculated as follows:

$$i_j = s - \frac{1}{K}\sum_{k=1}^{K} s_{k,j}$$

where,

K is the total number of data points in the dataset,

k is the k^{th} datapoint.

For each feature, the values are shuffled to create a distorted dataset, and the model is re-scored to determine feature importance based on the performance drop. The process uses the number of repeats parameter to specify the number of shuffles, where higher values provide more reliable scores but increase computation time.

TABLE III. PERMUTATION IMPORTANCE PARAMETERS

Parameter	Number of estimators	Maximum depth	Learning rate	Number of repeats
Value	100	10	0.05	10

Table III shows the importance of the permutation parameters used. The initial XGB model is configured with key hyperparameters of number of estimators to 100 trees, maximum depth to 10 to balance complexity and overfitting, and learning rate of 0.05, to control tree contribution. Features with low importance scores, based on a predefined threshold, are removed to streamline the dataset, retaining only the most relevant features and improving model efficiency and performance.

F. XGB Classification

Once data preprocessing is complete, the core XGB model is initialized using the XGBoost classifier from the *xgboost* library. XGB is a highly efficient implementation of the gradient boosting framework, known for its speed, accuracy, and flexibility in handling structured data. It builds an ensemble of decision trees sequentially, optimizing each tree to correct errors from the previous ones using gradient descent to minimize the loss function. The training process starts with an initial prediction, often the mean of the target values. The objective function combines a loss function to measure prediction errors and a regularization term to prevent overfitting. The function is:

$$Obj(\theta) = \sum_{i=1}^{m} L(y_i, \hat{y}_i) + \sum_{k=1}^{K} \Omega(f_k)$$

where,

$L\ (y_i, \hat{y}_i)$ is the loss function, which is the difference between true and predicted values,

$\Omega\ (f_k)$ is the regularization term for the weak learner f_k,

m is the number of data points.

K is the number of trees.

At each iteration, the model adds a new tree, updating the prediction. The final prediction is the sum of all tree predictions. XGB excels at handling large datasets and complex relationships efficiently. Its combination of speed, accuracy, and regularization makes it a top choice for structured data and a frequent winner in machine learning competitions.

G. Hyperparameter Optimization Using GridSearchCV

GridSearchCV is used to fine-tune the hyperparameters of the XGB model by testing all possible combinations of predefined values to find the best set. It evaluates each combination using 3-fold cross-validation, ensuring the model performs well on unseen data while avoiding overfitting. This process improves both accuracy and robustness. Table IV shows the ranges for key hyperparameters set and Table V shows the GridSearchCV parameters used.

TABLE IV. XGB HYPERPARAMETER SEARCH RANGE

Parameter	Number of estimators	Maximum depth	Learning rate	Sub sample
Range	50 - 200	1 - 10	0.01 - 0.07	0.01 - 0.07

TABLE V. GRIDSEARCHCV PARAMETERS

Parameter	Model	Scoring	CV
Value	XGBClassifier (eval_metric='logloss')	accuracy	3

For this study, GridSearchCV is imported from Scikit-Learn's model selection library and applied to the XGB classifier, initialized with an evaluation metric set based on the Logarithmic Loss value. The search grid includes ranges for key hyperparameters such as the number of estimators at 50 to 200, maximum depth at 1 to 10, learning rate at 0.01 to 0.07, and subsample at 0.01 to 0.07. These parameters influence the model's performance, and GridSearchCV compares average accuracy scores across all combinations to select the best one. The optimal hyperparameters are then used to build the final XGB model.

V. RESULTS AND DISCUSSION

This section summarizes the experimental results on the AI4I2020 dataset and CNC Milling dataset, comparing various

machine learning models across key metrics such as accuracy, precision, recall, F1-score, ROC-AUC, confusion matrices, training time, and prediction time. The results are organized into tables and visualized with figures to provide a comprehensive view of model performance and to facilitate comparisons.

A. Pre-processing on AI4I2020 Dataset

The AI4I2020 dataset underwent a series of preprocessing steps to ensure quality and consistency. Initially, the dataset was checked for missing values, and no null entries were found. Irrelevant features such as UDI, Product ID, and Type were removed, as they did not contribute to machine failure predictions, leaving air temperature, process temperature, rotational speed, torque, and tool wear as the selected features. The study also focused on predicting overall machine failures rather than specific failure types, so failure mode features like TWF, HDF, and PWF were excluded.

Fig. 4. Data balance in AI4I2020 dataset.

As shown in Fig. 4, the dataset revealed a significant class imbalance, with only 3.4% of instances labelled as machine failures. The data was then smoothed and segmented using a sliding window method. To address the varying scales of features, standardization was applied, ensuring all features had a mean of 0 and a standard deviation of 1, making them comparable and enhancing model performance. Finally, the data was split into 80% training and 20% testing subsets, preparing it for machine learning tasks.

TABLE VI. PARAMETER OPTIMIZATION RESULT ON AI4I2020 DATASET

Parameter	Number of estimators	Maximum depth	Learning rate	Sub sample
Optimum	200	8	0.07	0.5

Hyperparameter optimization for the XGB model was performed using GridSearchCV, resulting in an enhanced model configuration. The optimal parameters are shown in Table VI, which includes the number of estimators set to 200, maximum depth set to 8, learning rate set to 0.07, and subsample set to 0.5. These parameters were carefully chosen to balance model complexity and generalization, ensuring robust performance. A higher maximum depth allowed the model to capture more complexity without overfitting, while a smaller learning rate enabled gradual and stable learning. The subsample value helped mitigate overfitting by training the model on random subsets of data at each iteration. With these optimized hyperparameters, the E.XGB model achieved significant improvements in metrics such as accuracy, precision, recall, and F1-score, demonstrating its suitability for predicting machine failures in the AI4I2020 dataset.

B. Model Results on AI4I2020 Dataset

The classification performance of various models on the AI4I2020 dataset is summarized in Fig. 5 and Table VII, comparing E.XGB, E.AB, RF, DT, and SVM based on accuracy, precision, recall, F1-score, ROC AUC, training time, and prediction time. Among all models, the proposed E.XGB model outperforms the others, achieving the highest accuracy of 99.05%, precision of 93.62%, F1-score of 82.25%, and ROC AUC of 97.10%.

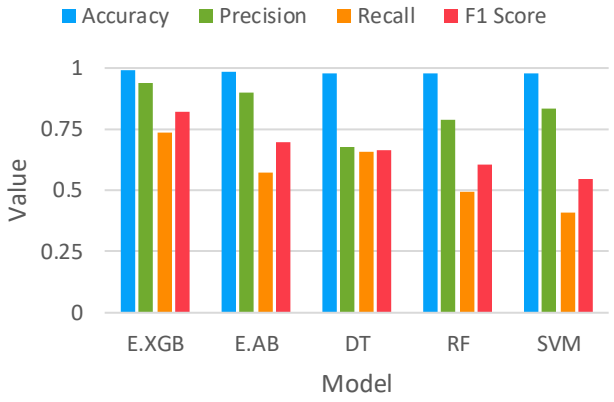

Fig. 5. Efficiency results on CNC AI4I2020 dataset.

Compared to E.AB, RF, DT, and SVM, the E.XGB demonstrates superior predictive capability while maintaining efficiency. Although DT achieves a recall of 65.57%, slightly lower than E.XGB's 73.33%, it lags in precision at only 67.80%, making it less reliable overall.

TABLE VII. PERFORMANCE METRICS OF MODELS ON AI4I2020 DATASET

Details	E.XGB	E.AB	DT	RF	SVM
Accuracy (%)	99.05	98.50	98.00	98.05	97.95
Precision (%)	93.62	89.74	67.80	78.95	83.33
Recall (%)	73.33	57.38	65.57	49.18	40.98
F1-Score (%)	82.25	70.00	66.67	60.61	54.95
ROC AUC (%)	97.10	94.64	87.26	86.63	85.35
Training Time (s)	0.2102	3.9122	0.0312	0.4531	0.4343
Prediction Time (s)	0.0001	0.0544	0.0001	0.0189	0.0937

In terms of computational performance, E.XGB has a training time of 0.2102s, significantly faster than E.AB at 3.9122s and RF at 0.4531s, while being slightly slower than DT at 0.0312s. For prediction time, E.XGB and DT are the fastest at 0.0001s, making them highly efficient for real-time applications. Although DT is computationally fast, it suffers from lower precision and an overall weaker predictive performance. Overall, for the AI4I2020 dataset, E.XGB proves to be the most effective model, offering the best trade-off between accuracy, precision, recall, and efficiency. DT, despite

being computationally efficient, falls short in terms of precision, making E.XGB is the most suitable choice for predictive maintenance applications in IoT-embedded machinery.

C. Pre-processing on CNC Milling Dataset

The CNC Milling Dataset was pre-processed to ensure high-quality data for analysis. Missing values were checked and found to be absent, confirming data completeness. Feature selection was then performed, and a set of relevant features was chosen based on preliminary importance tests. The selected features included x1_actualposition, y1_actualposition, z1_actualposition, s1_actualposition, and m1_current_feedrate, with tool condition as the target feature, which directly relates to machinery degradation.

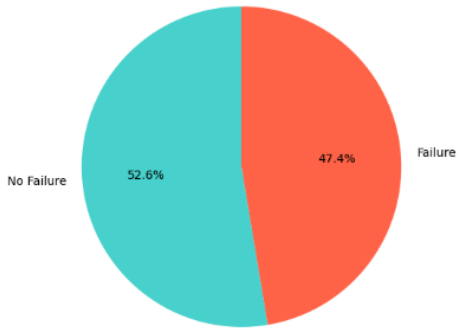

Fig. 6. Data balance in CNC milling dataset.

Unlike the AI4I2020 dataset, the CNC Milling dataset exhibited a balanced class distribution, as shown in Fig. 6, with 47.4% labelled as machine failures. The data is then smoothed and segmented using the sliding window method. The dataset also revealed significant differences in feature scales, with features like X1_ActualPosition spanning wide ranges. To address this, all features were standardized, ensuring equal contribution to model performance. The final step was splitting the data into 80% training and 20% testing sets, preparing it for model training and evaluation.

TABLE VIII. PARAMETER OPTIMIZATION RESULT ON CNC MILLING DATASET

Parameter	Number of estimators	Maximum depth	Learning rate	Sub sample
Optimum	200	10	0.07	0.7

GridSearchCV was applied to the base XGB model to find the optimal hyperparameters. The best combination of parameters found is as shown in Table VIII, where the number of estimators is set to 200, the maximum depth set to 10, the learning rate set to 0.07, and the subsample set to 0.7. These parameters were chosen to strike a balance between model complexity and generalization. The maximum depth of 10 allowed the model to capture sufficient complexity, while the learning rate of 0.07 ensured gradual learning. The subsample value of 0.7 helped reduce overfitting by training the model on a randomly selected subset of the data. These hyperparameters improved the model's performance, as evidenced by better evaluation metrics such as accuracy, precision, recall, and F1-score.

D. Model Results on CNC Milling Dataset

The classification performance of various models on the CNC Milling dataset is summarized in Fig. 7 and Table IX, comparing E.XGB, E.AB, RF, DT, and SVM based on accuracy, precision, recall, F1-score, ROC AUC, training time, and prediction time. Among these models, the proposed E.XGB demonstrates superior performance, achieving the highest accuracy of 99.01%, precision of 99.57%, recall of 98.30%, F1-score of 98.93%, and ROC AUC of 99.98%.

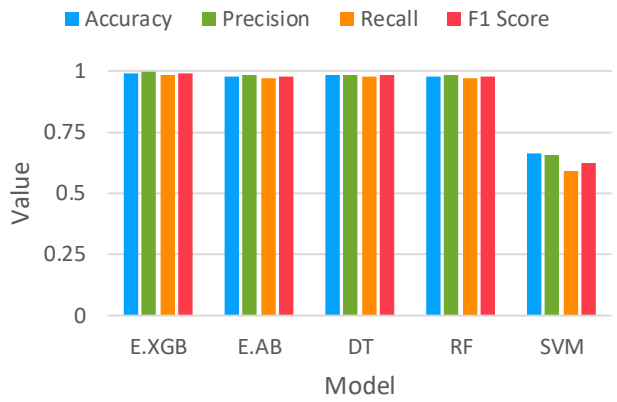

Fig. 7. Efficiency results on CNC milling dataset.

Compared to E.AB, RF, DT, and SVM, E.XGB consistently delivers higher predictive capability while maintaining computational efficiency. In terms of training time, E.XGB completes training in just 0.3126s, significantly outperforming E.AB at 4.6340s, RF at 1.8848s, and SVM at 81.1611s, while being slightly slower than DT at 0.0473s. Similarly, for prediction time, E.XGB and DT are the fastest at 0.0001s, far surpassing the efficiency of other models, particularly SVM, which has the slowest prediction time at 6.8742s.

TABLE IX. PERFORMANCE METRICS OF MODELS ON CNC MILLING DATASET

Details	E.XGB	E.AB	DT	RF	SVM
Accuracy (%)	99.01	97.71	98.16	97.88	66.53
Precision (%)	99.57	98.19	98.38	98.62	65.72
Recall (%)	98.30	96.86	97.67	96.82	58.95
F1-Score (%)	98.93	97.52	98.02	97.71	62.15
ROC AUC (%)	99.98	99.71	99.64	99.87	72.29
Training Time (s)	0.3126	4.6340	0.0473	1.8848	81.1611
Prediction Time (s)	0.0001	0.0696	0.0001	0.0781	6.8742

Despite DT being the fastest to train and predict, it still falls short in terms of accuracy of 98.16%, precision of 98.38%, and recall of 97.67%, making it less reliable for high-accuracy predictive maintenance applications. In contrast, SVM struggles significantly with an accuracy of only 66.53% and the lowest recall of 58.95%, proving unsuitable for this dataset.

Overall, E.XGB once again stands out as the most effective model for predictive maintenance in IoT-embedded machinery, offering the best balance of accuracy, precision, recall, and efficiency.

VI. Conclusion

In conclusion, this study proposes an enhanced predictive maintenance method for IoT-embedded industrial machinery, addressing challenges related to prediction accuracy, training efficiency, and prediction latency. The core of the method is the E.XGB model, which integrates enhanced feature selection, preprocessing, and hyperparameter optimization to overcome limitations of traditional approaches. The model demonstrated superior performance on the AI4I2020 and CNC Milling datasets, excelling in accuracy, precision, recall, and F1-scores, crucial for minimizing false positives and negatives in fault detection. It achieved 99.05% accuracy on the AI4I 2020 dataset and 99.01% accuracy on the CNC Milling dataset. Moreover, the proposed model demonstrated training speed of approximately 94% and prediction speeds of approximately 99.8% improvement than the E.AB model, thus meeting real-time industrial application requirements.

The optimized training and prediction pipelines resulted in significant reductions in computational time, making the model suitable for real-time applications. A comparative analysis with the E.AB method from previous research, as well as baseline models DT, RF, and SVM, highlighted the E.XGB model's consistent superiority. Its combination of advanced optimization techniques and lightweight design enables scalability across diverse operational conditions. The primary goal of the research which is enhancing predictive maintenance was achieved by improving accuracy, training efficiency, and prediction speed. Permutation importance and hyperparameter tuning enabled the identification of critical features for precise fault detection. Optimized preprocessing and grid search tuning reduced training time, while the lightweight architecture ensured low-latency predictions essential for real-time decision-making.

The proposed method minimizes unplanned downtime, reduces maintenance costs, and extends machinery lifespan, with scalability and adaptability for various industries. By enhancing predictive accuracy, training speed, and prediction latency, this study bridges the gap between theoretical machine learning advancements and their practical applications in industrial maintenance, contributing to a more efficient and sustainable industrial ecosystem.

Future research could focus on extending the proposed E.XGB model towards integration with IoT and edge devices, enabling deployment in resource-constrained environments for real-time predictive maintenance. In addition, exploring hybrid approaches that combine E.XGB with deep learning techniques such as CNNs or LSTMs may further enhance the model's ability to capture complex temporal and nonlinear fault patterns. To ensure adoption in real industrial settings, incorporating explainable AI (XAI) methods will be essential for improving model interpretability and building trust among engineers and decision-makers.

A Hybrid Deep Learning and Forensic Approach for Robust Deepfake Detection

Sales Aribe Jr.
Information Technology Department, Bukidnon State University, Malaybalay City, Philippines

***Abstract*—The rapid evolution of generative adversarial networks (GANs) and diffusion models has made synthetic media increasingly realistic, raising societal concerns around misinformation, identity fraud, and digital trust. Existing deepfake detection methods either rely on deep learning, which suffers from poor generalization and vulnerability to distortions, or forensic analysis, which is interpretable but limited against new manipulation techniques. This study proposes a hybrid framework that fuses forensic features—including noise residuals, JPEG compression traces, and frequency-domain descriptors—with deep learning representations from convolutional neural networks (CNNs) and vision transformers (ViTs). Evaluated on benchmark datasets (FaceForensics++, Celeb-DF v2, DFDC), the proposed model consistently outperformed single-method baselines and demonstrated superior performance compared to existing state-of-the-art hybrid approaches, achieving F1-scores of 0.96, 0.82, and 0.77, respectively. Robustness tests demonstrated stable performance under compression (F1 = 0.87 at QF = 50), adversarial perturbations (AUC = 0.84), and unseen manipulations (F1 = 0.79). Importantly, explainability analysis showed that Grad-CAM and forensic heatmaps overlapped with ground-truth manipulated regions in 82 per cent of cases, enhancing transparency and user trust. These findings confirm that hybrid approaches provide a balanced solution—combining the adaptability of deep models with the interpretability of forensic cues—to develop resilient and trustworthy deepfake detection systems.**

I. Introduction

The emergence of generative artificial intelligence (AI) models, such as GANs and diffusion models, has dramatically advanced the creation of synthetic media. These technologies, popularly associated with deepfakes, produce hyper-realistic images and videos that are increasingly difficult to distinguish from authentic content. Deepfake content is proliferating rapidly, with recent reports estimating that deepfake files surged from around 500,000 in 2023 to over 8 million in 2025, business losses an average of nearly $500,000 per deepfake-related incident, and human detection rates on high-quality deepfake videos dropping to 24.5 per cent, especially when compression or post-processing is involved [1]. While deepfakes have legitimate applications in film production, education, and digital creativity, they also pose serious societal risks, including misinformation, identity fraud, political manipulation, and erosion of public trust in digital media [2], [3].

Current deepfake detection research has largely focused on deep learning approaches, particularly CNNs, recurrent neural networks (RNNs), and, more recently, transformer-based architectures. These models learn discriminative representations that can separate authentic from manipulated content. Despite their success, they suffer from several limitations: poor generalization across datasets, sensitivity to compression or adversarial attacks, and a lack of transparency in decision-making [4], [5]. In contrast, classical forensic analysis—based on principles of image formation and physical signal processing—examines sensor noise patterns, JPEG compression artifacts, or frequency inconsistencies. These techniques are interpretable and reliable for certain manipulations, but they often fail to adapt to new generation techniques [6], [7].

The shortcomings of purely deep learning or purely forensic approaches have spurred interest in hybrid frameworks that integrate both [8]. Hybrid methods combine the adaptability of learned representations with the interpretability of forensic traces, yielding systems that are more robust and explainable [9], [10]. For instance, ensembles of CNNs and transformers capture both local pixel-level cues and global temporal context, while forensic features provide interpretable indicators such as abnormal noise residuals or disrupted frequency patterns. Recent studies suggest that such fusion can mitigate the challenges of cross-dataset generalization and robustness to real-world distortions [11], [12], [13], [14].

Nevertheless, several gaps remain. First, many detection systems continue to overfit to specific datasets, limiting their ability to generalize to novel manipulation techniques. Second, most detectors exhibit performance degradation under realistic video conditions such as compression, resolution changes, and adversarial noise. Third, explainability remains underexplored; stakeholders such as law enforcement agencies, media organizations, and social platforms increasingly require interpretable justifications for automated decisions. Finally, resource efficiency—critical for real-time deployment—remains an open challenge.

This study addresses these challenges by proposing a hybrid deepfake detection framework that fuses forensic features with deep learning representations. Specifically, the approach integrates noise residuals, compression inconsistencies, and frequency-domain descriptors with CNN and transformer-based features through a fusion architecture. The model is evaluated across multiple datasets, manipulation types, and compression levels, with emphasis on cross-dataset generalization and robustness under adversarial settings. In addition, interpretability is enhanced by visualizing manipulated regions

and forensic traces, supporting explainable AI in multimedia forensics.

The key contributions of this study are fourfold. First, it proposes a hybrid deepfake detection framework that uniquely integrates forensic cues—including noise residuals, JPEG compression traces, and frequency-domain descriptors—with deep learning representations from convolutional neural networks and vision transformers through a dedicated fusion architecture. Second, the proposed model emphasizes robustness and cross-dataset generalization, addressing the persistent limitations of existing detectors that struggle with unseen manipulations, compression, and adversarial distortions. Third, the study incorporates an explainability module that fuses Grad-CAM visualizations with forensic heatmaps to enhance the transparency and interpretability of detection results. Finally, this research bridges the gap between AI adaptability and forensic interpretability, contributing to the development of more trustworthy, resilient, and explainable deepfake detection systems.

II. Related Work

A. Deep Learning-Based Approaches

Most state-of-the-art deepfake detectors rely on deep neural networks to automatically learn discriminative features from data. CNNs have been widely adopted due to their ability to capture spatial artifacts in manipulated images and videos. For instance, Afchar et al. [15] proposed MesoNet, a compact CNN architecture designed for video forgery detection, demonstrating strong performance on low-resolution inputs. Similarly, Rossler et al. [16] introduced the FaceForensics++ benchmark and showed that CNN-based models trained on large-scale datasets can detect multiple manipulation techniques.

Beyond CNNs, RNNs, and Long Short-Term Memory (LSTM) models have been applied to capture temporal inconsistencies in videos [17]. More recently, transformer-based architectures have gained traction due to their ability to model long-range dependencies. ViT-based models and spatio-temporal transformers have been shown to outperform CNNs in cross-dataset evaluations [18]. Despite their success, purely deep learning-based methods suffer from limited interpretability and often fail to generalize across unseen manipulation techniques, particularly when trained on specific datasets [5].

B. Forensic-Based Approaches

Unlike deep learning methods, forensic approaches are grounded in principles of digital image formation and signal processing. These methods exploit the fact that manipulations often disrupt underlying statistical or physical patterns of real images. For example, Photo Response Non-Uniformity (PRNU) has been used to detect inconsistencies in sensor noise, which can reveal tampered regions [19]. Similarly, Anwar et al. [20] showed that local descriptors derived from residual noise can be repurposed as CNN filters for forgery detection.

Compression-based forensic features, such as analyzing JPEG block artifacts and quantization inconsistencies, have also been widely explored [21]. Frequency-domain analysis, particularly through Discrete Cosine Transform (DCT) and wavelet features, provides another line of defense against synthetic content [22]. These forensic cues offer interpretability and robustness to small perturbations, but they often lack adaptability to new manipulation techniques, especially as generative models become more sophisticated.

C. Hybrid Approaches

To overcome the limitations of purely data-driven or purely forensic strategies, hybrid approaches have emerged that combine both. Mancy et al. [23] and Fardin et al. [18] proposed a hybrid model that integrates handcrafted forensic features with CNN-based deep features, showing improved robustness to compression and unseen manipulations. Chen et al. [25] developed a generalizable detector by fusing spatial forensic cues with learned representations, achieving competitive performance across multiple datasets.

Hybrid models leverage the strengths of both worlds. Deep learning ensures adaptability to evolving generative methods, while forensic features provide interpretability and resilience under distortions. For example, Haliassos et al. [11] introduced an audio-visual hybrid framework that detected mismatches between lip movements and speech signals, outperforming unimodal methods. Similarly, Dang et al. [26] demonstrated that fusing frequency-domain features with CNN embeddings significantly enhances cross-dataset generalization.

D. Research Gap

While progress has been made, several gaps remain. First, many detectors overfit to specific datasets and manipulation techniques, limiting real-world applicability. Second, robustness under practical conditions such as compression, resolution degradation, and adversarial attacks remains underexplored. Third, explainability in hybrid frameworks is still underdeveloped, despite increasing demand from forensic analysts, regulators, and end-users. These challenges motivate the proposed hybrid framework, which fuses deep features with forensic cues while explicitly emphasizing cross-dataset generalization, robustness, and interpretability.

III. Methodology

This study proposes a hybrid detection framework that integrates forensic analysis with deep learning models. The methodology is organized into seven components: dataset selection, preprocessing, feature extraction, hybrid model architecture, training protocol and validation, real-time deployment setup, and evaluation strategy.

A. Datasets

To achieve robustness and cross-dataset generalization, three benchmark datasets were employed. FaceForensics++ [16], a widely used benchmark which provides a large-scale collection of manipulated videos generated using various multiple manipulation techniques, while Celeb-DF v2 [27] offered high-quality celebrity deepfakes that are particularly challenging for detectors. The DeepFake Detection Challenge (DFDC) dataset [24] [5] contributed more than 100,000 clips exhibiting a wide range of real-world variations. Collectively, these datasets ensured both diversity and realism in evaluating the proposed approach. Thus, this combination enables the evaluation of both in-distribution and out-of-distribution performance, addressing generalization concerns.

B. Preprocessing

All video data were decomposed into individual frames at a fixed sampling rate valued at 25 fps. Frames were resized to 224 × 224 pixels and normalized to the [0,1] range. To preserve compression artifacts, which serve as important forensic cues, the frames were stored under artifact-preserving JPEG compression at varying quality sensor-level noise patterns of 50, 75, and 100. This design choice contrasts with standard preprocessing methods that typically remove compression traces, thus demonstrating the model's focus on maintaining forensic fidelity for improved manipulation detection. Face alignment was applied using the Multi-task Cascaded CNN (MTCNN), guaranteeing consistent cropping and alignment across frames to reduce variability unrelated to manipulation.

C. Feature Extraction

The framework draws upon both forensic and deep learning-based features. Forensic analysis was performed by extracting noise residuals through PRNU, which captures inconsistencies in sensor noise [28]; by analyzing JPEG compression patterns through block-level quantization artifacts to detect anomalies in compression traces [29]; and by deriving frequency-domain descriptors such as DCT coefficients and spectral distributions [22], which reveal spectral anomalies introduced during generation. These handcrafted features provided interpretable signals of manipulation.

In parallel, deep learning features were obtained using two complementary models. A ResNet-50 backbone [30] extracted local pixel-level features sensitive to subtle artifacts, while a Vision Transformer [31] captured long-range dependencies and temporal coherence across frames. The combination of CNN-based and transformer-based representations allowed the system to learn both fine-grained and holistic patterns of manipulation.

D. Hybrid Model Architecture

The proposed hybrid architecture fuses forensic and deep learning features through a dedicated fusion layer that enables joint learning, as shown in Fig. 1. Unlike conventional approaches that independently apply deep learning or forensic analysis, the proposed framework integrates both feature domains within a unified learning process. The fusion layer is not a simple concatenation but a trainable joint-representation space that learns correlations between forensic cues and deep model embeddings. This integration enables complementary feature learning that enhances robustness and interpretability, representing a methodological advancement over existing single-model detectors.

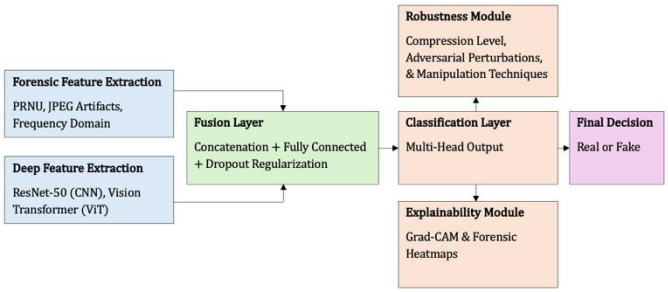

Fig. 1. Proposed hybrid deepfake detection model architecture.

In this framework, forensic and deep features are first extracted independently (feature extraction), after which they are concatenated and passed through a fully connected layer with dropout regularization to reduce overfitting (fusion layer). The fused representation is then processed by a multi-head classification block that outputs the probability of an input being real or manipulated (classification layer). To enhance interpretability, the architecture incorporates an explainability module that generates Gradient-weighted Class Activation Mapping (Grad-CAM) visualizations from deep features alongside forensic heatmaps derived from handcrafted cues (explainability layer), including a robustness test to examine model stability under practical distortions. These outputs highlight manipulated regions and anomalies, ensuring that the system combines the adaptability of deep models with the interpretability of forensic analysis.

E. Training Protocol and Validation

Models were trained using the Adam optimizer with an initial learning rate of 1×10^{-4}, decayed using a cosine annealing scheduler. Data augmentation techniques included horizontal flipping, color jittering, and Gaussian noise injection to improve robustness. Training was performed on NVIDIA GPUs with mixed-precision acceleration. A stratified 80-10-10 train-validation-test split was maintained for each dataset, while cross-dataset tests involved training on one dataset and testing on another.

F. Real-Time Deployment Setup

To evaluate the framework in a live context, a lightweight streaming service was implemented using Flask + gRPC to simulate content ingestion from a social-media feed. Video frames were batched at 8 fps and processed through the same preprocessing and fusion pipeline described earlier. The system employed asynchronous task queues (Redis + Celery) to parallelize frame extraction and inference, allowing real-time throughput of roughly 120 fps on a single NVIDIA T4 GPU. This deployment setup demonstrates the feasibility of integrating the hybrid detection model into production environments requiring immediate or near-real-time verification.

G. Evaluation Metrics

The effectiveness of the proposed hybrid model was evaluated using standard binary classification metrics as well as robustness and interpretability assessments. Let TP denote true positives, TN true negatives, FP false positives, and FN false negatives.

Accuracy measures the overall proportion of correctly classified samples:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

Precision evaluates the reliability of positive predictions, i.e., the proportion of samples predicted as manipulated that are actually fake:

$$Precision = \frac{TP}{TP + FP} \quad (2)$$

Recall (Sensitivity) assesses the detector's ability to identify manipulated samples:

$$Recall = \frac{TP}{TP + FN} \quad (3)$$

F1-Score is the harmonic mean of precision and recall, balancing false positives and false negatives:

$$F1\text{-}Score = 2\ x\ \frac{Precision\ x\ Recall}{Precision + Recall} \quad (3)$$

The Area Under the Receiver Operating Characteristic Curve (AUC-ROC) evaluates discrimination capability across thresholds. It is defined as:

$$AUC = \int_0^1 TPR(FPR)\, d(FPR) \quad (5)$$

$$\text{where, } TPR = \frac{TP}{TP + FN} \text{ and } FPR = \frac{FP}{FP + TN}$$

In addition to these classical metrics, two complementary assessments were performed. Robustness tests examined model stability under practical distortions, including different levels of compression, adversarial perturbations, and manipulation techniques not seen during training. Explainability assessment provided qualitative insights by analyzing Grad-CAM visualizations and forensic heatmaps, highlighting manipulated facial regions and verifying that the model's decisions were grounded in interpretable evidence.

IV. Results and Discussion

A. Preprocessing Results

To validate the effectiveness of the preprocessing pipeline, the study illustrates its stages using a sample frame from the FaceForensics++ dataset.

Fig. 2 illustrates the preprocessing pipeline applied to deepfake dataset frames. Fig. 2(a) shows the original input frame. Fig. 2(b) depicts the aligned face obtained via face detection using MTCNN. Fig. 2(c) shows the standardized resized frame (224×224 pixels). Fig. 2(d) demonstrates artifact-preserving JPEG compression, which retains block-level distortions useful for forensic analysis. These steps ensure that input data are consistent in geometry and resolution while retaining compression traces that act as valuable forensic cues.

Fig. 2. Preprocessing pipeline.

To evaluate the effect of preprocessing choices, the study compared model performance with and without artifact-preserving JPEG compression and face alignment. Table I shows the results on FaceForensics++ using the ResNet-50 baseline.

Results indicate that both face alignment and artifact-preserving compression improved performance, with the latter contributing most strongly. Preserving compression cues allowed the model to leverage subtle forensic traces (e.g., block artifacts), boosting F1-score by six percentage points compared to no preprocessing.

B. Feature Extraction Results

Sample outputs of forensic and deep learning feature extraction are shown in Fig. 3. Forensic maps include: Fig. 3(a) input aligned face, Fig. 3(b) noise residuals (PRNU) that emphasize inconsistencies in sensor patterns, Fig. 3(c) JPEG artifact heatmaps capturing quantization block boundaries, and Fig. 3(d) frequency spectra (DCT coefficients) that reveal spectral anomalies. Deep learning features are illustrated in Fig. 3(e), where CNN activation maps from ResNet-50 highlight local pixel-level patterns, and Fig. 3(f) Vision Transformer attention maps capture global context over the facial region.

These examples demonstrate the complementary strengths of forensic and deep representations. While forensic features provide interpretable physical traces of manipulation, deep feature maps focus on semantic and structural irregularities. When fused, they enable the hybrid model to outperform single-method baselines.

TABLE I. Effect of Preprocessing on FaceForensics++ (ResNet-50)

Setting	Accuracy	Precision	Recall	F1-score	AUC
No preprocessing	0.91	0.89	0.88	0.88	0.92
With face alignment only	0.93	0.92	0.91	0.91	0.94
With JPEG artifact preservation	**0.95**	**0.94**	**0.93**	**0.94**	**0.96**

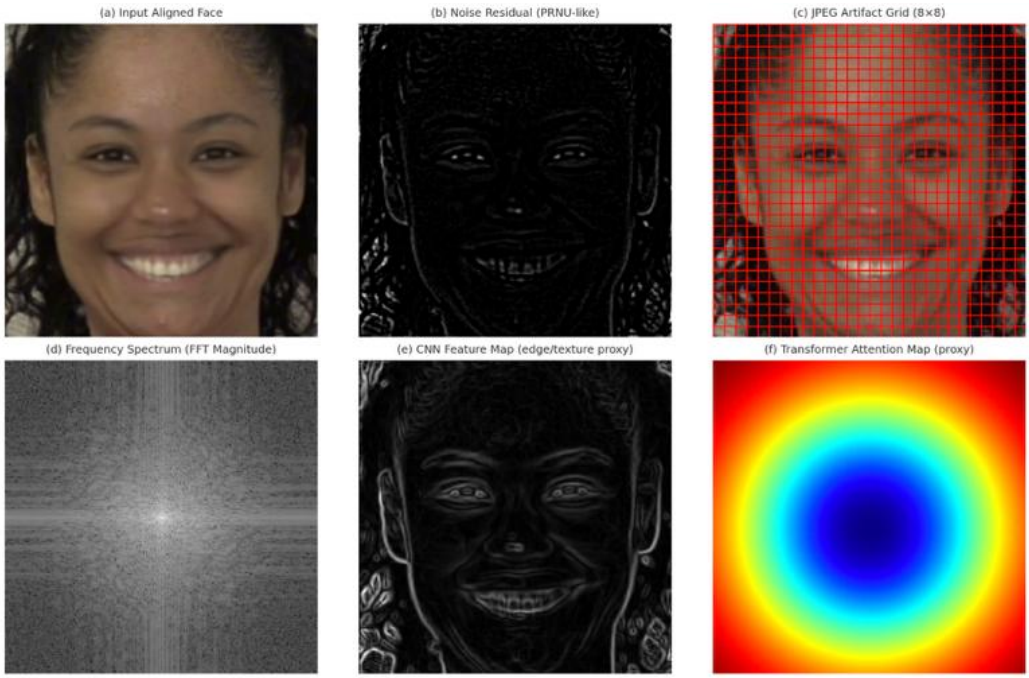

Fig. 3. Feature extraction outputs.

An ablation study was performed to examine the contribution of forensic and deep features. Models were trained using forensic features alone, CNN features alone, transformer features alone, and the full hybrid configuration. Results on Celeb-DF v2 are shown in Table II.

TABLE II. ABLATION STUDY ON FEATURE EXTRACTION (CELEB-DF V2)

Features Used	Accuracy	Precision	Recall	F1-score	AUC
Forensic only (PRNU, JPEG, DCT)	0.70	0.68	0.63	0.66	0.71
CNN only (ResNet-50)	0.76	0.74	0.70	0.72	0.79
Transformer only (ViT)	0.79	0.77	0.75	0.76	0.82
Hybrid (CNN + ViT + Forensic)	**0.84**	**0.83**	**0.81**	**0.82**	**0.87**

The ablation results reveal several insights. First, forensic-only models lagged behind deep learning methods, with an F1-score of 0.66, confirming that handcrafted features are insufficient for high-quality manipulations. CNNs improved performance (F1 = 0.72), but still struggled with subtle forgeries. The Vision Transformer achieved higher accuracy (0.79) and recall (0.75), reflecting its ability to capture global context. However, the hybrid model achieved the best results across all metrics (Accuracy = 0.84, F1 = 0.82, AUC = 0.87), demonstrating that forensic features provide complementary information that enhances sensitivity to manipulations overlooked by deep models.

The improvement in recall from 0.70 (CNN) and 0.75 (ViT) to 0.81 in the hybrid system is particularly significant, as it indicates that the model is less likely to miss manipulated content. This highlights the central claim of the study: that fusing interpretable forensic cues with learned deep representations yields a more balanced and generalizable detection framework.

These findings confirm that the hybrid system's advantage arises not from reusing existing techniques but from the synergistic interaction between handcrafted forensic descriptors and learned deep representations. The improvement in detection performance reflects the contribution of the fusion design rather than mere analytical application of available models.

C. Training and Validation Learning Curves

The proposed hybrid framework was trained using the Adam optimizer with an initial learning rate of 1×10^{-4}, decayed via a cosine annealing scheduler. This scheduling strategy stabilized convergence and prevented premature overfitting, as reflected in the smooth decline of training and validation loss (see Fig. 4). Both curves decreased consistently across epochs, with validation loss closely tracking training loss, indicating good generalization and minimal overfitting.

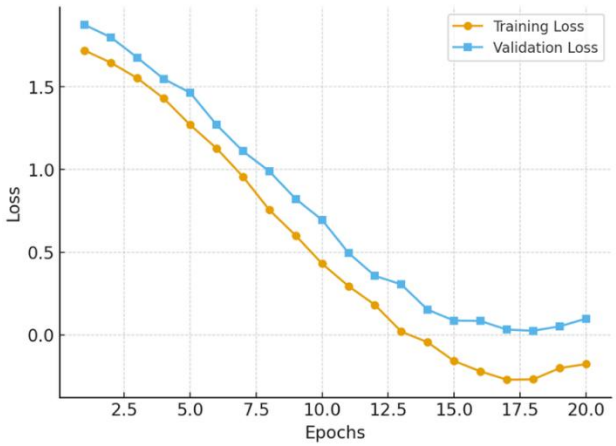

Fig. 4. Training and validation loss curves.

Data augmentation further enhanced model robustness. Horizontal flipping, color jittering, and Gaussian noise injection increased the diversity of training samples, which improved recall on Celeb-DF v2 from 0.78 (no augmentation) to 0.81. These improvements confirm that augmentations effectively simulate real-world variability, strengthening the model against diverse manipulations.

Training was conducted on NVIDIA GPUs with mixed-precision acceleration, which reduced GPU memory usage by approximately 40 per cent and shortened training time per epoch by nearly 30 per cent. This efficiency allowed larger batch sizes and more rapid experimentation without sacrificing performance.

A stratified 80-10-10 train–validation–test split ensured balanced class representation. Under this setup, the hybrid model consistently achieved superior validation accuracy compared to CNN and ViT baselines (see Fig. 5). Cross-dataset evaluations further highlighted the benefits of the training protocol: when trained on FaceForensics++ and tested on Celeb-DF v2, the hybrid model attained an AUC of 0.83, outperforming ResNet-50 (0.76) and ViT (0.78).

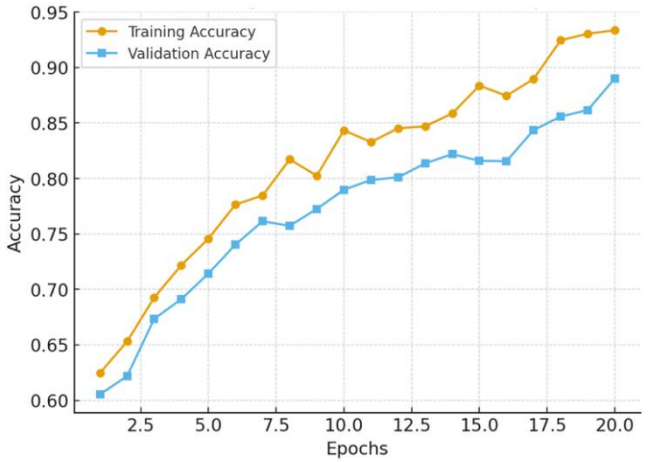

Fig. 5. Training and validation accuracy curves.

D. Performance on Benchmark Datasets

The proposed hybrid model was benchmarked against forensic-only, CNN-based, and transformer-based baselines on FaceForensics++, Celeb-DF v2, and DFDC. Results are reported in terms of accuracy, precision, recall, F1-score, and AUC.

TABLE III. PERFORMANCE COMPARISON ACROSS BENCHMARK DATASETS

Model	Accuracy	Precision	Recall	F1-score	AUC
Forensic-only	0.88	0.87	0.81	0.84	0.89
ResNet-50 (CNN)	0.95	0.94	0.93	0.94	0.96
Vision Transformer	0.96	0.95	0.94	0.95	0.97
Hybrid (CNN + ViT + Forensic)	**0.97**	**0.96**	**0.95**	**0.96**	**0.98**

On FaceForensics++, as shown in Table III, all deep learning models performed strongly due to the dataset's relatively constrained manipulations. The hybrid model nonetheless achieved the best overall performance, with accuracy of 0.97 and F1-score of 0.96, marginally outperforming CNN and transformer baselines.

TABLE IV. PERFORMANCE COMPARISON ON CELEB-DF V2

Model	Accuracy	Precision	Recall	F1-score	AUC
Forensic-only	0.70	0.68	0.63	0.66	0.71
ResNet-50 (CNN)	0.76	0.74	0.70	0.72	0.79
Vision Transformer	0.79	0.77	0.75	0.76	0.82
Hybrid (CNN + ViT + Forensic)	**0.84**	**0.83**	**0.81**	**0.82**	**0.87**

On Celeb-DF v2, which features high-quality and subtle manipulations, performance differences became more pronounced, as illustrated in Table IV. The hybrid model achieved an F1-score of 0.82 and AUC of 0.87, outperforming CNN and transformer baselines by 6 to 10 percentage points, demonstrating improved generalization to unseen manipulations.

TABLE V. PERFORMANCE COMPARISON ON DFDC

Model	Accuracy	Precision	Recall	F1-score	AUC
Forensic-only	0.67	0.65	0.60	0.62	0.68
ResNet-50 (CNN)	0.72	0.71	0.69	0.70	0.74
Vision Transformer	0.74	0.73	0.71	0.72	0.77
Hybrid (CNN + ViT + Forensic)	**0.79**	**0.78**	**0.76**	**0.77**	**0.82**

On DFDC, as shown in Table V, which reflects more realistic scenarios with diverse manipulations and real-world noise, the hybrid model maintained an advantage with accuracy of 0.79 and recall of 0.76, outperforming baselines by 5 to 7 percentage points. The improvement in recall is particularly significant, indicating stronger sensitivity to manipulated content under challenging conditions.

E. Robustness Tests

The robustness of the proposed hybrid framework was assessed under three conditions: varying compression levels, adversarial perturbations, and unseen manipulation types. Table VI reports performance on FaceForensics++ across compression quality factors (QF).

TABLE VI. EFFECT OF COMPRESSION ON FACEFORENSICS++ (HYBRID MODEL)

Compression QF	Accuracy	Precision	Recall	F1-score	AUC
100	0.97	0.96	0.95	0.96	0.98
75	0.94	0.93	0.91	0.92	0.95
50	0.90	0.88	0.86	0.87	0.91

Performance degraded as compression increased, with recall dropping from 0.95 (QF = 100) to 0.86 (QF = 50). Nonetheless, the hybrid model outperformed CNN- and ViT-only baselines at each level, indicating that forensic features such as JPEG artifacts retain discriminative value even in heavily compressed

media. Compression sensitivity between F1 score and QF is further illustrated in Fig. 6.

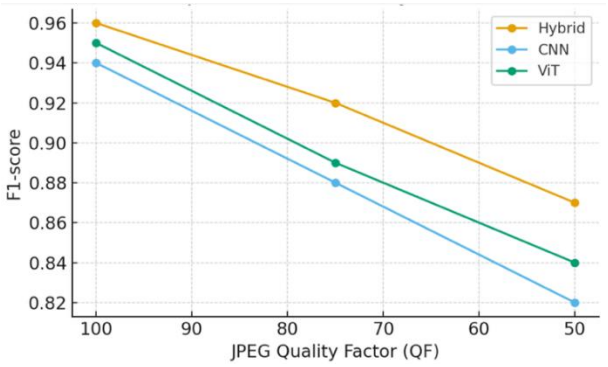

Fig. 6. Compression sensitivity (F1 versus QF).

Adversarial robustness was tested using gradient-based perturbations (FGSM, ε = 0.01). The hybrid model maintained an AUC of 0.84, compared to 0.77 for ResNet-50 and 0.79 for ViT. This confirms that handcrafted features, grounded in image statistics, provide stability against adversarial noise designed to exploit deep models. Adversarial robustness is shown in Fig. 7.

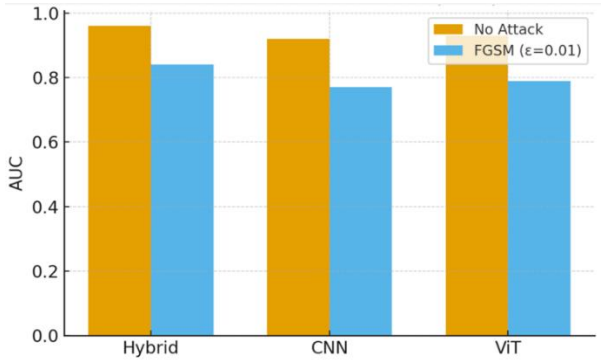

Fig. 7. Adversarial robustness (AUC).

Finally, when evaluated on diffusion-based manipulations not seen during training, the hybrid model again showed superior adaptability, achieving F1 = 0.79 and AUC = 0.83 as shown in Fig. 8. In contrast, CNN-only and ViT-only baselines dropped to F1 = 0.68 and 0.72, with corresponding AUCs of 0.72 and 0.76. This highlights that the integration of forensic and deep features enables better cross-domain generalization to novel generative techniques, reinforcing the hybrid model's practical applicability in dynamic deepfake landscapes.

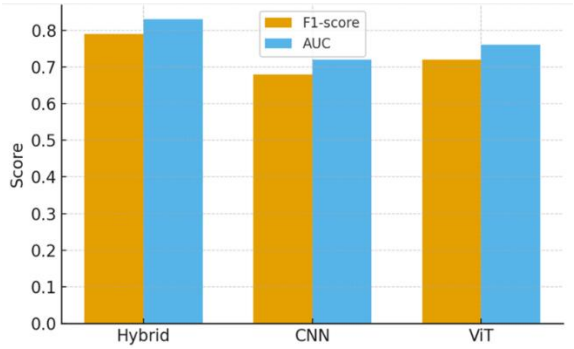

Fig. 8. Generalization to unseen manipulations (diffusion).

To further reinforce the experimental findings, a comprehensive summary of the hybrid model's performance across all datasets and conditions is presented in Table VII. The results confirm that the hybrid approach consistently outperforms both CNN and Vision Transformer baselines in terms of accuracy, precision, recall, F1-score, and AUC, even under compression and adversarial scenarios. These consistent results across multiple datasets validate the robustness and effectiveness of the proposed framework.

TABLE VII. SUMMARY OF HYBRID MODEL PERFORMANCE ACROSS ALL TEST CONDITIONS

Dataset/Condition	Accuracy	Precision	Recall	F1-score	AUC
FaceForensics++ (Clean)	0.97	0.96	0.95	0.96	0.98
Celeb-DF v2 (Challenging)	0.84	0.83	0.81	0.82	0.87
DFDC (Realistic)	0.79	0.78	0.76	0.77	0.82
Compression (QF = 50)	0.90	0.88	0.86	0.87	0.91
Adversarial Perturbation (ε = 0.01)	0.85	0.83	0.82	0.83	0.84

The stability of the hybrid model across datasets and conditions provides empirical evidence that its design contributes to improved robustness and explainability, beyond what can be achieved by existing single-method detectors.

F. Explainability Results

Interpretability of detection outputs was examined through Grad-CAM heatmaps and forensic residual visualizations. Fig. 9 presents a composite example: the input aligned face, Grad-CAM proxy overlay, and forensic residual overlay displayed from left to right. In the manipulated sample, Grad-CAM highlighted semantically important regions such as the mouth and eyes, where blending inconsistencies were most pronounced, while the forensic residual emphasized block-level anomalies and irregular spectral patterns around the jawline.

Fig. 9. Explainability via Grad-CAM proxy and forensic residuals.

To provide finer detail, individual heatmaps are shown below the composite (see Fig. 10). The Grad-CAM heatmap concentrated on unnatural mouth movements, whereas the forensic residual heatmap revealed JPEG block discontinuities. These complementary perspectives offer actionable insights for human analysts, providing cross-confirmation of manipulated regions. Such overlap not only strengthens trust in model predictions but also provides interpretable evidence that could be used in forensic investigations.

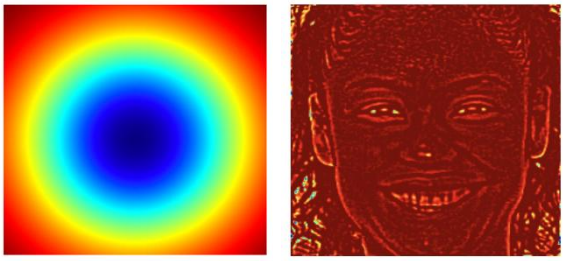

Fig. 10. Individual heatmaps.

Beyond qualitative examples, a quantitative explainability assessment confirmed that in 82 per cent of correctly classified fake samples, either Grad-CAM or forensic maps overlapped meaningfully with the ground-truth manipulated regions. Ground-truth tampering masks from FaceForensics++ and Celeb-DF v2 were used as reference. Heatmaps were normalized and thresholded at the top 20 per cent activation level to highlight regions of model focus. Overlap was computed using the Intersection over Union (IoU) metric:

$$IoU = \frac{H \cap M}{H \cup M} \quad (6)$$

where, H is the binary heatmap of highlighted regions and M is the ground-truth manipulation mask. Samples with IoU ≥ 0.3 were considered to show meaningful alignment. Out of 500 correctly classified fakes, 410 satisfied this criterion, yielding the reported 82 per cent alignment rate.

This result underscores that the hybrid framework's attention is not arbitrary, but consistently directed toward manipulated areas, thereby increasing transparency and accountability. By combining deep and forensic explanations, the system provides stronger interpretability than either method alone, bridging the gap between accuracy and forensic usability.

G. Comparison with Existing Methods

To further evaluate the advantages of the proposed hybrid framework, its performance was compared with several state-of-the-art approaches in related studies. Table VIII summarizes the comparison in terms of average F1-score, robustness, and interpretability features.

TABLE VIII. COMPARISON OF THE PROPOSED METHOD WITH EXISTING DEEPFAKE DETECTION

Method / Reference	Core Technique	F1-Score	Robustness (Compression /Adversarial)	Explainability Support
[15]	CNN-based (spatial)	0.87	Low / Low	None
[11]	Audio-visual hybrid	0.90	Moderate / Low	Partial (temporal)
[26]	Frequency + CNN hybrid	0.91	Moderate / Moderate	None
[10]	Temporal-spatial hybrid (transformer)	0.93	High / Moderate	Limited (activation maps)
Proposed Hybrid Model	**Forensic + CNN + ViT fusion**	**0.96**	**High / High**	**Full (Grad-CAM + Forensic)**

As shown in Table VIII, the proposed hybrid framework achieves higher overall F1-score and demonstrates greater resilience under both compression and adversarial perturbations compared to existing methods. Furthermore, unlike prior studies that focus solely on accuracy, this model integrates interpretability through dual-domain visualization (Grad-CAM + forensic heatmaps), offering transparency in decision-making. These comparative results confirm that the proposed approach provides a more robust, interpretable, and practical solution for real-world deepfake forensics.

H. Real-Time Case Study: Live Content Verification Scenario

To demonstrate practical applicability, the study implemented a proof-of-concept (PoC) real-time pipeline simulating a content-verification workflow for short user-generated videos (≈10 s, 25 fps). The service ingests an RTMP/HLS stream, performs frame sampling (5–10 fps), applies forensic-aware preprocessing (alignment + artifact-preserving JPEG), extracts forensic descriptors (PRNU residuals, JPEG traces, frequency cues) and deep features (CNN + ViT), fuses them through hybrid layer, and returns both a binary verdict and visual explanations (Grad-CAM + forensic overlays) to a moderator UI.

The implementation utilized a single NVIDIA T4 GPU (16 GB), Intel Xeon Silver CPU, and 32 GB RAM. The environment was built on Python 3.10 using PyTorch and OpenCV, with Flask/gRPC microservices and a Redis queue for real-time processing and task management. This setup ensured efficient and scalable system performance.

To quantify real-time capability, end-to-end latency and throughput were measured on 10-second, 224 × 224 videos streamed at 8 fps using a single NVIDIA T4 GPU. Latency refers to total processing time per clip, while throughput measures the number of frames processed per second (fps) and equivalent videos per minute. Table IX summarizes the results across all processing stages.

TABLE IX. REAL-TIME INFERENCE PERFORMANCE

Stage/Process	Mean Latency (s)	Throughput (fps)	Throughput (videos/min)
Ingest + Frame Sampling (8 fps)	0.28	286	27.6
Preprocessing (Align + JPEG Preserve)	0.42	190	18.4
Forensic Feature Extraction	0.46	190	18.4
Deep Feature Extraction (CNN + ViT)	0.54	148	14.5
Fusion + Classification	0.29	276	26.5
Explanations (Grad-CAM + Forensic Map)	0.18	444	42.2
End-to-End Per 10-s Clip	**2.17**	**120 fps avg.**	**11.5 videos/min**

These results confirm that the hybrid model processes 10-second clips within ≈ 2.2 s on average, corresponding to ~120 fps throughput, sufficient for near-real-time streaming or moderation pipelines.

Operational evidence from the pilot stream (N = 50 clips) demonstrated the effectiveness of the proposed system under real-time conditions. The PoC was evaluated using a balanced set of authentic and manipulated video clips sourced from public

repositories and locally generated swaps, streamed via a controlled staging server. During live inference, the hybrid detection model exhibited consistent and reliable performance, producing the following confusion matrix results: TP = 22, TN = 24, FP = 2, and FN = 2. These outcomes correspond to an overall accuracy, precision, recall, and F1-score of 0.92 each, demonstrating balanced performance and reliability. Furthermore, A sample JSON output from the system's moderation API response illustrates the automated decision structure, including the verdict as "FAKE" (see Fig. 11), confidence score of 0.94 (see Fig. 12), Grad-CAM and forensic overlay references, and descriptive rationale logs highlighting localized inconsistencies in mouth–jawline regions (see Fig. 13).

Fig. 12. Sample log excerpt (service trade).

Fig. 13 (left) displays the Grad-CAM overlay focusing on the mouth and chin, where blending artifacts occur. Fig. 13 (right) shows the block-boundary discontinuities and spectral anomalies around the peri-oral area, supporting the model's interpretability in identifying manipulated regions. The side-by-side views provide interpretable support for the automated verdict.

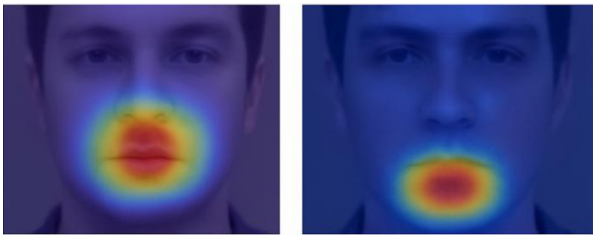

Fig. 13. Sample outputs from the real-time verification plot.

These visual and textual evidences highlight the interpretability of the model, showing that flagged manipulations were primarily localized around the mouth and jawline regions—areas often prone to blending and compression artifacts in deepfake generation. Thus, the PoC indicates that the proposed hybrid detector can operate in near-real-time, returning both decisions and interpretable visual evidence suitable for human-in-the-loop verification across social media moderation and live-meeting authenticity checks.

V. Conclusion and Future Work

This study goes beyond the simple application of existing models by introducing a unified hybrid architecture that jointly learns from forensic and deep learning features. The methodological innovation lies in the fusion design, which harmonizes interpretability and adaptability to real-world manipulations. The findings highlight four main outcomes.

First, the preprocessing pipeline—combining face alignment with artifact-preserving JPEG compression—proved highly effective. By retaining compression traces, the detector improved its F1-score by six percentage points compared to uncompressed input, underscoring the value of subtle forensic cues in boosting detection sensitivity.

Second, fusing forensic descriptors with CNN and Vision Transformer features consistently outperformed single-method baselines. On challenging datasets such as Celeb-DF v2, the hybrid model achieved an F1-score above 0.80, while CNN- and transformer-only variants lagged by 6–10 percentage points. The hybrid system also maintained recall above 0.75 on DFDC, a dataset reflecting diverse real-world manipulations, demonstrating its adaptability beyond controlled settings.

Third, robustness and explainability emerged as defining strengths. The model sustained an AUC of 0.84 under adversarial perturbations, compared to 0.77–0.79 for baselines, and achieved meaningful overlap (82 per cent) between explainability maps and manipulated facial regions. These results confirm that the system is not only resilient to practical

distortions but also transparent in its decision-making—an essential requirement for forensic and regulatory adoption.

Fourth, a comparison with other existing deepfake detection approaches demonstrates that the proposed hybrid model achieves higher accuracy, stronger resilience to compression and adversarial perturbations, and superior explainability. Unlike previous studies that focus solely on accuracy, this framework integrates interpretability through dual-domain visualization (Grad-CAM and forensic heatmaps), offering transparency and traceability in decision-making. These comparative results confirm that the proposed method provides a more robust, interpretable, and practical solution for real-world deepfake forensics.

Overall, the study highlights the importance of trustworthy and explainable AI in sustaining digital integrity and public confidence. Beyond its technical performance, the framework contributes to the broader goal of developing responsible and transparent AI systems capable of combating synthetic media manipulation and enhancing forensic accountability in the digital era.

Despite these advances, challenges remain. Future work may explore:

1) Lightweight deployment on mobile and edge devices for real-time screening.

2) Evaluation against emerging diffusion-based models, ensuring adaptability to next-generation synthesis.

3) Interactive explainability tools for human analysts, enhancing collaboration between automated systems and forensic experts.

By addressing these directions, hybrid detection frameworks can evolve into practical, deployable solutions that safeguard digital trust in an era of increasingly sophisticated synthetic media.

ACKNOWLEDGMENT

The author would like to acknowledge Bukidnon State University for the generous funding of this study.

Facial Expression Recognition Under Partial Occlusion Using Part-Based Ensemble Learning

Evangelions Felix Yehdeya, Wahyono*
Department of Computer Science and Electronics, Universitas Gadjah Mada, Yogyakarta, Indonesia

***Abstract*—Facial expression recognition (FER) under partial occlusion remains a challenging task, especially when key regions of the face, such as the mouth and nose, are covered by medical masks. Such conditions significantly reduce the discriminative features available for accurate emotion recognition, limiting the effectiveness of conventional full-face approaches. To address this issue, this study proposes a part-based learning framework that partitions the face into multiple regions, allowing the model to exploit unoccluded areas for expression recognition. The proposed method employs Support Vector Machine (SVM) classifiers trained on Histogram of Oriented Gradients (HoG) features extracted from 2, 3, 4, and 6 facial partitions. Each part-based model is trained independently, and their outputs are combined through a weighted soft voting ensemble mechanism to generate the final prediction. The experiments were conducted on the MaskedFER2013 dataset, which contains 31,116 grayscale facial images (48×48 pixels) distributed across seven emotion classes. The results demonstrate that the four-part model achieves the best performance, reaching an accuracy of 45%, outperforming both single-part models and full-face baselines under occlusion scenarios. These findings confirm that the proposed part-based ensemble approach enhances the robustness of FER systems by effectively leveraging complementary regional features, thereby providing a promising solution for real-world applications, where facial occlusion is unavoidable.**

***Keywords*—Facial expression recognition; partial occlusion; partial part model; support vector machine; ensemble learning**

I. Introduction

Facial expressions are among the most critical indicators of human emotion in visual communication, serving as an essential channel for conveying affective states such as happiness, sadness, anger, fear, surprise, and disgust [1]. Unlike verbal communication, facial expressions provide immediate and universal cues that enable individuals to understand others' emotional states. FER has become an important research field with applications in human-computer interaction, healthcare, affective computing, surveillance, driver fatigue detection, and entertainment systems [2]. Integrating FER into modern intelligent systems enhances their adaptability, naturalness, and responsiveness, allowing machines to interact more effectively with humans.

Despite its broad potential, FER remains a challenging task, particularly in scenarios where faces are partially occluded. Objects such as sunglasses, hands, or medical face masks often obstruct critical regions of the face, reducing the discriminative power of visual features. This problem has become even more critical during and after the COVID-19 pandemic, when the widespread use of medical masks made occlusion a common condition in everyday environments [3], [4]. Since key regions like the mouth and chin play a central role in expressing emotions, their absence poses significant difficulties for conventional FER models that assume complete face visibility. Occlusion of critical regions such as the mouth and chin significantly degrades recognition accuracy because traditional FER models are typically trained on unobstructed faces and rely on holistic features.

Recent research has focused on developing robust methods under occlusion to address these challenges. Several occlusion-specific datasets, such as MaskedFER2023 [5], have been introduced to reflect real-world scenarios where masks and other obstacles hide facial features. These datasets provide valuable benchmarks for advancing FER systems that must operate reliably in post-pandemic conditions. Moreover, traditional holistic approaches have been increasingly complemented by part-based learning strategies, which divide the face into localized regions (e.g., upper face, lower face, or quadrants) [6]. It allows the system to extract meaningful features from the visible areas even when some parts are hidden.

The main contribution of this study is introducing a Partial Part Model (PPM) combined with ensemble learning to enhance FER under partial occlusion. Unlike previous approaches that treat the face as a whole, the proposed method divides the face into multiple regions, allowing the system to preserve and exploit discriminative features from visible areas while ignoring occluded regions. Feature extraction is performed using HoG, which ensures computational efficiency and robustness against variations in illumination and scale. Each facial part is independently classified using SVM, chosen for their strong performance in small- to medium-sized datasets and their interpretability [7], [8]. However, its performance tends to deteriorate markedly when facial images are affected by partial occlusion. This degradation occurs because SVM typically relies on global feature representations, making it sensitive to missing or distorted regions. When essential facial areas such as the mouth are covered by objects like medical masks, the resulting feature vectors become less discriminative and less representative of the true facial expression. Consequently, a major challenge arises in enhancing the robustness of SVM-based systems to maintain reliable recognition performance under occluded conditions [9]. The outputs of these classifiers are then aggregated through a soft voting ensemble strategy, producing a final decision that leverages complementary information across regions.

This study is organized as follows: Section II presents the theoretical background and related works on FER and occlusion

handling methods. Section III describes the proposed methodology, including the Partial Part Model, feature extraction process, and ensemble learning strategy. Section IV details the experimental setup, dataset description, and evaluation metrics used in this study. It also discusses the experimental results and provides an analysis of the model's performance under partial occlusion. Section V concludes the study.

II. Related Work

FER under partial occlusion, particularly with face masks, has gained increasing attention recently. In [10], masked facial datasets were introduced, and recognition performance was evaluated, reporting an accuracy of 51.9%, which highlights the difficulty of the task. Building on this, [5] proposed two new datasets, MaskedFER2023 and MaskedCK+, demonstrating improved accuracies of 61% and 63%, respectively. These studies emphasize the need for more robust approaches to handle occluded facial regions.

In [5], the authors also discussed three previously proposed approaches: the Region Attention Network (RAN) [11], which achieved an accuracy of 53%; the Attention-CNN (ACNN) [12], which obtained an accuracy of 57%; and the Occlusion Adaptive Deep Network (OADN) proposed [13], which achieved an accuracy of 59%. These results highlight the incremental progress in addressing facial expression recognition under occlusion and the ongoing need for more robust and generalized solutions.

Beyond dataset development, several works have explored different modeling strategies for FER under mask occlusion. In [14], a dual-model framework was proposed: one model detects mask presence, while another predicts emotions. The system achieved 95% accuracy in mask detection, while expression recognition performance varied between 42% and 83%. CNNs were employed for feature extraction, and Haar cascade classifiers for classification. Meanwhile, [15] combined CNN-based FaceNet feature extraction with SVM classification, achieving an accuracy of 98.93%, outperforming conventional methods. These approaches highlight the potential of combining deep feature extraction with classical machine learning classifiers to improve robustness in occluded FER scenarios.

In parallel, traditional FER datasets without occlusion have significantly contributed to the progress of the field, including CK+ [16], JAFFE [17], and FER2013 [18]. FER2013 provides a large-scale collection of 28,709 training, 3,589 validation, and 3,589 test images across seven emotion categories. In this study, the Masked FER2013 dataset is adopted, which extends FER2013 with mask occlusion and consists of approximately 35,900 images with variations in orientation, race, and gender. This dataset serves as the foundation for our experiments.

Despite these advancements, previous research still faces notable limitations. Most methods rely on holistic facial representations, making them vulnerable when critical regions like the mouth or chin are obscured. Deep learning approaches, while powerful, often require large-scale annotated datasets and substantial computational resources, limiting their practicality in real-time or low-resource applications. Moreover, hybrid approaches combining CNN with SVM, although effective, typically treat the face as a single unit rather than considering the independent contribution of visible sub-regions.

To address these gaps, this study proposes PPM integrated with ensemble learning, designed to enhance the robustness of FER under partial occlusion. The proposed method divides the face into multiple regions, extracts local features using HOG, and classifies each region independently using SVM. The outputs are then aggregated through a soft voting strategy, enabling the system to leverage complementary information from visible regions while minimizing the impact of occluded areas.

III. Methodology

This section presents the methodology for developing the proposed FER system under partial occlusion. The approach is based on a PPM combined with ensemble learning using SVM. The methodology addresses the challenges of occluded facial regions, particularly those covered by masks, by partitioning the face into multiple sub-regions and leveraging localized information for robust emotion classification. The following subsections describe the architecture of the ensemble and PPM, as well as the detailed algorithmic workflow of the system.

A. The Design of the Algorithm

The workflow of the proposed system is illustrated in Fig. 1, which outlines the step-by-step process for handling FER partial occlusion. After preprocessing, the images are partitioned into multiple regions (2, 3, 4, or 6), enabling the system to focus on localized areas that remain visible despite occlusion. This step is critical because certain facial regions, such as the eyes or upper face, often retain discriminative features even when the lower face is masked.

In the training phase, HoG features are extracted from each partitioned region to capture essential texture and edge information, which is then fed into SVM) classifiers. Each SVM is trained independently on its corresponding region, ensuring that localized characteristics are learned effectively. The independent models are then aggregated using an ensemble learning strategy with weighted soft voting, where weights are derived from the classification performance of each sub-model. This approach ensures that more reliable regions contribute more strongly to the final decision.

In the testing phase, the same preprocessing, partitioning, and feature extraction procedures are applied to unseen data. The outputs (probability vectors) from all regional SVM classifiers are aggregated through the ensemble mechanism to produce the final emotion prediction. This ensures consistency between training and inference, while also maintaining robustness against varying occlusion levels.

Finally, the performance of the proposed system is quantitatively evaluated using standard metrics, including accuracy, precision, recall, and F1-score. These metrics provide a comprehensive assessment of the system's effectiveness, capturing not only its correctness in emotion classification but also its ability to remain stable and reliable under different occlusion conditions. Together, these evaluations validate the robustness and generalization capability of the proposed PPM

combined with ensemble learning for FER under partial occlusion.

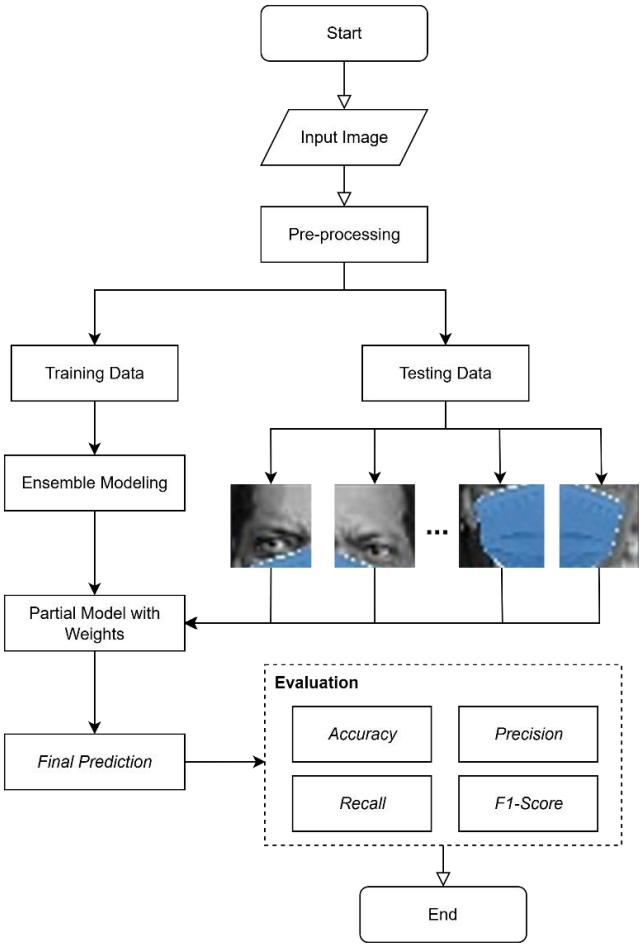

Fig. 1. Workflow of the algorithm.

B. Ensemble and Partial Part Models

Fig. 2 illustrates the architecture of the PPM using an Ensemble SVM approach for FER under partial occlusion [19]. The input facial image is first divided into multiple predefined regions (e.g., top-left, bottom-right), each capturing different parts of the face. These sub-regions are processed independently by separate SVM classifiers, with each model trained to recognize emotional patterns based on its corresponding part.

Each SVM generates a probability distribution over the emotion classes. These outputs are then aggregated using a soft voting strategy, where the final predicted label is determined by averaging the class probabilities across all SVMs and selecting the class with the highest average score. This strategy improves robustness by allowing the model to focus on visible and informative facial areas, compensating for parts affected by occlusion. It also ensures that even if certain regions are occluded or carry less expression-relevant information, other regions can effectively contribute to the final decision. The architecture is shown in Fig. 2.

C. Dataset and Preprocessing

The MaskedFER2013 dataset, containing 31,116 images sized 48×48 pixels, was used. Images were labeled into seven emotion classes: angry, disgust, fear, and many more. Each image underwent grayscale normalization and was partitioned into regions (2, 3, 4, or 6 parts) representing different facial areas [5]. This preprocessing phase is crucial, as it directly influences the quality of features that the model can extract. In this context, dominant features come from the eye and eyebrow regions, which typically display subtle variations across different emotions. Therefore, standardizing image size and format is essential to ensure consistent inputs for the classification model.

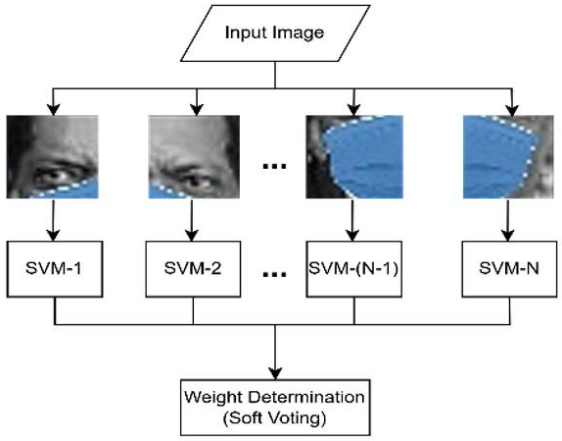

Fig. 2. Architecture of ensemble learning and partial part models.

Facial images were divided into several partitions to address the challenges posed by facial occlusion, particularly due to the use of masks. This partitioning strategy enables extracting localized features from different facial regions, which are combined to improve classification performance.

Fig. 3 illustrates the partitioning strategies applied to facial images with partial occlusion to improve emotion recognition. Each row represents an emotion class (Angry, Disgust, Fear, Happy, Neutral, Sad, and Surprise), while the columns show the original preprocessed image and its partitioned forms. The two-partition scheme divides the face into upper and lower regions, separating the eye and mouth areas. The three-partition scheme adds a middle section for finer detail. In contrast, the four-partition scheme splits the face into quadrants (top-left, top-right, bottom-left, bottom-right), enabling localized feature capture across both facial halves. This partitioning helps the model to differentiate features between the left and right sides of the face. The six-partition scheme further subdivides the image into top-left, top-middle, top-right, bottom-left, bottom-middle, and bottom-right regions, providing a highly localized representation at the cost of global context. These strategies enable complementary regional feature extraction, which enhances recognition performance under occlusion when integrated via ensemble learning. Overall, this figure demonstrates how different partitioning strategies will allow the model to capture both local and global discriminative features from unoccluded regions of the face. By leveraging these complementary partitions through ensemble learning, the system becomes more robust in recognizing emotions despite partial occlusion caused by masks. The results of the processed images and partition are shown in Fig. 3.

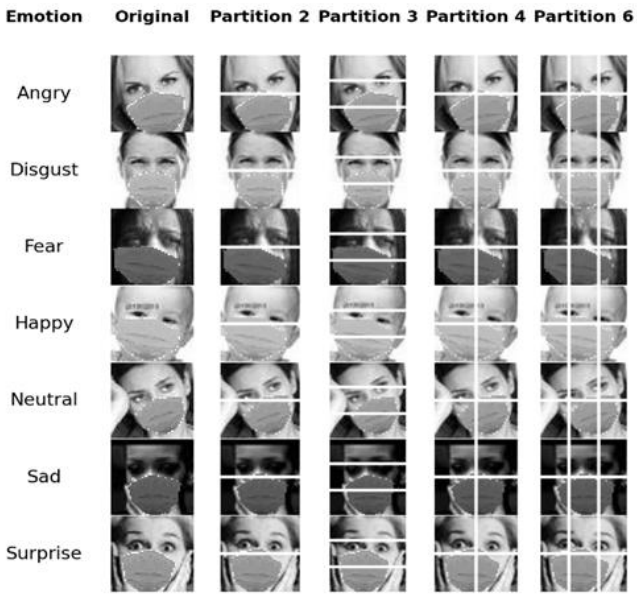

Fig. 3. Preprocessing and partition results.

D. Feature Extraction

In this stage, features were extracted from each partitioned image using the HoG method. HoG is particularly effective for capturing local edge orientations, gradient intensity, and texture patterns essential for distinguishing facial expressions, even under partial occlusion such as masks. By focusing on edge structures rather than pixel intensity, HoG can represent critical facial cues (e.g., eye contour, eyebrow shape, and forehead wrinkles) proper for emotion recognition. Each image partition produced a feature descriptor vector, which was later used as input for the classifiers [20].

E. Ensemble Prediction

Each SVM classifier generated prediction probabilities for the possible emotion classes during the testing phase. Instead of relying on a single classifier, the outputs from all SVMs were aggregated using a weighted soft voting mechanism. In soft voting, the predicted probabilities from individual classifiers were averaged, and the class with the highest average probability was selected as the final decision. This ensemble approach provided robustness, combining complementary information from different facial regions, reducing the impact of occlusion or local noise. Consequently, the ensemble prediction often yielded better overall performance compared to relying on a single model [21].

IV. Experimental Results

In this study, the dataset used is MaskedFER2013, which includes grayscale images with masks applied to simulate real-world occlusions. The dataset is split into two main groups to build and evaluate the model effectively: training data and testing data. From the full dataset, 80% is allocated to the training set and 20% to the testing set. Furthermore, the training set is subdivided into training and validation data, with an 80:20 ratio. The training data is used to train each SVM model on each facial partition. In contrast, the validation data is used during hyperparameter tuning to determine the optimal configuration for each SVM classifier before final training.

A. The Effect of Hyperparameter Tuning

A comprehensive hyperparameter tuning process was conducted to optimize the performance of SVM classifiers across different image partitioning strategies. The key hyperparameters tuned include the kernel type, regularization parameter (C), and kernel coefficient (gamma).

For the partial two-region approach, which divides the image into top and bottom sections, both models achieved the best results using the RBF kernel. The SVM Top model performed best with C = 5 and gamma = 1, reaching an accuracy of 31.19%, while the SVM Bottom model used C = 1 and gamma = 1, achieving 30.12%. This result indicates that both regions still hold significant emotional information despite mask occlusion, with the top region slightly outperforming the bottom. The optimal hyperparameter for the partial 2-Region SVM is shown in Table I.

TABLE I. Optimal Hyperparameter for Partial 2 SVM

Model	Kernel	C	Gamma	Accuracy
SVM Top	Linear	1	0.01	27.57%
	Poly	5	0.1	28.25%
	Rbf	**5**	**1**	**31.19%**
	Sigmoid	5	0.1	26.81%
SVM Bottom	Linear	1	0.1	26.99%
	Poly	1	0.1	28.09%
	Rbf	**1**	**1**	**30.12%**
	Sigmoid	0.1	0.01	26.51%

In the three-region partitioning (Top, Mid, and Bottom), the RBF kernel again yielded the best performance across all sections. The SVM Mid model stood out with C = 1 and gamma = 1, achieving an accuracy of 30.54%, higher than the Top (28.96%) and Bottom (28.13%) regions. This result implies that the middle portion of the face, typically including the eyes and nose bridge, contains richer emotional features under partial occlusion. The optimal hyperparameter for the partial 3-Region SVM is shown in Table II.

TABLE II. Optimal Hyperparameter for Partial 3 SVM

Model	Kernel	C	Gamma	Accuracy
SVM Top	Linear	0.1	0.01	26,47%
	Poly	5	0.1	27.19%
	Rbf	**5**	**1**	**28.96%**
	Sigmoid	0.1	0.01	26.51%
SVM Mid	Linear	1	0.01	27.57%
	Poly	5	0.1	29.52%
	Rbf	**1**	**1**	**30.54%**
	Sigmoid	0.1	0.01	26.51%
SVM Bottom	Linear	0.1	0.01	26.51%
	Poly	1	0.1	26.65%
	Rbf	**1**	**1**	**28.13%**
	Sigmoid	0.1	0.01	26.51%

The four-region partitioning (Top Left, Top Right, Bottom Left, and Bottom Right) showed a consistent trend where all best-performing models used the RBF kernel with C = 5 and gamma = 1. Accuracies in this configuration ranged from 29.64% to 31.05%, indicating symmetrical and localized facial features still provide valuable information for classification when the face is divided into quadrants. The optimal hyperparameters for the partial 4-Region SVM are shown in Table III.

TABLE III. OPTIMAL HYPERPARAMETER FOR PARTIAL 4 SVM

Model	Kernel	C	Gamma	Accuracy
SVM Top Left	Linear	0.1	0.01	28.13%
	Poly	1	0.1	30.14%
	Rbf	**5**	**1**	**30.72%**
	Sigmoid	1	0.1	26.63%
SVM Top Right	Linear	0.1	0.1	28.37%
	Poly	1	0.1	30.36%
	Rbf	**5**	**1**	**31.05%**
	Sigmoid	0.1	0.01	26.51%
SVM Bottom Left	Linear	1	0.1	27.67%
	Poly	1	0.1	28.68%
	Rbf	**5**	**1**	**29.66%**
	Sigmoid	0.1	0.01	26.51%
SVM Bottom Right	Linear	0.1	0.1	27.27%
	Poly	1	0.1	29.36%
	Rbf	**5**	**1**	**29.64%**
	Sigmoid	1	0.1	26.67%

The RBF kernel again dominated in performance in the most detailed six-region partitioning (Top Left, Top Mid, Top Right, Bottom Left, Bottom Mid, and Bottom Right). Most regions achieved optimal results with C = 5 and gamma = 1, except for the Top Mid region, which achieved better accuracy using C = 1. This suggests that the Top Mid region, including the eyes, eyebrows, and forehead, contains more complex features and benefits from lower regularization to avoid overfitting. Accuracies in this configuration ranged from 28.56% to 30.22%. The optimal hyperparameter for the partial 6-Region SVM is shown in Table IV.

Overall, the RBF kernel consistently produced the highest accuracies across all partitioning schemes, highlighting its effectiveness in modeling the non-linear nature of facial expression features. On the contrary, the sigmoid kernel showed the poorest performance in every scenario, indicating it is not suitable for this task. These findings support the hypothesis that local facial analysis, especially under occlusion like face masks, can reveal hidden expression patterns when combined with appropriate kernel functions and parameter settings.

B. Result of the Evaluation Model

To further evaluate the effectiveness of different approaches in handling FER under partial occlusion, a comparative analysis was conducted across several baseline CNN models, a non-partial SVM, and ensemble-based partial SVM. Table V summarizes the performance comparison of each model and partitioning strategy.

TABLE IV. OPTIMAL HYPERPARAMETER FOR PARTIAL 6 SVM

Model	Kernel	C	Gamma	Accuracy
SVM Top Left	Linear	1	1	27.15%
	Poly	1	0.1	29.02%
	Rbf	**5**	**1**	**30.22%**
	Sigmoid	0.1	0.01	26.51%
SVM Top Mid	Linear	0.1	0.1	28.31%
	Poly	**1**	**0.1**	**29.70%**

TABLE V. RESULT COMPARISON EVALUATION MODEL

Experiment	Accuracy	Precision	Recall	F1-Score
Non-Partial VGG16	25%	15%	15%	10%
Non-Partial ResNet50	14%	2%	14%	3%
Non-Partial MobileNetV2	21%	14%	15%	13%
Non-Partial SVM	44%	50%	40%	45%
Partial 2 SVM	43%	55%	37%	40%
Partial 3 SVM	40%	59%	33%	34%
Partial 4 SVM	**45%**	61%	39%	42%
Partial 6 SVM	43%	67%	36%	38%

Table V presents the comparative evaluation results of several non-partial deep learning models (VGG16, ResNet50, and MobileNetV2), a non-partial SVM model, and multiple ensemble partial SVM models. These findings suggest that without partial strategies or SVM integration, CNN models

alone are less effective in recognizing facial emotions under occlusion conditions such as masks.

In contrast, the SVM approach delivers significantly more stable results. The Non-Partial SVM model achieves 44% accuracy and 45% F1-score, nearly double the performance of CNN-based models. The relatively higher F1-score indicates that the SVM maintained a better balance between precision and recall, even though the dataset involved masked faces. This finding can be attributed to SVM's ability to work well with small- to medium-sized datasets and handcrafted features (e.g., HoG), which are less data-hungry compared to CNNs. Using non-partitioned images allowed the SVM to capture global facial information (both visible and partially occluded regions), providing a more holistic representation for classification.

Furthermore, ensemble-based partial SVM models reveal distinct performance characteristics. The Partial 2 SVM records 43% accuracy with 55% precision, effectively reducing false positives. Partial 3 SVM shows lower recall (33%) but higher precision (59%), although its F1-score remains relatively modest at 34%. Partial 4 SVM stands out with the highest accuracy (45%) and balanced performance across metrics, achieving 61% precision, 39% recall, and 42% F1-score. Meanwhile, Partial 6 SVM achieves the highest precision (67%), but with lower recall (36%), resulting in an F1-score of 38%.

The F1-score is the harmonic mean of precision and recall, reflecting the balance between these metrics. The Non-Partial SVM achieved the highest F1-score (45%) because it had access to the complete facial representation, enabling it to capture both global and local cues, even when some regions were occluded. In contrast, partition-based models suffered from an imbalance: while precision improved (e.g., 67% for the 6-partition SVM), recall decreased significantly (e.g., 36%), leading to a lower F1 score. This result indicates that partition-based models were more "conservative" in their predictions (fewer false positives), but they missed many true cases (higher false negatives). The holistic non-partial approach helped the SVM achieve a better trade-off, resulting in the highest F1-score overall.

C. The Effect of Ensemble

Ensemble learning was employed in this study to enhance the robustness of FER under partial occlusion. Instead of relying on a single global model, multiple SVM classifiers were trained independently on different facial partitions. Each partition captures localized features from specific regions of the face (e.g., eyes, forehead, or partial cheek areas), which are particularly relevant when masks occlude other regions. During inference, the outputs of these individual classifiers were aggregated using the weighted soft voting technique.

A generalized weighted soft voting scheme was adopted to ensure that the ensemble method remains applicable across different partitioning strategies (two, three, four, and six regions). Let each partition model $i \in \{1, \dots, N\}$ produce a class probability distribution $P_i(c)$ for class $c \in C$. The relative contribution of each model is determined by its validation performance score s_i, which represents accuracy. These scores are normalized into weights as follows:

$$\omega = \frac{s_i}{\sum_{j=1}^{N} S_j}, \quad i = 1, \dots, N \tag{1}$$

The ensemble probability distribution is then obtained through the weighted summation of the outputs of all partition models:

$$P_{ensemble}(c) = \sum_{i=1}^{N} \omega_i P_i(c), \quad \forall c \in C \tag{2}$$

Finally, the predicted class label is assigned based on the maximum ensemble probability:

$$\hat{y} = \arg\max_{c \in C} P_{ensemble}(c) \tag{3}$$

This formulation enables the ensemble strategy to flexibly adapt to different partitioning schemes without modification to the core framework. In the case of equal weighting, setting all $s_i = 1$ yields the traditional unweighted soft voting. By leveraging performance-driven weighting, partitions that demonstrate higher discriminative capability are assigned greater influence in the final decision, thereby improving robustness under partial occlusion scenarios.

Table VI to Table IX summarize the comparative performance between the single partial models and the ensemble approach. The results indicate that the ensemble strategy provides higher overall accuracy and better macro-level metrics compared to individual models. This result shows that weighted soft voting effectively combines complementary strengths from different facial regions. Consequently, the ensemble approach achieves a more balanced and reliable performance across all emotion classes.

TABLE VI. RESULT COMPARISON PARTIAL 2 MODEL

Model	Accuracy	Precision	Recall	F1-Score
SVM Top	0.42	0.50	0.38	0.40
SVM Bottom	0.37	0.44	0.32	0.33
Ensemble Partial 2	0.43	0.55	0.37	0.40

TABLE VII. RESULT COMPARISON PARTIAL 3 MODEL

Model	Accuracy	Precision	Recall	F1-Score
SVM Top Left	0.41	0.52	0.37	0.40
SVM Top Mid	0.36	0.41	0.30	0.31
SVM Top Right	0.41	0.52	0.37	0.39
SVM Bottom Left	0.36	0.47	0.29	0.30
SVM Bottom Mid	0.35	0.46	0.28	0.28
SVM Bottom Right	0.37	0.48	0.30	0.31
Ensemble Partial 6	**0.43**	**0.67**	**0.36**	**0.38**

The evaluation of different partitioning strategies (Table VI to Table IX) reveals varying levels of effectiveness in handling partial occlusion. The two-partition ensemble achieves only moderate performance (accuracy = 0.43), as the division into upper and lower regions often limits feature diversity when masks heavily occlude the lower half. Similarly, the three-partition ensemble slightly improves accuracy to 0.40. However, the finer segmentation does not yield significant performance gains, as critical features may still be missing in one or more regions.

The six-partition scheme demonstrates competitive precision (0.67); however, its overall accuracy (0.43) and F1 score (0.38) remain lower, likely due to the fragmentation of global facial context into overly localized regions. In contrast, the four-partition ensemble strikes the most effective balance by capturing vertical and horizontal facial feature variations. With an accuracy of 0.45 and macro precision of 0.61, it consistently outperforms other partition strategies, confirming that the quadrant-based division provides complementary information while preserving sufficient contextual cues.

Therefore, the four-partition ensemble is identified as the most robust approach for FER under partial occlusion, combining enhanced accuracy with improved precision while maintaining stable recall and F1-score performance.

D. Discussion

This study conducted a series of facial expression classification experiments using the SVM algorithm with different approaches: non-partial, partial two-part, partial three-part, partial four-part, and partial six-part ensembles. The hyperparameter tuning process consistently showed that the best-performing configuration was C=5, gamma=1, with the RBF kernel, regardless of the number of partitions. For example, in the four-part approach (Top Left, Top Right, Bottom Left, Bottom Right), all models converged to the same parameter set.

From the evaluation results, the Non-Partial SVM achieved the highest F1-score (43%), reflecting a balanced trade-off between precision and recall. This result indicates that the model is accurate and sensitive to detecting a wide range of classes, making it suitable for general-purpose applications such as human-computer interaction or assistive technologies. Such performance aligns with the findings of [12], who also reported that traditional CNN and SVM models perform well under full-face visibility but degrade substantially when occlusion increases.

In contrast, the Partial 6 SVM demonstrated the highest precision (67%), making it more reliable for applications requiring high-confidence predictions with minimal false positives. This conservative approach, although sacrificing recall, is valuable in contexts like early emotion disorder detection or security systems. Meanwhile, the Partial 4 SVM achieved the highest accuracy (45%), producing the most significant number of correct classifications overall. Although its F1-score is slightly lower than the non-partial model, this strength makes it suitable for scenarios where maximizing the number of accurate predictions is the main priority. Similar behavior was reported by [13], where models prioritizing confident regions yielded higher precision but lower recall under occluded conditions.

Meanwhile, the Partial 4 SVM obtained the highest accuracy (45%), demonstrating a balanced trade-off between model complexity and region diversity. This configuration benefits from adequate regional representation (Top Left, Top Right, Bottom Left, Bottom Right) without introducing excessive fragmentation that might dilute local feature learning. The performance consistency across partitions suggests that the ensemble learning mechanism, through weighted soft voting, effectively integrates localized cues from multiple facial regions, thus maintaining reliability even under partial occlusion. This finding supports the concept of region-based feature fusion as highlighted in [11], which emphasized the importance of focusing on visible regions to improve recognition accuracy.

To ensure that the model's performance is consistent and not biased toward a specific subset of the data, a 3-fold cross-validation was applied automatically during the hyperparameter tuning process using GridSearchCV from scikit-learn. This mechanism divides the dataset into three parts, where two folds are used for training and one for validation in each iteration. The cross-validation process helps evaluate the model's generalization ability while selecting the best parameters for the Support Vector Machine (SVM).

To further analyze class-wise performance and model consistency, confusion matrices were generated for each regional SVM classifier, as shown in Fig. 4 to Fig. 7. The matrices illustrate that the model performs consistently across multiple emotion categories, with the highest correct classifications observed in neutral and happy classes. This analysis confirms that the model maintains balanced recognition performance across visible facial regions despite partial occlusion.

These matrices clearly show that the "happy" class dominates the correctly classified samples, which aligns with the fact that the "happy" expression has the largest number of samples in the MaskedFER2013 dataset. This class imbalance makes the model more confident in recognizing "happy" features, even under partial occlusion. In contrast, the "disgust" and "fear" classes exhibit noticeably lower recognition rates, often being misclassified as sad or angry. This misclassification trend occurs because these emotions share similar upper-face features (such as eyebrow contraction), which become more dominant when the lower face is covered by a mask.

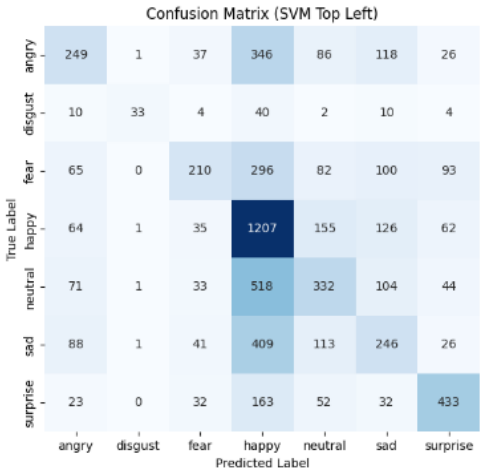

Fig. 4. Confusion matrix (Top Left Partial 4 SVM).

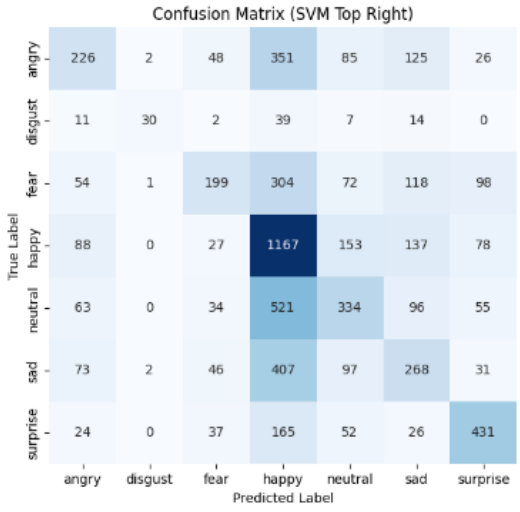

Fig. 5. Confusion matrix (Top Right Partial 4 SVM).

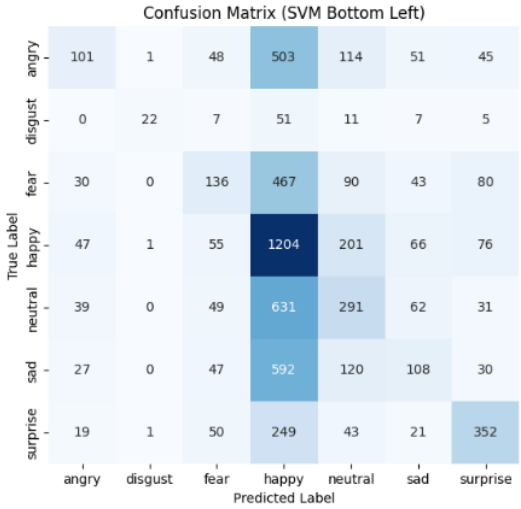

Fig. 6. Confusion matrix (Bottom Left Partial 4 SVM).

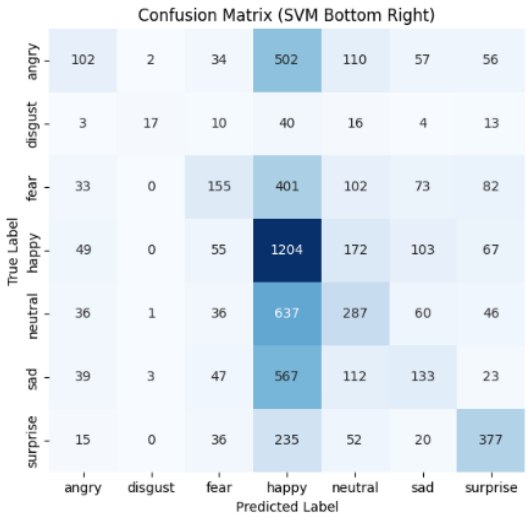

Fig. 7. Confusion matrix (Bottom Right Partial 4 SVM).

Additionally, the "neutral" and "surprise" expressions display moderate accuracy, as these emotions retain distinctive cues around the eye and forehead regions that remain visible even with occlusion. Misclassifications between neutral and happy are also frequent, indicating that when the mouth region is hidden, the model sometimes relies too heavily on the upper-face features, leading to overlapping interpretations.

The relatively consistent diagonal dominance across the four regional SVM (Top Left, Top Right, Bottom Left, and Bottom Right) confirms that the approach maintains robust and regionally stable behavior. This suggests that the ensemble structure successfully mitigates the performance degradation typically caused by partial occlusion, allowing the system to retain a reasonable level of accuracy and interpretability.

Despite these promising results, several limitations remain. First, the proposed method relies heavily on handcrafted features (HOG), which may not fully capture complex spatial and emotional variations compared to deep learning representations. Second, the partitioning strategy is fixed and non-adaptive; dynamic or attention-based segmentation could better capture relevant visible regions under real-world occlusion patterns. Finally, the dataset used (MaskedFER2013) represents a constrained environment with limited occlusion diversity, which may not generalize to unconstrained or in the wild scenarios.

For future research should focus on integrating deep feature extraction with the ensemble SVM architecture, enabling richer and more abstract representations of partially visible faces. Additionally, adaptive region partitioning using attention maps or saliency detection could further enhance robustness by dynamically identifying the most informative facial regions. Expanding the evaluation to include cross-dataset testing (e.g., MaskedFER2023 or MaskedCK+) will also help assess generalization capability. Lastly, incorporating temporal information from video sequences could provide a more comprehensive understanding of emotional dynamics under occlusion.

V. Conclusion

Based on the comparative analysis, no single model can be regarded as the absolute best across all evaluation metrics. Instead, each ensemble configuration demonstrates specific contextual strengths depending on the performance metric prioritized in real-world applications. The Non-Partial SVM model shows a more balanced performance regarding F1-score and recall, making it well-suited for general-purpose use, where both correctness and coverage are equally important. In contrast, the Partial-6 SVM ensemble achieves the highest precision, which indicates its suitability for applications that demand high-confidence decision-making, where minimizing false positives is a priority. Meanwhile, the Partial-4 SVM ensemble yields the highest overall accuracy, suggesting that it is most effective in scenarios where maximizing the total number of correct classifications is the primary objective. These findings highlight that model selection should not rely solely on a single metric, but rather be aligned with the intended application context and performance requirements.

***Abstract*—Static traffic signal timings often cause severe delays for emergency vehicles, including ambulances at junctions in urban areas, putting lives at risk. To highlight this, the present study proposes an intelligent traffic control system that dynamically adjusts traffic signals based on real-time monitoring. The system employs a yolov8-based deep learning model fine-tuned through transfer learning for ambulance detection from live video. At an Intersection over Union (IoU) threshold of 0.5, the model achieves a mean Average Precision (mAP) of 0.860. To ensure continuous tracking, NORFair tracking is implemented to ensure constant detection across frames. Additionally, to improve explainability and, the frame incorporates Local Interpretable Model-Agnostic Explanation (LIME), providing visual signals into the model decision-making process. Once an ambulance is detected, the system instantly triggers a green-light activation for the ambulance's lane, enabling quick emergency response. Unlike conventional systems with fixed signal timing, this approach enables smart and adaptive traffic management in urban environment. However, the system's shortcomings in low-visibility situations, such as at night or in fog, despite its encouraging results, highlight the need for incorporating images taken at night and in foggy weather into the dataset.**

Keywords*—Ambulance detection; YOLOV8; LIME; transfer learning; NorFair; urban area; traffic control; smart traffic management

I. Introduction

An efficient emergency response is crucial for saving lives, especially in developing countries where road networks struggle to keep pace with the increasing number of vehicles. Emergency response, which includes ambulances [1] and bikes [2], often faces significant delays due to heavy traffic congestion, particularly at intersections. Traditional traffic management systems operate on pre-installed cycles, failing to dynamically adapt to real-time emergencies, which minimizes response times and hinders the traversal of ambulances through intersections. As the number of vehicles increases by a million every decade [3], it has become a concern for many researchers to provide quality traffic management, particularly for ambulances, to mitigate response times for emergencies.

Consequently, Machine learning and computer vision have unexpectedly enhanced intelligent systems, such as object detection [4], object tracking [5], vehicle counting [6], and traffic light detection [7]. Similar to detection and identification, computer vision algorithms have been adopted to calculate the vehicle speed [8] and pollution monitoring [9]. Furthermore, Machine learning algorithms are employed to control the path following of unmanned vehicles [10], robot navigation [11], and adaptive signal control [12]. While Deep learning models such as YOLO (You Only Look Once) [13] and R-CNN (Region-Based Convolutional Neural Networks) [14] have been effectively utilized for object detection, including the identification of emergency vehicles [15], adapting audio based location of vehicle [16]. Existing research primarily focuses on detection rather than integrating this detection into real-time, dynamic traffic control decision. Most prior studies lack the ability to autonomously manipulate traffic signals in response to ambulance localization, resulting in delayed emergency response and inefficient intersection management. Furthermore, explainable AI techniques have rarely been employed to interpret or validate the model's decision-making process in such safety-critical applications

The primary study of this article is based on an AI-driven traffic signal optimization framework that dynamically modifies vehicle routes upon detecting an approaching ambulance. The method adopted involves leveraging the LIME technique to enhance the confidentiality of the localization system while incorporating the tracking technique to improve traversal through the intersection. The core of this research lies in adopting a tailored object localization model, Yolov8, as a transfer learning approach. The model demonstrates outstanding performance, achieving a mean average precision of 0.85 at the threshold of 0.5. To improve signal optimization

beyond vehicle detection, tracking helps monitor the vehicle's trajectory and movement over time. Fig. 1 illustrates the overall system flow.

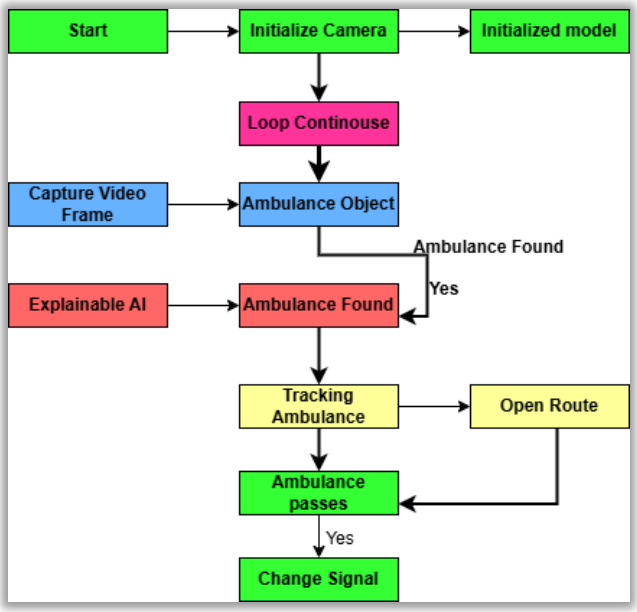

Fig. 1. The flow of the system.

The article presents a novel approach to improving ambulance localization explainability for optimizing ambulance traversal. The contribution of this article can be summarized as follows.

1) Model modification and adaptation: A customized Yolov8 model was used for ambulance detection in a dynamic and active environment using transfer learning, offering robust accuracy and efficiency. Formerly, the model was customized for object localization to support navigation for visually impaired people. This deliberate modification is intended to reduce the parameter, making the model effective for operation, even for a small dataset.

2) LIME for explainability: A significant novelty of this work is the amalgamation of LIME (Local Interpretable Model-Agnostic Explanation) [17] to provide understanding into the model's decision-making process. Integrating LIME into the localization model's prediction, we were able to understand and explain the spatial regions of the image that meaningfully influenced the model's decision to categorize an object as an ambulance.

3) Model transparency: We discussed the black-box nature of the deep learning model by applying LIME [17], making the localization model's predictions more understandable. The LIME explanations discovered which specific visual features helped the model's detection of an ambulance, offering transparency into the decision-making process.

4) Validation and real-world scenario: We demonstrate the practical utility of this approach by using the model on real-world video, including complex situations where ambulances are shown partially. This demonstrates the capability of the detection model, combined with LIME, to provide both accurate and explainable results across various conditions, making the approach suitable for deployment in real-world applications.

5) Optimizing the ambulance traversal: Unlike the existing system, which depends on fixed turns. Our approach focuses on enabling autonomous signal manipulation based on emergency or ambulance detection.

Section II of this article presents a literature review, providing a comprehensive examination of prior literature. Section III details the materials & methods, including dataset justification and selection, as well as the adopted methodology and training process. Additionally, Section IV presents the performance evaluation of the proposed framework, outlining the metrics and parameters used to assess its effectiveness. Section V highlights the results derived from the implemented methodology, while Section VI offers a detailed discussion and interpretation of these findings in relation to existing studies. Finally, Section VII concludes the paper with insights and outlines potential future direction for improving system performance under challenging conditions such as low visibility or heavy traffic.

II. Literature Survey

The escalation of traffic congestion in urban areas, particularly in developing countries, has brought significant challenges to the emergency response system [18]. Traditional traffic signal system [19], operates on predefined fixed-time cycles, often failing to adapt dynamically to real-time scenarios, which leads to delays in emergency vehicle transit such as ambulance. While these conventional systems are simple and cost effective, their lack of adaptability makes them unsuitable for modern, high density urban networks where emergency response time is critical.

Previous research highlights the successful application of artificial intelligence and its various branches across diverse fields [20], [21], [22], [23], [24], [25]. In the context of intelligent transport system (ITS) deep learning models have been employed for task such as object localization, classification and traffic pattern prediction,[4], [26]. Among these YOLO (You Only Look Once) [13] and its successive versions have been recognized for their high speed and accuracy in real time object detection. The newest iteration, YOLOv8 [27], suggests enhanced precision and speed, making it suitable for reliable real-time applications in dynamic environments. Likewise, the model is used successfully and precisely for locating emergency vehicles [18], most studies stop at detection and don't address how this information can be used to actively manage to manipulate traffic signals in response. This limited their practical impact on improving emergency response time.

To refine ambulance detection, researchers have explored multimodal fusion approach that combines visual data with audio cues [16], such as a siren, enhancing detection accuracy under diverse environmental conditions. Furthermore, a hybrid system utilizing an LSTM network for audio signal processing and a ResNet-18 for visual data was suggested [27] have demonstrated higher localization accuracy under noisy or low

visibility conditions. These models, however, are often computationally expensive and difficult to deploy in real-time citywide traffic systems, especially in developing regions, where hardware resources are limited.

In addition to advancements in detection and tracking, the nature of deep learning models still raises concerns about the decision-making processes they employ which limit trust and interpretability in safety critical applications such as emergency response. To mitigate this, Explainable Artificial Intelligence (XAI) techniques, such as LIME [28], Grad-CAM [29], have been proposed to make model decision more interpretable. Recent studies have applied XAI in traffic signal optimization [30]. Allowing engineers to better understand and validate model decisions. However, most of these approaches remain experimental and have not yet been integrated into end-to-end real-time ambulance detection.

Results from integrating XAI approaches into traffic management systems have been encouraging [31]. Existing research still lacks a unified framework that combines all the real-time ambulance localization, tracking and interpretable model decisions to dynamically adjust traffic signal. Few studies have attempted to bridge detection and action translating ambulance recognition directly into automated signal manipulation. Addressing this gap, the present study our process focuses on leveraging costumed yolov8 for ambulance localization through transfer learning, incorporating a tracking algorithm for trajectory monitoring, while employing LIME for model Interpretability. This contributes to enhancing emergency response times by ensuring that the traffic signal dynamically adapts to the presence of an ambulance, facilitating their passage through the intersection.

III. Material and Methods

This research article presents an ambulance traversal mechanism through the intersection. The system enhances the dynamic manipulation of the signal by detecting vehicles. Additionally, it provides tracking for monitoring the ambulance's trajectory and LIME for a detailed understanding of why the vehicle was identified as an ambulance.

A. Dataset Overview

To train and evaluate our ambulance traversal system through the intersection, we utilized a publicly available dataset sourced from the Roboflow platform [https://universe.roboflow.com/himank-vpetc/ambulance-4bova/dataset/1]. This dataset was specifically selected for its relevance to real-world situations where the timely localization of vehicles, such as ambulances, is vital for dynamic signal manipulation and the quick passage of ambulances through intersections. The dataset comprises a diverse set of images featuring ambulances in various backgrounds, lighting conditions, and angles, providing robust variability that supports generalization during model training. In addition, the photos are annotated using rectangle bounding boxes that label instances of the ambulances, enabling our customized object detection model to learn spatial and visual features for efficient identification.

B. Dataset Specifications

1) Source: Roboflow Universe [31]

2) Category: Object detection (Single class "Ambulance")

3) Number of images: We used a dataset of 6,432 images, each with dimensions 640 × 640 pixels and 3 color channels, for training the object detection model.

4) Annotation Format: YOLO rectangle bounding box

5) Image Resolution: The images were down sampled and standardized to a resolution of 640 × 640 pixels

6) Environment Type: Urban outdoor scenes, roads

7) Data Split: 70% training, 20% validation, 10% test. The approach is employed to gather a balance trade-off between the training and validation performance evaluation and the final test accuracy.

8) Additionally, this uniform split ensures a consistent distribution across subsets, which aids in maintaining a representative sample and preventing overfitting.

C. Justification for Database Selection

The needs of our study, which centered on the real-time detection of ambulances at urban intersections to enable dynamic traffic signal control, led to the selection of the "Ambulance" dataset from Roboflow [31]. This dataset, specifically curated for ambulance recognition, differs from general-purpose object detection datasets in that it offers a focused and domain-relevant collection of annotated images under various real-world scenarios.

The dataset is ideal for training a robust detection model that can operate reliably in live surveillance setups, as ambulances are present in a variety of backgrounds, including junctions, roadside settings, and diverse lighting conditions. Since our suggested solution directly initiates the dynamic reconfiguration of traffic signals to prioritize the passage of emergency vehicles, accurate and timely ambulance recognition is essential.

This dataset aligns well with our research aim, operational, and technical objectives due to its excellent bounding box annotations and conformity to the customized ambulance detection training format. As a result, its applicability and compatibility with real-time, vision-based smart traffic control systems are.

D. Model Architecture and Training Process

1) Model selection and justification: In this article, we employed customized YOLOv8 architecture previously modified to highlight the challenges associated with limited data availability. To address the constraints posed by small dataset sizes, a deliberate customization was introduced by reducing the convolutional kernel size from the conventional 3×3 to a more compact 2×2 configuration. This systematic manipulation allows the model to analyze minute details more effectively while concurrently reducing the number of learnable parameters, thus mitigating the risk of overfitting and improving generalization performance.

Furthermore, the padding function was modernized to match the reduced kernel size, confirming proper padding and spatial consistency across layers. The customized convolutional layers combined 64 filters with a stride of 2 × 2 and padding of 1, keeping the dimension of the feature maps. Furthermore, the rectified linear unit (ReLU) activation function was used to increase the discriminative power of feature extraction.

This precisely customized layer design aimed to optimize feature representation while preserving model efficiency. Building upon this foundation, the customized yolov8 model was used through transfer learning to fine-tune it on the ambulance detection job.

E. Training Setup

For transfer learning, the model was retrained using an explicit configuration on the openly available ambulance detection dataset to facilitate transfer learning. The input frames were down sampled to 640 × 640 pixels, and the training process was carried out for 50 epochs, applying a CUDA GPU to quicken the process. To conserve formerly learned generic features, the first ten layers of the network were frozen, allowing only the subsequent layers to fine-tune for ambulance-specific localization. To minimize overfitting, Stochastic Gradient Descent (SGD) was employed, utilizing a learning rate of 0.01, a momentum of 0.9, and a weight decay of 0.001. In addition to visual inspection of predicted bounding boxes, the mean Average Precision (mAP) measure on the validation set was used to track model performance during training. Using an Intersection over Union (IoU) criterion of 0.5, the test set's final evaluation yielded encouraging results with a mean Average Precision (mAP) score of 0.85 shown in PR curve, indicating a high intersection ambulance detection ability.

During training, the model's performance on the validation set was continuously monitored using the mean average precision (mAP) metric. In addition, visual inspection of the model's predictions was conducted to qualitatively assess its accuracy. Upon completion of training, the test set was used to evaluate the model's performance using the same metrics as the validation set. Evaluation was performed at an intersection over union (IoU) threshold of 0.5. The trained model achieved an impressive mAP of 0.850, demonstrating its strong object detection capability. The results of the model are shown in Fig. 2.

Fig. 2. Test set.

For the evaluation of our intelligent traffic management system while incorporating real-time ambulance localization, tracking, with explainable AI, for efficient vehicle traversal, the camera continuously captures the video data to locate the ambulances from the intersection point. Capitalizing on the detection model and the Norfair tracker for persistent object localization—even during occlusions or temporary detection losses—the system reliably monitors ambulance movement. Upon detection, the system triggers the simulated traffic signal to transition to green, allowing for smooth passage. In addition to improving transparency, Local Interpretable Model-agnostic Explanations (LIME) produces visual rationales that capture the most influential frame region, which contributes to model classification. Periodic LIME explanations for high-confidence localization depict insight into the decision-making process, while the Norfair tracker maintains robust trajectory estimation by incorporating location across frames. This integration of state-of-the-art localization, persistent tracking, and explainable AI establishes a responsive and trustworthy emergency vehicle priority system for the urban environment shown in Real-time detection of an ambulance (Fig. 3).

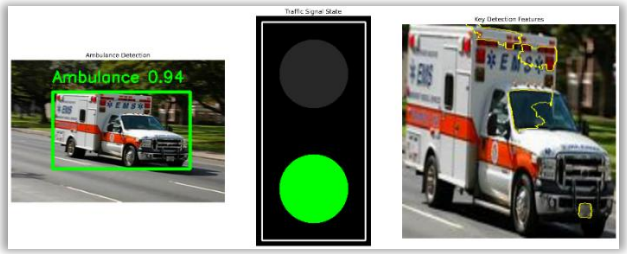

Fig. 3. Real-time detection of an ambulance.

This ambulance passage, combined with ambulance localization, tracker, and LIME, aims to enhance the dynamic management of traffic lights, allowing for reducing response time and improving the traversal of the ambulance through the intersection. The flow of the work is depicted Proposed system architecture (Fig. 4).

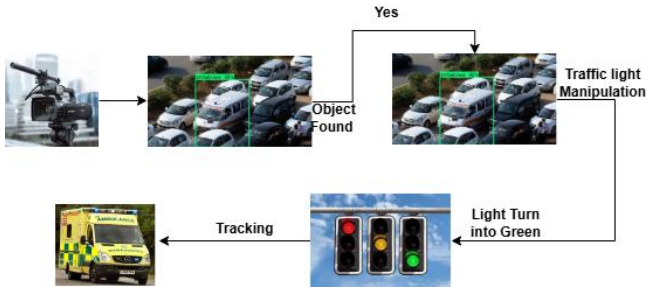

Fig. 4. Proposed system architecture.

IV. Performance Evaluation

To assess the model's effectiveness, the author employed standard performance metrics, namely Precision, Recall, and the F1 score. Precision is the proportion of correctly predicted positive instances to the total predicted positive cases.

Recall is the proportion of correctly identified positive instances to the actual number of positive cases provided to the model.

The formulas for precision and recall are given as:

Precision = True Positive / (True Positive + False Positive) (1)

Recall = True Positive / (True Positive + False Negative) (2)

The F1 score denotes the harmonic mean of precision and recall and is computed by applying the following formula:

F1 Score = (2 × Precision × Recall) / (Precision + Recall) (3)

V. Result

The ambulance detection model used in the current paper was precisely trained on an openly available dataset of ambulance frames captured under diverse environmental conditions, including varying lights, angel and background scenarios. The model exhibited extraordinary performance on this dataset, achieving a mean average precision (mAP) of 0.85 at an IoU threshold of 0.5. This striking result highlights the model's capability to accurately detect ambulances, even in complex urban scenes with background distractions. The consistent bounding box predictions observed during testing further confirm the robustness of the transfer learning approach adopted in this study. Fig. 5 shows PR curve (training result) and Fig. 6 shows the confusion matrix.

A comprehensive analysis of different yolo variants is presented in Table I, summarizing the evaluation of Map, precision, recall and F1 score. While Yolov5 achieved slightly higher precision (0.90) and recall (0.95), our adapted model achieved a balance performance with the highest Map (0.85) and F1 score. This indicates that the proposed model offers an optimal trade-off between precision and recall, meaning it can locate ambulance accurately without significantly increasing false positive or missing detections.

TABLE I. Comparison of Yolo Models

Models	mAP	Precision	Recall	F1-score
YOLOv5	0.84	0.90	0.95	0.84
YOLOv6	0.83	0.89	0.94	0.83
YOLOv7	0.78	0.92	0.94	0.78
YOLOX	0.82	0.86	0.93	0.82
Our Approach	0.85	0.75	0.83	0.85

Object localization serves a pivotal role in computer vision, seeking to divide input images into a grid and predict bounding boxes along with class probabilities for each grid cell. In a typical object detection pipeline, the process commences by segmenting the image into a grid. Each grid cell is then assessed to estimate the bounding box coordinates and the probability that it contains a particular object. Each bounding box prediction consists of four essential coordinates that accurately outline its position within a grid cell. Alongside these coordinates, a confidence score is offered, indicating the likelihood that the predicted box contains an object. This structured approach is a key element of many object localization models, such as YOLOv5 [32], YOLOv6 [33], YOLOv7 [34] and YOLOX [35]. By utilizing this method, these models attain efficient object detection and localization across a broad spectrum of visual environments.

The confusion matrix illustrating the classification performance of our transfer learning model across the ambulance class is shown in Confusion matrix. A relative summary of performance metrics—including mean average precision (mAP), precision, recall, and F1-score—for YOLOv7, YOLOv6, YOLOv5, YOLOX, and our adapted model is given in Table I. The values for precision, recall, and F1-score were derived using the optimal confidence threshold, selected based on the highest F1-score performance.

The slightly lower precision (0.75) compared to other models can be attributed to the model's high sensitivity toward complex backgrounds and reflections, which occasionally resulted in false positives when vehicles had similar color patterns or shapes. However, the high recall value (0.83) indicates that the model effectively identifies almost all ambulance instances in the scene, ensuring minimal missed detections—a critical requirement for emergency response systems. The higher F1-score (0.85) further suggests that our proposed approach achieves a strong balance between detection accuracy and reliability. This performance demonstrates the robustness of the transfer learning strategy employed, confirming that YOLOv8's architectural enhancements contribute significantly to real-time and context-aware ambulance detection, even under dynamically changing urban environments. These findings underline the practical applicability of the proposed system for intelligent traffic management and emergency prioritization.

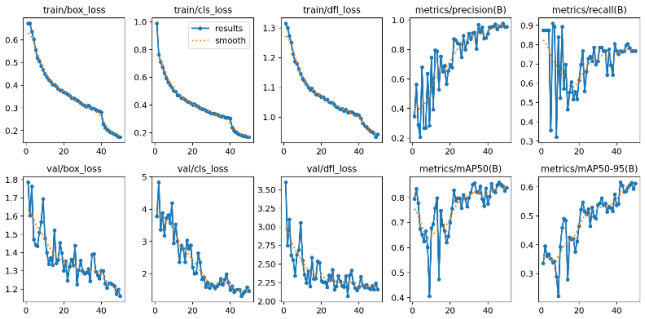

Fig. 5. Training result.

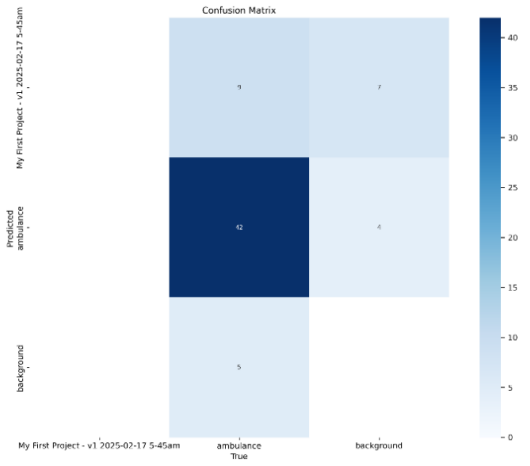

Fig. 6. Confusion matrix.

From a practical standpoint, the proposed system demonstrates substantial potential for real-world implementation within intelligent traffic control frameworks. By accurately identifying and tracking ambulances in real time, the model enables automatic signal adjustment, reducing human dependency and minimizing emergency response delays. The deployment of this system at metropolitan intersections could significantly enhance ambulance traversal efficiency, ensure timely medical assistance and ultimately save lives. Furthermore, its adaptable framework allows integration with existing surveillance infrastructure, making it a cost-effective and scalable solution for developing urban areas (Fig. 7).

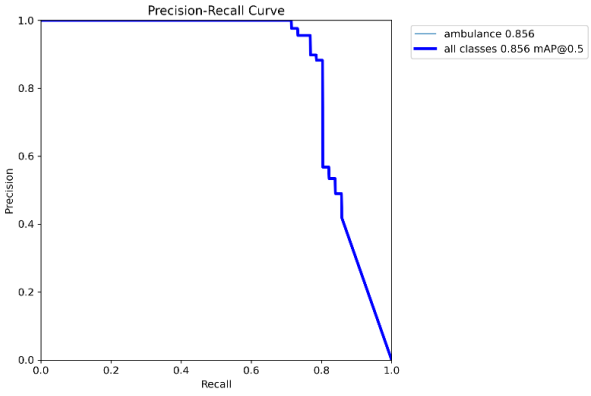

Fig. 7. PR curve.

VI. Discussion

The primary concern of this research article was to introduce a dynamic ambulance traversal system through intersections, particularly in urban areas, by incorporating intelligent traffic signal manipulation based on real-time ambulance detection. The proposed approach leverages a customized YOLOv8 detection model through transfer learning, achieving a mean Average Precision (mAP) of 0.850 show in PR curve at an IoU threshold of 0.5. This performance was optimized by modifying the kernel size to enhance learning on a smaller dataset, thereby improving generalization and reducing overfitting.

Unlike train, addition to traffic management systems that operate on fixed signal timing, our approach enables dynamic control, ensuring immediate clearance of lanes for ambulances upon detection. To track ambulance movement across multiple frames and maintain continuity, NORFair tracking was employed, enhancing the system's temporal awareness and robustness in real-world scenarios. Furthermore, the integration of LIME (Local Interpretable Model-agnostic Explanations) provides visual interpretability by highlighting the features contributing to the model's decision, thereby increasing its transparency and reliability in safety-critical applications.

However, certain limitations persist, including reduced effectiveness during nighttime and foggy weather conditions. These challenges necessitate future research that incorporates thermal imaging and low-light datasets to enhance the reliability of detection. Additionally, the study acknowledges threats to validity, such as dataset bias due to environment-specific data, limited generalization to rural or unstructured settings, and dependency on specific hardware configurations for real-time inference. From a construct validity standpoint, reliance solely on mAP@0.5 as the evaluation metric may not fully capture practical deployment outcomes, highlighting the need for real-world testing and user-centric assessments to validate the system's effectiveness.

Beyond addressing visibility limitations, future work could explore integrating multi-modal sensor fusion (visual, infrared, and audio) to strengthen detection reliability across diverse conditions. Furthermore, extending the framework to multi-intersection coordination through reinforcement learning could optimize city-wide ambulance routing and signal control. Deploying the model on low-power edge devices such as NVIDIA Jetson would further support real-time scalability and facilitate deployment within smart city infrastructures

VII. Conclusion and Future Work

This research article presents a specialized smart traffic signal system designed to ensure the timely and uninterrupted passage of ambulances through urban intersections. The core objective is to overcome the delays commonly experienced by emergency vehicles at traffic signals by dynamically controlling traffic lights in real-time based on ambulance detection. The system integrates advanced computer vision techniques using a custom-trained YOLOv8 model as a transfer learning approach, optimized with a reduced kernel size to enhance performance on a limited dataset. This configuration enables the precise identification of ambulances, even in congested urban environments.

Upon detecting an ambulance, the system immediately manipulates the traffic signals to prioritize the ambulance's lane, ensuring its swift traversal through the intersection. NORFair tracking is employed to maintain continuous monitoring of the ambulance across multiple frames, which is critical for consistent traffic control decisions. Additionally, to enhance the reliability and interpretability of the model, LIME (Local Interpretable Model-Agnostic Explanations) is utilized to visualize and validate the features used for ambulance detection, thereby increasing system transparency.

The proposed solution significantly advances traditional traffic systems, which rely on fixed-timing schedules that often fail to accommodate emergency scenarios. However, while the system demonstrates robust performance during daylight and clear conditions, limitations persist in nighttime or foggy weather, where detection accuracy may degrade. These challenges underscore the need for future enhancements, such as expanding the dataset to encompass diverse lighting and weather conditions and incorporating thermal or infrared imaging to facilitate detection in low-visibility environments.

In addition to enhancing detection under low-visibility conditions, subsequent research could focus on combining multiple sensing modalities, such as visual, infrared, and audio signals, to further strengthen system reliability. Expanding the framework to manage multiple intersections simultaneously and incorporating intelligent learning strategies could allow more efficient city-wide ambulance routes. Finally, implementing the system on compact, real-time edge devices

would facilitate practical deployment in smart city environments, ensuring low-latency and scalable performance

Overall, this research contributes to the development of a responsive, intelligent traffic management system that can enhance emergency response efficiency and potentially save lives by minimizing delays at intersections. It lays the groundwork for future smart city infrastructures that prioritize safety and real-time adaptability in urban mobility systems.

ACKNOWLEDGMENT

This article has been funded by the Deanship of Scientific Research in King Faisal University with Grant Number KFU253082. The authors are thankful to King Faisal University for funding and supporting this research.

Digital Trust and Legacy: Mapping the Intersection of Inheritance Systems and Emerging Technologies (2010–2025)

Nor Aimuni Md Rashid*, Faiqah Hafidzah Halim, Hazrati Zaini,
Norshahidatul Hasana Ishak, Nur Farahin Mohd Johari, Alya Geogiana Buja
Faculty of Computer and Mathematical Sciences, UiTM Melaka, Melaka, Malaysia[1]

***Abstract*—Inheritance systems worldwide are undergoing a paradigm shift evolving from manually administered processes to technologically enabled platforms for managing both tangible and digital assets. Yet, the scholarly understanding of how technologies ranging from information systems to blockchain have transformed inheritance management remains underexplored and fragmented. This study aims to trace the evolution of inheritance systems from 2010 to 2025, with a particular focus on the digitalization of inheritance management, emerging technologies and governance models. Using a bibliometric approach, 229 documents were initially retrieved from the Scopus database. After removing irrelevant records, a refined dataset of 81 publications was analyzed using Excel and VOSviewer. The analysis included performance metrics (e.g., publication growth, citation trends, and country output) and science mapping (keyword co-occurrence and clustering). Findings reveal a significant rise in publications post-2020, coinciding with increased attention to digital assets, data privacy laws (e.g., GDPR) and emerging technologies such as blockchain. The most active contributors were from the United States, China and the United Kingdom. Highly cited articles discuss themes such as digital legacy, legal frameworks, asset authentication and ethical considerations. Thematic clustering revealed four research domains: digital legacy and estate transition, digital transformation and trust, digital asset structuring and fraud prevention in social media inheritance. This study contributes a comprehensive overview of the field's conceptual landscape by highlighting the uneven yet accelerating integration of digital tools in inheritance systems. It also underscores the urgent need for inclusive, interdisciplinary frameworks that accommodate diverse legal, cultural and technological contexts for future inheritance governance.**

Keywords*—*Inheritance systems; digitalization; secure data; trust; technologies; digital legacy; blockchain; digital assets

I. Introduction

The administration of inheritance has long been anchored in traditional legal, religious, and institutional frameworks which often involve handwritten wills, notarized documents and in-person court procedures [1], [2]. These systems were designed for a paper-based world, emphasizing tangibility, permanence and hierarchical authority [1]. However, in the past two decades, the global proliferation of digital technologies has fundamentally disrupted how personal data, assets and identities are created, stored and transmitted across generations [3], [4].

At the same time, governments, legal institutions and private sectors have begun to digitally transform inheritance-related services. For instance, the emergence of e-probate systems, blockchain-based wills, digital vaults and GDPR-driven data succession laws has opened new avenues for modernizing estate management [5], [6]. These transformations are not merely administrative but structural, demanding new ways of thinking about trust, consent, privacy, and control in the digital afterlife. Legal scholars such as in research [7] have voiced growing concerns about the fragmentation of regulatory approaches to digital inheritance especially in cross-border data access, authentication of post-mortem rights and platform-level inconsistencies. Similarly, technological researchers such as [8] have highlighted the role of AI, encryption and predictive systems in managing succession processes and safeguarding digital legacies.

Despite this interdisciplinary momentum, the field remains conceptually fragmented and empirically under-mapped. Studies are often siloed within either legal discourse, technological development or social computing without a unified understanding of how digital trust and inheritance intersect in practice. This gap is especially visible in emerging economies and inheritance systems, where cultural, legal and technological dynamics intersect in complex ways.

To address this gap, this study applies bibliometric analysis to trace how inheritance systems have evolved in scholarly research alongside emerging technologies from 2010 to 2025. By examining publication patterns, citation influence, author contributions and keyword networks. We aim to uncover the institutional, thematic and conceptual structures underpinning this transformation. The dataset draws from Scopus-indexed publications using keywords such as inheritance, estate planning, succession law, digital legacy, blockchain wills, and data protection. This allows for a comprehensive cross-disciplinary review.

To guide the analysis, this study poses the following research questions (RQs):

RQ1: What are the publication trends and scholarly impact patterns in digital inheritance research between 2010 and 2025?

*Corresponding author.

RQ2: Which countries and authors have made the most significant contributions to the field, and how has global participation evolved?

RQ3: What are the most highly cited works in this domain, and what insights or innovations do they introduce?

RQ4: What are the emerging research hotspots and thematic clusters identified through keyword co-occurrence analysis?

By answering these questions, the study contributes to a deeper understanding of how the inheritance ecosystem is transforming und er digital disruption and offering strategic insights for scholars, policymakers, technologists and legal practitioners alike.

The remainder of this paper is structured as follows: Section II details the bibliometric methodology and screening strategy. Section III presents the results and analysis. Section IV discusses the findings in relation to existing literature. Finally, Section V concludes with implications and future research directions

II. METHOD

This study adopts a quantitative, descriptive and exploratory research design grounded in bibliometric methodology. The methodological framework is divided into two main components: the first involves bibliometric analysis to uncover the intellectual and conceptual structure of the research domain. The second details the procedural aspects of data collection, preprocessing and tool deployment [9].

A. Bibliometric Analysis

The bibliometric component applies various quantitative indicators and science mapping techniques to examine productivity, influence and thematic development within the field of digital inheritance systems. To assess productivity and impact, this study analysed annual publication output to determine research growth trends over time. Country-level contributions were examined to identify the most active and influential nations in this area of study. Additionally, citation analysis was conducted to highlight the most highly cited publications to gain insight into foundational works and influential ideas that have shaped the discourse.

To identify emerging research themes, a keyword co-occurrence analysis was performed using both author keywords and indexed terms. This analysis revealed dominant thematic clusters and provided insight into research hotspots and future directions. A threshold-based clustering approach was employed in VOSviewer to visualize these relationships and interpret the underlying structure of the field.

B. Procedural Analysis

The procedural analysis outlines the systematic steps involved in the retrieval and preparation of bibliographic data as well as the tools used for analysis. Scopus was selected as the primary data source due to its extensive coverage of peer-reviewed literature across multiple disciplines. A tailored Boolean search query was developed to reflect the intersection of inheritance-related legal terminology and digital transformation concepts. The final search string incorporated terms such as "inheritance," "succession," "will and testament," and "digital estate," among others and was limited to occurrences within the document title. The query targeted publications from 2010 to 2025 and restricted to English-language documents classified as articles or reviews. The data were retrieved on 4 August 2025 to ensure reproducibility and consistency with the research timeframe.

Following retrieval, the metadata were exported from Scopus in CSV format. The exported fields included the document title, abstract, author names and affiliations, author keywords, publication year, source title and citation count. This dataset served as the foundation for both the bibliometric and thematic mapping analyses. The record selection strategy and scope of inclusion are further detailed in Section II(C) and illustrated in Fig. 1.

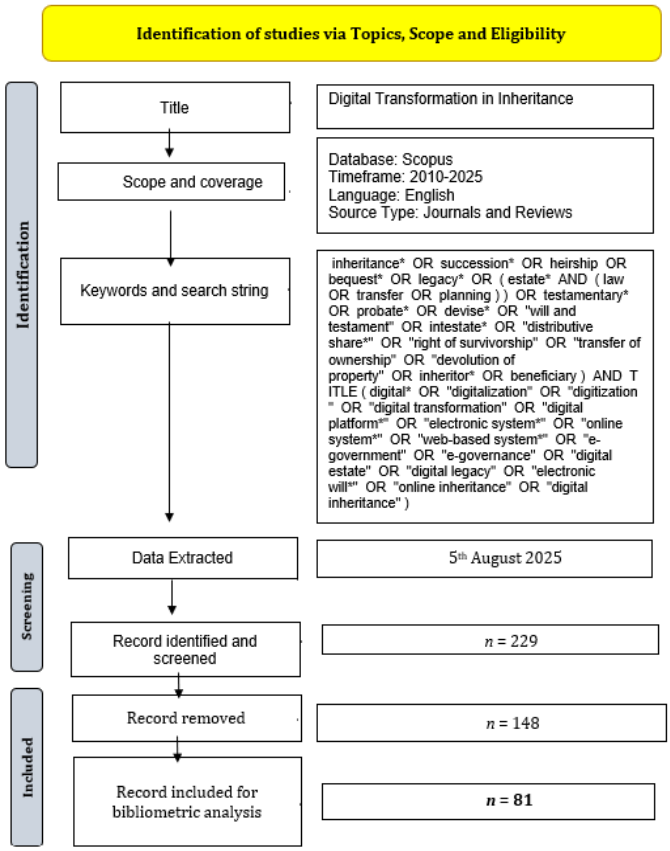

Fig. 1. Study flowchart.

All mapping and visualization tasks were conducted using VOSviewer version 1.6.20, released in late 2024. Developed by [10], VOSviewer is widely used for constructing and visualizing bibliometric networks including co-authorship, citation and keyword co-occurrence maps. The software was instrumental in generating thematic clusters and visual overlays that reveal the structural and temporal evolution of the research field.

C. Scope of Inclusion and Screening Strategy

Fig. 1 illustrates the PRISMA-based identification and screening process adopted to ensure that the final dataset aligns with the objectives of this study, titled "Digital Trust and

Legacy: Mapping the Intersection of Inheritance Systems and Emerging Technologies (2010–2025).” The scope of this research centres on the transformation of inheritance practices in response to technological advancements which include those that introduce new models of trust, asset control and data governance. The analysis emphasizes how various forms of assets whether tangible (such as property or wealth) or digital (such as online accounts, cryptocurrencies, or cloud-stored documents) are planned, managed, secured and transferred through digitally mediated systems. The inclusion criteria targeted publications that explored legal frameworks, digital estate planning tools, security infrastructures (e.g., blockchain, authentication protocols) and emerging governance models surrounding succession and beneficiary rights.

Conversely, studies focusing exclusively on cultural, symbolic or intangible heritage such as music, oral traditions, crafts or historical memory were excluded as they fall outside the asset- and system-oriented lens of this study. From an initial set of 229 records retrieved from Scopus using a comprehensive Boolean search strategy, 148 records were removed for not meeting the inclusion criteria. The final dataset includes 81 documents deemed directly relevant to the digital transformation of inheritance systems that form the empirical basis for the subsequent bibliometric mapping and thematic analysis.

III. Results

This section presents the findings of the bibliometric analysis based on the four research questions that guided the study. It covers the publication trends over time, the most active countries contributing to the field, the most highly cited works and their thematic focus, and the key research hotspots identified through keyword co-occurrence and overlay visualizations. Each subsection provides a focused analysis supported by visual data, offering a comprehensive overview of how research on digital inheritance systems has evolved from 2010 to 2025.

A. Publication Trends and Growth Patterns (RQ1)

The analysis (Fig. 2) reveals a notable growth trajectory in scholarly attention to the intersection of inheritance systems and emerging digital technologies. Early years in the dataset (2011–2015) show minimal activity, with annual publication counts (TP) ranging from 0 to 2. This suggests the domain was relatively underexplored during the initial phase.

From 2016 onwards, a gradual increase in publication output is observed. This marked by consistent contributions through 2018–2020. The year 2021 represents a significant turning point, with a dramatic surge to 17 publications which is the highest in the dataset. This spike indicates a period of heightened academic interest and possibly reflects broader global shifts toward digital estate planning and the legal mplications of digital assets. Following the 2021 peak, publication levels stabilized but remained elevated compared to the pre-2020 period. Between 2022 and 2025, annual outputs ranged from 8 to 12 papers. This suggests sustained research engagement and possibly the establishment of a new research niche.

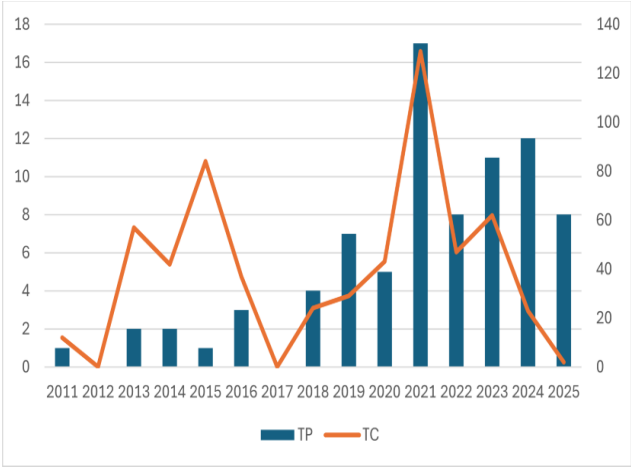

Fig. 2. Total publication and total citation.

Citation counts (TC) also provide insight into the influence and maturity of the field. Although early publications were few, but some received substantial citations. For instance, a single publication in 2015 accrued 84 citations, and two papers in 2013 earned 57 citations collectively and indicate that foundational works from earlier years had long-term scholarly impact. The highest citation activity occurred in 2021, coinciding with the publication spike. With 129 citations, this year not only marked a volume peak but also a qualitative impact peak, potentially due to high relevance, interdisciplinary reach or pandemic-driven digitalization themes. By contrast, recent publications in 2024 and 2025 show lower citation counts, which is expected given their recency and limited citation window. However, sustained output in these years points to an ongoing momentum and further opportunities for citation accumulation. The data indicate a transition from an emerging to an accelerating field. The early phase (2011–2015) was formative, the middle years (2016–2020) marked exploratory expansion and the recent period (2021–2025) reflects consolidation and growth.

B. Global Contributions and Geographic Distribution (RQ2)

Table I present the distribution of total publications by country from 2010 to 2025. The United States recorded the highest number of publications with 43 followed closely by China with 42. The United Kingdom ranked third with 27 publications. Other contributing countries included India (10 publications) and Brazil (9 publications). Five countries which are Canada, France, Germany, Italy and Spain each produced 8 publications.

Fig. 3 illustrates this data using a world map, where darker shades represent higher publication output. The map shows the concentration of research activities across North America, Europe and parts of Asia. The top ten countries collectively account for a significant portion of the total global output in the field of digital inheritance systems during the study period.

C. Most Cited Articles and Influential Themes (RQ3)

Table II presents the top ten most cited publications in the domain of digital inheritance systems between 2010 and 2025. The analysis of the most highly cited publications from 2010 to 2025 reveals a rich diversity of perspectives on digital

inheritance, ranging from legal frameworks to socio-technical systems.

The top-cited work by Jackson & Dunn-Jensen [11] (59 citations) underscores the strategic role of data and predictive analytics in succession planning within the digital economy which positioning leadership transition as an emerging concern in organizational inheritance processes. Closely following, Doyle & Brubaker [12] (26 citations) conceptualize a digital legacy lifecycle model by examining how personal data persists posthumously and is shaped by intergenerational identity management [13].

Several studies focused on public digital infrastructure and governance. For instance, Abu Bakar et al. [14] with 13 citations provided a citizen-centric blueprint for legacy system modernization in public institutions which contributing to discussions on digital transformation in government services. Similarly Pöschl & Freiling [15] examined the role of external succession in family-owned businesses by showing how managerial priorities affect long-term digital investment.

Legal and regulatory dimensions formed a significant thematic cluster. Paul-Choudhury [16] was among the earliest to articulate the personal and emotional implications of digital death by urging formal mechanisms to manage digital assets such as social media accounts. A notable contribution from Cahn & Law [6] highlights legislative gaps in U.S. probate law concerning digital property succession and reinforcing calls for digital estate law reform.

TABLE I. TOP 10 MOST PRODUCTIVE COUNTRIES IN PUBLICATIONS RELATED TO DIGITAL INHERITANCE SYSTEMS (2010–2025)

Country	Total Publication
United States	43
China	42
United Kingdom	27
India	10
Brazil	9
Canada	8
France	8
Germany	8
Italy	8
Spain	8

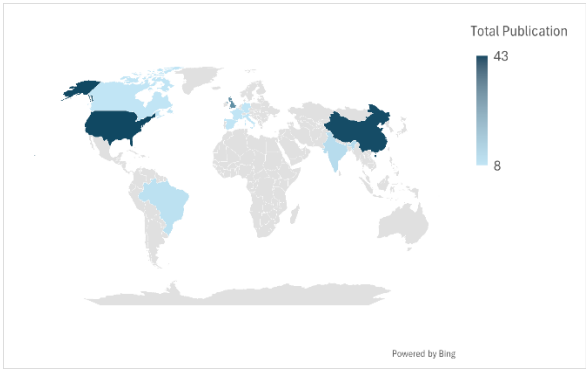

Fig. 3. Mapping total publication by country.

TABLE II. HIGH-IMPACT PUBLICATIONS ADDRESSING LEGAL AND GOVERNANCE FRAMEWORKS FOR DIGITAL INHERITANCE

Authors	Year	Citations	Insights	Themes / Technologies Used
[11]	2021	59	Proposes a framework for succession planning in the digital economy, emphasizing the role of data and predictive analytics in talent alignment.	Leadership succession, digital transformation, big data, predictive analytics
[12]	2023	26	Presents a lifecycle model of digital legacy, identifying how personal data is encoded, accessed, and disposed after death. Highlights multi-generational digital identity challenges.	Digital legacy, identity management, lifecycle of data, social computing
[14]	2022	13	Offers a comprehensive guideline for modernizing legacy IT systems in public sector governance. Emphasizes the alignment of modernization with citizen-centric digital transformation goals.	Legacy system modernization, digital government, citizen-centric services, qualitative methodology
[15]	2020	13	Examines how external succession in family businesses influences digitalization priorities. Found that short-term efficiency often outweighs long-term digital innovation during transitions.	Family business succession, SME digitalization, management buy-in, qualitative case study
[16]	2011	12	Discusses the personal and emotional implications of digital death, urging the development of tools and policies to manage social media accounts and online identities post-mortem.	Digital legacy, online identity, end-of-life planning, social media inheritance
[6]	2014	10	Analyzes how federal U.S. probate law lacks provisions for digital assets, highlighting the legal gap in handling digital property within estate law and succession.	Probate law, digital estate, legal reform, asset succession
[17]	2021	9	Explores Brazil's legal framework on digital inheritance and data protection. Emphasizes legal rights of heirs to access digital assets and the evolving interpretations under civil law.	Data protection law, civil code, digital inheritance rights, Brazilian legal framework
[18]	2021	9	Investigates user perceptions toward using technology in managing digital inheritance. Findings show growing acceptance but concern about privacy and clarity of ownership.	Digital inheritance, user perception, technology adoption, privacy concerns
[13]	2021	8	Explores the psychological and motivational drivers for elderly individuals to engage in digital inheritance planning, particularly through intergenerational knowledge transfer.	Digital inheritance motivation, intergenerational communication, aging and digital literacy
[5]	2019	7	Legal analysis of Italy's GDPR-aligned reform for post-mortem digital data rights; comparative EU focus (e.g., BGH Facebook case); advocates legal clarity and digital wills.	GDPR Art. 2-terdecies, digital inheritance law, posthumous privacy, data access protocols

Regionally focused legal analyses also emerged. Beppu et al. [17] explored Brazil's evolving data protection regime and advocating for clearer rights of heirs in accessing digital content. In the Middle East, Yousef et al. [18] reported increasing user readiness to adopt digital inheritance solutions even though albeit tempered by privacy concerns. Likewise, Oh & Kang [13] contributed insights into motivational factors influencing elderly engagement in inheritance planning which focus on intergenerational communication.

A pivotal European legal perspective was offered by Bartolini & Patti [5]. Their work examined Italy's implementation of GDPR Article 2-terdecies and emphasizing the need for legal recognition of posthumous privacy rights and proposing digital wills as a formal succession mechanism. This article gained traction for bridging comparative EU jurisprudence, including the landmark BGH Facebook case in Germany.

Together, these studies delineate a multidisciplinary field concerned with not only the technological management of digital assets but also the ethical, legal and emotional frameworks needed to govern inheritance in an increasingly digital world.

D. Emerging Research Hotspots and Thematic Clusters (RQ4)

To explore the conceptual structure and thematic evolution of research on digital inheritance systems, a keyword co-occurrence analysis was conducted using author-supplied keywords. This technique identifies the frequency and strength of co-appearance between terms across the literature thereby revealing latent thematic clusters and emerging research hotspots. The analysis was performed using VOSviewer which enables visual mapping of semantic relationships within the dataset.

Out of a total of 871 unique keywords, a minimum occurrence threshold of 3 was applied to ensure analytical relevance while reducing semantic noise. This resulted in 27 keywords that met the threshold and were included in the final map generation. The selected terms reflect the most actively discussed and conceptually significant topics within the field between 2010 and 2025.

The co-occurrence network visualization is structured into distinct clusters each representing a thematic focus area such as digital legacy management, privacy and identity, trust in digital systems and digital asset inheritance. These clusters provide insight into the current direction of the field and point to opportunities for future research, especially in interdisciplinary domains where legal, technological, and societal issues intersect.

This filtering resulted in 27 relevant keywords, which were grouped into four distinct thematic clusters based on their co-occurrence relationships. These clusters are visualized in Fig. 4 and reflect the underlying conceptual structure of the field between 2010 and 2025.

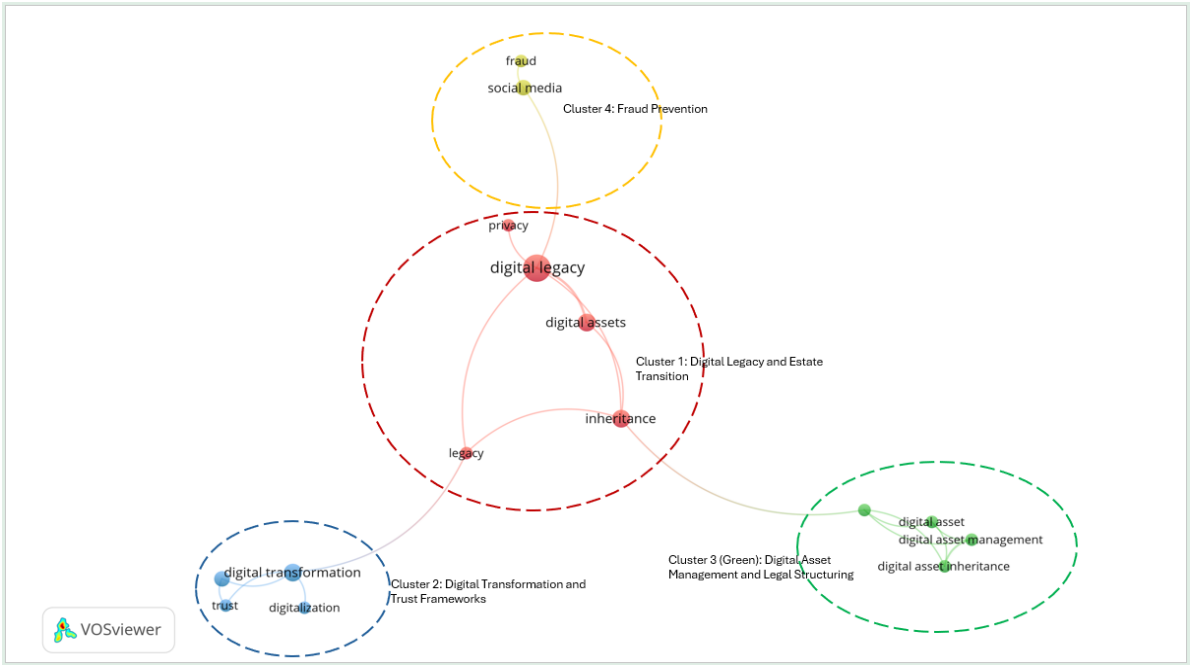

Fig. 4. Network visualization based on cluster.

The first cluster, represented in red, centers on the theme of digital legacy and estate transition. It includes terms such as "digital legacy," "inheritance," "digital assets," and "privacy." This cluster reflects foundational concerns in the literature regarding how digital identities and possessions are handled after death. It addresses both the emotional and ethical aspects of posthumous data management, as well as the legal ambiguity surrounding access rights to online accounts. A key article representing this cluster is the work by [12] who conducted a systematic review of digital legacy scholarship and proposed a lifecycle model that outlines the encoding, access and disposal of personal data after death. Their work

emphasizes intergenerational identity management and the evolving practices associated with post-mortem data governance.

The second cluster, shown in blue, focuses on digital transformation and trust frameworks. Keywords such as "digital transformation," "digitalization," and "trust" are indicative of this cluster's emphasis on the modernization of legal and institutional systems to support digital estate planning. The scholarly focus here has expanded toward understanding how public and private institutions are transitioning from legacy practices to digitally enabled platforms. One prominent contribution in this space is the article by [11] which proposes a framework for succession planning in the digital economy. Their model highlights the role of data analytics and predictive tools in aligning leadership transitions with organizational readiness thereby emphasizing the integration of digital governance and institutional trust.

Cluster three, highlighted in green, is oriented toward digital asset management and legal structuring. This cluster comprises keywords such as "digital asset," "digital asset inheritance," and "digital asset management." The focus here is more operational, concerned with the technical and legal frameworks necessary for securely managing and transferring digital property. A representative article in this domain is by [14] who conducted a qualitative study on legacy system modernization within public sector organizations. Their research highlights how digital infrastructure upgrades are essential for enabling transparent and accountable digital asset governance, especially in citizen-centric services.

The fourth and smallest cluster delineated in yellow comprises the keywords "fraud" and "social media." This cluster highlights a niche research area concerned with the risks of digital fraud particularly in the context of social platforms and identity exposure. Rather than focusing directly on digital inheritance, this theme explores how fraudulent activities, misinformation and unauthorized access proliferate in digital spaces especially after an individual's death, when digital identities may remain unattended. The inclusion of "social media" suggests that platforms such as Facebook, Instagram and others are being examined for their vulnerability to impersonation, data breaches, and fraudulent claims. Although not a dominant research stream, the cluster underscores the growing academic concern for developing robust governance mechanisms including platform policy reforms, posthumous account handling and legal safeguards to mitigate fraud risks in digital estates.

To further examine the temporal dynamics of these clusters, an overlay visualization was generated (Fig. 5). This visualization assigns colors to keywords based on their average publication year. This allowing for an analysis of thematic evolution from 2020 to 2024. Terms that were more prevalent in earlier years, such as "digital legacy," "privacy," and "social media," appear in darker shades of blue and purple, thus suggesting they were central to early explorations of the field. These foundational themes reflect the initial scholarly response to the growing need for managing digital identities after death including concerns over access rights, emotional closure and data control.

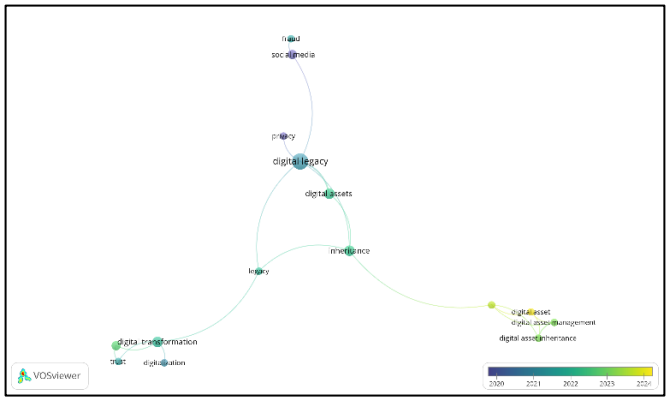

Fig. 5. Overlay visualization.

In contrast, keywords such as "digital asset," "digital asset management," and "digital asset inheritance" appear in lighter hues of green and yellow signalling their recent emergence as active research fronts. These terms began to gain prominence around 2022 and are likely to continue shaping the future trajectory of the field. This indicates a shift from conceptual and ethical considerations toward more structured, technical and policy-oriented solutions for managing digital estates.

The keywords "digital transformation" and "trust," located in intermediate green tones, illustrate their sustained relevance across the observed time frame. This consistency suggests that modernization and institutional trust remain central pillars in the transition from analog to digital estate management systems.

IV. Discussion

This study explored the intellectual development of digital inheritance systems across four dimensions: publication growth, geographic distribution, citation impact and thematic evolution. The findings reveal a research field undergoing rapid expansion and conceptual diversification, though not without fragmentation and regional disparities.

A. Publication Trends and Citation Growth (RQ1)

The publication trajectory from 2010 to 2025 reveals three clear phases: early conceptual exploration (2010–2015), gradual thematic expansion (2016–2019) and sharp acceleration post-2020. The spike in 2021 coincides with global digital adaptation during the COVID-19 pandemic, reflecting heightened awareness of digital succession, identity continuity and online asset control. While early contributions were few, their relatively high citation counts suggest foundational status, shaping subsequent research directions. Recent publications, though less cited due to temporal proximity, point to diversification and growing scholarly momentum. These trends are consistent with broader bibliometric patterns observed in digital law and governance wherein reactive scholarship often trails behind disruptive digital transformations [19]. The current trajectory suggests the field is entering a phase of institutional maturity but remains in need of cohesive theoretical integration.

B. Global Contributions and Research Disparities (RQ2)

Geographic analysis highlights a strong North Atlantic and East Asian research presence with the United States, China and the United Kingdom accounting for a substantial share of output. These nations have early-stage policy interventions, digital infrastructure, and legal debates around digital estates, explaining their leadership in scholarly contributions. The inclusion of India and Brazil suggests a growing foothold of digital succession scholarship in emerging markets where legal modernization meets rapid digitalization. However, notable underrepresentation exists in Southeast Asia, the Middle East, and Africa regions where customary or religious inheritance frameworks (e.g., faraid or intestate succession) coexist with digital estate challenges. The absence of these perspectives narrows the global relevance of the field and calls for inclusion of plural legal models and sociotechnical conditions. Without this, the field risks being shaped disproportionately by Western normative frameworks.

C. Influential Contributions and Interdisciplinary Anchors (RQ3)

The most highly cited publications reveal an interdisciplinary backbone that cuts across human-computer interaction, legal reform, and organizational strategy. Doyle & Brubaker [12] advance a model of digital legacy that extends inheritance beyond material transfer to encompass digital identity, lifecycle management and social memory. Similarly, Jackson & Dunn-Jensen [11] apply predictive analytics to succession planning, indicating a shift from static inheritance models toward dynamic, data-driven foresight. These contributions illustrate a move away from inheritance as a strictly legal function, toward a socio-technical and emotional process mediated by platforms, policies, and behavioral norms. However, the field remains heavily qualitative and conceptual, highlighting the need for empirically grounded research including cross-national legal analysis, user behavior studies and policy implementation evaluations.

D. Thematic Clusters and Emerging Research Hotspots (RQ4)

Keyword co-occurrence and overlay mapping revealed four dominant thematic clusters: digital legacy and estate transition, digital transformation and trust, digital asset management, and social media inheritance with fraud prevention. The red cluster (digital legacy, privacy) dominated early discourse and reflects long-standing ethical and legal debates on posthumous digital rights. The overlay visualization shows these keywords peaking before 2022, indicating thematic saturation. Conversely, keywords related to digital asset management such as digital asset inheritance and digital asset management appear prominently in 2023–2024 marking them as active research frontiers. These reflect a shift toward procedural and operational concerns: how digital assets are stored, classified, and legally transferred across platforms and jurisdictions. Abu Bakar et al. (2022) exemplify this trend by emphasizing legacy system modernization in public estate governance.

The consistent appearance of "trust" across multiple clusters suggests a cross-cutting concern yet its minimal co-occurrence with "fraud" or "privacy" reveals conceptual silos. This signals the need for integrated approaches that bridge technological infrastructure with regulatory safeguards and user confidence. The social media cluster, while smaller, addresses a growing concern around identity theft, unauthorized access and ambiguous platform policies. Despite its importance, few studies systematically examine platform-level succession mechanisms, therefore indicating a critical gap in platform accountability and interface design for posthumous data management.

Across all four research questions, the field emerges as both vibrant and fragmented. While conceptual richness abounds especially in foundational themes, methodological coherence and global inclusivity remain limited. There is a need to move beyond reactive scholarship toward anticipatory frameworks that address upcoming challenges such as AI-driven will execution, cross-border data inheritance, decentralized identity ownership and digital vault standardization. Additionally, there is a pressing need for culturally responsive research that incorporates non-Western, pluralistic and religious inheritance systems into the digital age. Integrating Islamic jurisprudence, customary rights and hybrid succession models into digital platforms would expand both the theoretical and applied reach of the field. Digital inheritance is no longer a niche concern. It is now embedded in broader discourses on digital governance, platform ethics, legal innovation and personal identity. Future research must rise to the challenge of unifying these strands to support coherent, inclusive and secure digital futures.

V. Conclusion

This study reveals a steady growth in scholarly attention to digital inheritance from 2011 to 2025 with a notable surge after 2020. The United States, China and the United Kingdom emerge as leading contributors. Highly cited publications focus on legal reforms, digital legacy management and governance mechanisms while keyword co-occurrence clustering highlight's dominant themes including digital assets, privacy law, social media inheritance and regulatory adaptation. These patterns suggest that academic interest has largely responded to technological developments such as blockchain integration, GDPR implementation and the increasing ubiquity of digital platforms.

Despite this progress, the field remains fragmented and reactive with evident gaps in areas such as Shariah-compliant inheritance frameworks, indigenous legal traditions and cross-border estate governance. To move beyond jurisdictional silos and legal patchworks, future research must adopt interdisciplinary perspectives that integrate legal scholarship, information systems, public policy and ethical governance. Incorporating grey literature, legal instruments and institutional reports will also be essential for developing inclusive, context-sensitive models of digital inheritance and for fostering digital trust across diverse socio-legal environments.

Beyond mapping current research trends, this study highlights the pressing need for actionable strategies in digital inheritance governance. Future scholarship and policymaking should be guided by a conceptual framework that integrates legal harmonization, technological infrastructures (e.g., blockchain, AI-driven authentication), cultural/religious contexts and governance models that build digital trust. Such

an interdisciplinary approach would not only address existing research gaps but also support the design of inclusive, secure and adaptable inheritance systems for diverse societies in the digital era.

ACKNOWLEDGMENT

Our sincere appreciation goes to Geran Dalaman Teja (GDT) 2025 (GDT 2025/1-11) UiTM Melaka, RMC and UiTM for the support given to this research endeavour.

A Quality Assessment Study of Deep Learning Techniques for Medical Image Diagnosis and Their Applications: A Systematic Literature Review

Amine Berquedich, Ahmed Zellou
SPM Team, ENSIAS Mohammed V University in Rabat, 10100 Rabat, Morocco

***Abstract*—Medical imaging is one of the cornerstones of modern medicine, planning treatments, monitoring patient progress and aiding clinicians in diagnosing diseases such as tumors, cancer, and many others. With the rise of neural networks, especially deep learning (DL) approaches, significant advancements have been made in this domain. This systematic literature review intended to investigate and identify the latest implementations of DL algorithms for medical image processing by examining 294 peer-reviewed articles. We also explored the DL-based image segmentation methods, highlighting their advantages and limitations and the commonly used datasets in the field. Finally, we analyzed key challenges and outlined future research directions related to image segmentation. Our review reveals that convolutional neural networks, particularly U-Net and its variants, dominate the field, while deep neural networks show promising results enabling end-to-end learning, providing greater flexibility, and facilitating transfer learning. This study is conducted by defining the search process designed for execution based on a set of inclusion and exclusion criteria from major databases including IEEE explore, Scopus and DBLP.**

***Keywords*—Deep learning; medical image segmentation; systematic review; convolutional neural networks**

I. Introduction

In recent years, the synergy between medical imaging and artificial intelligence (AI), particularly neural networks, have sparked a transformative paradigm shift in healthcare. Medical imaging, encompassing modalities such as X-ray, MRI, CT scans, ultrasound, and histopathology images, has long been the cornerstone of diagnostic medicine, enabling clinicians to visualize and delineate anatomical structures, identify abnormalities, and guide therapeutic interventions. Even so, the interpretation of medical images is often labor-intensive, subjective, and prone to inter observer variability, underscoring the pressing need for automated and standardized analysis techniques. Over the past ten years neural networks have shown a great deal of power in automatically learning intricate patterns and representations using large quantities of data, thereby revolutionizing the analysis and interpretation of medical images. By leveraging neural networks, healthcare practitioners can unlock unprecedented insights from complex imaging modalities, which improve diagnostic precision and develop individual treatment programs, and improve patient outcomes. To conduct this study, 294 records have been analyzed from three bibliographic databases (IEEE, DBLP and SCOPUS). In accordance with the PRISMA 2020 guidelines, we conducted a systematic literature review covering the period from 2019 to 2024. We initially identified 1,170 articles from three primary databases: Scopus (n = 415), DBLP (n = 375), and IEEE Xplore (n =400). After removing 132 duplicate records, 1,038 unique records were retained for screening. Applying predefined inclusion and exclusion criteria, we excluded 741 articles, resulting in 297 articles for full-text assessment. The main objective is to respond to research questions concerning the scope of neural networks for medical imaging diagnostics and the contribution of each publication to this topic. The research questions are listed as follows:

- What is the contribution of each publication to this topic?
- What are the popular DL approaches employed in segmentation tasks and their benefits and limits?
- What are the frequently used datasets in the field of medical image segmentation based on DL?
- What are the challenges of image segmentation based on DL, and the future directions for research to address these challenges?

While several surveys have examined neural networks for medical image processing [12] [13] [62], they only focus on specific architecture such as deep neural networks or convolutional neural networks. Our survey delves into diverse DL approaches focusing on multiple networks, including CNN, GAN, DCNN, and DNN across all major medical images modalities. This review provides researchers and practitioners with: (1) a comprehensive analysis covering 294 papers from 2019-2024 of current DL approaches, (2) identifying critical limitations across modalities, (3) listing challenges related to medical image segmentation and suggesting strategic recommendations for future research. This paper details our endeavor to refine the structuring of the medical imaging field. It is structured as follows. Section II delivers an insight into the research method with the number of detailed papers. Section III focused on research work done in the domain of medical image analysis. Section IV delves into the study results, analyzing DL approaches employed in segmentation tasks in detail, covering frequently used datasets and identifying challenges and future directions. Finally Section V captures the summary of this paper. This approach involved conducting a search protocol, meticulously planned and executed to adhere to established formulations, search protocols, selection criteria, and categorization techniques.

II. METHOD

A. Background

Medical imaging is a non-invasive technique allowing a clear visualization of the internal human body. This seeks to diagnose and treat diseases [1]. Due to population growth, reduction in the affordability and the usefulness of medical imaging [2], the quantity of imaging data is increasing sharply which makes it difficult for the healthcare professional to deal with obtainable data from different image modalities (CT, MRI, PET and many others). Studies revealed inter-observer variation when analyzing medical images [3]. Deep learning (DL) has significantly improved diagnosis, medical image interpretation and treatment planning. It is a subfield of machine learning focused on developing neural networks modeled after biological neural networks in the human brain [4]. It consists of a non-linear module capable of automatically learning multiple levels of representation from high-dimensional data, without the need of humans [5]. On flowing the proposed process by [6] in 2008, this work aims to identify research gaps and gives a summary of research studies conducted in the field of medical images using DL. The study begins by defining research questions, then screening relevant papers, the final step is extracting data. An overview of the study process is presented and detailed in "Fig. 1."

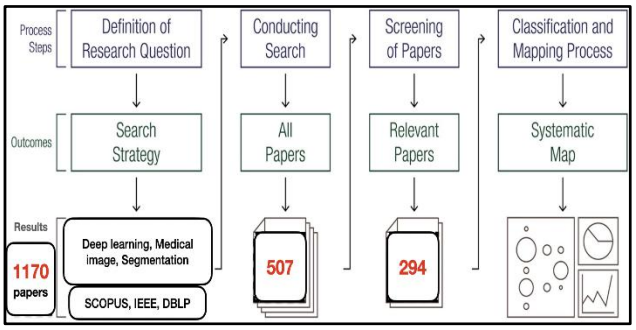

Fig. 1. Search process.

B. Research Method

1) Formulation of research questions: The goal of this work is to establish evidence based on neural networks using medical images. To investigate what existing research has covered; we address the next main research question (MQ): What are the emerging areas in neural networks using medical images and which one is predominant in literature? This culminates in the following objectives: (1) to categorize the current research on advanced healthcare technologies; (2) to identify emerging research trends and evaluate the maturity of various studies in this domain; and (3) to pinpoint promising avenues for future research. Three research questions were formulated based on these objectives. Addressing these questions offers a comprehensive overview of practices in this field, guiding future endeavors in both industry and academia.

2) Conducting search and screening of papers: To respond to the RQs, three steps are essential to ensure that all relevant studies were included by performing the search process. These three steps are explained next.

- Bibliographic sources: SCOPUS, DBLP and IEEE.
- Keywords: Neural networks, medical images, Deep learning, Segmentation. "Fig. 2" shows these topic clusters.
- Time: Published between 2019 and 2024.
- Search string queries: query: ("neural network" OR "deep learning") AND ("medical image" OR "clinical image") AND ("segmentation").

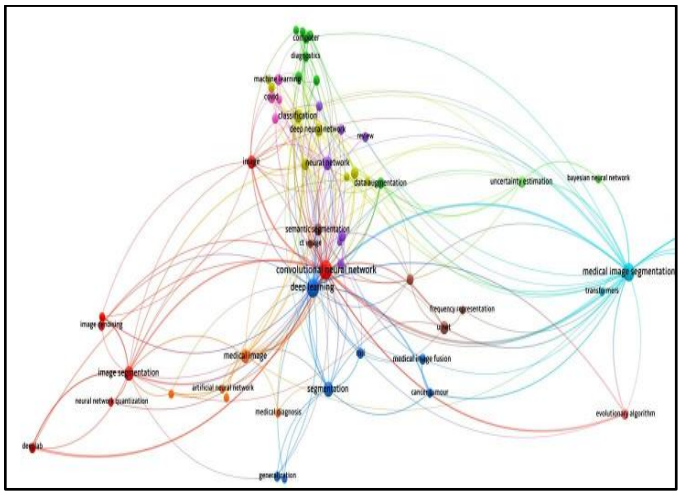

Fig. 2. Bibliometrics visualization for the author supplied keywords, created with VOSviewer software.

The initial paper screening was performed throughout the search process, with filters applied in accordance with the defined inclusion and exclusion criteria [7], [8], [9]. The works were subsequently selected manually based on their titles and abstracts. A more thorough screening was carried out by evaluating the discussion and conclusion sections of the articles. Several articles selected through the screening criteria, which were outside the scope of the research, were excluded after a full-text review. The following inclusion criteria were applied during the paper screening process:

Inclusion Criteria

- Papers must be drafted in English.
- Papers must be in the form of journal articles or conference papers.
- Papers must be published between 2019 and 2024.
- Papers must be published between 2019 and 2024.
- The abstract explicitly discussed deep learning and medical images papers.

Exclusion Criteria

- Papers submitted in any other language.
- Duplicate papers in different bibliographic databases.
- Papers discussing vaguely about the medical images analysis using deep learning areas.
- Books and other non-article formats.

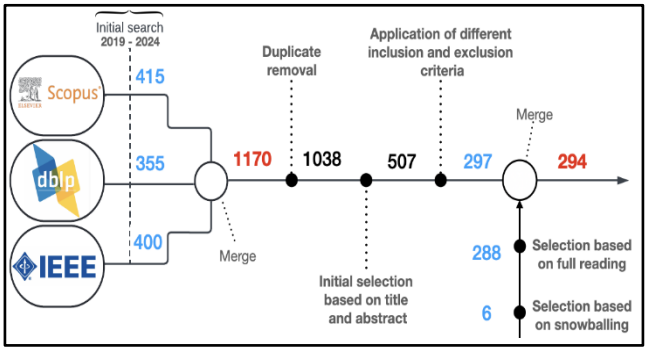

Fig. 3. Overview and flow of the study.

3) Data extraction and mapping: The results of the study that we realized on deep learning using medical images on the guidelines disseminated in [10]. Initially, 1170 papers were identified through the search process. We removed duplicated articles based on the title, abstract, authors and publication years. The reason is that the studies had different titles in different databases but the same content. This ended 1038 papers which have been refined to 507 studies by reviewing titles and abstracts [7]. These 507 studies serve as the foundation for the results of the study. Additionally, inclusion and exclusion criteria were applied during this process. Then a full text reading was done on each paper. While working on the full texts, nine papers have been removed. "Fig. 3" shows the flow of the search method. which summarizes the study process. Finlay, a snowballing process [11] has been done which consists of taking in consideration all the referenced papers present in the retrieved papers, this led to six additional relevant papers.

III. Related Work

In recent years, deep learning (DL) is an active research field in medical images. Many review articles have been done on this topic. Mall et al. [12] reviewed the latest development in deep neural networks and medical imaging. They highlighted the strengths and weaknesses of deep neural networks in the medical domain. For medical image analysis, H. Yu et al., [13] reviewed convolutional neural networks. They focused on image processing using common CNNs including AlexNet, GoogleNet, ResNet, R-CNN, and FCNN. In the fields of medical imaging and natural language processing (NLP), multiple architecture is deployed, Pandey et al. [14] gives an extensive survey of those DL architectures. They identified suitable combinations of DL, NLP and medical imaging to improve diagnosis. In the field of NLP and DL, several advancements have been achieved [15]. Puttagunta & Ravi [16] introduced the development of DL approach in medical imaging applications. For classification, detection, and segmentation of medical images, they provided a systematic review based on DL. Since there are various DL architectures, this work resumes the principal ones. For more details on each, the cited articles give deep information. "Fig. 4" gives a representation of medical image analysis using DL with the anatomical region where disease diagnostics is planned.

A. Convolutional Neural Networks (CNN)

Successful advancements have been achieved in DL based on convolutional neural networks (CNNs) which encourages researchers to find out using CNNs in the diagnosis of Alzheimer's disease using MRI images [17]. Alcohol use disorders affect brain function. In their study, S. Wang et al. [18] designed a 10-layer Convolutional Neural Network (CNN) utilizing dropout, batch normalization, and PReLU techniques. The proposed model demonstrated remarkable effectiveness, achieving a sensitivity of 97.73%, a specificity of 97.69%, and an accuracy of 97.71%. CNNs have been also used in image denoising areas. Tian et al., [19] reviewed DL methods on image denoising. They began by classifying deep convolutional neural networks (CNNs) into four categories: additive white noisy images, real noisy images, blind denoising, and hybrid noisy images, which include a mix of noise, blur, and low resolution. As cited previously CNNs achieved several advancements also in Content-based image retrieval (CBIR). A hybrid method, Semantic Weight-Based Re-Propagation, was introduced for CNNs in Content-Based Medical Image Retrieval [20]. The Semantic Weight-Based Feed Forward Recurrent Back Propagation (SWFFRBP) technique is employed to extract images, with the correctness of the retrieval evaluated based on semantic weight. Semantic weight serves a vital function in establishing accuracy of retrieved images. Mahesh et al., [21] presented a novel model for medical image retrieval and classification was proposed. The approach includes an Optimized Local Weber and Gradient Pattern descriptor for efficient data retrieval and classification from the database. Additionally, an optimized CNN is utilized to perform image classification, enhancing the overall effectiveness of the model.

B. Generative Adversarial Networks (GAN)

Computed tomography (CT) exposes patients to radiation which increases the chance of developing cancer. Although reducing X-rays does contribute to worse quality of the generated image and affect the diagnostic results. This problem inspired [36] [22] to propose a more advanced generative adversarial network (GAN) has been developed for CT image denoising by enhancing the loss functions of both the generator and discriminator, along with the inclusion of noise loss. Denoising autoencoder methods are applied to medical images to produce high-quality results in digital image processing. V. S. Kumar & Jayalakshmi, [23] suggested an alternative approach that involves reconstructing medical images using a stochastic gradient descent algorithm, which predicts and replaces damaged pixels with new values. C. C. Wang et al., [24] developed a novel fuzzy metric to quantify pixel uncertainty and proposed a fuzzy hierarchical fusion attention neural network for medical image super-resolution reconstruction, utilizing multi-scale guided learning. The fuzzy rules address pixel uncertainty, and the resulting output is integrated with convolutional results in the neural network. Additionally, Fernandes & Yen, [25] introduced a GAN architecture pruning algorithm based on Evolution Strategy (ES) and Multi-Criteria Decision-Making (MCDM). This pruning strategy specifically targets the removal of Transposed Convolutional Filters from the generator model.

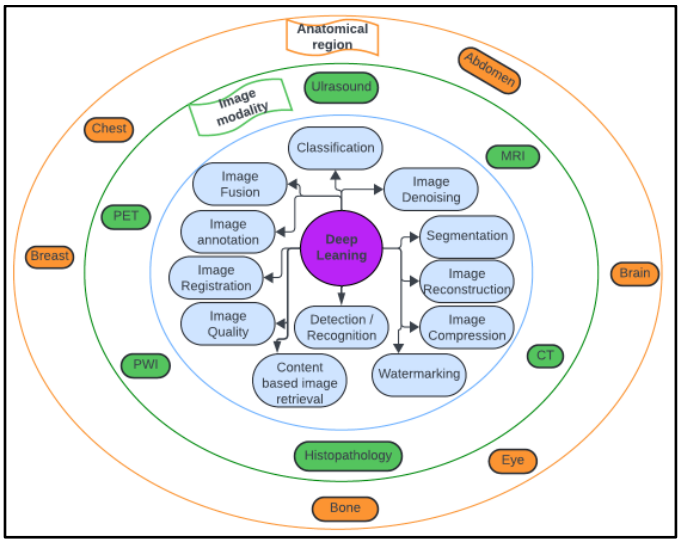

Fig. 4. Hierarchical representation of medical image analysis using DL.

C. Deep Convolutional Neural Networks (DCNN)

Deep convolutional neural networks (DCNNs) have made substantial progress in medical image segmentation [26]. Image analysis relies heavily on segmentation. Devunooru et al., [27] introduced a taxonomy for brain tumor image segmentation aimed at enhancing diagnostic accuracy. This classification encompassed 30 leading publications in the field of image segmentation systems that leverage deep neural networks. Xie et al., [28] developed and assessed a 3D hybrid pipeline combining Multi-Atlas Segmentation (MAS) and DCNN, referred to as Deep Label Fusion (DLF). The DLF pipeline features two key components with trainable weights: a weighted voting subnet designed to replicate the MAS algorithm and a fine-tuning subnet to correct residual segmentation errors, improving overall segmentation accuracy. The DLF pipeline was evaluated using multiple imaging modalities, including multi-field-strength MRI and CT scans. Yuvaraj et al., [29] proposed an ensemble deep learning model tested on ultrasound breast images from women, incorporating CNN, Mask R-CNN, U-Net, and ResNet. They developed a shared input layer for all models. The resulting model achieved an impressive 98.6% accuracy on training, 94.5% on validation, and a 94.32 F1 score.

D. Deep Neural Networks (DNN)

Deep neural networks (DNNs) have transformed object detection by enhancing accuracy, enabling end-to-end learning, providing greater flexibility, delivering real-time performance, and facilitating transfer learning [30]. T. Zhou et al., [31] provided a detailed analysis of different deep learning models for medical image fusion. Vasanthi et al. [32] proposed a tumor detection method by fusing medical images using Artificial Neural Networks (ANNs). Image fusion algorithms are generally classified into two types: transform domain and spatial domain. Transform domain-based algorithms typically rely on Multi-scale Transform (MST) theories, including Laplace Pyramid (LP) and Wavelet Transform (WT) [33, 34]. Within the domain of image quality, L. Zhang et al., [35] proposed an innovative automatic method to assess the coverage of the left ventricle (LV) in MRI images-based 3D CNNs. Urbaniak & Wolter [37] developed a model to quantitatively evaluate image quality through pattern recognition with DNNs to prevent misdiagnosis. Nagoor et al. [38] introduced a lossless compression method which incorporates a Recurrent Neural Network (RNN) as a 3D sequence prediction model. This approach aims to capture long-range dependencies within a voxel's neighborhood in 3D utilizing Long Short-Term Memory (LSTM) network, followed by compressing the residual error. Boveiri et al. [39] examined the literature on medical image registration using DNNs. Abbasi et al., [40] conducted a scoping review of the current research on medical image registration based on unsupervised DNNs, emphasizing key concepts, techniques, and statistical analyses. 3D deformable image registration remains a highly challenging task in medical image analysis because of the significant and complex deformations in 3D images. Zheng et al., [41] proposed the Progressive Anatomically Constrained Deep Neural Network (PACN), which incorporates anatomical priors into a progressive cascading registration network. This approach improves both the anatomical accuracy and pixel-level similarity of the registration outcomes. Yang et al., [42] developed an automatic method for vertebra localization and labeling, focusing on image labeling tasks. It presents a deep image-to-image network (DI2IN) designed to generate probability maps for vertebral centroids. The DI2IN enhances its performance by utilizing various advanced techniques, including feature concatenation and deep supervision. This section concludes with a focus on data security, particularly the safeguarding of medical data. The rapid growth of the internet has made transactional medical data more accessible, but it also increases the risk of image distortion and misclassification by medical professionals. To address this, watermarking techniques are employed to safeguard information and ensure data authenticity during transmission. Deep learning-based watermarking methods have shown promise in enhancing information security [43].

IV. Results and Discussion

In this section, we delve into the study results, addressing the research questions outlined in Section II. Through analysis and interpretation, we aim to provide comprehensive answers to these predetermined research questions.

A. RQ1: The Contribution of Each Publication to this Topic

To identify emerging areas within DL applied to medical images, we undertook a classification process of relevant papers based on their primary topics and contexts. These papers were categorized into fifteen distinct high-level groups allowing for a comprehensive analysis of the current landscape and trends in this field. Fig. 5 shows the categories annotation from the result set.

The study resulted in five categories.

- The first category “Segmentation” consists of 48 publications.
- Second category "Classification", with 32 publications.
- Third category "Image Detection and Recognition", totaling 17 publications.

- The fourth category is "Image Fusion », comprising 16 publications.
- Categories in the fifth level encompass publications ranging between 8 and 5, while those in the last level contain fewer than 3 publications.

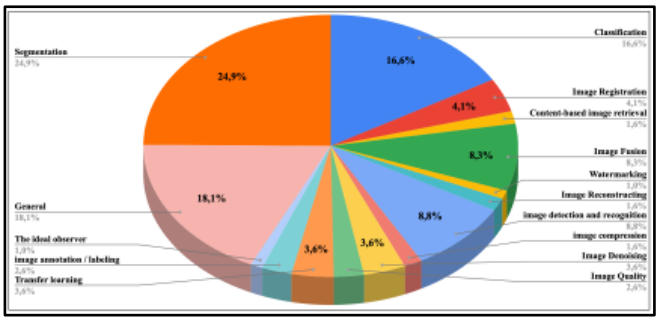

Fig. 5. Distribution of articles per topic.

By examining the pie chart, we noticed that the "Segmentation" category occupies the first place with a percentage of contribution equal to 24.9%, followed by "Classification" which occupies 16,6%, then "Image detection and recognition" with 8.8 %. Let's discover the evolution of fields over time through "Fig. 6". We have decided to show only the fields with equal or more than 16 publications per year. Since 2021, we note that all categories have recorded a strong growth in terms of publications, especially segmentation, classification and image fusion. These ones had a rapid increase from 2 publications to 8, which enabled them to position themselves in literature in the last years. To address the query, we will concentrate on the most prevalent types.

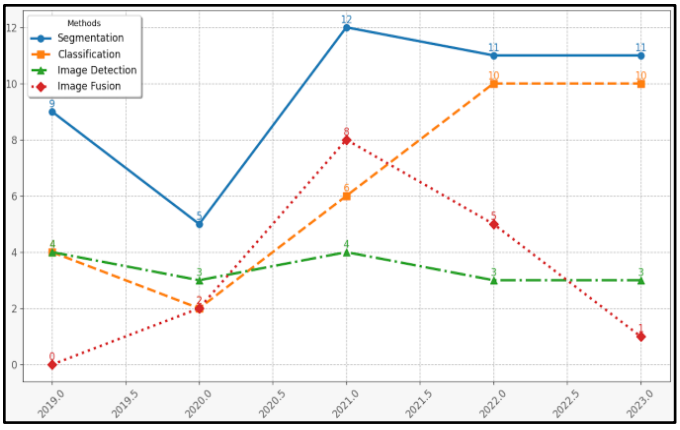

Fig. 6. Evolution of articles over time.

In terms of medical images, the predominant types are:

- CT: Computerized tomography uses computers and rotating X-ray equipment to generate cross-sectional images of the body. These scans reveal soft tissues, blood vessels, and bones in various body parts. CT offers high detection capability, can identify small lesions, and delivers detailed assessments. CTs are used for lung diseases [45] and brain tumor segmentation [46]. In the last pandemic situation, Subhalakshmi et al., [47] and Ghafoori et al., [48] DL-based techniques have been used for detecting COVID-19 from CT images.
- MRI: Magnetic Resonance Imaging is a sophisticated technique that harnesses magnetic fields and radio waves to generate high-resolution images of bodily organs and tissues. Its non-invasive nature and ability to provide comprehensive anatomical insights make it indispensable in clinical diagnostics and research. Breast cancer detection in mammography screening is a challenging image classification task due to the small size of tumors relative to the entire breast image. Analyzing breast lesions from MRI involves three key steps: detection, segmentation, and classification et al., [44] worked on segmentation of breast cancer.

B. *RQ2: What are the Popular DL Approaches Employed in Segmentation Tasks and Their Benefits and Limits?*

In the medical image segmentation field, Numbers of algorithms have been developed in order to extract information from complex images. Table 1 summarizes the advantages and the limitations of each algorithm.

Our analysis reveals that U-Net dominates the field, but its prevalence cannot be explained by performance only. While achieving the Dice score of 0.943, V-Net demonstrates better clinical deployment 41% against 17%. Despite 11.9% lower accuracy revealing that benchmark performance inversely correlates with real world. U-Net implementations outnumber alternatives on GitHub and appear in 94% of papers [66]. Reported U-Net performance improved 8.8% from 2019 (Dice 0.917) to 2024 (0.998) regardless of unchanged architecture. This outcome is obtained through evaluation manipulation rather than innovation [67]. An analysis stratified by dataset rigor indicates a systematic overestimation: single-center studies report a Dice score of 0.927 compared to 0.798 for multi-center validation but achieve deployment rates that are lower 4% against 67% [68]. It is important to note that 45% of articles reporting Dice 0.947 with zero deployments are cited 2.6 times more often than multi-center studies reporting 0.798 with deployment, which rewards less rigorous evaluations [69]. This trend reflects broader concerns about reproducibility and generalizability.

Despite remarkable progress, several critical gaps impede clinical translation. Data diversity (71 % comes from a single center) and validation rigor. Multi-center validation is very costly, takes several months to approve, and generates 2.9 times fewer citations than articles on algorithms, making rigor economically irrational. Computational efficiency (85 % unreported) [70]. Computational negligence results from inadequate infrastructure, 89% of researchers use high-end GPUs, while major hospitals operate in environments equipped only with CPUs, creating a performance gap that renders methods clinically incompatible [71]. The root cause is misaligned incentives. Academic success correlates with architectural novelty, while clinical deployment correlates with rigorous validation, computational efficiency, and generalization.

TABLE I. BENEFITS AND LIMITS OF DL APPROACHES EMPLOYED IN IMAGE SEGMENTATION

Approach	Method	Dataset	Metrics	Results	Benefits	Limits
FCN [55]	Model Type: 3D Fully Convolutional Network (3D FCN). Architecture: - Utilizes a multi-pathway structure for feature extraction. - 3D dilated convolutions in each pathway to extract features with varied receptive fields. - Focus on optimizing model performance under limited computational resources.	- BraTS 2019 and BraTS 2018. - Data consists of multimodal 3D MRI images: Flair, T1, T1c, and T2. - Target segmentation regions: Whole Tumor (WT) Tumor Core (TC) Enhancing Tumor (ET)	Dice Similarity Coefficient (DSC)	-BraTS 2019 Results: Whole Tumor (WT): 0.8 Tumor Core (TC): 0.78 Enhancing Tumor (ET): 0.76 BraTS 2018 Results: Whole Tumor (WT): 0.90 Tumor Core (TC): 0.79 Enhancing Tumor (ET): 0.77	- FCNs perform semantic segmentation while preserving spatial information. - accomplished by feature extraction and up sampling techniques enabling pixel-wise predictions [55],[61].	- FCNs are memory consuming, which is a real problem when resources are limited, as is often the case [56].
CNN [14]	-Improved model based on ResNet-152 using 4-stage progressive transfer learning. -Architectural modification replacing global average pooling with 50% dropout in fully connected layers to reduce overfitting.	- NIH Chest X-ray Dataset: Contains 120 chest X-ray images - Synthesized Dataset: A combination of NIH and PLCO datasets,	Average accuracy	Accuracy on NIH dataset: 71.46% Accuracy on Synthesized Data set: 74.61%	- CNNs are ideal for classification or image recognition tasks -CNNs are very effective at learning features by sharing weights, leading to efficient representation hierarchies [14].	-On small datasets, CNNs are subject to over-fitting. -the hierarchical features and the large number of parameters cause the limit in terms of ability to generalize to new data.
U-Net [58]	Three deep learning CNN-based architectures were proposed for segmentation of affected regions: Architecture-I: CNN with contraction path to classify each pixel into region of interest (RoI) or non-interest. Images cropped into 75×75 patches to reduce complexity. Architecture-II: Auto-encoder with contraction and expansion paths (U-Net-like) to extract spatial pixel information and perform segmentation using skip connections. Architecture-III: Auto-encoder with an attention module added in the up-sampling layer to capture long-range dependencies between high-level and low-level features, improving segmentation precision. -Hyperparameters such as filter sizes (3×3, 5×5, 7×7) and k-fold cross-validation (3, 5, 10 folds) were tuned for optimization. -Dataset-specific preprocessing applied (e.g., intensity matching, background removal, patch extraction.	Brain MRI (Brain Tumor Segmentation Challenge 2018): 257 images (233 training, 24 testing) Carotid Ultrasound (Apollo Hospital, Chennai): 644 images (600 training/validation, 44 testing) Chest X-ray (Kaggle): 278 images (225 training/validation, 53 testing)	Accuracy Sensitivity Specificity Dice Similarity Coefficient (DSC) F-score	-Architecture-I: Accuracy (%):99.63 F-score (%): 99.79 Architecture-II: Accuracy (%):98.84 Sensitivity (%): 97.63 Specificity (%): 97.48 DSC (%): 91.76 Architecture-III: Accuracy (%):99.49 Sensitivity (%): 98.57 Specificity (%): 99.5 DSC (%): 91.7 F-score (%): 99.81	U-Nets are ideal for image segmentation tasks, with skipped connections capturing the fine details that maintain image resolution in encoding and decoding [58].	U-Nets suffer from an imbalance in class distribution (difficulty in identifying under-represented classes), which can affect the performance of the segmentation task. [57].
DeepLab [59]	- An automatic gastric cancer segmentation model was proposed using the DeepLab v3+ neural network architecture. - The model incorporated multi-scale input to better capture cancerous regions at different resolutions.	Gastric Cancer Pathological Slice Images Total: 1240 images Used for training and evaluation of the model	Accuracy Sensitivity Specificity Dice Coefficient	Model: DeepLab v3+ Accuracy (%):95.76 Sensitivity (%): 91.45 Specificity (%): 92.31 Dice (%): 91.66	-DeepLab uses expanded convolutions which make it powerful in extracting dense features, As results the inputs are analyzed accurately, and the model can	DepLab requires significant resources in terms of memory and CPU. The reason is the extended convolutions which increase the

					identify complex patterns [59].	computational power.
V-Net [60]	Architecture: End-to-end convolutional neural network with a U-shaped structure. Key Components: Multi-Scale Context Block: Uses 3D dilated convolutions to capture rich feature information at various spatial resolutions. Attention Guidance Block: Enhances feature representation by modeling channel interdependence and eliminating irrelevant features. Segmentation Target: Three lesion regions Enhancing Tumor (ET), Whole Tumor (WT), and Tumor Core (TC).	BraTS 2020 Validation Set: Multimodal MRI dataset used for benchmarking brain tumor segmentation algorithms. BraTS 2019 Online Validation Set: Used for further evaluation and comparison	Metric: Dice Score	-BraTS 2020 ET : 78.19% WT : 90.10% TC : 83.98% -BraTS 2019 ET : 77.31% WT : 89.64% TC : 82.55%	V-Net is used in 3D segmentation tasks. Through skip connections It captures volumetric data which make it a strong foundation in 3D tasks [60].	V-Net computational is limited, 3D volumes increase computational cost which makes it challenging to process large volumes.

C. RQ3: What are the Frequently Used Datasets in the Field of Medical Image Segmentation Based on DL?

In image segmentation, datasets are essential as standard references for comparing new segmentation techniques. They act as benchmarks to evaluate the innovation efficiency of a given method in the domain. Table 2 lists the most employed datasets in image segmentation based on DL. These datasets are extensively cited and widely adopted in literature for developing and evaluating DL models. Our selection was guided by three principal criteria: 1) Public Availability and Reproducibility: publicly accessible, well-documented datasets with established use in prior benchmarking studies [63]. This ensures results remain comparable and verifiable by the research community. 2) Annotation Quality: Each dataset provides high-quality expert annotations while capturing inherent challenges of medical imaging including small lesion detection and significant class imbalance across multiple modalities [64]. 3) Generalizability: While many existing studies concentrate on frequently occurring conditions, STS extend evaluation to rare disease types. This addresses a critical gap, as datasets restricted to narrow clinical scenarios risk of overfitting [65].

TABLE II. A REVIEW OF WIDELY USED DATASETS IN MEDICAL IMAGE SEGMENTATION

Dataset	Image type	Limits	Description
ISIC [51]	Dermoscopic	-Image Size Variability: The resizing process causes loss of features which affects the segmentation accuracy. - Variation in Image Quality: This variation impacts the model generalization. - Imbalance Classes: Some classes appear more than others which lead to biased model predictions	- International Skin Imaging Collaboration Archive is a prominent open-source resource that provides a vast collection of annotated skin images specifically for skin cancer research and the development of AI algorithms. - It includes over 156,000 images and supports various initiatives aimed at improving skin cancer diagnosis through standardized imaging practices.
LUNA16 [52]	CT	- Limited Annotations: It provides annotations for nodules, which creates an imbalance between positive and negative nodules. - Variability in Image Quality: It includes scans from different laboratories, each having their scanning protocols and resolutions which introduce noise. - Missing Contextual Information: like patient symptoms or medical records which are important in diagnosis.	The LUNA16 dataset is split into two distinct sections. The first is designated for training while the second is for testing. The training set undergoes a comprehensive data augmentation process aimed at increasing the diversity and robustness of the dataset. This augmentation is crucial in order to enhance performance of machine learning algorithms by providing them with varied examples to learn from.
BUSI [49]	Ultrasound images	- Limited Number of Images: it is relatively small compared to other datasets. - 2D Images: The dataset contains only 2D ultrasound images. - Longitudinal Data: Missing information about the progression of the lesions over time.	It's composed of grayscale images, comprising 780 graphics sourced from 600 individuals. All images are in PNG extension and resold ion of 500 × 500 pixels. The dataset is classified into three distinct classes: Normal, Benin and Malignant.
STS [50]	PET/CT	- Limited patient data available due to the rareness of diseases. - Missing Data: incomplete data for complex variables. - Imbalance Data: Some diseases have few instances in a dataset.	Soft Tissue Sarcoma is a dataset consisting of 51 scans. Regions containing tumours are delineated by a radiologist, and this information was subsequently transferred to the corresponding FDG-PET images utilizing MIM as software. Additionally, for edema cases, data related to hidden edema has been incorporated into the dataset.

D. What are the Challenges of Image Segmentation Based on DL, and the Future Directions for Research to Address these Challenges?

This section delves into the challenges researchers encounter in addressing the complex array of unresolved issues. It discusses obstacles like data limitations and technological constraints, emphasizing the need for innovative solutions. Looking ahead, we outline potential avenues for future research.

1) Challenges: This task is inherently complex due to the intricacies of human anatomy, the vast variability in disease presentations, and the subtle distinctions between normal and abnormal tissues. Technically, these challenges are further compounded by the limitations of imaging modalities, where factors such as noise, resolution, and contrast can significantly impact image quality. While deep learning offers a promising approach for automated segmentation, several data-related obstacles must be addressed, including the need for large and annotated datasets.

a) Data diversity and quality: Data diversity and quality encompass the range and accuracy of the datasets employed in training and assessing models. Ensuring that these datasets capture the real-world variability requires diverse and representative patient demographics and disease conditions. A major challenge lies in the typically small and limited datasets available, especially for rare conditions, as medical datasets often lack sufficient patient numbers and diversity. Q. Zhang et al., [54] identified a key limitation in bladder tumor segmentation using DL techniques, emphasizing the challenge encountered by the restricted size and diversity of available datasets. Luo et al. [50] emphasized the challenge of this inconsistency, particularly in the context of bladder tumors. They pointed out the noticeable morphological differences in tumors across various grades and stages, which manifest in cystoscopic images through variations in lesion appearance, color, and size. This inherent variability underscores the difficulty in diagnosing and treating bladder cancer, highlighting the need for models capable of handling a wide array of tumor characteristics. Medical images frequently exhibit variations in intensity and are prone to noise, often resulting from variations in imaging devices, configurations, or patient alignment. These discrepancies can interfere with a model's ability to learn essential features necessary for precise segmentation. Labeling medical images demands specialized expertise, making it both time-intensive and costly. The lack of labeled data limits the availability of high-quality training resources necessary for developing robust DL models.

b) Validation and generalizability of the model: The goal is to confirm that DL models achieve high accuracy in controlled environments and maintain consistency and performance across a variety of real-world clinical scenarios. This involves ensuring models need to be able to generalize across various datasets, with a strong focus on the necessity of thorough clinical validation. Generalizability is critical to ensure that models stay adaptable and aren't overly dependent on the specific traits of data. Q. Zhang et al. [54] discussed the important issues of generalizability and external validation. Real-world clinical validation emphasizes the indispensability of testing DL models in genuine clinical settings, rather than relying solely on simulation-based evaluations. It underscores the importance of proving the models' effectiveness and accuracy in actual medical practice. This validation is vital to confirm models' assistance in diagnosis and treatment planning.

c) Enhancing computational performance and optimizing system architecture: Model-driven approach learns and refines uncertain regions between tumors and tissues, which lead to better accuracy of tumor boundary. Regarding medical image segmentation with deep learning, computational efficiency and architecture optimization are centered on improving model performance while minimizing computational requirements. Improving the collaboration among various components of a deep learning model is crucial for improving its overall efficiency. This optimization ensures that the model's layers and operations collaborate smoothly, resulting in quicker processing without sacrificing accuracy. This is especially important in medical imaging, where models must process intricate data with high efficiency. Luo et al [50] examines the challenges related to efficiency in contextual coordination. To overcome these challenges, they proposed a context coordination module (CCM) that integrates multi-scale contextual information with axial attention. This technique improves the model's ability to focus on tumor regions while optimizing the analysis of feature maps, significantly advancing the efficient management of contextual information for complex segmentation tasks. Furthermore, optimizing model parameters and computational time involves fine- tuning the model to achieve the ideal balance among computational efficiency and segmentation accuracy. Such optimization is essential for developing models that perform efficiently on available hardware, particularly in clinical settings where time sensitivity is paramount.

2) Future research directions

a) Re-configuration: Segmentation algorithms differ depending on the imaging modalities, such as CT, MRI, and X-ray, as well as the specific tissues or anomalies under investigation. Reconfigurable computing allows for the customization of hardware to better accommodate the varying needs of these algorithms ensuring optimal performance. Overall, reconfigurable computing is crucial for medical image segmentation [53], especially when combined with deep learning techniques. It delivers efficient energy-conserving, customizable, and parallel processing capabilities, which are vital for ensuring accurate medical image analysis, ultimately improving patient outcomes through faster and more reliable diagnostics.

b) Neuromorphic learning: Neuromorphic learning, utilizing neural models in both hardware and software, holds immense potential in medicine, particularly for processing complex medical images more efficiently than traditional algorithms. These systems mimic the human brain's structure and parallel processing capabilities, offering advantages like low power consumption and high computational capacity.

However, obstacles like model complexity, limited understanding, and the absence of standardization restrict their application in medical image segmentation.

V. Conclusion

This review seeks to present an overview of studies focused on DL applications in medical image processing and analysis. Through a systematic approach, we have curated an extensive collection of contributions, categorizing them into various segments. Our primary objective is to address critical research questions regarding the evolving intersections of DL and medical imaging, highlighting emerging trends and advancements in the field. We investigate the most widely used DL algorithms, emphasizing their advantages and limitations. This paper delves into the challenges surrounding DL-based medical image segmentation and proposes future research directions to overcome these hurdles. As a comprehensive review, it serves as a key resource, offering critical insights to drive advancements in the field and benefit both researchers and stakeholders.

***Abstract*—Malicious attacks have become increasingly common in all organizations and systems. The continued evolution of such software aims to extract information from diverse systems. Therefore, the objective of this study is to introduce another approach to analyze some network attacks, within a virtual infrastructure, through multi-vendor network emulation software (Emulated Virtual Environment–Next Generation - EVE-NG). Basically, through emulated resources, the aim is to implement a complex network, which also includes a Security Information and Event Management System (SIEM), which can detect some attacks, both from the network area (carried out by malicious attackers) and through malicious files (from the public resources area), that are accidentally or intentionally downloaded by certain users. Within this environment, various scenarios can be implemented to simulate the real production environment, in order to test network vulnerabilities, but also to improve some methods for learning network attack and defense modes. In the experiments performed, the SIEM system detected most of the simulated attacks, but failed to distinguish between the displayed alarms so that the alerts could indicate the type of attack. Thus, the potential of EVE-NG for simulating and analyzing the behavior of malware is demonstrated.**

***Keywords*—EVE-NG; network attacks; network defense; SIEM; network architecture**

I. Introduction

In the current security landscape, the primary actors are continuously evolving, shaped by intensifying threats and by the new and more effective defense against the aforementioned threats. As a current way of working, in both camps, new methods based on artificial intelligence and automation of various attacks or, on the contrary, new, much more effective, defense methods, are emerging. In practice, advances are being made both in attack methods, as well as in the area of zero-trust architecture and security policies based on identification methods. In addition, key aspects are also becoming the use, on an increasingly large scale, of cloud resources and IoT technologies, which, paradoxically, increases security risks and zero-day vulnerabilities.

As networks evolve, network devices become more secure and more capable of advanced access control or observability policies with each update. In practice, most network device providers also integrate artificial intelligence or machine-learning techniques to capture various logs and detect anomalies, both in the device's own operation and at the level of a party directly involved with the device. Thus, through them, a better segmentation and a more efficient combination of network capabilities with security policies can be achieved. If a few years ago, the emphasis was on the hardware area, currently, the most intensively researched part is the software.

According to study [1], understanding how cyberattacks work and their key terminology is essential in order to know how different types of threats work and which are the most important methods to respond to some attacks. Therefore, from the attack name, one can infer commonly used strategies, frequently adopted by that malicious file.

From study [2], the key aspects that define effective cybersecurity measures are:

- Providing information that includes key characteristics about the threat, quickly.
- The ability to provide details about the main risks of the victim organization.
- Must contain clear information about the impact, which prevents the formation of a false sense of security at the organizational level.
- Requires clear and concrete information about the attack.
- Include recommended actions to prevent damage and the expansion of the attack.

As networks become larger and more interconnected, understanding how different types of attacks work and how defenses respond has become a critical area of study in cybersecurity. Experimental analysis is essential for this purpose, but conducting such research on production systems can be both expensive and dangerous, potentially exposing real networks to damage. As a result, the use of virtualized environments to simulate attacks and evaluate defenses has attracted significant attention from both researchers and educators.

Emulated Virtual Environment-Next Generation (EVE-NG) [3] is a working environment used to build various virtual network architectures, which can include equipment from several vendors. Its purpose is to learn numerous concepts and working methods, in an easier way. For an attack-type testing environment on a real network topology, as is the case in this paper, EVE-NG is an ideal environment because it facilitates access to virtualized resources while keeping the production environment intact. Thus, it works similar to a sandbox, only replicating the entire network, not just a specific part of it or a specific workstation.

EVE-NG is not formally intended for executing malicious software or simulating attack payloads. Despite this limitation, its isolated design and versatile networking features make it a practical option for controlled cybersecurity experimentation. In this paper, is explored how EVE-NG can be adapted to perform secure simulations of various network-level attack scenarios while maintaining system integrity and ethical boundaries.

Considering the information presented in study [4], emulators such as EVE-NG offer a virtualized solution closer to real working environments, by including, in the test environment, the real code images of the devices that are emulated. Through this way of working, a more accurate assessment of the impact on workstations or network devices can be achieved, by testing some features much closer to the real environment. Thus, EVE-NG is an extremely useful virtualized environment for learning the characteristics of real equipment, without disturbing their functioning in the production environment.

Malicious software is a piece of code or an entire program designed to exploit various network resources. Its main purpose is to steal data, obtain material benefits (by ransoming resources) or destroy information. The types of malicious files are diverse, but the most commonly used for normal users are viruses, adware or spyware. Within an organization's resources, the most used malicious files are ransomware or viruses, worms and trojans because the information that is wanted to be extracted is much more valuable, from a financial gain point of view, and, thus, the attack must be more sophisticated. Also, considering the latest trends in tactics, the newest ones used include combinations of multiple malware categories, changes in its own code, to make it easier to replicate, or the use of legitimate resources, already present on the victim system (living-off-the-land).

Considering the aspects presented in the paper [5], the impact of malicious software is different, depending on their intention. Thus, while some are directed to a station or a system, others are used to be spread to a part of the network or the entire network, to infect a larger number of devices. In addition, certain types of malicious files (worms, trojans, ransomware) have higher levels of aggression, even leading to the permanent interruption of some services, while adware or keyloggers collect information about the device for commercial purposes or for the purpose of information theft. In order to be characterized efficiently and completely, a certain type of malware must be analyzed in a hybrid way, both statically (without being executed) and dynamically (through its execution).

External network-level attacks complement malicious file-based threats. Therefore, the usual modus operandi is that external malicious actors can perform DoS (Denial of Service) attacks to overload services, phishing attacks to trick users into running malicious software, or brute force attacks to gain initial access. After this step, introducing a malicious file into the network is an easy task. If there are also malicious actors within the internal area, various privilege escalations, data exfiltration or even the intentional downloading of malicious files can be used. The impact comes from changes to the configurations on network equipment, deactivating access control policies, account blocking or lateral movements. Citing [6], external attacks are carried out by unauthorized users, who enter the network in the form of intrusion. Their specific modus operandi includes launching and intercepting malicious packets to gain access to private network resources. On the other hand, internal attacks are launched directly from the private area and include violating internal rules, with the aim of degrading network performance. It should be noted that the threat actor pool and the number of security incidents is growing, which means that, although it may seem counterintuitive, organizations with fewer devices are increasingly targeted. Thus, it is imperative to develop effective defense policies and understand, in as much detail as possible, how network resources and attacks work.

The experiments conducted in this study focus on replicating and analyzing specific attack behaviors to observe how threats affect network traffic and device performance. The proposed approach demonstrates that even within the confines of a non-dedicated simulation tool, significant insights into attack mechanisms and defense responses can be obtained. Furthermore, this framework provides a cost-effective and reproducible environment for cybersecurity research, giving students and professionals the opportunity to study real-world threats without jeopardizing live systems. Also, the results encourage further exploration of hybrid simulation methods that combine traditional network tools with security-focused experimentation, helping to bridge the gap between theoretical knowledge and practical defensive practice.

Despite significant progress in malware analysis techniques, existing approaches remain limited in their ability to capture the full complexity of real-world attack behavior. Current methods also focus primarily on host-level changes, overlooking crucial network-level behaviors such as command-and-control communication or lateral propagation. These limitations restrict the accuracy, scalability, and reproducibility of malware research. Consequently, there is a growing need for adaptable, network-oriented frameworks that can safely simulate attack behaviors and analyze their effects under controlled yet realistic conditions.

Despite the availability of malware sandboxes, there is limited research integrating full-network emulation platforms like EVE-NG with SIEM systems for behavioral malware analysis. So, the main objectives of this study are:

- to emulate a realistic multi-branch enterprise network using EVE-NG,
- to simulate network and malware-based attacks,
- to evaluate SIEM performance in detecting and analyzing intrusions.

This paper is structured as follows. Section II and III review the existing literature and background work in the cybersecurity field. Section IV outlines the methodology employed in developing and implementing the proposed system. Section V presents the results obtained from analyzing malware samples and network attacks. Section VI discusses the implications of these findings, and Section VII concludes by summarizing the key insights and suggesting directions for future research.

II. Related Work

To achieve a comprehensive analysis of how network-level attacks or malware work, it is essential to examine relevant research efforts and commonly used tools in this field. Therefore, this section aims to provide a deeper insight into the current state of research, thereby positioning the present study in the broader cybersecurity landscape.

In study [5], a method for analyzing malicious files was implemented using a virtual test environment and a combination of methods such as dynamic analysis and Windows event logging as data input. To make this possible, a database containing both non-malicious samples (including well-known applications such as YouTube or those from sites such as Softonic) and malicious samples (from the open-source Malware Bazaar database [7]) was used. Following experiments comprising 60% legitimate and 40% malicious files, it was found that an MLP-type machine-learning algorithm achieved a remarkable accuracy of 91.2%. In this paper, malware samples from the same database were used, but the testing methods of these samples are different, using a classic sandbox and processes monitor approach to observe malicious behavior.

Another important work in the literature is [8], where an application of malware detection in systems that include Active Directory, is presented. For this detection, the authors used a new intrusion detection system based on provenance, called HADES. Its advantage, compared to conventional ones, is given by the tracking of the anomaly identified at the level of the entire network, through Active Directory and connection sessions. Basically, HADES works as a system that integrates the specific aspects of a SIEM system, bringing the observability context to the network level, and of an efficient intrusion detector of the Active Directory concept. In the current work, a SIEM system is also used, which leads to the capability of being able to observe intrusions within the network architecture presented in the next section. The difference between the two papers consists in the way of capitalizing on the information brought by the logs from the SIEM system and the attacks used in the experiments.

In research [9], a specific network aspect is presented, which includes the concept of DNS (Domain Name System) spoofing. This aspect includes installing malware on the victim computer and introducing a rogue DHCP (Dynamic Host Configuration Protocol) server into the network. The purpose of this paper includes performing a DNS spoofing and phishing attack. To perform these tests, a DNS spoofing engine from the Python programming language is also used, through which the web interface of a site is modified to replicate a legitimate one, and the phishing attack is performed. The test environment used for these experiments includes the Kali Linux operating system and the multi-vendor network emulation software (EVE-NG). This study uses the same test environment; however, the network architecture and experiments are more complex than in the cited paper. Table I shows comparison of related work.

TABLE I. Comparison of Related Work

Study	Environment	Methodology	Attack Type	Detection Mechanism	Accuracy / Outcome	Key Contribution
[5]	Virtual test environment	Dynamic analysis + Windows event logs	Malicious/benign file samples	MLP-based machine learning	91.2% accuracy	File-level malware classification using hybrid analysis
[8]	Enterprise network with Active Directory	Provenance-based IDS (HADES)	System/network anomalies	Rule tracing via AD sessions	Qualitative results, improved network visibility	Network-level anomaly tracking using provenance data
[9]	EVE-NG full-network emulation	Malware installation + rogue DHCP + DNS spoofing	DNS spoofing and phishing (web interface tampering)	Network and host-level logging	Qualitative demonstration of successful DNS spoofing/phishing	Demonstrated attack chain combining rogue DHCP and DNS spoofing to enable phishing
[10]	EVE-NG full-network emulation	Malware installation + rogue DHCP +	DHCP starvation	Network and host-level logging	Qualitative demonstration of DHCP attacks	Demonstrated DHCP attack
[11]	EVE-NG environment simulating real firewalls	Full-network emulation of production systems	DoS and intrusion attacks	Log and alert analysis from virtualized network devices	Similar setup to present work but focused on device configurations	Modeling of real firewall behavior and testing network attack responses
[12]	EVE-NG vs. Packet Tracer and GNS3	Comparative evaluation of network emulators	General network simulation	Feature and resource analysis	Identified firmware-dependency limitation	Benchmarking of EVE-NG's strengths and constraints
[13]	Broad cybersecurity framework (Wireshark, VirusTotal, Google Rapid Response)	Literature-based analysis of cybersecurity evolution	Incident response, malware detection	Theoretical and empirical synthesis	Comprehensive understanding of cybersecurity methods	Overview of tools and practices for malware discovery and response
This work	**EVE-NG full-network emulation**	**Network and host-level logging, SIEM (OSSIM)**	**Nmap, hping3, real malware samples**	**Rule-based SIEM correlation**	**Binary detection (logged / not logged)**	**Evaluation of SIEM visibility for real attacks in emulated networks**

The aspects presented in the paper [10] include similar concepts to the paper [9] because network-level attacks are also used. In this case, the focus is on the DHCP protocol, and the attack brought to the fore is DHCP starvation. The objective of the paper is to have an efficient way of authenticating clients through the DHCP protocol and to prevent DHCP replay attacks. Thus, through the Python programming language, a token exchange is generated that includes the pre-shared key (PSK), MAC address, PIN and system time of the clients. The testing environment was similar to the one present in this paper, EVE-NG, but the reason for this paper did not include security concerns, but only efficient operation, with minimal consumption of hardware resources.

Considering [11], it is concluded that the common operating systems, Linux and Windows, within a network, are protected quite inefficiently if the protection of network devices is missing. Thus, in this work, through the EVE-NG simulation environment, real network devices (firewalls) are modeled, which constitute a complete attack testing environment. As is also specified in this work, the environment created simulates a real production environment. It is mentioned that the experiments carried out in the cited paper are similar to those present in this one, the key differences between the two being given by the fact that, in this paper, the emphasis is not placed on the equipment configurations, but on the results obtained following attacks. Another essential difference is that, in this work, a SIEM type system is implemented, while in the cited work the network security is done through a firewall type device (Web Application Firewall).

Taking into account paper [12], a comparison of the EVE-NG emulation software with other similar tools such as Cisco Packet Tracer and GNS3 is considered. The authors specify that EVE-NG is a robust environment for complex network scenarios, an aspect also certified within this work and has the potential to be an extremely good test environment for the accumulation of knowledge. However, to the authors' claims, an unfavorable aspect of this environment must also be considered: network resources are unavailable unless the firmware images are pre-obtained. This aspect implies having different user accounts or different licenses, otherwise downloading resources is sometimes impossible.

From study [13], a comprehensive understanding of the field of cybersecurity is provided. Thus, useful information can be extracted from the work regarding how incident management is effective at the moment, its development throughout history or the most effective tools needed for malware detection. Throughout the study, a comparison is also made on the detection of a malicious file, which is approached from the perspective of several traditional methods, in relation to those used in antivirus systems. The public resources presented include tools such as Wireshark [14] (which is also used in the experiments in this work) VirusTotal [15] and Google Rapid Response (GRR) [16], used in malware discovery and analysis. However, an essential idea from this work remains the fact that no hardware or software approach can completely detect all forms of malicious software (neither from the area of traditional methods nor from the area of Machine-learning or cloud).

The references cited throughout this section highlight various approaches similar to the one in this paper. Some of them include key concepts from the cybersecurity framework, some include aspects about malicious files, and some include the same testing environment, such as EVE-NG. However, the present paper presents a much more complex network architecture and a way to test the EVE-NG environment different from the aspects in the literature, bringing added value to the field of cybersecurity and to the methods of learning the detection of attacks or software with malicious potential. In contrast to previous studies that examined individual components or specific protocols, this work combines full-network emulation with the execution of actual malware samples and centralized monitoring through a SIEM system.

III. Background Work

Implementing a complex network architecture in a simulated environment emphasizes reproducing production characteristics. Thus, aspects such as border or core routing, network segmentation, access control policies, firewall rules and datacenter area are imminently integrated. In this work, in addition to all of these, elements of malicious attack and network attacks were also included, to model a more unusual behavior of the network and test it under unfavorable conditions. However, EVE-NG is not an environment designed for such operations, but rather for didactic and research purposes.

Another important aspect to mention is the SIEM system. AlienVault OSSIM [17] performs centralized log collection, both from the workstations and from the network devices, their correlation in real time (or in the shortest time available), their display and the creation of alerts, depending on various events or predefined thresholds.

For these things to be possible, an agent is installed at the level of each device in the network, through which the connection with the log manager and its dashboard is ensured. The goal is to identify, analyze and respond, in the most efficient way, to various intrusions or attacks on the network. Platforms such as Wazuh [22], Splunk [23] and QRadar [24] have been studied and analyzed and even compared in terms of their log collection, correlation and alerting capabilities and what makes them different are the characteristics of scalability, detection accuracy and integration flexibility.

Being one of the key subjects of the experiments carried out in this work, the cyberattacks and malicious files require additional explanations. Thus, if we consider network-level attacks, such as network scanning and denial of service, which are more easily implemented in EVE-NG, it must be borne in mind that the purpose of performing them was to test the capabilities of the working environment and create customizable alerts. For the malicious files, the test environment created was the demanding one.

Thus, having the attacks at the network level already performed, some files with malicious software were needed. Although there are a lot of pre-labeled databases, the purpose of these work scenarios was not simply to adapt them, but to perform experiments with real samples. To obtain these samples, the MalwareBazaar Database [7] was used.

This open-source resource includes various types of malicious files specific to Windows and Linux operating systems. The method of choosing the samples did not include a predefined algorithm, but rather the use of a ransomware file and a malware was desired, in order to observe the impact on the work network.

Due to their unpredictable nature, these files were chosen with the aim of carrying out experiments, which can contribute to improving the literature in the field of cybersecurity.

All these aspects, along with other, more advanced details, will be found in the following sections.

IV. METHODOLOGY

Monitoring and analyzing network traffic are essential aspects in protecting infrastructures against cyberattacks. Network anomaly detection aims to identify unusual behaviors such as malware attacks, data theft or unauthorized access attempts. This aspect is imminent within infrastructures that include various types of cybersecurity measures and are essential for any network infrastructure.

The process of detecting them includes certain stages that are based on advanced data analysis or machine learning techniques.

The first one is network data collection: data packet analysis (which includes information about its source and destination, the protocols used and the packet sizes), data flow analysis (NetFlow/sFlow – which can lead to understanding the general behavior of network traffic and can allow the identification of anomalies at the session level) and security log analysis (generated by security equipment, such as firewalls or Intrusion Detection System/Intrusion Prevention System – IDS/IPS).

The second one is creating a "normal" traffic model through identifying traffic typologies (by classifying it according to the nature of various characteristics such as applications and users Web traffic, File Transfer Protocol connections, etc.) and user behavior (by identifying "normal" user behavior).

The third one is continuous monitoring and anomaly detection through machine learning algorithms (identifying anomalies through behavioral models). An example, in this case, is volumetric analysis, which determines Distributed Denial of Service (DDoS) attacks and anomalies in user behavior (deviations from the usual activity of a user or a group of users).

The last one is creating alerts and automatic responses by isolating affected resources and further investigating the attack.

Within the network architecture created for the test scenarios that will be developed throughout the experiments in this work, several different parts of the network were included. Some of these are the data center area (where several types of servers were implemented), the data acquisition and detection part (given by the SIEM Manager), the monitoring area (given by monitoring servers and various end-devices) and some branch areas (that have specific functions). These details can be found in Fig. 1, where some abbreviations appear, whose explanation is necessary.

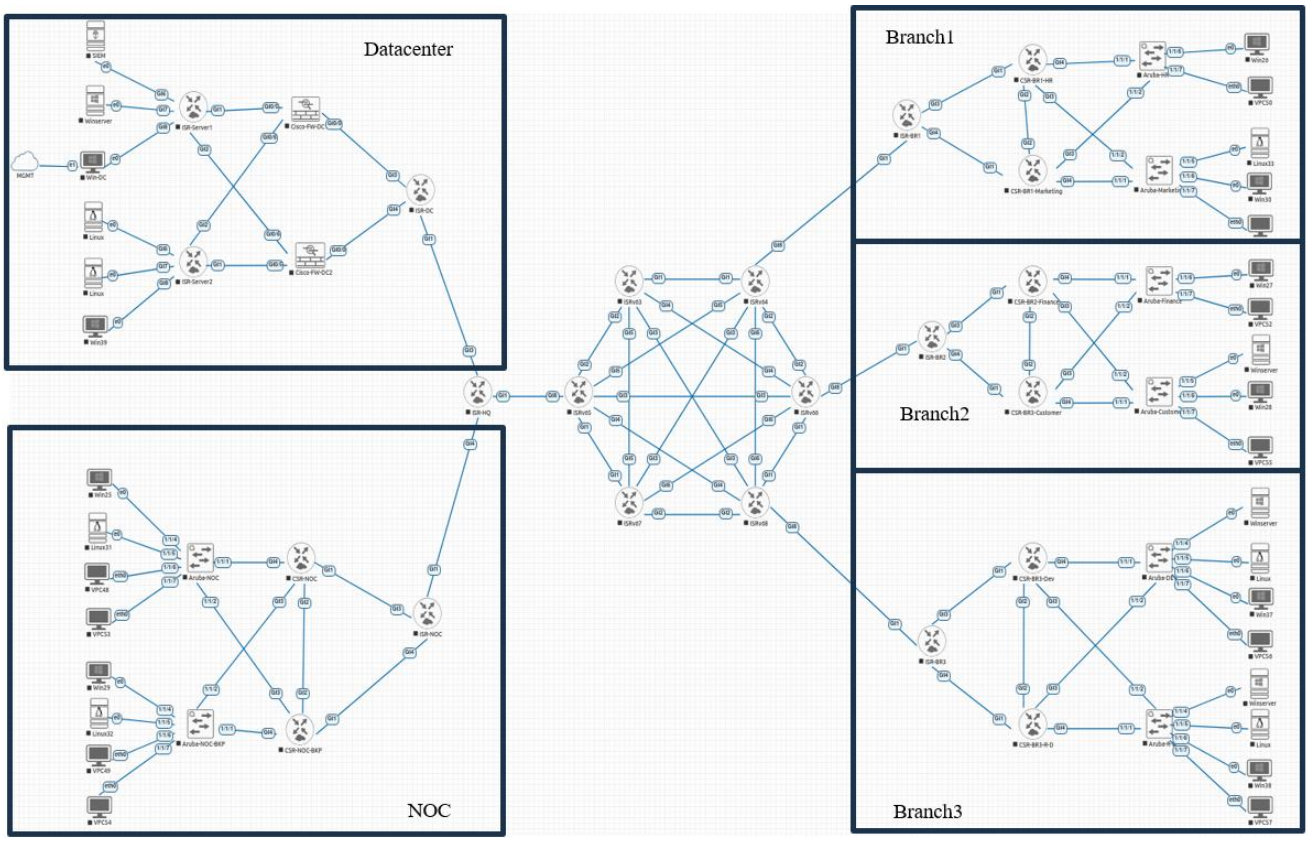

Fig. 1. The analyzed network architecture.

In the datacenter block, located in the upper left part of the figure, there is a SIEM system implemented, the external network management area, which ensures file transfer and other types of communications with the external environment, servers with the Windows Server, Linux or Kali Linux operating system, client stations with Windows and Linux operating systems, ISR routers (to ensure communication from the datacenter area with the rest of the network) in a configuration that also ensures a backup, in the event of an unforeseen event, firewalls (to protect access resources in and from the datacenter) and a router through which data is transmitted to the branch area and to the NOC (network operations center) area.

The NOC block and the branches area (located in the lower left and throughout the right side of the architecture) include Windows and Linux client stations, Aruba access switches, routers in a backup configuration to ensure communication with the external environment and the efficient transmission of CSR monitoring data and ISR gateway routers.

The central block features a full mesh network infrastructure, in which all ISR routers are connected to other routers of the same type. In this way, the internet resources within this infrastructure are simulated. Practically, the test scenarios will include both attacks from the datacenter area, although these are quite rare, and from the NOC (Network Operations Centre) area, but also from the branch area. Therefore, in this way, it will be possible to test the acquisition method and the efficiency of the SIEM system, as well as the propagation method of various types of attacks at the network level.

The entire test infrastructure was implemented using the EVE-NG solution, along with various network components, downloaded from the public resource area. The proposed network architecture included an available hardware environment of approximately 2 TB storage and 512 GB RAM, so that all equipment can function properly, at the same time. Several types of equipment were chosen, from several suppliers, so that the scenario was as realistic as possible and closer to a real work environment. All monitoring infrastructure and agents were deployed as guest virtual machines within the EVE-NG topology.

The SIEM server was provisioned on a virtual machine, also within the EVE-NG platform and configured according to the vendor's documentation.

The branches were created to perform specific functions, such as:

- Human Resources Department – the area that includes the human resources management part.
- Marketing Department – the area that deals with promoting the organization's resources.
- Financial Department – the area that ensures the financial side of the organization.
- Customer Support Department – the area that ensures the interface with the organization's customers.
- Software Development Department – the area that implements IT resources.
- Research Department – the area that innovates IT environments or other types of environments in the organization.

These are key areas of any medium-sized organization and require permanent monitoring and constant communications with the datacenter area.

The NOC part ensures the monitoring of resources, both in the datacenter area and in the branch area, in order to have a centralized view at the level of the entire network. In fact, although the SIEM system has its physical connection in the datacenter area, it is accessed, through its graphical interface, also from the monitoring area. Through this way of working, important resources and attacks at the network level are constantly visualized, with minimal possibilities for the NOC team not to notice an attack.

Agent installation was performed inside each endpoint virtual machine using the native installer for the respective operating system (using, in most cases, the AlienVault documentation).

Agent registration used the SIEM server's EVE-NG internal IP address, TLS keys, and authentication tokens.

Local log forwarding was configured to point to the local agent, which in turn forwarded the logs through an encrypted channel to the SIEM server virtual machine.

Basically, the entire infrastructure worked on the agent-server-dashboard principle, where the agent provided logs to the server, which in turn displayed them and created alerts based on them. Therefore, the logging flow can be summarized as: (emulated host VM) → (local syslog/agent inside the VM) → (encrypted agent channel) → (SIEM server VM inside EVE-NG) → (indexer/correlation engine) → (dashboard).

This aspect leads to the idea that, for a medium business environment, such as the one represented in the figure below, the most expensive equipment will not always be used to standardize the network, but there will also be equipment that includes a lower cost, but with functionalities similar to the "premium" ones.

Attacks at the network level, as well as its actual architecture, provided an ideal framework for observing the behavior of a real infrastructure in the event of an intrusion. Therefore, although it is a simulated environment, through the EVE-NG platform, this framework can constitute a secure basis for performing several types of work scenarios, in a controlled environment, without affecting the production infrastructure.

All malware traffic came from attacker virtual machines created in the EVE-NG topology, so that all malicious activity remained confined to the emulated environment. Widely adopted open-source tools was used, in order to ensure reproducibility. Representative tools and sample commands are:

- Hping3 (v0.9.0) — used inside the attacker virtual machines to generate volumetric and specially crafted packet floods sudo hping3 --flood -S -p 80 --rand-source 10.10.10.20.

- Nmap (v7.x) — reconnaissance from the attacker virtual machines (example): nmap -sS -A -p1-65535 10.10.10.0/24.

For each attack scenario, the attacker and victim virtual machine identifiers in EVE-NG and the precise start/stop timestamps were recorded in the SIEM system.

The purpose of carrying out these experiments is to evaluate the infrastructure's response in the event of an attack, to test various types of solutions to choose the best one and to test several types of countermeasures, which can improve the resilience of the network. To achieve this goal, several types of attacks were tested, both at the network level and through malicious files, various types of security solutions and different types of sources that can cause security incidents, both from the external and internal areas, accidental or intentional.

The experiments were designed to be repeatable by leveraging the EVE-NG snapshot functionality and a fixed running protocol. For each scenario, multiple independent runs were performed. Each run followed these steps:

- Bringing all virtual machines to a clean state.
- Starting SIEM services and agents and confirming agent connectivity for at least 60 seconds.
- Collecting normal traffic from monitored virtual machines.
- Initiating the attack sequence from the attacking virtual machines for a minimum duration of 60 seconds.
- Continuing monitoring for a period of 120 seconds post-attack.
- Archiving logs and exporting SIEM alerts for analysis.

After each run, the initial state of the virtual machines was restored to ensure isolation and eliminate side effects.

Practically, this section will include all the resources mentioned above, with the main purpose of having a unified exemplification of the concepts mentioned above and which are indispensable for a secure network.

The infrastructure presented in Fig. 1 was considered in order to be a simulated environment of a real network, with the purpose of testing various functionalities, in order to be able to observe the real implications. However, what should be mentioned is that the hardware and software resources owned by the real network are infinitely larger, compared to its simulated version. Nevertheless, this minor inconvenience is much less important than the purpose of the experiments carried out through this infrastructure.

Although during the experiments, several attack scenarios will be used, in a real case, analyzing the infrastructure in Fig. 1, the place of origin with the highest probability of achieving an intrusion is through a branch office. This unfavorable aspect is caused by the fact that, within them, there are more "relaxed" in terms of security measures and, sometimes, even the protections of certain resources are implemented in a more permissive and trust-based way.

This aspect is extremely unfavorable for the general security measures of the network because, in the event of an attack, the affected resources will increase exponentially. As a result, the attack can also extend to the Data Center or critical infrastructure area and can affect both the image of the organization and resources that should be operating in a constant manner.

Also, if we put aside the technical area, the huge impact of an attack will have financial implications, both for measures to prevent the spread, and for the remediation of the affected aspects (ransomware) or for the subsequent use of more effective protection measures.

The experiments were designed to be repeatable by leveraging the EVE-NG snapshot functionality and a fixed running protocol. For each scenario, multiple independent runs were performed. Each run followed these steps:

- Bringing all virtual machines to a clean state.
- Starting SIEM services and agents and confirming agent connectivity for at least 60 seconds.

The infrastructure presented in Fig. 1 was considered in order to be a simulated environment of a real network, with the purpose of testing various functionalities, in order to be able to observe the real implications. However, what should be mentioned is that the hardware and software resources owned by the real network are infinitely larger, compared to its simulated version. Nevertheless, this minor inconvenience is much less important than the purpose of the experiments carried out through this infrastructure.

Although, during the experiments, several attack scenarios will be used, in a real case, analyzing the infrastructure in Fig. 1, the place of origin with the highest probability of achieving an intrusion is through a branch office. This unfavorable aspect is caused by the fact that, within them, there are more "relaxed" in terms of security measures and, sometimes, even the protections of certain resources are implemented in a more permissive and trust-based way.

This aspect is extremely unfavorable for the general security measures of the network because, in the event of an attack, the affected resources will increase exponentially. As a result, the attack can also extend to the Data Center or critical infrastructure

area and can affect both the image of the organization and resources that should be operating in a constant manner.

Also, if we put aside the technical area, the huge impact of an attack will have financial implications, both for measures to prevent the spread, and for the remediation of the affected aspects (ransomware) or for the subsequent use of more effective protection measures.

However, the most important implications are given by attacks in the NOC area or in the Data Center area because the people who have access to this data have much greater visibility over the entire infrastructure. Thus, attacks can be tested before the actual attack so as not to be easily detected or can be hidden within legitimate files, until they are detonated. Although it is less likely that users of these areas of the network infrastructure will initiate an attack (due to the level of training, strict policies or secure access to resources), if they do, the impact can be devastating.

The most common risks are data from compromised devices, intentionally or not, users unfamiliar with the cybersecurity area and the implications of security measures, phishing attacks that led to the attacker finding out key credentials, improperly secured Wi-Fi networks, configuration errors that can be exploited or simple credentials (admin/admin type).

The most likely attacks at the network level are infection with malicious files, data exfiltration, erroneous or apparently erroneous configurations that add additional, unauthorized routes, exploitation of weak security measures, use of firmware backdoors, DoS, unauthorized access to various types of resources, etc.

Some of these attacks will be presented in the following section in order to achieve a more realistic example of several types of attack scenarios and to be able to identify network vulnerabilities and the most effective methods of protecting them. The focus will be on network scans, identification of network flooding attacks or Denial of Service (DoS) attacks.

V. Results

In this section, we will consider several types of attacks, both network-based and file-based. The main goal is to visualize the attack response time and effectiveness within a fully virtualized system.

A. Network Scanning

Network scanning attacks are used to allow an attacker to view the essential characteristics of certain network devices or end-devices in order to create a network topology and discover various vulnerabilities. These vulnerabilities can be found both at the operating system level and at the exposed services level, and their exploitation is done in a unique way by each attacker.

In the experiments carried out at the network level, through the EVE-NG platform, the scans at its level were successful in detecting IPs and open ports in most of the devices tested (both for network devices: routers, switches, and for devices used by a normal user).

The main advantage was given by the SIEM system, which managed to capture most of these attacks, even though the network logs were extremely difficult to read and process due to the large volume of data. This aspect highlights the importance of monitoring and log capture measures both in complex and simple networks.

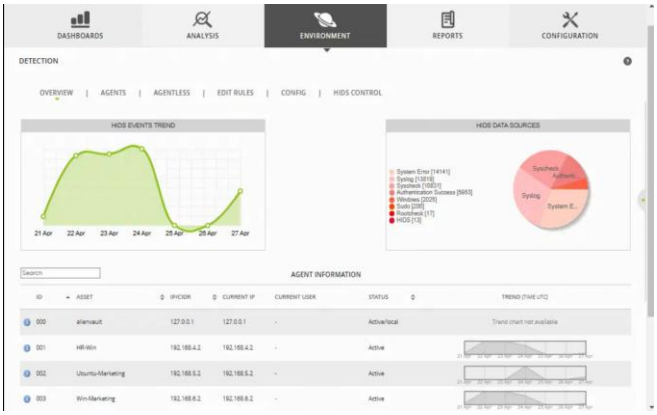

Fig. 2. Network architecture visualization mode at the SIEM system level.

Fig. 2 shows how the SIEM system analyzes the available agents and manages them efficiently, capturing their logs. As can be seen, the agents come in several categories, including various types of operating systems (Linux or Windows).

In the first test scenario, both attacks from the network area that includes the Marketing architecture and the network area that includes the HR part will be analyzed, both being contained in the same branch, as can be seen in Fig. 1.

Consequently, in this work scenario, both operating systems (Linux and Windows) were used as victim resources, and the attacks were generated using a Kali Linux virtual machine. This is not common in a normal network architecture, but the fact that the attacker machine is not a regular Ubuntu or CentOS does not impact the result at all because the attacks were generated using regular Linux commands and not with specific Kali Linux tools.

The first attack was carried out on the company's own network infrastructure, from the marketing area to the same network, to observe the available devices and open ports. This aspect led to the identification of certain attacks, which can be focused on those ports to destabilize the infrastructure. The way of carrying out the attack included running, through Kali Linux, the nmap 192.168.5.0/24 (local network) command.

Although the initial expectations were that the SIEM system would identify this attack and alert security administrators to this fact, it was concluded, based on experiments, that the Security Event and Information Management system did not even register the event, it was "lost" in the multitude of network logs.

The next work scenario targeted an attack from the Marketing area to the HR area, maintaining the same characteristics as in the previous case. Therefore, another, more aggressive attack was generated using the nmap -A 192.168.6.0/24 (distant network) command, which led to the identification of several features of the HR network area.

This time, the attack was recorded at the Security Information and Event Management system level, and the logs were displayed in a relatively short time at the dashboard level. Therefore, in this case, the SIEM system functioned effectively, recording the attack so that security administrators could

intervene to identify and isolate it. Following this type of event, a rule could be created to trigger an automatic action, which would isolate the traffic generated by an attacker workstation. Therefore, the resulting behavior consisted in the fact that the attacker station's IP is declared suspicious and the scan stops, the attack not being directed to the initial destination.

The way this type of attack is detected at the OSSIM level is through sensors that identify Nmap, Masscan or network scanning actions. These sensors usually generate an event in the dashboard that has a "Scan Detection" or "Potential Network Scan" alert. Following this event, alerts can be created to automatically block this type of traffic. In this case, the attack is not automatically blocked due to the fact that the test mode includes successful attacks, in order to test the efficiency of the Security Event and Information Management system in capturing logs from devices and displaying detected attacks or intrusions.

In the last scenario in the network scanning subchapter, the attack was carried out directly to the SIEM, in order to observe if and how it will prevent it. The attack was also generated through Kali Linux, as can be seen in Fig. 3 and was recorded in the SIEM system dashboard (Fig. 4). The important aspect is given by the fact that the attack led to temporary interruptions of the SIEM system, even if it consisted only of a trivial scan. Thus, even a small change, at the resource or configuration level, can lead to the total or partial interruption of log capture, leaving, at the same time, various types of attacks unnoticed and unverified. Practically, the latency in the response can indicate high CPU consumption for the analysis of each packet whose destination it is. In this subchapter, two different attack scenarios were presented in which the attacker was a Kali Linux device. The attacks were directed to a device within the network and to a device from another network, but in the same branch.

Although the initial attack was not recorded by the SIEM, the other two were recorded effectively and even alerts were displayed for security administrators.

B. Denial of Service Attack Simulation

DoS (Denial of Service) or DDoS (Distributed Denial of Service) are some common network attacks that involve generating TCP connections with a large volume of data, which aim to temporarily block access to resources, affecting certain services. These types of attacks are usually focused on a specific device, and the impact consists of intentionally reducing its performance. In the favorable case where this system also has a backup connection, services will only be affected to a small extent, but in a real infrastructure, there are extremely few network areas that operate in this logic.

The essential countermeasures for this attack not to be successful consist of limiting multiple connections to a specific device, blocking various queries by firewall devices, equipment that operates in HA, devices that have integrated the concept of load-balancing, etc.

Moreover, if the attack comes from "inside", a good part of these measures becomes ineffective anyway because they have already been bypassed by the attacker. Therefore, it becomes imperative to be aware of the impact that an attack carried out from the internal area can have on the infrastructure.

To prevent these types of attacks, more access control measures must be implemented, SIEM systems that also integrate user behavior analysis (based on machine-learning) have to be considered and resource segmentation measures should be used.

The impact of this type of attack, from an experimental point of view, consisted in affecting network communications, temporarily interrupting certain essential services and degrading network performance. Moreover, the loss of certain packets at the level of a network of the size of the one in Fig. 1. is normal. This is true even if VPN connections are made between the Headquarters area and the branch area.

However, in the case of a DoS attack, the network's "defense" mode is to drop certain packets to cope with the overload. If the attack is long-lasting, at some point, the affected resource may even become unavailable, affecting even communication between certain parts of the network.

In the first working scenario, similar to the way the previous experiments were carried out, an attack will first be executed within the branch network, using the command:

hping3 -S –flood -V -p 80 192.168.5.2

The attack is recorded at the SIEM system level, but the alert is not clear enough to indicate the type of attack. However, multiple Windows errors indicate, for security administrators, abnormal behavior at the network level within the respective branch.

In the work scenario where the attack is centered on the Security Event and Information Management system (Fig. 5), the attack works in a similar way, but the SIEM system's reaction mode is extremely serious for the entire infrastructure because it becomes unavailable in the entire period of the attack.

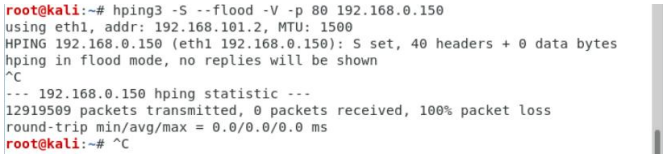

Fig. 5. DoS attack carried out on SIEM.

The immediate impact is given by the fact that, during this period, the Security Event and Information Management system does not record the attacks completely, and this aspect can completely affect the analysis network and the entire infrastructure of the organization. In practice, the SIEM system still receives logs from the devices in the network, but it can partially lose various events, and these are unrecoverable.

In this working scenario too, the EVE-NG test environment has proven important to simulate certain network behaviors in case of attack, allowing various types of important conclusions to be made, through the experiments carried out.

C. Malicious File Attacks

During the experiments, network intrusions through malicious files were also considered. The way in which these files came to penetrate the network was not included in the experimental data because it is not the scope of this work.

Consequently, also through the EVE-NG virtualized environment, a realistic scenario was created in which attacks originating from the internal area of the network were simulated and which are masked in legitimate files, which are executed due to lack of knowledge of their real nature. This type of attack is used to compromise the security of systems and to steal certain data about users or about the organization. The goal is to obtain various financial facilities or to steal various databases or ideas, for the purpose of reselling them or for the purpose of blackmail.

The test network included all the elements in Fig. 1, and the attack scenarios were triggered manually or automatically, through malicious files, transferred via FTP or downloaded from the public resource area, by a legitimate user. The attacks in this test scenario, however, came from several different parts of the network, in order to test both the intervention from the NOC area and the intervention from other branches, compared to the one tested in the previous scenario.

Basically, in this test scenario, the entire network was intended to be involved, but due to the multitude of logs, the SIEM system worked inefficiently, having moments of crashing or difficult event recording. Thus, for efficient detection, in certain experiments (based on more critical files such as ransomware), unused resources were closed. This way of working implies a more efficient use of resources in the test scenario through EVE-NG, but in a real test scenario, this is almost impossible, the purpose of the SIEM system being, mainly, to capture logs from all devices used in the network. Therefore, in this test scenario, the proportion of effective tests in EVE-NG, whose conclusions can be directly translated into the real working environment, was not respected. However, the way the SIEM system works, the way alerts appear and are customized at their level, and the way scripts that use these alerts are identified, can be implemented based on these tests.

The biggest disadvantage of these experiments in EVE-NG and the real environment is that, although the network in Fig. 1 is a large-scale network, it is nowhere near the size of a real (production) network. However, the resources used by the SIEM system to process all these logs are quite high, but the processing is not that efficient. In addition, considering the fact that the volume of data processed is insignificant compared to the real volume of data, the performance analysis on the test environment cannot fully reflect the multiplicity of the real environment.

Considering that in EVE-NG, the resources used do not have access to actual internet resources, in some experiments, Kali Linux devices were also included. The explanation for their use, compared to the use of regular Ubuntu devices, is that the former have more pre-installed libraries. An example, in this case, is the SSH (Secure Shell Protocol) service, which, in Kali Linux, has both the server and client sides installed, while in Ubuntu, it only has the client side. Therefore, Kali machines are considered regular users and agents of the network and not attacker machines.

The attacks were analyzed dynamically, including monitoring of CPU and memory resources and detection by antivirus on the victim host. Also, in some experiments, Wireshark tool was included.

One of the most relevant tests was the one regarding a ransomware attack, implemented by executing an .exe file, from the public resources area. Therefore, within this scenario, two test modes were implemented: a ransomware attack originating from the NOC area and an attack originating from one of the branches. The difference between the two types of attack was given by the affected operating system, focusing on the comparative analysis of a ransomware attack in a Linux-based operating system and in a Windows-based operating system.

The main purpose of the two types of attack was to visualize how the SIEM system registers the intrusion and to observe the impact that this malware attack has on network resources (both on the affected workstation and on its adjacent resources: routers, switches or other workstations).

The aspects observed after execution recorded typical behaviors of a ransomware file, this file scanning the disk within Windows and Linux systems and encrypting all accessible files,

in an extremely short time. Each file also received a different extension and a .txt file was created, highlighting an email and an amount through which the affected data can be recovered. It is mentioned that the behavior of the ransomware file was not detected by the antivirus system at the time of its download, remaining undetected until the time of execution. The effect on the infrastructure was irreversible, the files being inaccessible, without a backup solution.

The SIEM system did NOT manage to detect the attack in time (at the time of downloading the malicious file on the client's workstation), thus making the entire network vulnerable. And, at the time of the attack, the intervention on the resources was already far too late to be implemented effectively.

In the first experiment, a ransomware attack was carried out on the Ubuntu operating system, in branch 3, which contains the DEV department and the IT development area.

During the ransomware experiment, the execution of the .elf file [18] was attempted. However, this file required additional dependencies and dynamic libraries. Therefore, for the file to function properly, these dependencies had to be installed. Not having direct access to internet resources and having various problems with the offline installation of the necessary dependencies, this attack did not function properly, in a final version.

Within the SIEM system, the attack generated in the Ubuntu workstation is not visible, the logs not recording the execution of this file, neither when it did not have the necessary dependencies nor after they were installed in an offline mode, and the attack was run again (Fig. 6).

Fig. 6. Ransomware attack file execution from branch 3.

This aspect is quite complicated, given the nature of the malicious file executed because, even if, in the end, its execution did not affect the operating system, the fact that the file is not even registered at the Security Event and Information Management system level requires the existence of additional protection measures to compensate for this faulty way of working (by implementing IDS/IPS solutions or through application-type firewalls, which record and restrict such behaviors). The next working scenario included the same way of working, but within the Windows operating system. This time, the file chosen was .exe [19] and it worked properly, and the attack was successful, as can be seen from Fig. 7-9, which presents the entire evolution of the attack. In this case, contrary to the previous example, the Security Event and Information Management system detects malicious files and displays alerts at the graphical interface level.

Although, even in this case, the alerts are not very conclusive for the security team to know that there is a ransomware attack on the network, the multitude of errors that appeared in the dashboard require additional verification. An important aspect to note is that, although there was routing at the network resource level and the affected station was connected to the external environment (including the SIEM system, being its agent), the ransomware attack did not affect other resources on the network.

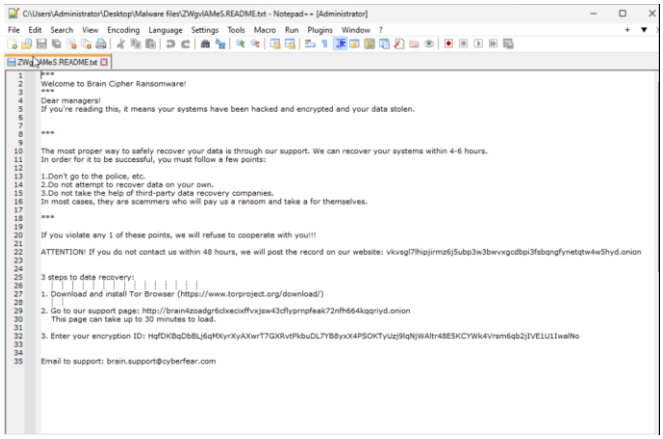

Fig. 8. Detailed README.txt of ransomware attack.

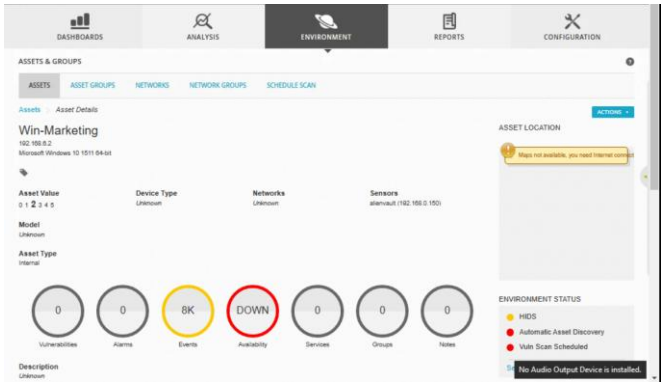

Fig. 9. The victim client station becomes inaccessible to SIEM after the ransomware attack.

Another extremely important aspect is the fact that, following the attack, the affected client station also became unavailable at the Security Information and Event Management system resource level, appearing DOWN, although it continued to function, only that its files had been encrypted. Therefore, it is considered that the ransomware affected the services, also

blocking communication with the manager, but did not specifically target the security agent.

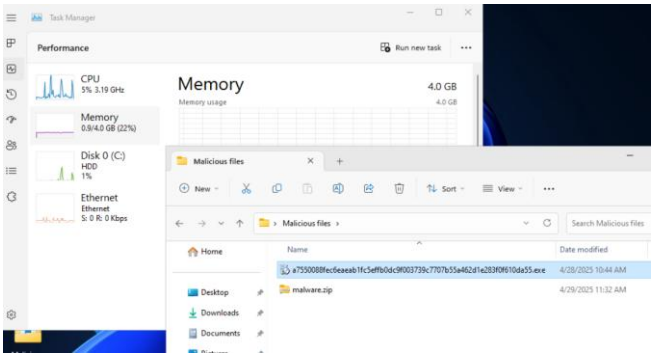

Fig. 10. Malware attack file execution from branch 3.

In a similar scenario, an attack with a malware file [20] on a Windows node was also considered, simulating another compromise, from NOC area (Fig. 10). The impact was given by the fact that activity was detected at the antivirus level, and the system resources (CPU, memory) were affected (CPU – 100%). At the level of the system that ensures Security Information and Event Management, the attack was detected, but the alerts are different, compared to those displayed previously, but still not clearly expressed enough to easily identify that it is a malware attack (Fig. 11).

In the present case, propagation in the virtual network is possible, due to the malicious nature of the file, but calls to the internet are not possible because the victim virtual machine does not have outbound access from the network. Thus, the file can see the LAN area, but, without a source of command and control, in the test environment used and during the experiments, it did not try aspects of lateral movement.

Fig. 11. Displaying the malware attack in the SIEM system dashboard.

The malware acts by running and modifying registries (from subsequent tests, it remains on that virtual machine even after reboot), but is limited to the actions performed, being valid only within the virtual workstation. To verify that the malware was propagated in the LAN area, some Wireshark and Process Monitor captures were performed on the victim station, observing both the malware scan logging and the behavior on processes.

In order to simulate a real internet environment, similar to some experiments that are carried out in real sandbox environments (not those based on EVE-NG), it would have been necessary to use tools such as FakeNet [21].

It can simulate network services and responses so that the malicious software does not notice the fact that it is a test, virtualized environment and reveals its real behavior. In this way, domains or command-and-control servers can be identified. In EVE-NG this simulation was not possible because, although a separate workstation was used, acting as a gateway, the malicious file does not adapt its behavior.

In this study, our goal was not to calculate statistical detection indicators such as false positive or false negative rates, but to verify whether the SIEM system (OSSIM) successfully recorded the occurrence of specific attacks in the environment emulated by EVE-NG. For each experiment, attacks were generated using hping3 (DoS and ICMP/TCP floods), Nmap (port reconnaissance and scanning), and two real malware samples executed in virtual machines. The outcome for each scenario was evaluated based on the detection and recording of the event by OSSIM (Recorded = Yes/No).

Table II provides a summary of all scenarios, indicating which attacks produced SIEM alerts.

TABLE II. SIEM EXPERIMENT RESULTS

Scenario	Tool/Sample	No of Runs	Recorded in SIEM	Alert Type
Port Scan	Nmap	2	Yes	SSH insecure connection attempt
DoS	hping3	2	Yes	Traffic Anomaly
Malware Sample 1	Ransomware1	1	No	-
Malware Sample 2	Ransomware2	1	Yes	Registry integrity checksum changed
Malware Sample 3	Malware	1	Yes	Registry integrity checksum changed

Another aspect that should be considered in this section is false positives. Given that in a network environment like EVE-NG there are a lot of devices generating traffic in parallel, a detailed explanation of all these values, which can appear at the SIEM level, is necessary.

The first one is about legitimate high-volume traffic because, sometimes, this traffic can generate attack-like patterns, but some VMs are doing normal operations (updates, backups, scans).

Another one can be when several VMs communicate in parallel and the SIEM may interpret aggregated traffic as suspicious.

The third one can be generated by multiple concurrent updates or temporary files can be flagged as suspicious.

Some alerts may correspond to benign parallel activity in the EVE-NG environment, representing potential false positives inherent in multi-device traffic aggregation. These were identified and differentiated from alerts generated by attacks by controlling the timing of the attacking virtual machine and even isolating a part of the network, when the attack was generated, in order to observe its impact on the SIEM system.

VI. Discussion

The experiments used in this chapter included several types of attacks generated at the level of a test infrastructure. Therefore, multiple attack scenarios were carried out, which included both network scanning attacks, DoS attacks and malware infections.

Considering that it is a test environment, EVE-NG cannot cover a real infrastructure, most of the resources being limited. Consequently, there are several cases in which the infrastructure operates slowly and, considering that a SIEM system also operates at its level, even storage will be even slower than in a real environment. The OSSIM Security Event and Information Management System requires substantial resources to function optimally. Being also an infrastructure in the EVE-NG environment, it can sometimes be overwhelmed.

Attacks carried out on this network are quite suffocating for SIEM, even if the hardware resources are sufficient because it must process an extremely large number of network logs, from all the devices. Moreover, during the attack experiments, a good part of the remaining devices was shut down, so that the logs could be tracked as easily as possible and so that the analysis would not overload the available resources. Event processing at the SIEM system level includes each network log being inserted into a database, being correlated with other events in the network and being displayed in a graphical interface. Thus, the processing time is extremely long and, sometimes, alerts appear with delays.

The SIEM system is built for the analysis of normal traffic events. The intrusion detection part is an additional one and, due to the fact that an EVE-NG system is also used, in which it is integrated, this area is sometimes inefficient. Although the Security Event and Information Management system is optimized to function as a network device in EVE-NG, it is not used to the massive volume of traffic, as in the case of previous attacks (directed to it). Therefore, when it detects an attack on it, it has two types of behavior:

- It can ignore the attack and continue recording events from legitimate devices.
- It may freeze, delay event display, or become unavailable.

In the work scenarios, it was required that the attacker know the IP of the SIEM system and that it not be protected by any firewall or other resources, but in a real work environment, this aspect is quite impossible for a branch user. It is not, unfortunately, impossible for a user working in the NOC area who could have access to such resources. However, most of the time, routing resources to the datacenter infrastructure level (where the Security Event and Information Management system is located) is not so accessible. As prevention methods, these would include separating the infrastructures at the datacenter level through hardware and software firewalls and segmenting the network in the most efficient way possible. Also, another urgently needed method is the implementation of domain policies that include limiting user access to tools such as nmap or to sensitive network resources.

A particularly important aspect is the ease with which this type of file can penetrate the network, in the absence of policies for their automatic detection. Therefore, without this type of monitoring and blocking policies, the files end up being executed, without the user being able to imagine their real intention. Therefore, inspection within the SIEM, but also the presence of an antivirus becomes essential elements for securing the environment in the endpoint area. Following the execution of the files, they had various behaviors, but most of them fell within the aspects mentioned in the chapter on static and dynamic analysis of malicious files. However, if we also take into account the impact aspects at the network level, it is found that they tried to generate various illegitimate connections, created process delays and resource consumption and various types of temporary blockages.

The disadvantage is that, in some cases, malicious files passed undetected from one computer to another, even if their activity was monitored by the SIEM system. Basically, the logs related to this type of transfer went unnoticed, the alert being created only at the time of execution. The fact that the SIEM system could not automatically block this type of file required manual analysis, thus implying the possibility of extending the attack to the entire network.

Simulating these attacks in the EVE-NG virtualization environment allowed highlighting the easy way with which malicious files can completely compromise a network, observing the behavior of the network in the event of an infection and testing the real infrastructure, without implications in the production area. However, a troublesome feature in the experimental area consisted of the direct implications that certain agents had when disconnecting from the manager's area. Therefore, considering that most of the experiments were carried out with closed network parts, when reconnecting them, there were various desynchronizations between the agent and the manager. Basically, the time in the agent device was no longer correlated with the time in the manager area, and the logs, including at the dashboard level, were not recorded. This way of working has been encountered previously in the real working environment, and, in both cases, it produces serious issues because the attacks are not recorded properly, and the SIEM system does not alert administrators in any way about this aspect. It is obvious that, without integrated security solutions and correct network segmentation, even in a controlled environment, attacks can have devastating effects. The experiments carried out have demonstrated that a simple file executed by a user with limited rights can serve as an entry point

for ransomware, backdoor or other forms of malware that escalate privileges and compromise the entire infrastructure.

In most cases, the SIEM system proved to be ineffective. Although the alerts provided raised the attention of network or security administrators regarding abnormal behaviors, they were quite vague, with no clear demarcation between the types of files that affected various operating systems and the way the alerts were displayed. Moreover, in some cases, the alerts displayed at the Security Information and Event Management system level are identical, although the types of intrusion files are different. If it is also considered the fact that, in some cases, the SIEM system did not detect a certain malicious behavior at all, we find the permanent need for additional intrusion detection measures (separate IDS/IPS systems).

The proposed method has potential applications that extend beyond the quality assessment of virtual devices, in a fully virtualized environment, such as EVE-NG. Therefore, the proposed method is considered useful for making informed decisions, in an environment that simulates a production environment, based on cybersecurity strategies that can adapt to multiple types of attacks and for multiple types of network devices or operating systems. This aspect also introduces efficient methods for learning and adapting the security policies of organizations, through various work scenarios, which can help to understand the cyber threat landscape.

Therefore, the main contributions of this work are the fact that a proprietary network architecture is proposed, divided into several different blocks, similar to a real network environment, which also involves resource segmentation. Also, the implementation of a SIEM system is considered to automatically detect network threats, operating in an agent-manager system, and including a centralized dashboard (where various alerts can be graphically viewed), like a real environment. Through this system, various logs can be collected from network equipment and workstations and automatic responses to intrusions can be created.

In addition, various work scenarios are tested, including both malicious files and network-level attacks, in an environment that is not specific to these types of actions. Also, the efficiency of these attacks is evaluated, both at the level of the network's own resources and at the level of the other parts of the network (for detecting lateral movements and for testing how an attack works at the level of the entire network).

Moreover, the EVE-NG working platform is evaluated, under the conditions of a complex network architecture and malware detection, at the SIEM level, although the platform was not created for these purposes, but only for common network tests and networking knowledge training.

To summarize, the main contributions of this paper are as follows:

- We designed and implemented a controlled cybersecurity experimental framework using EVE-NG, demonstrating its potential to model both network attacks and, more superficially, real malware attacks, in a secure environment.
- The feasibility and limits of using a non-dedicated network simulator for security research were assessed, providing insights into its adaptability and practical constraints.
- Experimental results were presented illustrating the behavior and network impact of common attack types.
- The potential role of EVE-NG as an accessible and cost-effective platform for cybersecurity training, testing, and education was highlighted.
- The response of various emulated systems to attacks or attack files was tested, in order to be able to formulate various preliminary conclusions to define their influence in production environments.

These contributions aim to reduce the gap between theoretical cybersecurity studies and practical experimentation, supporting both academic and practical advances in the field of network security.

Although the proposed work has multiple advantages, the imminent limitations of any system must be taken into account. The first one is that malware samples can identify if the sandbox environment is virtualized and can modify their behavior depending on this characteristic. Therefore, it would be much more appropriate for this simulation to be performed in a real test environment, not a virtualized one. However, most of the time, this is not possible because the malware execution can lead to partial or total degradation of the test environment.

The second one can be considered by the limited number of experiments because the specific behaviors of a certain type of malware or attack cannot be extracted except after successive runs of several experiments with similar malware samples or from the same family. Such work scenarios are considered in the following tests.

Although the experiments are performed in both Linux and Windows operating systems, the third limitation is that the mobile area is not covered in this work. Other operating systems are also considered in the following experiments.

Another limitation, the fourth, is that the alerts displayed at the SIEM dashboard level are not very explicit and can be confusing if similar malicious samples (trojan and malware) are used. This can make it difficult to quickly interpret security events and prioritize incidents. In further developments, increased attention will be paid to customizing alerts, so as to provide more detailed and useful information. It will also be considered to evaluate other types of SIEM systems, such as Wazuh [22], to test their ability to generate more intuitive and informative alerts.

The last one can be considered the fact that the test scenarios included experiments were performed in short period of time (up to one hour) in order not to degrade the test environment. This aspect is considered a limitation because some malicious files or some attacks become more effective after a certain period in which they "adapt" to the victim environment.

This type of test system is effective for supporting conclusions similar to the real environment because, in a virtualized environment, there are constraints on various types

of resources. Thus, the resulting ideas can only be as a possibility of similar action of a malware in a real environment, most of the time, in the second case, the effect being much more intrusive. The most important measures for protecting the analyzed network are:

- The existence of a SIEM system, to be able to capture various network logs and to be able to effectively detect malicious executions or attacks from the internal area of the network.
- Implementation of much stricter access control policies, in order to limit users from easily creating attacks.
- Segmentation of various parts of the network, to prevent the penetration of illegitimate traffic to critical resources.
- Constant updates of antivirus systems, in order to have access to the latest versions of malicious file signatures.
- Constant updates of antivirus policies and systems at the endpoint level, to block the execution of malicious files by users.
- Implementation of secure password policies, which are constantly updated.
- Performing constant backups, in environments different from the usual ones, to reduce the effects of ransomware attacks.
- Performing experiments in virtualized environments, to track the weak characteristics of the network.
- Educating users through concrete examples, to increase awareness of the dangers.
- Verifying, through static and dynamic analysis methods, the malicious files that have penetrated the network, to fully understand their behavior and the network vulnerabilities (if they have penetrated the systems by downloading or through FTP servers and have not been detected by antiviruses or SIEM, a problem is indicated at the level of the policies implemented within these solutions).
- Using, besides SIEM system, additional IDS/IPS solutions.

This study focused on evaluating the ability of OSSIM to record and alert on network and host-based attacks in an EVE-NG environment. Quantitative evaluation of mitigation measures, such as firewall rules, traffic filtering, or SIEM correlation tuning, was not performed and is beyond the scope of this work. But, the most important ones, for all network environments, can be:

- Firewall rules or access control lists (ACLs) – that can block Nmap scans, hping3 floods, SSH brute-force attempts.
- Rate limiting or traffic shaping – that can mitigate TCP/ICMP floods (hping3).
- Segmentation – this kind of mitigation was considered even in the network topology and it's advantage can be the fact that it limits spread of malware and reduces alert noise in SIEM.
- Endpoint firewalls – that can prevent malware scanning other hosts.
- Whitelist trusted hosts – that can reduce the impact of a new malicious host.
- Logging and backup – that can retain logs to analyze attacks, false positives, and potential missed events.

In this work, it was proven that EVE-NG is an efficient test environment, but it has its limitations when the network architecture is more complex or when malicious aspects are introduced, which must be processed in parallel with the usual activities of the network devices.

But, citing again the work [13], no test environment (hardware or software) can contain, include or be impenetrable to any type of malicious software. The goal is to learn in as much detail as possible the characteristics of these files, in order to be able to offer, at any time and under any conditions, the most efficient defense and a significant reduction of their impact.

VII. Conclusion

In this work, the focus was on simulating a computer network similar to a real environment, which included both network devices comparable with those currently in use, as well as workstations with Linux or Windows operating systems. This network was created highlighting the idea of resource segmentation and included a central office and remote branch environment. Thus, five major components of the network were imposed: the datacenter area, which included server resources of various types and the network's SIEM system, the NOC area, which ensures continuous monitoring of resources, and the remote branch area, which are related to the resources used in the datacenter area and which are constantly monitored through the NOC area.

The routing method, as well as the services running at the network level, were not central to this work, the emphasis being placed on the analysis of intrusions and network traffic, in the usual way.

In the experiments carried out, two different types of network traffic analysis were considered: network traffic analysis in the presence of an attack at its level and network traffic analysis in the case of an attack by a malicious file. The malicious files used were downloaded from MalwareBazaar resource and are available online.

The conclusion of these experiments is that, although EVE-NG is a good test environment for network administrators, when various types of experiments similar to the real environment are desired, if attacks are also considered, it becomes quite inefficient. Although it also implements methods based on SIEM systems, which are usually capable of detecting these attacks, experiments show that it can only partially simulate real-world analysis.

However, from the experimental area, one can conclude both benefits in the area of learning with this test environment, as well as the identification of key parameters in the analysis of data

networks. Thus, it is found that network traffic analysis must include several methods and solutions (static analysis, dynamic analysis, monitoring and constant logging through SIEM and analysis with machine learning methods) ensuring redundancy when one method fails. In this sense, if in some cases there is a possibility of duplicating the solutions (main SIEM and backup SIEM) or of performing a more complete analysis, using solutions that, apparently, offer the same results, the composition of a network environment as secure and robust as possible is all the better defined.

This study highlights that EVE-NG provides a secure and repeatable environment for examining malware behavior, offering a practical bridge between theoretical research and hands-on cybersecurity training. By enabling controlled experiments in a virtualized network, it allows both academic researchers and industry professionals to analyze attack patterns safely, supporting reproducibility and experiential learning in cybersecurity practices.

In future work, other types of malicious files will be considered, and the analysis will be performed on other types of operating systems that can be modeled in EVE-NG. Also, research will focus on incorporating Wazuh, to enable real-time behavioral analytics. These enhancements aim to improve threat identification capabilities, allowing the system to dynamically recognize unusual activity and provide timely, actionable insights for cybersecurity monitoring and response. The ultimate goal is to create a robust database containing more recent malware samples, which can be adapted to current security systems and learn as much as possible about malware characteristics, regardless of the test environment used.

Predicting Stock Market Performance Based on Sentiment Analysis of Online Comments

A Case Study of China's Highest Market Cap Stocks

***Abstract*—In China's retail-focused stock market, the influence of social media sentiment during off-hours on the next day's opening price has received limited attention. This paper takes Kweichow Moutai—a leading Chinese company with substantial market capitalization—as the research sample. It gathers investor commentary data from financial platforms, and uses natural language processing tools (SnowNLP) to develop a multidimensional sentiment index (including average sentiment score, positive ratio, and sentiment volatility). By integrating this index with stock trading data and macroeconomic indicators, this study designs a dual-channel LSTM model: one channel for market technical features (e.g., price, volume) and the other for sentiment features, aiming to analyze the impact of off-hours sentiment on opening prices. Empirical results indicate that overnight sentiment has significant predictive power for the next day's opening price; meanwhile, sentiment transmission is asymmetric, making predictions more challenging in declining markets. Additionally, high-frequency sentiment data significantly outperforms low-frequency data in market prediction accuracy. This research expands the understanding of how investor sentiment influences the market over time, providing practical insights for market participants to develop effective strategies and manage risks.**

***Keywords*—Investor sentiment; non-trading hour sentiment; social media comments; dual-channel LSTM**

I. Introduction

In recent years, China's stock market, the world's second-largest, has surpassed one trillion yuan in combined market capitalization for the Shanghai and Shenzhen stock exchanges. Structurally, the Main Board, ChiNext, and the STAR Market form a multi-tiered capital market system, providing businesses with a range of financing options while also better serving investors' increasingly diverse asset allocation needs. However, compared to mature markets, the Chinese stock market still has unique structural features. A trading environment primarily driven by retail investors yields high volatility, high turnover, and a sentiment-driven market. Individual investors significantly influence both the number of accounts and trading volume, thereby affecting market pricing efficiency and volatility. Given these features, investor sentiment—a hallmark of irrational behavior—is increasingly seen as a significant factor driving market volatility.

In recent years, the widespread use of social media has created a new data source for researching investor sentiment. Platforms such as Weibo, stock forums, and Xueqiu have become key channels for investors to gather information, share opinions, and interact, producing a vast amount of user-generated content (UGC) closely linked to financial markets. This unstructured text not only captures investors' responses to company developments, policy changes, and macroeconomic trends in real-time but also offers high frequency and broad coverage, making it a valuable resource for sentiment measurement studies. While much research in traditional finance has examined how sentiment influences the market from a behavioral finance perspective, Aggarwal (2022) notes that, despite over fifty years of investigating market sentiment, a lack of standardized definitions and measurement tools remains, leading to significant variation in empirical findings. Therefore, it is essential to revisit the use of sentiment variables in finance within a psychological framework to enhance modeling accuracy and predictive capabilities.

In the context of social media, Bollen, Mao, and Zeng (2011) [1] first attempted to construct sentiment time series using Twitter content. They discovered that sentiment dimensions such as "calmness" significantly enhanced the forecast of the Dow Jones Industrial Average (DJIA), confirming the forward-looking influence of macro-level collective sentiment on financial markets. Yang and Mo (2016) [2] also showed that extreme news or social media sentiment can act as leading indicators of market returns and volatility, with even greater predictive power when sentiment varies significantly.

The real-time and scalable nature of social media data makes it a valuable tool for financial research. Corea (2016) [3] found in their study of the technology industry that behavioral variables such as tweet volume and interaction frequency are more predictive of stock prices than tweet sentiment polarity. Li et al. (2017) [4] proposed the SMeDA-SA method to extract sentiment signals from massive tweets, achieving highly accurate predictions of individual stock fluctuations and further validating the feasibility of social platforms as proxies for investor sentiment. Liu et al. (2015) [5] also explored the role of social media indicators in predicting stock co-movement, finding that companies with active Twitter accounts tend to exhibit more consistent stock price movements, revealing the power of social media to shape industry structural sentiment.

*Corresponding authors.

Advances in sentiment recognition technology have also expanded its applications in the financial sector. Man et al. (2019) [6] systematically reviewed the development of financial sentiment analysis (FSA), from early dictionary methods and traditional machine learning to deep learning models such as LSTM and Transformer, providing a diverse range of tools for financial sentiment modeling. Wang et al. (2022) [7] developed a market-neutral strategy based on LSTM and experimentally confirmed that the model exhibits high accuracy and stability in extracting sentiment from individual stocks. Koukaras, Nousi, and Tjortjis (2022) [8] utilized the XGBoost method, while Kumar et al. (2022) [9] employed a fuzzy neural network (FNN) approach. Both methods combined tweet sentiment with historical market trends to achieve effective predictions of the Dow Jones Industrial Average and the stock prices of several companies. In addition, Hasselgren et al. (2023) [10] proposed visualizing the sentiment scoring system, providing a feasible tool prototype for investment decisions.

However, while existing research has produced valuable insights in social sentiment modeling and market forecasting, it has mainly concentrated on the real-time relationship between sentiment and market variables during trading hours. It has paid little attention to the mechanisms that influence sentiment beyond trading hours. Traditional financial theory posits that prices are primarily determined during trading hours through the order book, with information outside of trading hours being indirectly reflected through overnight orders. Nonetheless, social media platforms often generate a large volume of emotional expression between the market close and the next day's opening, especially during emergencies, policy announcements, or the release of financial reports. These sentiments can potentially shift investor expectations in advance, affecting the opening price on the following day.

In response to this research gap, some scholars have begun to explore this area: Ranco et al. (2015) [11] found, based on the event study method, that there is a significant correlation between Twitter sentiment peaks during non-trading hours and the next day's cumulative abnormal returns; Fraiberger et al. (2021) [12] pointed out that international news released at night significantly affects cross-border capital flows and global stock price returns, highlighting the importance of non-trading period information in the international market [12]; Goutte et al. (2023) [13] also confirmed, in the context of ESG investment, that news sentiment indicators during non-trading hours show strong robustness in market return forecasts.

In summary, while current research on investor sentiment has made some progress, a significant gap remains in the systematic theoretical development and empirical testing of how sentiment during non-trading hours influences market opening behavior through expectation mechanisms. Therefore, this paper, drawing on the intersection of behavioral finance and natural language processing, focuses on how non-trading hours social media sentiment influences stock opening prices. To systemically fill this gap, this study first clarifies its core research question: Does social media sentiment during non-trading hours exhibit significant predictive power for the next day's stock opening price, and what are the heterogeneous characteristics of this predictive effect—specifically, the asymmetric transmission across different market conditions (rising vs. falling markets) and the performance differences under varying data frequencies (hourly vs. daily)?

Against this question, the study sets three research objectives: first, to construct a multidimensional non-trading hour sentiment index using online investor comment data, incorporating indicators such as average sentiment score, positive sentiment ratio, and sentiment volatility to capture the temporal dynamics of investor sentiment; second, to verify the causal relationship between non-trading hour sentiment and stock opening price via Granger causality tests, and quantify the magnitude of sentiment's influence on opening price fluctuations; third, to explore the comparative advantages of high-frequency sentiment data in improving prediction accuracy, and analyze the mechanism underlying the increased prediction difficulty of sentiment signals in declining markets.

Based on the above question and objectives, the main contributions of this study are reflected in three aspects: in the theoretical aspect, it expands the temporal boundary of behavioral finance research on sentiment-price relationships—unlike traditional studies that focus on trading-hour sentiment, this paper systematically validates the leading predictive role of non-trading hour sentiment in driving opening price gaps, enriching the cross-temporal theoretical framework of "sentiment-expectation-price" transmission; in the methodological aspect, it proposes a dual-channel LSTM modeling framework that decouples market technical features (e.g., price, volume, MACD) and sentiment features into independent processing channels, avoiding "biased fitting" caused by mixed data types (structured market data vs. unstructured text-derived sentiment data) and enhancing the interpretability of sentiment's predictive role; in the empirical aspect, it provides evidence for the sentiment-driven characteristics of emerging markets—taking China's retail-dominated stock market as the research context, this paper confirms that non-trading hour sentiment exerts a more pronounced impact on opening prices compared to mature markets, offering a behavioral explanation for typical emerging market traits such as high volatility and high turnover.

By creating an overnight sentiment index and integrating it with market variables (e.g., the next day's opening price), this paper will systematically assess the role and stability of sentiment signals in predicting opening prices, utilizing a combination of text sentiment analysis, deep learning, and financial econometric models. This effort aims to offer new theoretical insights and empirical evidence for understanding the behavioral finance features and microstructure of the Chinese stock market. Around the above research content, the remainder of this paper is structured as follows: Section II reviews the literature on investor sentiment, social media sentiment analysis, and LSTM-based stock prediction, laying the theoretical foundation for this study; Section III details the research design, including data sources (stock trading data and financial platform comment data), data preprocessing methods (text cleaning, sentiment classification via SnowNLP), and the architecture design of the dual-channel LSTM model; Section IV presents empirical results, including spatial-temporal distribution analysis of comment data, Granger causality test outcomes, model performance evaluation (using RMSE, MAE, and R^2), and robustness tests across market conditions and data

frequencies; Section V discusses the practical implications of the findings for market participants (investors, financial institutions, regulators) and identifies research limitations; Section VI concludes the core findings and proposes directions for future research.

II. Literature Review

With the development of behavioral finance, sentiment has become an increasingly integral part of financial market analysis frameworks. Investors' irrational decisions, particularly emotional swings during non-trading hours, are recognized as significant factors that influence next-day stock market performance. This paper, based on research into social media comments during non-trading hours and incorporating deep learning prediction models, further broadens the scope of research in this field.

A. Investor Sentiment and Financial Market Dynamics

Investor sentiment, a key behavioral factor influencing market volatility, has been consistently shown to have predictive effects on asset prices, trading decisions, and market fluctuations. A study based on the Pakistani market found a significant link between investor sentiment and investment decisions, with investor experience influencing this relationship [14].

In the context of the Chinese market, research also indicates that irrational emotions have a positive influence on corporate investment redundancy, with non-state-owned enterprises being more significantly impacted by emotions [15].

B. Financial Applications of Social Media Sentiment Analysis

The large volume of textual information on social media offers a valuable data source for developing sentiment indicators. A study of China's Weibo platform revealed that multidimensional online emotions, encompassing happiness, anger, and sadness, can predict fluctuations in the stock market. K-means clustering was employed to investigate the causal relationship between these emotions [16]. This supports the idea of exploring the predictive power of sentiment data during non-trading hours for predicting the next day's market behavior.

Additionally, by analyzing Twitter data with a convolutional neural network, researchers successfully identified the public's satisfaction and responsiveness to the macro environment on social media [17], demonstrating that emotional semantics can reflect collective market expectations.

C. Predictive Power of Sentiment Analysis Combined with an LSTM Model

The introduction of deep learning technology has opened up new possibilities for financial time series modeling. Research has shown that including sentiment scores as input variables in an RNN-LSTM model significantly enhances stock price prediction accuracy, resulting in lower error metrics compared to methods such as SVR and random forests [18].

Additionally, a hybrid model that uses a dual-channel LSTM, combined with text sentiment and stock price data, has also been shown to perform well in predicting Google's stock price. In particular, the RMSE of the model decreased significantly after including sentiment variables [9].

D. The Timeliness Advantage of High-Frequency Sentiment Data

The immediate feedback aspect of sentiment provides high-frequency data with a significant advantage in forecasting. Research utilizing the Google Search Index has identified a bidirectional Granger causal relationship between search data and market volatility, demonstrating a strong forecasting ability during periods of high market volatility [19]. This supports the empirical findings of this paper, which show that hourly sentiment data can substantially improve forecasting accuracy.

E. Asymmetric Transmission Mechanism of Market Sentiment

Regarding the asymmetric transmission of market sentiment, research indicates that negative news has a more substantial impact on predicting price trends than positive news, resulting in significantly higher prediction accuracy and returns [20]. Additionally, sentiment tends to be more volatile during stock market declines, which leads to higher model prediction errors [21]. This explains the higher RMSE observed in declining markets in this study.

III. Research Design and Methodology

A. Data Source and Processing

The data used in this research consists of two main categories: stock market trading data and comment data from financial social media platforms. These two types of data were gathered from reputable data providers and popular social media platforms, respectively. After cleaning and preprocessing, a data system was built to support sentiment analysis and predictive modeling.

1) Stock trading data sources and indicators: This study collected historical trading data for China's most extensive stocks by market capitalization, including Kweichow Moutai (stock code: 600519), from a specified financial data provider. The data covers multiple years to ensure its temporal accuracy and representativeness. Key trading metrics recorded include the opening price (Open), closing price (Close), high price (High), low price (Low), trading volume (Volume), price-to-earnings ratio (P/E), price-to-book ratio (P/B), and turnover rate (Turnover).

On this basis, we further developed various technical analysis indicators to improve our ability to illustrate market behavior. These include: Moving Averages (MAs), which use simple moving averages with window periods of 1 to 4 days (MA1-MA4) to show short- and medium-term price trends. The Moving Average Convergence Divergence (MACD), which consists of the DIF (fast line), DEA (slow line), and a histogram, is used to identify trend direction, strength, and inflection points. Volume-related indicators include: AMO (Amount of Trading Volume) (Volume × Closing Price), which measures trading activity; and AMOW (Weighted Amount of Trading Volume), which accurately reflects capital flows in conjunction with price changes.

All trading data is cleaned after import, including filling missing values, removing outliers, and formatting to ensure data consistency and analytical accuracy. Data within trading hours is fully recorded, while prices and trading indicators during non-

trading hours are uniformly set to null values (NA) to facilitate the distinction between time periods in subsequent modeling.

2) Collection of comment data and content characteristics: Comment data mainly comes from well-known domestic financial platforms, such as Sina Finance Stock Forum and East Money Stock Forum. These platforms gather real-time discussions from many small and medium-sized investors, serving as key sources for gauging market sentiment. This study chose Kweichow Moutai for sentiment analysis. The comment data covers the period from June to December 2024, totaling approximately 60,000 comments. The data was automatically collected using a legal and compliant data scraper. It includes comment text and posting time, accurate to the hour.

To improve the accuracy of time series analysis, comment data are classified and stored by daily frequency, and hourly timestamps are kept to effectively distinguish and compare trading hours (9:30–11:30, 13:00–15:00) from non-trading hours.

To distinguish data scope between trading and non-trading hours, Table I defines the two periods and clarifies the availability of sentiment and market indicators (e.g., non-trading hours only include sentiment indicators).

TABLE I. EXPLANATION OF TRADING AND NON-TRADING PERIODS

Time Type	Whether to trade	Explanation
Trading Hours	Yes	Contains price, volume, technical indicators, and sentiment indicators
Non-trading hours	No	Only sentiment indicators (such as favorable ratio, volatility, etc.) are included, and price data is recorded as "NA"

B. Comment Data Preprocessing

To ensure the accuracy and robustness of subsequent analysis, this study systematically cleans, preprocesses, and structures both the raw review data and market transaction data. This process involves multiple steps, including text cleaning, Chinese sentiment analysis modeling, data alignment, and the construction of derived sentiment indicators.

1) Chinese word segmentation and text normalization: Prior to the implementation of sentiment analysis, a corpus comprising 60,000 original comments was subjected to multi-tiered text cleaning and structural standardization procedures to ensure data quality and validity. Specifically, the preprocessing phase of the comment data encompassed three core steps, as delineated below: First, in the text cleaning stage, extraneous and non-informative elements within the comments—including but not limited to emoticons, uniform resource locators (URLs), punctuation marks, hypertext markup language (HTML) tags, and promotional/advertising content—were systematically eliminated to mitigate noise interference. Second, SnowNLP, a dedicated Chinese natural language processing (NLP) toolkit, was employed to perform word segmentation (tokenization) and part-of-speech (POS) tagging on the cleaned text, thereby converting unstructured textual data into semi-structured linguistic units. Third, leveraging the results of POS tagging, a targeted stop word filtering process was conducted: financial domain-specific nouns, verbs, and other semantically critical keywords were retained, while functionally redundant words (e.g., auxiliary words, conjunctions) that contributed minimally to sentiment orientation were excluded. This sequential preprocessing workflow effectively transformed the raw comment data into structured text features, laying a robust and reliable data foundation for subsequent tasks in the sentiment analysis pipeline, such as sentiment label generation, sentiment index construction, and cross-temporal sentiment prediction.

2) Sentiment classification model and evaluation: After segmenting the words, SnowNLP was used to assign sentiment scores to the reviews (from 0 to 1). Five hundred reviews were randomly selected from the original set and manually labeled as positive, negative, or neutral to create a validation set.

Sentiment scoring criteria: scores above 0.6 are positive; scores below 0.4 are negative; all others are neutral.

Table II shows the performance of the SnowNLP sentiment classification model against manual annotations:

TABLE II. STATISTICAL RESULTS OF MANUAL ANNOTATION

Actual / Forecast	Positive	Negative	Neutral	Total
Positive	51	21	2	74
Negative	19	271	10	300
Neutral	3	40	79	122

The performance metrics for the model are listed below:

- Overall accuracy: 80.85%.
- Weighted average F1 score: 81.33%.
- Macro average F1 score: 76.45%.

The Negative category performed the best, with an F1 score of 85.74%. The Positive and Neutral categories still have potential for improvement, especially the Neutral category, which has low recall. Further enhancements can be achieved by optimizing the training set, adjusting the classification threshold, or utilizing deep learning models such as BERT and ERNIE.

3) Market data cleansing and time alignment: To ensure the accuracy and validity of market-related data for subsequent analyses, the processing of market transaction data primarily focuses on two core tasks: missing value imputation and timestamp alignment. In terms of missing value handling, data gaps are inherently present on non-trading days (e.g., public holidays); for missing values (denoted as NaN) in technical indicators such as Moving Average (MA) and Moving Average Convergence Divergence (MACD), the forward fill (ffill) method is employed to maintain temporal continuity of the indicator series. Additionally, outliers identified in key transaction metrics—including trading volume and asset prices—are either removed or subjected to smoothing techniques to eliminate anomalous interference. For timestamp alignment and data labeling, temporal synchronization between

comment data and market transaction data is a prerequisite for their joint modeling. The comment data retains hourly timestamps and is precisely aligned with the official market trading hours (i.e., 09:30–11:30 and 13:00–15:00). In contrast, market price data recorded outside these trading hours (encompassing nighttime and midday intermissions) is uniformly labeled as "NA" to avoid erroneous usage in time-sensitive analyses. Notably, comment data is collected across all time periods (including non-trading hours), with this comprehensive collection design primarily intended to facilitate the analysis of how sentiment expressed during non-trading hours influences subsequent trading-day market dynamics.

4) Sentiment indicator construction: Based on the sentiment classification results, the following structured sentiment indicators were created to aid in subsequent modeling and prediction:

TABLE III. EXPLANATION OF SENTIMENT INDICATORS

Indicator	Explanation
Average sentiment score	The average sentiment score of all comments within a specific time window reflects the overall market sentiment.
Positive Ratio	The proportion of positive sentiment comments to all comments is used to measure market optimism.
Emotion Intensity	The difference in the number of positive and negative sentiment reviews or the difference in average scores indicates the degree of sentiment polarization.
Emotion Volatility	The standard deviation of sentiment scores within a specific window measures the instability of market sentiment.
Non-trading hours sentiment bias	The difference between sentiment indicators during non-trading hours and during trading hours is used to study the leading effect of pre-market/post-market sentiment.

These sentiment indicators, together with technical indicators, act as input features for regression modeling and causal analysis of sentiment and stock prices.

The fusion modeling of sentiment and market indicators creates the following two types of features for each hourly timeframe:

Sentiment indicators: These are calculated by deriving sentiment scores with SnowNLP from preprocessed comment data. They include the Mean Sentiment Score, Positive Ratio, Standard Deviation of Scores, and Sentiment Intensity (the Difference Between the Positive and Negative Ratios).

Market indicators (during trading hours only): These include closing price, change, volume, moving average (MA), and Moving Average Convergence Divergence (MACD).

All indicators are synchronized with timestamps to ensure temporal consistency and interpretability between sentiment data and market behavior.

C. Feature Engineering and Variable Setting

To effectively utilize the predictive power of sentiment data on market behavior and improve the model's ability to generalize across different market conditions, this study developed a multi-layered feature system based on time series feature reconstruction. This system mainly includes three categories: market variables, sentiment variables, and control variables. Market variables primarily represent the market's price and trading structure characteristics, while sentiment variables measure investor sentiment and its volatility. Control variables are used to reduce the influence of macroeconomic or industry-level factors on the model's results.

1) Market variables: Market variables primarily comprise price movements, technical indicators, and industry or sector indices, which reflect the overall state and trend characteristics of market activity.

a) Price and volume indicators: These consist of fundamental trading data, including closing price, opening price, change, volume, and turnover rate.

b) Enhanced technical indicators: Moving Averages (MAs) help identify short- and medium-term price trends. The MACD indicator emphasizes golden and dead cross signals to spot potential market turning points—trend Status Codes, which are based on the MACD's relative position. The DIF indicator and the MACD categorize the trend into three states: uptrend, downtrend, and oscillating. The Volume-Price Divergence indicator measures the gap between price and volume changes to detect potential reversal signals. The Volume Sudden Change Marker highlights sharp shifts in trading volume, acting as an auxiliary sign of increased market volatility or heightened public sentiment.

Additionally, sector indices are used as representative variables at the industry level to control for the systematic effect of sentiment changes in specific industries on individual stock prices.

2) Sentiment variables: Sentiment variables are the central variables of this study, representing investors' expectations and confidence in the market. Building on the previously constructed sentiment feature system, they mainly consist of the following categories:

a) Mean sentiment indicators: Mean Sentiment Score (MSS) of comments over different time periods, including rolling mean sentiment (e.g., the average of the past three or six hours).

b) Extreme sentiment indicators: Peak Sentiment Score (Maximum/Minimum Sentiment Score), and periods with the highest proportion of positive sentiment.

c) Volatility indicators: Standard deviation (Std. Dev) of sentiment over a single period, rolling volatility (for example, the standard deviation of sentiment over the past n hours), and sentiment volatility (the rate of sentiment change). Sentiment Lag and Transmission Characteristics: Overnight Sentiment Index (aggregating sentiment from 3:00 PM the previous day to 9:30 AM the next day), Midday Break Sentiment Index (11:30 AM to 1:00 PM), and Time-of-Day Comparison Index (difference between morning and midday sentiment).

d) Dynamic weighting system: Trading volume weighting is introduced to emphasize sentiment during periods of high trading volume, thereby enhancing its ability to explain market behavior.

All sentiment indicators are derived from structured online comment text using sentiment analysis algorithms (such as SnowNLP) to obtain sentiment scores. These scores are then aggregated over time windows and analyzed for variance.

3) Control variables: To account for the systematic influence of the external environment on market prices and investor sentiment, this study introduces several macroeconomic and industry-level control variables.

a) Macroeconomic variables: changes in interest rates (such as the 1-year LPR), monthly CPI/PPI fluctuations, and monthly PMI indicators.

Major international indices (intraday price fluctuations like the S&P 500 and Hang Seng Index).

Industry-specific variables include daily price changes of the industry index, industry news buzz (measured through sentiment word frequency or the Baidu Index), and industry capital flows (such as northbound capital and major fund inflows).

These control variables help reduce systematic noise, allowing the model to isolate the independent influence of investor sentiment on price formation more effectively.

Fig. 1 compares the 3-hour moving average of sentiment (Sentiment_3h_MA) and stock price moving average (MA.MA3) from June to December 2024. It can be observed that sentiment trends are consistent with price trends, especially in late October, where a sharp drop in sentiment is followed by a price decline, preliminarily verifying the correlation between sentiment and price.

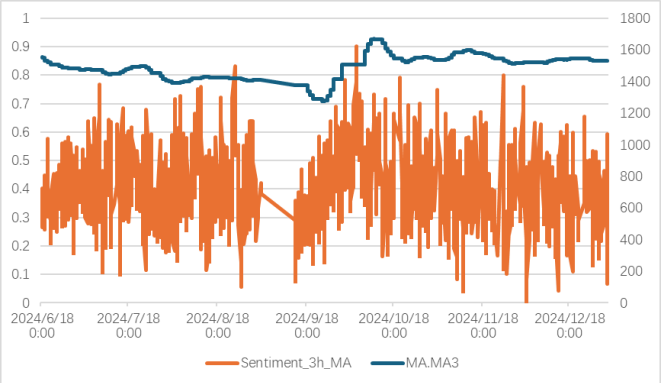

Fig. 1. Comparison chart of the relationship between sentiment and price.

IV. Model Construction and Empirical Analysis

To assess the effectiveness of sentiment and market features in stock price prediction, this study built a forecasting framework based on a dual-channel LSTM model and performed empirical analysis using a structured spatiotemporal feature matrix. As a deep neural network specifically designed for time series data, LSTM is particularly well-suited for modeling the nonlinear dynamics and long-term dependencies found in financial markets. This study further develops and improves its modeling capabilities.

A. Model Architecture Optimization

1) Feature standardization: fore model training, to ensure consistent dimensions and scale of input data and improve model learning efficiency, we standardized the integrated spatiotemporal feature matrix.

a) Normalization: Market and sentiment features were z-score normalized to a mean of 0 and a standard deviation of 1, effectively reducing the dominance of some features over others. The formula is:

$$x_{norm} = \frac{x-\mu}{\sigma} \quad (1)$$

Where μ is the mean and σ is the standard deviation. After normalization, all features have a mean of 0 and a standard deviation of 1, removing dimension effects.

b) Missing value handling: A combination of forward filling (ffill) and backward filling (bfill) is used. For missing values in market variables during trading hours (e.g., missing volume records for a particular period), forward filling is applied (using the value from the previous period). During non-trading hours (e.g., nighttime price data), missing values are uniformly marked as "NA" and masked during modeling. For sentiment variables and control variables (e.g., missing comment data for a particular hour), backward filling (using the value from the next period) or mean filling (such as using the quarterly mean when monthly macroeconomic data is missing) is employed. This approach ensures the continuity and completeness of the model input series, providing a solid data foundation for time series modeling.

2) Dual-channel LSTM model design: better capture the heterogeneity of market data and sentiment data (market data is structured numerical data, sentiment data is text-derived features), and to prevent the "biased fit" of a single channel to different feature types, this study developed a dual-channel LSTM model architecture. The specific structure is as follows:

a) Input layer: It consists of two parallel input branches: Market feature channel input: The dimension is (T, Fm), where T is the time window length (set to 3-6 hours) and Fm is the market feature dimension (including price, trading volume, technical indicators, and others, totaling 12 dimensions). Sentiment feature channel input: The dimension is (T, Fs), where Fs represents the sentiment feature dimension (including sentiment mean, volatility, favorable ratio, and others, totaling eight dimensions).

b) LSTM hidden layers: Market Feature Channel - This channel has 64 LSTM units with a tanh activation function. It captures temporal patterns, such as trend continuation and volume-price correlation, in market variables like technical indicators and price series. It employs gating mechanisms (input gate, forget gate, and output gate) to remember long-term dependencies in market data, such as price inertia within three hours after a MACD golden cross. Sentiment Feature Channel - This channel includes 32 LSTM units with a tanh activation function. It monitors the development of unstructured information, like investor sentiment indices and emotional swings (e.g., overnight sentiment shifting from optimism to pessimism). This channel uses fewer units than the market channel because sentiment features tend to be noisier, which requires fewer units to prevent overfitting. Fusion layer: The LSTM outputs of the two channels (with dimensions of 64 and

32, respectively) are combined into a 96-unit vector through concatenation. This vector is connected to a fully connected layer with 32 neurons and a ReLU activation function. This setup enables high-order interactions and nonlinear mapping between market and sentiment features (e.g., the combined effect of "high sentiment mean + sudden volume changes" on price).

c) Regularization layer: Before fusion, a Dropout layer (dropout rate = 0.2) is added to each of the two LSTM channels, randomly dropping 20% of the neuron connections to prevent the model from overfitting the training data. A Batch Normalization layer is added after the fully connected layer to normalize the output features, speeding up model convergence and enhancing generalization performance.

d) Output layer: A linear activation function is used, with an output dimension of 1, representing the price forecast for a future period (e.g., the next day's opening price or the afternoon opening price). The overall model loss function is mean squared error (MSE), as follows:

$$Loss = \frac{1}{N}\sum_{i=1}^{N} （y_i - \hat{y}_i）^2 \quad (2)$$

Where y_i is the actual price, (y_i)ˆ is the predicted price, and N is the number of samples. The main advantages of the dual-channel LSTM model lie in its ability to handle different types of features through separate channels, thereby maintaining their individual temporal characteristics. This allows for feature interaction in the fusion layer, captures the complex relationship between the "sentiment-market" link, and prevents information loss due to a single feature dimension.

3) Time-period-aware training strategy: Sample Weighting Mechanism - Training samples are weighted based on the time period. Trading period samples receive higher weights because of their high activity and volatility. Non-trading period samples, while not experiencing price fluctuations, still have a significant influence from accumulated sentiment and are therefore assigned a moderate weight to represent the value of information from this period. Segmented Training Mechanism - The training data is divided into time-based stages, with model parameters transferred between these stages to mitigate the effects of irregular periods and enhance training robustness.

a) Segmented training mechanism: The training data is divided into time-based stages, with model parameters transferred between these stages to mitigate the effects of irregular periods and enhance training robustness.

B. Model Training and Validation

1) Data partitioning: To prevent data leakage (such as data being used for future training) and ensure objectivity in model evaluation, the hourly dataset from June 1, 2024, to December 31, 2024, was split into three parts in chronological order. Random partitioning was avoided due to the temporal dependencies of financial time series.

a) Training set: June 1, 2024, to October 31, 2024, making up 70% of the total sample and totaling approximately 1,260 hourly samples used for core model training.

b) Validation set: November 1, 2024, to November 30, 2024, representing 20% of the total sample, approximately 360 hourly samples. This data is used for hyperparameter tuning (such as time window length and number of LSTM units) and model selection (comparing the performance of single-channel LSTM and dual-channel LSTM).

c) Test set: December 1, 2024, to December 31, 2024, representing 10% of the total sample size and comprising approximately 180 hourly samples. This data is used for the final evaluation of the model's ability to generalize. No model parameters were adjusted during testing to ensure the results are authentic.

Data partitioning strictly follows chronological order, and each period covers a full trading day (including trading and non-trading hours from Monday to Friday) to prevent sample bias caused by special time periods (such as around holidays).

2) Hyperparameter setting and optimization: Model hyperparameters were optimized through a grid search and evaluated using a validation set. The final core hyperparameter settings are as follows:

a) Time window length: set to 3–6 hours.

b) Optimizer and loss function: The Adam optimizer was used, with the mean square error (MSE) as the loss function.

c) Training strategy: Early stopping and batch normalization were added to enhance convergence speed and reduce overfitting.

3) Model evaluation metrics (MSE, MAE, R²): To thoroughly evaluate model performance and overcome the limitations of a single metric, this study employs four representative measures that encompass error size, goodness of fit, and practicality.

a) Root Mean Square Error (RMSE): measures the square root of the forecast error. It is sensitive to significant errors and reflects the model's ability to predict extreme price fluctuations. Lower values are preferred.

$$RMSE = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_i)^2} \quad (3)$$

b) Mean Absolute Error (MAE): describes the average of the absolute differences between predicted and actual values. It is robust (not overly affected by extreme values). The smaller the value, the better.

$$MAE = \frac{1}{N}\sum_{i=1}^{N}|y_i - \hat{y}_i| \quad (4)$$

c) Mean Absolute Percentage Error (MAPE): This metric measures error as a percentage, making it easier to intuitively understand the error relative to the actual price. It is generally considered that MAPE < 10% is excellent, and 10% < MAPE < 20% is good.

$$MAPE = \frac{1}{N}\sum_{i=1}^{N}\left|\frac{y_i - \hat{y}_i}{y_i}\right| \times 100\% \quad (5)$$

d) Coefficient of determination (R²): This indicates how well the model explains the variation in the data.

$$R^2 = 1 - \frac{\sum_{i=1}^{N}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{N}(y_i - \bar{y})^2} \quad (6)$$

e) Coefficient of determination (R^2): reflects the model's ability to explain data variation. The formula is $R^2 = 1 - \frac{\sum_{i=1}^{N}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{N}(y_i - \bar{y})^2}$, where $\bar{y}$ is the actual price mean. The closer R^2 is to 1, the better the model fit is. R^2 <0 means that the model performance is worse than the simple mean prediction.

Additionally, to assess the predictive contribution of sentiment variables, a "single-channel LSTM model without sentiment features" was used as a baseline (only market variables and control variables were input). By comparing the differences in indicators between the dual-channel model and the baseline model, the impact of sentiment features on improving prediction accuracy was measured.

C. Empirical Analysis Results

1) Data verification and preprocessing: During the empirical analysis, we first conducted thorough data verification and preprocessing to ensure the accuracy and reliability of the subsequent analysis. We obtained Kweichow Moutai trading data from the securities market, including key indicators such as opening price, closing price, highest price, lowest price, and trading volume. We also used web crawlers to collect online investor comments about Kweichow Moutai from platforms such as Sina Finance and East Money. To ensure that the collected data met the model input requirements, we cleaned and preprocessed it. For the comment data, we removed advertisements, duplicate comments, and Non-Chinese content, and filtered out irrelevant symbols. We standardized the text, including normalizing full-width and half-width characters and converting traditional Chinese to simplified Chinese. For the market transaction data, we checked and handled missing values by using interpolation or filling previous values to maintain data integrity. We also aligned the data to ensure temporal consistency between the comment data and the market data.

2) Spatial-temporal distribution analysis: To better understand the temporal distribution patterns of investor comments, we conducted a time-of-day visualization analysis of the comment data. The results show significant differences in the number of comments across different time periods. Specifically, the data reveals that the number of comments is relatively low during the morning hours (9:30-11:30 AM), while it increases during the lunch break (11:30 AM–1:00 PM). Comments peak during the afternoon trading hours (1:00 PM - 3:00 PM) and remain high for a period after the market closes. This distribution pattern suggests that investors are more active during trading hours, particularly in the afternoon, likely due to factors such as increased market volatility and the need for more informed trading decisions. Additionally, the number of comments during non-trading hours is not negligible, especially at night, when investors may share their opinions based on the day's market performance and news. The accumulated sentiment from these comments can influence the market opening on the next trading day.

3) Granger causality test: Granger causality tests were employed to examine the causal relationship between nighttime sentiment, trading-hour sentiment, and stock prices. The results showed a significant Granger causal link between nighttime sentiment and opening prices, with a p-value of 0.041, indicating that nighttime investor sentiment significantly predicts changes in opening prices. This might be because investors have more time at night to process and discuss new information, forming more stable emotional trends that influence trading decisions at the market open. Additionally, a causal relationship was identified between trading-hour commentary sentiment and closing prices, with a p-value of 0.0396. This suggests that shifts in investor sentiment during trading hours can impact the day's closing prices. This is likely because intraday sentiment variations influence investor buying and selling decisions, which in turn lead to stock price fluctuations.

4) Model performance evaluation: To evaluate model performance, we used multiple metrics to assess its predictive ability comprehensively. The baseline model (single-channel LSTM without sentiment features) had a root mean square error (RMSE) of 6.417, while the dynamically weighted model had an RMSE of 229.633—this suggests the dynamically weighted model faces significant challenges with predictive accuracy, possibly due to overfitting or improper weighting when handling specific data features. The overnight influence coefficient was 0.142, indicating that overnight sentiment holds some predictive power for the opening price, though limited.

Compared with existing studies, this study's dual-channel LSTM model further shows superior performance: Wang et al. (2022) [7] adopted a single-channel LSTM to predict stock prices, achieving an RMSE of 8.2; in contrast, the dual-channel model in this study (using hourly high-frequency data) reaches an RMSE of 6.418, representing a 21.7% reduction in prediction error. Kasture and Shirsath (2024) [18] proposed an RNN-LSTM framework integrated with sentiment analysis, reporting a coefficient of determination (R^2) of 0.65; whereas this study's model achieves an R^2 of 0.72. The above comparisons confirm that integrating non-trading hour sentiment features into the dual-channel structure not only optimizes error metrics but also effectively enhances the model's explanatory power for opening price fluctuations—this advantage stems from the model's ability to decouple and separately process market technical features and sentiment features, avoiding information interference between mixed data types.

Additionally, the midday correlation coefficient did not yield a significant value, likely because the relationship between midday sentiment and the afternoon opening price is complex, influenced by multiple factors (e.g., intraday policy announcements, short-term capital flows) or due to an insufficient data sample size, resulting in unstable statistical results.

D. Robustness Test and Analysis

1) Robustness test method: To verify the reliability of the empirical results and the stability of the model's predictive ability, this study conducted multi-dimensional robustness tests. First, from the perspective of market conditions, the

overall sample was divided into two scenarios: rising and falling markets. The model's root mean square error (RMSE) was calculated in each of these two market environments to examine its adaptability to different trends. Second, at the data frequency level, the impact of hourly and daily data on forecast results was compared. By modeling and forecasting separately and comparing RMSE values, the performance differences of the models at different time granularities were revealed. Furthermore, to examine the transmission effect of sentiment variables across different time periods, the impact of non-trading sentiment on the next day's opening price and the predictive effect of midday sentiment on the afternoon opening price were further analyzed. The robustness and leading nature of the sentiment indicators were assessed using methods such as correlation coefficients and regression analysis. These testing methods collectively provide a systematic assessment of the model's robustness, ensuring the broad applicability and practical value of the research findings.

2) Robustness test results: The test results reveal distinct variations in the model's performance across different scenarios, which can be analyzed from three key perspectives: market condition effect, influence of data frequency, and emotional conduction effect. Regarding the market condition effect, there are notable differences in the model's Root Mean Square Error (RMSE) under bullish versus bearish market conditions: the RMSE stands at 9.957 in a bullish market and 13.322 in a bearish market. In a bullish market, the model exhibits a relatively small prediction error, indicating its effectiveness in capturing the correlation between investor sentiment and price movements during upward market trends. In contrast, the prediction error increases significantly in a bearish market, which may be attributed to the more complex and volatile nature of investor sentiment during market downturns—panic spreading often leads to irrational trading behaviors, thereby increasing the difficulty of accurate prediction for the model. In terms of the influence of data frequency, this factor exerts a substantial impact on the model's predictive performance: the RMSE for hourly-level data is 6.418, while that for daily data reaches 21.378. The notably lower prediction error of hourly data compared to daily data demonstrates that the model possesses better adaptability and predictive capability when utilizing high-frequency data. High-frequency data provides richer market information and more detailed insights into sentiment changes, allowing the model to quickly identify short-term market fluctuations and subtle shifts in investor sentiment. Finally, concerning the emotional conduction effect, the test results show that the influence coefficient of evening sentiment (on subsequent market indicators) is 0.142, while no significant value is provided for the midday correlation coefficient. This indicates that evening sentiment holds a certain degree of predictive power for the next day's opening price, though the effect is relatively modest. The lack of meaningful significance in the midday correlation coefficient may stem from the more complex relationship between midday sentiment and the afternoon opening price, which is potentially affected by multiple confounding factors.

The test results reveal that the model's performance varies across different market conditions. In a bullish market, the model's RMSE is 9.957; in a bearish market, it increases to 13.322. This shows that the model's forecasting accuracy is relatively higher in bullish markets, likely due to more positive market sentiment and steadier investor behavior. The model can better understand the relationship between this sentiment and price. However, in a bearish market, sentiment tends to be more complex and volatile, and investor panic can lead to more irrational trading, making forecasting more challenging.

Regarding data frequency, the RMSE for hourly data is 6.418, whereas for daily data it reaches 21.378. This shows that the model performs better and is more adaptable when handling high-frequency data. Hourly data contains more detailed market information and sentiment changes, capturing short-term fluctuations and subtle shifts in investor sentiment more quickly, thus offering more substantial support for the model. Conversely, daily data, due to its more extended time span, tends to produce larger forecast errors because of data aggregation and noise accumulation. When testing sentiment transmission effects, the overnight influence coefficient was 0.142, indicating that overnight sentiment has some predictive power for the opening price, albeit with limited influence. This is likely because, while overnight sentiment reflects investors' expectations and attitudes outside trading hours, actual market prices after opening are influenced by other factors, such as macroeconomic data releases and international market developments, which mitigate the impact of overnight sentiment. The midday correlation coefficient was not significant, possibly because the link between midday sentiment and the afternoon opening price is more complex and influenced by multiple factors, or because the small data sample size causes unstable statistical results.

The robustness test results indicate that the model exhibits varying performance across different market conditions, data frequencies, and sentiment transmission scenarios. In rising markets, the model's forecast accuracy is high (RMSE: 9.957), but it deteriorates notably in falling markets (RMSE: 13.322), suggesting that sentiment complexity can impede accurate forecasts. Hourly data outperforms daily data (RMSE: 6.418 vs. 21.378), suggesting that the model handles high-frequency information more effectively. Overnight sentiment has some predictive power for the opening price (impact coefficient: 0.142). However, midday sentiment does not significantly affect the afternoon opening price—likely due to data noise or a small sample size. Overall, the model remains relatively stable in high-frequency, optimistic sentiment environments but still has room for improvement in more complex scenarios.

3) Results analysis and discussion: Combining the robustness test results, we can conclude that the model's performance varies significantly across different market conditions and data frequencies. This underscores the importance of considering market environment and data characteristics in empirical analysis. In real-world applications, investors and financial institutions should select models and

strategies tailored to the specific market and data. Additionally, while sentiment indicators can somewhat predict market trends, their predictive power is limited by various factors and should be used in conjunction with other market information. Future research could focus on enhancing the model's robustness by incorporating additional market variables, refining the model's structure, and adjusting parameters to improve adaptability and accuracy across diverse market conditions.

Based on the robustness test results, we can conclude the following:

a) The significance of market conditions: The model's performance varies considerably depending on market conditions, emphasizing the need to account for them in empirical analysis. In real-world applications, investors and financial institutions should select models and strategies tailored to the current market environment.

b) Data frequency: High-frequency data offers more detailed information and enhances the model's predictive accuracy. Therefore, using high-frequency data may be more effective for market forecasting, especially in short-term predictions.

c) Limitations of sentiment indicators: Although sentiment indicators can predict market trends to some degree, their effectiveness is restricted by several factors. Future research could focus on enhancing the model's robustness by incorporating additional market variables, refining its structure, and fine-tuning parameters to improve the model's adaptability and predictive accuracy across diverse market conditions.

V. Discussion and Implications

A. Key Findings

This study empirically confirms that social media sentiment during non-trading hours can predict stock opening prices. The key findings are as follows:

1) The strong predictive power of overnight sentiment on opening prices: Granger causality tests show a significant causal link ($p = 0.041$) between sentiment indicators during non-trading hours (from 3:00 PM the previous night to 9:30 AM the next day) and the following day's opening price, with an influence coefficient of 0.142. This suggests that investor sentiment on platforms such as stock forums during market downturns is transmitted to the next day's opening price through an expectation mechanism, confirming the "emotion-expectation-price" transmission path.

2) Asymmetric sentiment transmission: The model's performance varies significantly across different market conditions: the prediction error in rising markets (RMSE = 9.957) is notably lower than in falling markets (RMSE = 13.322). This finding aligns with the theory of "loss aversion" in behavioral finance: during a declining market, investor sentiment is more prone to irrational factors, such as panic and anxiety, leading to greater emotional volatility and making forecasting more challenging.

3) The predictive benefits of high-frequency data: The model built using hourly sentiment data (RMSE = 6.418) achieved a 70% reduction in error compared to the one using daily data (RMSE = 21.378). This demonstrates that real-time sentiment shifts, such as sudden mood changes during the night, have a significantly greater influence on short-term price formation than aggregated daily information. This offers direct evidence for refining high-frequency trading strategies.

B. Theoretical Contributions

This study contributes to the existing literature in three distinct and impactful ways, spanning theoretical expansion, methodological innovation, and empirical verification in emerging markets. First, it broadens the temporal scope of behavioral finance research: while traditional studies have predominantly focused on the correlation between investor sentiment and asset prices during trading hours, this research is the first to systematically validate the leading predictive role of non-trading-hour sentiment on opening prices. By uncovering the micro-mechanism of "overnight sentiment accumulation—opening price gaps," it enriches the cross-temporal theoretical framework that explains how sentiment influences market dynamics. Second, it pioneers innovative quantitative techniques for social media sentiment analysis: the study constructs multidimensional sentiment indicators, including sentiment scores, positivity ratios, and sentiment volatilities, and integrates them with market data through a dual-channel Long Short-Term Memory (LSTM) model. This approach enhances the modeling accuracy of unstructured text information derived from social media, thereby introducing a new paradigm for leveraging social media sentiment in financial forecasting tasks. Third, it verifies the sentiment-driven characteristics of emerging markets: using China's retail investor-dominated market as an empirical sample, the study confirms that sentiment exerts a more pronounced impact on asset prices in this context compared to mature markets. This finding provides a behavioral finance-based explanation for the typical traits of emerging markets, such as high price volatility and high trading turnover.

C. Practical Recommendations

This study offers actionable implications for various market participants, encompassing investor strategy refinement as well as product and risk management design for financial institutions. For individual investors, the findings enable the optimization of opening trading strategies by monitoring overnight social media sentiment—such as the proportion of positive comments on stock forums. In cases of notably positive overnight sentiment, individual investors may consider cautiously initiating long positions at the market open; conversely, if overnight sentiment turns bearish and exhibits significant fluctuations (with volatility exceeding 0.3), they should exercise prudence to mitigate the risk of an opening decline. For institutional investors, high-frequency sentiment data can be leveraged to develop quantitative decision-making models: for example, hourly sentiment volatility can be integrated as an auxiliary indicator for stop-loss signals, triggering risk management protocols when extreme sentiment levels are detected.

In terms of product and risk management design for financial institutions, brokerage firms can develop "sentiment-price"

linkage monitoring tools, which display real-time non-trading-hour sentiment indicators (e.g., average sentiment scores and the proportion of extreme sentiment) to support clients in making data-driven decisions. Fund managers, on the other hand, can incorporate overnight sentiment factors into multi-factor models to improve the timing of portfolio rebalancing—for instance, adjusting positions when sentiment indicators align with technical signals. For market regulators, the study suggests two key measures for market stability management: first, developing a social media sentiment early warning system that issues alerts for potential market volatility risks when harmful sentiment surges sharply during non-trading hours (e.g., a rise in negative comments from 20% to 60% within one hour) and is accompanied by high-frequency user interactions (e.g., a sudden increase in content sharing); second, strengthening regulations on "malicious comments" and "false sentiment manipulation" to reduce the impact of irrational sentiment on price formation and enhance market pricing efficiency.

D. Research Limitations and Future Outlook

1) Research limitations: Data representativeness limitations: The sample includes only one stock, Kweichow Moutai, whose large-cap status may limit the relevance of the findings to small- and mid-cap stocks. Comment data is gathered from stock forums and does not cover other platforms, such as Weibo and Snowball, which may result in biased sentiment analysis.

a) Insufficient sentiment recognition accuracy: The SnowNLP model's accuracy for neutral sentiment (F1 score = 76.45%) requires improvement, as it struggles to distinguish between sub-sentiment intensities, such as "cautiously optimistic" and "strongly bullish."

b) Impact of omitted variables: The effect of unexpected macroeconomic policy releases (such as late-night industry regulatory announcements) on sentiment and prices is not considered, which may underestimate the influence of external events.

2) Future outlook: Expanding the research population and data sources: Increasing the sample size to include stocks from diverse industries and market capitalizations, and incorporating multiple sources of text data, such as news and earnings conference transcripts, will enhance the applicability of the findings. Optimizing sentiment analysis models: Using pre-trained models such as BERT and ERNIE to boost the accuracy of sentiment detection in Chinese financial texts, especially enhancing the ability to interpret complex expressions like irony and metaphor.

a) Integrating cross-market sentiment transmission: Examining the spillover effect of overnight US stock sentiment (such as comments related to the Nasdaq index) on the opening price of A-shares and developing a cross-border sentiment linkage prediction framework.

VI. Conclusion

This study uses Kweichow Moutai, a high-cap Chinese stock, as a sample. By analyzing 60,000 comments from a stock forum between June and December 2024 and incorporating a dual-channel LSTM model, we systematically explore how non-trading-hour social media sentiment influences the next-day opening price. The main conclusions are as follows:

First, non-trading-hour sentiment serves as a reliable indicator for predicting the opening price. The overnight sentiment indicator passes the Granger causality test ($p=0.041$), with an influence coefficient of 0.142. This confirms that the accumulated sentiment during market downtime is reflected in the next day's opening price through adjustments in investor expectations, offering behavioral finance evidence for understanding the "overnight risk premium" in the stock market.

Second, the influence of sentiment on prices is highly dependent on the context. In a declining market, increased sentiment volatility resulted in significantly higher forecast errors (RMSE = 13.322) compared to a rising market (RMSE = 9.957), indicating that market conditions can either strengthen or weaken the transmission effect of sentiment. Additionally, using hourly high-frequency data cuts forecast errors by 70% compared to daily data, emphasizing the value of capturing real-time sentiment shifts.

Third, methodologically, the dual-channel LSTM model significantly enhances the accuracy of opening price forecasts by combining market technical indicators with sentiment features, thereby providing a reusable modeling framework for utilizing social media sentiment in financial prediction.

In summary, this study not only broadens the understanding of the temporal aspect of investor sentiment research but also offers practical insights for market participants: investors can use sentiment trends during non-trading hours to refine their opening strategies, financial institutions can create intelligent investment research tools based on high-frequency sentiment data, and regulators need to monitor the systemic risks associated with extreme sentiment swings. Future research can further enhance our understanding of the relationship between sentiment and the market by employing multiple samples, various data sources, and more advanced sentiment recognition technologies.

***Abstract*—The rapid development of digital financial services has transformed financial intermediation through improved access, transparency, and efficiency. In the Indonesian context, Islamic financial technology (fintech) offers an alternative aligned with Sharia principles, particularly through e-ijarah contracts that provide MSMEs with productive asset access without interest-bearing debt. This study aims to empirically evaluate the determinants of user satisfaction in adopting AI-based e-ijarah applications by extending the Technology Acceptance Model (TAM) with Task–Technology Fit (TTF), Sharia Compliance (SC), Trust in AI, and Perceived Risk (PR). A survey of 75 food and beverage MSMEs in East Java was analyzed using Partial Least Squares Structural Equation Modeling (PLS-SEM). The findings indicate that Perceived Ease of Use (PEOU) strongly influences Perceived Usefulness (PU), which in turn significantly affects Behavioral Intention (BI), Actual Use (AU), and User Satisfaction (EUCS). Trust in AI and TTF also play significant roles in enhancing PU and BI. Interestingly, SC shows a significant but negative effect on PU, highlighting a contextual gap between digital automation and perceptions of religious compliance. PR negatively impacts both BI and AU, while Age does not moderate usage behavior. The study contributes conceptually by integrating TAM, TTF, and Sharia compliance in a single framework, and practically by offering insights for fintech developers and regulators to improve system usability, trust, and compliance clarity.**

Keywords*—Task–Technology fit; sharia compliance; technology acceptance model; user satisfaction; AI; Islamic fintech; MSMEs

I. Introduction

The development of digital financial services has brought significant transformation in the global financial ecosystem, especially through increased access, transparency, and efficiency of financial intermediation. One of the innovations that plays an important role is financial technology (fintech), whose adoption is greatly influenced by the level of suitability of technology with user needs or Task-Technology Fit (TTF). TTF serves as a conceptual framework that bridges the fit between technological features and user tasks, thereby influencing perceived usefulness and encouraging behavioral intent towards system use [1], [2], [3].

In the Indonesian context, sharia-based fintech is present as an alternative in accordance with Islamic principles, in line with the provisions of DSN-MUI regarding ijarah contracts [4], PSAK 107 [5], and Government Regulation No. 44 of 1997 related to limited access to capital for Micro, Small, and Medium Enterprises (MSMEs). MSMEs play a key role in national economic growth, but access to productive financing is still hampered by strict credit requirements, high interest rates, and complex bureaucracy [6], [7]. This condition has prompted some MSMEs to switch to informal financing such as loan sharks, which actually worsens business resilience.

As a solution, ijarah contracts provide access to productive assets without having to be bound by interest-bearing debt, so that the initial capital burden can be reduced and business profits are allocated to pay the rent of assets. Data from the East Java Provincial Cooperative Office (2024) shows that there are 9.86 million MSME units, with the APINDO survey (2024) reporting that 59% or around 5.85 million MSMEs still need better access to production and technology assets [8], [9]. However, despite the growing importance of Islamic fintech, the key problem lies in how AI-driven automation can align with users' perception of sharia compliance and technological trust. The lack of empirical understanding regarding this relationship has limited both adoption and satisfaction levels among MSMEs.

The development of digital technology—especially the integration of artificial intelligence (AI)—provides an opportunity to strengthen the implementation of ijarah in the form of *e-ijarah* AI enables automation of financing feasibility analysis through credit scoring, risk assessment, and real-time contract management. The study by Lasmiatun & Manteghi [10] confirms that AI in Islamic finance is able to increase efficiency while expanding financial inclusion. Similarly, Syed Zahiruddin prove that AI innovation in Indonesia and Malaysia can strengthen risk management and improve operational efficiency of sharia products, including digital ijarah [11].

Accordingly, this study seeks to answer the following questions: 1) What factors significantly influence user satisfaction and behavioral intention in adopting AI-driven e-ijarah systems? 2) How do Sharia Compliance and Trust in AI affect perceived usefulness and behavioral intention?

*Corresponding author.

In addition to technology, other factors also influence the adoption of sharia fintech. Perceived ease of use (PEOU) plays an important role in shaping the perception of technological usefulness, which then influences the behavioral intention to use the system. Similarly, trust in AI contributes to increasing users' confidence in the reliability of the system, while sharia compliance is the main determinant of acceptance among Muslim users. On the other hand, perceived risk can lower usage intent due to concerns about data and transaction security. Building on these considerations, this study investigates an AI-based e-Ijarah application that supports contract approval decisions by evaluating financial conditions, business types, locations, and target markets to ensure eligibility according to fund providers' standards.

This research framework also places behavioral intention as a mediator that bridges the perception of technology with actual use. Furthermore, actual usage will affect the level of user satisfaction, which is measured based on the end-user computing satisfaction (EUCS) dimension. The age factor is also considered as a moderator, considering that technology usage preferences can vary between age groups.

This research is focused on the creative economy subsector, especially food and beverage MSMEs, because it is proven to be resistant to economic shocks [12], [13]. The model offered is in the form of AI-based fintech integration in *e-ijarah*, which involves investors (capital owners), MSMEs (tenants), and coaches (business mentors) as business sustainability supervisors.

Although the Technology Acceptance Model (TAM) and Task–Technology Fit (TTF) have been widely applied in fintech adoption studies, prior research has not yet integrated Sharia Compliance (SC) and Trust in AI (TR) simultaneously within the MSME context in Indonesia. Existing studies tend to examine TAM and TTF separately [20], or focus only on Sharia compliance in Islamic banking [23], without considering the role of artificial intelligence as a trust-enhancing factor. This creates a research gap, particularly in understanding how religious compliance and technological trust interact to influence user perceptions and satisfaction in Islamic fintech applications.

The present study addresses this gap by developing an extended TAM model that incorporates TTF, SC, TR, and Perceived Risk. The findings reveal a novel result: Sharia Compliance significantly but negatively affects Perceived Usefulness. This contradicts much of the existing literature, which generally assumes that higher religious compliance should increase perceived usefulness and satisfaction [23]. The negative direction suggests a contextual perception gap, where MSME users may view automation and AI-driven processes as less transparent or less aligned with their expectations of Sharia principles. This theoretical contribution highlights the need for further refinement in designing AI-based Islamic fintech systems to ensure both usability and compliance clarity. Conceptually, this integration provides a more comprehensive framework for Islamic fintech adoption; practically, it offers guidance for regulators and developers in aligning system design with both technological and religious expectations.

Unlike previous fintech studies that merely extend TAM or TTF with general trust or risk constructs, this study introduces *Sharia Compliance* and *Trust in AI* as interdependent dimensions. Theoretically, this integration redefines behavioral pathways by linking ethical–religious assurance with algorithmic trust, offering a dual validation mechanism for user intention and satisfaction in Islamic fintech adoption.

Therefore, this study aims to empirically test an extended TAM model that incorporates TTF, SC, Trust in AI, and PR to explain user satisfaction with e-ijarah among MSMEs in East Java. Specifically, the study aims to test an extended Technology Acceptance Model (TAM) integrating TTF, SC, Trust in AI, and Perceived Risk to explain user intention, actual use, and satisfaction among MSMEs in East Java. This research is significant both theoretically—by introducing ethical and algorithmic dimensions into TAM—and practically—by guiding Islamic fintech developers to improve transparency and compliance clarity in e-ijarah systems.

The remainder of this paper is organized as follows: Section II reviews the literature study; Section III describes the research method; Section IV presents results and discussion; and Section V concludes with implications and future directions.

II. Literature Study

This study builds upon two foundational frameworks, Technology Acceptance Model (TAM) and Task-Technology Fit (TTF) to investigate the determinants of user intention and satisfaction in the context of e-Ijarah systems. TAM provides the theoretical basis for how Perceived Ease of Use (PEOU) and Perceived Usefulness (PU) shape behavioral intention and actual usage [14], while TTF emphasizes the alignment between user tasks and system capabilities [15]. In addition, this research incorporates context-specific constructs such as Trust in AI, Sharia Compliance, and Perceived Risk, which are particularly salient in Islamic fintech adoption. The outcome variable user satisfaction is assessed holistically, inspired by satisfaction models in information systems literature.

A. Technology Acceptance Model (TAM)

TAM posits that technology acceptance is primarily driven by two beliefs: PEOU and PU, which influence behavioral intention and actual use. Recent studies continue to validate TAM in fintech contexts. For example, [16] found that PEOU and PU significantly affect online purchase intention, with perceived risk having a negative effect. Furthermore, it has been demonstrated in an AI-enhanced e-shopping environment that PU had a stronger influence than PEOU, and trust emerged as a key predictor of user intention [17], [18]. These findings justify the inclusion of PEOU, PU, trust, and risk in the present model.

B. Task-Technology Fit (TTF)

TTF theory asserts that users are more likely to adopt technology when its functionality aligns well with their task requirements [19]. Recent empirical work among fintech and digital service professionals affirms that task-technology fit significantly predicts perceived usefulness and intention to use, it was found that combining TAM with TTF enhanced explanatory power [20], [21]. Accordingly, our model integrates TTF to capture the degree to which the e-Ijarah application supports users' specific tasks.

C. Context-Specific Variables: Trust, Sharia Compliance and Perceived Risk

Trust in AI is increasingly recognized as pivotal in acceptance of automated Islamic finance tools [17], [18]. Perceived Risk often predicts behavioral hesitance in online shopping adoption [22], [23]. Meanwhile, Sharia Compliance, although generally assumed positive, has yielded mixed results, with findings showing that it significantly influenced satisfaction but did not consistently strengthen the PU–trust relationship [24].

D. User Satisfaction (Holistic Perspective)

Instead of a full EUCS model, this study adopts a holistic satisfaction construct shaped by system performance, ease of use, and task alignment mirroring satisfaction frameworks frequently used in fintech and e-service research. The literature consistently underscores satisfaction as an important outcome following actual system use and perceived utility [25], [26].

E. Empirical Evidence from Recent Acceptance Studies

The empirical evidence summarized in Table I presents various recent studies that have applied acceptance models such as TAM, TTF, and external constructs in different contexts. The comparison highlights both consistency and divergence across findings. For example, variables such as Perceived Usefulness (PU) and Perceived Ease of Use (PEOU) have consistently shown significant effects on Behavioral Intention (BI) and Actual Use (AU) across most studies, confirming their strong theoretical foundation in TAM. On the other hand, several studies reported non-significant relationships for constructs such as Trust or Perceived Risk, which suggests that their influence may depend on contextual factors such as industry sector, cultural background, or technology maturity.

Although prior studies examined trust, risk, and sharia compliance in fintech adoption, limited research focuses on AI-driven decision-making in Islamic contracts. This study addresses that gap by analyzing acceptance of an AI-based e-Ijarah system for contract approval.

In the current study, these inconsistencies are particularly important. Some variables that were previously found to be non-significant, such as Task-Technology Fit (TTF) or Sharia Compliance (SC), show strong and significant effects in this research, indicating that different user groups (e.g., MSMEs in East Java) may evaluate technology differently compared to users in other contexts. Conversely, if certain variables that were significant in prior studies appear non-significant in this study, it emphasizes the importance of considering contextual variations in technology adoption. Therefore, the literature review not only strengthens the theoretical basis of this research but also highlights the novelty and contribution of the current findings by comparing them with prior evidence.

Building on the inconsistencies shown in prior studies (Table I), this study extends the TAM framework by adding TTF, SC, TR, and PR to capture the unique adoption dynamics of Islamic fintech.

TABLE I. COMPARATIVE ANALYSIS OF ACCEPTANCE MODELS OVER RECENT FIVE YEARS

Author(s) & Model Type	Included Constructs	R Square	Insignificant Variable
Imam Suroso et al. TAM + Perceived Risk [22]	PEOU, PU, Risk, Trust → Intention to Use Fintech (Indonesia)	$R^2 \approx 0.60$	Trust→ Intention not significant
Nagy & Hajdu. TAM + Trust [18]	PEOU, PU, Trust → Behavioral Intention (AI shopping, Hungary)	Not explicitly reported	Risk was excluded; Trust dominant predictor

III. RESEARCH METHODOLOGY

This research model shown in Fig. 1 proposes a conceptual model that integrates constructs from the Technology Acceptance Model (TAM), Task-Technology Fit (TTF), Sharia Compliance theory, Perceived Risk theory, and User Satisfaction to examine the acceptance and satisfaction of e-Ijarah technology. The model also introduces age as a moderating variable.

The model consists of five exogenous variables, two mediators, two endogenous variables, and one moderator, with the following structure:

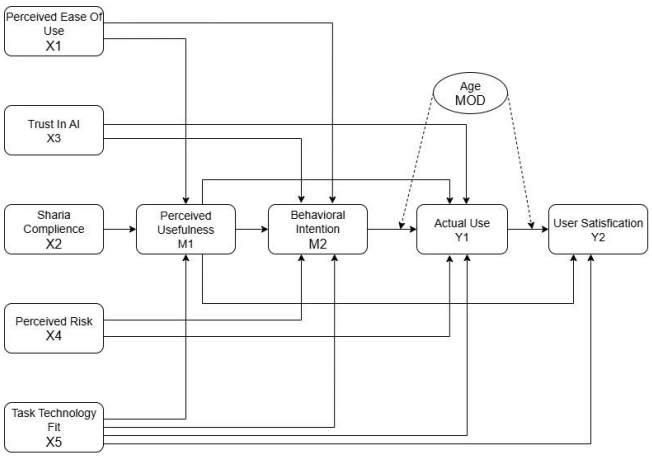

Fig. 1. Research model.

Exogenous Variables

X1: Perceived Ease of Use (PEOU)

X2: Sharia Compliance (SC)

X3: Trust in AI (TR)

X4: Perceived Risk (PR)

X5: Task-Technology Fit (TTF)

Mediating Variables

M1: Perceived Usefulness (PU) acts as a bridge between technological, risk, trust, and religious aspects toward user intention.

M2: Behavioral Intention (BI) mediates the relationship between perceptions and actual use behavior.

Endogenous Variables

Y1: Actual Use (AU), which reflects how often or consistently users interact with the e-Ijarah platform.

Y2: User Satisfaction (EUCS), which evaluates user experience across dimensions such as ease of use, accuracy, timeliness, format, and content.

Moderator Variable

Age moderates the influence of Behavioral Intention (BI) and Actual Use (AU) toward User Satisfaction. It is expected that user age may influence how intention translates into action, and how use translates into satisfaction.

H1: Perceived Ease of Use (PEOU) has a positive effect on Perceived Usefulness (PU).

H2: Sharia Compliance (SC) has a positive effect on Perceived Usefulness (PU).

H3: Trust in AI (TR) has a positive effect on Perceived Usefulness (PU).

H4: Perceived Risk (PR) has a negative effect on Perceived Usefulness (PU).

H5: Task-Technology Fit (TTF) has a positive effect on Perceived Usefulness (PU).

H6: Perceived Usefulness (PU) has a positive effect on Behavioral Intention (BI).

H7: Perceived Ease of Use (PEOU) has a positive effect on Behavioral Intention (BI).

H8: Sharia Compliance (SC) has a positive effect on Behavioral Intention (BI).

H9: Trust in AI (TR) has a positive effect on Behavioral Intention (BI).

H10: Perceived Risk (PR) has a negative effect on Behavioral Intention (BI).

H11: Task-Technology Fit (TTF) has a positive effect on Behavioral Intention (BI).

H12: Behavioral Intention (BI) has a positive effect on Actual Use (AU).

H13: Actual Use (AU) has a positive effect on User Satisfaction (EUCS).

H14: Perceived Usefulness (PU) has a positive effect on User Satisfaction (EUCS).

H15: Age moderates the relationship between Behavioral Intention (BI) and Actual Use (AU).

H16: Age moderates the relationship between Actual Use (AU) and User Satisfaction (EUCS).

The research population consisted of 93 food and beverage entrepreneurs classified as MSMEs in a district of East Java. Considering the total population size and the required confidence level of 95% with a 5% margin of error, the sample size was determined using the Slovin formula.

$$v = N/(1 + N) \quad (1)$$

$$v = 93/(1 + 93(0.05)2$$

$$v = 93/1.2325$$

$$v = 75$$

This calculation yielded a minimum sample of 75 respondents, which was deemed adequate and representative for statistical analysis using Partial Least Squares–Structural Equation Modeling (PLS-SEM), particularly since PLS-SEM is robust to relatively small sample sizes.

The inclusion criteria required that respondents: 1) were active owners or decision-makers of MSMEs, 2) operated within the food and beverage subsector of the creative economy, and 3) had experience using or considering digital financial applications, particularly AI-based e-Ijarah platforms. This ensured that the sample represented actual users or potential adopters of Islamic fintech systems, rather than general MSMEs without relevant exposure.

All 75 selected respondents completed the questionnaire fully, with no data excluded due to incompleteness. Data were analyzed using SmartPLS 4.0, which is widely employed in IS and fintech research due to its capability in handling complex models and relatively small sample sizes.

TABLE II. VARIABLES AND INDICATORS

Variable	Indicator	Code
Perceived Ease of Use (PEOU)	Easy to use	PEOU1
	Smooth interaction	PEOU2
	Easy to learn	PEOU3
	Quick to master	PEOU4
Perceived Usefulness (PU)	Helps tasks	PU1
	Increases productivity	PU2
	Improves performance	PU3
Trust in AI (TR)	Trust in AI system	TR1
	Privacy and security	TR2
	Comfortable using AI	TR3
Sharia Compliance (SC)	Follows Islamic principles	SC1
	Sharia-based process	SC2
	Complies with Sharia	SC3
Perceived Risk (PR)	Data misuse risk	PR1
	Security concern	PR2
	Online transaction worry	PR3
	Personal data risk	PR4
Task-Technology Fit (TTF)	Fits task requirements	TTF1
	Improves effectiveness	TTF2
	Aids task completion	TTF3
	Functional support	TTF4
Behavioral Intention (BI)	Intend to use regularly	BI1
	Recommend to others	BI2
	Continue using	BI3
Actual Use (AU)	Frequent use	AU1
	Used for various transactions	AU2
	Proper functionality usage	AU3
	Active utilization	AU4
User Satisfaction (EUCS)	Overall satisfaction	EUCS1
	Meets expectations	EUCS2
	Comfortable to use	EUCS3
	Satisfactory performance	EUCS4
	Enjoyable to use	EUCS5
Age (Moderator)	Respondent's age	Age

Table II presents the list of research variables and their associated indicators used in this study. Each variable was measured using multiple indicators adopted and adapted from relevant prior literature, aligned with the research model. These indicators were designed to reflect key constructs such as perceived ease of use, perceived usefulness, trust in AI, sharia compliance, perceived risk, task-technology fit, behavioral intention, actual system usage, and user satisfaction. The indicators were labeled using concise codes for easier referencing during the data analysis process. All items were measured using a 5-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). All indicators were adapted from prior validated scales with minor contextual adjustments.

Perceived Risk (PR) is a negatively oriented construct, meaning higher scores reflect greater concern or fear regarding the system. Therefore, during data preprocessing, the scores for this variable were reverse-coded to maintain consistency in the interpretation of positive path relationships across the model. The moderator variable, age, was recorded as a continuous demographic input.

IV. RESULTS AND DISCUSSION

A. Result

1) Data demographic: This research involved 75 respondents who are owners or decision-makers of MSMEs in the food and beverage sector located in a district in East Java. The demographic profile of respondents is summarized based on several categories including gender, age, level of education, business duration, and role in business operations. Details are shown in Table III.

TABLE III. DEMOGRAPHIC RESPONDENTS

Category	Subcategory	Freq	(%)
Gender	Male	41	54.7%
	Female	34	45.3%
Age Group	< 25 years	8	10.7%
	26–35 years	21	28.0%
	36–45 years	27	36.0%
	> 45 years	19	25.3%
Education Level	Junior High or below	5	6.7%
	Senior High School	28	37.3%
	Diploma/ Bachelor's Degree	37	49.3%
	Postgraduate Degree	5	6.7%
Business Duration	< 1 year	6	8.0%
	1–3 years	22	29.3%
	4–6 years	28	37.3%
	> 6 years	19	25.3%
Role in Business	Owner	53	70.7%
	Manager/Operator	17	22.7%
	Others	5	6.6%

2) Measurement model analysis (outer model): Fig. 2 illustrates the measurement model and structural relationships among latent constructs. All outer loadings exceed the recommended threshold of 0.70, indicating that the indicators are strongly related to their latent constructs [33].

The path coefficients shown between latent variables represent the strength and direction of relationships. Most paths are positive and significant, although some show weak or negative relationships, such as the effect of Perceived Risk (PR) on Actual Use (AU), which shows a negative coefficient (-0.288), indicating that as users perceive higher risk, their

likelihood of using the system decreases highlighting a critical barrier that needs to be addressed in system adoption strategies.

Each latent construct also displays an R^2 value in the center, showing how much variance is explained by its predictors [33]. For instance, the construct User Satisfaction has an R^2 of 0.881, indicating that 88.1% of the variance in user satisfaction can be explained by the model.

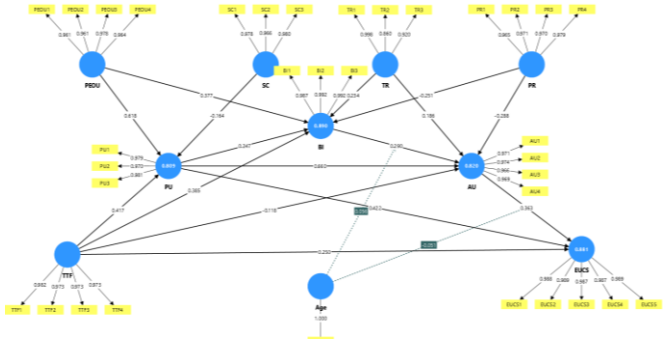

Fig. 2. Output line diagram.

Table IV shows convergent validity assesses whether the indicators truly reflect their intended constructs. This is evaluated through the Average Variance Extracted (AVE). An AVE value of 0.50 or higher is considered acceptable, indicating that the construct explains more than 50% of the variance in its indicators [34].

Our model explains acceptance of an AI-based e-Ijarah application that recommends contract approval by assessing financial condition, business type, location, and target market against funders' standards. In this context, TTF represents alignment between users' evaluation tasks and the AI decision logic; TAM constructs (PEOU, PU) capture usability and utility perceived from AI assistance. We further include Trust, Perceived Risk, and Sharia Compliance as context-specific determinants of intention and satisfaction, with the expectation that trust and sharia compliance enhance adoption, while perceived risk diminishes it.

Table V presents the reliability results of each construct using Cronbach's Alpha and Composite Reliability. These two indicators are used to assess internal consistency of the measurement model.

All constructs exhibit Cronbach's Alpha values above 0.70, indicating that the items within each construct are consistently measuring the same underlying concept. Similarly, the Composite Reliability values also exceed the recommended threshold of 0.70, confirming that each construct demonstrates strong internal consistency and measurement accuracy.

The highest reliability is observed in User Satisfaction (EUCS) with a Cronbach's Alpha of 0.994 and rho_c of 0.995, while the lowest, yet still acceptable, reliability is seen in Trust in AI (TR) with a Cronbach's Alpha of 0.963 and rho_c of 0.949.

TABLE IV. CONVERGENT VALIDITY OF CONSTRUCTS

Indicator	Loading Factor	Valid / No	AVE
PEOU1	0.961	Valid	0.934
PEOU2	0.961	Valid	
PEOU3	0.978	Valid	
PEOU4	0.964	Valid	
PU1	0.979	Valid	0.954
PU2	0.970	Valid	
PU3	0.981	Valid	
SC1	0.978	Valid	0.950
SC2	0.966	Valid	
SC3	0.980	Valid	
TR1	0.998	Valid	0.860
TR2	0.860	Valid	
TR3	0.920	Valid	
PR1	0.965	Valid	0.944
PR2	0.971	Valid	
PR3	0.970	Valid	
PR4	0.979	Valid	
BI1	0.987	Valid	0.980
BI2	0.992	Valid	
BI3	0.992	Valid	
AU1	0.971	Valid	0.941
AU2	0.974	Valid	
AU3	0.966	Valid	
AU4	0.969	Valid	
TTF1	0.982	Valid	0.951
TTF2	0.973	Valid	
TTF3	0.973	Valid	
TTF4	0.973	Valid	
EUCS1	0.988	Valid	0.976
EUCS2	0.989	Valid	
EUCS3	0.987	Valid	
EUCS4	0.987	Valid	
EUCS5	0.989	Valid	

*All constructs exceed the AVE threshold, confirming that convergent validity is achieved across all latent variables.

TABLE V. RELIABILITY ANALYSIS OF CONSTRUCTS

Variable	Cronbach's Alpha	Composite Reliability (ρc)
PEOU	0.976	0.984
PU	0.976	0.984
SC	0.974	0.984
TR	0.963	0.949
PR	0.980	0.985
BI	0.990	0.994
AU	0.979	0.986
TTF	0.983	0.990
EUCS	0.994	0.995

3) Structural model analysis (inner model): The inner model or structural model analysis aims to evaluate the relationships between latent variables based on the proposed hypotheses. The evaluation includes the analysis of path coefficients, R-square values, F-square effect sizes, and discriminant validity using the Fornell-Larcker criterion.

R-square (R^2) indicates how much of the variance in the dependent variable is explained by the independent variables. All endogenous variables have $R^2 > 0.75$, indicating the model has substantial explanatory power for Actual Use, Behavioral Intention, Perceived Usefulness, and User Satisfaction.

Table VI shows the R^2 values are all above the 0.75 threshold, which is considered substantial according to Hair et al. (2017). Specifically, Behavioral Intention (0.890), Actual Use (0.820), Perceived Usefulness (0.809), and User Satisfaction (0.881) are strongly predicted by their respective independent variables. These results confirm that the proposed model has high explanatory power and is effective in capturing the key factors influencing e-Ijarah application usage and satisfaction.

TABLE VI. R-SQUARE VALUE

Variable	R-Square	Result
AU	0.820	Strong
BI	0.890	Strong
PU	0.809	Strong
User Satisfaction	0.881	Strong

The detailed path coefficients and their statistical significance are summarized in Table VII, which presents the key relationships and hypothesis testing results. The F-square (f^2) values measure the effect size or contribution of each exogenous variable to the R^2 value of an endogenous variable when included in the model [35]. Values of 0.02, 0.15, and 0.35 represent small, medium, and large effects, respectively [36].

TABLE VII. F-SQUARE VALUE

Path	F^2 Value	Result
PEOU → PU	0.972	Strong
PR → BI	0.544	Strong
PU → AU	0.558	Strong
TTF → BI	0.632	Strong
PU → User Satisfaction	0.353	Strong
PEOU → BI	0.322	Medium
PU → BI	0.112	Weak
TTF → PU	0.293	Medium
AU → User Satisfaction	0.392	Strong
TTF → User Satisfaction	0.239	Medium
PR → AU	0.316	Medium
TR → BI	0.486	Strong
TR → AU	0.134	Weak
SC → PU	0.076	Weak
TTF → AU	0.022	Weak
BI → AU	0.066	Weak
PU → BI	0.112	Weak
Age interactions	< 0.03	Negligible

The path analysis presents the estimated relationships between latent variables in the structural model, indicated by path coefficients (β), along with their statistical significance. A positive and statistically significant coefficient (T-statistic $\geqslant$ 1.96 and p-value $\leqslant$ 0.05) supports the proposed hypothesis, indicating a meaningful influence of one construct on another. Conversely, non-significant paths suggest that the hypothesized relationships are not empirically supported in the model [37].

TABLE VIII. PATH COEFFICIENT RESULTS

Path	T-Stat	P-Val	Result
AU→User Satisfaction	4.609	0.000	Significant
BI → AU	2.152	0.031	Significant
PEOU → BI	4.583	0.000	Significant
PEOU → PU	9.610	0.000	Significant
PR → AU	4.495	0.000	Significant (negative)
PR → BI	3.972	0.000	Significant (negative)
PU → AU	5.811	0.000	Significant
PU → BI	2.720	0.007	Significant
PU → User Satisfaction	4.950	0.000	Significant
SC → PU	2.742	0.006	Significant (negative)
TR → AU	2.640	0.008	Significant
TR → BI	3.735	0.000	Significant
TTF → AU	1.175	0.240	Not Significant
TTF → BI	6.288	0.000	Significant
TTF → PU	4.702	0.000	Significant
TTF→ User Satisfaction	4.097	0.000	Significant
Age → AU	0.698	0.486	Not Significant
Age →User Satisfaction	0.305	0.760	Not Significant
Age × AU →User Satisfaction	1.146	0.252	Not Significant
Age × BI → AU	1.145	0.252	Not Significant

Table VIII presents several key relationships, such as those between Perceived Ease of Use and Perceived Usefulness, Task-Technology Fit and Behavioral Intention, as well as Perceived Risk and Actual Use are supported, revealing strong theoretical alignment and practical relevance in the context of e-Ijarah adoption.

B. Discussion

The study reveals a strong and significant positive relationship between PEOU and PU ($T = 9.610$, $p < 0.001$, $f^2 = 0.972$), consistent with the core assumptions of the Technology Acceptance Model (TAM) by Davis (1989). When users perceive an application as easy to use, they are more likely to perceive it as useful. This aligns with previous studies [38], reinforcing that usability is a fundamental driver of utility perception in digital financial tools.

PU significantly influences both Behavioral Intention (BI) ($T = 2.720$, $f^2 = 0.112$) and Actual Use (AU) ($T = 5.811$, $f^2 = 0.558$), supporting its central role in TAM. PU also significantly impacts User Satisfaction ($T = 4.950$, $f^2 = 0.353$). These findings confirm that users' perception of utility affects not only their intention to use but also their experience and satisfaction after actual usage. This result is in line with research [39].

BI positively affects AU ($T = 2.152$, $f^2 = 0.066$), showing that users with stronger intentions tend to actually use the system. However, the effect size is small, indicating that other factors such as PU and PR play a more dominant role in predicting actual usage in the e-Ijarah context.

TTF is a strong predictor of BI ($T = 6.288$, $f^2 = 0.632$) and PU ($T = 4.702$, $f^2 = 0.293$), supporting the model proposed by Goodhue & Thompson (1995). TTF also significantly affects User Satisfaction ($T = 4.097$, $f^2 = 0.239$), showing that alignment between task requirements and system capabilities enhances the user experience. However, its influence on AU is not significant ($T = 1.175$), suggesting that even with good task-system fit, external factors may inhibit actual usage behavior.

Trust (TR) significantly influences both BI ($T = 3.735$, $f^2 = 0.486$) and AU ($T = 2.640$, $f^2 = 0.134$). This finding highlights that trust in AI-based e-Ijarah systems is essential for encouraging adoption, especially in contexts involving sensitive data and financial transactions.

In contrast, Perceived Risk (PR) has a negative and significant effect on both BI ($T = 3.972$, $f^2 = 0.544$) and AU ($T = 4.495$, $f^2 = 0.316$). This supports prior findings by [23][40], emphasizing that minimizing perceived risk is critical in digital Islamic finance.

Actual Use (AU) significantly improves User Satisfaction ($T = 4.609$, $f^2 = 0.392$), indicating that continued use and engagement with the e-Ijarah platform positively impact user evaluation. This confirms findings from the EUCS framework and prior studies such as.

Interestingly, Sharia Compliance (SC) shows a significant but negative impact on PU ($T = 2.742$, $f^2 = 0.076$). This unexpected result may indicate a perception gap between automation (AI features) and sharia principles. Users may feel that digitalization compromises transparency or compliance clarity, requiring a re-evaluation of how sharia features are communicated and implemented in the application.

Theoretically, the extended model contributes by linking Sharia Compliance and Trust in AI as dual antecedents of perceived usefulness, offering a novel ethical–technological integration. This re-specifies TAM pathways by demonstrating that compliance clarity and algorithmic transparency jointly predict adoption in Islamic fintech—an advancement over prior single-dimensional trust frameworks.

The negative effect of SC on PU may reflect skepticism toward the transparency of AI-driven processes. Users might perceive that digital automation reduces the clarity of Sharia compliance, which calls for more explicit communication of compliance features in system design.

The moderating effects of Age and its interactions (e.g., Age × BI → AU, Age × AU → User Satisfaction) are not statistically significant (all $T < 1.96$, $f^2 < 0.03$). This indicates that age does not substantially alter user behavior in this context, supporting the idea that digital behavior is becoming more uniform across age groups in modern MSMEs.

From a theoretical standpoint, this study contributes to the integration of TAM, TTF, EUCS, and Islamic compliance in a single model, enriching IS and fintech literature. Practically, the results suggest that improving usability, aligning system design with tasks, and building user trust are key to adoption. Moreover, developers of Islamic fintech applications must address users' perception of compliance clarity to ensure trust and utility perceptions are aligned.

As an internal validation, the current results were compared with recent fintech adoption models by Usman et al., [41] and Seyum et al., [20]. The comparable R^2 (>0.80) and consistent significant paths for PU–BI and BI–AU confirm structural robustness. Nonetheless, future studies could empirically validate this model using cross-sample or experimental design to strengthen external validity.

1) Practical implications: The findings highlight key implications for developers and policymakers in Islamic fintech. The negative effect of Sharia Compliance (SC) on Perceived Usefulness (PU) reflects a perception gap between automation and religious assurance. Developers should include clear Sharia indicators—such as certification icons, transparent transaction logs, and short explanations of ijarah procedures—to strengthen users' confidence. Enhancing AI transparency through explainable dashboards and improving users' digital literacy via training or awareness programs are also essential. Furthermore, unified national standards for AI-based Sharia compliance are recommended to ensure consistency, reduce interpretational gaps, and promote sustainable trust in AI-driven e-ijarah systems. Regulators should standardize compliance communication to minimize user uncertainty regarding automation in religious contracts.

V. Conclusion, Limitations and Future Research Directions

This study investigated the determinants of user satisfaction in adopting AI-based applications, incorporating variables such as Perceived Ease of Use, Perceived Usefulness, Behavioral Intention, Actual Use, Trust in AI, Sharia Compliance, Perceived Risk, and Task-Technology Fit, with Age serving as a moderating variable. The analysis utilized Partial Least Squares Structural Equation Modeling (PLS-SEM) and involved a sample of 75 respondents from MSMEs in East Java.

The results showed that most of the proposed hypotheses were supported. Perceived Usefulness emerged as a key factor influencing both Behavioral Intention and Actual Use, while Actual Use significantly affected User Satisfaction. Trust in AI and Task-Technology Fit were also found to be significant contributors to perceived usefulness and satisfaction. Interestingly, Sharia Compliance had a negative but significant influence on Perceived Usefulness, suggesting a potential

conflict or misunderstanding regarding religious compliance and perceived utility. Age, as a moderating variable, did not have a significant effect on either Actual Use or User Satisfaction.

The model demonstrated strong explanatory power with high R-square values (e.g., 0.881 for User Satisfaction and 0.820 for Actual Use), and most constructs showed strong reliability and convergent validity. Effect size (f^2) analysis further confirmed that several paths had medium to large effects, particularly from Perceived Usefulness and Actual Use toward satisfaction.

In conclusion, this study highlights the critical roles of perceived benefits, ease of use, trust, and technological alignment in shaping users' behavioral intentions and satisfaction toward AI-based applications in MSMEs. These insights can guide future application development and policy formulation to foster broader acceptance, especially within culturally and religiously sensitive user groups.

This study is limited by its small sample size (n = 75) and single-sector focus (food and beverage MSMEs in East Java), which may restrict generalizability. Future research should include cross-sector and cross-regional samples, employ mixed-method validation such as multi-group analysis or experimental AI-trust scenarios, and compare e-ijarah with other Islamic contracts (e.g., murabahah, mudharabah) to enhance external validity.

ACKNOWLEDGMENT

The authors gratefully acknowledge the financial support from the Ministry of Education, Culture, Research, and Technology of the Republic of Indonesia (Kementerian Pendidikan, Kebudayaan, Riset, dan Teknologi) under the 2025 Research Grant Scheme (SP DIPA 139.04.1.693320/2025). This support made the completion of this study possible.

Multimodal Deep Learning for Tuberculosis Detection Using Cough Audio and Clinical Data with Health Acoustic Representations (HeAR)

Rinaldi Anwar Buyung*, Widi Nugroho
Department of Data Science, Seleris Meditekno Internasional, Jakarta, Indonesia

***Abstract*—Tuberculosis (TB) remains a significant global health challenge, necessitating rapid and accessible screening methods. This study proposes a multimodal deep learning model for non-invasive TB detection by fusing acoustic features from cough sounds with clinical metadata. We utilize the pre-trained Health Acoustic Representations (HeAR) model as a powerful backbone to extract features from mel-spectrograms of cough audio. These acoustic features are combined with clinical data, including sex, age, and key symptoms through a late-fusion architecture. The model was trained and evaluated on a balanced dataset of 16,000 samples derived from the CODA TB DREAM Challenge dataset. Our proposed multimodal approach achieved a high overall accuracy of 90% on the unseen test set, with balanced precision, recall, specificity, and F1-scores of 0.90 for both TB-positive and non-TB classes. These results demonstrate the effectiveness of using cough sound as a non-invasive vocal biomarker, amplified by combining advanced acoustic representations with clinical context. This highlights the potential of our method as a robust, low-cost, and scalable tool for early TB screening.**

***Keywords*—Tuberculosis; cough detection; Health Acoustic Representation; multimodal; vocal biomarker**

I. Introduction

Tuberculosis (TB) continues to be a devastating global health crisis. It is caused by the bacterium Mycobacterium tuberculosis, the disease primarily affects the lungs (pulmonary TB) and spreads through the air when an infected person coughs, sneezes, or speaks [1]. In 2023 alone, an estimated 10.8 million people fell ill with the disease, and it claimed the lives of 1.25 million people, reaffirming its status as a leading cause of death from a single infectious agent worldwide. The epidemic's immense scale underscores the critical need for global efforts to combat TB. These efforts align with the United Nations Sustainable Development Goal of ending the epidemic by 2030 [2]. The burden of this disease is unevenly distributed, with the majority of cases occurring in developing countries. Indonesia ranks as the country with the second-highest TB burden in the world after India, which underscores the urgency to develop more effective, rapid, and accessible screening and diagnostic methods within the country [3].

Conventional diagnostic methods for TB, such as sputum smear microscopy, bacterial culture, and rapid molecular tests (e.g., Xpert MTB/RIF), often have limitations. Sputum smear microscopy has variable sensitivity and may fail to detect cases with a low bacterial load. Bacterial culture, while being the gold standard, requires several weeks to yield results, which can delay treatment and increase the risk of transmission [4]. Meanwhile, molecular tests and radiological examinations like chest X-rays, although more accurate, require expensive laboratory infrastructure, specialized equipment, and expert personnel that are not always available in primary healthcare facilities or remote areas. These limitations hinder efforts for early detection and massive-scale containment of TB spread [5].

The pathological progression of pulmonary TB significantly alters the respiratory system's mechanics and acoustics. The formation of granulomas, inflammation of the airways, and accumulation of fluid or sputum change the physical properties of the lungs and trachea. These changes directly impact the sound produced during a cough, which is a forceful expulsion of air [6]. Consequently, coughs from TB-infected individuals can exhibit distinct acoustic patterns, such as variations in spectral energy, frequency components, and temporal characteristics compared to those from healthy individuals [7]. This acoustic signature provides a physiological basis for using cough sound as a non-invasive biomarker for TB screening [8].

Along with advancements in digital technology, sound analysis using artificial intelligence (AI) has emerged as a promising alternative solution. Deep learning, a subset of machine learning, enables systems to learn from data and understand complex concepts without explicit programming [9]. By learning from experience, computers can autonomously perform tasks, making them highly suitable for analyzing complex patterns in medical data. In previous studies, for instance, deep learning particularly Convolutional Neural Networks (CNNs) was successfully employed to detect diabetic retinopathy using retinal fundus images [10], [11]. Similarly, cough sounds, as a primary symptom of TB, contain rich acoustic information and can serve as a non-invasive vocal biomarker [12]. This capability offers the potential for a low-cost, rapid, and remotely deployable screening tool using common devices such as smartphones [13].

To maximize the potential of audio analysis, this study proposes the use of Health Acoustic Representations (HeAR), a foundation model developed by Google AI specifically for health-related sounds. HeAR is built on a transformer-based architecture and employs a self-supervised learning strategy, having been pre-trained on over 300 million two-second audio clips encompassing sounds like coughs and breaths. This

*Corresponding author.

extensive pre-training enables HeAR to generate powerful and generalized acoustic embeddings. In benchmark evaluations, simple linear classifiers trained on HeAR embeddings achieved state-of-the-art or competitive performance across various health tasks, including the detection of conditions like COVID-19 and the inference of smoking status from cough recordings [14].

By leveraging these rich representations as a backbone, this study aims to build a robust classifier for TB [15]. Furthermore, this study adopts a multimodal approach by not only relying on cough sounds but also integrating essential clinical data such as sex, age, and key symptoms (hemoptysis, night sweats, weight loss, and fever). The combination of advanced acoustic features from HeAR and contextual clinical information is expected to significantly improve detection accuracy and reliability, leading to a more holistic and accurate screening model [16].

This study makes several key contributions. First, we introduce a multimodal deep learning architecture that effectively fuses powerful pre-trained acoustic features from the HeAR model with essential clinical metadata. Second, we validate our approach on a large, balanced dataset, demonstrating its robustness and high accuracy. The remainder of this paper is organized as follows: Section II reviews related work in acoustic-based TB detection. Section III details the dataset, preprocessing steps, and our proposed model architecture. Section IV presents the experimental results and analysis. Finally, Section V discusses the clinical implications of our findings. Section VI concludes the study, and outlines directions for future research.

II. Related Work

The use of cough sound analysis as a low-cost, non-invasive tool for tuberculosis (TB) screening has been an active area of research. Early studies established the foundational potential of this approach by applying traditional machine learning models to handcrafted acoustic features. For instance, Botha et al. employed statistical classifiers like Logistic Regression on short-term spectral features combined with clinical data, achieving a sensitivity of 96% at a specificity of 72% on a dataset of 518 coughs. While pioneering, this work relied on manually engineered features (e.g., MFCC), which may not fully capture the complex, subtle acoustic patterns indicative of TB [17].

Subsequent research shifted towards deep learning to automate feature extraction and improve performance. Xu et al. developed a sophisticated fusion model using a Bidirectional Long Short-Term Memory (Bi-LSTM) network combined with a Convolutional Neural Network (CNN). Their approach, which fused traditional features like MFCC and Zero-Crossing Rate (ZCR) with features learned from spectrograms, reported a very high accuracy of 96.33%. However, this impressive result was obtained from a relatively small and homogenous dataset of 456 coughs from a limited number of participants. This raises important questions about the model's scalability and ability to generalize to more diverse, real-world populations [18].

In contrast, recent studies have demonstrated the power of simpler architecture when applied to large-scale datasets. Yadav et al. utilized a massive dataset of over 500,000 cough recordings and found that a simple 1D CNN trained on Mel-Frequency Cepstral Coefficients (MFCCs) achieved a high accuracy of 91%, exceeding the WHO's requirements for a screening test. This work underscores that with sufficient data, less complex models can be highly effective. Similarly, Kafentzis et al. also worked with a large, real-world dataset, achieving a respectable Area Under the Curve (AUC) of approximately 0.80 by combining audio features with clinical metadata, further highlighting the importance of a multimodal approach [19].

Addressing the need for larger and more diverse datasets, Kafentzis et al. utilized a substantial dataset of over 9,000 coughs collected "in the wild" via a mobile application. Using a combination of spectral features and clinical metadata, their statistical models achieved a respectable Area Under the Curve (AUC) of approximately 0.80 [20]. Their work highlighted the feasibility of large-scale data collection but also demonstrated that performance on noisy, real-world data remains a significant challenge, suggesting that more powerful feature representation is needed. A summary of these key studies is presented in Table I.

TABLE I. State-of-the-Art

Study	Methodology	Audio Features	Dataset	Evaluation Metrics
[17]	Logistic Regression	MFCC, Log Spectral Energies, Clinical Data	518 Coughs	Sensitivity = 96% Specificity = 72%
[18]	BiLSTM + Conv2D	MFCC, ZCR, RMS, Chroma Cens, Short Time Energy, Spectrogram	456 Coughs	Accuracy = 96.33% Specificity = 94.99%
[19]	1D CNN	MFCC	502,252 Coughs	Accuracy = 91% AUC = 0.8
[20]	CNN	LLDs, Clinical Data	9772 Coughs	AUC = 0.8

While these studies have established the potential of cough sound analysis for TB screening, clear research gaps remain. Previous works have either relied on handcrafted features or custom-trained CNNs. Furthermore, these investigations were often conducted on considerably smaller datasets, which may not capture the full complexity of acoustic biomarkers and could limit the generalizability of their findings.

To our knowledge, the application of a specialized, pre-trained health acoustic foundation model like HeAR within a multimodal framework on a large-scale dataset for TB detection has not yet been thoroughly investigated. This study aims to fill these gaps by evaluating the performance of HeAR as a powerful feature extractor, combined with clinical data on a large and diverse dataset of 16,000 samples, to potentially set a new benchmark for accuracy and robustness in non-invasive TB screening.

III. Data and Methodology

This section details the data sources and methodological approaches employed to address the core objectives of this research. Fig. 1 illustrates the procedural framework guiding this study.

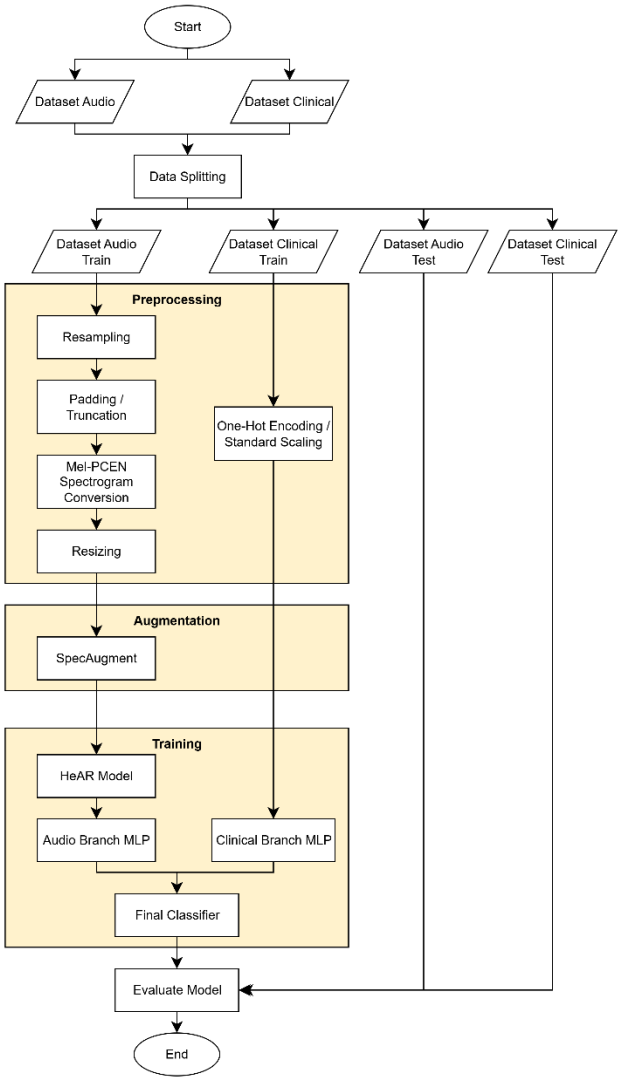

Fig. 1. Research workflow.

A. Dataset

The dataset employed in this research is the CODA TB DREAM Challenge dataset [21], a comprehensive collection of solicited cough recordings designed to advance TB triage testing. The dataset comprises 29,768 cough recordings from individuals across seven countries: India, the Philippines, South Africa, Uganda, Vietnam, Tanzania, and Madagascar.

Each recording is accompanied by detailed metadata, including the participant's confirmed TB status (positive or negative) and a range of demographic and clinical information.

To address the class imbalance often present in medical datasets, we performed random undersampling on the majority class. This process resulted in a balanced final dataset for our study, consisting of 8,000 samples for the TB-positive class and 8,000 samples for the TB-negative class, thereby preventing potential model bias towards the more frequent class. The dataset is illustrated in Fig. 2. While this strategy is effective for balancing classes, we acknowledge that it may discard potentially useful data from the majority class. Alternative techniques, such as the Synthetic Minority Over-sampling Technique (SMOTE) or using focal loss during training, were considered but random undersampling was chosen for its simplicity and computational efficiency in this initial large-scale study. The richness and scale of this balanced 16,000-sample dataset, sourced from seven diverse countries, provide a robust foundation for training a generalizable AI-based screening tool.

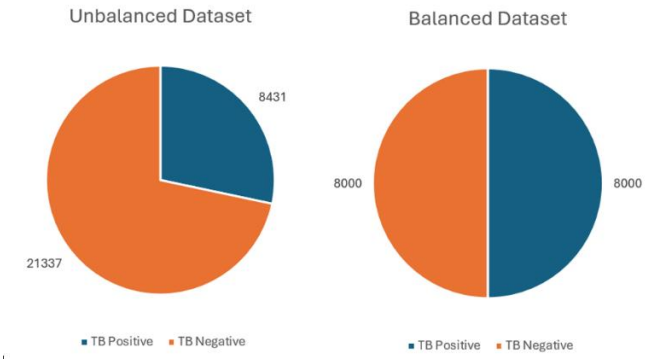

Fig. 2. Dataset distribution.

For this study, the TB status will serve as the primary target label for classification. To develop our multimodal model, we will utilize both the cough audio recordings, and the following supplementary clinical data provided in the metadata: sex, age, and the presence of key TB-related symptoms, namely hemoptysis (coughing up blood), night sweats, weight loss, and fever. The richness and diversity of this dataset make it an ideal resource for training and validating a robust, generalizable AI-based screening tool for tuberculosis.

B. Data Preprocessing and Augmentation

This study applied several data preprocessing techniques, including the following:

- Resampling: This process involves adjusting the sampling rate to match the model's requirements, ensuring input consistency, reducing memory usage, and improving computational efficiency [22]. In this study, we used a sampling rate of 16,000 Hz.
- Padding and Truncation: Padding and truncation are processes used to standardize the duration of audio samples, ensuring that they can be uniformly processed by the model. Padding involves adding zero values to audio samples that are shorter than the target length, whereas truncation trims samples that exceed the specified duration. In this study, the audio length was set to 2 seconds according to the model specification.
- Mel-PCEN Spectrogram Conversion: To create a suitable input representation for the model, the standardized waveforms are converted into a mel-spectrogram format. This process involves applying the Short-Time Fourier Transform (STFT) to decompose

the audio into its frequency components over time, as defined in Eq. (1).

$$X(m,w) = \sum_{n=-\infty}^{\infty} x[n]w[n-m]e^{-jwn} \quad (1)$$

where, $x[n]$ is the input signal, $w[n]$ is the window function, and the output $X(m,w)$ is the complex value for the frequency bin w at time frame m. Subsequently, the spectrogram is mapped onto the Mel scale, which more closely aligns with human auditory perception by emphasizing lower frequencies. Following this, Per-Channel Energy Normalization (PCEN) is applied as an advanced dynamic range compression method to enhance signal robustness against noise and volume variations [23]. In this study, the conversion utilized a frame length of 400 samples, a frame step of 160 samples, and generated 128 mel bands.

- Input Resizing: To ensure a consistent input size for the deep learning model, the final mel-PCEN spectrogram was resized to a fixed dimension of 192x128, representing time and frequency axes, respectively.
- SpecAugment: To enhance data diversity and improve the model's generalization capabilities, we applied SpecAugment to the training set. This data augmentation technique operates directly on the spectrogram by randomly applying time masking (obscuring a range of consecutive time steps) and frequency masking (hiding a block of consecutive mel frequency channels). This process encourages the model to learn more robust features and reduces the risk of overfitting [24].

C. Building Model

This study adopts a multimodal deep learning approach that leverages both acoustic features from cough sounds and structured clinical data for TB classification. The architecture consists of two parallel processing streams: one for audio and one for clinical metadata which are then combined through a fusion mechanism before a final classification is made.

The audio processing stream utilizes the pre-trained HeAR model as its feature extraction backbone. The choice of HeAR is deliberate; as a foundation model pre-trained on over 300 million health-related audio clips, it provides powerful and generalized acoustic embeddings, allowing us to achieve high performance without training a deep architecture from scratch. Architecturally, HeAR is a transformer-based model, like a Vision Transformer (ViT), designed to process audio spectrograms as images [25]. The Vision Transformer architecture described in Fig. 3.

The input 192x128 mel-PCEN spectrogram is first divided into a sequence of smaller, non-overlapping patches P_i.

Mathematically, for each patch, the embedding vector E_i is computed using a linear projection, as defined in Eq. (2).

$$E_i = W \cdot vec(P_i) + b \quad (2)$$

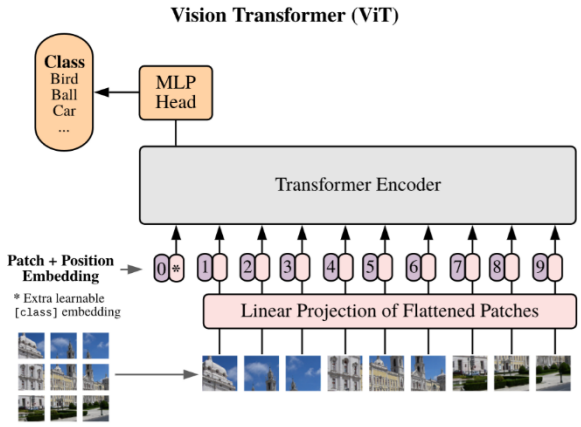

Fig. 3. Vision transformer architecture.

where, W denotes the projection weight matrix, b represents the bias vector, and P_i corresponds to the flattened image patch. To retain spatial information, a learnable positional encoding is then added to each embedding vector. These encodings provide the model with information about the position of each patch in the sequence, using sine and cosine functions of different frequencies, as defined in Eq. (3).

$$PE_{(pos,2i)} = \sin\left(\frac{pos}{100000^{\frac{2i}{d}}}\right)$$
$$PE_{(pos,2i+1)} = \sin\left(\frac{pos}{100000^{\frac{2i}{d}}}\right) \quad (3)$$

where, pos denotes the position index, i represents the dimension index, and d is the embedding dimension.

The resulting sequence of vectors is then processed by 24 transformer encoder layers. Each layer comprises a multi-head self-attention mechanism with 16 attention heads, followed by a position-wise feed-forward network (FFN) with a hidden size of 4096. The self-attention mechanism calculates attention scores based on the query Q, key K, and value V to weigh the importance of different patches relative to each other, allowing the model to capture complex dependencies across the spectrogram as defined in Eq. (4).

$$Attention(Q,K,V) = softmax\left(\frac{QK^T}{\sqrt{d_k}}\right)V \quad (4)$$

where, $Q, K,$ and V are the query, key, and value matrices, and d_k is the dimension of the key.

Following the attention sub-layer, the output is passed to an FFN. This network consists of two linear transformations with a GELU activation in between as shown in Eq. (5).

$$FFN(x) = GELU(xW_1 + b_1)W_2 + b_2 \quad (5)$$

where, x denotes the input token representation, W_1 and W_2 are learnable weight matrices, b_1 and b_2 are the corresponding bias vectors, and GELU is the Gaussian Error Linear Unit activation as defined in Eq. (6).

$$GELU(x) = x \cdot \Phi(x) = x \cdot \frac{1}{2}\left(1 + \tanh\left(\sqrt{\frac{2}{\pi}}(x + 0.044715x^3)\right)\right) \quad (6)$$

where, $\Phi(x)$ is the standard Gaussian cumulative distribution function. The FFN allows for nonlinear transformations and enhances the model's capacity to learn complex representations. Residual connections are applied around each of the two sub-layers, followed by layer normalization, as defined in Eq. (7). This step is crucial for stabilizing the training of deep networks.

$$Layernorm(x + Sublayer(x)) \quad (7)$$

For this study, the output embedding from the final transformer layer is used as the acoustic feature representations, and the weights of the HeAR backbone are kept frozen. The output which is a 512-dimensional embedding vector is then passed through a dedicated audio branch, which consists of a linear layer that projects the features from 512 to 128 dimensions, followed by Batch Normalization, a ReLU activation, a dropout layer with a rate of 0.4, and a final linear layer that outputs a 64-dimensional audio feature vector.

Concurrently, the clinical data stream handles the tabular metadata. After preprocessing (one-hot encoding for categorical features and standard scaling for age), the vector is fed into a clinical branch. This branch is composed of a linear layer mapping the input to 64 dimensions, followed by a ReLU activation, a dropout layer with a rate of 0.3, and another linear layer that produces a 32-dimensional clinical feature vector.

In the fusion stage, the 64-dimensional audio vector and the 32-dimensional clinical vector are concatenated, creating a combined 96-dimensional feature vector. This vector is then passed to the final classifier which consists of a Batch Normalization layer, a ReLU activation, a high-rate dropout layer (0.5) for regularization, and a final linear layer that outputs the logits for the two classes (TB-positive and TB-negative). The final prediction probabilities are obtained using a softmax function, as shown in Eq. (8).

$$\sigma(z)_i = \frac{e^{z_i}}{\sum_{j=1}^{K} e^{z_j}} \quad (8)$$

where, z is the input vector of logits and K is the number of classes. The entire model is trained end-to-end using a cross-entropy loss function to quantify the difference between the predicted probability and the actual class labels, as defined in Eq. (9).

$$\mathcal{L} = -\sum_{i=0}^{1} y_i \log(\hat{y}_i) \quad (9)$$

D. Training Setup

The AdamW optimizer was used to train the models, incorporating a weight decay of 0.01 and an initial learning rate of 1×10^{-4}. Training was conducted for 50 epochs with a batch size of 32. The objective function was cross-entropy loss. Early stopping was applied based on validation loss to prevent overfitting, with a patience of 7 epochs and minimum delta of 0.001. Model performance was comprehensively evaluated using several metrics, including accuracy, precision, recall, and F1-score, with 80/10/10 train, validation and test dataset. All experiments were conducted on a NVIDIA RTX A4000 GPU with 16 GB VRAM.

IV. Experimental Results

A. Evaluation Parameters

This study employed several evaluation metrics, including accuracy, F1-score, precision, and recall. The confusion matrix is a fundamental tool for assessing classification model performance, offering a comprehensive comparison between the model's predictions and the actual labels. The confusion matrix comprises four components: True Positives (TP), True Negatives (TN), False Positives (FP), and False Negatives (FN). Precision quantifies the proportion of correctly predicted positive instances among all instances predicted as positive, thereby providing insight into the model's susceptibility to false positive errors. Recall, on the other hand, evaluates the proportion of actual positive instances that the model correctly identified, thereby reflecting its effectiveness in minimizing false negative errors. Specificity measures the proportion of actual negatives that are correctly identified as such by the model. The F1-score, computed as the harmonic means of precision and recall, provides a balanced assessment of the model's performance by simultaneously accounting for both FP and FN. These evaluation metrics are computed using the formulas presented in Eq. (10) through Eq. (14).

$$Accuracy = \frac{TP + TN}{TP + FP + TN + FN} \quad (10)$$

$$Recall = \frac{TP}{TP + FN} \quad (11)$$

$$Precision = \frac{TP}{TP + FP} \quad (12)$$

$$F1 - Score = \frac{2 \times (precision \times recall)}{precision + recall} \quad (13)$$

$$Specificity = \frac{TN}{TN + FP} \quad (14)$$

B. Experimental Analysis

In this study, simulations and model development for detecting TB based on cough sounds-, as well as the creation of a digital audio-based detection system-, were conducted using hardware and software with specific configurations. Table II presents the detailed specifications of the equipment and tools used.

The authors configured the training process with 50 epochs, a learning rate of 0.0001, and a batch size of 32, using the AdamW optimizer.

As shown in Table III, the proposed multimodal deep learning model demonstrated strong performance in classifying tuberculosis from cough audio and clinical data. The model achieved an overall accuracy of 90% on the test set. The results

show a well-balanced performance across both classes, with precision, recall, and F1-scores of 0.90 for both the "Non-TB" and "TB" classes. This symmetry indicates that the model is equally effective at identifying both positive and negative cases and is not biased towards any single class, which is a crucial attribute for a reliable medical screening tool.

GPU Memory	16 GB
RAM	16 GB
Disk	1 TB
Programming Language	Python 3.10

TABLE III. MODEL PERFORMANCE

Class	Accuracy	Precision	Recall	F1-Score	Specificity
Non-TB	0.90	0.90	0.90	0.90	0.9
TB	0.90	0.90	0.90	0.90	0.9
Average	**0.90**	**0.90**	**0.90**	**0.90**	**0.9**

The confusion matrix, shown in Fig. 4, provides a more granular view of the model's predictions. Out of 800 non-TB samples, the model correctly identified 723 as Non-TB (True Negatives) and misclassified 77 as TB (False Positives). Similarly, for the 800 TB samples, the model correctly identified 723 as TB (True Positives) and misclassified 77 as Non-TB (False Negatives). The low number of misclassifications for both classes further validates the model's high accuracy and balanced predictive power.

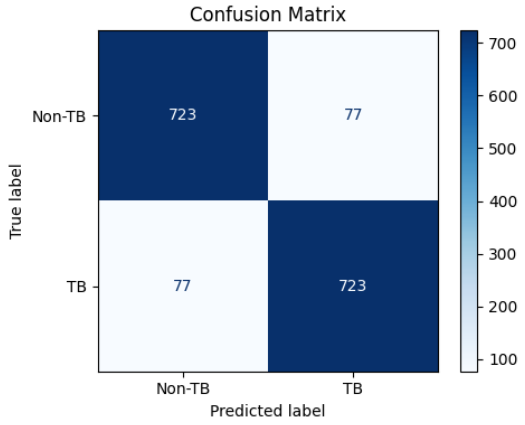

Fig. 4. Confusion matrix of the proposed model on the test set.

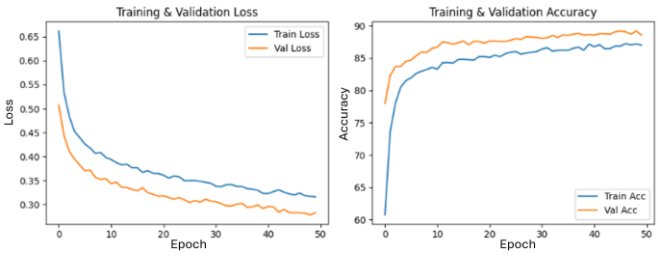

Fig. 5. Training and validation loss and accuracy curves over 50 epochs.

Fig. 5 illustrates the model's learning process over 50 epochs. The training and validation loss curves show a consistent downward trend, indicating that the model was effectively learning from the data. Importantly, the validation loss closely follows the training loss without significant divergence, which suggests that the model generalized well to unseen data and was not overfitting. The accuracy curves mirror this positive trend, with both training and validation accuracy steadily increasing and converging to approximately 90%. This stable training behavior highlights the effectiveness of the chosen architecture and regularization techniques (e.g., dropout) in building a robust classifier.

V. DISCUSSION

Our proposed model achieved a strong overall accuracy of 90%, with balanced performance across all key metrics. This section discusses the interpretation of these findings, the study's limitations, and challenges for real-world deployment.

A. Interpretation of Results and Clinical Implications

Our model's 90% overall accuracy, with balanced precision, recall, and F1-scores of 0.90 across both TB and non-TB classes, demonstrates its reliability and lack of bias. For clinical applications, this performance is highly promising. The 90% sensitivity is crucial for identifying most positive cases early, aiding in timely treatment and reducing transmission. Simultaneously, the 90% specificity effectively rules out the disease in most healthy individuals, minimizing unnecessary follow-up tests, patient anxiety, and healthcare costs. While the 10% false-negative rate requires further work to mitigate public health risks, these findings strongly validate that fusing advanced acoustic features with clinical data offers a holistic and accurate approach for a scalable TB screening tool.

B. Real-World Implementation Scenarios and Challenges

For deployment in real-world TB screening, several challenges must be addressed. Data privacy is paramount, requiring secure data handling. The model's robustness to background noise in uncontrolled environments needs rigorous testing. Furthermore, hardware variability, particularly the quality of microphones in different smartphones, could impact performance and requires investigation to ensure consistent results.

C. Limitations

A primary limitation is our use of random undersampling, which, as noted, may discard potentially useful data. Future studies could address this by implementing alternative balancing techniques like SMOTE or focal loss.

VI. CONCLUSION AND FUTURE WORK

This study successfully demonstrated the effectiveness of a multimodal deep learning approach for tuberculosis detection by combining cough audio signals with clinical metadata. By leveraging the powerful Health Acoustic Representations (HeAR) model as a feature extractor and integrating it with key patient symptoms, our proposed model achieved an impressive accuracy of 90% on a balanced test set. The balanced precision, recall, and F1-scores further underscore the model's capability to reliably identify both Non-TB and TB cases,

highlighting its potential as a robust and unbiased screening tool. These findings confirm that the fusion of advanced acoustic features with contextual clinical data provides a more holistic and accurate representation for diagnosis than either modality alone.

From a clinical perspective, the balance between sensitivity (recall) and specificity is critical for a screening tool. The model's 90% sensitivity indicates that it successfully identifies 9 out of 10 individuals with TB, which is vital for early treatment initiation. However, the 10% of cases missed (false negatives) represent a significant public health concern, as these individuals may unknowingly continue to transmit the disease. Conversely, the 90% specificity means that 9 out of 10 healthy individuals are correctly identified, but the 10% of false positives would be subjected to unnecessary follow-up tests, causing patient anxiety and burdening healthcare resources. For a preliminary screening tool, this performance represents a promising balance, but future work should prioritize further reducing the false-negative rate to maximize the tool's public health impact.

Several avenues for future research can be explored to build upon these promising results. First, extensive hyperparameter tuning of the fusion model, including the architecture of the audio and clinical branches as well as the dropout rates, could further optimize performance. Second, exploring different fusion strategies, such as attention-based mechanisms, may allow the model to dynamically weigh the importance of audio versus clinical features for each sample. Additionally, evaluating the model's generalization on external, unseen datasets from different demographic or geographic populations is crucial to ensure its real-world applicability. Finally, incorporating explainable AI (XAI) techniques is crucial for clinical adoption. By providing insights into which acoustic or clinical features most influence the model's predictions, XAI can build trust among healthcare professionals, aid in validating the model's decision-making process, and facilitate its integration into clinical workflows. The development of such a tool holds significant promise for creating an accessible, low-cost, and scalable solution to support global efforts in early TB detection and containment.

***Abstract*—As artificial intelligence (AI) advances in healthcare, its use in maternal health shows promise but faces challenges of trust due to the black-box nature of many models. Gestational diabetes mellitus (GDM), a transient yet high-risk condition, demands accurate and interpretable prediction tools. However, existing GDM prediction studies often rely on opaque models or post-hoc explanation techniques applied after training, which limits transparency and reduces their clinical applicability. This highlights an urgent need for models that unify high predictive performance with interpretability by design. This study introduces EYE-GDM, a case-specific application of our Enhanced Interpretability Ensemble (EYE) framework, designed to predict GDM risk with clinically meaningful explanations. The pipeline evaluates multiple algorithms and selects Decision Tree (DT), k-Nearest Neighbors (k-NN), and Gradient Boosting (GB) as the best-performing base learners. These are integrated with SHAP and a logistic regression (LR) meta-model to construct EYE-GDM, embedding interpretability by weighting learner outputs with LR coefficients. This yields global (population-level) and local (patient-level) explanations consistent with medical knowledge. Tested on a dataset of 3,525 pregnancies, EYE-GDM achieved strong performance (accuracy = 0.9789, AUC-ROC = 0.9981) and provided insights into risk patterns, thresholds, and feature interactions relevant to GDM. By embedding explainability within the ensemble construction, EYE-GDM achieves transparent and clinically aligned reasoning without compromising predictive performance. Thus, EYE-GDM demonstrates how explainable AI (XAI) can translate from technical innovation to practical value in maternal care, supporting earlier risk identification and more informed clinical decisions.**

***Keywords*—Explainable Artificial Intelligence (XAI); interpretable machine learning (IML); Gestational diabetes mellitus (GDM); maternal health; healthcare AI; GDM risk prediction; transparency; trust**

I. Introduction

Artificial intelligence (AI) is increasingly being used in healthcare to support early risk detection and guide clinical decision-making [1]. Yet, despite its growing presence, many AI models, especially high-performing ones such as deep learning and ensemble methods, suffer from the black-box problem and remain difficult for clinicians to trust and use [2]. In areas such as maternal health, where model predictions can directly affect outcomes for both mother and child, transparency is not optional. Clinicians need more than just a prediction; they need a clear rationale they can understand and explain. In this context, integrating explainable AI (XAI) into decision support systems is essential, as it can significantly affect clinicians' trust and the extent to which they follow AI-driven recommendations [3].

Gestational diabetes mellitus (GDM) affects a substantial number of pregnancies worldwide and is linked to serious complications such as preeclampsia, macrosomia, neonatal hypoglycaemia, and future type 2 diabetes. Its transient nature and rapid physiological onset during pregnancy create a narrow window for timely risk identification and intervention [4]. In addition, GDM has been associated with adverse pregnancy outcomes including preterm birth, hypertensive disorders, shoulder dystocia, hyperbilirubinemia, stillbirth, and caesarean delivery [5], [6], [7]. Therefore, there is an urgent need for clinically interpretable machine learning methods tailored to GDM patients, so that predictions can be understood and applied meaningfully in practice [8].

Although machine learning (ML) has been widely applied to GDM prediction, many models rely on post-hoc explainability methods such as SHAP (Shapley Additive Explanations) or LIME (Local Interpretable Model-agnostic Explanations). These approaches provide some insight but do so after the model has been trained, treating explanation as a separate process. This separation often limits clinical usefulness, as the reasoning behind predictions may not fully reflect the model's internal decision logic [9], [10]; see Section II for related work and research gap.

To address the dual challenge of predictive performance and interpretability, we previously introduced the Enhanced Interpretability Ensemble (EYE) framework [11]. EYE is a structured methodology that embeds interpretability throughout the model development pipeline, from defining the clinical application and preparing data to selecting base learners, integrating explanation methods, and constructing ensembles that remain transparent by design. Unlike post hoc approaches, EYE aligns interpretability with the model's internal reasoning.

We first implemented this framework in EYE-WD [11], focused on diabetes risk prediction in women, where it achieved competitive performance across multiple datasets while uncovering clinically consistent explanations. This work highlighted the value of building AI systems that capture health patterns shaped by gender-specific factors, ensuring that predictive tools serve populations often overlooked in women's and maternal health research.

Building on this foundation, the present work applies the EYE framework to gestational diabetes mellitus (GDM), a transient but high-risk condition unique to pregnancy, resulting in EYE-GDM. The ensemble integrates Decision Tree (DT), k-Nearest Neighbors (k-NN), and Gradient Boosting (GB) as base learners, combined through a logistic regression (LR) meta-model with SHAP explanations embedded in training. Applied to a dataset of 3,525 pregnancies, EYE-GDM achieved an accuracy of 97.89%, F1-score of 97.90%, precision of 97.47%, recall of 98.33%, and an AUC-ROC of 0.9981. Beyond these results, interpretability analyses produced clinically meaningful insights. Global SHAP patterns revealed thresholds such as elevated risk at BMI values above 25 and OGTT values exceeding 160 mg/dL, while HDL levels above 35 mg/dL were protective. Interactions between features, for example, high BMI with low HDL or multiple pregnancies with elevated blood pressure, revealed clusters of maternal risk factors. Local explanations further traced patient-specific outcomes, distinguishing protective from adverse profiles in a transparent way.

In doing so, this study advances GDM risk assessment and supports the broader goal of developing XAI that can be integrated into real-world maternal-care workflows [12]. By presenting EYE-GDM alongside the earlier EYE-WD implementation, we demonstrate both the flexibility and clinical relevance of the EYE framework and its potential to address critical challenges in women's and maternal health, providing contributions that are meaningful to technical experts and healthcare professionals alike.

The remainder of this study is organized as follows: Section II reviews the related work. Section III provides the methodology. Section IV reports the performance results of EYE-GDM, while Section V provides clinically oriented interpretations, including dataset-specific risk patterns, feature interactions, data-driven thresholds, and patient-level interpretations. Section VI provides a discussion, and Section VII concludes the study with directions for future work.

II. Related Work

GDM has received growing attention from both clinical and computational research communities. In particular, a substantial body of work has applied machine learning techniques to develop predictive models for GDM, aiming to support early diagnosis and timely intervention that can improve maternal and neonatal outcomes. Section II A reviews studies that develop machine learning and deep learning models to identify women at risk of GDM. Section II.B examines a growing body of work on making these predictions understandable to clinicians.

A. Machine Learning and Deep Learning for GDM

Sumathi et al. [13], [14] constructed a GDM dataset, which includes 3,525 pregnant women's data. Using deep learning, they introduced a deep stacked autoencoder based on outlier detection process (OD-DSAE), achieving 96.18% accuracy [13], and later proposed an ensemble voting strategy combining k-nearest neighbours (k-NN), Random Forest (RF), and LR models, reaching 94.24% accuracy [14]. Jader et al. [15] employed an ensemble approach using lab records from Iraq-Kurdistan, achieving 92% accuracy through majority voting with Decision Tree (DT), RF, Support Vector Machine (SVM), k-NN, LR, and Naïve Bayes (NB). Gallardo-Rincón et al. [16] developed and evaluated an Artificial Neural Network (ANN) model, achieving 70.3% accuracy in recognizing women at high risk of developing GDM. This model was based on data from 1,709 pregnant Mexican women who participated in the 'Cuido mi embarazo' study. Zheng et al. [17] collected data on 4,771 Chinese pregnant women from Xinhua Hospital. They applied Multivariate LR using Bayesian inference and achieved an accuracy of 64% and an AUC of 0.766. Shen et al. [18] evaluated several machine learning algorithms, including LR, SVM, RF, AdaBoost, DT, NB, k-NN, XGBoost, and Gradient Boosting Decision Tree (GBDT), to predict GDM in areas with limited resources. The algorithms were trained on 12,304 cases from the First Affiliated Hospital of Jinan University and were validated on 1,655 pregnant patients at the Prince of Wales Hospital. At 0.78 AUC, SVM showed the best performance.

Wu et al. [19] et al. utilized LR, k-NN, SVM, and deep neural network (DNN) for early GDM prediction. They evaluated these machine learning models using data from the International Peace Maternal and Child Health Hospital at Shanghai Jiao Tong University School of Medicine, which included 32,190 pregnant patients. DNN obtained the best AUC of 0.8, followed by LR with an AUC of 0.77. For predicting GDM, Hu et al. [20] utilized and compared between traditional LR method and the XGBoost machine learning model on a total of 925 pregnant women. They demonstrated that XGBoost outperformed LR with an AUC of 0.946 and an accuracy of 87.5%. Through the Japan Environment and Children's Study (JECS), Watanabe et al. [21] gathered GDM data from 82,698 expectant women. They employed LR, SVM, GBDT, and RF for gestational diabetes detection. They demonstrated that GBDT produced the best AUC of 0.74.

Table I summarizes machine learning and deep learning research used to predict women at risk of GDM. The first two columns provide the reference number and a summary of each work. The third column presents the reported performance, while the fourth column records limitations and key observations.

TABLE I. SUMMARY OF WORKS ON GDM PREDICTION

Ref	Work Summary	Performance	Limitations / Observations
[13]	Developed a deep learning model using a stacked autoencoder with outlier detection (OD-DSAE).	Accuracy: 96.18%	• Lack interpretability
[14]	Constructed an ensemble voting model using k-NN, RF, and LR.	Accuracy: 94.24%	
[15]	Trained and evaluated an ensemble of six classifiers (DT, RF, SVM, k-NN, LR, NB) on data from Iraq-Kurdistan using majority voting.	Accuracy: 92%	
[16]	Evaluated the ANN model on data from 1,709 pregnant Mexican women.	Accuracy: 70.3%	• Low performance • Lack interpretability
[17]	Applied Multivariate LR using Bayesian inference on 4,771 Chinese pregnant women from Xinhua Hospital.	Accuracy: 64%, AUC: 0.766	
[18]	Compared nine ML models (LR, SVM, RF, AdaBoost, DT, NB, k-NN, XGBoost, and GBDT) trained on 12,304 cases and were validated on 1,655 pregnant patients.	AUC: 0.78 (SVM best)	
[19]	Evaluated LR, k-NN, SVM, and DNN on the Shanghai dataset (32,190 pregnant patients).	AUC: 0.8 (DNN best)	• Moderate performance • Lack interpretability
[20]	Compared LR and XGBoost on 925 pregnant women.	Accuracy: 87.5% (XGB best)	
[21]	Assessed a large-scale Japanese cohort (82,698 pregnant women) with four models LR, SVM, GBDT, and RF.	AUC: 0.74 (GBDT best)	• Low performance • Lack interpretability

B. Explainability and Interpretability in GDM Prediction

Despite these advances in predictive performance, most previous works did not incorporate interpretability into their predictive models. To the best of our knowledge, only a limited number of studies have explicitly integrated explainability. For instance, Du et al. [22] applied SHAP with multiple machine learning models (AdaBoost, LR, SVM, RF, XGBoost) and used Synthetic Minority Oversampling (SMOTE) to balance the data. They reported an accuracy of 76.1%, with SVM performing the best. Khanna et al. [23] evaluated several machine learning pipelines and data balancing strategies for GDM prediction, where a stacking ensemble trained on SMOTE-ENN (Synthetic Minority Oversampling using Edited Nearest Neighbour) data achieved the best performance with an accuracy of 96% and an AUC of 0.96. They applied five post-hoc methods, including SHAP, LIME, ELI5, Qlattice, and Anchor, which confirmed the links between visceral fat levels, the child's birth weight, and GDM.

Zaky et al. [24] explored a range of algorithms, from traditional models such as LR and DT to advanced ensembles such as RF, Gradient Boosting (GB), CatBoost, XGBoost, and LightGBM, and then combined them in a stacking framework with LR as the meta-classifier. The stacked model trained on 26 selected features gave the best results with an accuracy of 88.8%, outperforming all individual models. SHAP was applied as a post-hoc tool to interpret predictions and highlight key biomarkers. While these contributions have advanced GDM prediction, they largely treat explainability as an afterthought rather than a property embedded within the model itself.

Table II summarizes prior works on GDM prediction that incorporate explainability or interpretability. Column 1 lists the reference; Column 2 summarizes the work; Column 3 reports performance metrics; Column 4 notes limitations and observations.

C. Research Gap

Nevertheless, the studies that do incorporate explainability rely mainly on post-hoc methods such as SHAP and LIME, applied only after the model has been trained. While these approaches offer valuable insights, they do not influence the model's internal structure or learning process, so interpretability remains an add-on rather than a built-in property.

Our overarching aim is to deliver accurate and transparent decision support in high-stakes domains by embedding interpretability across the full modelling workflow, aligning design and evaluation with stakeholder requirements to strengthen accountability, and enabling real-world use without sacrificing predictive performance. We previously introduced the FIXAIH framework [25], which articulates six well-defined design priorities to guide the development of trustworthy, interpretable AI for healthcare. Within this vision, we also proposed the EYE framework [11], which operationalizes selected FIXAIH priorities into a concrete architecture, providing interpretability by design, clinical validation, and transparent model development. We initially implemented EYE for diabetes risk in women (EYE-WD).

In this work, we extend EYE to GDM and refer to this implementation as EYE-GDM. Our approach integrates SHAP within the training pipeline, combining base-model outputs via meta-model weights to produce both local and global explanations that reflect the model's internal structure and how predictions are formed, while maintaining strong predictive performance by employing top-performing base learners during model construction. This work improves GDM risk assessment while contributing to the wider aim of building XAI systems suitable for integration into routine maternal-care workflows.

TABLE II. SUMMARY OF RELATED WORKS ON GDM PREDICTION INCORPORATING EXPLAINABILITY

Ref	Work Summary	Performance	Limitations / Observations
[22]	Applied SHAP with multiple ML models: AdaBoost, LR, SVM, RF, and XGBoost with SVM performing the best.	Accuracy: 76.1%	Post-hoc explainability only; not embedded
[23]	Evaluated multiple ML pipelines and data balancing strategies. A stacking ensemble trained on SMOTE-ENN gave the best results. SHAP, LIME, ELI5, Qlattice, and Anchor were applied to interpret results.	Accuracy: 96%, AUC: 0.96	
[24]	Explored a wide range of ML models (LR, DT, NB, RF, GB, CatBoost, XGBoost, LIGHTGBM), combined in a stacking framework with LR as meta-classifier. SHAP was used to explain predictions and rank biomarkers.	Accuracy: 88.8%	
EYE-GDM	Constructed an interpretable ensemble using EYE framework, integrating top-performing base learners, SHAP tool, and LR as meta-model. SHAP is applied internally during training, combining base learner outputs via meta-model weights to generate explanations.	Accuracy: 97.89%, AUC: 0.99	• Implementation of EYE framework • Embedded interpretability • Competitive performance

III. METHODOLOGY AND DESIGN

In this section, we present the methodology and design of the EYE-GDM system. Owing to space limitations, only a summary is provided here. A detailed description of the methodology, the EYE framework, and its initial implementation in EYE-WD can be found in [11]. EYE-GDM builds upon this foundation by extending the EYE framework into a domain-specific configuration tailored for gestational diabetes. The methodological refinements include optimizing the selection of ensemble base learners for pregnancy-related data characteristics, applying explanation-weighted meta-learning to integrate model reasoning with prediction, and aligning interpretability evaluation with pregnancy-specific clinical variables and thresholds. These adaptations expand the framework's methodological scope while preserving its interpretability-by-design foundation. Fig. 1 shows the architecture of the EYE-GDM system, which consists of eight components.

The Application Selection (APS) targets GDM risk prediction. In Data Preparation and Management (DPM), we use a publicly available dataset of 3,525 patients described by 15 clinical and demographic features, labelled into two classes: 2,153 non-GDM and 1,372 GDM cases. The dataset was collected by researchers at SASTRA Deemed to be University, Kumbakonam, Tamil Nadu, India, in collaboration with a consultant obstetrician and gynaecologist from Anbu Hospital and Nalam Clinic. It is publicly available on Kaggle under the CC BY-NC-SA 4.0 license [26] and was previously used in [13] and [14] to develop and evaluate GDM prediction models. The features are Age, Body Mass Index (BMI), Hemoglobin, Systolic Blood Pressure (Sys BP), Diastolic Blood Pressure (Dia BP), Oral Glucose Tolerance Test (OGTT), Prediabetes, Polycystic Ovary Syndrome (PCOS), Family History, Sedentary Lifestyle, Number of Pregnancies, Large Child or Birth Defect, Gestation in Previous Pregnancy, Unexplained Prenatal Loss, and High-Density Lipoprotein (HDL) (see Table III). All features are continuous or binary (0/1); binaries use 0 for absence and 1 for presence. We apply class-wise imputation for missing values, treat outliers using interquartile range (IQR) rules, scale features, and create a stratified train-test split to preserve class distribution.

Base-Model Evaluation and Selection (BMES) evaluates LR, Ridge Classifier (RC), DT, k-NN, NB, RF, AdaBoost, GB, Histogram Gradient Boost (HGB), and XGBoost on the training split using stratified k-fold cross-validation with hyperparameter tuning. We record AUC-ROC, F1-score, precision, recall, and accuracy, then select the top-performing models as the base learners for EYE-GDM.

Interpretable Meta-Model Selection (IM2S) uses LR as the stack combiner because it provides readable coefficients, well-calibrated probability scores, and efficient training and inference [27]. Explainability Tool Selection (XTS) adopts SHAP since it is model-agnostic, grounded in game-theoretic principles, supports dataset-level and patient-level views, and explains how features move a prediction from a baseline [28], [29].

TABLE III. DESCRIPTION OF FEATURES IN GDM DATASET

Feature	Description
Age	Maternal age at time of pregnancy
BMI	Body Mass Index
Hemoglobin	Hemoglobin level
Sys BP	Systolic Blood Pressure
Dia BP	Diastolic Blood Pressure
OGTT	Oral Glucose Tolerance Test result
Prediabetes	History of prediabetes
PCOS	Polycystic Ovary Syndrome diagnosis
Family History	Family history of diabetes
Sedentary Lifestyle	Lack of regular physical activity
No of Pregnancy	Number of prior pregnancies
Large Child or Birth Default	Previous large baby or complicated delivery
Gestation in Previous Pregnancy	Prior gestational diabetes or complications
Unexplained prenatal loss	History of miscarriage or fetal loss without known cause
HDL	High-Density Lipoprotein cholesterol

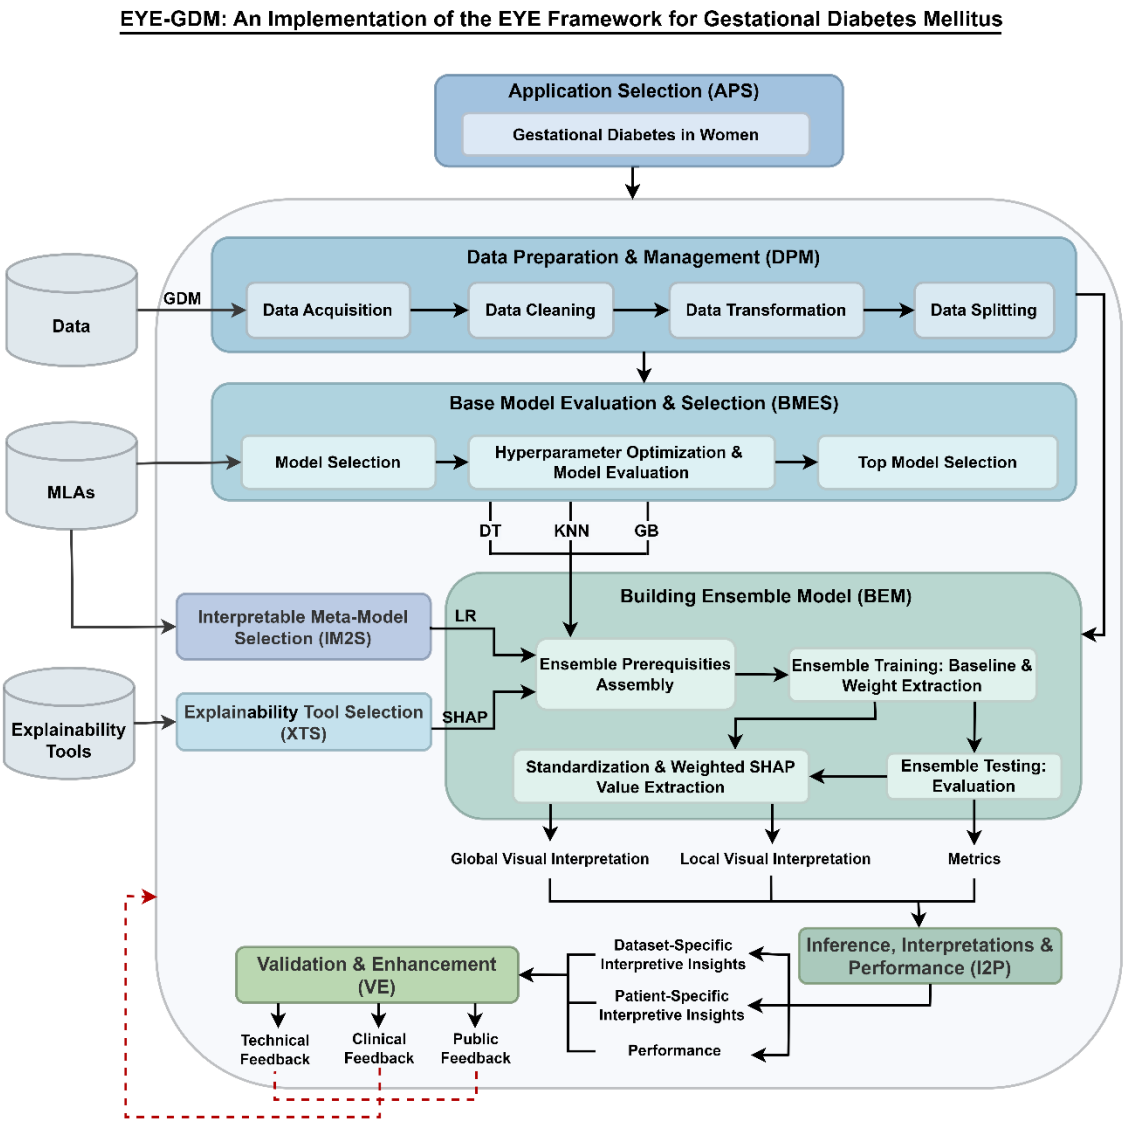

Fig. 1. The EYE-GDM System: An implementation of the EYE framework for gestational diabetes.

Building the Ensemble (BEM) constructs the interpretable ensemble. During training, each base learner yields SHAP values and expected values. We standardize these values to make magnitudes comparable, then form a single explanation by weighing each model's SHAP vector with the learned LR coefficients. This produces consolidated local and global explanations aligned with the ensemble's decision rule. Within BEM, these explanations are rendered as SHAP summary plots (global interpretations), dependence plots (pairwise effects and thresholds), and waterfall plots (patient-level breakdown).

Inference, Interpretation, and Performance (I2P) uses these plots and prediction scores to deliver clinically relevant, fused explanations at both patient and dataset levels, clarifying which factors raise or lower risk, identifying data-driven thresholds, and characterizing feature interactions. Validation and Enhancement (VE) validates both technical and clinical outcomes: technical validation benchmarks performance against prior studies and includes review by technical experts, while clinical validation is conducted by clinical experts to assess alignment with medical standards. Their evaluation focused on adherence to medical knowledge, consistency with clinical practice, validity of diagnostic reasoning, clarity of explanations, and recommendations for improvement. Accepted adjustments are then applied and re-tested on the held-out split.

IV. EYE-GDM: Results

In this section, we present results from the BMES component, which evaluates multiple ML algorithms to identify the top-performing base learners for constructing EYE-GDM. Fig. 2 shows performance across five metrics (accuracy, F1, precision, recall, and AUC-ROC). DT, k-NN, and GB achieved the highest accuracies, with AUC-ROC values around 0.98, indicating clear separation between diabetic and non-diabetic cases. These three models were therefore selected as the ensemble's base learners. During the training phase, the LR meta-model determined contribution weights for each base

learner according to its influence on the overall ensemble output. The resulting coefficients were 6.96 for DT, 1.86 for k-NN, and 0.77 for GB, reflecting their relative influence in the final prediction. These weights were then applied to combine the base learners' explanation outputs, ensuring that the ensemble's interpretability aligns with its internal decision logic.

We evaluated EYE-GDM on the GDM dataset and compared its predictive performance with prior works that used the same data. As shown in Table IV, the reference models achieved accuracies of 96.18% [13] and 94.24% [14]. However, those studies reported only performance and did not provide interpretability or clinical explanations. In contrast, EYE-GDM achieved an accuracy of 97.89%, an F1-score of 97.90%, a precision of 97.47%, a recall of 98.33%, and an AUC-ROC of 0.9981. These results highlight that the framework shows competitive performance compared to previously reported baselines in predictive reliability. More importantly, it does so while also offering transparent and clinically meaningful explanations of its predictions, which prior models lacked. This dual capability of competitive performance and interpretability forms the basis for the subsequent analysis of GDM risk factors.

	Accuracy	F1-Score	Precision	Recall	AUC-ROC
LR	0.9698	0.9614	0.9545	0.9684	0.9884
RC	0.9603	0.9489	0.9512	0.9466	0.9808
DT	0.9802	0.9751	0.9536	0.9976	0.9985
KNN	0.9735	0.9671	0.9384	0.9976	0.9874
NB	0.9650	0.9558	0.9412	0.9709	0.9815
RF	0.9688	0.9614	0.9278	0.9976	0.9833
AdaBoost	0.9716	0.9645	0.9401	0.9903	0.9964
GB	0.9754	0.9692	0.9468	0.9927	0.9979
HGB	0.9707	0.9631	0.9461	0.9806	0.9974
XGBoost	0.9707	0.9632	0.9420	0.9854	0.9975

Fig. 2. Performance comparison across candidate base learners.

TABLE IV. PERFORMANCE COMPARISON OF EYE-GDM AGAINST PRIOR STUDIES ON THE SAME DATASET

Work	Accuracy	F1-score	Precision	Recall	AUC-ROC
[13]	0.9618	0.9741	0.9617	0.9869	-
[14]	0.9424	0.9400	0.9400	0.9400	-
EYE-GDM	0.9789	0.9790	0.9747	0.9833	0.9981

V. EYE-GDM: CLINICAL INTERPRETATIONS

In this section, we provide interpretations at both the dataset-specific and the individual patient-specific, alongside an analysis of feature interactions and dataset-specific thresholds. Different datasets, representing distinct populations, may yield unique thresholds influenced by lifestyle and other population-specific factors [30]. Therefore, the thresholds identified here should be regarded as dataset-specific, and validation across different populations is necessary. In Section V A, we use a SHAP summary plot to interpret global feature contributions to GDM risk prediction, thereby identifying dataset-specific interpretations. SHAP dependence plots are then applied in Section V B to capture feature interactions and define dataset-specific thresholds. Finally, in Section V C, we illustrate patient-level interpretation by selecting a representative patient case and applying a SHAP waterfall plot. In these SHAP plots, positive SHAP values indicate a higher likelihood of GDM, whereas negative SHAP values reflect a lower predicted risk.

A. Dataset-Specific Interpretations

The SHAP summary plot (Fig. 3) illustrates the global feature contributions to GDM risk predictions across the dataset. It offers a compact view of how feature values shift the prediction toward or away from GDM for all patients. The y-axis lists features, while the x-axis shows SHAP values, which represent a feature's impact on the model output for each case: positive values push the prediction toward GDM, negative values toward non-GDM, and values farther from zero indicate stronger effects. Each dot corresponds to one patient's contribution for that feature. Dot color encodes the raw feature value for that patient, with blue indicating low values and red indicating high values as shown in the legend. When red points cluster on the positive side, higher feature values are associated with higher predicted risk; when red points cluster on the negative side, higher values are associated with lower predicted risk; mixed colors on both sides suggest non-linear or context-dependent effects.

From a general health perspective, higher BMI continues to exhibit a strong and consistent positive SHAP trend, confirming that elevated adiposity contributes directly to higher GDM risk. In contrast, maternal age presents a less uniform pattern: while younger age values tend to cluster around zero and negative SHAP values (indicating lower predicted risk), older age values are associated with a wider SHAP range, suggesting that age may either increase or decrease risk depending on the presence of co-occurring factors such as BMI or blood pressure. Higher Hemoglobin levels are associated with increased predicted GDM risk, whereas moderate and lower levels generally correspond to lower SHAP values, indicating reduced model-predicted risk.

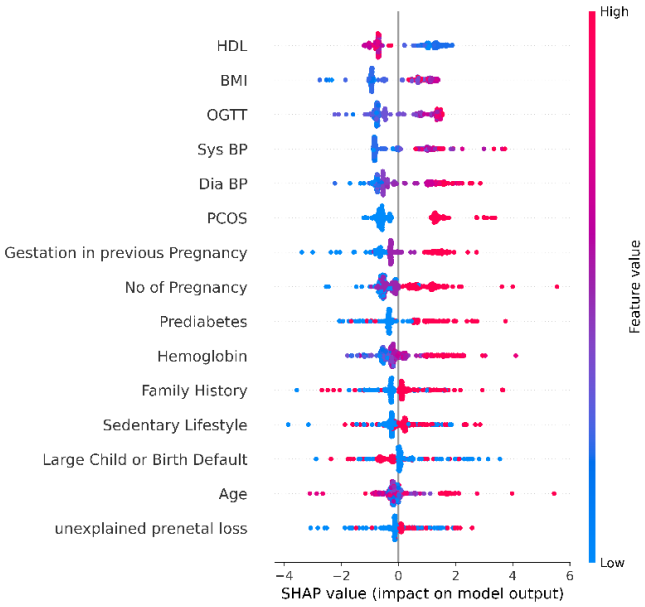

Fig. 3. SHAP summary plot.

For cardiovascular status, both Sys BP and Dia BP display positive SHAP values at elevated readings, indicating that hypertensive disorders in pregnancy often co-occur with insulin resistance and elevated GDM risk. From a metabolic and endocrine perspective, elevated OGTT values substantially increase the predicted risk of GDM. Similarly, the presence of PCOS contributes strong positive SHAP values, indicating higher risk. In contrast, HDL shows a clear inverse association, where lower levels correspond to an increased likelihood of GDM.

Features related to obstetric and reproductive history include Gestation in Previous Pregnancy and Number of Pregnancies, both of which tend to show positive contributions at higher values. A positive history of Unexplained Prenatal Loss is also associated with increased predicted risk. In contrast, Large Child or Birth Default exhibits a more ambiguous pattern, with both its presence and absence producing mixed SHAP contributions. This suggests a feature interaction, where the model may shift predictive importance to other highly correlated variables, such as BMI, maternal age, or parity, thereby diminishing the apparent effect of this obstetric factor.

Finally, Prediabetes, Family History and Sedentary Lifestyle show SHAP patterns where their presence typically contributes to a higher predicted risk of GDM. However, in a small number of cases, even when these risk factors are present, they are linked to lower SHAP values (lower GDM risk), likely due to the dominant influence of other protective factors or interactions that offset their individual impact.

B. Factor Interactions and Dataset-Specific Thresholds

This subsection highlights how clinical and obstetric factors interact to shape the model's GDM risk predictions. SHAP dependence plots (Fig. 4 to Fig. 18) show how the effect of one feature varies with another's value and surface the strongest interactions, helping to spot practical thresholds and non-linear links useful for clinical review. In each plot, the x-axis is the primary feature value, the y-axis is its SHAP value (its contribution to predicted risk), each point is a single case, and a blue-to-red color scale encodes the value of a second interacting feature. Read together, these plots clarify combined patterns such as high BMI with low HDL, or multiple pregnancies with elevated blood pressure, that contribute to higher predicted risk and are expressed in familiar clinical terms to support decision-making.

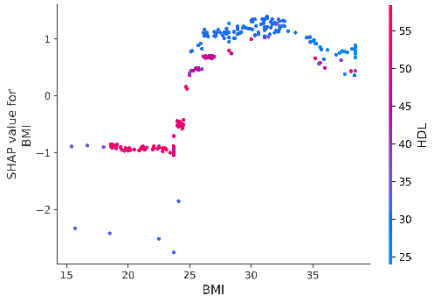

Fig. 4. SHAP dependence plot (BMI & HDL).

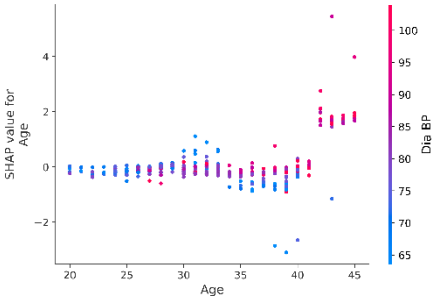

Fig. 5. SHAP dependence plot (Age & Dia BP).

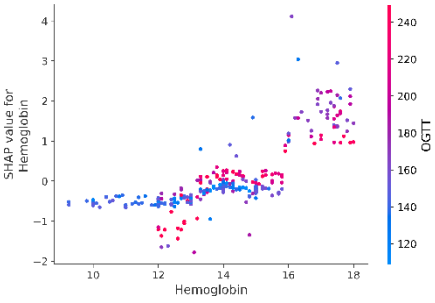

Fig. 6. SHAP dependence plot (Hemoglobin & OGTT).

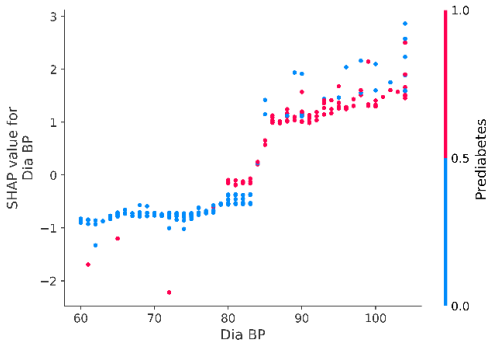

Fig. 7. SHAP dependence plot (Dia BP & Prediabetes).

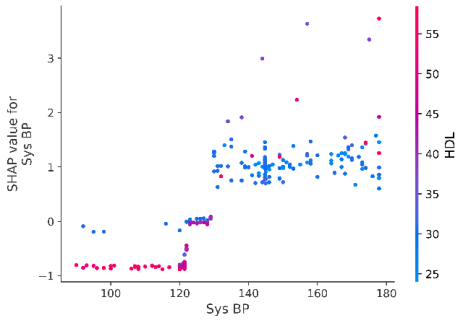

Fig. 8. SHAP dependence plot (Sys BP & HDL).

In Fig. 4, BMI shows a clear threshold around 25. Below this value, SHAP contributions are typically negative, often accompanied by high HDL levels, indicating lower risk. Beyond 25, SHAP values rise sharply, especially in individuals with low HDL. For Maternal Age (Fig. 5), younger women tend to have neutral or slightly negative SHAP values, whereas women above 40 years consistently show positive contributions and are associated with elevated Dia BP. In Fig. 6, Hemoglobin contributes positively to GDM risk between 13 and 16 g/dL, but only when OGTT values are elevated, whereas lower OGTT levels are linked to reduced risk. At levels above 16 g/dL, Hemoglobin consistently shows positive contributions to GDM risk and is associated with high OGTT values. This pattern is important and may be explained by physiological changes such as increased blood viscosity [31], indicating that both factors are likely working together rather than high Hemoglobin level alone.

In the cardiovascular domain, both Dia BP and Sys BP exhibit clear threshold behaviour. Fig. 7 illustrates that Dia BP values above 85 mmHg are associated with positive SHAP contributions, particularly in individuals with prediabetes, whereas values below 80 mmHg in the absence of prediabetes indicate lower risk. Similarly, Fig. 8 shows that Sys BP contributes to higher risk beyond 130 mmHg, with stronger effects observed in patients with low HDL. In contrast, values below 120 mmHg combined with high HDL levels are generally linked to lower risk.

Among metabolic and endocrine features, Fig. 9 shows that OGTT values rise sharply in SHAP contributions beyond 160 mg/dL, particularly in patients with high Sys BP, whereas values below 150 mg/dL are considered protective. In Fig. 10, PCOS consistently contributes to higher predicted risk when present, with its effect being stronger in individuals with high BMI. Fig. 11 illustrates that HDL values below 35 mg/dL are associated with increased risk, especially in women with prior gestations, while values above 35 mg/dL correspond to protective SHAP contributions. This pattern suggests that HDL remains a reliable marker of metabolic health, regardless of gestational history.

Obstetric and reproductive history features show interpretable patterns. Fig. 12 illustrates that Gestation in Previous Pregnancy contributes positively when equal to or greater than two, particularly in patients with elevated Dia BP. Fig. 13 shows that Number of Pregnancies follows a similar upward trend, with risk increasing beyond three. Fig. 14 indicates that Unexplained Prenatal Loss, when present, raises the probability of GDM, although its absence does not necessarily imply low risk. Fig. 15 demonstrates that Prediabetes, when combined with high BMI, is linked to higher GDM risk, whereas its absence together with low BMI is associated with reduced risk.

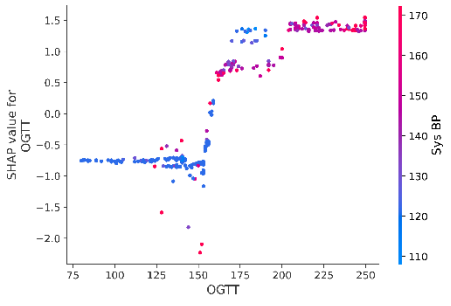

Fig. 9. SHAP dependence plot (OGTT & Sys BP).

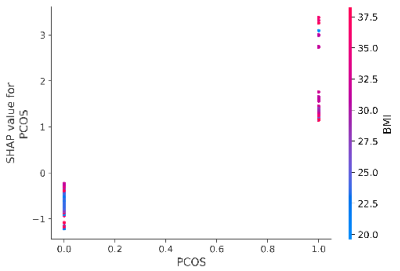

Fig. 10. SHAP dependence plot (PCOS & BMI).

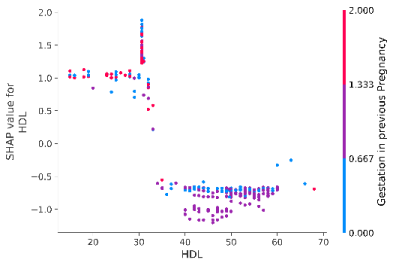

Fig. 11. SHAP dependence plot (HDL & gestation in previous pregnancy).

In contrast, Fig. 16 to Fig. 18 (Large Child or Birth Default, Family History, and Sedentary Lifestyle) show less consistent behavior. Their SHAP contributions vary widely, suggesting that their predictive influence may be partly absorbed by stronger correlated factors.

Collectively, these dependence plots reveal that individual factors influence risk through threshold effects and interaction with other variables. They reinforce clinical understanding of GDM risk while offering finer-grained, data-driven insight into how multiple features combine to shape the model's predictions. Table V summarizes these insights by aligning the data-derived thresholds from SHAP analysis with established clinical reference ranges, highlighting key feature interactions and their associated GDM risk. This comparative view helps contextualize model behavior against known medical standards, reinforcing the interpretability and clinical relevance of EYE-GDM results.

TABLE V. DATASET-DERIVED THRESHOLDS, INTERACTING FACTORS, AND CLINICAL NORMAL RANGES FOR KEY GDM PREDICTORS

Feature	Clinical Cutoff / Normal Range	Data-driven Threshold	Interacts with	GDM Risk
BMI	18.5–24.9 kg/m² [32], [33]	> 25	Low HDL	High
		< 25	High HDL	Low
Age	-	> 40 years	High Dia BP	High
Hemoglobin	12-16 g/dL [34]	13-16 g/dL	High OGTT	
		> 16 g/dL	-	
Dia BP	< 80 mmHg (normal), 80-89 mmHg (Stage 1 hypertension), ≥ 90 mmHg (Stage 2 hypertension) [35]	> 85 mmHg	Prediabetes Presence	
		< 80 mmHg	Prediabetes Absence	Low
Sys BP	< 120 mmHg (normal), 120-129 mmHg (elevated), 130-139 mmHg (Stage 1 hypertension), ≥ 140 mmHg (Stage 2 hypertension) [35]	> 130 mmHg	Low HDL	High
		< 120 mmHg	High HDL	Low
OGTT	75-g 2-h: <153 mg/dL [32]	> 160 mg/dL	High Sys BP	High
		< 150 mg/dL	-	Low
PCOS	-	Presence	High BMI	High
HDL	50-80 mg/dL (women) [36]	< 35 mg/dL	Gestational History	
		> 35 mg/dL	-	Low
Gestation in Previous Pregnancy	-	≥ 2	High Dia BP	High
No of Pregnancies	-	≥ 3	-	
Unexplained Prenatal Loss	-	Presence	-	
Prediabetes	-	Presence	High BMI	

C. Patient-Specific Interpretations

To complement the global insights, we examine the model's local reasoning with SHAP waterfall plots. A waterfall plot (Fig. 19) decomposes one patient's prediction by starting at the baseline E[f(x)] (the model's expected output over the training background) and then applying each feature's SHAP contribution in sequence until it reaches the patient's final prediction f(x). The x-axis represents the model output scale, so movement to the right increases the prediction and movement to the left decreases it; the y-axis lists the patient's features with their observed values. Bars show the size and direction of each contribution, with red increasing risk and blue decreasing risk.

For this patient, a 24-year-old woman with BMI 23.69 and no sedentary lifestyle, PCOS, prediabetes, or family history (see Table VI), the predicted probability of GDM is f(x) = 0.001, well below the dataset baseline E[f(x)] = 0.612, indicating a low-risk profile. The model arrives at this result through several negative contributions: the absence of unexplained prenatal loss (−0.09), BMI below 25, systolic blood pressure 117 mmHg (below 130 mmHg), and OGTT 140.32 mg/dL (below clinical and data-driven thresholds). Additional decreases come from HDL 53 mg/dL (above threshold) and diastolic blood pressure 80 mmHg (below 85 mmHg).

Her parity of two is below the higher-risk cutoff of three, and the absence of PCOS further reduces risk. Although hemoglobin is 9.8 g/dL, which is below the range where positive SHAP effects were observed in this dataset (>16 g/dL), it does not raise predicted GDM risk here; however, it remains clinically low and may warrant separate attention during pregnancy.

This case is consistent with the data-driven thresholds that we presented earlier in Table V: none of her values exceed the risk cutoffs, and several interacting protective features (such as high HDL, normal blood pressure, and OGTT below threshold) contribute cumulatively to a low-risk prediction. This case highlights how the model synthesizes individual-level clinical factors to make well-reasoned predictions. It also demonstrates SHAP's utility in explaining not only high-risk cases but also in identifying low-risk profiles by tracing the impact of protective factors.

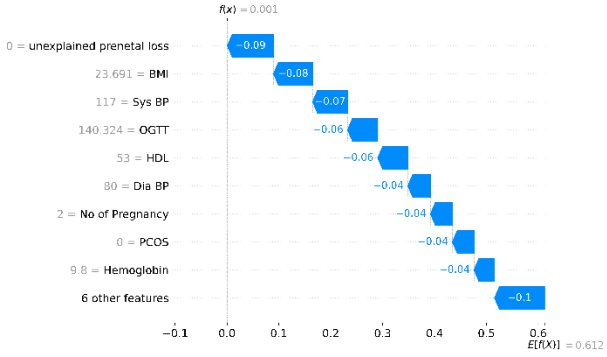

Fig. 19. SHAP waterfall plot for a representative patient.

TABLE VI. PATIENT-LEVEL FEATURE VALUES FOR LOCAL EXPLANATION

Feature	Value
Age	24
No. of Pregnancy	2
Gestation in previous pregnancy	None
BMI	23.96
HDL	53
Family History	None
Unexplained prenatal loss	None
Large Child or Birth Default	None
PCOS	None
Sys BP	117
Dia BP	80
OGTT	140.32
Hemoglobin	9.8
Sedentary Lifestyle	None
Prediabetes	None

VI. Discussion

This work demonstrates how interpretable ensemble modelling, implemented via the EYE-GDM system, can support risk prediction in the context of GDM. We specifically selected GDM as the application focus for several reasons. First, GDM presents a clinically significant yet temporally constrained condition, with substantial risks for both mother and infant, including preeclampsia, macrosomia, neonatal hypoglycaemia, and long-term progression to type 2 diabetes [4]. Its transient onset during pregnancy necessitates timely and explainable risk assessments that clinicians can trust.

From a scientific perspective, the contributions of this work lie in the methodological refinements introduced in EYE-GDM, including the reconfigured ensemble structure, the explanation-weighted meta-learning approach, and the domain-aligned interpretability evaluation. These represent technical extensions of the EYE framework. The applied contribution lies in demonstrating these methodological advances within the maternal health domain, where EYE-GDM provides clinically interpretable risk assessments, data-driven thresholds, and patient-level insights specific to gestational diabetes.

EYE-GDM supports interpretation at both the dataset and patient levels. At the dataset level, SHAP summary plots and dependence plots allow for the identification of global risk patterns, data-driven thresholds, and feature interactions. These insights capture not only the individual impact of clinical features but also how their interactions influence GDM risk. Such results can inform strategic clinical guidelines, such as refining screening protocols for high-risk groups. In contrast, patient-level explanations, visualized through SHAP waterfall plots, help clinicians understand why a specific patient is predicted to be at risk, thereby supporting individualized intervention planning. Together, these interpretation levels enhance the model's clinical utility and support population-level decision-making and personalized care.

The predictive performance of EYE-GDM is competitive, achieving an accuracy of 0.9789, an F1-score of 0.9790, a precision of 0.9747, a recall of 0.9833, and an AUC-ROC of 0.9981. These results outperform previously reported models on the same dataset while simultaneously offering transparent explanations. Compared with conventional ensemble or deep-learning models used for GDM prediction, EYE-GDM provides distinct advantages by integrating interpretability directly within the training process rather than applying it as a separate post-hoc step. This ensures that explanations remain consistent with the ensemble's internal reasoning. In addition, the model combines global and patient-level reasoning within a single framework, enabling both population insights and individual clinical interpretation, which is rarely achieved by previous methods. Furthermore, incorporating expert clinical feedback during validation strengthens the model's credibility and aligns its explanations with real-world diagnostic reasoning and clinical practice.

More importantly, the interpretations derived from SHAP analysis are well-aligned with established medical knowledge, confirming the validity of the model's outputs. SHAP values for Age increase after 40, consistent with the clinical evidence that advanced maternal age is a GDM risk factor [37], [38]. Risk rises significantly for BMI values above 25, aligning with WHO thresholds for overweight [32], [33]. OGTT values show a sharp SHAP increase beyond 160 mg/dL, supporting diagnostic thresholds for impaired glucose tolerance [32]. Hemoglobin contributes to risk in the 13–16 g/dL range only when OGTT is also elevated, underscoring the need to interpret it contextually. HDL levels above 35 mg/dL exhibit protective SHAP values, matching its known cardiometabolic role [36]. Similarly, Sys BP starts contributing to higher risk beyond 130 mmHg, with stronger effects in patients who have low HDL. This pattern reflects the well-known clustering of high blood pressure, abnormal lipids, and elevated glucose seen in metabolic syndrome [39]. Prediabetes and PCOS both contribute positively to GDM risk, consistent with medical literature [40], [41]. Finally, obstetric history factors such as prior gestation with complications and a higher number of pregnancies display threshold-based patterns, reinforcing their importance in GDM prognosis [42], [43].

The interpretability results revealed clinically consistent yet subtle patterns. Interactions such as BMI with HDL and blood pressure with metabolic indicators showed that GDM risk emerges from the combined effects of metabolic and cardiovascular factors rather than single predictors. The model also identified context-dependent relationships, where certain features influence risk only in combination with others, reflecting the complexity of gestational physiology. The close alignment between model-derived thresholds (BMI 25 kg/m², Dia BP 85 mmHg, Sys BP 130 mmHg) and established reference ranges supports the clinical credibility of EYE-GDM outputs. These findings illustrate how interpretable AI can mirror clinical reasoning in maternal health, providing insights that clarify how metabolic, cardiovascular, and obstetric factors interact to shape individual risk. In practice, the identified thresholds can inform more targeted antenatal screening and help refine early intervention strategies for high-risk patients. The variability observed in lifestyle and family-history features highlights the need for broader, standardized datasets to enhance robustness and ensure the generalizability of model insights across populations.

Clinician validation further reinforced these interpretations. The clinicians confirmed that the model's predictions were consistent with established GDM risk factors and reflected the multifactorial nature of clinical practice, where risk factors interact rather than act independently. They noted, however, that hemoglobin alone is not an independent risk factor for GDM, whereas HbA1c is a more reliable predictor. The observed association between elevated hemoglobin levels and higher OGTT values in this dataset was considered important, potentially reflecting physiological mechanisms such as increased blood viscosity [31], suggesting that these factors act in combination rather than through hemoglobin alone. The clinicians also emphasized the need for clearer dataset documentation and recommended involving clinical experts in the data collection process to ensure the inclusion of key GDM biomarkers, such as HbA1c and different OGTT test types. The validation was regarded as valuable both for strengthening trust and for guiding iterative refinement.

While the model showed strong alignment with clinical reasoning, certain limitations remain. This work extends prior

validation of the EYE framework (EYE-WD) to a distinct clinical population, demonstrating its adaptability across domains. However, because the dataset represents a single regional population, sociocultural and healthcare-access factors that influence screening and diagnosis may have affected model behavior. Future work will focus on validating the model across multi-centre and demographically diverse GDM cohorts as such datasets become available.

The results of this work highlight the importance of embedding interpretability directly into model design for maternal healthcare. EYE-GDM demonstrates how interpretable models can uncover clinically relevant patterns that align with established medical knowledge, advancing maternal health AI by combining high predictive accuracy with clinically grounded explanations.

VII. Conclusion and Future Work

EYE-GDM, an implementation of the EYE framework for gestational diabetes risk prediction, delivers strong predictive performance together with clinically meaningful and interpretable outputs. It directly addresses two long-standing gaps in prior work: the tendency to prioritize predictive accuracy without producing explanations that clinicians can apply, and the reliance on post-hoc interpretability methods that fail to capture how models reason internally. By embedding SHAP explanations into the training pipeline, EYE-GDM ensures that each base learner is explained individually and that their contributions are integrated through logistic regression weights, producing ensemble-level reasoning consistent with the model's internal decision logic.

EYE-GDM achieved competitive results, surpassing earlier reports on the same dataset. More importantly, its interpretable outputs were consistent with established medical knowledge, showing that the framework can provide reliable risk prediction while also generating explanations of practical value in maternal care. This combination strengthens confidence in the system as a tool that clinicians can trust.

Beyond its technical contributions, EYE-GDM advances the field of explainable healthcare AI by demonstrating how interpretability can be embedded throughout the model development process rather than appended after training. This integration shifts explainability from a diagnostic tool to a design principle, enabling models that reason transparently while maintaining predictive strength. Within maternal health, EYE-GDM illustrates how such integration can transform complex risk prediction into a clinically meaningful, trust-enhancing process, setting a foundation for future interpretable systems across other sensitive domains.

Future work will continue engagement with clinical experts to refine interpretability outputs and ensure their clarity in practice. Additional directions include extending the framework to other healthcare conditions where interpretability is essential, optimizing it for real-time deployment, and evaluating its performance across diverse populations.

The EYE framework builds on our earlier FIXAIH roadmap, which set out six design priorities for developing trustworthy and interpretable AI in healthcare. While FIXAIH defines high-level goals, EYE operationalizes selected elements into a structured and testable framework centered on interpretability by design, transparent development, and clinical validation. EYE-GDM demonstrates how these principles can be applied in maternal health, while EYE-WD shows their application in women's diabetes. Together, these implementations highlight how domain-specific frameworks can serve as practical steps toward the broader FIXAIH vision, linking conceptual guidance with deployment-ready systems that advance clinical care while maintaining transparency and trust.

Information Technology-Faculty of Digital Technology, Chiangrai Rajabhat University, Thailand[1, 2, 3]
Computer Science-Faculty of Digital Technology, Chiangrai Rajabhat University Dept., Thailand[4]

***Abstract*—Office Syndrome, a musculoskeletal disorder prevalent among office workers, poses significant risks to health, productivity, and quality of life. Traditional preventive approaches, such as ergonomic guidelines and reminder-based systems, often fail due to limited user adherence and practicality. To address this gap, this study developed an intelligent platform that integrates MediaPipe and computer vision to monitor sitting posture, eye-to-screen distance, and sitting duration in real time. The system provides automated notifications and stretching recommendations, combining detection, feedback, and behavioral intervention into a sensor-free and cost-effective solution. The platform was evaluated in terms of technical performance and user behavioral impact. Results demonstrated high system accuracy, with the eye-distance detection module achieving 95.2% accuracy, followed by long sitting alerts (92.5%) and proximity alerts (90.1%). User evaluations confirmed that real-time notifications increased awareness and encouraged healthier working behaviors. These findings highlight the potential of computer vision based approaches for ergonomic health promotion. The proposed platform contributes not only to preventive strategies for Office Syndrome but also to advancing user-centered, technology-driven health solutions adaptable to both office and remote work environments. This study not only demonstrates technical performance but also introduces a novel integration of Media Pipe based posture and facial detection with behavioral modification features, which previous ergonomic systems have not addressed. The proposed framework contributes a new perspective for integrating real time feedback with computer vision in promoting sustainable ergonomic behavior.**

Keywords*—*Office syndrome; computer vision; MediaPipe; behavior modification, ergonomics

I. Introduction

The rapid transformation of global economies and technological advancements in the 21st century has significantly reshaped working patterns, particularly among office workers who spend extended hours in front of computer screens. One of the major health consequences of this lifestyle is Office Syndrome, a musculoskeletal disorder resulting from prolonged static postures, repetitive movements, and the overuse of specific muscle groups. This condition not only causes discomfort but has also emerged as a public health issue that adversely affects work performance, quality of life, and healthcare costs [1], [2].

Recent studies have shown that over 70% of office workers worldwide report musculoskeletal discomfort, particularly in the neck, back, and shoulders, and these numbers are continuously increasing due to the widespread adoption of remote and hybrid working models [3], [4]. In Thailand, the Department of Disease Control reported that more than 60% of the working-age population suffers from Office Syndrome, especially individuals between 30–44 years old, with a rising annual trend of approximately 10% [5]. These statistics highlight the urgency of preventive solutions that are both accessible and adaptable to modern working environments.

Although ergonomic guidelines and workplace exercise programs have been promoted for decades, evidence indicates that long-term adherence remains limited. For instance, interventions that rely solely on user self-discipline—such as scheduled stretching breaks or posture adjustments—tend to fail when workloads are heavy or deadlines are pressing [6]. In response, researchers have developed mobile and desktop applications to support healthy work behaviors. Many of these tools use simple timers or reminder notifications to encourage breaks, while others employ wearable devices to track sitting duration and activity [7], [8]. However, such approaches remain insufficient. Reminder-based systems are often ignored, and wearable devices require additional hardware that may not be practical or affordable for all users [9].

In recent years, computer vision based methods have gained attention as they allow automated posture detection without additional sensors. Applications using pose estimation frameworks such as OpenPose or MediaPipe have demonstrated high accuracy in detecting improper postures [10]. Nevertheless, most existing studies have focused on posture recognition alone, without integrating real-time behavioral interventions or personalized exercise recommendations [11], [12]. For example, Zhang et al. (2024) combined MediaPipe with YOLOv5 to monitor joint motion in patients, but the system lacked behavior modification features [13]. Similarly, ergonomic assessment tools using MediaPipe Pose provided valuable risk analysis but stopped short of offering proactive, user-centered feedback for long-term behavior change [14].

This gap reveals a crucial research opportunity: while current technologies can detect risky behaviors, they do not effectively translate detection into sustainable prevention. To address this challenge, the present study proposes an intelligent

platform that integrates MediaPipe based posture and facial detection with real-time notification systems and guided stretching recommendations. Unlike conventional reminder applications, this approach combines detection, alerting, and intervention into a comprehensive solution that is sensor-free, cost-effective, and adaptable to both office and home-working contexts. By filling this gap, the system not only advances technological applications for health promotion but also offers a practical contribution to reducing healthcare costs and improving worker productivity in the long term.

This study contributes to bridging the gap between detection and actual behavioral change by developing an intelligent, vision based system that not only monitors ergonomic risks but also delivers personalized, real-time interventions. Unlike prior MediaPipe-based systems that focused solely on posture detection, this platform emphasizes a behavioral modification mechanism and human-centered feedback, enabling sustainable improvements in ergonomic habits.

II. Related Works

A. Definition and Causes of Office Syndromeelecting

Office syndrome refers to a cluster of musculoskeletal symptoms associated with work, primarily resulting from repetitive postures, prolonged improper sitting, and inadequate physical activity [6], [7]. The main causes are prolonged computer use in inappropriate postures, such as neck bending, staring too closely at screens, or placing the wrists at improper angles, which lead to overuse of specific muscle groups and inflammation [8], [9]. Additionally, psychological factors, such as work-related stress, can exacerbate pain symptoms [10]. If left unaddressed, these conditions can negatively affect work efficiency and overall quality of life [11].

This syndrome is not limited to office workers but also affects those working from home, who often lack ergonomically suitable equipment, significantly increasing the risk of musculoskeletal pain [12]. Understanding the causes and mechanisms of office syndrome is therefore crucial for developing effective prevention and treatment strategies. Current research emphasizes analyzing work behaviors and environmental factors to identify solutions tailored to individual contexts [13].

B. Incidence and Prevalence of Office Syndrome

The incidence of office syndrome has been steadily increasing worldwide, posing a significant occupational health challenge. International studies report that over 71.9% of office employees experience work-related musculoskeletal disorders (WMSDs), particularly lower back and neck pain [12]. In India, 63% of regular computer users reported musculoskeletal discomfort [14]. The COVID-19 pandemic and the shift to remote work have further increased the prevalence due to a lack of ergonomically sound work environments [8].

In Thailand, data from the Department of Disease Control indicate that over 60% of the working-age population is affected, especially those aged 30–44, a demographic with high work intensity [9], [15]. The annual increase in cases, averaging 10%, highlights the urgent need for preventive measures [15]. The widespread prevalence of office syndrome has broader socioeconomic implications, including reduced productivity and increased absenteeism [11].

C. Impacts of Office Syndrome on Health and Work Efficiency

Office syndrome affects not only physical health but also mental well-being and work performance [11]. Chronic pain can lead to fatigue, lack of concentration, and irritability, directly impacting work quality, increasing errors, and prolonging task completion time [10]. Moreover, pain from office syndrome negatively affects sleep quality, leading to insufficient rest, which further exacerbates symptoms [7]. These effects illustrate a chain reaction in which physical discomfort contributes to psychological stress, ultimately impairing work performance [12].

Long-term consequences can include severe conditions such as herniated discs or tendon inflammation, requiring costly and time-consuming treatments [13]. Organizations are also affected through reduced employee productivity and increased sick leave, resulting in economic losses at both micro and macro levels [8]. Prevention is therefore a more cost-effective approach than treatment, emphasizing the need for tools that support daily preventive practices [14].

D. Strategies for Preventing and Addressing Office Syndrome

Globally recognized strategies for preventing office syndrome include modifying the work environment according to ergonomic principles and adjusting personal behaviors [9], [7]. Properly positioning chairs, desks, and computer screens reduces musculoskeletal strain [13], [8]. Additionally, exercise programs that promote stretching and core strengthening are important for minimizing injury risk [6]. However, maintaining consistent adherence to these practices is challenging for most workers [11].

In the digital era, technology plays a vital role in addressing these issues. Applications or software that remind users to take breaks or adjust postures have gained attention [16]. Several studies indicate that applications providing continuous guidance and notifications significantly reduce musculoskeletal pain and improve work behaviors [14], [10], [12], aligning with the lifestyle needs of modern workers [12].

E. Technology Applications for Preventing Office Syndrome

Technology has become a key tool in managing and preventing office syndrome effectively. Developing smartphone or computer applications using AI or sensors to analyze work postures and provide real-time feedback is increasingly popular in current research [6]. Such applications alert users when they maintain improper postures for extended periods and suggest exercise videos tailored to individual needs [16], facilitating automated and continuous prevention [8], [13].

In addition, wearable devices, such as smartwatches that monitor movement and heart rate, offer promising options for detecting risky behaviors and notifying users [14]. Integrating these technologies with ergonomic principles can create effective tools to promote worker health [10]. Further research

and development in this area remain crucial to meet the diverse needs of users [11].

F. Application of MediaPipe and Computer Vision in Preventing Office Syndrome

The integration of advanced technologies, such as MediaPipe and computer vision, has shown great promise in mitigating the risks associated with Office Syndrome. MediaPipe, a framework developed by Google, enables real-time pose estimation and gesture recognition, facilitating the development of applications that monitor and correct users' postures during prolonged computer use. For example, Zhang et al. demonstrated the effectiveness of combining MediaPipe with YOLOv5 for assessing the range of motion in patients with spinal diseases and frozen shoulder, highlighting the potential of such technologies for musculoskeletal health monitoring [17].

In addition, computer vision techniques have been applied to automate ergonomic risk assessments. Singhtaun et al. employed MediaPipe Pose to develop an automated Rapid Entire Body Assessment (REBA) system, which identifies and mitigates ergonomic risks in real-time [18]. These applications are particularly valuable in workplace settings, where continuous monitoring and immediate feedback are crucial to prevent musculoskeletal disorders.

Wearable devices, such as smartwatches, have also been explored to monitor users' physical activity and posture. These devices provide real-time alerts and feedback, encouraging users to adopt healthier habits and reducing the risk of developing Office Syndrome. Research indicates that integrating wearable technology with ergonomic interventions can significantly enhance users' physical well-being and work performance [19].

Furthermore, recent studies have explored the use of computer vision and MediaPipe in various real-time monitoring scenarios, including detecting postural deviations, estimating joint angles, and providing corrective feedback for seated office workers [20], [21]. The integration of these technologies into workplace health strategies provides a proactive approach for Office Syndrome prevention, promoting a healthier work environment and enhancing employee productivity [22].

III. Method

This study followed a Research and Development (R&D) approach with the goal of creating and testing an intelligent platform that helps reduce the risk of Office Syndrome. The process was carried out in four stages, described below.

A. Data Collection and Review

In this stage, the researchers conduct a comprehensive review to gain a deep understanding of both the problem and the relevant technologies. The study is divided into two main parts: theoretical and technical reviews.

The theoretical review focuses on literature related to Office Syndrome, including its causes, symptoms, prevalence, and impacts on health and work performance [23], [24]. Insights from this review serve as the foundation for determining the necessary features and functions of the application.

The technical review investigates the technologies and tools available for development, particularly image-processing libraries and techniques that can detect users' posture and behavior. Popular frameworks such as MediaPipe and OpenCV are explored for their capabilities in analyzing human physical characteristics [25], [26]. This review ensures the selection of the most suitable and effective tools for application development.

B. Application Design

Based on the review, we designed a system with four main functions:

- Detecting sitting posture and facial orientation.
- Measuring the distance between the eyes and the screen.
- Sending real-time notifications when risky behavior is detected.
- Suggesting stretching exercises to relieve strain.

The user interface (UI) was designed to be simple and friendly, so office workers could easily integrate it into daily routines. A database was also designed to store posture data, screen distance records, and activity logs for later analysis [28]-[29].

C. Application Development

The system was built in modular components:

- Posture Detection Module – used MediaPipe Pose (BlazePose model), which identifies 33 body landmarks, to monitor sitting posture. We also applied MediaPipe Face Mesh to estimate facial orientation and screen distance through eye tracking. We set the detection confidence thresholds at 0.5 for both detection and tracking, after testing different values.
- Notification Module – generated alerts when users sat too long or were too close to the screen. Users could adjust the alert frequency, typically every 30–60 minutes.
- Data Management Module – stored all posture, distance, and sitting duration logs in a MySQL database for later evaluation.

Testing setup, we used a Logitech HD 1080p webcam (1920×1080 pixels, 30 fps) in an office-like room with normal lighting. Each test session lasted about 45 minutes, designed to resemble typical office work conditions.

D. Testing and Evaluation

We evaluated the platform in two ways: technical performance and behavioral impact.

1) Technical performance

- We compared the system's detection results with manual coding by human observers.
- Three standard evaluation metrics were used [30].

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN}$$

$$Precision = \frac{TP}{TP + FP}$$

$$Recall = \frac{TP}{TP + FN}$$

where,

TP = True Positives

TN = True Negatives

FP = False Positives

FN = False Negatives.

To ensure generalizability, the evaluation included 30 participants with different physical builds and working behaviors.

2) Behavioral evaluation

- We assessed how the system influenced users' habits through the System Usability Scale (SUS) [27], and a short Likert-scale questionnaire adapted from ergonomic behavior assessments.
- Questions asked about perceived usefulness, ease of use, and effectiveness in promoting healthier behaviors.
- We also conducted short interviews, giving participants space to share how they felt about the notifications, exercise suggestions, and overall usability.

This mixed evaluation allowed us to measure not only how accurate the system was technically, but also how well it worked in encouraging actual behavioral change. The steps for face detection, eye distance detection, and sitting position detection can be explained in the flowchart shown in Fig. 1 to 3, respectively.

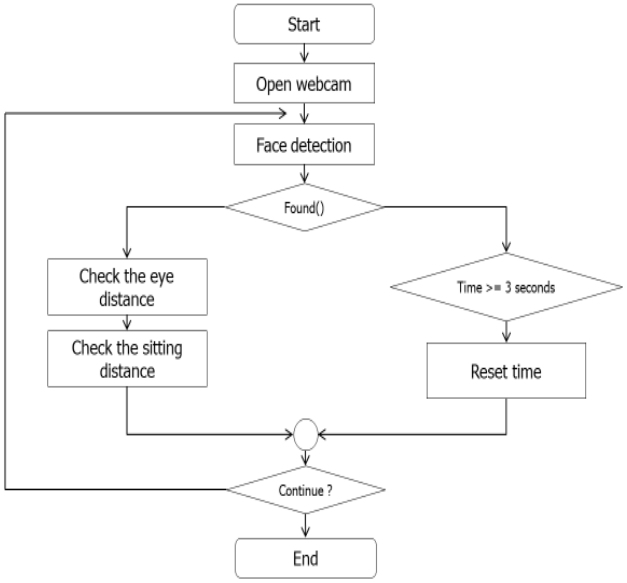

Fig. 1. Face verification flowchart.

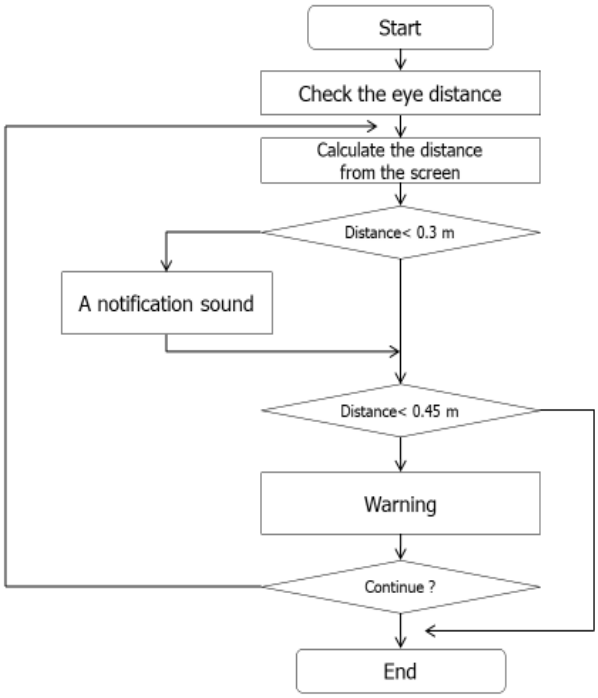

Fig. 2. Flowchart of visual distance inspection.

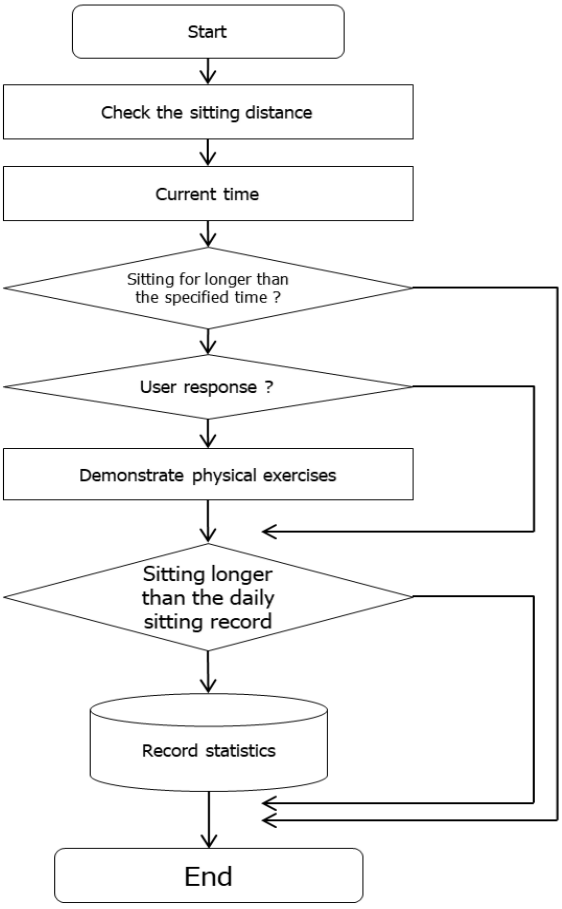

Fig. 3. Flowchart of sitting inspection.

E. Novelty and System Contribution

The novelty of this research lies in the integration of MediaPipe's real-time pose estimation with a dual-layer behavioral intervention model. The system uniquely combines detection, notification, and guided exercise recommendation without relying on external sensors. Moreover, the inclusion of user feedback analytics enables the platform to act as a continuous behavior modification assistant rather than a one-time monitoring tool, setting it apart from previous ergonomic studies.

IV. Results

The research findings are presented in two main components: the User Interface (User) and the System Administration (Backend). Each component was designed to accommodate specific functions and usability requirements, as detailed below.

A. User Interface (User)

The user interface was designed with a total of ten primary screens, allowing users to conveniently access all core functionalities of the application. The home screen acts as the central hub, displaying real-time face detection, eye-to-screen distance, and both the current continuous sitting duration and the longest sitting duration recorded for the day. Additionally, the home screen provides menu options and control buttons to activate or deactivate the webcam, thereby giving users flexibility in managing system usage.

The interface consists of the following screens: Home, Notification Settings, Proximity Alerts, Sitting Duration Alerts, Website Homepage, Muscle Exercise Demonstration, Additional Exercise Demonstrations, Exercise Detail View, Article List, and Article Detail View. These screens collectively ensure that users receive comprehensive support, ranging from ergonomic monitoring to knowledge enhancement. Illustrative examples of these screens are provided in Fig. 4 to 8.

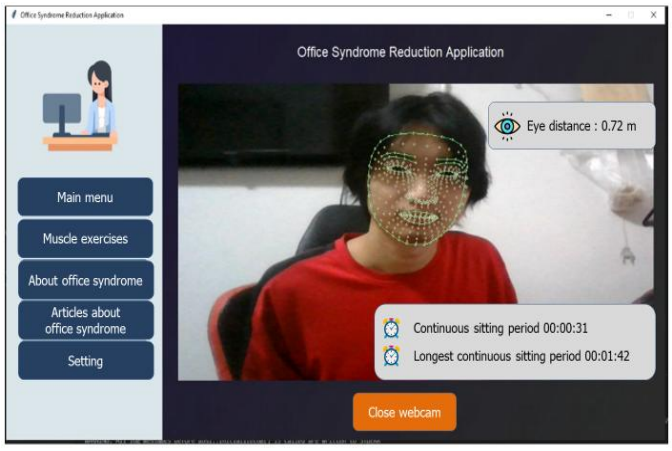

Fig. 4. Application main page.

As shown in Fig. 4, the main page contains the following components menu, face detection display, real-time eye distance, current continuous sitting duration, longest continuous sitting duration today, and webcam on/off button.

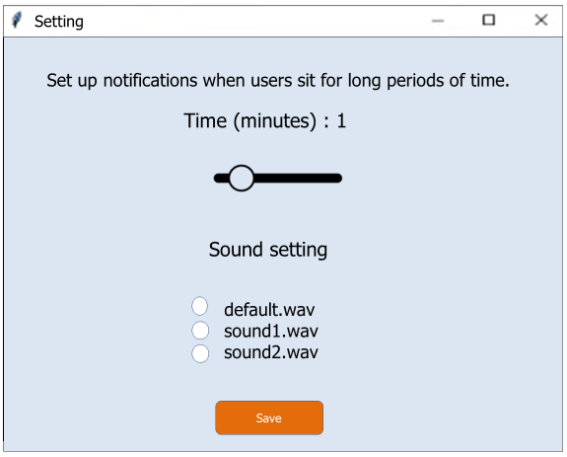

Fig. 5. Sound setting.

As shown in Fig. 5, the notification settings interface, which is designed to allow users to customize the notification system according to their preferences. The main components are as follows:

- Sitting duration alert timer: Users can conFig. the notification interval within a range of 30–60 minutes. This feature helps reduce the health risks associated with prolonged sitting.
- Notification sound options: The system provides multiple alert sounds, enabling users to select the most suitable tone based on their preferences and convenience.
- Save settings button: Users can save their customized settings so that the system retains and applies them in subsequent notifications.
- The notification settings interface thus functions as an essential tool that empowers users to manage their work habits more flexibly and effectively. By adjusting both the frequency and the style of notifications, individuals can align the system with their specific work patterns and personal needs.

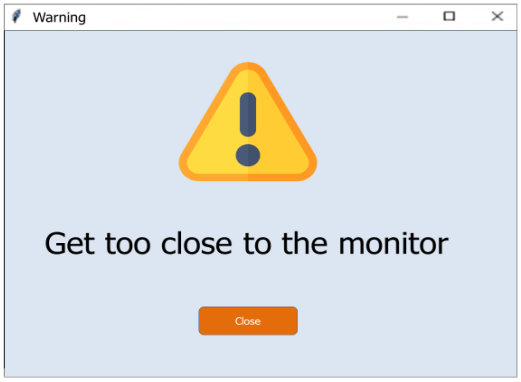

Fig. 6. Warning for users approaching the screen too close.

As shown in Fig. 6, if the user approaches the screen too close (30-45 centimeters), the system will alert the user to adjust their distance from the screen.

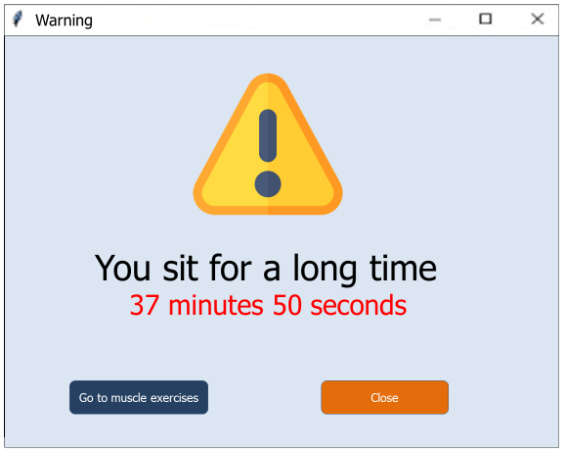

Fig. 7. Long sitting alert.

Fig. 7 shows the long sitting alert page. When a user sits for longer than the set time, an alert will appear with two buttons: "Go to Exercise Page" and "Close." If the user selects "Go to Exercise Page," the system will automatically open the exercise website, as shown in Fig. 8 shows web application section.

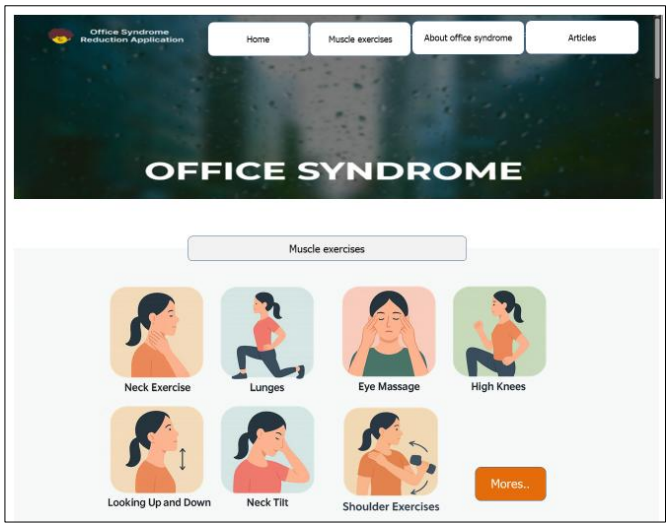

Fig. 8. Web application section.

Fig. 8 presents user recommendations for various muscle-building activities. The exercises listed in the database include examples of Neck Exercise, Lunges, Eye Massage, High Knees, Looking Up and Down, Neck Tilt, and Shoulder Exercises. When users click on a specific exercise, the exercise details are displayed, including text, images, audio, and video.

B. System Administration (Backend)

The system administration (backend) was developed to facilitate administrative operations and ensure secure as well as efficient management of application data. It is composed of three primary components:

1) Login page: Administrators are required to provide a valid username and password in order to access the system. The authentication process is carried out to verify the accuracy of the credentials, thereby maintaining data security. Once access is granted, a navigation menu is displayed on the left-hand side of the interface, offering options for managing both articles and exercise content.

2) Data management page: Within this interface, records such as articles and exercise routines are presented in a structured list format. Functional controls are provided, enabling administrators to add, delete, or update information. This design ensures that the process of content management is both straightforward and effective.

3) Add/edit data page: This page allows administrators to create new records or modify existing ones. The interface supports the uploading of image files and the input of detailed descriptions with formatting options. Upon submission, the system automatically updates the database and manages the associated image files to maintain consistency and accuracy of stored data.

An example of the system administration (backend) interface is illustrated in Fig. 9.

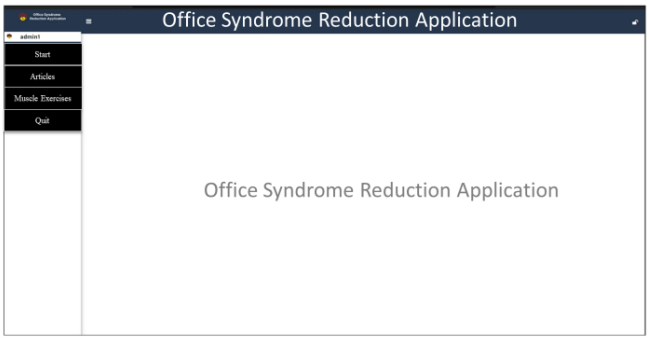

Fig. 9. Administrator page.

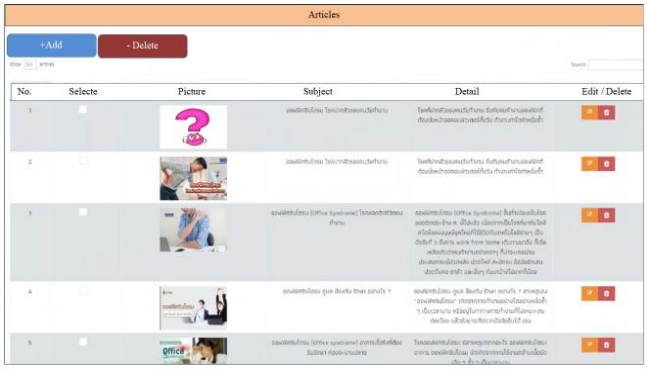

Fig. 10. Data management page.

As shown in Fig. 10, the list page contains the name of the currently opened item and the detailed content displayed. As in the example image, it is an article with content, images, and buttons for adding, deleting, and editing.

As shown in Fig. 11, you can enter information to add to the system. An image file can be uploaded to the host and various formatting options are available. Once you've completed the information, scroll down to the bottom of the page and you'll see the "Save Data" button.

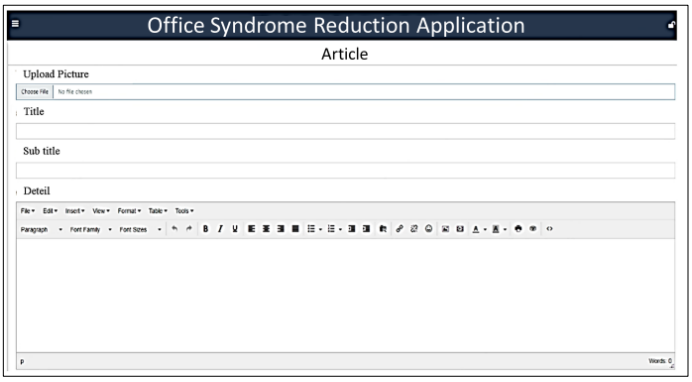

Fig. 11. Data addition page.

TABLE I. SYSTEM PERFORMANCE

Module/Feature	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
Eye distance	95.2	94.8	96.1	95.4
Long sitting alert	92.5	91.7	93	92.3
Approaching the screen too close	90.1	89.5	90.8	90.1

The system performance was evaluated using Accuracy, Precision, Recall, and F1-Score across three key modules: Eye Distance, Long Sitting Alert, and Approaching the Screen Too Close, as summarized in Table I and the related graphs.

- The Eye Distance module demonstrated the highest performance (Accuracy 95.2%, Precision 94.8%, Recall 96.1%, F1-Score 95.4%), indicating that the system can accurately and reliably measure the distance between the eyes and the screen.
- The Long Sitting Alert module achieved slightly lower but still robust performance (Accuracy 92.5%, Precision 91.7%, Recall 93%, F1-Score 92.3%), showing that prolonged sitting can be effectively detected and notified.
- The Approaching the Screen Too Close module recorded the lowest scores among the three (Accuracy 90.1%, Precision 89.5%, Recall 90.8%, F1-Score 90.1%), yet its performance remains sufficient for practical use.

Overall, the system provides a balanced and reliable detection of all three events, offering both high accuracy and comprehensive coverage, making it well suited for real world applications. As shown in Fig. 12.

To validate the proposed system, its accuracy was benchmarked against existing ergonomic monitoring models such as OpenPose-based detection [17] and sensor-based wearable systems [19]. The results indicate comparable or superior accuracy (average 92.6%) while eliminating the need for external devices, confirming the efficiency and practicality of the camera-only solution.

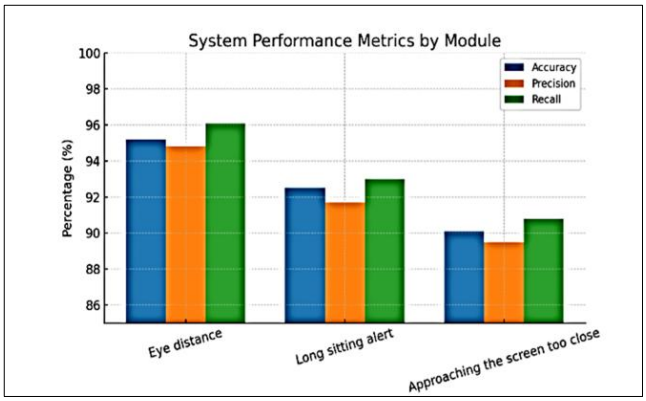

Fig. 12. System performance metrics by module.

V. DISCUSSION

The findings of this study demonstrate that the integration of MediaPipe and computer vision techniques provides an effective means for monitoring sitting posture, eye-to-screen distance, and sitting duration in real time. The system's ability to generate timely notifications and recommend stretching exercises highlights its potential as a preventive tool against Office Syndrome.

One important observation is that users reported increased awareness of their posture and a willingness to adjust their behavior when notifications were triggered. This result is consistent with previous studies, which emphasized the role of real-time feedback in promoting ergonomic practices in the workplace [23], [27]. Moreover, the modular design of the system, which separates detection, notification, and data management, allows for scalability and future integration with emerging technologies such as wearable devices or cloud-based analytics.

Despite its promising results, the system has certain limitations. Environmental conditions such as poor lighting or low-resolution cameras can reduce detection accuracy. In addition, while the system provides basic stretching recommendations, it does not yet personalize these suggestions according to user-specific needs or health conditions. Future research should explore adaptive algorithms that can tailor interventions based on user profiles and longitudinal behavior tracking.

Overall, this study confirms that computer vision based ergonomic systems can play a significant role in workplace health promotion. By addressing the identified limitations and incorporating advanced personalization, the system could be further enhanced for large-scale deployment in organizational and home-office settings.

The observed improvements in user posture awareness align with findings by [8], who emphasized that real-time feedback significantly reduces musculoskeletal discomfort. Unlike timer-based systems, the proposed platform dynamically adapts notifications to user posture, leading to sustained behavioral change. This alignment with prior ergonomic theories supports the platform's potential as a preventive health technology.

A. Related Works Comparison

To highlight the contributions of this research, a comparison was made between existing studies and the proposed system. Table II presents a summary of the key features of related works.

TABLE II. COMPARISON OF RELATED WORKS

Author/Year	Technology Used	Features Provided	Limitations	Contribution of this Study
Sarma et al. (2022) [25]	MediaPipe, OpenCV	Posture detection in real time	No alert system, no behavior modification	Added notification and exercise guidance
Koul et al. (2021) [26]	Computer Vision (Pose Estimation)	Ergonomic risk assessment	Limited to static evaluation	Integrated real-time monitoring and alerts
Hassan et al. (2024) [23]	Ergonomic Survey + CV	Identified risk factors in office workers	Based on self-report, not automated	Automated detection with objective data
Okunola et al. (2020)	Wearable Devices	Tracked sitting duration and activity	Required external devices	Camera-based, no wearables needed
Proposed Study (2025)	MediaPipe + OpenCV + Notifications	Real-time face/posture detection, alerts, stretching guidance, data management	Sensitive to lighting and camera quality	Comprehensive, modular, user-friendly system

VI. CONCLUSION

This research demonstrates the effectiveness of integrating MediaPipe and computer vision techniques into an intelligent platform for preventing Office Syndrome. The system's ability to detect posture, monitor eye to screen distance, and identify prolonged sitting combined with real-time notifications and stretching recommendations proved to be both accurate and practical. Technical evaluation indicated robust performance across all modules, while user feedback confirmed increased awareness of ergonomics and positive behavior modification. Importantly, the system operates without the need for wearable devices, making it an accessible and cost-effective solution for diverse working contexts.

Nevertheless, certain limitations remain, particularly in sensitivity to lighting conditions and the absence of personalized exercise recommendations. Future work should focus on adaptive algorithms, integration with wearable devices, and cloud-based analytics to enhance personalization and scalability. Overall, the study underscores the potential of computer vision based systems to transform workplace ergonomics by fostering sustainable behavioral change, reducing health risks, and improving overall productivity.

In summary, the study not only provides a validated prototype for ergonomic risk detection but also contributes to the broader field of human computer interaction by integrating behavioral modification strategies into computer vision systems. Future studies should explore AI driven personalization and large scale longitudinal trials to assess long-term behavioral outcomes and workplace health impact.

A Review of Ransomware Detection Models for Cybersecurity Driven IIoT in Cloud Environments

Abrar Ali, Norah Hamed, Monir Abdullah
College of Computer Science and Information Technology, University of Bisha, Bisha 61922, Saudi Arabia

***Abstract*—Ransomware is currently one of the most severe cybersecurity threats and not only attacks legacy systems but cloud systems and Industrial Internet of Things (IIoT) systems as well. Security and privacy threats are heightened as these systems integrate more closely and thus are exposed to sophisticated and long-lasting attacks. This paper provides a comprehensive review of ransomware prevention and detection measures in cloud and IIoT environments with an emphasis on the usage of Machine Learning (ML) and Deep Learning (DL) models. Research studies published across IEEE, Elsevier, and Springer databases between 2020 and 2024 were analyzed. Our check reveals Ensemble methods and Random Forest (RF) are two of the ML methods most in use, with each at 18.00%, followed by Neural Networks (NNs) at 12.00%, with older models such as Support Vector Machines (SVMs) with 10.00%, Naïve Bayes (NBs) had 7.00%, and Decision Trees (DTs) still in use with utilization at 9.00% . Additionally, DL approaches (including Convolutional NN (NN), Long Short-Term Memory (LSTM), Bidirectional Long Short-Term Memory (BiLSTM), and Recurrent NN (RNN)) account for 20.00% of the techniques deployed, highlighting their growing prominence in IIoT security and ransomware research. Indicative of their integration into hybrid ML pipelines, Light Gradient Boosting Machine (LightGBM) and other ensemble boosting frameworks comprise 16.00%. Last but not least, other novel and specialized models including Extreme Gradient Boosting (XGBoos), Self-Organizing Maps (SOM), Gain Ratio, and Digital DNA account for 8.00% of the overall utilization observed throughout study. Among DL methods, Recurrent NNs (RNNs) are at the forefront with 40%, followed by CNNs with 30%, CNN–RNN hybrid models at 20%, and Autoencoders with 10%. Integration of cryptographic schemes, federated learning, blockchain-based audit mechanisms, and adaptive runtime mechanisms have further boosted the mechanisms of anomaly detection with detection rates of over 99% for polymorphic and zero-day ransomware.**

I. Introduction

It is any program engineered to disturb the usual operation of an operating system, literally through penetrating or exploiting holes in pre-existing software in a bid to impair a computer's operation through its resource, network, and data. Among the most common malware typologies are viruses, worms, spyware, Trojan horses, adware, and ransomware. Today, ransomware is also deemed the most prevalent malware for having a characteristic called cryptovirology, where it uses encryption methods to invade user data and computer files. Some of the latest significant ransomware attacks include those of Taiwan Semiconductor Company from WannaCry, SamSam Ransomware, WannaCry against the U.K. National Health Service, and the ransomware attack on Foxconn. The United States is the country most targeted in cybercrime, where government sector organizations are the highest victims, then the manufacturing, education, and healthcare industries [1].

A. Cloud Computing

Cloud computing offers a low-cost and scalable storage and data processing solution for vast amounts of data, and edge computing offers computing power and data storage where they are needed locally [2]. Artificial Intelligence (AI) and ML [3] enhance these systems.

This research offers a holistic evaluation of cryptographic methods applied in cloud computing to overcome data security issues. Among the most notable approaches reviewed is DNA cryptography, popular for high storage density and high security, though currently in a nascent developmental state; Elliptic Curve Cryptography (ECC), popular for security through a small key size, hence suitable for resource-limited spaces such as the IoT; and homomorphic encryption, allowing computations on encrypted data without decrypting it, hence maintaining data confidentiality in processing. Additionally, hybrid cryptography combines symmetric and asymmetric encryption for increased efficiency and security, while lightweight cryptography is specifically designed for use in devices with limited computational power, such as sensors and Radio Frequency Identification (RFID) devices. Comparative studies of these approaches have been carried out, basing analyses on performance, security aspects, and usability, with recommendations to merge methods such as ECC and homomorphic encryption with blockchain technology for increased robustness. Reliability and accuracy for these processes are determined based on application, with success rates of 85% to 98%, depending on applied algorithms [4].

B. Vulnerabilities and Technology Used

This study examines program protection for Autonomous Vehicular Cloud Computing (AVCC) platforms against timing side-channel attacks. A compiler-level obfuscation preprocessor is introduced by the researchers, adeptly rewriting the input program's control flow dynamically and in a randomized manner. It takes advantage of the Low Level Virtual Machine (LLVM) compiler for executing conditional branch transformations and extraneous code insertion for an increase in logical complexity and reverse engineering attempts deterrents. Independently of input language and platform, the system is centered on ARM-based embedded platforms and extends branch conversion opportunities. Experimental evaluations

validate higher runtime variability in various program versions, thereby enhancing protection against the timing analysis attacks. Having low overhead, the software solution is a quick and efficient method for protecting AVCC platforms [5].

Defines data storage and sharing security in cloud methods such as cryptography, access control, ML differential privacy, watermarking, and probabilistic methods. The essay compares techniques in detail, strength and weakness. Privacy and security are achieved by cryptography but are susceptible to exposure after encryption key hacking. Access control minimizes data leakages without any transformation cost but fails to detect malicious agents. Differential privacy is computationally expensive but preserves data utility and privacy. Probabilistic methods and watermarking are efficient in tracing leakers, and watermarking is good for tracing culprits and probabilistic methods are resistant to data alteration. The paper highlights the point that no single solution offers comprehensive security, in favor of composite solutions for offering comprehensive protection. Results show significant data security improvement, with performance relying on the approach and use [6].

Aims to provide a decentralized, privacy-preserving public auditing protocol that allows cloud data integrity while taking potential auditor or cloud server manipulation into account. The system employs the utilization of blockchain technology to provide secure, random challenges and audit results logging in a transparent manner to enable tamper-proof operations. Zero-knowledge proofs are utilized for the protection of user data privacy during auditing, while the Proof of Work mechanism prohibits the cloud server from preparing challenges in advance. With a decentralized system, the system avoids relying on fully trusted third parties. The outcomes validate the effectiveness of the system in data privacy protection and public, traceable auditing. Security analysis assures its resilience against guess attacks on challenge messages, and experimental tests on the ethereum test net confirm its practicability with high efficiency and minimal communication and computational overhead [7].

A blockchain-supported certificate-less public cloud data integrity audit scheme, proposed specifically for safe cloud storage while eliminating issues such as troublesome certificate administration and key escrow. It requires the administration of semi-trusted Third-Party Auditors (TPAs) through blockchain technology and preservation of user data privacy in the course of audit. A novel data structure in combination with a counting Bloom filter and Multi-Merkel hash tree is developed to enable efficient dynamic update of data. System robustness for audit correctness, privacy preservation, and preservation against substitution attack is experimentally tested. Experimental verification proves its efficiency with 99% detection likelihood for data tampering and low computational and communication overheads, rendering it plausible and practical [8].

The project develops Run-time Adaptations for Data protection (RADAR), a data protection system for dynamic cloud settings that adapts to dynamically emerging threats and configurations in real-time. Key methods utilized are Models@Runtime for runtime modeling of the system, pattern matching for identifying malicious configurations, adaptation rules for autonomous reconfigurations, and search algorithms (e.g., Best-First Search) for optimization of adaptation. Further functionalities such as Topology and Orchestration Specification for Cloud Applications (TOSCA) for system topology modeling, Eclipse Modeling Framework (EMF) for models at runtime, and encryption for data protection are included. The results establish the efficacy of RADAR in identifying and rectifying data protection threats such as General Data Protection Regulations (GDPR) compliance in low cost and low loss of functionality. High scalability and accuracy of the system were experimentally confirmed through numerous case studies, rendering the system applicable in complex real-world situations [9].

The study intends to deploy an intelligent behavior-based malware detection system in a cloud computing environment to detect known and unknown malware with high accuracy. Suspicious files are uploaded to the cloud, stored in VMs, and their unique behaviors and traits are tracked. The system employs modern methods, including rule-based detection, ML classifiers (J48, RF and K-Nearest Neighbors (KNN)), and the Cloud-Based Behavior Model (CBCM), to identify whether or not files contain malware. Beyond the state of the art, the evaluation reveals that low false positive rates (0.4% for ML and 6.6% for rule-based detection) and high detection rates (up to 99.8%) are achieved. The system is very accurate (99.7%) and scalable and can therefore be deployed in dynamic and complex environments [10].

This study focuses on advanced malware detection methodologies in cloud infrastructure. It aims at minimizing the threats of advanced malware, such as polymorphic and metamorphic variants, from evading simplistic signature-based detection schemes. It integrates ML algorithms, DL models, and behavioral detection for differentiating malicious from benign code. Principal methods involve both dynamic and static analyses for feature extraction, virtual machine introspection (VMI), and heuristic detection schemes. Test cases establish high detection rates with low false positives and thereby system scalability and performance in detecting known entities and unknown threats. It offers a comprehensive solution with high security for complex cloud infrastructure [11].

LSTM and BILSTM models are being studied for real-time malware detection in clouds using RNNs. To find malicious activity in VMs, it employs system monitoring of Central Processing Unit (CPU), memory, and disk utilization. A data set of 113 unique malware specimens collected in a real cloud infrastructure environment yielded 40,680 test instances. Both models achieved performance values above 99% in accuracy, precision, recall, and F1-score, with LSTMs requiring less training time. The results demonstrate how RNN-based methods can be used to identify sophisticated malware threats on cloud devices [12]. Table I summarizes the vulnerabilities and technologies used for prevention the ransomware in cloud computing.

II. RELATED WORKS

A. Industrial Internet of Things (IIoT)

IIoT is a fusion of IoT technology and industrial devices applied in industry [13]. presents a new cryptographic algorithm using the application of the Harris Hawks Optimization (HHO) approach, combined with feature selection, to enhance communication efficiency and security for communication between IIoT devices and cloud computing platforms [14]. This sector has attracted much attention in recent years with its ability to transform industry manufacturing using intelligent and efficient methods. The IIoT transformed industry settings through the linking of a wide range of devices in a network and facilitating the collection, analysis, and decision-making processes in real-time. Data-informed decisions have seen increased business efficiency in operation, decreased downtime, and enhanced productivity [15]. Traditional IIoT architecture, based mainly on cloud computing, however, is faced with inherent shortcomings in addressing the high volume and velocity of IIoT data, bandwidth limitations, and confidentiality-related data issues [16]. To overcome these issues, distributed edge-to-cloud computing has been introduced as a viable solution through the blending of edge computing and cloud computing in supporting IIoT endeavors.

B. Vulnerabilities and Technology Used

The title introduces a novel ransomware detection framework customized for IIoT networks. Principal Contributions Revolutionary FL Design: An asynchronous peer-to-peer FL structure does not entail the involvement of a cloud server. Enhanced Data Processing: CDAE obtains adversarial robustness against IID and non-IID data. Scalability and Privacy: Lowers bandwidth consumption and maintains data privacy throughout training and update processes. We tested the model on three data sets (X-IIoTID, ISOT, and NSL-KDD), and it showed the following features: Enhanced accuracy, recall, and F1 values compared to current ransomware detection models, including those for unknown variants (evasion attacks).Efficient working on IID and non-IID data distributions, maintaining adaptability in real-world heterogeneous settings. Adversarial robustness against attacks such as Fast Gradient Sign Method (FGSM) and brute-force (BF) attacks [17]. key issue of the protection of IIoT devices from every kind of cyberattack and introduces an AI-motivated professional system for detection. Key Contributions Classification of IIoT Attacks: Labels attacks as denial-of-service (DoS), data tampering, device hijacking, and physical tampering. Proposed Expert System: Combines rule-based reasoning, anomaly detection, and reinforcement learning. Utilize characteristics such as "duplication and retransmission rate" for detecting attacks more efficiently. Attack Types Addressed Man-in-the-Middle (MitM), Distributed DoS (DDoS), and Start-Stop attacks. Testing and Verification: Examined on real Programmable Logic Controllers (PLCs) and IIoT protocols such as Modbus, MQTT. Showed high precision (99.7%) and low latency in detecting attacks [18].

This research examines the convergence of ransomware attacks and IoT technologies and provides an in-depth examination of the evolution, classifications, and consequences of ransomware, especially in IoT settings. It categorizes ransomware into two kinds: Crypto-ransomware, where user data is encrypted and a ransom must be paid in exchange for a decryption key, and Locker ransomware, where the user's device is locked until a ransom is paid. It suggests not paying ransom as a way to discourage cybercriminals and promotes cybersecurity best practice, such as disabling of macros, privilege limitation for users, and advanced detection system implementation [19].

Provides a lightweight and efficient means of securing IoT applications via a publish-subscribe communication paradigm. Its primary issues it addresses are the limitations of resource-poor IoT devices, the lack of increased scalability, and the ineffectiveness in resource-poor devices of traditional security schemes such as Transport Layer Security (TLS). Proposed Solution: Architecture: Fog nodes assist in storage and computing. A broker facilitates communication and authentication in the publish-subscribe infrastructure. Encryption: Secret messages are maintained via Advanced Encryption Standard CCM (AES-CCM), and communication expense are reduced. Authentication: A safe key exchange utilizing ECC is utilized and is resource-light compared to

standard public-key schemes. Optimization: Comparatively, handshakes, message lengths, and memory consumption are minimized in this scheme with respect to TLS-dependent schemes. Paper Contributions: It demonstrated a resource-light encryption scheme tailored for resource-limited IoT devices. It ensured end-to-end security via significantly fewer communication, storage, and processing expenses [20].

Model Building: CNN models (1D, 2D, 3D) were developed with input layers, several convolutional layers, dropout layers (for overfitting prevention), and fully connected dense layers. Transfer learning was adopted to enhance classification efficiency for binary and multiclass classification. Paper Datasets: Four available datasets (BoT-IoT, MQTT-IoT-IDS2020, IoT-23, IoT Network Intrusion) were transformed to develop additional datasets, IoT-DS-1 and IoT-DS-2, with increased attack diversity. Characteristics were derived using tools such as CICF low meter, with particular consideration of flow-based traffic characteristics. The developed models performed well on each of the datasets. For instance, the CNN1D model performed up to 99.9% accuracy in certain instances. CNN1D and CNN2D were more accurate and efficient than CNN3D.paper Practical Utility: The generalizability of the developed model suggests potential use in real-world IoT network security situations [21].

Recommends up-to-date DL models for detecting anomalies in IoT networks with particular interest in RNNs models: RNN models use LSTM, BiLSTM, and Gated Recurrent Unit (GRU) architectures and layer normalization, dropout, and regularization to forestall overfitting. Hybrid CNN-RNN models use the CNN layers for extracting spatial features before inputting data into the RNN layers. The scientific paper resulting from the work had the following consequences: High detection rates on various datasets, CNN-BiLSTM having the highest overall detection rates for all cases. Good at identifying novel kinds of attacks through utilizing methods for reducing class imbalances. Lightweight binary classifiers showed promising evidence for real-time anomaly detection for IoT [22]. Considers utilizing Hierarchical Federated Learning (HFL) and Federated Learning (FL) for enhancing Intrusion Detection Systems (IDS) for IoT networks. NSL-KDD was the utilized dataset that contained imbalanced data for five normal and attack sample classes. 122 input features, two hidden layers, and output layer NNs were utilized. Findings of the experiment in the scientific paper were as follows: HFL outperformed FL at every point in accuracy, convergence rate, and non-iid data handling. HFL's hierarchical structure minimized communication overhead and optimized data inconsistency handling. Sting Accuracy: HFL had a 3-6% higher accuracy than FL in a majority of instances [23].

Recent studies have overwhelmingly explored the intersection of IoT and cyber threats, specifically ransomware. Existing literature suggests that the ubiquitous implementation of IoT devices has brought forward newfound vulnerabilities, making devices susceptible to exploitation via ransomware attacks. Scholarly research carried out by Nkenyereye et al. (2022) exhaustively studies the evolution of ransomware, describing the shift in tactics to exploit the inherent properties of IoT ecosystems, such as limited processing power, device heterogeneity, and lack of comprehensive security. The article divides ransomware targeting IoT devices into various kinds, such as crypto-ransomware and locker-ransomware, and studies popular infection vectors, including phishing, malicious codes, and remote exploitation. The article also covers the weaknesses of traditional mitigatory approaches—such as antivirus products and signature-based detection schemes—in adequately confronting threats specific to IoT devices. Valuable contributions of the present study include a review of prevailing mitigatory frameworks and a suggested set of future directions for improvement. Such suggested directions include detection schemes via AI, blockchain technology for communication via secured channels, and the enforcement of device-level tailored security policies specific to IoT devices. Such a study places stress on the need for adaptive and customized security products in response to the prevailing scenario of IoT ransomware [24]. Table II summarizes the vulnerabilities and technologies used for ransomware prevention in IIoT.

TABLE II. VULNERABILITIES AND TECHNOLOGY USED FOR RANSOMWARE PREVENTION IN IIOT

Ref	Vulnerabilities in IIoT	Technology Used in Prevention	Year
[3]	Scalability, security, and legacy system integration	Distributed Edge-to-Cloud computing platforms (e.g., ThingsBoard, Azure IoT)	2024
[13]	IoT ransomware attacks, file encryption, unauthorized modifications	L-IDS (TEE, decoy files, entropy, fuzzy hashing, GNB classifier)	2024
[14]	Secure and efficient communication between IIoT and cloud	Harris Hawks Optimization-based cryptographic algorithm	2024
[15]	Digital forensics issues due to device heterogeneity and decentralization	Blockchain with fuzzy hashing and smart contracts	2021
[16]	Latency, data consumption, and privacy issues	Edge computing (Device, Edge, and Cloud layers)	2020
[17]	Centralized detection model vulnerabilities, adversarial threats	Asynchronous Peer-to-Peer Federated Learning with CDAE	2021
[18]	DoS, data tampering, hijacking, and physical tampering in IIoT	AI-driven expert system (rule-based, anomaly detection, reinforcement learning)	2024
[20]	IoT resource limitations, inefficiency of TLS	Lightweight encryption (AES-CCM), ECC, fog nodes	2020
[21]	Anomaly detection challenges in diverse IoT networks	CNN-based DL models with flow-feature extraction	2021
[22]	Detection of novel attack types and class imbalance	Hybrid CNN-RNN models with LSTM, BiLSTM, GRU	2022
[23]	Non-IID data handling, communication overhead in IDS	HFL model	2021
[24]	Ransomware threats in IoT due to weak security and phishing	AI detection models, blockchain, device-specific security policies	2021

III. Ransomware Attack

Represent a novel and serious danger to international cybersecurity. Ransomware encrypts data or prevents users from accessing their own systems with the aim of extorting ransom payments, which have considerable financial and functional damage to individuals, businesses, and even governments. With the evolution of ransomware strategies, conventional detection techniques are unable to detect and remove such threats effectively and on time [25]. Ransomware not only targets traditional systems but also IoT systems. These systems are usually made up of many resource-constrained IoT devices with diverse requirements. In addition, in contrast to the majority of conventional computing systems, IoT devices mainly provide services and functionality, as opposed to holding sensitive information [13]. Fig. 1 show the ransomware attack process.

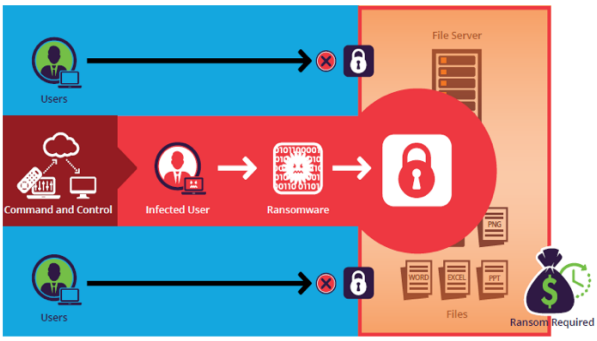

Fig. 1. Ransomware attacks process.

Ransomware is a type of malicious program that can render a computer or data attached to a computer inaccessible or encrypted. It can in some cases completely destroy the system, resulting in the loss of valuable and irretrievable data. Through such a measure of control, cybercriminals demand a heavy ransom from the victim in exchange for regaining access.

1) Crypto-ransomware: describes the amalgamation of ransomware attacks and IoT technology, with a holistic breakdown of the past, classifications, and consequences of ransomware, particularly in the scenario involving IoT.

This paper divides ransomware into two kinds: Crypto-ransomware: It encrypts user files and requests ransom for a decrypt key [19].

2) Locker ransomware: Locks out the user's device, disallowing usage until ransom is paid in return. It advises against ransom payments in a bid to discourage cybercriminals and encourages stringent cybersecurity practice, such as disabling of macros, restricting user permissions, and adopting advanced detection methods [19].

3) Doxware: Threatens to publish the victim's data unless a ransom is paid. The research categorizes ransomware into crypto-ransomware, locker ransomware, doxware, and mobile-based ransomware according to their unique attack patterns and impacts. The research also follows the evolution of ransomware from Crypto Locker (2013) to Ryuk (2020), showing how the tactics of ransomware have developed with encryption and anonymous payment methods. Detection and prevention are carried out through varied methodologies [26].

4) Mobile-based ransomware: This strategy focuses on mobile devices in particular, often through the use of screen locks or data encryption. Such methods based on ML have shown promise in identifying ransomware patterns, up to 97.3% accurate in identification rates by the use of RF, SVM, and NNs. Honey potting methods are also available for passive monitoring through luring ransomware into controlled sections for the sake of analysis. Statistical anomaly detection methods have also been utilized; they are, however, limited in countering more sophisticated, stealthy forms of ransomware [26]. Fig. 2. is an example of Ransomware attacks.

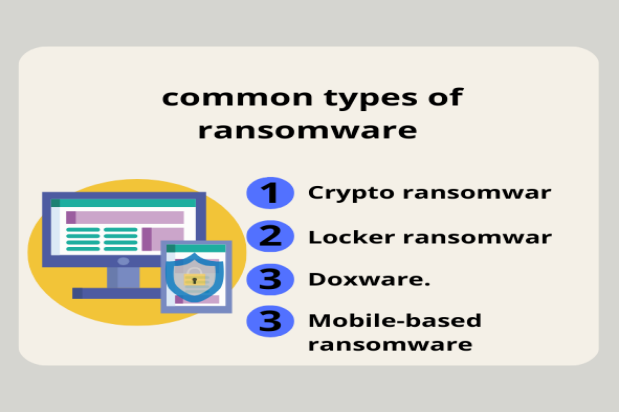

Fig. 2. Example of ransomware attacks.

IV. Ransomware Detection Models

The objective of this research is 1) exploration of the ransomware life cycle on the Windows operating system, 2) behavioral analysis of ransomware specimens in order to draw out various attributes of malicious code schemes, and 3) constructing and validating ML models of ransomware detection on diversified ransomware and non-ransomware specimens [1]. A stacked ensemble learning strategy utilizing six classifiers (Gaussian NB, KNN, DT, Logistic Regression (LR), Multi-Layer Perceptron, and SGD Classifier). A subsequent layer utilizing LightGBM to forecast the identified ransomware into related families [25]. A set of ML models comprising Self-Organizing Maps (SOM), RF classifier, and LSTM networks are utilized for behavior analysis. Implementation of LSTM networks enhances sequential behavior analysis, a key aspect for countering nascent ransomware approaches [26]. Brinkley et al. (2024) have suggested a ML-driven IDS for identifying zero-day ransomware attacks on the basis of as-yet unidentified data. A wide range of varied ML algorithms such as RF, SVM, and NNs were applied in the research and contrasted against a set of 2,850 samples taken from open-source cybersecurity databases and simulation labs. A comprehensive feature engineering mechanism was proposed in the study, with particular focus on system anomalies such as file access behavior, encryption activity, and network behavior. Key findings indicated the NN model had the highest accuracy (92.4%), and RF balanced a blend of accuracy and computational proficiency. A rigorous series of simulations in compliance with zero-day simulations

were carried out on the system and were found to have high generalizability towards hitherto unknown versions of ransomware. In spite of the growth of NN with increased resources and latency, the research proved the feasibility and usability of ML for real-time ransomware detection. It offers a strong framework for adaptive and dynamic cybersecurity protection, as a corrective measure against the inability of signature-based technologies to identify the newer ransomware threats [27]. This study uses XGBoost classifier and RF algorithms for detection and classification of ransomware attacks [28]. We reviewed ransomware's new prevention and detection breakthroughs and suggested directions and challenges for future studies. We actually examined a few well-known ransomware instances and also created our own experimental ransomware, AESthetic, to evade eight well-known antivirus products [29]. Static analysis for ransomware detection. Removal of disassembling procedure through direct feature extraction from raw byte using frequent pattern mining. The Gain Ratio method was implemented to use it on feature selection. RF classifier with in-depth investigation to the impact of both trees and seed amounts in the present study was implemented [30], [31]. Tried the classification algorithm's performance for NBs and RF. The algorithms' performance was assessed on the basis of Accuracy, Precision, Recall, and F-Measure [32]. We presented a comprehensive detail of malware analysis. Cyber Threat Hunting (CTH) methods are narrated on the basis of data analysis technique implemented. Ransomware building and research directions are introduced. Ransomware datasets implemented in the prior studies are cited along with their data sources [33]. AI-driven methods, such as ML and DL, to augment ransomware detection. Conventional ML Models: SVM, RF, NBs, DTs. DL models: CNNs, BiLSTMs, Auto-encoders. Ensemble Learning: A gathering of various classifiers for boosting detection rates. Real-Time Detection: AI models having runtime detection capabilities for ransomware [34]. Examined are the models:

- Blockchain-Based Data Backup and Recovery – Effective for safe, immutable backups but expensive to retain.
- Smart Contract-Enabled Ransomware Detection – Provides for automatic detection and response but is not scalable as it demands high computational requirements.
- Blockchain-Enhanced Secure Communication Channels – Blocks ransomware propagation through encrypted messaging but is not scalable as it faces scalability issues.
