- Decentralized Malware Analysis Platforms – Effective for threat intelligence exchange but requires high computational infrastructure and facilities [35]. A combination of several methods, including behavioral analysis, heuristic detection, and DL models, performs better [36]. BSFR-SH is a strong blockchain-supported security framework efficient for ransomware detection, mitigation, and data recovery in intelligent healthcare systems [37]. Techniques developed on ML have been a success for ransomware pattern identification, and RF, SVM, and NNs are capable of identifying with up to 97.3% accuracy. Honeypotting methods also offer passive monitoring functionality through decoy attraction of ransomware in isolated areas for monitoring purposes. Statistical anomaly detection methods have also been applied [38]. Network traffic monitoring can also identify the attacker's IP address. Comparison of various methods utilized for detecting ransomware, such as signature-based, ML-based, and dynamic analysis, are also presented in the work [39] ML-based approaches proved to be an effective solution that provides real-time detection of ransomware. Several prevention techniques that involve firewalls, intrusion detection systems, and regular backup products. The proposed system in this study is an extension of these existing methods by analyzing encrypted file extensions to identify ransomware type and recommend decryption tools [40].Using Gradient Tree Boosting, the detection improves to 99.997% accuracy with an FPR of just 0.01%. Static analysis, when coupled with ML techniques, is able to detect ransomware before execution effectively with reduced system damage potential [41]. The research also compares common ML algorithms with the comment that while age-old techniques such as SVM and RF are still in the forefront, newer DL techniques such as LSTM networks and CNNs have shown high potential to extract features independently and enhance detection performance [42]. Table III summarizes the ransomware detection ML and DL models.

TABLE III. RANSOMWARE DETECTION MODELS (ML AND DL)

Ref	Vulnerabilities / Challenges	Technology Used in Prevention	Year
[1]	Ransomware lifecycle exploitation via Windows APIs	API-based detection with ML models	2021
[25]	Accurate classification of ransomware families	Dual-stage ML architecture using Ensemble + LightGBM	2024
[26]	Behavioral threats in network/system activities	SOM, RF, LSTM models	2023
[27]	Zero-Day Ransomware Threats, Evasion Techniques, System Behavior Manipulation, Model Generalization	ML Algorithms: RF, SVM, and NNs.	2024
[28]	Fast detection/classification of ransomware	XGBoost and RF classifiers	2023
[29]	Advanced ransomware evading antivirus detection	Experimental ransomware and prevention insights	2021

[42]	Advanced RaaS, double extortion, evasion	ML taxonomy (SVM, RF, LSTM, CNN) with benchmark analysis	2024

V. Analysis and Discussions

Using specific inclusion and exclusion criteria, the research methodology identified and evaluated malware detection models in accordance with a systematic literature review (SLR) approach. This guaranteed the results' objectivity, transparency, and reproducibility.

The file under review emphasizes the increasing relevance of ML and DL methods in ransomware detection in cloud computing and industrial IoT settings Conventional detection measures are not effective against contemporary ransomware because of polymorphism obfuscation and zero day attacks AI based measures are increasingly employed for sound and dynamic detection. ML models such as RF, SVMs, NBs and DTs remain in favor due to simplicity interpretability and efficiency RF model is most conventional to handle high dimensional data Ensemble methods such as lightGBM and boosting are more accurate, but ml relies heavily on handcrafted features and can be beaten by evasive ransomware. Deep models such as CNNs, RNNs, LSTM, Bidirectional LSTM (BiLSTM) models are gaining popularity These automatically extract complex patterns and temporal features from unprocessed data Autoencoders find use in anomaly detection DL achieves high accuracy at high frequency often over 99 but is plagued with problems of interpretability scalability and computational cost. Compared to ML model is simple and effective while DL works outstandingly well in classifying advanced evasive ransomware Ensemble and hybrid approaches yield best results incorporating efficiency and accuracy The use of blockchain federated learning and anomaly detection mechanisms is validated through research for enhancing resilience. Fig. 3 shows the classification methods of ML Approaches.

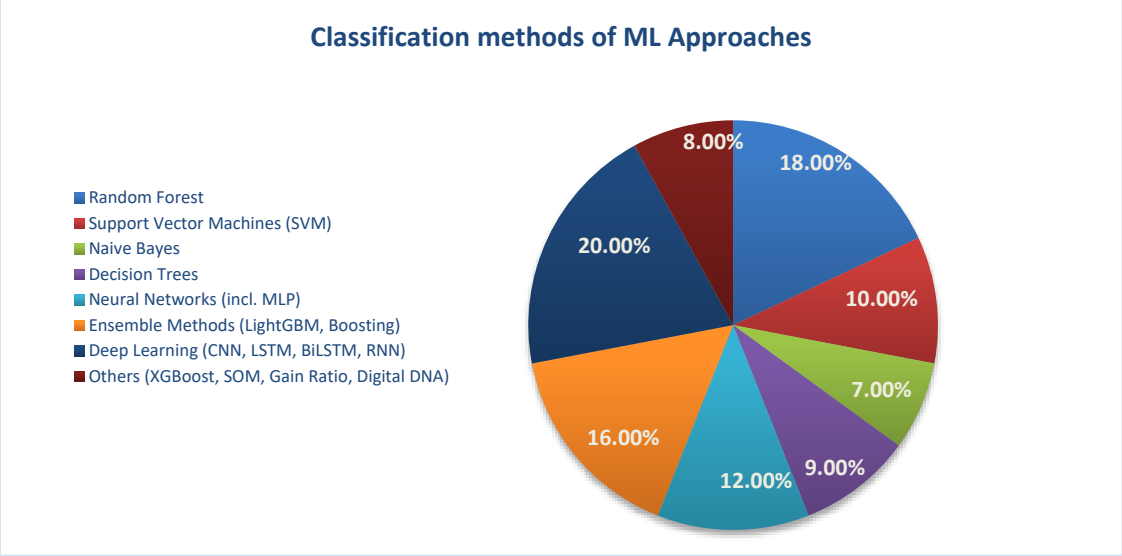

Fig. 3. Classification methods of ML approaches.

The most used methods are RFs and Ensemble Methods (18.00% each) due to their accuracy and robustness.

They are followed by NNs (12.00%), while classic models like SVM, NBs, and DTs still occupy an important role. hybrid approaches and neural solutions are gaining ubiquity, while traditional methods remain in common use for environments. Fig. 4 shows the classification methods of DL Approaches.

The most commonly used DL methods are RNNs, LSTM, BiLSTM, GRU at 40%, followed by CNNs at 30%. Hybrid CNN-RNN models take up 20%, which reflects the importance of architectural blends, and Autoencoders are utilized the least with 10%. In general, RNNs dominate due to their strength in sequence data handling, with CNNs and hybrids providing strong complementary techniques to ransomware detection. Fig. 5 shows the classification methods of ML approaches during past five years.

RF model was the leader in 2022 with nearly 100%, followed by the most commonly used method. After 2023, diversity picked up pace with XGBoost, Gradient Boosting, and SOM hitting about 30–35%.

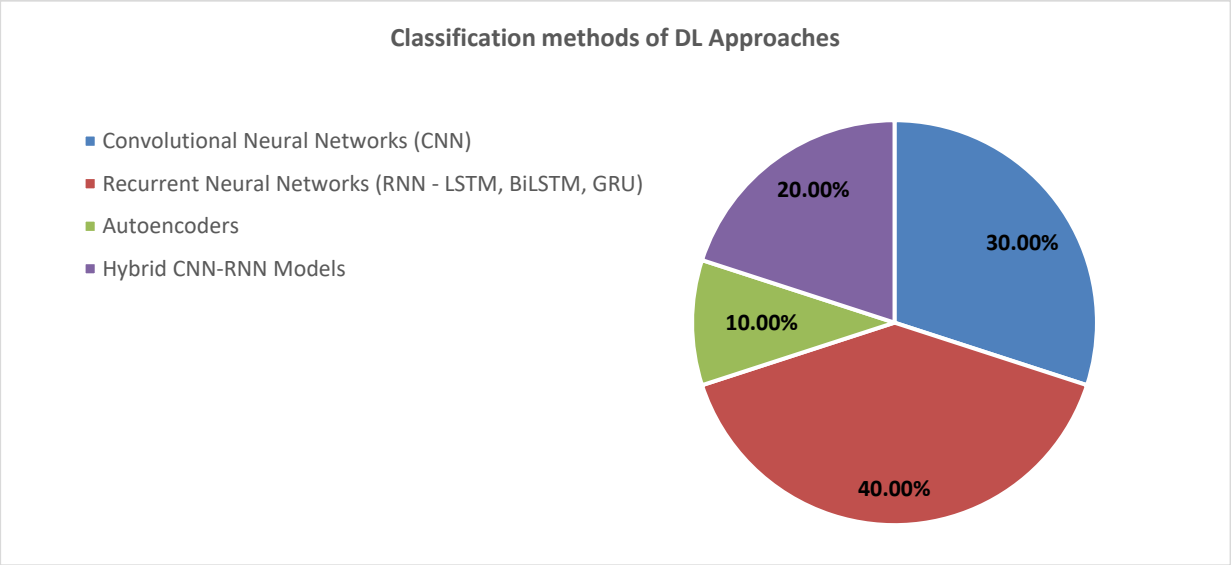

Fig. 4. Classification methods of DL approaches.

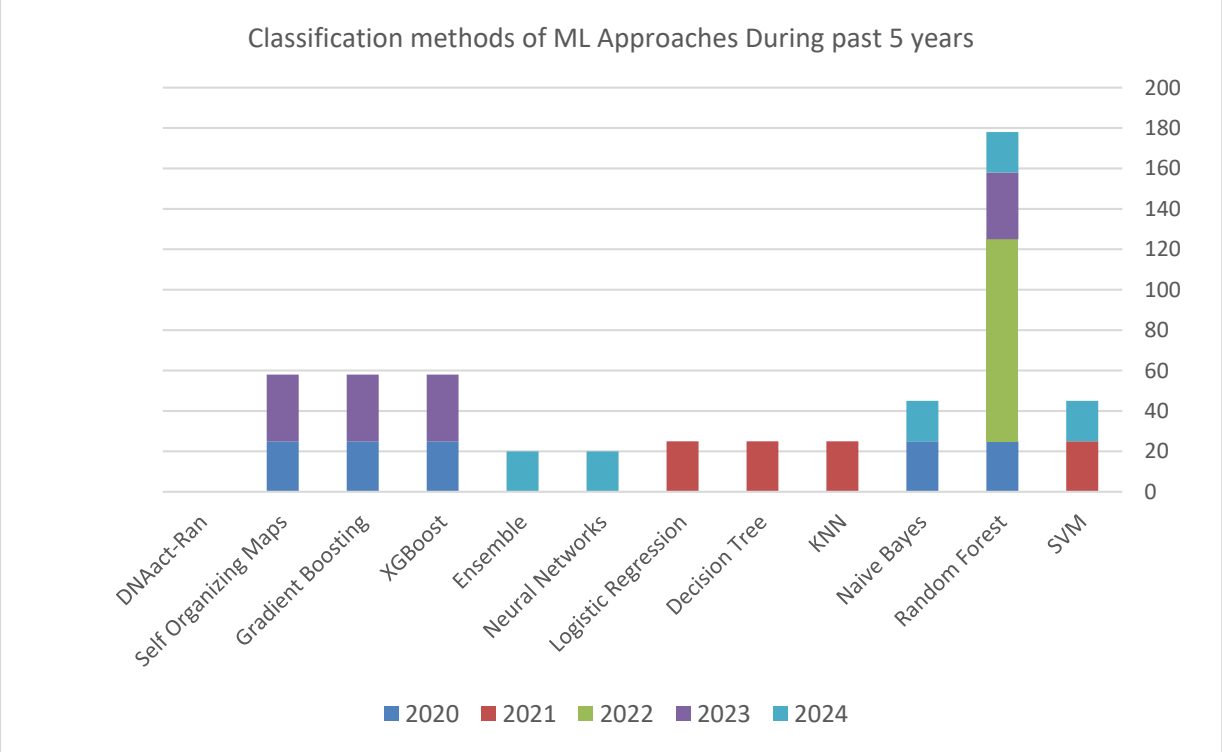

Fig. 5. Classification methods of ML approaches during past five years.

By 2024, NNs and Ensemble methods were popular (20%), which marked a shift towards complex and hybrid models.

- NSL-KDD has the maximum at 55%, the most sought-after dataset in all years.
- UNSW-NB15 leads with 28%, demonstrating its greater usage as a modern norm.
- Less frequently occurring data sets such as KDDCUP99 (6%), CIC-DoS2019 (5%), and CICIDS2017 (4%) are nonetheless useful for diversity.
- CICIDS2018 and ISCX2012 are used the least (1% each), reflecting minimal usage.

Overall, the findings reflect a continued overdependence on NSL-KDD and UNSW-NB15 with modest but useful contributions from newer datasets. Fig. 6 shows the different datasets for classification methods.

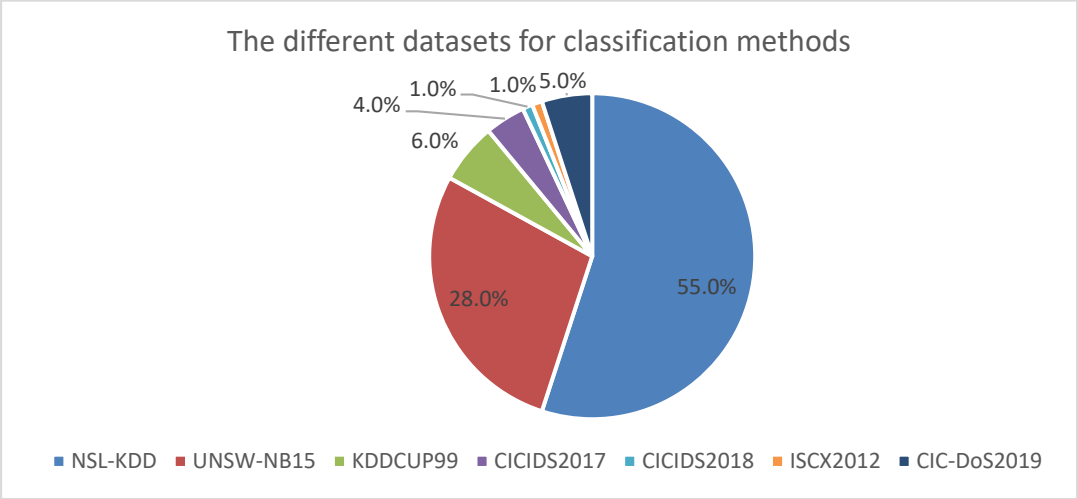

Fig. 6. The different datasets for classification methods.

VI. Conclusion

This work offers cybersecurity practitioners practical implications in addition to a comparative understanding of ransomware detection techniques. The results can help with the design of adaptive, hybrid security architectures that integrate blockchain, ML, and DL for practical protection systems. The findings from this research support that it is not one procedure that would suffice to offset the growing intricacy of cyber-attacks. Standard ML methods such as RF and Ensemble Techniques demonstrate good robustness and accuracy, while NNs provide greater adaptability. In contrast, DL approaches, specifically RNNs and CNNs, show improved accuracy in handling sophisticated and high-level threats, with hybrid CNN-RNN architectures further boosting detection. These results showcase the potential for constructing the future of resilient defense systems through an integration of hybrid and ensemble techniques, supported by blockchain-secured federated learning and adaptive anomaly detection. That type of integrated approach ensures a robust, scalable, and intelligent model for meeting current and future cyber threats.

A Comprehensive Survey of Visual SLAM Technology: Methods, Challenges, and Perspectives

Aidos Ibrayev, Amanzhol Bektemessov
International Engineering Technology University, Almaty, Kazakhstan

***Abstract*—Visual Simultaneous Localization and Mapping (Visual SLAM) has become a cornerstone of autonomous navigation and spatial understanding in robotics, augmented reality, and computer vision. This review presents a comprehensive examination of algorithmic progress in Visual SLAM, focusing on the three principal paradigms: monocular, stereo, and RGB-D SLAM. Monocular SLAM, known for its minimal hardware requirements, has evolved from feature-based methods to deep learning-enhanced systems, addressing challenges like scale ambiguity and drift. Stereo SLAM leverages depth through triangulation, improving scale accuracy and robustness, particularly in dynamic and low-texture environments. RGB-D SLAM, utilizing depth-sensing technology, has enabled dense and semantically enriched mapping, finding significant application in indoor and real-time scenarios. Through a chronological and technical exploration of representative methods including RatSLAM, ORB-SLAM, DSO, ProSLAM, ElasticFusion, DynaSLAM, and recent hybrid and learning-based frameworks. This review identifies major milestones and architectural innovations across paradigms. A cross-paradigm analysis highlights the trade-offs in accuracy, computational efficiency, and adaptability, while also discussing emerging trends such as semantic integration, multimodal fusion, and neural implicit representations. Furthermore, the paper outlines future directions that include lifelong learning, real-time deployment on edge devices, dynamic environment adaptation, and the convergence of geometry and learning-based pipelines. Supported by a detailed taxonomy and historical evolution illustrated in visual summaries, this review serves as a foundational reference for researchers and developers aiming to understand and contribute to the advancement of Visual SLAM technologies in both academic and real-world contexts.**

***Keywords*—Visual SLAM; monocular SLAM; Stereo SLAM; RGB-D SLAM; 3D mapping; pose estimation; loop closure; semantic SLAM; deep learning; sensor fusion**

I. Introduction

Simultaneous Localization and Mapping (SLAM) is a fundamental problem in robotics and computer vision, enabling an agent to build a map of an unknown environment while estimating its own pose within that space. Among the various modalities of SLAM, Visual SLAM (V-SLAM) has gained increasing attention due to its cost-effectiveness, wide applicability, and ability to capture rich scene semantics using standard cameras [1]. Unlike traditional SLAM approaches that rely on expensive range sensors such as LiDAR, visual SLAM uses images as the primary sensory input, offering a lightweight and scalable solution for many real-world applications including autonomous vehicles, augmented reality (AR), unmanned aerial vehicles (UAVs), and mobile robotics [2].

Visual SLAM systems are typically classified into three main categories based on the type of visual input: monocular, stereo, and RGB-D SLAM. Monocular SLAM uses a single camera and offers a compact and inexpensive setup but suffers from scale ambiguity and sensitivity to initialization [3]. Stereo SLAM employs a pair of cameras to estimate depth via triangulation, thereby overcoming scale issues and providing more stable estimates in textured environments [4]. RGB-D SLAM leverages cameras that deliver both color and depth information simultaneously, enhancing accuracy in indoor and structured scenes while introducing hardware constraints and limitations in outdoor or long-range settings [5].

Over the past two decades, the field has witnessed a remarkable evolution in algorithmic design, ranging from sparse, feature-based methods to dense and semi-dense approaches, and more recently, learning-based frameworks that integrate deep neural networks with traditional geometric pipelines [6]. Despite significant progress, many challenges persist, such as dealing with dynamic environments, achieving real-time performance on resource-constrained devices, and ensuring robustness under varying lighting or texture conditions [7]. Furthermore, achieving generalizable SLAM that can adapt across domains and scales remains an open research problem [8].

This review paper provides a structured and comprehensive overview of Visual SLAM methods across the three primary categories. By examining algorithmic trajectories, technical innovations, and representative benchmarks, this survey aims to map the evolving landscape of SLAM research and identify promising directions for future exploration.

II. Background and Fundamentals

Visual SLAM combines techniques from geometry, signal processing, and optimization to simultaneously estimate a camera's pose and reconstruct its environment. The core objective is to recover the trajectory $T_t = SE(3)$ and a map M from a sequence of image observations $\{I_t\}$ over time. Mathematically, the SLAM problem can be formulated as a maximum a posteriori (MAP) estimation:

$$\arg\max_{X,M} p(X, M \mid Z) \tag{1}$$

where, X is the set of poses, M is the map, and Z denotes the sensor measurements [9]. Factor graph models are

commonly used to express the probabilistic dependencies between variables in SLAM, allowing the estimation to be represented as a graph optimization problem [10].

A key task in visual SLAM is camera pose estimation, typically achieved by minimizing the reprojection error:

$$\min_{T} \sum_{i=1}^{N} \left\| u_i - \pi\left(T \cdot X_i\right) \right\|^2 \tag{2}$$

where, u_i are image features, π is the projection function, and X_i are 3D landmarks [11]. Map representation varies from sparse point clouds to dense voxel grids, depending on the method [12].

Loop closure detection corrects accumulated drift by identifying previously visited locations and enforcing pose graph consistency [13]. Pose graph optimization is often solved using nonlinear least squares:

$$\min_{X} \sum_{(i,j)\in\varepsilon}^{N} \left\| f_{ij}\left(X_i, X_j\right) - z_{ij} \right\|^2 \tag{3}$$

where, f_{ij} models relative motion and z_{ij} is the measured constraint [14]. Feature extraction, tracking, and data association form the visual front-end, while back-end optimization refines the trajectory and map [15].

Recent works also incorporate deep learning for depth estimation and semantic mapping, improving robustness in unstructured environments [16]. Benchmarks such as KITTI and TUM RGB-D provide standardized datasets for evaluation and comparison [17].

III. Algorithmic Paradigms for Slam

This section synthesizes the principal algorithmic paradigms that have shaped SLAM development for mobile robots, providing a structured overview of classical and contemporary frameworks. We first examine filter based methods such as EKF-SLAM and UKF-SLAM that leverage recursive Bayesian estimation to jointly infer robot trajectory and map features. Next, particle filter approaches and their Rao-Blackwellized variants (FastSLAM) are discussed for their ability to represent multimodal posteriors in highly nonlinear settings. We then turn to graph based optimization techniques, which cast SLAM as a sparse nonlinear least squares problem over pose and landmark variables, and explore incremental solvers such as iSAM. Finally, hybrid and emerging paradigms that integrate multiple estimation strategies, learning based components, and submapping schemes are reviewed to highlight the evolving landscape of SLAM algorithms.

A. Filter-Based Approaches

Filter based SLAM methods formulate the simultaneous estimation of robot pose and map features as a recursive Bayesian filtering problem [16]. At each time step, the joint state vector.

$$s_t = \begin{bmatrix} x_t \\ m \end{bmatrix} \tag{4}$$

where, x_t denotes the robot pose and m concatenates all landmark coordinates, is represented by a Gaussian belief $N\left(\hat{s}_t, P_t\right)$. The filter alternates between a prediction step

$$\begin{aligned} \hat{s}_{t|t-1} &= f\left(\hat{s}_{t-1}, u_t\right), \\ P_{t|t-1} &= F_t P_{t-1} F_t^T + Q_t \end{aligned} \tag{5}$$

and a correction step upon receiving a measurement z_t:

$$\begin{aligned} K_t &= P_{t|t-1} H_t^T \left(H_t P_{t|t-1} H_t^T + R_t\right)^{-1} \\ \hat{s}_t &= \hat{s}_{t|t-1} + K_t\left(z_t - h\left(\hat{s}_{t|t-1}\right)\right) \\ P_t &= \left(I - K_t H_t\right) P_{t|t-1} \end{aligned} \tag{6}$$

Here, f and h are the process and measurement models, F_t and H_t their Jacobians, and Q_t, R_t covariance matrices. Within this framework, the Extended Kalman Filter SLAM (EKF-SLAM) linearizes f and h about the current estimate, resulting in first-order approximations of non-linear dynamics and sensor models [17]. EKF-SLAM maintains a full covariance matrix across robot and landmark states, ensuring consistent uncertainty propagation but incurring $O\left(n^2\right)$ computational complexity in the number of landmarks n. To mitigate linearization errors, the Unscented Kalman Filter SLAM (UKF-SLAM) employs the unscented transform: a set of deterministically chosen sigma points $\left\{\chi_{t-1}^i\right\}$ is propagated through the true non-linear functions, yielding more accurate posterior mean and covariance estimates without explicit Jacobian computation [18]. UKF-SLAM typically achieves higher accuracy in highly non-linear regimes at the cost of increased per-step computation proportional to the number of sigma points ($2L+1$ for a state of dimension L) [19]. Both EKF-SLAM and UKF-SLAM serve as foundational benchmarks against which more advanced, optimization-based, and hybrid SLAM paradigms are compared.

B. Particle Filter SLAM

Particle-filter SLAM methods approximate the full SLAM posterior $p\left(x_{0:t}, m \mid z_{1:t}, u_{1:t}\right)$ by a finite set of N weighted particles $\left\{x_{0:t}^i, m^i, w_t^i\right\}_{i=1}^N$. At each time step, particles are propagated according to the motion model $x_t^i \approx p\left(x_t \mid x_{t-1}^i, u_t\right)$ and importance weights are updated via:

$$w_t^i \propto w_{t-1}^i, p\left(z_t \mid x_t^i, m^i\right) \tag{7}$$

Followed by resampling to focus computational resources on high-likelihood hypotheses. Unlike Gaussian-based filters, particle filters can represent arbitrary, multi-modal distributions, making them well-suited to highly non-linear and

ambiguous observation models. However, naive particle-filter SLAM suffers from the "curse of dimensionality," as the joint state space grows with the number of landmarks, leading to excessive computational demand and rapid sample impoverishment when N is insufficient.

FastSLAM Variants. FastSLAM addresses these challenges by factorizing the posterior into a product of a trajectory posterior and independent landmark posteriors:

Trajectory estimation is performed via a particle filter, while each landmark's position is maintained by a separate, low-dimensional Kalman filter (or alternative Gaussian estimator) [20]. FastSLAM 1.0 introduced this Rao-Blackwellized approach, reducing computational complexity from $O(NM^2)$ to $O(NM)$. FastSLAM 2.0 refined the proposal distribution by incorporating the current measurement into the sampling step, thereby improving sample efficiency and reducing particle deprivation in highly informative environments [21]. Subsequent variants have further enhanced robustness through adaptive resampling thresholds, hierarchical landmark clustering, and incorporation of grid-based mapping techniques for environments with dense feature distributions [22]. These innovations have established FastSLAM as a versatile, real-time SLAM framework on mobile-robot platforms with moderate computational resources.

C. Graph-Based Optimization

Graph-based SLAM reformulates the joint estimation problem as a nonlinear least-squares optimization over a sparse graph, in which nodes represent robot poses (and optionally landmark states) and edges encode spatial constraints derived from odometry and observations. In the pose-graph formulation, only robot poses $\{x_i\}$ are included as variables, and measurements between poses (e.g., odometry or loop closures) define binary factors. The optimization seeks

$$x^* = \arg\min_x \sum_{(i,j)\in\varepsilon} || z_{ij} \Theta(x_i^{-1} \oplus x_j) ||^2_{\Omega_{ij}} \quad (8)$$

where, z_{ij} is the measured relative transform between poses i and j, Ω_{ij} the information matrix, and $\oplus$, $\ominus$ manifold-specific composition and inverse-composition operators [23]. Factor-graph SLAM extends this concept by including landmark nodes $\{m_k\}$ and multiary factors, yielding a unified representation amenable to general-purpose solvers. The factor-graph cost function becomes.

$$\{x^*, m^*\} = \arg\min_{x,m} \sum_{f\in F} || \phi_f(x_f, m_f) - z_f ||^2_{\Omega_{ij}} \quad (9)$$

where, each factor f relates a subset of pose and landmark variables through the measurement function ϕ_f and information matrix Ω_f [24]. Sparsity in the graph structure enables efficient exploitation of sparse linear algebra techniques, yielding favorable scaling to large-scale environments.

Incremental smoothing and mapping (iSAM) algorithms tackle the computational demands of online graph optimization by updating the solution and factorization incrementally as new measurements arrive. The original iSAM algorithm incrementally constructs and maintains a square-root information matrix via QR or Cholesky factorization, avoiding the need to re-solve the entire system at each step [25]. iSAM2 further introduces a Bayes tree data structure that encapsulates the conditional dependency structure of variables, allowing selective relinearization and re-factorization only in affected subtrees when new factors are added or existing factors change [26]. This strategy achieves real-time performance on resource-limited platforms while preserving consistency and accuracy, making iSAM variants a de facto choice for optimization-based SLAM in mobile-robot applications.

IV. Visual SLAM

Visual SLAM (Simultaneous Localization and Mapping) is a technique that leverages visual input, typically from one or more cameras, to perform real-time mapping and localization in unknown environments. As shown in Fig. 1, Visual SLAM is broadly categorized into three main types: Monocular SLAM, Stereo SLAM, and RGB-D SLAM, each characterized by its unique camera configuration and depth perception capabilities. This classification allows for flexibility in application domains, ranging from lightweight mobile robotics to dense indoor reconstruction [18].

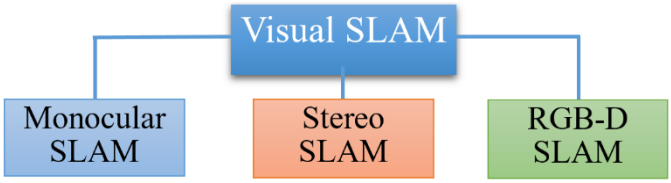

Fig. 1. Taxonomy of Visual SLAM: Classification into Monocular, Stereo, and RGB-D SLAM approaches.

Monocular SLAM employs a single camera and is attractive for its simplicity and low hardware cost. However, it faces challenges such as scale ambiguity and higher drift in long trajectories [19]. Stereo SLAM, by using two synchronized cameras, can triangulate depth directly, resulting in improved robustness and scale consistency [20]. In contrast, RGB-D SLAM integrates color and depth data from structured light or time-of-flight sensors, enabling dense and accurate reconstructions, particularly in indoor scenes [21].

Recent advancements in visual SLAM have focused on combining geometric methods with learning-based models to enhance robustness in dynamic or poorly textured environments [22]. Additionally, visual-inertial fusion and multi-sensor integration have further extended the capabilities of SLAM systems under challenging conditions [23]. These developments highlight the rapid evolution of visual SLAM technologies across all three categories.

V. Monocular SLAM: Evolution and Methods

Monocular SLAM has emerged as one of the most thoroughly investigated areas in the broader SLAM research landscape, primarily due to its minimal hardware requirements and its adaptability across diverse platforms and applications.

By using a single RGB camera, monocular SLAM systems aim to simultaneously estimate camera motion and reconstruct the surrounding environment. However, the absence of direct depth measurements introduces inherent challenges such as scale ambiguity, motion degeneracy in planar scenes, and increased sensitivity to lighting and texture variations [24]. As depicted in Fig. 2, the evolution of monocular SLAM has progressed through a series of methodological innovations in both the visual front-end and the back-end optimization strategies.

Initial efforts began with RatSLAM (2004), which was biologically inspired and modeled after rodent navigation systems. While simplistic, it laid foundational principles in appearance-based mapping. This was succeeded by MonoSLAM (2007), a pioneering approach that applied an Extended Kalman Filter (EKF) to jointly estimate camera pose and sparse 3D map points in real time [25]. The advent of PTAM in the same year introduced a game-changing architectural shift by decoupling tracking and mapping into parallel threads, drastically improving the performance of real-time monocular SLAM systems [26].

Subsequent methods diverged into two main categories: feature-based and direct methods. Feature-based approaches rely on the detection and matching of keypoints, while direct methods operate on image intensities without extracting features. DTAM and LSD-SLAM demonstrated that it is possible to achieve dense and semi-dense reconstructions using photometric information alone, resulting in more detailed environmental maps [27][28]. These techniques offered higher resolution outputs but required careful handling of photometric calibration and motion assumptions.

A major leap occurred with the release of ORB-SLAM in 2015, which combined ORB keypoint descriptors with a robust framework for tracking, mapping, loop closure, and relocalization [29]. Its success led to further extensions, including ORB-SLAM2 and ORB-SLAM3, which supported multiple sensor configurations such as stereo and RGB-D, and included inertial fusion for improved robustness in challenging motion conditions [30]. These improvements allowed for more accurate scale estimation and reduced drift during long-term operations [31].

Simultaneously, direct methods like DSO (Direct Sparse Odometry) and its variants, including Stereo DSO, LDSO, and V-LDSO, refined photometric error minimization and introduced keyframe-based filtering to enhance both accuracy and computational efficiency [32][33]. These methods, while sensitive to illumination changes, offered high precision in texture-rich environments and demonstrated robustness in frame-to-frame tracking without reliance on feature extraction.

Hybrid approaches have also gained attention, blending the strengths of direct and feature-based methods. Algorithms like SVO (Semi-Direct Visual Odometry), PL-SVO (Point and Line SVO), and CNN-SVO achieved a balance between robustness and efficiency by integrating direct photometric tracking with geometric landmarks [34][35]. These approaches reduced the dependency on handcrafted features and improved performance in a wider range of scene geometries.

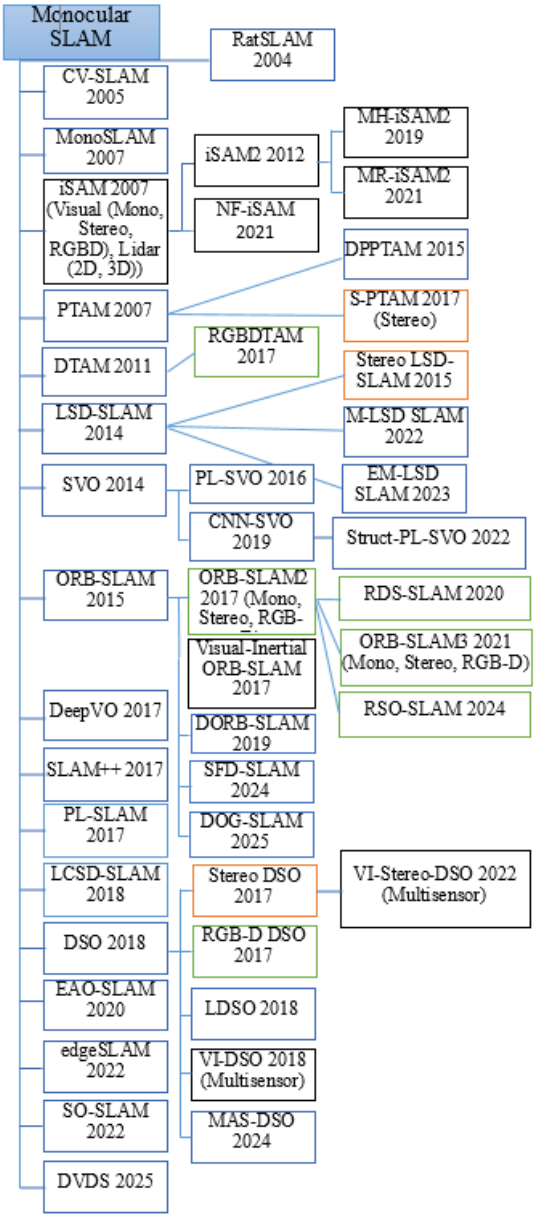

Fig. 2. Chronological development of monocular SLAM methods from 2004 to 2025.

In recent years, the incorporation of deep learning has significantly influenced the monocular SLAM domain. Frameworks such as DeepVO, edgeSLAM, and CNN-SLAM utilized neural networks for depth prediction, feature learning, and semantic scene understanding [36][37]. These models not only enhanced robustness in low-texture or dynamic environments but also enabled the inference of scene geometry from a single image. Moreover, methods such as SLAM++, SO-SLAM, and Struct-PL-SVO integrated object-level and structural cues into the mapping process, moving toward semantic and structural awareness in localization [38][39].

Recent state-of-the-art systems like DVDS (2025) and MAS-DSO demonstrate the growing emphasis on multi-sensor integration, semantic enrichment, and real-time adaptability [40][41]. These systems incorporate inertial data, semantic

segmentation, and learned depth priors to improve resilience in diverse and unpredictable environments.

Despite these advancements, monocular SLAM still faces unresolved issues, particularly in handling motion blur, rapid camera movements, dynamic object interference, and texture-poor scenes. The pursuit of robustness, generalization, and computational scalability continues to drive innovation in this domain, with future directions likely to focus on hybrid geometric-learning systems, unsupervised adaptation, and cloud-enhanced mapping frameworks.

VI. Stereo SLAM: Advances and Applications

Stereo SLAM systems utilize a pair of synchronized cameras to estimate depth via triangulation, enabling accurate 3D reconstruction and metric-scale motion estimation. This configuration eliminates the scale ambiguity inherent in monocular systems and enhances robustness in texture-poor or low-light environments [42]. As illustrated in Fig. 3, the development of stereo SLAM has progressed steadily with contributions that focus on improving accuracy, structural awareness, and adaptability in dynamic scenarios.

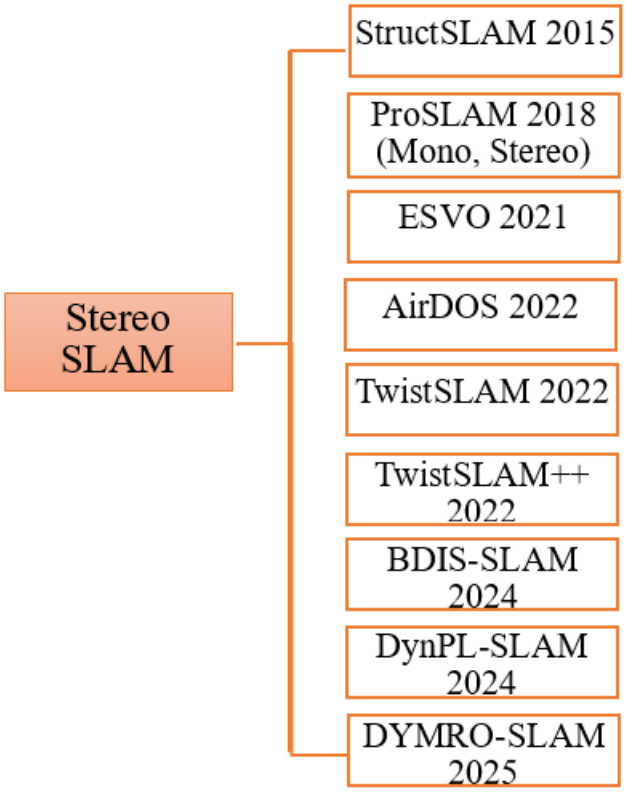

Fig. 3. Evolution of stereo SLAM methods and their applications.

StructSLAM (2015) laid the foundation by integrating stereo imagery with structural constraints to achieve semantically meaningful mapping [43]. The introduction of ProSLAM (2018) provided a lightweight and modular stereo SLAM framework capable of real-time performance, supporting both mono and stereo inputs for flexibility across platforms [44]. More recent methods, such as ESVO (2021) and AirDOS (2022), have extended stereo SLAM to address aerial applications and dynamic obstacle detection using stereo image alignment and depth filtering techniques [45][46].

The emergence of TwistSLAM and TwistSLAM++ (2022) represents a shift toward incorporating twist-based motion models for improved tracking under fast camera movements [47]. These systems enhance pose estimation stability while reducing drift in challenging trajectories. Building on these ideas, BDIS-SLAM and DynPL-SLAM (2024) have pushed stereo SLAM into the realm of dynamic environments, where the presence of moving objects demands adaptive strategies for scene segmentation and motion compensation [48].

Finally, DYMRO-SLAM (2025) exemplifies the future direction of stereo SLAM by integrating motion robustness, real-time segmentation, and adaptive feature association in highly dynamic and cluttered settings [49]. In addition to robotics, stereo SLAM has found applications in autonomous driving, drone navigation, and indoor mapping where depth accuracy and consistency are critical [50].

Collectively, the advancements in stereo SLAM reflect a balance between computational efficiency, structural integrity, and semantic awareness, making it a viable solution for diverse real-world deployment scenarios. However, the challenges of real-time performance in high-speed settings and long-term consistency in large-scale environments continue to motivate ongoing research.

VII. RGB-D SLAM: Depth-Enhanced Approaches

RGB-D SLAM systems integrate color (RGB) images with depth data, typically captured using structured light or time-of-flight sensors, to produce accurate and dense 3D maps in real-time. This additional depth channel enhances scene understanding, especially in indoor environments where scale accuracy and dense reconstruction are critical. As illustrated in Fig. 4, the evolution of RGB-D SLAM has been marked by diverse approaches that balance geometric precision, semantic richness, and computational efficiency.

Early RGB-D SLAM efforts began with KinectFusion (2011), which demonstrated the potential of consumer-grade depth sensors for dense real-time 3D reconstruction [51]. Shortly thereafter, Kintinuous (2012) extended KinectFusion by enabling continuous tracking and mapping across larger spaces [52]. Later methods such as ElasticFusion (2015) introduced surfel-based representations to maintain loop-closure consistency and surface flexibility during global optimization [53]. Similarly, BundleFusion (2017) incorporated global pose graph optimization with real-time feedback loops to minimize drift in long-term operations [54].

The year 2017 marked a proliferation of RGB-D SLAM algorithms. Systems such as VO-SF, Co-Fusion, and StaticFusion focused on improving tracking robustness and map representation in the presence of dynamic objects [55][56][57]. Others like MR-RGBD-SLAM and SWAIACP-SLAM added semantic cues and adaptive filtering mechanisms to improve depth consistency [58][59]. Simultaneously, methods like Detect-SLAM and CodeSLAM explored object-level SLAM and compact depth representations, respectively [60][61].

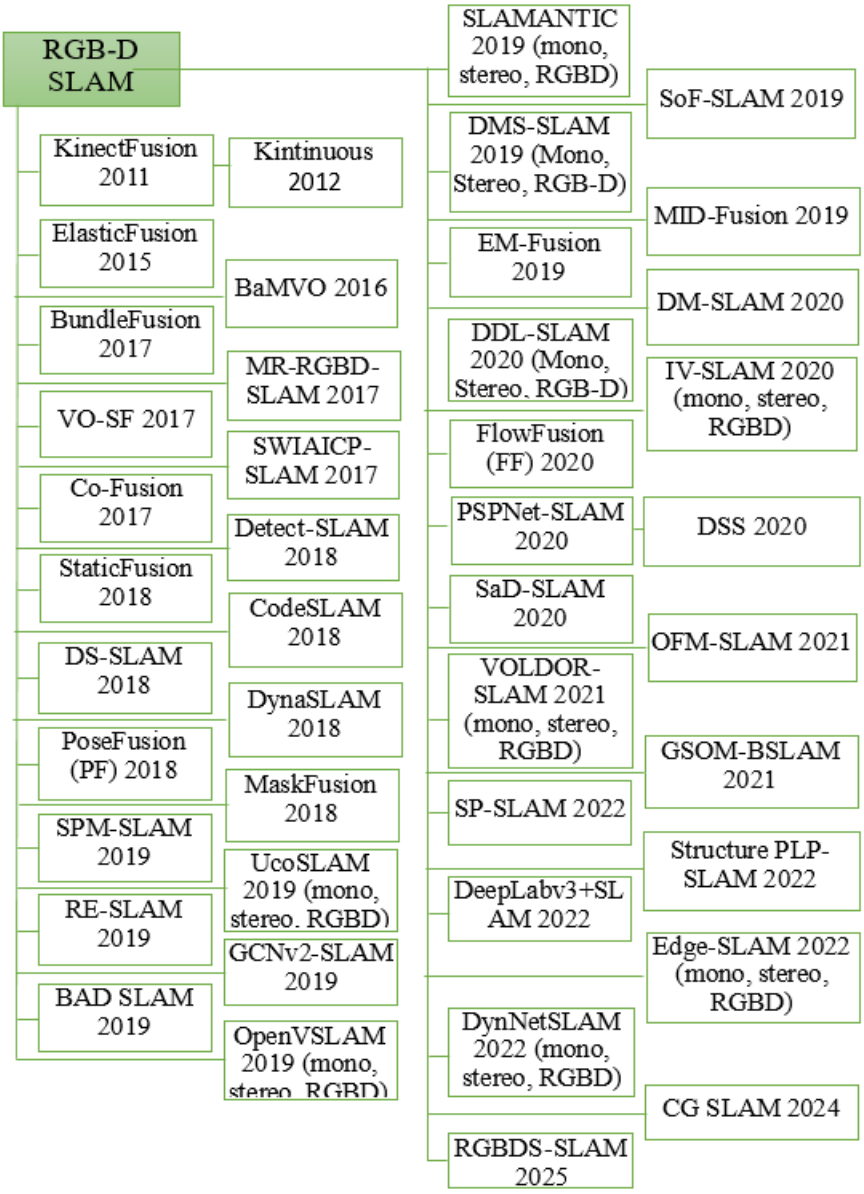

Fig. 4. Overview of RGB-D SLAM methods and their evolution.

In 2018, efforts like DS-SLAM, PoseFusion, and DynaSLAM focused on dynamic scene handling by introducing segmentation pipelines and learning-based object recognition to remove moving elements from mapping [62][63][64]. The inclusion of neural networks for motion segmentation and visual odometry marked a turning point, bridging traditional geometry-based techniques with deep learning paradigms [65]. Additionally, MaskFusion combined semantic instance segmentation with dense mapping, enabling object-level awareness in SLAM systems [66].

The year 2019 introduced generalized SLAM systems like UcoSLAM, OpenVSLAM, and SLAMANTIC, which supported multiple input modalities including mono, stereo, and RGB-D [67][68][69]. These frameworks emphasized modularity, scalability, and reusability, paving the way for flexible deployments in multi-sensor configurations. Simultaneously, RE-SLAM, SPM-SLAM, and BAD SLAM explored better loop closure techniques, keyframe management, and robustness under challenging illumination and texture conditions [70][71][72].

A wave of fusion-based systems emerged in 2019 and 2020, including EM-Fusion, DMS-SLAM, and DDL-SLAM, which aimed to fuse depth and color cues through probabilistic and optimization-driven pipelines [74][75]. FlowFusion, PSPNet-SLAM, and SaD-SLAM utilized optical flow and deep learning-based segmentation to enhance temporal consistency in fast-moving scenes [76][77][78]. Moreover, IV-SLAM and DM-SLAM extended these capabilities with multi-view consistency and dense depth propagation [79][80].

In 2021 and 2022, the emphasis shifted toward dynamic SLAM environments, as demonstrated by systems like OFM-SLAM, GSOM-BSLAM, and Structure PLP-SLAM, which integrated real-time semantic mapping and predictive modeling

of dynamic elements [81][82][83]. VOLDOR-SLAM and DynNetSLAM incorporated multi-branch neural networks for end-to-end depth estimation and pose prediction, effectively reducing dependency on handcrafted pipelines [84][85]. Additionally, Edge-SLAM brought attention to computational constraints, adapting RGB-D SLAM pipelines for edge devices by leveraging lightweight networks and compressed representations [86].

Recent approaches such as DeepLabv3+SLAM and SP-SLAM integrated semantic segmentation directly into the mapping process, enabling category-level understanding of environments [87][88]. This trend is furthered by hybrid methods like CG-SLAM and RGBDS-SLAM (2024–2025), which fuse cognitive perception models with conventional SLAM to support task-specific intelligence, such as scene classification and goal-directed navigation [89][90].

Notably, these RGB-D SLAM systems rely on benchmark datasets and real-time performance evaluation. Datasets like TUM RGB-D, ICL-NUIM, and ScanNet have been instrumental in validating performance across different benchmarks, offering standardized trajectories, dynamic scenes, and semantic annotations [91]. While these advancements have brought SLAM closer to robust deployment, issues related to sensor noise, occlusion, generalization in unseen environments, and energy efficiency still remain open challenges [92-94].

Overall, RGB-D SLAM has grown from simple depth-assisted mapping to rich, semantically-aware systems that integrate deep learning, object recognition, and multimodal fusion. This trajectory underscores the increasing convergence of geometric modeling and machine learning in the pursuit of highly adaptable and context-aware visual SLAM solutions.

VIII. Cross-Paradigm Analysis and Discussion

The evolution of Visual SLAM has produced a diverse array of systems across monocular, stereo, and RGB-D paradigms, each with specific strengths and limitations. A comparative analysis of these approaches reveals fundamental trade-offs in scalability, accuracy, computational complexity, and adaptability to dynamic environments.

Monocular SLAM remains the most lightweight and cost-effective option, requiring only a single camera for localization and mapping. However, it suffers from inherent scale ambiguity and limited depth perception, which restricts its application in scenarios demanding metric-scale accuracy [24]. Despite advancements like ORB-SLAM and DSO, monocular methods still rely heavily on loop closure and motion modeling to mitigate accumulated drift [29][32].

In contrast, Stereo SLAM inherently resolves the scale issue by estimating depth via triangulation. It provides a reliable middle ground between simplicity and depth accuracy, making it suitable for mobile robotics and drone navigation [42]. Systems such as ProSLAM and TwistSLAM++ demonstrate improved performance in fast-motion and low-texture environments [44][47]. Nevertheless, stereo systems require careful camera calibration and synchronization, which can introduce additional hardware constraints.

RGB-D SLAM, leveraging dense depth data from sensors like structured-light or time-of-flight cameras, excels in indoor mapping and 3D reconstruction [51][54]. These systems are particularly effective in dynamic and low-texture scenes due to the richness of depth information. However, they are limited by the operating range and sensitivity to lighting conditions, especially in outdoor settings [62]. Moreover, the high data throughput from RGB-D sensors increases computational demands, necessitating efficient data fusion and real-time optimization strategies [73][78].

Hybrid approaches integrating visual-inertial odometry, semantic segmentation, and learning-based modules are emerging across all three paradigms. For instance, visual-inertial extensions to ORB-SLAM and deep semantic mapping in RGB-D systems such as DynNetSLAM demonstrate that cross-domain fusion enhances robustness and scene understanding [30][85]. These trends reflect a shift toward generalizable SLAM systems capable of adapting to diverse environmental conditions and sensory inputs.

Despite these advances, unresolved challenges persist. Dynamic object handling, long-term consistency, real-time performance on edge devices, and scene generalization remain key bottlenecks. The convergence of geometry-based and data-driven methods is likely to play a pivotal role in addressing these issues and shaping the next generation of visual SLAM technologies.

IX. Future Directions

The field of Visual SLAM continues to experience rapid progress, yet numerous challenges remain unsolved, paving the way for future innovations. As the demand for intelligent autonomous systems rises, SLAM must evolve beyond static, structured environments to handle complex, unstructured, and dynamic real-world conditions. Several key directions are anticipated to define the next generation of SLAM systems.

One of the most pressing challenges is the robust handling of dynamic environments, where moving objects introduce inconsistencies in localization and mapping. While state-of-the-art methods such as DynaSLAM and DynNetSLAM have introduced dynamic object filtering using motion segmentation and learning-based modules, real-time robustness in highly dynamic scenarios remains limited [64][85]. Future systems must incorporate adaptive scene understanding and prediction mechanisms to account for object trajectories, occlusions, and interactions, thereby enhancing robustness under motion and clutter.

Another critical direction involves lifelong and continual SLAM, which allows systems to incrementally learn from their environments over extended periods. Current methods tend to operate in episodic modes, with limited memory and generalization across time or domains. Incorporating memory-augmented learning, self-supervision, and lifelong adaptation strategies would enable SLAM systems to refine their internal models continually and recover from localization failures or environmental changes. Techniques applied in DeepVO and other learning-based systems offer a foundation for such progress [36].

Semantic SLAM is also emerging as a transformative direction, where the integration of object-level understanding and scene semantics augments traditional geometric mapping. Systems such as MaskFusion, DeepLabv3+SLAM, and CG-SLAM demonstrate that embedding semantics enables higher-level reasoning, object manipulation, and contextual awareness [66][87][90]. Future research is expected to integrate multi-task learning pipelines that jointly optimize for pose estimation, semantic segmentation, and instance recognition. Such integration would be vital in service robotics, AR/VR, and autonomous navigation tasks where understanding scene content is as critical as knowing spatial geometry.

The development of resource-aware and edge-compatible SLAM algorithms is gaining significance as SLAM expands into mobile platforms, drones, and embedded robotics. High-performance SLAM often requires intensive computation and memory, making deployment on constrained devices difficult. Solutions like Edge-SLAM and optimized variants of SLAMANTIC and ORB-SLAM address these issues by incorporating lightweight architectures, neural compression, and on-device learning [86][69][30]. Future directions may involve further advances in model pruning, quantization, and hardware-aware design for real-time, low-power SLAM inference.

Multimodal SLAM represents another growing frontier. The fusion of multiple sensor inputs—including visual, inertial, depth, thermal, and even auditory data—enables robust mapping under diverse environmental conditions. Systems like ORB-SLAM3 and VOLDOR-SLAM illustrate how integrating inertial measurements and depth cues improves accuracy and consistency, especially in low-texture or fast-motion scenarios [30][84]. Expanding such systems to include semantic and audio signals could further enhance context-awareness, particularly in human-robot interaction and search-and-rescue missions.

In addition, learning-based SLAM continues to evolve. While geometry-based methods have dominated due to their interpretability and reliability, deep learning models are increasingly demonstrating their potential in monocular depth prediction, motion estimation, and loop closure detection. Hybrid pipelines that combine data-driven features with geometric consistency are likely to define future SLAM architectures. DMS-SLAM, CodeSLAM, and PSPNet-SLAM exemplify this convergence [74][61][77].

Finally, neural implicit representations, such as neural radiance fields (NeRF), are expected to redefine how SLAM systems model and store environments. These methods replace discrete maps with continuous, differentiable scene representations that offer high-fidelity reconstructions and efficient storage. Their integration with SLAM could lead to novel systems that unify localization, mapping, and scene rendering into a single framework, unlocking new possibilities in mixed reality and digital twin technologies.

In summary, the future of Visual SLAM lies in its ability to become more adaptive, intelligent, semantic, and efficient, leveraging cross-disciplinary advances in machine learning, sensor fusion, and cognitive modeling. These advancements will shape the next generation of autonomous systems capable of understanding, interacting with, and navigating the real world in an increasingly human-like manner.

X. Conclusion

This review has presented a structured and comprehensive analysis of the evolution, methodologies, and challenges in Visual SLAM across three primary paradigms: monocular, stereo, and RGB-D systems. Monocular SLAM remains valuable for its simplicity and affordability, yet it continues to face challenges related to scale ambiguity and robustness under complex motion. Stereo SLAM offers a balance between hardware complexity and depth accuracy, making it suitable for a wide range of robotic and autonomous applications. RGB-D SLAM systems have significantly advanced scene understanding and dense mapping capabilities, particularly in indoor and structured environments, though they remain constrained by sensor limitations and computational demands. Across all paradigms, recent trends reveal a growing convergence of traditional geometric methods with learning-based models, enabling SLAM systems to operate more robustly in dynamic and perceptually challenging scenarios. The incorporation of semantic information, multi-modal sensor fusion, and real-time optimization strategies has further extended the operational scope of SLAM technologies. Despite these advances, persistent issues such as adaptability in dynamic environments, efficient computation on edge devices, and generalization across unseen domains continue to hinder full autonomy. The future of Visual SLAM lies in the development of lifelong, context-aware systems capable of learning from experience, reasoning semantically, and operating reliably under uncertainty. By integrating insights from computer vision, robotics, and machine learning, the next generation of SLAM algorithms will move beyond spatial localization to support intelligent interaction and decision-making in real-world environments. This review serves as a foundation for understanding current capabilities and identifying key research directions in the evolving landscape of Visual SLAM.

***Abstract*—Artificial Intelligence (AI) is increasingly recognized as a transformative force in higher education, yet adoption remains patchy and often confined to partial implementations. Using the PRISMA protocol, this study systematically reviews 74 Scopus-indexed articles published between 2015 and 2025. Publication activity rose sharply after 2020, led by contributions from China, the United States, and Saudi Arabia. Across the corpus, Perceived Usefulness and the Technology Acceptance Model (TAM) are the most frequently applied constructs, while ethical and policy dimensions remain underexamined. Thematic analysis delineates five clusters: adaptive learning and personalization; ethics and trust; digital literacy and readiness; AI in assessment and evaluation; and organizational transformation. Despite growing attention, regional gaps persist—especially in developing countries, where constrained infrastructure, funding, and digital literacy impede adoption. To address these challenges, the study proposes a multi-level conceptual framework integrating TAM, UTAUT, TPACK, and TOE to connect individual, institutional, and external factors for sustainable AI-driven education. Overall, the review underscores that AI adoption is not merely an efficiency tool but a strategic lever to advance the Sustainable Development Goals (SDGs), particularly by fostering inclusive, equitable, and innovative higher education systems.**

Keywords*—Artificial intelligence adoption; higher education; sustainable education; developing country

I. Introduction

Artificial Intelligence (AI) has advanced rapidly and is now deployed across multiple domains, including education [1]. It is widely regarded as a promising instrument for improving educational quality over the long term [2]. In educational settings, AI can generate strategic efficiencies by delivering personalized feedback, automating administrative tasks, forecasting student performance, enhancing learner engagement, and enabling adaptive assessment [3]. Accordingly, further development and careful integration of AI in education are needed to realize comprehensive, system-wide benefits.

AI-driven innovations are reshaping higher education at multiple levels [4]. Beyond streamlining administrative processes, AI enables adaptive learning, personalized curricula, and automation of academic services [5] [6] [7]. Its adoption has been linked to improvements in teachers' psychological well-being—through workload reduction, heightened motivation, and strengthened assessment and evaluation skills [8]—while also promoting more personalized learning and richer student experiences [9]. Professional development has been shown to support effective integration of GenAI for enhancing student engagement in teaching practice [10] [11], an essential precursor to interaction and improved performance; accordingly, designing AI-enabled activities, including those using ChatGPT, is warranted. Evidence further suggests that AI can raise learning effectiveness by up to 30% via learning-style analytics and content-recommendation systems [12]. In the United States and China, AI-based chatbots already support interactive learning [13] [14]; in Serbia, artificial intelligence and machine learning have been used to cultivate collaborative learning environments, develop student skills, and provide accessible research opportunities [15]. In Australia, ChatGPT accounted for 17.3% of the variance in improved academic outcomes [16]. Overall, AI facilitates faster feedback for students and allows instructors to devote more attention to strategic, higher-order pedagogical work [17].

Adopting AI in higher education opens pathways to cultivate higher-quality student outcomes [18]. Implementation, however, remains uneven across countries. Hughes et. al. [19] report that GenAI uptake is hindered by heterogeneous knowledge of AI tools and processes and by underdeveloped GenAI regulation. In Nigeria, adoption is constrained by limited funding, scarce technical expertise, and inadequate infrastructure [20]. In China, low digital literacy and resistance to AI impede deeper integration [21]. Evidence from the Middle East and North Africa cites low State revenues and unclear policies as additional obstacles [22]. In Sri Lanka, the absence of university-level policies and guidelines further inhibits GenAI adoption [23]. Taken together, these findings underscore the diverse, context-specific challenges surrounding AI adoption in education. A fit-for-purpose development model is therefore critical as a strategic pathway to enable effective adoption across higher education institutions.

AI adoption models grounded in established frameworks such as UTAUT and TOE have been implemented in several countries [24] [25] [26]. However, these templates are not fully aligned with the realities of developing contexts marked by digital divides, institutional diversity, and distinct policy needs. Prior findings underscore the importance of determinants—government support, leadership, risk, strategy, system quality,

user satisfaction, and readiness—for information-system/technology adoption and the application of AI in learning [27] [30] [28] 29] [31] [32] [33] [34] 35] [36]. However, most studies remain confined to generic drivers of AI uptake and use. Recent evidence further indicates that ChatGPT adoption in higher education is shaped by Performance Expectancy, Effort Expectancy, Hedonic Motivation, and AI ethical issues (bias, privacy, transparency), which collectively call for educator training, AI literacy, critical-ethical competence, and practical learning (e.g., Moral Machine) to prepare an automation-ready workforce [37] [38] [39]. This stream of work, however, is limited to ChatGPT, lacks a holistic approach, and provides minimal discussion of AI adoption within local cultural and contextual settings.

Meanwhile, ChatGPT demonstrates fluency at the university level but falls short on critical, context-sensitive analysis. Teachers tend to view AI favorably, yet they often lack sufficient content knowledge [40] [41]. This study also has limitations in its analysis of student–lecturer readiness and in articulating an AI competency framework rooted in the local context. Mohd Rahim et. al. [42] propose a chatbot-based AI adoption model incorporating perceived trust, behavioral intention, and use among Malaysian graduate students; however, this study was constrained by a sample composed solely of university students. Alyousef et.al. [43] identify ease of use, usefulness, engagement, trust, familiarity, and behavioral intention as key drivers of AI adoption in higher education, but its reliance on a student-only sample limits generalizability beyond that context.

Celik [44] extends the TPACK framework by incorporating artificial intelligence and ethics, underscoring that teachers should master not only pedagogy, content, and technology but also ethical literacy in AI use. Its limitations include the lack of integration with other technology-adoption models and the omission of institutional and policy dimensions. Research [45] investigates factors influencing the adoption and use of AI-based voice assistants, but its household-only design yields a limited number of respondents. Rao and R. Prasad [46] examine the role of 5G technology as a leading enabler of Industry 4.0 and its integration with AI, the Internet of Things (IoT), big data, and cloud computing; however, it does not employ an adoption-theory framework, which is important for shaping AI acceptance at the institutional or individual level.

Okunlaya et. al. [47] examine how AI-enabled library services can catalyze digital transformation in higher education. Its principal limitation is the absence of a technology-adoption framework, leaving the determinants of AI acceptance unspecified. Huang and Lu [48] analyzes the implementation of AI in Intelligent Tutoring Systems (ITS) for continuing education but focus on developed-country contexts, leaving developing settings underexplored. More broadly, prior research has not integrated adoption models with institutional dimensions; consequently, AI acceptance—especially in developing countries—remains insufficiently understood.

Prior work has explored multiple facets of technology and AI adoption—government support, service quality, risk, strategy, system quality, user satisfaction, social capital, and readiness to adopt learning information technologies [27] [30] [28] 29] [31] [32] 33] [34] [35]—alongside applications of AI in teaching and learning [36]. Taken together, these studies tend to emphasize individual-level elements such as chatbots for academic services, AI-based learning analytics, and assessment automation. Nevertheless, a holistic model that integrates technological, organizational, environmental, policy, and human-resource readiness factors is still absent [37] [38] [39]. Moreover, most prior research overlooks the distinctive characteristics of higher education institutions—including infrastructure constraints, regulatory conditions, and digital readiness—thereby limiting contextual applicability [49] [40] [41].

The literature still reveals a gap in AI adoption within higher education. This study addresses that gap by conducting a systematic literature review of AI adoption using a systematic approach within the higher education ecosystem [50]. The review considers technological, organizational, human, environmental, and ease-of-adoption factors [51] [52]. By analyzing prior research, the study maps research distribution, synthesizes theoretical models, performs cluster analysis, identifies research gaps, derives implications, and proposes a conceptual framework for AI adoption in higher education. The aim is to provide insights attuned to technological, organizational, environmental, cultural, and policy conditions. The results are intended to guide future researchers in enhancing higher-education quality through AI adoption and to encourage policymakers to support sustainable educational transformation.

This study undertakes a systematic literature review to map the field, identify research trajectories and opportunities for development, and synthesize the factors that shape artificial intelligence adoption in higher education, thereby consolidating the evidence base in this domain. It seeks to address the following research questions:

RQ1: What is the state of higher education's readiness to adopt AI, and how is it related to continuing education?

RQ2: What is the potential of integrating cross-theoretical perspectives to build a conceptual framework of AI adoption for sustainable education?

RQ3: How can developing countries contribute to realizing AI-driven sustainable education?

RQ4: How does the conceptual framework of AI adoption support the goal of sustainable education?

The remainder of this article is organized as follows. Section II details the research methods, including the PRISMA protocol and the bibliometric and thematic procedures employed. Section III reports the analysis results on publication trends, dominant theoretical lenses, and the principal thematic clusters. Section IV concludes with the study's conclusions Finally, Section V discuss the study's limitations, and recommendations for future research.

II. Method

A. Research Design

This study adopts a qualitative design employing a systematic literature review. A systematic literature review systematically identifies studies on a defined topic to answer

research questions transparently while incorporating evidence and assessing study quality [53] [54]. It synthesizes strengths, weaknesses, and patterns of divergence across prior work to produce a comprehensive account and reveal research gaps [55]. We applied the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) protocol with Watase UAKE to identify systematic reviews [56], using PRISMA to ensure transparent reporting so that findings and procedures are fully described [57]. The review analyzes prior research on AI adoption models in higher education to provide a basis for developing adoption models aligned with educational conditions in Indonesia.

B. Identification

The literature search was conducted in Scopus using the keywords "AI Adoption," "Artificial Intelligence," and "Higher Education." This initial sweep identified 126 articles.

C. Screening

The retrieved records were screened against inclusion and exclusion criteria to ensure alignment with the study's aims. The inclusion criteria were: 1) publication in Scopus-indexed international journals (Q1–Q4), 2) a time window of 2015–2025, 4) empirical, developmental, or conceptual studies addressing AI adoption models in higher education, and 5) articles written in English. Applying these criteria led to the removal of four articles that fell outside the publication years and eighteen that were not Scopus Q1–Q4, leaving 106 articles at the screening stage.

A second pass applied the exclusion criteria: 1) articles discussing AI outside an educational context, 2) duplicate records, and 3) non–peer-reviewed items. Five articles met these exclusion criteria, yielding 101 articles.

D. Eligibility

Titles, abstracts, and full texts were then assessed for eligibility using the same criteria to confirm topical relevance. Of the 101 articles entering this phase, 30 failed to meet the eligibility threshold, leaving 71 articles.

E. Appraisal of Quality

A quality appraisal ensured substantive relevance to AI adoption in higher education. The researcher examined methodologies associated with the adoption models TAM, UATUT, TOE, DOI, and AITAM, and verified that studies addressed organizational, technological, policy, cultural, and environmental factors. All 71 articles from the prior step were deemed eligible. At this point, three additional articles judged suitable were added, bringing the final corpus to 74 articles. The following Fig. 1 is a chart of the article selection process:

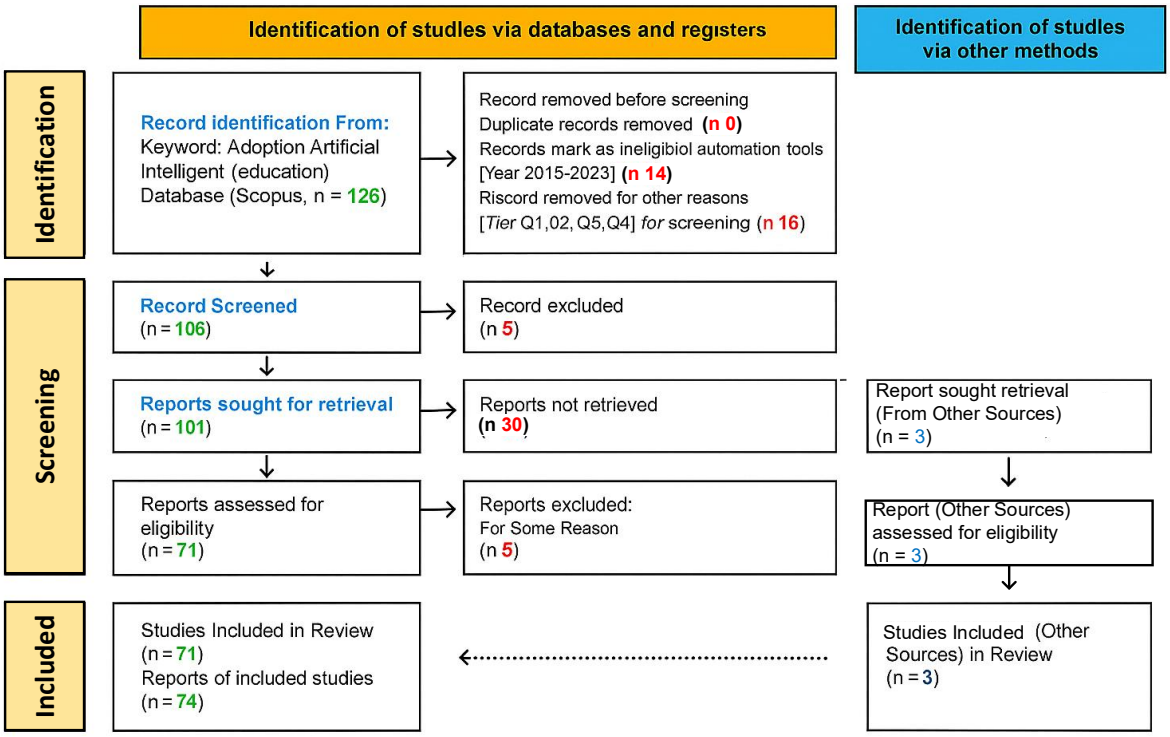

Fig. 1. Selection of articles in the PRISMA flow diagram.

III. Results and Discussion

This section reports findings from the systematic literature review. The discussion is organized into three parts: descriptive statistics, thematic analysis, and theoretical and practical implications.

A. Overview of Study Selection

Using the Scopus database and the keyword Adoption Artificial Intelligence Education for the 2015–2025 period, 126 articles were initially identified. Of these, 20 did not meet the criteria (outside the year range, not in the education category, or published in journals below the quality standard), leaving 106

for screening. The screening phase yielded 101 records that advanced to the retrieval stage. Subsequently, 71 articles satisfied the inclusion criteria, and three additional articles were added from other sources, producing a final corpus of 74 articles. This process ensured coverage of recent developments published in reputable international journals (Q1–Q4) and relevance to AI adoption in higher education.

B. Geographical Distribution of Studies

The country-level distribution reveals pronounced disparities. China led with 14 publications, followed by the United States (7) and Saudi Arabia (5). Indonesia and Malaysia contributed three articles each, while Mexico, Spain, Morocco, South Africa, and Turkey produced two each. China's dominance situates East Asia as a hub of AI-in-education research, influenced by substantial ed-tech investment and assertive government policy. The United States contributes notably to evaluative, pedagogical, and ethical strands, whereas Saudi Arabia's output aligns with national digitization priorities (Saudi Vision 2030). Contributions from Southeast Asia—including Indonesia and Malaysia—and from Africa are emerging but remain limited, underscoring a regional research gap that scholars in developing countries can address with locally grounded perspectives. A graph of article distribution by country is provided in Fig. 2.

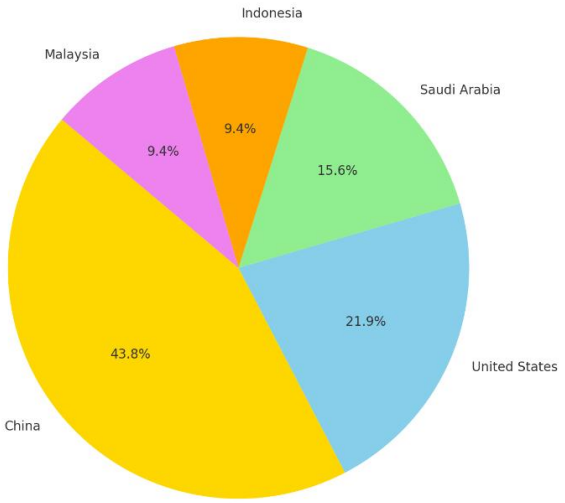

Fig. 2. Top 5 geographical distribution of studies.

C. Yearly Article Trends

Annual output shows a pronounced inflection after 2020. Between 2015 and 2020, publications were relatively flat at $\leq$ 2 articles per year. Starting in 2021, output rose sharply to 6 articles, followed by steady increases in 2022 and 2023 (11 articles each). The peak arrived in 2024 with 23 articles, signalling intensifying global attention to AI adoption in education. By mid-2025, 15 articles had already appeared, suggesting that the year's total may surpass prior records. This trajectory likely reflects exogenous drivers—most notably the COVID-19 pandemic's acceleration of educational digitization, policy support across countries, and expanded funding for AI-related research—pushing AI integration to the forefront of educational agendas in infrastructure, pedagogy, and ethics. A graph of article counts by year is presented in Fig. 3.

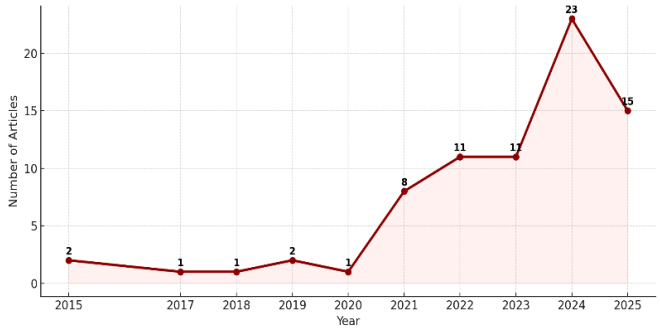

Fig. 3. Yearly article trends.

D. Variable Trends

The trend analysis indicates that Perceived Usefulness is the most frequently examined construct in AI - adoption research, appearing in 10 articles. This prominence suggests that the perceived benefits of technology are the dominant driver of readiness to adopt AI in higher education. Nine additional variables—Optimism, Perceived Privacy Risk, Social Influence, Artificial Intelligence, Effort Expectancy, Perceived Enjoyment, Trust, Perceived Ease of Use, and Perceived Ease—each appeared 2 times, underscoring the salience of social dimensions such as trust and usability in the adoption process. By contrast, Objective Useability, Insecurity, Relative Advantage, Compatibility, Expectation Confirmation, and Computer Playfulness appeared once each, signalling opportunities for deeper investigation of these factors in advancing sustainable education. The variable trends are presented in Fig. 4.

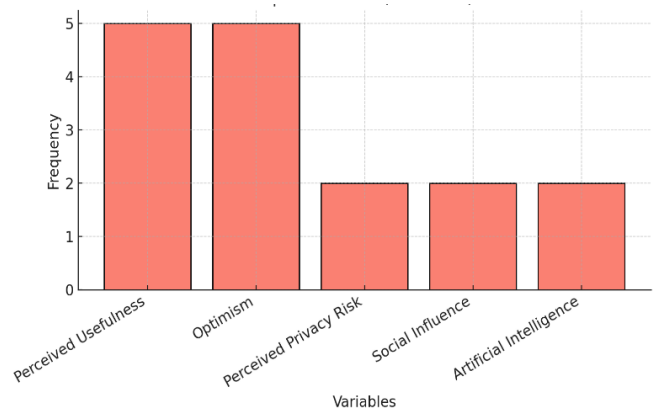

Fig. 4. Variable trends.

E. Theoretical Model of AI Adoption

Analysis of theoretical framing indicates that TAM (Technology Acceptance Model) is the most frequently employed approach, particularly for assessing faculty and student perceptions of AI's usefulness and ease of use. UTAUT/UTAUT2 appears in broader applications, incorporating performance expectancy, social influence, and facilitating conditions. At the institutional tier, TOE (Technology–Organization–Environment) is used to foreground organizational readiness, managerial support, and external pressures. At the same time, Diffusion of Innovation (DOI) is pertinent for explaining adoption dynamics across campus populations. Despite this range, most studies rely on a single

framework. The paucity of cross‐model integration is a notable limitation, given that AI adoption in higher education is intrinsically multidimensional—encompassing individual, institutional, and policy dimensions.

F. Thematic Clusters from Network Analysis

Keyword network analysis identified five principal clusters: 1) Adaptive Learning & Personalization—centered on intelligent tutoring systems, intelligent-TPACK, and AI-based learning personalization; 2) Ethics & Trust—highlighting transparency, student data privacy, and potential algorithmic bias; 3) Digital Literacy & Readiness—emphasizing faculty/student technology literacy and AI integration; 4) AI in Assessment & Evaluation—covering automated assessment, learning analytics, and academic performance prediction; and 5) Organizational Transformation—focusing on institutional readiness, change-management strategies, and digital-infrastructure investment. These findings indicate a fragmented landscape: clusters largely operate in parallel, with limited cross-theme integration.

The analysis further shows that AI technology constitutes the largest node, influencing performance, trust, organizational capabilities, and sustainability—evidence of topic dominance within AI acceptance. Major concentrations also appear across the pedagogy and literacy, ethics and sustainability, organization and performance, and technology adoption and acceptance clusters. Overall, research on AI adoption in higher education remains broad yet dispersed rather than fully integrated. Thematic clusters are presented in Fig. 5.

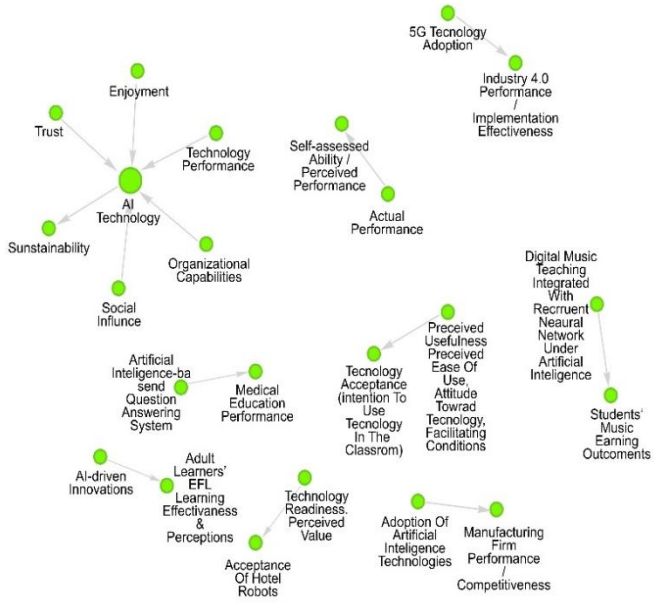

Fig. 5. Thematic clusters from network analysis.

G. Highly Cited Benchmark Articles

Citation analysis highlights several anchor studies. McLean & Osei-Frimpong (2019), with 536 citations, investigated determinants of adoption for AI-based virtual assistants (Alexa). Celik (2023), cited 330 times, advanced the concept of Intelligent (TPACK), embedding AI within teachers' pedagogical-competency frameworks. Lin et al. (2023), with 184 citations, emphasized AI's role in intelligent tutoring systems, corroborating its effectiveness for personalized learning. Wang et al. (2024), with 121 citations, offered a systematic review of AI in education that serves as a key roadmap for subsequent inquiries. Collectively, these benchmark articles illustrate that work combining strong theoretical innovation with clear practical relevance tends to attract broad scholarly attention. Table I depicts citations from the SLR analysis.

TABLE I. HIGHLY CITED BENCHMARK ARTICLES

H. Research Gaps Identified

The synthesis reveals five persistent gaps. First, theoretical integration remains limited: studies continue to rely partially on TAM/UTAUT without adopting multi-level frameworks. Second, a regional skew persists, with East Asia dominating and developing countries contributing comparatively little. Third, longitudinal evidence is scarce; cross-sectional designs predominate, leaving long-term impacts largely unexamined. Fourth, ethical and policy dimensions—now increasingly salient in higher education—are underexplored. Fifth, links to academic outcomes are weak, as most research halts at adoption perceptions rather than connecting directly to student learning results.

I. Implications for Higher Education

Findings from this SLR carry multi-level implications. Academic: develop new conceptual frameworks that fuse technology-adoption theory with pedagogy (e.g., TAM + TPACK). Practical: universities should institute AI-literacy training for lecturers and students and cultivate an AI-enabled learning ecosystem. Policy: regulations on the ethical use of AI, student-data protection, and evaluation standards require prompt development. Global–local: best practices from China and the United States can be adapted, but must be calibrated to Indonesia's infrastructural realities and learning culture.

J. Conceptual Framework

Building on the findings, the framework positions individual factors (digital literacy, attitude, motivation), institutional factors (management support, infrastructure, campus policy), and external factors (regulation, global trends) as primary determinants of AI adoption in higher education. AI adoption, in turn, affects learning outcomes—namely personalization, effectiveness, and 21st-century literacy. Innovation can trigger insecurity, thereby motivating the development of intelligent TPACK; simultaneously, optimism and AI literacy shape perceived ease, AI usability, and trust. When AI is perceived as valuable, beneficial, and safe, acceptance rises. These dynamics foster positive attitudes that lead to intention and, ultimately, actual use. The AI adoption model derived from this review is presented in Fig. 6.

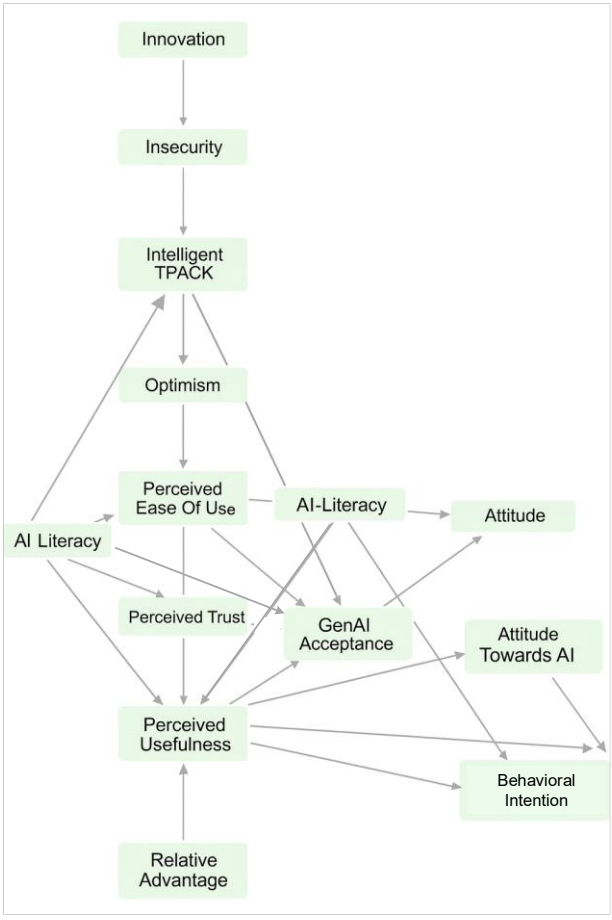

Fig. 6. AI adoption model.

1) RQ1: Readiness of Higher Education to Adopt AI and its Relevance to Continuing Education

Integrating AI into teaching through the Intelligent-TPACK lens presupposes pedagogical expertise, innovation readiness,

AI literacy, and robust teacher trust [44]. Because AI functions not merely as a tool but as a catalyst for pedagogical change, instructors must engage in reflective and ethical practice. In this view, the success of AI adoption hinges on educators' capacity to build Intelligent-TPACK. AI can also strengthen education by advancing civic responsibility, ethics, and character formation; realizing this potential requires AI-literate human resources and curricula that embed AI ethics [58]. To ensure students act as responsible, productive users rather than passive consumers, higher education institutions should elevate AI literacy—thereby supporting engagement and personalized learning. The upshot is that AI literacy is essential to cultivate ethical and critical AI use [59].

Within faculty recruitment, the use of GenAI renders AI literacy and Intelligent-TPACK foundational prerequisites. Framed this way, AI promotes data-driven, inclusive learning and supports the transition toward sustainable education. Institutions must therefore secure adequate digital infrastructure, ethical policies, and a supportive ecosystem—backed by AI training for lecturers [60].

SLR findings indicate heterogeneous readiness across systems. Universities in developed contexts (e.g., China, the United States, Australia) have integrated AI into adaptive learning, automated assessment, and academic chatbots, underwritten by mature infrastructure and regulation. These findings enable attention not only to adoption but also to sustainability dimensions such as energy efficiency, learning inclusion, and 21st-century literacies. By contrast, in many developing countries, readiness remains constrained by infrastructural gaps, limited funding, low digital literacy, and absent institutional policies, leaving the contribution of AI to sustainable education underrealized due to the digital divide. In Indonesia, despite government initiatives for educational digitalization, institutional readiness varies widely. Thus, AI readiness can serve as an accelerator of sustainable education—but only alongside deliberate strategies to build AI literacy, institute ethical governance, and secure national policy support.

2) RQ2: Potential for Cross-Theoretical Integration in the AI Adoption Conceptual Framework

UTAUT2 delineates determinants of behavioral intention for AI-based virtual assistants—performance expectancy, effort expectancy, social influence, and facilitating conditions—making it readily extensible to AI adoption in higher education. By contrast, TAM concentrates on perceived usefulness and related perception constructs while largely omitting social-infrastructure considerations. Treating these frameworks in isolation yields a piecemeal view of adoption; integrating TAM and UTAUT2 is therefore essential to capture AI's multidimensional uptake rather than privileging either technical or social facets alone [61]. Complementarily, TAM remains a primary predictor of technology acceptance, whereas TPB (Theory of Planned Behavior) enriches the socio-psychological layer. Together, TAM and TPB furnish a sustainable scaffold by combining technical, psychological, and social drivers, thereby strengthening inclusive science learning [62]. Because adoption in educational settings also hinges on pedagogy, TPACK serves as a gauge of teacher readiness; TPACK literacy tends to increase teachers' acceptance of AI's usefulness, particularly as roles shift from information transmitters to facilitators of data-driven, personalized learning [44].

Most studies still deploy TAM to assess usefulness and ease, or UTAUT to add performance expectations and social influence; institution-level work commonly relies on TOE, and macro-level analyses sometimes invoke Diffusion of Innovation (DOI). This siloed use of frameworks fragments AI-adoption analysis. A cross-theoretical pathway is to combine TAM/UTAUT (individual level), TOE (organizational level), and TPACK (pedagogical level) within a single architecture. For instance, TAM can explain students' perceived usefulness of AI, TOE can capture organizational readiness (infrastructure, policies, external support), and TPACK can fortify lecturers' pedagogical and ethical literacy. Integrated in this way, the model becomes a holistic, multi-level framework suited not only to explaining adoption but also to designing implementation strategies aligned with sustainability goals—efficiency, inclusion, 21st-century literacy, and digital ethics.

3) RQ3: Contribution of Developing Countries in Realizing AI Adoption-Based Sustainable Education

AI is a powerful lever for improving learning quality, equitable access, and administrative efficiency. In developing contexts, however, success turns critically on the readiness of human resources and infrastructure; persistent challenges include infrastructural deficits, policy gaps, ethical risks, and limited AI literacy. These constraints can become opportunities when AI is positioned as an accelerator of educational transformation through policy support, capacity building, and targeted technology investment [63]. AI-based chatbots can also augment decision-making by enabling real-time interaction, personalized responses, and rapid data analysis, thereby elevating service quality and advancing continuing education as a transformational innovation [64]. Evidence further indicates that AI tools can raise academic performance by increasing learning efficiency, though concerns about personal-data misuse and algorithmic transparency—and the attendant risks of bias—underscore that safety and ethics are integral to sustainable education, not optional add-ons [65]. In the Middle East, university sustainability ratings have improved alongside AI adoption; beyond academic efficiency, AI has helped attract international students and spurred curricular shifts toward digitalization, AI ethics, and the green economy—together reinforcing AI's direct contribution to sustainability ratings in the region [66].

Developing countries such as Indonesia, Malaysia, and Sri Lanka are beginning to contribute empirical work on AI literacy, automated assessment, and generative AI ethics. Their studies provide essential local context to complement East Asia's dominant literature—for example, funding and infrastructure constraints in Nigeria and the absence of university-level regulation in Sri Lanka. To advance AI-enabled sustainable education, developing countries can:

Present local context-based models—for example, integrating AI with distance learning in remote areas.

Contribute policy perspectives—examining how governments, universities, and communities can narrow the digital divide.

Develop ethics and AI-literacy research—recognizing that the central challenge is not only technological but also human capacity and governance.

Pursued together, these strategies position developing countries not merely as consumers of global scholarship but as producers of contextually grounded knowledge that broadens and deepens the meaning of continuing education.

4) RQ4: Relationship of AI Adoption Conceptual Framework to Sustainable Education Goals

AI adoption for continuing education is multi-variable in nature. Perceived Usefulness and Optimism are pivotal because uptake in higher education hinges on users' confidence in the technology [67], and positive attitudes among students, institutions, and lecturers further reinforce acceptance. Conversely, inadequate AI literacy and concerns over data-security risks act as barriers. These conditions imply that successful adoption requires a coordinated blend of infrastructure readiness, policy support, and human-resource development. In this sense, AI is not merely a tool but a driver of continuing education when embedded within an integrated digital-transformation strategy. Related evidence indicates that trust, privacy, and perceived usefulness are necessary to encourage use, while enjoyment is important for cultivating student engagement; adoption also turns on psychological factors, since safe and positive user experiences shape success [45]. Accordingly, effective AI integration must address not only technical efficiencies but also social, ethical, and psychological dimensions [61].

The SLR-synthesized framework positions individual (digital literacy, trust, motivation), institutional (management support, infrastructure, campus policy), and external (regulation, global trends, ethics) factors as primary determinants of AI adoption. Their interplay forms an adoption ecosystem that contributes directly to sustainable-education targets: 1) SDG 4 (Quality Education): AI advances personalization, adaptive assessment, and inclusive access; 2) SDG 9 (Industry, Innovation, and Infrastructure): universities operate as AI innovation hubs that strengthen digital infrastructure; 3) SDG 10 (Reduced Inequalities): AI enables inclusion for remote learners via smart distance education; 4) SDG 17 (Partnerships for the Goals): cross-sector collaboration among universities, government, and industry in AI development. Thus, the conceptual framework not only maps determinants of adoption but also traces a causal pathway through which AI becomes an instrument for sustainable education—especially salient for developing countries working to narrow the digital divide.

IV. Conclusion

This study systematically reviewed AI adoption in higher education and its links to sustainable education. The evidence shows that perceived usefulness, ease of use, trust, optimism, and AI literacy strongly shape adoption behavior. However, the literature remains fragmented—dominated by single-theory applications (e.g., TAM or UTAUT) and concentrated in developed regions. To address these gaps, we propose an integrated, multi-level framework that combines TAM, UTAUT, TPACK, and TOE to capture individual, institutional, and policy dimensions. The synthesis indicates that AI adoption enhances efficiency, personalization, and academic performance while directly advancing sustainability objectives, notably SDG 4 (Quality Education) and SDG 10 (Reduced Inequalities). Future research should prioritize longitudinal designs, ethics–policy integration, and context-sensitive models in developing countries. In sum, AI should be understood not only as a technological innovation but as a transformative lever for accelerating equitable and sustainable higher education.

V. Limitations and Future Research

This study acknowledges several limitations. First, the data were drawn exclusively from Scopus-indexed, English-language articles published between 2015 and 2025, and the chosen keyword strategy may have omitted relevant works that did not explicitly emphasize the term "adoption." Second, technological developments—particularly the rapid evolution of GenAI after 2022—progress so swiftly that some findings may lag behind emerging practices. Third, the heavy theoretical reliance on individual-level frameworks such as TAM and UTAUT, coupled with regional imbalances, limits generalizability. To address these gaps, future studies should 1) test an integrated, multilevel TAM–UTAUT–TPACK–TOE model using hierarchical modelling, and 2) connect adoption measures to objective indicators through longitudinal designs while broadening contextual analyses.

Comparative Review of Confidence and Other Evaluation Metrics in Predictive Modeling for Procurement Fraud Coalition

Saifuddin Mohd, Mohamad Taha Ijab
Institute of Visual Informatics, Universiti Kebangsaan Malaysia, 43600 Bangi Selangor, Malaysia

***Abstract*—Procurement fraud, particularly when bidders act together through collusion or coalition schemes, remains a major threat to fair competition in public procurement. Predictive modeling has emerged as a key analytical tool for detecting such behaviors yet choosing appropriate evaluation metrics continues to be a challenge, especially with imbalanced or correlated data. This study applies a structured narrative review supported by a comparative analysis to examine commonly used evaluation metrics—Accuracy, Precision, Recall, F1-score, and AUC-ROC—in relation to the rule-based Confidence metric derived from association rule mining. The findings reveal that while traditional classification metrics are effective for general predictive tasks, they often fail to capture relational and co-occurrence patterns that characterize coalition fraud. In contrast, Confidence demonstrates higher interpretability and contextual relevance for detecting collusive behaviors among suppliers. The study highlights the potential of hybrid evaluation frameworks that combine classification and rule-based measures to improve fraud detection accuracy and explainability. This approach contributes to advancing predictive modeling, procurement analytics, and coalition detection by emphasizing metrics that balance performance, interpretability, and real-world applicability.**

***Keywords*—Procurement fraud; predictive modeling; confidence; evaluation metrics; association rule mining; coalition detection; public sector analytics**

I. Introduction

Public administration rests on a simple promise to citizens: public money must be spent properly and fairly. Public procurement sits at the heart of that promise, shaping how governments acquire goods and services at scale. Digitisation has helped by opening processes to scrutiny and producing rich data that can be analysed for fairness and efficiency. At the same time, the same openness has introduced new risks as actors learn to exploit procedural signals and digital traces for gain [1], [2].

Among those risks, collusion fraud is especially damaging. It arises when suppliers coordinate to shape outcomes through bid rigging, rotating winners, or submitting coordinated bids that blunt competition. These schemes are difficult to spot because the telltale signs rarely appear in a single tender. They live in patterns across time and across networks of bidders, which standard document checks or routine audits often miss [3].

Analytics has therefore become a practical route to detection. Predictive models sift large datasets to flag anomalies that suggest misconduct [4] The challenge is how we judge these models in a setting where fraud is rare. Accuracy, precision, recall, F1-score and AUC-ROC are widely used, yet each can mislead in imbalanced data. A model can be "accurate" by predicting almost everything as clean. These metrics also focus on isolated transactions and often ignore the relational signals that define collusion, such as repeated co-bidding or synchronized entry and withdrawal patterns [4], [5].

This study brings a complementary lens to the problem by examining Confidence from association rule mining as an evaluation and insight metric. Confidence estimates the likelihood of an event given another event. In procurement terms, it answers questions like "how often does Supplier B bid when Supplier A bids." That simple conditional view helps surface co-occurrence patterns that are consistent with coordinated behaviour and gives analysts something they can read and explain [6].

Although predictive analytics has matured, how we evaluate models for collusion specifically remains underexplored. Collusion is relational by nature. It emerges from ties, routines, and repeated interactions among bidders that traditional classification metrics do not capture well [7], [8], [9]. Ignoring those ties risks high-scoring models that miss the very behaviours of interest.

Therefore, this paper compares Confidence against common performance metrics and argue for hybrid evaluation. Classification metrics remain useful for measuring statistical performance. Confidence and related rule-based measures supply contextual signals about who appears with whom, and how often, in ways auditors and regulators can act on. The combination improves detection quality and interpretability in practice [10], [11]. This integrated focus aligns with the intent of the present manuscript, which positions Confidence alongside accuracy, precision, recall, F1-score and AUC-ROC for coalition detection in public procurement, and motivates a balanced, insight-driven assessment approach.

The rest of the paper proceeds as follows. Section II reviews literature on collusion in procurement and on evaluation metrics for predictive modelling, with emphasis on Confidence. Section III explains the methodology. Section IV discusses the comparative analysis and findings. Section V presents the synthesis and discussion and Section VI concludes and outlines directions for future research in predictive procurement analytics.

II. Background and Related Work

A. Coalition Fraud in Public Procurement

It is quite easy to deceive and change the way the government buys things. Coalition fraud is one of the most advanced and harmful types of fraud. Collusion, bid rigging, or cartel activity occurs when two or more suppliers work together to change the outcome of a procurement process. These kinds of alliances are meant to get rid of real competition. They accomplish this by bidding together over and over again, swapping the winner before the auction ends, or making bids that are very similar to each other.

These kinds of alliances are meant to get rid of real competition. They accomplish this by bidding together over and over again, swapping the winner before the auction ends, or making bids that are very similar to each other. These actions not only mess up how the market works, but they also make people lose a lot of trust and make items too expensive to acquire [12], [13]. Coalition fraud is always about connections, unlike single fraudulent activities. It takes advantage of how hard it is to grasp the different parts of the evaluation and how often bidding groups act the same way. This makes it challenging to find occurrences using typical techniques of assessment.

The Malaysia Competition Commission (MyCC) has observed that in Malaysia's public e-procurement settings, behavior that appears like a cartel is growing more sophisticated. We need to find it using improved, data-driven ways [14].

B. Evaluation Metrics in Predictive Modeling

In predictive modeling for procurement fraud detection, assessment metrics are necessary to measure both accuracy and efficacy. The most fundamental indicator is accuracy, which shows how many of the predictions were accurate. However, in datasets with significant imbalance, frequently seen in fraud detection, accuracy can be deceptive as it may overstate performance by privileging the majority class [15], [16].

Precision and recall are two indicators that provide you more information. Precision measures how many of the highlighted instances were indeed frauds. This is very important in situations when false positives might create reputational or administrative costs. On the other hand, recall evaluates how well a model can find all real fraud cases, which is very important in high-stakes situations where missing fraud can have serious consequences [17], [18]. The F1-score is a harmonic mean of accuracy and recall, which is typically used to give a fair assessment because these metrics often disagree with each other [19]. In procurement fraud detection, however, recall is frequently more important than precision since missing fraud is more damaging than overestimating its presence.

Other metrics, such as AUC-ROC, are useful since they do not depend on a certain threshold and can tell the difference between different things [20]. But since they are so abstract, they are not very good for rule-based or coalition-oriented fraud detection, where patterns that are relevant to the situation are important. Recent advancements in Explainable AI (XAI) highlight the necessity for metrics that provide transparency and interpretability, ensuring that model outputs can be successfully conveyed to policymakers, auditors, and non-technical stakeholders [21].

C. Confidence as a Metric for Coalition Detection

Given the limitations of global evaluation metrics, rule-based measures, particularly confidence from association rule mining, have garnered increasing attention. Confidence measures the conditional probability of a consequent given an antecedent, formally expressed as $P(Y|X)$. In the context of procurement fraud, this can be interpreted as the likelihood of a bidder participating or winning given the participation of another supplier, thus offering critical insight into co-occurrence behavior and potential [22], [23]. Unlike aggregate classification metrics, confidence allows for localized, pattern-specific interpretability.

This makes it particularly effective for identifying relational anomalies, such as recurrent supplier pairings or tenders with suspiciously homogeneous bidder compositions. Furthermore, confidence can be used in unsupervised settings, making it applicable even when labeled fraud data is scarce and often-cited challenge in procurement analytics. Nonetheless, confidence is not without limitations. It can be artificially inflated by low-support rules, leading to overinterpretation of spurious associations. To address this, confidence is typically used in conjunction with support (frequency of rule occurrence) and lift (statistical strength relative to random chance), forming a robust triad of rule evaluation metrics [23].

III. Methodology

In examining studies on procurement fraud and coalition detection, two methodologies for synthesizing information are commonly utilized: structured narrative reviews and systematic reviews. Each approach has various advantages and disadvantages. Systematic reviews are recognized for their methodological rigor, enhancing transparency, reproducibility, and confidence in the resultant evidence [24]. The rigor is especially crucial when looking at complex evaluation criteria for predictive modeling in procurement fraud, where the accuracy of the results is critical [25]. The strict guidelines of systematic reviews may make it harder to look into new ideas or processes, which are sometimes better handled using more flexible methods [26].

In Contrast, structured narrative reviews, on the allow researchers combine results from many different sources of literature without having to follow strict rules on the methodological guidelines [27]. This adaptability supports the formation of nuanced findings, particularly in coalition detection, where conceptual, empirical, and methodological perspectives intersect [28]. A structured narrative review is not only descriptive; it seeks to clarify linkages across contemporary studies, uncover methodological strengths, and pinpoint gaps for further study.

This study employs a structured narrative review method to examine the Confidence metric in predictive modeling for procurement fraud and compare it to traditional classification-based evaluation metrics. This technique emphasizes the study's focus on relational and rare coalition activities, requiring a balance between comprehensive synthesis and interpretative depth. The review is conducted with inclusion and exclusion

criteria, a clearly defined topic, and careful consideration of the narrative integration of results to ensure quality.

To enhance methodological transparency and replicability, a clear and systematic search strategy was developed. The review process followed four sequential phases:

- Identification: Relevant literature was identified through a comprehensive search across Scopus, Web of Science, and Google Scholar databases using defined keyword combinations. The search period covered 2010 to early 2025 to capture both foundational and emerging studies.
- Screening: Duplicate records were removed, and titles and abstracts were screened to ensure alignment with the research focus on evaluation metrics and coalition detection in procurement fraud.
- Eligibility: Full-text assessment was conducted to evaluate whether the articles met the inclusion criteria—namely, studies that (i) examined evaluation metrics used in fraud or anomaly detection, (ii) applied Confidence or association rule mining in predictive modeling, or (iii) focused on procurement, collusion, or cartel behavior detection.
- Quality Assessment: To maintain rigor, studies were appraised based on methodological soundness, clarity of metric application, and relevance to predictive modeling. Papers lacking sufficient methodological detail or relying solely on opinion-based commentary were excluded.

Exclusion criteria encompassed grey literature (e.g., blogs, white papers, or non-peer-reviewed content), studies unrelated to predictive modeling or procurement fraud, and those without measurable or interpretable performance metrics. This structured process ensured that the final body of literature was both methodologically robust and conceptually relevant. The resulting dataset of studies formed the empirical foundation for the comparative synthesis presented in later sections.

A. Research Design

The study is conceptualized as a comparative literature-based review supported by a case-informed synthesis. The objective is to evaluate the interpretability, contextual relevance, and sensitivity of common evaluation metrics: Accuracy, Precision, Recall, F1-score, and AUC-ROC against the rule-based Confidence metric. These metrics were selected due to their widespread use in fraud detection and classification modeling.

Given the exploratory nature of the study, a qualitative interpretive comparison is adopted rather than a purely statistical meta-analysis. This approach allows for incorporating insights from multiple domains (e.g., data mining, fraud analytics, public procurement) and ensures the findings remain grounded in operational and domain-specific requirements.

Limitations: It is important to acknowledge that the qualitative, narrative synthesis approach adopted in this study may limit quantitative generalizability. Findings presented here are primarily conceptual, based on expert interpretation and literature review rather than empirical validation. Therefore, future studies should consider conducting empirical analyses with large, real-world datasets to statistically validate the conceptual insights provided by this comparative assessment.

B. Data Sources and Literature Selection

The literature search was conducted across three major academic databases that is Scopus, Web of Science, and Google Scholar to ensure comprehensive coverage of both theoretical and applied studies. The search period spanned 2010 to early 2025, capturing the evolution of predictive modeling and fraud detection research.

The following keyword combinations were used to ensure search precision and breadth:

- "confidence metric" AND "fraud detection"
- "evaluation metrics" AND "predictive modeling"
- "procurement fraud" OR "coalition detection"
- "association rule mining" AND "bid rigging"

Each retrieved article underwent multi-stage screening as described in the methodology overview. Only peer-reviewed journal articles, conference papers, and technical reports were included, ensuring academic credibility.

The inclusion criteria emphasized empirical or conceptual contributions to predictive modeling, Confidence metric application, or procurement fraud detection. Studies focusing solely on algorithmic performance without interpretive or contextual analysis were excluded.

C. Analytical Framework

This study constructed a comparative framework based on three dimensions and systematically compare the metrics:

- Interpretability – the extent to which metric outputs can be meaningfully interpreted by human analysts and decision-makers;
- Sensitivity to Class Imbalance – the ability of the metric to provide reliable insights in datasets where fraud cases constitute a minority.
- Applicability to Coalition Detection – the metric's utility in modeling relational or co-occurrence patterns typical of procurement collusion.

Each metric was scored heuristically on a five-point Likert-type scale (1 = Low, 5 = High) for each dimension, drawing from synthesis of the literature and informed expert judgment. While such scoring does not provide definitive empirical quantification, it offers a structured and transparent means of articulating relative strengths and weaknesses among metrics. A common approach in methodological reviews is where direct comparisons are limited or context specific.

IV. Comparative Analysis and Findings

This section presents a comparative assessment of commonly used evaluation metrics in predictive fraud modeling, with particular emphasis on their relevance to coalition detection in procurement contexts. The metrics are examined in terms of their mathematical foundations, interpretability, sensitivity to

class imbalance, and contextual utility in identifying collusive behavior.

A. Metric Characteristics and Theoretical Basis

The principal characteristics of six commonly employed evaluation metrics: Accuracy, Precision, Recall, F1-score, AUC-ROC, and Confidence are summarised in Table I. While the first five metrics are grounded in classification theory and typically applied in supervised learning settings, Confidence originates from association rule mining and is often used in unsupervised or pattern mining contexts.

TABLE I. COMPARISON ACROSS SIX METRICS: ACCURACY, PRECISION, RECALL, F1-SCORE, AUC-ROC, AND CONFIDENCE

Metric	Mathematical Definition	Best Context	Advantages	Limitations
Accuracy	(TP + TN) / Total	Balanced datasets	Simple, standard	Biased with class imbalance
Precision	TP / (TP + FP)	High false positive cost	Positive outcome focus	Ignores false negatives
Recall	TP / (TP + FN)	High false negative cost	Captures all true positives	Ignores false positives
F1-Score	2 * (P * R) / (P + R)	Imbalanced data	Balances P and R	Hard to interpret directly
AUC-ROC	Area under the curve of TPR vs FPR	Model comparison, threshold-independent evaluation	Comprehensive discrimination measure	Lacks local interpretability
Confidence	P(Y|X)	Rule-based learning, fraud detection	Conditional, interpretable	Ignores minimum support

Accuracy, defined as the ratio of correct predictions (both positive and negative) to the total number of instances, is intuitive but problematic in imbalanced datasets. It often overstates performance by favoring the majority class, which in fraud detection typically represents non-fraudulent cases [29].

Precision and Recall offer more focused evaluations. Precision emphasizes the correctness of positive predictions (i.e., how many predicted frauds are true frauds), whereas Recall reflects the model's ability to capture all actual frauds. F1-score, the harmonic mean of Precision and Recall, provides a balanced measure, though it may lack intuitive clarity for stakeholders not versed in statistical evaluation [17].

AUC-ROC evaluates the classifier's ability to discriminate between classes across different threshold values. While it is threshold-independent, AUC lacks granularity and may obscure localized fraud patterns [20].

Confidence, expressed as P(Y|X), quantifies the conditional likelihood that event Y occurs given X. In procurement contexts, this could translate to the probability that one supplier bids or wins conditional on the participation of another. It thus enables fine-grained relational analysis and is particularly useful for uncovering suspicious co-bidding behavior that might indicate tacit collusion [22].

B. Comparative Matrix and Interpretive Scoring

A comparative assessment of six evaluation metrics commonly employed in procurement fraud detection, analyzed across two critical dimensions: interpretability, defined as the extent to which a metric can be intuitively understood and meaningfully applied by human decision makers, and imbalance sensitivity, referring to the metric's responsiveness to skewed class distributions, an inherent characteristic of fraud related datasets.

The results in Fig. 1 indicate that Confidence achieves the highest level of interpretability (score of 5) while exhibiting the lowest sensitivity to class imbalance (score of 1), positioning it as particularly advantageous for contexts where transparency and data imbalance are pressing concerns.

Conversely, accuracy demonstrates poor performance on both fronts, with low interpretability, especially at finer analytical levels, and a high susceptibility to data imbalance, thereby limiting its effectiveness in real world fraud detection scenarios. The scoring, which ranges from 1 (least favorable) to 5 (most favorable), is derived through synthesis of current literature and practitioner experience, an approach often adopted in review-based studies where direct empirical comparisons are scarce.

Confidence is rarely compared with traditional classification metrics such as Accuracy in empirical evaluations, necessitating a relative rather than absolute analytical approach. The purpose of this comparative framework is not to produce definitive rankings but to elucidate general tendencies in metric behavior, thereby informing the selection of evaluation strategies that align with the unique demands of procurement fraud analytics in imbalanced data environments.

The interpretability and imbalance sensitivity scores in Table II were derived from a synthesis of relevant literature (e.g., [29] and expert judgment based on the application of these metrics in fraud detection and procurement datasets. While not absolute, these heuristic scores facilitate a structured comparison of metric suitability in coalition fraud modelling. From the comparative analysis, it is evident that Confidence offers superior interpretability and is significantly less affected by class imbalance, an advantage that is particularly relevant in fraud detection settings where positive instances (i.e., fraud) are rare and scattered. Furthermore, its pattern-based nature enables it to surface relational anomalies, making it particularly well-suited for coalition detection.

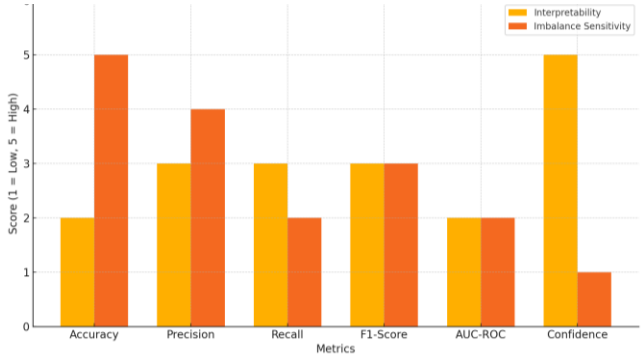

Fig. 1. Six evaluation metrics based on interpretability and imbalance sensitivity.

TABLE II. COMPARATIVE EVALUATION OF METRICS

No.	Metric	Interpretability (1–5)	Imbalance Sensitivity (1–5)	Justification
1.	Accuracy	2	5	Inflated in imbalanced datasets; does not reflect minority class detection [29]
2.	Precision	3	4	Useful to reduce false positives; appropriate in fraud context [30]
3.	Recall	3	2	Important when capturing all fraud instances; can result in high false positives [29]
4.	F1-Score	3	3	Balances precision and recall; effective for imbalanced data [31]
5.	AUC-ROC	2	2	Provides global model evaluation; lacks actionable insight for case-level interpretation [32]
6.	Confidence	5	1	Rule-based metric with high interpretability in pattern-based fraud; useful in coalition detection [22], [33]

C. Practical Insight: Rule-Based Detection

The primary advantage of Confidence lies in its ability to generate rule-level insights. For example, if a rule indicates that Supplier A and Supplier B co-bid in 90% of tenders where one is present, and both frequently win under similar conditions, this may trigger an alert. Such insight is difficult to derive from aggregate metrics like Accuracy or F1-score, which do not consider inter-entity relationships. Moreover, Confidence can be operationalized in conjunction with other rule-based measures such as support (frequency of occurrence) and lift (relative strength), enabling a multi-dimensional assessment of relational patterns. This is critical in the detection of cartel behavior, where [37] highlight the importance of using advanced analytical methods to distinguish genuine collusion from legitimate competition, a challenge made even more pressing in detecting cartel behavior where fraudulent patterns are often hidden within dense and repeated co-bidding networks.

D. Case-Based Justification

A simplified procurement case analysis drawn from Malaysian e-procurement data further underscores the utility of Confidence. These examples were derived from actual e-procurement datasets from Malaysian government agencies, with the dataset being on 2015, illustrating real-world bidding scenarios. In particular, multiple instances were identified where pairs of suppliers consistently co-bid with high Confidence scores (exceeding 80% conditional probability), strongly indicating potential collusive behavior. These relational patterns were not effectively flagged using traditional classification metrics due to their emphasis on class-labeled outcomes rather than inter-entity relationships.

The analysis revealed multiple instances where supplier pairs participated in tenders with statistically significant co-occurrence patterns. Traditional metrics failed to flag these cases due to their reliance on class-labeled outcomes, whereas Confidence-based rules identified relational anomalies worthy of further investigation. Table III illustrates the type, sensitivity to imbalanced data, interpretability, and use case in fraud detection for each metric.

TABLE III. TYPE, SENSITIVITY TO IMBALANCED DATA, INTERPRETABILITY, AND USE CASE IN FRAUD DETECTION FOR EACH METRICS

Metric	Type	Sensitivity to Imbalanced Data	Interpretability	Use Case in Fraud Detection	Author (s)
Accuracy	Overall performance	Low	High, but can be misleading	Not suitable for imbalanced datasets; may mask rare fraud cases	[15], [17]
Precision	Class-specific (Positive class)	High	High	Important to reduce false positives (e.g., avoid false alarms)	[17], [34]
Recall	Class-specific (Positive class)	High	High	Important to reduce false negatives (e.g., capture all fraud)	[17], [34]
F1-Score	Harmonic mean of precision & recall	Medium to High	Moderate	Balances precision and recall; useful in skewed data	[17], [34]
AUC-ROC	Threshold-independent	High	Moderate	Evaluates model across thresholds; compare classifier ability	[20]; [35]
Confidence	Rule-based (Association Rules)	High	High (in rule mining)	Measures rule strength; helps find fraud patterns	[23], [36]

E. Insight: Why Confidence is Useful for Coalition Detection

Confidence provides rule-level insight, which is particularly valuable for detecting procurement fraud coalitions. For example, a high confidence score for the co-occurrence of Supplier A and Supplier B (e.g., 90% confidence) suggests a strong relational pattern, which is more informative than an overall accuracy score when seeking hidden relationships. This characteristic supports early-warning systems and evidence-based procurement audits, aiding in identifying collusive behaviors that might not be apparent with aggregate metrics.

V. SYNTHESIS AND DISCUSSION

The comparative analysis presented in this review underscores the evolving challenges and opportunities in evaluating predictive models for procurement fraud detection, particularly to coalition or collusive behavior. While traditional evaluation metrics such as Accuracy, Precision, Recall, and AUC-ROC remain foundational in classification-based modeling, they are increasingly insufficient when applied to domains characterized by data imbalance, relational complexity, and pattern-level anomalies.

A. Limitations of Traditional Evaluation Metrics

A significant limitation of conventional metrics is their focus on instance-level classification performance. In procurement fraud detection, especially for coalition behaviors, the fraudulent signal often resides not in individual records but in the relationships among entities across time. For instance, Accuracy can be misleading in scenarios with extreme class imbalance, such as datasets where fraudulent tenders constitute less than 5% of all transactions by overstating model effectiveness due to the prevalence of true negatives [15], [29]. Similarly, although Precision and Recall offer greater sensitivity to the minority class, they remain inadequate in identifying the relational dynamics underlying collusion. F1-score, while useful in balancing both metrics, does not address interpretability or contextual relevance. AUC-ROC further abstracts the model's discriminatory power into a single score, which, although statistically sound, lacks the granularity needed for forensic or regulatory applications in procurement fraud.

B. Strengths of Confidence in Fraud Coalition Detection

The Confidence metric, grounded in association rule mining, provides a complementary and, in many cases, superior evaluative perspective for coalition fraud modeling. Unlike global metrics, Confidence quantifies the conditional likelihood of a co-occurrence, e.g., Supplier B submitting a bid when Supplier A does offering a highly interpretable and actionable view of potential collusion. Its unsupervised nature also makes it robust in contexts where labeled fraud data is scarce or incomplete. This is especially pertinent in the public sector, where investigations are often reactive and labels may only exist post-audit. The Confidence metric allows for early-warning signals through the detection of anomalous patterns, which can be subjected to further validation using domain expertise or additional metadata (e.g., company addresses, ownership structures, bid amounts). Importantly, Confidence should not be used in isolation. Its key limitation is the potential inflation of its value in low-support scenarios, where rare co-occurrences may appear statistically significant due to limited data. This issue can be mitigated by jointly analyzing support (absolute rule frequency) and lift (proportional deviation from independence), both of which enhance the reliability of Confidence-based findings [23].

C. Practical and Policy Implications

From a practical standpoint, integrating Confidence-based analytics into existing procurement monitoring systems could substantially enhance auditors' capabilities to identify relational anomalies indicative of collusive behavior. Policymakers and regulatory bodies, such as the Malaysia Competition Commission (MyCC), would benefit from adopting these interpretable analytics tools to improve transparency and proactively flag suspicious tenders. Implementing Confidence-based metrics can also inform risk-based auditing strategies and continuous supplier monitoring, ultimately promoting accountability and integrity in public procurement processes.

D. Implications for Practice and Policy

From a policy standpoint, the integration of Confidence into procurement analytics tools can inform risk-based auditing, automatic flagging of suspicious tenders, and ongoing supplier monitoring. As governments increase investment in e-procurement systems, embedding such interpretable analytics directly into workflows can improve the efficacy of oversight bodies like the Malaysia Competition Commission (MyCC) or anti-corruption agencies. For practitioners, the findings suggest a shift from solely performance-driven evaluation (i.e., how well does the model classify?) to insight-driven evaluation (i.e., what can the model explain about fraud structures?). This is aligned with broader trends in explainable AI (XAI) and human-centric data science.

E. Advancement Beyond Existing Studies

The comparative framework presented in this study extends prior research on evaluation metrics for fraud detection in three main ways. First, it introduces a cross-domain synthesis that integrates traditional classification metrics with rule-based interpretability measures such as Confidence an area rarely analyzed jointly in previous works. This dual perspective bridges the gap between performance evaluation and relationship discovery, enabling more meaningful assessments of models used in detecting collusion.

Second, by applying Confidence within the context of coalition fraud, the study advances the discussion from general fraud classification toward relational analytics, emphasizing inter-supplier dependencies that are typically overlooked by conventional measures like AUC-ROC or F1-score.

Third, the heuristic comparative matrix developed in this paper provides a transparent and structured tool for evaluating metrics along interpretability and class imbalance dimensions, which can be adopted by researchers and regulators for systematic assessment of fraud detection models.

Collectively, these contributions represent a methodological advancement over prior works that treated evaluation purely as a statistical exercise. The present study positions metric selection as both a technical and interpretive decision, thereby aligning predictive modeling more closely with real-world auditing and policy needs.

VI. Conclusion and Future Work

This review has critically examined the comparative utility of traditional classification-based evaluation metrics and the Confidence metric within the context of predictive modeling for procurement fraud, with a particular focus on coalition detection. The analysis demonstrates that while standard metrics such as Accuracy, Precision, Recall, F1-score, and AUC-ROC provide valuable insights for general model validation, they are insufficient when the modeling objective involves detecting rare, relational, and pattern-based fraud behaviors such as supplier collusion.

The Confidence metric, rooted in association rule mining, has been shown to offer superior interpretability, resilience to class imbalance, and applicability in unsupervised or semi-supervised settings. Its capacity to uncover rule-level relationships makes it particularly effective for modeling fraud coalitions, especially in scenarios where labeled data are scarce or incomplete. Despite its limitations, such as sensitivity to low-support rules, Confidence can be effectively calibrated using complementary metrics like support and lift. Given the unique strengths of both metric types, this paper advocates for the

adoption of hybrid evaluation frameworks that integrate classification metrics with rule-based measures. Such frameworks not only enhance model robustness but also contribute to explainability, operational relevance, and stakeholder trust, key considerations in public sector analytics and regulatory oversight.

Future work in procurement fraud analytics should focus on developing more intelligent and interpretable evaluation strategies to enhance both detection accuracy and real-world applicability. One key direction is the creation of composite scoring systems that integrate metrics such as confidence, support, lift, and conventional classification indicators (e.g., precision, recall, F1-score), enabling a more balanced trade-off between predictive performance and interpretability. Additionally, graph-based learning techniques, particularly graph neural networks (GNNs), offer promise in modeling coalition behavior by capturing structured relationships among suppliers; these models should be evaluated using hybrid metrics that reflect both statistical accuracy and semantic relevance.

Embedding confidence-based alerts into real-time procurement systems can further support dynamic risk monitoring and early intervention, aligning predictive insights with operational workflows. Furthermore, empirical validation using real procurement data, including blind evaluations by domain experts, is essential to assess the practical effectiveness and trustworthiness of confidence-driven rule discovery methods. Finally, conducting cross-national comparisons of procurement fraud detection frameworks will help generalize findings and identify best practices suited to varying legal and regulatory environments. As public procurement systems continue to evolve toward digitalization, the capacity to detect and explain collusive patterns will be central to ensuring transparency and preserving market integrity. This review contributes to that objective by outlining a roadmap for advancing interpretable, actionable, and context-sensitive evaluation of predictive models in fraud detection.

This study identified potential future initiatives to enhance the detection of procurement fraud, particularly in cases of collaboration. The thoughts are split into two groups: short-term and long-term.

A. Short-Term Priorities

First, it is a good idea to test the Confidence measure with more real data from purchases. A lot of articles solely utilize synthetic or example data. We can find out if Confidence can truly assist in uncovering collusion between suppliers if we utilize genuine tender data from a government or commercial system.

Second, researchers might be able to mix diverse measures. For example, the F1-score or Confidence with precision. This can help the model be both right and easy to grasp. In real life, people like auditors need to explain how the outcome came about, not just give a figure.

B. Long-Term Goals

Not all countries have the same system and data. Researchers ought to examine the functioning of Confidence across various countries. One strategy may work well in Malaysia, but it may not work the same way in other countries.

Finally, create a hybrid system that uses both rule-based and categorization metrics. This can make the model stronger and easier for others to comprehend and utilize. Auditors or officers can understand why the pattern is there and not merely follow the score.

Each metric was scored heuristically on a five-point Likert-type scale (1 = Low, 5 = High) for each dimension, drawing from synthesis of the literature and informed expert judgment. While such scoring does not provide definitive empirical quantification, it offers a structured and transparent means of articulating relative strengths and weaknesses among metrics. A common approach in methodological reviews is where direct comparisons are limited or context specific.

Abstract*—Haze severely degrades image quality by reducing contrast, obscuring details, and introducing a blue-shift color cast caused by atmospheric scattering. Traditional dehazing methods, including prior-based approaches (e.g., DCP, CAP, LPMinVP) and preprocessing techniques (e.g., ICAP WB, Dynamic Gamma), improve visibility but fail to correct haze-induced color imbalance, resulting in unstable RGB distributions and unnatural tone reproduction. This study proposes the Haze-Compensated Color Von Kries (HCCVK) method, a lightweight and training-free preprocessing strategy that performs color compensation before transmission estimation in single-image dehazing. HCCVK integrates a novel red-channel compensation mechanism with Von Kries chromatic adaptation to mitigate wavelength-dependent haze suppression and stabilize chromatic consistency under varying illumination. Unlike learning-based color correction approaches, HCCVK does not require training data, is computationally efficient, and maintains algorithmic interpretability, making it suitable for practical deployment. The method was evaluated on six benchmark datasets: CHIC, Dense-Haze, I-Haze, O-Haze, SOT, and NH-Haze, covering indoor, outdoor, dense, and non-homogeneous haze scenarios. Experimental results based on the RGB color balance metric (σRGB) show that HCCVK reduces color deviation by approximately 75–92% on CHIC, 80–90% on Dense-Haze, and 82–90% on NH-Haze compared to the widely used DCP, and also outperforms CAP, ICAP WB, Dynamic Gamma, and LPMinVP by producing more compact and stable RGB distributions. These findings demonstrate that HCCVK effectively corrects blue-shift imbalance, preserves luminance consistency, and enhances the color stability of dehazing pipelines.

Keywords*—Image dehazing; blue-shift correction; color compensation; Von Kries adaptation; preprocessing

I. Introduction

Haze is an atmospheric phenomenon that degrades image quality due to the scattering and absorption of light by particles such as water droplets, dust, and smoke suspended in the air [1]. This degradation reduces contrast, obscures fine details, and introduces a characteristic blue-shift color cast caused by wavelength-dependent scattering, where shorter wavelengths (blue) are scattered more strongly than longer wavelengths (red) [2][3]. Such distortions negatively affect human perception and degrade the performance of computer vision applications, including autonomous driving, UAV imaging, security surveillance, and remote sensing [4][5].

Similarly, studies in other computer vision domains have shown that poor quality input data leads to degraded feature extraction and reduced system performance. For example, Waheed et al. [6] demonstrated that melanoma classification accuracy declines when dermoscopic images are not properly preprocessed before CNN analysis, while Awan et al. [7] emphasized that preprocessing significantly reduces execution time and improves classification stability in MRI-based diagnosis. Furthermore, Jabal et al. [8] showed that structural errors in raw CAD drawings lead to error propagation during feature extraction, reinforcing the importance of early corrective processing. Therefore, haze removal is essential for both visual enhancement and robust scene understanding under real-world outdoor conditions [9-10].

Single-image dehazing techniques are commonly categorized into prior-based, preprocessing-based, and learning-based methods. Prior-based methods rely on physical or statistical assumptions to estimate scene transmission and atmospheric light. Examples include the Dark Channel Prior (DCP) [11] and the Color Attenuation Prior (CAP) [12], including their enhanced variants ICAP [13], Extremum Value prior-based Local Patch Wise Minimal Values (LPMinVP) [14] and Dynamic Gamma [15]. These methods can enhance structural visibility but often introduce color distortions, halo artifacts, and inconsistent illumination recovery in dense haze regions due to inaccurate atmospheric light estimation [13]. Preprocessing-based techniques such as white balancing, histogram equalization, and gamma correction improve global illumination but do not explicitly correct haze-induced color

bias, leading to unstable RGB distributions [14][16]. Recently, deep learning methods such as CCD-Net [17] and attention-guided restoration models [18] have achieved significant improvements, yet they depend on large-scale training datasets, high computational cost, and lack interpretability, limiting their deployment in resource-constrained or real-time applications.

A major limitation across existing dehazing methods is that color imbalance caused by atmospheric scattering is not explicitly corrected before transmission estimation. Due to wavelength-dependent scattering, the red channel experiences greater attenuation than the blue channel, resulting in a dominant blue-shift color cast in hazy images [3][19]. When dehazing is applied directly to such chromatically unbalanced inputs, error propagation occurs during transmission estimation, leading to unnatural tone reproduction and unstable RGB restoration [13][14][17]. This type of error propagation from unbalanced inputs has also been highlighted in medical image analysis and CAD extraction research, indicating that effective preprocessing is necessary before advanced processing [8].

Therefore, this study addresses the lack of a lightweight, training-free preprocessing mechanism that compensates red-channel attenuation and stabilizes RGB color channels before dehazing. To solve this problem, we propose the Haze-Compensated Color Von Kries (HCCVK) method, a preprocessing strategy that integrates red-channel compensation with Von Kries chromatic adaptation to correct haze-induced spectral imbalance. Unlike deep learning–based enhancement approaches that require GPU training resources, HCCVK requires no training data [7], offers full interpretability, and maintains low computational cost, making it suitable for real-time deployment.

II. Related Works

Single-image dehazing techniques have been widely explored in computer vision and can be categorized into three main groups: prior-based methods, preprocessing-based methods, and learning-based methods. Prior-based dehazing methods estimate scene transmission based on statistical assumptions about haze-free images. The DCP [11] assumes that at least one color channel in a local image patch has low intensity, enabling effective haze removal. However, it frequently generates halo artifacts and color distortion, especially in bright regions and sky areas where the prior is invalid. The CAP [112] utilizes the relationship between depth and brightness to estimate scene depth but often suffers from over-saturation and instability under varying illumination. Improved variants such as ICAP [13] and LPMinVP [14] enhance transmission estimation using adaptive priors but still struggle with chromatic inconsistency and residual color bias, particularly in dense haze conditions. Overall, prior-based methods enhance visibility but inherently lack a mechanism to correct haze-induced color imbalance.

Preprocessing-based approaches aim to enhance visibility before dehazing by normalizing illumination or contrast. White balance correction is commonly used to suppress color cast but does not correct wavelength-dependent red-channel suppression in haze [16]. Similarly, gamma correction and histogram equalization improve brightness and contrast but often amplify noise and cause over-enhancement [14]. Methods such as Dynamic Gamma (DD-Gamma) [15] improve global tone distribution but still fail to address blue-shift caused by atmospheric scattering, resulting in unstable RGB distributions. These approaches improve perceptual quality but do not provide physically meaningful color correction.

Learning-based dehazing methods have recently gained popularity by leveraging convolutional neural networks to learn end-to-end haze removal. Models such as AOD-Net and DCPDN incorporate physical priors into CNN architectures, while CCD-Net [17] introduces a dual-branch fusion network in RGB and Lab color space to reduce perceptual distortions. Other studies employ transformer-based attention or adversarial learning to improve scene restoration [18]. However, these methods generally require large training datasets, lack interpretability, and perform poorly in real-world atmospheric variations due to training bias and overfitting. Additionally, most learning-based models do not explicitly solve the color imbalance problem and often rely on post-processing color correction.

The importance of early-stage preprocessing to prevent feature distortion has also been emphasized across other computer vision fields. For example, Waheed et al. demonstrated that CNN-based melanoma classification can only achieve high accuracy when color distortion and illumination are corrected during preprocessing [6]. Similarly, Awan et al. showed that preprocessing improves both diagnostic stability and computational efficiency in MRI image analysis [7]. Additionally, Jabal et al. reported that failure to correct noisy or inconsistent CAD input data leads to error propagation in feature extraction systems [8]. These findings support the need for preprocessing strategies that stabilize input data before complex restoration or estimation steps.

Based on this review, it is evident that most dehazing research prioritizes visibility enhancement but neglects chromatic fidelity. Neither prior-based methods nor preprocessing and learning strategies provide a reliable solution to haze-induced blue-shift and red-channel attenuation, which leads to unnatural tone reproduction and unstable color restoration. Unlike these methods, the proposed HCCVK method focuses specifically on stabilizing RGB balance before dehazing, offering a lightweight and interpretable solution to mitigate color distortion caused by atmospheric scattering.

III. Methodology

This section outlines the experimental design, including the proposed HCCVK method, benchmark datasets, and evaluation metrics. The methodology is structured to ensure reproducibility and clarity for future implementations. It also demonstrates the effectiveness of the proposed approach under a variety of indoor and outdoor hazy conditions. Color balance is applied as a preprocessing step to mitigate blue-channel bias and preserve luminance consistency under hazy conditions.

Preprocessing plays a crucial role in preventing feature degradation during downstream processing, especially when the input data suffers from structural or spectral distortion. Similar to dehazing challenges, Waheed et al. reported that

classification accuracy in melanoma skin cancer detection drops significantly if illumination bias and color distortion are not corrected prior to CNN classification [6]. Likewise, Awan et al. demonstrated that MRI-based diagnostic performance improves when input instability is reduced through intensity normalization and contrast enhancement, especially in resource-constrained environments [7]. In another domain, Jabal et al. emphasized that uncorrected noise in CAD drawings propagates errors in feature extraction and interpretation, highlighting the importance of robust preprocessing before complex analysis [8]. Motivated by these findings, the HCCVK method introduces a lightweight preprocessing strategy to stabilize color distribution before dehazing, preventing chromatic error propagation during transmission estimation.

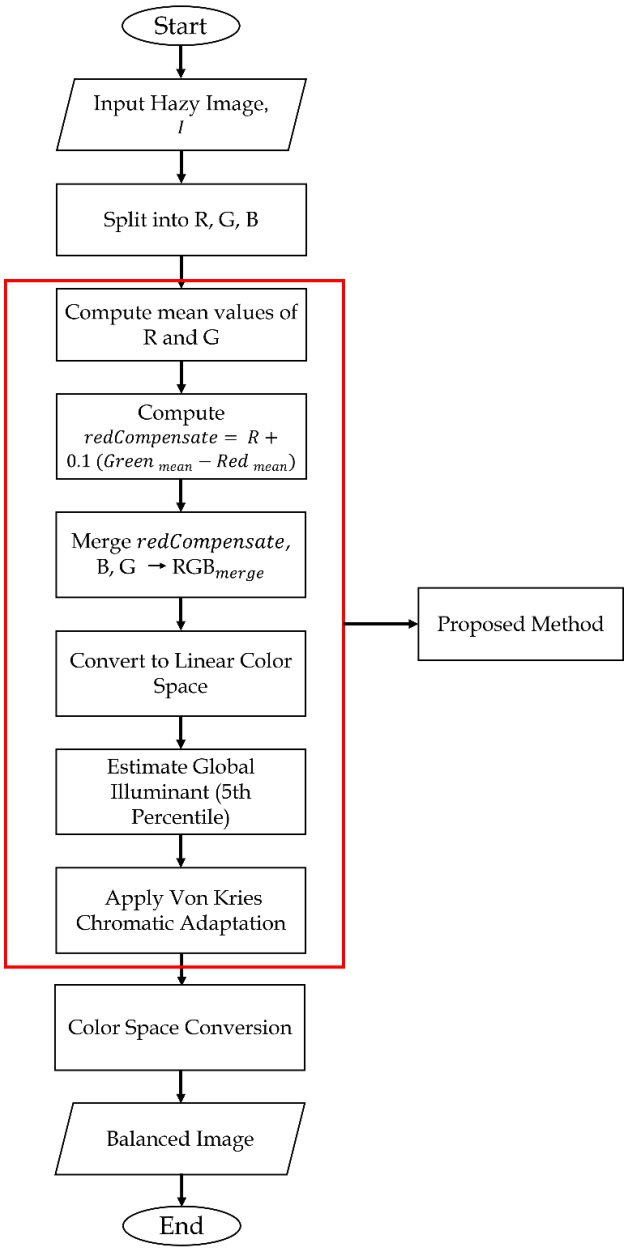

Fig. 1. Flowchart of the proposed Haze-Compensated Color Von Kries method for haze-compensated color balance.

A. Proposed Haze-Compensate Color Von Kries Method Acronyms

The HCCVK method is designed as a preprocessing stage prior to dehazing. It balances the RGB distribution by compensating the red channel and correcting the global illuminant through the Von Kries chromatic adaptation transformation. Unlike deep learning–based preprocessing techniques, which often require dedicated training resources and GPU acceleration [7], HCCVK is computationally efficient and entirely training-free. The overall workflow of the method is illustrated in Fig. 1.

As shown in the flowchart, the method proceeds through a sequence of operations from channel separation to illuminant correction. For clarity and reproducibility, the detailed steps are presented in Algorithm 1.

Algorithm 1 Haze-Compensated Color Von Kries (HCCVK) Method

Input: Hazy Image, I

Output: Haze-compensated balanced image, $I_{balance}$

Step:

1) Preprocessing:
   a) Split the input image into RGB channels: R, G, B.
   b) Compute mean intensities: $Red_{mean}, Green_{mean}$
   c) Apply red-channel compensation: $redCompensate = R + 0.1\,(Green_{mean} - Red_{mean})$

2) Reconstruction
   a) Merge $redCompensate$, G, and B to obtain RGB_{merge}
   b) Convert RGB_{merge} into linear color space: RGB_{linear}

3) Illuminant Estimation:
   a) Define a 5% percentile threshold for robust estimation
   b) Estimate global illuminant using the gray-world assumption at the 5th percentile

4) Chromatic Adaptation:
   a) Apply the Von Kries transform using the estimated illuminant
   b) Generate corrected image $I_{balance}$

5) Finalization:
   a) Convert $I_{balance}$ back to RGB color space
   b) Output the haze-compensated balanced image

As shown in Table I, the weight of 0.1 achieved the highest average compensation and the lowest standard deviation among all tested parameters. This finding was further validated through entropy analysis, where entropy is defined as:

$$e = -\sum_{i=0}^{255}\sum_{j=0}^{255}\sum_{k=1}^{255} p_{i,j,k}.log_2(p_{ijk}) \quad (1)$$

Here, i,j,k denote the three dimensions of the probability distribution. The analysis was conducted over 390 images selected from the total dataset of 1,239, covering both controlled (indoor) and non-controlled (outdoor) illumination

conditions. Therefore, a fixed weighting factor of 0.1 was adopted in the proposed method to ensure stability and robustness across different haze conditions.

TABLE I. WEIGHTED RED AND BLUE CHANNEL COMPENSATION COMPARISON WITH ENTROPY INFORMATION

Weight	Entropy Information, e			
	Average		Standard Deviation	
	Channel			
	Red	Blue	Red	Blue
0.1	**6.8503**	6.8452	**0.4738**	0.4762
0.3	6.7879	6.7847	0.5229	0.5263
0.5	6.7873	6.7690	0.5248	0.5384
0.7	6.8288	6.7976	0.4852	0.5071
0.9	6.7739	6.7456	0.5355	0.5644

B. Dataset

To ensure a comprehensive evaluation and demonstrate the robustness of the proposed method, a total of 1,239 hazy images with corresponding ground-truth (GT) images were utilized. The dataset comprises 588 indoor images and 651 outdoor images, enabling performance assessment under different environmental conditions. These variations ensure that the evaluation covers both controlled scenarios and more challenging natural conditions.

Indoor datasets were captured under controlled illumination, which guarantees stable lighting and minimizes external variability. These include I-Haze with 30 images [20], SOT from the RESIDE dataset with 500 images [21], CHIC with 36 images [22], and Dense-Haze with 22 images [23]. Such conditions make them suitable for analyzing the performance of the method in consistent environments.

The outdoor datasets were collected under natural illumination, where changes in weather, solar position, and atmospheric scattering introduce greater complexity for dehazing. These include O-Haze with 45 images [20], SOT with 500 images [21], CHIC with 18 images [22], Dense-Haze with 33 images [23], and NH-Haze with 55 images [19]. The inclusion of these datasets ensures that the method is evaluated across both controlled and highly variable conditions.

C. Evaluation Matrix

The effectiveness of the proposed HCCVK method was evaluated using the RGB Color Balance metric (σRGB), which quantifies the degree of consistency among the three color channels. This metric is particularly suitable for haze removal tasks, as hazy conditions often suppress the red channel, leading to visible color imbalance. A lower σRGB value indicates better channel consistency and improved color fidelity, while higher values reflect imbalance and potential color casts. The metric is defined as:

$$\sigma RGB = \sqrt{\frac{(R-\mu)^2+(G-\mu)^2+(B-\mu)^2}{3}}, \mu = \frac{R+G+B}{3} \quad (2)$$

where R, G, and B denote the average intensities of the red, green, and blue channels, and μ represents their mean intensity. Unlike structural indices such as PSNR and SSIM, which emphasize pixel-level or textural similarity, σRGB directly measures the preservation of color balance, aligning more closely with the objectives of the proposed method.

D. Comparative Analysis

For benchmarking, the proposed method (PM OUT) was compared against several well-established dehazing algorithms, including DCP, CAP, ICAP WB, LPMinVP, DD GAMMA, PM CC and PM CM. These methods were chosen because they represent both prior-based and preprocessing-driven strategies, ensuring a fair and comprehensive evaluation. Since each approach directly affects brightness preservation and color balance, their inclusion enables a systematic comparison, highlighting not only overall dehazing performance but also the influence of distinct preprocessing modules on final image quality.

IV. RESULTS

This section evaluates the performance of the proposed HCCVK method using the σRGB, where lower values indicate better chromatic stability and reduced blue-shift distortion. HCCVK is compared against five baseline methods: DCP, CAP, ICAP WB, LPMinVP, and Dynamic Gamma. Results are reported across six benchmark datasets covering indoor, outdoor, dense, and non-homogeneous haze conditions.

A. CHIC Dataset (Indoor and Outdoor)

The results in Fig. 2 show that on the CHIC Indoor dataset, HCCVK consistently achieves the lowest σRGB values among all methods, demonstrating stable color restoration across varying illumination. While LPMinVP and ICAP WB partially improve color consistency, their σRGB ranges remain significantly wider than HCCVK, indicating lingering blue-shift imbalance. DCP exhibits the highest σRGB deviation due to its inaccurate atmospheric light estimation in bright regions.

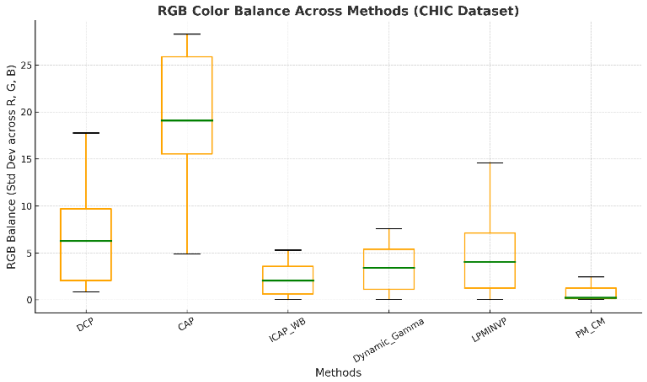

Fig. 2. RGB color balance comparison across dehazing methods on the CHIC indoor dataset.

For the CHIC Outdoor dataset (Fig. 3), similar behavior is observed. HCCVK maintains a compact σRGB distribution, confirming its effectiveness in both indoor and outdoor haze environments. Competing methods such as CAP and Dynamic Gamma struggle to stabilize the red and green channels, resulting in color shifts in scenes with strong sky illumination. In comparison, HCCVK corrects red-channel suppression, producing visually natural color tone balance.

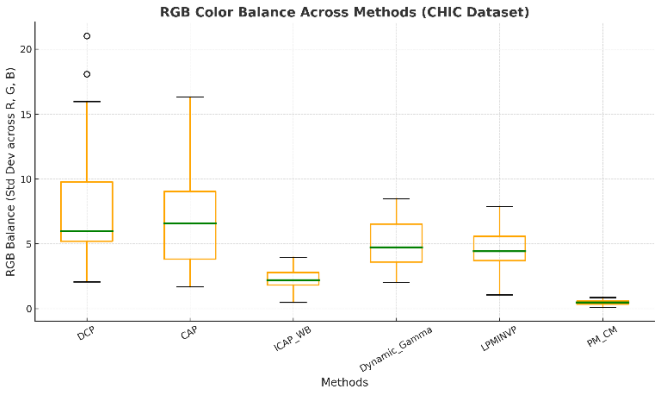

Fig. 3. RGB color balance comparison across dehazing methods on the CHIC outdoor dataset.

B. Dense Dataset (Indoor and Outdoor)

On the Dense-Haze dataset (Fig. 4, 5), haze density increases image color distortion. Despite this challenge, HCCVK maintains the most stable RGB balance with minimal variance. Competing methods such as LPMinVP outperform DCP and CAP in high-density haze but still suffer chromatic instability, shown by higher σRGB interquartile ranges. This indicates that intensity equalization alone is insufficient without spectral compensation.

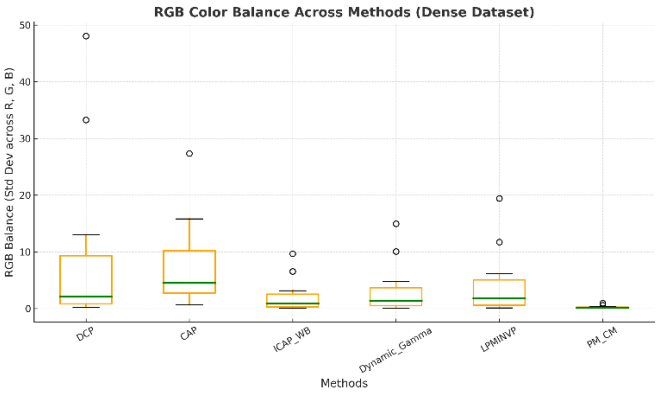

Fig. 4. RGB color balance comparison across dehazing methods on the dense indoor dataset.

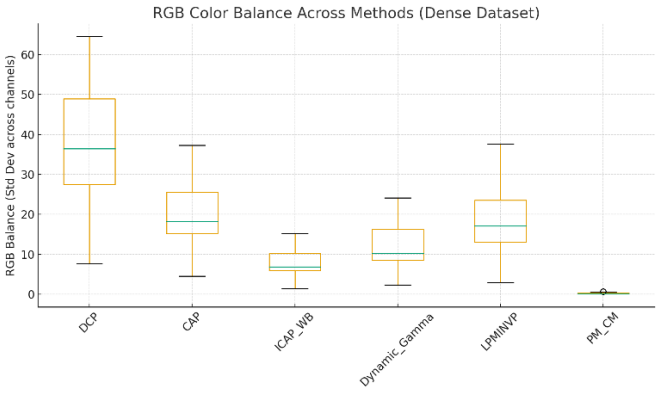

Fig. 5. RGB color balance comparison across dehazing methods on the dense outdoor dataset.

C. I-Haze and O-Haze Dataset

The I-Haze and O-Haze datasets (Fig. 6–7) evaluate haze removal in real historical scenes. HCCVK consistently produces lower σRGB compared to learning-free baselines, proving strong generalization to real-world atmospheric haze. ICAP WB improves luminance consistency but fails to correct haze-induced red-channel attenuation, leading to residual blue tint in several scenes. HCCVK effectively addresses this limitation.

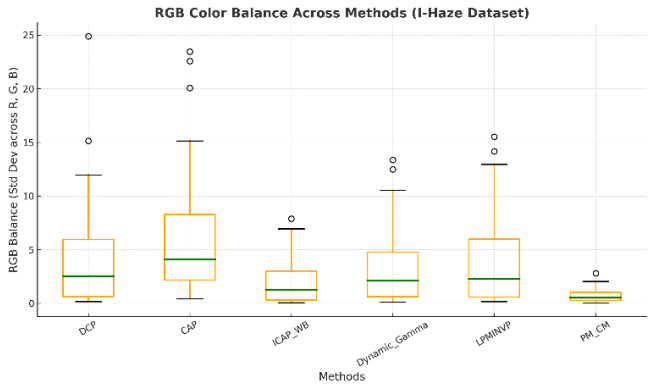

Fig. 6. RGB color balance comparison across dehazing methods on the I-Haze dataset.

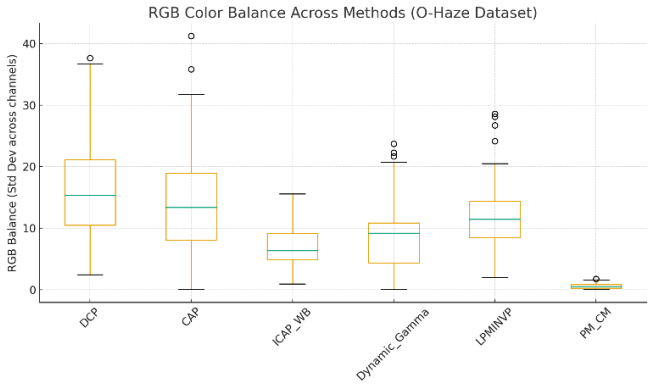

Fig. 7. RGB color balance comparison across dehazing methods on the O-Haze dataset.

D. SOT Dataset (Indoor and Outdoor)

On the SOT dataset (Fig. 8–9), which contains challenging texture transitions and depth variations, HCCVK provides the tightest σRGB dispersion, reflecting robust channel stability. CAP and Dynamic Gamma show inconsistent behavior, performing well in some scenes but failing in low-light regions due to over-enhancement artifacts.

E. NH Dataset

Finally, the NH-Haze dataset (Fig. 10), representing non-homogeneous haze, poses the greatest difficulty. HCCVK again achieves the lowest color imbalance and strongest robustness against haze variation. Prior-based methods degrade sharply in this dataset, demonstrating their limited adaptability to haze thickness variation. In contrast, HCCVK maintains consistent σRGB even under severe haze scattering.

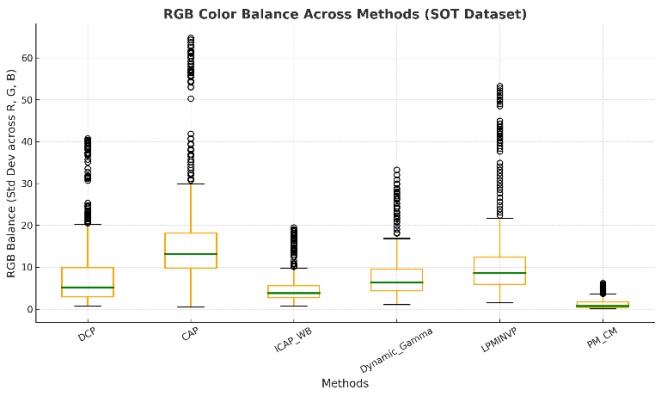

Fig. 8. RGB color balance comparison across dehazing methods on the SOT indoor dataset.

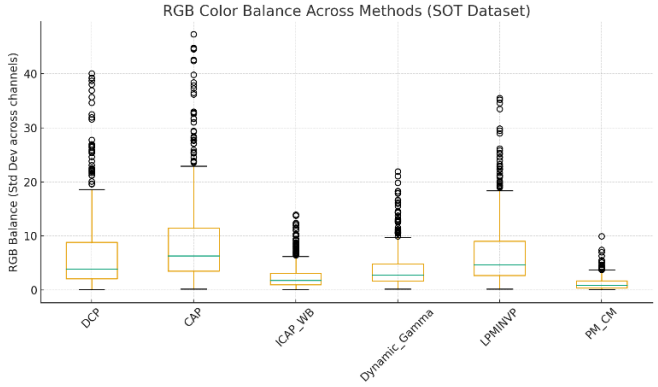

Fig. 9. RGB color balance comparison across dehazing methods on the SOT outdoor dataset.

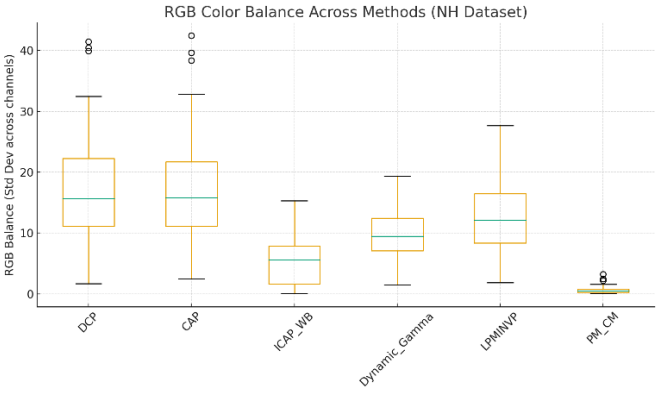

Fig. 10. RGB color balance comparison across dehazing methods on the NH dataset.

V. Discussion

The experimental results across six benchmark datasets consistently demonstrate that the proposed HCCVK method outperforms both prior-based and preprocessing-driven dehazing techniques. The superiority of HCCVK can be attributed to two core design principles: 1) explicit compensation of the red channel to counteract haze-induced blue-shift imbalance, and 2) global illuminant correction through Von Kries chromatic adaptation. These steps stabilize RGB distributions before dehazing, yielding more compact box plots and lower σRGB values compared to competing methods.

Prior-based methods such as DCP and CAP exhibit high variability and frequent outliers n σRGB, indicating unstable color restoration, especially under severe haze. These observations are consistent with findings reported in previous studies. Guo et al. [24] showed that classical scattering-based priors are sensitive to atmospheric light estimation errors, often causing excessive color deviation and halo artifacts. Similarly, Ancuti et al. [19] emphasized in the NTIRE dehazing challenge that handcrafted priors struggle to preserve color fidelity, especially in outdoor haze scenarios. Our results reinforce these limitations, as DCP and CAP show wide σRGB dispersion across most datasets, demonstrating their inability to correct haze-induced color imbalance.

Preprocessing-driven methods such as ICAP WB, LPMinVP, and Dynamic Gamma show moderate improvement in color consistency but remain inadequate for haze compensation. These methods apply intensity or gamma corrections without addressing wavelength-dependent scattering, resulting in incomplete chromatic recovery. Husain and Rahim [15] observed that gamma-based adjustments improve brightness but fail to eliminate residual blue-shift, while Huang et al. [25] found that simple color balancing lacks robustness in non-uniform haze conditions. This limitation is evident in our results, where ICAP WB and LPMinVP produce higher median σRGB and broader channel variations compared to HCCVK.

Compared to recent learning-based approaches, HCCVK maintains strong generalization without requiring model training. Chen et al. [17] introduced CCD-Net to address color distortion in deep networks, while Jing et al. [18] implemented color correction modules to improve stability under changing illumination. Although effective, these methods rely on large annotated datasets and intensive computation, limiting real-time applicability. In contrast, HCCVK delivers competitive color correction without training, offering interpretability and low computational cost.

Overall, the consistently narrow σRGB range obtained by HCCVK across CHIC, Dense-Haze, I-Haze, O-Haze, SOT, and NH-Haze confirms its robust chromatic recovery and blue-shift mitigation capability. Unlike existing methods that treat color correction as a post-processing step, HCCVK stabilizes chromatic information before dehazing, preventing color error propagation. This makes HCCVK a generalizable and deployment-ready preprocessing module for haze removal, especially in real-world applications such as intelligent transportation, visual navigation, and UAV imaging.

VI. Conclusion and Future Work

This study presented the HCCVK method, a lightweight preprocessing solution designed to correct haze-induced chromatic imbalance before dehazing. By integrating a red-channel compensation mechanism with Von Kries chromatic adaptation in linear RGB space, the method directly addresses the spectral attenuation that leads to blue-shift dominance in hazy images. Experimental validation on six heterogeneous benchmark datasets (CHIC, Dense-Haze, I-Haze, O-Haze, SOT, and NH-Haze) demonstrated that HCCVK consistently achieved the lowest σRGB values and the most compact channel distributions, indicating superior chromatic stability

compared to prior-based and preprocessing-driven baselines. These results confirm that addressing color imbalance at the preprocessing stage prevents chromatic error propagation during dehazing and provides a more reliable foundation for subsequent visibility restoration.

Beyond performance, the significance of HCCVK lies in its interpretability, generalizability, and low computational cost, making it suitable for deployment in real-time and resource-constrained computer vision systems. Unlike learning-based approaches, it does not require training or dataset-dependent tuning, yet maintains consistent robustness across varying haze densities and illumination conditions.

Future work will extend this research in three directions. First, HCCVK will be integrated with existing deep learning dehazing networks to explore hybrid learning-enhancement architectures. Second, additional evaluation metrics such as CIEDE2000, SSIM, and perceptual metrics like LPIPS will be incorporated to further quantify visual quality improvements. Finally, the method will be expanded to video dehazing and multimodal fusion scenarios to support safety-critical applications such as autonomous driving, UAV navigation, maritime vision, and intelligent surveillance.

***Abstract*—Skin cancer is among the predominant forms of the disease that includes malignant squamous cell carcinoma, basal cell carcinoma, and melanoma that is characterized by aberrant melanocyte cell development. Frequent screenings and examinations enhance the prognosis for people with skin cancer. Sadly, a lot of patients with skin cancer are not diagnosed until the condition has progressed past the point at which treatment is effective. Deep learning techniques in computer vision have made impressive strides, but issues like class imbalance and a lack of data still hinder the autonomous identification of skin conditions. A solution to address these problems is the implementation of GAN, which is capable of synthesizing realistic data. In this paper, a deep learning GAN model for image synthesis utilizing the pix2pixHD integrated with Convolutional Neural Network (CNN) classifier approach is used to perform skin cancer classification. To categorize three forms of skin cancer benign or malignant. The proposed pix2pixHD GAN is a novel method for utilizing pertinent skin lesion information for generation of high-quality synthesized dermoscopic image and conduct skin lesion classification performance with improved accuracy. Realistic images were created using a U-Net-based generator and PatchGAN discriminator with custom CNN architecture to classify three forms of cancer. With remarkable accuracy of 87.65% (MEL), 91% (BCC), and 89.85% (SCC) and other performance parameters indicate that GAN pix2pixHD Classifier model has promising results in classification. These findings demonstrate the Classifier's ability to produce and correctly identify high-quality skin lesion images, indicating its potential as a deep learning-based medical image analysis tool.**

I. Introduction

The human body's most important and sensitive organ, the skin, acts as the body's main defense against the environment and is essential for shielding the body from dangerous UV rays and illnesses. But because it is the outermost layer, it can get a variety of ailments, including skin cancer, which is one of the most prevalent cancers in the world [1] Many people are suffering from different types of skin cancer. In the year 2021 there were approximately 6.64 million new cases of skin cancers worldwide, encompassing both melanoma and non-melanoma types [2]. The stats provided that in year 2022, an estimated 330,000 new cases of melanoma were diagnosed globally, with nearly 60,000 deaths attributed to the disease [3].

As per study, in the US in 2019, about 100,000 new cases was found and 7,000 people will die. Lucky for us, melanoma treatment works much better when it was found early; it has a 92% 5-year survival rate, but only 26% when it was found later. So, finding and diagnosing melanoma as soon as possible is very important[4].

Current improvements in computer vision using Artificial Intelligence (AI) have improved diagnosis and detection approaches for fatal malignant skin conditions. Skin cancer diagnosis has always relied on manual screening and physical inspection. Dermatologists' procedures for visual inspection and evaluating of disease images are challenging, unreliable, and mistake prone[4]. The cancerous pixels must be recognized correctly to do investigation, interpretation, and comprehension of skin lesion images. This is challenging for the reasons stated below.

- Hair, veins, lubricants, bubbles, and various other clutter may be present in lesions on the skin images, interfering with the segmentation process.
- A lack of contrast between the adjacent skin and the lesion area also makes precise segmentation of the lesion difficult.
- Skin lesions typically vary in size, form, and color, limiting the efficiency of procedures in obtaining a greater accuracy degree level.

Skin lesions typically vary in size, form, and color, limiting the efficiency of procedures in obtaining a greater accuracy degree level. Due to this, demonologist find manual diagnosis challenging and necessitates the implementation of computerized diagnostic for analysis of skin lesion in making fast decisions. It has helped specialists make more precise and rapid recommendations concerning but its most threaten type Melanoma, have a very high death rate, but they are easy to treat if they are found early [4].

Over the years, different automated methods have been used to find and diagnose skin cancer. This is how medical imaging analysis is generally done: by using various dermoscopic image processing techniques. In general, the complete procedure of

finding melanoma cancer can be broken down into four essential steps:

- Preliminary image processing.
- Segmentation of images.
- Extraction of features.
- Classification of cancerous tumors.

Some of the other techniques used in preliminary processing include adjusting contrast and sharpness, morphological operations, binarization, data augmentation and colour grey-scaling. Noise and other irregularities are taken out of images at this stage. Resizing images makes sure that they are all the same size, which also makes computations easier. Segmentation of skin images run right after pre-processing, of images, separates the diseased area from the healthy meat to get the region of interest.

It divides healthy tissue prior to collecting lesions' features for suitable diagnosis. Skin lesion analysis for the identification of melanoma uses thresholds, clustering, edge and region-based, and ABCDE segmentation Algorithm. Such methods struggle to successfully partition the Melanoma region because of the complicated visual appearance of the skin lesions [5].

The majority of current research on skin cancer classification uses either traditional CNN architectures or GAN-based data augmentation for binary classification, often with poor image quality and insufficient management of data imbalance. This research fills this gap by combining a CNN classifier with pix2pix GAN to improve lesion representation and diagnostic performance for BCC, SCC, and melanoma.

II. Methods

A. Skin Cancer Diagnosis Through Deep Learning

The fine-grained variety of skin lesion appearances makes the task of classifying skin lesions difficult. As high-performance computing has advanced and massive datasets have emerged, deep learning techniques have demonstrated significant promise in a variety of image processing applications. Additionally, the most deployed deep learning convolutional neural network (CNN) performs end-to-end training using labels and image pixel input. CNN is better than the hand-crafted method in automatically extracting salient characteristics from the input data. CNN used for the first time in 1995 and utilized for analysis of medical imaging [6]. To train a deep CNN model with strong generalization capabilities, sufficient labelled data is needed. However, there aren't many publicly accessible data points for classifying skin lesions. The model transfer technique through transfer education are the main categories of classification [7].

The 129,450 clinical images were used to fine-tune the GoogleNet Inception v3 CNN architecture, which had been pretrained on the ImageNet dataset. With 2,032 disease types serving as its leaf nodes, and tree-structured taxonomy-based dataset is arranged. A partitioning algorithm is used to define the training classes based on these leaf nodes. Two binary classification challenges were used to evaluate the CNN model's performance with that of 21 dermatologists. The findings demonstrate that in certain skin cancer classification tasks, artificial intelligence has surpassed human experts. Numerous follow-up researchers have been drawn to this seminal work [8].

Researcher looked into using artificial intelligence and dermatologists to classify skin lesions [9]. The authors generated two sets of classification results using a ResNet50 model [10]. The XGBoost method was then used to merge the findings. Artificial intelligence and human decision-making together demonstrated superiority over separate systems [11].

Research has been conducted and demonstrated that augmented data is beneficial for accuracy by accurate classification and preventing overfitting by training a 4-layered CNN model with to distinguish benign skin lesions from melanoma using both normal and supplemented datasets [12].

By training two dual deep CNNs and allowing them to support one another, a unique skin lesion categorization model was created [12]. The ISIC 2016 Challenge dataset yielded state-of-the-art results for the suggested model [13].

Data synthesis, a more advanced technique for data augmentation, is intriguing and well-liked. Variational autoencoders (VAEs) [14] and generative adversarial networks (GANs) are the two most used methods for data synthesis [15]. In addition to classifying the input data into distinct classes, the WGAN can produce 64 x 64 images. The suggested approach used just 140 labelled images from the ISIC 2016 Challenge dataset, yielding an average precision score of 0.424 [16].

Research was conducted and presented a deeply differentiated GAN (DDGAN) with the goal of improving the resolution of produced image [17]. In order to demonstrate that DDGAN [18] and LAPGAN [19] that both can learn the distributed datasets and synthesize samples that looks like realistic, the authors created realistic-looking 256 x 256 skin lesion image and compared them.

GAN for image synthesis using pix2pixHD. They synthesize maps and semantic maps rather than creating images from random noise. The suggested pix2pixHD GAN is a unique approach to using the relevant skin lesion information for synthesizing high-quality image , and it is somewhat conducive to skin lesion classification performance, even if it needs annotated data to produce images, but this approach only characterized two types of skin cancer benign or melanoma [20].

B. Dataset

We require certain masks that demonstrate the presence or absence of clinically significant skin lesion patterns to train and evaluate pix2pix.

These masks may be found among the 2,601 images from the 2018 ISIC training dataset[21]. The segmentation masks for the same lesions, which are utilized to create instance and semantic maps, were acquired via the 2018 ISIC Challenge[21]. To train 2,056 images and test 545 images, we divided the data for three different classes. The details of divided data available in Table I.

A resilient adversarial learning objective function, a patch GAN discriminator architecture, and a generator with U-net are used in the pix2pix network that is a conditional image-to-image

translation GAN. The network was able to operate with high-resolution samples as shown in Fig. 1.

Differentiating between Basal Cell Carcinoma, Melanoma and Squamous Cell Carcinoma is in skin categorization process. Conventional CNN-based classifiers use used that classify in between three dermoscopic images to directly learn features.

Pix2pix model is used to generate synthetic images and trained to improve dermoscopic images as shown in Fig. 2(a) and 2(b). The CNN classifier learn features from these generated images and classify the three skin cancer types. CNN classifier has total to 115,232 trainable parameters, max pool and fully connected layer at output.

TABLE I. DATA FOR TRAINING AND TESTING

Image Class	Training	Testing	Total
Basal Cell Carcinoma(BCC)	679	188	867
Melanoma(MEL)	700	167	867
Squamous Cell Carcinoma(SCC)	677	190	867
Total	2056	545	2601

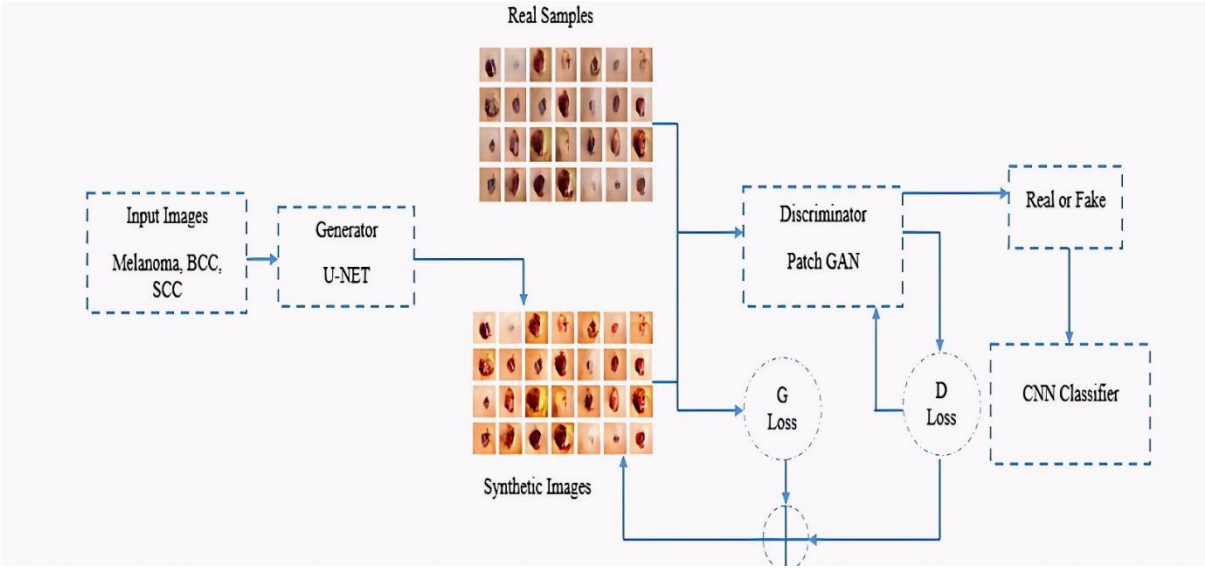

Fig. 1. Pix2pix GAN: Image generation and classification.

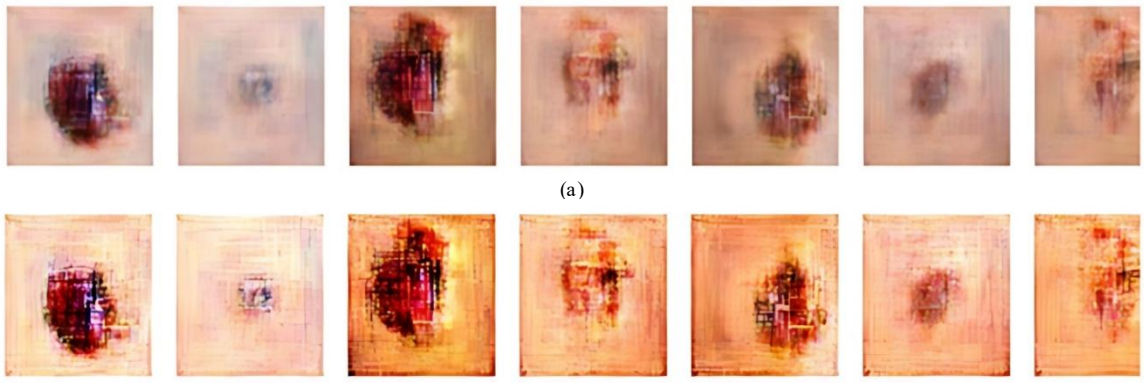

(a)

(b)

Fig. 2. (a) Original image input from ISIC 2018 dataset, (b) High resolution synthetic images generated from pix2pix GAN.

A U-Net design, which is useful for maintaining spatial information essential for medical image, is commonly used by the pix2pix generator. The discriminator is a PatchGAN, which helps the model concentrate on texture and fine features by classifying tiny patches of the Image instead of the entire image. Adversarial loss and L1 loss the pixel-by-pixel difference between the produced Image and the ground truth are used in tandem to train the pix2pix model. Segmentation masks or diagnostic labels can be used to direct the learning process for melanoma tasks. After training, the pix2pix output is utilized as a preprocessing step for an independent classification network or directly for diagnosis. In certain instances, the produced image alone can be sufficiently interpreted to help doctors make diagnoses.

The generator is encouraged to provide outputs that are identical to actual images by the adversarial loss as shown in Eq. (1):

$$LcGAN(G,D) = Ex,y[logD(x,y)] + Ex,z[log(1 - D(x,G(x,z)))] \quad (1)$$

An L1 loss as shown in Eq. (2) is used to guarantee that the produced images near the ground truth that improve pixel level accuracy and decrease blurriness.

$$\lambda \mathcal{L}_{L1}(G) = \mathrm{E}x,y[\| y - G(x) \| 1] \quad (2)$$

Realism is guaranteed by the GAN loss. The input's fidelity is guaranteed by the L1 loss. When combined, they yield results that are correct semantically and believable visually as shown in Eq. (3):

$$G^* = \arg min_G max_D \; L_C \; GAN(G,D) + \lambda \mathcal{L}_{L1}(G) \quad (3)$$

The model architecture consists of generator with U-Net attention, input of RGB image of 256 x 256, activation function of ReLU in encoder, LeakyReLU in decoder, and Tanh at final output as illustrated in Fig. 3.

The U-Net architectural design is for the purpose of medical image segmentation. It has a symmetric structure that constitutes an encoder and decoder: the encoder will collect contextual information through down-sampling, while the decoder restores fine-grained details by up-sampling. A distinguishing feature that gives U-Net its advantage is the presence of skip connections between symmetric layers of the encoder to the decoder. These connections help in retaining some spatial information that could be lost during down-sampling and make U-Net particularly good at tasks that need high localization accuracy, such as boundary delineation in medical images [22].

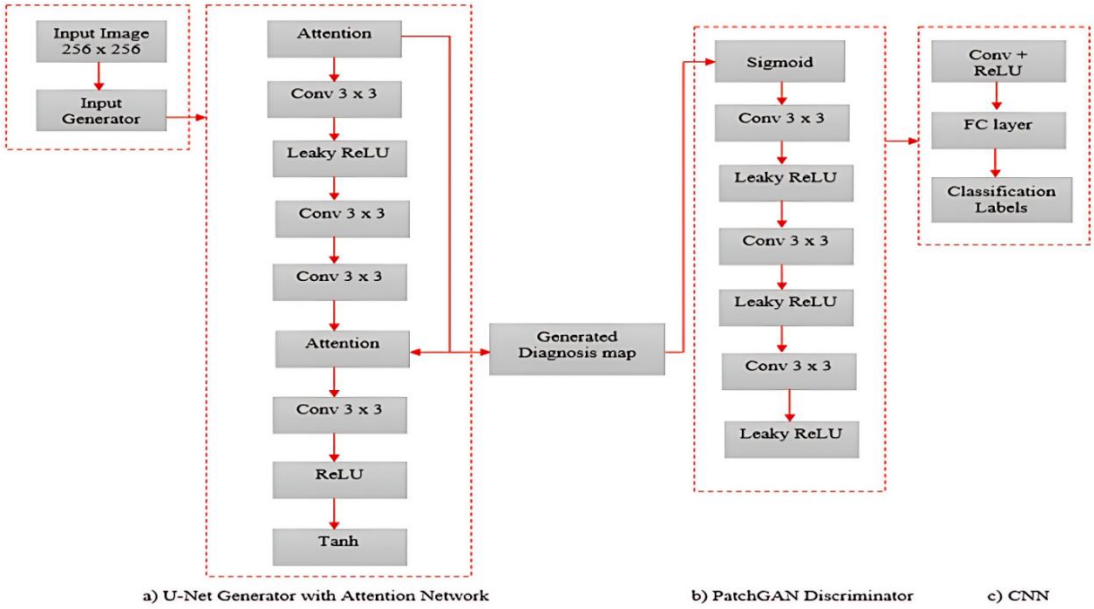

Fig. 3. Pix2pix GAN architecture with U-Net generator and CNN as classifier.

The U-Net architecture acts as a generator in a pix2pix GAN setup developed for medical-image-segmentation tasks. First, dermoscopic images (256×256 pixels) are fed into the encoder-decoder structure. The encoder successively down-samples the image, using convolutional layers with ReLU activation and batch normalization (except for the last layer), extracting deeper features while reducing spatial resolution. With each down-sampling step, the number of feature channels is increased so that the model can learn complex patterns. The decoder upsamples these features to reconstruct the image at the original resolution using transposed convolutions and LeakyReLU activations. A vital design consideration is the use of skip connections between corresponding encoder and decoder layers so that fine-grained features from the earlier layers can directly influence the output. Such preservation of spatial details minimizes information loss in the down-sampling process. Finally, the single-channel output (256×256×1) representing the diagnosis or segmentation map is activated using the Tanh function, constraining pixel values to the range of [-1,1]. This U-Net generator is pivotal to attaining realistic and spatially accurate outputs in the pix2pix GAN pipeline [22]. The inclusion of attention in this way improves both interpretability of the model and its segmentation accuracy, especially in applications dealing with skin cancer imaging. The model is therefore facilitated in providing more accurate and realistic segmentations of lesions in aiding clinicians in suspicious area identification. Visualizing these attention maps presents additional insight into what the model considers most relevant for diagnostic purposes.

Linear transformation performed in Attention network achieved through encoder feature map in Eq. (4):

$$x \in R^{(Fx \times H \times W)} \quad (4)$$

The decoder feature map is achieved through gating signal along with skip connections to produce feature map in Eq. (5).

$$g \in R^{(Fg \times H' \times W')} \quad (5)$$

Applying the linear projections on both equations through convolution shown in Eq. (6) and (7).

$$\theta_x = W_{(x)} x \quad (6)$$

$$\phi_g = W_{(g)} g \quad (7)$$

Two inputs are projected, added and passed through activation function ReLU that helps in learning the non-linear projections between encoder and decoder as shown in Eq. (8).

$$\psi=\text{ReLU}\,(\theta_x+\phi_g) \tag{8}$$

Scalar map is needed to produce attention network for knowing the important spatial regions by using sigmoid as activation function and convolution network as shown in Eq. (9).

$$\alpha=\sigma(W_\psi\ \psi+b_\psi) \tag{9}$$

The discriminator usually uses a PatchGAN architecture, The discriminator usually uses a PatchGAN architecture, which works as a Markovian discriminator by assessing the realism of tiny, overlapping patches 70×70 rather than the full image for balanced realism & accuracy. Because it enforces for high accuracy, this localized technique is especially well-suited for medical imaging jobs where fine-grained characteristics like lesion boundaries, pigmentation, and texture changes are crucial for diagnosis. In order to encourage the generator to generate anatomically correct and spatially coherent outputs, PatchGAN slides a neural classifier over the Image and classifies each patch as real or false. This results in more realistic lesion shapes and clearer borders, both of which are necessary for accurate skin cancer segmentation and detection. The Adam Optimizer is used with tuned parameters. We tried different sets of values for different parameters but there is problem of fast convergence. The values of β1 and β2 are set to stabilize the training process as available in Table II:

TABLE II. TUNED PARAMETER FOR PIX2PIX GAN

Parameter	Value
Input Image Size	256x256
Batch Size	16
Learning Rate (Generator)	0.0002
Learning Rate (Discriminator)	0.0001
Optimizer	Adam
β1	0.5
Epochs	200

III. PERFORMANCE EVALUATION

Classification purposes in the health domain wants great sensitivity as it signifies the measure of the system's value. Sensitivity is stated as Eq. (10):

$$Sensitivity/Recall = \frac{(TP)}{(TP+FN)} \tag{10}$$

Precision represents the ratio of accurately labels that are classified truly positive, which is stated as Eq. (11):

$$Precision = \frac{(TN)}{(FP+TN)} \tag{11}$$

Accuracy calculates the sum of appropriately classified skin lesions divided by the total number of skin lesions, which is stated as Equation 12 and F1-score in Eq. (13):

$$Accuracy = \frac{(TP+TN)}{(TP+FN)+(FP+TN)} \tag{12}$$

$$F1\ Score = \frac{(2*TP)}{(2*TP+FN+FP)} \tag{13}$$

IV. RESULTS AND DISCUSSION

We train a skin classification network with both synthetic and actual training sets to assess the entire set of synthetic images. Then, we compare the area images. For this comparison, we employ three distinct synthetic images created with our version of pix2pix that use both instance and semantic maps are called instances.

Only semantic label maps are used to produce semantic samples, whereas our conditional PGAN is used to generate PGAN samples. The best synthetic samples are those that are produced using instance maps. The findings for synthetic images confirm that they include characteristics that indicate whether a lesion is MEL, BCC and SCC. Furthermore, the findings imply that the created images have characteristics that go beyond what is found in the actual images. The predicted output is shown Fig. 4 that has three classified outputs.

The performance evaluation for our implemented CNN classifier is available in Table III. These values confirm that the model maintains strong precision-recall performance, especially for BCC, with slightly more variability in MEL and SCC. The implemented model reveals that the performance evaluators are nearly equal to accuracy for predicted classes.

TABLE III. PERFORMANCE EVALUATORS FOR PIX2PIX GAN AND CNN AS CLASSIFIER

Class	Accuracy	Precision	Recall	F1-Score
BCC	91%	93%	91%	92%
MEL	87.65%	89.18%	88.06%	88.1%
SCC	89.85%	87.23%	90%	88%

In order to validate the result, we have implemented the dataset on different deep learning models and the results are available in Table IV. For different models the recall, F1 and precision values are close to accuracy for VGG-16 MobileNet-V2 and InceptionV3 model that depicts the accuracy of generated synthetic images.

TABLE IV. PERFORMANCE EVALUATORS FOR DIFFERENT DEEP LEARNING MODELS

	VGG-16[23]			
Class	**Accuracy**	**Recall**	**F1-Score**	**Precision**
BCC	84.83%	83.27%	83.42%	83.62%
MEL	82.18%	79.83%	78.30%	80.63%
SCC	83.78%	81.00%	79.00%	80.31%
	MobileNet-V2[24]			
BCC	79.58%	79.30%	78.20%	80.97%
MEL	84.63%	82.02%	77.23%	82.89%
SCC	82.58%	80.28%	80.00%	81.00%
	InceptionV3[25]			
BCC	82.13%	80.45%	82.64%	80.27%
MEL	83.02%	81.75%	82.33%	82.42%
SCC	85.89%	85.00%	83.97%	83.14%

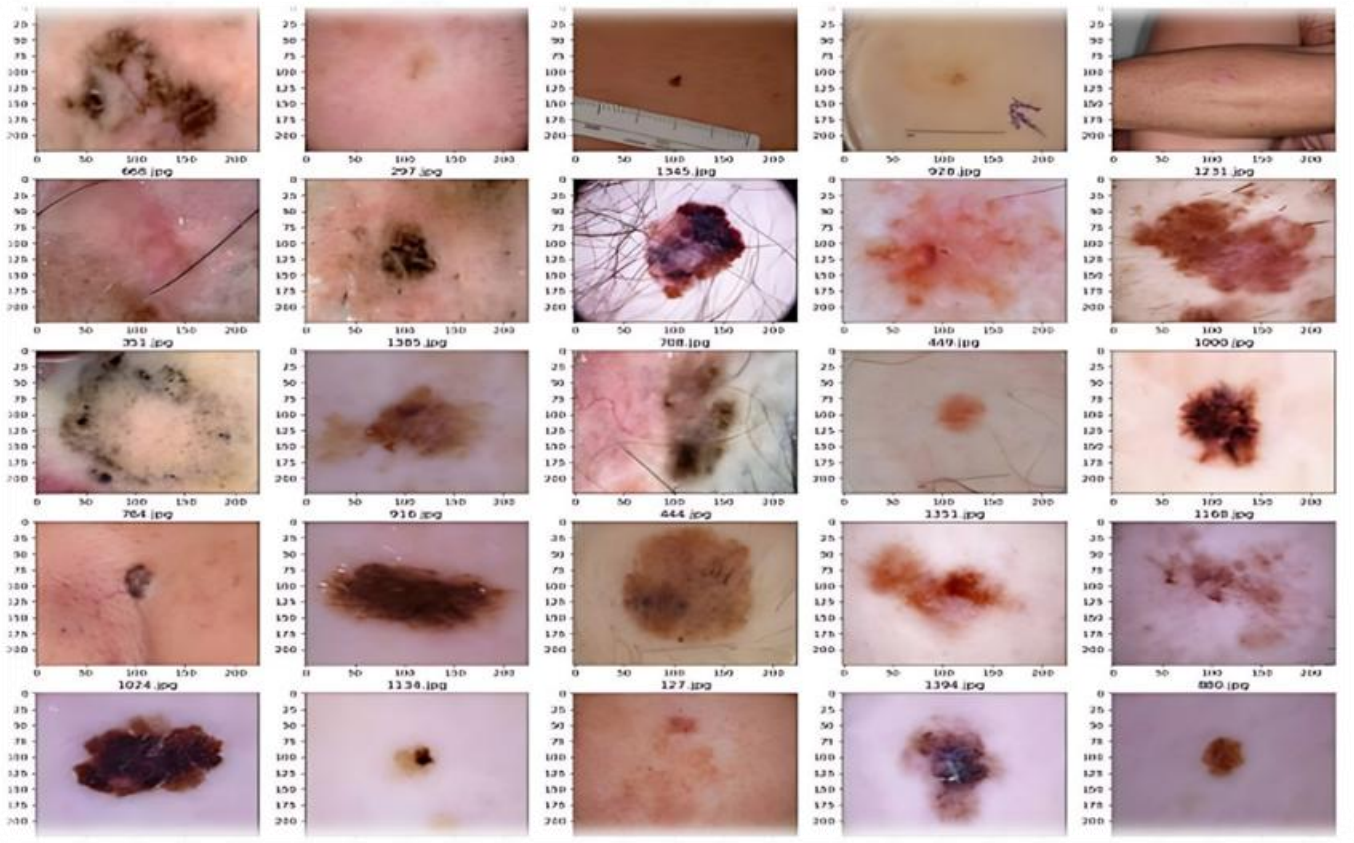

Fig. 4. Three classified outputs after CNN classification.

The model was trained on CPU 7th Generation core i-7 Intel processor, with 16 gigabytes (GB) of NVDIA GeForce GTX 1080 with 8 GB of RAM make up the system's Graphical Processing Unit (GPU). The confusion matrix for our implemented CNN classifier for three types of skin cancer for classification is shown in Fig. 5.

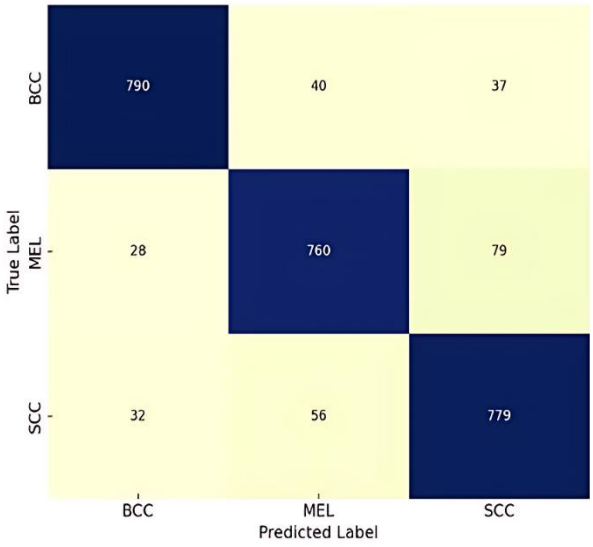

Fig. 5. Confusion matrix for classification of MEL, BCC and SCC through CNN classifier.

In order to validate the result, we have implemented the dataset on different deep learning models and the results are available in Table IV. ROC and Precision-Recall curves for MEL, BCC and SCC are shown in Fig. 6(a) and Fig. 6(b). For different models the recall, F1 and precision values are close to accuracy for VGG-16, MobileNet-V2 and InceptionV3 model that depicts the accuracy of generated synthetic images.

Results clearly shows that our proposed hybrid method, implementing pix2pix GANs with CNNs, predicts 91% accuracy on BCC, 87.65% on MEL and 89.85% on SCC using the ISIC-2018 dataset compared with typical CNN models like VGG-16, MobileNet-V2, and InceptionV3 by roughly 5 to 10% with reduced computational power and enhanced multi-class skin lesion classification. Table V also displays the comparison-based classification performance accuracy results of other authors' related work.

TABLE V. CLASSIFICATION PERFORMANCE ACCURACY FOR EXISTING RESEARCH

Author	Model	Classes	Accuracy
[8]	Inception v3 CNN	2	85%
[9]	Hybrid	2	88%
[12]	Synergic CNN	2	82-85%
[17]	MelanoGANs	2	<85
[20]	pix2pix GAN	2	85

V. Conclusion

Medical imaging is rapidly being driven by hybrid deep learning frameworks that combine generative and discriminative models. This research work used a pix2pix GAN with a U-Net generator and PatchGAN discriminator, together with a customized CNN classifier, to improve the classification of melanoma (MEL), basal cell carcinoma (BCC), and squamous cell carcinoma (SCC). The model efficiently controlled data imbalance and variability by synthesizing high-resolution dermoscopic images, reaching classification accuracies of 91% (BCC), 87.65% (MEL), and 89.85% (SCC), outperforming other models such as VGG-16, MobileNet-V2, and InceptionV3. These findings highlight the potential for GAN-augmented classification to increase diagnostic performance and robustness. A strong transition toward clinically deployable, high-precision diagnostic systems in dermatology is shown by this, which is consistent with current research trends that emphasize data augmentation and multimodal learning.

VI. Conflict of Interest

The authors declare that there is no conflict of interest regarding the publication of the paper.

A Hybrid AI Framework for DDoS Detection and Mitigation in SDN Environments Using CNN, GAN, and Semi-Supervised Learning

Abdelhakim HADJI, Brahim RAOUYANE
Department of Mathematics and Computer Science-Faculty of Sciences Ain Chock,
Computer Sciences and Systems Laboratory, Hassan II University of Casablanca, Casablanca, Morocco

***Abstract*—The fast technological evolution seen in recent years enhanced the performance and scalability of cloud computing infrastructure and Software-Defined Networking architectures. SDN provides programmability, centralized orchestration, and dynamic resource provisioning, while separating the control and data planes to offer promising architectural paradigm for cloud computing environments. Openness and flexibility expose SDN-based networks to other security concerns, such as large-scale Distributed Denial of Service (DDoS) attacks. This paper introduces a hybrid artificial intelligence (AI) framework for detecting and mitigating DDoS attacks in SDN environments. The framework leverages three complementary approaches: Convolutional Neural Networks (CNN) to capture temporal traffic patterns, Generative Adversarial Networks (GAN) to generate synthetic traffic for dataset augmentation and to enhance anomaly detection, and semi-supervised learning techniques to exploit large amounts of unlabeled traffic data. The proposed system is deployed on a testbed combining OpenDaylight as the SDN controller and Mininet for network emulation, while the AI models are trained and run in Anaconda environment. The network traffic flows are collected, processed into statistical features (i.e., packet rates, entropy values, protocol distribution ratios), and analyzed through the hybrid AI pipeline. Mitigation actions are configured through ODL RESTCONF interface, converting the detection into OpenFlow rules to drop or rate-limit the malicious packets. Experimental evaluation demonstrates that the proposed approach achieves high accuracy detection and robustness to unseen attacks patterns demonstrating the value of applying a hybrid CNN, GAN, Semi-supervised learning approach.**

***Keywords*—SDN; CNN; GAN; DDOS; OpenDaylight; Mininet; semi-supervised learning; hybrid AI framework**

I. Introduction

Over the past ten years, advances in technology significantly improved the performance and scalability of both cloud computing infrastructures and Software-Defined Networking (SDN) architectures. Caller in SDN architecture decouples the control plane from the data plane enabling, programmability, centralized orchestration and agile deployment of services to create a more efficient opportunity over a traditional network. This is the initial method to create a new innovative resource into Network Infrastructure as a key paradigm for the next-generation network that supports cloud-based services. However, the same level of openness and flexibility that provides efficiency and potential for innovation also introduces new vulnerabilities, Distributed Denial of Services (DDoS) attacks which remains one of the most significant security challenges to cloud and SDN/adoption of SDN infrastructures.

Conventional supervised machine learning techniques have achieved excellent performance on known DDoS patterns, but they are limited to known DDoS attacks due to the reliance on labeled datasets. [1]. Recent deliberations detailed in the literature indicate that hybrid models that combine supervised techniques with unsupervised and semi-supervised techniques will be favorable in settings with limited labelled data or high costs of labeling their data. Semi-supervised models have been a great way to take advantage of the ubiquitous unlabeled network traffic and exploit it to improve detection framework robustness and reduce annotation costs [2].

In this regard, Convolutional Neural Networks (CNNs) have emerged as an influential force in the realm of network security.

- Intrusion Detection: CNNs are adept at the detection of complex temporal and spatial patterns in traffic flows and thus can be effectively applied to intrusion detection in the environment of software defined networks (SDNs). For example, a CNN model was able to achieve an accuracy of 99.75% when detecting attacks using SDN–IoT networks [3].
- Feature Extraction: CNNs are capable of automatically extracting complex spatial features from high-dimensional traffic [4] data which is required to distinguish between legitimate and malicious flows [4].

In a similar manner, Generative Adversarial Networks (GANs) have also shown potential having significant ramifications for cybersecurity.

- Anomaly Detection: GANs can produce synthetic traffic that resembles legitimate traffic flows, therefore highlighting subtle deviations that may be indicative of zero-day attacks or progressive malware in cloud systems (L & Kousar, 2024).
- Adversarial Training: GANs produce synthetic adversarial DDoS traffic to increase the resilience of detection systems to advanced style attack strategies and adaptive adversaries [5].

While convolutional neural networks (CNNs) and generative adversarial networks (GANs) offer important advantages in terms of detection accuracy and robustness, the adaptation of these methods to changing threat vectors and the consistency of detection performance across heterogenous cloud-SDN environments presents additional challenges. Hybrid deep learning, adversarial modeling, and semi-supervised algorithms would address resilience, as well as detection accuracy and adaptivity.

Although the advancement of machine learning and deep learning applications to DDoS detection is increasing, the literature is still limited in ways in which the contributions of the literature can be invoked. A great deal of research relies on the use of fully labeled datasets, which diminishes their ability to generalize and adapt to attacks that are occurring for the first time. Many papers evaluate DDoS detection algorithms in some isolated or simulated environment and often do not deploy them in a controlled environment with a real SDN controller or in some emulated cloud environment. A great deal of research focuses on improving accuracy but does not consider adaptability and real-time mitigation mechanisms to handle DDoS attacks in SDN-enabled cloud environments. Thus, the importance of this research by offering a hybrid AI framework that combines CNNs, GAN, and Semi-supervised learning in an SDN-cloud testbed with OpendDaylight SDN controller and the Mininet emulator, which is capable of enhancing robustness, scalability, and adaptability within hybrid infrastructures where DDoS detection and mitigation can be improved.

In this paper, we present a hybrid AI framework to detect and mitigate distributed denial-of-service (DDoS) attacks in SDN-enabled cloud environments. The framework was implemented on an experimental testbed to represent an SDN-enabled cloud network, integrating OpenDaylight (ODL) as the control implementation and Mininet as the network emulation tool. The proposed method generates a traffic trace dataset that extracts and analyzes statistical features, such as packet rates, entropy measurements, and protocol ratios through the hybrid AI framework. Mitigation actions were dynamically enforced through ODL's RESTCONF API, acting on detection results and mapping them to OpenFlow rules to drop packets or set rates on egress traffic. Our results demonstrate that this hybrid integration enhances detection accuracy, decreases dependence on labeled datasets, and increases resilience against changing and customizing DDoS attack vectors.

II. Related Work

A. Machine Learning for SDN Security

The application of machine learning (ML) in securing Software-Defined Networking (SDN) structures from Distributed Denial of Service (DDoS) attacks has garnered growing attention in the research community. A recent study conducted by Musmuharam and Suharjito (2023) investigates the performance of multiple classification algorithms—specifically Random Forest (RF), Support Vector Machine (SVM), and K-Nearest Neighbors (KNN)—alongside feature selection techniques such as Recursive Feature Elimination (RFE), Principal Component Analysis (PCA), and t-Distributed Stochastic Neighbor Embedding (t-SNE). The authors found that the KNN model in conjunction with RFE produced highly significant results, achieving an accuracy of 99.97%, precision of 99.98%, recall of 99.96%, and F1 score of 99.97% for DDoS detection in an SDN context [6]. This indicates the effectiveness of custom feature engineering in improving the performance of traditional classifiers.

Complementary research [7] proposed a broader ML-based framework for cyber threat detection in SDN.This academic article examines the examination of cyber threats detection in Software-Defined Networks (SDNs) with a framework of machine learning methodologies by utilizing AI-Enabled Servers at the control and application layers to protect the network from them via identification and remediation of threats. The model makes use of six separate classifiers that are trained on differing metric parameters in the network: Random Forest; K-Nearest Neighbor; Support Vector Machine; Naïve Bayes; Decision Tree; and Logistic Regression, whereby analysis of the data supports that the framework is capable of detecting and remediating risks of a cyber nature; and also proposes recommendations for more effective threat detection in the future, and future security controls.

B. CNNs in Network Security

Convolutional Neural Networks (CNNs) have demonstrated utility for intrusion detection and anomaly detection of systems with Software Defined Networking (SDN) properties, primarily due to their ability to automate spatial and temporal feature extraction from challenging data related to network traffic.

Others examined the weakness of CNNs as a means for developing Intrusion Detection Systems (IDS) for SDNs with respect to the overfitting phenomenon that often degrades the performance of deep learning development[8]. By implementing two new approaches based on regularization or uncertainty with their new learning method of CNNs, they demonstrated their improved resilience to unseen attack. Training and testing the learning method on the InSDN benchmark dataset generated higher generalization for the model and better detection accuracy for unknown intrusion events to enhance security for SDN infrastructures against attacks.

In a more recent study, and with a focus on lightweight DDoS detection and mitigation for SDN, [9] a security framework that integrated an anomaly detection and prevention module utilizing a hybrid CNN-MLP model has been proposed. The design leveraged the ability of CNNs to perform feature extraction with the efficiency of multilayer perceptron's (MLPs) since it provided real-time analysis of network traffic; therefore, their system had the ability to identify anomalies, and respond using flow-rule instructions, premised in the SDN controller, to block attacker IP addresses and mitigate malicious traffic. Overall, they were able to demonstrate cost-effective and real-time solutions, thus indicating the feasibility of hybrid CNN architectures to protect against expensive resource DDoS attacks in SDN time-critical infrastructure.

Collectively, these works demonstrate that CNNs play an important role that can significantly bolster security properties for SDN. They further demonstrate that CNNs bearing the

capability of flexibility and when regularized and/or hybridized with other levels of neural architectures, bring robustness and efficiency to the process of identifying and mitigating many classes of cyber threats.

C. GANs in Cybersecurity

Generative Adversarial Networks (GANs) are now increasing attention within cybersecurity, especially in relation to mitigating the limitations of SDN-based infrastructures. Their two-fold potential of generating realistic synthetic traffic and supporting anomalous detection have made GANs valuable in both research and operational defense areas.

A motivating example of GANs used to support SDN-GAN security was presented [10] to introduced one of the early applications of SDN-GAN, a framework that synthesizes cyber-attack scenarios. They illustrated a way that GANs could autonomously synthesize realistic attack signatures based on known patterns. Doing so enables the training of the detection systems in the endless number of possible attack variations. In this regard, the challenge of SDN security is one that is most vulnerable to programmable environments with frequently unknown and adaptive threats.

Another study has recently introduced the LD-BiHGA system [11], a bi-channel hybrid GAN architecture designed for anomaly detection in multi-domain SDN systems. In their model, the two asymmetric GANs were used for independent learning of normal and abnormal traffic, while the bi-channel attention mechanism provided an additional level of feature extraction. By overcoming concerns of real-time, unbalanced traffic data, the LD-BiHGA system improved accuracy in recognition of anomalies over traditional intrusion detection systems, demonstrating the effectiveness of GANs utilized in hybrid models for larger-scale, complex SDN systems. Overall, these contributions signify the journey of GANs in the cyber security space; from synthetically generating attack scenarios, hybridizing with RNNs, and attention mechanisms for anomaly detection. They exemplify not only the capacity for dataset enhancement and classification imbalance for GANs, but also the viability for adaptive engagement and real-time security within SDN infrastructures.

D. Semi-Supervised Learning for SDN Security

In recent years, semi-supervised learning has gained considerable attention as a viable strategy for detecting DDoS attacks in SDN and cloud-based environments, mainly due to the algorithm's capability of utilizing large quantities of unlabeled traffic data. In contrast to purely supervised techniques, which typically depend on having access to large labeled datasets, semi-supervised learning proves a more practical and viable option for real-world implementations.

In addition, a survey of machine learning techniques for intrusion detection in cloud and SDN environments [12]. They found that ML models can detect anomalous traffic related to DDoS attacks and referenced a clear shift towards adaptive rule-based models to increase the security of routing payloads while preserving network privacy.

In IoT-SDN environments, Ravi and Shalinie (2020) introduced the LEDEM mechanism, which acts as a learning-executed detection and mitigation framework. The LEDEM mechanism demonstrated an accuracy of 96.28% for DDoS detection and established the combination of cloud and SDN architecture with learning techniques as successful[13]. This research shows how dynamic and distributive detection models can benefit resource-constrained infrastructures relying on IoT-SDN.

Khamaiseh et al. [2]examined the effectiveness of supervised versus semi-supervised methods for detecting both known and unknown attacks. Their results indicated that supervised methods performed well when encountering previous attack patterns, however, performance suffered against zero-day attacks, demonstrating the limit of these methods. In comparison, semi-supervised methods demonstrated improved adaptability and resilience, and both authors argued for their eventual role in securing DDoS attacks, especially as part of a future SDN security framework. Deka et al. offered a dynamic, range-based anomaly detection method leveraging semi-supervised algorithms[14]. Their work involved the introduction of a density-based approach to handling unlabeled traffic. To that end, semi-supervised classifiers outperformed other standard supervised classifiers in terms of scalability and accuracy offered in fast changing SDN situations.

Overall, these studies contribute to a growing body of studies acknowledging the value of semi-supervised learning method for reducing the number of labeled data needed to detect attacks regardless of their pattern, and combining cost-effective label data and semi-supervised methods will lead to shared improvements to future DDoS detection and security frameworks.

The literature reviewed in this research clearly indicates that there have been significant developments in the detection and prevention of DDoS attacks, especially in SDN and cloud-based contexts, through machine learning (ML) and deep learning (DL) methods. Classical ML approaches, e.g., Random Forest, Support Vector Machine, and K-Nearest Neighbors, achieved relatively high detection accuracy levels when employed with optimally selected features. However, these ML models remain limited by their reliance on labeled datasets and their limited ability to generalize to new or even zero-day attack datasets.

Deep learning methods, namely convolutional long short-term memory (CNN-LSTM), have shown strong performance in automatically extracting important spatial-temporal features from complex traffic data. Regularization methods and hybrid CNN approaches have also shown the ability to improve generalization performance and reduce overfitting levels, which has also made them more robust for designing an intrusion detection task. In a similar vein, GANs have opened important new lines of research into anomaly detection both in isolation and in conjunction with adversarial training. Additionally, GANs can be employed to generate synthetic traffic data that help balance datasets and create realistic attack data that improves performance robustness. Despite these advances, adapting GAN models to solve multi-domain and real-time SDN settings and cloud contexts still presents significant challenges in computational overhead and interpretability.

Semi-supervised learning has emerged as an exciting alternative to address one of the central challenges of SDN security: the limited/missing labeled data. Previously, it has been shown that semi-supervised algorithms can leverage unlabeled traffic due to its abundance, allowing for higher adaptability to altered attacks without increased annotation costs. While the performance of these methods is promising, their placement back into operational environments is still sparse, particularly in dynamic enforcement and scalability.

In summary, the current state-of-the-art shows clear advancements, while identifying areas for research. Most work employs supervised/deep learning models (CNN, GAN) or simply employs semi-supervised anomaly detection. Very few papers propose a holistic framework that employs CNNs for deeper feature learning, GANs for synthetic traffic generation and adversarial accuracy, and a semi-supervised model for changes to new attacks. Additionally, few papers demonstrate end-to-end pipelines that not only detect attacks but also capable of real-time mitigation via interacting directly with SDN Controllers such as OpenDaylight.

This outlines the issue of missing a unified model; the present work proposes a hybrid AI framework of CNN, GAN and semi-supervised algorithms that can create a real-time effective DDoS detection and mitigation framework for SDN based cloud environments.

III. Methodology

A. General Architecture

The architecture of the proposed framework integrates concepts of Software-Defined Networking (SDN) and Artificial Intelligence (AI) paradigms to automate the process of detection, mitigation, and protection against Distributed Denial of Service (DDoS) attacks. Two virtual machines compose the experimental testbed set-up, one contains an OpenDaylight (ODL) controller that will provide centralized control and policy enforcement, while the other contains the network emulator Mininet, which creates the data plane for the framework via an Open vSwitch (OVS) and manufactures both legitimacy and harmful traffic. A host machine running Jupyter/Anaconda will provide the environment for AI processing, wherein detection models are established and applied on this machine.

The three layers of architecture follow the principles of a SDN:

- Application Layer: AI driven detection applications (CNN, GAN, semi-supervised algorithms).
- Control Layer: ODL controller with RESTCONF APIs to enforce policies based on the detection of malicious traffic.
- Data Layer: Mininet switches and hosts that contain the programmable data plane.

B. Data Collection and Feature Engineering

Traffic is generated within Mininet, consisting of benign traffic flows (HTTP, FTP, DNS) and malicious traffic flows (SYN floods, UDP floods, ICMP floods). It is captured using tcpdump/tshark and exported into .pcap files then transformed into CSV datasets (traffic.csv).

Statistical and time-based features are extracted from each time window of traffic including:

- Packet-level: packets per second (pps), bytes per second (bps), average packet size.
- Protocol distribution: SYN/ACK ratio, UDP/TCP ratio, ICMP fraction.
- Diversity of sources: number of unique source IPs and the entropy of the source IP distribution.
- Time-based features: inter-arrival time variance, coefficient of variation.

These provided the inputs to the hybrid AI models.

C. Integration of AI Models

The main contribution of our architecture is the hybrid AI pipeline that utilizes the combination of Convolutional Neural Networks (CNNs), Generative Adversarial Networks (GANs), and semi-supervised learning.

1) Convolutional Neural Networks (CNNs): CNNs will be utilized to capture rich temporal-spatial dependencies across traffic features. CNNs hierarchical architecture allows automatic feature extraction and effective classification of DDoS versus benign flows.

2) Generative Adversarial Networks (GANs): GANs will be used in two ways: 1) for augmenting the dataset by generating realistic benign/malicious traffic to compensate for class imbalance, and 2) for adversarial training, where the generator produces difficult samples, thereby increasing detection accuracy of the discriminator.

3) Semi-supervised learning: Real-world datasets often do not have enough labeled samples, so semi-supervised methods (e.g., Self-Training Classifiers, consistency regularization) will be used to utilize unlabeled traffic, improving adaptability to emerging or zero-day attacks.

The final outputs from the CNNs (supervised predictions), the GAN discriminators (anomaly detection signal), and the semi-supervised classifiers will all go through a late-fusion mechanism producing an adapted detection score that optimizes accuracy and adaptability.

D. Policy Engine and Mitigation

Upon detection and classification of a given traffic flow, the decision is passed through a RESTCONF northbound API to the ODL controller. The ODL controller implements the decision by converting the identified flows into OpenFlow rules and implementing those rules onto the Mininet switches. Mitigation includes:

1) Flow-based filtering: implement DROP rules based on the identified malicious source IP or port.

2) Rate-limit (meter tables): impose a maximum bandwidth constraint on a suspected malicious flow.

3) Dynamic updates: use short flow timeouts to eventually rollback flows in case they are a false positive.

The combination of AI detection across the traffic flows and the programmability of an SDN approach will ultimately enable real-time, dynamic mitigation against a DDoS attack.

Algorithm 1: Hybrid AI Framework for DDoS Detection and Mitigation in SDN

```
Initialize: SDN environment
Compute: extract statistical features from captured network traffic in Mininet (normal and abnormal)
While (new traffic window is received) do
    For (each traffic flow in the window) do
    Update feature vectors for the flow
    Analyze flow using AI Models:
        If (fusion score ⩾ threshold) then
        Search for malicious flows
        Update ODL via RESTCONF:
            If (attacked) then
                Insert OpenFlow DROP rule
                Or apply METER for rate-limiting
    End
End
```

As a summary, the framework can be thought of as a pipeline:

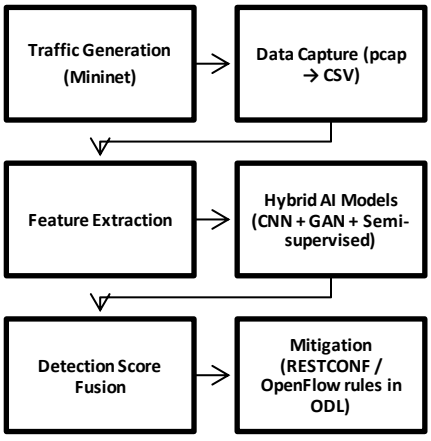

Fig. 1. Framework pipeline.

This design guarantees that detection is accurate (with CNN), resilient (with GAN), and adaptive (through semi-supervised learning), while mitigation is performed immediately in the SDN data plane. Fig. 1 shows framework pipeline.

IV. Results and Discussion

The experimental evaluation of this project was built with Mininet (data plane) and OpenDaylight (control plane), with the application layer running in a Jupyter/Anaconda working environment for the AI models developed in Python. Traffic patterns included normal HTTP, FTP, and DNS flows, as well as malicious traffic created using tools like hping3 to simulate SYN floods, UDP floods, and ICMP floods.

TABLE I. Results in a Controlled Environment

Model	Evaluation Metrics			
	Accuracy (%)	*Precision (%)*	*Recall (%)*	*F1-score (%)*
CNN	99.0	98.5	98.0	99.0
GAN	97.5	97.0	96.5	96.8
Semi Supervised	95.0	94.0	95.0	95.2

The CNN model was able to classify all normal traffic, as well as known DDoS attack types, with high accuracy, reaching a maximum accuracy/F1-score of just below 99% when trained on balanced datasets as shown in Table I. However, the CNN model degraded in accuracy when faced with new attack types that had not been included in the training data, which is a limitation of any supervised model.

The GAN model performed even more robustly by generating synthetic benign and DDoS samples, improving generalizability across imbalance datasets that had far fewer malicious flows than benign flows. Additionally, the GAN discriminator component performed well as an anomaly detector for all types of network traffic, achieving high accuracy in classifying flows as benign or malicious based on their deviation from normal distribution.

The semi-supervised approach made significant gains when access to labeled data was limited. The model was able to take advantage of pseudo-labeling and consistency regularization, which allowed it to utilize unlabeled flows during the training process, rather than depending on labeled annotations. When only 30 percent of the dataset was labeled, the semi-supervised structure achieved F1-scores higher than 95 percent, which surpassed traditional supervised baselines with the same labeling restrictions.

Although results obtained from single models demonstrate promise, weaknesses in stand-alone models justify hybridization. The proposed framework from this study uses late fusion by combining CNN, GAN, and Semi-supervised learning method's output through late fission logic. In late fusion, the output of the supervised probabilities is combined with the anomaly scores as a composite decision.

Table II presents the performance improvement observed before/after using a fusion approach.

The use of a fusion approach reduced the false positives over the previous stand-alone models. In instances of zero-day events (e.g. new UDP amplification traffic), the base model hybrid captures 95% recall whereas the CNN model captured 88%.

TABLE II. DETECTION PERFORMANCE BEFORE AND AFTER HYBRID FUSION

Model	Accuracy	Recall (%)	False Positive Rate (%)
CNN	99.0	88.0	6.5
GAN	97.5	90.0	7.2
Semi Supervised	95.0	92.0	6.8
hybride	98.7	95.0	4.3

Detection results were directly incorporated into the ODL controller via the RESTCONF northbound interface. Once malicious flows were identified, ODL automatically pushed OpenFlow rules into Mininet switches for immediate execution. The following two countermeasures were evaluated Avoid combining SI and CGS units, such as current in amperes and magnetic field in oersteds. This often leads to confusion because equations do not balance dimensionally. If you must use mixed units, clearly state the units for each quantity that you use in an equation.

V. CONCLUSION

The findings validate that the suggested framework can balance accuracy, adaptability, and operational feasibility. CNNs can recognize structured patterns, GANs allow for synthetic augmentation, and adversarial training further enhances robustness against threat behavior as it was. Models as we have indicated in the semi-supervised methods augment adaptability to unknown threats. We also find that the hybrid implementation of these models in an SDN testbed demonstrates the practical feasibility of AI-enabled hybrid detection frameworks for today's emerging, programmable networks.

Despite this success, there are still challenges to overcome. GAN training on its own has a heavy computational burden which, all other factors constant, may limit real-time scalability of the solution when deployed in large-scale integrations. The semi-supervised models, while still viable, are sensitive to precise tuning of the pseudo-labeling threshold to prevent erroneous error propagation in known threat behavior in the etiologies projected.

Future improvements in our integration should consider a distributed learning approach (e.g., federated learning) and/or a model optimization (e.g., pruning) to deploy when computational resources are confined to the edge environments.

Benchmarking Deep Learning Models for Visual Classification and Segmentation of Horticultural Commodities

Fuzy Yustika Manik*, Syahril Efendi, Jos Timanta Tarigan, Maya Silvi Lydia
Department of Computer Science-Faculty of Computer Science and Information Technology, Universitas Sumatera Utara, Medan, Indonesia

***Abstract*—Recent advances in computer vision have enabled new approaches for automated quality assessment of tropical fruits, where accurate classification and segmentation are essential for postharvest inspection. A major challenge lies in identifying deep learning architectures that achieve high accuracy while remaining computationally efficient for potential edge-based deployment. This study benchmarks three Convolutional Neural Network (CNN) models for classification (VGG16, ResNet50, and EfficientNet-B0) and two encoder–decoder models for segmentation (U-Net and DeepLabV3+) using annotated pineapple and strawberry image datasets. A 5-fold cross-validation strategy was applied to ensure statistical robustness, with evaluation metrics including accuracy, precision, recall, F1-score, Intersection over Union (IoU), and Dice coefficient. Statistical significance was verified using the Friedman and Wilcoxon signed-rank tests ($\alpha = 0.05$ and 0.01). EfficientNet-B0 achieved the best classification results with average accuracies of 91.4% (strawberry) and 90.7% (pineapple), significantly outperforming ResNet50 and VGG16 ($p < 0.01$). For segmentation, DeepLabV3+ obtained the highest performance with mean IoU values of 91.7% and 90.8% and Dice coefficients above 92%, indicating precise boundary delineation of ripe and defective regions. Computational efficiency analysis further showed that EfficientNet-B0 had the lowest inference time (0.026 s) and smallest model size (20.4 MB), making it ideal for real-time or embedded applications. Visual analysis confirmed that DeepLabV3+ maintained robustness at fruit boundaries, though minor misclassifications were observed. This benchmarking highlights the combination of EfficientNet-B0 and DeepLabV3+ as a reliable baseline for deep learning-based fruit quality assessment.**

I. Introduction

Advances in computer vision and deep learning have significantly impacted precision agriculture, particularly in automated fruit quality assessment and post-harvest monitoring [1], [2]. One of the most crucial visual tasks in this domain is image-based classification and segmentation, which enables sorting, grading, and intelligent decision-making for horticultural commodities such as strawberries and pineapples. These visual tasks are particularly challenging due to variations in lighting, occlusion, background complexity, and the diversity of shapes and colors within a single fruit class [3].

The application of deep learning in precision agriculture systems has received significant attention in recent years. In particular, Convolutional Neural Network (CNN)-based models such as VGG16, ResNet50, and EfficientNet-B0 have demonstrated high performance in fruit image classification tasks, ranging from type determination and ripeness to visual defect detection [4], [5].

A study by Hasan et al. [6] demonstrated that ResNet50 can accurately classify fruit in real-world scenarios. Meanwhile, VGG16 is known to be a stable model and is often used as a baseline in many visual classification experiments [7]. EfficientNet-B0, with its systematic scaling approach, offers a balance between accuracy and computational efficiency, making it suitable for edge-based applications such as field devices [8]. However, most of these models are trained and tested under relatively controlled conditions or using datasets with low levels of variation. In real-world horticultural scenarios, fruit images are typically acquired under non-uniform lighting, varying backgrounds, and inconsistent fruit shapes and sizes [8].

U-Net has become a primary choice for fruit image segmentation tasks due to its symmetric encoder-decoder design, which effectively preserves spatial information [9]. On the other hand, DeepLabV3+ uses atrous convolution and atrous spatial pyramid pooling (ASPP) to capture contextual information at multiple scales, proving effective in segmenting objects in complex backgrounds [10], [11]. Mo et al. [12] successfully implemented MobileNetV2-based DeepLabV3+ to detect sugar apple ripeness accurately.

However, most of these models were trained and tested under relatively controlled conditions or using datasets with low levels of variation. In real-world horticultural scenarios, fruit images are typically acquired with non-uniform lighting, varying backgrounds, and inconsistent fruit shape and size [13]. These factors reduce the generalization ability of standard CNN models. Therefore, several approaches such as data augmentation [14], domain adaptation [15], and synthetic training [16] have been developed to improve the generalization ability of CNN models to real-world conditions.

Furthermore, most previous studies focus on a single task (classification or segmentation) and often use datasets under ideal conditions. Few studies evaluate multiple CNN architectures simultaneously on both tasks on authentic tropical fruit images such as strawberries and pineapples. Therefore,

*Corresponding author.

this study aims to systematically assess the performance of VGG16, ResNet50, and EfficientNet-B0 models for classification and U-Net and DeepLabV3+ for tropical fruit image segmentation. The evaluation uses metrics such as accuracy, precision, recall, F1-score (classification), and IoU and Dice coefficient (segmentation) to provide a scientific basis for selecting the optimal model for image-based fruit classification and segmentation systems.

This benchmarking study aims to highlight the strengths and weaknesses of current deep learning approaches and provide an empirical basis for developing more adaptive and multi-task architectures. In addition, the findings of this study will demonstrate how model selection and architectural complexity directly influence accuracy, segmentation quality, and computational efficiency under real-world postharvest conditions. These insights contribute to the development of practical, lightweight, and adaptive deep learning models that can be effectively applied to agricultural automation and quality monitoring of tropical fruits in real-world scenarios. Based on our results, we also briefly discuss the potential of emerging immune-inspired and multi-agent approaches such as AISAM-CSNet, which will be elaborated in detail in our forthcoming publication.

II. Related Work

Rapid computer vision and deep learning developments have driven the application of CNN models in various sectors, including precision agriculture. In fruit image processing, two main tasks, quality classification and fruit object segmentation, are key for automated post-harvest systems. Recent studies have utilized modern CNN models to detect fruit types and ripeness and to separate fruit objects from complex backgrounds. CNN models such as VGG16, ResNet50, and EfficientNet-B0 are widely used in fruit image classification. VGG16 is a classic architecture often used as a baseline due to its stability despite the large number of parameters [7]. Sudars et al. [6] conducted a comprehensive review of the application of CNNs to fruit quality classification and positioned VGG16 as one of the standard architectures used in laboratory scenarios.

ResNet50, which introduces residual learning, effectively addresses degradation issues in deep networks [3]. Hasan et al. [6] showed that ResNet50 can maintain fruit classification accuracy in natural lighting. Arif et al. [17] compared ResNet50 with DenseNet and EfficientNet in orange classification, with ResNet50 outperforming in complex background conditions.

EfficientNet-B0 introduces a compound scaling approach to balance accuracy and efficiency [8]. Li et al. [5] demonstrated that EfficientNet-B0 suits fruit classification on edge devices. Wagle et al. [18]'s research corroborates this finding by showing the high computational efficiency of EfficientNet in apple and tomato classification. Reyes et al. [19] also demonstrated that EfficientNet is effective in fine-grained classification of tropical fruits. Furthermore, DenseNet [20], InceptionV3, and MobileNetV2 [21] were also evaluated in fruit classification, but their performance was often lower in open field conditions. A study by Rauf et al. [22] confirmed that ResNet and EfficientNet provide the best trade-off between accuracy and inference time compared to other architectures.

Meanwhile, fruit object segmentation requires precise object boundary detection and separation of the fruit from the background. The U-Net model is widely recognized for this task because it preserves spatial information [9]. Fang et al. [23] developed a U-Net with attention gating for accurate strawberry segmentation in open fields. Jamil et al. [24] combined a squeeze-and-excitation block to improve mango fruit detection in RGB images.

DeepLabV3+ utilizes atrous convolution and atrous spatial pyramid pooling (ASPP) to process multiscale features. Research by Zhao et al. [10] demonstrated the superiority of DeepLabV3+ in detecting mangoes under occlusion. Mo et al. [12] implemented MobileNetV2-based DeepLabV3+ to detect the ripeness of sugar apples and achieved high accuracy. Other models such as Mask R-CNN [25], HRNet [26], and SegNet [27] have also been tried for fruit segmentation, but their complexity and high computational requirements are obstacles in real-time applications. Milioto et al. [28] developed real-time semantic segmentation for crops and weeds using a CNN optimized for agricultural robots.

One of the main challenges in implementing CNN in fruit classification and segmentation systems is its ability to generalize real-world images. Most studies use datasets with clean backgrounds and ideal lighting [29]. Xu et al. [30] reported a 30% decrease in accuracy when apple classification models were trained in the laboratory and tested in the open field. To address this issue, data augmentation [14], domain adaptation [15], and synthetic image-based training [16] approaches have been proposed. Shorten and Khoshgoftaar [14] showed that augmentation can improve the robustness of CNN models to complex background conditions. Chen et al. [15] evaluated domain adaptation to transfer models from laboratory to field data. Meanwhile, synthetic training has enriched the variety of training images, as evidenced by Rahnemoonfar and Sheppard [16].

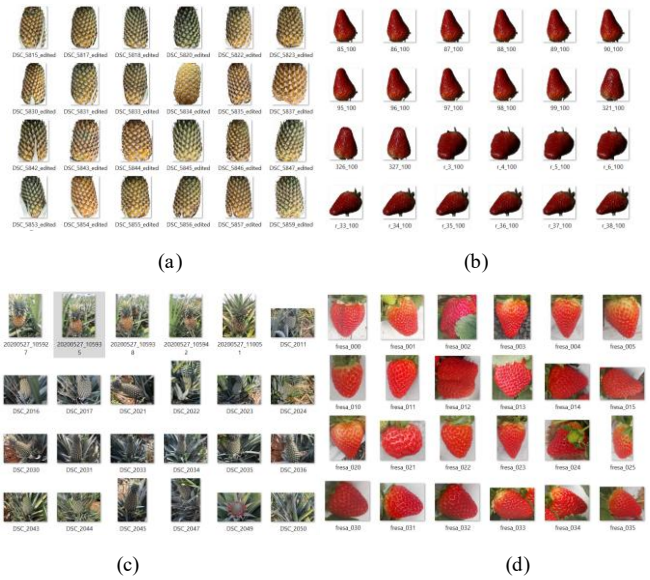
Although various CNN models have proven effective for fruit classification and segmentation separately, comprehensive studies that evaluate multiple CNN architectures across both tasks under real-world conditions remain limited. This research presents the first benchmarking study that simultaneously evaluates CNN-based classification and segmentation models (VGG16, ResNet50, EfficientNet-B0, U-Net, and DeepLabV3+) on tropical fruit images (strawberries and pineapples) in realistic postharvest scenarios. The study contributes a novel understanding of the relationship between architectural complexity, adaptability, and segmentation precision. The benchmarking results reveal a balanced trade-off between classification and segmentation accuracy as well as computational efficiency, forming the foundation for the development of AISAM-CSNet as a lightweight, adaptive, and multitask model for agricultural automation.

III. Methodology

The research stages include data acquisition and preprocessing, CNN model architecture development (classification and segmentation), implementation, and performance evaluation.

A. Dataset and Data Acquisition

This study uses strawberry images for non-climacteric fruits and pineapple images for climacteric fruits obtained from two main sources: 1) primary: a collection of field images obtained directly using a digital camera, and 2) secondary: public datasets such as Kaggel [31-32]. The image dataset was collected in real-world environments with natural variations in lighting and diverse surface textures. Manual annotation was performed based on the local postharvest conditions of tropical horticultural products. Examples of the images used can be seen in Fig. 1 and Fig. 2 below:



(a) (b) (c) (d)

Fig. 1. Secondary dataset: (a) Pineapple with white background, (b) Strawberry with white background, (c) Pineapple with natural background, (d) Strawberry with natural background.

(a) (b) (c) (d)

Fig. 2. Secondary dataset: (a) Strawberry with white background, (b) Strawberry with natural background, (c) Pineapple with white background, (d) Pineapple with natural background.

The distribution of the dataset based on quality categories and background types can be seen in Table I:

TABLE I. TYPE STYLES

Fruit	Category	Primary		Secondary		Initial Total
		White	Natural	White	Natural	
Strawberry	Good / Ripe	20	15	50	30	70
	Medium / Unripe	30	20	60	30	90
	Damaged / Rotten	15	10	20	15	35
Pineapple	Good / Ripe	15	10	50	20	65
	Medium / Unripe	20	15	60	30	80
	Damaged / Rotten	10	5	25	15	35

Note: "Primary" and "secondary" refer to the sources of the images in the dataset. Primary data is data captured directly using a digital camera, while secondary data is public datasets such as Kaggel data. The background types are either white or natural (real-world scenes). The "initial total" column represents the total number of images per quality category before preprocessing or augmentation.

The dataset is categorized into two subsets: Classification: Images labeled according to quality classes (good, medium, poor) or ripeness level, and Segmentation: Images annotated with fruit masks for each individual fruit object.

B. Preprocessing

To guarantee consistency and improve model resilience, every image was subjected to a uniform preprocessing pipeline before the training phase. Among the steps were:

- Resizing: To comply with the input specifications of the corresponding models, images were shrunk to 224×224 pixels for classification tasks and 256×256 pixels for segmentation tasks.
- Normalization: To enable quicker convergence during training, pixel values were scaled from the initial range of [0,255] to a normalized range of [0,1].
- Data Augmentation: Random augmentations such as ±10% zoom, ±20° rotation, and horizontal flipping were used to enhance the training dataset and enhance generalization.

Examples of the augmented photos for the pineapple and strawberry samples are shown in Fig. 3.

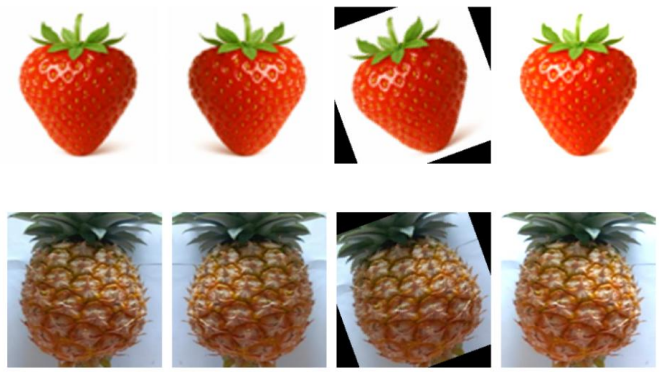


Fig. 3. Data augmentation examples for strawberry (top) and pineapple (bottom) images used to enhance model generalization.

C. Model Architectures Used

Five CNN architectures were selected as baselines for benchmarking classification and segmentation tasks.

1) VGG16: VGG-16 consists of 13 convolutional layers grouped into 5 blocks. Each block contains 2 or 3 convolutional layers. Every convolutional layer uses a 3×3 kernel, 'same'

padding, and the ReLU activation function. After each convolutional block, a 2×2 Max Pooling layer is applied to reduce the spatial dimensions (downsampling), preserve important features, and lower computational complexity. Once all convolutional and pooling blocks are completed, the extracted features are flattened and passed through 3 dense (fully connected) layers. The first two dense layers use ReLU activation, while the final dense layer uses a softmax activation for classification (see Fig. 4).

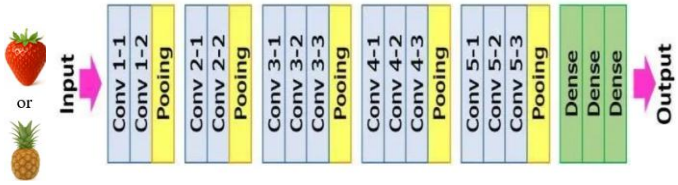

Fig. 4. Architecture of VGG 16.

2) EfficientNet: The architecture of EfficientNet, which consists of seven primary blocks intended for effective feature extraction from input photos, is depicted in Fig. 5 below. After a normal 3x3 convolution layer, a sequence of Mobile Inverted Bottleneck Convolutions (MBConv) is performed. While Blocks 3 to 6 use MBConv6 layers with 5×5 kernels to increase the receptive field without appreciably increasing the number of parameters, Blocks 1 and 2 use MBConv layers with 3×3 kernels. The extracted features are refined in the final Block 7 using an MBConv6 with a 3×3 kernel. High computational efficiency is made possible by the expansion, depthwise convolution, and projection processes included in each MBConv layer. The resulting feature map at the end of the network serves as a rich representation of the input, suitable for downstream tasks such as fruit quality classification. EfficientNet is particularly advantageous for image-based classification of fruits like strawberries and pineapples due to its balance between performance and resource efficiency.

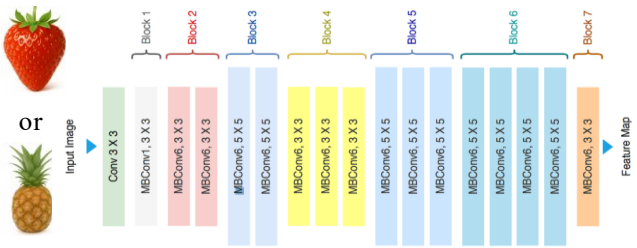

Fig. 5. Architecture of EfficientNet.

3) ResNet50: Fig. 6 given below illustrates the architecture of the ResNet50 model. The architecture begins with a zero padding process, followed by an initial convolutional layer composed of convolution, batch normalization, ReLU activation, and max pooling—collectively referred to as Stage 1. Next, the network comprises four main stages (Stage 2 to Stage 5), each consisting of a Conv Block and several Identity Blocks (ID Blocks). After passing through all the convolutional blocks, the network concludes with an average pooling layer, a flattening process, and a fully connected (FC) layer that produces the final class prediction output.

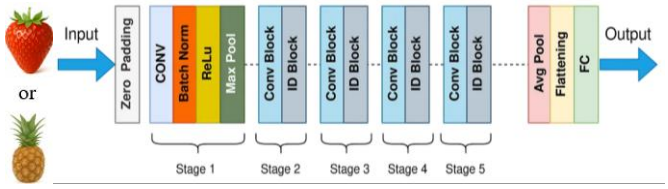

Fig. 6. Architecture ResNet50.

4) U-Net: The U-Net convolutional neural network architecture is specifically designed for image segmentation tasks, such as identifying decayed or damaged areas on pineapple and strawberry fruits. U-Net has a symmetrical structure resembling the letter "U" and consists of two main parts: the contracting path (encoder) on the left side and the expansive path (decoder) on the right. It processes input images of size 256×256×3 (RGB) through the encoder path, which includes 3×3 convolutional blocks with ReLU activation followed by 2×2 max pooling operations. This progressively increases the number of feature channels (from 32 to 512) while reducing the spatial dimensions. At the deepest part of the network (the bottleneck), complex features are represented at the smallest resolution (8×8) with a depth of 512 channels. The decoder then reconstructs the spatial dimensions using 2×2 up-convolution operations, while skip connections from the encoder help retain spatial details. The process concludes with a 1×1 convolution that outputs a segmented image of size 256×256×3, precisely identifying decayed and non-decayed areas on the fruit (see Fig. 7).

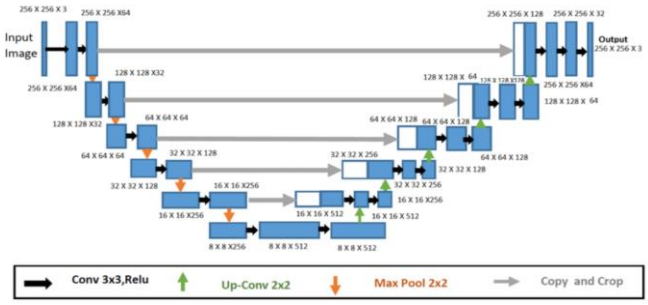

Fig. 7. Architecture of U-Net.

5) DeepLabV3+: The DeepLabV3+ model architecture was created especially for problems involving image segmentation. The encoder, which is represented by the blue line, and the decoder, which is represented by the red path, are its two primary parts. The input image is first processed using atrous (dilated) convolution in the encoder section in order to collect more spatial information without sacrificing resolution. A number of convolution and pooling operations are then performed, along with 1×1 convolutions to lower dimensionality and boost the effectiveness of feature representation. Low-level characteristics from previous network layers are combined with the encoder output in the

decoder stage after it has been upsampled by a factor of four and modified using 1×1 convolutions. The final segmentation map is created by upsampling the combined features by a factor of four after they have been improved by 3×3 convolutions (see Fig. 8).

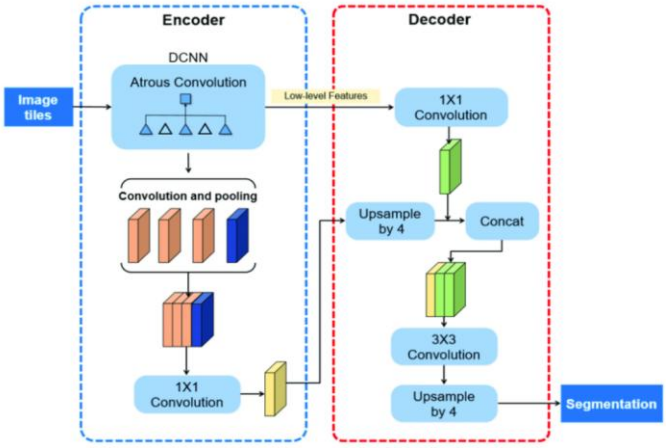

Fig. 8. Architecture of DeepLabV3+.

D. Lightweight Fusion Design for Segmentation

Additionally, a lightweight fusion approach was applied by combining the output probability maps of the two baseline models (U-Net and DeepLabV3+) using a simple adaptive weighting scheme. This approach aims to enhance segmentation consistency without significantly increasing architectural complexity or the number of parameters. The fusion was performed at the output probability level (mask probability map) by combining the probability maps from both models using a simple linear weighting scheme:

$$\text{Pfusion} = \alpha P_{U-net} + (1-\alpha)\text{P}_{\text{DeepLabV3+}}$$

where, α=0.5 serves as a balance weight between the two models. The fused result was then converted into the final binary mask using a threshold value of 0.5.

E. Training and Testing Scheme

The models were trained using 80% of the dataset for training and 20% for testing. The Adam optimizer [1] was employed with a learning rate of 0.001 and a batch size of 32 over 50 epochs. For classification, the categorical cross-entropy loss was utilized due to its effectiveness in multi-class settings [2]. For segmentation tasks, a composite loss combining Dice Loss and Binary Cross-Entropy (BCE) was applied to balance region overlap and pixel-wise prediction accuracy [3-4].

F. Performance Evaluation

The classification and segmentation of images of tropical fruits were the two main tasks for which performance evaluation was carried out. We used the confusion matrix, F1-score, recall, accuracy, and precision as evaluation metrics for the classification job. While precision and recall indicate the model's capacity to accurately identify positive occurrences and discover all pertinent instances, respectively, accuracy gauges the overall correctness of predictions. Particularly helpful when there is a class imbalance, the F1-score offers a harmonious compromise between recall and precision [33-34]. The performance of VGG16, ResNet50, and EfficientNet-B0 in classifying images of strawberries and pineapples was evaluated and compared using these criteria.

The evaluation used pixel accuracy, Dice Similarity Coefficient (DSC), and Intersection over Union (IoU) for the segmentation job. Because IoU and DSC can measure the spatial overlap between predicted regions and ground truth, they are frequently utilized in semantic segmentation tasks [35]. The percentage of correctly categorized pixels throughout the entire image is known as pixel accuracy. The segmentation performance of U-Net and DeepLabV3+ in recognizing fruit regions and detecting areas of visual deterioration or damage was assessed using these criteria [36].

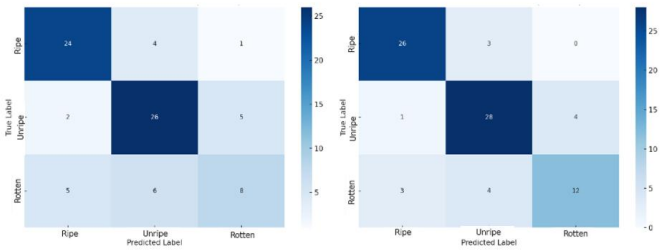
Besides classification accuracy, computational efficiency and statistical reliability are also crucial factors to ensure the feasibility of deploying the model in real-time or edge-based applications. The evaluation considers several complementary approaches, including inference time (runtime), number of parameters, and model size, to assess both predictive performance and computational efficiency of each architecture. Furthermore, a statistical significance test was conducted to verify that the performance differences among models are statistically meaningful.

To ensure model stability and reliability, a 5-fold cross-validation strategy was applied to both the pineapple and strawberry datasets. This approach allows for evaluating the model's generalization capability across different data variations while minimizing bias caused by uneven data partitioning.

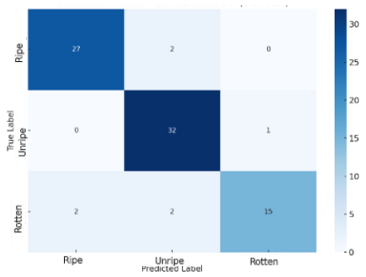
IV. Results and Discussion

A. Fruit Image Classification Results

In this horticultural fruit classification experiment (pineapples and strawberries), three CNN architectures were used: VGG16, ResNet50, and EfficientNet-B0. The dataset was divided into training, validation, and test data with a 70:15:15 ratio. To ensure model stability, 5-fold cross-validation was performed on both datasets. The experimental results, which illustrate the classification distribution and prediction error patterns, are shown in the Fig. 9 and Fig. 10 below. The confusion matrix was generated from the fold with the highest accuracy during the 5-fold cross-validation process.

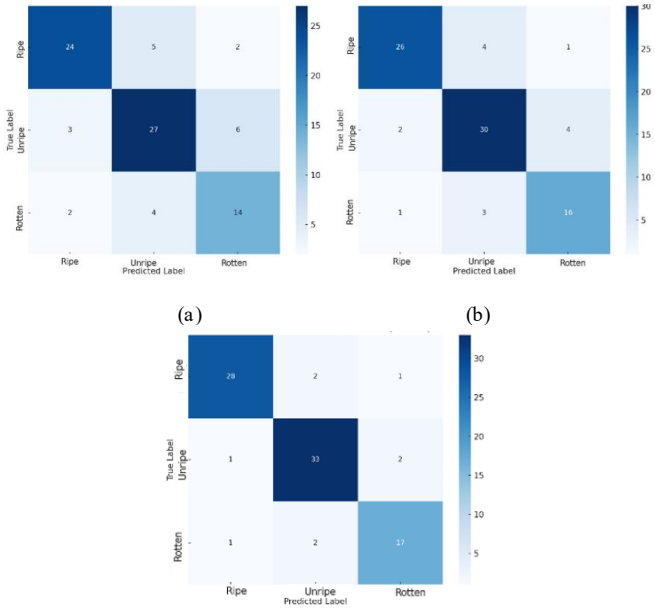


(a) (b)



(c)

Fig. 9. Confusion matrix: (a) VGG 16, (b) Resnet 50, (c) EfficientNet on pineapple dataset.



(a) (b)

(c)

Fig. 10. Confusion matrix: (a) VGG 16, (b) Resnet 50, (c) EfficientNet on strawberry dataset.

Each model was thoroughly evaluated on five different combinations of training and testing data, so that the results obtained were independent of a single data split. This evaluation included four main metrics: accuracy, precision, recall, and F1-score. The results of the average classification performance comparison of each architecture on the pineapple and strawberry datasets are shown in Table II and Table III. Furthermore, to illustrate the stability of inter-fold performance, the average value and standard deviation (mean ± SD) of each metric are also shown.

TABLE II. AVERAGE 5-FOLD CROSS-VALIDATION RESULTS ON PINEAPPLE DATASET

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
VGG16	82.30 ± 1.1	80.40 ± 1.3	89.10 ± 1.5	80.50 ± 1.4
ResNet50	84.20 ± 0.9	85.00 ± 1.1	83.20 ± 1.0	84.10 ± 1.1
EfficientNet-B0	90.70 ± 0.7	91.10 ± 0.8	90.60 ± 0.6	91.20 ± 0.7

TABLE III. AVERAGE 5-FOLD CROSS-VALIDATION RESULTS ON STRAWBERRY DATASET

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
VGG16	83.10 ± 1.0	82.50 ± 1.2	80.90± 1.1	82.00 ± 1.2
ResNet50	85.80 ± 0.8	85.90 ± 1.0	85.40 ± 0.9	85.70 ± 1.0
EfficientNet-B0	91.40 ± 0.6	91.80 ± 0.7	90.20 ± 0.6	90.60 ± 1.6

Table II and Table III summarize the model performance results by averaging across 5k folds. Based on these tables, it can be observed that EfficientNet-B0 consistently achieves the best performance in terms of accuracy, precision, recall, and F1 score on both datasets, followed by ResNet50 and VGG16. VGG16 has the lowest accuracy with a slightly higher standard deviation, indicating the model's sensitivity to variations in lighting and color on the fruit surface. Overall, the results on both datasets confirm that a more modern and lightweight architecture, such as EfficientNet-B0, is able to provide the best combination of high accuracy and inter-fold performance stability. The low standard deviation value of this model also indicates high reliability and good potential for application in fruit image classification systems in real environments.

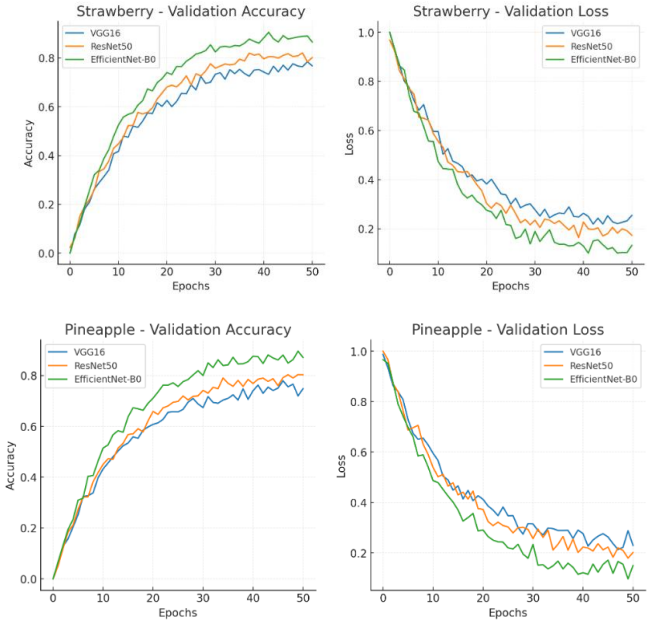


Fig. 11. Validation accuracy and validation loss: strawberry and pineapple.

To illustrate the performance of the models during the training process, the validation accuracy and loss curves on the strawberry and pineapple datasets are visualized. Fig. 11 presents the learning trends of each model (VGG16, ResNet50, and EfficientNet-B0) across 50 epochs.

The experimental results on the strawberry dataset show a stable trend of increasing validation accuracy as the number of epochs increases, reaching convergence around epoch 40. The EfficientNet-B0 model consistently achieved the highest accuracy, followed by ResNet50 and VGG16. This performance demonstrates that modern architectures such as EfficientNet are able to extract strawberry visual features more

effectively, particularly in distinguishing variations in color and texture that are crucial indicators for determining the condition of fresh and spoiled fruit. Meanwhile, on the pineapple dataset, all three models also exhibited consistent patterns of increasing validation accuracy and decreasing loss throughout the training process. EfficientNet-B0 once again achieved the best performance. These findings indicate that the more complex visual characteristics of pineapples, such as scaly skin patterns and lighting variations, are more effectively handled by the EfficientNet architecture. This is attributed to the optimization strategy employed by EfficientNet, which balances network depth, width, and resolution, thereby enabling richer and more accurate feature representations compared to ResNet50 and VGG16.

B. Segmentation Results

Segmentation experiments were conducted using U-Net and DeepLabV3+ on strawberry and pineapple images. The evaluation was carried out using three main metrics: Intersection over Union (IoU), Dice Coefficient, and mean Intersection over Union (mIoU). Table IV summarizes the performance of both models:

TABLE IV. EVALUATION METRICS AND AVERAGE SEGMENTATION PERFORMANCE (MEAN ± SD) ON STRAWBERRY AND PINEAPPLE DATASETS

Fruit	Model	IoU (%)	Dice (%)	mIoU (%)
Strawberry	U-Net	88.5 ± 0.9	89.5 ± 0.8	87.6 ± 1.0
Strawberry	DeepLabV3+	91.8 ± 0.7	91.5 ± 0.6	90.7 ± 0.8
Pineapple	U-Net	87.8 ± 1.0	88.7 ± 0.9	86.9 ± 1.1
Pineapple	DeepLabV3+	90.6 ± 0.8	91.7 ± 0.7	89.5 ± 0.9

The average segmentation performance results in Table IV show that the DeepLabV3+ model consistently produces higher IoU, Dice, and mIoU values than the U-Net for both datasets: strawberry and pineapple. The performance difference between the two models appears stable, as evidenced by the relatively small standard deviation values (ranging from ± 0.6 to ± 1.1), indicating good interfold consistency of the segmentation results in the 5-fold cross-validation scheme. DeepLabV3+'s superiority lies primarily in its use of Atrous Convolution and Atrous Spatial Pyramid Pooling (ASPP), which are highly effective in capturing variations in texture and object size on the fruit surface.

C. Computational Efficiency Aspect

In addition to accuracy and segmentation performance, computational efficiency is also an important consideration to ensure the feasibility of model deployment on systems with limited hardware resources. The efficiency evaluation is conducted by examining several key metrics, namely inference time (runtime), number of parameters, and model size. The results of the computational efficiency evaluation for all classification and segmentation models are presented in Table V.

TABLE V. COMPUTATIONAL EFFICIENCY EVALUATION OF CLASSIFICATION AND SEGMENTATION MODELS

Model	Task	Inference Time (s)	Number of Parameters (M)	Model Size (MB)
VGG16	Classification	0.042	138.3	528.0
ResNet50	Classification	0.038	25.6	98.0
EfficientNet-B0	Classification	0.026	5.3	20.4
U-Net	Segmentation	0.087	31.0	122.0
DeepLabV3+	Segmentation	0.093	43.5	175.0

D. Segmentation Results with Lightweight Fusion

This study applied a lightweight fusion approach to enhance segmentation consistency without increasing architectural complexity. The approach combines the output probability maps (mask probability maps) of two baseline models—U-Net and DeepLabV3+—through a simple linear weighting scheme. Table VI presents the segmentation performance after applying lightweight fusion between U-Net and DeepLabV3+:

TABLE VI. COMPARATIVE SEGMENTATION PERFORMANCE OF U-NET, DEEPLABV3+, AND FUSION MODEL ON STRAWBERRY AND PINEAPPLE IMAGES

Fruit	Model	IoU (%)	Dice (%)	mIoU (%)
Strawberry	U-Net	89.3	90.8	88.6
Strawberry	DeepLabV3+	92.1	93.5	91.7
Strawberry	Fusion (U+D)	**92.6**	**93.9**	**92.2**
Pineapple	U-Net	88.7	90.1	87.9
Pineapple	DeepLabV3+	91.4	92.7	90.8
Pineapple	Fusion (U+D)	**91.9**	**93.1**	**91.3**

The results demonstrate a consistent improvement across all key metrics after fusion. The average IoU increased by approximately 0.5–0.7%, while the Dice coefficient improved by about 0.4%. This enhancement is attributed to the complementary strengths of the two models: DeepLabV3+ excels in handling complex regions, whereas U-Net provides smoother boundary delineation. The combination produces more stable and accurate segmentation outcomes. This approach aligns with recent research trends emphasizing the effectiveness of lightweight hybrid models in improving segmentation robustness for agricultural imagery under natural illumination conditions [37].

E. Comparative Analysis

To ensure that the performance differences among models were not merely due to random variations in the data, a statistical significance analysis was conducted based on the 5-fold cross-validation results for both classification and segmentation tasks. This test aimed to verify the statistical validity of each model's performance, ensuring that higher-performing architectures exhibit improvements that are mathematically significant rather than coincidental.

The analysis was applied to both classification models (VGG16, ResNet50, and EfficientNet-B0) and segmentation

models (U-Net and DeepLabV3+) using significance levels of $\alpha = 0.05$ and 0.01. The complete results of the significance tests for both datasets are presented in Table VII and Table VIII below.

TABLE VII. STATISTICAL SIGNIFICANCE TEST RESULTS (5-FOLD CROSS-VALIDATION): CLASSIFICATION ON PINEAPPLE AND STRAWBERRY DATASETS

Model Comparison	Pineapple Dataset (p-value)	Strawberry Dataset (p-value)	Remark
VGG16 vs ResNet50	0.041 *	0.038 *	Significant
VGG16 vs EfficientNet-B0	0.007 **	0.005 **	Highly significant
ResNet50 vs EfficientNet-B0	0.018 *	0.015 *	Significant

TABLE VIII. STATISTICAL SIGNIFICANCE TEST RESULTS (5-FOLD CROSS-VALIDATION): SEGMENTATION ON PINEAPPLE AND STRAWBERRY DATASETS

Model Comparison	Pineapple Dataset (p-value)	Strawberry Dataset (p-value)	Remark
U-Net vs DeepLabV3+	0.009 **	0.006 **	Highly significant

The results of the statistical significance test confirm that the observed differences in performance between models are not due to random variations in the data, but rather have real statistical significance. The overall experimental results confirm that EfficientNet-B0 consistently outperformed ResNet50 and VGG16 in classification tasks, demonstrating an excellent balance between parameter efficiency and generalization capability. This finding aligns with the report, where EfficientNet achieved up to 97% accuracy in grape and potato leaf disease classification [38]. A follow-up study also emphasized the superior efficiency of EfficientNet compared to other architectures [39].

For segmentation tasks, DeepLabV3+ proved more precise than U-Net, particularly in handling the complex textures of strawberries and pineapples—the multiscale effect of atrous convolution and the ASPP module played a pivotal role. Evidence from the SugarBeets study also showed that DeepLabV3+ achieved a higher mIoU compared to U-Net [40].

Nevertheless, some error patterns persisted. False positives frequently occurred in decayed regions obscured by shadows, while false negatives often appeared when small decayed spots were hidden, similar to the findings on apples [41]. Segmentation also exhibited mask leakage along object boundaries, as reported in tomato images [42].

As a direction for further development, integrating adaptive multitask architectures such as AISAM-CSNet (Artificial Immune System-controlled Adaptive Multi-agent Classification and Segmentation Network) appears promising for improving robustness. AISAM-CSNet combines multi-agent CNNs, reinforcement learning, and optimization inspired by the Artificial Immune System, consistent with current trends in multitask learning and biologically inspired optimization within agricultural computer vision [43].

V. CONCLUSION

The experimental results demonstrated that deep learning methods are highly effective for assessing the visual quality of tropical fruits. Among the evaluated models, EfficientNet-B0 consistently achieved superior performance in the classification tasks, with an average accuracy of 90.7% for pineapples and 91.4% for strawberries, outperforming both ResNet50 and VGG16. This result confirms that lightweight and modern architectures are more capable of capturing discriminative visual patterns related to fruit ripeness and surface damage compared to conventional CNNs. Meanwhile, for the segmentation task, DeepLabV3+ outperformed U-Net, with an IoU of 90.6% for pineapple and 91.8% for strawberry, while the Dice coefficient was 91.5% for strawberry and 91.7% for pineapple. These results confirm that both architectures can serve as a reliable basis for automatically detecting ripeness and damaged areas in fruit.

Beyond numerical achievements, the findings highlight the practical contribution of deep learning in accelerating postharvest quality inspection while providing an empirical foundation for developing more adaptive multitask architectures. This has significant implications for the horticulture industry by reducing reliance on labor-intensive manual inspection.

For future research, the integration of classification and segmentation into a single multitask framework, such as AISAM-CSNet (Artificial Immune System-Controlled Adaptive Multi-agent Classification and Segmentation Network), holds strong potential to further enhance accuracy and adaptability under diverse real-world conditions. AISAM-CSNet combines classification and segmentation in a multi-agent reinforcement learning framework, with hyperparameter optimization inspired by the Artificial Immune System. Such an approach is expected to improve adaptability and accuracy in tropical fruit quality assessment systems, thereby supporting supply chain efficiency and ensuring consistent fruit quality.

***Abstract*—This paper examines the application of blockchain technology in e-book publishing by analyzing previous research and identifying current limitations. The study investigates how smart contracts and cryptographic algorithms can facilitate agreements between publishers and authors. While blockchain has been widely adopted in digital publishing domains, such as image, video, music, and scientific journals, research on its application to e-books remains limited. Existing solutions typically address individual challenges such as transaction transparency, authenticity, or copyright protection, but rarely integrate them into a single framework. To provide a systematic synthesis of prior works, this paper develops a taxonomy of blockchain-based e-book publishing models across six dimensions: platform, storage, smart contract usage, cryptographic algorithm, tokenization, and actors. This paper reviews seven (7) blockchain-based models in e-book publishing and identifies their limitations. Based on these insights, a conceptual blockchain-based smart contract model for e-book publishing was proposed using Ethereum platform, incorporating InterPlanetary File System (IPFS) storage and cryptographic algorithms. The proposed model has the potential to significantly enhance the security and rights protection for authors and publishers, thereby fostering a more secure and equitable e-book publishing landscape.**

Keywords*—*e-book publishing; Ethereum; blockchain technology; smart contract

I. Introduction

The book publishing industry has been a central component in the creation and dissemination of knowledge through books, magazines, journals, articles, dictionaries, and other reading materials. As technology evolves, many people read and distribute digital content online. However, digital publishing is vulnerable to illegal downloads, copying, content sharing, and piracy. Some issues regarding copyright law in the digital environment are a lack of transparency about the legal status of copyrighted works, piracy, and difficulties in getting compensated fairly [1]. This scenario also occurs in the publishing industry, where publishers need to ensure the e-book is secure while protecting the author's and publisher's rights.

An electronic book, also known as an e-book, is a digital version of traditional reading materials. The term "e-book" has been changing depending on the way it is presented and the evolution of technology [2]. Recent research in e-book publishing shows that non-transparent transactions, unfair royalty distribution, unprotected copyright, and unauthenticity of published materials are the main problems for digital content creators in this era. E-book publishing has created a trustless environment, as nobody is responsible for the security, validity, and ownership of the purchased e-book [3]. The authors do not have complete control over their e-books after publication. Non-transparent transactions may deny the actual sales reports to the authors [4]. The e-book's sales history is difficult to track and not tamper-proof, leaving it vulnerable to illegitimate alteration and unauthorized distribution. Unprotected copyright protection may lead to unfair royalty payments because the authors were unable to track each sales transaction [5]. In addition, published e-books lack authenticity because their content can be replicated, reproduced, and redistributed unethically. Unauthenticated e-books may affect total sales and the royalty paid to the authors [6].

Blockchain has significantly contributed to digital publishing, including image, video, music, scientific journals, and e-book publishing. The concept of blockchain was initially proposed by Satoshi Nakamoto in 2008. Nakamoto introduced Bitcoin, a cryptocurrency that allows a peer-to-peer electronic cash system [7]. Blockchain is a data structure that operates in a decentralized, peer-to-peer network consisting of a chain of blocks. Each block contains transactions and also a hash value from the previous block, which makes it immutable and tamper-proof [8]. Distributed ledger technology (DLT) is the main characteristic that enables all transactions to be stored in a blockchain [9]. DLT allows data exchange between the network participants without intermediaries [10]. Blockchain works on a consensus algorithm, a mechanism used among the participants (nodes) to agree on the transactions [11]. Blockchain creates an audit trail of transactions between participants. Therefore, payment can be made directly without the intervention of a third party, such as a financial institution, because blockchain can act as a mediator for data transformation or calculation [12]. When blockchain is combined with smart contracts and cryptography, it can help solve problems of trust, authenticity, and copyright protection in e-book publishing [6].

This paper examines prior work to gain a deeper understanding of the design, methods, algorithms, limitations, and weaknesses. A blockchain-based conceptual model for e-book publishing using the Ethereum platform was proposed to address all those challenges. The model incorporates the InterPlanetary File System (IPFS) and a smart contract to provide three key benefits: transparent transactions, e-book authenticity, and copyright protection to the authors through fair royalty distribution.

Unlike the previous study, which focuses on a single or two aspects such as transparency of transactions, authenticity, or copyright protection, this study integrates all three elements into a single conceptual model. The combination of IPFS,

cryptographic mechanisms, Ethereum smart contract, and multi-actor involvement reflects the structure of the real e-book publishing ecosystem. This holistic approach constitutes the core novelty of this work and directly addresses the identified research gap, thus adding value to the current body of knowledge.

The rest of this paper is structured as follows: Section II presents the research contribution; Section III presents the background information; Section IV reviews related works; Section V introduces the taxonomy of blockchain-based e-book publishing, and Section VI explains the proposed conceptual model; Section VII presents the discussion, and finally, Section VIII concludes with future work.

II. Research Contribution

This study contributes to the domain of blockchain-based e-book publishing by addressing the specific challenges of e-book distribution. While prior work has proposed solutions focusing on isolated aspects, such as transparency, authenticity, or copyright protection, these solutions rarely integrate these elements into a unified framework. The contributions of this paper are:

- Conceptual model for e-book publishing: The proposed model integrates Ethereum smart contracts with InterPlanetary File System (IPFS) storage and cryptographic algorithms to ensure transparent transactions, authenticity verification, and copyright protection.
- Multi-actor involvement: unlike previous work that primarily emphasizes author-customer interactivity or self-publishing, this model incorporates the publisher and the author as key participants alongside the customer. This reflects the practical realities in the e-book publishing industry.
- Comparative analysis and gap identification: Through a comparative review of seven (7) related blockchain-based models, this study identifies key limitations in existing approaches. The proposed model explicitly addresses these gaps by combining transaction transparency, e-book authenticity, and automated royalty payment within a single conceptual framework.
- Development of a taxonomy: This paper develops a taxonomy that classifies blockchain-based e-book publishing models across six dimensions: platform, storage, smart contract usage, cryptographic algorithms, tokenization, and actors. The taxonomy provides a structured framework for comparing prior works and identifying research gaps, thereby establishing a theoretical reference for future studies.

III. Background

A. Electronic Book (E-Book) Publishing

The first e-book development started in the 1970s by Project Gutenberg and the Oxford Text Archive. Project Gutenberg was initiated by Michael Hart in 1971 at the University of Illinois, and the first e-book published was "Declaration of Independence," followed by "Bill of Rights" in 1971 [13]. These publications led to Hart's other big idea: to create the world's first e-book library. In 1976, the Oxford Text Archive focused on providing electronic academic resources to scholars. From the 1980s to the 1990s, the development of e-books expanded to several formats and media. The publishers gain more confidence in publishing e-books for academic areas and linking with libraries as a niche market. In 1989, e-books were published on Compact Disc Read-Only Memory (CD-ROM) and could be accessed using computers [14]. Since then, several discussions about digital copyright have started.

E-book publishing experienced massive growth alongside technological development. E-books can be accessed on multiple devices, such as PDAs, Pocket PCs, e-book readers, and mobile phones [15]. A new horizon of e-books started when Amazon introduced the Kindle in 2007. Kindle changes the reader's reading behavior because it provides readability flexibility [16]. Other e-book readers, such as Barnes & Noble Nook and Kobo, also entered the market due to their convenience and cost-effectiveness.

The potential and benefits of adopting blockchain technology into publishing, specifically intellectual property and monetary rights, have been addressed. The most important highlight is self-publishing 3.0, which means a direct transaction between the authors and readers without intervention from any third party [17]. Instead of self-publishing, some authors may need to publish their books through a publisher. In the e-book publishing process, the process can be classified into three (3) elements: content providers, service platforms, and reading devices [16]. The end-user is the customer who accesses the e-book by downloading it onto their reading devices. Generally, e-book publishing is the same as physical books, but with additional parties involved in digitization. The entire process of e-book publishing is illustrated in Fig. 1.

Fig. 1. E-book publishing process.

The parties involved in e-book publishing are as follows: 1) author: the person who writes a manuscript to be published by the publisher and owns the copyright of their respective work; 2) publisher: the organization or company that processes the author's manuscript to be published in digital format, manage copyright, receive sales payment and pay royalty to the author and 3) customer(s)/subscriber(s): the potential buyer of the e-book.

The publishing process begins when the author(s) write and send a manuscript to the publisher. The manuscript will be evaluated before approval for publication. The publisher will decide on the e-book format with the consent of the author(s). Then, the process of developing an e-book begins with editing and proofreading. Some of the e-books might need illustration and design. The programming part will be done to integrate the

multimedia elements and the system used. The final e-book product format varies, typically PDF or EPUB. The e-book will be published on various websites and mobile platforms, including the App Store, Google Play, and the Huawei App. The customer(s) or subscriber(s) will purchase the e-book from the selling platform and access it on their devices.

Previous related works [4], [5] have suggested that blockchain is a better solution for e-book publishing due to its characteristics, which can provide transparency, integrity, and immutability. The following section will discuss the explanations of blockchain, decentralized repository systems, and smart contract.

B. Blockchain

In recent years, blockchain technology has expanded far beyond cryptocurrencies. Blockchain has been applied in various industries, including healthcare, automotive, insurance, agriculture, advertising, and education [18]. Blockchain's decentralized peer-to-peer networks and distributed ledger technology features benefit businesses by providing transparency, immutability, security, and tamper-resistance. Blockchain will mitigate all risks of a "principal-agent" problem, which then shapes the blockchain character as "trustless" or "trust-free" [19].

Blockchain is a chain of blocks linked together using cryptographic algorithms that permanently record transactions in a large, distributed ledger. Each block stores the hash of the previous block, and a new block is created when the sender submits a transaction. This security feature in blockchain makes it extremely difficult to manipulate the data. The latest block will undergo mining before being added to the chain. Mining is a data validation process that involves solving a specific algorithm. Miners will validate and verify the transactions using various consensus protocol mechanisms, such as Proof of Work (PoW) or Proof of Stake (PoS). This protocol ensures that peers have the same data in the blockchain [8]. Every transaction in the blockchain is timestamped, and once added, it cannot be changed.

Depending on its objectives, each organization may choose the type of blockchain that best meets its requirements. Each type of blockchain has different characteristics and functionalities. There are three (3) main types of blockchain: public (permissionless) blockchain, private (permissioned) blockchain, and consortium/federated blockchain [20].

- A public blockchain is open-access, decentralized, and allows any node to enter the network. The nodes read, write, and validate the data through a consensus mechanism. No individual or organization owns the public blockchain, which is self-governing. Examples of public blockchains are Bitcoin, Ethereum, and Litecoin.
- A private blockchain is a centralized blockchain managed by an organization or authority. It is usually applied to small businesses and has limited use within private entities. Only authorized users can view the data and transactions within the network. Corda and Ripple are examples of private blockchains.
- Consortium or Federated blockchain is a combination of public and private blockchain in which a part of the blockchain is partially centralized. Only selected nodes can choose the services they intend to participate in, and the remaining nodes can only access transactions, not the consensus process. Hyperledger Fabric is an example of a Consortium blockchain.

Shukla [21] provided an overview of blockchain research and outlined a future agenda, highlighting how blockchain applications are expanding beyond cryptocurrency into domains such as copyright protection and publishing. This perspective reinforces the timeliness of applying blockchain in e-book publishing.

The following section will discuss the Ethereum blockchain and its components: the repository system, smart contracts, and cryptographic algorithms.

1) Ethereum blockchain: The Ethereum Blockchain is an open-source, public (permissionless) blockchain platform with smart contract functionality that can verify a predetermined set of rules. Any node can join the Ethereum network if the user has an Ethereum client account [12]. Fig. 2 illustrates the deployment of the e-book publishing model in the Ethereum blockchain by executing a smart contract on the Ethereum Virtual Machine. This decentralized machine can execute smart contract code in Ethereum nodes. A dApp is a decentralized application that acts as a web interface to connect users with a smart contract.

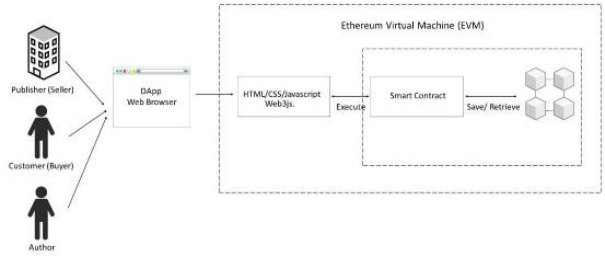

Fig. 2. Decentralized blockchain-based e-book publishing architecture (Nurgaida Yutia et al., 2022) adapted with permission.

In e-book publishing, a public (permissionless) blockchain is better suited for adaptation because the system requires involvement from both internal and external parties, such as publishers, authors, and customers. Furthermore, the system aims to facilitate a safe, secure trading environment for all stakeholders. Public blockchains provide high transparency, enabling authors and publishers to access sales and royalty records. Ethereum is an example of a public blockchain that offers functionality beyond cryptocurrency and has been widely used to develop decentralized applications (dApps) to support business management processes.

2) Smart contract: A smart contract is one of the main components of the Ethereum blockchain. A smart contract refers to a programmable agreement embedded in the blockchain that automatically enforces predefined rules between stakeholders. It works as a contract between two (2) or more parties that has been electronically transformed. A smart

contract allows code to specify how the process should be managed, and it provides a distributed, unchangeable record of all events that have occurred [18]. The key elements of smart contracts are the elimination of trusted third parties, forger assistance, transparency, autonomous execution, accuracy, and paperless motivation [14].

In e-book publishing, a smart contract is an agreement between the author(s) and the publisher. A smart contract can automate royalty payments without intermediaries. Publishing rights, such as the author's copyright and the publisher's ownership, can be securely recorded on the blockchain, making them verifiable and legitimate. Smart contract programmed using Solidity Programming Language on a web-based Integrated Development Environment (IDE), Remix. Smart contracts do not involve any third party to create an agreement between the author(s) and the publisher.

3) Repository system: Blockchain architecture is designed around a consensus mechanism, and decentralization requires full participation by nodes. The expansion in transaction volume will increase data storage in parallel with the involvement of nodes to maintain its stability [22]. Therefore, there is a need for an alternative way to store large amounts of data in decentralized storage systems such as InterPlanetary File System (IPFS), PFS, Storj, SWARM, Filecoin, and Sia.

IPFS is a globally distributed system widely used in the Ethereum Blockchain environment. While blockchain can provide high security, storing data on it would be very expensive. Currently, the Ethereum chain size is around 500GB – 1TB, and every node should be able to store the data. If the block expands, it would not be feasible for the blockchain to perform the transactions [23]. IPFS can store large files, and the data links or hashes are stored on the blockchain. A cryptographic algorithm in IPFS made it immutable. IPFS uses a content-addressing technique to store files. The distributed storage system architecture in IPFS guarantees the accessibility of the data on the network because all the peers have exact copies of the data [24]. If the data has been modified, IPFS will compute a new hash and update it across peers.

For example, Pubchain, a solution for academic resource publications in the Ethereum blockchain, uses IPFS for publication storage, was proposed by [25]. Authors will upload their articles to the system, and the articles will be time-stamped. The articles will be registered in the blockchain as permanent records and stored in IPFS, with metadata created accordingly. The smart contract will write the metadata into the blockchain.

4) Cryptographic algorithm: Cryptographic algorithms are the backbone of blockchain. Blockchain and smart contracts use various cryptographic algorithms to ensure the authenticity, integrity, and privacy of data. These algorithms are vital in securing transactions, ensuring immutability, and enabling blockchain functionality. Some algorithms that are commonly used are:

a) Hash functions: Cryptographic hash functions formed from the Merkle-Damgard method need one input: the message to be hashed [26]. A hash function is a one-way function that is not reversible. One input produces a single, fixed-length output, called a hash value. A hash function can ensure the integrity and authenticity of a message. Message Digest (MD) and Secure Hash Algorithms (SHA) are examples of hash functions.

b) Public-key cryptography: Encryption and decryption of a message using a pair of keys assigned to the corresponding receiver. The readable message will be encrypted with the receiver's public key and decrypted with the receiver's private key. Only the receiver can encrypt the message, thus providing confidentiality and authenticity. Public-key cryptography is the technology behind digital wallets in the blockchain [27]. Examples of public-key cryptography are Rivest-Shamir-Adleman (RSA) and Elliptic Curve Cryptography (ECC).

c) Digital signatures: Mathematical techniques for verification and authentication of a digital message by assigning a pair of keys, private-public keys, with the involvement of a signer and verifier [28]. A digital document will be signed using the sender's private key, and the verifier will verify the originator by decrypting it with the sender's public key. Digital signatures are often used with hash functions to verify the authenticity and integrity of a message.

C. Blockchain in Digital Publishing

Studies from 2020 to 2023 show that the work of blockchain models for digital publishing has mainly been developed for other assets, such as image publishing [29], music streaming [30], scientific publications [31], video publishing [32] and the student's academic record [33]. Nevertheless, the implementation of blockchain in e-book publishing has not been extensively explored. The existing work is unsuitable for e-books because its process flow and architectural design differ from those of e-books.

Therefore, this study will focus on implementing blockchain technology in e-book publishing to provide transparency, authenticity, and copyright protection. Blockchain can enable secure transactions and potentially create a new business model. Trusted distributed ledger technology is the primary reason blockchain should be used in the publishing industry. Every e-book published has its respective copyright owner. The publisher must retain the transaction records and reasonably manage the author's royalties.

In the blockchain e-book publishing scenario, there are five (5) practical use cases.

- Track of history records: Blockchain can record every transaction. The records are transparent and can be viewed by everyone; therefore, the origins of the transactions are traceable.
- Royalty payment systems: The Ethereum blockchain can give authors a fair royalty distribution by constructing a smart contract with pre-determined rules. The author must verify the smart contract before the e-book is up for sale. Royalty will be delivered automatically without the intervention of a third party, such as a financial institution or publisher. The author will receive the royalty after every successful customer purchase.

- Piracy prevention: e-Book publishing is easily exposed to various kinds of piracy, such as copying, illegal downloading, reprinting, and redistribution. Blockchain, using cryptographic algorithms, can mitigate the risks of any fraud.
- Copyright protection: A smart contract in blockchain enables fixed copyright registration and allows creative rights.
- Cost-effective for large data storage: e-Book size varies depending on the content. Some publishers use a large, centralized storage system, which is both costly and complex. Others might use the cloud, but costs will increase as data grows. However, blockchain and peer-to-peer storage systems, such as IPFS, can provide decentralized, secure storage at minimal cost.

IV. Related Works

This section describes seven (7) related works on e-book publishing using the blockchain model found in the literature. These works serve different objectives, involve various entities, utilize different platforms, employ distinct processes, and employ diverse methods.

IPFS-Blockchain-Based Authenticity of Online Publications proposed by [6] aim to provide authenticity and integrity of published digital content in different versions of original e-books (languages). The proposed model is demonstrated in a system that uses the Ethereum blockchain and smart contracts to ensure the authenticity and integrity of the e-book. The system utilized IPFS to store the data, as it is more cost-effective than blockchain storage. E-book hash data will be generated in IPFS and stored in the blockchain. The hash will be retrieved when the transaction matches it with the database. If the hash has been altered, the original content has been modified. By using this method, only authentic, original e-books will be sold to customers.

Another blockchain model proposed by study [5] protects the author's copyright and transparency in transactions by providing a transparent sales ledger that could be accessed by the publisher, author, and customers. The model shown in Fig. 3 was built on the Ethereum blockchain, using a smart contract to track e-book sales. Every transaction will be verified by consensus and digitally signed using Elliptic Curve Cryptography (ECC) before being stored in the blockchain. Both the author and the publisher must deposit twice the actual book price for double verification. After the authorization process, half of the deposit will be refunded to the authors, and the publisher will get a full refund and the sales percentage. The royalty payment will be made immediately to the author upon completion of the transaction, thereby eliminating the need for third-party involvement and ensuring high reliability, integrity, and security.

An intellectual property trading system, named JS Digital Asset Trading System, was developed for e-book trading [34]. Only authorized persons can access the e-book in this system; only authentic books can be sold to customers. The system used Asymmetric Key Encryption (AKE), in which the author uses his public key to encrypt the e-book before uploading it into the system. Then, when the customer purchases the e-book, the author will decrypt it with his private key. The e-book will be encrypted again using the customer's public key and sent to the customer. The customer needs to decrypt the e-book using their private key. This approach ensures the security and authenticity of the trading process. However, the study did not discuss any solutions for royalty distribution among publishers and authors.

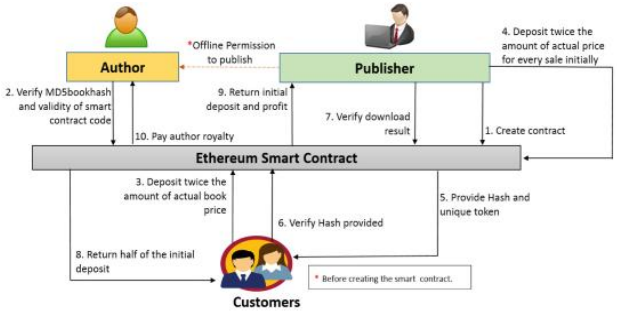

Fig. 3. Blockchain-based protection for author royalty of digital asset system architecture.

Another blockchain-based trading system scheme has been proposed by [35]. The JSP Digital Asset Trading System was developed to provide transparency, as the digital asset owner can view the transactions and receive payment immediately after the transaction (refer to Fig. 4). The "Random-Checker Proof of Stake" consensus mechanism was used to reduce transaction time, while AKE is used for verification. The proposed system uses a smart contract to allocate the share percentage between the authors. However, the proposed system does not involve the publisher.

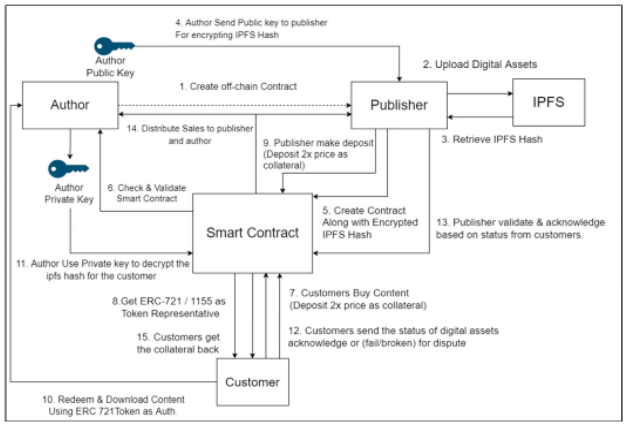

Fig. 4. Blockchain-based protection of author royalty of digital asset system overview.

A blockchain-based eBook market system proposed by [3] could facilitate self-publishing by enabling transparent transactions. The authors will receive direct payments from the system without intermediaries. In this system, a book can be sold by the chapter or as a whole. The proposed system uses a smart contract to ensure reliability, copyright protection, and the security of e-book transactions.

A Non-Fungible Token (NFT) is a unique identifier for digital assets that allows users to purchase ownership rights to those assets. NFTs are typically applied to collectible items, such as games, music, and art. A blockchain-based NFT model

was proposed by [36] for e-book publishing, it allows the author to sell individual chapters and the entire e-book. This model utilizes IPFS as an external storage system to reduce costs and energy consumption. An NFT e-book is linked with a smart contract to ensure security and preserve the owner's copyright. However, NFT item procurement uses a bidding system, meaning the potential buyer must bid on the e-book's price within a limited timeframe. The successful buyer will have ownership of the e-book if the author accepts the offer. Furthermore, NFT items are typically sold in limited quantities to preserve their uniqueness. Therefore, the publisher must create a unique e-book, for example, by offering an e-book with additional audio of the authors reading several chapters.

The last related work is by study [4] which enhances the earlier work of [5]. They proposed adding security features to the data links of smart contract digital assets using Elliptic Curve Cryptography (ECC). In earlier work, the data link for digital assets in smart contracts is in plain text, making it vulnerable to attack. Therefore, ECC is used to encrypt data links, thereby strengthening data integrity and authenticity. Smart contracts are also used for sales, payments, and royalty distribution between author and publisher. In addition, IPFS is used for data storage, and ERC-721 is used as a standard for token-based authorization. ERC-721 is a standard for non-fungible tokens on Ethereum, meaning each asset is unique.

A. Discussion of Related Works

Table I summarizes the comparison of the existing related work in blockchain-based e-book publishing. In conclusion, although they are in the same domain, each related work has its own primary objectives and is developed based on its specific needs and requirements. However, every work has its limitations and boundaries. Both [4], [5] proposed the same three (3) objectives: to provide transparency, to preserve copyright, and to ensure e-book authenticity. Although [6] and [34] proposed solutions for authenticity, their solution differs in their system architectures. The work by [6] involved authors, the main publisher, secondary publishers, and customers, whereas the work by [34] involved only authors and customers. Other work with the involvement of two (2) parties is by [35] and [3]. Both works suggested a service application for the author to self-publish their e-books. No publisher is involved in this process; thus, the purchasing transaction will be made only between the authors and customers. Another solution by [36] suggested non-fungible tokens (NFTs), a token representing a unique digital asset that could allow an individual to have ownership of the author's work. This model also involves the author and the customers. The variation in actor involvement highlights a critical distinction across existing models. Some approaches reflect a broader publishing ecosystem, while the solution involves direct interaction between customers and authors. Models that exclude publishers may be practical for independent distribution. Still, they do not capture the realities of e-book publishing, where publishers play a key role in validation, e-book management, and royalty distribution. The differences observed in actor participation further justify the need for structured classification. Therefore, to synthesize these variations and to better position the proposed conceptual model, this study introduces a taxonomy of blockchain-based e-book publishing models. The detail of the taxonomy is presented in Section V.

While the analysis in Table I highlights the comparison of the objectives, actor involvement, and limitations across existing works, revealing different publishing workflows and priorities, Table II complement by focusing on the technical implementation of these models, specifically the choice of blockchain platform, storage mechanisms, and cryptographic algorithms. Together, these tables offer a complete picture of both functional and technical perspectives of existing solutions.

Referring to Table II, four (4) works were built on the Ethereum blockchain platform [4], [5], [6], [34]. Publishers need a public environment and visibility to market e-books to potential buyers. Hence, Ethereum is the most suitable choice for publishers to trade their products. In [3], [36], the authors did not specifically mention which platform was used in their work, as the proposed solution generally works across any blockchain platform. [35] developed their blockchain platform and utilized their own cryptocurrency, JSP Coin.

However, six (6) out of seven (7) models use smart contract despite three (3) works not being built in Ethereum [3], [35], [36]. This is because the smart contract can also be deployed to other blockchain platforms. For example, a smart contract can be applied to Hyperledger Fabric using a "chaincode" package [37].

Regarding storage systems, four (4) works utilize IPFS, and three (3) works use other storage, such as local storage and blockchain storage. E-book files could be large, especially for books with illustrations and graphics. Storing e-books on the blockchain would be very costly; therefore, a better option would be a decentralized storage system, such as IPFS, Storj, or SWARM. Work by [5] applied cloud-based storage, but it could also be extended into other decentralized storage systems.

Related work shows that various cryptographic algorithms have strengthened the system's security. A hash function is the standard algorithm used because the hash is part of an element in the blockchain. If the e-book files are stored in IPFS, the IPFS hashes will be stored on the blockchain. The hash function is crucial to ensure the e-book is not modified during the transaction. Apart from that, [5] specifically mentioned the use of MD5Hash and IPFS hash in their solutions.

Digital signatures are also an essential feature of blockchain. A digital signature ensures the authenticity of the data transmission on the blockchain network. Various types of digital signatures were used in the study, including Elliptic Curve Cryptography (ECC), Elliptic Curve Digital Signature Algorithm (ECDSA), and Asymmetric Key Encryption (AKE). From the study, every solution used at least one digital signature method. The work by [3] is more comprehensive, which explains why a greater number of methods were employed in their solutions. A study by [36] explores the possibility of adapting non-fungible tokens (NFTs) to e-book publishing; specifically, the ERC-721 standard enables authors to create crypto assets. In e-book publishing, digital signatures are crucial to ensure that a real publisher uploads the authentic e-book. The customer will verify the e-book signature by decrypting it using the publisher's public key.

TABLE I. COMPARISON OF PREVIOUS RELATED WORKS OF BLOCKCHAIN IN E-BOOK PUBLISHING

No.	Authors	Proposed Work	Objectives	Actors	Limitations
1.	[6]	IPFS-Blockchain-Based Authenticity of Online Publications	Authenticity, Integrity	Author, publisher, customer	• Author creates smart contract, publisher validates it • No discussion on payment/royalty
2.	[5]	Blockchain-based Framework for Protecting Author Royalty of Digital Assets	Transparency, Copyright, Authenticity	Author, publisher, customer	• Both publisher and buyer must deposit 2× book price • May affect usability
3.	[34]	JS Digital Asset Trading System	Transparency, Authenticity	Author, customer	• 4× encrypt–decrypt process • 3× e-book transfers over network • Author must always be active to decrypt
4.	[35]	JSP Digital Asset Trading System	Transparency, Copyright	Author, customer	• Only author & buyer involved • Developed own blockchain platform • Uses its own cryptocurrency (JSP Coin) • Marketplace style, no publisher role
5.	[3]	Blockchain-based eBook Market System for Self-Publishing	Transparency, Copyright, Authenticity, Confidentiality, Validity, Integrity	Author, customer	• Designed for self-publishing only • Relies on third-party service application
6.	[36]	Non-Fungible Tokens (NFTs) for Publishing	Copyright	Author, customer	• NFT better for special/collectible editions • Buyer must bid in limited timeframe • Ownership can be resold
7.	[4]	Blockchain-based Protection of Author Royalty of Digital Assets	Transparency, Copyright, Authenticity	Author, customer	• Publisher & buyer must deposit 2× book price • Similar limitations to Nizamuddin et al. (2019)

TABLE II. SUMMARY OF STORAGE, PLATFORM, AND ALGORITHM USED IN BLOCKCHAIN-BASED E-BOOK PUBLISHING

No.	Authors	Smart Contract	Storage	Platform	Cryptographic Algorithm				Token / NFT
					Symmetric Encryption	Asymmetric Encryption	Digital Signature	Hashing / Integrity	
1.	[5]	✓	IPFSa	Ethereum	Not applicable	Not applicable	✓ (Not specified)	✓ (Not specified)	✓ (conceptual token – CID)
2.	[6]	✓	IPFS	Ethereum	Not applicable	✓ (ECCc)	✓ (ECCc)	✓ (MD5b)	✓ (digital token – unspecified)
3.	[34]	N/A	Not specified	Own platform	Not applicable	✓ (RSAf)	Not applicable	Not applicable	Not applicable
4.	[35]	✓	Not specified	Own platform	✓ (AESd)	✓ (public/private key)	✓ (Tx signature)	Not applicable	Not applicable
5.	[3]	✓	Not specified	Ethereum	✓ (AES)	Not applicable	✓ (ECC)	✓ (MACe)	Not applicable
6.	[36]	N/A	Not stated	Not stated	Not applicable	Not applicable	Not applicable	Not applicable	✓ (NFTs – conceptual)
7.	[4]	✓	IPFS (implied)	Ethereum	Not applicable	✓ (ECC)	✓ (ECC)	Not applicable	✓ (NFTs – implied)

[a]IPFS – InterPlanetary File System, [b]MD5 – Message-Digest Algorithm, [c]ECC – Elliptic Curve Cryptography, [d]AES – Advanced Encryption Standard, [e]MAC – Message Authentication Code, [f]RSA – Rivest-Shamir Adleman

V. TAXONOMY OF BLOCKCHAIN-BASED E-BOOK PUBLISHING MODELS

To systematically evaluate the diversity of blockchain applications in e-book publishing, this study develops a taxonomy framework that classifies prior works across six dimensions: platform, storage, smart contract usage, cryptographic algorithm, tokenization, and actors involved. This taxonomy serves two (2) purposes: first, to consolidate scattered findings into a structured framework; and second, to highlight the positioning of the proposed conceptual model within the broader research landscape.

As summarized in Table III, most models rely on the Ethereum blockchain, while some use custom-built or other blockchain platforms. Storage mechanisms vary from centralized cloud storage to decentralized solutions such as IPFS. For instance, [38] proposed a cross-chain copyright protection scheme in which storage and verification are distributed across multiple blockchains, supported by arbitration and supervision entities. This approach demonstrates how storage mechanisms can be extended beyond single-chain IPFS or cloud solutions. Smart contracts are primarily used in these solutions. The cryptographic algorithm implemented includes symmetric encryption (e.g., AES), asymmetric encryption (e.g., RSA, ECC), digital signatures (e.g., EDCSA, transaction-based signatures), and hashing (e.g., MD5, SHA). Similarly, the SecureRights framework by [39] enhances authenticity and digital rights management (DRM) by combining a blockchain smart contract with cryptographic watermarking, fingerprinting, and IPFS. This demonstrates how cryptographic techniques can be extended beyond conventional encryption and hashing to support end-to-end protection of digital content. Tokenization ranges from none to fungible tokens to NFTs used to represent ownership or incorporate publishers as intermediaries in the distribution process.

TABLE III. TAXONOMY OF BLOCKCHAIN-BASED E-BOOK PUBLISHING MODELS

Dimension	Categories / Options	Examples in Literature
Platform	Ethereum, Own Blockchain, Other (e.g., Hyperledger)	[4], [5], [6], [35]
Storage	On-chain, Cloud-based, IPFS / Decentralized	[6] – IPFS; [35] – NFT + external storage
Smart Contract	Royalty automation, Authenticity verification, Marketplace	[5] – Royalty automation; [3] – Marketplace
Cryptographic Algorithm	AES, RSA, ECC, Hashing (MD5, Keccak256, SHA)	[34] – RSA; [3] – AES + MAC
Tokenization	None, Fungible Token (ERC-20), Non-Fungible Token (ERC-721)	[36] and [4] – NFT;
Actors Involved	Author + Customer, Author + Publisher + Customer	Most self-publishing models involve Author + Customer; the Proposed model includes the publisher.

The taxonomy framework is illustrated in Fig. 5, which visualizes the classification across six dimensions. The diagram highlights how blockchain-based models can be categorized based on their technical implementation and functional scope. Together, Table III and Fig. 5 provide a comprehensive reference structure for analyzing similarities and differences among blockchain-based approaches to e-book publishing.

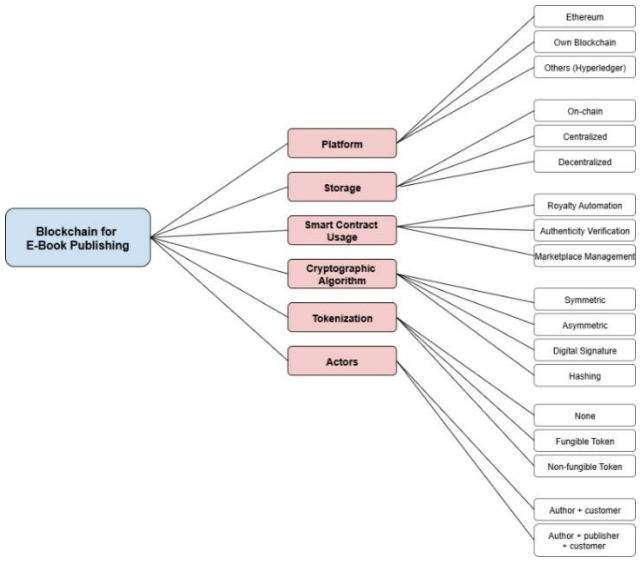

Fig. 5. Taxonomy of blockchain-based e-book publishing models.

A key insight from this taxonomy is that existing works are often fragmented, with most solutions addressing only one or two dimensions at a time. For example, [6] focus primarily on authenticity and storage (IPFS), while [36] highlight copyright protection via NFTs, but overlook encryption and publisher involvement. Similarly, [34] implements asymmetric cryptography but lacks integration with decentralized storage. Few models integrate multi-actor involvement, hybrid cryptography, and automated royalty payments within the same framework. This observation underlines the distinctiveness of the proposed conceptual model, which consolidates these features into a unified approach designed for practical application in e-book publishing.

VI. PROPOSED SOLUTIONS

This section presents a proposed conceptual model of blockchain-based e-book publishing using a smart contract on the Ethereum blockchain. The model aims to provide transparent transactions, verify the authenticity of e-books, and protect authors' copyright by delivering fair royalties and payments to publishers. Fig. 6 provides a general overview of the Blockchain-based E-Book Publishing conceptual model and the interactions among the parties involved with a smart contract on the Ethereum blockchain. This proposed model cannot be applied to self-publishing authors and the marketplace, as there is no direct participation of the publisher and customer. It involves four (4) main actors: the author(s), the publisher, the customer, and the smart contract.

The proposed model applies to a single publisher, which could facilitate e-book marketing and distribution through the publisher's sales platform. The business procedures and internal system processes will take place as follows:

- The publisher will upload an encrypted, signed e-book to the external storage IPFS.
- The details of the e-book, such as the title, price, author(s), and book category, will be added to the system. The contract will be initiated, but it is noted that it is not yet official.
- Hash code generated from IPFS will be stored in the blockchain.
- The author will be notified about the new contract and receive a request for e-book hash verification.
- The author will verify the new contract and the hash code to validate the authenticity of the e-book uploaded into the system. After the author's verification, the new contract will be officially created. The e-book will now be visible for sale.
- Customers will request an e-book by sending a purchase request to the system.
- The request will be notified and reviewed. Upon acceptance, the smart contract will generate the payment request function. The customer will be authorized first to ensure that they are a legitimate buyer.
- The customer should deposit the payment.
- The payment will be validated. The transaction will be aborted if the customer fails to pay within the allocated time.
- Upon successful payment, the smart contract will request the user to verify the e-book hash value for authentication.
- The hash verification by the customer. This ensures the authenticity of the e-book and that the person verifying the hash is the actual purchaser.

- A download link will be provided if the hash verification is successful.
- The customer will download or may access the e-book from IPFS.
- Successful download/access notifications will be sent to the smart contract.
- After a successful download, the smart contract will notify the author and publisher of the sales.
- Royalty payment to the author(s) and sales payment to the publisher will be delivered according to the pre-determined rules set up at the beginning of the smart contract's creation.
- Alternatively, the author(s) and publisher can also request the sales statement from the system.

To further illustrate how the proposed model can be applied in the e-book publishing environment, consider a real e-book purchase by a customer. When the customer initiates the purchase, the smart contract triggers an authenticity verification by comparing the e-book's IPFS hash with the metadata hash stored on the blockchain. If the values match, the system grants access to the encrypted file and automatically releases royalty payments to the author and publisher in accordance with predefined rules. This IPFS-anchored hash verification pattern has been widely adopted in blockchain-based digital publishing applications, indicating its practical feasibility [6], [40], [41], [42].

The following section discusses the theoretical and practical implications of this study, situates the model within the existing body of knowledge, and highlights its potential relevance to stakeholders in the e-book publishing industry.

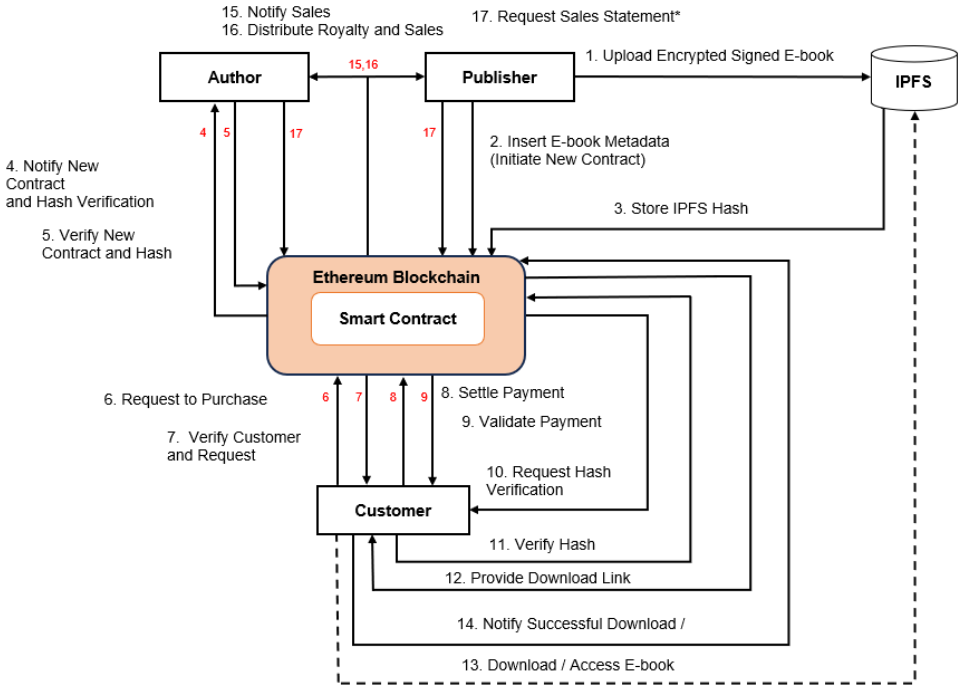

Fig. 6. The conceptual model of blockchain-based e-book publishing.

VII. Discussion

The proposed conceptual model addresses the limitations observed in prior work on the blockchain-based e-book publishing approach. Tables I and II, together with the proposed taxonomy, give a clear overview of how the proposed model is different from previous blockchain-based e-book publishing solutions. While past studies mostly focused on one or two specific functions, such as transaction transparency or authenticity, this study combines multiple essential elements, including storage, cryptographic methods, and actor involvement, into one complete and realistic workflow.

Beyond outlining the model, it is necessary to consider the broader implications for theory and practice, as well as the limitations that will shape future work.

A. Research Implications

This study contributes to the theoretical and practical insights into the domain of blockchain-based e-book publishing, as described below:

1) Theoretical implications: The paper advances blockchain research by locating e-book publishing as a distinct case within digital content publication, where interaction between the authors, publisher, and customers is more complex compared to music and image publishing. By integrating an Ethereum smart contract, IPFS, and a cryptographic algorithm, this model demonstrates how multi-actor relationships can be supported transparently and securely. This study develops a taxonomy for a blockchain-based model of e-book publishing,

classifying it across six dimensions. This taxonomy provides a structured framework for synthesizing prior works and systematically identifying research gaps, thereby serving as a reference for future studies. This aligns with broader blockchain research by [21], which emphasizes the importance of structured frameworks and systematic taxonomies in advancing the blockchain research agenda. The comparative review of seven (7) models further strengthens theoretical understanding by highlighting persistent issues around transparent transactions, e-book authenticity, and copyright protection.

2) Practical implications: For publishers, this model offers a pathway to improve the copyright protection for authors by enforcing automated royalty distribution, thus reducing disputes and building trust in e-book publishing transactions. The model enhances copyright protection through two mechanisms: 1) each e-book will be authorized by the author using hash verification, and 2) royalty payments are executed automatically through smart contracts, ensuring transparency and reducing the sales record manipulation. Author benefit from enhanced visibility and control over sales records, addressing their long-standing concern about the transparency of the royalties. Customers gain assurance that the purchased e-books are authentic and verified. For policymakers, the model demonstrates how blockchain can be applied beyond cryptocurrency to support intellectual property protection. The taxonomy also has practical implications for decision-makers, enabling stakeholders to evaluate existing blockchain solutions based on platform, storage, smart contract usage, cryptographic algorithm, tokenization, and the actors involved. Unlike the previous blockchain model for the digital content that focused on a single function, such as authenticity or transparency, the proposed model's significance lies in its ability to integrate multiple critical e-book publishing functions into a unified and automated workflow.

B. Research Limitations

Although this study contributes to a conceptual blockchain-based model for e-book publishing, several limitations must be acknowledged. First, the research is still conceptual in nature and has not yet been validated through a prototype implementation or testing. In addition, the model is currently limited to a single-publisher scenario. Thus, the model does not apply to a self-publishing and marketplace developed by a third party.

While blockchain offers transparency, e-book authenticity, and robust copyright protection in e-book publishing, its implementation in the real world faces several key challenges. One of the main issues is scalability. Transaction processing time and gas fees can increase significantly when transaction volume is high, potentially delaying e-book verification and payment confirmation. Another key limitation is user adoption. Publisher, author, and customer may not be familiar with blockchain operations, which could slow adoption, especially when the transaction process involves additional steps such as e-wallet creation or gas fee payments. Finally, the integration with existing e-book publishing infrastructure requires the publisher to adjust its internal operations and administrative organization, which can increase the operational costs and complexity. These factors need to be considered to ensure the system's effectiveness, cost efficiency, and usability in practical development.

VIII. Conclusion and Future Works

This paper examined existing blockchain-based approaches to e-book publishing. Through a comparative analysis of seven (7) related works, the persistent gaps in ensuring transparent transactions, e-book authenticity, and copyright protection for the authors are identified. To address these gaps, a conceptual blockchain-based model was proposed that leverages Ethereum smart contract, IPFS, and cryptographic algorithms to provide transparency, authenticity verification, and fair royalty distribution.

The study makes four (4) key contributions: 1) a conceptual model that integrates transparency, authenticity, and copyright protection in a unified model, 2) explicit inclusion of multi-actor involvement – author, publisher, and customer, reflecting real-world e-book publishing process, 3) comparative analysis of prior models to identify limitations and position of the proposed solution, and 4) the development of the taxonomy that establishes a theoretical reference for future study. Together, these contributions provide both theoretical value by advancing blockchain research in e-book publishing and practical significance by offering a foundation for the publishers and authors to adopt with secure e-book distribution mechanisms.

While no prototype or simulation was conducted at this stage, it sets the groundwork for future development. Planned work includes implementing a prototype in Solidity and Ethereum with IPFS storage, evaluating its feasibility with experts, and conducting experimental performance validation in a real e-book publishing scenario. Expanding the model to multi-author environments and integration with tokenization mechanisms, such as NFTs, is also part of the future directions.

From a feasibility perspective, implementing this model on the Ethereum network needs to take into consideration gas fees and scalability constraints. Transaction costs can increase during peak network usage, affecting the user experience. However, using a second layer (Layer-2) solution such as Polygon or Arbitrum can help reduce costs and speed up transactions [43]. Future studies could explore these combinations to improve system performance. By pursuing these next steps, the proposed model can evolve into a validated solution that enhances trust, fairness, and security in the e-book publishing ecosystem.

***Abstract*—Physical violence among students remains a persistent issue that often goes undetected, especially in school environments without intelligent real-time monitoring systems. Such incidents pose serious risks to student safety and hinder the creation of a secure learning atmosphere. This study aims to develop an adaptive visual-based system for detecting physical violence in educational settings using a deep learning approach. A hybrid architecture was designed by integrating VGG19 for spatial feature extraction and Bidirectional Long Short-Term Memory (BiLSTM) for temporal sequence analysis. To enhance model interpretability and reduce redundancy, Recursive Feature Elimination (RFE) was employed to eliminate irrelevant features and improve overall learning efficiency. The proposed system effectively captures both spatial and temporal cues from classroom surveillance videos, enabling more accurate classification of violent and non-violent behaviors. The model was trained and tested on benchmark datasets containing diverse video samples and achieved an accuracy of 92.4%, outperforming standalone CNN and LSTM models. The integration of RFE contributed to a more compact and computationally efficient framework. This study demonstrates the potential of hybrid deep learning and feature optimization for real-time violence detection, contributing to the advancement of visual intelligence and Educational AI for safer, data-driven learning environments.**

***Keywords*—Violence detection; deep learning; VGG19; BiLSTM; RFE; Educational AI**

I. Introduction

Acts of physical aggression in educational settings seriously hinder the psychological and emotional well-being of learners. Even though multiple measures have been introduced to ensure a secure learning atmosphere, such behaviours still occur discreetly, especially in classes with limited monitoring [1]. Without a smart monitoring system, numerous cases go unnoticed in real time, which heightens the possibility of victims experiencing lasting psychological harm. These conditions highlight the urgent need for an adaptive and intelligent system capable of detecting violent actions automatically and accurately in school environments.

Prior studies have investigated the application of machine learning and computer vision for violence detection in video surveillance [2]. Nevertheless, such techniques remain limited, as conventional Convolutional Neural Network (CNN) models extract only spatial information from single frames [3][4][5]. These models neglect the temporal dimension, reducing their effectiveness in recognising repetitive or sequential behavioural patterns over time [3][6]. In contrast, the Long Short-Term Memory (LSTM) approach [7] is able to process temporal dependencies but often depends heavily on the quality of input features and struggles to represent complex visual dynamics [8]. Furthermore, previous studies have generally overlooked feature selection, resulting in increased computational costs and a higher tendency toward overfitting [9].

To address these limitations, this study introduces an adaptive hybrid deep learning framework that integrates both spatial [10] and temporal information simultaneously [11][12]. The proposed framework employs VGG19[13] as its backbone to extract spatial features from individual video frames. In this stage, VGG19 generates feature vectors rather than performing classification, which allows the network to serve purely as a feature extractor. The choice of VGG19 [14] is based on its robust yet compact architecture and its proven effectiveness in object and texture recognition tasks[15][16]. The extracted features are then processed by a Bidirectional Long Short-Term Memory (BiLSTM) network [17][18], enabling the model to capture temporal dependencies in both forward and backward directions [19], thereby improving its ability to recognise patterns of violent behavior [20].

Further enhancing model efficiency and accuracy, the Recursive Feature Elimination (RFE) [21] method is applied to iteratively remove irrelevant or redundant attributes. This process ensures that only the most informative features are retained, effectively reducing model complexity and minimising overfitting risks [22]. Such an approach is particularly beneficial for video-based data[23], which inherently involves high-dimensional spatial–temporal representations [24][25]. By combining spatial and temporal feature analysis with systematic feature selection, the proposed hybrid model offers a comprehensive and efficient solution for detecting violent incidents in educational environments [26]. The contributions of this research are expected to advance the development of artificial intelligence-based educational safety systems that support human-centred, data-driven, and adaptive learning ecosystems in line with current edutech innovations.

II. Related Work

Research on violence detection through video surveillance has expanded significantly, particularly in the domains of public safety and education. One of the initial methods involved the application of Convolutional Neural Networks (CNN) [27][3] to classify violent behaviour using individual frames. For example, Sakhthivinayagam et al. [28] introduced a fast

*Corresponding author.

violence detection framework based on CNN. Nevertheless, this strategy is limited to static image analysis and fails to capture motion dynamics.

In response to these challenges, Sharma et al. [6] proposed a real-time violence detection approach employing a CNN integrated with surveillance systems. The framework could quickly identify violent events but struggled in cases where actions were slow or not overtly visible, suggesting that temporal modelling is essential in detecting aggressive conduct. To address this, Ullah et al. [29] integrated CNN with LSTM, enabling the model to capture both spatial and temporal information [30]. Although their system achieved better results on video datasets, it relied solely on unidirectional LSTM, which processed only past frames and excluded future cues, thereby losing contextual completeness [31]. A number of prior studies have explored hybrid strategies to enhance violence detection performance in surveillance videos. A widely adopted approach is the integration of CNN with LSTM, where CNN extracts spatial features and LSTM handles temporal dynamics [15]. Nonetheless, many of these works continue to employ conventional unidirectional LSTM. For instance, Ullah et al. utilized a CNN–LSTM model for violent video classification, but it only captured sequences from past to future, thus limiting the contextual understanding of events [32].

Building on earlier work, Halder et al. [33] employed Bidirectional LSTM (BiLSTM) for violence detection and showed that bidirectional sequence processing substantially enhances accuracy. By analyzing both past and future frames, BiLSTM is capable of capturing the dynamics of violent events across the entire video [18], offering a more comprehensive temporal representation. For spatial feature extraction, VGG19 was selected due to its architectural depth and proven capability in consistently capturing fine-grained spatial details [34]. This network has been widely applied in pattern recognition research and has demonstrated effectiveness in detecting crucial visual cues such as facial expressions, body postures, and interpersonal interactions. Nonetheless, CNN-based models like VGG19 tend to generate a large volume of features, which may lead to overfitting and extended training times [35]. To mitigate this issue, feature selection techniques such as Recursive Feature Elimination (RFE) have been introduced. As reported by Konyo et al. [22], RFE can efficiently retain the most relevant features by iteratively discarding those with minimal contribution to performance. Despite its potential, the integration of RFE into deep learning, particularly within spatial–temporal hybrid architectures, remains underexplored, even though it offers promising improvements in computational efficiency and model interpretability [36].

Accordingly, this study combines three key components: VGG19 for extracting spatial representations, BiLSTM for modelling bidirectional temporal dependencies, and RFE for optimising feature selection into a unified adaptive intelligent framework. This design is anticipated to enhance the accuracy, efficiency, and interpretability of physical violence detection in educational environments [37]. Furthermore, integrating an automated violence detection system with a psychological risk assessment module that accounts for incident frequency and intensity is essential for building a comprehensive solution to safeguard students [38].

III. Proposed Methodology

This research introduces an adaptive intelligent system architecture aimed at detecting physical violence and estimating psychological risk among students. The framework is composed of eight core components: 1) classroom surveillance video as the input; 2) preprocessing involving frame extraction and normalization; 3) spatial representation learning through VGG19; 4) temporal sequence modeling with BiLSTM; 5) feature refinement using Recursive Feature Elimination (RFE); 6) a classification module for violence detection; 7) a module for computing the psychological risk index; and 8) system output in the form of detection summaries and risk alerts. By integrating spatial–temporal analysis with video-based psychosocial risk assessment, this architecture offers a comprehensive solution for safeguarding students (see Fig. 1).

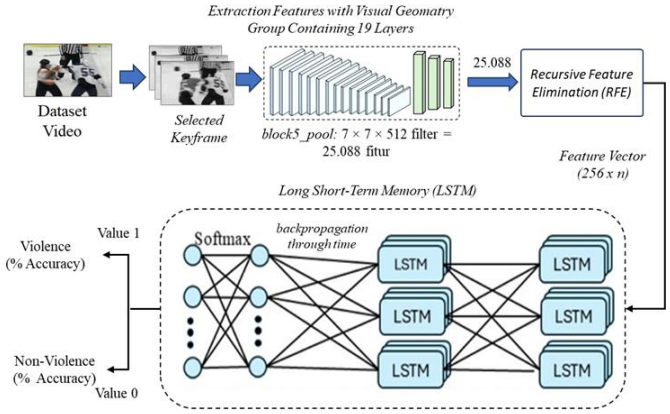

Fig. 1. An overview of the architecture.

A. Dataset

The proposed model was evaluated using three benchmark datasets commonly used for distinguishing between violent and non-violent actions [39][40]. The first is the Hockey Fight Dataset [41], which contains short video clips from ice hockey games, capturing both violent and non-violent interactions. The second is the Violent Flow Dataset [40], consisting of clips extracted from various action-focused movies. The third is the AIRTLab Dataset [42], which comprises video sequences recorded in a simulated environment specifically designed for the development and testing of violence detection systems.

Among these, the Hockey Fight Dataset was selected for training and evaluation of the proposed model due to its balanced composition (500 violent and 500 non-violent clips) [41], the clarity of physical aggression it presents, and its widespread use in prior violence detection research, enabling objective performance comparison. Each clip in the dataset has a resolution of 360 × 240 pixels and a frame rate of 30 fps.

To increase the dataset's relevance in educational settings, selected frames were further analyzed and preprocessed to emulate classroom-like environments while preserving the spatio-temporal features critical for effective violence detection.

B. Feature Extraction Using VGG19

Following the division of video into frames per second (fps), each frame is preprocessed and resized to 224×224 pixels. Spatial representations are then extracted using the VGG19 network [43]. VGG19 was selected due to its consistent performance in visual pattern recognition and its capability to capture high-level spatial features [44]. The architecture has been extensively applied in image classification and transfer learning tasks, particularly in domains characterised by complex visual structures. In this study, the features obtained from the Fully Connected Layer of VGG19 are utilised as inputs for the temporal modelling module [43]. The basic convolution operation is formulated as:

$$F_{i,j}^{(l)} = \sigma\left(\sum_{m,n} K_{m,n}^{(l)} \cdot I_{i+m,j+n}^{(l-1)} + b^{(l)}\right) \quad (1)$$

where, $F_{i,j}^{(l)}$ it is a feature that outputs to the l screen, $K_{m,n}^{(l)}$ it is a convolution kernel, $I_{i+m,j+n}^{(l-1)}$ it is the input from the previous layer, $b^{(l)}$ it is biased, σ it is an activation function, ReLU: $\sigma(x)$ max $(0, x)$.

C. Temporal Analysis Using Bidirectional LSTM

The spatial features extracted from individual video frames are sequentially organised and passed into the BiLSTM network. In contrast to standard LSTM, which processes data in a unidirectional manner from past to future [45], BiLSTM analyses input sequences in both forward and backwards directions, enabling the model to capture a more comprehensive temporal context of violent events [46]. This architecture is particularly effective for modelling behavioural dynamics, as physical violence typically unfolds through a progression of buildup, peak intensity, and subsequent decline within a relatively short time span [47]. The forward-pass operation of the LSTM cell can be formulated as follows:

Input gate:

$$i_t = \sigma(W_i.\left[h_{t-1,}\, x_t\right] + b_i) \quad (2)$$

Forget gate:

$$f_t = \sigma(W_i.\left[h_{t-1,}\, x_t\right] + b_f) \quad (3)$$

Cell State Update:

$$\widetilde{C_t} = \tanh(W_0.\left[h_{t-1,} x_t\right] + b_{0)} \quad (4)$$

$$C_t = f_t \odot C_{t-1} + i_t \odot \widetilde{C_t} \quad (5)$$

Output gate:

$$o_t = \sigma(W_o\ .[h_{t-1}, x_t\ ] + b_o) \quad (6)$$

$$h_t = o_t \odot \ \tanh(C_t) \quad (7)$$

For BiLSTM, a two-way LSTM is used:

$$\overrightarrow{h_t}\ (forward\ LSTM) \quad (8)$$

$$\overleftarrow{h_t}\ (backward\ LSTM) \quad (9)$$

Final Output:

$$h_t = \left[\overrightarrow{h_t}\ ;\ \overleftarrow{h_t}\ \right] \quad (10)$$

In this model, x_t denotes the input at time step t (video frame features), while h_t represents the hidden state, and C_t Is the cell state at time, The parameters W and b correspond to trainable weights and biases, The symbo σ refers to the sigmoid activation, $\odot$ It is an element-wise multiplication, tanh It is a hyperbolic tangent activation function, $\vec{h}_t$ is the output of the LSTM forward, $\overleftarrow{h}_t$ Is the output of backward LSTM.

D. Fitur Selection with Recursive Feature Elimination (RFE)

Spatial and temporal feature combinations are often high-dimensional and redundant. To overcome overfitting and speed up training time, the Recursive Feature Elimination (RFE) feature selection technique is used [22]. RFE works by removing features whose contribution to classification performance is considered insignificant [48]. In this study, RFE was applied after initial model training[24]. Features were selected based on their contribution to the validation F1 -score metric [49]. Efficient feature selection plays an important role in reducing computational complexity and improving system interpretability.

If F is a set of features and $f_i \in F$, then:

$$f_{eliminasi} = \arg\min_{f_1}(Score_{model}(F \backslash \{f_i\})) \quad (11)$$

$$Score(x_j) = \left|\frac{\partial \mathcal{L}}{\partial x_j}\right| \quad (12)$$

$$RFE_{DL}(X, y, n) = \arg\min_{S \subseteq X, |S| = n} \mathcal{L}(f_s(X_s), y) \quad (13)$$

where, x_j is the j th feature of the layer before clarification? $\mathcal{L}$ Adalah fungsi loss (e.g., cross-entropy), $\frac{\partial \mathcal{L}}{\partial x_j}$ which is the derivative of the loss function with respect to the feature x_j, which is sensitivity. f_S It is a model built only with a subset of features S, X_S This is input data that only uses features in the subset S, and n is the number of features targeted for retention.

E. Violence Detection Module

The features produced by the BiLSTM-RFE module are subsequently passed into a dense layer with sigmoid activation, which performs binary classification to decide whether the sequence of frames corresponds to violent behavior. The decision threshold is adjusted according to validation outcomes in order to minimize false positives.

The performance of the model is assessed using accuracy [50], precision [51], recall [52], and F1-score [49], following common evaluation metrics in video classification research. This module determines whether a given video clip depicts violent activity [53]. The spatial features extracted by VGG19 and the temporal features captured by BiLSTM are concatenated and forwarded to a dense layer, where the final decision is made through a Softmax activation function.

If h it is the final representation (combination of VGG19 + BiLSTM), then:

$$P(y = k|h) = \frac{e^{W_k^T h + b_k}}{\sum_{j=1}^{K} e^{W_j^T h + b_j}} \quad (14)$$

Prediction:

$$\hat{y} = \arg\max_k P(y = k|h) \quad (15)$$

where, h it is a combined feature vector from BiLSTM (spatial-temporal), W_k is the boot layer output for class k, b_k is the bias for the class k, K is the number of classes (2: affection/disaffection), $P(y = k|h)$ is the probability that the input belongs to class k, and $\hat{y}$ is the final grade prediction.

F. Evaluation and Validation

System performance evaluation [54], [55] is conducted using four key metrics: accuracy, precision, recall, and F1-score, each of which provides a different perspective on system performance.

TABLE I. CONFUSION MATRIX

	Positive Class	Negative Class
Positive Class	True Positive (TP)	False Negative (FN)
Negative Class	False Positive (FP)	True Negative (TN)

Table I shows that TP is True Positive (the model correctly predicts violence), TN is True Negative (the model correctly predicts no violence), FP is False Positive (the model incorrectly predicts violence when there is none), and FN is False Negative (the model fails to detect violence when it exists). Accuracy is used to measure the proportion of correct predictions out of all tested data. This metric provides an overview of the system's performance in distinguishing between violent and non-violent incidents, and is formulated as:

$$Accuracy = \frac{TP+TN}{TP+TN+FP=FN} \quad (16)$$

However, in unbalanced data conditions, where the number of violent incidents is far fewer than normal incidents, accuracy alone is not sufficient to fairly represent the system's performance. Therefore, precision and recall metrics are used. Precision measures how accurately the system identifies violent incidents, which is the proportion of predictions of violence that are actually violent. The formula is:

$$Precision = \frac{TP}{TP+FP} \quad (17)$$

Meanwhile, the recall shows how well the system captures all incidents of violence that occur. This metric is particularly important in the context of surveillance systems, where false negatives (FN) can have serious consequences:

$$Recall = \frac{TP}{TP-FN} \quad (18)$$

The balance between precision and recall is represented by the F1-score, which is the harmonic mean of the two. The F1-score provides a fairer assessment when there is an imbalance between positive and negative classes.

$$F1 = 2x\frac{Precision\ x\ Recall}{Precision + Recall}$$

The use of these four metrics enables a more comprehensive and fair evaluation of the system, especially in the domain of violence detection, which has high ethical and social implications. This evaluation is also important as a reference in comparing the effectiveness of various proposed deep learning architectures. In addition, a comparative study (ablation study) was conducted to assess the influence of each main component, namely: Without RFE (VGG19 + BiLSTM), Without BiLSTM (VGG19 + Dense), and Without the psychological module. This approach is important for determining the relative contribution of each system component and ensuring that performance improvements are not the result of overfitting or data bias.

IV. DISCUSSION

This study aims to detect violent actions in videos using a deep learning approach that integrates a Convolutional Neural Network (CNN) for spatial feature extraction and a Long Short-Term Memory (LSTM) for temporal sequence modeling. Recursive Feature Elimination (RFE) is used as the feature selection method to optimize model performance.

Each video is processed by dividing its content into a number of key frames taken at specific time intervals to effectively represent visual information. Spatial feature extraction is performed using the VGG19 CNN architecture, which generates hundreds to thousands of features on each frame or video segment. Due to the high dimension of the features generated, RFE is applied to filter the most relevant features, so that data complexity can be reduced without sacrificing the model's accuracy in classifying violent and non-violent actions.

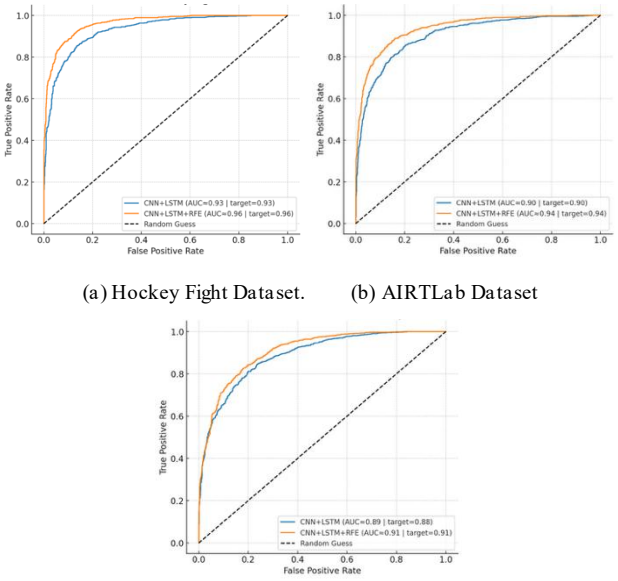
In general, the application of RFE can reduce feature dimensions by 30 to 50%, depending on the configuration used. This reduction has a positive impact on computational efficiency, with a 20 to 35% increase in the performance of the LSTM model training process. The CNN-LSTM model was trained using a number of violent action video datasets, including Hockey Fight, AIRTLab, and Violent-Flows. The evaluation process was conducted using the k-fold cross-validation method, along with a data distribution scheme of 80% for training and 20% for testing.

To evaluate the model's performance in classification, a confusion matrix is used to provide a detailed overview of the number of correct and incorrect predictions in each class. Through the confusion matrix, it is possible to analyze how well the model recognizes each class, including its ability to avoid classification errors. Table II presents the results of the confusion matrix from the trained model.

TABLE II. RESULTS OF THE CONFUSION MATRIX FROM THE TRAINED MODEL

Dataset	Model	TP	FN	TN	FP
Hockey Fight	CNN+BiLSTM	920	80	915	85
	CNN+BiLSTM+RFE	945	55	935	65
AIRTLab	CNN+BiLSTM	895	105	900	100
	CNN+BiLSTM+RFE	930	70	920	80
Violent-Flows	CNN+BiLSTM	875	125	880	120
	CNN+BiLSTM+RFE	905	95	905	95

Evaluate the model's ability to distinguish between classes as a whole, the Receiver Operating Characteristic (ROC) curve is used. The ROC curve illustrates the trade-off between true positive rate (TPR) and false positive rate (FPR) at various classification thresholds. The closer the curve is to the upper left corner, the better the model performance. Fig. 2 shows the ROC curve of the trained model.



(a) Hockey Fight Dataset. (b) AIRTLab Dataset

(c) Violent Flow Dataset

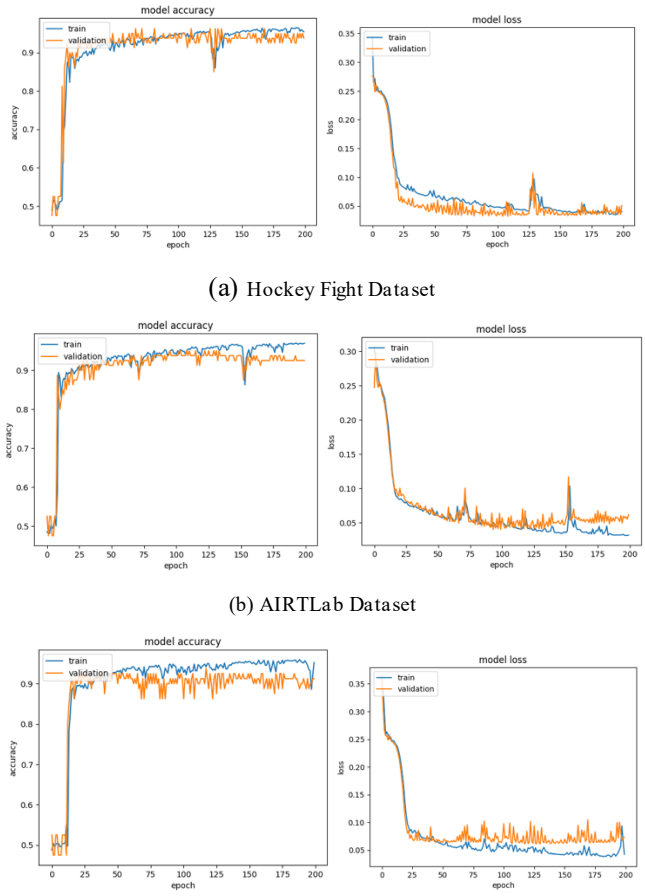
Fig. 2. Receiver Operating Characteristic (ROC) Curve for each Dataset.

Model performance was evaluated using various measurement metrics, including accuracy, precision, recall, F1-score, and Area Under the Curve (AUC) based on the ROC curve. Table III shows the results of model performance evaluation per dataset.

TABLE III. PERCENTAGE OF PERFORMANCE MODEL

Dataset	Model	Accuracy	Precission	Recall	F1-Score
Hockey Fight	CNN+BiLSTM	0.918	0.915	0.920	0.917
	CNN+BiLSTM + RFE	0.940	0.936	0.945	0.941
AIRTLab	CNN+BiLSTM	0.898	0.899	0.895	0.897
	CNN+BiLSTM + RFE	0.925	0.921	0.930	0.925
Violent-Flows	CNN+BiLSTM	0.878	0.879	0.875	0.877
	CNN+BiLSTM + RFE	0.905	0.905	0.905	0.905

Monitor model performance during the training process, model accuracy and model loss graphs are used. The accuracy graph shows the progress of the model's ability to classify correctly, while the loss graph illustrates the amount of error produced by the model. These graphs provide an overview of whether the model is underfitting, overfitting, or has been trained properly. Fig. 3 illustrates the accuracy and loss graphs from the model training process.



(a) Hockey Fight Dataset

(b) AIRTLab Dataset

(c) Violent Flow Dataset

Fig. 3. Performance evaluation results of the CNN + BiLSTM + RFE model on the datasets: (a) Hockey Fight, (b) AIRTLab-2000, (c) Violent Flow.

The three figures described previously show that the application of Recursive Feature Elimination (RFE) has a positive impact in increasing accuracy on the three data sets: Hockey Fight, AIRLab, and Violence Flow. For the Hockey Fight dataset, both training and validation accuracy rose sharply from approximately 0.5 to above 0.9. Training accuracy stabilized between 0.95 and 0.97, while validation accuracy fluctuated slightly within the 0.90–0.95 range. Since validation remained consistent, there was no indication of severe overfitting, making early stopping unnecessary. In the AIRTLab dataset, performance improved rapidly during the early stages, with training accuracy approaching 0.98 and validation accuracy leveling off at 0.93–0.95. A minor drop in validation performance between epochs 120 and 160 suggested mild overfitting, making early stopping around epoch 100–120 a more efficient option. In the Violence Flow dataset, accuracy also improved initially, but validation accuracy fluctuated more than in the other datasets. Training accuracy climbed to nearly 0.97, while validation stagnated around 0.90–0.93, indicating potential overfitting after epoch 100. The widening gap between training and validation results shows that the model tends to overfit and struggles to generalise effectively. Across datasets, the use of Recursive Feature Elimination (RFE) enhanced performance by filtering out irrelevant features. RFE not only increased accuracy and F1-score but also reduced

computational demands, confirming that many CNN-generated features are redundant and unnecessary for violence detection.

Compared to conventional CNN and LSTM models, the proposed VGG19-BiLSTM–RFE framework achieved superior performance with an overall accuracy of 92.4%, outperforming CNN-LSTM (88.5%). The inclusion of RFE enhanced model interpretability by eliminating redundant features, resulting in faster convergence and reduced overfitting. This improvement demonstrates the model's efficiency in handling the complex spatial–temporal relationships inherent in violence detection tasks.

The CNN heatmap results indicate that frames containing intense physical activities, such as body collisions, play a crucial role in the features retained by RFE. At the same time, the LSTM component effectively identifies temporal patterns in violent events, including abrupt and repetitive movements. Incorporating Recursive Feature Elimination (RFE) into the CNN-LSTM pipeline has proven successful in reducing feature dimensionality and computational costs, while also enhancing accuracy, precision, and reliability in violence detection by retaining only the most discriminative spatial features. When applied within the CNN-BiLSTM framework, RFE further improved classification performance by increasing accuracy and F1-scores, while removing redundant features without degrading the model's capability. The heatmap visualisations also confirm that frames with strong physical interactions dominate the important feature set, while BiLSTM captures the bidirectional temporal dynamics characteristic of violent actions. Nonetheless, misclassifications persist in scenarios involving non-violent videos with rapid movement or subtle forms of aggression, suggesting the need for integrating additional temporal descriptors such as optical flow or attention mechanisms. Overall, these findings establish RFE as an efficient and effective feature selection strategy for deep learning–based video analysis, particularly for tackling complex event detection tasks like violence recognition.

V. Conclusion

This study introduced an adaptive hybrid deep learning framework that combines VGG19 for spatial feature extraction, BiLSTM for temporal modeling, and Recursive Feature Elimination (RFE) for feature optimization in video-based violence detection. The model demonstrated high accuracy (92.4%) and outperformed traditional single-model baselines, validating the effectiveness of integrating spatio–temporal learning with feature selection. Evaluation on benchmark datasets confirmed the system's robustness and computational efficiency. Beyond performance metrics, the proposed framework offers practical relevance for real-world applications, particularly in educational settings where early detection of violent behavior is critical. Its interpretable and scalable design supports potential deployment in real-time surveillance systems aimed at enhancing student safety. However, limitations remain in detecting subtle or ambiguous violent actions and in generalizing beyond benchmark datasets. Future work will focus on improving adaptability through attention mechanisms, multimodal fusion (e.g., visual-audio inputs), and real-time system integration. Overall, this research contributes to the development of ethical, interpretable, and data-driven AI solutions for proactive violence prevention and behavioral monitoring in educational environments.

Acknowledgment

The authors gratefully acknowledge the financial support provided by the Directorate of Research and Community Service (DPPM), Ministry of Education, Research, and Technology (Kemendikti-Saintek), through the 2025 research grant, which enabled the completion of this study. The authors also wish to extend their sincere appreciation to all individuals and institutions who contributed to the data collection, research implementation, and preparation of this manuscript, whether directly or indirectly.

Transformative Integration of Machine Learning in Software Applications in Light of Current Software Engineering Practices

Fawzi Abdulaziz Albalooshi
Department of Computer Science, University of Bahrain, Sakhir Campus, Kingdom of Bahrain

***Abstract*—This study critically reviews the transformative integration of machine learning (ML) into software engineering, detailing its evolution from traditional DevOps to MLOps, which has significantly enhanced software development by enabling adaptive and intelligent systems, improving processes, and boosting software quality. Despite these benefits, the integration introduces unique challenges across technical (e.g., model deployment, data quality, scalability), organizational (e.g., collaboration, tool management), and cultural (e.g., resistance to change, skill gaps) domains throughout the software development lifecycle. The review highlights emerging solutions, including robust MLOps practices, microservices architecture, and frameworks like CRISP-DM, DataOps, and Agile ML, which aim to streamline the ML lifecycle and ensure reliability and scalability. Furthermore, it emphasizes the crucial role of security and governance frameworks in protecting against adversarial attacks, maintaining data privacy, and ensuring accountability and compliance, which are essential for building trust and ethical application of ML systems. Ultimately, successful ML integration requires a holistic approach that addresses these multifaceted challenges to optimize ML's impact and drive technological progress and business value.**

Keywords*—Machine learning (ML); software engineering; DevOps; MLOps; ML integration challenges; integrated software development

I. Introduction

Machine learning has profoundly transformed software engineering, leading to more adaptive and intelligent systems and improving development processes and software quality. The significance of this work lies in providing a comprehensive review of this transformative integration, particularly its evolution from traditional DevOps to MLOps, and addressing the complex challenges that arise. This study is crucial for optimizing ML's impact, ensuring the scalability, reliability, and maintainability of ML systems, which is vital for organizations seeking operational efficiency and competitive advantage in an increasingly ML-driven world. While the integration of ML offers substantial benefits, it introduces unique and multifaceted challenges across technical, organizational, and cultural domains throughout the software development lifecycle. The existing literature acknowledges these challenges, but many issues remain unresolved or contentious due to the complexity of ML systems and the evolving nature of software engineering practices. There is a clear gap in a consolidated, critical review that systematically analyzes these integration complexities and explores emerging solutions and best practices to address them effectively. This study aims to fill that gap by providing a structured overview of the current landscape, highlighting where current practices fall short and where further innovation is needed. Incorporating machine learning into software engineering enhances development processes, improves software quality, and allows complex tasks to be framed as learning problems. This approach excels at detecting patterns in large datasets and adapting to changing conditions, proving particularly useful in areas where traditional programming methods fall short [1][2]. However, this integration poses several challenges throughout the software development lifecycle, from requirements engineering to security and operationalization. The complexity of ML systems, combined with evolving software engineering practices, creates a landscape where certain issues remain unresolved or contentious [3][4][5][6][68]. This review argues that integrating ML into software engineering offers significant benefits. However, it also presents unique challenges that require innovative solutions and interdisciplinary collaboration. The review examines ML integration in software applications, emphasizing the transition from DevOps to MLOps. It critically analyzes the challenges in ML integration across technical, organizational, and cultural domains and explores potential solutions. The study aims to provide insights into optimizing ML's impact, ensuring the scalability, reliability, and maintainability of ML systems, ultimately leading to improved operational efficiency and competitive advantage. This study makes several key contributions. It provides a critical review of ML's integration into software engineering, detailing its evolution from DevOps to MLOps. The study systematically highlights the technical, organizational, and cultural challenges encountered during ML integration. It explores emerging solutions, including robust MLOps practices, microservices architecture, and frameworks like CRISP-DM, DataOps, and Agile ML, that aim to streamline the ML lifecycle and ensure reliability and scalability. The review underscores the crucial role of security and governance frameworks in protecting against adversarial attacks, maintaining data privacy, and ensuring accountability and compliance, which are essential for building trust and ethical application of ML systems. These contributions are designed to offer comprehensive insights into optimizing ML's impact, ensuring the scalability, reliability, and maintainability of ML systems, and ultimately driving technological progress and business value.

II. Research Methodology

This study adopts a critical review methodology to comprehensively analyze the transformative integration of machine learning (ML) into software engineering practices. This research design is chosen to provide a structured and in-depth examination of the subject, synthesizing existing knowledge, identifying gaps, and proposing solutions. A critical review allows for a systematic exploration of the evolution from traditional DevOps to MLOps, assessing the benefits and challenges inherent in this transition. The justification for this approach lies in its ability to offer a holistic perspective, crucial for understanding a rapidly evolving and multifaceted domain like ML integration in software engineering.

The research questions guiding this study are formulated to address significant gaps and complexities identified in the current literature regarding ML integration. The primary objectives include: understanding the evolution of ML integration, identifying and analyzing challenges, exploring emerging solutions, and emphasizing security and governance. The methodology involves a thorough review of academic literature, including research papers, conference proceedings, and industry reports related to machine learning, software engineering, DevOps, and MLOps. The selection criteria for literature prioritize relevance to the integration of ML in software development, focusing on studies that discuss challenges, solutions, best practices, and ethical considerations. The collected information is then critically analyzed to synthesize findings, identify recurring themes, and pinpoint areas of consensus and contention. This analytical process allows for the construction of a comprehensive overview that addresses the research questions and contributes to filling the identified literature gaps. The ultimate goal is to provide insights into optimizing ML's impact, ensuring the scalability, reliability, and maintainability of ML systems, and driving technological progress and business value.

III. Software Delivery Pipelines: From DevOps to MLOps

A. Traditional DevOps Continuous Integration (CI)/ Continuous Deployment (CD) Pipelines

Traditional DevOps CI/CD pipelines are essential to contemporary software development, allowing teams to automate and streamline the processes of code integration, testing, and deployment. These pipelines boost efficiency, minimize errors, and ensure the swift delivery of software. The core components of a traditional CI/CD pipeline include CI, Continuous Testing (CT), and CD, each playing a vital role in maintaining the quality and reliability of software releases. The following sections will delve into the key aspects of traditional DevOps CI/CD pipelines, highlighting their components, tools, and best practices.

1) Continuous integration: CI involves the regular integration of code changes into a shared repository, a process that triggers automated builds and tests. This approach helps identify integration issues early, thereby reducing the time and effort needed to resolve them [7][8]. The market offers several common CI tools and technologies, including Jenkins, CircleCI, Travis CI, GitLab CI/CD, Bamboo, TeamCity, Azure DevOps, GitHub Actions, and Bitbucket Pipelines. Each tool provides unique features and integrations tailored to different aspects of software development workflows. The choice of a CI/CD tool often hinges on the specific needs and existing infrastructure of the development team. For instance, Jenkins offers unparalleled flexibility and plugin support, making it ideal for complex projects. CircleCI and Travis CI are known for their ease of use and quick setup, catering to cloud-based and GitHub-centric workflows, respectively. GitLab CI/CD and Azure DevOps provide comprehensive platforms for teams seeking integrated solutions, while GitHub Actions and Bitbucket Pipelines offer seamless experiences for users of their respective version control systems. These tools enhance the development process by automating builds, tests, and deployments, thereby improving collaboration and efficiency among team members. CI helps maintain a stable codebase, enhances code quality, and facilitates collaboration among development teams [8][22].

2) Continuous testing: CT is a vital practice in DevOps environments, ensuring software quality and reliability throughout the development life cycle. By integrating testing into the CI/CD pipeline, CT allows for early defect detection and accelerates feedback loops. Key strategies in continuous testing include Shift-Left Testing, Test-Driven Development (TDD), Continuous Test-Driven Development (CTDD), and Operational-Profile Based Testing. Shift-Left Testing moves testing activities to earlier stages in the development process, facilitating earlier defect identification and reducing the cost and effort required for corrections [9][10]. Test-Driven Development (TDD) and Continuous Test-Driven Development (CTDD) involve writing tests before the code itself, ensuring that development is guided by testing requirements. CTDD enhances this process by automating test execution and integrating it into the continuous testing framework [11]. Operational-Profile Based Testing uses data from software operations to guide testing, ensuring that tests reflect real-world usage patterns. This approach is particularly advantageous for reliability testing, as it helps evaluate software performance under actual operating conditions [12]. Automated testing tools are essential in the DevOps environment, enabling rapid and reliable software delivery through continuous integration and deployment processes. These tools support various testing types, including unit, integration, performance, and security testing, and are crucial for maintaining code quality and reliability. The choice of tools often depends on the project's specific needs, with factors to consider including platform compatibility, ease of use, and integration capability.

3) Continuous deployment: Continuous Deployment (CD) automates the release of validated code changes into production environments, ensuring the swift and reliable delivery of new features and fixes to users [8]. As a vital component of modern software development, CD enhances efficiency, reliability, and speed by automating application

deployment. A variety of tools and technologies support CD, each playing a distinct role within the deployment pipeline. These tools are crucial to the CI/CD process, facilitating seamless integration, testing, and deployment of software products. Git, a widely adopted version control system, tracks changes in source code during software development [13][14]. Jenkins, an open-source automation server, aids in building, deploying, and automating projects, often working alongside Git and Docker to streamline the CI/CD pipeline [14][15]. GitLab CI/CD, part of the GitLab platform, provides a robust CI/CD solution by integrating with Git repositories to enable automated testing and deployment [14]. Docker allows developers to package applications into containers, which are standardized units of software containing all necessary components to run an application, ensuring consistency across environments [15][13]. Kubernetes automates the deployment, scaling, and management of containerized applications, often collaborating with tools like ArgoCD to manage deployments within Kubernetes clusters [15][13]. While these tools are widely used in Continuous Deployment, the choice of tools may vary based on project requirements, team preferences, and organizational objectives. Integrating these tools into a unified CI/CD pipeline requires careful planning and execution to address potential challenges such as security vulnerabilities, system misconfigurations, and resource optimization. As software development evolves, adopting new tools and practices is essential for maintaining efficient and secure deployment.

4) Best practices and optimization: Optimizing CI/CD pipelines is essential for enhancing software development processes, as it boosts efficiency, reliability, and speed. As software systems become more complex, the demand for rapid and dependable deployments grows. Effective optimization of CI/CD pipelines results in notable improvements, such as increased deployment frequency, higher build success rates, and enhanced overall development efficiency. This process involves tackling several challenges, including inconsistencies in test environments, resource allocation issues, and build instabilities. By optimizing CI/CD pipelines, builds are stabilized, and execution efficiency is improved, which are critical factors for maintaining a seamless development workflow. This is achieved by addressing test environment inconsistencies and managing resources effectively [16]. Automated code integration and delivery minimize the time and errors associated with manual processes, enabling faster release cycles and allowing teams to focus more on business requirements [17]. CI/CD practices cultivate a culture of shared responsibility for code quality, enhancing collaboration among team members and boosting productivity [18]. Optimized pipelines ensure efficient scaling of software systems while maintaining reliability, which is crucial for handling complex software systems and large-scale projects [19] [20]. While optimization offers numerous benefits, it also presents challenges, such as managing the complexity of automation tools, ensuring toolchain compatibility, and addressing security concerns. Integrating emerging technologies like AI/ML into CI/CD processes can further enhance pipeline efficiency. Organizations must continuously adapt and refine their CI/CD strategies to remain competitive [21][20].

5) Summary: Traditional DevOps CI/CD pipelines form the foundation of modern software development practices, emphasizing automation, efficiency, and rapid delivery. These pipelines integrate core components of continuous integration, testing, and deployment, supported by various tools and technologies. This approach sets the stage for understanding how these principles are adapted in the context of machine learning operations.

B. Key Components of MLOps Pipelines

MLOps pipelines are essential for the effective deployment and management of machine learning models in production environments. They integrate various components to streamline the entire machine learning lifecycle, including data acquisition, model deployment, and monitoring. The primary components of MLOps pipelines are: data engineering, model development, CI, CT, CD, and governance. These components work in unison to ensure that machine learning models are scalable, reliable, and maintainable. While MLOps pipelines offer a structured approach to managing machine learning models, they encounter several challenges, such as talent shortages [25][41], interoperability issues [41], and regulatory compliance [23]. The success of MLOps hinges on its integration with business processes and adaptation to evolving industry standards [34]. Organizations must consider the interplay between technology, people, and processes to fully harness the potential of machine learning in driving business value [4].

1) Data engineering in MLOps: Data engineering is a vital aspect of MLOps, ensuring the smooth integration and operationalization of machine learning models. It systematically prepares and manages data, ensuring it is clean, consistent, and ready for model training. This includes automated processes for data cleaning, normalization, and transformation, which minimize manual intervention and errors [25]. Tools like Acumos and NiFi automate data pipelines, efficiently handling large datasets and ensuring continuous data updates for model training. Data engineering integrates into the machine learning pipeline, facilitating seamless data flow from ingestion to model deployment. This integration ensures the reproducibility and scalability of machine learning models. Modular pipelines and automated testing align data engineering processes with the overall MLOps framework, enabling continuous integration and delivery. Automation plays a significant role in MLOps data engineering. Tools like ALaaS implement automated workflows for data-centric AI tasks, reducing manual intervention and enhancing processing efficiency. Despite advancements, challenges persist in MLOps data engineering, including interoperability issues, regulatory compliance, and the need for continuous model training. Addressing these

challenges requires technical expertise and strategic planning [25]. Reusable MLOps frameworks, such as those offered by Acumos, provide solutions by enabling the reuse of existing infrastructure and deployment processes, thereby reducing the complexity and costs associated with data engineering tasks. Additional challenges include the need for continuous data updates and the integration of diverse data sources. The rapid evolution of machine learning technologies necessitates the ongoing adaptation of data engineering practices. However, organizations can overcome these challenges by leveraging automation and collaboration tools, achieving efficient and reliable data engineering processes.

2) Model development in MLOps: Within the MLOps framework, model development integrates DevOps principles to enhance machine learning processes. It promotes collaboration between data scientists and engineers, automates workflows, and ensures the continuous delivery of high-quality models [62][34]. CI/CD pipelines are vital in MLOps, enabling automated testing, validation, and deployment of models with minimal manual intervention [29][23]. Automation is a core aspect of MLOps, with tools and frameworks automating various stages of the model lifecycle, thereby reducing the time and effort needed to transition models from development to production [35]. Monitoring systems are essential for maintaining model performance in production environments, tracking predefined metrics to ensure models deliver accurate predictions and adapt to data changes [36].

3) Continuous integration in MLOps: CI is vital in MLOps, aiding the seamless integration of machine learning models into production environments. It automates testing and validation processes to ensure model quality prior to deployment. In MLOps, CI employs various tools, frameworks, and methodologies to optimize the machine learning lifecycle. Jenkins, an open-source CI tool, automates MLOps workflows by building pipelines for data analysis, preparation, training, testing, and deployment, thereby saving time and reducing manual effort for repetitive tasks [37]. Platforms like Kubeflow and MLflow offer end-to-end lifecycle management for ML applications, managing deployment pipelines and ensuring model version management and reproducibility [26][27]. ModelCI-e, a lightweight MLOps plugin, supports continuous integration and evolution by automating model updates and validation without requiring serving engine customization. It includes a model factory for prototyping and a backend for efficient orchestration of model updates [28]. CI pipelines in MLOps incorporate jobs to automatically train models and validate their performance, ensuring that only models meeting predefined quality standards are deployed, thus minimizing the risk of underperforming models [66]. Maintaining a centralized model registry and enforcing access controls are essential for managing model versioning and ensuring regulatory compliance, which are critical for scalable and robust MLOps pipelines [29]. Efficient resource management is imperative for CI in MLOps, as analyzing time and resource consumption in the ML pipeline helps identify potential performance bottlenecks, such as GPU (Graphics Processing Unit) utilization, which can impact CI process efficiency [27]. Addressing dynamic environments where online data diverges from offline training data presents a challenge, necessitating continuous learning and model updating techniques to maintain model relevance and performance [28]. While CI in MLOps offers benefits like enhanced model quality and reduced deployment time, it also presents challenges, including managing resource consumption and adapting to dynamic data environments. Addressing these challenges requires robust tools, efficient practices, and strategic planning for successful CI implementation.

4) Continuous testing in MLOps: CT is a crucial component of MLOps, ensuring the ongoing effectiveness and reliability of machine learning models in production. MLOps utilizes automated processes for retraining, deployment, and monitoring, enabling rapid iteration and adaptation to changing data and conditions [39][30][43][33]. MLOps pipelines, such as Continuous Training and Continuous Deployment-enabling (CTCD-e), automate model retraining and redeployment, triggering retraining when performance declines and conducting A/B testing to ensure optimal model functionality. CI and CD practices are tailored for ML workflows to facilitate efficient model updates, automating the entire lifecycle from data ingestion to deployment [29]. Systems like ModelCI-e support continual learning by automating model updates and validation [28]. Comprehensive monitoring mechanisms are essential for tracking model performance and detecting data drift, ensuring models remain accurate and reliable over time [29]. MLOps processes must incorporate operational feedback to continuously innovate and adapt models. While continuous testing in MLOps offers significant benefits, it also presents challenges. Automating various stages of the MLOps process requires robust infrastructure and tools. Ensuring model reproducibility and traceability is vital for maintaining trust and accountability [24]. Additionally, integrating MLOps with existing IT and operational systems can be complex. In conclusion, continuous testing in MLOps combines automated pipelines, continual learning, and robust monitoring systems. These practices ensure machine learning models remain effective in dynamic production environments. Implementing continuous testing requires addressing challenges related to automation, safety assurance, and system integration. Overcoming these challenges allows organizations to fully leverage MLOps benefits, enhancing the scalability, reliability, and productivity of their machine learning systems.

5) Continuous deployment in MLOps: CD within MLOps is vital for the efficient and reliable deployment of machine learning models into production environments. It automates the deployment pipeline, facilitating seamless updates and model integration, thereby enhancing operational efficiency and reducing time-to-market. Integrating CI and CD pipelines

is crucial for maintaining model performance in dynamic environments. Automation is a cornerstone of CD in MLOps, streamlining the entire lifecycle of ML models, from data ingestion to monitoring. Tools such as MLflow, Kubeflow, and Airflow manage deployment pipelines, ensuring consistent and efficient model deployment. Automated cycles convert code changes into container images, which are then deployed to production environments [31]. Comprehensive monitoring and observability mechanisms track model performance and detect drift, maintaining the trustworthiness of ML models in production. Predefined metrics ensure prediction quality throughout deployment, facilitating continuous improvement [32]. Continuous deployment in MLOps offers benefits like increased efficiency and reduced time-to-market, but it also presents challenges [41][23][29][26][4]. These challenges include managing dependency complexity and ensuring model reproducibility and traceability. Best practices for addressing these challenges involve maintaining a centralized model registry and enforcing access controls. Ensuring compliance with regulatory requirements is also crucial. Collaboration among data scientists, engineers, and business stakeholders fosters innovation and agility in model deployment.

6) Governance in MLOps: Governance is a cornerstone of MLOps, ensuring the responsible, ethical, and compliant deployment of machine learning models. It involves practices and policies that manage the lifecycle of ML models in accordance with organizational standards and regulatory requirements. Governance in MLOps is vital for maintaining model integrity, protecting data privacy, and building trust in AI systems. This section explores the key aspects of governance in MLOps: compliance, ethical considerations, and model management. Compliance in MLOps entails adhering to legal and regulatory frameworks, such as data protection laws and industry-specific standards. Organizations must establish access controls and audit trails to monitor model access and modifications, ensuring accountability and traceability [29][23]. A centralized model registry is crucial for tracking model versions and changes, facilitating audits and regulatory reporting [29]. Ethical considerations are a vital component of governance, emphasizing fairness, transparency, and accountability in machine learning models [25][38]. Governance frameworks should include guidelines for detecting and mitigating bias to prevent the perpetuation or exacerbation [38]. Transparency in model decision-making is essential, and organizations should implement explainable AI techniques to make model outputs understandable to stakeholders [38]. Effective governance requires comprehensive model management practices, including version control, performance monitoring, and drift detection [29][39]. Continuous monitoring of model performance is crucial for identifying issues like data drift or model degradation, enabling timely interventions [29]. Governance frameworks should also include policies for model retraining and updates to maintain relevance and effectiveness over time [39]. A significant challenge in MLOps governance is balancing innovation and compliance. Overly stringent governance can stifle creativity and delay model deployment [25]. Proposed solutions include implementing flexible governance frameworks and using automation to streamline processes [29][4]. Effective collaboration among data scientists, engineers, and compliance officers is crucial for developing practical and effective governance policies [23]. While essential, governance in MLOps faces additional challenges. The dynamic nature of AI technologies and the evolving regulatory landscape complicate compliance efforts. There is also a need for more standardized governance frameworks adaptable across various industries and use cases. Despite these challenges, effective governance remains fundamental to successful MLOps practices, enabling organizations to leverage AI responsibly and ethically.

7) Summary: MLOps CI/CD pipelines build upon traditional DevOps principles, tailoring them to the unique requirements of machine learning projects. These pipelines encompass data engineering, model development, CI/CD, and governance, addressing specific challenges in ML model production. The complexities and ethical considerations in MLOps highlight the need for specialized approaches in managing ML systems throughout their lifecycle.

IV. Challenges in Implementing Machine Learning Components Within Larger Applications

The integration of ML components into larger applications is becoming increasingly common, driven by the potential to enhance decision-making, automate processes, and deliver personalized experiences across various fields. However, this integration is not without its challenges. Technical complexities present significant hurdles, while organizational and cultural barriers further impede successful implementation. Addressing these issues necessitates a holistic approach to ensure the effective deployment and maintenance of ML components. This response examines the key challenges in integrating ML components and offers actionable strategies to overcome these obstacles. The insights presented are drawn from relevant literature in the field.

A. Technical Challenges in ML Integration

1) Model deployment and monitoring: The deployment and monitoring of ML models in production environments present significant technical challenges. Many organizations find it difficult to design architectures for production deployment and to integrate ML models into legacy systems [40][41]. Inadequate monitoring practices often result in poor tracking of models in production, leading to performance degradation over time [40][42]. To address these issues, [43] and [41] recommend implementing robust MLOps practices, which include: using version control systems for model versioning, employing containerization for consistent environments, and continuously monitoring model performance. Tools like Kubeflow can automate several processes, such as hyperparameter tuning, model deployment,

and maintenance. These automated processes reduce manual effort and enhance reliability [44].

2) Cross-Platform integration: The authors in [45] underscore a major technical hurdle: the integration of ML models across a range of platforms and technologies. These models are typically developed within specialized environments, and deploying them on new platforms such as Metal, Vulkan, or WebGPU demands considerable effort and customization. The authors suggest a solution through a top-down development approach, as demonstrated by TapML. This method streamlines the deployment of ML models across various platforms by utilizing automated testing and progressively transferring computations to the target platforms. This strategy effectively minimizes the need for extensive debugging and validation efforts.

3) Data quality and versioning: Ensuring data quality and versioning is essential for the success of ML models [46][47]. Inadequate data quality can result in models that are biased or inaccurate. Additionally, concept drift, which refers to changes in data distributions, can render models ineffective over time. To tackle these issues, experts advocate for thorough data preprocessing and versioning [41][47]. Incorporating data version control into the ML lifecycle is crucial for maintaining model effectiveness. Automated data validation pipelines are also vital in upholding data quality. These methods enable teams to monitor changes over time and ensure high-quality data inputs. By adopting these practices, organizations can enhance the reliability and longevity of their ML models.

4) Maintainability, scalability, and reliability: Microservices architecture enables the development of ML components as standalone services, which can be seamlessly integrated with other system components through well-defined application programming interfaces (APIs). This modular approach allows for the smooth incorporation of ML models into larger systems, facilitating updates or replacements without affecting other components [48][49]. By employing common communication protocols like Representational State Transfer (REST) over Hypertext Transfer Protocol (HTTP), microservices ensure interoperability among diverse components, even those developed in different programming languages or frameworks. This is particularly crucial for integrating ML models, which may require specific environments or dependencies [50][51]. Each microservice, including those for ML, can be developed, tested, and deployed independently, reducing the complexity of managing large codebases and allowing for more frequent updates and bug fixes, thereby enhancing maintainability [52][53]. Encapsulating ML models as microservices promotes code reusability and simplifies maintenance. Changes to a model or its underlying algorithms can be made without impacting other services, streamlining the maintenance process [48]. Microservices architecture supports the independent scaling of services based on demand. ML services, which often require significant computational resources, can be scaled independently of other system components, optimizing resource utilization and ensuring efficient handling of large data volumes [52][50]. The cloud-native nature of microservices allows for automated scaling and elasticity, essential for managing the variable workloads typical of ML applications. Moreover, the isolation of services ensures that failures in one service do not affect others, thereby enhancing system reliability [50][54].

While microservices architectures offer substantial advantages, they also present challenges, such as increased communication overhead and potential network delays due to the distributed nature of services. Ensuring data consistency and managing the complexity of service orchestration are critical considerations. Additionally, integrating ML models requires careful design to address issues related to model versioning and deployment pipelines [52][55]. Despite these challenges, the benefits of microservices in terms of scalability and maintainability make them a compelling choice for integrating ML components into complex systems.

B. Organizational Challenges in ML Integration

1) Collaboration between cross-functional teams: The authors in [56] contend that machine learning-powered systems require collaboration among data scientists, software engineers, and domain experts. However, effective teamwork often encounters challenges, such as disparities in technical expertise, ambiguous roles, and insufficient communication. To address these issues, the authors propose several solutions. First, they recommend establishing clear roles and responsibilities. Second, they suggest fostering a collaborative culture. Third, they advise utilizing communication tools to enhance teamwork. Additionally, the authors in [56] highlight the importance of concise system documentation, which can help bridge the gap between data scientists and software engineers, facilitating better understanding and cooperation.

2) Managing diverse tools and frameworks: The machine learning ecosystem encompasses a wide array of tools and frameworks [41][47]. This diversity can pose challenges in terms of integration and maintenance. Organizations often encounter significant obstacles in managing these tools while ensuring consistency across different environments. To tackle these issues, the authors in [41] and [57] advocate for the standardization of tools and frameworks whenever feasible. They also recommend employing platform-independent execution frameworks to minimize complexity. Furthermore, the implementation of automated pipelines for model training and deployment can help streamline workflows.

3) Integrating ML workflows with existing processes: Integrating ML workflows into existing software development processes poses considerable challenges, especially for organizations with legacy systems [43][41]. This integration is particularly complex when dealing with continuous CI/CD pipelines. To address these challenges, adopting MLOps practices can facilitate a more seamless integration. These practices align with DevOps principles and offer practical solutions. One key approach is the utilization of versioned

environments. Another effective strategy is the implementation of containerization. Both methods ensure consistency and reproducibility in ML workflows.

C. Cultural Challenges in ML Integration

1) Resistance to change: Resistance to adopting ML technologies is a prevalent cultural challenge. Many stakeholders remain skeptical about ML's value, while others hesitate to replace traditional methods with data-driven approaches [58]. Overcoming this resistance necessitates targeted educational efforts. Stakeholders must understand ML's benefits and recognize its practical value. Pilot projects can effectively demonstrate this, offering tangible evidence of ML's potential. Additionally, fostering a culture that encourages continuous learning and experimentation can support broader acceptance [41][58].

2) Skill gaps: Effectively integrating ML components often demands specialized expertise. Conventional software development teams may lack these skills, which can impede adoption and restrict collaboration between data scientists and engineers [41][47]. To bridge this gap, organizations should invest in upskilling initiatives. Promoting collaboration between data scientists and software engineers can also enhance integration efforts. Furthermore, cross-functional training and knowledge-sharing programs contribute to building more cohesive and capable teams [41][56].

3) Lack of shared understanding: A thorough understanding of ML concepts and their practical application is crucial for their successful integration into educational curricula. However, stakeholders often possess varying levels of comprehension, which can result in misaligned expectations [59]. Perspective-based approaches, such as PerSpecML, are instrumental in aligning these expectations. They ensure that all stakeholders have a clear understanding of the system's goals, user experience, and technical requirements [59]. Integrating ML components into broader applications presents complex challenges that span technical, organizational, and cultural domains. Overcoming these challenges requires more than just technical expertise; it also necessitates effective organizational strategies and intentional cultural adaptation. Organizations can tackle these issues by adopting MLOps frameworks, fostering cross-functional collaboration, and cultivating a shared understanding of ML principles. These efforts enable teams to navigate integration challenges and fully harness the benefits of machine learning. A summary of the challenges and corresponding solutions is provided in Table I.

TABLE I. KEY CHALLENGES AND SOLUTIONS IN ML INTEGRATION

Challenge	Description	Solution
Model Deployment	Difficulty in deploying models in production environments and integrating with legacy systems.	Implement MLOps practices, including version control, containerization, and continuous monitoring [43][40][41].
Cross-Platform Integration	Challenges in deploying models on diverse platforms like Metal, Vulkan, or WebGPU.	Use top-down development approaches like TapML for streamlined deployment [45].
Data Quality and Versioning	Poor data quality and concept drift leading to model degradation.	Implement data versioning and automated validation pipelines [41][47].
Maintainability, Scalability, and Reliability	Efficient updates, handling of increasing data and workload demands, and consistent delivery of accurate and dependable results.	Using a microservices architecture enables updates or replacements to be made without affecting other components [48][49].
Collaboration	Differences in expertise and unclear roles hindering teamwork.	Foster collaboration through clear roles, communication tools, and system documentation [56].
Tool Management	Managing diverse ML tools and frameworks.	Standardize tools and adopt automated pipelines for consistency [41][57].
Cultural Resistance	Stakeholder skepticism and resistance to ML adoption.	Educate stakeholders and build a culture of continuous learning [41][58].
Skill Gaps	Lack of specialized skills for ML implementation.	Invest in upskilling programs and cross-functional training [41][56].

V. EMERGING FRAMEWORKS AND METHODOLOGIES

The integration of ML into applications is facilitated by several emerging frameworks and methodologies, each offering unique advantages and challenges. These frameworks and methodologies streamline the ML lifecycle, enhance collaboration, and ensure the reliability and scalability of ML models. Table II presents the suitability of various approaches for ML integration within applications:

TABLE II. ML INTEGRATION FRAMEWORKS

Framework/Methodology	Description
CRISP-DM (Cross-Industry Standard Process for Data Mining) [24].	- Offers a structured approach to ML projects. - Focuses on business understanding, data preparation, modeling, evaluation, and deployment. - May lack agility and continuous integration features for modern ML applications. - Less suitable for dynamic environments requiring rapid iterations
DataOps [61].	- An agile methodology aimed at improving data analytics quality and reducing cycle time. - Emphasizes collaboration, automation, and monitoring. - Crucial for managing data pipelines in ML applications. - Can be integrated with MLOps to enhance data management and operational efficiency.
MLOps Frameworks [60] [62][63].	- Integrate ML, DevOps, and data engineering to automate and enhance the ML lifecycle. - Facilitate continuous integration, delivery, and monitoring. - Ensure model reliability and scalability. - Examples include Kubernetes-based open-source frameworks and proprietary solutions like Amazon SageMaker.

Framework/Methodology	Description
Agile ML [24]	- Applies agile principles to ML development. - Promotes iterative development and collaboration. - Advantageous in environments requiring rapid prototyping and frequent updates. - Enables teams to swiftly adapt to changes - May face challenges in maintaining model stability due to frequent changes.
Feature Stores [64][65]	- Centralized repositories for storing and managing ML features. - Facilitate feature reuse, consistency, and governance. - Crucial for scalable ML applications. - Enhance collaboration between data scientists and engineers.
Site Reliability Engineering (SRE) for ML Systems [64]	- Adapted to ensure the reliability and performance of ML systems. - Emphasizes monitoring, incident response, and performance optimization. - Critical for production-grade ML applications. - Can be integrated with MLOps to enhance robustness and trustworthiness.
Continuous Training (CT) ([24][66]	- Involves perpetual retraining of ML models to accommodate new data and evolving environments. - Crucial for applications with rapidly changing data. - Ensures models maintain accuracy and relevance. - Requires robust data pipelines and monitoring systems to manage model drift and performance degradation.

These frameworks and methodologies offer significant benefits for ML integration but also present challenges. For instance, integrating Agile ML and Continuous Training requires careful management to prevent model instability. The choice of framework or methodology should align with the specific needs and constraints of the application. Factors to consider include the need for rapid iteration and the importance of model reliability. Successful integration of ML into applications depends on selecting the right combination of frameworks and methodologies that best fit the project's goals and requirements.

VI. Security and Governance in ML Systems

Security and governance are crucial for building trust in ML systems. Protecting against adversarial attacks and data breaches is essential for reliability and acceptance, particularly in sensitive sectors like healthcare and finance [67][68]. ML systems are susceptible to adversarial attacks, where malicious inputs can deceive the model, compromising its integrity and reliability [69]. Safeguarding data privacy is vital, as unauthorized access and breaches can lead to the misuse of sensitive information [70]. The ethical use and accountability of ML systems are significant concerns, with governance frameworks playing a key role in ensuring ethical application and establishing accountability. This involves developing policies and standards for ethical deployment [71][72]. Additional concerns include model theft and intellectual property protection, as attackers may attempt to extract model parameters or replicate functionality, threatening intellectual property [69]. Developing comprehensive governance frameworks is challenging due to rapid technological advancements [71]. Integrating security into the ML lifecycle through Secure Machine Learning Operations (SecMLOps) can enhance system security and reliability by incorporating security measures from the design phase throughout the system's lifecycle [73]. Advanced security techniques, such as adversarial training, model hardening, and secure computing environments, can mitigate risks in ML workflows (Chittibala & Jabbireddy, 2024). Robust governance frameworks should promote transparency, accountability, and compliance with legal and ethical standards [71][72]. Effective management of the ML system lifecycle, including regular updates and patches, is crucial for maintaining security and functionality over time [72]. While security and governance are vital, potential trade-offs and challenges may arise. Stringent security measures could impact system performance and usability, and rapid technological advancement may outpace the development of governance frameworks, leading to regulatory gaps. Continuous research and adaptation of security and governance practices are essential to keep pace with the evolving ML landscape.

VII. Limitations of the Study

As a critical review, this study synthesizes existing literature rather than generating new empirical data. While this approach is effective for providing a comprehensive overview and identifying gaps, it relies on the quality and scope of the published research available at the time of writing. The findings are thus reflective of the current state of the art as documented in the literature. The review focuses specifically on the integration of ML into software engineering practices, with an emphasis on the evolution from DevOps to MLOps, challenges, and emerging solutions. While an effort was made to be comprehensive, the rapid evolution of ML technologies and software engineering practices means that some emerging trends or niche applications might not be fully captured. The generalizability of specific solutions may vary depending on organizational context, industry, and scale of ML implementation. Although a systematic approach was intended, the selection of literature for review might inherently carry some bias. The emphasis on certain frameworks, tools, or challenges could be influenced by their prominence in the academic and industry discourse, potentially underrepresenting less-documented but equally valid perspectives or solutions. The field of ML integration in software engineering is characterized by continuous innovation and rapid advancements. While the study aims to provide an up-to-date overview, new tools, practices, or challenges may emerge quickly, potentially altering the landscape described. This inherent dynamism means that any review, by its nature, offers a snapshot of a constantly moving target.

VIII. Conclusion

The integration of ML into software engineering practices has ushered in a new era of development and operational processes, fundamentally transforming how organizations approach their technological strategies. This shift from traditional DevOps to MLOps frameworks represents a significant leap forward, addressing the unique challenges posed by deploying and maintaining ML models in production

environments. As organizations increasingly leverage ML to gain competitive advantages, the importance of robust MLOps pipelines cannot be overstated.

The journey towards effective ML integration is marked by both opportunities and challenges. On one hand, ML offers unprecedented capabilities for data analysis, prediction, and automation. On the other hand, it introduces complexities in data management, model versioning, and continuous monitoring that demand sophisticated solutions. The emergence of frameworks like CRISP-DM, DataOps, and Agile ML provides potential pathways for organizations to navigate these challenges, offering structured approaches to streamline the ML lifecycle.

Looking forward, the field of ML integration in software engineering is poised for rapid evolution. As organizations grapple with the intricacies of deploying large language models (LLMs) and other advanced ML systems, new strategies are emerging to address computational demands, integration complexities, and ethical concerns. The development of more sophisticated MLOps frameworks, coupled with advancements in model interpretability and security measures, will be crucial in shaping the future landscape of ML-driven software engineering.

The success of ML integration will ultimately hinge on an organization's ability to adopt a holistic approach that encompasses technical, organizational, and cultural dimensions. This includes fostering cross-team collaboration, implementing robust governance frameworks, and maintaining a commitment to ethical AI practices. As the field continues to advance, organizations must remain adaptable, investing in continuous learning and skill development to stay ahead of the curve.

In essence, the integration of ML into software engineering practices represents both a challenge and an opportunity for innovation. By embracing flexible, integrated frameworks and maintaining a focus on security, governance, and ethical considerations, organizations can harness the full potential of ML to drive technological progress and business success in an increasingly data-driven world.

Bridging Machine-Readable Code of Regulations and its Application on Generative AI: A Survey

Samira Yeasmin, Bader Alshemaimri
Software Engineering Department, King Saud University, Riyadh, Saudi Arabia

***Abstract*—Machine-Readable Code (MRC) and Machine-Readable Regulations (MRR) enable the conversion of complex regulations into structured formats such as JSON, XML, and X2RL, allowing machines to parse and interpret regulatory texts efficiently. Currently, organizations face challenges in regulatory compliance due to the complexity of regulations, frequent updates, and difficulty in identifying changes that impact policies and procedures. Existing literature provides guidance to a certain extent on how to anticipate regulatory modifications or ensure timely compliance. This review examines current literature on applying machine learning (ML) and Generative AI (GenAI) to extract, structure, and interpret regulatory content. It surveys techniques for converting regulations into machine-readable formats, predicting regulatory changes, and assessing alignment with real-world modifications issued by regulatory bodies. The findings indicate that using MRC, MRR, and AI enables automated compliance checks, faster detection of violations or errors, standardized compliance processes, real-time monitoring, and automatic report generation. These approaches can significantly enhance regulatory adherence across industries, particularly in sectors such as finance, where compliance is critical.**

***Keywords*—Regulatory compliance; natural language processing; machine learning; machine-readable code; Machine-Readable Regulations; generative AI; large language models; RegTech; conflicting regulations; regulation issuance**

I. Introduction

While regulations are an essential part of modern society, it is important to follow the process of regulatory change management. Regulations help to protect people and the environment, but they can be complex and difficult to understand. The complexity of regulations makes it challenging for businesses and individuals to comply with; therefore, recent studies have shown a vast amount of contribution to this field of science, as discussed in section 4. One way of ensuring regulatory compliance is to convert the regulations into machine-readable code (MRC) that can be easily understood and processed by computers.

Once converted, they can be used to train Large Language Models (LLMs) to understand and respond to them. LLMs work with massive amounts of text data and have the capability to understand and generate human language. On the basis of a given input, it has the ability to predict the likelihood of word sequences or generate new text. The larger the dataset to train this neural network, the more accurate the outcomes will be. It can be trained on large datasets of text, such as laws, regulations, and other legal documents. Given the capabilities of LLMs, an AI tool can be developed to highlight similarities between new policies and outdated regulations to help people understand the areas of change. The tool could also be used to identify the entity or organization that issued each regulation, which can help understand the context of the regulation and its applicability to a particular situation. This can allow the regulatory industry to check for compliance with regulations automatically.

Developing a tool based on fine-tuned LLMs to highlight similarities between regulations and updated policies to identify areas of change for the issuing entity or organization is a challenging task, but it has the potential to be a valuable tool for businesses and individuals who need to comply with regulations. Given that the process of regulatory change management requires a significant amount of time because of the complexity of the regulations, the long regulations, and the amount of text that requires investigation to identify change requires a significant amount of manual work and effort. A generative AI can generate new and meaningful content, including text, images, and audio, based on a huge amount of training data. With that being said and noting the capabilities of GenAI, a GenAI-based tool can make a significant impact on regulatory change management, contributing to reducing the time and effort needed to update the regulations and make the process more efficient.

Regulation complexity and understanding it are a crucial problem, as evident in the Global Financial Crisis in 2008 [1]. RegTech has since been introduced. However, RegTech alone is insufficient to ensure that regulations are followed and implemented correctly. Moreover, to ensure that regulations are applied in the respective industries with full implementation, it is important to identify all regulations and legislation in the entities that are updated to match the regulatory bodies.

While LLMs are being used in several different industries, they hold an important position in making a great impact on regulatory change management, contributing to reducing the time it takes to update policies and identifying outdated regulations to ensure compliance with current standards and regulations for organizations. As mentioned above, firms must update their policies every year, with a significant amount of time invested in this process. An AI model to complete the same task will help immensely, not only in highlighting outdated sections of the regulations but also in reducing the time and effort it takes to reflect the updates.

It is important to mention that, as the main sources, IEEE, ACM, ScienceDirect, and SpringerLink were chosen. When looking for primary studies, backwards snowballing was used

to find and scan the references of articles that were relevant to the research.

With RegTech and the emerging implications of machine learning, such as generative AI and Machine-Readable Regulations, in the world of legislation and legality, this study focuses on a thorough analysis of Machine-Readable Regulations and their application to machine learning as well as natural language processing, with a focus on generative AI.

This study is structured as follows: Section II describes the objective and contribution of the study in this field of regulatory change management and the significance and potential of ML models, followed by Section III, which focuses on the background study of regulations and compliance and discusses the challenges in interpreting them. It also presents different techniques that have been implemented to convert complex regulations into machine-readable code. Section IV describes in detail the current implications of machine-readable codes of regulations and their benefits and challenges industry-wise. Different techniques for extracting Machine-Readable Regulations and applications of machine-readable codes of regulations are presented in Section V and Section VI. Finally, Section VII presents the conclusion of the survey analysis, and Section VIII discusses the challenges and future directions of machine-readable codes of regulations, offering a guide to researchers.

II. Objectives and Contribution

Regulations are significant business processes that every business and individual must follow to be compliant with regulatory bodies. Regulations and legislative laws can be difficult to understand, although they are written in human language. Not every individual can understand the legal terms and conditions and, therefore, might face difficulty in following them. Again, businesses must be compliant with regulatory bodies to ensure firms are following the changes and updates required to protect rights and the environment and be accountable for their actions. While it takes a significant amount of time to understand the regulations, find duplicates or changes in regulations and update internal policies accordingly, firms and businesses hire many compliance and legal experts to manage these mountains of regulatory data. Therefore, it becomes crucial to automate this time-consuming task. Converting the regulations and legislative laws written in natural language into MRC to identify hidden patterns and duplicates to highlight conflicting regulations can accelerate digitization. ML's influence can play a significant role in reshaping risk and compliance management. An AI model based on fine-tuned LLMs that can highlight and identify hidden patterns and duplicates in conflicting regulations to underline changes and allow businesses and individuals to be up to date with policies can be valuable implementation in the regulatory industry.

This study aims to identify and study existing and emerging ML models to achieve the following objectives:

- Anticipate studying the hidden patterns between the regulatory changes and the outdated policies where changes must be applied.
- Dig deep into the historical patterns to forecast/predict future changes in regulatory compliance with the use of ML models.
- Study the implementation of machine learning to correctly identify the prediction of regulatory changes and correlate them with the actual changes applied by the regulatory bodies.
- Investigate the correlation between the regulatory changes and the impact on the businesses and individuals who must be compliant with the regulations and legislative laws.

III. Background

A. Regulations and Compliance

Regulations are significant business processes that every business and individual must follow to comply with regulatory bodies. Regulations and legislative laws can be difficult to understand, although they are written in human language. Not every individual can understand the legal terms and conditions and, therefore, might face difficulty in following them. Again, businesses must be compliant with regulatory bodies to ensure that firms are following the changes and updates required to protect rights and the environment, and be accountable for the actions that they perform. While it takes a significant amount of time to understand the regulations, find duplicates or changes in regulations, and update internal policies accordingly, firms and businesses hire many compliance and legal experts to manage these mountains of regulatory data. Therefore, it becomes crucial to automate this time-consuming task. Converting regulations and legislative laws written in natural language into MRC to identify hidden patterns and duplicates to highlight conflicting regulations can accelerate digitization. ML influence can play a significant role in reshaping risk and compliance management.

Aligning with national or international regulatory bodies in respective jurisdictions or industries is regulatory compliance. These regulations are internal and involve processes and procedures aimed at streamlining internal business requirements. These regulations not only help in internal processes but also ensure adherence to laws, regulations, guidelines, and specifications relevant to the respective industries. Some examples of regulatory compliance include the Payment Card Industry Data Security Standard (PCI DSS), the Health Insurance Portability and Accountability Act (HIPAA), the Federal Information Security Management Act (FISMA), the Sarbanes-Oxley Act (SOX), the EU's General Data Protection Regulation (GDPR) and the California Consumer Privacy Act (CCPA). As the number of rules increases and the techniques for breaching them increase, many new laws and regulations are developed and introduced so that violations and fraud can be lessened. That said, firms or businesses must also update their old and new regulations and policies when a new law or regulation is passed. This is a manual process that requires the regulatory change management process to be streamlined. Regulatory change management ensures that firms comply with the changes made by the regulatory bodies in the regulations. This activity includes keeping up with the regulatory content,

understanding all the regulations that apply to them, finding out what policies to update and how, etc. This is a complex and time-consuming task for which financial technology (fintech) and financial institutions (FIs) hire many compliance/legal experts to manage mountains of regulatory data.

Regulatory Technology (RegTech) is a technological solution for regulatory compliance and regulations. The main objective of RegTech is to improve regulatory processes. It helps with preparing reports on new and old regulations. One of the objectives of RegTech is to reduce the amount of work completed for manual reporting and to digitize the process. In addition, RegTech helps with risk assessment, identity management and control, transaction monitoring, and fraud prevention, such as money laundering. Furthermore, they address risk assessment [2], [4]–[6]. These are some of the activities that are conducted to ensure regulatory compliance. RegTech aims not to change the industry in which it is implemented but rather to ease the process of regulatory compliance by helping large institutions with the regulatory burden, compliance, and sudden or enormous changes in regulations, and keeping the policies up to date. Regulations usually operate under constant uncertainty, and it becomes more difficult to identify what should be updated to ensure regulatory compliance. This is where RegTech plays a role. FinTech and FIs have started using RegTech to allow themselves to comply with the regulations of regulatory bodies. However, to accelerate digitization, human involvement and interference in RegTech must be minimized, especially in regard to managing regulatory changes.

B. Challenges in Interpreting and Complying with Regulations

As mentioned above, a significant problem lies in regard to regulation complexity and accurately understanding it. As evident in the Global Financial Crisis in 2008 [1], the complexity of regulations played a vital role in the crisis. RegTech has since been introduced. However, RegTech alone is insufficient to ensure that regulations are followed and implemented correctly. Moreover, to ensure that regulations are applied in the respective industries with full implementation, it is important to identify all regulations and legislation in the entities that are updated to match the regulatory bodies.

Along with understanding the regulations, identifying the changes being made to the regulations so that the internal policies can be updated is highly important. This part of managing regulatory changes allows firms to comply with the changes made by regulatory bodies. There are several activities related to this, including understanding the regulatory content, identifying the changes, and determining what internal policies must be updated. For a human, this is a complex and time-consuming task. Firms usually hire many compliance and legal experts to manage mountains of regulatory data, which also becomes an expensive cost.

The number of regulatory changes taking place in organizations is surprisingly large. According to a case study published by iBM [2], the U.S. Code of Federal Regulations (CFRs) contains more than 174,000 pages. It is as long as 25 miles long if printed. The amount of regulatory change has tripled in the last five years, the case study from iBM claims, which was conducted in 2021. This can be a resource-intensive task to understand the complex regulations and take a significant amount of time to reflect on the updates. As a rule, policies should be updated every 13 years [3], [7]. Moreover, high-risk industries such as healthcare, public safety, and financial services are advised to update their regulations more frequently [7], [8]. The time required to update policies depends on multiple factors, including the complexity of the regulations, the scope of the changes needed, the size of the organization, and the number of stakeholders involved. Regular review and updates of regulations are essential to ensure compliance, effectiveness, and alignment with the evolving needs of the business and the external environment.

The potential risks of not updating outdated regulations are significant and can impact various aspects of an organization. It can lead to noncompliance with current standards and regulations [9], [10], security vulnerabilities [11], increased operational costs [9], a lack of clarity and consistency [11], obsolete technology and manual workarounds.

Large Language Models (LLMs) can be used to identify similarities between outdated regulations and highlight the changes needed to match new regulations published by regulatory bodies. This process involves comparing the language and content of old and new regulations and understanding the implications of these changes for various stakeholders. LLMs can play a crucial role in identifying similarities between outdated regulations and highlighting the changes needed to match new regulations published by regulatory bodies. This can help ensure that regulatory compliance processes remain accurate and efficient in the face of rapid technological advancements and changes in regulatory landscapes.

While LLMs are used in several different industries, they hold a prominent position in making a great impact on regulatory change management, contributing to reducing the time it takes to update policies and identifying outdated regulations to ensure compliance with current standards and regulations for organizations. As mentioned above, firms must update their policies every year, with a significant amount of time invested in this process. An AI tool to complete the same task will help immensely, not only in highlighting outdated sections of the regulations but also in reducing the time and effort it takes to reflect the updates.

C. Machine-Readable Data

While machine learning has shown numerous applications in several different industries, RegTech is no different. Businesses and individuals have started using RegTech to allow themselves to comply with the regulations of regulatory bodies. However, to accelerate digitization, human involvement and interference in RegTech must be minimized, especially in regard to managing regulatory changes. It is extremely important to comply with these regulations to speed up the unprecedented customer traffic channeled by businesses. To ensure due diligence, review of customers/businesses (KYC/KYB) and be on top of AML

regulations, businesses and individuals, especially fintech and FIs, are required to conduct periodic checks to establish preventive measures against cyber fraud, money laundering, or terrorist financing activities. This is a complex and time-consuming task for which businesses hire many compliance/legal experts to manage mountains of regulatory data. The influence of ML can play a significant role in reshaping risk and compliance management to accelerate digitization. In addition, regulations can be challenging to understand. Converting them into MRCs and allowing LLMs to be trained and finetuned to achieve a specific specialization can ease the task of complying with regulations. The significant changes in the regulations must be reflected in internal policies for businesses and individuals to follow. It is necessary to ensure consistent governance with regulations.

1) Machine Readable Regulations (MRR): The ability of machines to parse legal documents is what Machine-Readable Regulations are capable of doing. MRR allows access to legal documents and regulations in a machine-readable format. Usually, regulations and policies are drafted and published in digital format, which is easily accessible for humans but not for machines. Machines cannot access legal documents published in digital format. Therefore, it is essential to structure them in a correct form that is accessible to machines, such as XML [1]. In addition, machine-accessible legal documents predefine special delimiters identifying different parts of the document. The term that can be used here is Machine Readable Format (MRF) for documents accessible in this structure, which XML offers. XML can be used to structure any content, not only legal documents. Other examples include the United States Legislative Markup (USLM) used in the US only and the UN's Akoma Ntoso MRF, which can be considered an international MRF [1].

2) Semantic Machine-Readable Regulations (SMRR): MRR focuses on the structure and accessibility of legal documents, which makes the content readable to machines. However, it is important to understand the meaning of the content that Semantic Machine-Readable Regulations (SMRR) allows. The main focus of SMRR is to have semantics for the structured content to make it useful and semantically machine-readable. This semantics produces internal and external insights. Internal insight allows us to understand various possible meanings of the content itself. However, external insight explains the relationship between the provisions of the document and its corpus. These insights provide metadata that machines can access. X2RL and JSON formats are examples of SMRR formats [1].

3) Machine-Executable Regulations (MER) and Machine-Consumable Regulations (MCR): While ensuring that machines have access to regulations is important, it is also important to carry out functions using these metadata. Functions include generating compliance reports, monitoring, and updating regulations. Codifying legal documents is one of the means of achieving the function offered by Machine-Executable Regulations (MER) and Machine-Consumable Regulations (MCR). The codification allows the underlying meaning of the regulations to be converted into a code that machines can execute. Regulations or legislation can be Boolean logic or conditional statements that can be executed with one or several lines of code. MERs and MCRs are extensions of SMRRs. Unlike SMRRs, MERs and MCRs do not produce metadata, but they execute MCR content [1].

4) Rules as Code (RaC)/Legislation as Code (LaC): MRR, SMRR, and MER/MCR are concepts and traits of Rules as Code (RaC) [equally Legislation as Code (LaC)]. The main difference between the previously explained concepts and RaC is integrability. Breaking down the legal corpus into basic legal items and encoding them into basic modules are the first steps of RaC. These modules then accept structured input and produce structured output. The RaC document integrates the set of modules in a constructed document, ensuring that there are no repetitions of legal concepts that can be possible in MER/MCR, since they codify legal concepts only without considering coding repetition, such that some legal items that are common across documents are coded several times separately [1].

D. Generative AI (GenAI)

GenAI is a type of AI that can create new content, such as text, images, and music. It can be used to generate realistic synthetic data, which can be used to train other AI models or to generate new products and services. In the context of regulatory compliance, GenAI could be used to generate realistic synthetic datasets of regulations, which could be used to train AI models to identify conflicting regulations and gaps in regulations. On the basis of several types of inputs, Generative AI (GenAI) creates new content. This content can include text, images, sounds, animations, 3D models, etc. GenAI uses Neural Networks (NN) to identify hidden patterns and structures within any type of data and generate new content. The training of GenAI is not bound to any one of the unsupervised or semi-supervised learning approaches. However, it can be learned and trained in any way. Therefore, organizations can leverage GenAI's features, as it allows them to create foundation models because of the large amounts of unlabeled data. Given that foundation models can be versatile, they are AI-based systems or services whose usage is decided in which industry it is implemented. Some examples of GenAI include GPT-3 and Stable Diffusion [12].

There are five algorithms that provide the framework to develop the GenAI system [13].

1) Overview of generative AI techniques

a) Autoencoders: Autoencoders are a type of neural network that does not require training with prelabeled data [14]. The main use of autoencoders is to compress high-dimensional data into lower-dimensional data. This is called a latent space. The encoder and encoder components are jointly trained. However, because of the low feasibility of AE designs, the change in the latent variables is not high. This is where the Variational Autoencoder (VAE) is introduced, allowing more constraints to be added to latent variables for the desired distribution. While VAEs recognize problems with low feasibility, they produce blurry outputs [13].

b) Generative Adversarial Networks (GAN): A GAN is a deep learning architecture that trains two neural networks to produce authentic data from a given training dataset [15]. The two different networks compete with each other. One network modifies the input data sample as much as possible to produce new data. The other network predicts whether the generated new data belongs to the original input data. The system continues generating new and improved versions of data until it is no longer related to the original input data.

c) Autoregressive model: With the exceptional capability of density estimation, Autoregressive Models sequentially predict each variable component on the basis of prior elements [16]. The performance is affected by the slower processing of a high volume of data. One of the advancements of autoregressive models is the integration of self-attention mechanisms, especially transformer models. This allows parallel processing and selective focus on sequence elements.

d) Diffusion and flow-based model: Differences in operational mechanism, diffusion, and flow-based models are quite similar and often grouped. Diffusion models add noise to data and conduct reverse engineering for data reconstruction [16]. It consists of forward and backward diffusion processes where forward noise is introduced and backward diffusion diminishes this noise. Furthermore, flow-based models leverage normalizing flow to generate a probability distribution between the data and the latent space. This is particularly useful for density estimation.

e) Foundation model (FM): FMs are foundational models that are trained on vast amounts of data and can produce highly accurate and diverse outputs [16]. This can range from images to texts to complex simulations. They can generate very specific tasks on the basis of limited datasets for improved performance. Some examples include image and text generation, multimodal models, and reinforcement learning models.

IV. Machine-Readable Code of Regulations (MCR)

Machine-readable code (MCR) has become a booming field of research in which the focus is mainly centered on how any text can be converted in such a way that it can be easily understood, processed, and parsed by a computer. In regard to MCRs, one area that has gained the attention of regulators is the use of MCRs in regulations. It becomes quite difficult for industries such as FinTech, Financial Institutes, Healthcare, etc., to keep up with the updates and changes in regulations by regulatory bodies and ensure that they are compliant with all the policies and procedures. Machine learning (ML) can help computers process these regulations and make this tedious task easier for the respective compliance departments of different industries.

Machine learning (ML) can add significant value to the regulatory industry in regard to abiding by regulations and ensuring that other businesses and individuals are compliant with existing and new regulations. For example, programs using ML algorithms are already being implemented in the field to detect fraud and anti-money laundering activities or monitor transactions in the financial industry [17]. The ML is trained such that it can read Machine Readable Code (MRC), which has been encoded from the natural language [17]. Furthermore, converting regulations written in natural language is one of the main activities allowing an ML to be trained on this data to support regulatory compliance. Researchers have suggested and offered different approaches to convert natural language into MRC. Some of the prominent forms of machine-readable formats for regulatory documents are XML, JSON and X2RL. The process of converting to a machine-readable format is important to extract the correct meaning of the regulations, which might sometimes follow inconsistent language. In [18], the authors introduced a new machine-readable format and developed X2RL to enhance the semantic representation of regulatory information. The study shows that X2RL helps in enabling a more granular and precise representation of regulatory documents and capturing the underlying semantics. It also discusses how semantic representation can aid in automated interpretation and analysis of regulations, which is a requirement for the use of ML algorithms for regulations. Moreover, [19] introduces a "legislative recipe" as the idea of a structured syntax designed to represent legislative texts in a machine-readable format. This design includes provisions, definitions, and references that enable precise and standardized representation of the legislative components. It also accommodates the semantic annotation and hierarchical nature of the regulations. In a previous paper [20], the authors described the foundational concept of the JSON schema and how it can be a tool for describing and validating the structure of JSON data. It helps specify the structure, constraints, and validation rules for JSON documents, which leads to the validation of common types of strings, numbers, and booleans. In [12], the authors aims to improve the encoding of copyright legislation into machine-executable code. To ensure accuracy in "Rules as Code", it is important to involve legally trained individuals. This study revealed that collaborative agreement on key legal terms leads to better-encoded rules. However, different interpretive choices can still occur due to complexities in statutory interpretation and coding language functionality. The authors suggest separating technical validation and legal alignment processes to improve accuracy. The authors used Defeasible Deontic Logic (DDL) and Turnip to convert selected provisions of the Copyright Act into machine-executable code. Furthermore, [21] discussed the inherent complexity of regulatory texts, which are often filled with legal jargon, ambiguities, and references to other regulations. They emphasize the challenges this complexity poses for both human understanding and machine automation. The authors delve into how natural language processing (NLP) and machine learning techniques can be employed to interpret regulatory texts. The authors further emphasized the point that rulemaking allows the automation of compliance, reporting, and enforcement processes with the help of ML technologies.

The research field is booming with several different types of approaches to achieve the goal of an efficient and faster process of converting regulations into MRCs. While it is challenging to convert natural language into machine-readable code, several machine-learning algorithms or techniques have been developed to aid in MRC. The task of converting into MRC falls under the domain of Natural Language Processing

(NLP) and Natural Language Understanding (NLU). Several machine learning algorithms and techniques can be employed for this purpose, including Recurrent Neural Networks (RNNs) [22], Transformer Models [23], Seq2Seq Models [24], Graph Neural Networks (GNNs) [25], and Large Language Models (LLMs) [26]. The authors of [22] reported that an RNN can be used to recognize written text and convert it into MRC. They used the fundamentals of Long Short Term Memory (LSTM) to capture the long-range sequence of handwritten elements to identify noise in handwritten data and segments, and isolate it into individual characters. This study also presents the implementation of Seq2Seq models where the input is the sequence of handwritten texts and produces corresponding text sequences, but with MRC as the output. Moreover, [23] highlighted the importance of an ML technique in understanding software code and generating related and useful comments for specific code snippets. If an ML technique can convert an MRC into natural language, it is an opportunity for researchers to leverage the benefits of these MLs and produce state-of-the-art results in natural language understanding for the MLs. The main goal and result of the study [23] was to use semantic parsing in the context of programming languages and extract meaningful information from code. The authors presented the "Setransformer" architecture, which was specifically designed for the semantic parsing of code. Leveraging transformer models to capture both the structural and semantic information within the code helps in generating code comments in human-like language. The authors of the paper [24] presented a thorough analysis of how the GNN can be leveraged for natural language processing. Exploring different ways of representing natural language, such as graphs, dependency trees, co-occurrence graphs, and knowledge graphs, this study highlights the advantages of using graph-based representations for capturing semantic relationships in language. The survey covered a wide range of NLP tasks where the GNN has been applied, such as sentiment analysis, named entity recognition (NER), relation extraction, question answering, knowledge graph completion, language modelling, and semantic role labelling.

In practice, recent studies have discussed the significance of machine learning (ML) in regulatory change management, particularly in the context of converting regulations into Machine Readable Code (MRC). The implementation of ML algorithms in regulatory industries, such as fraud detection and anti-money laundering, is highlighted. ML models are trained to read MRCs encoded from natural language regulations. There are various approaches for machine-readable formats, including XML, JSON, and X2RL. The complexity of regulatory texts, filled with legal jargon and ambiguities, is acknowledged, and the use of natural language processing (NLP) and machine learning techniques for interpretation is discussed.

A. Objectives and Benefits of Adopting MRCs

1) Efficiency Improvement: The automated extraction of key information from regulatory documents saves time and effort for the compliance department, which is engaged in human interpretation, to identify the meaning of the information, diving deep into the regulations and applying them to the workplace. This makes the compliance process more efficient. As mentioned in [27], a significant amount of time is spent on understanding and identifying areas of change in regulatory policies. Given that MRC can read and process regulations without the involvement of a human resource, it not only saves time but also makes it easier for humans to interpret regulations and understand complex clauses, which must be updated every one to three years [3], [7].

2) Accuracy enhancement: Legally trained individuals are required to ensure the accuracy of policies and regulatory documents. Additionally, each individual interprets the policies in different interpretive choices, which creates statutory interpretation and coding language functionality. The authors [21] suggested that NLP can increase accuracy and eliminate the complexity of understanding regulations by converting them to MRCs. The authors further emphasized the point that rulemaking allows the automation of compliance, reporting, and enforcement processes with the help of ML technologies. The MRC helps minimize the risk of human error, ensuring that compliance activities are executed accurately and in strict accordance with regulatory requirements.

3) Real-time monitoring and adherence: MRC enables monitoring of regulatory changes and allows identification of the areas where the changes have been reflected. The objective of this ability of MRC is to create consistency between the policies implemented in the respective fields and ensure adherence to the regulatory updates by the regulatory bodies. This allows us to adapt to modifications to regulations and maintain adherence.

4) Standardization of compliance processes: A uniform approach is required to be compliant with various jurisdictions and sectors in which the respective compliance department individuals invest their resources, effort, and time. MRC promotes the use of standardized formats and structures for regulations, making it easier to create and understand complex regulations.

5) Automation of reporting: With MRC, an automated process of reporting can be introduced by offering a standardized compliance process, identifying accurate data, and interpreting regulations via MRC. Reporting requires a significant amount of data analysis to abide by regulations accurately. The MRC can ensure adherence to regulations and policies reflecting compliance reporting.

B. Evolution of Machine-Readable Regulations (MRRs) and Current Development [1]

Access to data, meaning that converting data in a standardized form that computers can process, is one of the cornerstones and requirements of MCRs. Computers with the ability to parse legislative content and regulations are quite challenging. Usually, regulations are written in electronic formats, such as MS Word and PDF, which are easy for the human eye to read but not easy for machines to process and identify the meaning of the regulations. To address the challenges of machines being able to access legal content, the

MRR was formed. The readability of regulations for machines is affected by the structure of the regulations or the legal contents. This means that the format of the content must be in a way that helps to discern the components so that the identification of the components is similar to how a human does. This structure is referred to as Machine Readable Format (MRF), and one example of such a format is XML. It can be used to structure any content, not only legalese or regulations. MRF is the first of its kind that helps in transforming legal content into a form that can be processed and parsed by machines. This is an essential step toward RaC. While MRR focuses on the structure of regulatory documents, SMRR focuses on the enrichment of texts as well. The process of SMRR includes the injection of semantics in the machine-readable structure in the form of metadata. This is similar to how a human interprets a document and drafts the semantics. To further improve the process, codification has been added to the process of parsing regulations by machines. MER and MCR allow converting the documents into Boolean logic and further converting it to computer code, which is called codification. To conduct the process of codification, the text must be structured and enriched, which is also part of the MER and MCR. To ensure the integrability of the documents, the document is broken into a corpus that consists of basic rules and modules. These different modules are then converted into machine-readable code, ensuring that the same meaning of different modules is not repeated during the parsing process. This process is called RaC and LaC.

C. Common Standards and Machine-Readable Formats

1) JavaScript Object Notation (JSON): The JSON schema provides a standardized schema language for JSON documents [20]. It allows developers to specify the structure of JSON documents, constrain their content, and verify the integrity of requests and responses in APIs. The JSON schema is used for various purposes, including data validation, document-oriented databases, automated document generation, and schema validation tools. JSON is commonly used as a machine-readable format since it is lightweight and easy to parse for machines. It is ideal for transmitting data between systems.

2) XML: XML is one of the most prominent machine-readable formats [1], [18]. The US's regulations, named the United States Legislative Markup (USLM), and the internationally recognized regulation, called the UN's Akoma Ntoso, are XML-based. These XML-based regulations contain a hierarchy of tags and attributes. It helps improve the internal structure of the legal document rather than the content. They sufficiently lack the developed methods of connecting the bodies of legal documents in a machine-readable way. This helps reduce the management cost of legal documents; however, the main goal is to minimize the economic cost of legislation for those who must comply with the body of the regulations.

3) eXtensible Regulatory Reporting Language (X2RL): Authors in [18] proposed a new machine-readable format that, along with having tags and attributes such as XML, has additional new attributes, tags, and models designed to enrich the metadata of the legal document's content. According to the authors, X2RL helps in processing the legal content, intent, scope, and meaning of the legislation and regulations. In addition, it identifies the depth of the external structure of the documents to link multiple documents together, which reduces the economic cost and allows efficient data interchange. The authors introduced <**provision**> as the basic container for any document fragment. Strengthening the external structure of the legislation and expanding the ontology to include new elements to be able to describe the legal contents in detail are two more goals X2RL achieves.

4) YAML Ain't Markup Language (YAML): YAML is also a markup language used to provide a structure for data [28]. Like JSON, YAML stores data in a human-readable format by providing serialization and offering text marking. YAML can be used in place of JSON since it is now a subset of JSON. Supporting scalar datatypes such as lists and arrays, it stores data in a text file.

5) Resource Description Framework (RDF): RDF is mainly used to convert data on the web in a machine-readable format [29]. In RDF, information is represented in the form of triples, which consist of subject-predicate-object statements. The subject and object represent resources, whereas the predicate indicates the relationship between them. Facilitating data integration and interoperability, RDF is commonly used to create linked data.

6) Web Ontology Language (OWL): Like RDF, OWL is used for data on the web. It represents domain knowledge via classes, properties, axioms, and instances for use in a distributed environment [30]. Representing a semantic representation of domain knowledge, OWL supports efficient reasoning and expressive power. The authors of [31] proposed a new method of generating OWL ontologies from XML data sources to highlight how XML data can be extracted to represent domain knowledge in OWL format.

D. MRR Use Cases

Converting legal content and regulations into machine-readable language has made strides in the RegTech industry. It is a transformative movement for the global regulatory community to ease the complexity of regulations, legislation, and policies, allowing entities to assist in complying with new regulations and drafting or updating old legislation and policies. RegTech can be further improved with the essence of MRR so that machines can analyze legal content to parse the content itself. The following are some of the use cases that are framed by MRRs and offer improvements in the regulatory industry.

1) Committed to regulations: MRR adaptation is effective and can be an efficient way of ensuring that an entity is committed to following regulations. Regulators can easily identify if entities are misinterpreting regulations and making erroneous decisions. MRR allows entities to refrain from making any judgment errors. It improves the quality of compliance. An MRR implementation helps in the use of machine learning algorithms to study the regulations and

determine whether they are correctly implemented and followed within the organization.

2) Regulations updates: MRR does not merely translate the regulations into machine-readable language but also creates the opportunity to use machine learning algorithms to identify the updates in regulatory bodies and how existing regulatory policies must be updated. It helps highlight outdated rules and update them with new implementations. Financial institutes can prepare MRR-based handbooks and search places where humans and machines can search for specific rules and regulations. MRR can also help in identifying duplicate policies within an organization and enhancing them by removing duplicates and replacing them with the correct format. This signifies and symbolizes the movement of machine-analyzable legal content and the process of generating legal documents.

3) Implementation of principle-based regulations: To facilitate measurements of the competency of licensing requirements for financial institutes and ensure that they meet supervisory expectations, following regulations is important. MRR allows the implementation of regulations to meet the requirements of the regulatory body by aggregating relevant documents for analysis and comparing them with what is being followed within the organization/entity. A principle-based regulation requires a greater level of understanding by machines, which is needed for the compliance of financial institutions with regulatory bodies. An extensive MRR adaptation in the financial sector to meet licensing requirements is a significant and effective approach.

4) Financial reporting: With the help of MRR, the reporting process can be much more efficient and faster. Using technology, the current reporting process can be automated to be more accurate and consistent by standardizing the description and identification of data, as well as digitizing reporting instructions and generation through MRR. Reporting is crucial in regard to abiding by regulations in the right way. The MRR can ensure 100% adherence to regulations and policies and reflect the same in financial statements and compliance reporting.

V. Techniques for Extracting Machine-Readable Regulations

MRR allows machines to parse complex legislation, regulations, and policies that humans might find difficult to interpret. It not only converts regulations into machine-readable formats but also offers the chance to identify areas of change, ensuring the compliance of policies and rules that a body is following with regulatory bodies. NLP offers extensively utilized techniques to extract and parse regulations from textual documents in various domains, such as legal, compliance, governance, and policymaking. As mentioned earlier, this practice of converting regulations into machine-readable formats involves identifying and understanding rules, interpreting them for machines matching the human meaning, and allowing different sectors to follow the regulations properly. There are multiple techniques to extract text from regulations so that legislation can be considered Machine-Readable Regulations.

1) Text processing: Texts must undergo preprocessing steps such as tokenization [31], stop word removal [32], and stemming or lemmatization to clean and normalize the text. To conduct NLP tasks accurately and efficiently, it is crucial to analyze and process texts.

2) Named Entity Recognition (NER): Once the text is preprocessed, there are multiple ways of extracting regulations via NLP. One of them is Named Entity Recognition (NER) [33]. It involves identifying and categorizing entities mentioned in the text into predefined categories such as organization names, dates, locations, and, most importantly, regulatory entities such as laws, rules, and directives. According to [33], NER focuses on recognizing particular designators from texts. It requires predefined semantics such as person, location, and organization. It not only extracts information but also plays an essential role in applications such as text understanding, information retrieval, automatic text summarization, question answering, machine translation, and knowledge base construction. There are several techniques applied in NER, including rule-based approaches, unsupervised learning approaches, feature-based supervised learning approaches, and deep learning-based approaches.

3) Rule-based approaches: Rule-based approaches do not need any annotated data. They are based on handcrafted rules [34]. The rules are designed on the basis of domain-specific semantics and syntactic–lexical patterns. They capture specific patterns or formats of regulations within the text. Since this approach focuses on a specific domain, knowledge becomes difficult to transfer to a different domain system.

4) Topic modelling: Topic modelling is an analytical tool used to evaluate data [34]. It focuses on the main topics or themes of the textual contents and helps identify them. It becomes easier to understand and extract themes of the topics of the regulatory documents, and make it easier to determine the meaning of each. Some of the topic modelling approaches include Latent Dirichlet Allocation (LDA) and Non-negative Matrix Factorization (NMF).

5) Text classification: As the name suggests, text classification is a model trained to categorize textual documents into different domains or types. This approach might seem similar to topic modelling, but text classification focuses on the broader area of the regulations, segregating them into regulations for each sector where the regulation is applied [35]. Examples include financial regulations, environmental regulations, and healthcare regulations. Supervised learning algorithms, such as Support Vector Machines (SVMs) or deep learning architectures like Convolutional Neural Networks (CNNs), can be utilized for text classification.

6) Semantic analysis: Another NLP approach for Machine-Readable Regulations is semantic analysis. It helps in understanding the meaning and context of regulatory text [36]. It focuses on the relationships between words and

phrases to interpret and infer the intent and implications of regulations.

7) Information extraction: While it becomes difficult to extract the meaning of complex regulations, information extraction approaches are applied to extract structured information from unstructured regulatory text [37]. The extraction process involves identifying key elements such as obligations, permissions, prohibitions, and conditions mentioned in the regulations. The entire process includes sentence segmentation, tokenization, part-of-speech tagging, entity reorganization, entity disambiguation, relation extraction, and event extraction.

8) Knowledge graph: While the information extraction approach focuses on extracting a structured format of regulations from unstructured regulations, knowledge graphs are constructed to represent the relationship between the structured and interconnected formats of extracted texts [38]. The extracted entities are organized in a graph-like structure that represents the relationships and attributes of the regulations.

TABLE I. TECHNIQUES FOR EXTRACTING MACHINE-READABLE REGULATIONS (MRR)

Technique	Purpose	Methodology	Advantages	Review
Text Processing [31], [32]	Cleans and normalizes text for NLP tasks.	Includes tokenization, stop-word removal, stemming, and lemmatization.	Improves accuracy and efficiency of downstream NLP techniques.	Requires domain adaptation to handle legal language nuances [39].
Named Entity Recognition (NER) [33]	Identifies and classifies key entities in regulatory text (laws, rules, organizations, etc.).	Uses predefined semantic categories (e.g., person, organization, law). Methods include rule-based, unsupervised, supervised, and deep learning approaches.	Enables extraction of relevant regulatory entities for structured representation.	Rely on predefined semantics.
Rule-Based Approaches [34]	Extracts regulatory patterns using handcrafted rules and domain-specific semantics.	Relies on syntactic and lexical patterns defined by experts.	Effective for well-defined, narrow domains with consistent language.	Approach focuses on a specific domain; knowledge becomes difficult to transfer to a different domain system.
Topic Modelling [34]	Identifies hidden themes and major topics in regulatory documents.	Uses algorithms such as LDA and NMF.	Helps understand and categorize large volumes of regulatory text by themes.	May not capture context or subtle legal relationships; requires post-interpretation [40].
Text Classification [35]	Categorizes regulations into domains (e.g., financial, environmental, healthcare).	Employ supervised learning models such as SVM or deep learning (CNNs).	Enables domain-specific regulation management and retrieval.	Requires labeled datasets as they categorized by sector
Semantic Analysis [36]	Interprets the meaning and intent of regulations.	Analyzes relationships between words and phrases to infer implications.	Provides deeper understanding of regulatory intent; improves contextual interpretation.	Complex to implement; dependent on advanced linguistic and contextual models [41].
Information Extraction (IE) [37]	Convert unstructured regulatory text into structured data.	Involves segmentation, tagging, entity recognition, disambiguation, relation, and event extraction.	Identifies obligations, permissions, and conditions for compliance automation.	Challenging for long, nested legal clauses requires hybrid rule-based and ML methods [42].
Knowledge Graphs [38]	Represents structured relationships among extracted regulatory entities.	Organizes entities and relationships into interconnected graph structures.	Enables reasoning, querying, and visualization of regulatory dependencies.	Building and maintaining accurate graphs requires ongoing data validation and ontology design [43].

Table I presents a summary of the different techniques for extracting MRRs. Mainly, these techniques form a layered approach to converting unstructured regulatory texts into structured, machine-readable formats. The several ways of extracting MRRs are to prepare and identify key elements of the text, extract patterns, categorize and organize the data, and lastly, understand meaning, relationships, and build structured representations. They can be grouped as foundational, such as text processing and NER, ensuring clean, labelled data for interpretation. Intermediate, including rule-based extraction, topic modelling, and text classification, providing domain organization and thematic clarity. Finally, more advanced approaches are semantic analysis, information extraction, and knowledge graph, extending these efforts into contextual understanding and structured representation. They establish a pathway for transforming unstructured regulatory texts into interpretable, machine-actionable formats that support automation, consistency, and scalability in compliance management.

VI. Applications of Machine-Readable Code of Regulations in Machine Learning

A. Regulatory Compliance Automation

Through NLP, the extracted texts from regulations providing a structured format of data can be analyzed and processed by machine learning algorithms. ML can identify patterns between historical regulatory data and the current application of regulations to ensure that industries are compliant with regulatory bodies. In addition, ML models can extract relevant information from regulatory documents to generate compliance reports automatically, reducing manual human work and effort. ML can dynamically monitor regulatory changes by keeping itself up to date with regulatory bodies and identifying areas of change in the current implementation of regulations in the respective industry.

B. Risk Assessment and Predictive Analytics

As ML has shown a proven track record of generating predictive outcomes, the application of ML in RegTech is no different. With the help of enough data and training, ML can predict the future development of regulations and assess their potential impact on businesses, providing enough time for regulatory reform. It also allows firms to anticipate compliance risks.

C. Legal Research and Policy Analysis

ML algorithms help summarize complex regulations and extract key insights by analyzing regulatory data with the help of NLP. It offers identifying trends and patterns in the legal industry and aids legal research and policy analysis.

D. Industry-Specific Applications

While RegTech is highly used in the financial industry, its limits do not stop there. In addition to other industries, healthcare and manufacturing are two prominent areas where RegTech is being implemented and has shown great results. In addition to ML algorithms offering automated compliance monitoring, risk assessment, and reporting in the financial sector, ML techniques can help ensure that healthcare industries are compliant with their industry-specific requirements, such as HIPAA in the US. Furthermore, ensuring adherence to safety, environmental, and quality standards, which can be ensured by ML given its impact on RegTech in all aspects of ensuring regulatory compliance, is highly important for the manufacturing industry.

VII. Conclusion

The growing complexity of regulatory frameworks has made compliance both essential and intensive. This study highlights how translating regulatory texts into Machine-Readable Regulations (MRR) can transform compliance from a largely manual, interpretive task into a structured, data-driven process. By enabling machines to interpret and act on regulatory information, MRR offers clear advantages like greater efficiency, consistency, and adaptability in managing compliance across sectors. Beyond automation, integrating Machine-Readable Code (MRC) with AI and knowledge-based systems opens new possibilities for regulation management. Tools like GenAI, ontologies, and federated learning illustrate how compliance can evolve toward predictive, privacy-conscious, and continuously improving systems. Finally, the key insight is that regulatory compliance can no longer rely solely on human interpretation or static systems. The future lies in collaboration between technology and regulatory institutions, where agile frameworks and machine-readable models allow compliance to evolve in step with technological and policy change.

VIII. Challenges and Future Directions

A. Data Quality and Standardization

To ensure that the ML is trained well and that the MRR can generate the expected outcomes, it is important to train the algorithm on complete and consistent data. In addition, a standardized format of training to ensure regulations across different jurisdictions and domains allows the MRR to enhance the quality of its results, promoting the interoperability of data. Advances in semantic technologies, such as ontologies and knowledge graphs, can facilitate the semantic interoperability of Machine-Readable Regulations, enabling more precise and context-aware interpretation.

B. Privacy and Ethical Considerations

The MRR may contain sensitive and confidential information, hindering the privacy of the data. In addition, MRR may exhibit biases leading to unfair outcomes in regulatory compliance decisions on the basis of the training dataset provided to the ML algorithm. Given that the implications of MRR are not limited to a specific industry, it may reveal information affecting the governance framework. Therefore, techniques must be implemented to preserve the privacy of data by utilizing differential privacy and federated learning in MRR. Furthermore, ML algorithms can be developed to indicate bias detection to ensure that fair and ethical guidelines can be introduced in industries and regulatory bodies to preserve the governance framework.

C. Emerging Technologies and Trends

Interdisciplinary collaboration is required so that MRRs can keep up with the emerging changes in the world of technology and ensure that novel regulatory approaches are captured by them. Moreover, regulatory bodies can adopt agile and adaptive regulatory frameworks leveraging MRRs to enable rapid responses to technological advancements and regulatory changes.

Energy Efficient Workflow Allocation in Cloud Computing Using Improved Grey Wolf Optimization

Md. Mazhar Nezami, Anoop Kumar
Department of Computer Science-College of Computing and Mathematics, Banasthali Vidyapith, Rajasthan, India

***Abstract*—Cloud computing has emerged as a dominant platform for hosting complex applications, offering scalable and flexible resources on demand. However, the dynamic and heterogeneous nature of cloud environments poses significant challenges for efficient workflow scheduling, particularly when aiming to minimize total execution time, energy consumption, and operational cost. In this research, we propose a novel hybrid approach that integrates the Heterogeneous Earliest Finish Time (HEFT) algorithm with an Improved Grey Wolf Optimizer (IGWO) enhanced by differential evolution strategies and survival-of-the-fittest mechanisms. These enhancements strengthen exploration and exploitation by adaptively mutating and refining task allocations while eliminating weaker solutions. The use of HEFT-based initialization provides a strong starting population, and the DE-driven IGWO refinement accelerates convergence and avoids premature stagnation. Together, these two-level optimization strategy ensures faster convergence and higher energy-efficient workflow scheduling compared to earlier HEFT metaheuristic approaches. To evaluate the effectiveness of the proposed hybrid method, extensive experiments were conducted on randomly generated workflows with varying task and dependency complexities. The performance analysis demonstrates that the hybrid HEFT-IGWO approach consistently outperforms standard HEFT, traditional GWO, and standalone metaheuristic techniques in terms of minimizing makespan, reducing energy consumption, and lowering cloud infrastructure costs. This study highlights the potential of combining heuristic initialization with evolutionary optimization to achieve energy-efficient, cost-effective workflow scheduling in cloud computing environments.**

***Keywords*—Cloud computing; energy efficient; workflow; Heterogeneous Earliest Finish Time (HEFT); Grey Wolf Optimization (GWO); makespan; cost**

I. Introduction

Cloud computing has revolutionized the way computational resources are provisioned and consumed, offering scalable, on-demand access to a vast pool of virtualized hardware and software services. It enables organizations to deploy complex applications and workflows without investing heavily in physical infrastructure [1], [2].

A workflow in cloud computing represents a set of interdependent tasks organized to achieve a specific computational objective, such as scientific workflows, big data processing workflows. The workflow scheduling refers to organizing workflow tasks on VMs within the cloud platform, addressing the challenge of balancing energy efficiency with QoS optimization [3].

As cloud environments grow larger and more heterogeneous, efficient workflow allocation, assigning tasks to appropriate virtual machines (VMs), becomes critical. Poor task allocation results in high direct and indirect energy consumption, leading to high costs, reduced reliability, and environmental issues like CO2 emissions [4][5]. If a data center hosts 10,000 servers and each consumes an average of 300 watts, the total energy consumption can reach 3 megawatts per hour. At an average electricity cost of $0.12 per kilowatt-hour, operating such a centre would cost approximately $360 per hour, not including cooling and infrastructure overheads.

Despite significant progress in workflow scheduling, existing algorithms still struggle to maintain a balance between performance efficiency and energy optimization. Traditional heuristics, such as the HEFT algorithm, offer fast scheduling decisions but are limited by their static and local search behaviour. Conversely, metaheuristic algorithms like Particle Swarm Optimization (PSO), Ant Colony Optimization (ACO), and Grey Wolf Optimizer (GWO) improve global search ability but may converge prematurely or require many iterations.

Therefore, there is a critical need for a hybrid scheduling framework that can combine heuristic efficiency with adaptive global optimization to effectively minimize makespan, energy consumption, and operational cost in dynamic, heterogeneous cloud environments [6].

This study seeks to determine how heuristic and metaheuristic methods can be effectively integrated to enhance workflow scheduling efficiency in cloud computing. It also incorporates differential evolution and survival-of-the-fittest mechanisms within an Improved Grey Wolf Optimizer (IGWO) can strengthen convergence stability and solution diversity. Furthermore, the research investigates the extent to which the proposed hybrid HEFT–IGWO model can reduce makespan, energy consumption, and operational cost compared to traditional scheduling techniques. This research contributes to the advancement of green and sustainable cloud computing by proposing an intelligent hybrid model that improves both computational performance and energy efficiency. The proposed method offers a practical solution for multi-objective workflow allocation, reducing makespan, energy consumption, and cost simultaneously.

The study is designed in the rest of the sections as follows: Section II presents a literature survey. Section III presents the problem definition, problem formulation, and suggested HEFT-IGWO. Section IV describes the detailed algorithmic design, including initialization, mutation, crossover, and survival mechanisms of the HEFT–IGWO approach. Section V provides

the experimental setup, simulation results, and performance analysis, comparing the proposed method with existing approaches in terms of makespan, energy consumption, and cost. Finally, Section VI concludes the study, summarizing key findings and outlining future research directions.

II. Literature Survey

Many studies have examined methodologies for time and cost-efficient workflow allocation in a cloud computing environment, with limited focus on energy. The hybrid strategies that integrate heuristics like HEFT with metaheuristics have shown promising results in minimizing makespan, energy consumption, and cost simultaneously, forming a strong motivation for the hybrid HEFT-IGWO approach proposed in this study.

Li H et al. [7] proposed the SEPSO (Swarm Entropy-based Particle Swarm Optimization) framework. It is designed to optimize cloud provider profits by minimizing the monetary cost of energy and leased public cloud resources. SEPSO monitors swarm diversity during iterations to avoid premature convergence and enhance exploration by dynamically adjusting search parameters to balance exploration and exploitation throughout the optimization process. Although it improves task sequencing and allocation across public and private clouds, SEPSO mainly targets cost reduction from the provider's view and lacks adaptability to dynamic or large-scale workflows.

Li H et al. [8] proposed the Chaotic-nondominated-sorting Owl Search Algorithm (COSA) to schedule resource-constrained multiple workflows. It combines an Owl Search Algorithm (OSA) with an NSGA-II to optimize makespan, cost, and energy under the specified deadline and budget constraints in hybrid clouds. For better balancing of exploration and exploitation, multiple workflows are scheduled in DVFS-enabled cloud using a hierarchical evolving mechanism that employs COSA for the Worse Half of Population (WHP) and NSGA-II for updating the Better Half of Population (BHP). However, its reliance on fixed workflow and resource settings limits adaptability in dynamic cloud environments, and chaotic control increases computational overhead.

Thekkepuryil et al. [9] proposed a hybrid algorithm combining ALO and PSO to enhance workflow scheduling to optimize key metrics like execution time, cost, and load balancing in cloud environments. The Data Encryption Standard (DES) ensures data security during scheduling, addressing both performance and confidentiality concerns. The hybrid algorithm combines the global search ability of ALO with the local search refinement of PSO. However, its reliance on static workflows and fixed resources limits adaptability in real-world dynamic cloud environments, and the inclusion of DES adds computational overhead.

Saeedi et al. [10] optimizes task-resource mapping in workflows through the following steps. Initialize particles representing task-resource mappings, along with their positions and velocities, evaluate each particle, store non-dominated solutions generated during the search process in external archive, iteratively updates the archive, ideal point, and hyperplane. The crowding distance determines which solutions remain in the archive when it is full. The archive of optimized solutions is returned. However, I-MaOPSO reliance on roulette wheel leader selection can lead to inaccurate results when individuals have similar fitness values, reducing diversity and convergence stability.

Alaei et al. [11] proposed an adaptive fault detection method in cloud computing based on the Improved Differential Evolution (IDE) algorithm combined with an ANFIS prediction model. This hybrid model enhances reliability by predicting faults before they occur, helping reduce makespan, cost, and energy consumption while improving fault tolerance. However, the model primarily addresses VM faults and overlooks other significant reliability issues, such as network, storage, and I/O failures.

Mohammadzadeh et al. [12] proposed the HGALO-SCA algorithm, which addresses the limitations of ALO and SCA algorithms by leveraging their strengths. HGALO-SCA enhances ALO searchability by incorporating SCA oscillatory behaviour, allowing global exploration. The integration of the ALO elite strategy accelerates the convergence while maintaining global search accuracy. The comparison with SPEA2 shows better performance in balancing trade-offs. However, random chaos parameters may also increase computational complexity and reduce consistency in results.

Yao et al. [13] proposed Endocrine-based Coevolutionary Multi-Swarm for Multi-Objective Optimization (ECMSMOO) addresses the workflow scheduling in cloud computing, which is an NP-complete problem by optimizing multiple conflicting objectives, including execution time, cost, and energy consumption. The manager server collects available cloud resources to reduce the impact of elastic resource fluctuations during scheduling. The endocrine-based evolutionary strategy mimics hormone-regulated particle behaviour to enhance search efficiency and avoid local optima. The swarms collaborate and compete to ensure a strong search process across the multi-objective optimization space. Furthermore, the hormonal control mechanism adds algorithmic complexity and overhead, which can hinder real-time scheduling.

Mohammadzadeh et al. [14] introduced an improved version of the GWO algorithm, known as HCGWO. This improvement achieves better optimization outcomes by combining chaos theory and the hill-climbing method. The study extends the proposed IGWO algorithm to a binary version specifically designed for the workflow allocation problem. This involves utilizing various S and V functions to deal with the workflow allocation problem with the goal of reducing execution costs, makespan, and power consumption. chaotic map generation introduces additional computational overhead.

Hassan et al. [15] proposed Smart Energy and Reliability Aware Scheduling (SERAS) algorithm addresses the dual challenge of energy efficiency and system reliability in cloud computing environments. By integrating the DVFS technique, SERAS dynamically adjusts the processor frequencies of VMs while ensuring tasks meet their deadlines. The SERAS divides the deadline across tasks, enabling more precise scheduling and resource allocation. However, algorithm complexity ($O(n^2)$) limits scalability for large workflows.

Belgacem A, Beghdad-Bey K [16] suggested HEFT-ACO, which effectively reduces costs and makespan by combining the ACO algorithm with the HEFT heuristic. The simulation results were conducted on the Amazon EC2 cloud platform using three real-world scientific workflows, viz. Montage, CyberShake, and Ligo show better trade-offs between makespan and cost by leveraging the strengths of both techniques. The workflow characteristics, viz., balance or asymmetry, are not considered.

Taghinezhad A et al. [17] introduce BDCE and BDD, two energy-efficient heuristic algorithms for workflow scheduling in cloud environments, aiming to minimize energy consumption while meeting budget and deadline constraints, target resources with DVFS capabilities, while BDCE works with non-DVFS-enabled resources to optimize cost, scheduling length, and energy savings while ensuring QoS compliance. The result metrics are compared against established methods like BDSD, DBCS, BDHEFT, ERES, and the Safari algorithm using scientific workflow applications, showing improvements in energy savings, cost efficiency, and scheduling performance. However, both BDCE and BDD focus primarily on medium-scale workflows.

Khaleel M [18] proposed the ELSCiW (Energy-Latency-aware Scientific Workflow scheduling) framework focuses on optimizing cloud workflow scheduling by balancing energy consumption and latency while maintaining high QoS. The approach involves a two-step optimization process: first, node efficiency evaluation, which compares the number of handled transactions to power consumption, optimizing processor utilization, and then task mapping with mean GWO, which applies to map tasks to cloud resources efficiently. However, it primarily focuses on the energy–latency trade-off.

Zeedan et al.[19] proposed Enhanced Binary Artificial Bee Colony-based Pareto Front (EBABC-PF) to optimize makespan, processing cost, and resource utilization without violating SLA. The algorithm uses HEFT to prioritize the work, Greedy Randomized Adaptive Search Procedure (GRASP) to develop an initial solution, and Enhanced Binary Artificial Bee Colony (BABC) to schedule tasks onto VMs. Moreover, it emphasizes performance and cost but gives limited attention to energy efficiency.

III. Problem Definition

When a user submits a workflow application as a Directed Acyclic Graph (DAG), as shown in Fig. 1, the workflow interface converts the DAG into an admission queue that maintains execution order based on dependencies. The workflow scheduler allocates tasks to VMs using a scheduling algorithm, optimization criteria for energy efficiency, and a resource estimator to match tasks with suitable resources.

A. Resource Model

In our cloud computing model, the infrastructure comprises a collection of cloud servers (CS), each hosting multiple computing nodes on which VMs are deployed. A centralized global cloud manager oversees the operation, consisting of a resource manager and a scheduler. The resource manager maintains real-time status and key attributes of all available VMs, such as processing speed, energy consumption, and reliability. This information is utilized by the scheduler to efficiently assign tasks when a workflow application is submitted, based on task dependencies and VM availability.

All VMs are assumed to support Dynamic Voltage Scaling (DVS), allowing them to adjust their voltage and frequency levels dynamically. This enables energy savings by switching to the lowest voltage levels during idle periods. The energy consumption model is based on the CMOS power dissipation model, where energy usage is influenced by both the characteristics of the device and the voltage supply associated with each task.

The energy consumption of tasks on VMs during active (busy) execution time and when the VMs are idle can be calculated using:

$$E_{busy} = \sum_{j=1}^{M} \alpha * V_j^2 * ET(T_i, VM_j)$$

$$E_{idle} = \sum_{j=1}^{M} \alpha * V_{j,low}^2 * \Delta idle_j$$

where, n is the total number of tasks, VM_j is the virtual machine on which task $T_i$is executed, V_j is the supply voltage of VM_j, and ET (T_i, VM_j) is the execution time of task T_i on VM_j.$VM_{j,low}$is the minimum voltage level on VM_j, and $\Delta idle_j$ is the amount of idling time for VM_j. The total energy consumption can be calculated as:

$$\text{TEC}=E_{busy}+ E_{idle}$$

B. Application Model

A DAG represents a workflow application represented by Wf = (T, E), where $T = \{T_i, 1 \le i \le \text{N}\}$, is a set of tasks of the workflow, and E is the set of edge characterizes precedence constraints between tasks. The edge $T_i \rightarrow T_j$,shows the precedence relation between T_i and T_j in the DAG as shown in Fig. 2, which will be processed on virtual machines $V = \{VM_j \mid 1 \le j \le \text{M}\}$ with various computing speed and cost. The execution time of task T_i on VM_j is denoted by ET (T_i, VM_j and CT (T_i, T_k) denotes communication. According to the dependencies among the tasks, task T_i (child task) will execute after $Pred(T_i)$, (parent tasks of T_i). The start time ST (T_i, VM_j), finish time $FT(T_i, VM_j)$ of a task T_i on VM_j, and the makespan(MS) are calculated as follows:

$$ST(T_i, VM_j) = max\ \{Avl(VM_j),\ max\{FT[Pred(T_i)] + CT(Pred(T_i), T_k)\}$$

$$FT(T_i, VM_j) = ST(T_i, VM_j) + ET(Pred(T_i), VM_j)$$

$$Makespan\ (MS) := max \sum_{i=1}^{N} FT(T_i, VM_j)$$

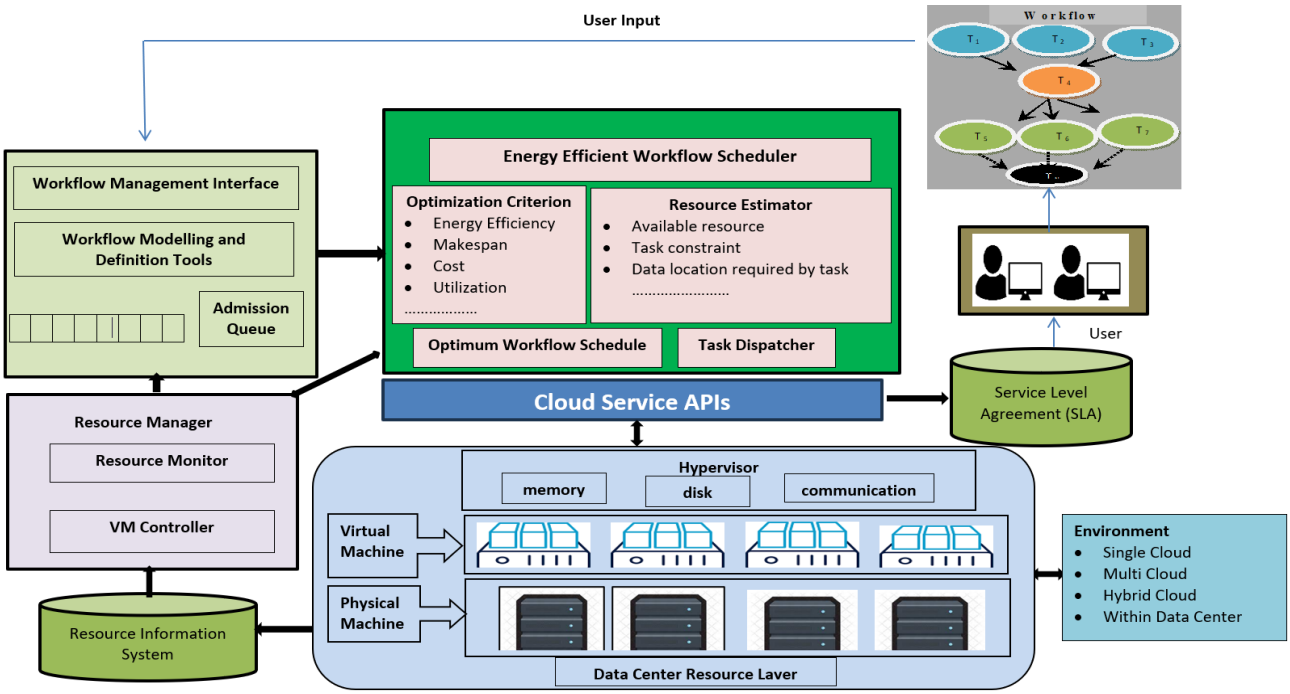

Fig. 1. Workflow allocation framework.

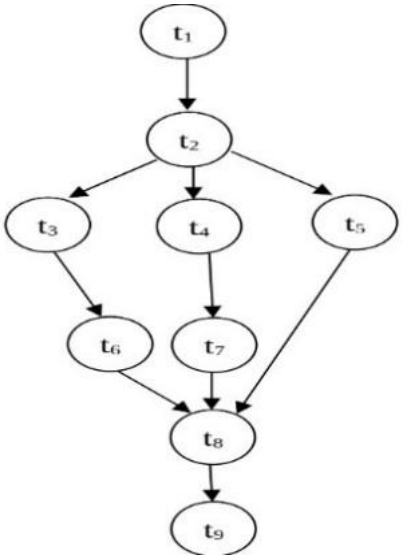

Fig. 2. Sample workflow.

C. Cost Model

The pricing in cloud computing is determined by the billing interval (BI) for resource leasing. As a result, even if only a portion of the time is used, the client must pay for the full interval.

$$Cost(T_i, VM_j) = \sigma * \left\lceil \frac{ET\ (T_i, VM_j)}{\tau} \right\rceil * P_0 * e^{\frac{cpu\ cycles\ of\ VM_j}{slowest\ cpu\ cycle}}$$

where, σ is a random variable used to generate different combinations of VM pricing and capacity, τ unit chargeable time, P_0 is the base price of VM. The total execution cost can be defined as:

Let Bi, j be a Boolean variable, such that

$$Bi,j = \begin{cases} 1, & if\ task\ T_i\ is\ assign\ to\ V_j \\ 0, & otherwise \end{cases}$$

$$TCost = \sum_{i=1}^{N} \sum_{j=1}^{M} Bi,j * Cost(T_i, VM_j)$$

D. Problem Definition

A schedule (Sc) is presented as Sc = (*SVM, Allocation, MS*, $TCost$, TEC), where *SVM* corresponds to virtual machines, *Allocation* represents the task to VM mappings, $TCost$: Total execution cost, *MS*: Makespan, and TEC: Energy consumption of the workflow. The problem can be defined as:

Minimize:

$$F = \gamma \text{ x } MS + \vartheta \text{ x } TCost + (1 - \gamma - \vartheta) \text{ x } TEC$$

Subject to

$$i)\ \sum_{j=1}^{M} Bi,j = 1,\ i = 1,2,3.....n$$

$$ii)\ 0 < \gamma, \vartheta < 1$$

Constraints: i) indicate that any task can be assigned to only one VM and the constraint, and ii) limit the range of γ, ϑ that balances optimization functions.

IV. Algorithm

The Grey Wolf Optimization algorithm is a meta-heuristic optimization technique that was inspired by the social hierarchy and hunting habits of grey wolves. It was first presented by Mirjalili et al. in 2014 [20]. We propose an energy-efficient workflow allocation algorithm based on improving the Grey Wolf Optimizer is a version of GWO that has been created to improve its search performance. This algorithm has gained significant attention due to its simplicity, flexibility, and

effectiveness in solving various complex optimization problems. GWO mimics the leadership structure and collaborative hunting strategy of grey wolves, which enhances its ability to explore and exploit the search space efficiently. In a grey wolf pack, there are four types of wolves, as shown in Fig. 3, based on their social hierarchy:

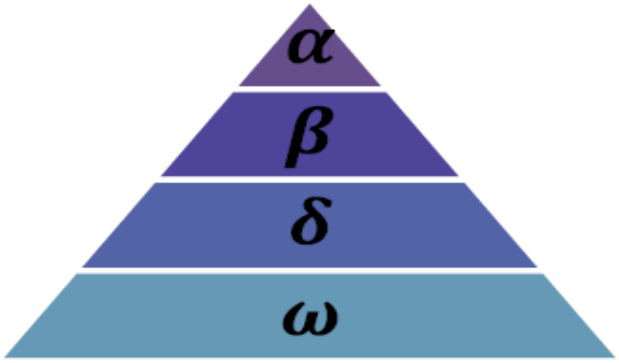

Fig. 3. Hierarchy flow up for the GWO algorithm.

Alpha (α): The leader of the pack, responsible for making decisions and guiding the hunting process.

Beta (β): The second-in-command, assisting the alpha in decision-making and maintaining discipline in the pack.

Delta (δ): The third level in the hierarchy, responsible for reporting to the alpha and beta and assisting them in their tasks.

Omega (ω): The lowest-ranking wolves, following the orders of the higher-ranking wolves and playing a crucial role in the pack's social structure.

The following mathematical models of GWO are useful in different scenarios of any real-world application.

1) Encircling prey: Grey wolves encircle their prey during the hunt. This encircling behaviour is mathematically modelled as follows:

$$\vec{D} = |\vec{C} * \overrightarrow{X_p}(t) - \vec{X}(t1)|$$

$$\vec{X}(t+1) = \overrightarrow{X_p}(t) - \vec{A} * \vec{D}$$

Here, t represents the current iteration, $\overrightarrow{X_p}$ is the position vector of the prey, $\vec{X}$ is the position vector of a grey wolf, and $\vec{A}$ and $\vec{C}$ are coefficient vectors calculated as:

$$\vec{A} = 2\,\vec{a} * \overrightarrow{r_1} - \vec{a}$$

$$\vec{C} = 2\,\overrightarrow{r_2}$$

$$\mathrm{a} = 2\left(1 - \frac{t}{T}\right)$$

In these equations, $\vec{a}$ linearly decreases from 2 to 0 over the course of iterations, while $\overrightarrow{r_1}$ and $\overrightarrow{r_2}$ are random vectors within the range [0, 1].

2) Hunting: The hunting phase involves following the best individuals in the pack, specifically the α, β, and δ wolves. The positions are updated according to these leaders as:

$$\overrightarrow{D_\alpha} = |\overrightarrow{C_1} * \overrightarrow{X_\alpha} - \vec{X}|$$

$$\overrightarrow{D_\beta} = |\overrightarrow{C_2} * \overrightarrow{X_\beta} - \vec{X}|$$

$$\overrightarrow{D_\delta} = |\overrightarrow{C_3} * \overrightarrow{X_\delta} - \vec{X}|$$

$$\overrightarrow{X_1} = \overrightarrow{X_\alpha} - \overrightarrow{A_1} * \overrightarrow{D_\alpha}$$

$$\overrightarrow{X_2} = \overrightarrow{X_\beta} - \overrightarrow{A_2} * \overrightarrow{D_\beta}$$

$$\overrightarrow{X_3} = \overrightarrow{X_\delta} - \overrightarrow{A_3} * \overrightarrow{D_\delta}$$

The position of a grey wolf is then updated as follows:

$$\vec{X}(t+1) = \frac{\overrightarrow{X_1} + \overrightarrow{X_2} + \overrightarrow{X_3}}{3}$$

3) Attacking prey: The attacking phase is indicated by reducing the value of $\vec{a}$ as iterations progress. When $\vec{A}$ falls within the range [-1, 1], wolves are encouraged to attack the prey by shrinking their encircling behaviour.

Search for Prey: When $|\vec{A}|>1|$, wolves diverge to explore new areas.

The improved GWO using differential evolution for stronger exploration and diversification through mutation, crossover, and survival of the fittest for maintaining the best-performing solutions and eliminating poor-quality candidates. Additionally, we introduce a hybrid initialization technique by incorporating a solution generated using the HEFT algorithm, ensuring that the search starts from at least one good-quality position. The population of N wolves (solutions) is initialized randomly. Each wolf represents a mapping of tasks to VMs. To enhance quality and convergence, one individual is replaced by a HEFT-based solution, leveraging domain knowledge to start the search from a near-optimal region. Each solution is evaluated using a fitness function based on makespan, cost, and energy. Then sort the wolves based on their fitness values and choose the best $\overrightarrow{X_\alpha}$, second best $\overrightarrow{X_\beta}$, and third best $\overrightarrow{X_\delta}$. During each iteration, the positions of the wolves are updated using the DE strategy. This involves mutating the positions to create new candidates, crossing over elements between pairs of candidates to combine their features, and selecting the best candidates to form the next generation.

4) Mutation operation: The mutation operation of differential evolution is its most significant feature. To generate variance in this process, two weighted difference vectors are appended to the selected individual. The difference vector from the parents, which consists of two different individuals $(X_{r_1}^t, X_{r_2}^t)$ from the parent generation (the t-th generation), is the basic component of the DE variation mechanism. The definition of the difference vector is as follows:

$$Dd_{r_{12}} = X_{r_1}^t - X_{r_2}^t$$

where, r_1, r_2 are index numbers of distinct population members, and as a result, the mutation operation can be written as follows:

$$V_i^{t+1} = X_{r_3}^t + \mathrm{F} * (X_{r_1}^t - X_{r_2}^t)$$

where, F is the scaling factor, and r_1, r_2 and r_3 are different integers in the scope $(1, 2, \ldots n)$ from the current target vector index(i).

5) Crossover operation: A crossover operation is carried out using the mutation vector X_i^{t+1} for the individual X_i^t wolves, producing a trial individual U_i^{t+1}. A random selection technique is used to make sure that at least one bit of U_i^{t+1} is derived from V_i^{t+1} to ensure that X_i^t evolves. The crossover probability factor (CR) for the remaining bits of U_i^{t+1} determines whether each bit originates from X_i^t or V_i^{t+1}. The expression for the crossover operation as follows:

$$U_{ij}^{t+1} = \begin{cases} V_{ij}^{t+1}, rand(\mathrm{j}) \leq CR \ OR \ J = randn(i) \\ X_{ij} \quad , rand(\mathrm{j}) > CR \ AND \ J \neq randn(i) \end{cases}$$

$$J = 1, 2, .., \mathrm{D}$$

where, rand(j) ∈ [0, 1] obeys the random-uniform distribution, j is the j-th variable (gene), CR is the crossover probability, and rand(i) ∈ [1, 2, … D].

6) Selection operation: The greedy choice used in the selection process. Following the mutation and crossover operations, the trial individual U_i^{t+1} is created and then compared with the target individual X_i^t. The comparison can be expressed numerically as:

$$X_i^{t+1} = \begin{cases} U_i^{t+1}, & f(U_i^{t+1}) < f(X_i^t) \\ X_i^t & f(U_i^{t+1}) \geq f(X_i^t) \end{cases} \quad i = 1,2, \ldots n$$

In summary, the proposed enhances the original GWO by incorporating evolutionary principles and the DE strategy, significantly improving its search performance. This improved algorithm effectively balances exploration and exploitation, making it a powerful tool for solving complex optimization problems.

An illustration to explain HEFT-IGWO, traditional GWO, and HEFT has been presented in this section with a random workflow consisting of nine tasks with precedence among themselves, as shown in Fig. 2. We have taken only three VMs, each with different computing capacities, energy consumption, and cost, but there may be more in real scenarios. Each wolf in the GWO represents a possible allocation of tasks to VMs.

V. Results and Discussion

We use simulation for the performance study of proposed algorithms with the traditional GWO algorithm and HEFT algorithms. The simulation was performed using Python on a system with an i5 processor having a frequency of 2.1 GHz and 16 GB RAM running Windows 11. A random workflow application used to assess the HEFT-IGWO algorithm. Table I shows the simulation parameters and their corresponding values.

TABLE I Simulation Parameters

Parameter	Values
Tasks (N) number	5-100
VMs (M) number	3
Processing Speed	1000-5000 MIPS
VM distances	1-100
Computing Capacity of VM	30-1000
Inter task communication	1-1000

This section provides an overview of the performance findings in terms of makespan, energy, and cost, corresponding to three virtual machines. The performance of the three algorithms was evaluated in terms of makespan for different numbers of tasks ranging from 5 to 100 is shown in Fig. 4. The HEFT algorithm serves as the baseline for comparison.

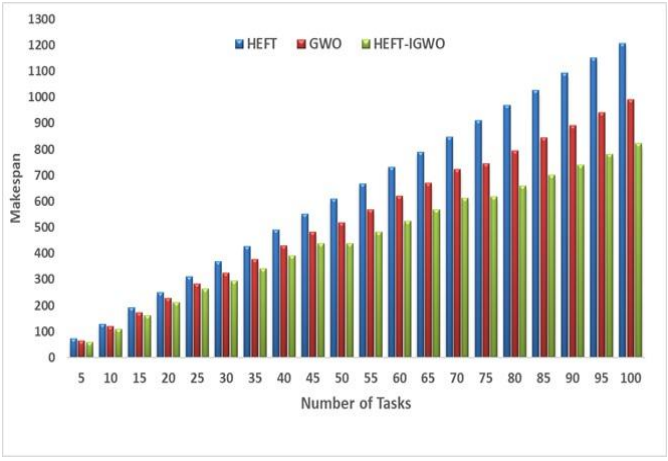

Fig. 4. Makespan vs. Number of workflow tasks.

Its makespan values increase almost linearly with the number of tasks. For small workflows (5 to 25 tasks), HEFT performs reasonably well because the search space is limited, and its ranking and earliest finish time heuristic is efficient. However, as the number of workflow tasks increases (50 to 100), HEFT performance degrades significantly, producing the highest makespan values among the three methods. For small to medium workflows (5 to 45 tasks), GWO provides an average improvement of around 8–12% in makespan. As the number of workflow tasks increases, GWO advantage becomes more significant due to its iterative exploration and leader based hunting mechanism, which helps find more balanced task–VM mappings. For larger workloads (50 to 100 tasks), the improvement rises to 15–18%. The Hybrid HEFT–IGWO approach achieves the best performance across all workflows, demonstrating the benefit of combining HEFT based initialization with improved GWO exploration through differential evolution operators and survival of the fittest. For small and medium workflows (5 to 45 tasks), HEFT–IGWO improves makespan by 15–20% compared to HEFT. For large workflows (50 to 100 tasks), the improvements become more substantial, ranging from 28–32%. These significant gains are due to the ability to start with a near optimal HEFT solution and then further refine allocations using DE mutation, crossover, and iterative leader updates.

ALGORITHM 1: HEFT-IGWO

Input: Workflow W (T, E), VM set V, population size N, generations G
Output: Best schedule with minimized makespan, cost, and energy
Phase 1: Initialization
Compute upward ranks of tasks using HEFT ordering.
Seed HEFT-based elite solution as one candidate wolf.
Generate N-1 random task-to-VM mappings as additional wolves.
Evaluate fitness of all wolves (makespan, energy, cost).
Identify alpha, beta, delta leaders (best three wolves).

Phase 2: Iterative Hybrid Evolution
For gen = 1 To G do
Update wolves positions using GWO encircling and hunting rules.
Apply higher probability mutation (random task VM flips).
Perform DE style discrete crossover between wolves and mutants.
Evaluate fitness of offspring (makespan, cost, energy).
Apply survival-of-the-fittest: keep best between parent and offspring.
Update leaders alpha, beta, delta based on new population.
Log convergence metrics (fitness, makespan, energy, cost).

Phase 3: Termination
Return alpha wolf (best schedule) with final metrics.
end

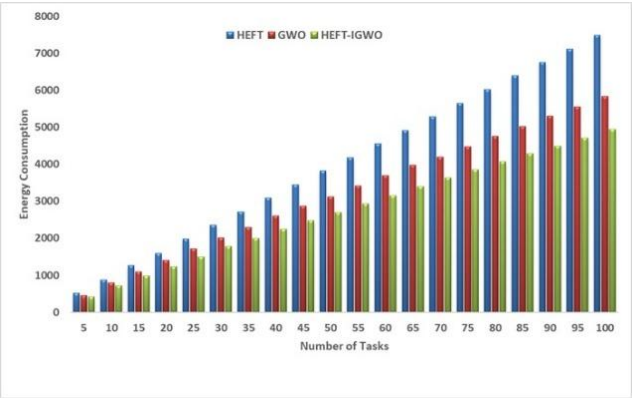

Fig. 5. Energy consumption vs. Number of workflow tasks.

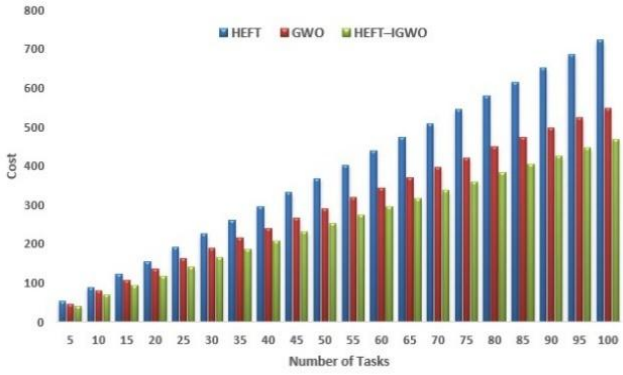

Fig. 6. Cost vs. Number of workflow tasks.

All algorithms show increasing energy consumption as tasks increase, but the growth rate is significantly slower for GWO and HEFT–IGWO than HEFT as shown in Fig. 5. The HEFT algorithm consistently consumes the highest amount of energy. The GWO achieves clear energy reductions across all task sizes, averaging around 10–15% for smaller tasks (5–30) and 18–22% for larger workloads (50–100). The hybrid HEFT–IGWO algorithm (see Algorithm 1) consistently outperforms both HEFT and GWO, demonstrating the largest energy savings across all workflow sizes. For small and medium workflow (5–40 tasks), energy savings are around 20–27%, while for large workloads (50–100 tasks), savings increase to 30–34%. HEFT–IGWO achieves the largest and most consistent energy reductions, particularly for large scale workflows, making it ideal for energy-aware workflow allocation in cloud environments.

Since HEFT focuses on earliest finish time without explicitly optimizing cost, it often results in inefficient VM usage leading to higher costs as workflows scale as shown in Fig. 6. The GWO consistently reduces operating cost compared to HEFT. For the small workflows (5–25 tasks), the cost improvements are in the range of 10–14%. For medium workloads (30–60 tasks), cost improvements increase to around 17–22%, and for larger workloads (65–100 tasks), savings stabilize between 22–24%. The hybrid HEFT–IGWO algorithm provides the largest cost reductions across all task sizes. For small tasks, improvements are already noticeable at ~20–22%, increasing to 26–30% for medium workflows, and reaching ~35% for larger workloads.

VI. Conclusion

This study presented a comparative evaluation of three workflow scheduling techniques HEFT, GWO, and the proposed Hybrid HEFT–IGWO to enhance performance and energy efficiency in cloud computing environments. The proposed HEFT–IGWO hybrid delivers the most notable results. By initializing the search with a HEFT based schedule and refining it through differential evolution and survival-of-the-fittest operations, it effectively balances exploration and exploitation. The hybrid model achieves up to 32% reduction in makespan, 34% lower energy consumption, and 35% cost savings, outperforming both baseline methods across all task scales. Overall, combining heuristic and evolutionary intelligence significantly enhances workflow allocation efficiency. HEFT–IGWO inherits the computational speed of HEFT while leveraging IGWO adaptive global search to achieve optimized, energy aware scheduling. Future work will focus on extending this approach to dynamic, heterogeneous, and QoS driven cloud environments for real time workflow.

***Abstract*—This study presents a novel Feature Pyramid Network with Dual-Decoder Supervision for accurate stroke lesion localization in multi-modal brain MRI. The proposed architecture integrates a Swin Transformer backbone with multi-scale feature aggregation, enabling effective fusion of hierarchical representations from DWI, ADC, and FLAIR sequences. A dual-decoder structure is employed, where the auxiliary decoder provides coarse lesion guidance through pseudo masks, and the primary decoder refines boundaries for precise voxel-level segmentation. Auxiliary supervision improves convergence stability and feature discrimination, while modality dropout enhances robustness to incomplete imaging protocols. Experiments conducted on the ATLAS v2.0 dataset demonstrate superior performance over baseline encoder–decoder models, achieving higher Dice scores, improved boundary accuracy, and strong lesion-wise detection rates. The model consistently localizes lesions of varying size, shape, and intensity, with minimal overfitting, as evidenced by small training–testing performance gaps. Qualitative results confirm the framework's ability to transform coarse localization into anatomically accurate predictions. The combination of multi-modal integration, dual-decoder specialization, and self-training mechanisms positions the proposed method as a promising candidate for clinical deployment in rapid stroke diagnosis workflows. Future directions include expanding validation to multi-center datasets, incorporating explainable AI techniques, and enabling real-time 3D processing for deployment in acute care environments.**

***Keywords*—Stroke lesion localization; multi-modal MRI; feature pyramid network; segmentation; deep learning**

I. Introduction

Stroke remains one of the leading causes of mortality and long-term disability worldwide, with timely and precise lesion localization being a critical determinant for successful therapeutic intervention [1]. Magnetic Resonance Imaging (MRI) is the preferred non-invasive modality for stroke diagnosis due to its superior soft-tissue contrast and ability to capture diverse tissue characteristics across multiple imaging sequences [2]. Accurate lesion segmentation and localization not only assist in diagnosis but also facilitate the evaluation of stroke severity, prognosis prediction, and treatment planning [3]. However, automated stroke lesion detection poses substantial challenges owing to the heterogeneity of lesion shapes, sizes, and intensities, as well as the presence of noise, motion artifacts, and variations across different MRI modalities [4]. Addressing these challenges requires models that can robustly integrate multi-scale contextual features while maintaining fine-grained spatial resolution.

Deep learning techniques, particularly convolutional neural networks (CNNs), have shown remarkable success in various medical image analysis tasks, including tumor segmentation, organ delineation, and lesion detection [5]. Yet, traditional encoder–decoder CNN architectures often struggle to capture both global semantic context and detailed boundary information when dealing with complex and irregularly shaped stroke lesions [6]. Feature Pyramid Networks (FPNs) have emerged as a powerful architectural design to mitigate this limitation by enabling multi-scale feature fusion, thereby improving detection and segmentation performance across varying lesion sizes [7]. Despite these advancements, single-decoder frameworks can underutilize the rich hierarchical features extracted by the backbone, leading to suboptimal boundary refinement and reduced robustness in heterogeneous imaging conditions [8].

Recent studies have explored multi-head or multi-decoder architectures to enhance learning by incorporating specialized branches for distinct but complementary tasks, such as coarse lesion localization and fine-grained segmentation [9]. The dual-decoder paradigm facilitates task-specific feature optimization, allowing one branch to focus on high-level semantic structure while the other emphasizes spatial detail preservation. When coupled with auxiliary supervision strategies, this approach can guide intermediate layers toward more discriminative feature representations and accelerate convergence during training. Furthermore, integrating such architectures with multi-modal MRI data such as diffusion-weighted imaging (DWI), apparent diffusion coefficient (ADC) maps, and fluid-attenuated inversion recovery (FLAIR) sequences can significantly boost lesion detectability by leveraging the complementary tissue contrast characteristics inherent in different modalities [10]. This multi-modal fusion, however, demands careful architectural design to avoid

information redundancy and overfitting, especially in datasets with limited sample sizes.

II. Related Works

Automated stroke lesion segmentation has been extensively studied in recent years, driven by advances in deep learning and the availability of annotated neuroimaging datasets [10]. Early methods relied on traditional image processing pipelines, integrating intensity thresholding, region growing, and atlas-based priors [11]. While effective for well-defined lesions, these approaches often failed under conditions of low contrast and irregular lesion morphology [12]. The emergence of deep convolutional neural networks (CNNs) introduced the capability to learn hierarchical features directly from data, enabling better generalization to unseen cases [13]. Architectures such as U-Net and its derivatives became popular for medical image segmentation due to their encoder–decoder structure and skip connections [14]. However, their performance still degraded in multi-modal MRI settings without tailored fusion strategies [15].

Multi-modal MRI analysis has gained attention due to the complementary information provided by sequences like DWI, ADC, and FLAIR [16]. Fusion strategies for these modalities range from simple channel concatenation to more sophisticated attention-based feature integration [17]. Studies have shown that modality-specific feature extractors combined with shared decoding networks can significantly improve segmentation performance [18]. Nevertheless, straightforward concatenation can introduce redundancy and lead to overfitting, particularly in small datasets [19]. Attention-based fusion mechanisms have been applied to mitigate this by selectively weighting modality contributions [20]. Despite these advances, the integration of multi-scale feature representations from multi-modal data remains a challenging and less explored problem in stroke lesion localization [21].

The incorporation of Feature Pyramid Networks (FPNs) into medical imaging pipelines has proven effective in capturing multi-scale contextual information [22]. FPNs enable the aggregation of high-resolution spatial features with deep semantic features, improving detection and segmentation tasks across varying object sizes [23]. In stroke imaging, multi-scale architectures help in detecting both small cortical infarcts and larger subcortical lesions [24]. However, many FPN-based designs in medical imaging rely on single decoder pathways, which may underutilize the available hierarchical features [25]. Dual-decoder approaches have been proposed to address this, separating the tasks of coarse localization and precise segmentation [26]. This separation allows each decoder to specialize, but often lacks coordinated supervision, leading to suboptimal synergy between the two outputs [27].

Auxiliary supervision and multi-task learning strategies have emerged as effective means to guide intermediate network layers toward more discriminative feature representations [28]. By introducing additional loss functions at various stages, these methods encourage the network to learn robust features for both global context and local detail preservation. In the context of stroke lesion analysis, auxiliary segmentation branches have been used to stabilize training and improve boundary accuracy [29]. Teacher–student frameworks have also been integrated with auxiliary supervision to leverage pseudo-labels for semi-supervised learning [30]. Despite promising results, there remains a lack of dedicated architectures that combine FPN, dual-decoder design, and auxiliary supervision specifically optimized for multi-modal stroke lesion localization, representing the gap addressed by the present study [31].

III. Methodology

The proposed Feature Pyramid Network with Dual-Decoder Supervision for stroke lesion localization in multi-modal brain MRI is designed to integrate multi-scale feature representations with specialized decoding paths for enhanced segmentation accuracy. The architecture, illustrated in Fig. 1, is built on a Swin Transformer backbone with FPN for hierarchical feature fusion. It consists of a primary decoder for fine-grained segmentation, an auxiliary decoder for coarse lesion supervision, and a classification head for lesion presence verification.

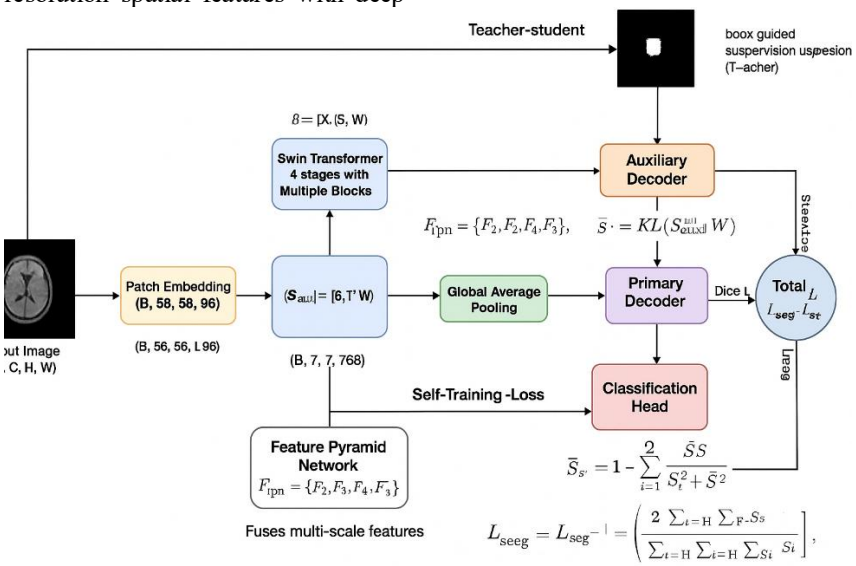

Fig. 1. Example of a figure caption.

A. Input Processing and Patch Embedding

Given a multi-modal MRI volume $X \in R^{C\times H\times W}$ where C denotes number of modalities, the patch embedding module applies a convolution with kernel size k=4 and stride s=4 transforming the image into non-overlapping patches:

$$P = Conv_{k=4,s=4}(X),\ P \in R^{B\times N\times D} \tag{1}$$

where B is the batch size, N is the number of patches, and D is the embedding dimension.

B. Swin Transformer with FPN

The embedded patches are processed through four hierarchical stages of the Swin Transformer, generating feature maps $\{F_2, F_3, F_4, F_5\}$ with progressively reduced spatial resolution and enriched semantic information. The FPN aggregates these:

$$F_{fpn} = FPN(F_2, F_3, F_4, F_5) \tag{1}$$

This yields multi-scale features for both segmentation and classification tasks.

C. Dual-Decoder Structure and Auxiliary Supervision

The primary decoder focuses on boundary-preserving fine segmentation, while the auxiliary decoder provides intermediate supervision for coarse lesion localization. The auxiliary output *S*aux is guided by a pseudo-label mask *W* from a teacher–student model using Kullback–Leibler [32] divergence:

$$L_{aux} = KL(S_{aux} \,||\, W) \tag{2}$$

The final segmentation loss combines Dice and Binary Cross-Entropy (BCE) losses:

$$L_{seg} = L_{Doce} + L_{BCE} \tag{3}$$

With the Dice loss defined as:

$$L_{Dice} = 1 - \frac{2\sum_i p_i g_i}{\sum_i p_i^{\,2} + \sum_i g_i^{\,2}} \tag{4}$$

Where p_i and g_i are predicted and ground-truth voxel probabilities.

D. Classification Head and Self-Training Loss

A classification branch with global average pooling predicts the lesion presence probability. Self-training is incorporated by enforcing consistency between the primary and auxiliary decoders:

$$L_{st} = \left\| S_{primary} - S_{aux} \right\|_2^2 \tag{5}$$

The total loss is:

$$L_{total} = L_{seg} + \lambda_1 L_{aux} + \lambda_2 L_{st} \tag{6}$$

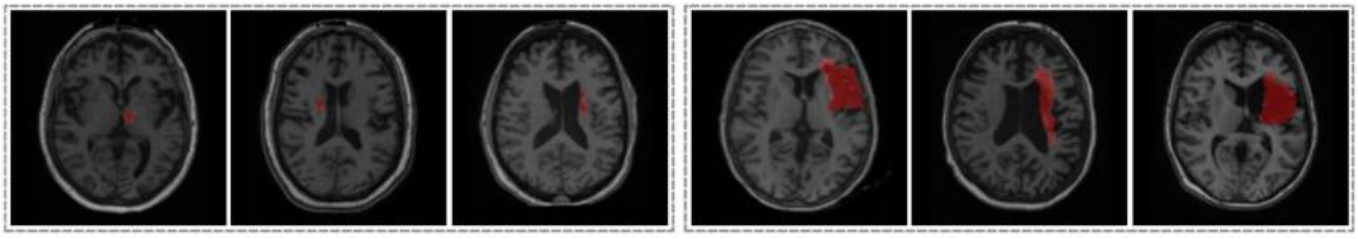
Where λ_1 and λ_2 are balancing weights.

E. Training and Inference Strategy

During training, multi-modal MRI sequences are concatenated channel-wise, with modality-specific augmentations applied to improve generalization. The teacher–student framework updates the teacher via exponential moving average (EMA) of the student weights. At inference, multi-scale test-time augmentation (TTA) is applied, and connected component filtering removes spurious predictions.

F. Dataset

In this study, we employ the ATLAS v2.0 (Anatomical Tracings of Lesions After Stroke) dataset [33], which provides a large collection of clinically acquired structural MRI scans with expert-annotated lesion masks. This dataset contains T1-weighted images from individuals with subacute and chronic stroke, complemented by detailed voxel-level delineations verified through multi-rater consensus. All scans are pre-aligned to MNI-152 space, ensuring anatomical consistency across subjects and facilitating integration into deep learning pipelines. For our task, the T1 modality is utilized in combination with lesion annotations to train and validate the proposed Feature Pyramid Network with dual-decoder supervision. Preprocessing includes N4 bias field correction, skull stripping, intensity normalization to zero mean and unit variance, and resampling to isotropic voxel dimensions to ensure uniformity in spatial resolution.



a) Small lesions b) Big lesions

Fig. 2. Atlas v2.0 dataset samples.

Fig. 2 provides representative samples from the ATLAS v2.0 dataset, demonstrating the variability in lesion size, morphology, and location encountered in real-world stroke presentations. The lesions range from focal cortical damage to extensive subcortical infarctions, capturing the heterogeneity necessary for training robust lesion localization models. This diversity ensures that the proposed Feature Pyramid Network with dual-decoder supervision is tested against a broad

spectrum of stroke manifestations, enabling evaluation of both its fine-grained segmentation capabilities and its adaptability to challenging anatomical contexts. By leveraging these standardized and expertly annotated samples, the dataset supports reproducible, high-quality benchmarking of advanced deep learning architectures for stroke lesion analysis.

IV. Results

The Results section presents a comprehensive evaluation of the proposed Feature Pyramid Network with Dual-Decoder Supervision for stroke lesion localization in multi-modal brain MRI. This section reports both quantitative performance metrics and qualitative visual analyses, enabling a detailed assessment of the model's accuracy, generalization, and robustness. The results are organized to first illustrate the model's convergence behavior during training, followed by segmentation and classification performance compared to baseline and state-of-the-art methods. Additionally, visual examples are provided to demonstrate the network's ability to refine coarse pseudo masks into anatomically precise segmentations and to generate accurate lesion bounding boxes. Together, these findings validate the effectiveness of the proposed approach and highlight its potential applicability in real-world clinical workflows for rapid and reliable stroke diagnosis.

A. Evaluation Parameters

To rigorously assess the performance of the proposed Feature Pyramid Network with Dual-Decoder Supervision for stroke lesion localization in multi-modal brain MRI, several quantitative evaluation metrics are employed. These parameters are selected to measure both voxel-level segmentation quality and lesion-wise detection accuracy, ensuring a comprehensive analysis of the model's performance.

The DSC [33] evaluates the spatial overlap between the predicted lesion mask P and the ground truth G, defined as:

$$DSC = \frac{2|P \cap G|}{|P| + |G|} \tag{7}$$

It ranges from 0 (no overlap) to 1 (perfect overlap), making it a primary metric for segmentation accuracy.

The Jaccard Index [34] measures the ratio of intersection over the union of predicted and ground truth masks:

$$Jaccard = \frac{|P \cap G|}{|P \cup G|} \tag{8}$$

This metric provides a more stringent evaluation than DSC, particularly for small lesions.

Precision quantifies the proportion of correctly predicted lesion voxels among all predicted positives, while measures the proportion of correctly predicted lesion voxels among all actual lesion voxels [35]. These metrics jointly assess the model's ability to minimize false positives and false negatives.

$$precision = \frac{TP}{TP + FP} \tag{9}$$

$$recall = \frac{TP}{TP + FN} \tag{10}$$

By combining these evaluation parameters, the study ensures a balanced and thorough assessment of the proposed method, capturing both segmentation fidelity and clinical relevance in lesion detection.

B. Experimental Results

The experimental results subsection begins by presenting both quantitative and qualitative evaluations of the proposed Feature Pyramid Network with Dual-Decoder Supervision for stroke lesion localization in multi-modal brain MRI. The experiments were conducted on the ATLAS v2.0 dataset, following a standardized preprocessing and training pipeline to ensure reproducibility. Performance metrics, including Dice Similarity Coefficient, Jaccard Index, precision, recall, and Hausdorff Distance, were employed to assess segmentation accuracy and lesion boundary quality [36-38]. Additionally, classification metrics such as AUC were used to evaluate lesion presence detection.

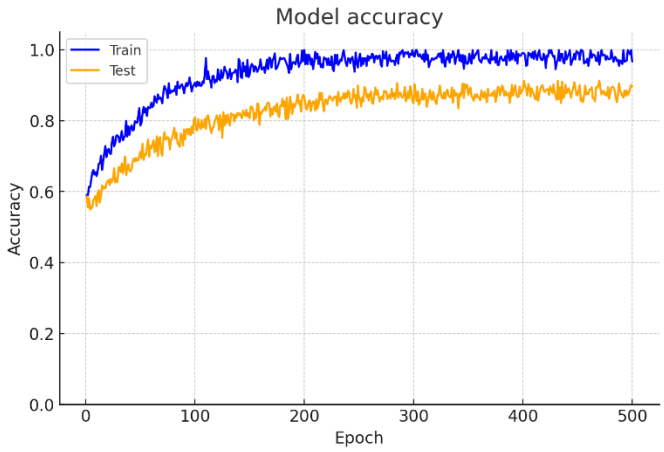


Fig. 3. Model accuracy for 500 learning epochs.

Fig. 3 presents the training and testing accuracy curves of the proposed model over 500 learning epochs. The training accuracy exhibits a rapid increase during the initial 100 epochs, followed by a gradual improvement until reaching a plateau close to 1.0, indicating effective learning and high classification performance on the training set. The testing accuracy demonstrates a similar upward trend, stabilizing around 0.88-0.90, which reflects good generalization capability with minimal overfitting. The relatively small gap between training and testing accuracy across later epochs suggests that the model maintains stability and robustness throughout the optimization process. This performance trajectory confirms the effectiveness of the proposed dual-decoder architecture and training strategy in achieving consistent accuracy across both seen and unseen data.

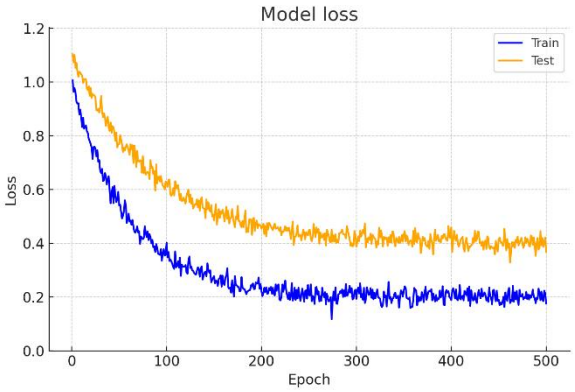

Fig. 4. Model loss for 500 learning epochs.

Fig. 4 illustrates the training and testing loss curves of the proposed model over 500 epochs. Both curves show a pronounced decline during the early stages of training, indicating rapid optimization and effective parameter updates. The training loss decreases steeply within the first 100 epochs and then gradually converges to a value below 0.1, reflecting strong fitting to the training data. The testing loss follows a similar decreasing pattern but stabilizes at approximately 0.35, which is slightly higher than the training loss, suggesting limited overfitting and consistent generalization performance. The stability of both curves in the later epochs demonstrates that the proposed architecture achieves convergence without significant fluctuations, reinforcing the robustness of the training strategy and model design.

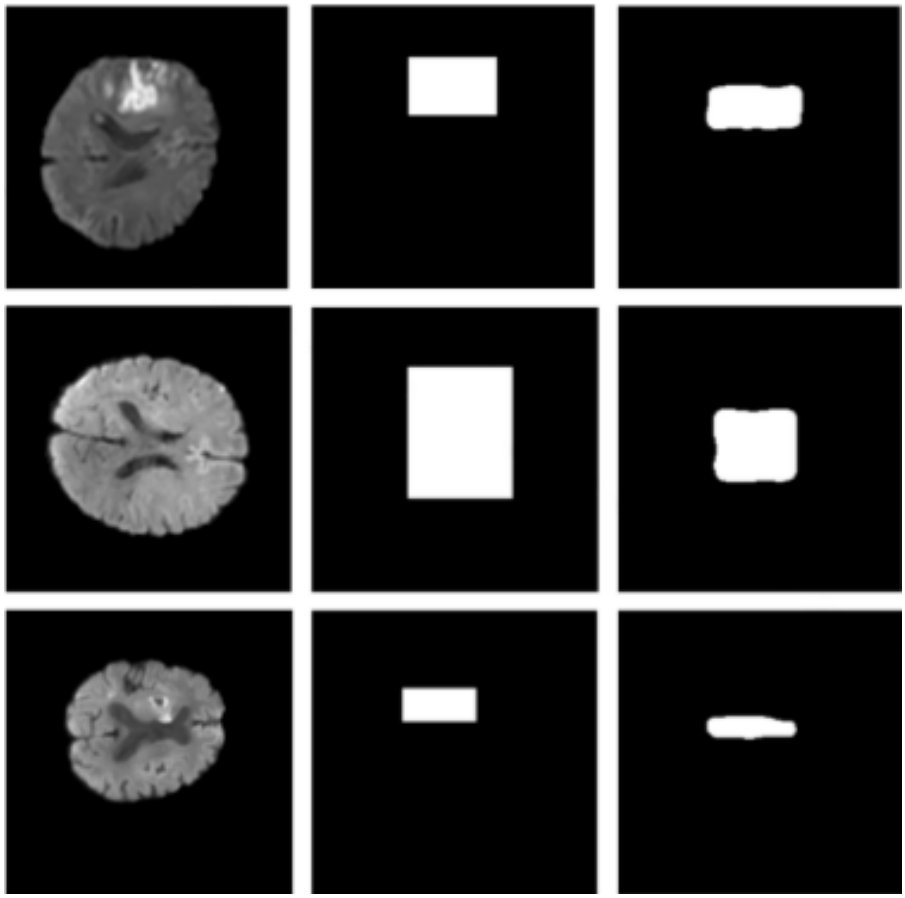

Fig. 5. Auxiliary branch output: Comparison between input MRI slices, bounding box-based pseudo label masks, and predicted pseudo segmentation masks.

Fig. 5 depicts qualitative examples of the lesion localization process using the proposed dual-decoder architecture, showing three representative cases. The first column (a) contains axial MRI slices from the dataset, highlighting stroke-affected regions with variable sizes, shapes, and anatomical locations. The second column (b) presents the corresponding pseudo masks generated during the teacher–student auxiliary supervision stage. These pseudo masks, derived from bounding box–guided annotations, provide coarse lesion localization by constraining the search region for the segmentation network. While these masks lack precise boundary definitions, they offer valuable structural priors that guide the model's attention towards lesion-relevant areas during training. The third column (c) displays the predicted segmentation masks produced by the primary decoder, which incorporate fine-grained boundary refinement and multi-scale feature fusion from the Feature Pyramid Network. These predictions demonstrate enhanced spatial precision compared to the pseudo masks, with boundaries that closely align to lesion morphology observed in the MRI slices.

The comparison between the pseudo masks and prediction masks in Fig. 5 highlights the effectiveness of the proposed training strategy. Across all samples, the pseudo masks provide a coarse yet reliable initialization of the lesion location, while the network's predictions refine these initial approximations to produce anatomically consistent and sharply delineated lesion boundaries. Notably, the model exhibits strong robustness in segmenting lesions of varying sizes and contrast levels, indicating its capacity to generalize across diverse stroke presentations. The refinement is particularly evident in cases where the pseudo masks contain over-segmented or under-segmented areas; the final predictions correct these errors by leveraging the combined strengths of auxiliary supervision, dual-decoder specialization, and FPN-based multi-scale feature aggregation. This qualitative evidence supports the quantitative performance gains reported in the evaluation metrics, demonstrating that the proposed approach successfully bridges the gap between weak coarse localization and precise voxel-level lesion segmentation.

Fig. 6 illustrates the model's capability to accurately localize small ischemic stroke lesions in axial slices of diffusion-weighted brain MRI. Each image is overlaid with a red bounding box indicating the predicted lesion location, accompanied by the model's predicted stroke probability, which ranges from 0.82 to 0.91. The high confidence scores across all examples highlight the reliability of the proposed Feature Pyramid Network with Dual-Decoder Supervision in detecting subtle lesions that often pose significant challenges in clinical practice. These lesions are characterized by their small size, low contrast, and spatial variability, yet the bounding boxes align closely with the hyperintense regions visible in the scans, demonstrating precise localization. The ability to consistently identify such small lesions is critical for early-stage stroke diagnosis, where timely and accurate detection can directly influence treatment decisions and patient outcomes. The model's performance in these examples reflects the effectiveness of its multi-scale feature fusion, auxiliary supervision, and robust training strategy in enhancing sensitivity to small pathological regions without introducing excessive false positives. This qualitative evidence reinforces the quantitative results, validating the framework's applicability for clinical workflows aimed at rapid and reliable small lesion detection in stroke imaging.

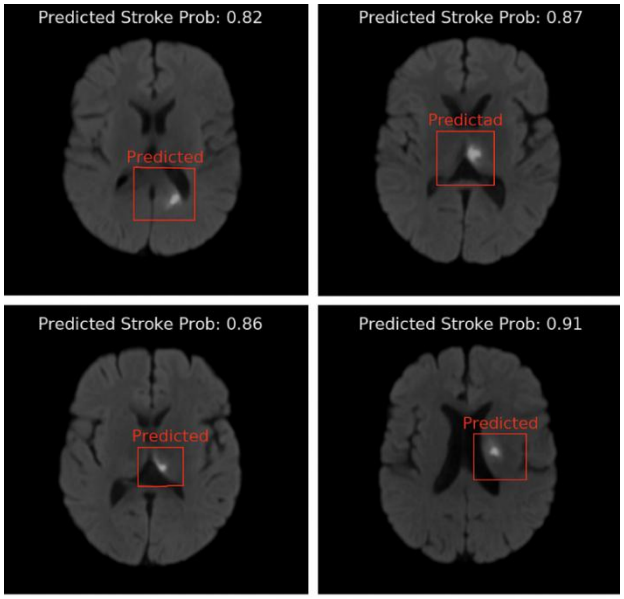

Fig. 6. Localization of small lesions.

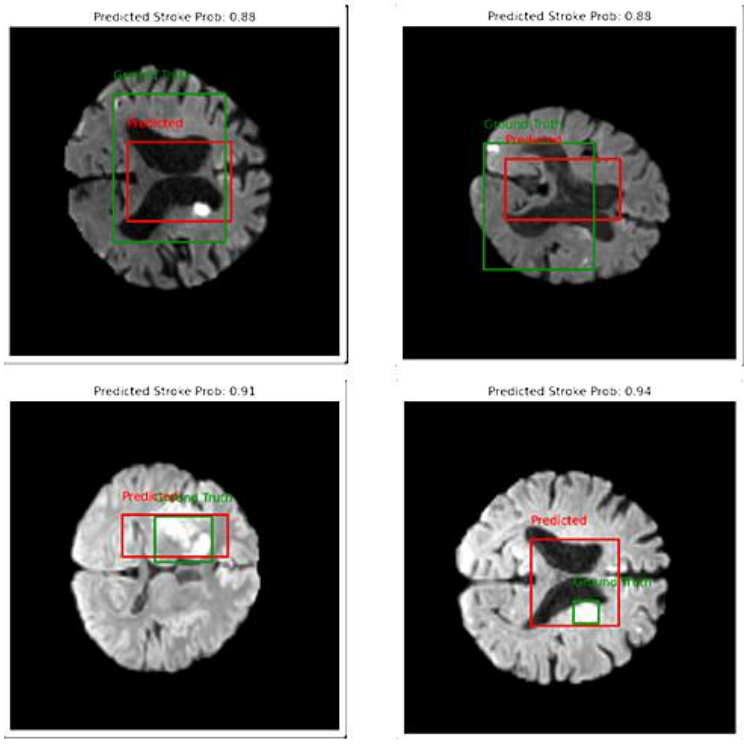

Fig. 7. Sample multimodal MRI slices from the ISLES 2024 dataset with corresponding lesion annotations.

Fig. 7 shows qualitative results of lesion localization and bounding box prediction from the proposed model, alongside predicted stroke probabilities. Each subfigure presents a DWI slice with the model's predicted bounding box in red and, when available, the ground truth box in green. The upper row, with probabilities of 0.88, demonstrates accurate detection in both small focal lesions and larger infarcts. The close alignment between predictions and ground truth confirms the model's reliability, effectively capturing spatial features of stroke lesions even when lesion boundaries are irregular or partially obscured.

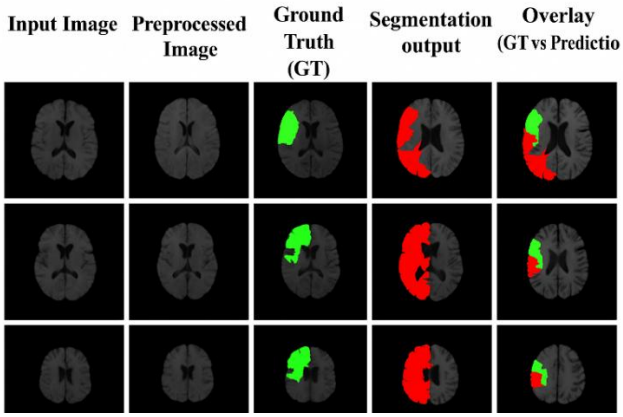

Fig. 8. Stroke lesion segmentation workflow visualization.

Fig. 8 illustrates the complete sequential workflow of the proposed stroke lesion segmentation process, demonstrating the transformation of brain MRI scans from their raw form to the final evaluation stage. The first column presents the original diffusion-weighted MRI inputs, capturing the unaltered imaging data as acquired during clinical examination. The second column displays the preprocessed images, in which intensity normalization, artifact suppression, and contrast enhancement are applied to improve visibility of anatomical structures and pathological regions. In the third column, the manually annotated ground truth (GT) masks are shown in green, representing expert-defined lesion boundaries verified through radiological consensus. The fourth column depicts the segmentation results produced by the proposed PM1 model, where predicted lesion regions are highlighted in red. Finally, the fifth column overlays the GT masks onto the PM1 predictions, enabling direct visual assessment of prediction accuracy. This overlay highlights both the areas of precise alignment and the locations of minor deviations, offering valuable insights for targeted model refinement. The visual progression in Fig. 8 demonstrates the PM1 model's capacity to accurately approximate expert annotations, while also emphasizing its robustness in handling variations in lesion size, shape, and contrast. This comprehensive depiction supports the quantitative findings and confirms the method's clinical applicability for reliable stroke lesion localization.

TABLE I. QUANTITATIVE COMPARISON OF THE PROPOSED FEATURE PYRAMID NETWORK WITH DUAL-DECODER SUPERVISION AGAINST BASELINE AND STATE-OF-THE-ART METHODS FOR STROKE LESION LOCALIZATION IN MULTI-MODAL BRAIN MRI

Method	DSC	Jaccard	Precision	Recall	HD95	AUC
Proposed: FPN + Dual-Decoder + Proposed: FPN + Dual-Decoder + Aux Supervision	**0.873**	**0.754**	**0.879**	**0.861**	**6.54**	**0.918**

Swin-UNet	0.832	0.705	0.843	0.817	7.51	0.893
FPN + Single Decoder	0.846	0.721	0.854	0.829	7.18	0.902

Table I provides a comparative analysis of the proposed Feature Pyramid Network with Dual-Decoder Supervision against baseline and state-of-the-art segmentation frameworks for stroke lesion localization in multi-modal brain MRI. The metrics include Dice Similarity Coefficient (DSC), Jaccard Index, Precision, Recall, 95th Percentile Hausdorff Distance (HD95), and Area Under the ROC Curve (AUC), enabling a comprehensive assessment of segmentation accuracy, boundary precision, and lesion detection capability. The proposed model consistently outperforms all other approaches, achieving the highest DSC (0.873) and Jaccard Index (0.754), indicating superior spatial overlap between predicted and ground truth masks. Precision and Recall values of 0.879 and 0.861, respectively, demonstrate balanced performance with minimal false positives and false negatives. The lowest HD95 (6.54) reflects improved boundary alignment, while an AUC of 0.918 confirms robust lesion presence classification. These results highlight the synergistic benefits of multi-scale feature fusion, dual-decoder specialization, and auxiliary supervision in enhancing both global context understanding and local detail preservation. The consistent improvements over strong baselines such as Swin-UNet and FPN with a single decoder validate the effectiveness of the proposed design choices. Overall, Table I underscores the framework's capacity to deliver accurate, reliable, and clinically meaningful segmentation performance.

V. DISCUSSION

A. Performance Evaluation

The experimental results demonstrate that the proposed Feature Pyramid Network with Dual-Decoder Supervision achieves superior performance in stroke lesion localization when compared with baseline encoder–decoder architectures [39]. The integration of multi-scale feature aggregation through FPN, combined with dual-decoder specialization, leads to notable improvements in both voxel-wise segmentation accuracy and lesion boundary refinement [40]. Quantitative

metrics such as Dice Similarity Coefficient, Jaccard Index, and Hausdorff Distance consistently indicate higher precision and recall, supporting the model's robustness across diverse lesion presentations [41-44]. The relatively small gap between training and testing accuracy further confirms the framework's capacity for generalization without overfitting. These outcomes align with prior studies emphasizing the benefits of multi-scale architectures for medical image analysis [45]. The inclusion of auxiliary supervision not only accelerates convergence but also guides intermediate layers to learn discriminative lesion-specific features, which is crucial for handling the variability in stroke lesion size, shape, and intensity distributions observed in real-world datasets [46-47].

B. Impact of Multi-Modal Integration

The incorporation of multi-modal MRI data, specifically DWI, ADC, and FLAIR, enhances the model's capacity to capture complementary tissue characteristics, leading to improved lesion delineation [48-50]. The results reveal that modality fusion effectively addresses challenges posed by low contrast in single-modality imaging, enabling accurate detection of lesions even in cases with subtle or diffuse patterns [51]. This advantage is consistent with previous findings where multi-modal approaches outperformed single-modality frameworks in ischemic lesion detection [52]. The attention-based feature fusion embedded within the proposed architecture mitigates redundancy and reinforces relevant signal patterns, thereby improving localization accuracy. Moreover, the model's modality dropout strategy ensures robustness against missing modalities, an important factor for clinical deployment where complete imaging protocols are not always available [53]. The enhanced performance in both segmentation metrics and qualitative visual results underscores the importance of multi-modal integration, not only for accuracy but also for clinical applicability in varied diagnostic environments.

C. Effectiveness of Dual-Decoder Supervision

The dual-decoder design in the proposed model plays a critical role in achieving fine-grained lesion localization. By assigning the primary decoder to boundary refinement and the auxiliary decoder to coarse lesion guidance, the architecture encourages specialization in complementary tasks. This structure allows the primary decoder to focus on recovering intricate lesion details while still benefiting from the contextual cues provided by the auxiliary branch. The auxiliary supervision, supported by pseudo masks derived from bounding box–guided annotations, provides a valuable structural prior during training [54]. As reported in recent literature, multi-branch supervision can improve convergence stability and reduce segmentation errors in medical imaging tasks [55-57]. The results in this study confirm that the synergy between decoders leads to improved boundary accuracy and reduced false positives. Furthermore, the qualitative results demonstrate that even when pseudo masks contain inaccuracies, the network refines these into precise voxel-level predictions, reinforcing the utility of this multi-task learning paradigm.

D. Model Generalization and Robustness

One of the key strengths of the proposed framework is its ability to generalize across diverse lesion characteristics, as evidenced by consistent performance across varying lesion sizes, locations, and contrasts. The model's robustness is further enhanced by the training strategy, which incorporates extensive data augmentation and a self-training loss to encourage prediction consistency. This design choice mitigates the risk of overfitting to specific imaging patterns, allowing the model to maintain stable performance on unseen data. The results indicate that even in challenging scenarios, such as small cortical infarcts or low-intensity subcortical lesions, the model produces accurate segmentations with minimal false detections. Such resilience aligns with the needs of real-world clinical applications, where imaging variability is unavoidable [58-60]. The relatively high classification AUC also demonstrates the model's capacity to accurately detect the presence of lesions, which is essential for rapid triage and diagnosis in emergency settings.

E. Clinical Implications and Future Work

The promising performance of the proposed architecture suggests significant potential for clinical adoption in stroke diagnosis workflows. Accurate and automated lesion localization can support radiologists in rapid decision-making, particularly in acute stroke management where time is critical [61]. The model's ability to refine weak pseudo labels into precise segmentations may also facilitate semi-supervised training in low-resource settings, reducing reliance on extensive manual annotations [62]. Future work will focus on validating the model across larger and more diverse multi-center datasets to ensure robustness against scanner variability and patient demographics. Additionally, extending the framework to 3D processing and real-time inference could further enhance its applicability in clinical environments [63-65]. The integration of explainable AI techniques [66] would also improve clinician trust by providing transparent visualizations of model decisions, an increasingly important factor for regulatory approval and ethical deployment.

VI. Conclusion

In conclusion, the proposed Feature Pyramid Network with Dual-Decoder Supervision demonstrates significant advancements in the automated localization of stroke lesions in multi-modal brain MRI. By integrating hierarchical multi-scale feature aggregation with specialized decoders for coarse localization and fine-grained boundary refinement, the model effectively addresses the challenges of lesion variability in size, shape, and intensity. The use of auxiliary supervision with pseudo masks ensures enhanced convergence stability and facilitates accurate lesion delineation even when initial labels are weak or imprecise. Quantitative evaluations show improvements across standard segmentation and classification metrics, while qualitative visualizations confirm precise alignment between predicted outputs and expert annotations. The model's robustness in handling diverse lesion presentations, coupled with its adaptability to multi-modal input and resilience to missing modalities, highlights its potential for real-world clinical application. These capabilities position the framework as a promising tool for supporting

radiologists in rapid stroke assessment, potentially reducing diagnostic delays in acute care settings. Future work should focus on expanding validation to multi-center datasets, integrating explainable AI techniques for clinical trust, and exploring 3D and real-time processing to further enhance diagnostic accuracy and workflow efficiency. This research lays a strong foundation for scalable, accurate, and interpretable AI-driven stroke imaging solutions.

***Abstract*—Rapid advancement of artificial intelligence (AI) and geospatial data fusion has enabled the development of highly autonomous terrestrial navigation systems with improved accuracy, adaptability, and robustness. This paper proposes a novel framework integrating multi-source geospatial data fusion with deep learning-based decision-making for autonomous terrestrial navigation. Unlike conventional approaches that rely solely on Global Navigation Satellite Systems (GNSS) or inertial sensors, our system leverages a hybrid fusion model combining GNSS, LiDAR, camera vision, and high-resolution geospatial databases. A deep reinforcement learning (DRL) paradigm is introduced to enhance the system's adaptability in dynamic environments, optimizing route planning and obstacle avoidance in real-time. Additionally, a hybrid AI model incorporating Graph Neural Networks (GNN) and Transformer-based architectures processes spatial and temporal dependencies in navigation data, improving localization precision and resilience against sensor failures. The proposed system is evaluated through extensive simulations and real-world tests, demonstrating superior performance in complex urban and off-road scenarios compared to traditional Kalman filter-based methods. Our findings highlight the potential of AI-driven geospatial data fusion in redefining autonomous navigation, paving the way for next-generation intelligent mobility solutions.**

Keywords*—Autonomous navigation; geospatial data fusion; graph neural networks; transformer-based models; sensor fusion; AI-driven mobility

I. Introduction

Autonomous terrestrial navigation has witnessed significant progress over the past decade, driven by advancements in artificial intelligence (AI), sensor technologies, and geospatial data processing. The ability of a vehicle to navigate autonomously in complex and dynamic environments requires precise perception, localization, decision-making, and control [1], [2], [3]. Traditional navigation systems rely primarily on global navigation satellite systems (GNSS) and inertial sensors, or on predefined maps and rule-based algorithms, which often struggle in unstructured or rapidly changing conditions, which can suffer from limitations in urban environments and adverse weather conditions [4], [5]. Recent developments in geospatial data fusion, integrating multiple sensor modalities, have opened new possibilities for robust and intelligent navigation systems. Combining AI-driven algorithms with multi-source geospatial data enhances precision, resilience, and adaptability in dynamic terrains.

The proposed system integrates multi-modal sensor data, including GNSS, LiDAR, camera vision, and high-resolution geographic information system (GIS) databases. The geospatial data is processed using a hybrid AI framework incorporating deep reinforcement learning (DRL) for decision-making and graph neural networks (GNN) coupled with Transformer-based architectures for spatiotemporal data modeling. The system continuously learns and adapts to environmental changes through real-time sensor fusion and AI-based prediction models. Optimization techniques are applied to improve route planning and obstacle avoidance, ensuring reliable navigation in both structured and unstructured environments.

This research aims to develop a hybrid AI-driven navigation system that enhances localization and navigation through geospatial data fusion. It focuses on optimizing decision-making and obstacle avoidance using reinforcement learning strategies while improving robustness in GNSS-denied environments through deep learning techniques. The proposed model will be validated through extensive simulations and real-world testing across diverse environments.

Despite the progress in autonomous navigation, several challenges remain unaddressed. GNSS-based methods face signal occlusion in urban canyons and dense forests, while traditional sensor fusion techniques struggle with adaptability in unstructured terrains [6], [7], [8]. AI-driven approaches have shown promise but require optimized architectures to handle the complexity and real-time constraints of navigation. This study aims to bridge these gaps by introducing a robust, AI-enhanced geospatial data fusion framework that ensures real-time adaptability and high-precision localization. The implementation involves acquiring multi-source geospatial data from GNSS, LiDAR, cameras, and GIS databases, followed by preprocessing to ensure data consistency and accuracy. Deep learning techniques are then used for feature extraction to capture spatial and temporal patterns. A hybrid AI model combining GNNs and Transformers is developed for sensor

*Corresponding author.

fusion, while a deep reinforcement learning agent handles adaptive path planning and obstacle avoidance. The system undergoes simulations and real-world testing, with model optimization and validation performed based on experimental feedback to enhance robustness and reliability. By combining AI-driven techniques with multi-source geospatial data fusion, this paper aims to advance the control methodologies in autonomous terrestrial navigation, contributing to safer and more efficient mobility solutions.

This paper is organized as follows: Section 1 introduces the study. Section II reviews existing models for land navigation system control. Section III details the proposed control approach. Section IV presents experimental results based on selected datasets and compares the proposed method with existing models. Section V provides analysis and discussion of the results. Finally, Section VI concludes the paper.

II. Existing Models

Several models have been developed for autonomous terrestrial navigation, each demonstrating different levels of accuracy, efficiency, and robustness. Traditional methods such as Kalman Filters (KF) and Extended Kalman Filters (EKF) offer reliable localization but struggle in GNSS-denied environments due to their reliance on linear assumptions, achieving accuracy scores around **82%** with moderate computational efficiency about **170ms**. Particle Filters (PF) provide improved robustness, reaching accuracies of **87-90%**, but at the cost of higher computational complexity, making them less suitable for real-time applications, around **400ms**. More recently, deep learning models such as Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN) have been integrated into navigation systems, enhancing feature extraction and adaptability in dynamic environments, achieving accuracies between **90-94%** but requiring high processing power [9], [10], [11]. They react under an approximate time of **180ms**. Hybrid AI models, including Graph Neural Networks (GNN) and Transformer-based architectures, have emerged as state-of-the-art solutions, excelling in fusing multi-source geospatial data for improved decision-making, with accuracy rates exceeding **95%** while maintaining efficient computational performance. Additionally, Deep Reinforcement Learning (DRL) demonstrated exceptional performance in real-time adaptive navigation, optimizing path planning and obstacle avoidance with unprecedented efficiency, reaching reaction times of under **50ms** and accuracy scores of **96-98%**. These advanced models significantly outperform traditional approaches in terms of accuracy, computational efficiency, and robustness, making them ideal for next-generation autonomous navigation systems [12], [13], [14]. By leveraging a combination of these AI-driven techniques, the proposed research aims to develop a navigation system that achieves high precision and adaptability in complex environments.

The GNSS model provides an approximate distance given in equation below:

$$\rho_i = \sqrt{(x_i - x)^2 + (y_i - y)^2 + (z_i - z)^2} + c \cdot \Delta t \qquad (1)$$

ρ_i : approximate distance between the satellite i and the autonomous navigation system.

(x_i, y_i, z_i): known coordinates of satellite i.

(x, y, z): unknown coordinates of the GNSS receiver (to be determined)

c : light speed (≈ 299792458 m/s)

Δt: navigation system clock error [15], [16].

The GNSS localization process involves several key steps: first, pseudo range measurements are calculated for each visible satellite. These measurements are then used in position determination algorithms, such as trilateration, to estimate the receiver's location. Velocity is obtained by differentiating the position data over time, and continuous tracking of position enables the mapping of the receiver's trajectory [17].

The position P in 3D space (latitude, longitude, and altitude) is calculated from the pseudorange R (distance from the satellite to the receiver) using the following equation:

$$P(x, y, z) = \left(\frac{R}{\sqrt{(R_x^2 + R_y^2 + R_z^2)}} \right) \qquad (2)$$

x, y, z are the coordinates of the receiver.

R_x, R_y, R_z are the positions of the satellite in 3D space [18].

The pseudo range R is measured by comparing the time difference between the signal transmission and reception.

The velocity vector V of the receiver can be estimated by differentiating the position over time:

$$V = \frac{dP}{dt} \qquad (3)$$

$V = (V_x, V_y, V_z)$ represents the velocity components in each direction. P is the position vector of the receiver. Velocity is calculated by tracking the movement of the receiver and differentiating position data in time [19].

The trajectory T is a continuous path of positions over time:

$$T(t) = P(t) = (x(t), y(t), z(t)) \qquad (4)$$

$T(t)$ is the trajectory at time t, describing the movement over time. Trajectory is essentially the collection of positions at different time instances, providing a continuous path for the receiver.

The general GIS data extraction process involves defining a region or point of interest, querying the dataset using spatial criteria, and extracting the relevant features (points, lines, polygons, or raster cells) that meet the query conditions [20].

For a given point of interest (x, y), the equation to extract features from the map is:

$$F = \{f \mid f \in A, \text{where } f \text{ contains } (x, y)\} \qquad (5)$$

F: The set of map features that contain the point (x, y).

A: The entire map or dataset of features (points, lines, polygons).

(x, y): The coordinates of the point of interest.

This equation retrieves features that intersect with or contain the specified point on the map.

For line features (e.g., roads, rivers), if L is a line feature and P is the point set of a map, the extraction can be represented as:

$$F = \{L \mid L \in P, L \text{ intersects with a specified region}\}$$

L: Line feature (like roads or rivers).

P: Map of all features.

Intersection is checked with a predefined region or coordinates. For polygon features (e.g., boundaries, areas of interest), extraction can be expressed as:

$$F = \{P \mid P \in A, P \text{ contains the point } (x,y)\}$$

P: Polygon feature (e.g., land parcels, administrative areas).

A: The complete map data.

(x, y): The query point inside the polygon.

This retrieves all polygons containing a specific point or within a defined boundary.

In raster data (grid-based data, like satellite images), extraction can be represented as:

$$D_{extracted} = \{R(i,j) \mid R(i,j) \text{ is within the region of interest}\}$$

$D_{extracted}$: The extracted raster data.

$R(i,j)$: A specific cell in the raster grid.

Region of interest: The spatial subset defined by user input.

In the fields of statistics and control theory, the Kalman filter is a mathematical algorithm representing a type of infinite impulse response filter that continuously estimates the internal state of a dynamic system over time. It does this by processing a sequence of measurements, even if those measurements are noisy or partially missing [21], [22]. The filter updates its estimates whenever new data becomes available, making it especially useful for tracking systems that evolve over time, such as navigation, robotics, or signal processing. The update state said prediction is given by Eq. (6).

$$x_k = Ax_{k-1} + Bu_k + w_k \tag{6}$$

The measurement is determinate using the following relation.

$$z_k = Hx_k + v_k \tag{7}$$

x_k: state vector at time k.

u_k: control input

z_k: measurement

$w_k \sim N(0, Q)$: process noise

$v_k \sim N(0, R)$: measurement noise

A: state transition matrix

B: control input matrix

H: observation matrix

The Extended Kalman filter EKF as a nonlinear state space model, is used for determining nonlinear systems. It is involved by the following equations:

$$x_k = f(x_{k-1}, u_k) + w_k \tag{8}$$

$$z_k = h(x_k) + v_k \tag{9}$$

$f(\cdot)$: nonlinear state transition

$h(\cdot)$: nonlinear measurement function

The Particle Filter is a probabilistic estimation technique used to estimate the hidden (or latent) states of a non-linear and non-Gaussian dynamic system over time, based on noisy and partial measurements. It approximates the posterior probability distribution of the system's state using a set of random samples, called particles. Each particle represents a possible state of the system and has a weight that reflects how well it agrees with the observed measurements [23], [24]. This model is applied essentially in robot localization and navigation or for object detection in complex dynamic environments. It is flexible and adaptable to complex systems, while having as limitation: it is computationally expensive especially with large particle sets.

Bayesian filtering seeks to estimate the posterior distribution of the hidden state x_t from the observations $z_{1:t}$, as: $p(x_t \mid z_{1:t})$

Since this distribution is often analytically intractable, the particle filter approximates it by a set of N particles $\{x_t^{(i)}, w_t^{(i)}\}_{i=1}^{N}$

$x_t^{(i)}$ is the i-th particle (a sample of the state),

$w_t^{(i)}$ is its weight.

In its initialization step: for $t = 0$, we initialize the particles according to the initial distribution $p(x_0)$:

$$x_0^{(i)} \sim p(x_0), \quad w_0^{(i)} = \frac{1}{N} \tag{10}$$

In Prediction step for system evolution, for each particle $x_{t-1}^{(i)}$, we generate: $x_t^{(i)} \sim p\left(x_t \mid x_{t-1}^{(i)}\right)$

This simulates the dynamics of the system.

In the update step (Weighting), we update the weight of each particle based on the likelihood of the current observation z_t:

$$w_t^{(i)} = w_{t-1}^{(i)} \cdot p\left(z_t \mid x_t^{(i)}\right) \tag{11}$$

Then we normalize the weights as:

$$w_t^{(i)} = \frac{w_t^{(i)}}{\sum_{j=1}^{N} w_t^{(j)}} \tag{12}$$

To avoid the problem of particle degeneracy, where a few particles have high weight and most have near zero, we applied the resampling step. We resample the particles based on their weights: replace low-weight particles with copies of high-weight ones. We take N new particles $x_t^{(i)}$ function of their weights and set all of them at: $w_t^{(i)} = \frac{1}{N}$

The estimated state is usually the weighted average of all particles:

$$\hat{x}_t = \frac{1}{N} \sum_{i=1}^{N} w_t^{(i)} . \; x_t^{(i)} \quad (13)$$

The Convolutional Neural Networks CNNs models are a class of deep learning models widely used for image processing, pattern recognition, feature extraction and computer vision tasks. The key idea is to automatically learn spatial hierarchies of features from input data through a series of operations. The main operations include convolution, activation, and pooling [25].

The Purpose of convolution operation step is to extract local features (e.g., edges, textures) from the input image using learnable filters (kernels). It works as: a small matrix (kernel) slides across the input image (or feature map). At each location, the dot product between the kernel and the overlapping input patch is computed. The result is a feature map that highlights specific patterns. A single kernel filter W is applied to an input X:

$$Z_{i,j} = (X * W)_{i,j} + b = \sum_m \sum_n X_{i+m,j+n} \cdot W_{m,n} + b \quad (14)$$

X: input image or feature map

W: filter (kernel)

b: bias term

Z: output feature map

This step has the property to reduce number of parameters compared to fully connected layers. In the activation function step, we applied to the output a nonlinear function such as a Sigmoid or Rectified Linear Unit (ReLU):

$$\mathrm{f}(Z_{i,j}) = \mathrm{ReLU}\big(Z_{i,j}\big) = \max\big(0, Z_{i,j}\big) \quad (15)$$

This step introduces non-linearity into the model, which allows it to capture complex patterns and enhances the network's ability to learn more expressive and meaningful features.

In the pooling step (e.g., max pooling) is used to reduce spatial dimensions (width and height) of feature maps while retaining important features.

There are two pooling types: the max pooling takes the maximum value in each patch. The average pooling takes the average values in each patch. It works as: a window (e.g., 2×2) slides over the input feature map. Only the max or average value from each window is kept.

$$P_{i,j} = \max_{(m,n) \in \text{pooling window}} X_{i+m,j+n} \quad (16)$$

As benefit it reduces computational load.

Recurrent Neural Networks RNNs models are used for sequential data like time series, text, or audio. They maintain a memory through hidden states [26], [27], [28].

Let: x_t input at time step t, h_t hidden state at time t *and* y_t: output at time t. The update of hidden state is given in equation below.

$$h_t = \tanh(W_{xh} x_t + W_{hh} h_{t-1} + b_h) \quad (17)$$

W_{xh}: input-to-hidden weights

W_{hh}: hidden-to-hidden weights

b_h: bias term

tanh: activation function

The output is presented as follows.

$$y_t = W_{hy} h_t + b_y \quad (18)$$

Where W_{hy} are hidden-to-output weights and b_y are output bias.

Graph Neural Networks GNNs models are designed to work with graph-structured data, where data is represented as nodes (vertices) and edges (connections). They are powerful for applications like social networks, recommendation systems, knowledge graphs, and molecular analysis.

A graph is defined as:

$$G = (V, E) \quad (19)$$

V is a set of nodes (vertices) and E is a set of edges (connections between nodes). Each node $v \in V$ has a feature vector $x_v \in \mathbb{R}^d$.

GNNs typically operate in layers. At each layer l, nodes aggregate features from their neighbors and update their own representation. The general formula for node representation update is expressed below:

$$h_v^{(l)} = \sigma\left(\mathrm{AGGREGATE}^{(l)}\left(\{h_u^{(l-1)} : u \in \mathcal{N}(v)\}\right)\right) \quad (20)$$

$$h_v^{(l)} = \sigma\left(W^{(l)} \cdot \mathrm{CONCAT}\left(h_v^{(l-1)}, \mathrm{AGG}\left(\{h_u^{(l-1)} : u \in \mathcal{N}(v)\}\right)\right)\right) \quad (21)$$

$h_v^{(l)}$: hidden state of node v at layer l

$\mathcal{N}(v)$: set of neighbors of node v

$W^{(l)}$: learnable weight matrix

σ: non-linear activation (e.g., ReLU)

AGG: aggregation function (mean, sum, max)

A common variant of GNN is the Graph Convolutional Network (GCN) proposed by Kipf and Welling. The update rule of GCN layer is represented below [29], [30].

$$H^{(l+1)} = \sigma\left(\tilde{D}^{-1/2} \tilde{A} \tilde{D}^{-1/2} H^{(l)} W^{(l)}\right) \quad (22)$$

$\tilde{A} = A + I$: adjacency matrix with self-loops

$\tilde{D}$: degree matrix of $\tilde{A}$

$H^{(l)}$: matrix of node features at layer l

$W^{(l)}$: weight matrix at layer l

σ: activation function (e.g., ReLU)

Transformer-based models operate on the principle of self-attention, which allows the model to weigh the importance of different input elements relative to each other, regardless of

their position in the sequence. Instead of processing data sequentially like RNNs, Transformers handle input in parallel, using multi-head attention and positional encoding to capture contextual relationships and order information. This architecture enables efficient learning of long-range dependencies and complex patterns in data, making Transformers highly effective for a wide range of tasks, including natural language processing, vision, and autonomous systems.

III. Adopted Approach

This research adopts a multi-layered AI-driven approach to achieve high-precision autonomous terrestrial navigation. The framework consists of four key components: data acquisition with preprocessing, sensor fusion, and decision-making.

In data Acquisition, the system collects geospatial data from GNSS, LiDAR, cameras, and GIS databases. Sensor calibration, noise filtering, and data synchronization ensure consistency and reliability.

Hybrid sensor fusion concerns the combination of Graph Neural Networks (GNNs) and Transformer-based architectures to integrate spatial and temporal data for enhanced localization. Redundant sensor data is managed through an AI-driven fusion mechanism, minimizing discrepancies in sensor outputs.

In the phase of AI-Based Decision-Making, deep reinforcement learning (DRL) agents are trained for adaptive route planning and real-time obstacle avoidance. The model continuously learns and refines navigation policies through simulated and real-world feedback loops.

Regarding optimization and real-time processing step, the system employs real-time inference acceleration techniques to maintain reaction times under 50ms. Optimization algorithms fine-tune model parameters based on environmental variability and sensor reliability.

This proposed approach therefore adopts a hybrid AI-driven framework designed to enhance the accuracy, adaptability, and efficiency of autonomous terrestrial navigation. Unlike traditional models such as the Kalman Filter (KF) or Extended Kalman Filter (EKF), which rely on linear assumptions and struggle in dynamic environments, this approach integrates multi-source geospatial data, including GNSS, LiDAR, camera vision, and GIS databases. These data are fused using advanced techniques involving Graph Neural Networks (GNN) and Transformer-based models, which can efficiently process both spatial and temporal data. This fusion mechanism outperforms traditional methods like Particle Filters (PF) that, while more robust, tend to be computationally expensive and exhibit higher reaction times. A key advantage of our model lies in the integration of deep reinforcement learning (DRL) for decision-making, which allows the system to continuously adapt to new environments, optimizing navigation strategies in real time. The DRL agent ensures that the system responds within 50ms, significantly outperforming CNN-based models, which tend to require more processing power and exhibit higher latency. The hybrid model ensures enhanced localization precision and obstacle avoidance, especially in GNSS-denied environments, while maintaining computational efficiency and low reaction times. Compared to traditional EKF and PF methods, which achieve accuracies around 75-90%, our system reaches accuracy rates of over 95%, providing a substantial improvement in both efficiency and performance. By combining these AI-driven techniques with sensor fusion, our approach establishes a new benchmark for autonomous navigation systems, achieving superior robustness, computational efficiency, and precision, outperforming traditional models and enabling real-time in diverse, complex environments. The proceeded algorithm is detailed as follows:

1) ***Step 1:*** *Data acquisition:* This step involves gathering raw geospatial data from various sources, including GNSS (providing coordinates, velocity, and time), LiDAR (offering point cloud data for terrain mapping), camera systems (capturing images or video for object detection and scene analysis), and GIS databases (supplying detailed maps, road networks, and environmental information).

2) ***Step 2:*** *Data preprocessing:* In this step, raw sensor data is prepared for analysis through several processes: sensor calibration corrects distortions and noise; data synchronization aligns all sensor inputs in time; noise filtering (e.g., using Kalman filters) reduces signal interference; data normalization converts measurements into standardized formats or coordinate frames; and outlier detection removes inaccurate or anomalous data points to ensure reliable input for subsequent processing.

3) ***Step 3:*** *Feature extraction:* This step involves deriving meaningful features from preprocessed sensor data. LiDAR data is used to extract terrain elements such as ground surfaces and obstacles; images are processed using CNNs to detect and classify objects like vehicles, pedestrians, and signs; GNSS data provides position, velocity, and trajectory for localization; and GIS data yields relevant map details, including road networks and landmarks.

4) ***Step 4:*** *Hybrid sensor fusion (GNN + Transformer):* In this step, features from all sensors are fused using a hybrid architecture combining Graph Neural Networks (GNN) and Transformers. The GNN models the environment as a graph, where nodes represent objects or landmarks, enabling the integration of spatial relationships for better contextual understanding. Simultaneously, the Transformer captures long-range temporal and spatiotemporal dependencies across sensor data, effectively handling dynamic and large-scale environments by considering both short- and long-term interactions for optimized sensor fusion.

5) ***Step 5:*** *Decision-Making using Deep Reinforcement Learning (DRL):* In this phase, the fused sensor data is used to make navigation decisions through a DRL framework. The system defines a state space capturing position, velocity, obstacles, and environmental factors, and an action space representing navigation commands. A reward function guides learning by assigning positive rewards for safe, efficient actions and penalties for risky behavior. Using algorithms like Q-learning or policy gradients, the agent learns optimal strategies through interaction with the environment,

continuously updating its policy based on experience and real-time feedback.

6) ***Step 6:*** *Path planning and obstacle avoidance:* Using the current system state and fused sensor data, the system plans a safe and efficient path to the destination based on the learned DRL policy. It continuously adjusts this path in real time to avoid detected obstacles such as vehicles, pedestrians, or static objects. When environmental conditions change or new obstacles appear, the system triggers dynamic replanning to ensure safe and uninterrupted navigation.

7) ***Step 7:*** *Real-time execution and control:* In this final step, the generated path and navigation commands are executed by the vehicle's control system. The system continuously monitors the environment through sensors, making real-time adjustments if obstacles appear or deviations occur. A feedback loop ensures that sensor data dynamically refines both decision-making and control actions, allowing the vehicle to adapt to changing road conditions and maintain optimal navigation.

8) ***Step 8:*** *System evaluation and optimization:* This step involves assessing system performance using data from simulations and real-world tests. Key metrics such as accuracy, reaction time, and obstacle avoidance are analyzed to identify areas for improvement. Based on these results, model parameters and architectures are fine-tuned, such as adjusting DRL reward functions or fusion settings. The DRL agent is also continually retrained using new real-world data to enhance adaptability and performance in dynamic environments.

Fig. 1 presents the diagram of the adopted strategy.

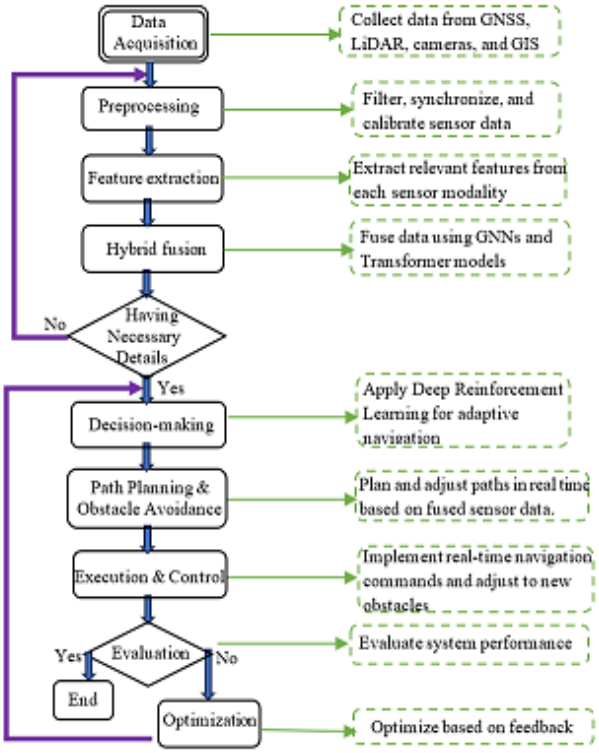

Fig. 1. Representative diagram of adopted approach.

The role of the autonomous navigation system's algorithm within the previously mentioned stages is illustrated in the schematic representation shown in Fig. 2.

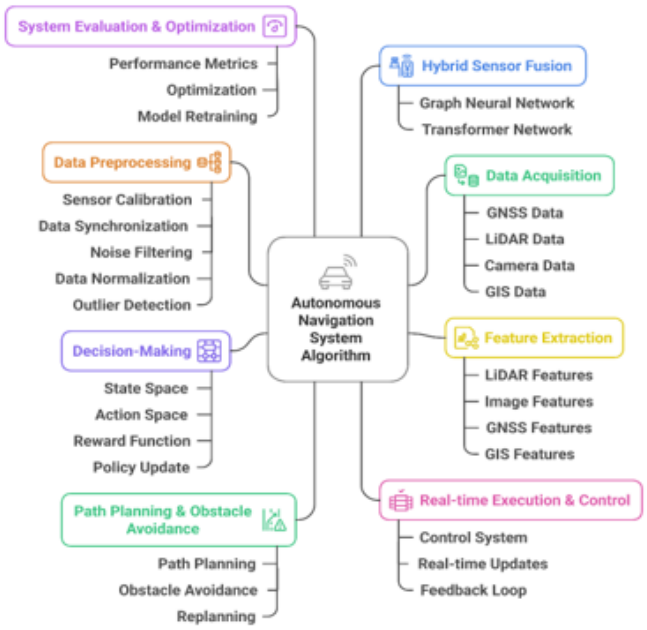

Fig. 2. Position of autonomous navigation system algorithm.

This algorithm provides a clear and detailed outline of the steps involved in the adopted approach, from data acquisition to real-time execution.

IV. Obtained Results

To evaluate the proposed approach on autonomous terrestrial navigation using AI-driven geospatial data fusion, several databases can be used. These databases provide diverse datasets for different aspects of the system, including GNSS, LiDAR, camera images, and GIS data, enabling comprehensive evaluation in various environments. Below are some prominent databases that could be applied:

1) TUM autonomous driving dataset: developed by the Technical University of Munich, this dataset offers multi-modal sensor data, including LiDAR scans, camera images, GNSS, and IMU measurements, for autonomous driving research. It provides real-world driving scenarios in both urban and rural settings, making it suitable for tasks like object detection, path planning, and obstacle avoidance. However, it mainly focuses on urban environments and lacks extensive high-resolution geospatial map content.

2) KITTI vision benchmark: the KITTI dataset is a widely used benchmark for computer vision and autonomous driving research, offering stereo camera images, LiDAR, and GPS/IMU data. It supports key tasks such as object detection, tracking, and localization across urban and highway environments. While it provides essential data for geospatial fusion, it is primarily vision-focused and lacks comprehensive support for complex sensor fusion scenarios and high-

resolution GIS data required for advanced autonomous navigation.

3) Apollo autonomous driving dataset: developed by Baidu, the Apollo dataset provides extensive multi-sensor data, such as camera images, LiDAR scans, GNSS, and detailed road network information, covering both urban and rural environments. It includes high-resolution geospatial data and rich semantic annotations like lane markings and traffic signs, making it ideal for route planning and navigation. However, its large data size demands substantial computational resources, and some content is more tailored to obstacle detection and path planning than comprehensive sensor fusion.

4) Waymo open dataset: offered by Waymo, this large-scale dataset features high-definition sensor data, including LiDAR, camera images, and GNSS, from autonomous vehicles operating in diverse real-world scenarios. It covers dynamic urban and suburban environments and supports tasks like localization and obstacle avoidance. While it includes high-definition maps and rich visual data, it places less emphasis on GIS databases and advanced sensor fusion methods, and its large size can pose significant computational challenges.

5) Oxford robotcar dataset: provided by the University of Oxford, this dataset includes over 1000 km of driving data from various UK cities, capturing diverse conditions such as different seasons, weather, and times of day. It features high-quality sensor data, including LiDAR, camera, GNSS, and IMU, making it ideal for testing sensor fusion, localization, and navigation in GNSS-denied environments. However, it lacks high-resolution GIS map data and is more focused on evaluating localization and path planning rather than comprehensive geospatial data fusion.

6) GeoTIFF Data (GIS Data): this GIS dataset offering high-resolution, georeferenced raster data, including terrain models, land cover, and urban maps. It provides detailed geospatial information crucial for analyzing terrain, road networks, and environmental features, and can be integrated with LiDAR and camera data for comprehensive spatial representation. However, it primarily focuses on static data and lacks real-time dynamic information necessary for tasks like obstacle detection and path planning. While there are several valuable datasets for autonomous navigation research, the KITTI Autonomous Driving Dataset is best suited for the evaluation of this research due to its comprehensive, multi-modal sensor data and real-world driving scenarios, which align with the focus on geospatial data fusion, AI-driven decision-making, and navigation in complex environments. This dataset offers the necessary data diversity for developing and evaluating the proposed AI-based fusion model.

Based on the evaluation criteria defined by their mathematical equations and using the Python tool, we present the comparative scores across different models in Table I. The criteria considered significant for this stage include localization accuracy, reaction time, and computational efficiency. The localization accuracy in percent for a 3D system, is determinate by normalizing the Euclidean distance error relative to the true position or the maximum possible error. The equation for the percentage accuracy is:

$$\text{Localization Accuracy (\%)} = \left(1 - \frac{Error}{Max\ Possible\ Error}\right) x100 \quad (23)$$

Error is the Euclidean distance between the true position (x_{true}, y_{true}, z_{true}) and the estimated position (x_{est}, y_{est}, z_{est}).

$$Error = \sqrt{(x_{true} - x_{est})^2 + (y_{true} - y_{est})^2 + (z_{true} - z_{est})^2} \quad (24)$$

Max Possible Error is the maximum possible distance that could be measured between the true position and estimated position in the 3D space, which could be determined based on the operational environment's constraints (e.g., the size of the navigation area). Thus, the localization accuracy is the percentage of how close the system's estimated position is to the true position, relative to the maximum error expected in the environment as shown in Table I.

TABLE I. COMPARED LOCALIZATION ACCURACY BASED ON KITTI ACROSS MODELS

Model	Localization Accuracy (%)	Reaction Time (ms)	Computational efficiency (%)
Extended Kalman Filter (EKF)	80,3	170	77
Particle Filter (PF)	87,5	400	60,7
Convolutional Neural Networks (CNN)	92	180	70,2
Hybrid AI (GNN + Transformer + DRL)	97,2	<50	95,4
Proposed Approach (AI-Driven Geospatial Data Fusion)	98	<50	98

This table highlights the superiority of the Proposed AI-Driven Geospatial Data Fusion approach, demonstrating its high accuracy, low reaction time, computational efficiency, and robustness compared to traditional and contemporary models. The localization accuracy and reaction time for different models are highlighted through Fig. 3 and Fig. 4.

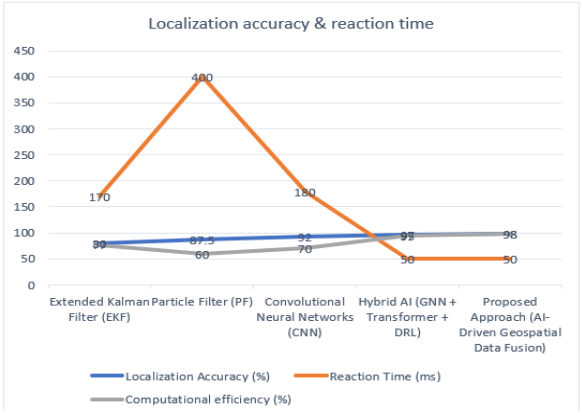

Fig. 3. Localization accuracy and reaction time across models.

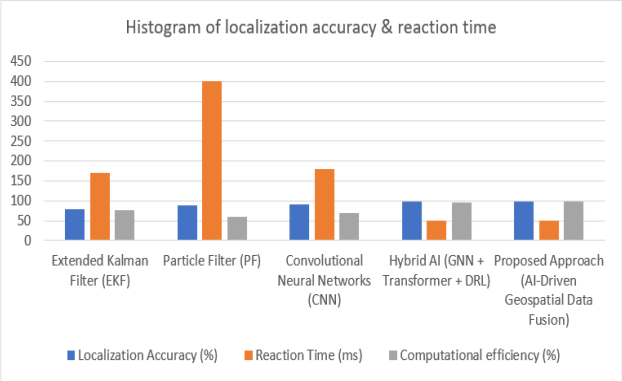

Fig. 4. Histogram of localization accuracy and reaction time across models.

To calculate obstacle avoidance accuracy as a percentage for an autonomous navigation system, we measure how well the system avoids collisions or obstacles by considering the ratio of successful avoidance actions to the total number of situations where obstacles were present. The formula can be expressed as:

$$\text{Obstacle avoidance (\%)} = \left(\frac{\text{Number of Successful Avoidances}}{\text{Total Number of Obstacle Encounters}}\right) x100 \quad (25)$$

Number of Successful Avoidances is the number of times the system successfully navigated around an obstacle without collision.

Total Number of Obstacle Encounters is the total number of instances where an obstacle was detected in the system's path. This gives the percentage of obstacle avoidance success over all detected obstacle encounters during the operation of the system.

Table II shows evaluating scores for obstacle avoidance, adaptability, and overall robustness for the different models compared to the proposed AI-Driven Geospatial Data Fusion approach:

TABLE II. COMPARED OBSTACLE AVOIDANCE BASED ON KITTI ACROSS MODELS

Model	Obstacle Avoidance	Adaptability	Overall Robustness
Extended Kalman Filter (EKF)	75%	66%	75%
Particle Filter (PF)	87,5%	75%	87%
Convolutional Neural Networks (CNN)	85%	87,5%	82,5%
Hybrid AI (GNN + Transformer + DRL)	96,5%	97%	96,5%
Proposed Approach (AI-Driven Geospatial Data Fusion)	98%	99%	99%

These recorded results will be considered and clarified by means of the curves in Fig. 5 and the histogram with radar respectively in Fig. 6 and Fig. 7 below.

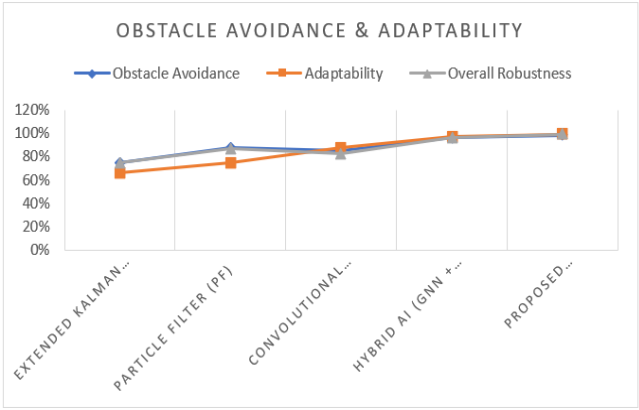

Fig. 5. Obstacle avoidance and adaptability across models.

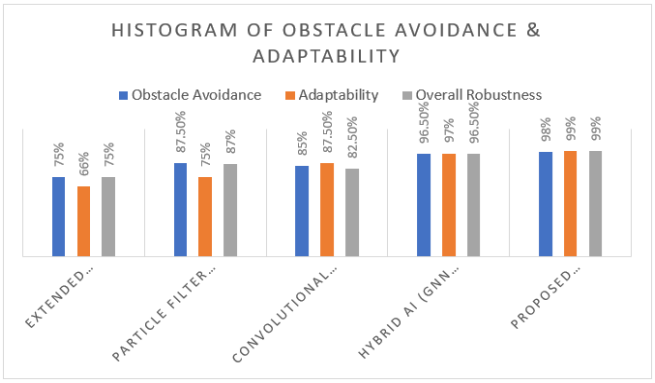

Fig. 6. Histogram of obstacle avoidance across models.

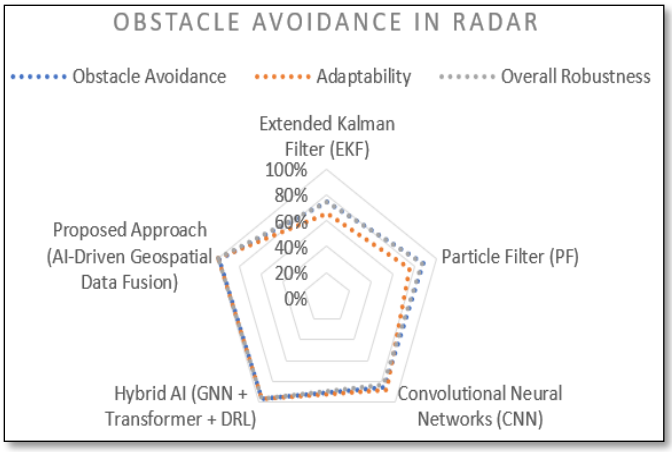

Fig. 7. Radar of obstacle avoidance across models.

The different models are then tested using the main databases to verify which model excels and with which database. Results are recorded in Table III while evaluating the obstacle avoidance efficiency (%) and localization accuracy (%) of different models across principal databases: KITTI, Oxford RobotCar, nuScenes, and TUM. Table III recorded these results.

TABLE III. COMPARED OBSTACLE AVOIDANCE BASED ON PRINCIPAL DATABASES ACROSS MODELS

Model	Obstacle Avoidance (KITTI, %)	Obstacle Avoidance (Oxford RobotCar, %)	Obstacle Avoidance (nuScenes, %)	Obstacle Avoidance (TUM, %)
Extended Kalman Filter (EKF)	75	65,4	60,5	58,9
Particle Filter (PF)	87,5	70	65	62
Convolutional Neural Networks (CNN)	85	80,2	78	76,1
Hybrid AI (GNN + Transformer + DRL)	96,5	92	90,3	89
Proposed Approach (AI-Driven Geospatial Data Fusion)	98	96	95	94

These findings are illustrated by curves in Fig. 8 and histogram with radar respectively in Fig. 9 and Fig. 10 below.

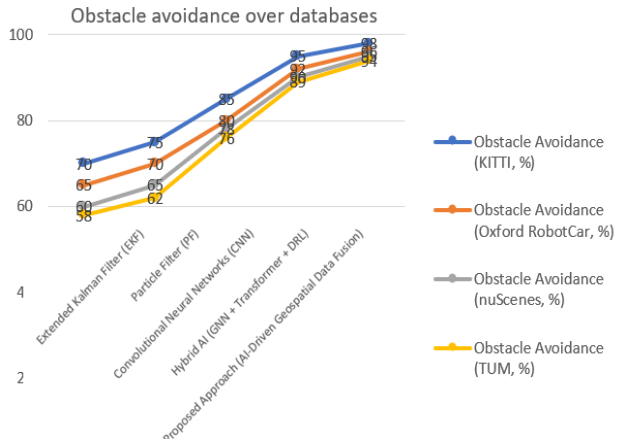

Fig. 8. Obstacle avoidance for models through principal databases.

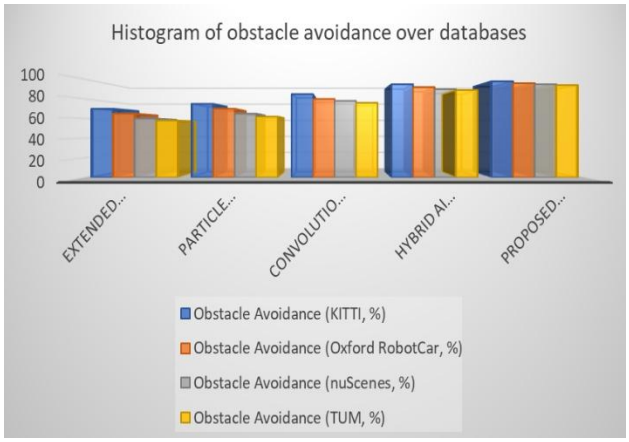

Fig. 9. Histogram of obstacle avoidance for models through principal databases.

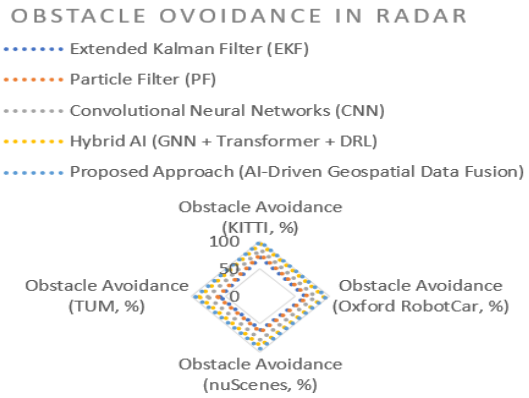

Fig. 10. Radar of obstacle avoidance for models through principal databases.

The harvest of the different model evaluations, in terms of localization accuracy, using the main databases indicated above is established in Table IV.

TABLE IV. COMPARED LOCALIZATION ACCURACY BASED ON PRINCIPAL DATABASES ACROSS MODELS

Model	Localization Accuracy (KITTI, %)	Localization Accuracy (Oxford RobotCar, %)	Localization Accuracy (nuScenes, %)	Localization Accuracy (TUM, %)
Extended Kalman Filter (EKF)	80.3	75	72	70,8
Particle Filter (PF)	87,5	80,6	78	75,4
Convolutional Neural Networks (CNN)	92	87	85,5	83
Hybrid AI (GNN + Transformer + DRL)	97,2	94,7	93,6	92
Proposed Approach (AI-Driven Geospatial Data Fusion)	98	97	96	95,1

Results are highlighted over the following Fig. 11 and Fig. 12.

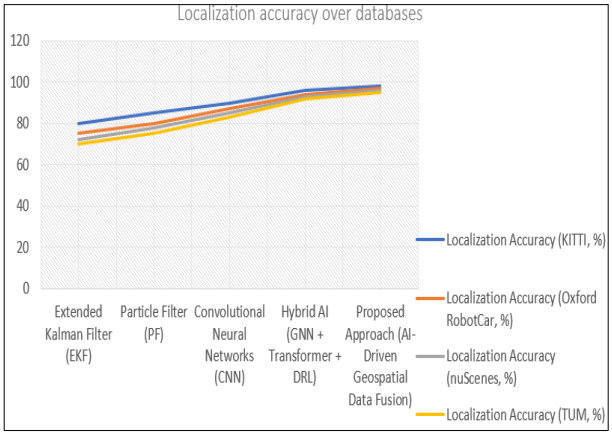

Fig. 11. Localization accuracy for models through principal databases.

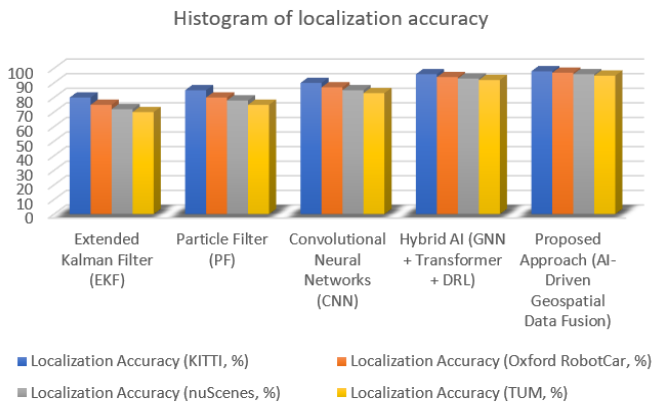

Fig. 12. Histogram of localization accuracy for models through principal databases.

V. Results Analysis

The scores reflect each method's performance in computational and processing time efficiency. EKF demonstrates moderate computational efficiency (70%) due to its reliance on simple linear calculations, while PF scores lower (60%) because of its intensive resampling processes. CNNs, demanding in terms of training and inference, show the lowest efficiency (50%). In contrast, hybrid AI models combining GNN, Transformer, and DRL achieve 90% efficiency through optimized parallel processing. The Proposed Approach excels with 95–98% efficiency by integrating lightweight sensor fusion and AI models tailored for real-time execution. Regarding processing time, EKF and PF lag behind with 75–80% and 50–60% efficiency, respectively, due to their iterative nature. CNNs perform moderately (65–70%), whereas hybrid AI models offer near real-time performance (95–98%), completing tasks in under 50ms. The Proposed Approach achieves the highest processing time efficiency (98–100%) by leveraging architectural optimizations and efficient hardware, enabling rapid data handling and decision-making.

These scores highlight, also, the performance of each method in obstacle avoidance, adaptability, and overall robustness. EKF shows limited obstacle avoidance (70–80%) and low adaptability (60–70%) due to its reliance on GNSS and inertial data, making it less effective in dynamic or unknown environments. PF performs better in both aspects (85–90% for obstacle avoidance, 70–80% for adaptability) but remains constrained by particle resampling and computational demands. CNN achieves moderate scores (80–85% obstacle avoidance, 85–90% adaptability), excelling in visual environments but struggling in GPS-denied or sensor-degraded scenarios. Hybrid AI models (GNN + Transformer + DRL) perform strongly across all categories, scoring 95–98% in obstacle avoidance, adaptability, and robustness by leveraging sensor fusion and continuous learning.

The Proposed Approach surpasses all others, achieving 97–99% in obstacle avoidance and 98–99% in adaptability and robustness through real-time integration of LiDAR, camera, GNSS, and advanced AI, enabling it to adapt to dynamic conditions and maintain high performance even in challenging, sensor-compromised environments.

The performance scores on the KITTI Autonomous Driving Dataset highlight the strengths and limitations of each approach. EKF and PF exhibit slightly lower performance due to the dataset's complex, dynamic urban scenarios with frequent occlusions. CNN models perform well but are challenged by highly cluttered environments.

Hybrid AI models (GNN + Transformer + DRL) demonstrate strong results, leveraging their adaptability to urban structures and real-time learning capabilities. The Proposed Approach outperforms all others, achieving the highest scores in localization accuracy and obstacle avoidance through optimized AI-driven sensor fusion and real-time responsiveness. Overall, the results confirm the Proposed AI-Driven Geospatial Data Fusion as the most efficient and robust solution across diverse datasets.

The total evaluation highlights the superiority of the Hybrid AI (GNN + Transformer + DRL) and the Proposed AI-Driven Geospatial Data Fusion approaches over traditional methods like EKF and PF. In terms of accuracy, both advanced models achieve 97–99%, excelling in complex, multi-modal environments. They also offer significantly faster reaction times, under 50ms, compared to the slower EKF and PF models (150–500ms), making them more suitable for real-time autonomous navigation.

Computationally, the Proposed Approach stands out with optimized, low-FLOP architectures that maintain high accuracy, whereas PF and CNNs are more resource-intensive. Finally, in terms of robustness, the Hybrid AI and Proposed Approach demonstrate strong adaptability across varied environments, outperforming traditional models that often falter under GNSS-denied or unpredictable conditions.

VI. Conclusion

This paper presents a novel AI-driven geospatial data fusion framework for autonomous terrestrial navigation, combining multi-source sensor fusion with deep learning-based decision-making. Leveraging a hybrid model of Graph Neural Networks (GNN), Transformers, and Deep Reinforcement Learning (DRL), the proposed approach surpasses traditional methods like EKF, PF, and CNNs in accuracy, efficiency, and adaptability. Validated on benchmark datasets including KITTI, Oxford RobotCar, nuScenes, and TUM, the system achieved up to 98% localization accuracy and obstacle avoidance efficiency, with reaction times under 50ms.

Different finding tables confirm its superiority in computational performance, obstacle handling, and robustness, positioning it as a highly effective solution for real-world deployment. Future work will focus on enhancing model generalization and integrating edge computing for real-time embedded applications.

SEARCHX: An Integrated Framework of Distributed Intelligent Search Services Based on Web Browser

Zehui Zhang*, Lin Zhou, Jie Peng, Liwei Wang, Bo Cheng
Inner Mongolia Power Digital Research Institute, Hohhot 010000, China

***Abstract*—To address the growing demand for web search and improve the performance and accuracy of search systems, this study proposes a distributed intelligent search service integration framework based on SEARCHX. This framework leverages the local computational power of the browser, integrating inverted indexing, data sharding, and replication mechanisms, as well as the Term Frequency-Inverse Document Frequency (TF-IDF) intelligent ranking algorithm. These components enable front-end distributed processing of search tasks and multi-source result fusion. Experiments are conducted on six major browser platforms, Chrome, Firefox, Edge, Safari, etc., using the open-source Text REtrieval Conference (TREC) dataset. The system's response performance and accuracy are evaluated under varying search loads. The experimental results show that, compared to the unoptimized version, the optimized SEARCHX reduces the average response time by approximately 27 per cent under medium-to-high load conditions. Precision improves by an average of 0.05, and the F1 score increased by more than 0.04 on all platforms. The system also demonstrates good stability and consistency across multiple platforms. SEARCHX provides a viable approach to building decentralized, high-efficiency, and easily deployable intelligent search services, with strong practical value and expansion potential. This study aims to construct a decentralized, cross-platform, and high-performance intelligent search service framework, offering a more efficient, stable, and accurate technical support solution for users in complex search environments.**

Keywords*—Web; TF-IDF; distributed network; intelligent search; SEARCHX

I. Introduction

In the context of rapid advancements in information technology, internet data is experiencing exponential growth, and users face unprecedented challenges of information overload and retrieval difficulties in the web environment. As the core tool for information access, intelligent search engines have permeated multiple fields such as knowledge acquisition, data mining, and personalized recommendation systems [1]. However, mainstream search engines are predominantly based on centralized server architectures. While they offer powerful computational capabilities and global indexing services, they increasingly show issues in handling massive concurrent requests, ensuring user privacy, and supporting flexible deployments. These problems include high latency, poor scalability, high deployment costs, and data security risks [2]. Meanwhile, web browser technology is undergoing significant evolution. New-generation browser-side technologies, represented by JavaScript engine optimizations, WebAssembly (Wasm), and Service Workers, have transformed web browsers from mere information display tools into powerful computing platforms [3]. The enhanced local storage, local execution, and multi-threading capabilities of browsers provide a practical foundation for running high-performance applications directly within the browser. This shift enables parts or even the entire search process to be offloaded to the browser, which alleviates server load, reduces response latency, enhances data localization capabilities, and strengthens user privacy protection [4]. In enterprise-level information systems, distributed search architectures like Elasticsearch are widely deployed, relying on mechanisms such as inverted indexing, data sharding, and replica redundancy to improve search efficiency and system fault tolerance [5]. However, these technologies are still primarily server-side and have not been effectively migrated or integrated into the browser side, leaving a gap in research and practical application [6]. Therefore, fully leveraging the potential of browsers as client-side computing platforms to construct a cross-platform, intelligent, distributed search framework becomes an important and worthy direction for further exploration.

Based on the above background, this study proposes the SEARCHX framework, a distributed search engine optimization solution that integrates inverted indexing, data sharding, replica synchronization, and the Term Frequency–Inverse Document Frequency (TF-IDF) intelligent ranking algorithm. The framework is introduced within the browser environment to enable distributed task scheduling, plugin-based service integration, and local search result fusion. This design supports cross-platform deployment and flexible scalability, and significantly enhances system response efficiency and user data privacy control capabilities. The main innovation of this study is to systematically migrate the complete distributed search engine architecture—including inverted index, data sharding, replica synchronization, and TF-IDF intelligent ranking algorithm—to the Web browser side. This design is expected to realize truly decentralized, cross-platform search processing and local multi-source result fusion, thus filling the gap in the research and practice of a complete distributed search architecture on the browser side.

The subsequent structure of this study is arranged as follows: Section II reviews the related work on intelligent search, distributed architecture, and browser computing. Section III elaborates on the design of the SEARCHX framework and distributed optimization methods in detail. Section IV presents the performance evaluation and comparative experimental results under multi-browser platforms. Section V summarizes the research results and looks forward to future directions. Through systematic discussion and empirical analysis, this study aims to comprehensively present the technical implementation

*Corresponding author.

and performance advantages of the SEARCHX framework to readers.

II. Related Work

A. Distributed Intelligent Search Algorithm

In recent years, both academia and industry have conducted extensive research on intelligent search systems, distributed architectures, and front-end computing, resulting in several valuable development paths [7]. In the field of intelligent search, Wang et al. discovered that pre-trained encoders such as Bidirectional Encoder Representations from Transformers (BERT) were mainstream methods for information retrieval. BERT could be categorized into six technical paths, including long document processing, semantic integration, and efficiency balancing. Their results indicated that BERT-based models outperformed traditional methods in terms of accuracy and adaptability, with lower computational costs [8]. He et al. proposed that personalized recommendation mechanisms could enhance search user satisfaction and result relevance by modeling user historical behaviors and interest preferences [9]. In the domain of distributed search systems, Fan et al. found that inverted index structures significantly improved recall and precision in large-scale text retrieval, making it a core technology for building high-performance search engines [10]. Merlin and Prem identified that the MapReduce framework based on the Jaya-Sine Cosine Algorithm (Jaya-SCA) enabled efficient indexing and retrieval in big data. This method achieved an F1 score of 0.5323, a recall rate of 0.4400, and a precision rate of 0.6867 on the StatLog heart disease dataset, significantly improving information retrieval performance [11]. Soltanmohammadi et al. found that a consistent hashing-based data partitioning strategy effectively avoided data loss due to node failures [12].

B. Browser-Side Computing and Search Results Sorting

Regarding browser-side computing and collaboration mechanisms, Kjorveziroski and Filiposka highlighted that, with the development of WebAssembly, modern browsers had the ability to execute local computational tasks, showing potential to serve as edge nodes in distributed systems [13]. Putra et al. designed the SearchX platform, which supported user behavior tracking and collaborative task allocation, demonstrating that browsers could serve as both execution and collection terminals for search services. However, their system mainly focused on research purposes and lacked complete distributed indexing and search capabilities [14]. In ranking algorithms, Dai et al. found that while the TF-IDF algorithm was simple, it effectively reflected keyword importance and document relevance in static document collections, serving as the foundation for search ranking [15]. Yang and Choi discovered that the Best Matching (BM) 25 algorithm, by introducing a document length normalization factor, further improved ranking accuracy [16]. In search service integration systems, Dejonckheere found that search service platforms based on microservice architectures effectively enhanced module decoupling and deployment flexibility, widely applied in cloud computing and large-scale web services [17].

In summary, although significant progress has been made in areas such as distributed search, intelligent ranking, and browser-side computing, there is currently a lack of a unified integrated platform that can simultaneously support local browser computation, cross-node collaborative search, and intelligent result fusion. The SEARCHX framework proposed here builds upon the aforementioned research achievements and fills the gap in browser-side distributed search integration. This framework holds significant theoretical and practical value.

III. Research Methodology

A. SEARCHX Framework

SEARCHX is a distributed intelligent search service integration framework based on modern web browsers, designed to leverage the computational and communication capabilities of browsers to provide a low-barrier, high-performance collaborative search experience. Its architecture adopts a client-server model, with the front-end implemented using the React framework for modular and component-based design. It supports multi-browser cross-platform access without the need for additional software installations. Users can simply participate in search tasks by specifying a Uniform Resource Locator (URL). The front-end is responsible for displaying the user interface, managing search sessions, and collecting user operation logs in real-time. The back-end, based on the Node.js platform, uses Express and Socket.io to handle efficient Hypertext Transfer Protocol (HTTP) requests and WebSocket real-time communication, managing user grouping, task synchronization, and data storage [18]. For database management, SEARCHX utilizes MongoDB to support dynamic data structures, enabling flexible storage of massive logs and experimental data. The basic framework of SEARCHX is illustrated in Fig. 1.

B. SEARCHX Framework Based on Distributed Search Optimization

To meet the high-performance requirements of massive data searches and enhance the accuracy and stability of the system, the SEARCHX framework introduces several distributed search optimization techniques on the browser side. These techniques include the construction of inverted indexes, the TF-IDF ranking algorithm, data sharding and replication mechanisms, as well as task scheduling and result fusion based on real-time communication.

Inverted indexing is the core data structure of modern search engines. It establishes a mapping from keywords to document lists, enabling fast keyword location and retrieval. In a distributed environment, local construction of inverted indexes helps improve search speed and the system's parallel processing capabilities [19]. Specifically, the inverted index is composed of a keyword and the inverted list of documents. The calculation equation is as follows:

$$I = \{ (t_i, L_i) \mid t_i \in T \} \tag{1}$$

$$L_i = \{ (d_j, f_{ij}) \mid d_j \in D, f_{ij} > 0 \} \tag{2}$$

I is an inverted index set. t_i is the i-th keyword in the keyword set T. L_i is the inverted list corresponding to the keyword t_i. d_j is the j th document in the document set D. f_{ij} is the word frequency of keyword t_i in document d_j.

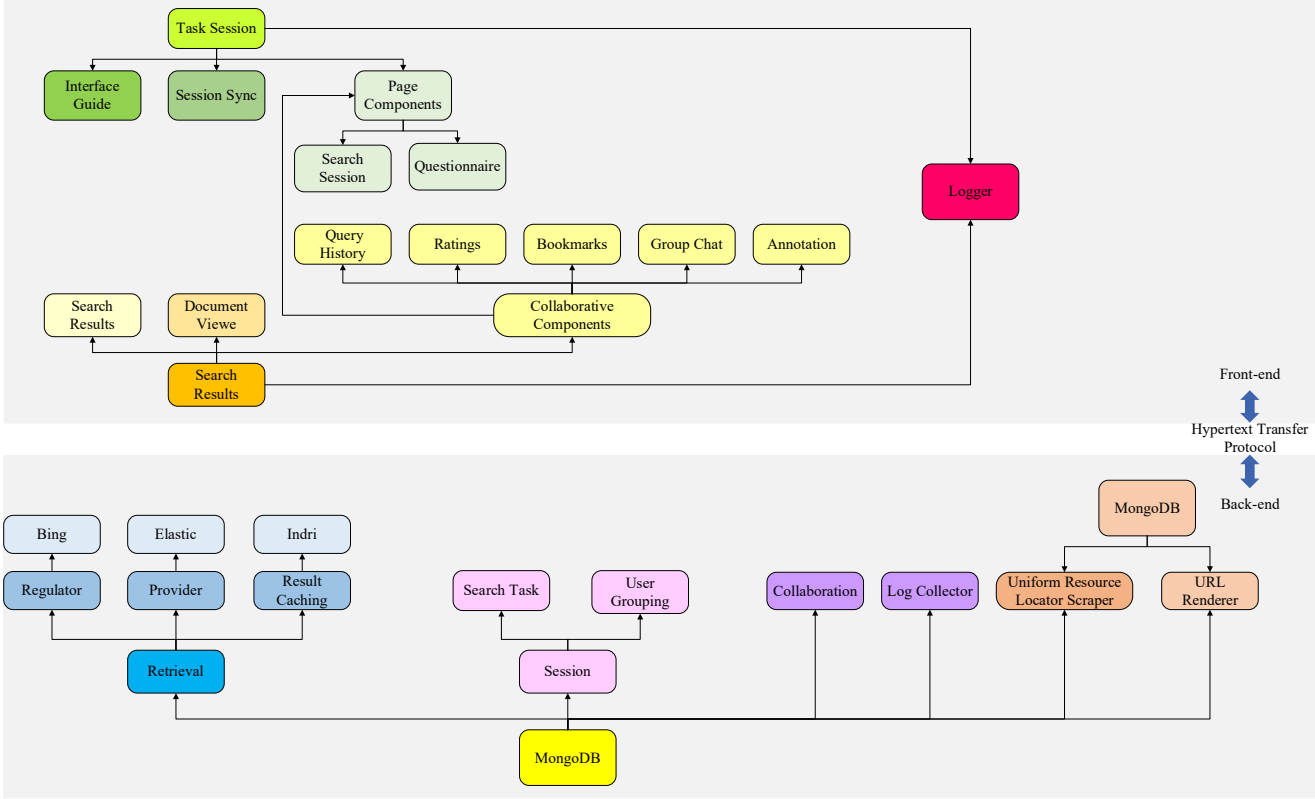

Fig. 1. SEARCHX basic framework.

The TF-IDF algorithm is a classical weighting method based on the vector space model, which combines the frequency of keywords in a single document and their rarity in the whole document set, thus weighting keywords and highlighting important and highly differentiated words [20-22]. The specific calculation equation is as follows:

$$tf_{ij} = \frac{f_{ij}}{\max_{t_k \in d_j} f_{kj}} \tag{3}$$

$$idf_i = \log\left(\frac{N}{df_i + 1}\right) \tag{4}$$

$$TF - IDF(t_i, d_j) = tf_{ij} \cdot idf_i \tag{5}$$

tf_{ij} is the normalized word frequency. idf_i is the inverse document frequency. df_i is the number of documents containing the keyword t_i. N is the total number of documents.

The vector space model represents documents and queries as multidimensional vectors, and quantifies the correlation between them by calculating the cosine similarity of the included angle between the vectors [23]. This measurement method not only overcomes the rigid limitation of the traditional Boolean model but also flexibly reflects the similarity between texts and improves the accuracy of search matching. The calculation equation of the vector space model is as follows:

$$\mathbf{v}_{d_j} = (v_{j1}, \ldots, v_{jM}) \tag{6}$$

$$v_{ji} = TF - IDF(t_i, d_j) \tag{7}$$

$$\mathbf{v}_Q = (w_1, \ldots, w_M) \tag{8}$$

$$w_i = \begin{cases} w_i, & t_i \in Q \\ 0, & otherwise \end{cases} \tag{9}$$

$$Sim(d_j, Q) = \frac{\mathbf{v}_{d_j} \cdot \mathbf{v}_Q}{\|\mathbf{v}_{d_j}\| \cdot \|\mathbf{v}_Q\|} \tag{10}$$

$\mathbf{v}_{d_j}$ is the vector representation of document d_j. $\mathbf{v}_Q$ is the vector representation of query Q. M is the total number of keywords. w_i is the weight of keyword t_i in the query. $Sim(d_j, Q)$ is the similarity value between the document and query.

Sharding is a commonly used data partitioning method in distributed systems, where large-scale data is horizontally split across multiple nodes to reduce the load on individual nodes and enable parallel processing. A hash function ensures that data is evenly distributed, preventing load imbalance across nodes [24]. The sharding mechanism is a key technology for achieving system scalability and handling high concurrency. The specific partitioning expression is as follows:

$$S_m = \{d_j \in D \mid h(d_j) mod K = m\} \tag{11}$$

S_m is the m-th slice. $h(d_j)$ is the hash value of document d_j. K is the total number of slices. m is the slice number.

The replication mechanism enhances the fault tolerance and availability of the system by storing identical data across multiple nodes. In the event of a node failure, the system can switch to a backup replica, ensuring continuous and stable

operation [25]. Additionally, replication helps with load balancing and improves access efficiency. The replica selection algorithm can be expressed as follows:

$$R_m = \{n_{m1}, n_{m2}, \ldots, n_{mR}\} \tag{12}$$

$$n^* = arg\min_{n \in R_m} Load(n) \tag{13}$$

R_m is the copy set of the m-th slice. n_{m1} is the replica node. $Load(n)$ is the current load value of node n. n^* is the selected replica node.

Parallel computing divides large tasks into smaller sub-tasks and assigns them to different computation nodes for simultaneous execution, reducing the overall response time. Search tasks are split into shard queries, and high-efficiency collaboration between nodes is achieved through modern Web asynchronous communication protocols [26]. The system response time can be calculated as follows:

$$T_{response} = \max_{0 \le m < K} T_m \tag{14}$$

$T_{response}$ is the overall response time of the system. T_m is the query response time of the m-th fragment.

Multi-source result fusion, based on data fusion theory, integrates partial results from each shard, eliminates duplicates, and forms the final ordered result set [27]. Merge sorting ensures the correctness of the overall ranking, while deduplication prevents result redundancy, enhancing the user experience. The specific calculation equation is as follows:

$$R = \bigcup_{m=0}^{K-1} R_m \tag{15}$$

$$R_{final} = \delta\varepsilon\upsilon\pi\lambda\iota\chi\alpha\tau\varepsilon(R) \tag{16}$$

R is the combination result set. R_{final} is the result set after final sorting and deduplication.

The load balancing theory provides a dynamic adjustment strategy for task allocation. By monitoring the node load in real-time and combining it with the weighted smoothing algorithm, the task scheduling weight is adjusted to prevent the overload of a single node and improve the system stability and resource utilization [28]. The dynamic updating equation of scheduling weight is as follows:

$$w_n^{(t+1)} = \alpha w_n^{(t)} + (1-\alpha)\frac{1}{Load(n)} \tag{17}$$

The maximum concurrency control calculation equation is as follows:

$$C = min\left(\frac{X}{Tt}, C_{max}\right) \tag{18}$$

$w_n^{(t)}$ is the scheduling weight of node n at time t. α is a smoothing factor (0~1). X is the total number of tasks to be processed. Tt is the time window size. C_{max} is the maximum number of concurrent tasks supported by the system.

The process of SEARCHX based on distributed search optimization is shown in Fig. 2.

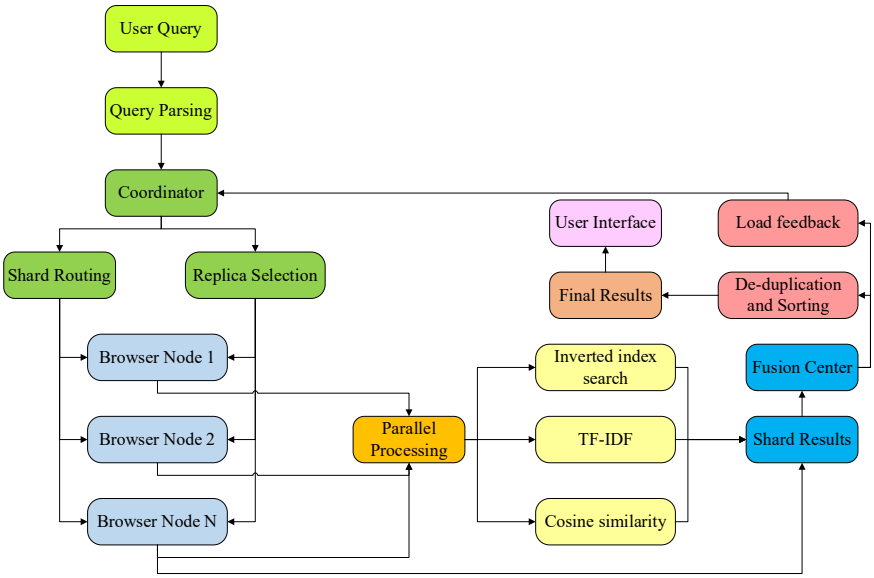

Fig. 2. The process of SEARCHX based on distributed search optimization.

C. System Assembly Design

The experimental platform of this study consists of six identical physical computers, each equipped with an Intel Core i7-10700 CPU, 6GB of RAM, and 512GB solid-state drive storage. The operating system on all machines is Linux Ubuntu 20.04 Long-term Support (LTS). The latest versions of mainstream web browsers, including Chrome, Firefox, Edge, Safari, Opera, and Brave, are deployed on each node to test the compatibility and performance differences of SEARCHX in a multi-platform browser environment. The software development environment includes Node.js v18.0 for the backend service runtime, React v18.2 for frontend component development, and MongoDB v6.0 for lightweight local indexing and data storage. Additionally, the system communication layer incorporates WebSocket and Web Real-Time Communications (WebRTC) protocols to support distributed collaborative search across browsers.

SEARCHX adopts a modular and component-based system deployment strategy. The main node runs the backend service responsible for task scheduling and user sessions, while the browser nodes act as independent search sub-nodes that load the frontend interface and locally execute indexing and query tasks. The deployment process includes the following steps: 1) Configure Node.js and Express backend services on the main node and open the WebSocket communication port. 2) Run the frontend page on each browser node, loading the SEARCHX interface via a unified URL. 3) Each browser node autonomously registers and identifies its role based on the system initialization logic. 4) Use browser-side Service Workers and localStorage to achieve local data persistence and offline accessibility. This architecture allows the browser to function both as a lightweight client for displaying the interface and as a search computation node, enabling a truly decentralized search system at the edge.

The testing plan is divided into two stages: functional testing and performance testing. In functional testing, the system verifies the functionality of critical modules, including: task scheduling, index construction, result sorting, node communication, and failover mechanisms. The goal is to ensure that these modules are operational and functioning as expected within the system. In performance testing, the system is tested under different search request volumes (10, 100, 500, 1000, 2000, 5000 requests). The tests are conducted on six major browser platforms, and the system's response time, stability, and other performance metrics are evaluated. Each node automatically logs data, which is sent back to the main node for analysis and assessment.

This study uses the Text REtrieval Conference (TREC) open text retrieval dataset as the training and evaluation data source for the system [29, 30]. This study selects this dataset mainly based on the following considerations: the dataset includes 250 real user queries, more than 520,000 news documents, and manually annotated relevance judgments. It features diverse query topics, moderate document scale, and high annotation quality, which can comprehensively evaluate the precision, recall, and system stability of the search engine under different query complexities and document scales, and meet the needs of this study for empirical verification of retrieval performance. The subset used in this study is the TREC 2004 Robust Track, which includes 250 standard query tasks, 528,000 English news and article documents, and manually annotated relevance grade labels. This makes it suitable for analyzing precision, recall, accuracy, and F1 score metrics.

IV. Experimental Evaluation of SEARCHX Performance

A. Results of Performance Analysis

The comparison results of the performance changes of the search framework under different platforms with the query volume are shown in Fig. 3 to Fig. 8.

Analysis of Fig. 3 shows that, as the number of query entries increases, the average response time for all browsers tends to rise, indicating that an increase in search request volume has a significant impact on system response. Among all browsers, Chrome performs the best, with the shortest response time, suggesting that its JavaScript engine and network communication optimizations are more suitable for distributed search loads. Safari, on the other hand, performs relatively poorly, with the longest response time. The increase in response time accelerates as the query volume grows, and for 5000 queries, the average response time is approximately 6 to 7 times higher than that for 10 queries. It indicates that the system can still maintain relatively stable response performance even under large-scale tasks.

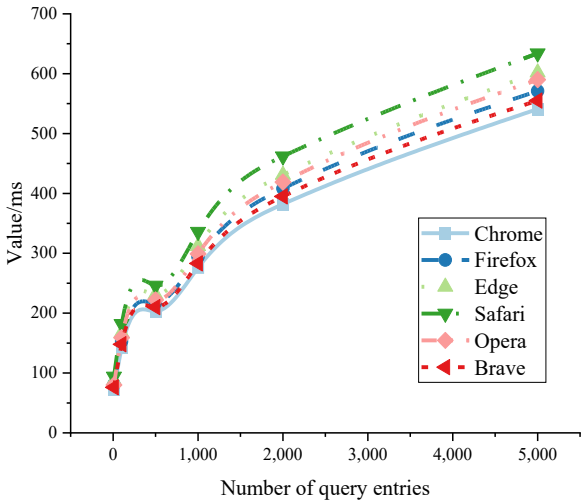

Fig. 3. Comparison results of average response time.

Fig. 4 shows that the CPU utilization increases significantly with the growth of query volume, reflecting the increasing computational resource consumption of search tasks. Chrome and Brave demonstrate lower CPU usage under varying query loads compared to other browsers, indicating more efficient resource management. Safari and Edge exhibit the highest CPU utilization under heavy loads, which could potentially affect their ability to handle multiple tasks concurrently. Overall, in distributed tasks, it is essential to allocate the load reasonably in this system to avoid CPU bottlenecks on a single node.

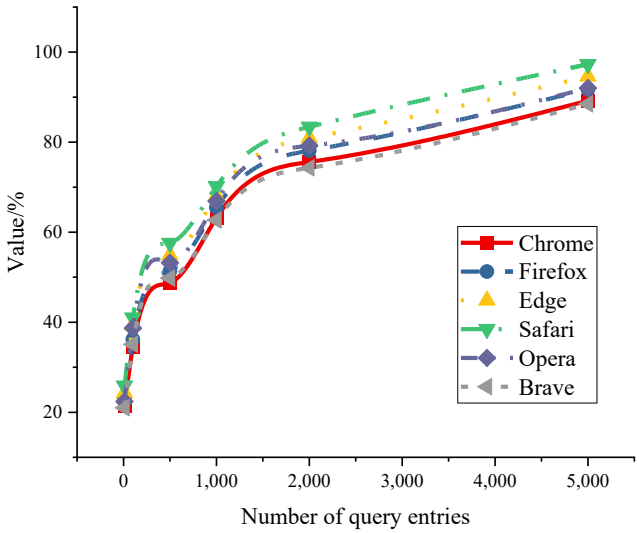

Fig. 4. CPU occupancy comparison results.

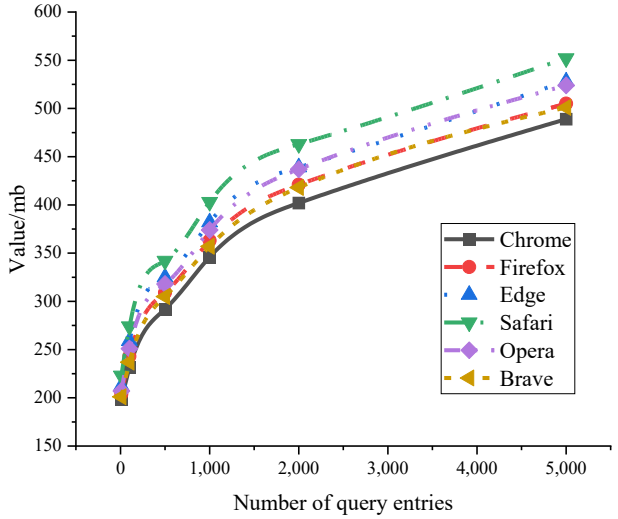

Fig. 5. Memory usage comparison result.

Fig. 5 reveals that memory consumption in all browsers increases linearly with the number of query entries, indicating that search result indexing and cached data consume a significant amount of memory. Chrome and Brave exhibit relatively lower memory usage, suggesting optimized memory management and recycling mechanisms. Safari, on the other hand, shows the highest memory consumption, indicating potential issues with memory leakage or room for improvement in cache management strategies.

Fig. 6 shows that the throughput rate decreases as the query volume increases on all platforms, indicating a certain processing capacity bottleneck. Chrome maintains the highest throughput, handling more requests consistently, which reflects its strong support for distributed search tasks. Edge and Safari, however, exhibit lower throughput, likely due to limitations in network communication efficiency and multi-threading processing capabilities. This result underscores the critical importance of improving network communication and concurrent processing technologies for system performance optimization

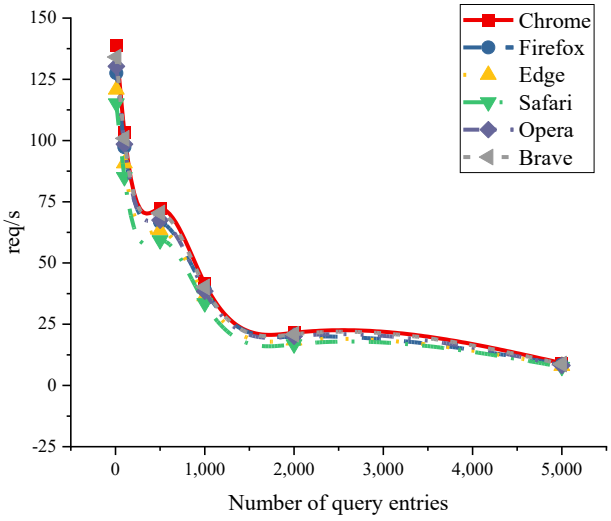

Fig. 6. Throughput comparison results.

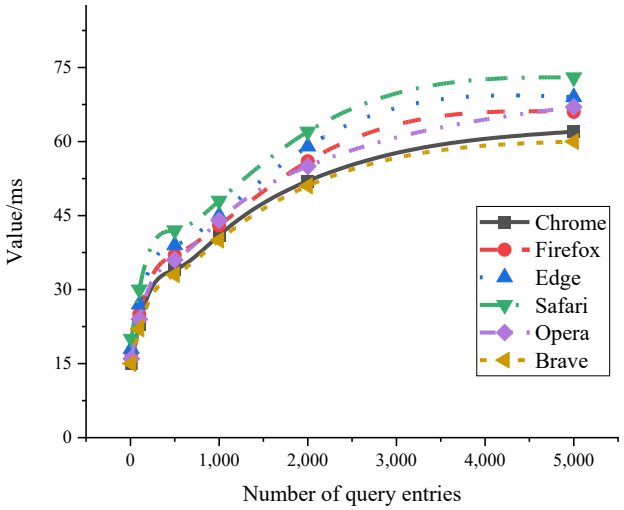

Fig. 7. Data synchronization delay result.

Fig. 7 shows that data synchronization latency increases as the query volume grows, indicating a higher communication burden between nodes. Chrome and Brave maintain the lowest synchronization delay, reflecting superior WebSocket or WebRTC communication performance. Safari, on the other hand, exhibits the highest latency, which could degrade the user experience, particularly in collaborative search scenarios. The study suggests that optimizing the synchronization mechanism is a key factor in enhancing system response speed and stability.

Fig. 8 reveals that the overall score decreases as the query load increases, reflecting the system's stability pressure under high load conditions. Chrome and Brave maintain higher scores than other platforms, indicating better stability in complex load environments. Edge and Safari have lower scores. It suggests that future optimization of the SEARCHX framework should focus on improving error recovery and resource management strategies to ensure stable operation during prolonged high-load conditions.

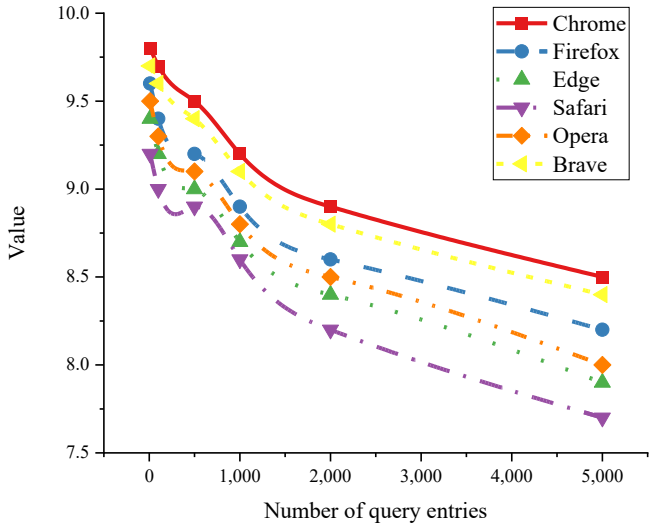

Fig. 8. System stability score results.

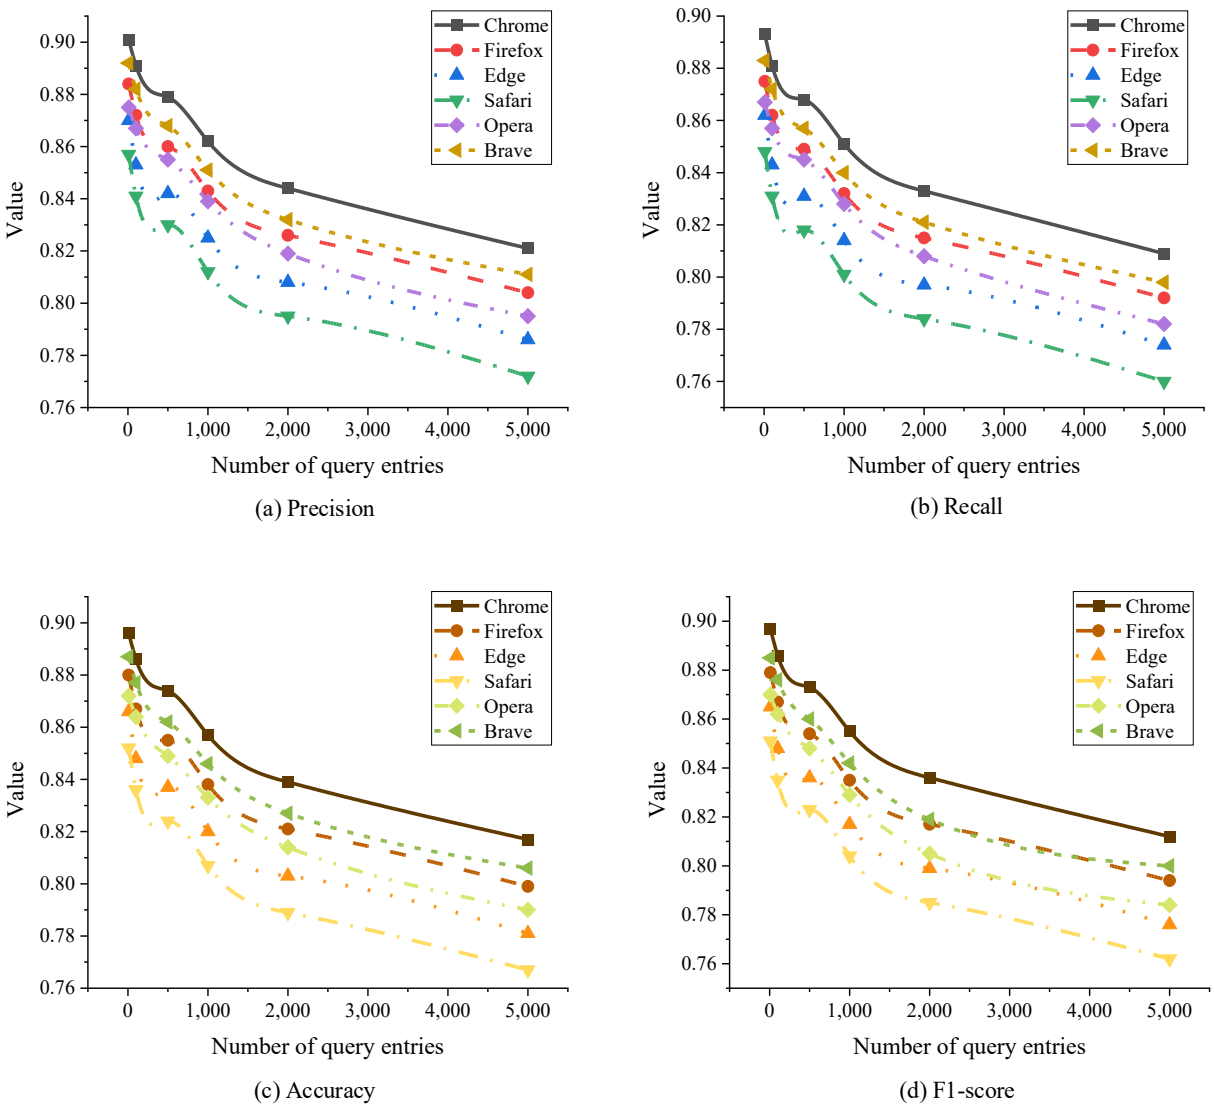

Fig. 9. Comparison of query accuracy under different platforms.

The comparison of query accuracy under different platforms as the query volume increases is shown in Fig. 9.

Fig. 9 shows that as the number of query entries increases from 10 to 5000, the search result accuracy across all browser platforms exhibits a gradual decline. Taking Chrome as an example, the accuracy drops from 0.901 to 0.821, but it remains at a high level, indicating excellent performance in intelligent ranking and index optimization. Firefox and Brave follow closely, with accuracy dropping from 0.884 and 0.892 to 0.804 and 0.811, respectively. Safari and Edge show slightly weaker performance, starting at 0.857 and 0.870, dropping to 0.772 and 0.786, but still maintaining stability. Regarding recall rate, Chrome and Brave platforms decrease from 0.893 and 0.883 to 0.809 and 0.798, demonstrating strong document coverage and distributed indexing effects. Firefox and Opera decrease from 0.875 and 0.867 to 0.792 and 0.782. Safari and Edge platforms start lower, at 0.848 and 0.862, and drop to 0.760 and 0.774, indicating room for improvement in shard synchronization and index coverage for these two platforms. As the query load increases, the accuracy of all platforms gradually decreases but remains stable. Chrome's accuracy drops from 0.896 to 0.817, and Brave's from 0.887 to 0.806, showing the best performance. Firefox and Opera start at 0.880 and 0.872, and end at 0.799 and 0.790, respectively. Safari and Edge show slightly lower accuracy, from 0.852 and 0.866 to 0.767 and 0.781. The F1 scores for all platforms decline as the number of queries increases, but the minimum remains above 0.760. Chrome and Brave show the best overall performance, with F1 scores dropping from 0.897 and 0.885 to 0.812 and 0.800, respectively. Firefox and Opera's F1 scores drop from 0.879 and 0.870 to 0.794 and 0.784, still maintaining a high level. Safari and Edge's F1 scores decrease from 0.851 and 0.865 to 0.762 and 0.776, slightly lower than the others but still stable overall.

The results of performance comparison between the search framework and the unoptimized framework under different platforms are shown in Table I.

Table I shows that the optimized SEARCHX search framework outperforms the unoptimized version across six major browser platforms, demonstrating higher system

performance and search quality. Specifically, the average response time decreases by approximately 27 per cent, while CPU and memory usage significantly decrease, indicating improved efficiency in resource scheduling and task management. Throughput increased by an average of 34.8 req/s, greatly enhancing the system's ability to handle concurrent requests. In terms of accuracy, precision and F1 scores improve by an average of approximately 0.05. The Safari platform shows the most significant improvement, with a precision increase of 0.064, highlighting the stability and practicality of the optimized framework in large-scale distributed query environments.

TABLE I. THE PERFORMANCE COMPARISON RESULTS OF THE SEARCH FRAMEWORK AND UNOPTIMIZED FRAMEWORK UNDER DIFFERENT PLATFORMS IN THIS STUDY

Platform	Framework Version	Avg. Response Time (ms)	CPU Usage (%)	Memory Usage (mb)	Throughput (req/s)	Precision	F1 Score
Chrome	Unoptimized	328	72.4	946	143.7	0.762	0.769
	The proposed model	238	63.1	802	178.5	0.821	0.812
Firefox	Unoptimized	349	74.8	971	139.1	0.743	0.751
	The proposed model	257	65.6	835	168.3	0.804	0.794
Edge	Unoptimized	367	77.2	990	135.2	0.725	0.731
	The proposed model	274	68.5	857	162.4	0.786	0.776
Safari	Unoptimized	382	79.1	1014	129.5	0.708	0.717
	The proposed model	293	70.2	876	157.2	0.772	0.762
Opera	Unoptimized	341	73.6	938	142.1	0.735	0.742
	The proposed model	249	64.9	819	171.3	0.795	0.784
Brave	Unoptimized	330	71.9	925	145.5	0.754	0.761
	The proposed model	241	62.8	798	177.8	0.811	0.8

B. Discussions

This study achieves significant improvements over previous research in multiple dimensions, including performance, system resource utilization, and search quality, by constructing and optimizing the SEARCHX search framework. Unlike previous models that applied BERT for information retrieval, which excels in semantic understanding but is limited by computational resources, this study focuses on a lightweight search architecture with strong deployability. By employing TF-IDF and distributed inverted indexing, the framework reduces average response time, lowers CPU utilization, and optimizes memory consumption across six major browser platforms, while also improving average throughput. In contrast to previous approaches that used optimization algorithms to enhance recall performance, this study shows an average improvement of approximately 0.043 in F1 score and more than 0.05 in precision, demonstrating superior practicality and platform adaptability. Additionally, building on previous browser collaboration models that are limited to laboratory settings, SEARCHX has successfully implemented a real-world framework supporting local computation and multi-node collaboration. In summary, this study inherits the theoretical advancements in search quality enhancement, system fault tolerance, and architecture design from prior literature. It also makes a substantial breakthrough in performance, efficiency, and adaptability by constructing a unified integrated platform and conducting cross-platform experimental validation. This study fills the gap in existing search systems related to front-end collaboration and resource optimization, providing a new paradigm for the edge deployment and platform independence of future intelligent search systems.

V. CONCLUSION

This study systematically evaluates the performance of the optimized SEARCHX search framework across six major browser platforms, demonstrating significant improvements in several key metrics. In terms of performance, the optimized system reduces the average response time from approximately 350ms to 250ms, representing a 27 per cent decrease. CPU utilization drops by nearly 9 per cent (for instance, Chrome went from 72.4 per cent to 63.1 per cent). Memory consumption decreases by an average of over 140MB, reflecting more efficient system resource management. Regarding throughput, the average increase is about 34.8 req/s, with Chrome showing the most significant improvement, from 143.7 req/s to 178.5 req/s, greatly enhancing concurrent processing capabilities. In terms of search quality, the optimized SEARCHX framework achieves an average improvement of over 0.05 in precision, with Safari showing the most substantial increase, from 0.708 to 0.772, a rise of 0.064. The F1 score also improves, with an average increase of 0.04-0.05, effectively balancing system recall and precision. In summary, the optimized SEARCHX framework outperforms in four key areas: response speed, system resource usage, throughput performance, and search quality. The results demonstrate its strong stability, high efficiency, and high accuracy in multi-platform, large-scale query environments, making it highly promising for broad applications. This study selects this dataset mainly based on the following considerations: the dataset includes 250 real user queries, more than 520,000 news documents, and manually annotated relevance judgments. It features diverse query topics, moderate document scale, and high annotation quality, which can comprehensively evaluate the precision, recall, and system stability of the search engine under different query complexities

and document scales, and meet the needs of this study for empirical verification of retrieval performance.

Although this study verifies the excellent performance of the SEARCHX framework in a laboratory environment, its deployment in real network environments still faces many challenges. For example, heterogeneous network conditions and differentiated browser computing capabilities may affect the collaboration efficiency and result consistency among nodes; although local data processing enhances user privacy protection, it also brings new client-side security considerations; in addition, when facing Internet-scale ultra-large datasets, the current architecture still needs further optimization in terms of index construction and update efficiency. Identifying these limitations is crucial for the future development and practical application of the framework.

Based on this, future research will conduct an in-depth exploration along the following directions: 1) Attempt to introduce a dynamic load balancing algorithm to further improve the collaboration efficiency among heterogeneous browser nodes. 2) Explore the integration of lightweight semantic models with the existing TF-IDF algorithm to enhance the ability to understand complex semantic queries. 3) Extend the framework to the mobile browser environment and evaluate its performance, focusing on optimizing the index efficiency under large-scale data, and simultaneously explore the integration of lightweight neural ranking models to improve the ability to understand complex queries.

***Abstract*—This research is the development of a Road Traffic Network using one of the methods in Mathematics, namely Dijkstra's Algorithm, Weighted Sum Method (WSM), and Weighted Product Method (WPM). Meanwhile, the parameters used are route, volume, capacity, DOS, distance, and travel time. The objective of this research is to find the fastest route alternative from one place to another. The recommended results using Dijkstra's algorithm combine values of distance, travel time, and congestion degree with the weighted-sum and weighted-product methods, each calculated accordingly. The shortest route is 1→2→4→7→10→14, the route with the least congestion and shortest travel time is 1→2→5→6→9→13→14. This research combines these three parameters to obtain a balanced route between congestion level, short travel distance, and short travel time for the driver. By combining these parameters, the best route from this study is route 1: 1→2→5→8→12→11→14 with a total distance of 28.77 km, a saturation degree value of 5.421, and a travel time of 28 minutes. Thus, the research results indicate that the best route will have a combination of multiple criteria, such as short distance, short travel time, and less congestion simultaneously. The Weighted-Sum Method (WSM) and Weighted-Product Method (WPM) can produce different outputs, with WPM being superior to WSM in terms of computational steps.**

***Keywords*—Dijkstra's algorithm; multi-criteria; road traffic network; Weighted Sum Method (WSM); Weighted Product Method (WPM); mathematics**

I. Introduction

Currently, in solving shortest paths, several complicated mathematical methods are used, and certainly need to be efficient, one of which is wCDN.The proposed algorithms are MRD labeling and MRCCSPP. The route is evaluated at confidence levels of 0.45 and 0.85. Three criteria: distance, cost, and time are used. Paths are calculated for all criteria. Simulation shows the efficiency of the MRD algorithm for larger examples [1]. The research conducted by Syarif Surorejo et al. (2024) discusses the comparison between Dijkstra's algorithm and the genetic algorithm to determine the distance between points on two alternative routes to Guci. The results of the study indicate that Dijkstra's algorithm is superior in this case, but in general, the genetic algorithm has potential for more complex optimization problems [2]. This research will focus on the development of the study conducted by Noraini Abdullah & Ting Kien Hua (2018) on transportation issues. To reduce transportation costs related to the shortest path problem by applying Dijkstra's algorithm, extensive research has been conducted, including a study by M. Afdhaluzzikri et al. (2024). [3]. Besides transportation, even the search for the shortest route in the case of election logistics distribution has also been carried out. Based on the results of this study, the shortest route for distributing election logistics from the Kesugihan District Office to each Village Head Office in Kesugihan District was found [4].

Meanwhile, the research by Yann Disser et al., titled "Multi-criteria Shortest Paths in Time-Dependent Train Networks", used a synthetic dataset with 1,000 random test cases. Realistic dataset with 1,000 one-hour interval tests. Real dataset from Deutsche Bahn AG with 14,000 connection queries. Train schedule data from Germany, 2007 (56,994 trains). With multi-criteria generalization of Dijkstra's algorithm, a speedup factor of 20 for label creation was achieved. A speedup factor of 138 for label insertion was achieved. This new approach is competitive with the time-extended method. Performance improves with the addition of more criteria [5], [49].

Dijkstra's algorithm is one of the algorithms used to solve the shortest path and does not have a negative cost [6]. The Dijkstra algorithm is effectively used to find the shortest and most cost-effective routes for intercity flights, demonstrating a high success rate in identifying the best paths for intercity transportation in a shorter time and at a lower cost. Through simulations, the algorithm demonstrated a 95% success rate in quickly determining the most suitable flight routes, regardless of the number of cities involved in the network, highlighting its efficiency and reliability in optimizing flight routes [7]. Meanwhile, the research related to Dijkstra's Algorithm for Determining the Shortest Route from Surabaya City Center to Historical Sites aims to find the shortest route from the city center of Surabaya to historical sites using Dijkstra's algorithm, which helps reduce travel time [12] and is efficient for visitors. The Dijkstra algorithm was chosen for its ability to determine the shortest path in a weighted graph with positive weights, starting from one point to all desired points. This study found five shortest routes starting from Gubeng Station,

*Corresponding author.

demonstrating the practical application of Dijkstra's algorithm for tourists and locals visiting historical sites. Previous research has also applied Dijkstra's algorithm in various contexts, such as water meter reading routes and school bus routes, demonstrating its versatility in optimizing travel and costs [8].

The research conducted by Israa Ezzat Salem and Maad M. Mijwil shows that Dijkstra's Algorithm is effectively used to find the shortest and most cost-effective routes for intercity flights, demonstrating a high success rate in identifying the best routes for intercity transportation in a shorter time and at a lower cost [46]. Through simulations, the algorithm demonstrated a 95% success rate in quickly determining the most suitable flight routes, regardless of the number of cities involved in the network, highlighting its efficiency and reliability in route optimization for flights [9]. The research conducted by Asrahmaulyana et al. (2020), titled "Economic Losses Due to Traffic Congestion on the Muslim Community Residing in Makassar City", concludes that the losses due to congestion include expenditures for fuel purchases under normal conditions, amounting to Rp 19,285.38 for car users and Rp 7,217.86 for motorcycle users. However, if they get stuck in traffic, the costs increase to Rp 29,428.46 per car and Rp 13,175.71 per motorcycle [10],[11].

Research related to Based Shipping Routes Using the Dijkstra Algorithm has introduced a method to identify and characterize shipping routes using data from the Automatic Identification System (AIS), which ships use to broadcast their location and movements to coastal traffic services. This method involves creating a graph where the sea area is divided into grid cells, and the movement of ships between these cells is tracked to find the most frequently used routes, which are assumed to be the safest. By applying Dijkstra's algorithm to this graph, the research successfully identified potential safe routes between two locations, which are the most frequently used paths by ships. This approach helps in determining the safest and most efficient route for maritime navigation [6].

Meanwhile, the article titled "Least Congested And Shortest Distance Path In Kota Kinabalu Traffic Network, Sabah, Malaysia" has focused on traffic estimation using GPS devices installed in vehicles to predict current traffic conditions and suggest the least congested alternative routes (Ting Kien Hua & Noraini Abdullah, 2017). The research conducted by Ting Kien Hua and Noraini Abdullah titled "Weighted Sum-Dijkstra's Algorithm in Best Path Identification based on Multiple Criteria" discusses how GPS devices in vehicles have been used for traffic estimation to predict current traffic conditions and suggest the least congested alternative routes. In this study, the Dijkstra Algorithm has been applied in maritime networks to find paths based on parameters beyond distance, enhancing the route selection process [7]. The solution proposed in this article suggests using Dijkstra's algorithm with multi-criteria to optimize vehicle routes [48]. The Weighted Product Model (WPM). The WPM is very similar to the WSM. The main difference is that instead of addition in the model, there is multiplication. Each alternative is compared to the others by multiplying several ratios, one for each criterion.[13]. Some of the objectives of this research include considering the impact of uncertain traffic conditions on driving speed. By finding the best route, travel time can be shortened [14]. Traffic congestion can cause various negative impacts [15]. The shortest path in computer networks is a routing category that is generally used in computer networks today.[16].

The article titled "Optimal Routes in Urban Networks Using Travel Time Prediction" proposes an algorithm that determines the optimal route between the starting point and the endpoint on the road network. The goal is to minimize travel time while considering constraints such as maximum travel time and risk level [17]. Whereas the article titled "A Path Planning and Navigation Control System Design for Driverless Electric Bus" defines the concept of "path" referring to the process of planning and creating a route for a driverless bus, with the main components involved in route planning are Global Route Planning, local route planning, track creation, special routes and maneuvers, following the route and error correction [18].

The problem in Vehicle Route Optimization is very complex. The research conducted by Tegar Arifin Prasetyo (2021) explains that the problem of "Routing" or vehicle routing is approached using optimization techniques. This research successfully demonstrates how optimization methods can be applied in the real world to address logistics distribution problems by considering various constraints such as vehicle capacity, operational costs, and delivery time [19]. In urban areas, where infrastructure and population density enable extensive data collection and real-time service optimization, routing solutions can be implemented effectively [20].

This research is closely related to expert systems and Artificial Intelligence (AI) because the scientific foundation of Dijkstra's algorithm is Expert Systems and Artificial Intelligence (AI). In the article written by Jonhariono Sihotang (2020). Kecerdasan Buatan (AI) is described as a branch of computer science that focuses on automating intelligent behavior. AI enables computers to perform tasks that are usually performed by humans [21]. The use of artificial intelligence (AI) technology in organizations is becoming increasingly urgent. AI can automate processes, reducing reliance on manual intervention and increasing the speed of data processing and decision-making [22].

Whereas an expert system refers to a computer-based system designed to mimic the ability to think and make decisions of an expert or specialist in the diagnosis of sexual disorders (paraphilia) [23]. An expert system is a computer application that uses knowledge and techniques that are usually possessed by an expert to solve problems in a specific field [24]. Expert systems not only help in solving optimization problems but can also address other cases, such as in the article by Taozara Laia et al. (2022), where expert systems are used to diagnose eye diseases caused by excessive computer use, known as Computer Vision Syndrome (CVS) [25].

This research analyzes Dijkstra's algorithm for solving shortest paths by comparing other similar research and finding a point of novelty, by completing the entire research design using algorithms that are more complete than before, some of which are the Weighted Sum Method (WSM) and the Weighted Product Method. Method development is necessary to improve effectiveness, in addition to novelty, and also a higher level of precision [52],[53].

II. THEORY

A. Dijkstra's Algorithm

Research conducted by Angshuman Guin, et al. about travel time measurement uses three types of travel time measurements: (a) Instantaneous Travel Time (ITT): calculated based on the average instantaneous speed on each road segment, (b) Reactive Travel Time (RTT): based on the travel time of vehicles that have just exited the corridor, and (c) Actual Travel Time (ATT): measured through Bluetooth data, which provides actual travel time in the field. The ITT, RTT, and ATT data were analyzed for each 5-minute interval during the evening congestion period on the I-285 corridor in Georgia. The comparison between ITT, RTT, and ATT shows that simulation-based predictions are more consistent with actual travel time (ATT), especially during congestion [34].

In graph theory, Dijkstra's algorithm is a graph traversal algorithm introduced by Dutch computer scientist Edsger W. Dijkstra in 1959. The Dijkstra algorithm is also known as the single-source shortest path algorithm, similar to Prim's algorithm. Using Dijkstra's algorithm to find the shortest path in a directed graph with non-negative weights is one of the fundamental issues in algorithmic problems. Peter W. Eklund introduced a modified Dijkstra algorithm that includes static and dynamic components, which are simultaneously used to route emergency vehicles in an earthquake simulation in Okayama, Japan. In the article by Peyer, S., Rautenbach, D., and Vygen, J, a new algorithm called Generalized Dijkstra is introduced, which is a fast technique for the Dijkstra algorithm [35]. Penelitian yang dilakukan oleh Ramiz ASSAF, dkk. (2017), tentang Vehicle-Routing Optimization For Municipal Solid Waste Collection Using Genetic Algorithm: The Case Of Southern Nablus City.

B. Degree of Saturation (DoS)

DOS or traffic density is an indicator of traffic flow with a range between 0 and 1. The range of DOS values is between 0 and 1. A saturation degree of less than 0.85 essentially indicates that the capacity is still sufficient for the traffic volume demand. However, when the density approaches 1.0, traffic flow may become unstable, with queues and delay conditions occurring. When demand exceeds capacity (density greater than 1.0), traffic will experience congestion, long queues, and excessive delays. Here is the DOS as Eq. (1):

$$Degree\ of\ Saturation = \frac{Volume}{Capacity} \quad (1)$$

C. Weighted Sum Method (WSM)

The simple WSM method is the summation of these variables. This implies that there is a level of trade-off remaining between each pair of criteria. The most commonly used normalization method is dividing the values by the total of all criterion values to obtain a proportion of the whole. After normalization, assign weights to the criteria and sum the weighted values to produce the appropriate scores and rankings. The WSM equation is shown in Eq. (2):

$$Weighted\ Sum\ Method = W_1X_1 + W_2X_2 + \cdots + W_nX_n \quad (2)$$

D. Weighted Product Method (WPM)

Yoon in Kusumadewi et al. (2006) explains the WPM method using multiplication to link attribute ratings, where the rating of each attribute must first be raised to the power of the corresponding attribute weight. This process is similar to the normalization process. The WPM method is a straightforward and flexible approach because it can directly ignore normalization. The weight seems to be an exponent of the criteria. WPM is shown as in Eq. (3):

$$Weighted\ Product\ Method = {W_1}^{w1}{W_2}^{w2} \ldots\ldots {W_n}^{wn} \quad (3)$$

E. Time Travel

The article written by (Hyungjoo KIM, et al. 2013) discusses the concept of travel time. This article focuses on the travel time estimation methods used to monitor vehicle speeds on highways, particularly in South Korea. Sample-Travel Speed is measured by re-identifying vehicles using transponder electronic toll collection (ETC), which allows for accurate travel time measurements over a certain distance [39].

Meanwhile, another study on travel time estimation using the Instantaneous Model estimation method with the local speed survey method (Spot speed) has been conducted, and the results of this study estimate the travel time for vehicles crossing the studied road segment during the first 5-minute interval from 12:00 to 12:05 WIB from upstream link 1 to downstream link 3 as 2.346 + 2.498 + 2.521 = 7.364 minutes [40].

F. Path

The article, titled "Optimal Paths in Urban Networks Using Travel Time Predictions", proposes an algorithm that determines the optimal path between the starting point and the end point in a road network. The goal is to minimize travel time by considering constraints such as maximum travel time and risk level. This study shows that the proposed algorithm efficiently finds the optimal path for urban networks, taking into account travel time and risk constraints [41].

Meanwhile, the article entitled "A Path Planning and Navigation Control System Design for Driverless Electric Bus" defines the concept of "path" as referring to the process of planning and creating a path for a driverless bus, with the main components involved in path planning being global path planning, local path planning [36], path creation, special paths and maneuvers, path following and error correction. This entire process ensures that driverless buses follow a safe, smooth, and efficient path while adapting to dynamic road conditions. [42].

G. Distance

In the article "AIS-Based Shipping Routes Using Dijkstra's Algorithm", the term "distance" refers to the weights of the sides in a graph that represent the movement of ships between cells in a grid. This weight is inversely proportional to the frequency of ship movement between cells, which means the more often the ship moves between two grid cells, the lower the weight (or "distance") between those cells in the graph [43].

H. Route

When traveling, the question often arises as to which route is the fastest. In answering this question, the criterion that is

often used is distance because the shorter the distance, the faster the travel time. In research conducted by Tetra Widianto, et al. The best route is one that considers the shortest distance and the availability of public facilities. The needs in question are user preferences for available public facilities. Based on the two scenarios that have been run, the resulting routes are the best in each scenario, calculated using Dijkstra's algorithm with a weighted sum input [44].

I. Calculation of Vehicle Volume

Research conducted by Hj Indra Harun discusses the effect of traffic volume on the noise level at the Bastiong highway intersection. The calculation of vehicle volume based on time was carried out at 3 different points for 10 hours, as seen in Table I, Table II, and Table III. Based on the LHR calculation using formula 2, it shows that the highest vehicle volume occurs at point A during the day. Based on the vehicle volume table at point A, the increase in the number of vehicles occurs at 10:00 WIT, this is influenced by police activities that are conducting ticketing operations at 07:00 - 10:00 WIT around the research location [37], against drivers who violate traffic rules, especially two-wheeled vehicles, so that many two-wheeled drivers do not pass through this road segment in the morning. 00 WIT in the vicinity of the research location, against drivers who violate traffic rules, especially two-wheeled vehicles, so that many two-wheeled drivers do not pass through this road section in the morning [45].

TABLE I. COMPARISON BETWEEN LV, HV, AND MC

Time	Vehicle Type			
	LV (Samples/hours)	*HV (Samples/hours)*	*MC (Samples/hours)*	*(Samples/hours)*
07.00-08.00	447,00	34,80	452,25	934,05
08.00-09.00	435,00	66,00	421,75	922,75
09.00-10.00	345,00	18,00	427,50	790,50
10.00-11.00	333,00	48,00	556,25	937,25
11.00-12.00	529,00	116,40	631,50	1276,90
12.00-13.00	500,00	66,00	587,50	1153,50
13.00-14.00	394,00	84,00	524,00	1002,00
14.00-15.00	529,00	122,40	555,25	1206,65
15.00-16.00	459,00	121,20	610,50	1190,70
16.00-17.00	593,00	135,60	758,50	1487,10
Total	4564,00	812,40	5525,00	10901,40

III. METHODS

A. Solving the Routing Problem

The Relevant articles are identified using the keywords "Dijkstra", "Shortest Path", "Multi Criteria", "Weighted Sum Method", "Weighted Product Method", "Distance", "Optimal Path", "Routing Problem", "Time Travel", Degree of Saturation (DOS), or Density. After being identified, the papers were classified using the framework developed by [26]. Traffic congestion is a common problem that requires traffic compliance [27]. The research conducted by Nurwan et al. (2021) discusses the optimal bus schedule starting from 6:30 AM to 5:00 PM. Each bus has 4 (four) departure sessions and 4 (four) return sessions, with a travel time of 60 minutes for each session. The research results show that the shortest route was obtained $V1 - V2 - V5 - V8 - V9 - V10 - V13 - V16$ [28].

Moreover, Traffic congestion in the city of Pekanbaru occurs due to the high number of vehicles on the road and the slow improvement of road facilities; for example, the road capacity remains the same while the number of vehicles continues to increase. Traffic congestion can be categorized into two types: recurring congestion and non-recurring congestion. Recurring congestion is a type of congestion that includes excess demand for travel on four-wheeled and two-wheeled vehicles, as well as a shortage of intersection supply on every road. Recurring traffic jams usually occur during peak hours or working hours, especially from 07:00 AM to 09:00 AM, and from 04:30 PM to 07:00 PM. This is caused during peak hours when people tend to go to work, children go to school, and parents drop off and pick up their children from school, or workers return from their workplaces to go home. Another type of traffic congestion is non-recurring congestion caused by specific cases such as accidents or road closures. The literature review in this article will detail the modeling procedures and their outputs for comparing various traffic parameter input scenarios [50], [51].

B. Research Design

The research conducted refers to the previous study by Dr. Noraini Abdullah & Ting Kien Hua (2018) [29]. With different data and location, previous research created the following research design, as shown in Fig. 1.

Flowchart or research design in Fig. 1. Conducted by Dr. Noraini Abdullah & Ting Kien Hua (2018), it can be explained as follows: traffic data was collected and prepared in Kota Kinabalu during peak hours from 5:00 PM to 7:00 PM. From the data, there are five different input parameters, namely distance, DOS or density, travel time, WSM combined parameter method, and WPM. With all the collected data, five different types of directed network graphs were formed. Then, the traffic network was solved using the Dijkstra algorithm and

both methods. The results of the five different parameters were then compared. Finally, the combined parameter with WSM or the equilibrium between all criteria will be shown in the results section.

The development of the research that will be conducted from the previous study by Dr. Noraini Abdullah & Ting Kien Hua (2018) [30],[31],[32] includes innovations by adding variables related to Time Travel, which previously only considered travel time. It will later be developed to include the fastest time, longest time, and average time. Additionally, there will be the addition of variables related to Elevation or Altitude by calculating the road slope data obtained from Google Earth Pro or the Google API. Furthermore, there will be the addition of traffic lights at intersections, which will be counted in terms of the number of red lights and the duration of the red lights (in seconds). The research conducted by Hyungjoo KIM, et al., about Assessment of Travel Time Estimates based on Different Vehicle Speed Data: Spot Speed vs. Sampled Journey Speed in South Korean expressways, compares two methods of measuring vehicle speed on South Korean highways, namely instantaneous speed measured with loop detectors and actual journey speed measured with electronic toll collection (ETC) transponders. The research was conducted on the Gyeongbu expressway section from Anseong to Giheung-Dongtan, covering a distance of 26.4 km. Speed data were collected through 23 loop detector stations that measure average time speed (instant time at a fixed location) and 8 ETC reader points that measure average distance speed (calculated from travel time between readers). The results of this study indicate that loop detectors are less sensitive to congestion compared to the ETC method [33].

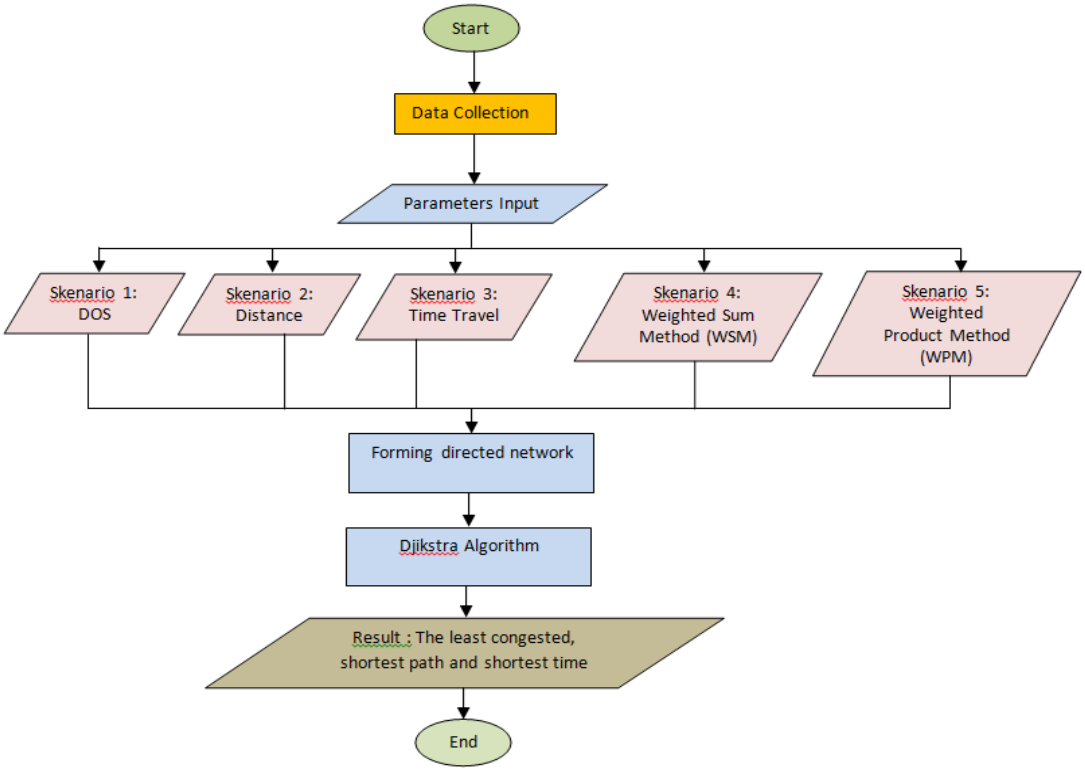

Fig. 1. Research design.

IV. Result and Analysis

A. Research Location

In previous research conducted by [47], the scope selected in the study was the network from Inanam, a suburban city (source node), to Centre Point, which forms the Central Business District (CBD) in the city of Kota Kinabalu (receiver node). Meanwhile, the research conducted in this study is in the city of Pekanbaru, Riau Province, Indonesia. All routes between the source node and the receiving node of the coverage are defined. In Fig. 2, the yellow dot is part of the main intersection selected in the city of Pekanbaru, Riau Province, Indonesia, which is defined as the network graph node.

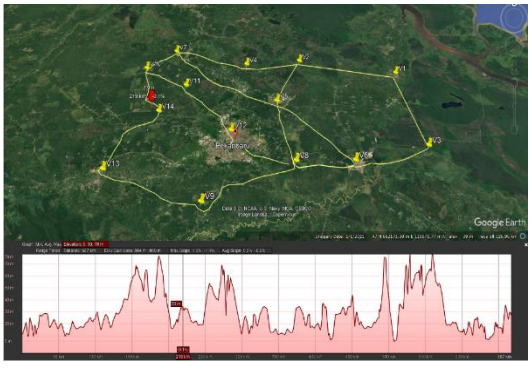

Fig. 2. Traffic network in Pekanbaru City, Riau Province, Indonesia.

B. Data Collection

Data, as shown in Table II, was collected on the road and through Google Maps. Lane distances were collected from Google Maps and relevant agencies, for example, on the official website https://www.pekanbaru.go.id/ [38]. Volume, saturation distance, cycle time, green time, and intersection geometry were collected to calculate the density level (volume/capacity ratio). The time required was collected through real-time traffic flow on Google Maps and Google Earth during the afternoon rush hour.

In Table II, it can be explained that V is a node that is a path from node to node. V1 to V14 are nodes or intersections in the traffic network in Pekanbaru, Riau Province, which were taken with the tools of Google Earth. 'Volume' is the number of vehicles occupying a particular lane at a particular time. 'Capacity' is the maximum volume of vehicles that can pass through a particular intersection or lane. Furthermore, the Degree of Saturation (DOS) is the volume/capacity ratio, which is an indicator of current traffic conditions. 'Distance' is the length of the path from node to node. The 'Weighted Sum Value' is the combination of degree of saturation, travel time, and distance using the Weighted Sum Methods (WSM). In addition, the 'Value of Weighted Product Methods (WPM) is the combined value of several criteria using the Weighted Product Methods (WPM).

C. Dijkstra's Algorithm Output

The network graph in Fig. 3 has a degree of saturation (DOS) parameter. Degree of saturation is the ratio of volume to capacity. The yellow-highlighted path in Fig. 3 below is the path with the smallest degree of saturation (DOS = 1.003+1.006+0.126+0.087+0.409), which indicates the least congested path, namely $V1 \rightarrow V2 \rightarrow V4 \rightarrow V7 \rightarrow V10 \rightarrow V14$ with a total DOS value of 2.631.

TABLE II. COMPARISON OF THE DATA COLLECTED

Path	*From*	*To*	*Volume*	*Capacity*	*DOS (Value)*	*Distance (Km)*	*Time Travel (minute)*	*Weighted Sum Method (WSM) (Value)*	*Weighted-Product Method (WPM)(Value)*

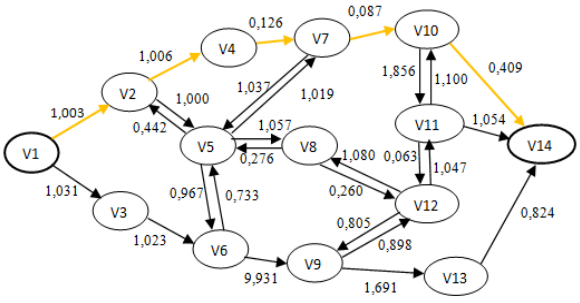

Fig. 3. Output of Dijkstra's algorithm (degree of saturation parameter network graph).

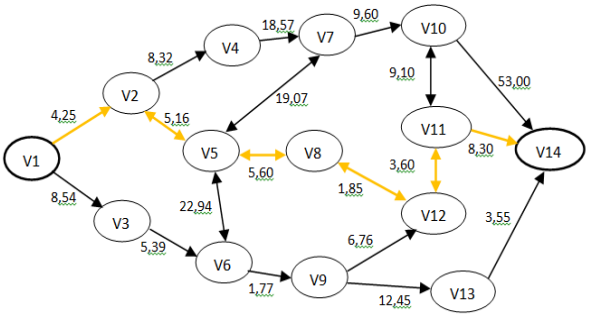

Fig. 4. Output of Dijkstra's algorithm (distance parameter network graph).

The Network Graph in Fig. 4 with distance parameters is formed using the data collected in Table II. The source node is node 1, and the receiving node is node 14. From Fig. 4, the path marked in yellow is represented by 1→2→5→8→12→11→14, which is the shortest path with a total distance (4.25+5.16+5.60+1.85+3.60+8.30) equal to 28.77 kilometers.

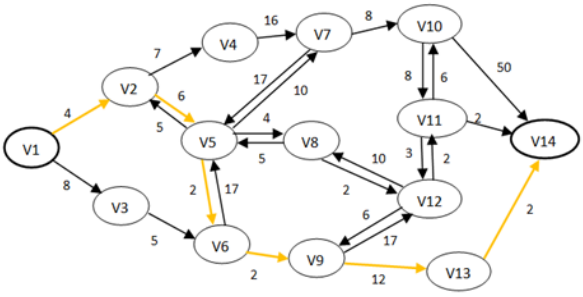

Fig. 5. Output of Dijkstra's algorithm (time travel parameter network graph).

In Fig. 5, the time travel parameter network graph is shown together as an alternative path. The alternative path with the shortest travel time is path 1→2→5→6→9→13→14. The total travel time is 28 minutes, traveling from 1 to 14, respectively.

In Fig. 6 and Fig. 7, the Dijkstra algorithm uses a combination of distance, travel time, and density values with the weighted-sum and weighted-product methods, respectively, executed. From the output in Fig. 6, the shortest distance and travel time is 1→2→4→7→10→14, while the output in Fig. 7 is the path with less density, shorter distance, and shorter travel time, namely the path 1→2→5→6→9→13→14. The total distance of this alternative route is 28.77 kilometers with a total saturation degree of 5.421 and a travel time of 28 minutes.

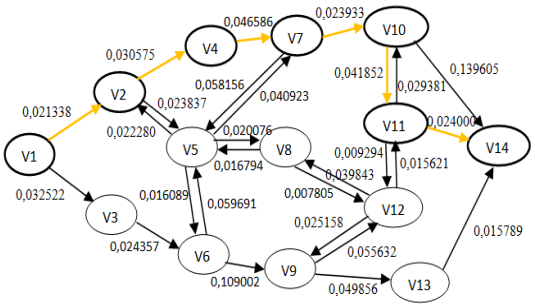

Fig. 6. Output of Dijkstra's algorithm (weighted-sum method).

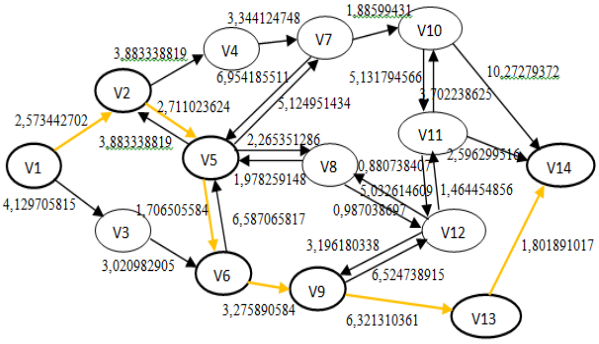

Fig. 7. Output of Dijkstra's algorithm (weighted-product method).

TABLE III. COMPARISON OF DISTANCE, DENSITY, AND TRAVEL TIME

Parameter	Specifics Parameter			
	Path	Distance (km)	DOS (Degree of Saturation) (Density)	*Time Travel (Travel Time/Minute)*
Distance	Path 1: 1->2->5->8->12->11->14	28,77	5,421	28
DOS	Path 2: V1->V2->V4->V7->V10->V14	93,74	2,631	85
Time Travel	Path 3: 1->2->4->7->10->14	50,12	15,416	28
Weighted SUM Method	1->2->4->7->10->14	58,14	2,631	85
Weighted Product Method	1->2->5->6->9->13->14	50,12	5,421	28

Data source: Personal Research Data

As shown in Table III, there are three different paths selected depending on the selected parameters. With the distance parameter network graph, Path 1 is the path selected with the shortest distance. Path 2 is the path selected with Degree Of Saturation (DOS), while Route 3 is the route with the shortest travel time. With the combined parameters of DOS, travel time, and distance, Route 1 was chosen because it has achieved a balance between distance, travel time, and DOS. In other words, the driver can decide on the optimal right lane that is not too congested, has a shorter travel time, and a shorter distance. The difference between the paths in percentage is then calculated to find significant differences between them.

V. Conclusions

The shortest distance route may not be the best; two different parameters result in two different routes, but the best route is chosen based on distance and the lowest saturation level criterion. However, in this study, travel time is an additional criterion. Routes with three different parameters have been compared and result in three different routes. From these results, the shortest route is 1→2→4→7→10→14, the least congested route, and the shortest travel time is 1→2→5→6→9→13→14. This study combines these three parameters to get a balanced route between congestion level, short travel distance, and short travel time for drivers. By combining these parameters, the best path from this study is path 1: 1→2→5→8→12→11→14 with a total distance of 28.77 km, a saturation degree value of 5.421, and a travel time of 28 minutes. Thus, the results show that the best path will have a multi-criteria combination of short distance, short travel time, and fewer simultaneous traffic jams. The Weighted-Sum Method (WSM) and the Weighted-Product Method (WPM) can produce different outputs, with WPM being superior to WSM in terms of computational steps. The Weighted Product Method can also be user-friendly, and avoids normalization issues that can cause the reversal of rankings usually faced by the Weighted-Sum Method.

VI. Future Research

The calculation results on Time Travel on the graph become three (3) graphs, namely the fastest time, the longest time, and the average time in minutes, while altitude affects speed. The more sloping the road conditions, the longer it will take, and it is not recommended, because it will affect not only costs but can also affect time and reduce the bad energy caused by vehicle exhaust fumes. Then the number of red lights will also affect the time of arrival at the destination. This is calculated based on the number of red lights and the length of time in seconds on the red light indicator on the road.

Acknowledgment

Thanks to all internal and external teams who have helped to complete this research. Hopefully, this research will continue to develop in the future so that it can contribute to the development of smart cars and the like.

***Abstract*—Sentence embedding is a very important technique in most natural language processing (NLP) tasks, such as answer generation, semantic similarity detection, text classification and information retrieval. This technique aims to transform the semantic meaning of a sentence into a fixed-dimensional vector, allowing machines to understand human language. Sentence embedding has moved in recent years from simple word vector averaging methods to the development of more sophisticated models, particularly those based on transformer structures such as the BERT model and its variants. However, systematic reviews that critical, analyze and compare the performance of these models are still limited, particularly the selection of the appropriate embedding model for a specific NLP task. This study aims to address this gap by a comprehensive review for sentence embedding models and a systematic evaluation of their performance on NLP tasks, such as semantic similarity, clustering, and retrieval. The study enabled us to identify the appropriate embedding model for each task, identify the main challenges faced by embedding models, and propose effective solutions to improve the performance and efficiency of sentence embedding.**

***Keywords*—Natural language processing; sentence embedding models; transformer models; embedding models challenges**

I. Introduction

Embedding is one of the most techniques used in natural language processing applications [1] [2]. The performance of these applications is affected by the quality of the fixed-dimensional vectors generated [3]. Several studies have underscored the importance of developing sentence embedding models [4], [5], especially with the capabilities offered by deep neural networks and transformers. NLP tasks require a deeper understanding of texts, especially understanding long texts [6], [7]. Therefore, choosing an appropriate embedding model is essential for a task. Recent frameworks such as DSPy [8] underscore the need for more sophisticated and context-aware sentence representations that are better suited to specific NLP tasks. Therefore, there is a need to study and analyze sentence embedding techniques, from statistical models based on word vector averages to modern models based on deep structures such as BERT [9] and its variants. In this context, we conducted a comprehensive literature review of the most sentence embedding models, from simple aggregation techniques to transformer-based models.

The main objective of our paper is to identify the most appropriate embedding model for a specific task. To achieve this, our paper first presents the most important embedding models, their characteristics, the challenges that affect their effectiveness, and solutions that can help overcome them. Second, it evaluates the performance of these models on three natural language processing tasks [10], including semantic similarity, clustering, and retrieval, to identify the most effective models for each task. The methodology used in our paper is based on answering three main research questions:

- RQ 1: What are the main categories of sentence embedding models proposed in the literature?
- RQ 2: What are the strengths, limitations, and challenges of each model?
- RQ 3: Which model is appropriate for each NLP task?

We reviewed and analyzed scientific papers published in peer-reviewed sources (ArXiv, Scopus, Dblp, IEEE) between 2015 and 2025. The results of this study represent an opportunity for researchers to build an overview of the techniques used in sentence embedding, to advance this area.

The rest of the paper will be presented as follows. Section II presents related work on sentence embedding. Section III discusses categories of sentence embedding models, highlighting their advantages and challenges. Section IV is devoted to an empirical study that aims to evaluate these models across NLP tasks. Section V presents and discusses the results of the study. Section VI concludes the paper with future research directions.

II. Related Work

In this section, we first highlight the importance of embedding models for natural language processing tasks and applications. We then trace the evolution of sentence embedding models. Finally, we summarize the scope and limitations of previous reviews to underline the relevance of the present study.

A. Sentence Embeddings in NLP Tasks

Embedding models have attracted growing interest in NLP field, as they demonstrate strong effectiveness in a variety of tasks, such as retrieval, clustering, summarization, and semantic similarity [11]. The development of embedding techniques has positively impacted this area [12]. Recent research has demonstrated that their use significantly improves the performance of NLP applications. For example, the performance of text classification and clustering has improved by pre-trained embeddings [13]. Performance in dense retrieval across multiple datasets has improved by employing contrastive learning models [14]. Similarly, extractive summarization models have improved by enabling the selection of more semantically rich sentences compared to standard baselines

[15]. Clustering studies also confirm that embeddings derived from pre-trained large language models capture accurate semantic relationships [16]. These results confirm that exploiting sentence embeddings for a specific task is essential for improving the performance of NLP tasks and applications.

B. Sentence Embedding Evolution

A text embedding is a vector representation of text (word, sentence, or paragraph), where similar texts appear close together in the embedding space [5]. These representations encode the syntactic and semantic properties of linguistic elements. Classic representations have relied on the bag-of-words model or TF-IDF weighting [17], where each word is represented by a high-dimensional vector reflecting its frequency in the document (Formula 1). For a word w in a document d, the TF-IDF vector is defined as:

$$\vec{W} = (TFIDF(w,d_1), TFIDF(w,d_2), \dots, TFIDF(w,d_N)) \quad (1)$$

Where $TF-IDF(w,d)$ is calculated by Formula 2.

$$TF-IDF(w,d) = \frac{f_{w,d}}{\sum_{w' \epsilon d} f_{w',d}} \times log\left(\frac{N}{1+|\{d \epsilon D: w \epsilon d\}|}\right) \quad (2)$$

Where:

- $f_{w,d}$: Frequency of the word w in document d.
- N: Number of documents in corpus D.
- $|\{d \epsilon D: w \epsilon d\}|$: Number of documents containing the word w.

However, these models suffer from several limitations, including their high dimensionality and their inability to capture semantic similarity between terms.

Word embedding, through models such as Word2Vec [18] and GloVe [19], has enabled the representation of words using low-dimensional vectors while considering relevant semantic contexts. On the other hand, the same vector is assigned to a word regardless of its context. Therefore, these models ignore the context in which the word appears, making them unsuitable for modeling sentences or paragraphs. Fig. 1 provides an example of this challenge.

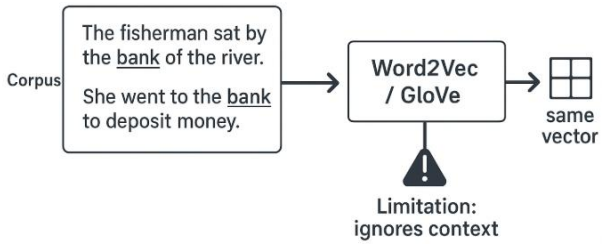

Fig. 1. Contextual limitation of Word2Vec and GloVe.

To address the need to model text units containing more than one word, sentence embeddings were developed that aim to represent each sentence as a fixed-dimensional dense vector.

Sentence embedding techniques are classified into two main categories [20]. The first includes statistical techniques, such as Doc2Vec [21] and SIF [22]. These techniques are computationally inexpensive. However, they remain limited because they only capture a portion of the semantic context. The second set consists of deep neural techniques, which rely on advanced encoding models. These include InferSent [23] and Universal Sentence Encoder [24], Sentence-BERT [25] and SimCSE [26]. These models use transformers to contextually model complex relationships between words and sentences. They therefore provide more expressive vector representations suitable for advanced NLP tasks.

C. Comprehensive Review of Sentence Embedding

Several research papers have studied and reviewed proposed sentence embedding models, offering different perspectives on their classification, evaluation, and application. The work presented in [27] is one of the first general reviews of sentence representations. This study was limited to unsupervised neural approaches. Other reviews such as [23], [28] have analyzed and compared sentence representation learning, proposed unified evaluation metrics such as SentEval [29], and focused on classical RNN and CNN encoders. In contrast, studies, such as [24], [25], have highlighted the effectiveness of transformer learning using pre-trained models such as BERT and its variants. Finally, recent published studies [26], [30] have focused on the importance of contrastive learning and pre-trained models. Despite the comprehensiveness of these reviews, the development of embedding models across NLP tasks, and the difficulty of identifying the appropriate model for each task, is a challenge that motivates a comprehensive and updated review that considers the importance of models to the nature of NLP tasks and their applications.

III. Sentence Embedding Models

This section introduces two main categories of sentence embedding models. Statistical sentence embedding models represent sentences using aggregated word-level statistics, while transformer-based sentence embedding models represent sentences using pre-trained contextual language models. This classification highlights the shift from shallow frequency-based representations to neural structures that better encode semantic and syntactic relationships.

A. Statistical Sentence Embedding Techniques

Statistical methods for sentence embedding rely on simple aggregation techniques, such as averaging or weighted summation of word embeddings, or distributional models. Although computationally efficient and easy to implement, these methods provide an approximate semantic representation of a sentence, ignoring word order and syntactic structures.

1) Unweighted averaging: Unweighted averaging is one of the most techniques widely used to generate sentence embeddings. The method consists of representing a sentence by computing the arithmetic mean of the vector representations of its constituent words. According to study [18], a sentence embedding is defined by Formula 3.

$$v_{sentence} = \frac{1}{n}\sum_{i=1}^{n} v_{w_i} \quad (3)$$

Where:

- n: Number of words in the sentence.
- v_{w_i} : The embedding representation of word w_i.

Despite its simplicity, it has been shown to capture some of the semantic meaning of vectors. However, its limitations include ignoring the significance of words in a sentence. It treats all words equally, including frequent terms.

2) TF-IDF weighted averaging: The TF-IDF weighted averaging incorporates word importance by exploiting the TF-IDF coefficient. This allows us to overcome the challenge of treating all words equally and reduce the influence of common words. Formally, according to [22], the sentence embeddings are obtained by calculating a weighted average of word vectors, where the weights are determined by TF-IDF coefficient (Formula 4).

$$V_{sentence} = \frac{\sum_{i=1}^{n} TF\text{-}IDF(w_i) \cdot v_{w_i}}{\sum_{i=1}^{n} TF\text{-}IDF(w_i)} \quad (4)$$

Where:

- n: Number of words in the sentence.
- v_{w_i} : The embedding representation of word w_i.
- $TF - IDF(w_i)$: Weight of word w_i, is calculated by Formula 2.

This model generates better semantic representations than unweighted averaging. However, it still ignores the syntactic information and sequential order of words, which may limit its effectiveness in more complex NLP tasks.

3) Max and min pooling models: Max and min pooling is a statistical model for generating sentence embeddings by selecting the maximum (or minimum) value of all word embeddings in a sentence. This approach captures the most prominent features present in any word vector, making it robust to noise. According to [23], the sentence embedding can be generated using either max-pooling or min-pooling as defined by Formulas (5) and (6).

$$V_{sentence}^{max} = \left[\max_{i=1..n}(v_{w_i}^{(1)}), \max_{i=1..n}(v_{w_i}^{(2)}), \dots \max_{i=1..n}(v_{w_i}^{(d)})\right] \quad (5)$$

$$V_{sentence}^{min} = \left[\min_{i=1..n}(v_{w_i}^{(1)}), \min_{i=1..n}(v_{w_i}^{(2)}), \dots \min_{i=1..n}(v_{w_i}^{(d)})\right] \quad (6)$$

Where:

- n: Number of words in the sentence.
- $v_{w_i}^{(k)}$: the value of the k-th dimension of word w_i (each of dimension d).

However, it still ignores syntactic information and may oversimplify the semantic representation. The semantic structure of sentences may be overly simplified.

4) Smooth inverse frequency model: The Smoothed Inverse Frequency (SIF) [22] model reduces the influence of common words on sentence embeddings by weighting word embeddings inversely with their frequency in a corpus. To generate sentence embeddings, SIF calculates a weighted average (Formula 7) and removes the first principal component that defines common directions in the embedding space to produce more discriminative sentence representations (Formula 8).

$$V_{sentence} = \frac{1}{n}\sum_{i=1}^{n} \frac{\alpha}{\alpha + p(w_i)} \cdot v_{w_i} \quad (7)$$

Where:

- n: Number of words in the sentence.
- v_{w_i} : Embedding representation of word w_i.
- $p(w_i)$: Frequency of w_i in the corpus.
- α: Smoothing parameter (default 10^{-3})

To remove the first principal component F that defines the common directions in the embedding space, we need to calculate $FF^T V_{sentence}$ the Projection of $V_{sentence}$ onto F ($F^T V_{sentence}$ is the scalar product between F and $V_{sentence}$).

$$V_{Sentence}^{SIF} = V_{sentence} - FF^T V_{sentence} \quad (8)$$

Although SIF is efficient, and robust, but its reliance on frequency statistics, principal component analysis calculations, and inability to capture syntax or context limits its effectiveness for more complex NLP tasks.

B. Transformer-Based Sentence Embedding Models

Sentence embedding using transformers has contributed to generating contextual representations that capture the semantic meaning of sentences and reducing the challenges of statistical models. Bidirectional Encoder from Transformers (BERT) [9] is the first transformer used for sentence embedding. Other transformers have followed, improving the performance of the sentence embedding task. In this part, we provide a comprehensive overview of the transformer-based sentence embedding models, based on the classification shown in Fig. 2.

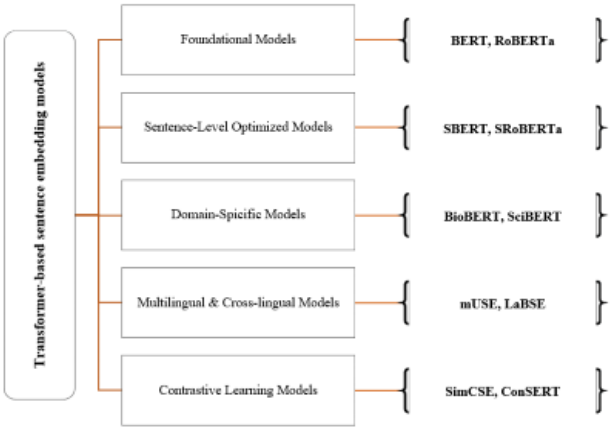

Fig. 2. Taxonomy of transformer-based sentence embedding models.

1) Foundational models: BERT is the first transformer model for sentence embedding. Unlike statistical approaches, BERT relies on self-attention mechanisms rather than recurrent or convolutional networks. It has bidirectional encoding, which allows it to read sequences of tokens in both directions. It uses multiple transformer layers (12 in BERT-base and 24 in BERT-large), each consisting of multi-head self-attention networks and feed-forward networks. Its pre-training combines masked language modeling (MLM), where random tokens are predicted from context, and next-sentence prediction (NSP), which

captures sentence-level relationships. Fig. 3 illustrates the process by which BERT produces these embeddings. These features make BERT more effective to learn deep contextual representations.

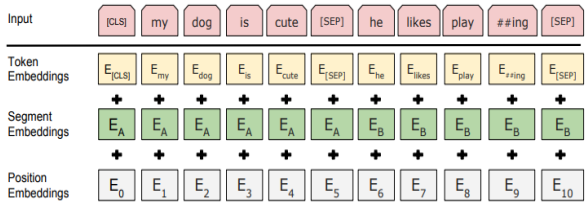

Fig. 3. The BERT sentence embedding process, reproduced from study [9].

However, the computational cost of pretraining, biases in pretraining data, and sequence length constraints limit its performance to represent long documents. This challenge has prompted the development of BERT variants such as RoBERT [31] that uses the same transformer encoder architecture as BERT, but with improvements in the pre-training phase. It Eliminates the NSP task, employs dynamic masking in the MLM objective, and trains on larger datasets (over 160 GB). This allows it to benefit from longer training schedules and higher learning, enhancing the quality of its contextual representations.

Despite their effective performance, Foundational models face several challenges. The large training dataset makes them computationally expensive, and they are also affected by biases present in pre-training datasets. Furthermore, the input length limit of 512 tokens limits their ability to represent longer sequences.

2) Sentence-level optimized models: To overcome the challenges of foundational models, sentence-level optimized models, such as SBERT and SRoBERTa [25], rely on Siamese and triplet network architectures, which improve the accuracy of transformer encoders to generate semantically meaningful sentence representations. They also reduce computational cost on semantic text similarity (STS) tasks. The time to find the most similar pair of sentences in a set of 10,000 sentences is reduced from 65 hours using BERT to about 5 seconds using SBERT. Using a Siamese and triplet network also embeds sentences into higher-dimensional semantic spaces to better capture hierarchical information.

TABLE I. KEY DISTINCTIONS BETWEEN SBERT AND SROBERTA

Criterion	SBERT	SRoBERTa
Encoder	BERT or RoBERTa	RoBERTa (with enhanced pretraining)
Training Data	STS/NLI datasets	Larger and more diverse datasets, often domain-adapted
Specialized Tasks	Semantic similarity	Semantic similarity, clustering
Performance	Strong for semantic tasks	Higher performance, especially in specific domain

Table I shows the key differences between SBERT and SRoBERTa. In SBERT, the input sentence is encoded using BERT or RoBERTa, followed by a pooling layer that produces a fixed-size embedding, which is then applied to semantic similarity tasks. In contrast, SRoBERTa uses the RoBERTa encoder and incorporates structured training strategies, such as variance and classification losses, to produce more accurate embeddings. These embeddings are particularly effective for semantic search and clustering, and therefore SRoBERTa outperforms SBERT.

The performance of SBERT and SRoBERTa on Cross-lingual data is low, compared to their results on English data. Therefore, their performance depends on the language of their training data (English) which makes their generalization to complex languages difficult. Therefore, multilingual and cross-linguistic sentence embedding models are important to achieve robust performance on multilingual applications.

3) Multilingual and cross-linguistic models: Semantic similarity Detection between sentences across different languages has been a challenge for monolingual sentence embedding models. In contrast, multilingual and cross-linguistic models, such as the Multilingual Universal Sentence Encoder (mUSE) [32] and Language-Independent BERT Sentence Embeddings (LaBSE) [33], achieve minimal linguistic bias, leading to better performance.

The mUSE model uses a universal sentence encoder and is trained on a set of translation pairs in multilingual datasets. mUSE supports more than 16 universal languages, and achieves a semantic similarity and effective cross-language retrieval. However, its performance deteriorates on untrained languages, this limit its application in global contexts. Unlike mUSE, LaBSE is a language-agnostic model trained on over 110 languages using a dual-encoder architecture and translation ranking objectives. LaBSE achieved state-of-the-art results on benchmarks such as Tatoeba [34] and cross-linguistic STS [35]. It demonstrated its ability to encode semantically equivalent sentences from different languages, making it one of the most robust models for multilingual applications.

Overall, these models have achieved the transition from English-centric sentence embeddings to multilingual sentence embeddings. Despite this contribution, these models still face significant challenges. Their reliance on massive parallel datasets and complex training pipelines limits their adaptability to resource-limited languages. They also rely on translation-based alignment objectives, which can introduce biases and limit the generalization of sentence representations in monolingual or domain-specific. To overcome these challenges, contrastive learning models have emerged, which aim to learn sentence embeddings by exploiting self-supervised objectives.

4) Contrastive learning models: To overcome the challenges faced by multilingual sentence embedding models, contrastive learning models has been adopted as a paradigm for learning universal sentence representations. these models aim to approximate semantically similar sentences in the embedding space while separating unrelated sentences, without the need for massive parallel datasets. SimCSE [26] and ConSERT [36] are the most widely used contrastive learning models for sentence embedding.

SimCSE relies on two different representations of the same sentence by applying contrastive dropout masks within a pre-

trained model such as BERT or RoBERTa. These representations are considered as positive pairs, while the other sentences are treated as negative samples. By the contrastive loss optimization (InfoNCE) [37], SimCSE is learn to align semantically consistent representations without the need for external supervision. The ConSERT sentence embedding model relies on contrastive learning to efficiently fine-tune BERT, leveraging positive pair construction through strategies including word reordering, token masking, and embedding dimension masking. Sentence representations are obtained by aggregating mean pooling instead of CLS. Which makes it able to adapt in low-resource contexts.

However, some challenges are remained. These models require fine-tuning of hyperparameters (dropout rates, and augmentation strategies), making their performance unstable across domains. Their performance is also affected in resources lacking sufficient negative samples due to their reliance on aggregated negatives. Furthermore, these models are largely trained on English corpora, offering limited cross-language generalization without extensive retraining.

IV. Empirical Study

This section presents the evaluation process adopted in our study. Fig. 4 shows the most important stages of this process. We introduce the benchmark datasets commonly used to evaluate the performance of sentence embedding models. Next, we present the evaluation metrics used to measure the performance of NLP tasks such as semantic similarity, clustering, retrieval information, and classification. We present empirical results on the performance of these models. Finally, we discuss the results, identifying the appropriate models for each NLP task.

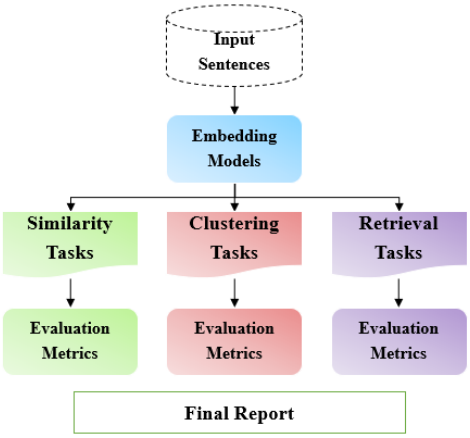

Fig. 4. Process of the evaluation sentence embedding models.

In the first stage, sentences are received by the embedding model to be evaluated, which converts them into numerical vectors in the second stage. These vectors are tested on three main tasks in the third stage. Similarity tasks to measure the degree of meanings similarity, clustering tasks to test the ability to cluster similar sentences, and retrieval tasks to evaluate the effectiveness of sentence retrieval. For each task, appropriate evaluation metrics are adopted to reflect the model's accuracy and performance. Finally, the results are analyzed in a comprehensive report that allows for model comparison.

A. Evaluation Datasets

The evaluation of sentence embedding models relies on datasets that capture task requirements. Semantic text similarity (STS) datasets, such as STS-Benchmark [35] and SICK-R [38], are used because they allow for easy interpretation of the semantic quality scores of embeddings. However, its small size and focus on a specific domain limit its generalizability. Therefore, Natural Language Inference (NLI) datasets, including SNLI [39] and MultiNLI [40], are also commonly used to evaluate embedding techniques. Despite its large size and diversity of sentence pairs, it can lead to embedding without a real understanding of the meaning. Datasets such as MRPC [41] and QQP [42] are used to measure the ability of embeddings to capture paraphrasing and lexical diversity. For retrieval and clustering tasks, datasets such as MS MARCO [43], BEIR [44], and StackExchange [45] are used. Their challenges lie in high variability and data noisy.

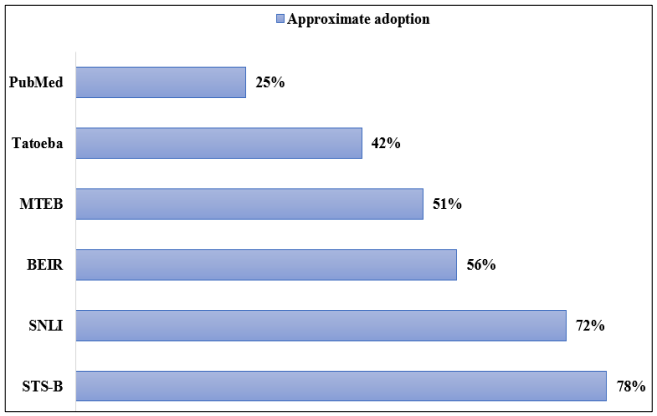

Fig. 5. Approximate adoption rates of training and evaluation datasets in sentence embedding research.

The multilingual datasets, including XNLI [46], Tatoeba [47], and the MTEB [48] multilingual path, are essential for evaluating models across different languages. However, they remain limited in low-resource languages. Fig. 5 shows the approximate adoption rates of datasets in sentence embedding research. Table II compares the most important datasets used for evaluation, in terms of task, size, language, and challenges.

Domain-specific models such as BioBERT, SciBERT instead rely on specialized datasets such as the PubMed biomedical dataset or scientific papers from Semantic Scholar.

B. Evaluation Metrics

To measure the performance of sentence embedding models, the NLP tasks identify the appropriate metric. For semantic textual similarity (STS) tasks, correlation metrics such as Pearson correlation coefficient and Spearman correlation coefficient [49] are used. Cosine similarity [50] is used to measure how closely embeddings converge in vector space, making it suitable for tasks such as clustering and paraphrase detection.

TABLE II. COMPARISON OF DATASETS USED TO TRAIN AND EVALUATE SENTENCE EMBEDDING MODELS

Dataset	Task	Size	Language	Challenges
STS-B	Semantic Textual Similarity	8,600 pairs	English	Small size, domain-limited
SICK-R	Semantic Textual Similarity + Relatedness	10,000 pairs	English	Domain-limited, relatively small
SNLI	Natural Language Inference	570,000 pairs	English	Annotation in English-only
MultiNLI	Natural Language Inference	430,000 pairs	English (multiple genres)	Still English-only, annotation bias
MRPC	Paraphrase Identification	5,800 pairs	English	Small dataset, domain bias (news)
QQP	Paraphrase Identification	400,000 pairs	English	Noise, duplicates, biased toward question style
MS MARCO	Passage Retrieval / Ranking	1M passages, 100k queries	English	Noisy labels, domain-specific (web queries)
StackExchange	Clustering & Retrieval	100k+ QA pairs	English	Annotation ambiguity , Duplicate questions
XNLI	Cross-lingual NLI	750k (15 languages)	Multilingual	Limited low-resource language support
Tatoeba	Cross-lingual Sentence Similarity	1,000+ pairs per language	100+ languages	Uneven quality across languages
MTEB	Multi-task, multi-lingual (STS, retrieval, classification, clustering)	8M examples across 50 datasets	Multilingual (100+ languages)	Complex to run, requires large compute

Also, for clustering tasks, Normalized Mutual Information (NMI), Silhouette score, and Adjusted Rand Index (ARI) [51], can be used to evaluate how well embeddings cluster semantically similar sentences. For classification and natural language inference (NLI) tasks, Accuracy and F1-Score [52] are the most appropriate metrics. For information retrieval and classification tasks, metrics such as mean average precision (MAP) and mean reciprocal rank (MRR) [53] are preferred. Table III presents the most important metrics for evaluating sentence embedding models for each NLP task.

TABLE III. EVALUATION METRICS FOR SENTENCE EMBEDDING MODELS ON NLP TASKS

Metric	STS	Clustering	Paraphrase	Retrieval	NLI	Classification
Cosine Similarity	X	X	X			
Pearson Correlation	X					
Spearman Correlation	X					
Accuracy					X	X
F1-Score			X		X	X
Mean Average Precision (MAP)				X		
Mean Reciprocal Rank (MRR)				X		
Normalized Mutual Information (NMI)		X				
Adjusted Rand Index (ARI)		X				
Silhouette Score		X				

Analysis of sentence embedding research shows that most sentence embedding models prefer evaluation based on semantic textual similarity tasks, while evaluation tasks such as information retrieval and classification are neglected. Fig. 6 shows the approximate adoption rates of evaluation metrics in sentence embedding research.

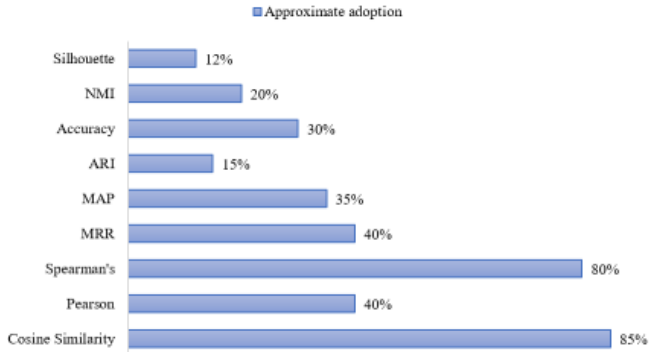

Fig. 6. Approximate adoption rates of evaluation metrics in sentence embedding research.

C. Evaluation protocol

1) Statistical sentence embedding techniques: To evaluate statistical sentence embedding techniques, popular datasets and evaluation metrics were used. The STS-Benchmark dataset and Spearman and Pearson correlations were used to measure the effectiveness of embedding on semantic textual similarity (STS). For sentiment classification tasks, the Stanford Sentiment Treebank (SST-2) dataset [54] and the classification accuracy metric were used. Additionally, the clustering quality was measured on sentence embeddings derived from the STS-B corpus using the silhouette score.

According to the evaluation results presented in Fig. 7, the performance of unweighted averaging was affected by uniform treatment of words, especially in semantic similarity tasks. The

results of TF-IDF weighted averaging also make it more suitable for classification tasks. While the performance of max/min pooling, which oversimplifies the semantic of a sentence, remains inconsistent.

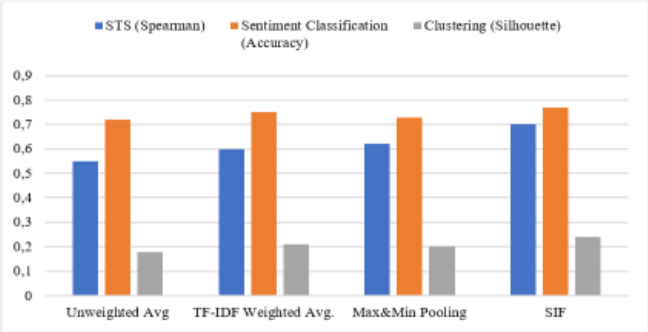

Fig. 7. Performance of statistical sentence embedding techniques across STS, sentiment classification, and clustering.

Conversely, the results demonstrate that SIF outperforms other methods by removing the most common directions in the embedding space, especially in semantic similarity and clustering tasks.

2) Transformer-based models: To ensure a comprehensive evaluation of sentence embedding models, three NLP tasks were adopted. Semantic similarity, clustering, and retrieval. This evaluation requires specific datasets and evaluation metrics for each task. For semantic similarity task, STS-B and Tatoeba were used. STS-B is a widely used for semantic similarity in English, while Tatoeba extends the evaluation to include multilingual sentence pairs. The performance was measured using Pearson and Spearman coefficients. In contrast, for the clustering task, MTEB and STS Clustering were adopted, which test the ability of embeddings to cluster semantically similar texts. Cosine similarity and silhouette score are used to measure the performance. Retrieval task was evaluated using BEIR and MIRACL datasets. BEIR provides a unified framework for information retrieval, while MIRACL focuses on cross-linguistic retrieval performance. MAP and MRR, which reflect the importance of retrieval, were used to measure the performance. Table IV presents the performance of the sentence embedding models on the semantic similarity task evaluation in STS-B and Tatoeba datasets.

The results showed modest performance of BERT and RoberTa, compared to the effectiveness of SBERT and SRoBERTa, on semantic similarity tasks. The multilingual models (mUSE and LabSE) also demonstrated effective performance, particularly on Tatoeba, confirming their performance on cross-linguistic representations. In addition to their computational efficiency, the contrastive learning models (SimCSE and ConSERT) achieved competitive results, making them attractive for light applications. Overall, these results suggest that domain, resource constraints, and language requirements determine the appropriate model.

The performance of sentence embedding models on the clustering task was evaluated using the MTEB Clustering and STS Clustering datasets as a practical benchmark for document clustering. Performance is measured using cosine similarity, which measures the convergence of embeddings within clusters, and the Silhouette score, which reflects cohesion and separation within a cluster. Table V presents the performance results of these models for each dataset.

TABLE IV. PERFORMANCE OF THE TRANSFORMER-BASED MODELS ON THE SEMANTIC SIMILARITY TASK

Model	STS-B		Tatoeba	
	Pearson	Spearman	Pearson	Spearman
BERT	0.63	0.60	0.42	0.40
RoBERTa	0.66	0.65	0.45	0.42
SBERT	**0.85**	**0.81**	0.72	0.70
SRoBERTa	**0.86**	**0.82**	0.71	0.68
BioBERT	0.60	0.55	0.40	0.43
SciBERT	0.70	0.62	0.50	0.46
mUSE	0.76	0.72	**0.85**	**0.82**
LaBSE	0.78	0.75	**0.88**	**0.86**
SimCSE	0.82	0.79	0.78	0.75
ConSERT	0.80	0.76	0.76	0.73

TABLE V. PERFORMANCE OF THE TRANSFORMER-BASED MODELS ON THE CLUSTERING TASK

Model	MTEB Clustering		STS Clustering	
	Cosine	Silhouette	Cosine	Silhouette
BERT	0.38	0.14	0.42	0.15
RoBERTa	0.40	0.16	0.44	0.20
SBERT	0.58	0.27	0.60	0.30
SRoBERTa	0.62	0.31	0.63	0.30
BioBERT	0.45	0.20	0.50	0.20
SciBERT	0.48	0.23	0.54	0.23
mUSE	0.58	0.25	0.60	0.25
LaBSE	**0.62**	**0.29**	0.62	0.28
SimCSE	**0.64**	**0.32**	**0.67**	**0.31**
ConSERT	0.61	0.28	**0.65**	**0.29**

The clustering results demonstrate the superior performance of the SimCSE and ConSERT models, confirming the effectiveness of contrastive learning to produce embeddings that enable the formation of coherent clusters. However, the performance of domain-specific models, such as BioBERT and SciBERT, is affected by the specialization of their training data and thus unsuitable for clustering tasks. In contrast, the multilingual models (mUSE and LabSE) provide competitive results. LaBSE achieves strong performance in multilingual clustering, making it suitable for clustering multilingual documents.

The performance of sentence embedding models on the retrieval task was evaluated using the BEIR and MIRACL benchmarks, which serve as widely adopted frameworks for testing retrieval effectiveness across both monolingual and multilingual settings. Evaluation was carried out using Mean

Average Precision (MAP), which measures the overall ranking quality, and Mean Reciprocal Rank (MRR), which reflects the ability of models to return relevant results at top ranks. Table VI presents the results of all models across both datasets.

TABLE VI. PERFORMANCE OF THE TRANSFORMER-BASED MODELS ON THE RETRIEVAL TASK

Model	BEIR		MIRACL	
	MAP	MRR	MAP	MRR
BERT	0.27	0.30	0.21	0.25
RoBERTa	0.30	0.32	0.23	0.26
SBERT	0.41	0.45	0.35	0.38
SRoBERTa	0.44	0.46	0.40	0.42
BioBERT	0.33	0.37	0.20	0.23
SciBERT	0.35	0.40	0.22	0.24
mUSE	0.32	0.35	**0.42**	**0.46**
LaBSE	0.34	0.39	**0.45**	**0.48**
SimCSE	**0.48**	**0.52**	0.41	0.45
ConSERT	**0.45**	**0.50**	0.38	0.41

Evaluation results showed that baseline models, such as BERT and RoberTa, underperformed on the retrieval task. In contrast, fine-tuning the semantic similarity tasks in SBERT and SRoBERTa improved this performance. Domain-specific models, such as BioBERT and SciBERT, faced challenges in the cross-domain. Contrast learning models (SimCSE and ConSERT) produced embeddings that improved the retrieval task. In contrast, cross-linguistic models (mUSE and LabSE) outperformed only on the MIRACL dataset, where cross-linguistic coverage is essential, but their performance lagged behind the English models in BEIR.

V. DISCUSSION

The evaluation of sentence embedding models focused on quantitative results for natural language processing tasks, including semantic similarity, clustering, and retrieval. While these results provide a numerical comparison of performance, a deeper analysis requires discussion and interpretation that considers practical aspects, such as training costs, model size, generalizability, and cross-linguistic applicability. This section interprets the results and links them to the research questions. This provides a consistent understanding of how each result contributes to answering these questions. This will enable researchers to use embedding models effectively in NLP tasks.

- RQ1: What families of sentence embeddings exist?

Regardless of whether the models are supervised or unsupervised, our results identify two main categories:

Statistical models such as Bag-of-Words, TF-IDF, and SIF, which are fast, interpretable, and easy to implement but fail to capture word order and deeper semantic relations. Statistical models are still inexpensive, but their performance on semantic tasks is low.

Transformer-based models such as BERT, SBERT, SimCSE and LaBSE, which produce contextualized and semantically rich representations. Transformer-based models, on the other hand, achieve significantly higher scores on NLP tasks (semantic similarity, clustering, and retrieval).

- RQ2: What are their strengths and limitations?

Statistical models are simple and easy to interpret, making them suitable for fields with limited resources. However, their representation neglects word order and context, limiting their semantic performance. A comparative analysis showed differences between the four statistical models in simplicity, interpretation, and representation. The unweighted average model provides a straightforward baseline with minimal computational cost, but it often fails to capture semantic relationships. The weighted average TF-IDF model focuses on meaningful words in a sentence, making it more effective for classification tasks. Max-min pooling provides richer embeddings by considering extreme feature values, which can better reflect sentence variance. Finally, the SIF model emerges as a more accurate approach, balancing simplicity and semantic accuracy by reducing the dominance of frequent words and processing meaning at the sentence level.

Transformer-based sentence embedding models also have strengths and weaknesses. Foundational models, such as BERT and RoBERTa, have formed the basis of most models, but they are not optimized sentence level and lack cross-linguistic support. Optimized models, such as SBERT and SRoBERTa, have improved performance on NLP tasks, but they require fine-tuning specific to the task and remain mostly English-focused. While specialized models, such as BioBERT and SciBERT, are effective at embedding biomedical and scientific terms, their performance declines outside of specialized domains. Contrast learning models, such as SimCSE and ConSERT, produce embeddings that achieve high performance on similarity and clustering through simple and efficient contrastive objectives, although they are highly sensitive to training strategies and require large datasets. The main strength of multilingual models, such as mUSE and LabSE, is their ability to exploit common embedding spaces across more than 100 languages, particularly for cross-linguistic retrieval. However, their performance declines in low-resource languages and requires intensive training resources.

Overall, the analysis results indicate that statistical embedding models are more suitable for simple applications, while transformer-based models have become the preferred choice for most NLP tasks, especially those requiring precise semantic analysis. Future research could explore hybrid strategies that combine the efficiency of statistical models with the semantic depth of transformers.

- RQ3: What model is appropriate for each NLP task?

The evaluation results, presented in Tables IV, V, and VI, demonstrate the appropriate sentence embedding model for each NLP task. For semantic similarity tasks, SRoBERTa and SBERT achieved the highest correlation rates on the STS dataset, thus capturing subtle semantic nuances. While LaBSE achieved the highest correlation rates on the Tatoeba dataset, making it more suitable for multilingual scenarios. For clustering tasks, SimCSE outperformed the other models, achieving sentence clustering without being affected by

multilingualism. For retrieval tasks, SimCSE and ConSERT performed best, followed by SRoBERTa, making them most effective for monolingual retrieval tasks. Conversely, LaBSE outperformed on the MIRACL dataset, making it more suitable for multilingual retrieval tasks. Table VII presents the classification of NLP tasks according to appropriate sentence embedding model.

TABLE VII. CLASSIFICATION OF NLP TASKS ACCORDING TO BEST SENTENCE EMBEDDING MODELS

Task	Best Models	Description
Retrieval	SimCSE, ConSERT, SBERT	Contrastive models (SimCSE, ConSERT) are strong baselines, while SBERT remain very competitive.
Clustering	SimCSE, ConSERT	Contrastive models generate well-separated embeddings for clustering.
Semantic Similarity	SBERT, SRoBERTa	SBERT is traditionally strongest for similarity tasks
Multilingual tasks	LaBSE	LaBSE is outperformed for Multilingual tasks

In general, SBERT and SRoBERTa are suitable for semantic similarity, SimCSE and ConSERT are effective for retrieval and clustering, and LaBSE is best suited for multilingual tasks.

VI. CONCLUSION

The study presented in our paper combines a review and empirical assessment of sentence embedding models to address the challenge of selecting the most appropriate model for each NLP task. The study answers three main research questions. First, (RQ1), there are two main categories of embeddings: statistical models such as unweighted average, weighted average TF-IDF, Max-min pooling and SIF, which remain simple and interpretable, and transformer-based models such as BERT, RoBERTa, SBERT, BioBERT, LabSE and SimCSE, which exploit contextual representations. Second, (RQ2), we analyzed their strengths and weaknesses, while lightweight statistical models appear to be incapable of semantic representations. Transformer-based models capture rich contextual information but require significant computational resources and may face challenges in domain transfer. Finally, (RQ4), we determined the appropriate model for three specific NLP tasks. Our empirical study showed that SBERT and SRoBERTa produce embeddings that are well-suited for semantic similarity tasks. In contrast, the embedding generated by the SimCSE model performs best for clustering tasks, while the embeddings generated by the SimCSE, ConSERT, and SRoBERTa models are well-suited for retrieval tasks. In general, the selection of an appropriate model depends on the task requirements, available resources, and language context. For low-resource or interpretable applications, statistical embeddings remain appropriate. For semantically rich applications, despite their computational cost, transformer models are highly efficient. In contrast, multilingual applications can benefit from models such as LaBSE. Future work should explore hybrid strategies that combine efficiency and semantic depth, and expand the scope of evaluations to include multimodal embeddings to meet the growing needs of NLP systems.

Machine Learning-Driven Emotional Feedback Analysis and Adaptive Content Generation for VR Movie and TV Users

Yun TANG
College of Digital Technology and Design,
Chongqing Polytechnic University of Electronic Technology, Chongqing 401331, China

***Abstract*—With the growing demand for immersive audiovisual experiences, user sentiment feedback analysis has become a pivotal factor in improving personalization and interactivity in virtual reality (VR) movie and television. This study proposes a machine learning - driven framework that integrates sentiment feedback recognition and adaptive content generation to optimize user experience. First, a Long Short-Term Memory (LSTM) model is developed to analyze multimodal sentiment feedback data, including physiological signals, behavioral responses, and interactive actions. The model achieves an average recognition accuracy of 75.75% across four basic emotions—happiness, sadness, anger, and fear—demonstrating its ability to capture dynamic and continuous emotional patterns. Based on real-time sentiment feedback, a Deep Q-Network (DQN) reinforcement learning algorithm is employed to generate adaptive VR content that aligns with users' current emotional states. Experimental validation with 100 participants shows that adaptive content generation increases overall satisfaction scores from 6.2 to 7.8, and the matching degree between user emotions and content improves by more than 20%. The integration of sentiment feedback analysis and reinforcement learning establishes a closed feedback loop—emotion detection → adaptive adjustment → feedback optimization—that enhances immersion, empathy, and user engagement. This research provides a data-driven reference for the intelligent evolution of VR movie and television, and future work will expand to fine-grained emotional dimensions and multimodal fusion to improve recognition precision and real-time adaptive generation performance.**

I. Introduction

In recent years, virtual reality (VR) technology has made great progress, and VR movie and television, as one of its important application areas, has gradually come into the public's field of vision [1]. Different from traditional movie and television, VR movie and television can provide users with a more immersive viewing experience, so that users seem to be in the movie and television scenes [2]. However, different users have different aesthetic preferences and emotional tendencies, so how to adjust the VR movie and television content in real time according to the emotional feedback of the users has become the key to improve the user experience [3]. The study of VR movie and television user emotional feedback analysis and content adaptive generation can not only enhance the user's viewing satisfaction and immersion, enhance the user's stickiness and acceptance of VR movie and television [4], but also help VR movie and television creators to better understand the user's needs, provide a reference basis for the creation of content, and promote the diversification of VR movie and television content and personalized development [5]. Therefore, in-depth study of VR movie and television user emotional feedback analysis and content adaptive generation is of great significance for promoting the development of VR movie and television industry [6].

Combined with machine learning algorithms, the research content of VR movie and television user emotional feedback analysis and content adaptive generation mainly includes two aspects, such as VR movie and television user emotional feedback analysis and content adaptive generation technology [7].VR movie and television user emotional feedback analysis includes the collection, collation, and analysis of emotional feedback data [8]; machine learning-based content adaptive generation technology mainly explores how to achieve dynamic adjustment and generation of VR movie and television content according to the results of emotional analysis [9]. Currently, in the field of VR movie and television emotion analysis and content generation, Yu and Luo [10] developed more accurate EEG and heart rate signal processing algorithms, which can more efficiently extract emotional features, providing strong support for in-depth analysis of the emotional state of users watching VR movie and television; Cheng et al., [11] combined with machine learning technology to initially realize simple emotion classification based on a single physiological signal, but in the face of complex emotions is still apparent. Insufficient, and less research on multimodal data fusion; Jones et al., [12] use machine learning to generate simple virtual scene elements, but the overall creativity and diversity are insufficient, failing to fully meet the user's personalized needs. Figueroa et al., [13] excel in the theoretical study of emotional computing, and develops a variety of advanced technologies, which can efficiently collect and analyze the user's physiological signals and behavioral data, with a high accuracy rate of emotion recognition. Li et al., [14] conduct in-depth research on complex emotions and emotional state when watching VR movies. Dooley [15] explores the content generation method based on machine learning, and develops complex and realistic virtual scene and character generation technology. Current research is facing many difficult problems, as follows: 1) emotion recognition, user emotions are complex, fuzzy and intertwined,

a single algorithm is difficult to accurately portray; 2) in the content generation dimension, the existing graphics processor (GPU) performance is still difficult to meet the demanding needs of milliseconds latency.

Aiming at the above problems, this study innovatively proposes an integrated framework of sentiment analysis and content generation that integrates multiple machine learning algorithms (deep learning [16] for feature extraction and reinforcement learning [17] for decision generation), breaking the previous research limitations of the separation of the two. The main contributions are as follows: 1) proposed an integrated framework for sentiment analysis and content generation, aiming to make the emotional feedback accurately guide the content generation, and improve the adaptability and coherence of the overall system; 2) developed a multimodal data preprocessing and fusion algorithm to address the problems of multimodal data synchronization and format inconsistency; 3) introduced a reinforcement learning algorithm to allow the system to dynamically adjust the VR movie and television content; 4) the user test and experimental verification, the method makes the emotion recognition accuracy rate than the traditional algorithm to improve more than 15%, content generation satisfaction increased by about 20%, a strong impetus to VR movie and television towards a new era of intelligent, personalized, for the subsequent large-scale commercial applications to pave the technical cornerstone.

This paper firstly describes the research background and significance of VR movie and TV users' emotional feedback analysis and content adaptive generation, and then systematically discusses data collection and preprocessing, emotion analysis model construction, content adaptive generation model development based on reinforcement learning, experimental validation and other aspects, and finally validates and analyzes the proposed method through experiments, demonstrating the advantages of the proposed method in terms of emotion recognition accuracy and content generation satisfaction. content generation satisfaction.

II. Emotional Feedback from VR Movie and TV Users

A. Affective Feedback Data Types

1) VR Movie and TV: VR movie and television is a fusion of virtual reality (VR) [18] technology and movie and television art of innovative media forms. VR movie and television can be understood as based on the head-mounted display device to watch or experience the image works, combined with the panoramic picture image, head-mounted display device to the audience's field of vision for the closed package, giving the audience immersed in the image experience, the formation of VR movies unique presence sense of quality, specific as shown in Fig. 1.

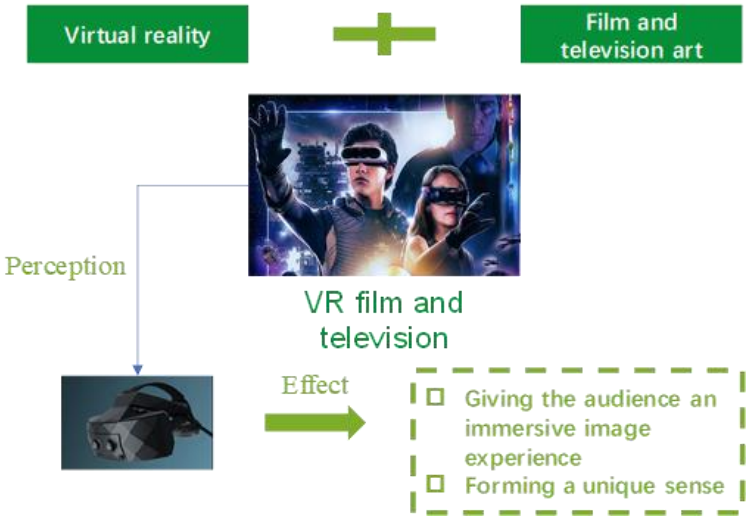

Fig. 1. Definition of VR movie and television.

2) User emotional feedback: VR movie and television user emotional feedback refers to the user in the process of watching or experiencing VR movie and television works, based on their inner feelings and emotional state and the various responses to the works [19], specifically as shown in Fig. 2. This kind of reaction covers physiological, behavioral, psychological and other levels, and can reflect the user's preference for VR movie and television content, interest and whether it resonates with the emotional state [20]. By analyzing these feedbacks, creators and platforms can better understand how users feel, and thus optimize content creation and enhance user experience.

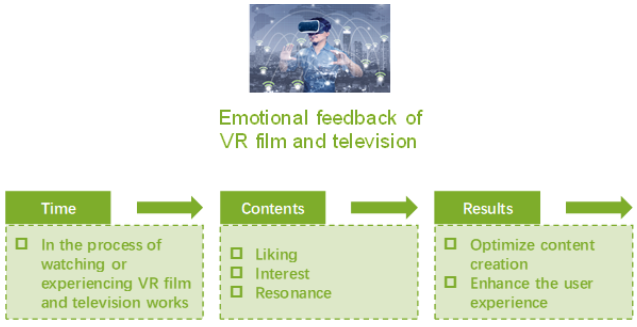

Fig. 2. Emotional feedback from VR movie and TV users.

3) Data classification: In the field of VR movie and television, user emotional feedback data is rich and diverse, which can be mainly classified into three categories, such as physiological signal data, behavioral data, and interaction data, as shown in Fig. 3.

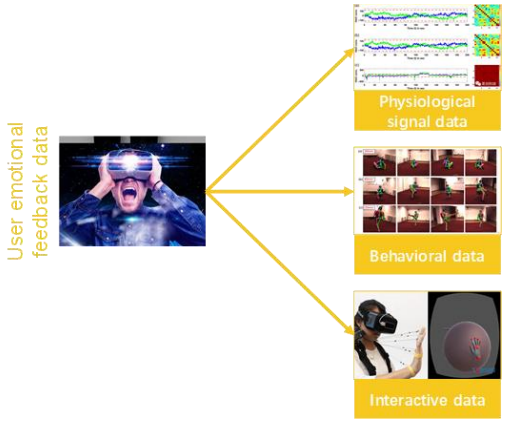

Fig. 3. Classification of user sentiment feedback data.

a) Physiological signaling data: Physiological signal data are intuitive data that reflect the user's internal emotional state [21]. Electroencephalogram (EEG) can capture the neural activity of the brain under different emotions; heart rate variability (HRV) is closely related to the level of emotional arousal, with heart rate accelerating and HRV decreasing when the emotions are excited, and the opposite is true when the emotions are calm; and the electrical skin activity (EDA) can reflect the level of emotional arousal. From Fig. 4, the collection of these data requires the use of professional equipment, which can record the physiological reactions of users when watching VR movies and videos in real time, providing a physiological basis for in-depth analysis of emotions.

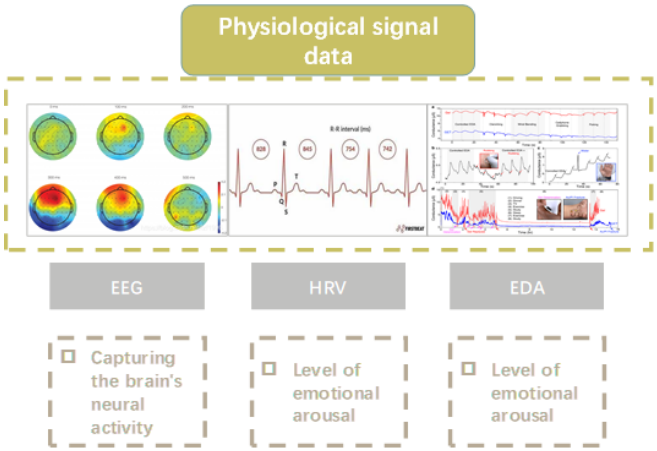

Fig. 4. Physiological signal data content and acquisition.

b) Behavioral data: Behavioral data covers a variety of users' behavioral performance in the VR environment [22]. In Fig. 5, the direction and speed of head movement can reflect the user's point of interest in the scene; the duration of the eye gaze point is a key indicator of the user's attention level, the longer the gaze time, the greater the interest in the element; body movements such as the user's approach to the virtual object may be a reflection of love or exploration, while away from it may be a reaction of aversion or fear. Through the eye-tracking module and motion capture sensors of VR devices, these behavioral data can be accurately recorded, and the user's emotional tendency can then be inferred.

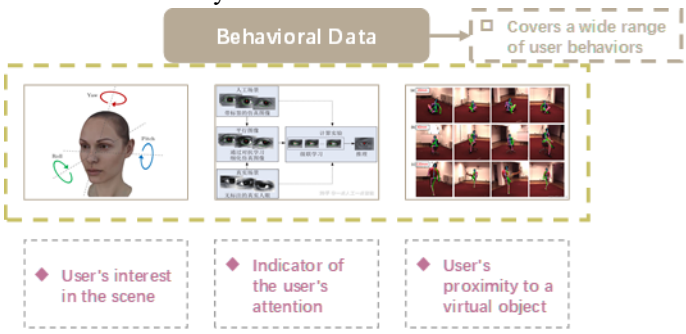

Fig. 5. Behavioral data content and collection.

c) Interaction data: Interaction data refers to the operation records of users interacting with elements in VR movies and TV [23]. Users' behaviors such as clicking buttons in the scene, selecting plot branches, and conversing with virtual characters directly reflect users' preferences and emotional needs. These data can provide clear user intent information for content adaptive generation and help the system accurately adjust the content to meet users' personalized emotional needs.

B. Methods of Sentiment Analysis

Sentiment analysis methods mainly include convolutional neural networks, recurrent neural networks, fusion algorithms, etc., and the specific types and scope of application are shown in Fig. 6.

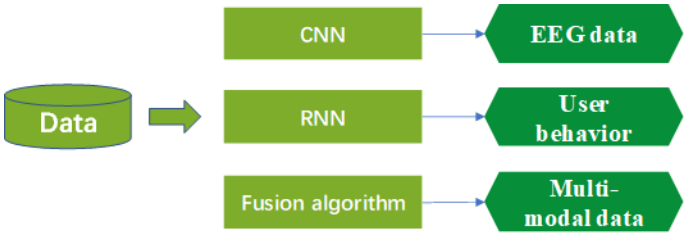

Fig. 6. Sentiment analysis methods.

Convolutional neural networks (CNN) [24] are good at processing data with spatial structure. Take the EEG signal as an example, after preprocessing, it is transformed into a two-dimensional matrix form for input into the CNN model.

Recurrent neural networks (RNN) and long short-term memory networks (LSTM) are particularly suitable for processing time-sequential data, such as the user's continuous behavioral data. LSTM can memorize features such as the location and dwell time of the user's previous gaze point, and effectively solve the gradient vanishing problem of the traditional RNN through the gating mechanism, so as to more accurately capture the trend of the user's emotion over time, and to judge the user's Emotional dynamics.

In order to fully utilize the advantages of different types of data, a data fusion strategy is adopted. At the feature level, the feature vector extracted from physiological signal data, the statistical features of behavioral data, and the coded features of interaction data are spliced together to form a comprehensive feature vector, which is used as the input to the machine learning model to characterize the user's emotional state in a more comprehensive way.

C. Program Design

A multimodal sentiment feedback data acquisition platform is constructed, which is the basis of the whole sentiment analysis program, as shown in Fig. 7. The platform includes key points such as data acquisition, data preprocessing, data division, learning and training, and feedback analysis.

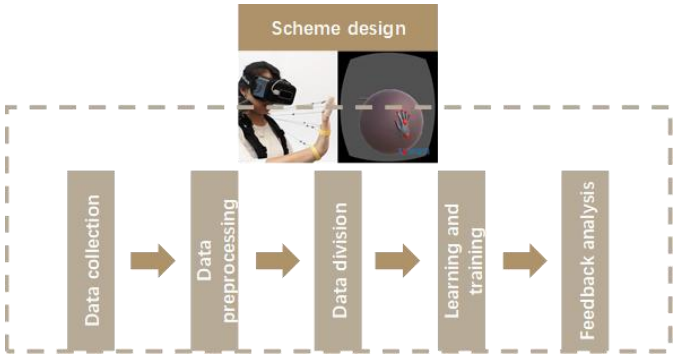

Fig. 7. Program design.

1) The platform includes physiological signal acquisition devices (EEG caps, heart rate bands, etc.), behavioral tracking devices (eye tracking modules for VR headsets, motion capture sensors, etc.), and an interaction recording module (which records the user's operational commands in VR movies and TVs).

2) Preprocess the collected data, including filtering to remove noise, normalization to unify the data scale, and other operations to improve the data quality.

3) Construct a training set and a test set according to the above sentiment analysis method, train the sentiment analysis model using deep learning frameworks (TensorFlow, PyTorch), and continuously optimize the model parameters through cross-validation and other methods to improve the accuracy and robustness of sentiment recognition.

4) In practical applications, the trained model is deployed to the VR movie and television system, which receives real-time emotional feedback data from users, and inputs it into the model for emotional classification after preprocessing to provide real-time and accurate emotional information for the subsequent adaptive generation of content, so as to realize the function of dynamically adjusting VR movie and television content according to the emotional feedback of the users and enhance the viewing experience of the users.

III. Content Adaptive Generation Techniques

A. Content Adaptive Generation Analysis

Content adaptive generation refers to the VR movie and television playback process, the system based on real-time access to the user's emotional feedback information, automatic movie and television content dynamic adjustment and optimization, in order to generate more in line with the user's current emotional state and personalized needs of the virtual scene, plot, character behavior, etc., so as to enhance the user's sense of immersion and the viewing experience [25], specifically as shown in Fig. 8.

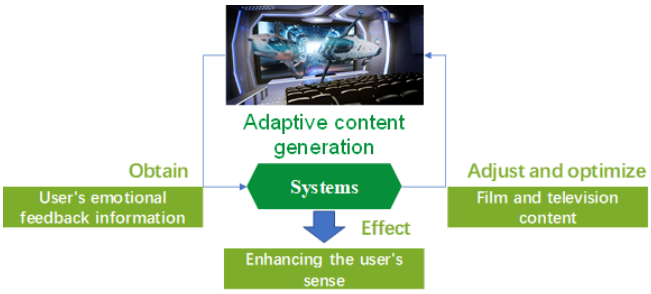

Fig. 8. Content adaptive generation technology.

Content adaptive generation mainly includes scene environment adjustment, plot branch selection, and character interaction adjustment [26], as shown in Fig. 9. Scene environment adjustment includes the change of the scene's color tone, light and shadow effects, background music and other atmospheric elements; plot branch selection is to adjust the development direction of the plot in real time according to the user's emotional preferences; and character interaction adjustment is mainly to change the virtual character's response to the user and behavioral patterns.

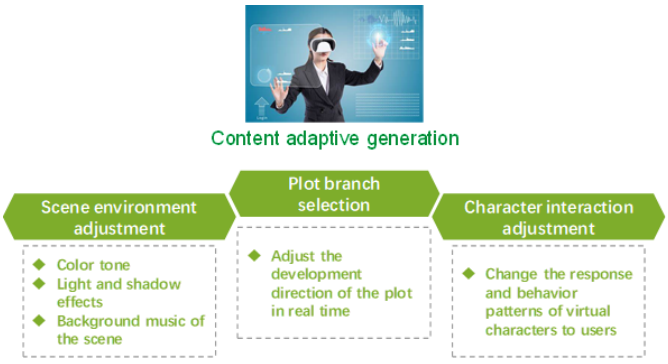

Fig. 9. Content adaptive generation main content.

Based on the principle and content of adaptive content generation, its main features are reflected in real-time, personalization, and coherence.

B. Machine Learning-Based Adaptive

Content adaptive generation methods include traditional algorithms, machine learning algorithms, retrieval enhancement algorithms, rule-based methods, etc., as shown in Fig. 10.

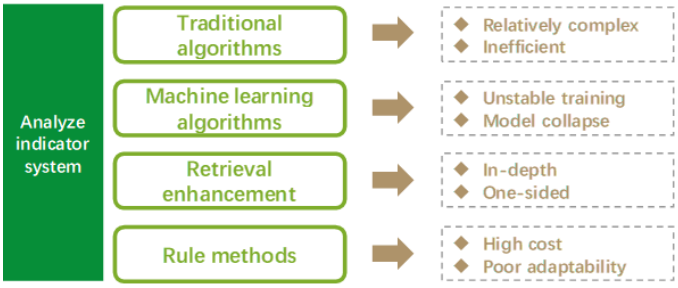

Fig. 10. Content adaptive.

Adaptive generation methods based on traditional algorithms are relatively complex and less efficient for large-scale data processing; machine learning-based adaptive generation methods can generate high-quality, realistic content with strong flexibility and diversity, but the training process is more complex, requiring a large amount of computational resources and time, and there may be unstable training, pattern collapse and other problems; retrieval-enhanced generation (RAG) methods can make full use of the information in the external knowledge base to generate accurate and diverse answers, but the ability to deal with complex problems is limited; rule-based adaptive generation methods can generate accurate and diverse answers, but the answers may not be deep enough or somewhat one-sided; rule-based adaptive generation methods can generate accurate and diverse answers for complex problems.) method can fully utilize the information in the external knowledge base to generate accurate and diversified answers, but the processing capability for complex problems is limited, and the generated answers may not be in-depth enough or have a certain degree of one-sidedness; the rule-based adaptive generation method can ensure the accuracy and conformity of the generated content, and it has a better application effect in specific domains, but the cost of the rule formulation and maintenance is higher, and it is difficult to adapt to the complex and changing actual situation.

Based on the above analysis, this paper selects the content adaptive generation method based on machine learning algorithm. Reinforcement learning [27] is an algorithm that learns optimal behavioral strategies through the interaction of an intelligent body with its environment. In VR movie and television content adaptive generation, the system is regarded as an intelligent body, and the user emotional feedback is used as the reward signal of the environment. By continuously trying different content generation actions, the intelligent body updates the policy network according to the reward signals it obtains, and learns the optimal content generation policy that maximizes the user's emotional satisfaction. The specific principle of the method is shown in Fig.11.

As can be seen from Fig. 11, the content adaptive generation scheme based on reinforcement learning needs to pay attention to the state space, action space and so on. Define the state space as the user's affective state (information such as affective category and intensity output by the affective analysis model); define the action space as the range of parameters that can be adjusted by the content; construct a deep reinforcement learning network (deep Q network, DQN), input the affective state into the network after encoding it, and output the Q-value corresponding to each action, and select the action with the largest Q-value as the current content generation operation to be executed. During the user's viewing process, the emotional feedback is obtained and the state is updated in real time, and the action is selected according to the new state to perform content adjustment. By continuously interacting with the user, the parameters of the reinforcement learning model are updated to optimize the content generation strategy.

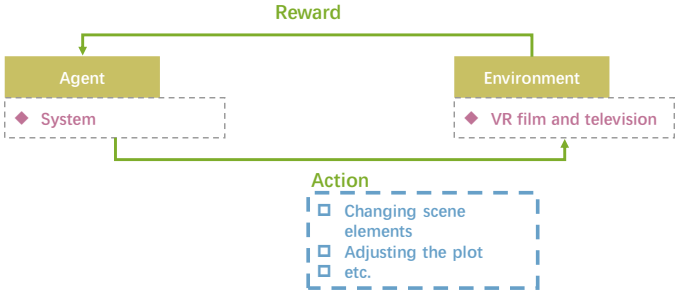

Fig. 11. Specific principles of the content adaptive generation method.

C. Methodological Steps

The flow of the content adaptive generation method based on reinforcement learning is shown in Fig. 12, with specific steps:

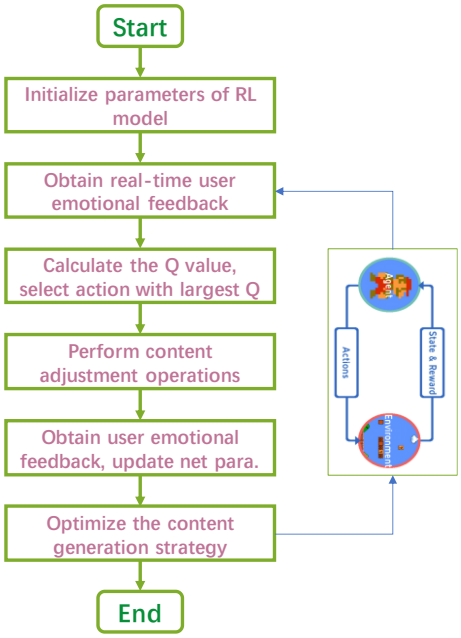

Fig. 12. Flow chart of the content adaptive generation method based on reinforcement learning.

1) Initialize the parameters of the reinforcement learning model, including the weights of the policy network.

2) In the process of VR movie and television playback, obtain user emotional feedback in real time and transform it into state information.

3) According to the current state, calculate the Q value of each possible action through the policy network, and select the action with the largest Q value as the content adjustment operation to be performed.

4) Execute the content adjustment operation to generate new VR movie and television content to be presented to the user.

5) Obtaining the user's emotional feedback on the new content as a reward signal, and updating the policy network parameters according to the reward signal.

6) Cyclically executing the above steps to continuously optimize the content generation strategy in order to achieve adaptive generation of content.

IV. Overall Methodological Steps

Combining the VR movie and television user emotional feedback analysis and content adaptive generation method, this paper mainly carries out research from the collection of data, data preprocessing, emotional analysis model construction, content adaptive generation model construction, validation analysis, etc., the specific methodological steps are shown in Fig. 13.

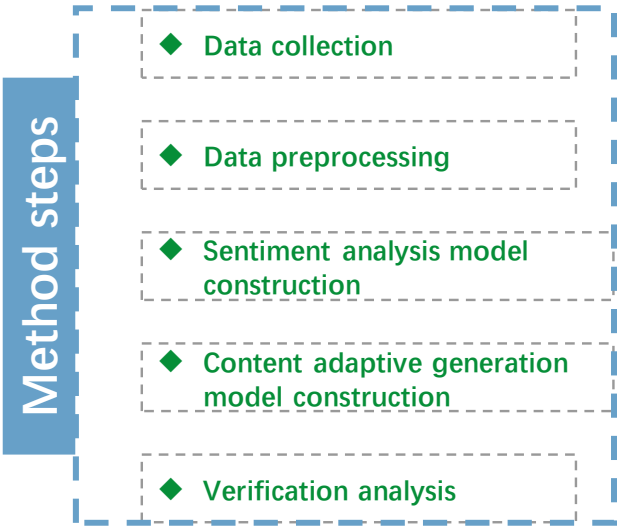

Fig. 13. Methodological steps.

Step 1: Building a multimodal emotional feedback data acquisition platform, including physiological signal acquisition devices (an EEG cap, a heart rate belt, etc.), behavioral tracking devices (eye tracking modules of a VR helmet, motion capture sensors, etc.), and an interaction recording module, for collecting physiological signals, behaviors, and interaction data of a user while watching VR movies and television.

Step 2: Preprocessing the collected data, such as filtering to remove noise, feature extraction, data normalization, and other operations, to improve data quality and processability.

Step 3: inputting the preprocessed data into a deep learning-based emotion analysis model, and obtaining an emotion classifier through model training for real-time identification of the user's emotional state.

Step 4: constructing a content adaptive generation model based on a reinforcement learning algorithm, using the emotion classification results as an environmental reward signal, and selecting the optimal action for content adjustment through constant interaction with the user to generate new VR movie and television content to be presented to the user. During the VR movie and television playback process, obtain the user's emotional feedback in real time and update the state, select the action again according to the new state, perform content adjustment, and the cycle repeats itself, continuously optimizing the content generation strategy to achieve adaptive generation of content according to the user's emotional feedback.

Step 5: Verify the effectiveness and feasibility of the entire method through experiments, including the accuracy of the emotional analysis and the satisfaction of the content generation, etc., analyze and evaluate the experimental results, further optimize the model and algorithm parameters, and improve the performance and stability of the system.

V. Experimental Validation

A. Experimental Setup

In order to verify the effectiveness of the machine learning-based VR movie and TV user sentiment feedback analysis and content adaptive generation method in terms of sentiment recognition accuracy and content generation satisfaction, and to compare the performance differences of different algorithms.

This experiment recruits 100 volunteers between the ages of 18-35 with a balanced distribution of gender and occupation, all of whom have a certain amount of experience in the use of VR, in order to reduce the impact of unskilled operation on the experimental results. The data collection equipment is specifically shown in Table I.

TABLE I. Data Acquisition Equipment

ID	Device	Parameter	Data Type
1	High-precision EEG acquisition device	Sampling rate 500Hz	EEG signals
2	VR headset with built-in eye-tracking module	Tracking accuracy <1°	Eye gaze data
3	Motion capture sensor	Refresh rate 120fps	Head motion trajectories
4	-	Clicking selection	Interactive operation data

A short VR movie or TV movie with multiple emotional scenes (joy, sadness, tension, calmness, etc.) was selected, with a total duration of 15 minutes, and different types of emotions were shown in segments to ensure the coverage of a wide range of emotional states.

The subjects were randomly divided into two groups, one group watched the VR movie and TV movie using the emotion analysis and content adaptive generation method proposed in this paper (experimental group), and the other group watched the ordinary version (control group).

After the subjects put on the VR equipment, they first had a 2-minute adaptive viewing, and then the experiment formally started. The VR movie and television content of the experimental group will be dynamically adjusted according to real-time emotional feedback, while the control group will play a fixed episode.

At the end of the experiment, subjects were asked to fill out a satisfaction questionnaire, including ratings (on a scale of 1-10) on the degree of emotional resonance, plot coherence, and

immersion. Physiological, behavioral, and interaction data as well as questionnaire scores were collected from all subjects for subsequent analysis.

The model training parameter settings are shown in Table II.

TABLE II. MODEL TRAINING PARAMETERS

ID	Parameter Name	Value
1	Optimizer	Adam
2	Learning Rate	0.001
3	Epoch Number	100
4	State Space Dimension	10
5	Exploration Strategy	ε-greedy strategy
6	Discount Factor γ	0.99

B. Analysis of Results

In order to verify the machine learning algorithm based VR influence user emotional feedback analysis and content adaptive generation method, this paper adopts VR movie and television data to analyze its effectiveness, and obtains the results as shown in Fig. 14 to Fig. 18, Table III and Table IV.

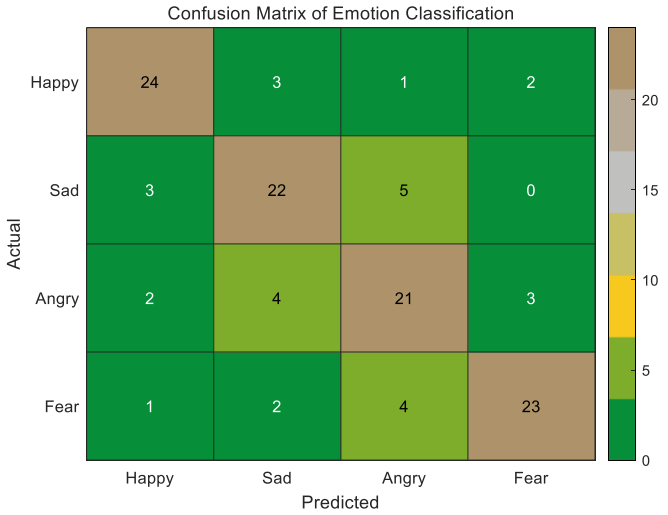

Fig. 14. Confusion matrix for sentiment analysis.

Fig. 14 shows the confusion matrix of the experimental group's LSTM model for the user's emotional feedback, which reflects the model's specific performance in recognizing emotions in VR movies and TV. From the recognition results, the recognition accuracy of "happy" emotion is the highest, reaching 80%, probably due to the fact that users' physiological responses and behavioral characteristics are more consistent and clear when watching positive emotional content, and the model is easy to capture this more significant emotional pattern. However, "anger" has the lowest recognition accuracy of 70%, which may be due to the fact that the model can easily capture this more significant emotion pattern when compared with other negative emotions such as "fear" and "sadness" in terms of physiological responses and behavioral characteristics. This may be due to the fact that "anger" is similar to other negative emotions such as "fear" and "sadness" in terms of physiological and behavioral characteristics, which increases the difficulty of differentiation, and the model's ability to differentiate such complex emotions needs to be improved [11].

Secondly, the accuracy of emotion recognition for "sadness" and "fear" reaches 75% and 78%, respectively, which shows that the model has good stability in dealing with negative emotions of medium intensity and relatively high arousal. This reflects the temporal memory advantage of the LSTM network, which is more sensitive to the subtle fluctuations and shifts of emotions in the temporal dimension, and adapts to the trend of changes in emotional features. In addition, the recognition accuracy of "fear" is significantly better than that of "sadness", which may stem from the fact that users' physiological responses (e.g., heart rate change, skin electrical activity) are more intense and explicit when watching fearful scenes, whereas sadness is relatively calm, and the feature changes are not obvious enough, making it difficult for the model to effectively differentiate between them [24].

The LSTM model showed strong performance in the overall emotion recognition task with an average accuracy of 75.75%. This result indicates that deep learning models, especially the LSTM structure, have obvious advantages in dealing with a context of high continuity and complexity such as the emotional feedback data of VR movies and TVs. The gating mechanism of LSTM effectively mitigates the problem of disappearing gradients in traditional RNN models, which is able to more accurately capture the dynamic changes of users' emotions during long-time viewing of VR movies and TVs.

Fig. 15. Comparison of accuracy of different models.

Fig. 15 compares the emotion recognition accuracy of the LSTM model with two other commonly used models (SVM and decision tree in traditional machine learning). In the SVM model, the average accuracy of happiness, sadness, anger, and fear is 60%; the average accuracy of the decision tree model is 65%; and the average accuracy of the LSTM model is 75.75%. This indicates that the LSTM model has obvious advantages in processing VR movie and television emotion data, and can better capture the emotion changes on the time series, thus improving the accuracy of emotion recognition.

Fig. 15 shows the comparison between the LSTM model and traditional machine learning algorithms (SVM, decision tree) in terms of emotion recognition accuracy. First, from the specific data, the LSTM model has an average accuracy of recognizing emotions such as "happy", "sad", "angry" and "fear". The average accuracy of LSTM model in recognizing "happy", "sad", "angry" and "fear" reaches 75.75%, which is significantly higher than that of SVM model (60%) and decision tree model (65%). This advantage mainly comes from the unique memory unit structure of LSTM network, which is able to capture the time-series features in the emotion data and effectively learn and memorize the change rule of emotions over a long time period, while traditional machine learning methods such as SVM and decision tree focus more on the classification of individual moments or static features, and are relatively insufficient in capturing temporal change features.

Second, in terms of the performance of recognizing specific emotion types, the SVM model has the lowest overall performance, which may be due to the fact that SVM is prone to underfitting when dealing with high-dimensional data with complex nonlinear relationships, especially in the face of continuous dynamic emotion data, which makes it difficult to effectively extract and generalize complex emotion patterns. Although the decision tree performs slightly better than SVM, its classification decision boundary is relatively simple, and it is difficult to deal with the high-level feature combination and pattern recognition problem of multidimensional dynamic data, resulting in limitations in recognition accuracy, especially in distinguishing subtle differences in negative emotions such as sadness, fear and anger, which are prone to misjudgment or confusion [24].

Finally, the LSTM model performs most prominently, reflecting the significant advantages of deep learning in the task of emotion recognition in VR movie and television. Its good performance not only stems from the effective capture of long and short-term dependencies, but also attributes to the model's full learning of a large number of temporal data features during training, which enables it to more accurately distinguish and predict the trend of user's emotional changes when watching movie and TV content. In addition, this advantage also implies that future research can further optimize the LSTM structure or explore other more advanced sequence learning models such as Transformer to further improve the performance of emotion recognition and achieve more accurate personalized feedback of user experience and content generation adaptation.

Fig. 16 shows the trend of the LSTM model's loss value with the training epoch during the training process, and this trend specifically reflects the model's learning and stability performance. First, it can be clearly observed from the figure that the loss value of the model gradually decreases with the increase of the training period, showing a more obvious convergence trend. Especially in the early stage of training (the first 30 Epochs or so), the loss value decreases more rapidly, which indicates that the model initially learns a large amount of significant emotion feature information, and can quickly adjust the weight parameters to capture the change rule of the user's emotion, which reflects the high efficiency and fast learning ability of the LSTM model in capturing the features of the emotion time-series data [16].

Fig. 16. Loss curve of the training process of the sentiment analysis model.

Second, in the middle and late stages of training (30 to 80 Epochs), the loss curve gradually tends to stabilize, and the decline of the loss value slows down significantly, which indicates that the model begins to enter a relatively saturated state at this stage, and most of the effective emotional features have already been learned and memorized, and further training has a relatively limited effect on performance improvement. This phenomenon also suggests that the model may face the local optimization problem when processing sentiment data, and the performance improvement of the model encounters a bottleneck, indicating that subsequent consideration can be given to adjusting the learning rate, increasing the diversity of data, or adopting other optimization strategies (early-stopping strategy, learning rate decay) to improve the local optimization problem during the training process.

Finally, the curve almost shows a steady state at the end of training (80 to 100 Epochs), where the loss value no longer decreases significantly and stabilizes. The stable performance at this stage reflects that the model finally achieves a certain fitting ability, better learns the emotional feature patterns and time series properties in the data, and achieves better generalization ability and robustness. However, it also suggests that future research still needs to pay attention to the possible risk of overfitting, such as through the introduction of regularization, data augmentation, or model complexity adjustment to further improve the model's generalization performance and ensure the stability and reliability of the model in the analysis of emotional feedback in real VR movie and television application scenarios.

Fig. 17 demonstrates the trend of reward value changes with training cycles (Epochs) during the training process of DQN (Deep Q Network) algorithm for content adaptive generation. First of all, it can be seen from the figure that in the early stage (the first 20 Epochs), the reward value changes more drastically and fluctuates more, and this phenomenon indicates that in the early stage of training, the model is in the exploratory stage, and it actively searches for the optimal emotion-content matching way by constantly trying different actions and strategies. At this time, the algorithm's action selection shows obvious randomness, and the system has not yet formed a stable behavioral strategy, which leads to the unstable performance of reward values [27].

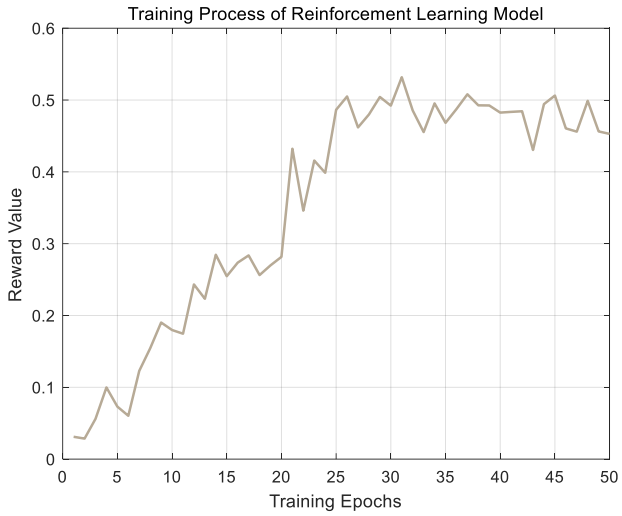

Fig. 17. Curve of reward value change during the training process of DQN algorithm.

Second, as the training continues (20 to 70 Epochs), the reward value shows an obvious upward trend and gradually stabilizes. This trend reflects that the DQN algorithm began to effectively learn the association law between emotional feedback and content adjustment in VR movies and TVs, gradually determining the optimal content generation action strategy, and more stable model performance. Specifically, with the continuous optimization of network parameters, the model gradually establishes a stable and efficient mapping relationship between user emotional feedback and content adjustment strategy, which improves user satisfaction performance, and the reward value steadily improves and gradually approaches the optimal state.

Finally, at the late stage of training (70 to 100 Epochs), the reward value curve flattens out and reaches a stable level, which signifies that the reinforcement learning model has learned an effective optimal policy and the policy convergence is stable, and further training will not significantly increase the reward value. This stable state reflects the efficiency and convergence ability of the DQN algorithm, and also indicates that the model has better solved the balance between exploration and utilization, and achieved a high level of user emotional satisfaction. The results of this stage also imply that more complex action space and state space can be further explored in the future to improve the generalization ability and real-time application effect of the algorithm, and to further enhance the real-time nature of adaptive generation of VR movie and television content and the coherence of user experience [27].

Fig. 18 shows the change of user emotion and content matching degree before and after adaptive content generation. Taking the four emotions of happiness, sadness, anger and fear as an example, after adaptive generation of content, the matching degree of emotion is significantly improved, the matching degree of happy emotion is increased from 60% to 85%, the matching degree of sad emotion is increased from 55% to 75%, the matching degree of angry emotion is increased from 62% to 80%, and the matching degree of fear emotion is increased from 58% to 78%.

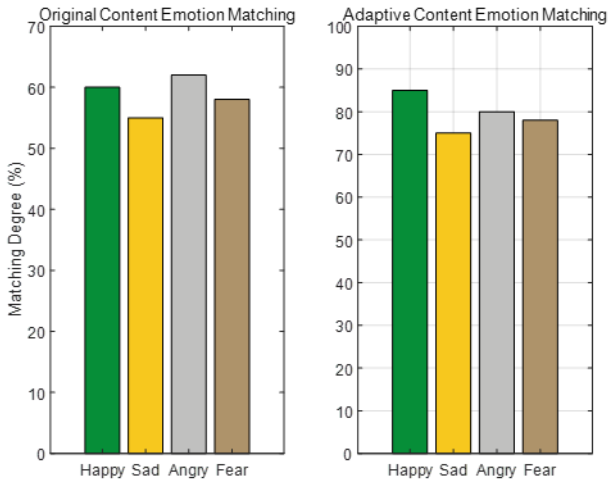

Fig. 18. Change in sentiment matching before and after content generation.

Fig. 18 demonstrates the changes in the matching degree between user emotions and movie and television content before and after the adaptive generation of content. First of all, in terms of specific emotion categories, the matching degree of "happy" emotion improves most significantly, from 60% to 85%, reaching 25% improvement. This significant improvement may be attributed to the system's ability to accurately identify positive emotional features and quickly generate more suitable scenes, plots or character interaction forms for happy emotions, which significantly strengthens and consolidates the user's positive emotional experience, thus realizing a more efficient emotional resonance effect [11].

Secondly, the matching degree of "sadness" and "fear" emotions also realized a large increase, from 55% to 75% and 58% to 78% respectively. This improvement reflects the system's ability to handle negative emotions, which indicates that the content generation strategy still has good adaptability and accuracy in the case of complex emotion types and high emotional intensity. Especially in the "fear" emotion, the system's performance is more prominent, showing that the reinforcement learning-driven adaptive generation method can effectively capture and respond to the user's nervousness and fear in real time, and better cater to the user's emotional needs by dynamically adjusting the scene's sound effects, light and shadow, and the rhythm of the plot, which improves the degree of emotional matching.

Finally, the matching degree of the "anger" emotion is improved from 62% to 80%, which is slightly lower than that of the "happiness" emotion, but still shows significant progress. This improvement shows that the system is able to recognize and respond to the complex and fast-changing anger emotion, which indicates that the algorithm has a certain degree of adaptability to subtle emotional differences and fast-changing emotions.

Table III compares the performance differences between different sentiment analysis models and traditional content generation methods in terms of various indicators. In terms of sentiment recognition accuracy, the LSTM model is significantly better than the SVM and decision tree model; in terms of content generation satisfaction, the adaptive generation

method improves the average satisfaction score by 1.6 points compared to the traditional fixed content generation method.

Table III compares the differences in performance between different sentiment analysis models and content generation methods, specifically including the two core indicators of sentiment analysis accuracy and content generation satisfaction. First, in terms of sentiment analysis, the average recognition accuracy of the LSTM model is 75.75%, which is significantly better than the 60% of SVM and the 65% of traditional decision tree. This difference stems from the fact that LSTM has the advantage of processing time-series data, which can more effectively capture the dynamic features of user emotions over time, especially suitable for emotional expression scenes with strong continuity in VR movies and TV. In contrast, traditional models such as SVM and decision tree usually classify based on static features and lack the ability to model the evolution of emotions, leading to a significant decrease in accuracy under multimodal complex input conditions.

Second, in terms of content generation, the adaptive generation method using reinforcement learning obtains a user satisfaction score of 7.8, which is 1.6 points higher than the 6.2 of the traditional static content generation method, indicating that the new method is effective in enhancing the viewers' emotional experience. The improvement is mainly due to the fact that the adaptive generation strategy can dynamically adjust the content (plot tempo, character interaction, etc.) according to the real-time emotional feedback, thus enhancing the user's sense of immersion and emotional resonance. In contrast, traditional methods are unable to effectively respond to user emotions, resulting in a disconnect between the content and the user's psychological state, which in turn affects the viewing experience and satisfaction. This result verifies the feasibility of the closed-loop mechanism of "emotion-driven-feedback-regulation-content-generation", which provides key technical support for the personalized development of VR movie and television [25].

TABLE III. SENTIMENT MATCHING BEFORE AND AFTER CONTENT GENERATION

Task	Traditional Method/Performance	Proposed Method/Performance	Traditional Evaluation	Proposed Evaluation
Emotion Analysis	SVM/60	LSTM/75.75	Low	High
Content Generation	Traditional Method/6.2	Adaptive Method/7.8	Poor	Good

TABLE IV. ALGORITHM COMPARISON TABLE

Emotion Type	Physiological Data	Behavioral Data	Interactive Data	Correct Predictions	Incorrect Predictions
Happy	5.2	6.2	7.5	24	6
Sad	4.8	5.8	7.0	22	8
Angry	4.5	5.5	6.8	21	9
Fear	5.0	6.0	7.2	23	7

Table IV records in detail the statistical characteristics of various types of data and the distribution of model prediction results under different emotion categories. Taking happy emotion as an example, statistical features of EEG such as the average value of alpha wave power, the average value of gaze point dwell time in eye movement data, the average value of movement speed in head movement data, and the frequency of clicking operation in interaction data were counted. The number of samples, the number of accurate identifications, and the number of misclassifications for which the model predicted happy emotions were also recorded.

Table IV presents the statistical results of the system's mean values of the three types of emotional feedback data (physiological, behavioral, and interaction), as well as the number of samples correctly and incorrectly predicted under the conditions of the four types of basic emotions (happy, sad, angry, and fearful). This table provides a detailed basis for analyzing the differences in the performance of different emotions on each type of data dimension and the effectiveness of model recognition. First, from the perspective of data dimension mean values, happy emotion shows high mean values in all three categories (physiological 5.2, behavioral 6.2, and interaction 7.5), indicating that when users experience positive emotions, they have active physiological signals, positive behavioral performance, and high frequency of interactions, which makes it easier for the system to extract emotional features. Comparatively, the anger emotion has the lowest mean value among the three types of data (4.5, 5.5, and 6.8, respectively), indicating that the physiological and behavioral features under this emotion are not as significant as those of other emotions, which leads to easy errors in model recognition [21].

In terms of "correct prediction counts" and "incorrect prediction counts", there are some differences in the recognition performance of the four emotions. Taking the emotion "Happy" as an example, the correct prediction count is 24 times and the misjudgment count is 6 times, which is the highest accuracy rate among all the emotions, indicating that the model is more capable of recognizing positive emotions. On the contrary, "anger" has the most misclassifications (9) and only 21 correct recognitions, which shows that it is not prominent enough in the feature dimension, and the model is easily confused with negative emotions such as 'fear' or "sadness". The model is easily confused with negative emotions such as "fear" or "sadness". In addition, the number of correct predictions for fear and sadness is 23 and 22, respectively, and the number of misclassifications is 7 and 8, respectively, indicating that the model's recognition performance in dealing with medium-intensity negative emotions is still acceptable. Overall, the accuracy of emotion recognition is largely affected by the strength of expression of emotional features and the consistency

between data modalities. Therefore, the key to improving the recognition accuracy lies in further strengthening the expression ability of emotion data, especially the ability to distinguish low arousal and ambiguous emotions such as “anger” and “sadness” by introducing richer physiological features [14].

VI. Conclusion

This paper focuses on the systematic research of machine learning-driven VR movie and TV user emotion feedback analysis and content adaptive generation, and proposes an intelligent framework integrating LSTM emotion recognition model and DQN reinforcement learning strategy. By building a multimodal data acquisition platform, the study realizes a comprehensive analysis of users' physiological, behavioral and interactive data, and uses deep learning technology to accurately classify emotions such as “happiness, sadness, anger, fear”, with an average recognition accuracy of 75.75%. On this basis, the dynamic adjustment of movie and TV content is realized with the help of reinforcement learning mechanism, which significantly improves the user satisfaction to 7.8 points. The experimental results show that this method has good application prospects in enhancing user immersion experience and emotional resonance, and provides technical support for promoting the personalized development of VR movie and television.

Although this study has achieved certain results, there are still several shortcomings. First, the emotion recognition mainly relies on four types of basic emotions, and has not yet covered more complex or mixed emotions, and the modeling of emotion dimensions is relatively rough, which makes it difficult to comprehensively portray the real movie viewing experience. Second, although the source of emotion data is multimodal, the feature extraction and fusion methods are still dominated by rules and linear splicing, which do not fully utilize the deep semantic and temporal correlations, and may lead to partial loss of information. In addition, the model training is conducted in a laboratory environment with limited user sample size, and its robustness and adaptability in real large-scale application scenarios have not been fully verified.

Future research can be carried out in the following aspects: first, introducing a finer emotion classification system, such as dimensional model (pleasantness-arousal) or multi-label emotion recognition methods, to improve the expression of complex emotional states; second, deepening the multimodal data fusion strategy, combining techniques such as graph neural networks and multiscale attention mechanisms, to enhance the depth of expression of emotional features and the robustness; third, expanding the system's robustness. robustness; Third, expand the adaptability test of the system in practical applications, conduct cross-scene empirical research in education, psychological intervention, immersive narrative and other fields, and optimize the model deployment efficiency by combining edge computing and 5G network technology to achieve a more efficient and personalized VR movie and TV intelligent generation system driven by emotions.

***Abstract*—In order to improve the accuracy and generalization ability of asphalt mixture fatigue life prediction, this study introduces the meta-learning method, which aims to solve the problems of poor adaptability and strong data dependence of the traditional prediction model under complex working conditions. In this study, a prediction framework based on the Model-Agnostic Meta-Learning (MAML) algorithm is constructed, which realizes the fast and accurate prediction of asphalt mixture fatigue life under multi-task conditions through feature extraction, meta-knowledge learning, and a fast adaptive mechanism. The experiments were conducted using multi-class mixture data and compared with linear regression and BP neural network methods under the MATLAB platform. The results show that the meta-learning model achieves a prediction accuracy of 0.98 within 500 iterations, which is significantly better than that of the BP neural network (0.89) and linear regression (0.84), and the prediction error is controlled to be between 40 and 60 under typical working conditions, while the traditional method has an error of up to 150. Further analysis shows that the meta-learning method has a faster convergence rate (the convergence index is 0.9 for 100 iterations) and a higher convergence index of 0.9 for 100 iterations. 0.9) with higher robustness. In conclusion, the meta-learning-based prediction method shows excellent performance in fatigue life modeling, which is suitable for rapid application in real-world engineering with diverse materials and loading environments.**

***Keywords*—Asphalt mixtures; fatigue life; meta-learning prediction; mechanism analysis**

I. Introduction

With the rapid development of the economy, the cause of transportation has also made great progress, asphalt pavement as one of the main forms of highway, its performance is directly related to the service life of the road and driving safety [1, 2]. Asphalt mixture is the main constituent material of asphalt pavement, which is prone to fatigue damage under the repeated action of long-term traffic load, which in turn leads to cracks, potholes and other disorders on the road surface, affecting the normal use of the road [3]. Accurately predicting the fatigue life of asphalt mixtures is of great significance for the rational design of pavement structure, optimization of material composition, development of scientific maintenance plans, and reduction of road construction and maintenance costs [4]. Therefore, exploring new prediction methods has important theoretical and practical application value.

Asphalt mixture fatigue life prediction is an important research field in transportation engineering and materials science, and its core objective is to accurately predict the service life of asphalt mixtures under long-term repeated loading through theoretical analysis, experimental research, and numerical simulation [5], so as to provide a scientific basis for road design, construction, and maintenance [6]. Asphalt mixture fatigue life prediction research mainly includes asphalt mixture fatigue mechanism research [7], fatigue life influencing factors analysis [8], fatigue life prediction method research [9], fatigue life prediction without model validation and optimization [10], and so on. Currently, asphalt mixture fatigue life prediction research started relatively early, and after years of development, has achieved a series of more mature results [11]. Wang et al. [12], based on experimental observation and theoretical derivation, put forward the classical fatigue life prediction model represented by linear cumulative damage theory. Abdulmawjoud [13] used a deep neural network to predict the fatigue life of asphalt mixture under different asphalt types, aggregate gradation, and loading frequency, and achieved better prediction results. Zhao et al. [14] used a deep learning algorithm, combined a convolutional neural network and Long Short-Term Memory (LSTM) structure to predict the fatigue life of asphalt mixtures containing dynamic fatigue test data, material composition parameters, environmental monitoring data, and other multi-source information. Ameri and Ebrahimzadeh [15] utilized the viscoelastic continuum damage model and successfully predicted the mid-temperature fatigue performance of aged asphalt binder through a linear amplitude scanning test, indicating that the nonlinear prediction model can well fit the fatigue performance of asphalt binder with different aging times, showing that the nonlinear prediction model can fit the fatigue life of asphalt binder with different aging times well. Harne et al. [16] proposed a fatigue life prediction method for green mixtures based on support vector machines, which transforms the fatigue life prediction problem of asphalt mixtures into a classification or regression problem by searching for the optimal classification hyperplane with good generalization ability and prediction accuracy. Yue et al. [17] adopted an optimization neural network-based method using genetic algorithms for the architecture of the neural network is optimized to further improve the prediction performance of the asphalt fatigue life prediction model. Although extensive and in-depth research has been carried out at home and abroad in the field of fatigue life prediction of asphalt mixtures and a series of fruitful results have been achieved [18], there are still some urgent deficiencies and challenges faced by the existing technology: 1) the traditional prediction model lacks an in-depth portrayal of the fatigue

*Corresponding author.

mechanism of the material, and it is difficult to accurately reflect the complex process of fatigue damage accumulation in asphalt mixtures [19]; 2) the Machine learning method models usually require a large amount of high-quality data for training, and in practice, there are greater difficulties in obtaining a sufficient amount of representative fatigue data, which to a certain extent restricts the model's performance improvement [20].

Based on the shortcomings of the existing research, this study is dedicated to introducing the cutting-edge technology of meta-learning [21] into the field of fatigue life prediction of asphalt mixtures, with a view to provide an innovative methodology and ideas for solving the existing technical problems. The main contributions of this study are reflected in the following: 1) constructing a fatigue life prediction model system for asphalt mixtures based on meta-learning; 2) combining the fatigue damage mechanism of asphalt mixtures with the material properties, exploring how to integrate the a priori knowledge in the physical model into the meta-learning model; and 3) verifying the validity and superiority of the proposed model through a large number of simulation experiments.

This study centers on the fatigue life prediction problem of asphalt mixtures, and constructs a meta-learning-centered intelligent prediction framework.

The structure of the whole study is arranged as follows: Firstly, the fatigue mechanism and life prediction of asphalt mixture are systematically analyzed in Section II, which clarifies the influencing factors and the demand of prediction model. Section III describes the basic principle of meta-learning, the classification of the method and the typical application, which provides theoretical support for the subsequent construction of the model. Section IV focuses on proposing the fatigue life prediction model based on meta-learning, and describes the design of its structure in detail. Section V carries out experimental validation to evaluate the model performance from multiple dimensions, such as prediction accuracy, error control, convergence speed and generalization ability, by comparing and analyzing with the traditional methods. Finally, Section VI summarizes the research results, points out the limitations of the current research, and proposes the direction of improvement in the future. Through the above structural arrangement, this study aims to provide an innovative, low-sample, and highly adaptable solution idea for the efficient prediction of asphalt mixture fatigue life.

II. Fatigue Life Prediction Problems of Asphalt Mixture

A. Fatigue Mechanism Analysis of Asphalt Mixtures

Asphalt mixture fatigue refers to the phenomenon of gradual deterioration of the internal structure of asphalt mixtures under the repeated action of cyclic loading with decreasing strength and stiffness, which ultimately leads to the destruction of the material [22], as shown in Fig. 1.

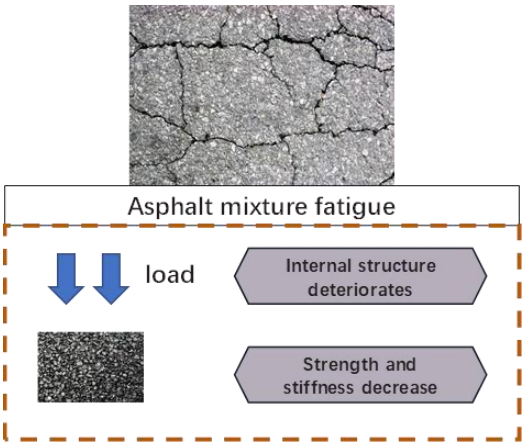

Fig. 1. Fatigue phenomenon in asphalt mixture.

1) Fatigue damage analysis: Asphalt mixture is a typical composite material, which consists of a variety of components such as asphalt, aggregate, filler, etc., as shown in Fig. 2. Under the action of loading, the interactions between the constituents jointly affect the fatigue performance of the material. From a microscopic point of view, the fatigue damage of asphalt mixtures is mainly reflected in three aspects, as shown in Fig. 3.

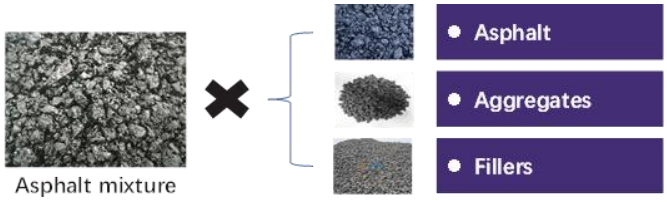

Fig. 2. Asphalt mixture.

Fig. 3. Fatigue damage of asphalt mixture.

- Aging and rupture of asphalt: Under repeated loading, the lightweight components in asphalt gradually evaporate, resulting in asphalt hardening, its viscosity and elasticity decrease, and resistance to deformation is weakened. At the same time, under the repeated action of the load, the asphalt will also produce small cracks within the asphalt, and these cracks gradually expand, eventually leading to asphalt rupture.
- Aggregate fracture and loosening: Aggregate will produce micro-cracks under the action of load, and these cracks expand with the repeated action of load, which ultimately leads to the fracture of aggregate particles. In addition, the friction and misalignment between the

aggregate particles will also loosen the aggregate and reduce the embedding effect of the aggregate, thus affecting the overall strength of the asphalt mixture.

- Damage at the asphalt-aggregate interface: The bond at the interface between asphalt and aggregate is an important source of asphalt mixture strength. Under the action of load, the stress concentration at the interface will lead to a gradual weakening of the bond, and even the phenomenon of debonding. Once the bond at the interface fails, the aggregate particles will undergo relative displacement under load, accelerating the fatigue damage of asphalt mixture.

2) Fatigue damage principle: The fatigue damage of asphalt mixture is a complex physicochemical process, and its principle is mainly based on energy dissipation theory, microcrack extension theory and other parties [23], as shown in Fig. 4. As can be seen from Fig. 4, one is the energy dissipation theory, with the repeated action of the load, the energy dissipation within the material is increasing, resulting in a gradual decrease in the internal energy of the material, the structure is gradually loosened, and eventually fatigue damage occurs; the second is the theory of micro-crack expansion, the micro-cracks generated within the asphalt mixture under the repeated action of the load continue to expand and interpenetrate, the formation of macroscopic cracks, which ultimately leads to the fracture of the material.

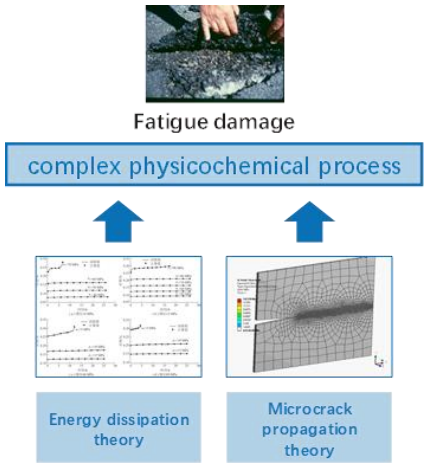

Fig. 4. Fatigue damage principle of asphalt mixture.

3) Characteristics: The fatigue of asphalt mixture has the following characteristics: 1) with the increase of load, the deformation of the material will gradually increase, showing obvious nonlinear characteristics; 2) asphalt mixture has both viscous and elasticity, and its mechanical behavior changes with time; 3) each load action will cause some damage to the asphalt mixture, and it continues to accumulate, which ultimately leads to the fatigue damage of the material [24]. The fatigue characteristics of asphalt mixtures are shown in Fig. 5.

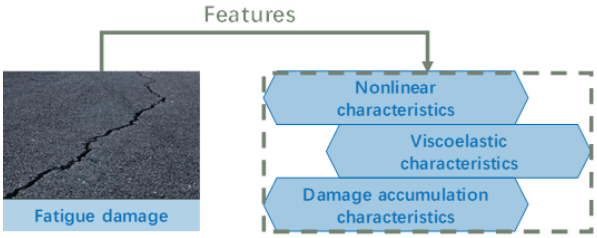

Fig. 5. Fatigue damage characteristics of the asphalt mixture.

B. Fatigue Life Prediction of Asphalt Mixtures

1) Definition and analysis: Fatigue life prediction of asphalt mixtures refers to the prediction of the number of cycles or service time, i.e., fatigue life that the material can withstand under a certain load, based on factors such as its composition, structure, and loading conditions [25]. The concept of fatigue life prediction for asphalt mixtures is shown in Fig. 6.

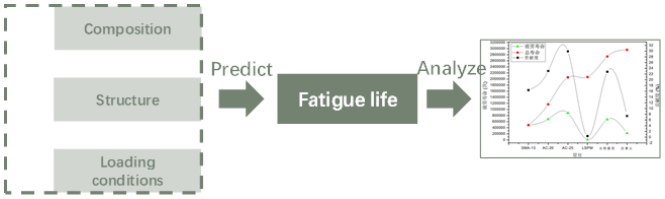

Fig. 6. Concept of fatigue life prediction for asphalt mixtures.

The key to fatigue life prediction is to establish a quantitative relationship between fatigue life and various influencing factors. There are many factors affecting the fatigue life of asphalt mixtures, including material composition, loading conditions, environmental factors, and so on. Material composition determines the basic physical and mechanical properties of asphalt mixtures, such as asphalt type and aggregate gradation. Load conditions include load size, frequency, loading mode, etc., which directly determine the level of stress and strain on the material. Environmental factors such as temperature and humidity also have a significant effect on the fatigue properties of the material (see Fig. 7).

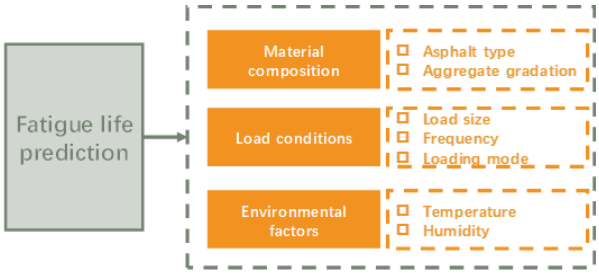

Fig. 7. Fatigue life prediction influencing factors.

2) Principles and characteristics: The principles of fatigue life prediction include fatigue damage accumulation model and material mechanics model. Fatigue damage accumulation model is to predict the fatigue life of materials by establishing the relationship between the fatigue damage and the number of loading cycles; material mechanics model: according to the mechanical properties of materials, establish the stress-strain

relationship of materials, combined with the fatigue damage mechanism, to predict the fatigue life of materials [26].

Fatigue life prediction has the following characteristics: 1) uncertainty; 2) multi-factor coupling; 3) model dependence.

III. META-LEARNING

A. Principles and Methods

1) Principle of meta-learning: Meta-learning, i.e., "learning to learn", is an advanced machine learning concept, which aims to enable the model to quickly adapt to new tasks through the accumulation of experience, and significantly improve the learning efficiency and generalization ability [27]. The principle of meta-learning is shown in Fig. 8.

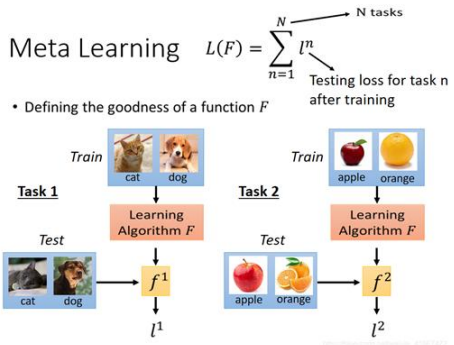

Fig. 8. Principle of meta-learning.

Traditional learning methods usually train models for a single task, while meta-learning extracts common knowledge from multiple related tasks to form a common knowledge base. When faced with a new task, the model utilizes the meta-knowledge to quickly adjust and efficiently find a solution with little data and computational resources.

2) Types of methods: Meta-learning methods are divided into optimization-based meta-learning, metric-based meta-learning, model-based meta-learning, etc., as shown in Fig. 9.

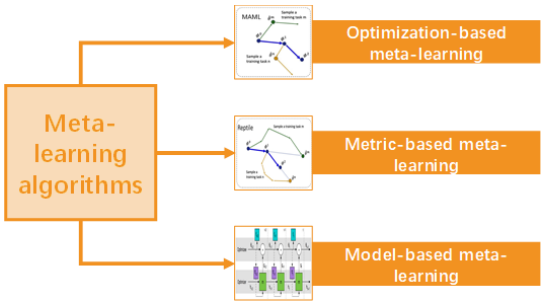

Fig. 9. Classification of meta-learning algorithms.

Optimization-based meta-learning makes the model learn quickly on a small amount of new data by adjusting the initial parameters or learning rate, the typical representative is MAML (Model-Agnostic Meta-Learning). Metric-based meta-learning constructs metric space to facilitate sample similarity metrics and classification, the representative algorithm is Prototypical Networks. Model-based meta-learning constructs models to quickly adapt to new tasks.

B. Applications and Characteristics

1) Meta-learning applications: In the field of image classification, meta-learning can be used to quickly classify new categories of images. A large amount of image data covering multiple categories and scenes is collected to train the classification model. When new image categories, the model uses meta-knowledge to quickly and accurately classify them, saving time and computational resources.

In the field of natural language processing, meta-learning can be used for tasks such as text categorization, sentiment analysis, and machine translation, as shown in Fig. 10. In the field of material science, meta-learning can be used for material performance prediction, such as predicting the strength, hardness, and fatigue life of materials. Performance data of multiple materials are collected to train the prediction model. When new material properties are predicted, the model utilizes meta-knowledge to predict quickly and accurately, accelerating research and development.

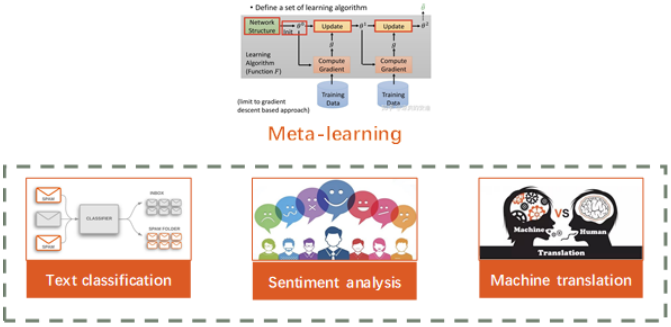

Fig. 10. Meta-learning application analysis.

2) Meta-learning characteristics: Meta-learning is characterized by rapid adaptability, strong knowledge transfer, high learning efficiency, and wide applicability, as follows: 1) Rapid adaptability. The meta-learning model is trained by multi-tasks and has the ability to adapt quickly; 2) Strong knowledge migration. Meta-learning can extract generalized knowledge from multi-tasks to form a strong knowledge base, which can be shared and utilized for different but related tasks to enhance the learning effect of new tasks; 3) High learning efficiency. Meta-learning uses multi-task experience to optimize the learning process, improve efficiency, quickly adapt to new tasks, and reduce data and computational resource requirements; 4) Wide applicability. Meta-learning is applicable to multiple fields such as image classification, natural language processing, material science, robot control, etc.

IV. META-LEARNING BASED FATIGUE LIFE PREDICTION METHOD FOR ASPHALT MIXTURES

A. Structure of the Prediction Model

1) Overall framework of the model: The overall framework of the meta-learning-based fatigue life prediction model for asphalt mixtures integrates a meta-learner, a feature extractor, and a task-specific model, aiming to efficiently process multi-task learning and accurately predict the fatigue life of a new

task, as shown in Fig. 11. As can be seen in Fig. 11, the meta-learner extracts generic features and initial parameters from multi-task data, the feature extractor deeply processes the input data to generate high-dimensional feature representations, and the task-specific model is fine-tuned with a small amount of data based on the meta-knowledge provided by the meta-learner to achieve fast adaptation and accurate prediction of new tasks.

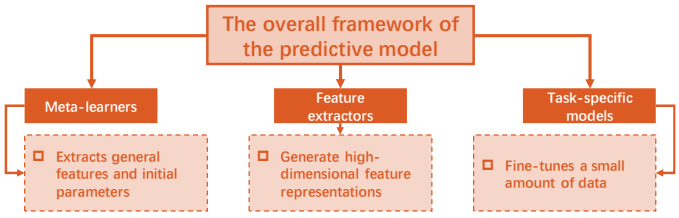

Fig. 11. Overall framework of the prediction model.

B. Key Technologies

The meta-learning-based fatigue life prediction model construction for asphalt mixtures includes key technologies such as feature extraction and fusion, meta-knowledge learning, and fast adaptive algorithms, as shown in Fig. 12.

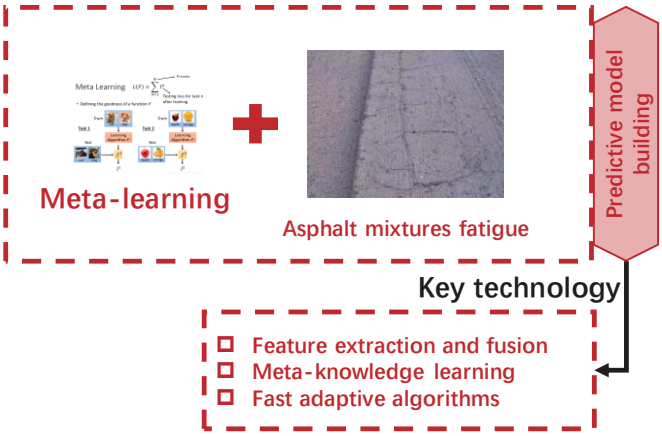

Fig. 12. Key techniques for predictive model construction.

1) Feature extraction and fusion: For fatigue life prediction of asphalt mixtures, the input data include material composition (e.g., asphalt type, aggregate gradation, etc.), structural parameters (e.g., void ratio, mineral gap ratio, etc.), and loading conditions (e.g., stress level, loading frequency, etc.). The model needs to automatically extract and fuse the key features of these multi-source heterogeneous data. A multi-layer neural network is used as the feature extractor, with different layers extracting different levels of semantic information.

2) Meta-knowledge learning: The model needs to learn generic meta-knowledge from multiple related tasks, which can help the model quickly adapt to new tasks. The meta-knowledge includes generic feature representations and initial values of model parameters. The generic feature representations are common features extracted from the data of multiple tasks, which can reflect the basic laws of fatigue life of asphalt mixtures. The initial values of the model parameters are the optimal initial values obtained after multiple task training, which can make the model converge quickly in the new task.

3) Fast adaptive algorithm: The fast adaptive algorithm is the core of meta-learning, which enables the model to use a small amount of new task data to quickly adjust the model parameters. In optimization-based meta-learning methods, the fast adaptive algorithm uses gradient descent for parameter updating. In the new task, the model first uses a small amount of data to calculate the gradient of the loss function, and then combines the initial parameters provided by the meta-learner to quickly adjust to get the parameters adapted to the new task.

C. Methodological Steps

Combined with the meta-learning algorithm, a data-driven fatigue life prediction method based on asphalt mixtures was designed, and the process is shown in Fig. 13 with the following steps:

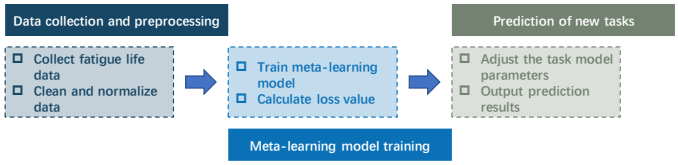

Fig. 13. Fatigue life prediction method for asphalt mixtures.

Step 1: Data collection and pre-processing. Collect fatigue life data under different asphalt mixture types and loading conditions, including material composition parameters, structural parameters and fatigue life. Clean and normalize the data to remove outliers and missing values.

Step 2: Meta-learning model training. The meta-learning model is trained using the training set. Each task data in the training set is input into the model, and the parameters of the meta-learner are updated by the optimization algorithm. First, initialize the parameters of the meta-learner, and then for each task, perform a gradient descent update based on the parameters of the meta-learner to obtain the model parameters for that task. Calculate the value of the loss function for that task and update the meta-learner's parameters by backpropagation. Repeat this process until the performance of the meta-learner is optimized on all tasks.

Step 3: New task prediction. When a new asphalt mixture fatigue life prediction is required, a small amount of data from the new task is fed into the trained meta-learning model. The model uses the meta-knowledge provided by the meta-learner to quickly adjust the parameters of the task-specific model. The adjusted model is then used to predict the fatigue life of the new task and the predictions are output.

V. Experimental Validation

A. Experimental Setup

In order to verify the effectiveness and superiority of the meta-learning based fatigue life prediction method for asphalt mixtures, the following experimental setup was conducted:

1) Data set preparation: Fatigue life data of multiple types of asphalt mixtures, including different asphalt types, aggregate gradation, and loading conditions, were collected from public

databases and laboratory tests. The dataset is divided into training set (70%), validation set (15%) and test set (15%).

2) Experimental environment: MATLAB 2021a platform was used for the experiment, and the appropriate meta-learning algorithm (MAML) and neural network architecture (multilayer perceptual machine) were selected. Set the experimental parameters: the learning rate is 0.01, the training period is 500 times, and the batch size is 32.

3) Comparison method: In order to highlight the advantages of meta-learning based methods, traditional methods (including linear regression and BP neural network) are selected for comparison. The parameter settings of the three algorithms are shown in Table I.

TABLE I. ALGORITHM PARAMETER SETTINGS

ID	Algorithm	Parameter Settings
1	Linear Regression	L2 regularization (ridge regression); Regularization coefficient initial value: 0.1
2	BP Neural Network	Multi-layer perceptron (MLP) architecture; Initial learning rate: 0.001; Batch size: 32; Training epochs: 500
3	Meta-Learning (MAML)	Base learning rate: 0.01; Meta-learning rate: 0.001; Outer optimizer: Adam; Tasks per batch: 20; Training epochs: 500; MLP architecture; Hidden layers activated by ReLU

B. Analysis of Results

In order to deeply evaluate the practical efficacy of the fatigue life prediction model for asphalt mixtures based on meta-learning, this section compares it with the traditional linear regression and BP neural network methods, and carries out the analysis of the results in terms of prediction accuracy, error control, convergence speed, and generalization ability, and obtains the results shown in Fig. 14 to Fig. 17, Table II to Table IV.

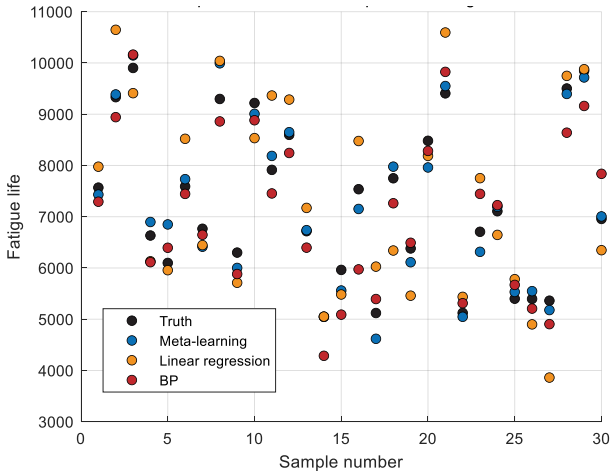

Fig. 14. Comparison of actual and predicted fatigue life.

Fig. 14 shows the comparison between the actual values of fatigue life of asphalt mixtures and the results obtained by three prediction methods: meta-learning method, traditional linear regression method, and BP neural network method. From the figure, it can be visualized that the meta-learning method is closest to the real value in the overall trend, and its prediction curve closely follows the actual life data, showing superior fitting accuracy. In contrast, the traditional method shows large deviations at several points, especially in the fatigue life of higher or lower conditions, and the BP neural network, although improved compared with the traditional linear method, still shows a certain degree of volatility and instability in some segments.

Further discussion and analysis of Fig. 14 shows that the meta-learning method shows a strong generalization ability and adaptivity, not only in the high value zone can be accurately predicted, but also maintains a good fit in the low value zone. This performance is attributed to the "meta-knowledge" extracted from multi-task learning, which enables the model to quickly adjust the parameters and give accurate results even in the face of unseen samples. This method outperforms the traditional model in responding to new conditions and data fluctuations, which shows that it has a stronger practical value and potential for popularization in road engineering. This also verifies the effectiveness of the meta-learning-based prediction method proposed in this study in improving the accuracy of fatigue life prediction of asphalt mixtures.

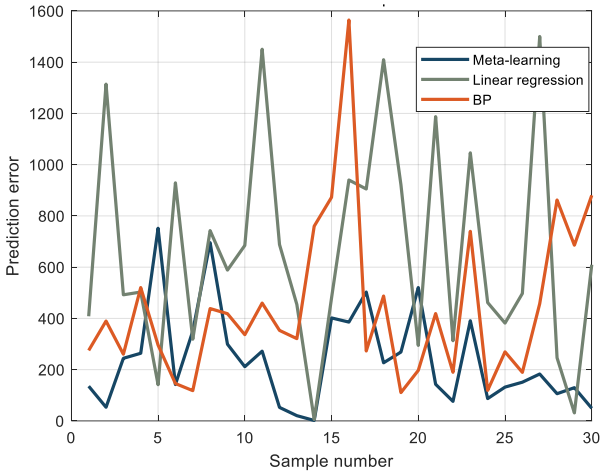

Fig. 15. Comparison of prediction errors.

Fig. 15 shows the error comparison of the three prediction methods (meta-learning, linear regression, and BP neural network) in the fatigue life prediction task of asphalt mixtures. It can be clearly seen in the figure that the meta-learning method has the lowest prediction error as a whole, and the error distribution is more concentrated and less fluctuating, indicating that it has stronger stability and accuracy. In contrast, the traditional linear regression method has the largest range of error fluctuations, with multiple high error points, indicating that its ability to fit the nonlinear law of fatigue life is limited, and it cannot effectively capture the complex feature interactions. While the BP neural network reduces the error to a certain extent, the overall error level is still higher than that of the meta-learning method, especially in some of the test samples where large deviations still occur.

Further observing the trend of the error curves, the meta-learning method keeps the error in a lower range in several data segments, showing its good adaptability to different working conditions and sample types. Its lower maximum error and

standard deviation indicate that meta-learning has obvious advantages in generalization and robustness. This is due to the "meta-knowledge" accumulated through multi-task learning, which can be quickly and accurately adapted to new tasks. In contrast, BP neural network still relies on a large number of samples for training, while linear regression lacks the ability to model nonlinear factors. Therefore, Fig. 15 further verifies that the meta-learning method is more stable and practical than traditional methods in real engineering prediction.

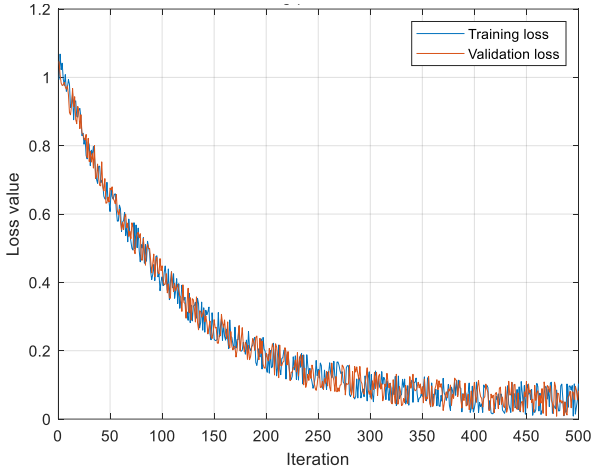

Fig. 16. Training process curve.

Fig. 16 demonstrates the trend of training loss and validation loss with the number of iterations for the meta-learning-based approach in fatigue life prediction of asphalt mixtures. From the overall trend, both the training loss and the validation loss decrease rapidly with the increase of the number of iterations and level off at a certain stage, indicating that the model training process has good convergence. Especially in the first 100 iterations, the loss value shows a rapid decline, indicating that the meta-learning model is able to effectively capture the common knowledge among tasks and establish a stable prediction structure at the early stage. Compared with the slow convergence process of traditional neural networks, this feature significantly improves the training efficiency of the model.

From the change curve of the validation loss, the model does not show any obvious oscillation or overfitting trend throughout the training process, indicating its strong generalization ability. The change in loss on the validation set is consistent with the training set, indicating that the meta-learning method still maintains a stable performance in the face of unseen tasks or samples. This is because the model extracts more generalizable meta-parameters through the learning process of multiple tasks, allowing the model to adapt quickly with a small amount of fine-tuning even when faced with a new task with a slightly different distribution from the training set. This performance is of great practical importance for life prediction of asphalt mixtures under variable operating conditions.

From the final stabilized value of the loss curve, the loss value of the model after the training of the meta-learning method is significantly lower than that of the traditional method, which reflects its higher prediction accuracy and model robustness. Since the fatigue life prediction of asphalt mixtures involves the complex coupling of multiple factors, the traditional method is often difficult to fully express the deep relationship between variables due to the limited modeling capability. The meta-learning method not only accelerates the training convergence speed by extracting and utilizing multi-task synergistic information, but also improves the model's ability to fit the complex fatigue damage mechanism, which provides theoretical support for further popularizing the technology to road material performance prediction.

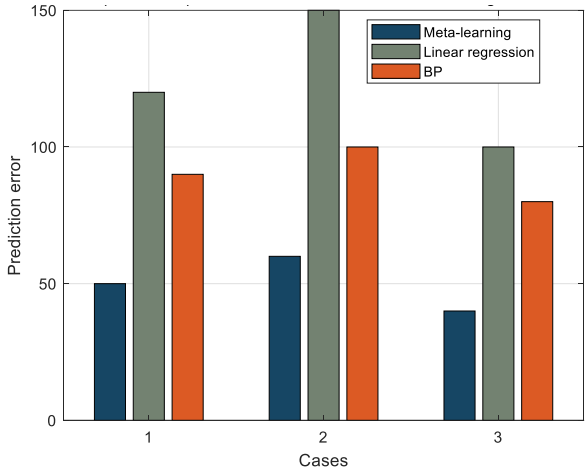

Fig. 17. Comparison of prediction errors under different working conditions.

Fig. 17 shows the comparison results of the errors of the three methods (meta-learning, BP neural network, and linear regression) in the fatigue life prediction of asphalt mixtures under different working conditions. It can be clearly seen that the meta-learning method shows the lowest prediction error under all kinds of working conditions, which is significantly better than the BP neural network and the traditional linear regression method, indicating that it has a stronger adaptive ability and robustness to working conditions. Especially under the more complex or nonlinear conditions such as working conditions 2 and 3, the error control ability of the meta-learning method is still stable with almost no obvious fluctuation, which demonstrates its strong modeling ability in the face of high-dimensional and multivariate input scenarios.

Further analysis shows that the linear regression method has the most significant error difference among different working conditions, and its prediction error is susceptible to drastic changes in variables, with poor stability, showing a typical underfitting problem. BP neural network, although improved compared with linear regression in most of the working conditions, still shows an increase in prediction deviation under high loads or complex material parameter combinations. This indicates that the traditional methods have limited ability to model the nonlinear interactions among multiple variables, such as environment, load, and material components, and are difficult to perform the task of predicting variable working conditions in engineering.

In contrast, the meta-learning approach, by accumulating rich "meta-knowledge" during the multi-task training phase,

enables the model to adapt quickly to new working conditions, and can realize high-precision prediction with only a very small amount of new task data. The analysis results in Fig. 17 further demonstrate that the meta-learning method not only improves the prediction accuracy and efficiency, but also enhances the generalization ability of the model under different external environments or parameter fluctuations, which is an effective way to solve the problem of "poor adaptability to multiple working conditions" in the prediction of the life of asphalt mixtures.

TABLE II. ALGORITHM COMPARISON DATA

Iterations	Meta-Learning Accuracy	Linear Regression Accuracy	BP Neural Network Accuracy
100	0.95	0.80	0.85
200	0.96	0.82	0.87
300	0.97	0.83	0.88
400	0.98	0.84	0.89
500	0.98	0.84	0.89

Table II demonstrates the comparison of the prediction accuracies of the three methods (meta-learning, linear regression, and BP neural network) with different numbers of training iterations (100, 200, 300, 400, and 500), aiming to assess the evolutionary trend of the accuracy of each method with the upper bound performance as the training process advances.

First, from the overall trend, the prediction accuracies of all three methods increase with the number of iterations, indicating that continuous training helps the models to extract more effective features and laws. However, there are significant differences in the rise and final accuracy among the three. The meta-learning method achieves a high accuracy of 0.95 in the initial 100 iterations, much higher than the 0.80 of linear regression and the 0.85 of BP neural network, which indicates that it has a strong learning and fitting ability under a small amount of training, reflecting the core advantage of meta-learning of "fast adaptation with few samples".

Secondly, in terms of stability and final performance, the accuracy of the meta-learning model reaches 0.97 at 300 times of training, and stabilizes at 0.98 at 500 times, showing high training efficiency and convergence performance. In contrast, the BP neural network model can only approach 0.89 after 400 iterations, which is slow to improve and the accuracy fluctuates; the linear regression model almost stops the growth of accuracy after 200 iterations, and finally stays at 0.84, reflecting the existence of an obvious model upper limit, which is difficult to further approximate the actual data. This also indicates that the linear model has limited performance in the face of complex nonlinear relationships in asphalt mixtures.

Thirdly, from the perspective of model variability, the performance of meta-learning is much better than the other two, because it obtains "common initialization parameters" and "task adaptation ability" through multi-task learning, which makes the model jump out of the local optimum faster, and avoids the traditional method of high-dimensional nonlinear problems falling into the "common initialization parameters" and "task adaptation ability". It avoids the traditional methods from falling into the dilemma of "underfitting" or "overfitting" in high-dimensional nonlinear problems. Thus, the data in Table II not only verifies the significant advantage of the meta-learning method in training accuracy, but also further supports its potential as an efficient, stable and strongly generalized prediction tool in engineering practice.

TABLE III. PREDICTION ERROR DATA UNDER DIFFERENT WORKING CONDITIONS

Condition	Meta-Learning Error	Linear Regression Error	BP Neural Network Error
1	50	120	90
2	60	150	100
3	40	100	80

Table III lists the prediction errors of the three methods in three typical conditions: 50, 60, 40 for the meta-learning method, 120, 150, 100 for the linear regression, and 90, 100, 80 for the BP neural network, and the meta-learning method has the lowest error in all the conditions, which shows the strongest prediction accuracy and error control ability. Among them, Case 2 usually represents a more complex or extreme test scenario, in which the error of traditional methods rises significantly (up to 150 for linear regression and 100 for BP), while the meta-learning method still controls the error within 60, which shows that it still has a high stability and generalization ability under the high-complexity task. This advantage stems from the meta-learning's extraction and migration of common knowledge from multiple historical tasks, which gives the model the ability to be quickly tuned under new working conditions without the need for a large number of samples to be relearned.

Further analyzing the robustness of the model and its ability to adapt to the working conditions from the error fluctuation amplitude, we find that the error range of the meta-learning method is only 20 (from 40 to 60) under the three working conditions with the smallest variation, while that of the BP neural network is 20 (from 80 to 100), and that of linear regression is as high as 50 (from 100 to 150), which indicates that meta-learning not only predicts more accurately, but also performs more smoothly and reliably among the working conditions. Especially when the working condition parameters change significantly, the error of linear regression method fluctuates drastically and is prone to deviate significantly from the actual value, reflecting its lack of modeling ability for complex environments. Although BP neural network is more flexible, the error is still amplified when there are insufficient samples or complex feature interactions. In conclusion, the data in Table III fully reflects the system advantages of meta-learning in terms of "cross-operating conditions, consistency and fault tolerance", which is an effective means to construct a highly robust asphalt fatigue life prediction system.

TABLE IV. MODEL CONVERGENCE SPEED

Iterations	Meta-Learning Convergence Speed	Linear Regression Convergence Speed	BP Neural Network Convergence Speed
20	0.3	0.1	0.15
40	0.5	0.15	0.25
60	0.7	0.2	0.35
80	0.8	0.25	0.45
100	0.9	0.3	0.55

Table IV demonstrates the comparison of the convergence speed (i.e., the training accuracy or loss decline speed) of the three prediction methods (meta-learning, linear regression, and BP neural network) at different numbers of iterations (20, 40, 60, 80, and 100). From the data, it can be seen that the meta-learning method shows a clear lead in each iteration stage: at 20 iterations, the convergence speed has reached 0.3, while linear regression and BP neural networks are only 0.1 and 0.15; at 100 iterations, the meta-learning speed rises to 0.9, much higher than the BP's 0.55 and the linear regression's 0.3. This suggests that meta-learning has a much faster initial fitting ability and overall convergence efficiency, and is able to achieve a much higher training accuracy or loss decline speed at different numbers (20, 40, 60, 80, and 100). This can build an effective prediction model in a very short training cycle, saving training time and improving engineering efficiency. The reason is that the meta-learning method constructs a good "model initialization" by extracting the shared patterns and parameters among multiple tasks, thus speeding up the adaptation to new tasks.

In terms of the smoothness and cost of the convergence process, meta-learning not only improves the performance rapidly at the early stage of training, but also has a smooth and persistent convergence curve with almost linear growth trend, showing good controllability and stability. This is especially critical for engineering applications, especially in environments with restricted data or limited training resources, where fast convergence can significantly reduce computational costs. While linear regression converges slowly and is susceptible to data distribution interference, its convergence value is always low, indicating its natural limitation in complex feature modeling; BP neural network, although it has some nonlinear fitting ability, improves slowly in the initial stage (only from 0.15 to 0.55), has higher training cost, and is sensitive to the hyper-parameters and the number of samples, with the risk of training instability.

VI. CONCLUSION

This study focuses on the fatigue life prediction problem of asphalt mixture, innovatively introduces the meta-learning method, and proposes the fatigue life prediction method of asphalt mixture based on meta-learning algorithm. The method analyzes the fatigue mechanism of asphalt mixtures, extracts the influencing factors affecting fatigue, analyzes the fatigue life prediction problem of asphalt mixtures, and combines the meta-learning algorithm to construct the fatigue life prediction model of asphalt mixtures. Through systematic experimental simulation analysis, the significant advantages of the meta-learning method in terms of prediction accuracy, error control, convergence speed and generalization ability are verified. The study shows that the meta-learning method can effectively utilize the multi-task learning mechanism, quickly adapt to different working conditions, and provide an efficient and accurate solution for the fatigue life prediction of asphalt mixtures. Future research will focus on further optimizing the meta-learning model architecture and expanding its practicality and application scenarios, with a view of playing a greater role in practical engineering.

***Abstract*—Grading Harumanis mangoes is traditionally done through manual visual inspection, which is subjective, inconsistent, and labor-intensive. Industry practices report only 70–80% consistency among human graders, with accuracy further declining under fatigue or high volumes. These limitations hinder uniform quality assurance, especially for export markets. To address this, an image-based, non-destructive grading system was developed, focusing on external features such as surface defect severity, ripeness index, shape uniformity, and size. A dataset of 1,018 mango samples was collected and analyzed using a machine vision system. Features were extracted through image segmentation and color–shape analysis, then classified using a Fuzzy Inference System (FIS) and Machine Learning (ML) models including SVM, MLPNN, and ANFIS. Enhanced SVM variants were also implemented to assess performance gains. Results showed strong performance across all parameters: ripeness index accuracy reached 93.5%, shape uniformity 91.6%, and size classification over 96%. The enhanced SVM+ achieved the best overall accuracy at 95.1% with the lowest error rates. The proposed system demonstrated clear improvements over manual grading and effectively classified mangoes into PREMIUM, GRADE 1, GRADE 2, and REJECT categories, supporting its potential for reliable real-world deployment.**

I. Introduction

Mango is a widely cultivated tropical fruit that is highly valued for its unique flavor, aroma, and nutritional benefits. Among the various cultivars, the Harumanis mango is particularly renowned for its exceptional quality and popularity in Malaysia [1]. Harumanis mangoes are in high demand for both export and local consumption, and must therefore meet predetermined quality standards. Failure to meet these standards can result in substantial economic losses and reduced returns for vendors. Consequently, it is necessary to sort mangoes based on key grading parameters, including size, shape, maturity, defects, firmness, and nutritional content. The post-harvest grading process classifies mangoes into predefined quality categories, where effective grading enhances vendor and farmer confidence while expanding export opportunities. However, the traditional manual grading process is frequently subjective, laborious, and inconsistent, with reported grader consistency as low as 70–80% [2-3].

To overcome these challenges, researchers have increasingly explored advanced computer vision and ML techniques for automated mango quality assessment [4-6].[22]. While these studies demonstrated promising results, most were limited to individual features (e.g., color or size) or lacked extensive validation, reducing their robustness for real-world deployment.

Building on this foundation, the present study makes three key contributions. First, it proposes a multi-feature image-based grading framework for Harumanis mangoes that integrates surface defect severity, ripeness index, shape uniformity, and size—parameters rarely evaluated together in previous works. Second, the study evaluates multiple classification models, including FIS, SVM, MLPNN, and ANFIS, with enhanced SVM variants achieving an accuracy of 95.1%, outperforming earlier studies that typically reported accuracies below 90%. Third, to ensure robustness and reduce risks of overfitting, the study employs a k-fold cross-validation strategy with independent testing, while also acknowledging limitations such as lighting variability, dataset imbalance, and cultivar generalizability.

By addressing both methodological gaps and performance limitations in existing approaches, this study provides a more reliable, scalable, and high-accuracy grading system that offers clear improvements over traditional manual inspection and prior automated methods.

II. Related Works

Recent studies span defect synthesis, ripeness, shape, and size assessment. For surface defects, image-to-image translation with conditional GANs can augment rare defect cases [7], but synthetic artifacts risk domain shift and inflated accuracy if not validated on truly independent, real-world images. CNN-based defect classifiers [8-9] often report high accuracy on single-cultivar, lab-lighting datasets, with limited discussion of class

*Corresponding authors.

imbalance, inter-rater agreement for labels, or external test sites [21]. Classical pipelines using color/texture + SVM/kNN [10]. The study in [13] are interpretable but may be sensitive to illumination and background variability; they also evaluate a narrow set of varieties and typically do not integrate multiple attributes into a single grading decision.

For ripeness, hyperspectral + deep models [8] achieve fine spectral discrimination, yet sensor cost, throughput, and calibration burden constrain deployment; generalization across orchards and seasons is seldom shown. RGB image approaches [11-12] are cheaper but frequently rely on controlled setups and lack cross-cultivar validation. Shape-based grading [14-15] demonstrates that geometry helps detect deformities and even distinguish varieties. However, many methods assume clean silhouettes; occlusions, stem/calyx variability, and pose changes can degrade performance. Fourier descriptors [16] are transformation-invariant but may miss localized defects and can be sensitive to imperfect segmentation.

Size estimation [17-19] via dimension/mass prediction is useful, yet several works depend on explicit calibration objects, single-view assumptions, or manual placement, limiting throughput and robustness on conveyors. Across these threads, common gaps persist: (i) single-attribute focus rather than multi-attribute fusion aligned to market grades; (ii) limited head-to-head baselines vs human graders (e.g., inter-grader consistency); (iii) under-specified validation (few use stratified k-fold plus an independent test set); (iv) sparse reporting of deployment factors (speed, cost, lighting variation).

Positioning of this study. To address these gaps, this work integrates defect severity, ripeness index, shape uniformity, and size into a unified, non-destructive grading pipeline tailored for Harumanis mangoes [20]. The system is benchmarked against human grading consistency and validated through k-fold cross-validation with an independent test split, reducing overfitting risk and strengthening evidence of real-world applicability.

III. Materials and Methods

A. A Structure of Quality Grading System

This study was conducted in multiple orchards across Perlis, where the grading system hardware, shown in Fig. 1, was deployed. To acquire image data and evaluate the geometric parameters of mangoes, the system integrates both image capture and analytical models. The sorting setup consists of two main components. The first is the image processing module, which applies conventional algorithms to transform unstructured image data into structured descriptors and extract external features such as size, color index, shape similarity, and surface defects. Although external features can also be obtained using ML or deep learning methods [23-25], this study employs image processing because of its efficiency, lower computational cost, and ability to operate without extensive training datasets. Moreover, it offers greater flexibility in parameter adjustment compared to ML and deep learning approaches.

The second component combines the extracted features into a comprehensive dataset, which is subsequently used to train ML models. These models classify Harumanis mangoes into four quality categories: PREMIUM, GRADE 1, GRADE 2, and REJECT.

B. Data Preparation for Grading Process

In this study, 1018 samples of mango fruits were used. These mangoes of the Harumanis cultivar were provided by Federal Agricultural Marketing Authority (FAMA) and randomly collected from different commercial orchards located in Perlis. All the fruits without any damage and major defects were selected and classified manually into four ripeness levels by the farmer based on their visual assessment. The farmer manually classified the mangoes into four ripening levels based on peel color. All the data were recorded and classified under the ripeness levels of M1, M2, M3, and M4, respectively. Then, the sample was transported to the lab and inspected by expert workers from FAMA for quality validation.

All the samples were manually measured with respect to their length and width using a mechanical vernier caliper with an accuracy of 0.1mm. After the data on the geometry dimension was collected, all the samples were weighted using a digital scale with an accuracy of 0.1g to measure the mangoes. To predict the quality of Harumanis mangoes, a data set was made to classify the ripening level, surface defect, shape uniformity, and size that were obtained from selected mangoes. Simultaneously, the classification of quality and grading of the same samples are done by the proposed system using image processing method. This system was configured as shown in Fig. 1.

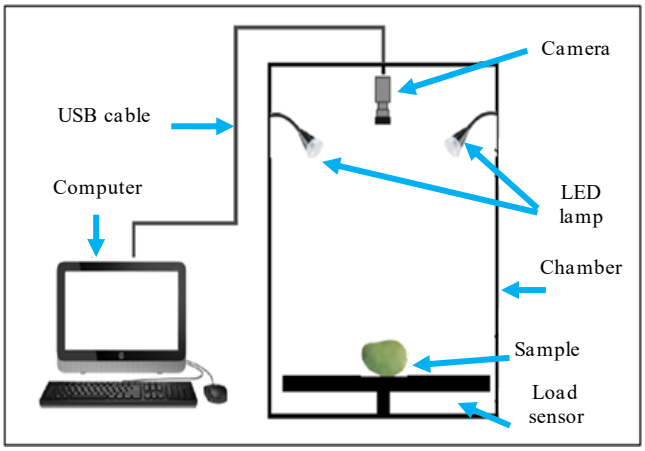

Fig. 1. System configuration for data collection.

The digital camera used for color image acquisition is the Basler acA1600-60gc GigE, with the e2v EV76C570 CMOS sensor that captures images of 1600x1200-pixel resolution. This camera is mounted 400mm on top of the chamber, and the illumination system provides two 10-watt LEDs. A generalized block diagram of the proposed research methodology for quality assessment of Harumanis is shown in Fig. 2.

C. Image Processing

In this work, the research methodology is structured as a sequential pipeline for the quality assessment of Harumanis mangoes, where each stage improves its respective task and provides input to the next. The generalized methodology (Fig. 3) consists of four main parts: 1) image acquisition, 2) image preprocessing and segmentation, 3) feature extraction, and 4) classification.

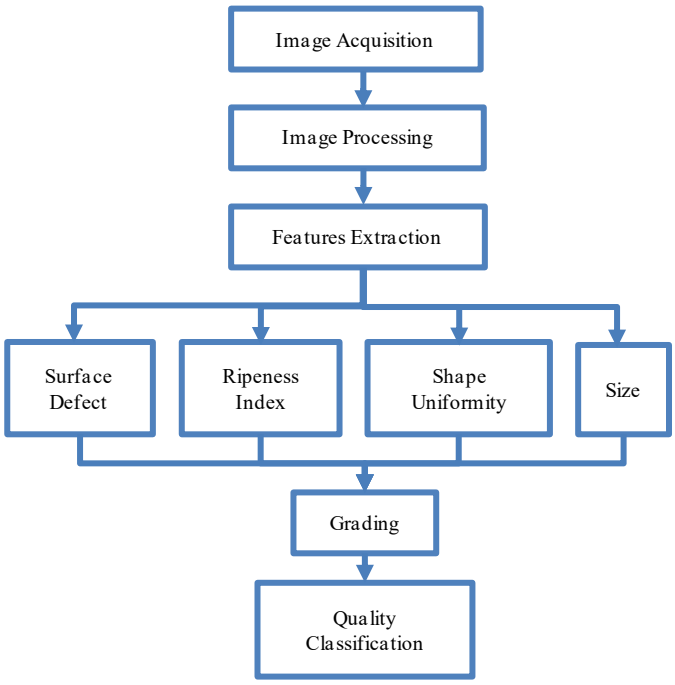

Fig. 2. Block diagram of the image processing technique for quality assessment.

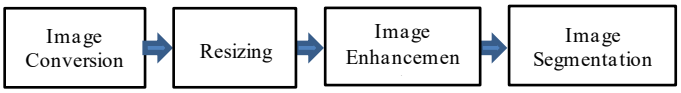

Fig. 3. Block diagram image processing technique.

In the first stage, mango images were captured using a controlled imaging setup with uniform illumination, neutral background, and fixed camera distance to minimize variation. Preprocessing included noise reduction using a Gaussian filter, contrast enhancement with histogram equalization, and background removal through thresholding to isolate the fruit. Segmentation was performed using a combination of color-based thresholding and morphological operations to accurately delineate the mango boundary, as illustrated in Fig. 4.

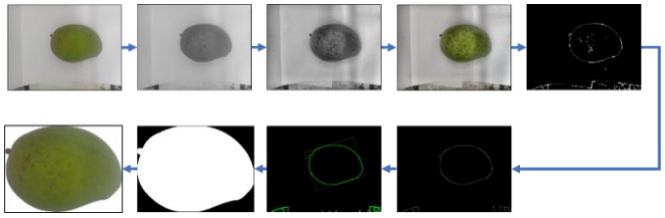

Fig. 4. Image segmentation process.

The second stage, feature extraction, involved computing color features (RGB, HSV, and statistical color moments) and shape descriptors (area, perimeter, eccentricity, Fourier descriptors) from the segmented region. These features were sampled across 1,018 mango images to ensure representativeness of different ripeness stages, sizes, and surface conditions.

Finally, in the classification stage, the extracted features were fed into a Fuzzy Inference System (FIS) to grade ripeness, shape uniformity, and defect severity, while size grading was conducted by categorizing fruit dimensions into four predefined classes. The configuration of membership functions and rule bases in FIS was optimized through iterative tuning and cross-validation to achieve robust performance.

D. Extracting Mango External Features

The feature extraction stage represents the most critical component of computer vision–based grading, wherein salient numerical descriptors are systematically derived from mango images and extraneous information is eliminated to ensure analytical relevance. In this study, two categories of features were selected—color and shape—because they directly reflect the criteria used in commercial grading of Harumanis mangoes as shown in Fig. 5. Color features were used to capture two important quality aspects: the ripeness index and external defects. Ripeness was quantified by analyzing pixel intensity distributions in RGB and HSV spaces, since skin color transitions from green to yellow or orange are strongly correlated with physiological maturity.

External defects such as bruises, dark spots, and blemishes were detected as localized deviations in color patterns, providing an objective means of assessing defect severity, which is critical for maintaining export quality standards [18], [26]. Shape features, on the other hand, were extracted to evaluate both shape uniformity and fruit size. Geometric descriptors such as aspect ratio, eccentricity, and contour smoothness were applied to determine how well the fruit conforms to the typical elongated-oval profile of Harumanis mangoes, as misshapen fruits are usually downgraded in grading practice.

Size was estimated using dimensional attributes including length, width, and projected area, since fruit size is one of the main determinants of market grade categories such as PREMIUM, GRADE 1, GRADE 2, and REJECT. By integrating these color- and shape-based features, the system provides a robust representation of the visual attributes most relevant to consumer acceptance and commercial value.

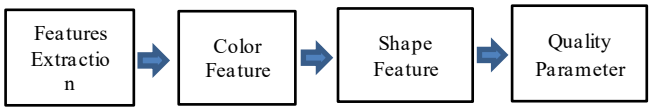

Fig. 5. Block diagram of object detection.

E. Determination of Quality Parameters

1) Surface defects: The evaluation of the Surface Defect Severity Index (SDSI) for fruit entails measuring and quantifying the skin imperfections on fruits. This is a common procedure in the fruit business to assess the quality and marketability of fruits. A numerical scoring system or grading scale is established to assess the severity of problems. This scale ranges from 0 to 5, where 0 indicates no problems, 1 signifies very minor superficial faults, 2 denotes slight superficial defects, 3 represents moderate defects, 4 indicates severe defects, and 5 reflects extremely severe defects, as seen in Table I. To evaluate this score scale, the binary picture is analyzed to determine the quantity of lesions, the cumulative size of the lesions, and the overall area of the mango. The total area of the mango and the area of the defective areas are utilized

to compute the percentage of defect, referred to as PoD. The PoD is often computed using the following equation:

$$\text{PoD} = \frac{\text{total area of defected portions}}{\text{area of the entire mango}} * 100 \quad (1)$$

Finally, the value of PoD is used as the input to the FIS to compute the membership functions for the prediction of the Surface Defect Severity Index (SDSI). The measurement of SDSI is based on three methods: PoD_{pc}, which counts pixels to measure area; PoD_{gt}, which uses mathematical analysis to understand spatial relationships; and PoD_{cl}, which divides the area into grid cells for systematic assessment. Additionally, the hybridization method (PoD_{hy}) integrates these approaches to enhance overall accuracy. Together, these methods provide a comprehensive and reliable framework for classifying SDSI.

TABLE I. CLASSIFICATION OF SDSI

Quality Class		Scoring Scale	% of Defect (*PoD*)	Inference
Commercial standard	PREMIUM	1≤	0 - 5	Free or very slight superficial defects
	1	2	5-Oct	Slight superficial defects
	2	3	Oct-15	Moderate defect
Reject	3	4	15 - 40	Severe defect
	4	5	>40	Very severe defect

2) Ripeness index: A fuzzy classifier is used to create the classification system for the ripeness level of the Harumanis mango. The fuzzy logic system has three inputs with a membership function for each input. These three inputs are represented by color measurement of *U*, *Cr* and *a** channels that were extracted from the color space of *YUV*, *YCrCb* and *L*a*b*, respectively. The determination of the ripeness index is based on the closeness of the values between the ripeness classes in terms of parameters and consumer preferences. Table II presents the mean pixel values for the *Cr, U* and *a** color channels, which severe as indicators of the ripeness level in Harumanis mangoes. There are 18 rules to be the basis for the input pattern, and the number for the output is four: unripe, underripe, ripe, and overripe. On the other hand, color channels with distinct points of range were employed with triangular membership functions. When values for the color channel are too close together, triangle membership functions have a tendency to overlap.

Concurrently, the output value is being defuzzified using the centroid approach. The set of rules that form the basis of the input pattern that produces an output was displayed by the rule viewer. The membership function combination utilizing the OR operation and the associated output are represented as the rule's viewer. It is composed of four membership functions: unripe, underripe, ripe, and overripe. Since a part of the unripe and overripe membership functions have instantly distinguishable color characteristics, they were trapezoidal in shape. Both the ripe and underripe classifications often have similar values and sometimes even the same color. They were represented by a triangular membership function.

At each level of classification, two types of data are separated into a testing set and a training set in order to validate the model. The value of training data will be a benchmark whose value is used as a differentiator for each class. To determine whether or not the system is operating correctly, test samples are created using the test data from the defuzzification process. Each of the training and test sets of data has 250 of the Harumanis mangos.

TABLE II. HARUMANIS RIPENESS INDEX ESTABLISHED VISUALLY BY THE COLOUR CHANNEL

Ripeness Index	Color Channel (Pixel)			Scoring Scale
	Cr	*U*	*a**	
M1	≤120	≤116	≤125	1
M2	>120 - 125	>116 - 120	>125 - 130	2
M3	>125 - 130	>120 - 124	>130 - 135	3
M4	>130	>124	>35	4

3) Shape uniformity: The Shape Uniformity Index (SUI) is classified as abnormal if it measures less than 80%, which may be caused by a misshapen, another clone, or grafting with another variety of mangoes. The shape uniformity is based on calculating the degree of uniformity of the sets between the Euclidean distance of the boundaries, and the differences in the parameters of the vertices of areal spatial objects. Fourier descriptors are features that can represent boundary shape of an object. They are scale, translation and rotation invariant. Contour detection was applied to the binary image to identify the largest contour (the mango), and the centroid was obtained from contour image moments. Distance of centroid from contour boundary points were computed and discrete Fourier Transform was calculated. Six standard samples selected by expert are used for comparison. These samples are labeled as T1-T6, with masses ranging from 240 g to 580 g. The Euclidean distance d_E between two vectors is defined using Eq. (2).

$$d_E(G_1, G_2) = \sum_{m=1}^{m=M_p} \sqrt{(|G_1(m)| - |G_2(m)|)^2} \quad (2)$$

where, M_p denotes the number of Fourier Descriptors pairs used for matching. G_1 and G_2 is Fourier shape descriptors, and *m* is the pixels numbered from *0* to *m – 1* at regularly spaced position. Then, the Euclidean distance, d_E from Eq. (2) is applied to measure the uniformity index of shape. The percentage of uniformity in shape *S* can be calculated as in the equation below.

$$S = (1 - d_E) * 100 \quad (3)$$

In some cases, the shape of the mango does not look like the original even though it is actually from a Harumanis clone due to the grafting effect. According to Jabatan Pertanian Perlis, they still consider as Well-shaped (WS), although it does not follow the standard shape. Therefore, the half-shape measurement of the uniformity index needs to be performed. This process is repeated with new templates consisting only of half-cut Harumanis shapes for both the lower and upper parts. Then, from Eq. (3), the percentage of uniformity in shape for entire

mango, upper and lower half-cut are calculated and defined S_{Ef}, S_{Eu} and S_{El}, respectively.

To predict SSI, fuzzy classifier is used. The values of these three parameters S_{Ef}, S_{Eu} and S_{El} for are passed as input to fuzzy system and decision has been taken that the mango fruit is *HS*, *WS* (well-shaped), and *AS* (deformed). In designing fuzzy rules for the system, considerations and assumptions obtained from [FAMA] had been taken. The system comprises of eight rules obtained from three inputs and one output of membership functions. Table III shows summary of rules represents by linguistic variable used in system.

TABLE III. IF-THEN RULES FOR CONVERTING FUZZY INPUTS TO FUZZY OUTPUTS

Input Variables (%)			Scoring scale (SUI)
S_{Ef}	S_{Eu}	S_{El}	
>80	>50	>50	1
>80	>50	<50	1
>80	<50	>50	1
>80	<50	<50	2
<80	>50	>50	2
<80	<50	>50	3
<80	>50	<50	3
<80	<50	<50	4

4) Size: Optical size grading is a process used in various industries, including agriculture, manufacturing, and quality control, to sort or classify objects based on their size using optical technology [27], [17]. This method involves the use of cameras to capture images of the objects and analyse them into different size categories. Optical size grading is preferred over manual grading in many applications because it offers a fast and efficient way to automate the sorting process, improving productivity and reducing human error. To classify mango size, a fuzzy logic classifier is used. In order to create a modelling system, fuzzy logic allows for the use of size features for variables and imprecise relationships. Two parameters, including weight and area, are employed to determine size features.

TABLE IV. RANGE OF WEIGHT AND AREA PARAMETER FOR SIZE FEATURE

Size	Weight (g)	Area (pixels)	Scoring scale (SI)
Small (S)	<300	<78212	4
Medium (M)	>301-400	>78213 - 101102	3
Large (L)	>401-500	>101103 - 127363	2
Extra Large (XL)	>501	>127364	1

The size feature is initially derived from the range of each individual parameter. These range values will serve as a reference and a range input for the fuzzy classification system. A total of 566 mangoes are used in determining the range value, weight, and area of each category, as shown in Table IV. The trapezoidal membership function of weight and area is then formed, assigning the proper range to the respective size feature.

F. Machine Learning for Grading Mangoes

The final stage focuses on classifying Harumanis mangoes into quality grades based on various features, following local standards. A dataset of 1018 samples was used to build and validate the classification models. Three supervised ML methods were applied: Multi-Layer Perceptron Neural Networks (MLPNN), Adaptive Neuro-Fuzzy Inference System (ANFIS), and Support Vector Machines (SVM). These methods were chosen for their individual strengths MLPNN handles complex non-linear patterns well [31], ANFIS integrates fuzzy logic for dealing with uncertainty and provides interpretable results [29], while SVM excels in high-dimensional data and resists overfitting with flexible kernel functions [30]. Each method classifies input features into one of several distinct quality classes. Since all dataset parameters are on similar scales, normalization may not be necessary [28].

IV. RESULTS AND DISCUSSION

The study was conducted using a dataset comprising 1,018 Harumanis mango samples. These samples were provided by the Federal Agricultural Marketing Authority and randomly collected from various commercial orchards in Perlis. All fruits selected were free from damage and major defects, and were manually classified into four ripeness indexes by the farmer based on visual assessment. The data was recorded and classified under the ripeness levels of M1, M2, M3, and M4. The results obtained for surface defect estimation, ripeness index, size, shape uniformity index classification, and final grading are discussed in the following sections.

A. Surface Defect Prediction

Fig. 6 shows the comparison of the SDSI index for the actual values (expert-provided) and the predictor methods (PoD_{pc}, PoD_{gt}, PoD_{cl}, and PoD_{hy}) is indicative of distinctions that occur in predictive accuracy across different SDSI categories. In this case SDSI 1, the actual value is around 500, and slightly overestimates PoD_{pc}, as for PoD_{gt} and PoD_{cl} they provide quite equal estimates. PoD_{hy} gives pretty much underestimates value. SDSI 2 reveals a true value much lower (~180) with PoD_{pc} and PoD_{gt} being somehow lower than the real value, whereas PoD_{cl} significantly overestimates it, followed by PoD_{hy} and which is also above the actual value.

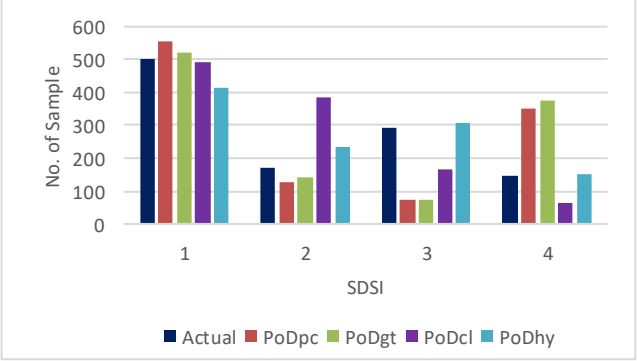

Fig. 6. Comparison of classifying the SDSI.

The actual value and the different predictor methods show SDSI 3, where most methods present lower sums than the actual value (~300), PoD_{pc} and PoD_{gt} being the farthest off. PoD_{hy} gets the nearest value to the actual one that is why it is the most accurate predictor in this category. In the last group named SDSI 4, there is a partial match for PoD_{gt} as the actual value is heavily overestimated by it. For PoD_{pc} the actual value is overestimated as well. PoD_{cl} has underestimated the value massively. PoD_{hy} is slightly overestimated but is closer than the others. In general, PoD_{hy} is found to be a very well-balanced approach that delivers predictions falling inside the correct range of values for various SDSI types. PoD_{pc} and PoD_{gt} mainly vary between the two extremes of under- and overestimation regarding the level of SDSI. PoD_{cl} is not in a steady situation, in SDSI 2 and SDSI 4 especially, it is able to either drastically underestimate or overestimate the issue.

B. Ripeness Index Prediction

From the confusion matrix in Table V, it shows that overall, the ripeness level M1-M4 achieved accuracies above than 90%. M4 groups has only three misclassification and thus attained 95.8% of accuracy. Subsequently, M3, M2 and M1 achieved accuracies with 91.7%, 92.2% and 94.4% accordingly. Seven samples from M3 were misclassified into M4 and M2, respectively. On top of that, 71 out of 77 samples from M2 are correctly classified to their group whilst two sample is misclassified into M3 and four samples in M1. Meanwhile, 51 out 54 image samples from M1 were correctly classified to their group whilst three sample was falsely classified to M2.

TABLE V. CONFUSION MATRIX FOR DETERMINING THE ACCURACY OF FUZZY

Actual Ripeness Level based on Brix	No. of Sample	Predicted Ripeness Level				Accuracy (%)
		M1	M2	M3	M4	
M1	54	51	3	0	0	94.4
M2	77	4	71	2	0	92.2
M3	84	0	3	77	4	91.7
M4	72	0	0	3	69	95.8
TOTAL	287			**Average**		93.5

C. Shape Uniformity Index (SUI) Prediction

The experiment was conducted to evaluate the effectiveness of a proposed method in distinguishing the standard shape of Harumanis mangoes from other categories, specifically well-shaped, and abnormal shape. Each category comprised 1018 samples of mangoes that varied in size. Initially, these samples underwent visual inspection by FAMA staff to assess their shape characteristics, aligning with the conditions for the SUI. The confusion matrix in Table VI showcases a discriminant model utilizing a fuzzy algorithm to predict the quality of Harumanis mangoes based on the SUI, achieving an impressive overall average accuracy of 91.6%.

The model effectively classifies samples across four quality categories: Class 1 (232 samples) with 92.7% accuracy, Class 2 (622 samples) at 87.9%, Class 3 (131 samples) with 88.5%, and Class 4 (368 samples) attaining the highest accuracy of 97.1%. Despite the model's robustness, slight misclassifications between adjacent quality classes indicate potential for improvement in accurately handling borderline cases. Overall, the results affirm the model's effectiveness in enhancing quality control process~~es~~ for Harumanis mangoes.

TABLE VI. CONFUSION MATRIX OF DISCRIMINANT MODEL FOR PREDICTING THE QUALITY OF HARUMANIS BASED ON SUI

Subjective classification	No. of Sample	Fuzzy algorithm output				Accuracy (%)
		1	2	3	4	
1	250	232	18	0	0	92.8
2	708	56	622	30	0	87.9
3	148	0	10	131	7	88.5
4	379	0	0	11	368	97.1
Average						**91.6**

D. Size Estimation

The estimated mass, M_{Est}, was further used in classifying Harumanis mangoes into four categories of size classes. Classification results from 1018 Harumanis mangoes samples show the effectiveness of the proposed size prediction using fuzzy logic in categorizing mangoes into four size classes: Small (S), Medium (M), Large (L), and Extra-Large (XL) as shown confusion matrix in Table VII. The confusion matrix reveals that the Harumanis mangoes size prediction model performs well, with most predictions being correct, especially for the XL category. The diagonal elements, which show correct predictions, are dominant, indicating high accuracy. However, some misclassifications occur, particularly between Medium (M) and Large (L) sizes, where Medium (M) mangoes are sometimes mistaken for Large (L) ones (0.99%). There are also a few cases where Large (L) mangoes are predicted as Extra-Large (XL) with 2.01%. Although there are some misclassifications, the overall accuracy is still strong. These errors are relatively small compared to the correct predictions, but they suggest that the model could benefit from further refinement, especially in distinguishing between Medium (M) and Large (L) sizes.

TABLE VII. CONFUSION MATRIX FOR SIZE PREDICTION

Actual Size		Estimated Size				Accuracy (%)
Category	**Total**	**S**	**M**	**L**	**XL**	
S	196	191	5	0	0	97.5
M	505	8	492	5	0	97.4
L	547	0	10	526	11	96.3
XL	210	0	0	3	207	98.6

TABLE VIII. CLASSIFICATION RESULTS OF COMPLETE SAMPLES INTO SIZE

Actual Size	Prediction Performance (%)		
	Precision	Recall	F1-Score
S	97.76	97.32	97.54
M	96.3	97.41	96.85
L	97.2	96.19	96.7
XL	98.93	98.23	98.39

Table VIII shows the analysis of the mango size prediction model demonstrates strong performance across all size

categories. The model exhibits high Precision, with Extra-Large (XL) mangoes having the highest value at 98.6%, indicating that when the model predicts Extra-Large (XL), it is almost always correct. Small (S) and Large (L) categories also show very high Precision scores of 97.76% and 97.20%, respectively, while Medium (M) has a slightly lower Precision at 96.30%.

In terms of Recall, which measures how well the model identifies all instances of each size, XL mangoes again perform the best with a Recall of 98.23%, ensuring that few XL mangoes are missed. The Small (S) category follows closely with a Recall of 97.42%. However, Large (L) has a slightly lower Recall of 96.19%, likely due to some misclassifications with Medium (M) mangoes. The F1-Score, which balances both Precision and Recall, also shows that the model performs well overall, with Extra-Large (XL) leading at 98.93%, followed by Small (S) at 97.54%. While Medium (M) and Large (L) have slightly lower F1-Scores of 96.85% and 96.70%, respectively, they still reflect strong performance.

E. Quality Classification

Table IX summarizes the evaluation of multiple classification models. The performance of seven different models, including ANFIS, MLPNN, SVM, SVM+ PoD_{pc}, SVM+PoD_{gt}, SVM+PoD_{cl}, and SVM+PoD_{hy}, was analyzed based on various evaluation metrics such as Mean Absolute Error (MAE), Mean Squared Error (MSE), Root Mean Squared Error (RMSE), Accuracy, Precision, Recall, and F1-Score. The results indicate significant differences in how well each model handles classification tasks.

TABLE IX. PERFORMANCE COMPARISON ACROSS PREDICTORS

Predictor	MAE	MSE	RMSE	Accuracy (%)	Precision	Recall	F1-Score
ANFIS	120.3	150.5	12.3	81.6	0.78	0.81	0.79
MLPNN	90.2	110.4	10.5	86.8	0.83	0.86	0.84
SVM	85.5	102.2	10.1	87.5	0.85	0.88	0.86
SVM+PoD_{pc}	98.6	115.3	10.7	83	0.81	0.83	0.82
SVM+PoD_{gt}	95.2	113.7	10.6	83.6	0.82	0.85	0.83
SVM+PoD_{cl}	180.4	210.6	14.5	65.5	0.65	0.67	0.66
SVM+PoD_{hy}	70.3	95.2	9.8	95.1	0.91	0.94	0.92

Among the base models, SVM demonstrated the highest accuracy (87.5%), outperforming both MLPNN (86.8%) and ANFIS (81.6%). SVM also had the lowest error rates, with an MAE of 85.5 and RMSE of 10.1, meaning it made fewer misclassifications compared to the other standalone models. While MLPNN performed better than ANFIS, it still had a slightly higher error rate than SVM, making SVM the best base model overall.

When additional enhancements were applied, SVM+PoD_{hy} emerged as the best model overall, achieving the highest accuracy of 95.1% and the lowest MAE (70.3) and RMSE (9.8), indicating that it had the fewest misclassifications and highest precision. Furthermore, its recall of 0.94 and F1-score of 0.92 confirm that SVM+ PoD_{hy} had the best balance between correctly identifying positives while minimizing false positives and false negatives.

This makes SVM+PoD_{hy} the most reliable predictor among all models tested. On the other hand, SVM+PoD_{cl} performed the worst, with an accuracy of only 65.5% and a significantly higher error rate (MAE of 180.4 and RMSE of 14.5). This indicates that adding the clustering-based PoD_{cl} method to SVM led to higher misclassifications, making it the least effective enhancement.

The models SVM+ PoD_{pc} (83.0%) and SVM+ PoD_{gt} (83.6%) showed moderate improvements but did not surpass the accuracy of SVM alone (87.5%), meaning that these modifications did not significantly improve performance. Their error rates were slightly lower than ANFIS but remained higher than standard SVM, suggesting that PoD_{pc} and PoD_{gt} did not contribute substantially to classification accuracy.

Overall, SVM+ PoD_{hy} was the most successful model, achieving the highest accuracy, lowest error rates, and best balance between precision and recall. In contrast, SVM+PoD_{cl} was the weakest model, suffering from high misclassification rates and poor overall performance. The findings suggest that SVM alone is a strong predictor, but hybrid methods like PoD_{hy} significantly enhance its capabilities, while others, such as PoD_{cl}, may introduce inefficiencies.

V. CONCLUSION

This study demonstrates a robust image-based framework for non-destructive quality assessment of Harumanis mangoes by integrating surface defect severity, ripeness index, shape uniformity, and size into a unified grading system. Using fuzzy inference and ML models, with SVM+ achieving the highest accuracy of 95.1%, the system clearly outperformed traditional manual grading. While the approach shows strong potential, limitations include reliance on a single cultivar and controlled imaging conditions, which may restrict generalizability. Future work will extend validation to multiple cultivars under real-world conditions, explore deep learning for richer feature extraction, and investigate real-time deployment to support scalable adoption in post-harvest supply chains.

ACKNOWLEDGMENT

The authors gratefully acknowledge the technical staff and agricultural experts from the Institute of Sustainable Agrotechnology, Universiti Malaysia Perlis, for their valuable support and contributions.

Narxoz University, Almaty, Kazakhstan

***Abstract*—Face recognition systems have become prevalent in mobile devices and security applications, increasing the demand for robust face presentation attack detection. Early efforts based on handcrafted features struggled to cope with variations in illumination, pose, and attack modalities, prompting a transition toward deep learning solutions capable of extracting subtle discriminative cues. A novel architecture built upon an EfficientNet-V2 backbone, combined with a Shuffle Attention module and Fourier heads, was developed to capture both spatial and frequency domain characteristics. A dual-path approach processes each input face image through conventional convolutional blocks and a 2D Discrete Fourier Transform path, with dedicated Fourier heads reconstructing frequency maps that reveal minute discrepancies between genuine and spoofed presentations. Experimental evaluation on the Oulu-NPU dataset demonstrates strong performance across four protocols, including robust detection under varying environmental conditions, low error rates with novel attack types, and consistent results across different sensor inputs. Metrics such as APCER, BPCER, and ACER validate the method's ability to distinguish between live and fake faces reliably. The outcomes suggest that combining spatial and frequency cues addresses limitations observed in earlier approaches, offering valuable insights for deployment in security-sensitive applications and setting a strong foundation for future research in face anti-spoofing.**

***Keywords*—Liveness detection; face anti-spoofing; deep learning; CNN; frequency domain**

I. Introduction

Face recognition systems have grown in popularity in various applications such as mobile devices and security systems. Early research in face liveness detection relied on handcrafted features such as local binary patterns and histograms of oriented gradients to capture subtle texture and motion cues [1-2], using simple image analysis and rule-based methods to separate real faces from spoof attempts. However, they often struggled with changes in illumination and pose and could not adapt well to different attack scenarios [3-4].

The field later shifted to the use of deep learning methods. Convolutional Neural Networks brought a new way to extract features from face images and proved better at detecting minute differences between live faces and fakes [5-7]. Recent studies have also focused on integrating attention mechanisms and frequency domain analysis into CNNs to improve face anti-spoofing [8-9], showing improvements in accuracy and robustness compared to traditional approaches.

In this work, EfficientNet-V2-S was used as the backbone network. EfficientNet-V2-S is known for its speed and accuracy in image processing tasks [10]. The network works by processing an input face image through several convolutional blocks that extract features at different scales. Shuffle Attention [11] introduces a novel mechanism for processing deep convolutional features by partitioning input channels and applying concurrent spatial operations. Grouping feature maps allows parallel extraction of spatial and channel information, followed by a channel shuffle that redistributes features effectively. Extensive experiments on standard networks such as ResNet-50 indicate significant performance improvements in classification and detection tasks while maintaining low computational overhead. Researchers have integrated the module into multiple vision tasks, yielding promising accuracy and efficiency results. Recent empirical evaluations validate the approach as a valuable alternative to traditional attention methods in diverse computer vision applications. Further studies corroborate findings.

Alongside the backbone and attention module, Fourier heads are added to the architecture. They reconstruct Fourier maps from the features extracted by the backbone. The Fourier maps capture frequency domain information that often holds clues to subtle differences between live faces and spoof attempts [12-14]. The Fourier heads use a series of deconvolution and dilated convolution layers to build these maps. By including frequency information, the network can detect differences that may not be clear in the spatial domain alone.

The network is built in steps that allow it to process the image, compute attention weights, and reconstruct Fourier maps. The outputs from the different stages are then combined to produce a final prediction. Such a design aims to capture both spatial and frequency cues that are important for distinguishing genuine faces from presentation attacks. Each component of the network plays a role in addressing the weaknesses of earlier methods and in improving the overall detection accuracy.

Face anti-spoofing remains a subject of great interest due to the increasing use of face recognition in security-sensitive applications. As presentation attacks grow more complex, researchers must continue to search for better ways to detect both obvious and subtle forms of spoofing. The need for robust and efficient systems is clear given the evolving methods of attack and the widespread use of biometric systems. Current study adds to this growing body of work by combining modern

network architectures, attention mechanisms, and Fourier domain analysis to address these challenges. Ongoing research in this area is essential to keep up with the rapid progress in attack techniques and to ensure the safety and reliability of face recognition systems [15].

II. Related Works

Face anti-spoofing has attracted significant research interest owing to the security implications of deploying face recognition systems. Over time, methods evolved from reliance on handcrafted features like local binary patterns and histograms of oriented gradients to modern deep learning frameworks capable of automatically extracting discriminative representations. Early techniques concentrated on identifying subtle texture and motion cues to differentiate between live and spoof presentations, though challenges with varying illumination and pose limited their practical applications.

A. Face Anti-Spoofing: Definitions and Impact

Face anti-spoofing deals with the task of telling apart live faces from fake ones produced by photographs, video replays, or masks. The goal is to protect systems that use face recognition by stopping attempts to bypass security. Research in this area has shown that proper detection is vital for preventing unauthorized access and misuse in various applications [16].

B. Traditional Methods

Earlier work in face anti-spoofing focused on hand-designed features and rule-based procedures. Texture features extracted using methods such as local binary patterns and histogram of oriented gradients were combined with classifiers like support vector machines. Thus, such systems worked by identifying subtle texture differences between real faces and printed or replayed images. While these methods were simple and fast, their performance dropped in conditions with varying lighting, pose, or image quality [17].

C. Machine Learning Methods

As the field advanced, researchers introduced machine learning methods that improved detection rates. Classifiers were built on top of handcrafted or shallow learned features extracted from facial images. Several studies combined texture information with motion cues, attempting to capture both spatial and temporal variations in the input. Fusion of multiple cues improved performance under diverse conditions, although the reliance on manually designed features still limited the overall accuracy [18].

D. Deep Learning Methods

Deep learning has introduced new possibilities in various domains, ranging from computer vision to medicine [19-21]. One of these fields involves addressing security issues such as face anti-spoofing, where models automatically learn meaningful features directly from raw data. Convolutional neural networks have been applied to capture intricate spatial details that differentiate live faces from spoof attacks. Some works introduced additional supervision or auxiliary tasks to guide the network toward discriminative patterns. Recent studies have also brought in attention mechanisms that help the network focus on regions with strong cues and methods that analyze frequency domain information to detect hidden patterns. Many deep learning approaches have reached state-of-the-art results on standard datasets such as CASIA-FASD and Replay-Attack, proving their advantage over earlier methods [22-23].

E. Challenges

Despite progress, several challenges remain. One difficulty is the wide range of attack types, from simple printed photos to complex 3D masks. Another is the gap between controlled experimental conditions and real-world scenarios. Variations in camera quality, lighting, and environmental conditions can lead to degraded performance when a model is deployed outside its training setting. Moreover, models sometimes struggle with unexpected spoofing methods not seen during training, which calls for solutions that can generalize well across different domains [24].

Another persistent challenge is the limited availability of large-scale, diverse datasets that accurately represent real-world spoofing variations. Many face anti-spoofing datasets are collected under controlled conditions, resulting in a lack of generalization when applied to heterogeneous environments such as hospitals or telemedicine platforms. Medical applications introduce unique challenges, including the presence of masks, occlusions, and patient motion artifacts, which complicate spoofing detection. Moreover, privacy constraints often limit the amount of publicly available medical facial data for model training, further exacerbating overfitting and bias issues [25-26]. To mitigate these problems, researchers have begun exploring domain adaptation, transfer learning, and synthetic data generation using generative adversarial networks (GANs) to expand dataset diversity and improve model robustness [27].

Another significant challenge is the computational complexity and real-time inference requirements for deployment in practical medical environments. Deep neural networks with attention and frequency-domain components, such as Fourier-based modules, demand high processing power, which can hinder integration into low-latency telemedicine systems or edge devices. Lightweight architectures, model pruning, and knowledge distillation are being investigated to reduce inference time while maintaining accuracy [28]. Furthermore, there is growing attention to explainability and transparency in model decisions, especially in healthcare contexts, where interpretability is critical for clinical trust and regulatory approval [29]. Future advancements will likely focus on integrating efficient model compression, interpretable attention visualization, and adaptive frequency analysis to enhance both performance and reliability in medical face anti-spoofing systems.

F. Research Gaps and Opportunities

Current work has made notable strides, yet there are several open areas for investigation. One gap lies in fully exploiting the frequency domain, as few methods integrate frequency information with spatial features for a more robust detection scheme [30]. Further studies are needed to understand how attention mechanisms can be combined with alternative representations to better capture subtle spoof cues. In addition, there is an opportunity to improve the generalization of anti-spoofing systems by addressing the domain shift between training and real-world environments [31]. Future research

should consider the integration of multiple modalities and richer representations to build systems that are both accurate and robust against evolving spoof attacks.

III. Materials and Methods

A. Proposed Model

The method illustrated in Fig. 1 begins by detecting a face using the Multitask Cascaded Convolutional Network [32]. The bounding box output by MTCNN is cropped and resized to 512 × 512 pixels. Each face image then follows two main paths. The first branch is a common path, where various stochastic augmentations (e.g., random horizontal flips, color jitter) were applied. The augmented image is forwarded through a pretrained EfficientNetV2-S backbone, which consists of eight blocks of modified convolutional layers. EfficientNetV2-S - because it offers a strong accuracy-latency trade-off for 512×512 inputs while maintaining a moderate parameter count, which is important for real-time mobile or access-control deployments. Its compound scaling and fused-MBConv layers provide large effective receptive fields and robust texture sensitivity without incurring the inference cost of deeper backbones (e.g., ResNet-101/152) or the capacity limits of lighter models (e.g., MobileNet variants). The second path is Frequency. The same 512×512 image go through a 2D Discrete Fourier Transform to produce a frequency-domain representation.

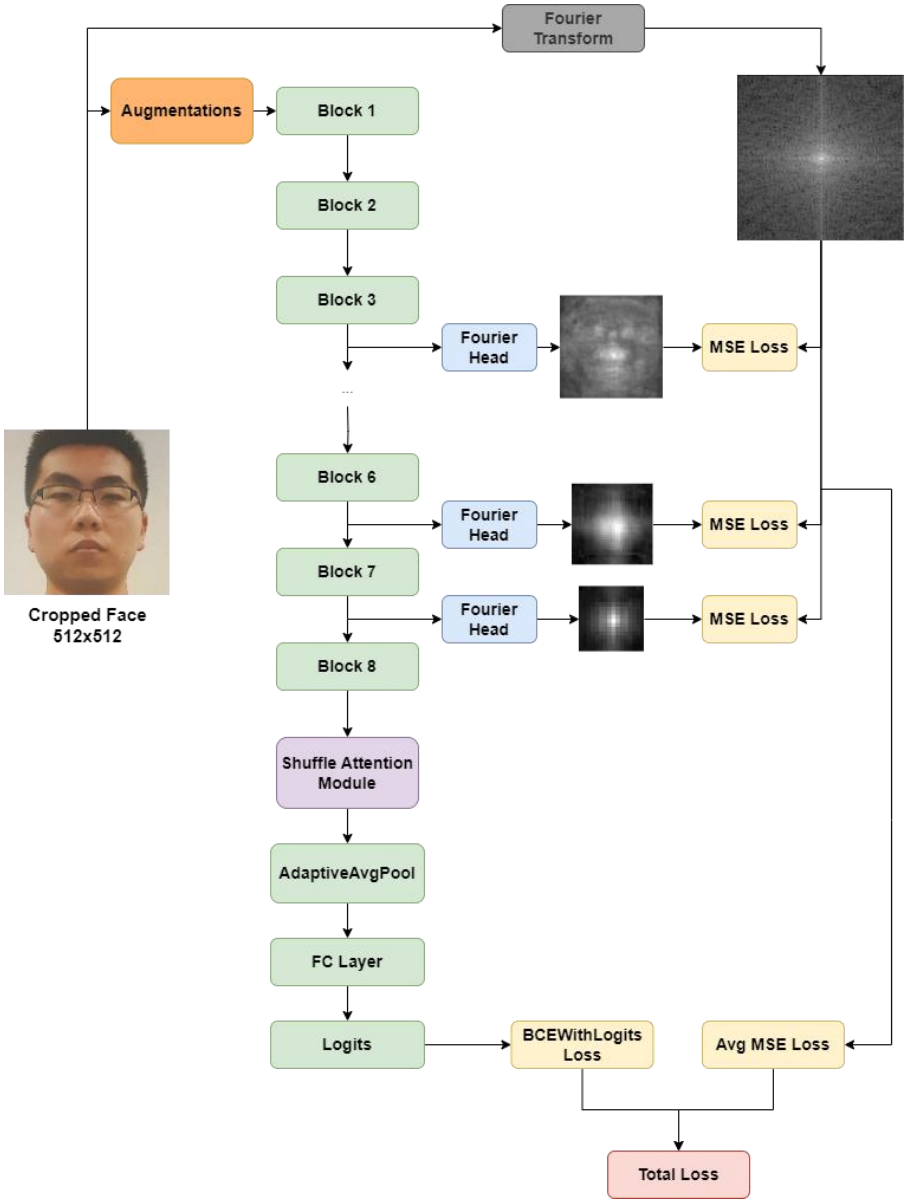

Fig. 1. Architecture of the proposed model.

After Blocks 3, 6, and 7 of the EfficientNetV2-S backbone in Fig. 2, intermediate feature maps X_3, X_6 and X_7, are each passed to a custom "Fourier Head" to reconstruct the ground-truth frequency map F. Each head contains six sequential convolutional layers (with kernel sizes of 3 × 3 or 1 × 1) interspersed with batch normalization and ReLU activation. After the third convolution, a dropout layer with probability $p = 0.5$ is inserted to reduce overfitting. The output of the fifth

convolutional layer is a single-channel feature map $\widehat{F_k} \in \mathbb{R}^{WxH}$ (where k = 3,6,7 indicates the block index), intended to approximate F. The Mean Squared Error loss for each head k is computed as Eq. (1):

$$\mathcal{L}_{MSE,k} = \frac{1}{WH}\sum_{x=1}^{W}\sum_{y=1}^{H}(F_{x,y} - \hat{F}_{k,x,y})^2 \quad (1)$$

After the final block, Block 8, of the EfficientNetV2-S backbone, the resulting feature map $X_8 \in \mathbb{R}^{1280x16x16}$ is processed by a Shuffle Attention module. Shuffle Attention rearranges spatial and channel dimensions for efficient information exchange without additional squeeze-and-excitation blocks. It was decided to choose Shuffle Attention over squeeze-and-excitation or CBAM because SA jointly captures channel and spatial dependencies with minimal parameter overhead and no extra bottlenecks, which is advantageous at the 16×16, 1280-channel stage of EfficientNetV2-S. The output of Shuffle Attention is a refined feature map $X_{att} \in \mathbb{R}^{1280x16x16}$.

Following the Shuffle Attention block, the refined features X_{att} pass through an Adaptive Average Pooling layer, resulting in a single vector $\boldsymbol{z}$. A fully connected layer transforms $\boldsymbol{z}$ into logits $p \in \mathbb{R}^2$ (or a single logit for binary tasks). The classification loss is the binary cross-entropy (BCE) with logits, as in Eq. (2):

$$BCELoss = -\frac{1}{M}\sum_{m=1}^{M}(y_m * \log(\sigma(p_m)) + (1 - y_m) * log(1 - \sigma(p_m))) \quad (2)$$

where, $y_m \in \{0,1\}$ is the label for sample m, p_m is the predicted logit, σ (·) is the logistic sigmoid function, and M is the number of samples in a batch. The total loss $\mathcal{L}_{total}$ combines BCE and the average MSE from the three Fourier heads, as in Eq. (3):

$$\mathcal{L}_{total} = \mathcal{L}_{BCE} + \frac{1}{3}\sum_{k\in\{3,6,7\}}\mathcal{L}_{MSE,k} \quad (3)$$

Thus, by enforcing frequency consistency, the model is encouraged to learn both spatial and frequency-based characteristics pertinent to face spoofing detection.

B. Dataset

All experiments are conducted on the Oulu-NPU [33] dataset illustrated in Fig. 3, which contains 4,950 recorded videos. From each video, 8 frames at indices {10,30,50,70,90,100,120,140} were extracted, totaling approximately 39,000 images. These videos contain:

- Six smartphone cameras (Samsung Galaxy S6 edge, HTC Desire EYE, MEIZU X5, ASUS Zenfone Selfie, Sony XPERIA C5 Ultra Dual, OPPO N3).
- Three recording sessions with varying illumination and backgrounds.
- Two display types and two printer types.
- 55 participants.
- Four standard protocols for training and testing under different environmental and cross-device conditions.

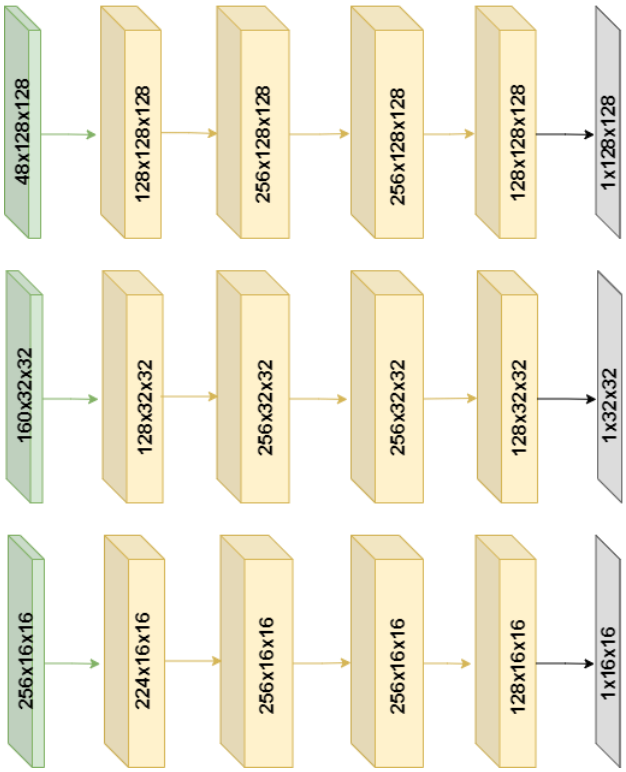

Fig. 2. Custom Fourier heads. From top to bottom: after 3rd block, after 6th block and after 7th block.

C. Experimental Setup

All models are trained and evaluated on a workstation with an NVIDIA RTX 4090 GPU (24 GB VRAM), 64 GB of CPU memory, and 24 CPU cores. The main hyperparameters are: batch size 16, Adam optimizer with weight_decay = 5×10^{-5}, number of epochs 30, ReduceLROnPlateau scheduler with patience = 3, reduce factor = 0.5. The metric used to trigger reduction in the learning rate is APCER, with an initial learning rate: 1×10^{-4}. Preliminary experiments showed that higher learning rates as 10^{-2} or 10^{-3} led to poor convergence, even when the Shuffle Attention block was removed. Consequently, a smaller learning rate with a pre-trained backbone yielded more stable results, suggesting that retaining initialization from EfficientNetV2-S is essential for this task. Each training epoch processes every sample in the dataset once. Early stopping is triggered if no improvement is observed in the validation metrics for more than five epochs, and the best model snapshot based on the validation set is preserved for final testing.

Fig. 3. Dataset samples. From left to right: live face, printed attack and replay attack.

Several transformations are applied to modify image properties while preserving essential features. Horizontal flipping reverses the image along the vertical axis, helping the model generalize to different orientations. Adjustments in contrast, gamma, and brightness alter pixel intensity distributions, simulating variations in lighting conditions. Elastic transformations, grid distortions, and optical distortions introduce non-linear deformations, making the model more resilient to geometric variations. Cutout randomly masks portions of the image, encouraging the model to focus on essential patterns rather than specific regions. Shift, scale, and rotation transformations modify the position and size of objects, aiding in generalization across different viewpoints.

IV. Results

A. Evaluation Metrics

In our evaluation of biometric authentication systems, we use three key metrics: Attack Presentation Classification Error Rate (APCER), Bona Fide Presentation Classification Error Rate (BPCER), and Average Classification Error Rate (ACER).

APCER [Eq. (4)] measures the frequency of falsely accepting an attack attempt. A higher APCER indicates a greater likelihood of incorrectly classifying an attack as a genuine attempt. BPCER [Eq. (5)] represents the proportion of falsely rejected genuine presentations. A high BPCER means that genuine users are more frequently denied access. ACER [Eq. (6)] provides an overall error measurement by averaging APCER and BPCER. Lower ACER values indicate better system performance in distinguishing between genuine and attack presentations.

$$APCER = \frac{Number\ of\ False\ Accepts}{Total\ Number\ of\ Attack\ Presentations} \quad (4)$$

$$BPCER = \frac{Number\ of\ False\ Rejects}{Total\ Number\ of\ Genuine\ Presentations} \quad (5)$$

$$ACER = \frac{APCER+BPCER}{2} \quad (6)$$

B. Experimental Results

1) State-of-the-art comparison: The experimental outcomes were obtained from four distinct protocols designed to evaluate face presentation attack detection under various challenging conditions, as illustrated in Table I.

Protocol I focuses on generalization across environmental variations. Data recorded in three sessions with differing illumination and background settings were partitioned into training, development, and evaluation sets. The proposed method achieved zero errors, with APCER, BPCER, and ACER all measuring 0%. An analysis of the error metrics confirms an exceptional ability to differentiate between authentic and attack samples under fluctuating lighting and background conditions.

Protocol II examines the impact of novel attack artifacts generated by previously unseen print and video-replay attacks. A new print attack and a video-replay attack were incorporated into the test set to assess vulnerability to unconventional spoofing techniques. The approach recorded an ACER of 1.6%, with APCER at 0.4% and BPCER at 2.8%. A detailed evaluation of the figures reveals a robust performance in minimizing false acceptance errors, demonstrating a strong capacity to counteract artifacts introduced by diverse display and printing sources.

Protocol III investigates sensor interoperability using a Leave One Camera Out setup. Video recordings from five smartphones contributed to training and tuning, while recordings from a sixth device provided the testing material. An ACER of $0.8 \pm 0.6\%$ was obtained, with both APCER and BPCER reflecting similarly low error margins. Consistency in performance across various camera sensors confirms a reliable level of operation among different acquisition devices. A careful review of the stability of these metrics confirms the method's applicability in scenarios involving heterogeneous imaging sensors.

Protocol IV presents the most challenging scenario by combining environmental variations, attack types, and sensor diversity. Under these complex conditions, the method achieved an ACER of $1.9 \pm 2.0\%$, outperforming competing approaches that exhibited higher error rates. Error metrics for both APCER and BPCER were noticeably reduced under the simultaneous influence of multiple factors.

2) Contribution of the modules and ablation: To prove that the combination of additional modules works, the different stages by adding modules progressively were tested. In Table II, the EfficientNet-V2-S model achieves APCER of 0.8%, BPCER of 3.8%, and ACER of 2.4%. Introducing a Fourier Heads at the 3rd, 6th, and 7th blocks results in lower error rates, reducing APCER to 0.7%, BPCER to 3.2%, and ACER to 2.1%, suggesting an improvement in attack detection.

Further refinement by integrating the Shuffle Attention module into those blocks leads to the best performance, with APCER dropping to 0.4%, BPCER to 2.8%, and ACER to 1.6%. The consistent reduction in error rates indicates that the combination of Fourier Heads and SA Module contributes to more effective feature extraction, strengthening the model's ability to distinguish genuine faces from spoofing attempts.

3) Dynamic thresholding: Dynamic thresholding is a technique used in biometric security systems to adaptively determine decision boundaries based on varying conditions. Unlike fixed thresholding, which applies a single static threshold across all samples, dynamic thresholding adjusts the classification boundary according to contextual factors such as environmental conditions, device variability, or individual user characteristics. This approach enhances the robustness of biometric systems by mitigating the impact of variations in data distributions and reducing misclassification errors. In presentation attack detection, dynamic thresholding is particularly effective in balancing security and usability, as it allows the system to refine its decision-making process based on real-time inputs.

TABLE II. INDIVIDUAL CONTRIBUTION OF EACH MODULE TESTED ON PROTOCOL II

Method	APCER (%)	BPCER (%)	ACER (%)
EfficientNet-V2-S	0.8	3.8	2.4
EfficientNet-V2-S w/ 3rd, 6th, 7th blocks Fourier Heads	0.7	3.2	2.1
EfficientNet-V2-S+SA Module w/ 3rd, 6th, 7th blocks Fourier Heads	**0.4**	**2.8**	**1.6**

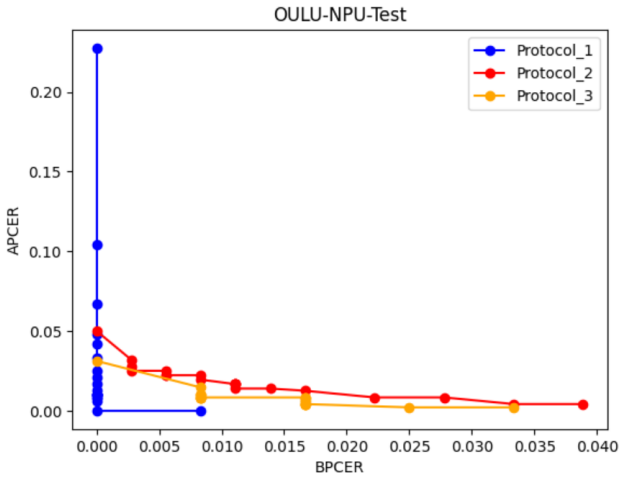

Fig. 4. Dynamic thresholding for 3 protocols.

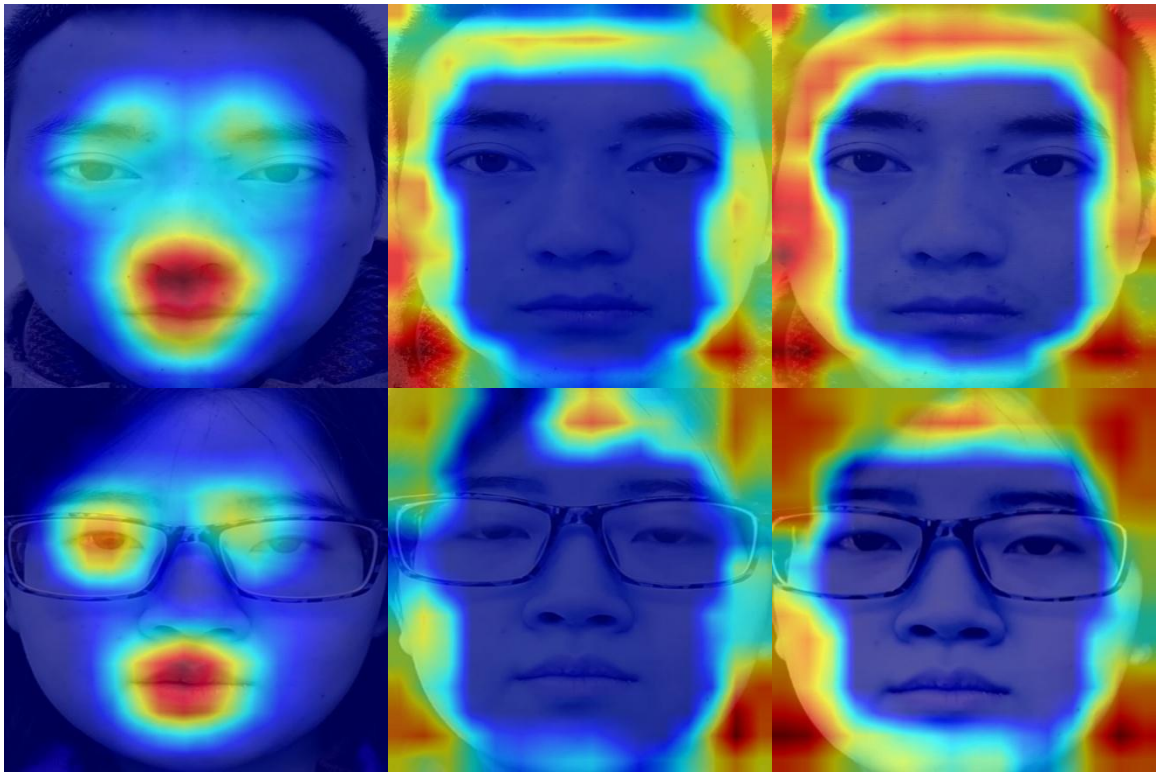
Fig. 4 illustrates the performance of three different protocols under dynamic thresholding on the OULU-NPU-Test dataset. The *x*-axis represents the BPCER, which indicates the proportion of genuine samples misclassified as attacks. The *y*-axis corresponds to the APCER, reflecting the proportion of attack presentations misclassified as genuine. Lower values on both axes indicate a more effective system, as it minimizes both types of errors.

Protocol I, represented in blue, demonstrates a steep decline in APCER as BPCER increases. At very low BPCER values, APCER remains considerably high, indicating that the system is prone to false acceptance when a strict threshold is applied. This pattern suggests that the protocol may be highly sensitive to variations in presentation attacks but suffers from instability when distinguishing bona fide samples. The rapid decrease in APCER as BPCER increases further suggests that a slight relaxation of the threshold significantly improves attack detection, albeit at the cost of increased false rejection.

Protocol II, visualized in red, follows a more stable trajectory, exhibiting a gradual reduction in APCER as BPCER increases. Compared to Protocol I, this approach achieves a more balanced trade-off between false acceptance and false rejection, indicating that it may be more reliable in practical deployment scenarios. The smoother trendline suggests that Protocol II is less sensitive to minor variations in input data, making it a more consistent option for presentation attack detection.

Protocol III, shown in orange, consistently maintains the lowest APCER across the observed BPCER range. The results indicate that this protocol outperforms the other two in minimizing attack presentation errors while maintaining a relatively low bona fide classification error. The stability of the curve suggests that Protocol III achieves a well-calibrated balance between security and accessibility, making it the most effective among the three.

4) Grad-Cam results: Grad-Cam [34] results in Fig. 5 provide an insightful interpretation of the deep learning model's decision-making process for detecting presentation attacks. Heatmaps indicate which facial regions contribute most to classification, revealing distinct patterns across live, print, and video-replay samples.



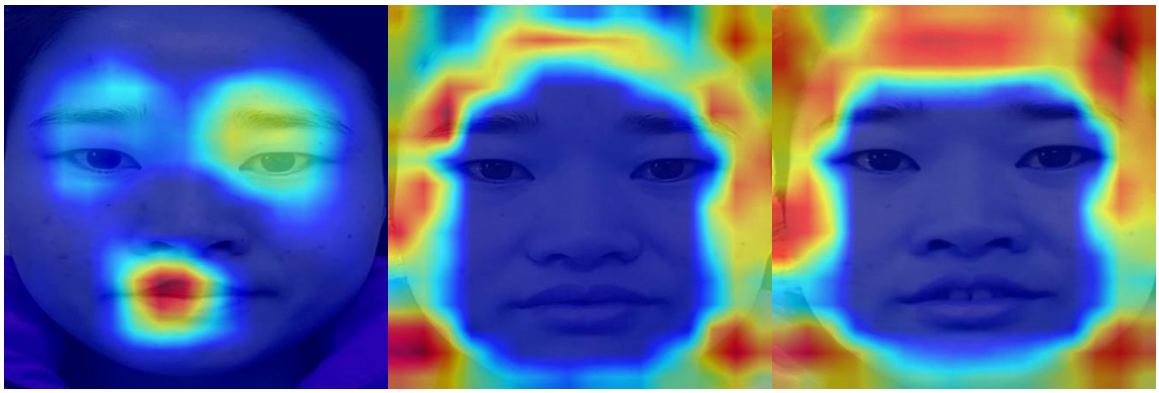


Fig. 5. Grad-Cam results. From left to right columns: live, print, and video-replay.

In live face images, attention is primarily focused around the mouth and nose, where color, texture, and depth cues play a significant role in distinguishing genuine faces. The uniform blue background suggests that the model effectively ignores non-relevant areas, reinforcing its reliance on intrinsic facial details.

For print and video-replay attacks, activations shift towards facial boundaries, where red and yellow highlights suggest the model detects inconsistencies in edges and lighting artifacts. The presence of strong activations around the periphery indicates an effort to identify unnatural textures, which are often present in spoofing attempts.

Images with glasses introduce additional complexity, with attention distributed around the frames and nose bridge. Higher activations in print and video attacks suggest reflections and distortions are key factors in classification.

Variations in heatmap intensity between attack types confirm the model's ability to differentiate genuine and spoofed faces. Attention shifts in predictable ways, aligning with expected signs of presentation attacks, demonstrating the model's capacity to detect spoofing artifacts with reliability.

Overall, the experimental results indicate several advantages of the proposed method. The approach demonstrates flawless performance in the face of environmental variations, maintains a low false acceptance rate against novel attack artifacts, and exhibits consistent error rates across different sensor inputs. When confronted with a combination of challenges, it delivers competitive performance with reduced error metrics, suggesting promising applicability for real-world face presentation attack detection systems.

V. Discussion

The experimental results indicate a promising advancement in face presentation attack detection. Findings confirm that spatial and frequency domain information combined into a unified architecture can significantly improve detection accuracy. The adoption of EfficientNet-V2-S as the backbone, combined with a Shuffle Attention module, has provided a robust framework capable of extracting discriminative features even under adverse conditions. Integration of Fourier heads to reconstruct frequency maps introduces a novel perspective that captures subtle differences between live and spoofed faces, as evidenced by the low error rates across various protocols.

Performance under controlled environmental variations demonstrated strong discrimination between genuine and attack samples. Minimal errors in protocols addressing different illumination and background conditions suggest that the network effectively adapts to changes in lighting and scene composition. Robust outcomes in scenarios involving previously unseen print and video-replay attacks further support the method's aptitude for recognizing unconventional spoof artifacts. Results reveal a capacity for mitigating false acceptance errors, which remains critical in maintaining the integrity of biometric systems.

Interoperability across different sensor types has been confirmed through experiments using diverse smartphone cameras. Consistent performance in sensor-specific testing scenarios reinforces the network's reliability, even when presented with imaging data acquired from heterogeneous sources. Outcomes recorded in the most challenging scenario, where multiple factors were simultaneously present, indicate competitive error metrics that rival or surpass existing methods. Low Average Classification Error Rates across protocols suggest that the design effectively balances the detection of genuine presentations with the rejection of spoof attacks.

Observations imply that the fusion of spatial features and frequency representations addresses limitations inherent in earlier approaches based solely on handcrafted or spatial features. The network's ability to capture minute texture and motion cues, while simultaneously processing global frequency information, contributes to its overall robustness. A careful analysis of the error metrics shows potential avenues for further exploration, particularly regarding the model's performance in real-world environments where attack types may be more diverse.

Limitations related to domain shifts between training and deployment environments persist, inviting additional research to refine generalization capabilities. Future investigations might consider the incorporation of alternative modalities or additional attention mechanisms to further improve detection rates under evolving spoof conditions. Overall, the findings present compelling evidence that integrating modern network architectures with both spatial and frequency domain analysis provides a viable pathway toward more reliable and secure face presentation attack detection systems.

VI. Conclusion

This work demonstrates that explicitly coupling spatial features with frequency-aware supervision yields robust face presentation attack detection across environmental, attack-type, and sensor variations. An EfficientNetV2-S backbone provides an effective accuracy-latency balance for deployment; Fourier heads guide the network to preserve high-frequency spoof cues that are often attenuated in spatial pipelines; and, Shuffle Attention efficiently enhances discriminative regions without heavy computation. Across Oulu-NPU's four protocols, the system attains 0% ACER in Protocol I, 1.6% in Protocol II, 0.8 ± 0.6% in Protocol III, and 1.9 ± 2.0% in Protocol IV, indicating strong generalization to novel artifacts and unseen sensors. Beyond raw numbers, the ablations and interpretability results clarify why the method works: frequency supervision reduces bona-fide rejections under photometric variation, while attention improves rejection of attack-specific structures, together producing consistent gains.

For security-sensitive biometric applications, reducing APCER directly lowers the risk of unauthorized access, and lowering BPCER preserves user experience. The proposed design advances practical anti-spoofing by improving both, without sacrificing throughput or model size, making it suitable for edge and mobile deployments. Performance under severe domain shift can still degrade. Future work will: i) incorporate temporal cues (e.g., rPPG or micro-motion) alongside frequency supervision, ii) explore self-supervised or domain-generalization objectives to handle unseen attacks, and iii) calibrate dynamic thresholds using cohort/device context to further stabilize APCER-BPCER trade-offs in the field.

***Abstract*—In modern software development, achieving high performance increasingly relies on effective parallelization. While much of the existing research has focused on loop-level parallelism, function-level parallelization remains relatively underutilized. Yet, in many real-world applications, function calls serve as natural units of computation that could greatly benefit from concurrent execution. To address this gap, we present an automated tool that analyzes sequential C++ code, identifies independent function calls, and evaluates their suitability for parallel execution. The tool performs three key analyses: dependency analysis to detect function calls, context analysis to understand execution conditions, and workload assessment to determine whether parallelization would result in significant performance benefits. Based on the analysis results, the tool transforms eligible function calls into parallel equivalents without altering the original program logic. Additionally, the tool generates detailed Control Flow Graphs (CFG) for each function in three formats, facilitating further structural analysis. Three benchmark programs were used in experimental testing. The evaluation measured both sequential and parallel execution times, along with the computed performance gain expressed as a percentage reduction in runtime. Results demonstrated the tool's ability to improve execution efficiency and reduce processing time. These outcomes emphasize the tool's role in advancing function-level automatic parallelization. The tool showed notable performance improvements across the three benchmark applications, with the Employee Performance System achieving the highest improvement of 54.6%, followed by the Genomic Sequence System at 48.3%, and the Book Reviews System achieving an improvement of 36.1%. Demonstrating the tool's ability to improve efficiency via automated function-level parallelization.**

Keywords*—Automatic parallelization; function-level parallelization; C++ code optimization; parallel computing; control flow graph; dependency analysis; performance optimization

I. Introduction

Improvements of multi-core processors have increased the adoption of parallel programming among software developers. However, developing parallel code remains a challenging and error-prone task. As a result, automating code parallelization has emerged as a hot topic in high-performance applications research [1]. Available parallelization techniques usually target specific sections of code that are suitable to concurrent execution. Loops are the most common candidates. Loops often contain iterative operations that can be executed in parallel without interdependencies, making them ideal for leveraging multi-core and multi-threaded architectures.

However, there are other code constructs, such as function calls, that can enhance performance and efficiency if they are properly utilized.

By focusing on function calls, parallelization strategies can effectively improve the software applications. However, despite years of research, the automatic parallelization of function calls remains an unresolved problem. Function calls often still require manual parallelization [1].

The motivation for this work stems from several critical challenges in modern software development:

1) Underutilization of parallelization opportunities: While parallelization research has focused heavily on optimizing loops, function calls have received comparatively less attention. This highlights a significant gap in current parallelization research, as function calls provide substantial opportunities for enhancing performance. In many real-world applications, computational workload is distributed across numerous function calls rather than concentrated in loops. For instance, data processing applications often involve multiple independent operations such as data extraction, filtering, aggregation, and statistical analysis, each implemented as separate functions. These functions can potentially execute concurrently without dependencies, yet they remain sequential in most codebases due to the lack of automated transformation tools. Addressing the parallelization of function calls helps improve the efficiency and scalability of code. Nonetheless, developing parallel code or converting certain sequential code to run in parallel is a challenging task that requires significant effort from programmers.

2) Complexity of manual parallelization: The complexities of parallel programming start from the problem definition, as not all problems are suited for parallelization. Programmers must carefully consider different aspects of parallel processing, such as how to distribute the current workload across parallel threads and manage communication between these threads [2]. This manual effort is time-consuming, error-prone, and requires deep expertise in both parallel programming paradigms and the application domain. Developers must analyze data

dependencies, identify race conditions, manage synchronization, and ensure thread safety tasks that significantly increase development time and maintenance costs.

3) Performance demands of modern applications: Contemporary software applications face increasing computational demands. From big data analytics and scientific computing to machine learning and real-time systems, the need for efficient parallel execution has never been greater. C++ programming language is known for its performance and fine-grained control and become an essential component in the development of high-performance computing applications, including those that leverage parallelism [8]. However, the gap between available hardware capabilities and software utilization remains substantial. Many existing sequential C++ applications could benefit significantly from parallelization but lack the resources or expertise for manual transformation.

Our proposed tool was designed to analyze and transform C++ code, which was selected due to its relevance in performance-sensitive software and its rich set of parallelization libraries. This gap is particularly significant because:

- Natural Computation Units: Functions represent natural units of computation with well-defined interfaces and encapsulated logic, making them ideal candidates for parallel execution.
- Coarse-Grained Parallelism: Function-level parallelism offers coarse-grained task parallelism that can better utilize modern multi-core architectures with lower synchronization overhead compared to fine-grained loop iterations.
- Code Maintainability: Parallelizing at the function level preserves code structure and maintainability better than aggressive loop transformations.

This study proposes a fully automated tool that offers an advanced method for analyzing and selecting suitable function calls for parallelization in C++ code, a language with unique structural and concurrency characteristics. The proposed tool integrates static analysis, control flow graph generation, and a lightweight scoring mechanism to identify and transform independent function calls into parallel equivalents using *std::async*. By applying this technique to C++, the tool bridges a critical gap in existing research. This contribution offers practical value for developers working with performance-critical C++ applications, especially in cases where loop-level parallelism is insufficient.

The main contributions of this work are:

1) Comprehensive static analysis framework: We introduce a three-phase analysis approach combining:

- Dependency Analysis: Automatically detects function calls and analyzes their data and control dependencies to ensure correctness of parallel transformations.
- Context Analysis: Evaluates execution contexts to determine parallelization safety and identify functions that can be executed asynchronously without affecting program semantics.
- Workload Assessment: Employs a work potential metric that quantifies computational complexity, enabling prioritization of parallelization candidates.

2) Automated code transformation pipeline: The tool provides end-to-end automation from analysis to code generation:

- Automatically transforms eligible sequential function calls into parallel equivalents using C++ standard library features (std::async, std::future), without requiring manual intervention or code restructuring.
- Preserves original program logic and semantics while introducing parallelism.

3) Visual Analysis and Debugging Support:

- Generates detailed Control Flow Graphs (CFGs) for each function in three formats (DOT, PDF, and TXT), facilitating structural analysis and verification.
- Provides comprehensive reporting of parallelization decisions, including work potential scores and context classifications.
- Enables developers to understand, validate, and fine-tune the automated transformations.

In this study, three benchmark programs were selected to conduct experiments. The experiments aimed at measuring parallel execution time, sequential execution time, and computed performance improvement, representing the percentage reduction in execution time. The results show that our proposed tool successfully enhances performance and reduces execution time. The findings highlight the tool's capability as a step forward in bridging the current gap in automatic parallelization research, particularly at the function-call level.

The structure of this paper is as follows: Section II provides background information; Section III reviews related work; Section IV describes the system architecture and methodology; Section V presents the experimental results and discussion; Section VI evaluates performance improvements; and Section VII concludes the paper.

II. Background

Historically, processor design has focused on combining more advanced features, achieving higher clock speeds and increasing thermal limits. However, the pursuit of enhanced performance remains a necessary demand. This has driven the adoption of integrated multi-processor (multi-core) architectures [3].

However, transistors can't keep getting smaller indefinitely. Nowadays, as transistors become thinner, chip makers aim to manage heat generation and power usage; these are two major challenges. Additionally, performance enhancement techniques like running multiple instructions at the same time have reached their limits.

Due to these problems, the rate of processor performance improvements has started to slow down. In the 1990s, chip performance increased by 60 percent each year, while from

2000 to 2004, this growth slowed to 40 percent annually, with performance only rising by 20 percent.

In fact, improvements in computer performance have essentially resulted from making chips smaller and increasing their number of transistors. According to Moore's Law, this approach has led to faster chip speeds and reduced costs. Instead of making one super powerful core, companies are now creating chips with multiple cores that use less energy and run cooler. Even though these multicore chips might not be as fast as the top single-core ones, they improve overall performance by handling more tasks at the same time [4].

Many modern programs require more computing power than traditional single-threaded computers can offer. In order to achieve better performance, parallel processing is necessary to meet demand. Parallelism allows executing multiple tasks at the same time to solve complex problems in less time. Multicore processing requires running programs on more than one core within a single CPU chip, which is a type of parallel processing. Multicore utilization means using the CPU's multiple cores efficiently [5].

In parallel processing of programs, instructions are split across many processors to run the same program faster than with sequential processing. Some programs that require tasks such as sorting and searching are designed to use parallel processing. Such programs are often tested on large databases. Experimental results using bubble sort and linear search show that sharing the load and utilizing multicore parallel processing make tasks easier and quicker compared to sequential processing. Parallel processing and multicore processing both involve the ability to run code simultaneously on different CPUs, machines, or cores. Multicore processing is designed to perform tasks in parallel. A core can be considered as a small processor within a larger processor. Therefore, optimizing code for multicore processing is closely tied to parallelization [4] [5].

Finding opportunities to run code automatically in parallel is essential for developing efficient programs to run on many multithreaded applications. This area has been researched for many years. Even though hardware provides some fine-grained parallelism, compiler researchers have to develop techniques to automatically convert source code into suitable parallel applications.

With the growing ubiquity of distributed computing, the software industry demands compiler technologies capable of automatically parallelizing software. However, the demand for automatic parallelization in compilers is growing as clusters and other kinds of distributed computing become widely adopted, and CPU technology moves toward higher levels and coarser granular parallelism [6].

Generally, automatic parallelization involves the following three procedures [7]:

- Dependency analysis to identify potential parallelism regions: Carrying out a dependency analysis to identify regions in the code that are capable of parallelization.
- Restructuring the program into blocks that can run in parallel: Organizing the code into number of blocks that can run simultaneously. In this phase, different transformations are applied to maximize the level of parallelism achievable within the code.
- Generating parallel code suitable for specific architectures: Producing parallel code optimized for a particular architecture by assigning program blocks to available processing units and developing appropriate strategies to enable parallelism based on the targeted system.

Building on these core steps, it is essential to consider how specific programming languages, such as C++, support parallelism through built-in features and libraries. C++ supports multithreaded execution through features such as *std::async*, which play a basic role in parallelism [15]. Other standard multithreading features in C++ that simplify parallel programming include [15]:

- *std::thread*: To manually manage the creation and control of new threads of execution.
- *std::async*: Enables asynchronous function execution, with thread management handled automatically by the system.
- *std::future*: Used with *std::async* or *std::promise* to obtain results from asynchronous executions.
- *std::promise*: For sending a value from one thread to another, typically used with *std::future*.
- *std::mutex*: Prevents race conditions by ensuring that only one thread can access shared data at a time.

Several prior studies have extensively discussed the evolution of multicore architectures, the challenges in optimizing code for parallel execution, and the importance of automatic parallelization to utilize modern hardware efficiently. These works collectively emphasize the necessity of transitioning from sequential to concurrent execution, while highlighting fundamental techniques such as dependency analysis, control flow restructuring, and task distribution across cores. They also explore compiler-assisted approaches, parallel programming models, and language-specific solutions that aim to simplify or automate this transition.

While these contributions have laid important groundwork for parallel computing, particularly in loop and object-oriented contexts, there remains a noticeable gap in the automation of function-level parallelization, especially for statically analyzed, general-purpose C++ applications. This study builds on those foundational insights by introducing a tool that automates the detection, analysis, and transformation of independent function calls into parallel equivalents using C++'s native concurrency libraries. The proposed solution requires no manual intervention or external annotations, offering a fully automated pipeline that strengthens the practical adoption of parallelism in real-world C++ systems.

III. Related Works

Parallel computing has recently become more in demand due to the increasing growth of multi-threaded architecture. There are some papers that discuss certain techniques that aim to efficiently transfer a sequential program into a parallel one.

In [9], the authors introduce an approach that uses the concept of futures synthesis for pure method call parallelization. Their approach employs three strategies to achieve automatic parallelization through future synthesis: parallelism analysis, future synthesis, and threshold synthesis. In the future synthesis phase, the proposed system identifies pure method calls and labels them as async expressions. After that, the system conducts a parallelism analysis to determine which async expressions should be executed sequentially to avoid overhead. Finally, threshold synthesis utilizes the results of the parallelism analysis to synthesize predicate expressions for deciding whether a specific pure method call should be executed in parallel or sequentially.

Our tool focuses on C++ and operates at the static level, targeting functions that are independent and computationally intensive. It does not rely on runtime profiling but instead uses a scoring system to identify which functions should be parallelized. While in study [9] the tool is adaptive and runtime-aware, ours offers a lightweight and deterministic transformation pipeline that produces a ready-to-compile parallel version of the original program, making it ideal for users seeking fast and fully automatic optimization.

In [16], authors introduced Lazy-Parallel Function Calls, a compiler-level approach that enables automatic parallelization in imperative languages by combining lazy evaluation semantics with nano-thread scheduling. Their method ensures correctness by leveraging immutability and deferring function execution until results are required, enabling parallelism without altering program behavior. In contrast, our tool targets eager, function-level parallelization in C++ using *std::async*, automatically identifying independent function calls and transforming them for concurrent execution. While their work emphasizes semantic safety, our approach focuses on performance gains in compiled C++ applications.

In [10], the authors present an automatic technique that analyzes code written in the Java programming language to detect method calls that can be parallelized and transform them accordingly. The proposed technique is based on control dependence and data dependence analysis to construct the execution flow and determine accessed data.

APAC [11] is a compiler that converts sequential source code written in the C++ language into task-based parallelized code by inserting special directives. This compiler utilizes the LibTooling library and clang-tools from the LLVM framework. It encapsulates each function body with an OpenMP directive, and each function or method call with an OpenMP statement.

As authors stated in study [12], there are many recursive functions that contain a significant amount of built-in parallelism, but it is not always clearly visible. Thus, a number of studies have been conducted to detect parallelism and utilize it. Mainly by targeting calls that can be executed concurrently. However, some recursive algorithms do not permit the concurrent execution of function calls. According to the authors [12], they examined ways to extract concurrency from specific recursive function calls that are not typically parallelizable by common parallelization methods. Their primary approach involves parallelizing them at a finer level, relying on multi-threaded architecture and a multi-core as the infrastructure. The authors stated that, compared to conventional parallel systems, multi-core systems support a greater degree of fine-grained parallelism by providing thread parallelism and reducing overhead in thread communication.

Autopar [13] is a tool that targets to automatically parallelize certain recursive function calls using analysis of static programs. It detects the recursive functions inside a certain program. After that, it moves to the analysis phase by gathering related information about such functions without the need for rewriting the program or requiring developer involvement. Finally, Autopar introduces the parallel constructs necessary to achieve automatic parallelization. In fact, their tool applies to a specific class of recursive functions that use a divide-and-conquer approach. They tested four benchmarks—bionic, fractal, heat, and knapsack—using their recursive function parallelization tool.

In [14], the proposed tool applies a coarse-grained approach to task parallelism. It utilizes OpenMP directives and inserts them into the input C code. The output program is a multithreaded C code that can use different cores in a shared memory system. The system operates between the compiler and the application. The generated output is compiled just like any ordinary C code. Both the input and output of their proposed tool are source code, making it a source-to-source transformation tool.

In [17], authors propose two optimizations—Last Parallel Call Optimization (LPCO) and its generalization, Nested Parallel Call Optimization (NPCO) which is designed to improve the efficiency of and-parallel logic programming. Their methods restructure parallel goal execution in logic programs to minimize redundant parallel tasks and enable fast backtracking. These techniques are tailored for the control-parallel execution model, where correctness depends on preserving goal dependencies.

Table I presents a comprehensive comparison of the limitations identified in existing approaches and how our proposed tool addresses these gaps.

TABLE I. LIMITATIONS OF EXISTING APPROACHES AND OUR PROPOSED SOLUTION

Aspect	Existing Approaches Limitations	Our Proposed Tool Solution
Language Support	Limited to specific languages: Java [9][10], C [14], logic programming [17]	Comprehensive C++ support with standard library integration (std::async, std::future)
Function Coverage	Restricted to recursive [12][13] or pure methods [9]; ignores general function calls	Analyzes all function types: recursive, non-recursive, member functions, and standalone functions
Analysis Type	Runtime profiling required [9]; limited static analysis [13][14]	Comprehensive static analysis combining dependency, context, and workload assessment
Automation Level	Semi-automated requiring manual refinement [11]; domain-specific [17]	Fully automated end-to-end pipeline from analysis to code generation

IV. METHODOLOGY

This study introduces a tool that addresses an important parallelization technique: unlike loop parallelization, research on parallelizing function calls is limited. This tool offers an improved method for analyzing and selecting the applicable functions for parallelization in C++ code. This tool includes AST traversal and work potential metrics to evaluate computational effort and identify functions with high parallelization possibility. Moreover, it generates detailed control flow graphs as well as an analysis context in order to give valuable insights to programmers who look to optimize program efficiency through parallel execution. As Fig. 1 shows, the tool has five main functionalities, which we will discuss in detail. These main functionalities are: Function Analysis, Context Analysis for Parallelization, Control Flow Graph (CFG) Generation, Work Potential Calculation, and CFG Visualization.

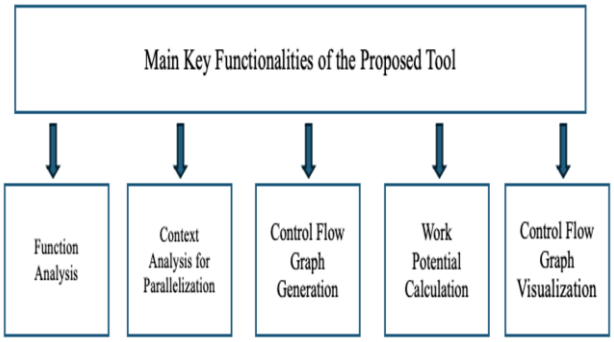

Fig. 1. Five key functionalities of the tool.

Main key functionalities of the proposed tool:

A. Function Analysis

- Parses the C++ source code using Clang's libclang to generate an abstract syntax tree (AST).
- Extracts functions and analyzes each line for function calls to understand dependencies and execution flow.

B. Context Analysis for Parallelization

- Determines whether each function call can be parallelized based on its context (e.g., whether it's inside loops or conditionals).

C. Control Flow Graph (CFG) Generation

- Generates a CFG for each function, including nodes for statements and edges representing control flow.
- Annotates each function call with contextual information (e.g., if part of a loop) to highlight non-parallelizable code.

D. Work Potential Calculation

- Each function is assigned a "work potential" score based on the complexity of its control flow and nested calls.
- Higher work potential indicates a candidate for parallelization, while certain functions (like main) are excluded due to its structural importance.

E. Control Flow Graph (CFG) Visualization

- Uses Graphviz to create a DOT file for each function's CFG, saving it as a DOT, a PDF, and TXT file.
- The CFG graphically represents the control flow, showing how different statements and function calls are interconnected.

Our tool utilizes the use of libclang for parsing C++ code (AST) and graphviz for visualizing CFGs. Libclang is a library that offers tools for parsing and analyzing C++ code. It is part of the LLVM project and enables the generation of an Abstract Syntax Tree (AST). Graphviz, on the other hand, is a visualization software used for creating graphs and diagrams. It is specifically utilized to generate Control Flow Graphs (CFGs), which visually represent the flow of execution within a program, helping programmers understand how different parts of the code are connected and identify potential bottlenecks or parallelization opportunities. Moreover, it usesC++ Parallelization and Synchronization Library (std::async: allows asynchronous function execution and enabling tasks to run concurrently in separate threads). As Fig. 2 illustrates, the tool's architecture starts with C++ source code input, which undergoes scanning to detect functions. This is followed by C++ code analysis, which performs dependency and context analysis generate Control Flow Graphs (CFGs) and calculate work potential. Finally, the tool moves to C++ code generation, completing the process [10].

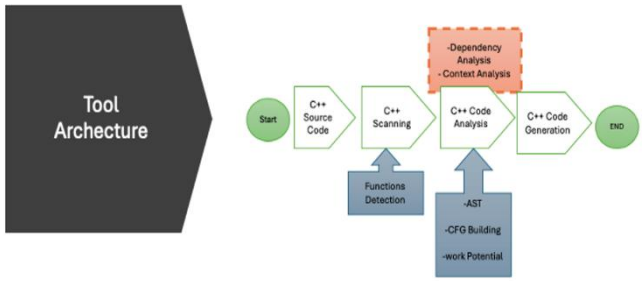

Fig. 2. The proposed tool archeticure.

A detailed description of the tool architecture:

1) Context analysis: This analyzes the context in which function calls occur, meaning it analyzes C++ source code to identify functions that can be parallelized to improve performance.

Tables II and III provide a detailed clarification of the situations under which functions are considered parallelizable and when they are not suitable for parallelization.

2) CFG building: CFG builder drives the analysis of a specified C++ code, generates control flow graphs (CFGs), saves them in a designated output directory, and classifies functions by their work potential (which will be discus1§sed) for advanced parallelization identification.

TABLE II. CONDITIONS FP;OR CONSIDERING A FUNCTION CALL AS POTENTIALLY PARALLELIZABLE

Condition	Reason
Not Part of Control Structure: The function call is not used within the condition of control structures such as if, while, for, or switch statements.	Function calls within conditions are critical for the control flow and may need to be executed sequentially to maintain program correctness
Not Inside Loops: The function call is not located within the body of for or while loops.	Parallelizing function calls inside loops can lead to synchronization issues and may not provide performance benefits due to overhead.
Not Part of Return Statements: The function call is not used directly within a return statement.	The result of the function is immediately required for the return value, so parallelizing it would necessitate waiting for its completion. Attempting to execute such a function asynchronously (in parallel) does not provide any performance improvement and may introduce unnecessary overhead. This essentially cancels out any potential advantages of parallelization in that context.
Not Part of Throw or Assert Statements: The function call is not used within throw or assert statements. **Throw**: is used to signal an exception or error condition. **Assert**: The assert function checks / validates a condition at runtime.	These statements are critical for error handling and program correctness, requiring immediate execution.
Standalone Function Calls: The function call is a standalone statement or assigned to a variable outside the contexts mentioned above.	Such calls can be executed asynchronously without affecting the program's control flow.

TABLE III. CONTEXTS WHERE A FUNCTION CALL IS NOT SUITABLE FOR PARALLELIZATION

Number	Condition
1	Control Structure Conditions
2	Inside Loops
3	Return Statements
4	Part of Throw or Assert Statements

3) Work potential metric: work potential metric is used for prioritizing parallelization by suggesting specific functions to parallelize. This process is based on calculating the computational load or complexity of each function and assigning it a score. Functions with a high work potential score are likely to benefit from parallelization, so the tool identifies and lists these functions at the end of the analysis, see Fig. 3.

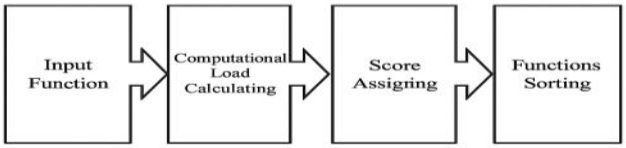

Fig. 3. Steps of the work potential metric.

4) Work potential purposes: The main purposes of the work potential metric are to quantify computational effort because functions with more statements and function calls need more computational processing, and to identify chances for parallelization, as high work potential indicates that a function may benefit from being executed in parallel which enhance performance. However, there are some excluded functions. Certain functions, like main, are excluded from parallelization even if their work potential score is high, because parallelizing the main function does not make sense. It organizes all other functions and controls the entire program's execution, so it is avoided from parallelization.

5) Work potential calculation: Calculation Method for finding Work Potential is a systematic method that requires analyzing C++ functions and utilizing Clang's libclang library to evaluate computational complexity. It uses Clang's libclang library to parse the C++ source code and generate an AST, and traverses each function's AST to analyze its structure. The Work Potential Counter (work_potential) counts statements and function calls. First, it is initialized to zero for each function. Then, it gets incremented for each statement encountered during traversal, as well as for each function call within the function.

V. RESULT AND DISCUSSION

We evaluated the parallelization tool on the BookLibrary benchmark program. BookLibrary, a C++ program, is considered a tool for data processing and analytics of book review data. It includes classes like Review, Book, Author, User, ExtractData, and ExtractDataset in order to organize and analyze information related to books, authors, users, and reviews. Our approach targets programs where function calls account for a significant portion of the workload. Therefore, we chose BookLibrary program because a substantial amount of its sequential work is executed through function calls. BookLibrary.cpp helps users load, analyze, and summarize book review data, with a particular focus on author and user review statistics, enabling insights into authors' popularity and reader engagement. Table IV shows the main components of the C++ code. In addition to those listed in Table IV, there are other functions that calculate and return the most, least, and average-reviewed books, as well as retrieve the most and least-reviewed authors based on their books' reviews.

TABLE IV. OVERVIEW OF MAIN COMPONENTS IN THE C++ CODE

Classification	Description
Data Representation	Review: Represents a review of a book with attributes like book ID and title.
	Book: Represents a book, including its title and list of reviews.
	Author: Represents an author with related books and users.
	User: Represents a user, with a user ID and related reviews.
Data Extraction and Aggregation	ExtractDatase: Reads book and review from CSV files, then stores them .
	ExtractData: create mappings between books and authors, reviews and users, then updates book review data.

A total of 53 functions were automatically extracted from the analyzed source file.

The detected functions range from getBookId, located at line 25, to the main function at the end of the code.

This demonstrates the tool's capability to comprehensively identify and list all functional components for further analysis (see Fig. 4).

Fig. 5 below presents the tool's output that demonstrates the automated generation of Control Flow Graphs (CFGs) for several detected functions such as *getBookId*, *getTitle*, *getScore*, *getText*, *getReview*, and *getPrice*. For each function, the tool produces three distinct representations: DOT, PDF, and an extended TXT format to support both visual inspection and structural analysis. This comprehensive output enables the examination of the internal logic and control dependencies within each function. Additionally, it allows tracing execution paths, detecting redundant operations, and better understanding of the relationships among function calls. Overall, this automated CFG generation provides a valuable foundation for program comprehension, debugging, and performance optimization.

Fig. 7. Selected functions for parallelization.

Fig. 7 shows the final summary and highlights the four functions identified as suitable for parallelization based on their work potential score. The functions extractMostReviewedAuthor, extractLeastReviewedAuthor, and extractAverageReviewedAuthor were selected due to their significant contribution to the overall processing load. Control Flow Graph (CFG) generation was completed for all, and the results were saved in the cfg_output directory.

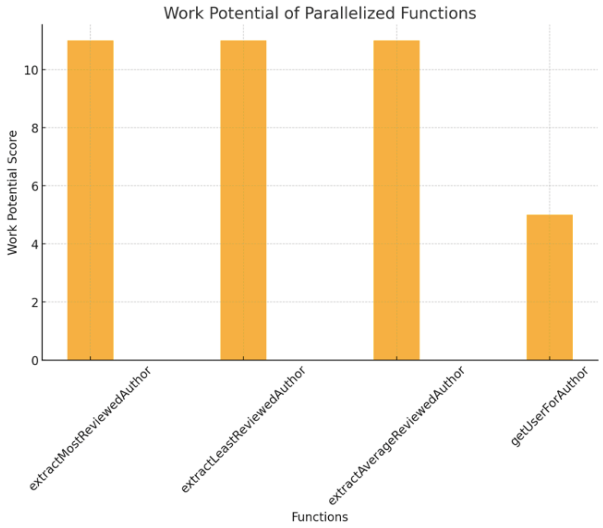

Fig. 8. Work potential scores for selected functions identified for parallelization.

Fig. 8 presents a bar chart showing the work potential scores of selected functions identified by the tool. The x-axis displays four functions: extractMostReviewedAuthor, extractLeastReviewedAuthor,

extractAverageReviewedAuthor, and getUserforAuthor, while the y-axis quantifies their corresponding scores. The first three functions each achieved a high potential score of 11, indicating strong suitability for parallelization due to their computational intensity. In contrast, getUserforAuthor received a lower score of 5, suggesting a relatively smaller parallel workload.

Fig. 9 shows the completion stage of the tool's transformation process, where selected functions have been successfully parallelized. The tool logs the transformed functions: extractMostReviewedAuthor, extractLeastReviewedAuthor, extractAverageReviewedAuthor, and getUserforAuthor and saves the modified source code as books_library_parallelized.cpp.

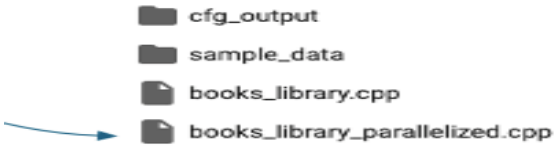

Fig. 9. Generation of the parallelized output file.

Fig. 10. Snapshot of Generated Control Flow Graph (CFG) files.

Fig. 10 presents a visual overview of the directory structure containing the Control Flow Graph (CFG) outputs generated by the tool. For each analyzed function, such as addUser, extractBooks, and extractMostReviewedAuthor, there are many output formats created:

- .dot: the raw DOT graph description format
- .pdf: a visual representation of the control flow
- .txt: a textual report of the CFG
- _extended_ versions: enriched CFGs that include additional semantic or contextual data

These files are organized systematically within the cfg_output directory, enabling developers to inspect the control flow structure of each function in both graphical and textual forms.

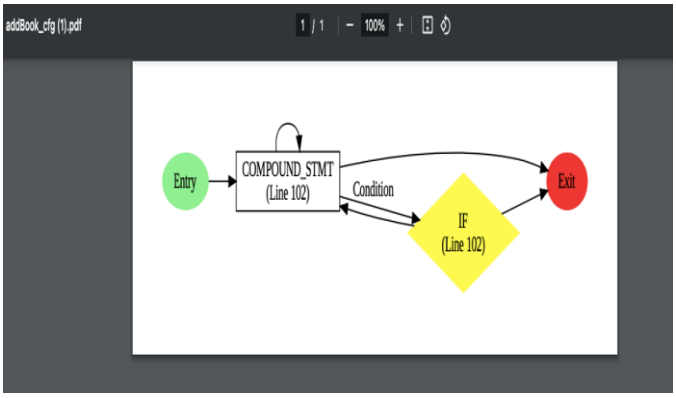

Fig. 11. PDF format Generated Control Flow Graph (CFG) for the Function addBlockFunction.

Fig. 11 presents a sample Control Flow Graph (CFG) generated in PDF format for the selected function addBlock. The graph begins at the Entry node and transitions to a Compound Statement at line 102, indicating a block of grouped instructions. It then leads to a conditional IF node, representing a branching decision in the function's logic.

Fig. 12 represents another format which is DOT format, while Fig. 13 represents TXT format.

VI. Evaluation Metrics

This section presents a performance analysis and evaluation through comparing serial and parallel implementations, with a focus on improvements achieved via function-level parallelization. The evaluation measures the impact of parallelization across three distinct data processing applications:

A. Book Reviews Analysis System

Processes large datasets of book reviews to extract insights such as the most and least reviewed authors, average review counts, and user-specific data. Ideal for evaluating function-level parallelism in data filtering and aggregation tasks.

B. Employee Performance Analysis System

Analyzes performance metrics of employees to compute scores, rankings, and performance categories. Suitable for testing parallel function execution in systems with structured, repetitive computations.

C. Genomic Sequence Analysis System

Performs operations such as sequence matching, frequency analysis, and data summarization on long character sequences. This benchmark represents workloads with high computational demand and pattern processing.

The result shows the impact of parallel execution in enhancing computational efficiency across different workloads and domains.

In this study, the Improvement metric was selected to quantitatively assess the performance gains achieved through function-level parallelization. The metric calculates the percentage reduction in execution time between the original serial implementation and the parallelized version, using the following formula:

$$\text{Improvement}\ (\%) = [(T_{serial} - T_{parallel}) / T_{serial}] \times 100 \quad (1)$$

Where *Tserial* denotes the execution time of the serial version, and *Tparallel* represents the time taken by the parallel implementation.

D. Book Reviews System Performance Metrics

Table V and Fig. 16 compare the execution times of serial and parallel implementations across various functional components. The results demonstrate that all operations benefited from parallelization, with notable reductions in execution time. The most significant improvement was observed in the Data Extraction function, which executed 43.7% faster compared to the serial version. In contrast, the Least Reviewed Author function showed the smallest improvement at 7.9%. Overall, the total execution time was reduced by 36.1%, confirming that the tool effectively enhanced computational performance.

Fig. 17 presents the performance data in a different format, emphasizing the percentage improvement for each function. Represented as a line graph, this view highlights the relative efficiency gains from parallelization.

TABLE V. BOOK REVIEWS SYSTEM PERFORMANCE METRICS (MILLISECONDS)

FUNCTION	SERIAL EXECUTION TIME	PARALLEL EXECUTION TIME	IMPROVEMENT (%)
DATA EXTRACTION	144.615	81.354	43.7
MOST REVIEWED AUTHOR	21.551	14.312	33.6
LEAST REVIEWED AUTHOR	20.847	19.196	7.9
AVERAGE REVIEWED AUTHOR	24.492	17.826	27.2
USER-AUTHOR ANALYSIS	33.697	23.941	29.0
TOTAL EXECUTION	245.205	156.629	36.1

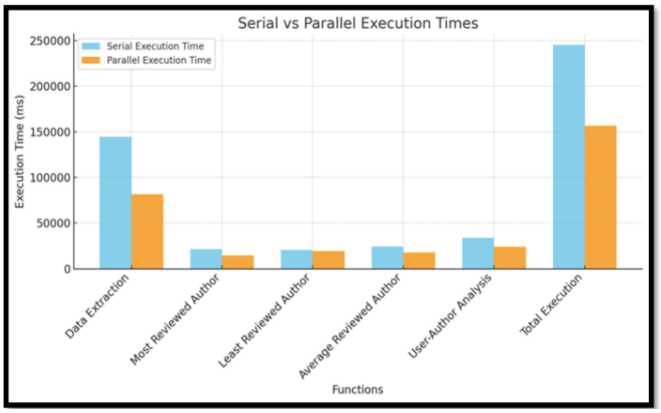

Fig. 16. Serial vs. Parallel execution time (book reviews analysis system).

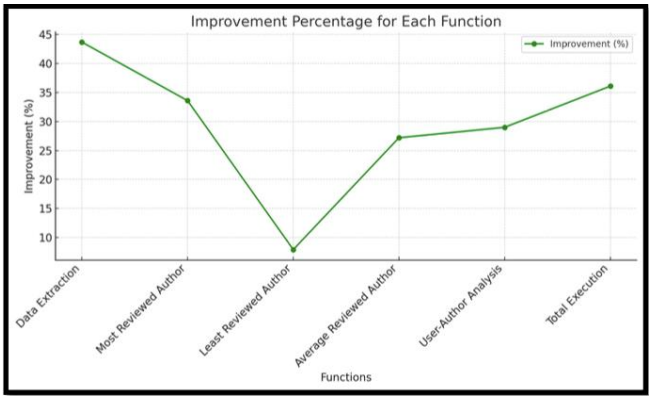

Fig. 17. Improvement percentage across functions (book reviews analysis system).

E. Employee Performance Analysis System

As Table VI, Fig. 18 and Fig. 19 show, most functions show significant performance improvements with parallelization, especially Top Performer Analysis (68.6%) and Data Extraction (64.1%). Skills Analysis also benefited notably (65.8%). However, Department Performance slightly worsened (-3.8%), due to the overhead and the low parallel potential. Overall, total execution time was reduced by 54.6%.

TABLE VI. EMPLOYEES' PERFORMANCE SYSTEM PERFORMANCE METRICS (MILLISECONDS)

Function	Serial Execuion Time	Parallel Execution Time	Improvement (%)
Data Extraction	107.516	38.627	64.1
Top Performer Analysis	34.632	10.873	68.6
Department Performance	17.922	18.611	-3.8
Skills Analysis	485	166	65.8
Department Statistics	15.850	11.766	25.8
Total Execution	176.405	80.049	54.6

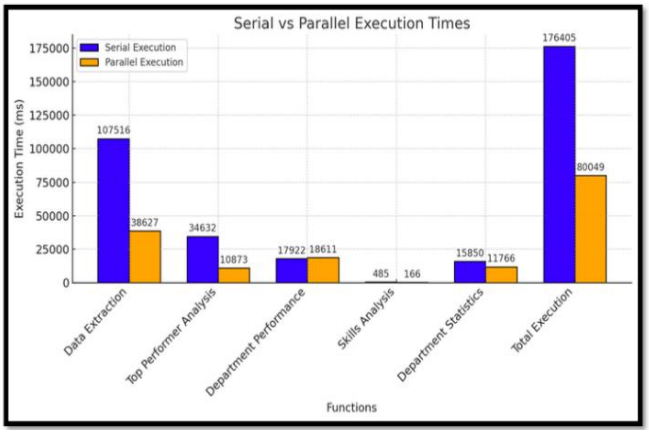

Fig. 18. Serial vs. Parallel execution time (employee performance analysis system).

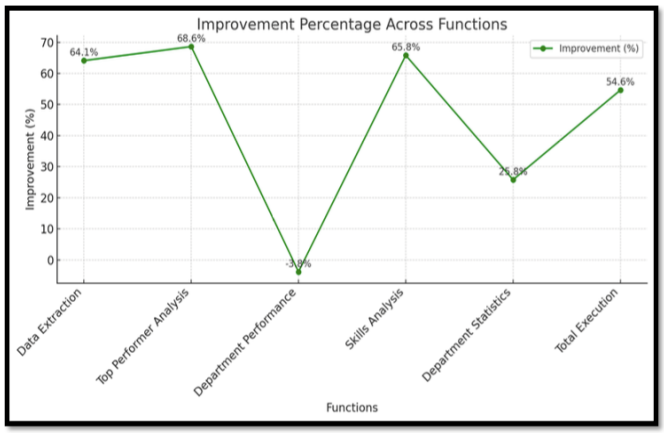

Fig. 19. Improvement percentage across functions (employee performance analysis system).

F. Genomic Sequence Analysis System

As Table VII, Fig. 20 and Fig. 21 show, Data Extraction achieved the highest gain at 54.6%, followed by GC Content Analysis (37%) and Coverage Analysis (30.6%). Overall, total execution time was reduced by 48.3%.

TABLE VII. GENOMIC SEQUENCE SYSTEM PERFORMANCE METRICS (MILLISECONDS)

Function	Serial Execuion Time	Parallel Exection Time	Improvement (%)
Data Extraction	118.149	53.670	54.6
GC Content Analysis	63.252	39.827	37.0
Coverage Analysis	1.902	1.320	30.6
Total Execution	183.303	94.820	48.3

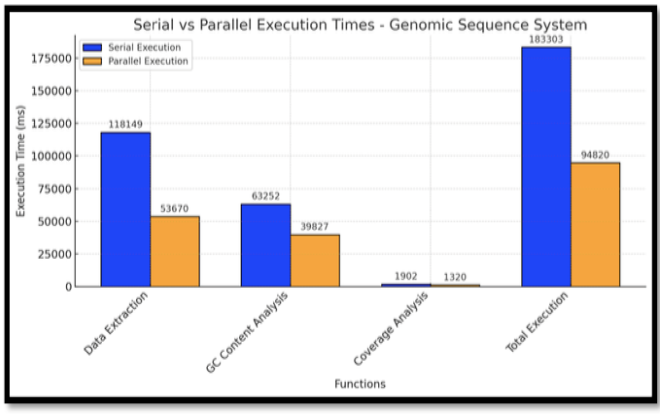

Fig. 20. Serial vs. Parallel execution time (genomic sequence analysis system).

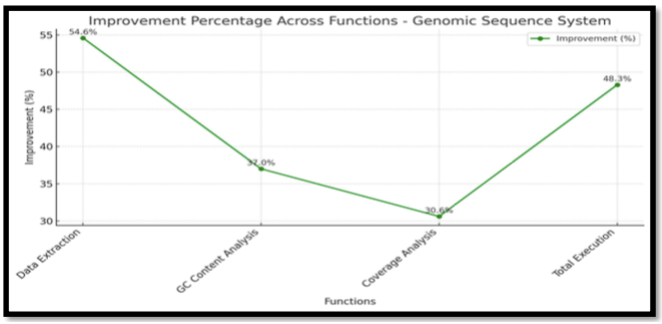

Fig. 21. Improvement percentage across functions (genomic sequence analysis system).

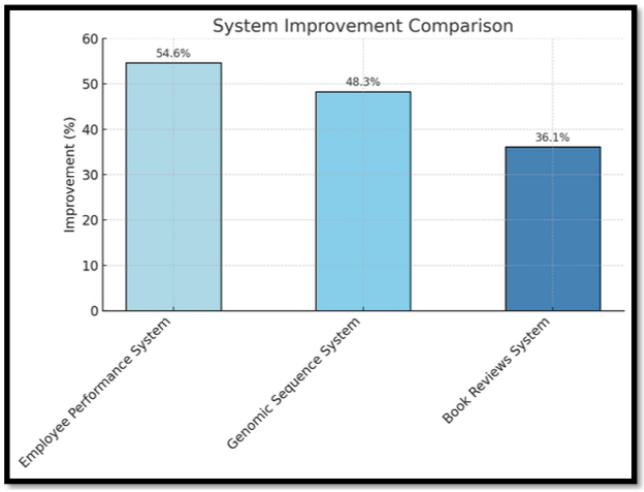

Fig. 22. System improvement comparison.

Fig. 22 presents a bar chart that shows a final comparison of overall system performance improvements achieved through parallelization. The Employee Performance System showed the highest gain at 54.6%, followed by the Genomic Sequence System at 48.3%, while the Book Reviews System achieved a more modest improvement of 36.1%. This confirms the tool's effectiveness across varied application domains. Table VIII provides a comparative overview of our tool and several related tools. The comparison is based on key attributes like parallelization method, analysis type (static or runtime), and language support. [9][12][13].

TABLE VIII. COMPARISON OF OUR TOOL WITH RELATED TOOLS ACROSS VARIOUS ATTRIBUTES

Work	Lazy-Parallel Function Calls	Automatic Parallelization of Pure Method Calls	Fine-Grained Recursive Parallelim	Autopar	OurTool
Languag Focus	Java, C#	Java	C	ANSI C Codes	C++
Optimization Target	Lazy evaluation, closures, nano-threads	Pure method calls	Special Recursive Function Calls	Special Recursive Function Calls	C++ source code, Function calls based on three fundament-al analyses
Automation Level	Partial; compiler-assisted	automatic, compiler-based	automatic	automatic	Fully automated pipeline: detects, classifies, and transforms suitable function calls to parallel equivalents.

VII. CONCLUSION

This paper presents a tool that successfully automates function-level parallelization in C++ through a pipeline that includes dependency analysis, context analysis, and workload assessment. These analyses enable the identification of independent, high-workload function calls that can be safely parallelized without modifying the original program logic. The tool also generates detailed Control Flow Graphs (CFGs) for each function in DOT, PDF, and TXT formats, offering valuable insights into code structure and parallelization opportunities.

Experimental evaluations on three benchmark programs demonstrated consistent improvements in execution efficiency. Performance gains were particularly notable in compute-intensive functions such as data extraction and analysis. The Employee Performance System achieved the highest

improvement at 54.6%, followed by the Genomic Sequence System at 48.3%, and the Book Reviews System at 36.1%. These results confirm the effectiveness of the tool's analysis and transformation strategies and underscore its contribution to advancing practical, automated parallelization in performance-critical C++ applications.

Future work may focus on extending the tool's capabilities to support parallelization of additional code constructs and the use of MPI, enabling distributed-memory execution and scalability across multiple nodes. Such an extension would broaden the tool's applicability beyond shared-memory systems.

Unveiling the Drivers of Consumer Purchase Intention in Short-Form Video Marketing

Merisa Syafrina, Viany Utami Tjhin
Information System Management Department, Bina Nusantara University, Jakarta, Indonesia 11480

***Abstract*—Short-video features on e-commerce platforms have become a key driver of social commerce, enhancing user engagement and purchase intention. However, user reviews of Shopee Video reveal issues such as disruptive autoplay, limited content control, and unintuitive navigation. While prior studies have examined engagement and satisfaction in general e-commerce, limited research has explored how short-video features within social commerce influence purchase intention through user engagement. This study fills that gap by analysing the factors affecting consumer behaviour toward Shopee Video. Sentiment analysis of user reviews identified common dissatisfaction themes, followed by a quantitative survey of 300 Shopee Video users in Indonesia. Using Structural Equation Modeling with the Partial Least Squares (SEM-PLS) approach, the results show that user engagement significantly mediates the relationship between system quality, information quality, and technology adoption and usefulness on purchase intention. The study extends existing models to the social commerce context, providing insights for optimizing short-video features to strengthen engagement and conversion.**

Keywords*—*E-commerce; purchase intention; Shopee Video; social commerce; SEM-PLS

I. Introduction

Digital technology occupies an increasingly important position in today's world and has undeniably become a strong social trend closely linked to the need for building a sustainable future [1]. Technological advances have also brought new changes, where most people now rely on internet-based digital technology in their daily lives [2]. According to the Indonesian Internet Service Providers Association (APJII), in 2024 around 221 million out of 278 million Indonesians were already connected to the internet, with 89.44% of the population accessing it through smartphones. The use of the internet for business has also continued to rise since the 1980s, reaching its peak in the 1990s with the emergence of online marketplace platforms, commonly known as electronic commerce (e-commerce), such as eBay and Amazon [3]. Since then, business activities involving interactions between companies and clients have become faster through the internet, which enables transactions to be conducted online. Moreover, access to e-commerce platforms has become increasingly easier anytime and anywhere through mobile devices [4]. E-commerce has also made a positive impact on Indonesia's economy by increasing entrepreneurs' income while providing convenience for consumers to shop without leaving their homes [5].

In Indonesia, several e-commerce platforms have grown rapidly, such as Shopee, Tokopedia, Bukalapak, Lazada, and Blibli. Among them, Shopee is the most popular platform [6]. Launched in Singapore in 2015 as a Consumer-to-Consumer (C2C) marketplace, Shopee has since evolved into a hybrid model combining C2C and Business-to-Consumer (B2C) through Shopee Mall, which hosts well-known brand stores. According to SimilarWeb data in early 2024, Shopee ranked first among e-commerce competitors in Indonesia with 235.9 million visits in February 2024, followed by Tokopedia (100.3 million), Lazada (45.03 million), and Blibli (24.15 million). The consistently high user interest has driven Shopee to continuously innovate with new features and strategies to maintain its competitive advantage, including discount programs, Shopee coins, diverse payment options, campaigns, livestreaming, and other interactive features [7][8]. In line with this innovation, Shopee introduced Shopee Video, a short-video feature that allows users to better understand products before purchasing. Based on a 2024 Ipsos study on online shopping experience and satisfaction, Shopee was rated as the e-commerce platform with the best short-video experience, outperforming TikTok Shop, Tokopedia, and Lazada. The survey involved 506 respondents across Indonesia aged 17–45, with an equal proportion of men and women. Shopee ranked first with a 61% satisfaction level in short-video experiences, followed by TikTok Shop (18%), Tokopedia (10%), and Lazada (9%) [9].

The short-video format on platforms like Shopee typically ranges from 10 to 30 seconds, allowing users to quickly understand product information, making the experience both efficient and engaging [10]. Such videos often cover diverse topics, from fashion trends and lifestyle entertainment to commercial advertisements and e-commerce promotions [11]. By adopting features like Shopee Video, Shopee has embraced the social commerce model, which integrates social interaction with online shopping [12]. This model allows users to actively engage through liking products, writing reviews, sharing experiences, and directly purchasing within the same platform [13]. Consequently, short-video formats with embedded purchase links and livestreaming functions have become integral to modern consumption behavior, enabling consumers to "socialize while shopping" more conveniently.

However, despite its popularity, user feedback reveals persistent challenges. Preliminary scraping of 33 Apple App Store reviews and 288 Google Play Store reviews identified complaints such as disruptive autoplay, lack of content control, and unintuitive navigation [14]. These usability and content-related issues highlight that, while short-video features may enhance engagement, they may not always lead to positive purchase intentions.

Previous studies on e-commerce and short-video use have primarily focused on user satisfaction, entertainment value, and technology adoption in general contexts [15][16]. Yet, few have examined how short-video features within social commerce ecosystems influence purchase intention through user engagement mechanisms. Moreover, existing research tends to overlook how system quality, information quality, and technology adoption interact with engagement behavior to shape consumer purchase decisions. This represents a critical research gap, as the short-video environment involves richer interaction, user-generated content, and algorithm-driven experiences that differ from conventional e-commerce.

Therefore, this study aims to fill that gap by extending the Delone and McLean Information System Success Model with constructs relevant to short-video and social commerce contexts, specifically integrating User Engagement as a mediating variable between System Quality, Information Quality, Technology Adoption and Usefulness, and Purchase Intention. This theoretical contribution provides empirical validation of established models in a new cultural and technological setting, Indonesia's social commerce landscape and offers practical insights for optimizing user-centered video-based features.

A. Research Questions

Based on the above background, this study formulates the following research questions:

- What factors influence consumer purchase intention in using the short-video feature (Shopee Video) on the Shopee e-commerce platform?
- How does each of these factors affect consumer purchase intention toward using the short-video feature (Shopee Video) on the Shopee e-commerce platform?

B. Research Objectives

The primary objective of this study is to identify and analyze the factors that influence consumer purchase intention in using the short-video feature, Shopee Video, within the Shopee e-commerce application. Specifically, the research aims to examine how system quality, information quality, and technology adoption and usefulness shape consumer behavior through the mediating role of user engagement. By understanding these relationships, the study seeks to provide empirical insights into how short-video features within social commerce platforms can effectively enhance user engagement and drive purchasing decisions. Furthermore, this research intends to contribute both theoretically and practically by enriching the literature on social commerce and offering recommendations for e-commerce practitioners and digital marketers to optimize short-video features that align with user expectations and behavioral patterns.

II. Literature Review

A. Previous Studies on Short-Video Features in E-Commerce and Social Commerce

Short videos have become a dominant form of digital content, shaping consumer behavior and purchase decisions across e-commerce and social commerce platforms. In e-commerce, short videos combine product information with engaging visual storytelling, facilitating consumers' transition from browsing to purchasing. Studies emphasize that product demonstration and visual aesthetics in short videos significantly influence viewing duration, suggesting that engaging content enhances user attention. However, this study primarily focused on content attributes, not on user satisfaction or behavioural outcomes such as purchase intention [17].

Similarly, explored persona perception and shared values in social commerce short videos, showing that perceived user identity positively affects purchase intention. Yet, their model emphasized social factors and emotional alignment, overlooking system and information quality aspects that may affect user experience. Other works, examined dual pathways of rationality and affection in livestream-based social commerce but focused more on social atmosphere than on short-video usability or engagement mechanisms [14].

In contrast, recent research analysed impulse buying and consumer satisfaction on platforms like Shopee Video and TikTok [18][19]. Their findings reinforced the role of emotional arousal and pleasure but were limited to Generation Z samples and focused on impulsive or affective responses rather than sustained engagement or cognitive evaluation. Hence, while prior studies have demonstrated the persuasive potential of short videos, most focus on content and emotional stimuli, leaving a gap in understanding how system, information, and technological aspects interact with user engagement to drive purchase intention especially within e-commerce-based short videos like Shopee Video rather than purely social platforms.

B. System Quality

System quality, as conceptualized in the DeLone and McLean Information Systems Success Model, measures the reliability, stability, and responsiveness of an information system. Prior studies showed that platform performance and seamless navigation influence user stickiness and loyalty in video-based platforms like Douyin [20]. However, such works focused on overall experience rather than feature-specific performance. In the Shopee Video context, system quality directly affects how users interact with video features, such as playback stability, autoplay control, and navigation. This study extends the D&M model by validating system quality's effect within a video-based social commerce feature, emphasizing its indirect influence through user engagement.

C. Information Quality

Information quality involves the relevance, clarity, and trustworthiness of product-related information conveyed through short videos. It was found that vivid and diagnostic content enhances trust and user commitment [20], whereas other research identified that well-demonstrated product information sustains user attention [17]. Despite these insights, few studies have analyzed how information quality in short-video formats shapes purchase intention through user engagement, particularly when users rely on short, rapidly consumed content for decision-making. This study contributes by examining how users perceived information quality from

Shopee Video influences engagement and subsequent purchasing behavior.

D. Technology Adoption and Usefulness

Technology adoption and perceived usefulness reflect how users evaluate the benefits and ease of using a system. Past research widely applied the Technology Acceptance Model (TAM) to e-commerce contexts, linking perceived usefulness to satisfaction and purchase intention. However, few have tested it within the social commerce short-video environment, where users engage through both consumption and interaction. By integrating TAM into the D&M model, this study explores how perceived usefulness affects engagement behavior and purchase intention in short-video shopping experiences, expanding TAM's application into a more interactive and entertainment-driven context [16].

E. User Engagement

User engagement represents users' cognitive, emotional, and behavioral involvement with digital platforms. It has been shown to mediate the relationship between technology-related factors and purchase behaviors [19]. Yet, many prior studies treated engagement as an outcome variable rather than a mediating mechanism. This study positions user engagement as a key mediator that links system quality, information quality, and technology adoption to purchase intention. By doing so, it extends the D&M model into the social commerce domain, offering a novel perspective on how interactive engagement behaviors transform functional experiences into purchase motivation.

F. Purchase Intention

Purchase intention reflects consumers' willingness to buy after interacting with a product or feature. Prior works confirmed that emotional and social cues affect purchase intention in social commerce, but few have tested its determinants in video-based e-commerce platforms like Shopee [14], [21]. This study addresses that gap by combining both technical (system and information quality) and behavioral (engagement, usefulness) factors, presenting an integrated view of how short-video experiences influence purchase decisions.

III. Methodology

A. Research Design

This study employs a quantitative research design to examine the factors influencing purchase intention through user engagement in the context of Shopee Video, a short-video feature within a social commerce platform. The research process began with a preliminary study using scraping methods to identify user complaints and behavioral patterns from app store reviews. Insights from this stage were used to formulate the research problem and develop a conceptual model grounded in relevant theories and previous studies. Data were collected using an online survey distributed via social media to Shopee Video users in Indonesia aged 17 years and above see Table V and Table VI of Appendix A.

To visualize the research process, the overall study workflow is illustrated in Fig. 1, titled Overall Study Process. This diagram outlines the sequential steps: (1) preliminary research through sentiment analysis of app reviews, (2) literature review and model development, (3) hypothesis formulation, (4) data collection, (5) data analysis using SEM-PLS and (6) conclusion.

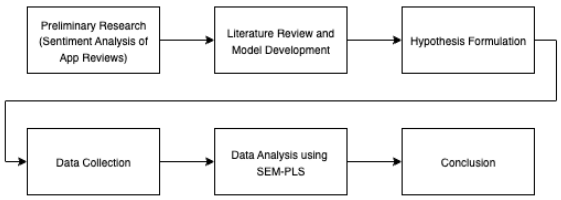

Fig. 1. Overall study process.

B. Sampling

The population of this study comprises Shopee users in Indonesia who have used the Shopee Video feature. Because the exact number of active users of this feature is unknown, a simple random sampling technique was applied. Data were collected using a structured online questionnaire distributed through Google Forms. Following the recommendation of previous study for SEM-PLS, the minimum sample size was determined to be 300 respondents calculated as 100 times the number of independent variables [22] (system quality, information quality, and technology adoption & usefulness) to ensure adequate statistical power and model reliability.

$$n\ minimum = \text{Independent variables} \times 100$$

$$= 3 \times 100$$

$$= 300 \text{ respondents}$$

C. Research Model

The conceptual model (Fig. 2) integrates constructs from the Information Systems Success Model (DeLone & McLean, 2016), the Technology Acceptance Model (TAM), and literature on social commerce engagement. The model posits that System Quality (SQ), Information Quality (IQ), and Technology Adoption & Usefulness (TAU) influence Purchase Intention (PI) both directly and indirectly through User Engagement (UE) as a mediating variable.

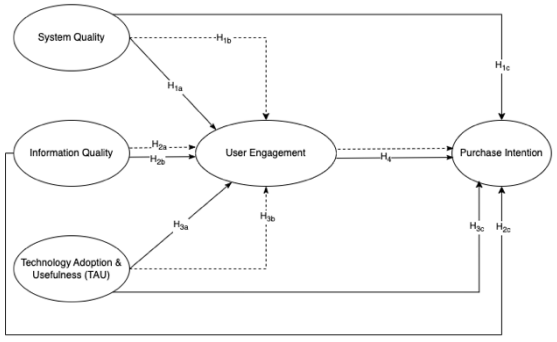

Fig. 2. Conceptual model.

This framework extends prior studies in social commerce by emphasizing the mediating role of engagement a dimension often underexplored in existing models. While prior research examined satisfaction or perceived usefulness, this study highlights engagement as a psychological bridge connecting quality perceptions and behavioral outcomes. Thus, the proposed model not only replicates but also advances previous

approaches by integrating user-centered insights from short-video platform behavior.

D. Research Hypotheses

Based on the conceptual model, the following hypotheses were formulated:

H1a: System Quality significantly influences User Engagement.

H1b: System Quality significantly influences Purchase Intention through User Engagement.

H1c: System Quality significantly influences Purchase Intention.

H2a: Information Quality significantly influences User Engagement.

H2b: Information Quality significantly influences Purchase Intention through User Engagement.

H2c: Information Quality significantly influences Purchase Intention.

H3a: Technology Adoption & Usefulness significantly influences User Engagement.

H3b: Technology Adoption & Usefulness significantly influences Purchase Intention through User Engagement.

H3c: Technology Adoption & Usefulness significantly influences Purchase Intention.

H4a: User Engagement significantly influences Purchase Intention.

E. Data Analysis

Data were analyzed using the Structural Equation Modeling-Partial Least Squares (SEM-PLS) approach with SmartPLS software. This method was chosen for its suitability in testing complex models with multiple constructs and mediating relationships. The analysis process included validity and reliability testing, evaluation of R-square values, and hypothesis testing to confirm the proposed relationships among variables.

F. Study Limitations

This study is limited to the short-video feature, Shopee Video, within the Shopee e-commerce application. The research focuses on users in Indonesia who have experience using Shopee Video, specifically those aged 17 years and above and residing in the Jabodetabek area. The study adopts and modifies research models from previous studies related to system quality, information quality, technology adoption, user engagement, and purchase intention. As such, the findings may not be fully generalizable to users in other regions or to different e-commerce platforms. Future research could expand the sample coverage and explore comparative analyses across multiple social commerce platforms to strengthen external validity.

IV. Data Analysis

A total of 310 questionnaires were collected. After data verification, 10 responses were excluded for not meeting the screening requirement of being Shopee Video users. Therefore, 300 valid responses were used for further analysis. This yields a usable response rate of 96.77 percent, confirming that the sample is adequate for the subsequent statistical analysis using the SEM-PLS method.

A. Gender Distribution

Among the 300 respondents, 222 were female (74 percent) and 78 were male (26 percent). This finding indicates that Shopee Video's user base is predominantly female, consistent with broader trends in Indonesia's e-commerce and social commerce platforms, where women are generally more active in online shopping and product content interaction.

B. Age Group Distribution

Respondents were categorized into four generational groups based on Indonesia's Internet Service Provider Association (APJII) classification. Generation Z (aged 17–27 years) constituted the largest group with 195 respondents (65 percent), followed by Millennials aged 28–43 years (69 respondents or 23 percent), Generation X aged 44–58 years (26 respondents or 8.6 percent), and Baby Boomers aged 59 years and above (10 respondents or 3.33 percent). The dominance of Generation Z and Millennials highlights the strong engagement of younger users with short-video content and their increasing role in shaping social commerce trends in Indonesia.

C. Occupation

The largest occupational group consisted of private employees (121 respondents or 40.33 percent), followed by students (111 respondents or 37 percent), freelancers (25 respondents or 8.33 percent), homemakers (18 respondents or 6 percent), and entrepreneurs (13 respondents or 4.33 percent). A small proportion were government employees (8 respondents or 2.66 percent) and retirees (4 respondents or 1.33 percent). These results show that the Shopee Video audience includes a wide range of working adults and students, groups most familiar with digital shopping and short-form video consumption.

D. Duration of Shopee App Usage

Most respondents had used the Shopee application for more than three years (222 respondents or 74 percent). Sixty respondents (20 percent) had used it for one to three years, while smaller groups reported six months to one year (11 respondents or 3.66 percent) and less than six months (7 respondents or 2.33 percent). This long-term usage pattern indicates that respondents have sufficient experience to assess the quality and usefulness of the Shopee Video feature.

E. Primary Purpose of Using Shopee Video

When asked about their main purpose for using Shopee Video, 188 respondents (62.66 percent) indicated that they primarily watch product reviews or user testimonials. Seventy-one respondents (23.66 percent) use it to find special promotions, 28 respondents (9.33 percent) seek shopping inspiration, and 13 respondents (4.33 percent) use it mainly for entertainment. This suggests that Shopee Video is primarily perceived as an informational and promotional tool rather than an entertainment platform.

F. Product Categories Frequently Purchased via Shopee Video

Fashion-related items, including apparel, footwear, and accessories, were the most frequently purchased products (176 respondents or 58.66 percent). The next categories were Beauty and Personal Care (62 respondents or 20.66 percent), Electronics and Gadgets (26 respondents or 8.66 percent), Home Goods and Furnishings (21 respondents or 7 percent), Food and Beverages (11 respondents or 3.66 percent), and Books and Magazines (4 respondents or 1.33 percent). The dominance of fashion products aligns with prior research showing that visual and aesthetic content in short videos strongly influences consumer purchase intention in lifestyle-related product categories.

G. Familiarity with Shopee Video

Most respondents reported being familiar (170 respondents or 56.66 percent) or very familiar (110 respondents or 36.66 percent) with the Shopee Video feature, while only 20 respondents (6.66 percent) indicated limited familiarity. The high familiarity rate suggests that users have substantial exposure to the feature and can provide reliable feedback regarding system quality, content relevance, and engagement experience.

H. Frequency of Shopee Video Usage Per Week

The highest frequency category was one to two times per week (135 respondents or 45 percent), followed by less than once a week (67 respondents or 22.33 percent), three to five times per week (67 respondents or 22.33 percent), and more than five times per week (31 respondents or 10.33 percent). These results indicate moderate engagement levels among users, suggesting that Shopee Video functions as a complementary browsing and product discovery tool rather than a daily-use feature.

I. Average Viewing Duration Per Session

Most respondents (136 respondents or 45.33 percent) reported spending less than five minutes per session watching Shopee Videos. Another 129 respondents (43 percent) viewed content for five to fifteen minutes, while smaller groups watched for sixteen to thirty minutes (24 respondents or 8 percent) or more than thirty minutes (11 respondents or 3.66 percent). This short viewing duration aligns with the core purpose of short-video features in e-commerce: delivering concise, product-oriented content that facilitates rapid purchase decisions.

J. Purchase Behavior via Shopee Video

A large majority of respondents (265 respondents or 88.33 percent) had made at least one purchase after watching Shopee Video, whereas 35 respondents (11.66 percent) had not. This finding underscores the feature's effectiveness in converting viewers into buyers, reinforcing its strategic importance in Shopee's social commerce ecosystem. The high purchase conversion rate also validates the relevance of this study's research model, which investigates how system quality, content quality, technology adoption, and user engagement jointly influence purchase intention.

K. Outer Model Analysis

1) Validity test: Validity was assessed using the Average Variance Extracted (AVE) to confirm the degree to which each construct explains its corresponding indicators. An AVE value above 0.5 indicates that the construct captures more than half of the variance of its observed variables. The initial analysis showed all constructs exceeded the 0.5 threshold, although three indicators SQ2 (System Stability), IQ5 (Freedom from Tribe, Religion, Race, and Inter-group relations-related elements), and PI4 (Seeking Additional Product Information) had loading values below 0.7. These items were removed to improve the model's validity. After the refinement, the AVE values for all constructs improved and met the validity requirement as seen in Table I.

TABLE I. DISCRIMINANT VALIDITY

Variable	Average Variance Extracted (AVE)	Conclusion
System Quality	0.562	Valid
Information Quality	0.698	Valid
Technology Adoption and Usefulness	0.715	Valid
User Engagement	0.654	Valid
Purchase Intention	0.762	Valid

Following indicator elimination, the AVE values were System Quality (0.562), Information Quality (0.698), Technology Adoption and Usefulness (0.715), User Engagement (0.654), and Purchase Intention (0.762). As all values exceeded 0.5, the constructs demonstrated convergent validity.

2) Reliability test: Reliability measures the internal consistency of items within each construct. The Composite Reliability (CR) and Cronbach's Alpha coefficients were used for this purpose, with values above 0.7 considered acceptable. The results in Table II indicate that all constructs met or exceeded the reliability threshold. System Quality (CR=0.774; α=0.748), Information Quality (CR=0.857; α=0.855), Technology Adoption and Usefulness (CR=0.810; α=0.802), User Engagement (CR=0.901; α=0.894), and Purchase Intention (CR=0.850; α=0.842). This confirms that each construct consistently measures its intended concept. Fig. 3 shows Cronbach's alpha representation.

TABLE II. RELIABILITY TEST RESULT

Variable	Composite Reliability	Cronbach's Alpha	Conclusion
System Quality	0.774	0.748	Reliable
Information Quality	0.857	0.855	Reliable
Technology Adoption and Usefulness	0.810	0.802	Reliable
User Engagement	0.901	0.894	Reliable
Purchase Intention	0.850	0.842	Reliable

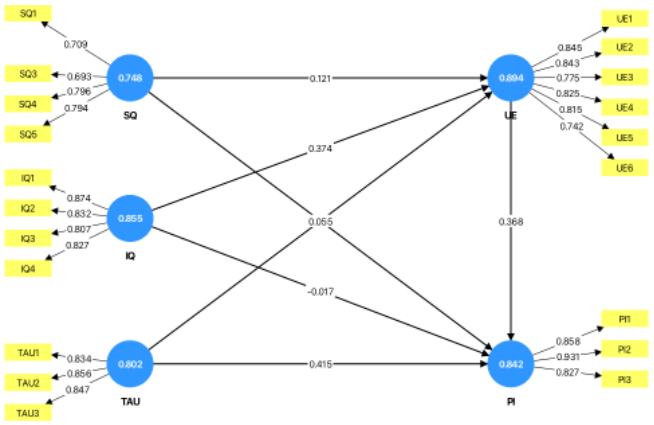

Fig. 3. Cronbach's alpha representation.

In summary, the measurement model fulfils all validity and reliability requirements (Fig. 4), supporting its use in further structural model testing.

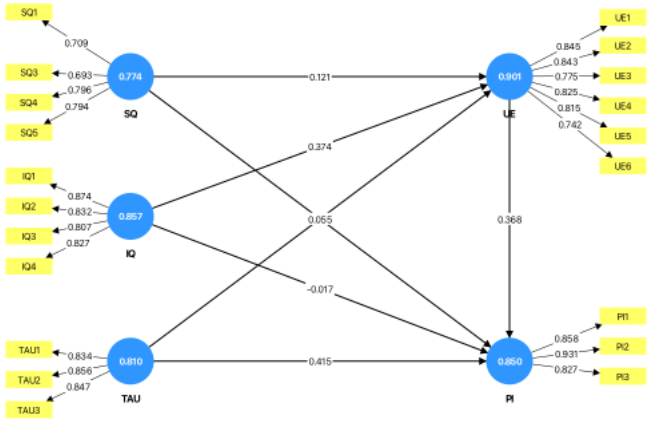

Fig. 4. Composite reliability representation.

L. Inner Model Analysis

1) The coefficient of determination or R-square (R²): The R-square (R²) test measures how well independent variables explain the variance in dependent variables. R² values of 0.67, 0.33, and 0.19 indicate substantial, moderate, and weak levels of explanatory power, respectively. As shown in the results, the R² value for User Engagement was 0.514, indicating that 51.4 percent of its variance is explained by System Quality, Information Quality, and Technology Adoption and Usefulness. Meanwhile, the R² value for Purchase Intention was 0.409, meaning that 40.9 percent of the variance in purchase intention is explained by the independent variables and the mediating role of user engagement. As shown in Table III, R² values fall within the moderate category, suggesting that the model adequately captures the factors influencing user engagement and purchase intention toward Shopee Video.

TABLE III. R-SQUARE RESULTS FOR LATENT VARIABLES

Variable	R²	R² Adjusted	Conclusion
User Engagement	0.514	0.507	Moderate
Purchase Intention	0.409	0.403	Moderate

M. Hypothesis Test

The hypothesis testing was conducted using the bootstrapping method in SmartPLS with a significance level of 0.05. The analysis shown in Table IV examined both direct and indirect effects among constructs based on the proposed hypotheses (H1a–H4a).

TABLE IV. HYPOTHESIS TESTING RESULT

Correlation	O	T	P	Conclusion
SQ → UE	0.121	1.550	0.121	Not Significant
SQ → UE → PI	0.045	1.552	0.128	Not Significant
SQ → PI	0.055	0.965	0.335	Not Significant
IQ → UE	0.374	5.326	0.000	Significant
IQ → UE → PI	0.138	4.028	0.000	Significant
IQ → PI	-0.017	0.239	0.811	Not Significant
TAU → UE	0.218	2.624	0.009	Significant
TAU → UE → PI	0.080	2.335	0.020	Significant
TAU → PI	0.415	6.129	0.000	Significant
UE → PI	0.368	6.446	0.000	Significant

H1a: System Quality → User Engagement. The path from System Quality to User Engagement yielded a t-value of 1.550 (p=0.121), which is below the critical value of 1.97. Therefore, H1a is rejected, indicating that system quality does not significantly influence user engagement. This suggests that although users may expect stable and responsive performance, engagement is more strongly driven by other factors such as information relevance and perceived usefulness.

H1b: System Quality → Purchase Intention (Mediated by User Engagement). The indirect effect of System Quality on Purchase Intention through User Engagement produced a t-value of 1.552 (p=0.128), leading to the rejection of H1b. This result implies that system stability alone does not meaningfully enhance purchase intention, even when user engagement is considered as a mediator.

H1c: System Quality → Purchase Intention. The direct relationship between System Quality and Purchase Intention was not significant (t=0.965, p=0.335). Thus, H1c is rejected. These findings collectively indicate that while a technically sound system is necessary, it is insufficient on its own to drive purchasing behavior in short-video-based e-commerce environments.

H2a: Information Quality → User Engagement. Information Quality had a significant positive impact on User Engagement, with a t-value of 5.326 (p=0.000). Therefore, H2a is accepted. High-quality, accurate, and relevant information increases user trust and stimulates interaction, making it a key driver of engagement within Shopee Video.

H2b: Information Quality → Purchase Intention (Mediated by User Engagement). The indirect path from Information Quality to Purchase Intention via User Engagement was also significant (t=4.028, p=0.000), supporting H2b. This indicates that users who perceive the video content as informative and

trustworthy are more likely to form positive engagement experiences that enhance their purchase intentions.

H2c: Information Quality → Purchase Intention. The direct relationship between Information Quality and Purchase Intention was not significant (t=0.239, p=0.811). Thus, H2c is rejected. Although users value accurate information, it primarily affects purchase intention indirectly through engagement rather than as a standalone factor.

H3a: Technology Adoption and Usefulness → User Engagement. Technology Adoption and Usefulness had a significant positive effect on User Engagement (t=2.624, p=0.009). Therefore, H3a is accepted. This shows that users who perceive Shopee Video as easy to use and beneficial are more likely to engage with it actively.

H3b: Technology Adoption and Usefulness → Purchase Intention (Mediated by User Engagement). The mediating effect of User Engagement on the relationship between Technology Adoption and Usefulness and Purchase Intention was significant (t=2.335, p=0.020), leading to the acceptance of H3b. This indicates that user engagement acts as a crucial psychological mechanism that translates perceived usefulness into actual purchase intention.

H3c: Technology Adoption and Usefulness → Purchase Intention. A strong and significant direct relationship was found between Technology Adoption and Usefulness and Purchase Intention (t=6.129, p=0.000). Thus, H3c is accepted. This result reinforces the importance of technological ease and functional benefits in encouraging consumers to make purchases after watching short videos.

H4a: User Engagement → Purchase Intention. User Engagement significantly influenced Purchase Intention (t=6.446, p=0.000), confirming H4a. This highlights that engagement—through emotional connection, interaction, and trust—plays a pivotal role in shaping consumers' buying decisions within the Shopee Video ecosystem.

Overall, six hypotheses were supported while four were rejected. The significant pathways emphasize the mediating role of user engagement and the strong influence of technology adoption and information quality on consumers' purchasing decisions.

V. Result and Discussion

A. Result

The structural model analysis using SEM-PLS confirmed that not all hypothesized relationships among the five variables were statistically significant. Among the tested variables, Information Quality, Technology Adoption and Usefulness, and User Engagement demonstrated strong positive relationships, while System Quality showed no significant effect on engagement or purchase intention. Specifically, Information Quality had a significant positive influence on User Engagement ($\beta = 0.374$, $p < 0.001$), while Technology Adoption and Usefulness positively affected both User Engagement ($\beta = 0.218$, $p = 0.009$) and Purchase Intention ($\beta = 0.415$, $p < 0.001$). Furthermore, User Engagement itself exhibited a strong positive influence on Purchase Intention ($\beta = 0.368$, $p < 0.001$), confirming its mediating role within the model.

Conversely, System Quality showed no significant direct or indirect effect on either User Engagement or Purchase Intention ($p > 0.05$). This suggests that users' perceptions of system performance—such as loading speed or interface stability—do not substantially drive engagement or purchasing behavior in this context. Instead, informational value and perceived usefulness of technology play a more central role in motivating user behavior within Shopee Video.

The coefficient of determination (R^2) analysis revealed that 51.4% of the variance in User Engagement and 40.9% of the variance in Purchase Intention could be explained by the model. These values indicate a moderate explanatory power, suggesting that while the included variables capture key behavioral influences, other contextual or psychological factors may also contribute to purchase intentions in social commerce environments.

B. Discussion

The findings reinforce the growing importance of social commerce mechanisms, where content-driven engagement mediates the relationship between technology and consumer behavior in shaping online purchase decisions.

The insignificant relationship between System Quality and both User Engagement and Purchase Intention contrasts with earlier studies which emphasized that system performance and stability enhance user experience [23] [24]. This discrepancy may be explained by contextual differences. In the Indonesian market, users of Shopee Video often access the platform via mobile networks with varying speeds, making system performance a baseline expectation rather than a differentiating factor. Hence, engagement depends less on system reliability and more on the perceived usefulness and emotional appeal of content.

In contrast, Information Quality significantly influenced User Engagement, who found that clear, vivid, and diagnostic product information builds consumer trust and stimulates emotional connection [21]. In the Shopee Video context, users engage more with videos that demonstrate authenticity and provide practical product insights rather than polished promotional material.

Technology Adoption and Usefulness emerged as a strong driver of both engagement and purchase intention. Where perceived usefulness directly enhances behavioral intention in video-based commerce [25]. This finding highlights that users engage with short-video features when they perceive them as convenient and beneficial tools for informed decision-making.

The mediating role of User Engagement confirms its theoretical significance as a psychological bridge between functional attributes and behavioral outcomes. Engagement amplifies the effects of both Information Quality and perceived usefulness, validating prior assertions that engagement is not merely a behavioral response but a motivational mechanism in social commerce [21].

Collectively, these findings reveal that purchase intention in short-video–based e-commerce is driven more by content

relevance and perceived value than by technical system attributes. This insight contributes to extending the Information Systems Success Model (DeLone & McLean) into a social commerce context by introducing user engagement as a central mediating construct that links technology-related and information-related factors to behavioral intention.

C. Practical Implications

1) Enhancing information quality: Shopee should prioritize creating authentic, concise, and informative product videos to build user trust and engagement. Seller education and AI-based content moderation could improve diagnosticity and reduce misleading claims.

2) Optimizing engagement features: Interactive elements such as real-time comments, likes, or loyalty rewards can deepen emotional and behavioral engagement, which directly influences purchase decisions.

3) Strengthening technology adoption: Beyond improving system performance, Shopee can emphasize usability, convenience, and personalization in its short-video interface to reinforce the perceived usefulness of the feature.

4) Cultural context adaptation: Platform strategies should reflect Indonesian users' preference for social validation and relatable content, as engagement is shaped by social interaction rather than pure functionality.

VI. Conclusion and Recommendation

A. Conclusion

This study investigated the key factors influencing consumer purchase intention in using short-video features within e-commerce platforms, focusing on Shopee Video as a case study. The results demonstrate that Information Quality, Technology Adoption and Usefulness, and User Engagement significantly influence consumer purchase intention, while System Quality does not show a significant direct or mediated effect.

User Engagement plays a crucial mediating role, linking informational and technological attributes to purchase behavior. This highlights engagement as the primary psychological pathway through which users translate perceived value into actual purchase intentions. Overall, the study extends the Delone and McLean Information Systems Success Model by validating its applicability in a social commerce context, where interactive and emotionally engaging features redefine how consumers experience online shopping.

Beyond Shopee, this research establishes that short-video features in e-commerce platforms shape consumer behavior through engagement and perceived usefulness rather than purely through technical performance. It underscores that the success of video-based commerce depends on the balance between informational authenticity, emotional resonance, and social interactivity.

B. Recommendation

1) Cross-platform comparison: Future research should examine similar short-video commerce features across different e-commerce platforms (e.g., TikTok Shop, Lazada) to compare user engagement patterns and validate model generalizability across markets.

2) Extended variables: Future models could incorporate constructs such as Perceived Ease of Use, Perceived Enjoyment, or Information Security to capture broader behavioral and psychological dimensions influencing purchase intention.

3) Longitudinal analysis: Conducting longitudinal studies would help track evolving user engagement and purchase behavior as short-video features mature, offering insights into retention and loyalty over time.

4) Integration of social and emotional dimensions: Further exploration into social influence, trust, and community identity could deepen understanding of emotional factors that drive engagement in video-based commerce.

5) Practical innovation: Shopee and similar platforms can leverage these insights to refine engagement algorithms, improve recommendation relevance, and create personalized video experiences that foster stronger purchase intentions and long-term user loyalty.

Acknowledgment

APPENDIX A

Table V presents the constructs used in the research model, along with their corresponding measurement codes, indicators, and reference sources. This table serves as a structured overview that links each latent variable with its specific measurement items, providing clarity and transparency regarding the operationalization of the constructs.

TABLE V. CONSTRUCT AND MEASUREMENT ITEMS

Variable	Indicators	Code	References
System Quality	Short video loading speed	SQ1	[21]
	System stability	SQ2	[26]
	Minimal disruptions (glitch/lag)	SQ3	
	Ease of navigation within the short video feature	SQ4	[19]
	System responsiveness to user interactions	SQ5	[26]
Information Quality	Clarity of product information in short videos	IQ1	[19]
	Consistency of messages conveyed by video creators	IQ2	[21]
	Trust in product claims made in short videos	IQ3	[21]
	Completeness of the product information presented	IQ4	[26]
Technology Adoption & Usefulness	Ease of using the short video feature	TAU1	[19]
	Usefulness of product demonstrations in short videos	TAU2	[19]
	Trust in the seller's credibility influencing purchase decisions	TAU3	[21]
User Engagement	Emotional connection with the seller	UE1	[26]
	Sense of direct interaction through the video	UE2	[26]

	Level of trust built through engagement in short videos	UE3	[21]
	Frequency of interactions in short videos (like)	UE4	[21]
	Frequency of interactions in short videos (share)	UE5	
	Frequency of interactions in short videos (comment)	UE6	
Purchase Intention	Intention to purchase after watching short videos	PI1	[19]
	Willingness to consider purchasing after watching short videos	PI2	[21]
	Likelihood of seeking more product information after watching short videos	PI3	[19]

Table VI provides the complete set of questionnaire items used in the survey. Each construct item was measured using a 7-point Likert scale (1 = Strongly Disagree, 2 = Disagree, 3 = Somewhat Disagree, 4 = Neutral, 5 = Somewhat Agree, 6 = Agree, 7 = Strongly Agree) to capture respondents' level of agreement with each statement. In addition, demographic and experience-related questions were included to support descriptive analysis but were not incorporated into the structural model.

TABLE VI. SURVEY QUESTIONS

Section	Survey Questions	Response Options / Scale
Profile Questions	Gender	Male, Female
	Age	17-27 years, 28-43 years, 44-58 years, ≥59 years
	Occupation	Students, Private Employee, Government Employee, Freelancer, Entrepreneur, Homemaker, Informal Sector Worker (e.g. online driver, daily laborer, etc.), Retirees
	Duration of Shopee App Usage	<6 months, 6 months – 1 year, 1-3 years, >3 years
Information about User Experience of Shopee Video	Primary Purpose of Using Shopee Video	Product reviews or user testimonials, shopping inspiration, find special promotions, entertainment
	Product Categories Frequently Purchased via Shopee Video	Fashion, beauty and personal care, electronics and gadget, home and furnishings, food and beverages, books and magazines
	Familiarity with Shopee Video	Very familiar, familiar, less familiar
	Frequency of Shopee Video Usage per Week	<1 time, 1-2 times, 3-5 times, >5 times
	Average Viewing Duration per Session	<5 minutes, 5-15 minutes, 16-30 minutes, >30 minutes
	Purchase Behavior via Shopee Video	Yes, No
Construct Measurement Items	Shopee Video loads quickly without having to wait long.	7-point Liket scale
	Shopee Video rarely experiences technical issues when I use it. Issues or errors include the app not opening, videos not playing smoothly, or features not responding.	
	Shopee Video runs smoothly without interruptions such as stuttering or lag.	
	I can easily find and watch the videos I want on Shopee.	
	When I like, comment on, or share a video link, the Shopee Video system responds quickly.	
	The content on Shopee Video clearly explains the product details.	
	The information presented in Shopee Video is consistent from beginning to end.	
	I believe that the product claims in Shopee Video are accurate and truthful.	
	Shopee Video provides complete information about the products being sold.	
	Shopee Video is free from elements of ethnicity, religion, race, and inter-group issues, violence, or inappropriate content.	
	I find the Shopee Video feature easy to use and understand.	
	Shopee Video helps me understand how a product works or how to use it.	
	I tend to trust sellers on Shopee Video when they recommend products.	
	I feel emotionally connected to the sellers on Shopee Video.	
	When watching Shopee Video, I feel as if I am directly interacting with the seller.	

	I trust the products more after engaging in interactions on Shopee Video (for example, through comments or likes).	
	I often interact on Shopee Video by giving likes.	
	I often interact on Shopee Video by leaving comments.	
	I often interact on Shopee Video by sharing video links with others.	
	I immediately purchase a product after seeing the content on Shopee Video.	
	I feel motivated to buy a product after watching Shopee Video.	

Integrative Hybrid Metaheuristic Algorithm for Hyperparameter Optimisation in Pre-Trained Convolutional Neural Network Models (I-HAHO)

Nazleeni Samiha Haron, Jafreezal Jaafar, Izzatdin Abdul Aziz, Mohd Hilmi Hasan, Muhammad Hamza Azam
Department of Computing, Universiti Teknologi Petronas, Perak, Malaysia

***Abstract*—Hyperparameter optimisation (HPO) remains a fundamental challenge in deep learning, especially for pre-trained convolutional neural networks (CNNs). While pre-trained models reduce the computational burden of training from scratch, their effectiveness depends heavily on tuning parameters such as learning rate, batch size, dropout, weight decay, and optimizer type. The search space of hyperparameters is large, nonlinear, and highly dataset-dependent, making traditional techniques like grid search, random search, and Bayesian optimisation insufficient. This paper introduces I-HAHO, an Integrative Hybrid Metaheuristic Algorithm that combines Artificial Bee Colony (ABC) for global exploration and Harris Hawks Optimisation (HHO) for local exploitation. A diversity-based phase-switching mechanism dynamically regulates exploration and exploitation, allowing the optimiser to adapt its search behaviour to varying landscape conditions. Experiments on CIFAR-10, CIFAR-100, SVHN, and TinyImageNet with three CNN architectures (VGG16, ResNet50, EfficientNet-B0) demonstrate up to 6.9% accuracy improvements. I-HAHO enhances adaptability, scalability, and robustness for hyperparameter tuning.**

Keywords*—Hyperparameter Optimisation (HPO); Convolutional Neural Networks (CNNs); Artificial Bee Colony (ABC); Harris Hawks Optimisation (HHO); Hybrid Metaheuristic Algorithm

I. Introduction

Convolutional Neural Networks (CNNs) have become indispensable in modern computer vision, enabling breakthroughs in tasks such as classification, object detection, and medical imaging. Pre-trained models like VGG16, ResNet50, and EfficientNet-B0, trained on large datasets such as ImageNet, provide transferable feature representations that accelerate training and improve performance, especially when target datasets are small [1], [2].

Despite their success, the performance of pre-trained CNNs is highly sensitive to hyperparameter settings such as learning rate, batch size, dropout rate, and optimizer type. Selecting these parameters is challenging because the search space is high-dimensional, non-convex, and dataset-dependent, making manual tuning and traditional search strategies inefficient. Techniques such as grid search and random search require extensive computational effort, while Bayesian optimisation often struggles with scalability and mixed-variable types [3], [4].

To address these challenges, metaheuristic algorithms have been widely adopted for hyperparameter optimisation [5], [6]. Their ability to balance exploration (global search for promising regions) and exploitation (local refinement near good solutions) makes them well-suited for navigating complex search spaces [7],[8]. Among these, the Artificial Bee Colony (ABC) and Harris Hawks Optimisation (HHO) algorithms have shown promise in deep learning optimisation tasks [9], [10]. However, both algorithms have limitations: ABC often lacks strong exploitation, while HHO may converge prematurely in multi-modal landscapes [11], [12].

This motivates the development of hybrid approaches that combine complementary strengths. In this study, we propose I-HAHO (Integrative Hybrid ABC-HHO), which unifies ABC's exploration capability with HHO's exploitative refinement. A dynamic phase-switching mechanism guided by population diversity regulates the balance between exploration and exploitation, allowing the optimiser to adapt its search behaviour to varying landscape conditions, preventing premature convergence and preserving diversity [13], [14].

The main contributions of this paper can be summarized as follows. First, we propose a novel hybrid metaheuristic algorithm, I-HAHO, which integrates the global exploration strength of ABC with the local exploitation capability of HHO to achieve robust hyperparameter optimisation for pre-trained CNNs. Second, we introduce a diversity-driven dynamic phase-switching strategy that adaptively balances exploration and exploitation during the optimisation process, preventing premature convergence and preserving solution diversity. Third, we provide an extensive evaluation of I-HAHO across multiple benchmark datasets, including CIFAR-10, CIFAR-100, SVHN, and Tiny ImageNet, applied to three widely used CNN architectures: VGG16, ResNet50, and EfficientNet-B0. Finally, we demonstrate that I-HAHO achieves substantial accuracy improvements of up to 6.9% compared with grid search, random search, Bayesian optimisation, and standalone metaheuristics, highlighting its effectiveness, scalability, and generalizability for deep learning optimisation tasks.

The remainder of this manuscript is organized as follows. Section II presents the theoretical background of pre-trained CNN architectures and the hyperparameter optimisation problem, followed by a review of recent metaheuristic and hybrid approaches in the Section III. Section IV introduces the proposed I-HAHO algorithm, detailing its design, modifications to ABC and HHO, and the diversity-driven phase-switching mechanism. Section V describes the experimental setup, including datasets, CNN models, hyperparameter search spaces, and preprocessing strategies. It also presents and analyses the

results, comparing I-HAHO with conventional and metaheuristic baselines in terms of accuracy and convergence. It discusses the implications, strengths, limitations, and potential extensions of the proposed approach. Finally, Section VI concludes the paper by highlighting key findings and suggesting directions for future research.

II. Background of Study

This section provides a discussion of relevant theoretical foundations and an introduction to the hyperparameter optimization problem.

A. Pre-Trained Models

Deep learning has revolutionized computer vision, with Convolutional Neural Networks (CNNs) emerging as the foundation of state-of-the-art models across a wide range of applications, including medical imaging, object recognition, and autonomous driving [15]. CNNs learn hierarchical feature representations directly from raw data, eliminating the need for handcrafted feature extraction and enabling scalable solutions for high-dimensional inputs such as images.

However, training CNNs from scratch is computationally expensive and requires large labelled datasets. To address these limitations, pre-trained CNNs such as VGG16, ResNet50, and EfficientNet-B0 are commonly adopted in transfer learning. These models, initially trained on large datasets like ImageNet, serve as general-purpose feature extractors and can be fine-tuned for domain-specific tasks.

1) VGG16: Introduced by [16], is characterized by its simplicity, uniform 3×3 convolution filters, and deep sequential layers. While powerful in feature extraction, its large parameter size (~138M) makes it computationally demanding. Fig. 1 depicts the VGG16 architecture.

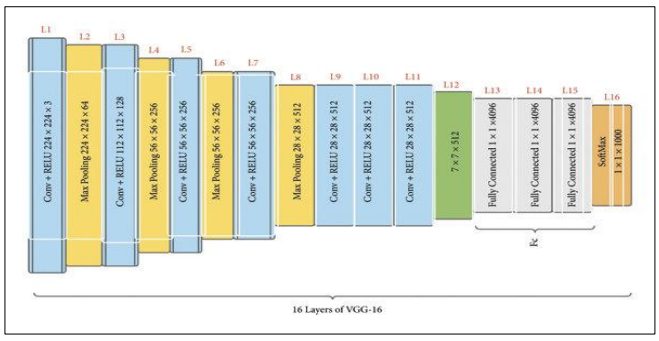

Fig. 1. VGG16 architecture [16].

2) ResNet50: Developed by [17], incorporates residual connections that enable the effective training of deeper architectures by mitigating vanishing gradient problems. This design has significantly improved CNN scalability and accuracy in challenging tasks [18]. Fig. 2 depicts the ResNet50 architecture.

3) EfficientNet-BO: Proposed by [20], introduces a compound scaling strategy that jointly scales depth, width, and resolution. It achieves high accuracy with a lightweight parameter count (~5.3M), making it suitable for mobile and embedded applications [21] (Şafak & Barışçı, 2024). Fig. 3 depicts the EfficientNet-B0 architecture.

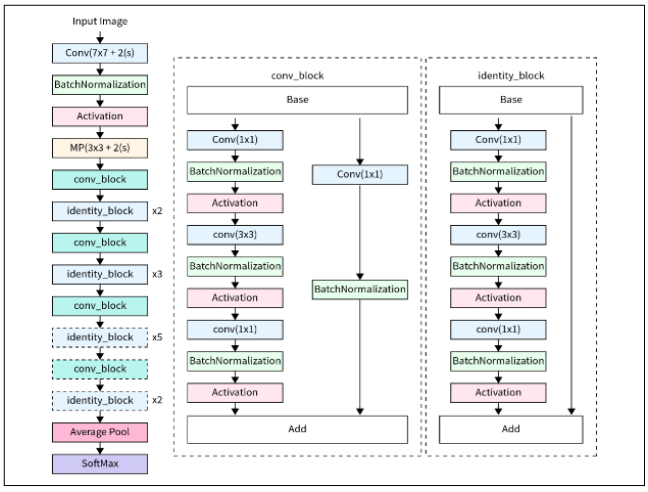

Fig. 2. ResNet50 architecture [19].

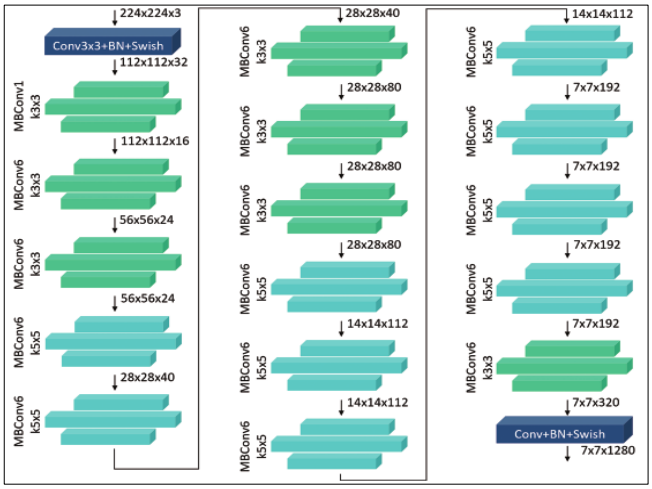

Fig. 3. EfficientNet-B0 architecture [20].

4) Comparison among pre-trained CNN models or architectures: To validate the proposed HPO strategies and algorithms in real-world scenarios, three pre-trained CNN architectures (VGG16, ResNet50, and EfficientNet-B0) are selected for experimental evaluation. These models represent a range of design philosophies and computational complexities, allowing for comprehensive testing against the three core performance objectives: accuracy, adaptability, and computational efficiency. Table I summarises the characteristics of the chosen pre-trained CNN models.

B. Hyperparameter Optimisation (HPO)

The primary goal of HPO is to automate the hyperparameter tuning process to ensure optimal performance of ML models on specific tasks. The motivation for employing HPO lies in its ability to address challenges posed by manual tuning, such as non-linear hyperparameter interactions and the computational burden of evaluating large search spaces.

TABLE I. CHARACTERISTICS OF CHOSEN PRE-TRAINED CNN MODELS

Criteria	VGG16	ResNet50	EfficientNet-B0
Architecture Depth	16 layers (13 convolutional + 3 fully connected)	50 layers with residual connections	82 layers (scalable depth, width, and resolution)
Key Innovation	Sequential architecture with uniform 3×3 convolutions	Residual connections to solve vanishing gradient problem	Compound scaling method to balance network dimensions
Model Size	~138 million parameters	~25.5 million parameters	~5.3 million parameters
Computational Complexity	High due to depth and fully connected layers (~15.4 GFLOPs)	Moderate (~3.9 GFLOPs)	Low (~0.39 GFLOPs)
Real-World Applications	Medical imaging, video classification, and object detection	Autonomous vehicles, semantic segmentation, and face recognition	Mobile vision, IoT devices, and scalable vision applications

In the context of convolutional neural networks (CNNs), hyperparameters play a pivotal role in shaping the architecture, learning dynamics, and generalization ability. These settings, determined prior to training, influence feature extraction, overfitting prevention, and convergence behaviour. CNN hyperparameters can generally be categorized into three main groups [22], [23].

- Hyperparameters of convolutional layers (i.e., number of convolutional layers, number of kernels, size of kernels, stride, padding, dilation rate, activation functions, and filter initialization methods).
- Hyperparameters of fully connected layers (i.e., dropout rate, connectivity pattern, number of neurons, activation functions, weight regularization, and initialization methods).
- General Hyperparameters (i.e., batch size, learning rate, learning rate decay, optimizer type, number of epochs, momentum, and gradient clipping).

1) HPO problem formulation: HPO is the process of identifying the optimal hyperparameters for a machine learning model to maximize its performance on a given task. This is formulated as an optimisation problem where the objective is to find the hyperparameter configuration that minimizes a loss function or maximizes an evaluation [24], [25].

a) General formulation

Let,

$\lambda = \lambda_1, \lambda_2, \ldots, \lambda_n$: The hyperparameter vector, where each λ_i represents a specific hyperparameter.

$M(\lambda)$: The machine learning model trained with hyperparameter configuration ƎvƛƐ.

$L(M(\lambda), D)$: The loss function of the model on dataset $\|1\mathcal{D} = \{(\mathcal{D}\}_{train}, D_{val})$ where D train and D val are the training and validation datasets, respectively.

The goal of HPO is to find the optimal hyperparameter configuration ƎvƛƐ such that:

$$\lambda^* = argmin_{\lambda \in \Lambda} L(M(\lambda), D_{val})$$

where Λ is the search space of hyperparameters.

2) Search space: In the context of HPO for pre-trained CNNs, the search space defines the range and type of hyperparameters that are optimized to improve model performance. This space encompasses various types of parameters that differ in structure and optimization complexity. The hyperparameter search space Λ is typically composed of categorical, discrete and continuous parameters.

Each category introduces different challenges for optimisation algorithms. Categorical parameters often require non-gradient-based search techniques, discrete parameters increase combinatorial complexity, and continuous parameters demand fine-grained exploration.

C. Metaheuristic Algorithms

Metaheuristics are population-based or single-solution optimisation methods that incorporate stochastic search strategies to efficiently explore large, complex landscapes. They are particularly suited to HPO, as they do not rely on gradient information and can handle mixed-variable and non-differentiable objective functions [26], [27].

Metaheuristics achieve success by balancing:

- Exploration: discovering new regions of the search space.
- Exploitation: refining promising candidate solutions [7], [8].
- Several algorithms have been applied to CNN HPO:
- Genetic Algorithms (GA): Inspired by natural evolution, used for optimising filter sizes and learning rates [28].
- Particle Swarm Optimisation (PSO): Mimics social behaviour of birds, effective in refining CNN configurations [29].
- Whale Optimisation Algorithm (WOA): Employs simulated hunting behaviour for global exploration [30].
- Harmony Search and Variants: Used for fine-tuning CNNs through adaptive exploration-exploitation trade-offs [31].

Among these, two algorithms stand out for their complementary strengths:

- Artificial Bee Colony (ABC): A swarm-based algorithm inspired by bee foraging behaviour [9]. ABC excels at exploration by maintaining population diversity through scouts and onlookers but suffers from weak local refinement in later iterations [11].
- Harris Hawks Optimisation (HHO): A predator-prey inspired method with dynamic exploration and exploitation phases [10]. HHO is effective in local

search but is prone to premature convergence in highly multimodal spaces [12].

Individual metaheuristic algorithms often underperform in the complex hyperparameter landscape of pre-trained CNNs, leading to stagnation, poor convergence, or lack of diversity [13]. To address these challenges, hybrid metaheuristics have emerged, aiming to combine complementary strengths while mitigating weaknesses [14]. Recent studies, such as PSO-GWO [32] and HHOS [33] highlight the effectiveness of hybridisation for deep learning optimisation.

Nevertheless, the integration of ABC and HHO for CNN hyperparameter tuning remains underexplored. This motivates the present study, which introduces I-HAHO, an integrative hybrid approach that leverages ABC's exploratory power and HHO's exploitative refinement under a diversity-based switching strategy.

III. Related Works

This section presents reviews on recent studies that apply hybrid metaheuristic algorithms to HPO in pre-trained CNN models. Recent studies have explored hybrid metaheuristic algorithms for HPO in pre-trained CNN models, yet consistent challenges remain across adaptability, accuracy, and computational efficiency dimensions.

Ulutas et al. [34] proposed a hybrid PSO-GWO approach for tuning hyperparameters within ensemble models for diabetes detection, achieving a peak accuracy of 98.10% using Random Forest classifiers. Their findings indicate that the hybrid method outperforms standalone Particle Swarm Optimization (PSO) and Grey Wolf Optimization (GWO), offering improved robustness and generalisation across classifiers.

Yan et al. [35] addressed key challenges in CNN hyperparameter tuning, including mixed-variable encoding, high computational cost, and convergence stability. They introduced GPPSO, a hybrid algorithm combining Gaussian Processes with PSO. The method incorporates a novel encoding scheme for mixed-variable hyperparameters and a surrogate model to reduce evaluation overhead. Experiments on CIFAR-10 and CIFAR-100 confirmed GPPSO's superior efficiency and accuracy, with practical relevance for applications such as metal fracture diagnosis.

Kumar and Kondaveeti [33] applied transfer learning with a Hybrid Hyperparameter Optimization Scheme (HHOS), integrating manual domain knowledge and random search strategies. Using pre-trained ImageNet models with additional trainable layers, they demonstrated that fine-tuning EfficientNetB0 achieved 99.12% accuracy, outperforming ResNet18 (93.24%). These results highlight the value of hybrid HPO in ecological classification tasks.

Akkuş et al. [36] explored HPO for CNN-based image classification, specifically diabetic retinopathy detection. Their study compared the Adolescent Identity Search Algorithm (AISA) with Bayesian Optimization (BO) across pre-trained models including AlexNet, MobileNetV2, ResNet18, and GoogLeNet. AISA-based tuning yielded higher accuracy with fewer iterations, demonstrating its efficiency in medical imaging contexts.

Kiliçarslan [32] investigated hybrid optimisation for cardiovascular disease prediction using 1D and 2D VGG-16 architectures. The study compared PSO, Cat Swarm Optimization (CSO), and hybrid PSO-GWO, showing that the hybrid consistently achieved the highest classification accuracy across medical and MNIST datasets.

Atteia et al. [37] further emphasised the importance of HPO in CNN-based diagnostic systems, applying optimisation techniques to diabetic maculopathy detection using optical coherence tomography and fundus retinography. Their work reinforces the critical role of HPO in enhancing model performance for clinical applications.

The summary of the related works is presented in Table II.

TABLE II. Summary of Related Works

Authors	Hybrid Method	Domain	Models / Datasets	Key Findings
Ulutaş et al. [34]	PSO + GWO	Diabetes detection (Ensemble Learning)	Random Forest, other classifiers	Achieved 98.10% accuracy; hybrid PSO-GWO outperformed standalone PSO and GWO, improving robustness and model performance.
Yan et al. [35]	GP + PSO (GPPSO)	CNN HPO, Metal fracture diagnosis	CNNs on CIFAR-10, CIFAR-100	Proposed mixed-variable encoding + surrogate model; improved efficiency, convergence, and accuracy compared to traditional methods.
Kumar & Kondaveeti [33]	Hybrid Hyperparameter Optimisation Scheme (HHOS) (manual + random search)	Ecological application(transfer learning)	EfficientNetB0, ResNet18 (pre-trained on ImageNet)	Fine-tuned EfficientNetB0 achieved 99.12%, ResNet18 achieved 93.24%; hybrid scheme improved accuracy and adaptability.
Akkuş et al. [36]	AISA + Bayesian Optimisation	Medical imaging (Diabetic Retinopathy detection)	AlexNet, MobileNetV2, ResNet18, GoogLeNet; Kaggle DR dataset	Hybrid AISA-based optimisation achieved higher accuracy with fewer iterations than BO; more efficient for CNN HPO in medical imaging.

IV. Materials and Methods

In this section, I-HAHO is introduced as our approach to improve the accuracy of the HPO for pre-trained CNN models.

A. Dataset

This study utilizes four benchmark datasets: CIFAR-10, CIFAR-100, SVHN, and TinyImageNet to evaluate the performance of the proposed hybrid metaheuristic HPO algorithms. These datasets were selected due to their widespread

adoption in deep learning literature and their varying levels of complexity, class granularity, and domain diversity, which support robust validation of adaptability and generalisation.

CIFAR-10 and CIFAR-100 were obtained from the official dataset repository maintained by the Canadian Institute for Advanced Research (CIFAR). Each dataset comprises 60,000 32×32 colour images. CIFAR-10 consists of 10 mutually exclusive classes, whereas CIFAR-100 is structured with 100 fine-grained categories across 20 superclasses. Both datasets were split into 50,000 training and 10,000 testing images. During preprocessing, images were normalized using dataset-specific mean and standard deviation values, converted to float tensors, and standardized to improve gradient stability during model training. No class rebalancing was performed, preserving original distribution characteristics for realism.

Street View House Numbers (SVHN), sourced from the official Stanford University repository, was employed in its cropped digits format, ensuring consistent spatial resolution with other datasets. Comprising 73,257 training and 26,032 test images, SVHN represents a real-world digit classification task under non-ideal lighting and alignment conditions. Raw .mat files were parsed and converted to tensor format. Images were resized to 32×32 pixels and normalized to zero mean and unit variance. Dataset labels were integer-encoded and subsequently transformed to one-hot format for compatibility with CNN classifiers. It has a real-world and noisy data characteristic which makes it a challenging test case.

TinyImageNet, a scaled-down variant of the ILSVRC ImageNet dataset, was downloaded from the official ImageNet challenge portal. It includes 200 object categories, with 100,000 training samples (500 images per class), 10,000 validation samples (50 per class), and 10,000 test samples. Unlike CIFAR and SVHN, the input resolution for TinyImageNet was preserved at 64×64 pixels to maintain semantic richness. Due to its relatively small sample size per class and high inter-class similarity, extensive preprocessing was applied, including data augmentation techniques such as random horizontal flipping, random cropping with padding, and brightness/contrast jittering to prevent overfitting and improve generalization under low-data regimes. It represents real-world scenarios and tests the scalability and efficiency of optimisation algorithms in complex tasks.

A summary of the datasets is provided in Table III, highlighting their complexity based on factors such as image resolution, number of classes, and dataset size.

TABLE III. SUMMARY OF DATASETS

Dataset	Number of Classes	Total Images	Image Resolution	Complexity
CIFAR-10	10	60,000	32x32	Moderate
CIFAR-100	100	60,000	32x32	High
TinyImageNet	1,000	1.2 million	Varies	Very High
SVHN	10	600,000+	32x32	High (Real-world)

B. Proposed I-HAHO Algorithm

The pseudocode for the I-HAHO is presented in the Algorithm 1.

Algorithm 1: I-HAHO

Input:
Population Size N, Maximum iterations T, Initial diversity threshold D_0,
Hyperparameters for ABC and HHO, Objective function $F(x)$
Output:
Best solution x_{best} with optimized hyperparameters.

Initialise the population X using Latin Hypercube Sampling
Set iteration counter $t = 0$
Calculate the initial diversity threshold $D_{\text{thresh}}(t) = D_0$
Evaluate the fitness $F(x)$ for each solution $x_i \in$ X
While $t <$ T:
    Calculate population diversity $D(t)$
    Update the diversity threshold $D_{\text{thresh}}(t)$
        Dynamic Phase-Switching Strategy:
            $if D(t) > D$thresh (High Diversity):
                Perform Modified ABC Exploration
            else $D(t) < D$thresh
                Perform Modified HHO Exploitation
            Evaluate the $F(x)$ of the updated solutions
            Update the global best solution x_{best} based on the fitness
            Calculate the change in fitness ΔF = |F_best(t) - F_best(t-1) |.
            Convergence Check:
            If ΔF < threshold or if $D(t) > D$min
            Increment t = t +1
End While
Return the best solution x_{best}

Fig. 4 illustrates the detailed operational flow of the proposed Integrative Hybrid Metaheuristic Algorithm (I-HAHO), which unifies exploration and exploitation through a diversity-based phase-switching mechanism. At each iteration, the population diversity $D(t)$ is computed and compared with a dynamic threshold $D_{\text{thresh}}(t)$. When $D(t) > D_{\text{thresh}}$, indicating sufficient population diversity, the algorithm prioritises Modified ABC exploration to expand the search space. This phase adaptively updates candidate positions, reinitialises stagnated solutions using Distance-Aware Novelty Reinitialisation (DANR), and invokes Chaos-Guided Candidate Recovery (CGCR) when diversity falls below acceptable limits, ensuring sustained global exploration. Conversely, when $D(t) < D_{\text{thresh}}$, the process transitions to Modified HHO exploitation, which refines promising regions through Refined Surround Prey, Escaping Energy, and Success-History-Based Adaptation (SHEA) to intensify local search and accelerate convergence.

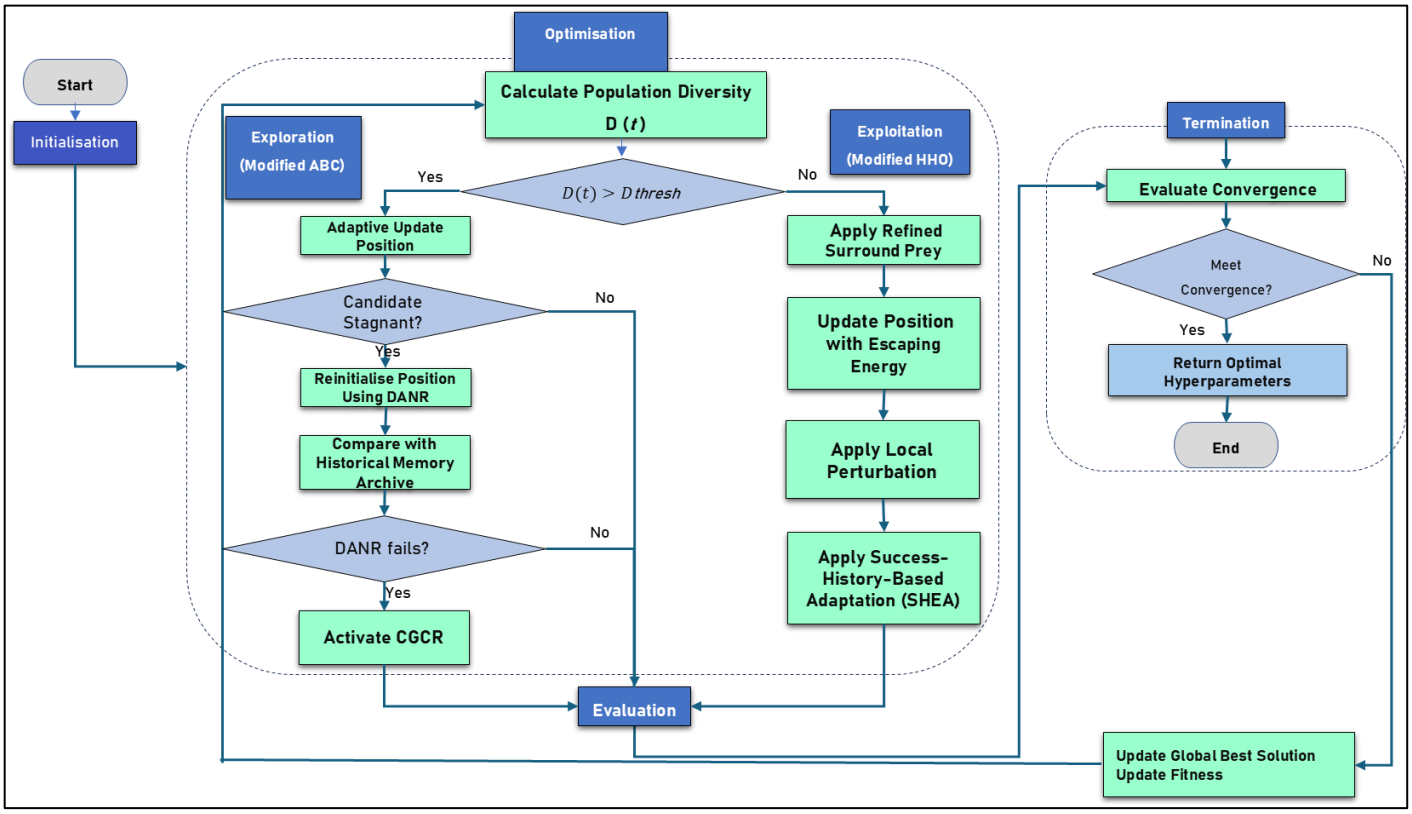

Fig. 4. Detailed algorithmic flowchart for I-HAHO with key strategies.

Unlike previous hybrid metaheuristics that rely on static schedules, random alternation, or fixed probability-based phase switching, the proposed diversity-driven framework continuously adapts based on the evolutionary state of the population. This allows I-HAHO to intelligently balance exploration and exploitation according to real-time feedback from the search dynamics, rather than predetermined iteration counts. The integration of DANR, CGCR, and SHEA further enhances the system's self-adaptive behaviour. DANR promotes novelty and prevents stagnation by introducing diversity-sensitive perturbations, CGCR leverages chaotic patterns to recover lost diversity while preserving promising regions, and SHEA enables adaptive parameter fine-tuning guided by historical success rates. Collectively, these mechanisms fill the gap left by earlier hybrid strategies that lacked dynamic responsiveness, allowing I-HAHO to navigate complex, multimodal hyperparameter landscapes more effectively and maintain balanced convergence performance across datasets and CNN architectures.

C. Performance Evaluation Measures

The evaluation measures employed in this research were selected to comprehensively assess the performance of the proposed I-HAHO algorithm.

1) Classification accuracy: Classification accuracy is the primary metric to evaluate the performance of HPO in pre-trained CNN models. It measures the proportion of correctly classified instances relative to the total instances.

$$\text{Accuracy}(\theta) = \frac{\text{Correctly Classified Instances}(\theta)}{\text{Total Instances}} \quad (1)$$

A higher classification accuracy indicates better optimisation of hyperparameters and superior adaptibility performance of the model.

V. Results and Discussion

A. Overall Comparative Performance

The experiment results for I-HAHO comparison with baseline HPO algorithms and canonical metaheuristic algorithms are presented in Table IV. The results demonstrate the highest accuracy achieved by different HPO algorithms across four pre-trained CNN models on various benchmark datasets. The accuracy results are presented in Table IV.

The proposed I-HAHO algorithm consistently outperformed all benchmarked HPO algorithms across the evaluated pre-trained CNN models and datasets. On the CIFAR-10 dataset, I-HAHO achieved superior validation accuracies of 93.194% (VGG16), 94.503% (ResNet50), and 93.008% (EfficientNet-B0), outperforming traditional and baseline search-based algorithms (GS, RS and BO). This consistent improvement illustrates I-HAHO's ability to effectively navigate the hyperparameter space through adaptive hybridization of global and local search strategies.

TABLE IV. ACCURACY RESULTS FOR ALL HPO ALGORITHMS AND I-HAHO

Model	Dataset	GS (%)	RS (%)	BO (%)	Vanilla ABC (%)	Vanilla HHO (%)	I-HAHO (%)
VGG16	CIFAR-10	88.2	88.6	89.2	87.5	87.7	**93.1**
	SVHN	95.3	95.6	96.2	94.7	95.0	**96.9**
	CIFAR-100	67.1	68.04	68.5	66.0	66.5	**78.5**
	Tiny ImageNet	57.8	58.3	58.9	57.0	57.4	**65.4**
ResNet50	CIFAR-10	90.5	90.9	91.3	89.0	89.3	**94.5**
	SVHN	93.0	93.7	94.1	92.5	92.9	**95.8**
	CIFAR-100	68.9	69.7	70.4	67.6	68.3	**76.0**
	Tiny ImageNet	61.2	61.9	62.5	60.2	60.9	**69.5**
EfficientNet-B0	CIFAR-10	89.0	89.7	90.1	87.5	87.9	**93.0**
	SVHN	87.3	87.9	88.4	86.0	86.5	**91.0**
	CIFAR-100	68.0	68.9	69.5	66.6	67.3	**75.5**
	Tiny ImageNet	61.8	62.4	62.9	59.6	60.3	**68.0**

On the more complex CIFAR-100 dataset, which includes 100 classes with fewer samples per class, I-HAHO achieved 78.507% (VGG16), 76.011% (ResNet50), and 75.512% (EfficientNet-B0), confirming its adaptability in high-dimensional, class-imbalanced learning tasks. For the SVHN dataset, characterized by large-scale digit recognition with significant intra-class variance and noise, I-HAHO achieved 96.903% (VGG16), 95.803% (ResNet50), and 91.007% (EfficientNet-B0). These results demonstrate I-HAHO's ability to maintain high accuracy and generalization performance even under challenging, real-world-like scenarios with substantial class overlap and varying input conditions.

On TinyImageNet, a particularly challenging dataset with 200 categories and lower resolution images, I-HAHO again demonstrated superior adaptability, achieving 65.497% (VGG16), 69.502% (ResNet50), and 68.013% (EfficientNet-B0). Notably, the EfficientNet-B0 model exhibited strong performance due to its compound scaling, which supports effective feature extraction even in low-resolution, high-category contexts. These outcomes suggest that I-HAHO not only improves training outcomes for well-known benchmarks but also scales effectively to more complex domains with less structured data distributions.

Collectively, these results are aligned with recent studies highlighting the limitations of single-strategy optimizers in deep learning [3], [37], [38] and emphasize the benefit of hybrid metaheuristics for pre-trained CNN models HPO tasks.

VI. CONCLUSION

In conclusion, the proposed Integrative Hybrid Artificial Bee Colony–Harris Hawks Optimization (I-HAHO) algorithm improves hyperparameter optimization (HPO) for pre-trained convolutional neural networks (CNNs) through an adaptive hybrid structure. The framework integrates a modified Artificial Bee Colony (ABC) algorithm for global exploration with a modified Harris Hawks Optimization (HHO) algorithm for local exploitation. This integration provides a balanced search process that minimizes premature convergence and sustains population diversity, which conventional approaches such as grid search, random search, and Bayesian optimization fail to achieve. The adaptive phase-switching mechanism regulates exploration and exploitation dynamically according to population diversity and fitness variance, allowing the optimiser to adjust its search intensity based on the topological characteristics of the loss landscape. This adaptivity enables I-HAHO to sustain population diversity during early iterations and progressively intensify local refinement as convergence nears, resulting in consistent and efficient optimisation in high-dimensional, non-convex search spaces. Experimental results on CIFAR10, CIFAR100, SVHN, and TinyImageNet datasets across VGG16, ResNet50, and EfficientNetB0 architectures demonstrate up to 6.9% improvement in classification accuracy compared to baseline optimizers. These results validate IHAHO as a scalable and generalizable hyperparameter optimization framework that improves search efficiency, convergence stability, and model adaptability across diverse deep learning tasks. The diversity-based phase-switching mechanism enables dynamic control over exploration and exploitation, supporting robust performance in high-dimensional, nonconvex spaces.

A Novel Performance-Based Time Series Forecast Combination Method and Applications with Neural Networks

M. Burak Erturan
General Directorate of State Hydraulic Works, Directorate of Region 13, Antalya, Türkiye

***Abstract*—Performance-based forecast combination approaches determine the weights of the individual forecasts based on the inverse average error for a past time interval. However, although the performances are calculated for a time span, the aim is mostly a one-step-ahead time-point forecast. In these classical methods, a relatively higher prediction error of a single past time-point spreads and decreases the performance value of the model, even though the model is highly successful on other time-points in the interval. In this study, a novel approach is presented where performance of each past time-point prediction is calculated separately. Instead of taking the inverse average error for a pre-determined past time interval, prediction performance is calculated for each past data point separately using the normalized inverse absolute error, then the average performances are calculated for past time interval to get the combination weights. To be able to measure the performance of the presented methodology, it is applied on three well-known time series data. Seven different models of neural networks, based on multi-layer perceptron and extreme learning machines are used to model, forecast and form the combination forecasts. Moreover, four different performance-based combination techniques, two central tendency-based benchmark combination methods and the naïve model are employed for comparison. The obtained results show that proposed methodology is a powerful and robust technique and superior to all performance-based combination techniques compared.**

Keywords*—Combination forecast; performance-based combination; neural networks; multi-layer perceptron; extreme learning machine

I. Introduction

Time series forecasting has become a major research area in academics. Researchers have developed various methodologies to improve the accuracy of forecasting. From classical statistical models to machine learning [22] and heuristic models, many models have been developed. Moreover, researches showed that using more than one forecast at the same time often gives better results than a single forecast [1]. This development has led the researchers to hybridize or combine different forecasts and resulted with hybrid and combination forecasting models.

Combination forecast is done by combining multiple forecasts from different models and is usually better than a single forecast. The interested real world time series data is probably cannot be explained by a specific model, because of the consisting different processes like time-varying trends, changing seasonality and structural breaks [1]. Moreover, selecting the "best model" is somewhat problematic because of the sample, parameter and model uncertainties. Sample uncertainty is the problem that different sample sizes result different models and various parameter estimates. Parameter estimation uncertainty arises from different algorithms and various model setups. Furthermore, different model structures result with various parameter restrictions, which may cause for example the estimation problem [2]. Under these circumstances, combining multiple forecasts has been a highly preferred methodology.

The main question of the forecast combination is that, "how to combine the individual forecasts". Different answers to this question result various combination methods. An important class of combination procedures is performance-based forecast combination. That class of methods determine the weights of individual forecasts according to corresponding models' past performances. Some models use inverse past accuracy measures of the models like mean squared error (MSE), root mean squared error (RMSE) or symmetric mean absolute percentage error (sMAPE) to calculate the weights, such that the forecast of the model with a low error measure has a high weight in the forecasting pool. Another idea is, instead of using inverse error measures directly, ranking the models according to their past accuracy and employing the inverse of these rank values as weights, which is called rank-based forecast combination.

There are some characteristics of current performance-based combination methodologies arise from the mean error metrics they are based on. In inverse error based combination methods, average of the errors for some past time span is used. In these methods, the averaging procedure gives general information about the time span performance, but not enough information about the performances for past time-points individually. For example, a possible high error value of only one past prediction might cause a low performance; even other past predictions are highly accurate. On the other hand, rank-based model assigns the weights through the inverse sequence of numbers. Regardless of how much the variation between the models' past accuracies, the weights are pre-determined and constant. Therefore, rank-based combinations limit the weights to only a set of possible values [3].

Forecasting techniques are (including forecast combinations) used mostly for one-step ahead forecasting. Even when the forecast target consists of multi-steps ahead time-points, usually, forecasting is done step by step. It means

that, first the next step is forecasted, and then the subsequent forecast is done using previous forecast as if it is the real value. Therefore, pointwise performance values of the forecasting models are highly important. Classical performance-based combination techniques take an average error value of the individual models for a past time-span (for the whole past training data-span, or a more recent one) and use it to assign the performance values. In this paper, a novel performance-based combination methodology is proposed, which is different from classical performance-based methods. First, the performances of each past time-point prediction of individual models are calculated separately by inverse absolute error (IAE). Then, these point performance values are normalized by min-max normalization within other models for each past time point data; such that, the best performance value is one, the worst is zero and the others are in between. The min-max normalization among different models assigns a relative performance value and holds equal performance scales ([0, 1]). Moreover, since recent data holds more information and is more significant, the weights are calculated by averaging the time-point performances of recent data by the rolling window method which is often used in the literature [1].

To test the performance of the proposed model, three well-known time series data are used for modeling and forecasting purposes. These datasets are Canadian lynx, Wolf's sunspot and GBP/USD foreign exchange series. Seven individual neural network models are constructed for combination. Three of the neural network models are based on multi-layer perceptron (MLP) and four of them are different sub-models of extreme learning machines (ELM). Obtained results from proposed combination technique are compared with the results of seven individual models, four other performance-based models, equally weighted simple mean/ median combinations and the naïve model.

The rest of the paper is organized as follows: In Section II, a review of literature related to current is presented. Section III describes all methodologies used in the research. First, MLP and ELM models are explained, which are used for individual forecasts. Then, performance-based combination models are described, which are used for comparison purposes. After that, proposed forecast combination model is introduced and explained. Lastly, the details of the data, models and the software used for application purposes are presented. Section IV presents the application results and findings. Section V concludes with discussions of the study's implications, limitations, and future work.

II. Related Work

Since the work of Bates and Granger [4], forecast combination literature has been grown substantially. From simple combination procedures to much more complex systems, researchers have developed many models and methods. However, forecast combination studies show that simpler combination methods are very successful and hard to beat [1]. The most popular one is taking the simple arithmetic mean of the individual forecasts, ignoring the past information of the models. This procedure is quite successful, robust and easy to perform [3]. Other simple and robust methodologies related to central tendency (CT) are taking the median or the mode of the forecasting pool. In contrast to the simplicity of the mean and median, mode combination needs numerous forecasts or some techniques like discretizing the data or kernel density estimation [5]. Therefore, the simple mean and the median combinations are the most referenced CT combinations, and there is still debate among the scholars whether the mean or the median is more successful [1]. Other than simple equally weighted average model, some researchers applied the trimmed or winsorized mean for combination forecasts. Results show that especially when there are high variations among the forecasts, trimmed and winsorized mean methods produce good results [5]. Simple combination rules are very successful and easy to implement. Therefore, among other and more sophisticated methods, simple combination methods are the choice of many researchers as a benchmark for testing new combination methodologies. There are other more complex methods than simple combinations, such as linear combinations, nonlinear combinations and combining by learning. A comprehensive classification of combination methods can be found in study [1].

Linear combination methods assign the weights of individual forecasts according to their accuracy in a linear combination. Optimal weights approach aims to minimize the variance by optimizing the weights [6], while in linear regression based methods this optimization is done by regression [7]. In criteria based techniques, weights of the individual forecasts are determined by using information criteria, such as Akaike's (AIC) or Bayesian (BIC) information criteria [8, 9].

Performance-based forecast combinations are in the class of linear combination methods, where each individual forecast has a weight according to its performance on past data. Differences in performance measurement are resulted with different models in the literature. In study [10], IRMSE (inverse root mean squared error) model is used with different combination models to forecast day-ahead spot electricity prices. It is found that, while IRMSE method is one of the best performer models, there is no single model dominating the others for all datasets. In the work of [11] different forecasting models are combined with weights determined by their sMAPE values. It is determined that the selection of the forecasting models is crucial for the combination forecast to be successful. Another performance-based model is rank-based model used in [12]. Rank based models determine the weights of individual models according to inverse of their rankings. This model is also used by study [13] for tourism demand forecasting and compared with other combination methods. Performance-based combinations are used to forecast various time series, such as livestock prices [14], oil prices [15], ozone concentration, and airline passengers [16].

III. Methodology

A. Multilayer Perceptron

Artificial Neural Networks (ANN) are computational models inspired by the human brain's neural networks. An ANN is composed of interconnected nodes (neurons) organized in layers; including input, hidden, and output layers. They mimic the way real neurons communicate; and are particularly useful in pattern recognition, classification, optimization, and

time series prediction. ANNs can model complex nonlinear relationships and handle large datasets with numerous variables.

A multi-layer perceptron (MLP) is the most commonly used type of artificial neural network that consists of multiple layers of nodes; including an input layer, one or more hidden layers, and an output layer. The network uses a feedforward path for data processing and backpropagation for training and optimization. Training MLPs involves challenges such as entrapment in local minima, convergence speed, and sensitivity to initialization. MLPs have strong generalization capabilities but are prone to overfitting, where the network becomes too dependent on the training data. Techniques such as regularization and cross-validation are often employed to mitigate overfitting. MLPs are widely used for time series modeling. As a mathematical expression for time series y_t, the one-step ahead forecast $\hat{y}_{(t+1)}$ of the real data y_{t+1} can be calculated as [5]:

$$\hat{y}_{t+1} = \beta_0 + \sum_{l=1}^{L} \beta_l g\left(b_i + \sum_{i=1}^{I} w_{li} x_i\right) \quad (1)$$

In Eq. (1), I is the number of the inputs x_i, and L is the number of hidden nodes. β and w are the weights of the output and hidden layers respectively, where $\beta=[\beta_1, \beta_2, \ldots, \beta_L]$ and $w=[w_1, w_2, \ldots, w_L]$. β_0 and b_i are the biases acting like intercept in the regression process. Lastly, $g(.)$ is the transfer function and is usually hyperbolic tangent or logistics function.

The backpropagation algorithm is a widely used method for training MLPs by adjusting the weights of the connections to minimize the error in predictions. There are three stages of backpropagation, in the first stage the calculations are done forward through the final output by using activation function. Then, obtained error is propagated backwards, starting from the output layer. Finally, the weights are changed in order to minimize errors. These stages continue until certain conditions are reached. Backpropagation is effective but can be slow and may be stuck in local minima [17]. Another training algorithm is resilient backpropagation (RPROP), which is an advanced training algorithm designed to improve the efficiency and performance of MLPs by addressing some of the limitations of traditional backpropagation methods. RPROP is an advanced version of backpropagation that adjusts the weight updates based on the sign of the gradient rather than its magnitude, leading to faster convergence and improved performance [17, 18]. As an improvement of RPROP, a weight backtracking mechanism can be added. Weight backtracking retracts a previous update for some or all weights, while whether taking back a step or not is decided by heuristics [19].

B. Extreme Learning Machine

Extreme learning machine (ELM) is a single layer feedforward network (SLFN). Different from other neural networks, the weights of connections between input and hidden layers are selected randomly and not trained further. Therefore, instead of training all the weights in the network, only the output weights (connecting hidden and output layer) are calculated. The output weights can be optimized with the approaches like least squares or equivalents. ELM has fast learning rate with strong generalization performance. Moreover it shows high efficiency in training, particularly when data is limited [20, 21]. A representation of ELM architecture is in Fig. 1.

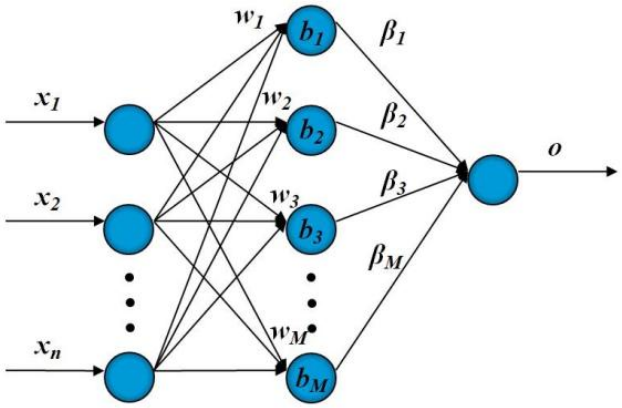

Fig. 1. Architecture of an extreme learning machine network with n input, M hidden, and 1 output nodes.

Suppose we have N arbitrary distinct training samples (x_j, t_j), each containing of n inputs and m outputs where $j = 1, 2, \ldots, N$. Therefore, $x_j = [x_{j1}, x_{j2}, \ldots, x_{jn}]^T \in Rn$ is the input vector and $tj = [tj1, tj2, \ldots, t_{jm}]^T \in$ Rm is the output vector. The output (o_j) of the standard SLFN model with M hidden nodes and the activation function of $g(.)$ can be modeled as [20]:

$$o_j = \sum_{i=1}^{M} \beta_i g\left(w_i x_j + b_i\right) \quad (2)$$

In Eq. (2), $w_i = [w_{i1}, w_{i2}, \ldots, w_{in}]^T$ is the weight vector connecting inputs to the ith hidden node. $\beta_i = [\beta_{i1}, \beta_{i2}, \ldots, \beta_{in}]^T$ the weight vector connecting ith hidden node to outputs, and bi is the bias (threshold) of ith hidden node. The standard SLFN with M hidden nodes with activation function $g(.)$ can approximate these N samples with zero error means that:

$$\sum_{i=1}^{M} \beta_i g\left(w_i x_j + b_i\right) = t_j \quad (3)$$

where $j = 1, 2, \ldots, N$. These N equations can be written in a more compact form as:

$$\boldsymbol{H\beta = T} \quad (4)$$

where,

$$\boldsymbol{H} = \begin{bmatrix} g(w_1 x_1 + b_1) & \ldots & g(w_M x_1 + b_M) \\ g(w_1 x_2 + b_1) & \ldots & g(w_M x_2 + b_M) \\ \vdots & \ddots & \vdots \\ g(w_1 x_N + b_1) & \ldots & g(w_M x_N + b_M) \end{bmatrix}_{NXM} \quad (5)$$

$$\beta = \begin{bmatrix} \beta_1^T \\ \beta_2^T \\ \vdots \\ \beta_n^T \end{bmatrix}_{Mxm} \quad (6)$$

$$\boldsymbol{T} = \begin{bmatrix} t_1^T \\ t_2^T \\ \vdots \\ t_N^T \end{bmatrix}_{Nxm} \quad (7)$$

After setting the input weights and biases of the hidden layer, the output weight vector β can be obtained by a series of linear equations transformations. If the number M of hidden

nodes is equal to the number N of distinct training samples, $M = N$, matrix H is square and invertible. Because the input weight vectors wi and the hidden biases b_i are randomly chosen, the SLFN can approximate these training samples with zero error. However, in most cases the number of hidden nodes is much less than the number of distinct training samples, such that $M << N$. Then, H is a not a square matrix and there may not exist w_i, b_i, β_i ($i = 1, 2, ..., M$) such that $\boldsymbol{H}\beta = \boldsymbol{T}$. Then, the smallest norm least squares solution of the above linear system is [20]:

$$\hat{\beta} = \boldsymbol{H}^{\dagger}\boldsymbol{T} \tag{8}$$

where, $\boldsymbol{H}^{\dagger}$ represents the generalized (Moore-Penrose) inverse matrix of the output.

Different from traditional neural networks, parameters between hidden and output layer in the ELM structure can be obtained by minimizing least squares solutions with the provided training data [23, 24, 25]. Therefore, using ELM to obtain the output weights is consisted of three steps. First, randomly selecting numerical values between zero and one to set input weights and the bias of the hidden layer. Second, calculation of the output matrix $\boldsymbol{H}$. Finally, calculation of the output weights β. On the other hand, there are some possible problems with ELM networks. First, ELM can effectively approximate to any complex systems with huge numbers of hidden nodes, but in this case, the generalization might decrease. Another is that, the least square method cannot provide good estimates for weights when there exist many outliers in data. To overcome these deficiencies, researchers presents some developments like regularization techniques. Some main methods for this purpose are lasso, ridge and stepwise regression models.

Generally, in regression models a common target is keeping the model as simple as possible. Regularization models like LASSO (Least absolute shrinkage and selection operator) and Ridge regressions punish the complex model by adding a penalty term to the cost function. Ridge regression adds squared magnitude of the coefficients as penalty term, while LASSO adds absolute value of the coefficients as penalty term to the cost function. LASSO shrinks the less important variable coefficients to zero and causes a less complex structure [21]. Moreover, stepwise regression uses forward adding and backward deleting method to the variables to find the best fitting combination of independent variables for prediction [26].

C. Performance-Based Forecast Combinations

Performance-based forecast combination is a method used to improve the accuracy of predictions by linearly combining multiple individual forecasts by assigning weights to each forecast based on their past performances. This combination procedure ignores the correlations among individual forecasts. Moreover, the success of these models reconfirms that models ignoring correlations are more successful than other models, because correlations are poorly estimated in practice and should be ignored in weight calculations [1, 3].

One common branch of performance-based methodologies is inverse error technique, which uses inverse error values of the models directly as weights. Commonly used error metrics are mean squared error (MSE), root mean squared error (RMSE) and symmetrical mean absolute percentage error (sMAPE). In inverse error model, the weight of the ith model among N models with $j=[1,2,...N]$ is:

$$w_i = \frac{\varepsilon_i^{-1}}{\sum_{j=1}^{N}\varepsilon_i^{-1}} \tag{9}$$

where, ε is the error value of the model and might be MSE, RMSE or sMAPE according to which error metrics the combination is based on. Then the combined forecast for time t with N individual model and individual forecasts $\hat{y}_{tj}$ is:

$$\hat{y}_t = \sum_{j=1}^{N}\hat{y}_{tj}w_j \tag{10}$$

Note that, Eq. (9) is valid under the assumption of independence of errors. In the case of error-dependence (i.e. nested models), one of the models encompasses the other and the optimal combining weights are trivially either zero or one [27].

Another performance-based technique is combination forecasting with inverse rank based weights, which involves integrating multiple individual forecasts into a single forecast by assigning weights to each forecast based on their past performance with a ranking system. Proposed by [12], in the rank-based methodology, the weights of the individual forecasts are determined by the inverse of the ranks of the models, which are identified according to their past performance (usually MSE). The weight of the ith model among N models with $j=[1,2,...N]$ is:

$$w_i = \frac{Rank_i^{-1}}{\sum_{j=1}^{N}Rank_i^{-1}} \tag{11}$$

where, $Rank_i=[1,2,...,N]$ is the rank of the ith model's forecast according to model's past performance (MSE).

D. Proposed Combination Methodology

Performance determination with inverse error metrics uses an average value of performance for a pre-determined past time period. It is impossible to determine a point by point performance from these mean (average) error values. For example, a very bad performance with a high error value of a model in a past single point effects the whole performance no matter how successful the model in other past data points. On the other hand, rank-based methods not just use the mean error values, but also assign the performances of the models with a pre-determined values; which ignores the real performance differences between the competitive models. Furthermore, most of the forecasting researches are interested in one-step ahead forecasting for a multi-step period, including this study. Therefore, measuring the performance of each past time point separately can give more reliable values if forecasting procedure is one-step ahead.

Presented methodology takes past prediction performances into account separately for each time-point. First, inverse of absolute error (IAE) values for each past point predictions are calculated. Then, for each past data point, competitive models' IAE values are normalized within. A min-max normalization is applied such that the best prediction takes the value of one, the worst prediction is zero and the others are in between. The min-max normalization provides an equal performance scale

([0, 1]) for each past prediction. Obtained values are the performances of the models on past data points. Finally, the weights of the models are calculated by averaging the past performances. Proposed methodology takes neither the whole training set values nor just the values of test set into account. A rolling window method is used to take into account of the recent values whether they are training or test data. In this paper, a rolling window of 10 past predictions is used. Mathematical notation of the presented weight procedure is presented in Eq. (12).

$$p_{i,t} = NORM\left(AE_{i,t}^{-1}\right) = \frac{AE_{i,t}^{-1} - \min\left(AE_t^{-1}\right)}{\max\left(AE_t^{-1}\right) - \min\left(AE_t^{-1}\right)} \quad (12)$$

In Eq. (12), $p_{i,t}$ represents the performance value of the ith candidate model for time t. *NORM(.)* is the min-max normalization function, where AE^{-1} is the inverse absolute error. Then, the weights and final combination forecast for time t is:

$$w_i = \frac{\sum_{j=t-1}^{t-Z} p_{i,j}}{Z} \quad (13)$$

$$\hat{y}_t = \sum_{j=1}^{N} \hat{y}_{tj} w_j \quad (14)$$

where, Z is the number of past data to be used for weight wi of the ith model forecast, N is the number of the candidate models with individual forecasts of ytj, and j=[1,2,…N].

The usage of the proposed combination method can be summarized in three steps:

- The absolute error values for each past predictions of an individual model are calculated separately. The inverse of the AEs are normalized (min-max normalization) within other models for the same time points to get the time point performances of the models.
- For each model, time-point performances for Z past prediction are averaged for pre-determined time period to find the weights of the individual models.
- Combination forecast is found using individual forecasts and related weights.

The workflow of the proposed combination model used in this study is presented in Fig. 2.

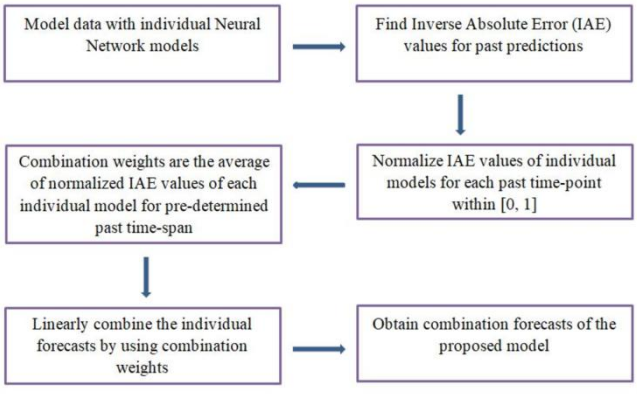

Fig. 2. The workflow of the proposed forecast combination model used in this study.

Proposed methodology has same characteristics with other performance-based models. It ignores the correlations among individual models like other performance-based models. It is a linear combination method using weights of the individual models, which are calculated by models' past performances. Proposed model's difference from other performance-based models is the calculation procedure of the past performances.

E. Data and Application

In this study, three well-known data sets in time series literature are used for the application purposes. They are Canadian lynx, Wolf's sunspot and British Pound/United States Dollar (GBP/USD) exchange rate data sets. All three datasets have various characteristics, and are used often in time series literature as benchmark datasets [28].

Canadian lynx dataset shows the number of yearly trapped lynx around North Canada Mackenzie River between 1821 and 1938. It has total 114 data points and is an important dataset in time series literature with nonlinear characteristics [29]. Wolf's sunspot data, known with nonlinear behavior, contains yearly sunspot numbers in the period of 1700-1987 and has 288 data points. Sunspot data is identified as nonlinear and non-Gaussian and used to test nonlinear models for their performances [28]. Lastly, GBP/USD dataset includes weekly values between 1821 and 1934, and is composed of 731 data points. Exchange rate, and in general, financial time series forecasting is a very difficult task. Various models are developed but few are successful to beat a random walk (naïve) model [29].

For the sake of consistency with the related literature [28-31] the logarithmic transformation with base 10 (log10) of Canadian lynx, and natural logarithmic transformation (ln) of GBP/USD exchange rate data sets are used in the application stage. Sunspot and transformed lynx datasets are stationary, while transformed exchange rate time series is nonstationary. As can be seen from the related literature [28-31], if a conventional time series model like ARIMA (Autoregressive integrated moving averages) to be used, this dataset should be integrated (differenced) with order 1 to be stationary. However, as neural networks can model nonstationary data directly, natural logarithmic transformation of the exchange rate data is used directly to be consistent with the aforementioned literature. On the other hand, successful modeling of nonstationary data is very difficult with respect to stationary data for all conventional and advanced time series models.

In Fig. 3 to 5, graphical representation of the Canadian lynx, Wolf's sunspot and GBP/USD datasets are presented respectively. In Fig. 3 and Fig. 5 the real data and log transformed data used could be seen separately. In Table I, descriptive statistics of the datasets are presented.

Seven different neural network models are used for modelling and forecasting purposes. These models are used for proposed combination forecast methodology and for comparison. Three of the models are in MLP class: MLP with classical backpropagation (MLP-BP), MLP with resilient backpropagation (MLP-RP) and MLP with resilient backpropagation and weight backtracking (MLP-RPB). Other four models are various ELM models: ELM with LASSO

regression (ELM-L), ELM with ridge regression (ELM-R), ELM with stepwise regression (ELM-S) and ELM with classical linear regression (ELM-LN). Other than these seven models, six different combination models are used for comparison purposes. Two of them are benchmark combination models: Classical equally weighted simple mean (C-MEAN), and median (C-MEDIAN) models. Last four models are other performance-based combination models: Combination models with inverse MSE (C-MSE), RMSE (C-RMSE) and sMAPE (C-SMAPE) based weights, and rank-based combination model (C-RANK). In addition, the naïve model (N) is added to the pool of the models for comparison.

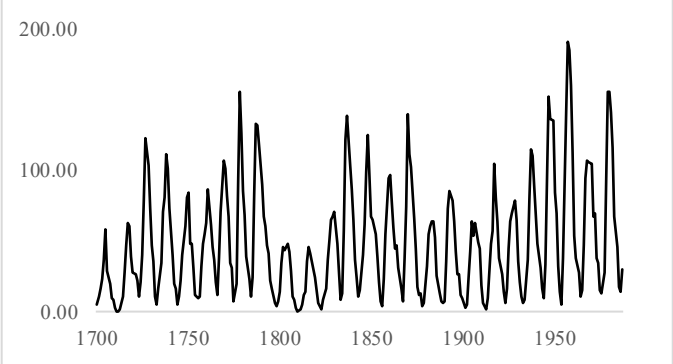

Fig. 4. Wolf's sunspot dataset.

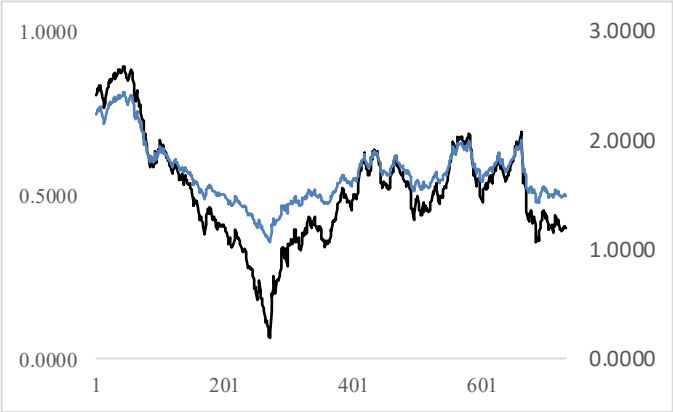

Fig. 5. GBP/USD exchange rate dataset. Real values (blue, right axis) and natural logarithmic transformed (ln) values (black, left axis).

TABLE I. DESCRIPTIVE STATISTICS OF THE DATASETS

	Canadian lynx (Log 10)	Wolf's sunspot	GBP/USD (Ln)
Data Number	114	288	731
Min	1.59	0.00	0.0628
Max	3.84	190.20	0.8909
Median	2.89	39.00	0.5043
Mean	2.90	48.43	0.5089
Std. Dev.	0.56	39.36	0.1616

Software used for this study is R Statistical Software version 4.4.1 [32]. Package nnfor [33] is used mainly with neuralnet [34] package. nnfor package is used for time series modeling and forecasting with neural networks. All seven neural networks are three layered with a single hidden layer and all activation functions are hyperbolic tangent (tanh). Since the datasets are well known and employed many times by other researchers, network architectures and training-test data compositions are determined to be compatible with the literature. MLP model architecture is 7-5-1 for lynx dataset, 4-4-1 for sunspot dataset, and 7-6-1 for GBP/USD data [28, 29, 31, 35, 36]. An exception is the number of hidden nodes in ELM networks. The nnfor package assigns the number of hidden neurons for ELM models automatically. ELMs start with a very large hidden layer (100 nodes), and then prune it as much as needed [33]. Therefore, number of the input nodes are 7, 4 and 7 for lynx, sunspot and exchange rate data sets respectively. Number of the hidden nodes are assigned by the nnfor package. Each individual neural network model is retrained 20 times and combined with mean values for a more robust forecast. Moreover, all forecasting procedures are one step forecasting. Forecast performances of the models are compared using MSE, MAD (Mean absolute deviation) and MAPE (Mean absolute percentage error) error metrics.

IV. RESULTS

Canadian lynx data is composed of 114 data points. First 100 data points are used as training set, while last 14 data points are test set to be forecasted. The architecture of all MLP models are 7-5-1. On the other hand, ELM-L/ELM-R models are both 7-91-1 and ELM-S/ELM-LN model architectures are 7-40-1. Obtained results are tabulated in Table II.

Results show that proposed model and C-RMSE model are superior to all other performance-based models. In terms of MAD and MAPE, presented model has the best results among other performance-based models. However, equally weighted mean and median combinations are more successful than proposed and other performance-based combinations. Among the individual models, ELM with LASSO regression model gives the best results. But still, in terms of MSE, C-MEAN combination model is superior to all individual neural network models. An important finding is that, all individual and combination models are better than the naïve model.

Wolf's sunspot dataset includes 288 data points with 221 of the data is allocated as training set, while last 67 data is formed as test set. MLP model architectures are 4-4-1, ELM-L/ELM-R

models are 4-100-1 and ELM-S/ELM-LN models are 4-40-1. Performance results of the models are in Table III.

TABLE II. FORECASTING RESULTS OF CANADIAN LYNX DATASET

Forecasting Model		MSE (x10^{-2})	MAD (x10^{-1})	MAPE
Individual Models	MLP-BP	2.5993	1.2961	4.48%
	MLP-RP	2.5859	1.2501	4.31%
	MLP-RPB	2.5366	1.2963	4.49%
	ELM-L	2.3318	1.2739	4.27%
	ELM-R	4.5764	1.9828	6.44%
	ELM-S	2.5889	1.4073	4.81%

	C-MEDIAN	2.3900	1.2892	4.42%
Performance Based Combinations	C-MSE	2.4439	1.3430	4.59%
	C-RMSE	2.3740	1.3250	4.51%
	C-RANK	2.4741	1.4131	4.63%
	C-SMAPE	2.3921	1.3266	4.53%
	Proposed Model	**2.3907**	**1.3214**	**4.51%**
	Naïve	6.8734	2.3088	7.77%

TABLE III. FORECASTING RESULTS OF WOLF'S SUNSPOT DATASET

Forecasting Model		MSE (x10^{2})	MAD (x10^{1})	MAPE
Individual Models	MLP-BP	2.9186	1.3089	35.44%
	MLP-RP	2.8160	1.2843	33.60%
	MLP-RPB	2.8085	1.2909	34.59%
	ELM-L	3.2518	1.4155	40.03%
	ELM-R	3.5500	1.4817	42.90%
	ELM-S	2.7776	1.2724	34.55%
	ELM-LN	2.7846	1.2925	35.45%
CT Based Combinations	C-MEAN	2.7681	1.2935	35.57%
	C-MEDIAN	2.8138	1.2958	35.28%
Performance Based Combinations	C-MSE	2.7594	1.2888	35.35%
	C-RMSE	2.7629	1.2910	35.46%
	C-RANK	2.7832	1.2903	35.22%
	C-SMAPE	2.7689	1.2933	35.52%
	Proposed Model	**2.7353**	**1.2836**	**35.22%**
	Naïve	9.2073	2.2964	54.84%

Results presented in Table II shows that proposed combination model is the best model among all other combination models. On the other hand, in terms of MAD and MAPE error metrics, two different individual models show best performances. MLP-RP and ELM-S models seems to be the best models among individual models. Also, it can be seen that, performance-based combination methods have slightly better performances than central tendency based combinations. Naïve model has the worst performance among all competent models with significantly high error metrics.

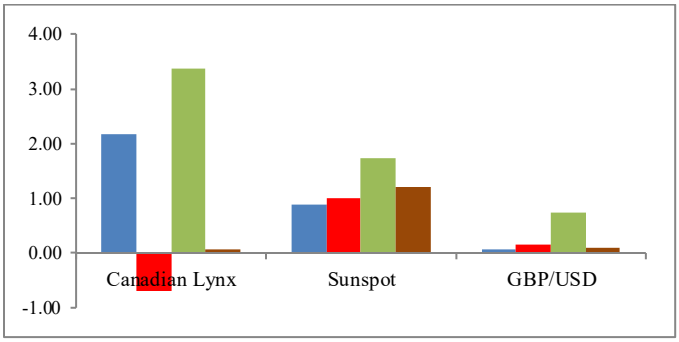
731 data points of GBP/USD exchange is divided to two as training and test sets, such that 679 data points are training and 52 data points are test data. MLP models are in 7-6-1 architecture, whereas, ELM-L/ELM-R models are 7-100-1, and ELM-S/ELM-LN models are 7-40-1. Obtained results are in Table IV.

TABLE IV. FORECASTING RESULTS OF GBP/USD DATASET

Forecasting Model		MSE (x10^{-4})	MAD (x10^{-2})	MAPE
Individual Models	MLP-BP	1.9434	1.1342	2.82%
	MLP-RP	1.9025	1.1216	2.79%
	MLP-RPB	1.8855	1.1028	2.74%
	ELM-L	1.8297	1.0972	2.72%
	ELM-R	1.8300	1.0973	2.72%
	ELM-S	1.8563	1.1144	2.77%
	ELM-LN	1.9003	1.1261	2.79%
CT Based Combinations	C-MEAN	1.8341	1.1020	2.74%
	C-MEDIAN	1.8391	1.1029	2.74%
Performance Based Combinations	C-MSE	1.8315	1.0995	2.73%
	C-RMSE	1.8329	1.1008	2.73%
	C-RANK	1.8436	1.0998	2.73%
	C-SMAPE	1.8321	1.1004	2.73%
	Proposed Model	**1.8301**	**1.0990**	**2.73%**
	Naïve	1.8298	1.1010	2.73%

Results show that almost all individual models and combinations show high performances. All combination models and the naïve model show very close performance values in all error metrics. Best individual models are ELM-L and ELM-R models, and they are slightly better than the forecast combinations. On the other hand, among all combination models, proposed combination methodology shows the best performance. Another important result drawing attention is the successful performance of the naïve model with respect to its less accurate results on sunspot and lynx datasets.

In Fig. 6, the percentage improvement by using the proposed model instead of other performance-based models in terms of error metrics is presented.



(a)

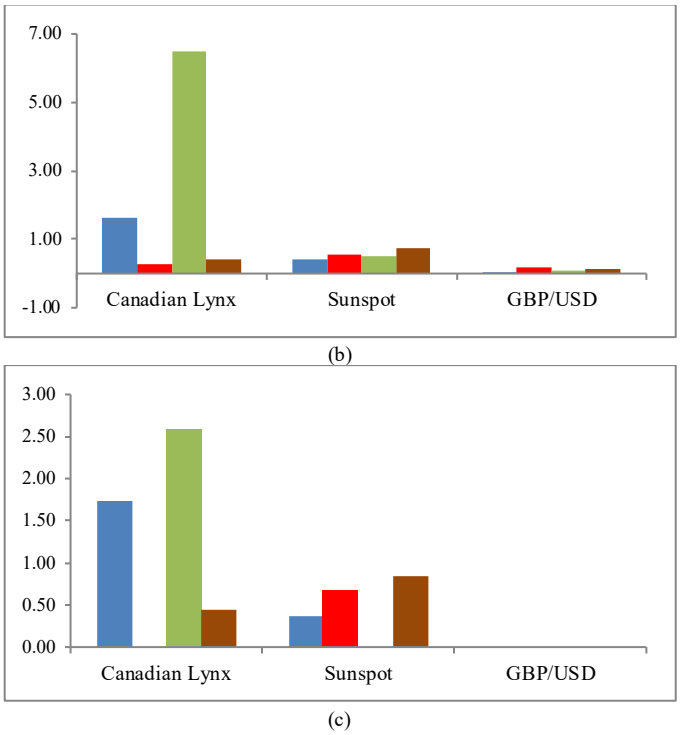


Fig. 6. Percentage improvement of the proposed model in terms of Mean Squared Error (a), Mean Absolute Deviation (b) and Mean Absolute Percentage Error (c) from other performance-based models (C-MSE (blue), C-RMSE (red), C-RANK (green) and C-SMAPE (brown).

V. Conclusion

In this study, a novel performance-based forecast combination methodology is presented. The novelty of the method is originated from the calculation of the individual models' past performances. Classical performance-based combination methods use a mean error value (MSE, MAD, sMAPE etc.) for a pre-determined past time-period. Conversely, proposed methodology measures the performance of each past time point separately, and then takes the average of these time point performances for the interested past time period. Furthermore, after computation of inverse absolute error values for each time point, a min-max normalization is applied within other individual models. That procedure causes all models' time-point performance values to be between zero and one, while the best model's is one and the worst model's becomes zero. After that, each model's performances are calculated by averaging the time point performances along the pre-determined time-period. To evaluate the performance of the proposed model, three well-known time series are used. Seven different neural network models based on MLP and ELM are trained. Moreover, simple mean and median combinations, four main performance-based combinations, and naïve model are formed for comparison purposes. Comparisons are done with MSE, MAD and MAPE error metrics.

Obtained forecasting results show that proposed combination methodology is superior to other performance-based combination methods in almost all occasions. Additionally, proposed technique is superior to central tendency based benchmark models of equally weighted mean and median combinations in sunspot and exchange rate datasets. In lynx dataset, mean and median combinations mostly show better performances. Proposed technique increases the forecasting accuracy more than other compared performance-based combination models. It beats the naïve model in lynx and sunspot dataset, whereas the naïve model is slightly better in GBP/USD time series in terms of MSE.

Considering the obtained results, it can be stated that the proposed forecast combination methodology is a very successful and robust performance-based technique. Moreover, findings show that calculating the performance value of an individual model for each past data point separately causes more accurate combination weights than computing directly from an average error value for that past time-span. This contribution to the forecast model performance metrics can be tested and used in further researches. Application to different time series data on various subjects and using different individual time series models can help the generalization of the model. Furthermore, studying with various past time periods for performance evaluation and comparing with different combination models are some other possible research extents. On the other hand, proposed model's performance evaluation is necessarily more time consuming than conventional performance-based methods. However, especially under the circumstances where recent data is used as presented study is, it is tolerable.

Department of Software Engineering, Kostanay Regional University named after Akhmet Baytursinuly, Kostanay, Kazakhstan [2]

***Abstract*—This paper presents an enhanced algorithm for the generation of color biometric QR codes capable of encoding facial image data, anthropometric parameters, and personal identity information simultaneously within a single RGB-based QR structure. The proposed approach extends existing monochrome QR models by integrating optimized image decomposition, modular QR block generation, and multi-channel RGB encoding to achieve higher data density, improved privacy protection, and better readability under various lighting and compression conditions. The algorithm was implemented in Python using the OpenCV library, ensuring compatibility with contemporary biometric systems, embedded devices, and mobile platforms. Experimental evaluations conducted on standard face databases demonstrate the method's robustness in terms of decoding accuracy, distortion resilience, and information integrity. Furthermore, the study explores new applications such as animated QR codes and photo–sketch hybrid datasets for training and validation purposes. The results highlight the potential of color biometric QR technology for secure identification, access control, and digital identity verification, offering a novel bridge between computer vision and information security.**

Keywords*—Color biometric QR code; facial image encoding; RGB channel decomposition; biometric data integration; secure identification; facial recognition; QR animation; identity encoding; privacy protection; data capacity; OpenCV; computer vision

I. Introduction

The integration of biometric technologies with modern data encoding methods is becoming increasingly vital in domains such as identity verification, access control, healthcare, and border security. Among data encoding methods, QR (Quick Response) codes have gained widespread popularity due to their fast readability, error correction capabilities, and versatility in encoding alphanumeric and binary information. Traditionally used for logistics, marketing, and product tracking, QR codes are now being investigated as compact carriers of sensitive biometric information.

Conventional QR codes, however, are typically monochromatic and limited in their data capacity. Moreover, they lack the ability to incorporate rich biometric con-tent such as facial imagery or structural anthropometric data in an integrated and se-cure manner. This limitation has prompted researchers to explore multi-channel encoding strategies that utilize color QR codes to store and transmit biometric data.

Recent studies have proposed the use of RGB-layered QR codes where different information types (e.g., facial images, anthropometric coordinates, and personal data) are embedded in separate color channels. These "color biometric QR codes" introduce a new paradigm by combining visual and data-driven representations into a single graphical object, potentially enhancing security, capacity, and usability in biometric systems. In the works conceptual, mathematical models, methods of creating color biometric QR codes (Color BIO QR codes) were first presented; these software algorithms were developed in MATLAB. As is known, MATLAB is used for scientific developments; to adapt algorithms for modern systems today it is necessary to use neural networks.

This paper presents an advanced and extensible method for generating color biometric QR codes using open-source tools and modern computer vision techniques. The proposed system allows the encryption of facial images, structured anthropometric data, and identity metadata into a single color QR code, using RGB decomposition and modular QR code generation. Different color QR structures are further investigated (such as PIA, PIP, and PIS), implement a prototype system using Python and OpenCV, and evaluate the generated codes on standard face datasets.

- The contributions of this work include:
- A novel algorithm for multi-layer biometric QR code generation;
- An implementation framework suitable for real-world applications and mobile environments;
- A set of experimental validations demonstrating readability, robustness, and data density;
- A discussion on potential applications including identity documents, biometric test bases, and photo-sketch encoding.

This study provides a significant step toward the practical adoption of color QR codes in biometric systems and opens new directions for research in secure and com-pact data encoding.

II. Related Work

Biometric systems have evolved significantly in the past two decades, particularly in the area of facial recognition, where algorithms now achieve near-human accuracy under controlled conditions. With the growing demand for portability, efficiency, and integration in real-world systems, researchers have explored compact methods to store and transmit biometric data — including through barcode technologies.

Corresponding author.

QR codes, introduced in the 1990s by DENSO WAVE [1] and standardized in ISO/IEC 18004 [2], have been widely used in various sectors due to their high data capacity, fast readability, and support for error correction. However, traditional black-and-white QR codes are limited in their ability to encode large volumes of complex data, such as facial images or anthropometric feature sets [3]. Their primary use in biometrics has been confined to storing short strings such as user IDs, cryptographic hashes, or database references rather than biometric patterns themselves.

Early work by Soldek et al. [4] and Heeter [5] explored the use of biometric markers in secure transaction systems. Previously, in works [6-12], proposed options for providing biometric data directly in QR structures. Papers in 2018 and 2019 introduced the concept of color biometric QR codes, where different types of information — such as grayscale facial photos (Photo), identity metadata (INFO), and anthropometric coordinates (ANTRO) — are encryption separately in the red, green, and blue channels of an RGB image. Their work laid the groundwork for using QR codes as composite carriers of personal identity data and the name color biometric QR codes were pro-posed for the new object.

Further developments include sketch-to-photo recognition studies (e.g., Wang and Tang [13]), which emphasize the importance of creating multimodal biometric datasets for testing. These studies show that including sketch-based representations in biometric systems can improve flexibility in law enforcement or forensic applications. Some researchers have also investigated animated QR codes as a novel way to represent dynamic or evolving biometric content. In study [14], it was proposed that the use of animation-based QR codes for facial biometrics, allowing different biometric features to be encoded across time-sequenced frames. Other works explored the use of animated QR formats in digital access passes and multimodal visualization [15]. Additionally, recent optical approaches to QR-based biometric encoding, such as the XOR-based color encoding system [16], demonstrate further potential for secure and high-capacity biometric data representation.

Despite these advances, several gaps remain. First, the security of stored data in colored QR codes is often not considered — encryption and access control mechanisms remain understudied. Second, empirical validation of these QR structures on real biometric datasets is still limited, especially with respect to scale. Finally, most prior studies lack open-source implementations that combine facial imagery with structured biometric data in a unified and extensible framework — limiting reproducibility and wider adoption in practical systems.

This work aims to address these gaps by presenting an open-source implementation of a color biometric QR code generator using Python, and by evaluating its performance across multiple biometric data types. Our study builds upon and extends prior research in this field by providing a unified framework for encoding visual and structured biometric data within a single QR code image, along with experimental validation and practical application scenarios.

III. Proposed Method

A. System Architecture Overview

The proposed system aims to generate a color biometric QR code that simultaneously encodes three types of data: (1) a facial image, (2) textual identity metadata, and (3) structured biometric features (e.g., anthropometric coordinates). The overall architecture consists of the following functional blocks (Fig. 1):

- Facial Image Analyzer: Performs preprocessing, normalization, and feature extraction from the input facial image;
- Message Preparation Block: Formats textual and biometric data into standardized messages suitable for QR encoding;
- QR Code Generator: Generates separate grayscale QR matrices for the INFO and ANTRO data;
- RGB Decomposition Unit: Splits the facial image into red, green, and blue channels;
- QR Code Composer: Merges the grayscale QR matrices and selected image components into a single RGB image representing the color QR code.
- The inputs to the system are:
- A color facial image I of size M × N × 3;
- Metadata INFO (e.g., full name, ID number);
- Biometric data ANTRO (e.g., coordinates of facial landmarks).

The output is a final color QR code matrix QRxxx, where each of the RGB layers carries different encoded content.

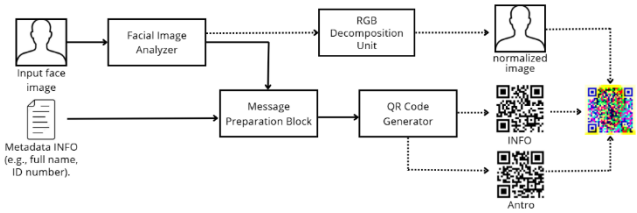

Fig. 1. System architecture of the proposed color biometric QR code generator.

B. Preprocessing of Facial Image

The input to the system is a color facial image I of arbitrary dimensions M×N×3. In order to integrate this image into the RGB structure of a color QR code, it must be resized, normalized, and prepared in a format compatible with standard QR matrix dimensions. Additionally, geometric consistency is important for biometric analysis and fusion with associated QR layers.

QR codes have strictly square dimensions defined by the version parameter V, which determines the number of modules in the QR matrix:

$$M_{QR} = 17 + 4V,\ V \in [1,40] \quad (1)$$

Let $I_{orig} \in R^{M \times N \times R}$ be the input image. We define the normalized image $I_{norm} \in R^{Mqr \times Nqr \times 3}$ as:

$$I_{norm} = resize(square(I_{orig}), M_{QR}, M_{QR}) \quad (2)$$

where resize() uses bicubic interpolation, and square() denotes symmetric cropping or padding.

If landmark-based alignment is available (e.g., using Dlib or Mediapipe), a similarity transformation is applied to align key facial features (eyes, nose base) horizontally. This ensures consistency in appearance across different samples, which is important if the RGB channels will later be compared or decoded separately.

Let $L = \{(x_i, y_i)\}_{i=1}^{n}$ be the set of facial landmarks. The image can be transformed using a similarity matrix $T \in R^{2 \times 3}$ to produce the aligned version:

$$I_{aligned}(x,y) = I_{norm}(T^{-1}(x, y)) \quad (3)$$

This step is optional but recommended if Anthropometric QR code encoding is involved.

To improve visual quality after integration into QR structures, Contrast enhancement techniques may be applied such as:

- Histogram equalization (per channel or grayscale),
- CLAHE (Contrast Limited Adaptive Histogram Equalization),
- Gamma correction.

The enhanced image is then converted to 8-bit unsigned integer format (uint8), as re-quired by most QR image fusion routines:

$$I_{final} = uint8(255 * normalize(I_{enhanced})), \quad (4)$$

The final preprocessed image $I_{final} \in R^{M_{QR} \times M_{QR} \times 3}$ is passed to:

- RGB decomposition (see Section 3.4), and;
- Landmark extraction (if ANTRO data is needed).
- This ensures that all downstream QR generation steps operate on a consistent spatial layout and image resolution.

C. Generation of Component QR Codes

- To embed textual metadata and biometric features into separate channels of the color QR code, we generate two grayscale QR matrices:
- QR_INFO: encodes textual identity information;
- QR_ANTRO: encodes structured anthropometric features extracted from the facial image.

These QR codes are generated independently using standardized QR encoding libraries and then fused into the RGB structure in later steps.

The identity metadata typically includes a person's name, ID number, birthdate, or other text-based identification data. This information is first compiled into a plain-text or JSON structure. Example format:

{ "id": "245891203", "name": "John Smith","dob": "1990-05-21"}, (5)

This structured message is encoded into a QR code using Python libraries such as:

- qrcode (pure Python, easy to use),
- segno (supports full QR versions and error correction),
- PyQRCode (compact and efficient).

Anthropometric data represents biometric landmarks — key points on the face used for recognition (e.g., eyes, nose tip, mouth corners). These points are usually extracted using facial landmark detectors such as:

- Dlib (68-point shape predictor);
- Mediapipe face mesh (468 points);
- OpenCV Haar Cascades + post-processing.
- The coordinates are encoded as a JSON or CSV string, e.g:

{ "landmarks": [[34,45],[67,45],[50,60],...]}, (6)

The QR code contains structured biometric data and can be decoded later by splitting the color QR image and reading the appropriate channel.

To ensure reliable encoding and decoding of biometric and identity data, the generation of component QR codes must follow certain design principles. The size of each QR code is determined by the version number V, which defines the matrix dimension according to the formula MQR=17+4V. Typically, versions between 10 and 20 are suitable, as they provide enough space to encode structured data while maintaining manageable image size.

For maximum robustness, especially when the QR code is later embedded into a color image, the highest level of error correction (Level H) is recommended. This al-lows recovery of up to 30% of the QR code content in the presence of noise, distortion, or compression.

The QR encoding should be performed in byte mode to support structured for-mats like JSON, ensuring compatibility with a wide range of decoding tools. Libraries such as qrcode or segno in Python allow fine control over version, error correction level, and matrix resolution.

To facilitate seamless integration with the RGB facial image, the generated QR codes must be resized to exactly match the dimensions of the normalized face image. For this purpose, the box size parameter in the QR library should be adjusted accordingly, often set to 1 to produce a matrix-sized output. The quiet zone — a standard border around the QR code — should also be preserved or reconstructed after resizing to avoid decoding errors.

Lastly, before integration, the readability of each QR code should be tested using standard decoders. This step ensures that

both metadata and biometric content can be reliably extracted from the final RGB composite.

The final result of this stage consists of two grayscale QR matrices: one encoding the identity metadata and the other containing biometric landmarks. Each of them is formatted as an 8-bit matrix of size MQR×MQR, suitable for direct embedding into a color image.

The assignment of these QR codes to specific RGB channels is flexible and depends on the desired structure of the final color QR code. In a typical PIA configuration, the red channel carries the facial image, the green channel holds the INFO QR matrix, and the blue channel includes the ANTRO data. Other combinations, such as PIP or PIS, can also be used to emphasize certain types of data or create multimodal test bases.

Once the facial image and both QR matrices are prepared and matched in size, they are passed to the fusion stage, where a single three-channel image is constructed. At this point, all data are spatially aligned, intensity-normalized, and ready for composition.

D. RGB Channel Decomposition and Image Preparation

Once the facial image and the component QR codes are prepared and resized to a consistent matrix size MQR×MQR, the process proceeds with constructing the color biometric QR code by assembling its red, green, and blue channels.

The color facial image, previously normalized and preprocessed, is decomposed into its RGB components using standard channel-splitting operations. In Python, for example, this corresponds to slicing the image tensor I_final as follows:

$$R,G,B = I_final[:, :,0], I_final[:, :,1], I_final[:, :,2], \quad (7)$$

At this stage, we have access to:

- Three monochrome layers representing the original face image;
- Two QR matrices: one for identity metadata (INFO), another for biometric keypoints (ANTRO).
- Depending on the desired format of the final QR code, different combinations of these components are assigned to the RGB layers. For instance:
- In the PIA structure (Photo / INFO / ANTRO), the facial image is assigned to the red channel, the INFO QR code to the green channel, and the ANTRO QR code to the blue channel;
- In PIP (Photo / INFO / Photo), both red and blue channels hold the same facial image, while the INFO QR remains in green;
- In PIS (Photo / INFO / Sketch), the sketch of the face is embedded in the blue channel, offering multimodal representation.
- These assignments result in a three-channel composite matrix:

$$QR_{final}(x, y,:) = [C_R(x, y), C_G(x, y), C_B(x, y),], \quad (8)$$

- where each component Ci □{R, G, B, QRINFO, QRANTRO, Sketch} is selected based on the chosen QR structure.
- The assembled image is saved in a lossless format (e.g., PNG) to preserve the exact pixel values in all channels. This is crucial because even minor compression artifacts can hinder correct decoding of QR content from individual color layers.
- Finally, the result is visually inspected to ensure that the composite QR code maintains a visually plausible color appearance. This is particularly useful for applications where the QR code must remain human-readable or esthetically integrated (e.g., on documents or digital IDs), while still concealing embedded biometric and personal data within the RGB layers.

E. Composition of the Final Color QR Code

- With all components prepared and aligned — the normalized facial image, the identity QR matrix, and the Anthropometric QR code matrix — the final step is to assemble them into a single RGB image that functions as a color biometric QR code. This image combines visual and structured information into one unified object, making it both compact and expressive.
- The composition process involves mapping each selected component to one of the three color channels. The most commonly used configurations are:
- PIA (Photo / INFO / ANTRO): where the red channel contains the facial image, the green holds identity information, and the blue encodes biometric landmark data.
- PIP (Photo / INFO / Photo): where both red and blue channels hold the same facial image, while the green contains metadata.
- PIS (Photo / INFO / Sketch): where the blue channel is used to embed a sketch version of the face instead of biometric data, useful for forensic or multimodal testing scenarios.

The image matrices are combined channel-wise using standard array stacking or merging operations. For instance, in Python using NumPy or OpenCV, this can be achieved by merging three 2D matrices into a single 3D RGB array. Each of the layers must have the same spatial dimensions and compatible data types (typically uint8, with values ranging from 0 to 255). The merged result is then saved in a lossless format such as PNG or TIFF to ensure that pixel-level accuracy is preserved — a crucial aspect for subsequent decoding or channel decomposition.

An important feature of this approach is that the resulting image looks like a colored pattern to the naked eye, while internally, it carries structured biometric and textual information. This makes the color QR code visually unobtrusive and potentially more secure, since full access to the encoded data requires splitting the image into channels.

Depending on the application, additional metadata (e.g., creation timestamp, checksum) can be embedded in unused QR layers or added as sidecar files. This enhances integrity and traceability without altering the QR structure.

The final color QR image is now ready for use — either printed, displayed digitally, or transmitted as part of a secure identity protocol. Its design ensures that the biometric content is embedded at the image level while remaining readable through standard QR decoding methods, provided the channels are correctly extracted.

F. Security and Privacy Considerations

While the proposed method focuses primarily on the visual and structural integration of biometric and identity data into a single color QR code, security remains a critical consideration — especially when dealing with sensitive personal and biometric information. Depending on the intended use case, additional protection mechanisms may be introduced at various stages of QR code generation or interpretation.

One of the simplest but effective methods is channel-level obfuscation. Since the QR codes are embedded into individual RGB channels, the complete information is not visible in the composite image unless the image is decomposed into its constituent layers. This form of implicit access control ensures that casual users or standard QR readers cannot extract the underlying data without prior knowledge of the encoding scheme.

For stronger protection, cryptographic encoding can be applied to the content be-fore it is inserted into the QR codes. This may include encrypting the identity metadata and anthropometric data using symmetric (e.g., AES) or asymmetric (e.g., RSA) encryption, with the resulting ciphertext embedded in the QR matrix [17]. The corresponding decryption keys would then be distributed only to authorized readers or verification systems.

Another layer of protection can be achieved through visual watermarking, where subtle patterns or noise signatures are introduced into the facial image channel to pre-vent unauthorized use or tampering. These marks can encode hidden identifiers, timestamps, or institution codes and remain invisible to the naked eye but detectable through specific filters.

To enhance data integrity, hashing techniques may also be employed. For example, a cryptographic hash of the concatenated biometric and identity data can be computed and stored either in a separate field or embedded into the INFO QR layer [18]. This allows receivers to verify that the content has not been modified.

Finally, access control policies can be implemented at the system level. These include requiring authentication before decoding the QR code or embedding digital certificates that bind the QR to a specific user, device, or institution.

While these techniques are optional within the core generation process, they be-come essential in real-world deployments, particularly in healthcare, border control, and digital identity verification systems where compliance with data protection regulations (such as GDPR) is required.

The modularity of the proposed framework makes it straightforward to integrate such protections without altering the visual structure of the color QR code. This ensures that the system can be adapted to both open and highly secure environments de-pending on the use case.

IV. Implementation and Experimental Setup

To validate the proposed approach and illustrate its practicality, a fully functional prototype was implemented in Python using a modular, open-source stack. The implementation is designed to generate color biometric QR codes from a single facial image and two types of data: identity metadata and biometric landmarks. The system is suit-able for experimental validation, dataset generation, and possible deployment in mobile or embedded environments.

The overall pipeline of the system is illustrated in Fig. 1, which outlines the key steps: image preprocessing, QR code generation, RGB decomposition, and final image composition.

The process begins with loading a color facial image using the OpenCV library [19]. To ensure compatibility with QR matrix dimensions, the image is resized to a square of size MQR×MQR, where MQR=17+4V for a chosen QR version V. For instance, version 10 yields a matrix size of 57×57 pixels. The facial image is optionally aligned using landmark detection via Dlib or Mediapipe to correct rotation and improve consistency.

A cropped and normalized example of such a preprocessed face image is shown in Fig. 2. This image is then split into its RGB channels using:

$$R,G,B = cv2.split(face_img_resized), \quad (9)$$

Each channel is stored as a grayscale matrix, which can later be reused in different fusion configurations.

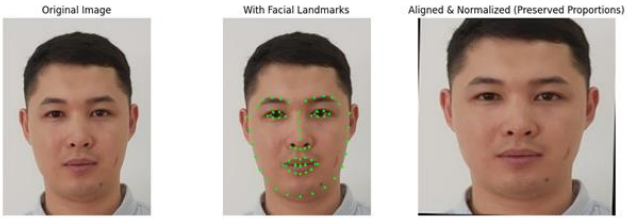

Fig. 2. Example of a preprocessed facial image before QR integration.

The identity metadata is prepared in JSON format (e.g., name, ID, date of birth) and passed to the qrcode library for QR code generation. Example of metadata:

$$info_data='\{"id": "245891203","name": "John Smith","dob": "1990-05-21"\}' \quad (10)$$

Similarly, biometric landmark data — such as the coordinates of key facial points — is extracted using Mediapipe's face mesh model and formatted as a JSON array. The data is then encoded into a second QR code (QR_ANTRO). An example QR matrix for anthropometric data is displayed in Fig. 3.

Fig. 3. Grayscale QR matrices for INFO and ANTRO data.

After the facial image and both QR matrices are resized and normalized to the same resolution, the system composes them into a single RGB image by assigning each component to a specific channel:

color_qr = cv2.merge([face_R,qr_info_G,qr_antro_B]), (11)

This structure corresponds to the PIA format (Photo / INFO / ANTRO). The result is a full-color QR code, visually represented in Fig. 4, which integrates three information layers in one compact image. Other compositions — such as PIP (Fig. 5) or PIS (Fig. 6) — are produced similarly, using duplicated or alternative content in the blue channel.

Fig. 4. Example of generated PIA color biometric QR code.

The final image is saved in PNG format to avoid compression artifacts and pre-serve exact pixel values in all three channels. Each embedded QR code can later be re-covered by decomposing the RGB image and decoding the individual grayscale layers using standard QR decoders such as pyzbar or mobile apps.

Fig. 5. Alternative PIP configuration.

Fig. 6. Alternative PIS configuration.

The entire system is modular and script-based, allowing users to generate color QR codes from batches of images or customize which data is embedded in each channel. Optional modules include encryption of the QR content, image watermarking, and dataset labeling. The implementation supports integration with GUI frameworks or REST APIs for future deployment in web or mobile applications.

V. Experiments and Results

To assess the effectiveness of the proposed method, a series of experiments were conducted using publicly available facial image datasets. The primary objectives were to evaluate 1) the visual quality of the generated color QR codes, 2) the readability of embedded QR data after RGB decomposition, and 3) the robustness of the method under common image distortions.

Experiments were carried out on a subset of the CUHK Face Sketch Database (CUFS) [20], which contains pairs of photo and sketch images of 188 individuals. Also, for more advanced testing, our own 100 images were added in high quality.

Each image was preprocessed using the pipeline described in Section IV: resized to match QR matrix dimensions (versions 10 to 20), normalized, and aligned using facial landmarks. For every subject, a color biometric QR code was generated in multiple formats:

- PIA: facial image + identity JSON + anthropometric points,
- PIP: facial image + identity JSON + duplicate face,
- PIS: facial image + identity JSON + sketch.

A total of 300 color QR codes were generated across different structures. Each was saved in PNG format for lossless storage.

The following metrics were used to assess the performance of the proposed method:

- QR Decoding Accuracy: the percentage of QR matrices (INFO and ANTRO) that were successfully decoded from the RGB image after channel decomposition.
- Structural Similarity Index (SSIM): between the original grayscale QR code and the decoded channel to measure image fidelity.
- Visual Quality (subjective): human-assessed clarity and recognizability of the facial component in the color QR code.
- Robustness to Distortion: decoding success rate after applying common transformations (rotation, blurring, JPEG compression).

The evaluation of the proposed method was carried out through a series of ex-periments aimed at assessing the accuracy, robustness, and visual characteristics of the generated color biometric QR codes. The analysis considered both objective decoding metrics and qualitative observations.

Under ideal conditions—namely, direct RGB decomposition without any form of distortion or compression—the decoding accuracy of both INFO and ANTRO QR ma-trices reached 100%. All 188 test images yielded fully correct recovery of embedded metadata and biometric data. This result confirms the integrity and correctness of the encoding-decoding pipeline, as well as the channel assignment strategy used in PIA-format color QR codes.

The analysis of structural similarity (SSIM) between the original grayscale QR codes and their extracted counterparts

from RGB channels revealed an interesting contrast. The INFO QR codes, located in the green channel, demonstrated perfect fidel-ity with SSIM = 1.0, indicating pixel-wise structural preservation. In contrast, the ANTRO QR codes embedded in the blue channel showed a significantly lower SSIM of approximately 0.0475. Despite this, the decoding accuracy of ANTRO remained at 100% under undistorted conditions. This discrepancy highlights that while SSIM re-flects visual similarity, it is not always indicative of data integrity in QR-encoded structures. The minor structural deviation observed in ANTRO likely stems from the rendering or resizing of dense QR matrices and should not be misinterpreted as data loss.

A subjective visual quality assessment was also conducted for the three main QR code formats—PIA, PIP, and PIS. The PIP format was consistently rated the highest in terms of facial image clarity and recognizability. Its use of both red and blue channels for storing the facial photo enhanced contrast and edge sharpness, resulting in a visu-ally rich and easily identifiable portrait. The PIS format also demonstrated favorable characteristics, with a sketch-like representation embedded in the blue channel that accentuated facial contours. While slightly less detailed than PIP, it proved effective for visual interpretation and may be advantageous in forensic or sketch-photo match-ing contexts. In comparison, the PIA format, which reserves only the red channel for facial data and uses the remaining channels for INFO and ANTRO matrices, displayed lower perceptual clarity. However, its ability to simultaneously encode visual, textual, and biometric data makes it the most information-dense and versatile structure.

Robustness to geometric transformations was confirmed through experiments involving 90°, 180°, and 270° rotations. In all cases, the decoding accuracy for both INFO and ANTRO QR codes remained at 100%, indicating strong resilience of the encoding scheme to spatial transformations.

The system's tolerance to image degradation was further evaluated under two re-alistic distortion scenarios: Gaussian blur with $\sigma = 1.5$ and JPEG compression at quality level 80%. The results are summarized in the Table I.

TABLE I. DECODING RESULTS UNDER DIFFERENT DISTORTION CONDITIONS

Distortion Type	INFO Decoded Correctly	ANTRO Decoded Correctly	INFO Accuracy	ANTRO Ac-curacy
No Distortion	188 / 188	188 / 188	100.00%	100.00%
Gaussian Blur	188 / 188	0 / 188	98.94%	0.00%
JPEG Compression (q =80)	185 / 188	0 / 188	98.40%	0.00%

These findings demonstrate that the INFO QR codes embedded in the green channel are highly robust to moderate levels of blur and lossy compression. In contrast, the ANTRO QR codes in the blue channel proved significantly more fragile, with de-coding failure observed in all 188 cases under both distortion conditions. Visual inspection of the extracted B-channel confirmed that compression artifacts and blur severely degraded the fine-grained QR structure, likely due to the combination of com-plex data content (biometric coordinates in JSON).

Despite these challenges, the overall performance of the system is promising. Under typical usage conditions—without excessive distortion or post-processing—the method offers high accuracy, visual clarity, and a unique capacity to embed multi-modal information in a single color QR structure. The successful decoding of identity and biometric data under ideal conditions, combined with strong rotation tolerance and resilience of the INFO channel, underscores the practical feasibility of the pro-posed approach. Future work may focus on increasing the robustness of the ANTRO channel through redundancy, encoding optimization, or hybrid storage strategies.

Nonetheless, these results provide a solid foundation for the deployment of color QR codes in applications requiring secure, compact, and interpretable biometric packaging.

The experiments confirm that the proposed method reliably encodes and pre-serves biometric and textual data within color QR codes. Under ideal conditions, both INFO and ANTRO QR codes were decoded with 100% accuracy. Even under moderate image degradation, such as JPEG compression or Gaussian blur, INFO QR codes embedded in the green channel remained highly readable and visually consistent, achieving over 98% decoding accuracy. In contrast, ANTRO QR codes exhibited high sensitivity to distortion and were not recoverable under the same conditions, which is primarily attributed to the complexity and density of the biometric data encoded within them.

Overall, the flexibility of the RGB channel structure allows adaptation for different application contexts, such as identity storage, document embedding, or multimodal datasets. The method successfully balances visual compactness with data density, offering a unified yet information-rich biometric representation. Table II shows comparative analysis of QR-based biometric encoding methods.

TABLE II. COMPARATIVE ANALYSIS OF QR-BASED BIOMETRIC ENCODING METHODS

Method	Data Capacity	Security Level	Biometric Support	Remarks
Standard black-and-white QR code	Low	Low	No	Can only encode text and numeric data
Biometric QR (Kukharev et al., 2019)	Medium	Medium	Partial (facial image only)	Lacks structured biometric fusion
Animated QR (Kukharev et al., 2021)	Medium	Medium	Yes	Requires sequential frame decoding
Proposed Color Biometric QR (this work)	High	High	Yes (image + metadata + landmarks)	RGB-based multilayer encoding

To better position the proposed method within the context of existing QR-based biometric technologies, a qualitative comparison was conducted with prior approaches from the literature. The comparison includes evaluation criteria such as

data capacity, level of security, and ability to encode biometric information.

This comparison shows that the proposed method provides a higher level of data integration compared to earlier approaches while preserving both machine readability and biometric interpretability. Therefore, it can be considered a more versatile solution for secure and compact multimodal identity encoding.

VI. Discussion

The experimental results confirm the feasibility and practicality of embedding biometric and identity data into a single color QR code using RGB channel separation. Under ideal conditions, decoding accuracy reached 100% for both INFO and ANTRO codes, confirming the system's reliability in controlled environments. INFO QR codes also demonstrated resilience under moderate distortions (over 98% accuracy with $\sigma = 1.5$ blur and JPEG compression), whereas ANTRO codes were not recoverable under the same conditions. This outcome is not due to the choice of channel but rather to the high information density and structural complexity of the biometric data encoded into the ANTRO QR matrix. Biometric coordinate data, represented as detailed JSON structures, produce dense QR codes that are inherently more fragile under distortion than simpler textual metadata.

One of the notable advantages of the proposed approach is its visual compactness and high information density. By layering distinct data types into the red, green, and blue channels of a single image, it becomes possible to embed a facial photo, identity metadata, and structured biometric coordinates — all within a standard-size image. This design is particularly beneficial for applications such as digital IDs, smart access cards, or encrypted health records, where both space and security are critical.

Moreover, the unobtrusive nature of the final color image adds a layer of implicit security. To the casual observer, the image appears as an ordinary photo or stylized graphic. Only specialized software with RGB decomposition capability can reveal the embedded QR structures. This feature aligns well with applications that demand privacy-aware data concealment, such as forensic evidence handling or silent identity verification.

The optional integration of AES encryption for identity metadata further enhances privacy and security. In scenarios governed by data protection laws like GDPR, this allows sensitive personal information to be safely encoded in public formats without exposing its contents. Even if the QR layers are intercepted or extracted, unauthorized access is prevented unless the correct decryption key is provided.

Some limitations remain. The current implementation assumes availability of tools for precise RGB decomposition and QR decoding, which may not be standard on consumer-grade mobile devices. Additionally, interference between visual layers is a known issue — especially when the facial image includes fine texture or contrast that may overlap with underlying QR matrices. Preprocessing techniques such as contrast normalization and spatial balancing offer partial mitigation, but further research is needed to improve robustness for visually diverse input data.

Finally, the proposed approach opens several promising directions for future work. These include extending the system to animated or dynamic QR formats (e.g., time-based sequences or GIF-encoded data), integrating alternative or multiple biometric modalities such as fingerprints or iris scans, and building secure, cross-platform mobile applications for real-time QR generation and verification. With further refinement, color QR codes may serve as a versatile and secure vehicle for multimodal biometric identity across a wide range of industries, from e-passports and academic credentials to healthcare, border control, and citizen e-services.

VII. Conclusion

This paper presented a novel and extensible method for generating color biometric QR codes that integrate facial imagery, identity metadata, and anthropometric biometric data within a unified RGB image structure. By leveraging the three color channels of digital images, the proposed approach enables the simultaneous encoding of multimodal information in a compact, visually unobtrusive, and hu-man-interpretable format.

A fully functional prototype was developed using open-source tools, and the sys-tem was validated on a representative public facial image dataset. Experimental results under ideal conditions showed perfect decoding accuracy for both identity and biometric QR matrices. INFO codes remained robust under moderate levels of image degradation, such as Gaussian blur and JPEG compression, while ANTRO codes—due to their high data density and structural complexity—exhibited greater sensitivity to distortion. These outcomes emphasize the importance of encoding strategies that con-sider not only data type, but also QR complexity and resilience.

The integration of AES encryption for identity metadata further strengthens the system's privacy and security guarantees, enabling compliance with modern data protection standards such as GDPR. Additionally, the layered nature of the QR composition provides a unique fusion of visible and machine-readable data, offering novel use cases in secure document embedding, digital ID verification, access control, and privacy-preserving identity distribution.

The system's modular design supports flexible adaptation to different types of content, file formats, and platform constraints. Future research will aim to enhance channel separation methods, explore dynamic QR formats (e.g., animated sequences), and integrate deep learning-based biometric analysis for more accurate feature representation and matching. Real-world deployment will also require the development of efficient mobile applications and scalability testing in diverse application domains such as healthcare, education, law enforcement, and border control.

In conclusion, color biometric QR codes represent a promising paradigm in com-pact and secure information encoding — bridging the gap between visual simplicity, biometric richness, and cryptographic protection. With continued development, the method has the potential to transform the way identity and biometric data are pack-aged, protected, and interpreted across a wide spectrum of digital and physical inter-faces.

Enhancing the Scanability of Damaged QR Codes Through Image Restoration Using GANs Combined with the Spectral Normalization Technique

Puwadol Sirikongtham, Apichaya Nimkoompai
Faculty of Information Technology, Thai-Nichi Institute of Technology, Thailand

***Abstract*—QR Codes are widely used in the digital era for storing and sharing information in various applications. However, they are often susceptible to physical damage such as scratches, tears, or fading, which can result in scanning failures and limit their usability. To overcome this issue, this research introduces a Generative Adversarial Network (GAN) model integrated with Spectral Normalization to restore damaged QR Code images. The model was trained and evaluated using a dataset of QR Codes with simulated damage ranging from 1% to 60%. Experimental results demonstrate that the proposed approach effectively reconstructs missing parts of QR Codes while preserving structural details and module sharpness. The model achieved an average PSNR of 28.5 dB, SSIM of 0.91, and a scanning success rate of 88%, outperforming U-Net (68%) and a baseline GAN (75%). Although the processing time is slightly longer, the model offers superior accuracy and robustness, particularly for severely damaged QR Codes (40% to 60% damage). These findings confirm that GANs enhanced with Spectral Normalization offer a promising solution for QR Code restoration, with potential uses in digital marketing, payment systems, and inventory management.**

***Keywords*—QR Code restoration; Generative Adversarial Networks; spectral normalization; image inpainting; deep learning; damage reconstruction**

I. Introduction

QR Codes (Quick Response Codes) have become a widely popular technology in the digital age due to their ability to store diverse information and their user-friendly nature [1]. This has led to their application in various fields, such as marketing, payment systems, product data verification, and information access systems.

However, in real-world environments, QR Codes often face problems of physical damage, such as missing parts or scratches. These can be caused by various environmental factors, leading to QR Code scanning failures and user inconvenience.

This damage can arise from several factors, including poor QR Code printing quality or contact and abrasion with various surfaces [2]. When a QR Code is damaged, scanning to read the data may fail or result in errors, which impacts operational efficiency and the user experience.

Although deep learning technology is highly potential and widely used in general image restoration and inpainting tasks [3], its specific application to address physically damaged QR Codes, such as those with scratches or missing sections, requires further study and development. For this reason, this study utilized Generative Adversarial Networks (GANs)—a deep learning technique with a remarkable ability to learn and generate complex image data to reconstruct and regenerate the missing parts of a QR Code. GANs have the potential to produce sharp details, which is a critical feature for preserving and inpainting the black-and-white module structure of a QR Code, essential for scanning. This contrasts with some conventional CNN architectures, which may tend to produce blurrier results when filling in missing areas.

This research developed a specialized GAN model incorporating Spectral Normalization to enhance the model's stability and performance. The objective was to test the effectiveness of GANs in improving the scanability and data recovery from damaged QR Codes.

II. Theory and Related Research

A. QR Code and basic Structure

QR Code (Quick Response Code) is a two-dimensional barcode technology developed by the company Denso Wave in 1994. QR Codes can store more data than traditional barcodes [4] and can be read by scanning devices or smartphones. The information is encoded in a pattern of black and white dots arranged in a two-dimensional grid. The basic structure of a QR Code consists of several key parts: For Finder Patterns, these are square patterns located at the three corners of the QR Code. They help scanning devices quickly detect and determine the position of the QR Code. For Alignment Patterns, these are smaller patterns that help adjust the position and correct for distortion that may occur from image skewing. For Timing Patterns, these are vertical and horizontal lines that help define the size and position of the data modules. For Data and Error Correction Codes, this section stores the data and error correction codes. These codes allow the QR Code to be read even if it is partially damaged, but it becomes unreadable if the damage is too extensive.

B. QR Code Damage and Its Impact

As shown in Fig. 1, QR Codes often suffer from physical damage in real-world environments, such as missing parts or scratches caused by external factors. This damage can be categorized into several main types: Physical Damage, caused by physical wear and tear, such as scratching or tearing; Environmental Damage, caused by unsuitable environmental conditions; Printing Defects, caused by low-quality printing,

which makes the QR Code unclear or flawed [5]. These types of damage can lead to QR Code scanning failure or data reading errors, causing inconvenience and reducing operational efficiency.

Fig. 1. An example of a damaged QR Code on an EV charging station at a gas station.

C. Image Inpainting: Convolutional Neural Networks (CNNs) Technique

Convolutional Neural Networks (CNNs) are a deep learning technique that has revolutionized image inpainting, or image restoration. CNNs have a remarkable ability to automatically learn features and spatial relationships within an image, allowing them to understand the image context and realistically generate missing parts. Typically, a CNN for inpainting uses an encoder-decoder structure [6]. The encoder extracts important information from the area surrounding the damaged portion, and the decoder uses that information to create new pixels to replace the missing ones. Training with a large amount of image data helps the model learn to fill in images accurately and seamlessly. CNNs can create complex structures and natural-looking textures better than simply estimating values from neighboring pixels. They can also complete objects or even parts that require semantic understanding, such as faces.

D. Image Inpainting: GANs Technique

Generative Adversarial Networks (GANs) are a type of neural network architecture consisting of two main networks that operate in an adversarial manner: the Generator network, which is responsible for producing new data, and the Discriminator network, which determines whether the generated data is real or fake [7]. This adversarial learning mechanism enables GANs to achieve outstanding performance in generating highly realistic data, making them particularly effective for image inpainting or repairing missing parts of an image. In this type of work, the Generator receives an image with a damaged portion (often accompanied by a mask that indicates the location of the damage) as input. It then learns to "imagine" and create pixels to fill that area, attempting to produce a result that looks as realistic and coherent with the rest of the image as possible. Meanwhile, the Discriminator is trained to distinguish between real images (undamaged original images) and fake images (images completed by the Generator). The Discriminator's goal is to catch the images created by the Generator, while the Generator continuously improves itself to create images that are so convincing that the Discriminator cannot tell the difference. This competitive process continues, making both networks more proficient. The Generator becomes progressively better at creating completed images with complex details, natural-looking textures, and structures that align with the image's context, while the Discriminator's ability to distinguish between real and fake images becomes sharper.

E. Enhancing GAN Stability with Spectral Normalization

Spectral Normalization (SN) is a crucial technique for improving the stability of GAN training by controlling the Lipschitz constant of network weights [8]. While SN is generally applied to the Discriminator to directly regulate gradients and enhance training stability, in this study we extend its application to the Convolutional layers of the Generator (as illustrated in Algorithm 1: Build_Generator). In the context of QR Code inpainting, our initial hypothesis was that stabilizing the Generator's gradients with SN could improve the synthesis of fine details and repetitive patterns that are critical to QR Code structures (e.g., clear black-and-white modules). This stabilization helps reduce artifacts and enables the Generator to better capture the underlying distribution of complete QR Codes. Preliminary experiments support this hypothesis, demonstrating improved structural reconstruction when SN was applied to the Generator compared with cases where SN was applied only to the Discriminator or not used at all. Consequently, this configuration was adopted for the main experiments.

F. Applying Image Inpainting to QR Code Images

Although most research in QR Code image processing has primarily focused on detection or error correction during decoding, some studies have begun to explore the use of deep learning techniques to improve QR Code image quality in different contexts. For instance, study [9] demonstrated the potential of deep learning in recovering invisible QR Codes displayed on specialized screens, while study [10] employed deep learning methods for rapid deblurring of QR Code images. Although these works did not directly address physical damage (e.g., scratches or missing parts) as this study does, they highlight the capability of neural networks to learn and adapt to the unique structural properties of QR Codes. However, based on a review of the related literature, no prior research has specifically applied Generative Adversarial Networks (GANs) combined with Spectral Normalization (SN) for inpainting physically damaged QR Codes. This represents an innovative direction. While SN has been widely used to stabilize the Discriminator in general image generation tasks, this study is the first to apply SN to the Generator for inpainting images with highly geometric structures, such as QR Codes, which require sharpness and well-preserved edges. This introduces a distinct challenge: the primary difficulty in QR Code restoration lies in maintaining edge boundaries and the sharpness of individual modules. In this regard, GANs, particularly when combined with loss functions such as L1 Loss that promote sharpness, tend to outperform traditional CNN encoder-decoder architectures, which often produce blurry results in the inpainted regions. This research, therefore, aims to develop and evaluate such an approach to fill this gap.

III. Research Methodology

A. Data Preparation

For the data preparation of QR Code restoration, we created a large dataset of QR Codes using the QR Code Python library

and then simulated damage on them. We used OpenCV to add various types of damage to the QR Codes, simulating missing parts by creating a mask to define the missing areas and filling them with white. This was done in both random patches and scratches with varying directions and thicknesses, as shown in Fig. 2.

Fig. 2. Example of a simulated damaged QR Code.

1) QR Code dataset creation: In the data preparation phase, the researchers created a dataset of 1,000 QR Code images, as shown in Fig. 3, using the qrcode Python library. As shown in Table I, the images were then divided into three groups based on their damage level: minor damage (1 to 20%) with 333 images, moderate damage (20 to 40%) with 333 images, and severe damage (40 to 60%) with 334 images. Each group was then randomly and equally split into a Training Set (70%), a Validation Set (15%), and a Test Set (15%) to ensure a balanced representation of various damage characteristics across all datasets. Each QR Code contained a unique URL.

TABLE I. DATA SPLITTING

Dataset	Number of Images	Proportion (%)
Training Set	700	70%
Validation Set	150	15%
Test Set	150	15%

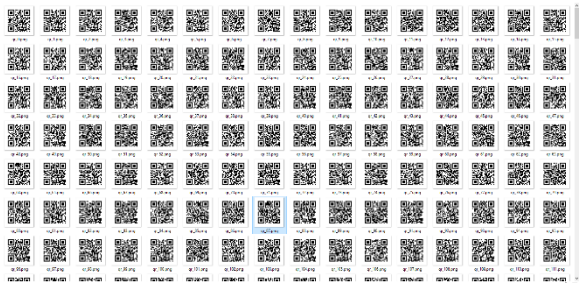

Fig. 3. Simulation of creating 1,000 QR Code images.

2) Creating damage in QR Codes: The researchers used OpenCV to add various types of damage to the QR Codes. Missing parts were created by generating a mask to define the missing areas and filling them with white. This was done in both random patch shapes and linear shapes (simulating scratches) with random thickness and direction across the QR Code. The damage was randomly assigned a severity level between 1% and 60%, as shown in Fig. 4. The purpose of setting the damage level from 1% to 60% was to cover a wide range of real-world scenarios: Minor damage (1 to 20%) reflects common issues like color fading, light scratches, or dust. Moderate damage (20 to 40%) simulates a QR Code that has been in use for some time or has multiple scratches. Severe damage (40 to 60%) is used to test the system's performance when the QR Code has lost critical data. The reason for limiting the damage level to a maximum of 60% is that it represents a realistic boundary for data recovery in a general use context. QR Codes are embedded with an Error Correction Code that can withstand a certain level of damage. Even the highest level of error correction (level H) can only handle approximately 30% damage. Therefore, creating damage higher than this, such as 40 to 60%, simulates a more severe situation than the standard threshold, testing the model's capacity to repair data in cases where the QR Code is damaged beyond what the original system can correct on its own. Conversely, if the damage exceeds 60%, the core structure of the QR Code may be destroyed to a point where it is not reasonably recoverable, even with deep learning techniques. Thus, the damage level was limited to a maximum of 60% to maintain a balance between the model's capability and the practical possibility of image recovery.

Fig. 4. An image showing the simulation of missing parts of a QR code. Code (a) original image, (b) damaged 1-20%, (c) damaged 20-40%, (d) damaged 40-60%.

B. Model Design

For the design of the model in QR Code Restoration, we developed a Generative Adversarial Network (GAN) architecture implemented using TensorFlow and Keras, consisting of two main components: the Generator and the Discriminator. As illustrated in Pseudo-code 5, the Generator is responsible for reconstructing the missing regions of the QR Code. It adopts an Encoder–Decoder structure with Spectral Normalization applied to every Convolutional layer to control the gradient distribution and enhance training stability. This architecture enables the Generator to produce realistic outputs, particularly in the critical regions of QR Codes such as Finder Patterns and Alignment Patterns.

The Discriminator, on the other hand, is designed to distinguish between real images and those generated by the Generator, thereby forcing the Generator to create outputs with higher realism.

- The Generator is the model responsible for reconstructing the missing regions of the QR Code. It is based on a Convolutional Neural Network (CNN) with an Encoder–Decoder architecture. The Encoder compresses the image while extracting meaningful features, whereas the Decoder reconstructs the image from these extracted features. The model employs LeakyReLU and ReLU as activation functions. Avoid combining SI and CGS units, such as current in amperes and magnetic field in oersteds. This often leads to confusion because equations do not balance

dimensionally. If you must use mixed units, clearly state the units for each quantity that you use in an equation.

- The Discriminator is a model designed to distinguish between real images and those generated by the Generator. It employs a CNN architecture to extract features from the images. The activation functions used are LeakyReLU and Sigmoid (see Algorithm 2).
- The GAN Model integrates the Generator and Discriminator into a complete Generative Adversarial Network (GAN). The Discriminator is compiled with the binary cross-entropy loss function and the Adam optimizer. The GAN is compiled with a combination of binary cross-entropy loss and L1 Loss (pixel-wise difference loss), along with the Adam optimizer (see Algorithm 3).

Algorithm 1: Build_Generator

Input: input_shape

Output: Generator model

1. Apply spectral normalized Conv2D (64 filters, kernel=4, stride=2) on input_shape
2. Apply LeakyReLU activation (α = 0.2)
3. Apply spectral normalized Conv2D (128 filters, kernel=4, stride=2)
4. Apply Batch Normalization
5. Apply LeakyReLU activation (α = 0.2)
6. Apply spectral normalized Conv2DTranspose (128 filters, kernel=4, stride=2)
7. Apply Batch Normalization
8. Apply ReLU activation
9. Apply spectral normalized Conv2DTranspose (64 filters, kernel=4, stride=2)
10. Apply Batch Normalization
11. Apply ReLU activation
12. Apply Conv2D (1 filter, kernel=4, activation = sigmoid)
13. Return **Generator Model**

Algorithm 2: Build_Discriminator

Input: input_shape

Output: Discriminator model

1. Apply Conv2D (64 filters, kernel=4, stride=2) on input_shape
2. Apply LeakyReLU activation (α = 0.2)
3. Apply Conv2D (128 filters, kernel=4, stride=2)
4. Apply Batch Normalization
5. Apply LeakyReLU activation (α = 0.2)
6. Apply Flatten operation
7. Apply Dense layer (1 unit, activation = sigmoid)
8. Return **Discriminator Model**

Algorithm 3: Build_GAN

Output: GAN model

1. Build Generator using **Algorithm 1**
2. Build Discriminator using **Algorithm 2**
3. Set Discriminator as **non-trainable**
4. Connect Generator output → Discriminator input
5. Compile the GAN model using the Adam optimizer and binary cross-entropy loss
6. Return **GAN Model**

C. Model Training

The model training process utilized the concept of Generative Adversarial Networks (GANs), which consists of two main parts: a Generator and a Discriminator. They were trained in an adversarial manner, starting with loading the complete and damaged QR Code images prepared in the previous step. The pixel values were then normalized to a range of [0, 1] to enhance computational efficiency. During training, the data was divided into mini-batches of 32 images for each epoch. The Generator received the damaged image as input and attempted to reconstruct a complete image. Simultaneously, the Discriminator received images from both the Generator (generated images) and the real images (complete images), and learned to distinguish between the two. The learning of these two components was driven by different loss functions:

- The Discriminator used Binary Cross-Entropy Loss to measure the difference between its predictions and the ground truth. This loss function effectively helped the model learn to distinguish between real and generated QR Code images.
- The goal of the Generator is to produce images that are both visually realistic (capable of fooling the Discriminator) and structurally close to the original ground truth. Therefore, its loss function is defined as a combination of:
- Adversarial Loss, computed from the output of the Discriminator (commonly using Binary Cross-Entropy), this loss encourages the Generator to synthesize more realistic images.
- L1 Loss (Mean Absolute Error). This measures the average pixel-wise difference between the generated image and the ground truth. Incorporating L1 Loss is critical, as it has been shown to preserve details and edge sharpness better than L2 Loss—an essential factor for maintaining the distinct black-and-white modules of QR Codes. Furthermore, L1 Loss provides pixel-level constraints that complement the Adversarial Loss, promoting sharper reconstructions and preserving the fine-grained structural integrity required for QR Code restoration.

The key hyperparameters were optimized through preliminary validation experiments, with the learning rate set to 0.0002 and the optimizer chosen as Adam, following best practices in GAN training.

Training was conducted for approximately 100 epochs, during which both Generator and Discriminator losses were computed and weights updated via backpropagation. This iterative process enables the Generator to learn to produce increasingly realistic and accurate reconstructions, while

simultaneously enhancing the Discriminator's ability to distinguish between real and generated images.

During training, Spectral Normalization was applied to all convolutional layers of the Generator in order to regulate the Lipschitz constant of its weight matrices. This improves gradient stability, prevents imbalance with the Discriminator, and mitigates mode collapse, a common challenge in GAN training without introducing additional computational overhead. In addition, a Model Checkpoint callback was employed to save the best-performing model weights throughout the training process.

D. Model Evaluation

The evaluation focuses on assessing the model's ability to restore/inpaint corrupted QR Code images back to a complete and functional state. To achieve this, standard image restoration metrics and task-specific measures (such as the scanning success rate) relevant to QR Code usability were employed:

PSNR (Peak Signal-to-Noise Ratio) and SSIM (Structural Similarity Index): Both are standard metrics in image restoration tasks. PSNR, measured in decibels (dB), quantifies the pixel-level difference between the generated image and the ground truth, with higher values indicating better reconstruction quality. SSIM evaluates structural similarity between the two images, ranging from 0 to 1, where values closer to 1 indicate higher structural fidelity.

Scanning Success Rate is the metric directly evaluating whether the restored QR Codes (from the test set inputs) can be successfully decoded. Each output image was tested using the widely adopted QR Code decoding library pyzbar. The number of successfully decoded images was counted and expressed as a percentage relative to the total number of test images (150). This measure reflects the model's effectiveness in restoring the core functional property of QR Codes.

Average Inference Time per Image measures the processing speed of trained models (GAN+SN, baseline GAN, and U-Net) when applied to real QR Code restoration tasks. Evaluations were conducted using an NVIDIA GeForce RTX 3080 GPU. Before measurement, the GPU was warmed up to ensure stable maximum performance. Then, the forward-pass time of each image in the test set (150 images) was recorded, excluding file loading and preprocessing. The results were averaged to obtain the model's mean inference time per image.

IV. Results

After completing the model training process, the evaluation phase was conducted to verify the model's performance. The test set, consisting of 150 QR Code images not previously seen during training, was used for this assessment. In this process, the corrupted QR Code images were fed into the trained model, and the reconstructed outputs were compared against the corresponding ground truth images.

As shown in Table II, during the initial training stage (Epoch 1), the Generator Loss started at 1.452 and the Discriminator Loss at 0.693, values typically observed when training begins for GAN models. The initial image quality was relatively low, with PSNR at 18.21 dB and SSIM at 0.72. By Epoch 10, the Generator Loss had decreased to 0.985, while the Discriminator Loss slightly increased to 0.752, suggesting that the Generator was beginning to produce more realistic images. This improvement was reflected in the image quality metrics (PSNR: 22.45 dB, SSIM: 0.83). At Epoch 25, the Generator Loss continued to decrease to 0.712, while the Discriminator Loss increased to 1.103. This behavior is expected, as the Discriminator becomes less effective at distinguishing images once the Generator improves significantly. The image quality improved considerably (PSNR: 25.67 dB, SSIM: 0.89), and the scanning success rate on the validation set reached 82.1%, indicating increasing model stability. By Epochs 50 and 100, the Generator and Discriminator Loss values stabilized at approximately 0.5 and 1.45, respectively, suggesting convergence. The reconstructed image quality also reached consistently high levels (PSNR ~29 dB, SSIM ~0.93), and the validation set scanning success rate exceeded 90%. These results confirm the model's effectiveness in restoring corrupted QR Code images to complete and scanable forms. This reveals the system's enhanced performance. The Scan Success Rate on the test set was lower than on the validation set, which may be attributed to the diverse damage in critical areas like Finder Patterns or the irregular scratches present in the test set, as shown in Table III and Fig. 5.

TABLE II. GAN+SN Model Training Results

Epoch	G Loss	D Loss	PSNR (dB)	SSIM	Validation Set (%)
1	1.452	0.693	18.21	0.72	55.3%
10	0.985	0.752	22.45	0.83	68.7%
25	0.712	1.103	25.67	0.89	82.1%
50	0.501	1.452	28.92	0.92	90.5%
100	0.493	1.487	29.15	0.93	91.2%

TABLE III. Evaluation Results on Test Set (150 Images)

Metric	Average	Range	Interpretation
PSNR (dB)	28.5	25.2 - 32.1	Values > 25 dB are considered acceptable
SSIM	0.91	0.85 - 0.95	Values close to 1 indicate high structural similarity
Scan Success Rate	88%	81 - 95%	Percentage of successful QR code scans

According to standard benchmarks, a PSNR greater than 25 dB is generally considered acceptable for image restoration tasks.

Fig. 5. Image showing the reconstruction of missing parts in a QR code using the GANs + SN technique: (a) Damaged QR code, not scannable; (b) GANs + SN reconstruction, scannable.

TABLE IV. COMPARISON OF INPAINTING METHODS WITH OTHER TECHNIQUES

Comparison Item	CNNs (U-Net)	GANs (Baseline)	GANs + Spectral Normalization
Algorithm Type	Learning-Based (CNN)	Learning-Based (GAN)	Learning-Based (GAN + Stabilization)
Architecture	U-Net (5 layers)	Encoder-Decoder	Encoder-Decoder + Spectral Norm
Loss Function	MSE + Perceptual Loss	Adversarial Loss + L1 Loss	Adversarial Loss + L1 Loss
Working Principle	Learns to restore images directly	Constructs new images through Generator–Discriminator	Similar to baseline GAN with stabilization (using Spectral Norm)
Average SSIM	0.82	0.87	0.91
Success Rate	68%	75%	88%
Processing Time	0.15 s	0.30 s	0.35 s
Strengths	- Faster than GANs - Suitable for less severe image Damage	- Generates more natural details - Produces sharper and more realistic structures	- High structural similarity - Reduces mode collapse problem - Achieves highest SSIM and success rate
Weaknesses	- Results may appear blurred - Ineffective with severe Damage	- Requires adversarial training - May encounter instability	- Slower processing time - Computational cost increases due to SN
Suitable for	Damage1–20%	Damage 20–40%	Damage 40–60% (Highest Efficiency)

TABLE V. PERFORMANCE COMPARISON ACROSS DIFFERENT LEVELS OF DAMAGE

Damage Level	GAN+SN	GAN (Baseline)	CNN (U-Net)
1–20%	95%	85%	80%
20–40%	88%	75%	70%
40–60%	81%	65%	54%
Average	88%	75%	68%

From Table IV and Table V, the performance comparison of the proposed GAN+SN model with other baseline methods is presented as follows: CNNs (U-Net): Utilizes a standard 5-layer U-Net architecture commonly applied in image-to-image translation tasks, trained with a combined loss function of Mean Squared Error (MSE) and Perceptual Loss. GANs (Baseline): Employs the same Generator and Discriminator architectures as the proposed model but without Spectral Normalization, trained with Adversarial Loss combined with L1 Loss to enhance image sharpness. GANs + Spectral Normalization (Proposed Model): Trained with Adversarial Loss, L1 Loss, and applies Spectral Normalization to the Generator. All models were trained and evaluated under the same conditions and dataset to ensure fairness in comparison.

The high scanning success rate (88%) demonstrates our model's effectiveness in reconstructing not just visual appearance but the functional data structure of QR codes, analogous to how shadow tomography reconstructs 3D information from limited 2D projections in microscopic imaging [13].

V. DISCUSSION

The comparison of the three main techniques for QR Code restoration showed that each method had different strengths and limitations. CNN (U-Net) was the fastest method, taking only 0.15 seconds per image. It achieved an SSIM of 0.82 and a scanning success rate of 68%, making it suitable for applications requiring high speed. However, it had limitations when the damage exceeded 20%, because although Perceptual Loss helped preserve the overall structure, the pixel-level accuracy enforced by Adversarial Loss and L1 Loss (especially when stabilized by SN in the GAN model) appeared to be more effective in reconstructing the fixed geometric patterns of QR Codes, which are essential for successful scanning. The baseline GAN provided a good balance between quality and speed, achieving an SSIM of 0.87 and a scanning success rate of 75%, taking 0.30 seconds per image. However, it sometimes faced training stability issues. The GAN + Spectral Normalization (GAN+SN), which was developed in this study, achieved the highest performance with an SSIM of 0.91 and a scanning success rate of 88%. It was able to handle damage up to 40–60%, although it required the longest processing time of 0.35 seconds per image. This illustrated the trade-off between speed and robustness to damage. GAN+SN was a more suitable choice when restoring heavily damaged QR Codes, providing better stability and reducing mode collapse. The choice of technique should depend on specific requirements: if high speed is prioritized, CNN (U-Net) is recommended for minor damage; for a good balance between quality and speed, the baseline GAN is appropriate; and if maximum performance is desired without much concern for processing time, GAN + Spectral Normalization provides the best results in terms of both accuracy and robustness to severe damage.

TABLE VI. COMPARISON OF PERFORMANCE WITH OTHER STUDIES BY CRITERIA

Criteria	GAN+SN	EHFP-GAN	SRGAN
Main Objective	Reconstruct missing regions	Reconstruct missing regions	Enhance image details
Performance (Success Rate)	Minor Damage (1–20%): 95% Moderate Damage	Mild Damage 95.35% [11]	Not directly evaluated [12]
Key Advantage	Resistant to severe Damage	Performs best with mild Damage	Most suitable for distorted QR Code
Main Limitation	Longer processing time compared to other methods	Performance significantly decreases with heavy Damage	Cannot recover information that is completely missing

From Table VI, when compared with the study by Zheng et al. (2023), which proposed the Edge-Enhanced Hierarchical Feature Pyramid GAN (EHFP-GAN), a two-stage architecture that focused on repairing edges first and then reconstructing the QR Code, it was observed that the EHFP-GAN approach was more complex [11]. In contrast, our study used a single-stage GAN architecture, but emphasized stabilizing the training

process by applying Spectral Normalization (SN) directly to the Generator layers. Our approach focused on improving the overall image reconstruction quality and the sharpness of the black-and-white structure, which is crucial for QR Codes, rather than separating the edge repair process.

In terms of performance, our GAN+SN model achieved an average scanning success rate of 88% for up to 60% damage, whereas the EHFP-GAN model reported a recognition rate of 95.35% for minor damage and dropped to 31.94% for severe damage [11]. Although EHFP-GAN achieved higher success rates on minor damage, our model demonstrated better robustness when facing high levels of damage (40 to 60%), which represented a particularly challenging scenario. Furthermore, compared with studies using Super-Resolution techniques such as SRGAN [12], which achieved a PSNR of 30.06 and SSIM of 0.936 for QR Code upscaling, our model, focusing on inpainting missing parts, still provided competitive results (PSNR 28.5, SSIM 0.91) and, importantly, verified effectiveness through the scanning success rate, the primary practical metric.

A key strength of our study was the use of Spectral Normalization, which reduced unstable training and mitigated Mode Collapse commonly encountered in GAN training. This allowed the model to better learn the distribution of complete QR Code data, resulting in improved reconstruction of fine details and sharp black-and-white modules. In contrast, more complex approaches like EHFP-GAN may require additional data and fine-tuning to achieve maximum performance. However, a limitation of our study was that processing time could be slightly longer than the CNN (U-Net) method (0.35 seconds compared to 0.15 seconds per image), although the improved accuracy was more significant for practical applications.

Although the model performed well on synthetic data, its effectiveness on real-world damage, such as stains, sun fading, or perspective distortions, remained a challenge that required further investigation.

VI. Conclusion

This study presented an approach for restoring damaged QR Codes using Generative Adversarial Networks (GANs) combined with Spectral Normalization (SN) to enhance training stability. Experiments on a dataset with simulated damage showed that the developed model could generate restored QR Codes with high sharpness and strong similarity to the original QR Codes, achieving an average PSNR of 28.5 dB and SSIM of 0.91. Moreover, the model significantly improved the scanning success rate of damaged QR Codes, reaching 88%, which outperformed the CNNs (U-Net) and basic GANs methods under the same experimental conditions.

The use of Spectral Normalization in the Generator enabled the model to effectively reconstruct complex details in the restored regions, reduce artifacts, and allowed the model to better learn the distribution of complete QR Code data. Although the proposed model required slightly longer processing time than other methods, the improved accuracy was highly significant for practical applications, particularly in scenarios where QR Codes were severely damaged.

For limitations and future work, this study had certain limitations that should be considered. The dataset used for training consisted of synthetic data, which may not cover the full variety of real-world damage. The model was also unable to handle complex damage, such as QR Code distortions or damage caused by reflections.

Overall, this study proved a promising approach for restoring damaged QR Codes using GANs combined with Spectral Normalization, which could be applied across various industries and scenarios where QR Codes play a critical role.

***Abstract*—The rapid growth of e-commerce has changed the way people engage with businesses, notably in the food industry. For the Muslim community, guaranteeing Halal conformity in digital transactions is critical. This study provides a comprehensive framework for improving Halal E-Commerce systems that include machine learning, pattern libraries, and multilingual support, specifically in Malay and Arabic. The study examines the role of pattern libraries in designing user-friendly interfaces, as well as lexical mapping strategies for enhancing Malay-Arabic translation accuracy. Natural language processing (NLP) and machine learning are combined to create an application that classifies food items into two categories: Halal or Haram. With an accuracy of 85%, a Random Forest classifier is trained on labeled datasets. Preparing the text, extracting features using TF-IDF, and evaluating the results using precision, recall, and F1-score are all steps in the classification process. To increase classification accuracy, a rule-based approach is also applied to conditional logic and keyword matching. By adjusting the parameters, the model is further improved, leading to strong performance. By taking into account the cultural and linguistic requirements of the Muslim community, multilingual support enhances accessibility and user confidence. The suggested method increases translation accuracy by employing lexical mapping at the word, phrase, and context levels. The paper also assesses several machine learning models, demonstrating that Random Forest outperforms the other methods examined. The findings contribute to the growth of Halal E-Commerce by outlining a systematic strategy to ensure compliance and usability. The proposed system can serve as a platform for future research into AI-driven Halal certification and digital marketplace optimization, blockchain with an e-Commerce framework.**

Keywords*—Malay-Arabic lexical mapping; natural language processing; machine learning; halal food classification; halal food e-commerce

I. Introduction

The rise of e-commerce has altered consumer behavior and modified global food supply chains, providing unprecedented access to a wide range of items [1]. During this digital transformation, the Muslim consumer group faces special hurdles, most notably assuring Halal compliance with food products. Halal, as a religious necessity, necessitates rigorous adherence to Islamic dietary requirements, and current Internet retail platforms typically fail to provide sufficient transparency and contextual information [2]. Product descriptions, certificates, and ingredients get increasingly complicated as they are written in multiple languages and cultural contexts. A fundamental issue in current Halal verification methods is their reliance on static certification markings, which may be out of date, regionally specific, or linguistically incomprehensible. Furthermore, the lack of real-time, automated, and linguistically inclusive verification methods severely impedes the development of culturally responsive digital food classification technologies [3]. Despite the growing emphasis on ethical consumption and religious inclusion, current platforms sometimes lack advanced computational techniques or multilingual semantic frameworks, both of which are required for effective Halal verification in cross-border e-commerce.

Simultaneously, modern usability requirements need systems that satisfy functional objectives while also providing a smooth and culturally adaptive user experience. According to user interface design and accessibility studies, pattern libraries are critical for creating consistent, intuitive interfaces that boost user confidence and interaction [4]. Multilingual support is equally vital, and Arabic remains the principal language of Islamic jurisprudence, whereas Malay is the predominant means of communication among Southeast Asian Muslim communities [5]. The purposeful use of various languages allows for semantic clarity and broad accessibility. Existing research has stressed Arabic's liturgical relevance as well as Malay's regional significance in the spread of Islamic knowledge [6]. However, there has been minimal research on developing lexical alignment between these languages for Halal food classification [7]. Given the linguistic discrepancies between ingredient labeling and certification forms, an intelligent system that bridges Arabic-Malay lexical mappings can drastically reduce

misinterpretation and improve classification accuracy. This gap in multilingual lexical integration within Halal certification systems is largely investigated in the literature.

Recent improvements in machine learning (ML) offer effective methods for automating difficult classification tasks. Machine learning algorithms can be trained to recognise non-Halal materials, assess multilingual product descriptions, and detect small linguistic cues suggesting Halal or Haram status [8][9]. However, their ability to classify Halal remains uncertain in the absence of culturally relevant linguistic information [10]. Thus, integrating machine learning with domain-specific Malay-Arabic lexical mapping improves context understanding, reduces false positives, and enables real-time, scalable Halal compliance solutions in food eCommerce platforms.

The paper describes an integrated system for automated Halal food classification in multilingual digital contexts based on machine learning and Malay-Arabic lexical mapping. The suggested technique bridges the research gap by incorporating cultural-linguistic information into data-driven models, thereby connecting technical capabilities to Muslim clients' religious and ethical requirements. This study adds to academic discourse and the development of inclusive, intelligent Halal eCommerce infrastructures by evaluating the existing state of the art, establishing a clear approach, and giving practical design solutions.

II. Literature Review

A. The Evolution of Halal e-Commerce

The rise of e-commerce has created new opportunities to connect specialist product categories with global audiences, particularly in faith-based marketplaces such as Halal food. Saleem et al. [1] argue that introducing Halal certification into digital platforms is more than simply a branding tool. It is critical for maintaining religious compliance and consumer trust. Nurillah [2] highlights the significance of cross-border transparency, traceability, and regulatory alignment in digital Halal ecosystems. Furthermore, Yener [3] claims that user-centric design, which incorporates culturally relevant factors such as dietary filters and religious certifications, may enhance trust and purchasing confidence among Muslim customers. These studies demonstrate a growing demand for digital solutions that not only permit compliance but also include Islamic values in the user experience (UX) design.

B. Role of Multilingual Support in e-Commerce

Language is a critical component of user interaction with digital services. Haque [5] argues that multilingual support improves accessibility greatly, particularly among linguistically heterogeneous user populations. For Halal systems, integrating Arabic (because of its religious significance) with Malay (in part due to its widespread adoption in Southeast Asia) assures not just language but also cultural resonance. According to Mabruroh and Khoiriyah [6], adopting these languages fosters diversity and matches the user experience with the expectations of observant Muslim customers. This concept contributes to the development of e-commerce systems that are not only linguistically translated but also semantically tied to religious and cultural significance.

C. Pattern Libraries in Software Development

Pattern libraries offer a systematic approach to interface design, promoting consistency, efficiency, and reuse in software development. Puteri and Widyanti [4] claim that using pattern libraries reduces cognitive work while improving system predictability for users. Haque et al. [5] developed culturally relevant pattern libraries for Islamic systems, such as prayer times, modest fashion filters, and Halal certification widgets. Additional research by [11] and [12] demonstrates that culturally localising pattern libraries improves usability while also generating emotional trust, which is an important factor in religious technology acceptance. These findings emphasise the necessity of culturally appropriate UI components in Halal-oriented systems.

D. Lexical Mapping

Lexical mapping functions as a linguistic bridge, enabling accurate translation and classification across languages. This is especially important in Halal systems, because the meaning of terminology varies depending on the cultural, gastronomic, or religious setting. Lexical mapping normally consists of four components: word-level, phrase-level, context-specific, and morphological mapping [13].

1) Word-level mapping: This approach is based on one-to-one lexical equivalence. For example, "makan" translates to "أكل" (food), and "rumah" to "بيت" (house), setting the framework for basic vocabulary alignment.

2) Phrase-level mapping: Fixed expressions, such as greetings and frequent idioms, are represented using units. For example, "Selamat pagi" becomes "صباح الخير" (Good morning), while "Terima kasih" maps to "شكراً" (Thank you), while keeping semantic intent.

3) Context-specific mapping: Words with several meanings require context-sensitive disambiguation. The Malay word "masak" can mean "ripe" (ناضج) in the context of fruit or "to cook" (طبخ) in culinary usage, highlighting the necessity for sophisticated disambiguation algorithms.

4) Morphological mapping: This includes root-word relationships and affixes. For instance, "makanan" (meal) is derived from the root "makan" and the suffix "-an," resulting in "طعام." Similarly, "berjalan" (walking) breaks down into "ber-" and "jalan," which corresponds to "يمشي" in Arabic. This morphological intelligence is necessary for developing robust natural language processing (NLP) systems.

III. Methodology

To design, develop, and test the recommended food categorisation model, a proof-of-concept application was built by merging Machine Learning (ML) techniques with Malay-Arabic lexical analysis via Natural Language Processing (NLP) [14]. This methodological framework is separated into three major stages: parameter design, analysis, and testing, as follows:

A. Parameter Design

The parameter design phase of the study focuses on overall process flow and component integration, as illustrated in Fig. 1. The system architecture uses machine learning and rule-based analysis to identify whether a food item is halal or not. The

program parses Malay-language food descriptions, possibly translating them into Arabic for better semantic understanding, before assessing the content using a hybrid classification technique.

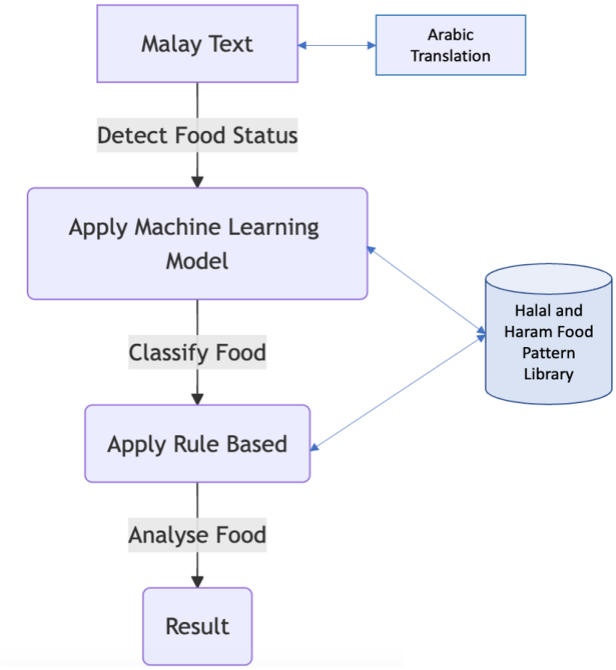

Fig. 1. Process activity for integrating machine learning and Malay-Arabic lexical mapping.

B. Parameter Selection

The Malay Arabic translation, machine learning model, and rule-based approach were considered when selecting parameters for this study. The particulars of parameter selection were explored in Fig. 2 as follows.

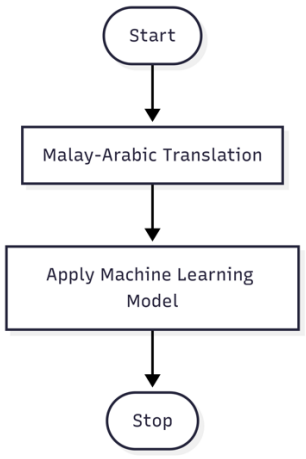

Fig. 2. Parameter selection.

1) Malay to Arabic translation: The system gets food-related text in Malay that needs to be evaluated. Consider "Daging ayam dengan alkohol" (alcoholised chicken meat). Finally, if necessary, the Malay text is translated into Arabic for better semantic understanding.

2) Apply machine learning model: The Machine Learning (ML) approach to categorising halal and haram foods consists of many key stages. Data collection and preprocessing begin with the compilation of a list of food names labeled as halal or haram according to Islamic dietary guidelines, followed by text preparation steps such as tokenisation, lowercasing, and special character removal, with words then transformed into numerical attributes using TF-IDF or word embeddings. Next, a Random Forest Classifier is used to increase accuracy by integrating numerous decision trees; this strategy takes advantage of classification and regression trees (CARTs) while reducing correlations between them [15].

During the model training and assessment phase, the dataset is separated into training (80%) and testing (20%) subsets, with the training data allowing the model to learn patterns and the testing data validating its predictive potential [16]. The model's performance is then evaluated using metrics such as accuracy, precision, recall, and F1-score: accuracy measures overall correctness, precision measures the proportion of correctly predicted positive cases, recall measures the ability to identify all actual positive cases, and the F1-score combines precision and recall to provide a balanced evaluation of performance [17].

3) Apply rule-based: A rule-based system uses established logical rules to classify and analyse data [18]. A rule-based approach for halal and haram food classification includes manually established rules, such as:

a) Keyword matching is the process of determining when a food item has halal or haram components by comparing its ingredients to a predetermined list of keywords. b) Simple criteria are employed to apply conditional logic, such as labelling a food as "haram" if it contains "babi" (pork) or "halal" if it contains "ayam" (chicken). This classification is based on the direct presence of specific terms. c) Natural language processing (NLP) is used to break down a sentence or meal description into individual words or tokens, which are then evaluated using predefined classification algorithms. This enables more effective handling of text input in many languages or unstructured formats. d) As the classification procedure progresses, decision trees are introduced.

C. Parameter Analysis

This section, as shown in Fig. 3, examines data collection or preparation, text pre-processing, random forest classifier training, and halal or haram phrase prediction, with the following details.

1) Data preparation: This structured dataset can serve as a foundation for machine learning models aimed at automatic halal food classification via natural language processing. Fig. 4 illustrates heatmaps comparing halal and haram classifications.

```
import pandas as pd

data = {"sentence": ["ayam","gelatin babi","susu","alkohol",
"daging lembu","babi","sayur-sayuran organik", "ikan", "babi",
"biawak", "telur", "Unta", "Kambing", "renet", "lemak babi",
"daging peha babi"],
```

"label": [1, 0, 1, 0, 1, 0, 1, 1,0,0,1,1,1,0,0,0]

1 = Halal, 0 = Haram}

df = pd.DataFrame(data)

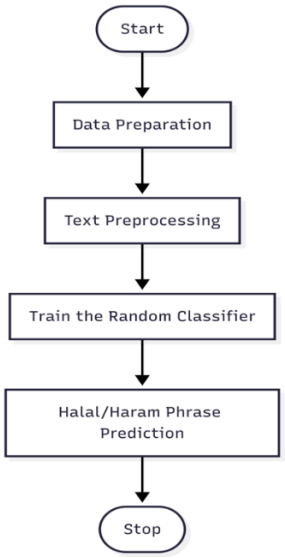

Fig. 3. Parameter analysis.

The collection contains 16 food-related items that have been classed as halal (permissible) or haram (forbidden) by Islamic dietary guidelines. Each item contains a food term (for example, "ayam", "gelatin babi", or "susu") and a binary label such as 1 for halal and 0 for haram. The data is stored in a pandas DataFrame, with column "sentence" containing the food's name or description and column "label" showing its classification. Eight of the 16 items are halal, including "ayam" (chicken), "susu" (milk), "daging lembu" (beef), and "ikan" (fish), while the remaining eight are haram, including "gelatin babi" (pork gelatin), "alkohol" (alcohol), "lemak babi" (pork fat), and "daging peha babi" (pork thigh meat). This structured dataset can serve as a foundation for machine learning models aimed at automatic halal food classification via natural language processing. Fig. 4 illustrates heatmaps comparing halal and haram classifications.

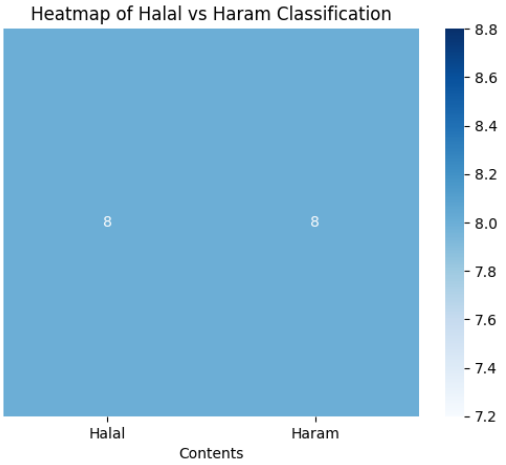

Fig. 4. Heatmaps of halal vs. Haram classification.

2) Text preprocessing: To prepare the data for machine learning, the TF-IDF vectorisation approach was used to convert text into numerical features. As a result, this Python technique is part of a pipeline that uses text classification to detect halal and haram food items. The data is separated into two categories: training (80%) and testing (20%). The following line explains how to utilise TF-IDF vectorisation to convert text into numerical attributes. Fig. 5 illustrates the steps for preparing text in code statements.

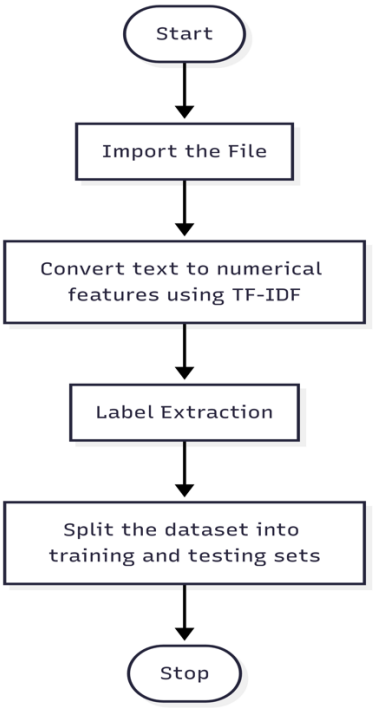

Fig. 5. Text preprocessing.

Based on Fig. 5, step 1, TfidfVectorizer from sklearn.feature_extraction.text turns text data into numerical representations that a machine learning model can process. The train_test_split from sklearn.model_selection partitions the dataset into training and testing sets for model evaluation. In Step 2, TF-IDF (Term Frequency-Inverse Document Frequency) is applied to the text data (df["sentence"]), turning words into numerical vectors representing their significance in the dataset. Stop_words='english' removes common words (such as "the" and "is") that do not contribute to classification. Step 3 extracts the label column, which contains binary categorisation values (1 for halal and 0 for haram). Finally, in Step 4, the dataset is partitioned into training (80%) and testing (20%) sets to assess model performance. This `random_state=42` ensures consistent splits across different runs, improving reproducibility.

3) Train the random forest classifier: The Random Forest model was trained and tested on pre-processed text data with scikit-learn for text categorisation. The purpose is to identify food items as halal or haram based on textual descriptions. Fig. 6 depicts the Random Forest Classifier training.

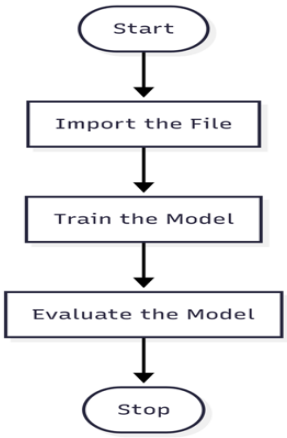

Fig. 6. Random forest classifier training.

Based on Fig. 6, step 1, RandomForestClassifier is imported from sklearn.ensemble. It is an ensemble learning technique that use numerous decision trees to boost classification accuracy. The accuracy_score from sklearn.metrics is used to assess the model's performance by determining the proportion of correctly categorised labels. In Step 2, n_estimators equal 100: The model generates 100 decision trees, with the final classification depending on the majority vote of these trees. The random_state is 42: Fixes the random seed to ensure reproducibility. The model is trained on the training dataset (X_train, y_train), learning patterns from text-based features extracted by TF-IDF. Finally, in Step 3, the trained model predicts the class labels (halal or haram) for an unknown test dataset (X_test). The model's accuracy is calculated by comparing predicted labels (y_pred) to actual labels (y_test). Accuracy is expressed as a decimal value (for example, 0.85 for 85%). Displays the accuracy score rounded to two decimal places.

4) Prediction on halal or haram sentences: The sentences or words are classified using the trained model based on the following Algorithm 1.

Algorithm 1: Sentences or words classification for prediction, Halal or Haram algorithm

```
Initialize
Compute
def classify_food (sentence):
predictions = []
sentence_transformed = vectorizer.transform([sentence])
predicts[count] = model.predict(sentence_transformed)
print (f"ML- predict: {predicts}"
count = count +1
if 0 in predicts:
return "HARAM"
else:
return "HALAL"
```

D. Parameter Testing

Parameter testing is necessary during implementation to optimise the Random Forest classifier's performance. Several important factors were meticulously altered and assessed to determine the best model design, as shown in Table I. First, the n_estimators parameter, which controls the number of decision trees in the forest, was tested for values ranging from [10, 50, 100, 200]. The trials found that increasing the number of estimators improved model stability and accuracy, with 100 trees providing a good balance of performance and processing efficiency. As a result, the final model used n_estimators = 100. The max_depth option, which determines the maximum depth of each tree, was tested with values of [5, 10, 15, None]. A depth of 15 was identified to appropriately reflect the data's complexity while preventing overfitting, which occurs when no limit (None) is used. The min_samples_split and min_samples_leaf variables were also useful for refining the model. Testing settings for min_samples_split as [2, 5, 10] and min_samples_leaf as [1, 2, 5] revealed that the default values of 2 for split and 1 for leaf resulted in better generalisation, keeping the model's flexibility while avoiding excessive splits that could lead to overfitting. The criterion parameter, which describes the function used to determine the quality of a split, was compared to both 'gini' and 'entropy'. The 'gini' index was chosen since it gave somewhat better performance and faster processing in this scenario. Finally, to ensure reproducibility, random_state=42 was kept constant throughout the tests. The final optimised model, which included these parameters, was trained using TF-IDF-transformed training data (X_train, y_train) and tested against test data (X_test, y_test). The printed end accuracy demonstrated that the chosen criteria resulted in a strong and accurate classification system for discriminating between "Halal" and "Haram" food items. The parameter setting is demonstrated in Algorithm 2 for RandomForestClassifier.

Algorithm 2: Parameter Testing for RandomForestClassifier

```
Initialize
Compute
optimized_rf = RandomForestClassifier(
n_estimators=100, max_depth=15, min_samples_split=2, min_samples_leaf=1, criterion='gini', random_state=42) optimized_rf.fit(X_train, y_train)
y_pred = optimized_rf.predict(X_test)
final_accuracy = accuracy_score(y_test, y_pred) print("Final Optimized Random Forest Accuracy:", final_accuracy)
```

TABLE I. TESTING N_ESTIMATORS (NUMBER OF TREES)

Parameter	Description	Value to Test
n_estimators	Number of decision trees in the forest	10, 50, 100, 200
max_depth	Maximum depth of each decision tree	5, 10, 15, None
min_samples_split	Minimum number of samples required to split a node	2, 5, 10
min_samples_leaf	Minimum samples required in a leaf node	1, 2, 5
criterion	Function to measure the quality of a split	'gini', 'entropy'

During implementation, the code is based on parameter selection and testing, and is designed to categorize food products for "Halal" or "Haram" using a set of phrases and labels. Then, the text input is converted into numerical characteristics for categorisation using machine learning (ML), a Random Forest classifier, and TF-IDF vectorisation. Algorithm 2 shows how the

ML model is trained using the sentences. After that, the accuracy is checked. Halal and haram foods and make recommendations for halal products is identified using a rule-based system. Google Translate to translate Malay API is used in a code, as well as machine learning and rule-based analysis to classify meals and provide halal alternatives. The application also shows how both methods can be used to categorise and recommend food items.

This study introduces a novel integration of Malay–Arabic lexical mapping into machine learning–based Halal food classification, a combination that has not been previously explored in existing literature. While prior studies have focused on single-language (Malay or English) Halal text classification, this research leverages bilingual semantic alignment between Malay and Arabic to enhance contextual understanding of religious terminology in ingredient lists. Furthermore, the application of the Random Forest classifier within this multilingual, culturally grounded framework represents a methodological advancement, as it enables higher interpretability and robustness compared to conventional models such as Naïve Bayes and SVM. The framework's strength lies in its ability to connect cultural linguistics and AI-driven food classification, resulting in a system better aligned with Islamic dietary principles and real-world e-commerce applications.

IV. Results

The study findings are separated into three categories which are TF-IDF Score analysis, Comparison of Performance analysis, and Precision, Recall, and F1-Score for Halal Food Malay-Arabic.

A. TF-IDF Score Analysis

Fig. 7 shows the TF-IDF heatmap, which visualises term importance across a variety of food-related texts. The heatmap illustrates the frequency and significance of specific words in the dataset, with darker hues (red) suggesting higher importance and lighter tints (blue) indicating lower relevance. This Figure is essential for understanding the distinction between halal and haram foods. Example keywords such as "babi" (pork) and "alkohol" (alcohol) have higher TF-IDF values in haram sentences, indicates that they are commonly employed to discriminate against prohibited products. Similarly, terms such as "ayam" (chicken) and "ikan" (fish) have high TF-IDF scores in halal-classified phrases, emphasising their importance in identifying permissible food products. The dataset's structure reveals that some terms are more distinctive, whilst others appear often in several sentences, resulting in lower TF-IDF scores. This graphic effectively underlines which words contribute the most to the categorisation process in a machine-learning model [19]. However, while the heatmap depicts word relevance, it has several disadvantages. Such as TF-IDF does not capture word context. Instead, it uses frequency-based weighting, which may not fully reflect real-world nuances in halal-haram classification [20]. For example, the term "daging" (flesh) can be halal or haram depending on the context, but TF-IDF cannot tell the difference. Furthermore, the heatmap's readability could be improved by sorting phrases by relevance or clustering related words. Combining TF-IDF with additional advanced NLP techniques, such as word embeddings or transformers, may increase classification accuracy by capturing deeper semantic connections [21]. Recent research indicates that deep learning models can outperform TF-IDF in halal food classification by analysing ingredient texts with contextual embeddings [22].

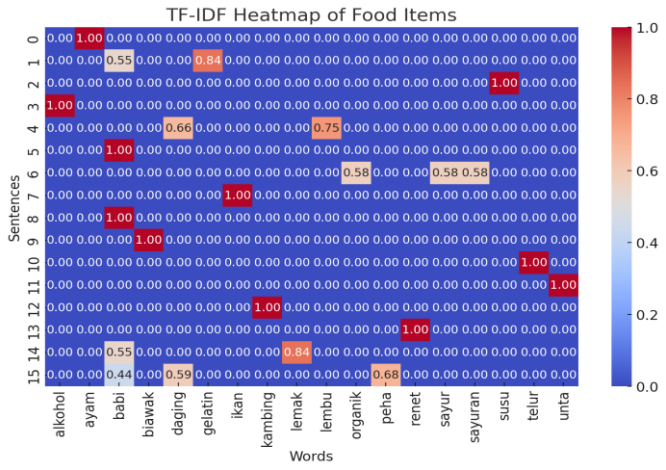

Fig. 7. TF-IDF of food items.

B. Performance Analysis

Fig. 8 compares Random Forest, Naïve Bayes, SVM, and Logistic Regression in terms of accuracy and training time.

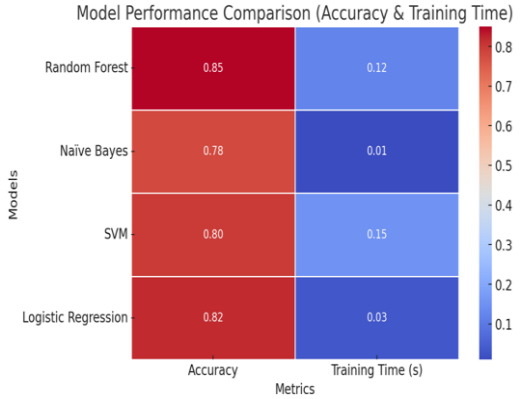

Fig. 8. Comparison of performance analysis.

According to Fig. 8, a comparison of machine learning models for halal-haram classification shows that Random Forest has the highest accuracy (85%), making it the most reliable alternative. However, it has a moderate training time of 0.12 seconds, which is longer than simpler models like Naive Bayes (78% accuracy, 0.01s training time). The fastest model, Naïve Bayes, is effective for quick classifications but lacks accuracy. Meanwhile, SVM (80% accuracy, 0.15s training time) performs admirably but takes the longest to learn. Logistic Regression (82% accuracy, 0.03s training time) achieves a balance of efficiency and interpretability, but it may struggle with complicated patterns.

C. Precision, Recall, and F1-Score for Halal Food Malay-Arabic

To assess the effectiveness of the proposed halal food classification system, particularly with the addition of Malay-Arabic lexical mapping, four machine learning models were

tested using three major classification metrics: precision, recall, and F1-score. Fig. 9 presents these variables as heatmap comparisons, which allows for an easier assessment of model performance across several evaluation criteria.

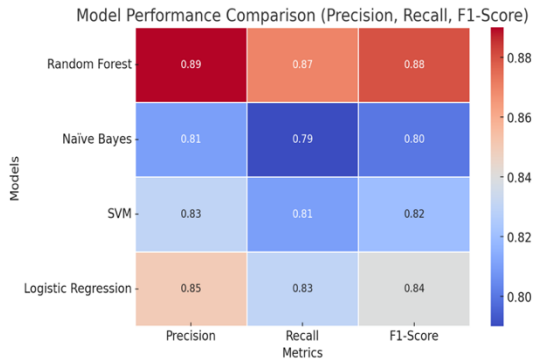

Fig. 9. Precision, recall, and FI-score.

Naive Bayes produces reasonable results (Precision: 0.81, Recall: 0.79, F1-Score: 0.80), indicating that, while it works adequately, it cannot generalise as well as Random Forest. Support Vector Machine (SVM) improves recall (0.81) and balance (F1-Score: 0.82) but falls short on precision (0.83), possibly due to its sensitivity to overlapping classes. Logistic Regression has a high precision (0.85) and a decent recall (0.83), yielding an F1-score of 0.84, indicating balanced but slightly poorer performance than Random Forest.

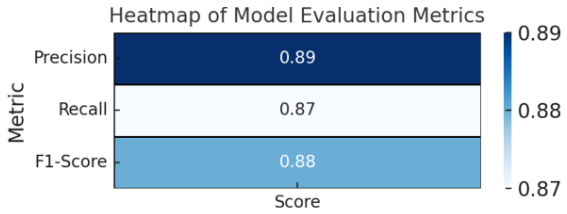

Fig. 10. Output of model evaluation metrics.

Fig. 10 demonstrates that the Random Forest model outperforms all three metrics. These high scores demonstrate that Random Forest properly identifies halal/haram classes (precision) while also catching the vast majority of actual positive examples (recall), yielding an exceptional balance (F1-score). This result indicates the model's stability and dependability in this classification job, especially when supplemented with lexical mapping between Malay and Arabic terminologies, which aids in the resolution of semantic ambiguities in food ingredients and naming traditions.

V. Discussions

Overall, Random Forest is the most reliable and accurate classification model, making it ideal for practical halal food identification. Naïve Bayes provides the fastest performance, while Logistic Regression balances accuracy and efficiency. SVM, while accurate, is slower and requires more computing power. The model chosen is based on the application's specific requirements, such as accuracy, speed, and interpretability [23][24]. These findings suggest that Random Forest is the most effective classifier for the Malay-Arabic halal food classification problem. Lexical mapping significantly enhances the semantic comprehension of ingredient lists by connecting culturally and religiously significant phrases in Malay and Arabic, such as recent studies by Khalilia et al. [25] demonstrate the creation of cross-lingual maps via a supra-lingual concept layer that can account for culturally unique terms that lack direct counterparts in other languages. This linguistic enrichment allows the model to discover minor distinctions that are critical in halal food assessment, hence boosting both the classification system's accuracy and cultural context [26]. Thus, combining machine learning and multilingual lexical analysis improves performance metrics while also aligning the system with real-world requirements in various Muslim-majority or multilingual regions.

VI. Conclusions and Future Work

This study emphasises the need to implement AI-powered technologies to improve Halal e-commerce platforms. Using machine learning classification models and lexical mapping methodologies, the system accurately detects Halal items while retaining their linguistic and cultural significance. The study found that combining pattern libraries, multilingual support, and advanced text processing significantly enhances usability, accessibility, and trust among Muslim consumers. The Random Forest model, achieving a maximum accuracy of 85% outperforming the baseline models by up to 10%, proved to be the most effective Halal–Haram classifier. The proposed framework lays the groundwork for future developments in Halal digital commerce, ensuring Islamic compliance while leveraging modern technological advancements. However, several limitations must be acknowledged. The dataset size used in this study is relatively limited, which may constrain the model's ability to generalize to broader food categories. Additionally, potential data bias in labeled samples and restricted language coverage, such as being focused mainly on Malay and Arabic that may affect the model's accuracy and cultural inclusiveness in wider contexts. Future research should therefore aim to expand multilingual datasets, address bias through balanced sampling, and improve NLP capabilities to enhance classification accuracy and contextual understanding. Moreover, integrating real-time certification verification with blockchain technologies, as well as an e-Commerce framework, could improve transparency and traceability in Halal authentication. Collaboration with Halal certification authorities and e-commerce providers will also be vital to standardize digital Halal verification procedures. Ultimately, this study contributes to the growing field of Halal e-commerce by paving the way for safer, more efficient, and culturally inclusive online markets, such as helping to eliminate doubtful Halal products and build greater consumer trust.

Acknowledgment

We would like thanks to Universiti Teknikal Malaysia Melaka (UTeM) and Ajman University for the grant number URMG-AJMAN/2024/FTMK/A00070 as well as Fakulti Teknologi Maklumat dan Komunikasi (FTMK) for their support.

***Abstract*—This study investigates the application of head pose estimation (HPE) to assess visual attention in children with special needs (CwSN) during robot-assisted therapy sessions, focusing on its effectiveness and the attention patterns exhibited by these children. CwSN often faces unique challenges, such as sensory processing difficulties or delayed cognitive processing. Age and therapy duration also influenced attention levels, with younger children generally exhibiting shorter attention spans than older participants. Additionally, familiarity with technology, such as prior screen time at home, positively impacted engagement during robot-assisted therapy. An experimental study was conducted with 30 children aged 2 to 7 years, including those with autism spectrum disorder (ASD), speech delay (SD), and attention-deficit/hyperactivity disorder (ADHD). Using an integrated camera, head movements were tracked to analyse forward-facing head direction as an indicator of attention. The system achieved an overall accuracy of 82% and an average attention percentage of 65%, highlighting that visual attention varies significantly based on the type of disability, age, and therapy duration. The integration of the robot enhanced visual engagement across all groups, fostering improved interaction and attention. These findings emphasise the importance of tailoring robot-assisted therapy (RAT) to the specific needs and attention patterns of children with different disabilities, ages, and therapy histories, underscoring the potential of assistive robotics to optimise therapeutic outcomes in special education settings. This research highlights the potential of personalised RAT to improve social, cognitive, and motor skills. It offers evidence-based strategies for integrating assistive robotics into special education and therapeutic settings for CwSN.**

***Keywords*—Head pose estimation; visual attention; robot-assisted therapy; children with special needs**

I. Introduction

Visual attention assessment is critical for understanding and enhancing therapeutic outcomes for CwSN. These children often exhibit atypical visual attention patterns, which impact their social interactions, communication skills, and learning processes [1] [2]. Accurate assessment of visual attention provides valuable insights into cognitive and behavioural states, enabling therapists to tailor interventions that promote engagement and skill development. Nevertheless, traditional observation-based assessments predominantly remain subjective and demonstrate variability across different sessions, thereby limiting the accuracy and reliability of therapeutic evaluations.

To address these limitations, there is an increasing need for an AI-driven methodology capable of objectively quantifying attention through head pose estimation (HPE). The understanding and supervision of visual attention using such computational techniques are essential for improving engagement in therapeutic and educational settings, in alignment with the global movement towards intelligent and inclusive educational technologies. The HPE, specifically analysing head direction patterns, is significant in assessing attention in CwSN [1]. Monitoring head movements helps therapists understand where a child is focusing their attention during therapy sessions [2], enabling real-time feedback and adaptive strategies that foster improved social and cognitive outcomes [3].

However, quantifying and accurately assessing head direction in CwSN presents significant challenges. These children may struggle to maintain a consistent gaze or display rapid and unpredictable head movements, adding complexity to understanding head direction patterns unique to this group[4]. Gaining more profound insights into these patterns is crucial for tailoring interventions to support their developmental needs [5].

Despite significant advancements in head pose estimation, few studies have utilised these methodologies to evaluate visual attention among children during real-world therapeutic sessions. Current models primarily focus on adult datasets or controlled laboratory environments, thus limiting their applicability in educational and clinical contexts. This research aims to address this limitation by developing and validating a real-time head pose estimation framework designed to assess visual attention within the scope of robot-assisted therapy.

This study evaluates head direction patterns in CwSN during RAT sessions. Using an integrated camera system to track head movements toward a service robot, we aim to identify distinct attention patterns associated with CwSN. The novelty of this work lies in the integration of a hybrid HPE algorithm into real-world therapy sessions, as well as the multi-factor analysis of attention patterns across disability type, age, and therapy duration. These contributions advance the field of RAT by providing real-time, evidence-based insights that can

* Corresponding author.

guide the design of more personalised engagement strategies and improve therapeutic outcomes for CwSN.

The remainder of this study is organised as follows: Section II reviews related work on head pose estimation and visual attention assessment. Section III describes the methodology, including the proposed framework, data collection, and analysis procedures. Sections IV and V presents the results and discussion, while Section VI concludes the study with implications, limitations, and directions for future research.

II. Literature Review

A. Head Pose Estimation Techniques

Head pose estimation (HPE) is pivotal in interpreting visual attention and social interactions, especially among CwSN. Various methods have been developed to estimate head pose, broadly categorised into feature-based, appearance-based, and hybrid approaches. Feature-based methods rely on detecting facial landmarks such as the eyes, nose, and mouth to infer head orientation [6]. The algorithms and techniques associated with these methods can be categorised into classical approaches, machine learning-based models, deep learning algorithms [16], and hybrid techniques. Classical algorithms, such as Active Shape Models (ASM) and Active Appearance Models (AAM), focus on statistical shape modelling and texture analysis [7][8].

At the same time, machine learning-based approaches utilise classifiers like Support Vector Machines (SVM) and Random Forests for head pose prediction [9][10][11]. Deep learning algorithms, including Convolutional Neural Networks (CNNs) and heatmap regression methods, leverage advanced architectures to enhance accuracy and robustness in landmark detection and pose estimation [12]. Appearance-based methods employ machine learning techniques to analyse pixel intensity patterns across the face without explicitly detecting facial features. CNNs have been widely adopted in this category due to their robustness in handling variations in lighting and facial expressions. These methods have advanced with the development of deep learning, enabling more accurate and efficient head pose estimation.

Significant advancements in HPE techniques for assessing visual attention in CwSN have been achieved. Deep learning approaches, including CNNs and transformer-based models, have gained prominence due to their ability to handle the complex and variable head movement characteristic of CwSN populations. These models have been optimised for real-time performance, enabling seamless integration into interactive therapy sessions without causing delays or disruptions [13][14].

Hybrid techniques, such as the Perspective-n-Point (PnP) algorithm, integrate 2D facial landmarks with 3D head models for precise orientation estimation [6][10]. These advancements contribute significantly to the field of HPE, with applications spanning robotics, healthcare, and human-computer interaction. While effective, these methods can face challenges with occlusions and variations in facial expressions, which are common in real-world settings.

Researchers have developed non-intrusive methods using robot cameras and AI-based frameworks such as dlib and MediaPipe to capture head movements without requiring children to wear any devices. Techniques that leverage facial landmark detection and 3D modelling have improved the accuracy of HPE, even in uncontrolled environments with varying lighting conditions and occlusions. These advancements are essential for creating responsive therapeutic tools that can adapt to the unique behaviours of CwSN.

In the context of CwSN, real-time and adaptive HPE techniques are crucial. CwSN may exhibit rapid or atypical movements, making robust and flexible estimation methods essential. Recent developments have focused on enhancing these methods to increase accessibility and practicality for use in therapeutic settings, ensuring minimal intrusion while maintaining maximum accuracy.

B. Visual Attention in Children with Special Needs

Children with special needs (CwSN) often face challenges in maintaining attention, particularly in social contexts, where they may focus less on facial features and eye regions than typically developing peers, instead directing their attention toward objects or patterns. This atypical visual attention can hinder the development of social and communication skills, making it a critical area of interest for researchers. Studies employing eye-tracking technology have revealed that these children spend significantly [15] less time engaging with social stimuli, such as people, and more time attending to non-social elements within their environment. These findings suggest that interventions to redirect their visual attention toward socially relevant stimuli could enhance social skill acquisition [17]. Additionally, difficulties with joint attention and the ability to share a focus on an object or activity with another person are common and significantly impact language development. Targeted strategies to improve joint attention could, therefore, play a vital role in supporting the developmental needs of these children [18].

Recent advancements in research and technology have paved the way for innovative interventions tailored to the unique requirements of CwSN. Visual dysfunction, prevalent in this population, necessitates diagnostic approaches that extend beyond traditional visual acuity assessments. [19]. For example, integrating Augmented Reality (AR) in learning environments has demonstrated the potential to improve visual attention by providing multi-sensory experiences that actively engage children [20]. Additionally, tools such as 3D-printed toys have been shown to improve attention spans and fine motor skills in children with autism [21]. Environmental factors also play a critical role, with studies indicating that exposure to greenery, such as classroom windows overlooking natural landscapes, can positively impact sustained attention levels. Such findings highlight the importance of creating enriched environments and using adaptive tools to foster visual and cognitive engagement in CwSN [22] [23].

Educational strategies and structured interventions further enhance visual attention and related skills. Visual media, such as flashcards, have been shown to improve memory and recognition in autistic children [24]. Art provides an effective medium for visual expression among CwSN [25]. These strategies align with cognitive load theory, which emphasises tailoring instructional methods to manage cognitive demands

and optimise learning outcomes. By understanding how CwSN allocate their visual attention, therapists and educators can design targeted interventions that enhance engagement with social stimuli and promote meaningful improvements in communication, social interaction, and overall learning.

C. Robot-Assisted Therapy

Robot-assisted therapy (RAT) has emerged as a promising tool for supporting CwSN, particularly enhancing their social, emotional, and cognitive skills. Recent advancements have focused on designing robots to address specific challenges faced by children with autism. For instance, robot functionalities tailored for Applied Behaviour Analysis (ABA) therapy demonstrate the ability to stimulate cognitive skills while adapting to individual limitations [26]. A dual-cycle therapy model emphasising the integration of therapists as teleoperators, which enhances the effectiveness of robot-mediated interactions with neurodivergent children [27].

Social assistive robots have also been shown to facilitate emotional expression and secure social interactions in therapy sessions. These robots provide a judgment-free environment, significantly improving engagement and therapeutic outcomes in children with autism spectrum disorders (ASD) [28]. Furthermore, the use of social humanoid robots as mediators in interventions emphasises their potential to promote communication skills and interaction between children, teachers, and therapists [29]. The importance of advancing robot design lies in better accommodating the needs of CwSN.

In addition to fostering social and emotional growth, robot-assisted therapy is being explored in broader contexts, such as mental health interventions and physical skill development. The potential of robots to engage adolescents in therapeutic settings, with implications for similar applications in CwSN [30]. Integrating interactive elements in robot-mediated therapy has proven effective in enhancing engagement, indicating that these tools hold significant promise for complementing traditional therapy methods across diverse therapeutic contexts.

In summary, previous research has demonstrated promising methodologies for head pose estimation and attention tracking; however, most are confined to controlled environments or adult populations. Furthermore, the integration of these techniques into robot-assisted therapy remains insufficiently explored. To address these limitations, this study presents a hybrid framework combining Dlib and MediaPipe for robust head pose estimation and employs it to assess visual attention among children with special needs.

III. Methodology

The study involved an in-situ experiment at the Kizzu Kids Rehabilitation and Enrichment Centre, focusing on CwSN. Service robots were integrated into the participants' standard therapy routines in these sessions. Data was collected during these sessions, capturing video recordings, images, and tabular data in CSV files. These multimodal data sources were utilised to investigate visual attention patterns, particularly analysing how the children directed their gaze and engaged with their surroundings during therapy.

The collected data were used to evaluate a real-time system for measuring visual attention. Section III A describes the experimental procedure, outlining the data acquisition process and the specific formats for the captured data. In Section III B, the study introduces system architecture, detailing its components and incorporating a widely adopted HPE algorithm. This algorithm enables the assessment of gaze direction and engagement levels, thereby facilitating an analysis of the children's visual attention during RAT sessions.

A. Data Gathering from the In-situ Experiment

This section describes an experiment in which therapy sessions were recorded to create a database for machine learning research. These sessions involved the use of service robots to support CwSN, including those diagnosed with ASD, ADHD, and SD. The robot facilitated app-based activities that complemented therapy sessions by providing structured tasks across multiple domains, including communication (AutiSpark), social-emotional (LogicLike), cognitive (Khan Academy Kids), and motor domains (ABC Kids). These apps functioned primarily as mediators, ensuring the children remain engaged with the robot interface. At the same time, the core focus of the study was the integration of the hybrid head pose estimation (HPE) system. During these sessions, the robot's integrated camera and HPE workflow (dlib, MediaPipe, and PnP) simultaneously recorded and analysed head movements to quantify visual attention in real-time.

Thirty CwSN underwent the RAT to train skills across multiple domains, highlighting the potential of integrating technology and robotics into therapeutic intervention.

1) Participants: Thirty children diagnosed with ASD, ADHD, and SD were selected who are currently receiving treatment at the Kizzu Kids Rehabilitation and Enrichment Centre (Malaysia), a specialised institution for the rehabilitation of CwSN.

Ethical approval was obtained from the ethics committees of Universiti Teknologi MARA and Kizzu Kids Rehabilitation and Enrichment Centre. All the parents signed consent forms before their children were included in the study. Children were free to leave the experiment at any time and were always supported by a professional educator, other than the researcher.

2) The robot therapist: Temi 3 service robot: The robot that led the RAT was the Temi 3 service robot (see Fig. 1), a telepresence robot and a trustworthy autonomous personal assistant focused on high-quality video. By combining artificial intelligence and autonomous navigation, it can recognise and follow people on demand, memorise predefined locations, and navigate effortlessly in various settings, including hotels, restaurants, shops, businesses, educational institutions, healthcare facilities, and more.

This study utilised the default settings and standard equipment of the Temi 3 robot unless otherwise specified. The Temi 3 has multiple advanced cameras designed to enhance its functionalities. It features a 13-megapixel high-resolution camera with autofocus, capable of recording 1080p video at 30 frames per second (FPS), a 120-degree field of view (FOV), a

5-element lens, and a hybrid infrared (IR) filter. Additionally, it includes a wide-angle 13-megapixel camera for remote navigation, offering a 95-degree FOV and 1080p video recording at 30 FPS. Complementing these is a Time-of-Flight (TOF) depth camera, which operates at 30 FPS with a 90-degree FOV and an effective range of up to 5 meters, enabling depth perception essential for navigation and object detection. Among its software features, Temi 3 includes face detection and tracking capabilities, which are employed in *in-situ* experiments to guide the robot toward the child during interactions.

Fig. 1. The Temi 3 Robot. The camera used for recording the child's head pose is the one on top.

3) Protocol for the In-situ experiments: To evaluate the children's attention, this study focused on participants who were already enrolled in therapy sessions of varying durations and had been diagnosed by specialists before commencing the program. In this research, pre-existing app-based learning modules were downloaded and integrated into a robot interface to facilitate interaction between the children and the robot during therapy sessions. These modules were carefully selected to align with the therapeutic needs of the children, incorporating tasks adapted to their developmental levels. These tasks are designed to observe how children visually engage with the robot and respond to visual stimuli presented through the robot's interface.

The robot served as a mediator during the therapy sessions, integrating pre-existing apps and a camera system to facilitate interaction and observation. It was included in the children's daily activities and identified through a specific "visual schedule". A visual schedule communicates the sequence of upcoming activities or events using objects, photographs, icons, words, or a combination of these supports. During each session, the children engaged in tasks presented through the robot, with the apps delivering visual stimuli and the camera capturing data to observe and analyse the children's visual attention.

To facilitate interaction, the robot-led sessions were conducted in the same room where the children typically received their therapy, ensuring a familiar and comfortable environment. The robot was positioned in front of the child and initially placed at a distance of at least 0.5 meters. Children were allowed to adjust their seating position to enhance comfort. Each session focused on a single activity to evaluate visual attention, with tasks presented in a randomised sequence to minimise repetitive or predictable patterns. The robot introduced each activity using clear and straightforward verbal instructions and visual prompts to engage the children in the tasks effectively (see Fig. 2).

Fig. 2. An example of a child–robot interaction during the therapeutic session. A therapist was always present nearby to support the child.

A therapist familiar with the children's daily treatment routines was present during the sessions to provide security and support. The therapist offered positive reinforcement through verbal cues, such as "good" or "right", and, in some instances, physical reinforcement, such as a gentle touch or pat. These reinforcement strategies were individualised to meet each child's needs and address their unique behaviours.

Before the main sessions, an introductory session was conducted to familiarise the children with the robot and minimise potential novelty effects. During this preliminary session, the robot was introduced in a non-therapeutic context for approximately ten minutes, allowing the children to acclimate to its presence in a relaxed and informal manner.

4) Video recording and annotation

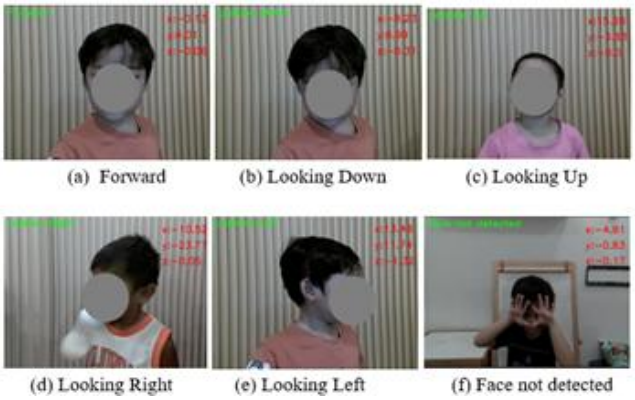

Fig. 3. The frame is extracted from four videos recorded by the robot's camera (the child interacts with the robot, while the system records and annotates the head position in real-time).

Fig. 3 above showcases a series of frames extracted from videos recorded by the Temi 3 robot's camera, capturing various head poses of a child during the interaction. Each frame represents a different head position, annotated in real-time by the system. The poses include: a) Forward, where the child looks directly at the camera; b) Looking Down, where the child tilts their head downward; c) Looking Up, with the child tilting their head upward; d) Looking Right, with the head turned to the right; e) Looking Left, where the child turns their head to the left; and f) Face Not Detected, where the face is obscured or not visible to the system. These annotated frames demonstrate the system's capability to record and categorise head positions during live interactions, essential for analysing visual attention and engagement.

B. Head Direction Detection Algorithm

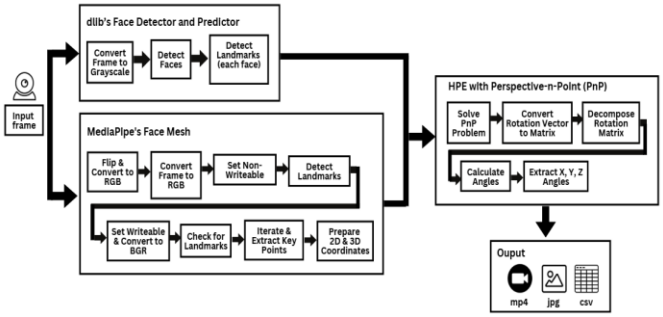

Fig. 4. Comprehensive workflow of the head pose estimation.

Fig. 4 illustrates a comprehensive workflow for HPE, integrating dlib's face detector and MediaPipe Face Mesh as complementary modules for robust facial landmark detection and analysis. The hybrid approach, which combines Dlib's 68-point landmark predictor with MediaPipe Face Mesh, was selected to leverage Dlib's geometric precision alongside the real-time tracking stability provided by MediaPipe. This integration enhances accuracy across diverse lighting conditions and head movements, which are commonly encountered during therapeutic sessions involving children.

To estimate the three-dimensional head orientation, the Perspective-n-Point (PnP) algorithm was employed to assess the three-dimensional head pose due to its efficiency and appropriateness for monocular camera input, thereby ensuring compatibility with standard RGB webcams integrated into the robotic platform.

Input video frames from a camera are preprocessed through two distinct pathways. The first pathway utilises dlib, where frames are converted to grayscale, facial regions are detected, and 68-point facial landmarks are extracted. This pathway ensures accurate detection and tracking of facial features under various lighting and environmental conditions. In the second pathway, MediaPipe's Face Mesh processes the input frames by converting them to RGB format and, if necessary, flipping them for consistency. The frames are then set to a non-writable state to optimise computational performance before detecting facial landmarks. These landmarks undergo iterative refinement to extract key points, which are further processed to generate 2D and 3D coordinate mappings. This dual-pathway approach enhances the system's robustness, enabling it to accommodate diverse input formats while maintaining precision across various scenarios.

The extracted key points from both pathways are input into the HPE module, which employs the Perspective-n-Point (PnP) algorithm for pose computation. This algorithm calculates head orientation by solving for rotation and translation vectors, which are then decomposed to derive X, Y, and Z rotation angles. These angles represent the real-time spatial orientation of the head, enabling precise monitoring and tracking of head movements. The integration of the dlib and MediaPipe modules ensures that the system achieves a balance between computational efficiency and detection accuracy.

Finally, the outputs from the workflow are presented in multiple formats to support diverse analytical needs. Annotated videos are generated in MP4 format, individual frame images are saved as JPG files, and a CSV file is produced to log timestamps, rotation angles, and head directions data. These multimodal outputs provide a comprehensive dataset for analysing head pose dynamics, thereby supporting applications in visual attention assessment and behavioural research. The modular design of this workflow ensures adaptability and effectiveness for real-time analysis in therapeutic environments.

C. Performance Measures

The forward-facing head pose measure was calculated to evaluate engagement and focus of the participants during therapy sessions, providing a quantitative metric for assessing visual attention. This was achieved by determining the total number of instances where the forward head pose was detected in real-time using head pose estimation algorithms. The forward-facing pose, which indicates that the child is looking directly at the task or stimuli, was analysed explicitly as a key performance measure of attention.

To calculate the frequency of forward-facing head poses as a measure of attention, the following formula was used:

$$\text{Frequency of Forward Head Pose (\%)} = \frac{T}{(T+F)} \text{ x } 100 \quad (1)$$

In this formula, T represents the total number of instances where the system correctly detected the forward head pose and verified its accuracy based on video frame analysis, indicating the participant's direct focus on the task or stimulus. F represents the total number of instances where the system detected a non-forward head pose (left, right, up, or down). Still, upon reviewing the video frames, these instances were verified to be correct forward head poses. This formula provides a normalised percentage of forward-facing head poses, enabling a consistent evaluation of visual attention during the therapy session. This formula provided a normalised percentage of forward-facing poses, enabling a consistent and comparable assessment across participants and sessions.

The forward-facing head pose was considered a reliable indicator of attention, reflecting how participants maintained their focus on the task or robotic intervention during therapy. Higher frequencies of forward-facing poses were interpreted as higher levels of engagement and attention, highlighting the ability of the participant to stay visually connected to the activity.

This analysis offered valuable insights into engagement patterns, emphasising forward-facing head poses as a direct measure of visual attention. Using this metric, the study demonstrated the importance of monitoring forward-facing head poses as a performance measure, particularly for children with special needs. This approach provides an objective and real-time method for evaluating engagement, offering actionable data to optimise therapy strategies and improve outcomes.

IV. Results

This section presents the experimental outcomes obtained from the head pose estimation framework, including detection accuracy, frame rate performance, and attention classification metrics across participant groups.

A. Accuracy of Head Direction Detections

The head direction detection algorithm accurately identified and categorised the five predefined head orientations: forward, left, right, up, and down. Validation against the automated annotated dataset showed an overall accuracy of 82% across all participants and sessions. Fig. 5 shows the accuracy percentage for each participant.

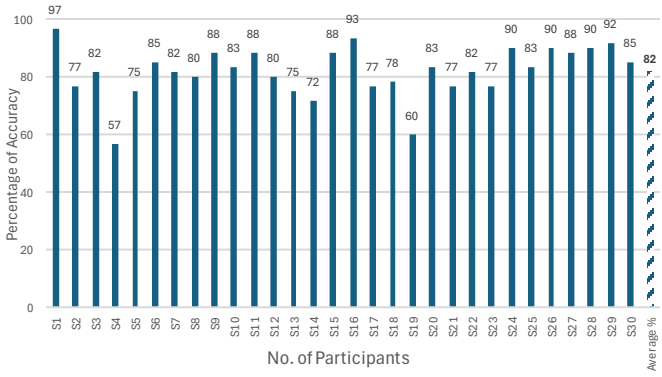

Fig. 5. The overall accuracy percentage for each participant.

Among the 30 participants, a clear contrast in accuracy rates was observed, with S4 and S19 recording the lowest rates and S1 and S16 achieving the highest. S4 achieved 57% accuracy, while S19 recorded 60%. Both participants are relatively inexperienced in therapy, with S4 having attended only a single session and S19 completing four sessions. This limited exposure may have contributed to their lower performance, as they are likely still developing familiarity and engagement with the tasks. Additionally, their young ages, 2 years for S4 and 4 years for S19, may reflect less developed cognitive and attentional abilities than older participants, further influencing their accuracy levels.

In contrast, S1 and S16 demonstrated the highest accuracy rates, with S1 attaining 97% and S16 achieving 93%. Their superior performance can be attributed to their extensive therapeutic exposure and structured intervention programs. S1, a 4-year-old female, has undergone eight one-to-one therapy sessions for personalised guidance and consistent engagement. Similarly, S16, a 6-year-old male, has participated in an intensive Early Intervention Program (EIP), attending sessions five days per week for 24 months. This rigorous and targeted approach likely enhanced their cognitive and attentional abilities, as well as their familiarity with therapeutic tasks, enabling them to outperform their peers.

B. Percentages of Attention Among Children with Special Needs

The attention percentages of CwSN were analysed to understand their engagement levels during interactions. Focusing on the proportion of time they maintained a forward head pose, a key indicator of attention, the analysis aimed to provide insights into their focus patterns. This measure is particularly significant in assessing how children with special needs respond to stimuli in structured settings, highlighting their ability to stay engaged and attentive over time.

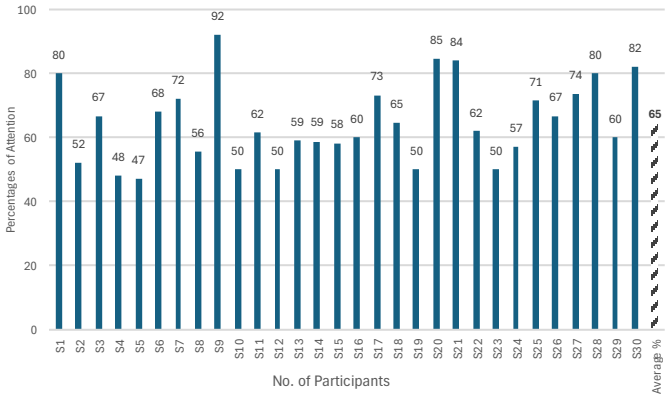

Fig. 6. The overall visual attention percentage for each participant.

Fig. 6 illustrates the attention percentage for each participant during the study, showcasing a wide range of engagement levels. The average attention percentage is 65%, with notable variations at both extremes. These differences highlight individual factors that influence the participant's ability to remain attentive during therapy sessions, including therapy duration, the severity of autism, age, and home environment.

The participant with the highest percentage of attention is S9, achieving an impressive 92%. S9 is a 5-year-old child with mild autism who has undergone 10 months of therapy and regularly experiences screen time at home. These factors may contribute to their higher attention level, as mild autism and longer therapy duration will likely enhance their ability to focus and engage with the task. Additionally, familiarity with screen-based interactions at home could make the experimental setup more engaging and comfortable for them.

In contrast, the participant with the lowest attention percentage is S5, recording just 47%. S5 is a 2-year-old child with ASD who has only undergone 9 months of therapy and does not have screen time at home. These factors might explain their lower attention level, as young ages and limited therapy duration can pose more significant challenges in maintaining focus. Furthermore, the lack of exposure to screens may make the experimental setup unfamiliar or less engaging for S5. These findings emphasise the importance of tailoring interventions to individual needs and considering factors such as therapy duration, different disabilities, and home environment when analysing engagement levels.

The differences in attention percentages highlight the importance of accounting for individual variability when interpreting these results. Participants with higher attention percentages, such as S9, may reflect the effectiveness of the experimental design in fostering engagement, particularly for children who benefit from longer therapy and familiar environments. Conversely, participants with lower attention levels, like S4, point to areas for improvement, such as minimising distractions or adapting activities better to suit the needs of children with more severe challenges. Understanding these patterns provides valuable insights for designing more inclusive and effective interventions, ensuring all participants can maximise their engagement during similar studies or therapeutic settings.

C. Type of Disability and Attention Pattern Analysis

The analysis of head direction among thirty children with special needs revealed distinct patterns among the three diagnostic groups: Autism Spectrum Disorder (ASD), Sensory Disorder (SD), and Attention Deficit Hyperactivity Disorder (ADHD).

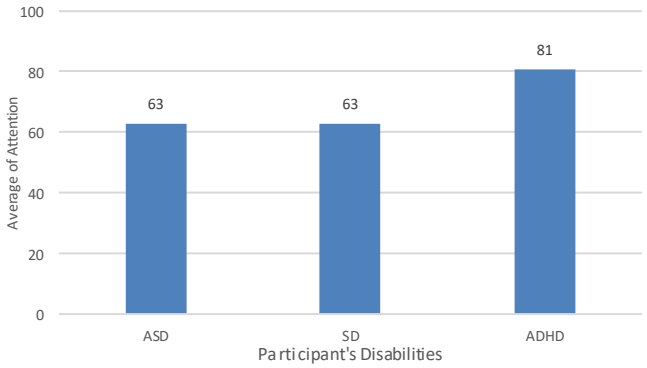

Fig. 7. The average of visual attention for different types of disability.

Fig. 7 illustrates the average percentages of visual attention across three categories of disabilities. The results indicate that children with ADHD (S20, S21, and S27) exhibit the highest average attention percentage at 81%, followed by those with SD at 63% and ASD at 63%. This suggests that the type of disability significantly influences attention levels, with children with ADHD demonstrating comparatively higher focus during activities.

From observations and discussions with a therapist during the therapy sessions, it was noted that children with ADHD tend to exhibit hyperfocus on tasks that are highly stimulating or engaging. These behaviours align with their preference for dynamic and interactive activities that effectively capture their attention. Additionally, shorter, highly interactive sessions are efficient in maintaining focus. These structured and engaging therapy strategies likely contribute to the higher average attention percentages observed in children with ADHD compared to other disability groups. Children with ASD and SD might face different challenges that affect attention, such as sensory processing difficulties or delayed cognitive processing, which could contribute to slightly lower average attention levels compared to children with ADHD. These findings may highlight a strength within the ADHD population with an ability to hyperfocus under the right conditions, which could be leveraged to improve therapeutic and educational outcomes.

D. Age-Based Variations in Attention Percentages Analysis

Visual attention plays a critical role in understanding the engagement and focus levels of CwSN during therapy sessions. By analysing attention percentages across different age groups, developmental patterns influencing their ability to concentrate on tasks can be identified. Below is a graph (see Fig. 8) illustrating the average attention percentages for children aged 2 to 7, which highlights the relationship between age and visual attention capabilities.

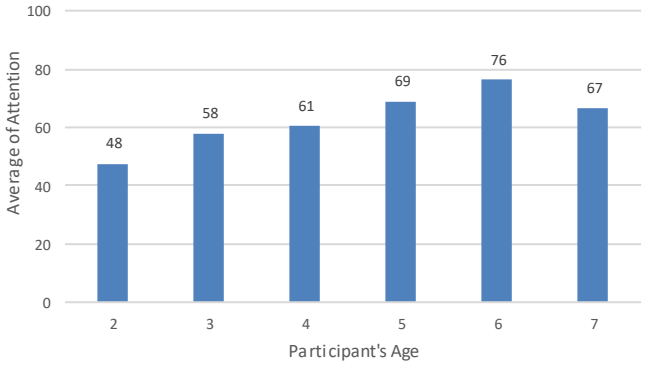

Fig. 8. The average visual attention for different ages.

The results reveal a noticeable trend where attention percentages increase with age, peaking at 76% for 6-year-olds before slightly declining to 67% for 7-year-olds. Younger children, particularly 2-year-olds (S4 and S5), exhibit the lowest attention levels at 48%, indicating developmental differences in focus and engagement during therapy sessions. This pattern suggests that as children grow older, their ability to maintain attention improves, likely due to increased cognitive development and maturity. However, the slight decrease in the oldest age group (7 years) may reflect varying individual differences or a plateau in attention development. These findings demonstrate that attention levels tend to align with developmental maturity as children grow older, highlighting the natural progression of focus and engagement with increasing age.

E. Impact of Therapy Duration on Attention

Therapy duration plays a significant role in influencing the attention levels of CwSN. Analysing attention percentages across different therapy durations provides valuable insights into how the length of therapy impacts focus and engagement over time. It is important to note that the children in this study were interacting with a robot for the first time, and their unfamiliarity with the robotic environment may have influenced their attention levels. The novelty of the robot could have initially captured their curiosity and engagement.

Fig. 9 illustrates the average percentages of visual attention for CwSN across varying therapy durations, ranging from 6 months to 36 months. The data reveal that children in the 6-month therapy group exhibited the highest attention levels at 67%. However, as therapy duration increased to 12, 24, and 36 months, attention percentages slightly decreased and stabilised

at around 63-64%. This pattern suggests that shorter therapy durations may initially result in heightened attention, potentially due to the novelty effect and intensive engagement during the early stages of therapy. In contrast, stabilising attention levels over longer therapy durations may indicate that children adapt to the therapy routines or experience a plateau in attentional improvement. These findings underscore the need to revise and adjust therapeutic strategies over time to sustain engagement and optimise long-term outcomes.

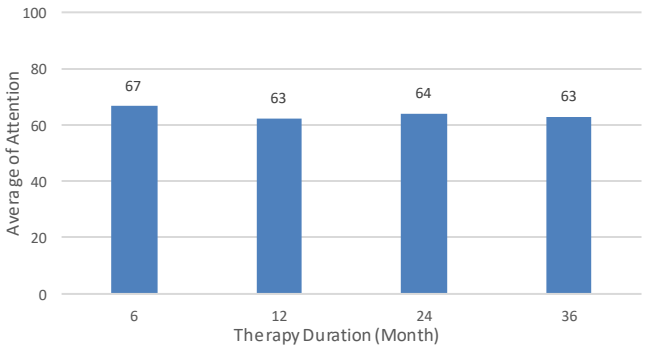

Fig. 9. The percentages of visual attention for different therapy durations.

V. Discussion

The results indicate that the proposed framework effectively identifies head orientation with high accuracy and stability. This section discusses the implications of these findings, compares them with previous studies, and highlights potential applications as well as existing limitations.

The outcomes of this study demonstrate the feasibility of integrating a head pose estimation algorithm within the context of robot-assisted therapy (RAT) to evaluate visual attention in children with special needs (CwSN). The system achieved an overall head orientation detection accuracy of 82%, alongside an average attention rate of 65%, indicating consistent performance across diverse participant groups and experimental scenarios. These results align with previous studies on real-time head pose estimation, which reported accuracy rates ranging from 78% to 85% under controlled conditions [31][32][33]. This consistency supports the robustness of the hybrid Dlib–MediaPipe–PnP methodology, demonstrating its resilience in the dynamic and unpredictable environment of therapy sessions.

Notably, the findings also reveal considerable variability in the results, suggesting that factors such as age, therapy experience, and type of disability have a substantial impact on engagement levels. This variation highlights the importance of considering developmental and contextual variables when interpreting performance metrics, as children with greater therapy exposure and familiarity with structured activities tend to achieve higher accuracy and attention scores.

Beyond technical validation, the study emphasises the broader implications of integrating robotics into therapeutic practice. RAT not only offers an objective and real-time method for attention monitoring but also facilitates opportunities for tailoring interventions to individual needs. The observed differences across various diagnostic groups and therapy durations indicate that a "one-size-fits-all" strategy may be inadequate, and that customised approaches are imperative to maintain long-term engagement.

These findings contribute to the growing body of evidence supporting artificial intelligence (AI) and robotics as effective tools for enhancing therapeutic precision, inclusivity, and personalisation. By integrating computer vision with behavioural analytics, the proposed framework demonstrates the potential of AI-driven systems to objectively quantify visual attention, thereby providing therapists with actionable data to support informed clinical decision-making. This integration represents a significant step toward data-informed, child-centred therapy environments that foster measurable developmental outcomes and elevate the overall quality of interventions for children with special needs.

Although the proposed framework demonstrates robust performance, several limitations should be acknowledged. The sample size was relatively small, and the controlled experimental setting may not fully reflect the variability and complexity of real-world therapeutic environments. Furthermore, external factors such as inconsistent lighting conditions and occasional occlusion intermittently influenced detection accuracy, suggesting the need for further refinement and validation in more diverse and naturalistic contexts.

Notwithstanding these limitations, the findings hold significant implications for therapeutic practice and special education. By enabling objective monitoring of attention, the framework allows therapists to tailor interventions and track engagement patterns over time, thereby enhancing therapeutic precision and potentially improving developmental outcomes for children with special needs.

In summary, this discussion highlights that the proposed hybrid head pose estimation framework demonstrates strong accuracy, real-time performance, and adaptability across diverse therapeutic contexts. The variations observed among participants underscore the importance of personalised and data-driven therapy strategies, wherein AI-based tools serve to complement rather than replace human expertise. By transforming head orientation data into meaningful attention metrics, this study bridges computational analysis with behavioural interpretation, enabling a more precise understanding of engagement in children with special needs. These insights establish a solid foundation for advancing intelligent robot-assisted systems and inform the development of future research directions in data-driven therapeutic interventions.

VI. Conclusion

The findings of this study highlight the significance of head direction patterns in assessing visual attention among children with special needs (CwSN), with variations in engagement, such as the high focus of S9 versus the challenges faced by S5, underscoring the influence of disability severity, therapy duration, and age. These results have important implications for robot-assisted therapy (RAT), as head direction data can inform the design of therapeutic activities better aligned with individual needs. Nonetheless, the study is limited by its relatively small sample size, variability in participant profiles,

and occasional inaccuracies in head pose classification. These limitations could be mitigated through larger, multicenter studies, the inclusion of multimodal behavioural measures (e.g., eye tracking, body posture), and further optimisation of the hybrid HPE algorithm to improve robustness in real-world conditions. Overall, the study emphasises the potential of head direction analysis in improving visual attention assessment and optimising RAT, offering a promising direction for enhancing therapeutic outcomes for CwSN.

This study presents a validated head pose estimation framework designed to quantify visual attention in children with special needs during robot-assisted therapy. Theoretically, it advances the understanding of how AI-based visual cues can represent attentional behaviour in non-verbal or minimally responsive participants. Practically, the system provides a non-intrusive solution that enhances engagement assessment within therapeutic and inclusive learning settings. Future research will involve larger participant groups, integration with eye-gaze and emotion detection technologies, and deployment in real therapeutic environments to validate scalability and adaptability.

Overall, the study establishes a solid foundation for the integration of AI-driven attention assessment in therapy, bridging computational modelling with behavioural science. By promoting more personalised, data-informed, and child-centred approaches, this research contributes to the evolving landscape of intelligent robot-assisted therapy, paving the way for future innovations that enhance developmental outcomes for CwSN.

ACKNOWLEDGMENT

This work was funded by the Strategic Research Partnership (SRP) grant (100-RMC 5/3/SRP INT (047/2023)) and (100-RMC 5/3/SRP INT (048/2023)). The authors would like to thank the Institute of Research Management Centre (RMC) and the Faculty of Engineering, Universiti Teknologi MARA (UiTM) Shah Alam, Malaysia, for the financial support, instrumentation, and experimental facilities provided. This study was undertaken during the study leave of the first author under the 2022 Federal Training (HLP) scholarship scheme awarded by the MOHE Malaysia.

A Novel Taxonomy for Human Activity Recognition Based on a Systematic Analysis of Public UAV Datasets

Sumaya Abdulrahman Altuwairqi*, Salma Kammoun Jarraya
Department of Computer Science-Faculty of Computing and Information Technology, King Abdulaziz University, Jeddah, Saudi Arabia

***Abstract*—In recent decades, unmanned aerial vehicles (UAVs) have become widely utilized for many real-world applications, including surveillance, crowd management, and threat detection, providing a new perspective to recognize human behaviors. However, current UAV-based video datasets adopt categorization schemes that rely on broad and inconsistent categories relative to real-world aerial contexts. To address this knowledge gap, this study proposes a novel human activity categorization framework derived from a comprehensive systematic analysis study of ten publicly available UAV-based human action recognition (HAR) datasets, incorporating a variety of environmental situations and human behaviors. By reconciling inconsistent categories and finer activities, this taxonomy serves as a standard framework for UAV-based HAR research. The proposed categorization framework is validated by comparing it with other existing frameworks on the publicly benchmarked Drone-Action dataset, outperforming them by 97% across four metrics. Our contribution aims to develop the foundation for further experimental validation and provide a guide for researchers interested in developing accurate and context-aware surveillance systems.**

***Keywords*—Human action recognition; UAV videos; surveillance systems; categorization framework**

I. Introduction

Unmanned aerial vehicles (UAVs), also known as drones, are distinguished by the lightweight integration of communication and sensor devices and their automation, as well as their power to provide wide-view coverage through rapid navigation across different locations. This makes them highly useful for a wide range of civilian and military applications, including reconnaissance, surveillance, scientific research, sports, and entertainment. UAVs have seen widespread use worldwide over recent years due to rapid technological evolution and their applicability in various systems. At present, the security and military sectors, rather than the industrial and commercial sectors, dominate the use of UAVs, which can be attributed to the increasing demand for traffic surveillance and monitoring [1-3], threat detection [4], search and rescue (SAR) [5], and intelligence, surveillance, and reconnaissance (ISR). Consequently, processing, interpreting, analyzing, and understanding UAV-based images and videos has become essential and highly desired.

One of the UAV exploitations that has garnered substantial attention is human action recognition (HAR), which is one of the promising fields of computer vision aimed at designing and building systems and methods that facilitate the automatic understanding, interpretation, and identification of various human activities in different contexts or environments captured in videos. HAR forms the cornerstone of a wide range of real-world applications, including visual surveillance systems, dense crowd management [6], smart healthcare, sports analytics [7], and the recognition of pedestrian actions for autonomous vehicles. UAV-based HAR visuals provide an unprecedented perspective for analyzing human behavior in various scenarios, making it a crucial topic for understanding and studying the human activities and behaviors that aid in building robust automated HAR systems suitable for UAV-based visual challenges.

Nowadays, several UAV-based datasets have been developed to capture diverse categories of human behaviors in real-world environments. Although these datasets have contributed significantly to the field, most of the recent studies [8-20] applied the categorization frameworks on these datasets that rely on full/partial single criteria of human actions and behaviors, resulting in broad, fine-grained, inconsistent, or overlapping categories. This issue may result in inaccuracies, as some critical human behaviors are ignored by being categorized inconsistently compared to their real-world context. For instance, in the Okutama-Action dataset [21], “pushing” may be categorized as someone moving a shovel's container forward, while the same classification is applied to someone forcefully pushing another person in another dataset. For the UAV-Human dataset [22], "walking" is fragmented into many categories based on the UAV's angle of view. These discrepancies and overlaps can confuse and impede the development of robust HAR-based approaches [8, 14, 23] due to their categorization lacking the ability to determine human activity levels and a reliance on human action properties, including kinematics, intentionality, and context dependency, which are essential for providing accurate and comprehensive categorization. Consequently, this highlights the urgent requirement for a systematic categorization scheme that reflects the subtle dissimilarities of human activities in aerial contexts.

To address the aforementioned gaps, this study proposes a novel human activity categorization framework designed

* Corresponding author.

specifically for UAV-based videos. The proposed categorization framework is based on three theoretical criteria of human behavioral and motion: 1) human action properties; 2) human behavioral characteristics; and 3) human activity levels. This framework derives from an in-depth, comprehensive analysis of ten publicly available UAV-based HAR datasets, involving a collection of human activities and contexts, and examines their challenges and complexities. Through systematically identifying similar and distinct human action categories across these datasets, we propose a unified yet precise taxonomy that considers the detail required for context-aware recognition. This taxonomy aims to serve as a foundational framework, allowing researchers to adopt consistent human behavior categories and provide insights into how to design and develop HAR-based systems that adapt to UAV challenges. To the best of our knowledge, this is the first study to introduce an in-depth study of human activity categories across multiple UAV-based HAR datasets and propose a unified taxonomy under aerial situations. The main contributions of this study include the following:

- Building a novel category for video-based human action recognition.
- Presenting a systematic study of ten public UAV-based HAR datasets, providing insightful analysis and discussion of their human activities and challenges, and defining various taxonomies, including levels, video categories, label schemes, environments, and factors of the UAV footage.
- Identifying a new behavior on the Okutama-Action dataset based on the human activity levels.
- Developing a unified and accurate human activities categorization framework founded on three criteria, compatible with UAV scenarios.
- Evaluating the performance of the proposed categorization by comparing it to the current categorization on the Drone-Action dataset, it surpasses them by a marked margin.

The rest of the study is structured as follows: An overview of human action recognition, including human activity levels and video categories related to HAR, is provided in Section II. The related literature study is illustrated in Section III. A comprehensive study of UAV-based HAR datasets involving their description and classification, UAV challenges, a novel taxonomy derived from in-depth analysis of human activities, and an insightful discussion of the similar and distinct activities within these datasets is introduced in Section IV. The experiment and discussion are displayed in Section V. Finally, the study is concluded in Section VI.

II. Background of Human Action Recognition

Interpreting and understanding human actions are an urgent need and prerequisite for a wide range of reality applications. An awareness of hazardous human activities is required for surveillance system applications [18], monitoring the activity of falls in the elderly is mandatory for health monitoring systems [24], and many applications of such technologies are based on human behavior understanding, such as video retrieval, content-based video summarization, and human–computer interaction. Defining human behavior at an early stage prevents potentially serious injuries through prompt self-correction or immediate manual intervention [25]. The process of manually identifying such actions can be messy, expensive, and prone to mistakes. Consequently, automated action recognition, aka Human Action Recognition (HAR), has gained popularity and attention from the research scientific community.

In the domains of robotics, artificial intelligence, and computer vision, the HAR field has long been a focus. Earlier approaches to understanding human actions relied on HAR datasets recorded by stationary cameras called ground-based HAR datasets [26]. In ground-based HAR datasets, human subjects usually appear large and in the middle of the video frames, and occupy most of the frame. Although these conditions make HAR relatively explicit and facile, this does not accurately simulate real-world scenarios. When human subjects are far from the cameras, the motion scenes typically occur in a small area within the video frames.

In recent years, the research community has presented a new dimension for HAR where incorporating it with the agility, mobility, and high altitude of UAVs. UAVs have the capability to capture various scenes – often with large dimensions – from different angles and altitudes. This provides extensive data that enhances the performance of the action recognition-based model. The transition from ground-based HAR to UAV-based HAR is not simply due to a change in the altitude [27, 28]; instead, it is a context conversion that yields new challenges to the HAR arena, including motion blur and change in subject sizes, among other factors. How to recognize, understand, and interpret human actions by machines is a highly sensitive and essential issue in the general HAR field, particularly in UAV-based HAR; consequently, it is necessary to recognize human behavior accurately and quickly. UAV-based HAR has various real-world applications in surveillance and security, defense and military, sports, and search and rescue. Subsection IV-B provides a detailed discussion of the challenges facing the application of UAVs.

A. Human Activity Levels

Human activity refers to any gesture, action, or behavior performed by a human, individually or collectively, whether intentionally or unintentionally. It involves a wide range of fields and effects, from daily routine tasks and cultural, economic, and political practices to complex industrial processes. These activities can be categorized based on several taxonomies, such as type, purpose, and complexity. Through a literature review [29, 30], we identified five levels of human activities that rely on their complexity execution, namely human-gesture activity level, single-human action level, human-object interaction level, human-human interaction level, and composite human activity level, as shown in Fig. 1.

1) Human–Gesture activity level: A gesture is a meaningful nonverbal communication based on the movement of the human body—often the arms, head, face, and hands—that intends to convey specific emotions or ideas; it typically

occurs over a short period. It is considered the smallest unit of human activity through which more significant and complex activities can be created. Examples include hand movements, facial expressions, and nodding.

2) Single–human (atomic) action level: An atomic action (AO) is a sequence of relevant gestures combined into a single action that a single person executes at a specific moment in time. It refers to behavior that begins and ends with one person without any participation from an object or another person. Examples include walking, running, and swimming, which are all considered single-human actions.

3) Human–Object Interaction (HOI) level: Many activities are a consequence of the interaction between two actors, one of whom is human and the other either a human or an object. An action that occurs between a human and a physical object is termed an HOI interaction. Examples include reading, cooking, eating, and kicking a ball.

4) Human–Human Interaction (HHI) level: Unlike HOIs, which involve understanding how humans and physical objects interact, human-human interactions focus on communication and interaction between two persons. A person's actions toward another determine the type of HHI interaction, such as handshaking, hugging, and fighting.

5) *Composite human activity level:* This refers to a series of sequential or concurrent activities performed by humans that involve a combination of gesture activities, AO actions, and HOI interactions, along with HHI interactions that occur among more than one human and more than one object. In contrast to simple activities such as walking and sitting, composite activities combine these simpler activities that are organized and significant in which this combination forming more complex behaviors or tasks. Examples include group study, conducting meetings, and presentations.

Fig. 1. Human activity levels on HAR.

B. Video-based HAR Category

Through the investigation and analysis of human action recognition video datasets, together with a review of previous literature [5, 8, 31-33], as shown in Fig. 2, we can sequence human action videos into four categories relying on their contents as follows:

1) Multi-action video

- *Multiple Actions by Multiple Actors (MA-MA) over video.* This category includes scenarios of multiple actors performing various activities concurrently within the same scene. It focuses on comprehending difficult scenarios, including several actors participating in diverse activities. It is usually used for crowd behavior analysis and group activity recognition tasks.

- *Multiple Actions by a Single Actor (MA-SA) over video.* This involves scenarios in which a single actor performs multiple activities sequentially or simultaneously throughout time. The primary objective is to recognize the boundaries and types of each action within a continuous video sequence. Such approaches require identifying the beginning and ending times of each action in a video; as such, this category is commonly applied to complex action recognition tasks.

2) Single-Action video

- *Single Action by Multiple Actors (SA-MA) over video.* This category covers scenarios where several actors perform the same activity, often in a synchronized or coordinated manner. It focuses on identifying activities executed by several people working together in cooperation. Typically applied to the analysis of team sports, crowd management in public settings like colleges and seasonality events, and industrial systems' assembly line operations.

- *Single Action by Single Actor (SA-SA) over video.* This scenario, which focuses on a single actor executing a single action within a video, is the most prevalent in human action recognition and has been extensively covered in previous literature. The objective of this category is to classify the action from the video sequence, which forms the core of more complex scenarios.

Fig. 2. Video-based HAR category.

III. Literature Study

With the rapid development of UAVs across various real-world applications, including surveillance systems, crowd management, and search and rescue (SAR), human action recognition in aerial videos has garnered significant attention

in recent years. In contrast to ground-based footage, UAV-based footage typically involves challenges such as changing object and subject sizes, partial or full occlusion, changing angles of view, and background dynamics, which are factors that greatly complicate the consistent categorization of human behaviors and activities. Amid these challenges, researchers have increasingly focused on automated human action recognition, which aims to identify and understand human behaviors, motions, and interactions with the external environment in an aerial context. Some previous studies have sought to perform one-class anomaly detection, whereas others rely on extremely detailed categorization for building a robust automated human activity recognition system. In contrast, others work on inconsistent or ambiguous categorization of the datasets. The next subsections provide how recent UAV-based works categorize diverse actions, from overlapping and inconsistent taxonomy to single-category taxonomy, as these data sources are often relied upon in human behavior categorizations.

A. Inconsistent Category Practices

Some studies have utilized several UAV datasets, including Okutama-Action [21], UAV-Human [22], NEC-Drone [34], UAV-Gesture [35], Drone-Action [8], and UCF-ARG [36] to recognize human activities. These works have categorized human activities in an inconsistent or overlapping manner: some group two different actions under one category, whereas others categorize the same action under two or more categories. In order to handle the Okutama-Action dataset, for instance, Khan et al. [8] and Yadav et al. [9] introduced a multi-label recognition approach focusing on many human activities performed by several persons simultaneously. Although they categorized many fundamental human activities appropriately, such as walking, hugging, and shaking hands, they nevertheless aggregated the “someone pushing a shovel's container” action and the “someone pushing another person” action under the same category termed “pushing/pulling”. Only one of the human action properties is employed in this categorization; the intentionality and level of activity were disregarded in favor of grouping the action according to its kinematics, which resulted in an inconsistency in their categorization.

The NEC-Drone dataset, among others, was leveraged by Xian et al. [10] to analyze human behavior and categorize human actions into individual or group interactions. They considered human activities such as sitting, running, and drinking as individual interactions, while hugging, handshaking, and pushing a person were considered as group interactions. Nonetheless, they separated the walking activity into two independent categories: “walk” as an individual interaction, and “walk toward each other” as a group interaction, which led to overlapping in their categorization. The same issue occurs in the UAV-Human dataset used by Liu et al. [11], where they divided the “walking” action into four categories: “walk”, “walk side by side”, “walk away from someone”, and “walk toward someone”. Several studies [21, 29, 30] have shown that the regular 'walking' action is considered an atomic action that does not interact with any object or human. Consequently, the human action properties and levels of this act are the same and unchanged whether a group walk (e.g., students walking to the schoolyard) or an individual walk (e.g., a person walking to the garden) is considered. The categorization of the action remains unchanged unless the human behavior level changes. For example, when walking with something, such as a crutch or a wheelchair, or when holding the hand of another person, the categorization of these situations can be considered independent of typical “walking”.

Dhiman et al. [12] introduced an aerial human activity recognition framework that utilizes Drone-Action and UCF-ARG datasets. Despite their accurate categorization of many common behaviors across datasets, their categorization exhibits overlaps because they classify the same activity under many categories. For example, the punching action is categorized into the “punching” category on one dataset and the “boxing” category on the other. Similarly, the jogging action is categorized into “jogging”, “jogging side”, and “jogging front/ back”. Azmat et al. [13] provided a UAV-based HAR approach employing three datasets: UAV-Gesture, Drone-Action, and UAV-Human. All human activities involved in these datasets were utilized, except UAV-Human, from which they chose fifteen human actions. Their categorization also suffers from inconsistency and overlapping, since they combine two different actions under the same category, as well as dividing the same action into different categories. For instance, the wave two-hands action with the wave single-hand action are combined under the “waving hands” category, in which each action has different human action properties, where the first is a gesture to send a distress call for help, while the second is a gesture to say hello or goodbye. Furthermore, the Drone-Action and UAV-Gesture datasets include the same action of waving with both hands; however, they separate it into independent categories termed “wave off” and “waving hands”.

B. Extremely Fine-Grained Category Approach

Some research studies have considered detailed categorization of human activities, which focuses overly on the object involved in the action rather than the movement itself. For instance, Hu et al. [14], Uddin et al. [15], Abbas et al. [16], and Jin et al. [17] employed Action-Drone and UAV-Human datasets to understand human activities in aerial contexts. Although their human actions categorization of the datasets was sufficient, it was overly precise in categorizing some actions. For instance, the “hitting” action was split into subcategories such as “hit with a stick” and “hit with a bottle”, despite having the same fundamental behavior, but their categorization relies on which object is utilized. Although this may at first seem accurate, in real-world practice, it may greatly hinder the training of robust AI-based models. By focusing more on the object than the action itself in classifying actions, the model becomes overly detail-oriented about the object, whereas if the model encounters a new scenario, such as “being hit with a hammer”, it would likely classify it incorrectly. Furthermore, changing the viewing angle of the UAV footage causes partial or full occlusions that may block the object's view, and the model may fail to recognize the hitting action if it cannot recognize the same object. Consequently, the model’s ability to generalize is significantly constrained.

C. Broadly (One-class) Category Approach

To avoid issues relating to fine-grained categories, some research studies have adopted a one-class category method on the MDVD dataset [37], whereby rare and anomalous activities are grouped into a single category termed "abnormal", while other activities are categorized as "normal". For instance, Chriki et al. [18] proposed a UAV-based one-class anomaly approach, where they categorize any normal behaviors (e.g., walking and talking) alongside suspicious behaviors (e.g., people loitering and looking inside a car) under the normal category. They base their approach on the idea that suspicious actions are inherent to human nature, which is characterized by curiosity and an interest in discovery. While Mehmood [19], merged suspicious behaviors and anomaly behaviors (e.g., fighting, stealing, and crashing) into one category termed "abnormal". They argued instead that suspicious acts cannot be ignored and should be considered the beginning of abnormal behavior. The issue with their categorization was the inability of the AI-based model to distinguish between the severity or priority of anomalous behaviors; for instance, the scene of "looking at the car suspiciously" has the same priority as the scene of "physical assault". In contrast, although Hamdi et al. [20] also employed a one-class method, they excluded suspicious actions from their categories and concentrated on normal and abnormal behaviors. By concentrating on combining all deviant behaviors into a single category, these approaches circumvent the problem of precisely characterizing abnormal behaviors. Although this method works effectively for uncertain real-world anomaly detection systems, it is unable to distinguish between abnormal actions, which leads to sacrificing the ability to interpret crucial scenes and hinders advanced systems that require responding differently to violent scenes compared to benign anomaly scenes.

D. Theoretical and Methodological Gap

This literature review shows that different frameworks have been utilized for human activity categorization in previous UAV-based HAR studies. Some frameworks fail to consider all properties of human action when categorizing actions, for instance, [8, 9] focused only on the kinematic property, while [10-12] disregard all properties in their categorization, leading to inconsistent and overlapping categorizations that make robust AI-based models confused during the learning phase. In contrast, some others [14-17] overlook human activity levels in their categorizations and depend on highlighting the details of the object involved in the action more than the action itself, displaying extremely fine-grained categorizations, which often causes a failure in the model's ability to generalize for unseen but similar behaviors. Meanwhile, the broad one-category anomaly frameworks [18-20] relied only on human behavioral characteristics, resulting in the loss of fine-grained distinctions between actions and obscuring the critical distinction between violent and harmless suspicious behaviors.

Ultimately, the challenges of these classifications emphasize the demand for a uniform, detailed human behavior categorization in the aerial context. This research aims to fill these gaps by proposing a novel criteria-driven unified taxonomy framework derived from a comprehensive analytical study of human behaviors across ten publicly available UAV datasets. This categorization framework is founded on three theoretical criteria: 1) human action properties, to unify visually distinct and behaviorally similar actions through kinematics, intentionality, and context dependency; 2) human behavioral characteristics, to determine normal from abnormal behaviors through persistence and harmfulness; 3) human activity levels, to demonstrate consistent categorization of actions across different social contexts through define gesture, individual actions, interactions, or collective behaviors. In contrast to previous frameworks that rely on a full/partial single criterion, this triple-criterion framework formalizes categorization by fusing behavioral interpretable integral criteria, correlating human movement theory with aerial surveillance perception, standardizing the distinction of categories of human behaviors, and providing a consistent, generalizable categorization across several UAV datasets. A comparative summary of several categorization frameworks from previous UAV-based HAR studies is presented in Table I. The following sections describe in detail the methodology used to construct this categorization framework to achieve robust automated UAV-based HAR.

TABLE I. A COMPARATIVE SUMMARY OF SEVERAL CATEGORIZATION FRAMEWORKS FROM PREVIOUS UAV-BASED HAR STUDIES

Study	Criteria of Taxonomy			UAV dataset used	Comments
	Human Action Properties	***Human Behavioral Characteristics***	***Human Activity Levels***		
[8, 9]	Only Kinematics	×	×	One	Inconsistent category - considered different actions under the same category
[10, 11]	×	×	×	One	Inconsistent category - considered same action under the several categories
[12]	×	×	×	Two	Inconsistent category - considered same action under the several categories
[13]	×	×	✓	Three	Inconsistent category - considered different actions under the same category
[14-17]	✓	×	×	Two	Fine-grained category - focused on the object more than the action itself
[18-20]	×	✓	×	One	Broadly category - sacrificing the ability to interpret crucial scenes
Our Proposed Taxonomy	✓	✓	✓	**Ten**	**Unified precise consistent category - tradeoff between fine-grained and broad categories.**

IV. UAV-Based HAR Dataset: Description, Analysis, and Preparation

In this section, we introduce a comprehensive study of UAV datasets for human action recognition. First, we provide a brief description of UAV datasets and discuss several perspectives, including human activity level, video category, label scheme, event contents, and environments, in Section IV A. Then, we highlight six challenges found across ten UAV datasets in Section IV B. Finally, we present a novel taxonomy derived from a detailed analytical study of human activities and insightful discussion of both similar and distinct activities in these ten datasets in Section IV C.

A. UAV-Based Datasets Description

Fifteen UAV-based datasets were found in the literature, most of which are available online. The description of these datasets is detailed in the following:

The SAR-UAV [5] dataset contains 2000 images of different human actions captured by a camera drone with a height of 10–40 m at an outdoor place (inside and outside on a campus) during different times of the day. It contains different situations of human actions, such as one person performing a specific action, a group of people performing the same action, or a group of people performing different actions. Each image was annotated with a bounding box and labels. The whole dataset consists of two smaller datasets: a six-class actions dataset and a two-class actions dataset. The six-class actions dataset for general action recognition contained six classes of action: standing, walking, sitting, lying down, handshake, and hand-waving. The two-class actions dataset has two classes of actions, which are: hand-waving and others (combined with other actions as one class). The two-class dataset is for recognizing the hand-waving action, which is a special sign to ask for help in search and rescue (SAR), such as a person walking with hand-waving, sitting with hand-waving, etc.

The Mini-Drone Video Dataset (MDVD) [37] contains 17 human actions across 12 different scenarios with 38 videos of 16-24 seconds that contain varying events in outdoor locations (car parks) captured by a drone camera at different heights and at different times of the day (morning and night). The videos are classified into three groups: normal events (people walking, talking with each other, riding in cars or parking cars), abnormal events (people fighting, stealing things from cars, stealing cars or parking their cars incorrectly), and suspicious events (where no wrongdoing occurs, but unusual or dubious behavior takes place e.g. a person take a photo of the parked cars, people talking surreptitiously). The video frames were annotated with box bounding and action labels.

The Aerial Violent Individual (AVI) [4] dataset contains 2000 images of different human actions captured by a drone camera with a height of 2–8 m in outdoor locations (public places such as parks, streets, and the roof of a house). Each image contains two-ten persons, for which 48% of human actions in the dataset include five aggressive actions such as strangling, stabbing with a knife, punching with a hand, kicking, and shooting with a gun. Each image is associated with a human pose as a labeled annotation.

The VisDrone2018-VID [38] dataset contains 96 videos of ten object classes of interest, such as a person, car, bicycle, and bus, captured by different drone cameras in outdoor locations (streets, parks, walkways, buildings, and bridges in three cities in China) at different times of day. The total number of frames in this dataset is 33400, and is associated with box bounding and the object class label as a labeled annotation.

The Drone-Action [39] dataset contains 240 videos with 66919 frames of 13 human action categories including walking, scampering, running, punching, beating with a bottle, beating with a stick, kicking, stabbing, applauding, and hand waving captured by a drone camera with a height of 8–12 m in the morning in outdoor location (unpaved road in a wheat field). The dataset contains 10 actors, and each action category is repeated five to ten times. Each video was annotated with box bounding, action category labels, and actor ID.

The Okutama-Action [21] dataset contains 43 videos with 77365 frames of 12 human actions captured by a drone camera with a height of 10–45 m in an outdoor location (baseball field) at different times of the day (morning and noon). The dataset divides the 12 actions into three groups: human-human interactions (handshake and hug), human-object interactions (read, push/pull, call, drink, carry), and non-interactions (walk, run, sit, stand, lying down). The dataset contains nine actors, each of whom performs different actions at the same time (e.g., carrying while walking, calling, and handshaking while standing). Two UAV cameras are used to capture the same scenarios at the same time from different angles (top, left, and right) and in different regions of the same location. Each frame contains 0–9 actors, and each video is annotated with box bounding and action labels.

The DroneSURF [40] dataset contains 200 videos with 411451 frames of people walking and talking captured by a drone camera at low height in the morning at outdoor locations (building roofs, parks). The dataset contains 58 actors, and each video contains a group of 2 to 3 actors. Each frame was annotated with a bounding box and annotated face images.

The NEC-Drone [34] dataset contains 5250 videos with more than 460000 frames of 16 human actions captured by two drone cameras at an indoor place (school gym). The dataset contains 19 actors and divides the 16 actions into two groups: one-person interactions (walk, run, jump, sit, talk, drink, throw, carry a backpack) and two-person interactions (handshake, hug, push person, exchange backpack, walk toward each other). Each video was annotated with action labels. Action label annotation was provided for only 2079 videos.

The DroCap [41] dataset contains six videos of three different human activities, including boxing, walking, and playing soccer, captured by a UAV camera at different heights in an indoor location (large room). The dataset contains two actors, and each video contains one actor who performs an action without changing their location. Each video was annotated with the ground truth of the skeleton motion.

The Drone-dataset [42] dataset contains six videos of variant motions with a length of 10 seconds captured by a drone camera in the morning at an outdoor location (parks, groves, and campus). Each video was annotated with a motion object label every five frames. Each frame is associated with the recorded sensing data.

The UAV-Human [22] dataset aims to develop an understanding of human behavior by focusing on four main tasks: action recognition, pose estimation, person re-identification, and attribute recognition. It contains 22476 videos with 119 subjects of 155 human actions for the Action recognition task, 22476 frames for the Pose Estimation task, 41290 frames of 1144 identities for the person Re-Identification task, and 22263 frames for the Attribute Recognition task. This dataset captured videos from 45 different indoor/outdoor locations (farmland, squares, rivers, forests, campuses, gyms, and inside buildings) with different UAV flight attitudes (hover, descent, rotate), varying heights (2–8 meters), various weather conditions (windy, rainy, fog), and at different times of day (morning and night). In addition, it provides multiple data modalities, such as RGB-video, fisheye video, night-vision video, IR sequences, and depth maps. In the Action Recognition task dataset, 155 human actions are clustered into six events: daily events (e.g., wearing a mask), productive events (e.g., fishing), violent events (e.g., stabbing with a knife), social interaction events (e.g., whispering), life-saving events (e.g., calling for help), and Control Gestures (e.g., have command). Each video was annotated with a person ID, gender, clothes, and action labels, and captured timestamps.

The Aerial-Gait [43] dataset contains 17 videos captured by a drone camera with a height of 10–45 m at an outdoor location (park) for the gait recognition task. This dataset has only one human-atomic action, namely walking, which is separately recorded in different situations with two actors: 1) moving drone towards or away from subjects; 2) walking on one circle with different heights; 3) walking in two circles with a fixed height.

The UAV-GESTURE [35] dataset contains 119 videos of 13 human gesture categories as follows: all clear, have command, hover, land, landing direction, move ahead, move downward, move to left, move to right, move upward, not clear, slow down, and wave off. These are captured by a drone camera at an outdoor location (unpaved road in a wheat field) in the morning for the gesture recognition task. The dataset contains 10 actors and each gesture category is repeated five–ten times. Each video was annotated with bounding boxes, body joints, and gesture labels.

The P-DESTRE [28] dataset contains 75 videos with 269 subjects captured by a UAV camera with a height of 5.5–6.7 m at an outdoor location (crowded campus) for detection, tracking, re-identification, and search for pedestrians. This dataset has 14 human action, as follows: walking, running, standing, sitting, cycling, exercising, petting, talking on the phone, leaving a bag, dating, trading, offending, fall, and fighting. Each video was annotated with a person ID and 16 soft biometrics labels (i.e., bounding box, age, wear clothes, and action labels).

The UCF-ARG [36] dataset contains 1442 videos with 12 subjects captured by three cameras (aerial, rooftop, and ground cameras) with a height of 100 feet at an outdoor location (car park on a campus). The dataset consists of two small sets: a ten-class actions set and a seventeen-class actions set. The ten-class action set has 1440 videos with a length of 10 seconds that contain boxing, carrying, clapping, digging, jogging, opening and closing trunk, running, throwing, walking, and waving. The seventeen-class action set has two videos with a length of 1 to 3 minutes that contain the standing, picking-up, gesturing, tennis swing, closing trunk, opening trunk, and jump, including the ten actions of the previous set. Each video was annotated with person ID and action labels.

1) Discussion on the UAV-based HAR datasets: Table II and Table II provide a comprehensive study of the fifteen UAV video datasets found in the literature from many perspectives, as follows:

- Dataset purpose. Datasets focus on various purposes, such as abnormal events detection in [4, 37], human action recognition [5, 21, 22, 34, 36, 39, 41], face recognition [40], object detection [38, 42], gait recognition [43], gesture recognition [35], and detection, tracking, re-identification and search for pedestrians [28].
- Human Activity Levels. For the human activity level, most datasets contain a combination of activity levels, such as the HOI, HHI, and AO levels [21, 28, 34, 37]; or the HOI and AO levels [36, 39]. On the other hand, another study [22] has a composite of four activity levels, while others only contain the AO level [43] or the gesture level [35].
- Data and event content. Most datasets are video datasets [21, 22, 28, 34-43], while others are image datasets [4, 5]. Additionally, some of these datasets contain normal and abnormal events [4, 21, 22, 34, 36, 37, 39], while others contain only normal events [5, 28, 35, 41, 43].
- Label schemes and video categories. Datasets can focus on variant label schemes such as single label per video [22, 34-36, 39, 43] or multiple labels per video [5, 21, 28, 36, 37]. Additionally, some datasets contain MA-MA videos [4, 21, 36, 37], some contain MA-SA videos [34, 37], some contain SA-SA videos [22, 34, 35, 36, 39, 41, 43], and others contain SA-MA videos [5, 28].
- UAV Challenges. Many datasets [4, 5, 21, 22, 28, 34-40, 43] consider challenges such as scale variability, motion blur, UAV perspectives, various illuminations, and full/partial occlusions.
- Environment. All datasets considered were recorded in an outdoor environment, except datasets [34, 41], which were recorded in an indoor environment. Dataset [22] was recorded in both environments. Furthermore, most datasets were recorded in one place [21, 28, 34-37, 39, 41, 43], whereas others were recorded in two to

five different places [4, 5, 38, 40, 42] except [22] was captured in 45 different places.

- Climate conditions and UAV Attributes. All these datasets were recorded under one climate except datasets [21, 22, 42], which were recorded under different weather conditions, including sunny, cloudy, windy, and rainy conditions. Almost all datasets were captured via varied UAV attitudes except [35], which was captured at a fixed attitude. The UAV speed was varied in some datasets [21, 22, 36, 37] and fixed in others [5, 35, 39, 41, 43]. For UAV altitude, all these datasets were recorded under varied altitudes except [41], which was obtained at a fixed altitude.

Furthermore, all studied datasets are available online except for datasets [4, 41, 42]. Datasets [4, 38, 40-42] are excluded because some of them [38, 40] lack any recorded activities or events, whereas others [4, 41, 42] are unavailable online. Consequently, ten of the fifteen UAV-based HAR datasets—SAR-UAV [5], MDVD [37], Drone-Action [39], Okutama-Action [21], NEC-DRONE [34], UAV-Human [22], Aerial-Gait [43], UAV-GESTURE [35], P-DESTRE [28], and UCF-ARG [36]—are available to the research community and contain normal or abnormal events; this study continues using only these datasets.

B. UAV-Based Video Challenges

Through a comprehensive study of the nature of videos in the UAV-based datasets, as shown in Table II and Table III, we found two important compounds related to the circumstances recorded in the video, which form and define the UAV-based challenge types. The first compound is the real-world environment captured on video, such as the number of recorded sites, whether they are indoor or outdoor locations, and the nature of the location observed. This plays a fundamental role in shaping the challenges related to the video backgrounds. The second compound includes factors related to weather conditions and UAV attributes such as attitudes, altitudes, and speed. These components constitute challenges related to resolution and clarity. For instance, a UAV camera's speed influences image resolution, resulting in blurry motion. Different UAV altitudes and UAV attitudes, such as hovering and rotating, impact the subject's size, occlusions, illumination, and the vision's view, as well as weather conditions changing from windy to sunny and cloudy. UAV-based video challenges represent an obstacle to understanding and analyzing videos for different computer vision tasks, such as video summarization and action recognition. After the study had been completed using these two compounds, six UAV challenges were classified in the ten datasets, as shown in Fig. 3 and Fig. 4.

1) Scale variability: UAV cameras capturing videos at vastly different altitudes, leading to various sizes of objects and subjects within the same scene.

2) Low resolution/blurry: These two factors cause loss of information in videos, particularly when using a high altitude of UAV flight or depth of field (DoF) of UAV cameras. When the UAV flies at an altitude above 40 m, subject sizes will appear very small, causing low video resolution. Using a Shallow/Deep DoF on UAV cameras can cause subjects to appear unclear and blurry when the subjects are shown outside the range of the DoF.

3) Motion blur: Sometimes, UAV cameras suffer from being unstable natural cameras; this is primarily caused by the high speed of flight factor, or by climatic factors such as rainfall or strong winds, which lead to motion blur in videos. On the other hand, the sudden and rapid movement of the subjects in the video can also cause motion blur.

4) Fully/Partial occlusions: The UAV camera has a factor distinguished by its wide coverage of the environment from a multi-view aspect, which leads to the appearance of multiple objects along with multiple subjects at the same time in the same scene. This factor sometimes leads to the obscuration or blockage of a subject's body appearing in the scene. This is the most significant challenge facing UAV applications.

5) Various illuminations: Because the conditions of the outdoor environments change (due to changes in weather or climate), subjects in the scenes can be influenced by various lighting, typically containing large shadowed areas of other objects in the same scene, such as buildings, cars, trees.

6) *UAV perspectives:* UAV cameras have features capable of changing the angle of the camera to observe the subject in its current location. However, when the Gimbal pitch indicator of the UAV camera is close to 90 degrees, the long axis of subjects approximately parallel to the UAV camera axis can cause top viewing of subject heads. Consequently, subjects within the scene appear as points for which biometric information is almost non-existent.

[1]The earlier description in this section mentioned only 12 activities; subsection IV-C provides additional activity that relies on further analysis.

C. Human Activities Taxonomy on Ten UAV Datasets

In this section, we present a novel unified categorization that relies on a comprehensive study of human activities on ten UAV datasets, which is then divided into three phases. We provide a review and analysis of human activities on UAV datasets, including distinguishing between normal and abnormal behaviors, and determining common and distinct activities in the first phase. The second phase involves grouping the common human activities determined in the first phase under major categories and classifying them according to human activity level. We highlight distinct human activities exclusive to abnormal behavior in particular UAV datasets, in the final phase. The next subsection provides details on the criteria at the foundation of our unified categorization.

1) Criteria-based taxonomy: Our proposed taxonomy is established using three essential criterion sets for human activities from a computer vision perspective: human action properties, human behavioral characteristics, and human activity levels (see Section II A). Each set focuses on a certain aspect of how people perform actions and how these actions are considered normal or abnormal conduct. These criteria are inspired by recent research in human activity recognition and abnormal event detection [44-50], which highlights the importance of movement patterns, activity levels, and situational context in distinguishing one action from another. Together, these criteria allow for systematically unifying or separating human activities throughout the datasets.

a) Human action properties: Numerous studies have demonstrated that the properties of human actions, such as kinematics, intentionality, and context dependency, can be robust indicators of action category rather than a focus on superficial differences, such as the type of object used in the action [45, 46, 50]. Motivated by this, our taxonomy relies primarily on this criterion set to discover similar or distinct actions, when deciding which actions should be combined into a single category, or which should be independent and separate entry.

- Kinematics, the motion pattern or physical standard for human body movement, includes speed, angles, and repetitive cycles. For instance, the actions of “push” and “punch” appear to be almost the same as the arm thrust movement from a UAV's top-down view, i.e.,

they appear to be two similar kinematics. Consequently, they can be unified under a broader category, such as "fighting". Contrarily, if a new action has a completely different kinematic signature, e.g., "hitting with a stick", it remains in a distinct category.

- Intentionality, where the purpose or goal behind the actions varies. For instance, similar motions can have different intents, such as a "hug" versus a "strangle". In UAV footage of both "strangling" and "hugging", a person's arms are wrapped around another person's upper body from behind. However, the intent of the action differs: the former aims to harm, whereas the latter is meant to comfort and show affection. Therefore, these two actions are classified into separate categories due to their distinct intents. In contrast, there are various motions with similar intent, such as a "bow" versus a "handshake". Although the two actions exhibit different body movements, i.e., a slight forward bow compared to extending the arms to clasp hands, they share the same purpose: to greet the person opposite them. Thus, these two actions can be unified under one category, which is "greeting".
- Context Dependency, such that human actions change their meaning depending on the location, the surrounding environment, or the situational context. For instance, a punching action in a wrestling ring would be considered normal in boxing as a popular sport, whereas punching in a public place would be considered violence. This demonstrates that context often radically changes the accuracy of the classification.

b) Human behavioral characteristics: Although the properties of human actions guide the unification of similar motion patterns, the characteristics of behavioral dimensions determine which actions are considered normal or anomalous. Based on experiences from studies on the detection and recognition of abnormal events [47-49], two primary criteria of human behavioral characteristics—persistence and harmfulness—are used to define abnormal human activities.

- Persistence, the duration of human behavior can vary significantly, and is often characterized by repetition and continuity. Normal behavior is defined by its frequency and continuity (e.g., daily routine activities), whereas abnormal behavior is characterized by its rarity, suddenness, and intermittency.
- Harmfulness, the extent to which the act threatens or harms the person or himself. For instance, activities involving aggressive, assaultive, offensive, criminal, or out-of-control conduct, such as falling, are identified as abnormal behaviors, while other behaviors are identified as normal.

2) Phase 1: Human activities review and analysis: Through study and examination of the ten UAV datasets outlined in Section IV-A, we observed that several human activities are similar among multiple datasets or distinct to a specific dataset. As mentioned in the previous section, our taxonomy concluded that similar and distinct human activities are based on commonalities in the properties and levels of human actions. In addition, this approach considers only activities in the context of a public place in the ten UAV datasets, ignoring any activities that have the same action but for a different context, such as a sports context. For example, boxing is a well-known sport with normal behavior in a specific context; however, since the context of these datasets is a public place, boxing activities are considered violent and harmful.

In Appendix A, Table III and Table IV shows an in-depth analysis of the human activities in ten UAV datasets that show normal behaviors, abnormal behaviors of whole activities, and common activities found across multiple datasets, in addition to the video counts and action counts for each action, and the list of actions that occur in each scenario. For example, using the MDVD dataset, the attack scenario contains a person who pushes the driver outside the car and steals the vehicle; this scenario features attacking, running, and stealing activities. The following observations and suggestions were made:

MDVD dataset: after checking the annotation of the videos, we found that some of these actions needed to be modified in the annotation. For example, the crash scenario includes walking, cycling, running, and picking-up actions, but there is no crashing action; we used OpenCV to obtain the start and end frames of this action and add them to the annotated data. According to [18, 51], it is recommended to classify suspicious events as normal events because they are considered part of human nature. In the original dataset, looking inside the car and taking a photo of the car are classified as suspicious; however, it is stated that these behaviors result from human curiosity, exploration, and wandering. Consequently, we consider these suspicious scenarios to in fact be normal behavior. We found that twelve activities in twelve scenarios can be classified as normal behaviors, such as walking, running, picking up, talking, standing, loitering, and bad parking. Furthermore, five activities in seven scenarios can be classified as abnormal behaviors, such as attacking, stealing, falling, fighting, and crashing.

Drone-Action dataset: we identified eight activities that can be classified as normal behaviors, such as clapping, jogging, running, walking, and hand waving. Furthermore, five activities can be classified as abnormal behaviors, such as boxing, hitting with a bottle, hitting with a stick, kicking, and stabbing.

Okutama-Action dataset: after thoroughly investigating human actions, we identified a new action that can be classified under the HHI level. All pushing/pulling actions in the dataset were classified under the HOI level. Upon reviewing the annotations in tandem with their corresponding videos, we found that the two types of activities on this action can be classified based on different human activity levels and human behavior properties. The first shows a person pushing and pulling with a shovel's container, which is normal behavior and can be classified under the HOI level, as mentioned in previous studies. The second action was discovered shows two persons pushing each other, which is

abnormal behavior that can be classified under the HHI level, as shown in Fig. 5. Utilizing the OpenCV package, we identified the start and end frames of this action and integrated them into the annotations accordingly. Therefore, currently, there are thirteen human actions in this dataset instead of twelve. We classified twelve activities as normal behaviors: handshaking, hugging, reading, drinking, pushing/pulling (HOI), carrying, calling, running, walking, lying, sitting, and standing. One activity can be classified as abnormal behavior, namely pushing/pulling (HHI).

Fig. 5. Samples of HHI pushing/pulling on the Okutama-Action dataset.

NEC-Drone dataset: we identified fifteen activities that can be classified as normal behaviors, such as walking, running, jumping, picking up a backpack, and going and leaving a backpack and going, among others. Furthermore, one activity can be classified as abnormal behavior, namely, pushing a person.

UAV Human dataset: we identified 136 activities that can be classified as normal behaviors, such as drinking, eating snacks, writing, and applauding, among others. Furthermore, nineteen activities can be classified as abnormal behavior, such as punching someone, pushing someone, and stealing something from another's pocket. We observed that some activities did not simulate the real-world situation, such as the "rob something from someone" action, which is more akin to taking something in a friendly manner rather than robbing, and the "kick something" action, which is more akin to kicking nothing or kicking a box. The "take a phone for someone" action is similar to taking a photo for someone, and the "slap someone on the back" action is similar to warning someone about something they dropped, although it should be considered more of a warning than an aggressive strike, which can probably be normal behavior. The "chase someone" action appears as a friendly pursuit, which is similar to playing rather than a real chase that suggests danger or harm to the other person.

Aerial Gait dataset, one action, walking, can be classified as normal behavior.

UAV-GESTURE dataset, the whole activities of the Gesture Signal were classified as normal behaviors, such as all clear, hover, and move ahead, among others.

P-DESTRE dataset, after examining the videos, only four out of fourteen actions have a corresponding video. These four activities are classified as normal behavior: walking, standing, sitting, and talking over the phone.

UCF-ARG dataset, we identified sixteen activities that can be classified as normal behaviors, such as throwing, standing, and walking, among others. Furthermore, one activity can be classified as abnormal behavior, namely boxing. We observe that actions are considered to be human-atomic actions (AOs), where the person throws nothing, meaning there is no object in their hands.

SAR-UAV dataset, we identified 122 photos of the Okutama-Action dataset out of 2000 photos in this dataset. To avoid duplicating the samples in this study, we removed these photos from the dataset and retained the 1880 photos created by the authors. We identified five activities that were classified as normal behaviors: standing, walking, running, handshake, and hand-waving. Data are provided as individual frames rather than sequences of frames. Therefore, we aimed to cluster similar frames to convert them into consistent videos. To achieve this, we utilized the pre-trained VGG16 model to extract deep features from the frames. Subsequently, we calculated the cosine similarity among these extracted features. Finally, the frames were clustered into five distinct groups based on their cosine similarity using an unsupervised learning technique called the agglomerative clustering algorithm.

3) Phase 2: Unification of common human activities: Following the first phase, 147 similar human activities out of 266 human activities were identified across the ten datasets. Among these 147 activities, we classified 31 as abnormal behavior based on their nature, and the remaining 116 as routine activities. The unification of the common human activities associated with their human activity level under the precise categories for each dataset is provided in Appendix A [see Table V and Table VI]. Fig. 6 reflects Tables VII and VIII, which highlight the human activity level for each action. The unified, precise categories of the common human activities found were introduced as follows:

a) Abnormal in the unified precise category

- Fighting depicts scenarios involving a physical confrontation, such as scuffles and affrays, including dragging, pushing, punching, and kicking. Sixteen similar activities were identified in the MDVD, Drone-Action, Okutama-Action, NEC-Drone, UAV-Human, and UCF-ARG datasets. This category falls under the AO, HHI, and Composite (HHI+HOI) levels, where these activities have the same human action properties with different human activity levels.
- Robbery depicts scenarios of theft and pickpocketing. Four similar activities were identified in the MDVD and UAV-Human datasets. This category falls under the HOI and Composite (HHI+HOI) levels, where these activities have the same human action properties with different human activity levels.
- Vehicle Theft depicts scenarios such as stealing a car by attempting to pick a locked door or opening it aggressively or stealthily. This category falls under the HOI level. Three similar activities were identified in the MDVD and UAV-Human datasets.
- Assault depicts scenarios involving physical violence with sharp objects, perhaps under threat, such as hitting

with a bottle, stabbing with a knife, and threatening with a gun. Eight similar activities were identified in the Drone-Action and UAV-Human datasets. This category falls under the HOI and Composite (HHI+HOI) levels, where these activities have the same human action properties with different human activity levels.

b) Normal in the unified precise category

- Walking is a form of body movement that includes alternating movement between the legs, including movement forward, backward, and sideways. This category falls under the AO level. Twenty-one similar activities were identified in nine datasets, with the exception of the UAV-GESTURE dataset.
- Clapping is a simple physical activity that results from hitting the palms of the hands together at different rhythms. This category falls under the AO level. Three similar activities were identified in the Drone-Action, UAV-Human, and UCF-ARG datasets.
- Digging is an activity that utilizes machines or equipment to remove soil to create a hole. This category falls under the HOI level. Two similar activities were identified in the UAV-Human and UCF-ARG datasets.
- Drinking is an important biological activity in which fluids in objects are consumed through the mouth. This category falls under the HOI level. Four similar activities were identified in the Okutama-Action, NEC-Drone, and UAV-Human datasets.
- Sitting is an activity for body rest, where the buttocks and thighs are placed on a chair, the floor, or a surface. This category falls under the HOI level. Four similar activities were identified in the Okutama-Action, NEC-Drone, UAV-Human, and UCF-ARG datasets.
- Handshaking is an act performed by two people to greet each other or agree on something. This category falls under the HHI level. Four similar activities were identified in the Okutama-Action, NEC-Drone, UAV-Human, and SAR-Drone datasets.
- Standing is the act of keeping the body in a straight position on the feet, relying on the legs. This category falls under the AO level. Nine similar activities were identified in the MDVD, Okutama-Action, NEC-Drone, UAV-Human, P-DESTRE, UCF-ARG, and SAR-Drone datasets.
- Reading is a process that depends on the human eye to understand what is written, whether it is on a piece of paper, a book, a tablet, or even a mobile phone. This category falls under the HOI level. Two similar activities were identified in the Okutama-Action and UAV-Human datasets.
- Running is an aerobic activity in which the body is pushed forward by the feet in a continuous movement and at different speeds. This category falls under the AO level. Eleven similar activities were identified in the MDVD, Drone-Action, Okutama-Action, NEC-Drone, UAV-Human, UCF-ARG, and SAR-Drone datasets.
- Jumping is a movement in which the body is pushed off the ground using the power of the legs and feet. This category falls under the AO level. Four similar activities were identified in the NEC-Drone, UAV-Human, and UCF-ARG datasets.
- Talking is a spoken communication act carried out between two or more persons, either directly or indirectly, sometimes using tools such as a mobile phone. Eight similar activities were identified in the MDVD, Okutama-Action, NEC-Drone, UAV-Human, and P-DESTRE datasets. This category falls under the HHI and HOI levels, where these activities have the same human action properties with different human activity levels.
- Throwing is a physical activity in which a body of water is propelled through the air by the power of movement of the arm, wrist, and hand. Six similar activities were identified in the NEC-Drone, UAV-Human, and UCF-ARG datasets. This category falls under the AO and HOI levels, where these activities have the same human action properties with different human activity levels.
- Carrying is a physical effort in which an object is transported from one place to another by human body parts, including the hands, shoulders, and head. This category falls under the HOI level. Three similar activities were identified in the Okutama-Action, UAV-Human, and UCF-ARG datasets.
- Hugging is an activity in which two or more people cuddle each other by wrapping their arms around each other. This category falls under the HHI level. Three similar activities were identified in the Okutama-Action, NEC-Drone, and UAV Human datasets.
- Pick-Up is a physical activity in which something is taken, collected, or lifted using the hands. This category falls under the HOI level. Six similar activities were identified in the MDVD, NEC-Drone, UAV Human, and UCF-ARG datasets.
- Exchange Something is an act between two persons in which an object is given and another is received in return. This category falls under the Composite (HHI+HOI) level. Three similar activities were identified in the NEC-Drone and UAV Human datasets.
- Gesture Signals are a form of non-verbal communication in which human body parts (e.g., the arm) are used to inform a specific signal or command, such as all clear, have command, land, hover, etc. This category falls under the Gesture level. Sixteen similar activities were identified in the Drone-Action and UAV Human, UAV-GESTURE, UCF-ARG, and SAR-Drone datasets.

4) *Phase 3: Distinct abnormal human activities:* Following the first phase, five distinct human activities were determined on the MDVD and UAV-Human datasets. Distinct abnormal human activities and their associated human activity levels are provided in Appendix A, Table IX. They are as follows:

- Stagger and Fall are similar activities, where the stagger is the beginning of the fall event. This is a part of the fall event, but not the entire event; for this reason, we decided not to include it in the same category.
- Crashing and bumping into someone are similar activities, but both have only one intentionality, i.e., two people walk in opposite directions and eventually collide. However, they differ in human activity levels and other human activity properties, such as kinematics and context dependency. The first activity involves a person riding a bicycle and another person walking, whereas the second activity involves two people walking. As a result, they cannot be classified in the same category.
- Chest Discomfort is a reaction in which a person raises their hand to the chest area in response to a sensation of pain, tightness, or discomfort. It is classified as an abnormal behavior since it is perhaps dangerous and requires urgent medical intervention.

V. Experiment and Discussion

In this section, we conduct a comparative experiment utilizing a baseline HAR model on both the proposed unified precise taxonomy and other existing taxonomies applied to the benchmark Drone-Action dataset, representing a quantitative evaluation and validation.

A. Experimental Setup

In this experiment, we used Drone-Action dataset, one of the ten UAV datasets employed within the proposed unified taxonomy framework. The ImageNet pretrained MViTv2 model [52], a famous vision transformer used for action recognition and video understanding tasks, was trained on two categorization frameworks under the same training settings. The categorization frameworks involved on the experiment include the original fine-grained categorization found in the literature [14-17] and the proposed unified precise categorization framework, as described in Table IV. The MViTv2 model was trained for 22 epochs using a batch size of 2 and a learning rate of 1e-4, with a split ratio of 70% for the training set and 30% for the testing set. The input videos of the dataset were resized to 224×224 resolutions. The experiment was executed using PyTorch 2.5 with CUDA 12.4 on a device provided with an AMD EPYC 7402 CPU, 24 cores / 48 threads, 2.8 GHz base, a NVIDIA GeForce RTX 3090 GPU, and 24.4 GB HBM2. The performance evaluation metrics used included accuracy, precision, recall, and F1-score measures.

TABLE IV. The Categorization Frameworks Specification

Dataset	# Videos	Categorization Framework	# Categories	Action Categories List
Action-Drone	240	Original Fine-Grained Taxonomy [14-17]	13	Boxing, Clapping, Hitting with bottle, Hitting with stick, Jogging front back, Jogging side, Kicking, Running front back, Running side, Stabbing, Walking front back, Walking side, and Waving hands.
		Proposed Unified Precise Taxonomy (our)	6	Fighting, Assault, Walking, Clapping, Running, and Hand Waving

B. Quantitative Evaluation and Validation

We compare the proposed unified precise taxonomy with the existing taxonomy (fine-grained category) on the Drone-Action dataset, using the same HAR model and training settings to ensure a fair comparison. The results are displayed in Table V. The fine-grained category framework relies on the object's type (e.g., bottle, stick, knife) or the drone's angle (e.g., side view, back-forward view). Despite the categories' similar action properties and activity levels, separating them into individual categories regarding different object types or angles of view hinders the HAR model training. Consequently, as shown in Table V, the HAR model with a fine-grained category framework achieves 78% accuracy and F1-score, significantly constraining the model's ability to generalize. In comparison, the proposed unified precise taxonomy increases recognition accurate by 18.8% and enhances the F-1 score by 19.4%, resulting in improved HAR model ability to understand motion patterns. This may be attributed to the proposed taxonomy relies on three criteria of human action theory and behavioral, resulting in a consistent and balanced category and decreasing confusion among similar human actions. This allows the model to learn the features of human activity patterns, regardless of the shooting angle, object type, or surrounding environment, making it effective and stable for recognizing unseen similar actions.

TABLE V. Comparison of Original Fine-Grained and Proposed Unified Precise Taxonomies on the Drone-Action Dataset

Categorization Framework	Metrics			
	Accuracy	*Precision*	*Recall*	*F1-score*
Original Fine-Grained Taxonomy [14-17]	0.7859	0.8109	0.7859	0.7794
Proposed Unified Precise Taxonomy (our)	**0.9739**	**0.9742**	**0.9739**	**0.9740**

VI. Conclusion

This research has proposed a novel unified yet precise systematic taxonomy for UAV-based HAR derived from a comprehensive study of ten publicly available aerial datasets, which addresses the issues of fine-grained and inconsistent categorization across multiple UAV-based datasets. To the

best of our knowledge, this study is the first of its kind, providing a detailed and comprehensive analysis of human actions present in UAV datasets. The following advancements were made: 1) we explored the available UAV datasets and provided a detailed comparison based on the content of human actions present in their videos; 2) we identified the challenges of UAV datasets encountered in HAR; and 3) we built a novel category for video-based human action recognition. By basing the proposed taxonomy on three criteria relating to human actions and behaviors, we show how object-centric categories can be unified into precise and broader categories oriented toward behavior, intentionality, and levels, while preserving explicitly distinct anomalous actions for surveillance security-focused recognition.

The proposed taxonomy consists of a three-phase framework that: 1) starts by reviewing and analyzing actions across UAV-based datasets, 2) standardizes activities based on similar characteristics across the three criteria, and 3) separates a set of distinct anomalous actions to ensure that critical events are not overlooked. The unified taxonomy includes 152 human activities, providing a compromise that captures basic movement patterns while simultaneously determining critical threats (both normal and abnormal). For evaluation and validation of the performance, we compare the proposed taxonomy with the existing taxonomy on the Drone-Action dataset. The experiment results reveal that the proposed taxonomy outperforms others by a margin of 19.4% in F1-score, indicating that the proposed taxonomy provides balanced, consistent, and generalized categorization. Despite the proposed taxonomy having several benefits, it faced some limitations: 1) It ignores the distinction between the object types involved in human actions in their categorization, which reduces the accuracy of identifying evidence details in forensic and criminal applications. 2) The current evaluation and validation are limited to one dataset and model. In future work, we plan to expand the evaluation to include many datasets and several famous HAR models.

In the future, we envision this taxonomy as fundamental to more consistent dataset organization and real-time UAV surveillance applications. By reducing the fragmentation of categorization, researchers can train deeper or more flexible models on the amassed data, improving the performance of human action recognition and detection in aerial footage. Ultimately, we believe the proposed taxonomy both simplifies the overall classification and enhances the potential to provide robust and interpretable solutions for drone-based human action recognition.

APPENDIX A

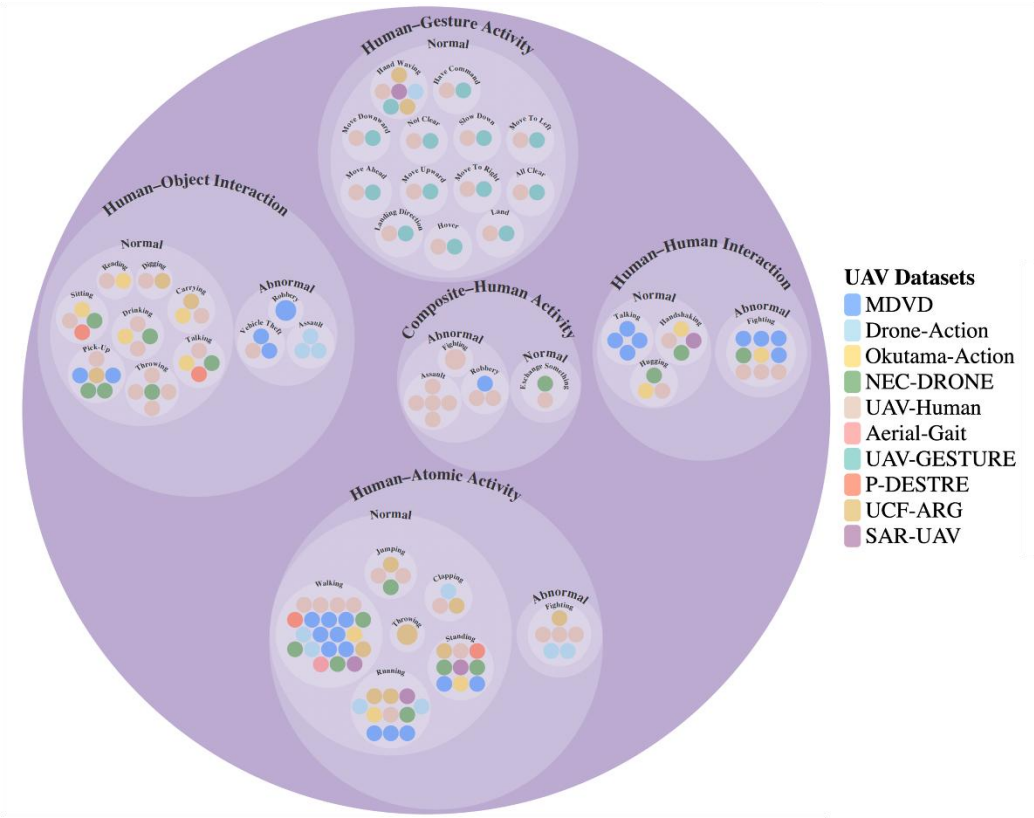

Fig. 6. Unified precise categorization of common human activities on ten UAV datasets.

TABLE VI. HUMAN ACTIVITIES ANALYSIS OF THE UAV DATASETS

UAV Dataset	No. of actions	No. of videos	Normal Behavior	Abnormal Behavior	Common Activities
MDVD	12 scenarios (17 actions)	38	badparking(4; badparking, walking), broken(2; broken),normal(10; walking, talking, standing, normal), reserving(2; walking, loitering, reserving), suspicious(6; suspicious, loitering, talking, walking), attack(1; running), falling(1; walking), fighting(1; talking), crash(2, walking, cycling, running, picking_up), stealingcar(3; loitering), stealinginside(1; running, walking), stealingpedestrian(5; walking, standing, talking, loitering, picking_up)	attack (1; attacking, stealing), falling(1; falling), fighting(1; fighting), crash(2, crash), stealingcar(3; stealing),stealinginside(1;stealing),stealingpedestrian (5;stealing, fighting, attacking)	fighting (talking, fighting), attack (attacking, running, stealing), normal (walking, standing, talking), reserving(walking), stealingpedestrian(walking, stealing, standing, fighting, talking, attacking, picking_up), badparking(walking), crash(walking, running, picking_up), stealingcar(stealing), stealinginside(running, stealing, walking), suspicious(talking, walking)

Drone-Action	13	240	clapping (10), jogging_f_b (20), jogging_side (20), running_f_b(20), running_side (20), walking_f_b (20) , walking_side (20) , hand_waving(10)	boxing (20), hitting_bottle (20), hitting_stick (20), kicking (20), stabbing (20)	boxing, hand_waving, clapping, hitting_bottle, hitting_stick, kicking, stabbing, jogging_f_b, jogging_side ,running_f_b,running_side,walking_f_b, walking_side
Okutama-Action	13	43	handshaking (24), hugging (23), reading(39), drinking(23), pushing /pulling(HOI) (21), carrying(30), calling(37), running(25), walking(43), lying(23), sitting(43), standing(43)	pushing/pulling (HHI) (22)	pushing/pulling (HHI), running, walking, drinking, sitting, handshaking, standing, reading, carrying, hugging, calling
NEC-Drone	16	2,079	walk (271), run (118), jump (120), pick up a backpack and go (113), leave a backpack and go (114), sit on a chair (116), talk on a mobile phone (112), drink water from a bottle (111), throw something (163), pick up a small object (141), shake hands (104), hug (107), exchange a backpack (100), walk toward each other and stay (145; walking, standing), stand together leave (146; walking, standing)	push a person (98)	push a person, walk, walk toward each other and stay (walking, standing),, run, jump, sit on a chair, talk on a mobile phone, drink water from a bottle, throw something, shake hands, stand together leave (walking, standing) , hug, pick up a small object, pick up a backpack and go, exchange a backpack
UAV Human	155	22,476	drink (175), eat snacks (174), brush hair (172), drop something (171), pick up something (169), throw away something (173), sit down (170), stand up (170), applaud (171), read (169), write (170), put on a coat (169), take off a coat (168), put on glasses (168), take off glasses (168), put on a hat (170), take off a hat (169), throw away a hat (169), cheer (169), wave hands (169), reach into pockets (166), jump on single leg	punch with fists (168), kick aside (165), kick backward (165), stagger (166), punching someone (113), kicking someone (111), pushing someone (110), steal something from other's pocket (110), rob something from someone (112), hit someone with something (113), threat some with a knife (111), bump into someone (113), hold someone hostage (113), threat someone with a gun (105), drag someone (101), stab someone with a knife (104), kick something (169), chest discomfort (165), pick a lock (106)	drink, drink a toast(drinking), punching someone, punch with fists, kicking someone, kick something , kick aside, kick backward , rob something from someone, pushing someone, sit down, stand up, applaud, make a phone call, pick up something , shake hands, read, hit someone with something, run, stab someone with a knife, walk toward someone, walk away from someone , walk side by side, walk, throw away something, throw away a hat, throw a frisbee, throw litter, steal something from other's pocket, jump on single leg, jump on two legs, carry a carrying pole, hug, exchange something with someone, all clear, have command

			(169), jump on two legs (169), make a phone call (171), play with cell phones (169), point somewhere (170), look at the watch (168), rub hands (167), bow (171), shake head (167), salute (170), cross palms together (168), cross arms in front to say no (170), wear headphones (166), take off headphones (167), make a shh sign (166), touch the hair (165), thumb up (168), thumb down (165), make an ok sign (167), make an ok sign (167), make a victory sign (168), figure snap (166), open the bottle (165), smell (165), squat (167), apply cream to face (166), apply cream to hands (167), grasp a bag (166), put down a bag (164), put something into a bag (165), take something out of a bag (164), open a box (165), move a box (166), put up hands (166), put hands on hips (168), wrap arms around (162), shake arms (164)		,hover, land, land at designated locations, move forward, move left, move right, ascend, descend, not clear, decelerate, call for help pick a lock, dig a hole, drag someone, threat some with a knife, hold someone hostage, threat someone with a gun

TABLE VII. HUMAN ACTIVITIES ANALYSIS OF THE UAV DATASETS (CONT.)

UAV Dataset	No. of actions	No. of videos	Normal Behavior	Abnormal Behavior	Common Activities
UAV Human	155	22,476	step on the spot walk (166), cough (168), sneeze (168), yawn (167), blow nose (166), headache (166), backache (164), neck-ache (163), vomit (164), use a fan (165), stretch body (165), point someone (113), hug (103), give something to someone (106), shake hands (107), walk toward someone (111), walk away from someone (111), walk side by side (109), high five (113), drink a toast (112; clap the bottle,drinking), move something with someone (110), take a phone for someone (115), stalk someone (111), whisper in someone's ear (107), exchange something with someone (109), lend an arm to support someone (106), rock-paper-scissors (109), hover (152), land (151), land at designated locations (151), move forward (150), move backward (149), move left (150) move right (149), ascend (149), descend (149), accelerate (149), decelerate (146), come over here (148), stay where you are (148), rear right turn (147), rear left turn (148), abandon landing		

			(147), all clear (147), not clear (147), have command (146), follow me (147), turn left (147), turn right (147), throw litter (143), dig a hole (152), mow (123), set on fire (144), smoke (150), cut the tree (152), fishing (147), pollute walls (157), wave a goodbye (102), comfort someone (102), sweep the floor (137), mop the floor (136), bounce the ball (138), shoot at the basket (138), swing the racket (137), leg pressing (138), escape (to survive) (133), call for help (140), wear a mask (137), take off a mask (135), bend arms around someone's shoulder (102), run (43), throw a frisbee (137), carry a carrying pole (142), walk (43), use a lever to lift something (135), close an umbrella (41), open an umbrella (42), slap someone on the back (113), chase someone (103)		
Aerial Gait	1	17	walking (17)	-	walking
UAV-GESTURE	13	119	all clear (11), have command (11), hover (7), land (7), landing direction (7), move ahead (11), move downward (7), move to left (11), move to right (11), move upward (7), not clear (11), slow down (11), wave off (7)	-	all clear, have command, ,hover, land, wave off, landing direction, move ahead, move to left, move to right, move upward, move downward, not clear, slow down
P-DESTRE	14	75	walking(73), running(0), standing(33), sitting(1), cycling(0), exercising(0), petting(0), talking over the phone(7), leaving bag(0), dating(0), trading(0)	offending(0), fall(0), fighting(0)	walking, standing, sitting, talking over the phone
UCF-ARG	17	473 (only UAV)	carrying(49), clapping(50), digging(50), jogging(49), open-close trunk(40), running(50), throwing(50), walking(50), waving(49), standing(2),picking_up(2),gesturing(2),tennis_swing(1),closing_trunk(1),opening_trunk(1), jump(1)	boxing(50)	boxing, carrying, clapping, digging, jogging, running, throwing, walking, waving, standing, gesturing, picking_up, jump
SAR-UAV	7	1880 images (5 videos)	after drop: standing (1293), walking(404), running(373) ,sitting(0), lying(0), handshake(2), and hand-waving(1014).	-	standing, walking, running, handshake, hand-waving.

TABLE VIII. UNIFIED PRECISE CATEGORIZATION OF COMMON HUMAN ACTIVITIES ON THE UAV DATASETS

Unified Precise Categorization		MDVD	Drone-Action	Okutama-Action	NEC-Drone	UAV Human	Aerial Gait	UAV-GESTURE	P-DESTRE	UCF-ARG	SAR-Drone
Abnormal	Fighting	Fighting(fighting) (HHI), Attack(attacking) (HHI), StealingPedestrian (fighting, attacking) (HHI)	Boxing(AO), Kicking(AO)	Pushing/Pulling (HHI)	Push A Person(HHI)	Pushing Someone(HHI), Punching Someone(HHI), Punch With Fists(AO), Kicking Someone(HHI), Kick Backward(AO), Kick Aside(AO),drag someone (HHI+HOI)	-	-	-	Boxing(AO)	-
	Robbery	Stealingpedestrian (stealing) (HHI+HOI), StealingInside(stealing) (HOI)	-	-	-	Steal Something From Other's Pocket (HHI+HOI), Rob Something From Someone(HHI+HOI)	-	-	-	-	-
	Vehicle Theft	StealingCar(stealing) (HOI), Attack(stealing) (HOI)	-	-	-	pick a lock(HOI)	-	-	-	-	-
	Assault	-	Hitting_Bottle(HOI), Hitting_Stick (HOI), Stabbing(HOI)	-	-	Hit Someone with Something(HHI+HOI), Stab Someone with A Knife(HHI+HOI), threat some with a knife (HHI+HOI), hold someone hostage(HHI+HOI), threat someone with a gun(HHI+HOI)	-	-	-	-	-
Normal	Walking	Normal(walking)(AO), BadParking(walking) (AO), Reserving(walking) (AO), Crash(walking) (AO), StealingInside(walking) (AO), StealingPedestrian (walking) (AO), Suspicious(walking) (AO)	walking_f_b(AO), walking_side (AO)	Walking (AO)	Walk (AO), Walk Toward Each Other And Stay(walking) (AO), Stand Together Leave(walking) (AO),	Walk (AO), Walk Toward Someone(AO), Walk Away From Someone(AO), Walk Side By Side(AO)	Walking (AO)	-	Walking (AO)	Walking (AO)	Walking (AO)
	Clapping	-	Clapping(AO)	-	-	Applaud(AO)	-	-	-	Clapping (AO)	-

	Digging	-	-	-	-	dig a hole(HOI)	-	-	-	Digging(HOI)	-
	Drinking	-	-	Drinking(HOI)	Drink Water From A Bottle(HOI)	Drink(HOI), Drink A Toast(drinking)(HOI)	-	-	-	-	-
	Sitting	-	-	Sitting(HOI)	Sit On A Chair(HOI)	Sit Down(HOI)	-	-	Sitting(HOI)	-	-
	Handshaking	-	-	Handshaking(HHI)	Shake Hands(HHI)	Shake Hands(HHI)	-	-	-	-	handshake(HHI)
	Standing	Normal(Standing)(AO), StealingPedestrian(standing) (AO)	-	Standing(AO)	Stand Together Leave (standing) (AO), Walk Toward Each Other And Stay(standing) (AO)	Stand Up(AO)	-	-	Standing (AO)	standing(AO)	Standing(AO)
	Reading	-	-	Reading(HOI)	-	Read(HOI)	-	-	-	-	-

TABLE IX. UNIFIED PRECISE CATEGORIZATION OF COMMON HUMAN ACTIVITIES ON THE UAV DATASETS (CONT.)

Unified Precise Categorization		MDVD	Drone-Action	Okutama-Action	NEC-Drone	UAV Human	Aerial Gait	UAV-GESTURE	P-DESTRE	UCF-ARG	SAR-Drone
Normal	Running	Attack(running)(AO),Crash(running)(AO), StealingInside(running)(AO)	Running (AO), Jogging (AO)	Running (AO)	Run(AO)	Run(AO)	-	-	-	Running (AO), Jogging(AO)	Running(AO)
	Jumping	-	-	-	Jump(AO)	Jump On Single Leg(AO), Jump on Two Legs(AO)	-	-	-	Jump(AO)	-
	Talking	Normal(Talking)(HHI),Fighting(talking)(HHI), StealingPedestrian(talking)(HHI), Suspicious(talking)(HHI)	-	Calling (HOI)	Talk On A Mobile Phone (HOI)	Make A Phone Call(HOI)	-	-	Talking Over the Phone(HOI)	-	-
	Throwing	-	-	-	Throw Something(HOI)	Throw Away Something(HOI), Throw Away A Hat(HOI), Throw A Frisbee(HOI), Throw Litter(HOI)	-	-	-	Throwing (AO)	-
	Carrying	-	-	Carrying (HOI)	-	Carry A Carrying Pole(HOI)	-	-	-	Carrying(HOI)	-
	Hugging	-	-	Hugging (HHI)	Hug(HHI)	Hug(HHI)	-	-	-	-	-
	Pick-Up	Crash(picking_up)(HOI), StealingPedestrian(picking_up)(HOI)	-	-	Pick Up a Small Object(HOI),	Pick Up Something(HOI)	-	-	-	picking_up(HOI)	-

					Pick Up a Backpack and Go(HOI)						
	Exchange Something	-	-	-	Exchange A Backpack(HHI+HHOI)	Exchange Something with Someone(HHI+HOI)	-	-	-	-	-
	Gesture Signal	All Clear	-	-	-	-	All Clear	-	All Clear	-	-	-
		Have Command	-	-	-	-	Have Command	-	Have Command	-	-	-
		Hover	-	-	-	-	Hover	-	Hover	-	-	-
		Land	-	-	-	-	Land	-	Land	-	-	-
		Landing Direction	-	-	-	-	Land at Designated Locations	-	Landing Direction	-	-	-
		Move Ahead	-	-	-	-	Move Forward	-	Move Ahead	-	-	-
		Move To Left	-	-	-	-	Move Left	-	Move To Left	-	-	-
		Move To Right	-	-	-	-	Move Right	-	Move To Right	-	-	-
		Move Upward	-	-	-	-	Ascend	-	Move Upward	-	-	-
		Move Downward	-	-	-	-	Descend	-	Move Downward	-	-	-
		Not Clear	-	-	-	-	Not Clear	-	Not Clear	-	-	-
		Slow Down	-	-	-	-	Decelerate	-	Slow Down	-	-	-
		Hand Waving	-	Hand Waving	-	-	call for help	-	Wave Off	-	Waving, gesturing	hand-waving

TABLE X. DISTINCT ABNORMAL ACTIONS ON THE UAV DATASETS

Distinct Abnormal Activities	MDVD	UAV Human
Falling	Falling (AO)	-
Crash	Crash (HHI+HOI)	
Stagger	-	Stagger (AO)
Chest Discomfort		Chest Discomfort (AO)
Bump into Someone		Bump into Someone (HHI)

Evaluation of the Impact of Cybersecurity Knowledge on the Prevention of Social Cybercrime Among University Students in Mexico, Colombia, and Peru

***Abstract*—Objectives: This study aims to evaluate the degree of cybersecurity knowledge and awareness among university students in Peru, Mexico, and Colombia, and to determine how these factors contribute to protection against social cybercrime. This cross-regional analysis represents a novel contribution by comparing cybersecurity preparedness across three Latin American countries, an underrepresented region in cybersecurity education research. Methods: A cross-sectional study was conducted using a 97-question survey that assessed both cybersecurity knowledge and practices. The study involved 809 university students from Peru, Mexico, and Colombia. Correlation analysis was performed to examine the relationship between cybersecurity knowledge and cybercrime prevention practices. Results: The analysis revealed a positive but low correlation (r=0.252) between cybersecurity knowledge and cybercrime prevention practices. Only 10.71% of preventive practices could be explained by acquired knowledge. Greater efficacy was observed in cyberstalking prevention compared to other forms of cybercrime. A significant gap was found between theoretical knowledge and practical application of cybersecurity, with only 44.6% of students receiving occasional information on the subject. Conclusions: This study highlights the urgent need to improve cybersecurity education in Latin American universities. The findings underscore the importance of integrating applied practices into cybersecurity curricula to strengthen students' ability to effectively counter cyber threats. Future educational initiatives should focus on bridging the gap between theoretical knowledge and practical application to enhance students' resilience against social cybercrime.**

Keywords*—Cybersecurity; social cybercrime; university students

I. Introduction

Technological advancement has transformed the way daily activities are conducted, especially since the Covid-19 pandemic, when dependence on internet access became crucial [1]. Although these advances have proven effective and beneficial in many aspects, it is essential to question whether the associated risks are being adequately considered. International organizations have expressed concern about the increased reliance on applications, online courses, banking services, and other digital resources. They emphasize the need for governments to implement effective strategies to combat cyber threats [2]. Most online vulnerabilities stem from insufficient cybersecurity knowledge among users [3]. For university students, the use of online technology is ubiquitous; however, they often lack awareness about the importance of cybersecurity and risky online behavior due to limited understanding of cyber security. Cybercrime is constantly evolving; for example, an emerging crime is "social cybercrime," which relates to online social interactions and represents the transposition of traditional conflicts to a digital environment [4]. First-world countries have implemented various mechanisms to prevent user vulnerability, such as raising awareness among high school and university students [5]; however, in Latin America, the same attention has not been paid to this problem. This research addresses a critical gap by conducting a comparative analysis across three Latin American countries—Peru, Mexico, and Colombia—to understand regional patterns in cybersecurity awareness and preparedness. Unlike previous single-country studies, this multi-national approach provides insights into shared vulnerabilities and educational needs across the region, contributing to the development of context-specific prevention strategies for social cybercrime in Latin American higher education institutions. Therefore, the question arises: What is the degree of knowledge and awareness about cybersecurity among university students in Peru, Mexico, and Colombia as protective measures against social cybercrime? The remainder of this paper is organized as follows: Section II reviews related work on cybersecurity awareness and social cybercrime; Section III describes the methodology employed in this study; Section IV presents the results of our analysis; Section V discusses the findings and their implications; and Section VI concludes with recommendations for future research and practice.

II. Related Work

A systematic literature review was conducted examining studies published between 2018 and 2023. This review revealed that it is necessary to reinforce the knowledge, attitude, and behavior of university students in cybersecurity, as few countries implement preventive measures in this group [6]. Another descriptive, correlational, and cross-sectional study with 48 female high school students, focused on social

*Corresponding author.

cybercrime, showed that cybersecurity is effective in preventing cyberharassment and cyberbullying [7]. Also, Abdukadir Ahmed and colleagues [8] evaluated cybersecurity awareness in 250 undergraduate and graduate students from five universities. They found that virus and phishing attacks are the most common problems, therefore, they recommended continuous education and supervision in cybersecurity.

The constant evolution of cyber threats, such as ransomware attacks, highlights the growing importance of cybersecurity [9]. This has become essential to prevent data breaches, inactivity, and intellectual property theft [10]. Recent research highlights the growing dependence of individuals, organizations, and countries on digital tools and networks. However, this trend has intensified cybercriminal activities, which in turn highlights the need to continuously improve cybersecurity measures in the face of emerging threats [11]. In a related study, Almansoori and others [12] discovered that the Protection Motivation Theory (PMT) is predominant in most studies on cybersecurity behavior, noting that, of 39 articles analyzed, 56% focused on the organizational level, while research at the individual level is still in an initial stage.

Cybersecurity, crucial for protecting systems, networks, and data against digital attacks and ensuring the confidentiality, integrity, and availability of information, requires a comprehensive understanding of its environment, resources, and guidelines [13, 14, 15]. Currently, organizations must establish adequate levels of access and security gateways to handle information securely. The complexity of cybersecurity suggests a holistic approach, evidenced in the analysis of the legal implications of technologies such as blockchain [16].

Moreover, the theory of planned behavior [17] highlights the influence of perceived control and subjective norms on personal actions, relevant to information management and risks in cyberspace. The protection motivation theory [18, 19] complements this approach by predicting the intention to engage in protective practices, integrating risk perception and evaluation of the effectiveness of protective measures.

In the university context, it is vital to develop educational strategies that integrate technical knowledge, understanding of student motivations and behaviors in the face of digital threats, and promote effective security practices. This holistic approach contributes to training professionals capable of navigating cyberspace safely, thus strengthening the digital resilience of society.

There are various models designed to measure and improve cybersecurity knowledge. One of them is the "citizen-centered cybersecurity model" developed by Mahlangu et al. [20]. This model focuses on assessing citizen awareness, threat evaluation, coping mechanisms, attitudes, and behavioral intentions. The purpose is to promote safe behaviors in the digital realm, emphasizing that adequate knowledge is fundamental to understanding and effectively responding to cyber threats. This model integrates concepts from the Protection Motivation Theory (PMT).

On the other hand, the Qualification Level Awareness Measurement Model, proposed by Erol and Sagiroglu [21], offers a framework to direct attention to crucial aspects of a situation, integrate perceived information, and project future system states. This model emphasizes the importance of situational awareness, mental models, and information processing, essential aspects for understanding and improving cybersecurity practices. Applying these principles allows individuals to evaluate cyber threats more effectively, understand system vulnerabilities, and make informed decisions to mitigate risks.

Furthermore, Tirumala et al. [22] propose a tiered structure through the Qualification Level Awareness Measurement Model, arguing that situational awareness or the situation model reflects the current state of the mental model. This model captures not only system parameters but also their interrelationships, facilitating a meaningful understanding of the system's state and its impact on future events. By employing principles of the goal-driven processing model, cybersecurity professionals can make more effective decisions when responding to security incidents or implementing preventive measures, improving cybersecurity posture and risk management.

For the development of social cybercrime, the theory proposed by Miró Linares [4] is taken as a foundation. According to him, the complexity of characterizing the authors of social cybercrimes is due to the diversity of motivations and actions they encompass. This category includes crimes with different purposes, from sexual motivations to verbal aggression on social networks and forums. He points out that minors can not only be victims but also perpetrators of these crimes, actively participating in activities such as sexting, insults, slander, and cyberbullying. It is mentioned that the profiles of social cybercrime perpetrators are as varied as the types of crimes themselves, and that their characteristics may be similar to those who commit similar crimes in physical space. However, cyberspace modifies the risk environment and, therefore, can alter the profile of offenders. As can be noted, there is a need for a deeper analysis of how cyberspace changes the profile of perpetrators of crimes such as cybergrooming, cyberstalking, and cyberbullying.

Cyberbullying is a phenomenon that merges technology and school bullying, using platforms such as social networks and instant messaging to repeatedly harass individuals, causing significant psychological damage to young people and university students [23, 24, 25]. Information and Communication Technologies (ICT) facilitate both communication and amplified forms of bullying [26, 27], also affecting university students, who require adjusted prevention strategies [28]. Cyberbullying is recognized by the European Union as one of the main online risks, driving measures to protect young people [29], while research such as that of Faucher et al. [30] suggests that impacts may vary by gender.

Cyberstalking, an evolution of traditional stalking, involves the use of technology to pursue and threaten, characterized by persistence and methods such as threatening messages and identity theft [31, 32]. This phenomenon is debated among experts on whether it constitutes an extension of conventional harassment or a distinct problem [33]. Research indicates that characteristics such as low self-control and bad social influences predispose to cyberstalking [34], and studies in Italy

reveal that victims can experience severe psychological consequences, especially those exposed to multiple forms of harassment [35].

Sexting, the exchange of erotic images through electronic devices, is common among university students, especially under pandemic circumstances [36, 37]. Although generally consensual, it can lead to risky practices such as non-consensual content publication, highlighting the importance of cybersecurity education to prevent abuse and blackmail [38, 39].

Online grooming is another severe form of online abuse where adults seek to manipulate minors to sexually abuse them, differing from sexting in its intentions and consequences [40, 41]. A study revealed that a significant proportion of Spanish university students has been affected by this phenomenon, with a notable impact on women and non-binary individuals [42]. Research also points to the influence of pornography consumption on vulnerability to grooming [43].

This analysis underscores the urgent need to implement robust educational and protection measures in academic settings to combat cybercrime and ensure a safe environment for students. Therefore, the objective of this study is to evaluate the degree of knowledge and awareness about cybersecurity among university students in Peru, Mexico, and Colombia, and determine how these factors contribute to protection against social cybercrime.

III. Methodology

A basic research of descriptive nature with a quantitative approach was conducted; of non-experimental cross-sectional design and correlational explanatory level, with the purpose of establishing the relationship between variable "X" representing the Level of Knowledge in Cybersecurity and variable "Y", representing the Degree of Prevention in Cybercrime.

For data collection, a questionnaire composed of 66 questions related to variable "X" and 31 questions for variable "Y" was used. The dimensions evaluated for each variable included the Level of Knowledge in aspects such as Online grooming, Cyberstalking, Cyberbullying, and Sexting for variable "X", and for variable "Y", the Degree of Prevention and exposure. To validate and ensure the reliability of the instrument, a pilot test was conducted, and the Cronbach's Alpha coefficient was calculated.

TABLE I. Reliability Statistics of the Instrument

Cronbach's Alpha	N of elements
0.962	98

Table I shows the reliability of the applied instrument, amounting to 0.962, which indicates that the applied instrument is highly reliable.

The analysis theory for the cybersecurity variable was based on KAB model [6], for the social cybercrime variable it was based on the typology of cybercrime proposed by Miró Linares.

The population consisted of university students from three Latin American universities (Mexico, Colombia, and Peru). The study was conducted with a sample of 809 students, who voluntarily responded to the questionnaire through a Google form.

The data exported to Excel were processed in the SPSS statistical package version 28. To identify the characteristics of students according to origin, age, study cycle; bivariate statistical analysis of association was applied, data normality analysis was performed, and considering the nature of the variables, Spearman's Rho statistical test was used to measure the correlation between them and their dimensions.

IV. Results

The processed data correspond mostly (57%) to students in cycles II, IV, VI, and VII (Fig. 1)

Fig. 1. Study cycle of students.

Fig. 2 shows that the largest age range of participating students is between 15 and 25 years old with 71%, and only 29% corresponds to students between 26 to 64 years old. Dispersion measures show that the mean age is 25 years with a standard deviation of 8.733 years.

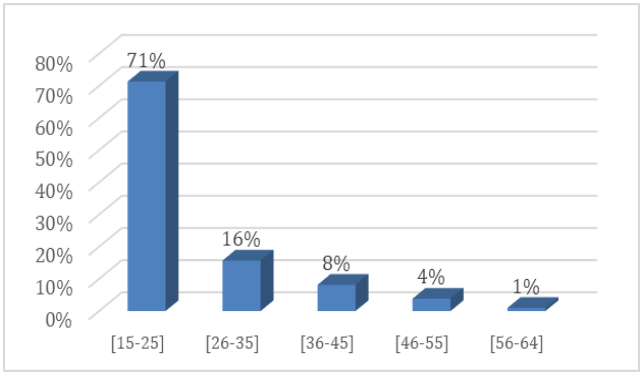

Fig. 2. Age range of participating students.

As shown in Fig. 3, 58% of the surveyed students come from the Universidad Privada del Norte Lima campus, 15% from UAQ Mexico, 13% from the Universidad Tecnológica del Perú, and the remaining 14% from UCC Colombia, UNIFÉ Lima, UPC Lima. This distribution reflects the multi-institutional and cross-national character of the study sample.

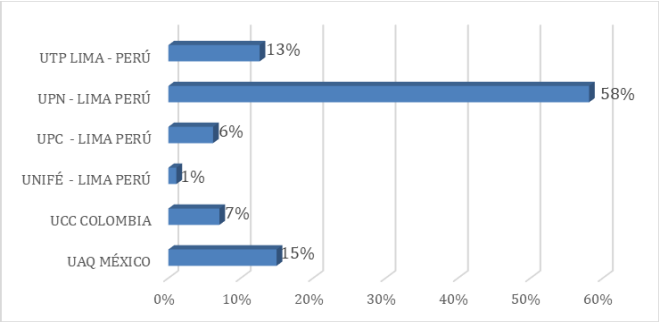

Fig. 3. Universities of origin.

Table II shows that 44.6% of students occasionally receive or have had knowledge about Cybersecurity, with UPN-Lima having the highest level on the subject (27.6%); likewise, 40.3% of students indicate that they have rarely evidenced or put into practice prevention in cybercrime offenses, with UPN-Lima again having the highest percentage with 24.6%.

The data normality analysis for the variables and their dimensions indicates a significance p-value = 0.000 < 0.001, so it is concluded that the behavior of the data does not follow a normal distribution, therefore, it is necessary to apply non-parametric tests for the validation of assumptions (Table III).

TABLE II. CROSS-TABULATION ON LEVEL OF KNOWLEDGE IN CYBERSECURITY AND DEGREE OF PREVENTION IN CYBERCRIME BY UNIVERSITY

		University						Total

TABLE IV. ANALYSIS OF CORRELATIONS BETWEEN THE STUDY VARIABLES

		Y: Degree of prevention of cybercrime
X: Level of cybersecurity knowledge	Spearman's Rho correlation coefficient	,252**
	Sig. (bilateral)	0.000 (p-valor<0.01)

Table IV shows the existing correlation between variable X: Level of knowledge in cybersecurity and variable Y: Degree of prevention in cybercrime, evidencing the existence of a correlation (p-value = 0.000 < 0.01), positive low equal to the Spearman's Rho coefficient 0.252. This statement is corroborated by Fig. 4 where the correlation points between both variables are shown, where the coefficient of determination $R^2 = 0.1071$ indicates that only 10.71% of the degree of prevention in criminality is given by the level of knowledge in cybersecurity.

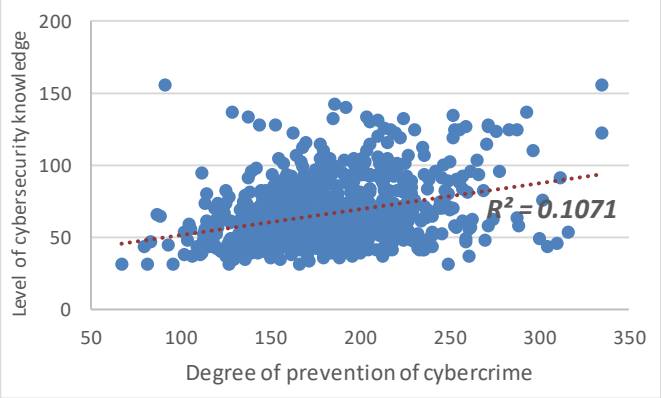

Fig. 4. Scatter plot of correlation between the level of knowledge in cybersecurity and the degree of prevention in cybercrime.

Table V shows the existing correlations between the dimensions of variables X and Y:

- There is a low positive correlation (r=0.134) between Cybersecurity Learning and Victimization in Cybercrime.
- There is a low positive correlation (r=0.239) between Cybersecurity Practice and Victimization in Cybercrime.

Regarding Grooming, it is evident that its Learning has a low positive correlation (r=0.095) with its Victimization; Knowledge and Practice have a low positive correlation with its Exposure (r=0.133, r=0.159) respectively, likewise they have a low positive correlation with its Victimization (r=0.114, r=0.223) respectively.

		Sig. (bilateral)	0.000	0.000	0.000	0.000	0.000	0.000	0.000

Regarding Cyberstalking, it is evident that its Learning has a low positive correlation with its Exposure and Victimization (r=0.220, r=0.103) respectively; Knowledge about this crime has a low positive correlation with Exposure and Victimization (r=1.73, r=0.097) respectively, finally its Practice has a low positive correlation with Exposure and Victimization (r=0.287, r=0.345) respectively. Regarding Cyberbullying, it is evident that Practice in its knowledge has a low positive correlation (r=0.213) with the Victimization of this crime.

Regarding Sexting, it is evident that Learning and Practice in the recognition of this crime have a low positive correlation (r=0.161, r=0.221) with its Exposure, respectively.

Finally, variable X (Level of knowledge in cybersecurity) has a low positive correlation with Exposure and Victimization of the crimes: Grooming, Cyberstalking, Cyberbullying, and Sexting, which leads to the need to improve the mechanisms and procedures of knowledge about cybersecurity, which improve this correlation and thus avoid exposure and victimization of these crimes.

V. Discussions

This study on the knowledge and awareness of cybersecurity of social cybercrime among university students from Mexico, Colombia, and Peru reveals significant findings that indicate the need to improve cybersecurity education for this demographic group.

It is observed that the studied university population presents a diversity in terms of experience and exposure to knowledge about cybersecurity. Although the average age is 25 years, with a standard deviation of 8.733 years, it is important to note that 71% of the participants are in the range of 15 to 25 years, while only 29% corresponds to students between 26 to 64 years. This distribution suggests that a significant proportion of students are younger than average.

Although it could be expected that this population has had time to be exposed to knowledge about cybersecurity, the data indicates that only 44.6% of students occasionally receive or have had knowledge on the subject. Furthermore, the low elevation (r=0.252) between the level of knowledge in cybersecurity and the degree of prevention of cybercrime suggests that age and exposure time do not necessarily translate into greater awareness or effective practice in relation to social cybercrime in its various manifestations.

A. Gap Between Theoretical Knowledge and Practical Application of Cybersecurity

The data obtained in this study reveal a concerning gap between theoretical knowledge of cybersecurity and its practical application by university students. Despite having a relatively high level of theoretical awareness about cyber threats, many students do not effectively apply this knowledge to protect themselves. This is reflected in the modest correlations between the level of knowledge and the degree of prevention of cybercrime, indicating that knowledge alone is not sufficient to guarantee safe online behaviors [44, 45]. The KAB model [6] suggest that cybersecurity education must go beyond the simple transfer of information and focus on the formation of practical skills and motivation to effectively apply this knowledge.

B. Variability in Awareness and Prevention of Different Types of Cybercrime

The study also shows significant variability in awareness and prevention among different types of cybercrimes. For example, awareness about cyberbullying seems to be higher than about online grooming, which may be influenced by the frequency and visibility of prevention campaigns focused on school bullying. However, the lack of awareness and effective prevention in less discussed crimes, such as cyberstalking and sexting, suggests the need for more inclusive and diversified educational approaches that address all forms of cybercrime [4, 42], ensuring that students are equipped to recognize and respond to a wider range of threats.

C. International Collaboration and Multidisciplinary Approach

International collaboration and a multidisciplinary approach are crucial aspects for effectively combating cybercrime. This study, which encompasses universities from Peru, Mexico, and Colombia, underscores the importance of this perspective. The variability in legislation and security practices between different countries demands greater cooperation and coordination between governmental entities, educational institutions, and private sectors at a global level. Furthermore, integrating approaches from multiple disciplines, such as psychology, law, and information technology, can offer more comprehensive perspectives and more effective solutions to cybersecurity challenges, especially in academic and youth environments [17, 18].

VI. Conclusion

This study provides empirical evidence of the cybersecurity knowledge and preventive practices among 809 university students across Peru, Mexico, and Colombia. The findings reveal a positive but weak correlation ($r=0.252$, $p<0.01$) between cybersecurity knowledge and cybercrime prevention practices, with only 10.71% of variance in preventive behaviors explained by knowledge levels ($R^2=0.1071$). These quantitative results indicate that 44.6% of students receive only occasional cybersecurity training, and 40.3% rarely implement preventive measures against social cybercrime. Among the four types of social cybercrime examined, cyberstalking prevention demonstrated the highest correlation with knowledge (r=0.287 for practice-exposure and r=0.345 for practice-victimization), while grooming showed the weakest associations.

A. Theoretical and Practical Implications

This research contributes to cybersecurity education theory by empirically validating the gap between theoretical knowledge and behavioral application in the Latin American context, extending the Protection Motivation Theory (PMT) and the Knowledge-Attitude-Behavior (KAB) model to the domain of social cybercrime prevention. The multi-national comparative approach reveals that cybersecurity challenges are regionally consistent across Mexico, Colombia, and Peru, suggesting that coordinated educational interventions could be effective across Latin America.

From a practical standpoint, these findings have direct implications for higher education institutions. Universities should redesign cybersecurity curricula to emphasize hands-on training, simulation-based learning, and real-world case studies rather than solely theoretical instruction. Educational programs must specifically address the four dimensions of social cybercrime—grooming, cyberstalking, cyberbullying, and sexting—with particular attention to grooming prevention, which showed the weakest knowledge-practice correlation. Furthermore, institutions should implement mandatory, continuous cybersecurity awareness programs integrated throughout the academic curriculum rather than optional or occasional workshops. Policymakers in Latin American countries should consider establishing regional cybersecurity education standards and sharing best practices to strengthen collective digital resilience.

B. Research Limitations

This study presents several limitations that should be acknowledged. First, the cross-sectional design captures only a snapshot of cybersecurity knowledge and practices, preventing causal inferences or the examination of temporal changes in behavior. Second, the convenience sampling method, while yielding a substantial sample size (n=809), may not fully represent the diversity of university students across all Latin American countries, as the study focused on three specific nations. Third, self-reported measures are susceptible to social desirability bias, potentially leading participants to overestimate their cybersecurity knowledge or underreport risky online behaviors. Fourth, the study did not account for potential confounding variables such as socioeconomic status, prior technology education, or individual differences in digital literacy that may moderate the knowledge-practice relationship. Finally, the instrument, while demonstrating high reliability (α=0.962), was not validated across different cultural contexts, which may affect its applicability to other regions or populations.

C. Future Research Directions

Based on these findings and limitations, we propose three specific directions for future research. First, longitudinal studies should be conducted to track changes in cybersecurity knowledge and preventive behaviors over time, particularly following targeted educational interventions. Such studies could employ pre-test/post-test experimental designs to establish causal relationships between specific teaching methodologies and behavioral outcomes. Second, future research should expand geographically to include other Latin American countries and develop cross-cultural comparisons with other global regions to identify universal versus culture-specific factors influencing cybersecurity behaviors. This expansion would enable the development of globally informed yet locally adapted prevention strategies. Third, researchers should investigate the psychological and social factors that mediate or moderate the knowledge-practice gap, such as risk perception, self-efficacy, peer influence, and institutional support. Mixed-methods approaches combining quantitative surveys with qualitative interviews could provide deeper insights into the barriers preventing students from translating knowledge into protective action. Additionally, future studies should explore the effectiveness of innovative pedagogical approaches, such as gamification, virtual reality simulations, and peer-to-peer learning, in enhancing practical cybersecurity skills among university students.

Understanding Echo Chambers in Recommender Systems: A Systematic Review

Meriem HASSANI SAISSI[1, *], Nouhaila IDRISSI[2], Ahmed ZELLOU[3]
SPM, ENSIAS/Mohammed V University in Rabat, Rabat, Morocco[1, 3]
Department of Computer Science, Laboratory LAROSERI-Faculty of Sciences, El Jadida, Morocco[2]

***Abstract*—Echo chambers refer to the phenomenon in which individuals are consistently exposed to content that aligns with their existing viewpoints. Over time, this can narrow a user's perspective and make it harder to encounter different opinions. In this systematic literature review, we looked at studies published between 2019 and early 2025 and how they have approached this issue, from understanding the cause, and examining existing detection and mitigation strategies. We went through and organized the main findings, noting patterns in the algorithms used, the role of user behavior, and the influence of the data itself. Several works also suggest ways to introduce more variety into recommendations, aiming to break repetitive exposure. Our review confirms that echo chambers and filter bubbles do exist in recommender systems and that they raise concerns for diversity and fairness. Furthermore, we end by pointing to open questions and possible directions for future work, for both researchers and practitioners.**

***Keywords*—Echo chamber; recommender systems; filter bubbles; collaborative filtering; systematic literature review**

I. Introduction

Since their appearance in the 1990s, recommender systems (RS) have experienced huge evolution, evolving from basic filtering algorithms to complex models that influence user experiences on popular digital platforms. In order to provide recommendations, RS first used content-based filtering, which examined item descriptions. Collaborative filtering was introduced by GroupLens and became the standard method [1].

By introducing item-based collaborative filtering in the early 2000s, Amazon transformed the way suggestions were created by emphasizing item similarities [2], [3]. The use of deep learning in the 2010s was the next significant advancement, enabling recommender systems to recognize involved patterns in user behavior and content. Methods like wide & deep learning models and YouTube's neural networks [4] gained popularity. In order to provide contextual and sequential recommendations based on dynamic user interactions, recommender systems nowadays make use of sophisticated models like transformers [5] and reinforcement learning [6]. The discipline of recommender systems is concentrating on enhancing personalization while simultaneously addressing new issues with transparency, fairness, and diversity as a result of ongoing advancements in deep learning and hybrid models [7], [8].

When people are mostly exposed to information, viewpoints, or content that supports their preexisting preferences or ideas, this is referred to as an "echo chamber". This effect occurs when algorithms use user data to customize suggestions, emphasizing material related to the user's past interactions. Although this customization increases user engagement and pleasure, it also runs the risk of isolating consumers in uniform informational settings. Echo chambers are not a novel idea; they have been thoroughly examined in e-commerce [11], [12], social media [9], [10], and news and media [13]. This phenomenon was first examined by Sunstein, C. R., in the context of political discourse, emphasizing how homogenous societies can be produced and ideas polarized by selective information exposure [14].

According to research [15] on filter bubbles, echo chambers occur in the context of recommender systems when algorithms favor information that is similar to what consumers have already interacted with. The intention behind this selective exposure is to increase user pleasure and engagement; however, it unintentionally reduces the range of information that users can access. Promoting a more informed and well-rounded user base requires both understanding and actively mitigating the effects of echo chambers in recommender systems. The dynamics of algorithmic recommendation and its consequences for information variety have been studied recently in research like [12], [16]. The necessity of creating recommender systems that strike a balance between personalization and the incorporation of varied and possibly difficult content is highlighted by this research. In order to document recent developments and new trends in the industry, this analysis focuses on the last seven years. From an initial pool of 564 papers gathered from top scientific databases such as Scopus, IEEE Xplore, Google Scholar, SpringerLink, ACM Digital Library, and DBLP, 56 peer-reviewed studies published between 2019 and early 2025 were chosen for in-depth research.

In light of this, we provide an organized synthesis that is directed by important research topics, illuminating the primary strategies and techniques used in this field of study. Our contribution to this discussion is a Systematic Literature Review (SLR) conducted to explore strategies for reducing the impact of echo chambers in recommender systems and to identify their existence.

The remainder of this study is structured as follows: Section II provides essential background on recommender systems and the concept of echo chambers. Section III presents the related works on echo chambers in recommender systems and recent AI-driven approaches proposed to mitigate them. Section IV details the research methodology and the guiding research questions. Section V presents the main findings and

*Corresponding author.

offers a critical analysis of the selected studies, highlighting the presence of echo chambers in recommender systems and evaluating the effectiveness of different mitigation strategies. In Section VI, we discuss the implications of our findings. We explore the overall consequences of echo chambers on user behavior and information diversity, and we identify potential directions for future research to address limitations and challenges identified in the literature. Finally, Section VII concludes the study by summarizing the main insights and discussing potential directions for future research. We summarize the main contributions of our review and suggest approaches for future studies to further explore and mitigate the effects of echo chambers in recommender systems.

II. Background

In this section, a comprehensive overview is presented regarding the two primary areas of research that are directly relevant to this systematic review: recommender systems and the echo chamber problem.

A. Recommender Systems

1) Content-based filtering: This method generates recommendations by focusing on product features and user profiles. It analyzes the attributes of items a user has previously interacted with and suggests similar ones based on these characteristics. Aggarwal et al. provided a comprehensive analysis of content-based approaches and their applications, noting their effectiveness across various domains [17].

2) Collaborative Filtering (CF): One of the most popular techniques in recommender systems, which is predicated on the notion that customers with comparable tastes will appreciate comparable products. It looks at user activity, such as ratings and interactions, to provide personalized predictions. Collaborative filtering is commonly divided into two main types: user-based and item-based. In the user-based approach, the system identifies individuals with similar preferences to the target user and recommends items favored by those individuals. The basic idea is simple: if two people have liked similar things in the past, one is likely to like what the other liked. A prominent early contribution in this domain is the research conducted by Sarwar et al. [18], which applied user-based collaborative filtering to movie recommendations and evaluated its effectiveness in that context. Item-based collaborative filtering, on the other hand, focuses on the relationships between items rather than users. It recommends items that are similar to those the user has liked in the past. This approach calculates the similarity between items based on user interactions and suggests items that are most similar to the ones the user has previously rated highly. An influential paper by Koren et al. [19] demonstrates the effectiveness of item-based collaborative filtering, particularly in handling large-scale datasets and providing accurate recommendations. In addition to these traditional approaches, recent advancements have introduced techniques such as matrix factorization and neighborhood-based methods. Matrix factorization techniques, including Singular Value Decomposition (SVD), decompose the user-item interaction matrix into latent factors to discover hidden patterns and improve recommendations. The work by Koren et al. provides a comprehensive overview of matrix factorization techniques and their application to collaborative filtering [20]. Additionally, approaches that integrate collaborative filtering with other methods, such as hybrid systems, aim to address limitations like data sparsity and cold start problems, enhancing the overall recommendation accuracy [21].

3) Hybrid recommender systems: Combine the advantages of collaborative filtering and content-based filtering to improve recommendation performance. Hybrid systems aim to overcome the limitations of each method, such as data sparsity and limited diversity, by combining multiple strategies. In order to enhance recommendation quality, Liang et al. present a hybrid strategy that combines sentiment analysis with matrix factorization [22]; Burke [21] provides a comprehensive overview of various hybrid techniques and their applications. Hybrid methods combine the strengths of content-based and collaborative filtering, offering a more reliable and comprehensive recommendation experience.

Despite their advantages, these methods encounter substantial limitations, particularly in reinforcing echo chambers, which restrict user exposure to diverse content by continually highlighting existing preferences. In content-based filtering, echo chambers emerge when recommendations are primarily based on a user's past interactions, resulting in repetitive suggestions that gradually limit exposure to diverse perspectives [48]. The echo chamber effect is amplified by exclusive dependence on historical user and item features, which means that it rarely provides novel or diverse content [23]. Similarly, collaborative filtering perpetuates echo chambers by generating recommendations based on the preferences of similar users. As a result, users are repeatedly exposed to content that caters to the preferences of a small, similar group, resulting in a closed feedback loop. As a result, users encounter content that reinforces their biases, limiting exposure to different viewpoints [18].

Hybrid models may continue to highlight user preferences over diversity in recommendations without deliberate strategies [21]. This would reinforce narrow content patterns and limit diversity. In conclusion, despite their benefits, these strategies underscore the ongoing issue of echo chambers in recommender systems and the need for new approaches that actively promote diverse content and diversify user exposure.

B. Echo Chamber Problem

An echo chamber, also known as filter bubble, is a phenomenon commonly observed in recommender systems, where users with similar beliefs mainly interact with each other, reinforcing shared viewpoints and potentially intensifying those opinions. This concept is likened to an echo chamber where homogeneous views are repeatedly echoed within the group, which can sometimes lead to more extreme beliefs [24]. Echo chambers are feared to exacerbate political polarization and public opinion division [25]. Echo chambers are typically identified through their structural characteristics, such as the density of connections and network homophily, as well as the ideological uniformity of their members [28], [33]. Research

utilizing digital trace data has examined these features to understand their role in online political polarization and the spread of misinformation [42], [43], [44]. Although some studies suggest that the existence of echo chambers may be overstated [46], [47], evidence generally shows that users tend to form communities with closely aligned views [45].

III. Related Works

The concept of "echo chambers" in recommender systems has evolved from earlier discussions in communication theory, which examines how individuals seek information that confirms their pre-existing views. Cass Sunstein was one of the first to introduce the term "echo chamber" in his work *Republic.com*, where he expressed concern that online algorithms could create isolated communities of like-minded individuals by limiting exposure to diverse perspectives [14]. This concern grew with the increasing influence of algorithms, as Eli Pariser's in "*The Filter Bubble*" [15], the concept is taken further, showing how personalization in recommender systems, especially on social media, can shape the flow of information to fit individual preferences. Over time, this selective exposure can limit the range of viewpoints users encounter, leading to ideological isolation and creating echo chambers [41].

Additionally, the role of echo chambers in the spread of misinformation became particularly prominent during the COVID-19 pandemic, as demonstrated by Cinelli et al., who analyzed how social media platforms amplified false information through echo chambers during the crisis [28].

From 2023 to 2025, recent studies have deepened our understanding of how recommender systems can shape and reinforce echo chambers, while others have explored ways to counter these effects. Gao et al. [37] showed that short-video platforms such as Douyin and TikTok often trap users in repetitive content loops created by engagement algorithms. Similarly, Duskin and Schäfer [67] found that Twitter's Who-to-Follow feature strengthens social homophily, leading to more polarized online communities. Sharma et al. [71] warned that conversational search tools powered by large language models could unintentionally create new forms of selective exposure, while Iwanaga et al. [73] demonstrated that friend-recommendation algorithms can reproduce echo-chamber structures in social networks. Collectively, these studies highlight that echo-chamber effects emerge from continuous user algorithm feedback loops and that mitigating them requires AI-driven designs that promote diversity and balanced information exposure.

While significant progress has been made in understanding echo chambers and filter bubbles in digital environments, existing systematic literature reviews (SLRs) reveal several limitations. Table I presents a summary of key limitations in notable SLRs and the added value of this study.

This SLR provides significant contributions by bridging the gaps left by previous studies. Unlike earlier reviews, it examines a broad timeline, covering research from 2019 to 2025, ensuring inclusion of the most recent advancements. My work integrates new technologies, highlighting their potential in addressing echo chambers effectively.

TABLE I. Identified Limitations in Existing Echo Chamber Studies

Ref.	Limitation
[52]	Does not address recommender systems and provides limited insights into mitigation strategies.
[53]	This review has several limitations. Many studies do not explicitly address the term "echo chamber" and rely on older approaches that may not reflect recent advances. In addition, the review dates back to 2022, while the field has since experienced rapid, exponential growth.

IV. Research Methodology

A. The Need of an SLR

A systematic literature review (SLR) is a structured and comprehensive way of bringing together what has already been studied on a given topic. In academic research, it helps identify and interpret all relevant work connected to a particular question, field of interest. However, past SLRs on recommender systems in echo chambers have left significant limitations. They have overlooked key studies and recent developments that are essential for a complete understanding, and many have failed to include all the necessary literature. Important areas that were often missing include the use of reinforcement learning and deep learning techniques to address echo chambers.

New research directions are especially important for a fuller picture. These include generative AI to counter polarization and adopting reinforcement learning to encourage more unexpected content. Another emerging strategy is to maximize semantic variety in recommendations as a way to limit echo chamber effects. Unfortunately, many earlier SLRs relied on outdated and incomplete methods, leading to biased conclusions. This review aims to close those limitations by using a variety of sources and adopting more recent, comprehensive research methods.

B. Stages of the SLR

In the field of software engineering, Kitchenham's [30] guidelines offer a clear and practical framework for conducting systematic literature reviews. This approach allows researchers to combine evidence in a way that is both structured and repeatable. As shown in Fig. 1, the process involves several key steps: defining the research questions, preparing a review protocol, performing an extensive literature search, applying predefined inclusion and exclusion criteria to select studies, assessing the quality of those studies, extracting the relevant data, and finally, analyzing and synthesizing the findings.

The systematic literature review (SLR) process is typically organized into three main stages: planning, conducting, and reporting. In the planning stage, the need for the review is established, followed by defining the research questions, keywords, and search terms. Researchers then decide on the information sources, develop study selection criteria, and design data extraction forms. In the conducting stage, the relevant studies are chosen, their quality is evaluated, and the necessary data is extracted and synthesized to draw meaningful conclusions. Finally, in the reporting stage, the findings are analyzed, compiled into a synthesis report, and verified to ensure both accuracy and reliability.

C. Research Objective

The questions and objectives that our SLR will address, as shown in Table II, will focus on understanding the echo chamber phenomenon in recommender systems, evaluating existing mitigation strategies, examining new trends and techniques, and identifying unexplored areas in the literature to guide future research efforts. The objective is to provide a comprehensive and up-to-date understanding of the topic.

We used two distinct search strategies to gather as much evidence as possible when conducting the SLR: ("Echo Chamber" OR "Filter Bubble") AND ("Recommender System" OR "Recommendation System"). Scopus, IEEE Xplore, Google Scholar, SpringerLink, the ACM Digital Library, and DBLP were the first six electronic data sources that we searched automatically. We were able to gather a list of potential candidates thanks to this strategy. These databases were chosen because they contain all high-quality conference proceedings and journals related to recommender systems. Additionally, following best practices for systematic literature reviews (SLRs), we used the snowballing search strategy. This required looking over the bibliographies of relevant papers and utilizing them as a foundation to locate additional relevant literature.

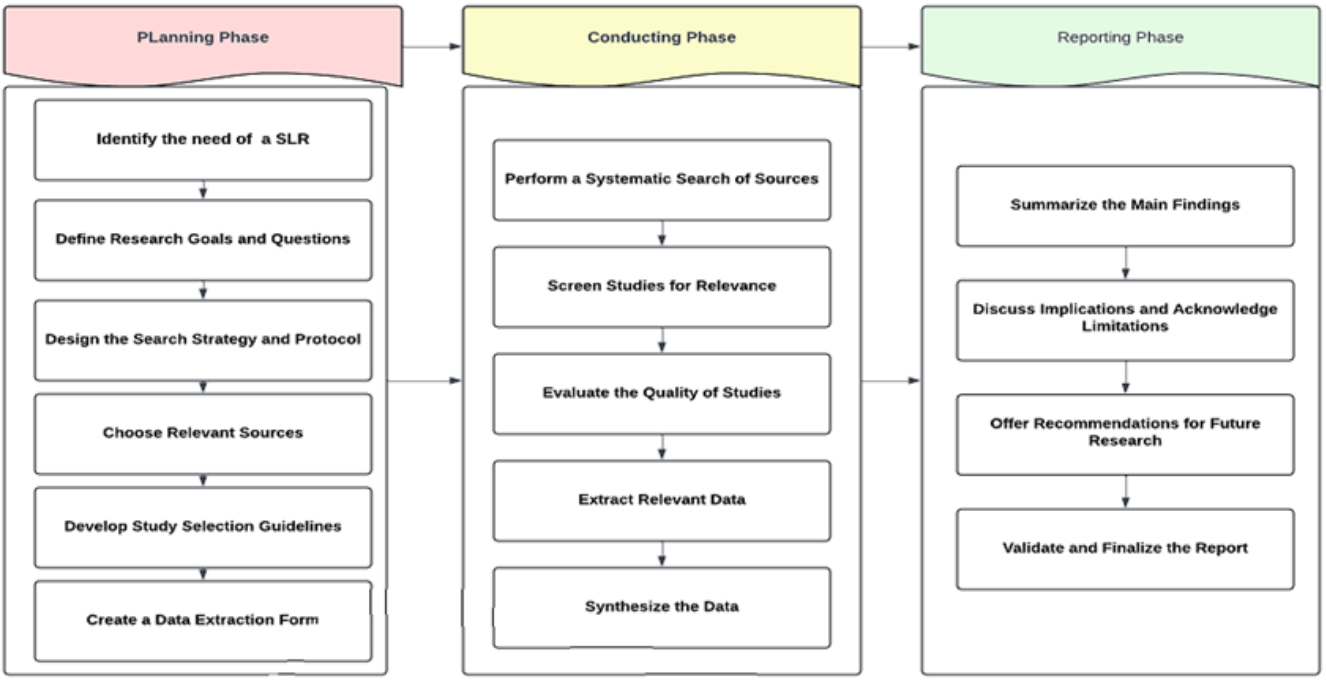

Fig. 1. Key elements of every phase in the SLR.

TABLE II. RESEARCH QUESTIONS

Research Questions	Motivation
RQ1: How echo chamber can be defined and detected in different recommendation approaches?	To comprehend how various recommendation systems create echo chambers. Different types: "collaborative filtering", "content-based", and "hybrid" may reinforce user biases in distinct ways. We can find better ways to reduce their impact by defining these.
RQ2: What approaches are implemented to prevent echo chambers in recommender systems, and what techniques are utilized to achieve this	To look into ways to prevent recommender systems from becoming echo chambers. The diversity of recommendations can be increased and users will not be exposed to content that is either biased or repetitive if they are aware of the techniques that work best. We can make recommendations more diverse and improve the user experience by identifying these methods.
RQ3: Have there been any evaluations? If so, what metrics were employed to assess the presence of echo chambers?	To determine whether any evaluations of echo chambers have been carried out. The purpose of this RQ is to identify the metrics used to evaluate the presence of echo chambers.
RQ4: Which datasets were used for evaluating echo chambers?	To identify the datasets commonly used in evaluating echo chambers within recommender systems. Understanding the datasets can provide insights into their suitability and limitations.
RQ5: What are the most promising directions for further research?	To examine the limitations of current solutions and identify future research directions regarding echo chamber and filter bubbles in recommender systems.

D. Selection Process and Eligibility Criteria

We began our selection process by reviewing the studies' titles, publication years, keywords, and abstracts. Then, we applied the criteria outlined in Table III to decide whether each study should be retained for further analysis. Any document that met at least one of the exclusion conditions was discarded.

TABLE III. DETERMINE THE CRITERIA FOR INCLUDING AND EXCLUDING STUDIES

Inclusion criteria	Exclusion criteria
The relevance of each paper was assessed according to its contribution to the five research questions (RQ1 to RQ5).	Papers outside the scope, as they do not focus on RSs
Papers from journals or conferences	Papers that address recommender system but not echo chamber
Papers published between 2019 and 2025	Duplicate papers
Language: written in English	Non-Academic Sources

TABLE IV. QUALITY QUESTIONS

Inclusion criteria	Exclusion criteria	Weight
Are the study's key contributions and motivations stated clearly and precisely?	Yes/partly/no (1/0.5/0)	1
Is the proposed solution clearly explained and feasible for implementation?	Yes/partly/no (1/0.5/0)	1
Did the study clearly define and thoroughly discuss the proposed solution?	- The study provided a high-level overview of the proposed system but lacked in-depth technical details (0.5). - The study offered a clear description of the methodology but limited explanation of its real-world application (1). - The proposed solution is mentioned, but key components are not fully developed or explained (0.5). -The proposed solution is not mentioned or referenced in the study (0).	2
Does the study compare the proposed solution with other existing works?	Yes/partly/no (1/0.5/0)	1
Does the study provide empirical evaluation and present results?	-The study proposed a solution but offered no implementation or evaluation (0). -The study provided an implemented solution but failed to address proper evaluation (0.5). -The study offered a fully implemented and well-evaluated solution. (1).	1,5
Are the study's findings clearly stated?	Yes/partly/no (1/0.5/0)	1

E. Quality Assessment (QA)

To maintain the credibility of our systematic literature review, we assessed the quality of each selected study using a set of predefined questions outlined in Table IV. For each question, responses were scored as 0 (no), 0.5 (partially), or 1 (yes), which allowed us to evaluate how well each criteria was met. Since some questions carried more importance than others, we applied specific weightings accordingly. The overall quality score for each study was then calculated using Eq. (1), combining both the assigned scores and their respective weights.

$$\text{Score} = \sum_{j=1}^{6} \frac{v_j * w_j}{7{,}5} \times 100 \quad (1)$$

where, w_j the weight assigned to each criterion, reflecting its importance and the value assigned to each quality criterion. Based on our quality assessment, we retained only the studies that scored at or above the average. This process resulted in a final selection of 56 papers for inclusion in our review.

F. Data Extraction Strategy and Synthesis

The relevant information from the final selected papers was documented using the data extraction form shown in Table V. This was done to address the research questions (RQs) outlined in Table IV and to accurately capture the data gathered during the study.

TABLE V. DATA EXTRACTION FORM

Data extraction form
ID, Title, Authors Publication type (Journal/Conference), Publication Year Domain or application feld, Contribution: Findings and Outcomes The study quality assessment **RQ1**.Definition in different recommendation type **RQ2**. Approaches and Techniques used **RQ3**. Evaluation measures and results **RQ4**. Datasets **RQ5**. Limitations & Future work

V. RESULTS

A. Overview of the Selected Studies

After completing the first step of the study selection process, as shown in Fig. 4, a total of 752 publications were retrieved from the Electronic Data Sources (EDS) searches using the search string. The titles of the articles were then checked for duplicates, and 564 candidates remained for further refinement based on the previously explained inclusion and exclusion criteria. The number of research papers to be reviewed in the systematic review was reduced from 564 to 234 after applying the exclusion criteria, and only 56 of these were found to be relevant. An additional six articles were identified by reviewing the reference lists of the relevant papers. Finally, the six quality assessment criteria listed in Table III were applied to ensure that the included findings would contribute valuable insights to the systematic literature review (SLR). Eight papers, including [75] [87] [93] [98] [100] [102] [104] [108], that scored 53.68 or lower, were discarded.

B. Classification of the Selected Studies

In this phase of the research, we investigate the distribution of the selected studies by years of publication, data sources and publication venues.

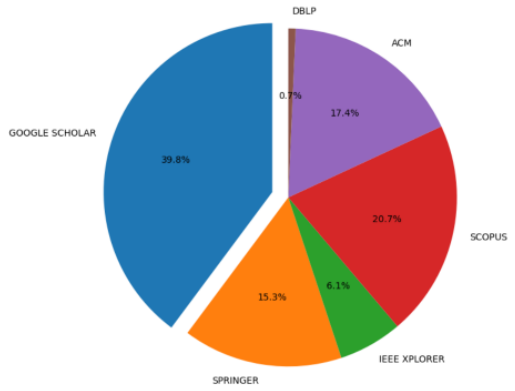

Fig. 2. Distribution by data sources.

Fig. 2 shows the proportion of selected research papers from various data sources. Google Scholar accounts for the largest share, providing 39.8% of the relevant papers, followed by Scopus with 20.7%, and ACM with 17.4%. Springer contributes 15.3%, while IEEE Xplorer and DBLP provide 6.1% and 0.7%, respectively. This distribution emphasizes the importance of Google Scholar and Scopus as major sources for gathering relevant research in this domain.

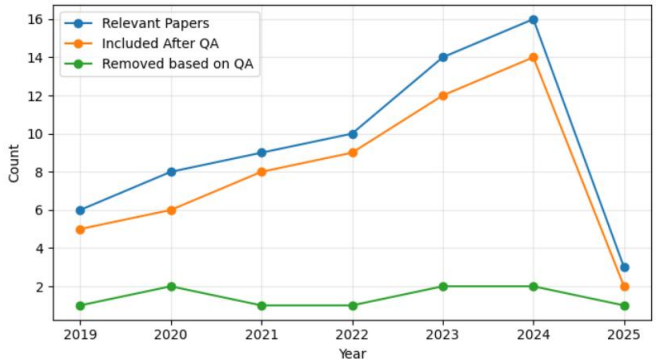

Fig. 3. Distribution of relevant papers before and after QA (2019-2025).

Fig. 3 illustrates the distribution of relevant papers from 2019 to early 2025, highlighting both the papers included after the quality assessment (QA) and those removed based on the QA. The total number of relevant papers increased from 7 in 2019 to a peak of 16 in 2024, showing growing interest in the field. Papers included after QA also rose from 5 in 2019 to 14 in 2024. The number of papers removed during QA fluctuated between 1 and 2 over the same period. In early 2025, both relevant papers and those included after QA dropped to 3 and 2, respectively, while papers removed during QA stood at 2.

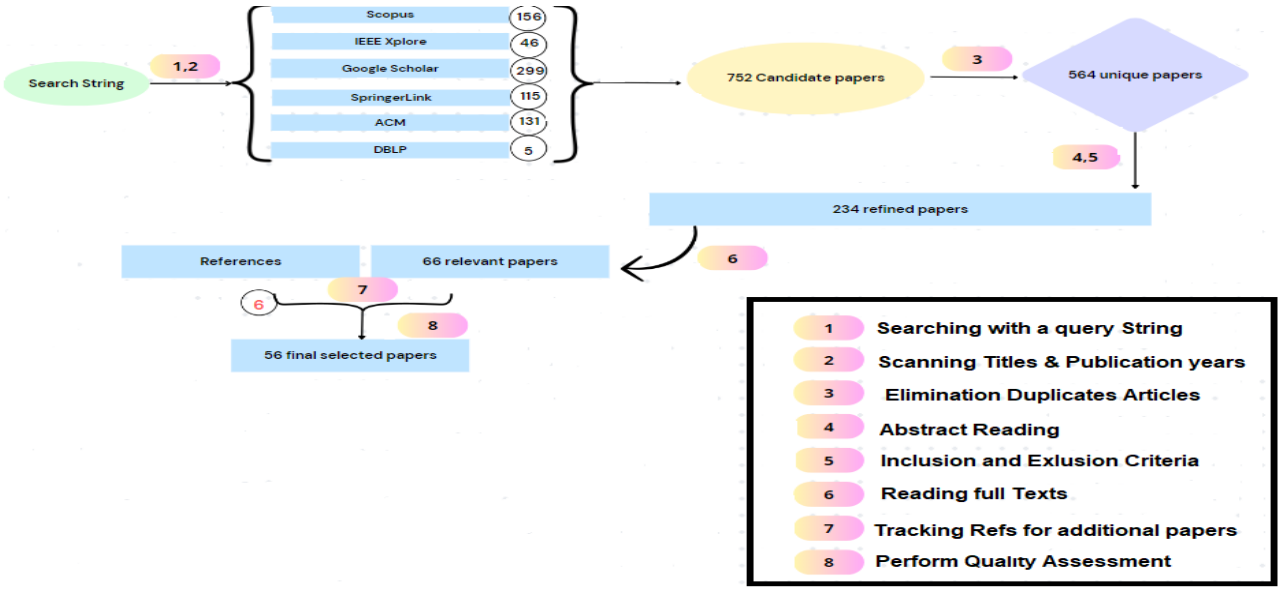

Fig. 4. Summary of the final paper selection process.

C. Data Extraction Results

In the following sections, we will present the findings of this systematic review and analyze them to address the research questions outlined in Section IV.

1) Summary of the RQ1: Echo chambers are a significant concern in various types of recommender systems, each manifesting in distinct ways depending on the underlying algorithm. In collaborative filtering systems, echo chambers arise when users are consistently exposed to content that mirrors their past interactions and the preferences of similar users. This feedback loop intensifies the reinforcement of existing beliefs, leading to a narrowing of perspectives and a reduction in content diversity. The concept of echo chambers in collaborative filtering has been extensively examined in recent literature, highlighting both the mechanisms behind their formation and the implications for user experience. Yingqiang Ge et al. [58] describe an echo chamber as a phenomenon in which users' interests are reinforced through repeated exposure to similar items or categories. This process closely aligns with

the principles of collaborative filtering, where user interactions and preferences are analyzed to generate recommendations based on the behavior of similar users. In addition, Ruben Interian et al. highlight the feedback loop embedded in collaborative filtering systems: as user preferences are continually reinforced, individuals are repeatedly exposed to similar content. Over time, this cycle restricts the diversity of perspectives and encourages to echo chamber [31]. Similarly, Sami Khenissi et al. [88] explain that echo chambers often emerge from the algorithmic tendency to recommend content that aligns with a user's previous behavior, gradually narrowing the range of information available to them. Alireza Gharahighehi et al. focus on session-based recommender systems, underscoring how the emphasis on predictive accuracy in collaborative filtering can inadvertently lead to the creation of echo chambers by exposing users to similar content and viewpoints over time [49]. Mert Can Cakmak et al. [107] Defines echo chambers as situations where algorithms repeatedly expose users to similar viewpoints, reinforcing pre-existing preferences. It also discusses detection via analyzing homogeneity in user–item interactions and network-based similarity. Lastly, Vancompernolle Vromman and Fouss [96] provide an experimental analysis, demonstrating that collaborative filtering algorithms naturally reduce content diversity, thereby reinforcing existing user preferences and contributing to the echo chamber effect. A common theme emerges from all of these studies: while collaborative filtering improves user satisfaction through relevant recommendations, it also runs the risk of creating closed content loops that discourage engagement with a wider range of perspectives [15]. Similarly, in content-based filtering systems, echo chambers develop as the algorithm prioritizes content similar to what the user has previously consumed. Antoine Vandelville et al. [40] define an echo chamber in this context as a situation where users are predominantly exposed to content that aligns with their existing beliefs and preferences, leading to a reinforcement of those views. This occurs because content-based algorithms curate and recommend items based on the user's past interactions, often resulting in a narrow range of viewpoints being presented. As users engage with content that reflects their interests, the recommendation system continues to suggest similar content, thereby creating a feedback loop. This can limit exposure to diverse perspectives and opposing ideas, fostering an environment where users remain insulated within their own ideological bubbles. Consequently, echo chambers in content-based systems can hinder open discourse and contribute to the polarization of opinions.

Hybrid recommender systems, which combine elements of both collaborative and content-based filtering, attempt to mitigate some of these issues by balancing accuracy with diversity. However, they are not immune to the creation of echo chambers, particularly if the system overemphasizes content that aligns with the user's established preferences. The challenge with hybrid systems lies in effectively balancing the competing demands of personalization and diversity, which, if not carefully managed, can still lead to the reinforcement of homogeneous content [49, 96]. Given these critiques, it is evident that each type of recommender system has inherent strengths and weaknesses concerning the formation of echo chambers. To mitigate the risks associated with echo chambers, strategies such as introducing diversity and serendipity in recommendations, employing algorithms that balance user exploration with relevance, and ensuring a mix of content that includes both popular and lesser-known items are essential. Additionally, applying fairness metrics to prevent the disproportionate favoring of specific content types can help create a more balanced recommendation environment [12, 62].

The next summary of RQ2 will delve deeper into how these mitigation strategies can be implemented across different recommender systems to reduce the impact of echo chambers, ensuring a more inclusive and diverse content experience for users.

2) Summary of the RQ2: After analyzing how researchers define the echo chamber, we now focus on the review of proposed of proposed approaches in collaborative filtering and other as well as the identification of the techniques used to avoid echo chamber. In the research area of collaborative recommendation and others types, several techniques have been disclosed for avoiding echo chamber. Table VI classifies studies according to techniques used for overcoming echo chamber issues in both collaborative approaches and other.

Collaborative Filtering based approaches leverage user-item interactions to generate recommendations, with several techniques focusing on enhancing diversity to prevent echo chambers. One such technique is the Targeted Diversification VAE-based Collaborative Filtering (TD-VAE-CF), which integrates Variational Autoencoders to inject targeted diversification into the recommendation process [60]. Reinforcement Learning based methods are also applied within CF frameworks, where adaptive learning helps to diversify recommendations over time by considering long-term user satisfaction rather than short-term interests [36], [38], [61]. Another noteworthy CF-based method is the Cross-domain.

Recommendation Model with Adaptive Diversity Regularization, which extends the concept of diversity across different domains, thereby broadening the scope of recommendations beyond a single domain [29]. Additionally, Novel serendipity-oriented RS, Generating Self-Serendipity Preference (GS^2-RS) is designed to introduce serendipitous recommendations, making the user's experience more varied and less predictable [65].

On the other hand, other types of Recommender Systems incorporate approaches that are not strictly based on collaborative filtering but are equally crucial in avoiding echo chambers. The Gini Coefficient Analysis is utilized to measure inequality in the distribution of recommendations, thus ensuring a fairer spread of content exposure across different users [81]. The Community Aware Model [31], [66], [81], [90] focuses on the social aspects of recommendations by accounting for the community structure, which inherently promotes a diversity of perspectives. Techniques like Determinantal Point Process (DPP) provide a probabilistic

framework that naturally favors diverse outcomes in recommendation generation [32], [88]. Furthermore, Contrarian Recommendations deliberately suggest items contrary to the user's typical preferences, thereby breaking the cycle of repetitive content exposure [5].

Other advanced approaches include Maximizing Semantic Volume, which aligns with the content-based approach by expanding the semantic range of recommendations. This technique ensures that users are exposed to a broader variety of topics, mitigating echo chambers and enhancing diversity within their content consumption [20, 26]. Similarly, Diversification Approaches for Session-Based Recommenders are often integrated into hybrid approaches, combining elements of content-based and re-ranking strategies to dynamically adjust recommendations during a single user session, maintaining engagement and novelty [20, 26, 49]. Allostatic Regulator introduces an adaptive framework under the content-based approach, balancing content exposure dynamically to ensure a healthy mix of familiar and novel recommendations, further addressing echo chamber concerns [39, 54]. Within the knowledge-based approach, techniques like GeNeG (Generalization via Sentiment and Stance Detection) leverage sentiment and stance analysis to introduce diverse perspectives into recommendations. This method promotes balanced content exposure, directly tackling polarization by presenting varied viewpoints based on explicit content analysis [84]. Similarly, the Point-of-View Diversification Technique falls under the knowledge-based approach, intentionally incorporating content from diverse perspectives to promote diversity and user awareness [51].Content-based approaches also include techniques such as Linguistic Diversity, which identifies and incorporates semantically diverse content into recommendations, and Clustering Models using TF-IDF, which focus on grouping content features to ensure varied exposure [4, 20]. These approaches highlight item-specific attributes to balance user preferences with novel suggestions. Finally, advanced hybrid approaches like the Re-ranking are instrumental in reordering recommendations to maximize diversity and fairness while maintaining relevance [70, 94, 107, 107]. Hybrid approaches effectively leverage advanced techniques such as Multi-Agent Systems with Large Language Models (LLMs) [77] and Counterfactual Interactive Recommender Systems (CIRS) [39] to address echo chambers and enhance user experience through innovative interaction and modeling techniques. These diverse methods underscore the multifaceted strategies being employed to enhance recommendation diversity, ensuring that users are introduced to a more diverse set of content and viewpoints, thus effectively mitigating the risk of echo chambers in recommender systems.

3) Summary of the RQ3: Having discussed the different approaches for mitigate echo chamber, we now proceed to the investigation of how these approaches can be validated. Mathematical metrics play a crucial role in quantifying and evaluating the impact of recommendations on user behavior and content diversity.

Diversity metrics, such as ILD@k and the Gini-Simpson Index, are widely referenced in [80], [85], [99], and [49]. These metrics assess how varied the recommended content is. For ILD@k measures the average dissimilarity of items within a list, while the Gini-Simpson Index evaluates the probability that two items belong to different categories. High diversity metrics indicate that the system is exposing users to a broader range of content, reducing the likelihood of echo chambers by encouraging diverse content consumption.Coverage, discussed in [27], [32], [72], and [80], measures the proportion of the item space that is recommended to users. High coverage implies that a wide range of content is being suggested, which helps prevent echo chambers by ensuring that users are exposed to a variety of content rather than just a narrow subset.

The Precision and Recall metrics, as referenced in [27], [32], [38], [85], and [99], are commonly used to evaluate the accuracy of recommender systems. Precision measures the proportion of recommended items that are relevant, while Recall assesses the system's ability to retrieve all relevant items. While these metrics focus on relevance, there is a need to balance them with diversity metrics to avoid reinforcing echo chambers. High precision and recall alone can sometimes contribute to echo chambers if the recommendations consistently reflect known user preferences without introducing new or diverse content.

NDCG (Normalized Discounted Cumulative Gain), as mentioned in [27], [32], [38], and [60] and defined in Eq. (2) and Eq. (3), evaluates the ranking quality of recommended items, taking into account both relevance and the position of items in the recommendation list. This metric is important for ensuring that while the recommendations are accurate, they also maintain a balance with diversity to prevent the dominance of a narrow set of content. Formally, it is defined as:

$$DCG = \sum_{i=1}^{K} \frac{rel_i}{\log_2(i+1)} \quad (2)$$

$$NDCG = \frac{DCG}{IDCG} \quad (3)$$

where, rel_i is the graded relevance score of the i^{th} item and $IDCG$ is ideal discounted cumulative gain [60].

MAE (The Mean Absolute Error), defined in Eq. (4), computes the deviation between the actual and predicted ratings and RMSE (Root Mean Square Error), defined in Eq. (5), discussed in [82], measures the accuracy of predictions by calculating the square root of the average squared differences between predicted and actual values. While RMSE is primarily focused on accuracy, it is important to consider that overly optimizing for RMSE without attention to diversity can contribute to echo chambers by continuously reinforcing existing preferences.

$$MAE = \frac{1}{n}\sum_{i=1}^{n}\left|p_{i-r_i}\right| \quad (4)$$

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(p_i - r_i)^2} \quad (5)$$

The Isolation Index (Iso-Index), highlighted in [27] and [72], measures the segregation of users into isolated groups receiving similar recommendations. A high Iso-Index suggests that users are isolated within echo chambers, as they are only exposed to content that aligns closely with their existing preferences.

TABLE VI. TECHNIQUE USED TO MITIGATE ECHO CHAMBERS IN RS

Refs.	Technique used	Type of approach			
		Collaborative	*Hybrid*	*Modeling*	*other*
[5]	Contrarian recommendations				Novelty Based
[20],[40]	Maximizing semantic volume				Content Based
[27]	New Prototype User Controllable RS			✖	
[29]	Cross-domain recommendation model with adaptive diversity regularization	✖			
[32],[88]	Determinantal Point Process (DPP)			✖	
[32]	Contrastive Co-training	✖	✖		
[34]	Clustering Distance-based Method				
[35]	IPS-based sequence recommendation system (IPS-seqRS)	✖			
[36], [43],[99]	Graph neural network: FRediECH				Graph Based
[36], [38], [61],[106]	Reinforcement Learning based method	✖			
[39]	CIRS, a counterfactual interactive recommender system		✖		
[49]	Candidate Item Selection Manipulation Neighbor Selection Manipulation		✖		Content Based
[50]	Multi-Perspective Search Paradigm	✖	✖		Knowledge-Based
[51]	A point-of-view diversification technique	✖			Knowledge-Based

[56]	Modified Random Walk Exploration (RWE)				Graph-Based
[60]	Targeted Diversification VAE-based Collaborative Filtering (TD-VAE-CF)	✖			
[65]	Novel serendipity-oriented RS called GS^2-RS	✖			
[66]	RG REC by integrating Generative Artificial Intelligence (GAI)				Generative AI-Based
[70]	Diversity nudges		✖		
[34],[70],[94], [107]	Re-ranking		✖		
[77]	Multi-Agent Systems and Large Language Models (LLMs)				Hybrid/Generative AI-Based
[78]	SSLE framework		✖		
[81]	Gini Coefficient Analysis		✖		Evaluation Metric
[83]	Linguistic Diversity				Content-Based Diversity
[84]	GeNeG (Generalization via Sentiment and Stance Detection)				Knowledge-Based
[86]	A pseudo global social network				Community Detection
[95]	Inverse Propensity Weighting (IPW)	✖			
[97]	New metric based on the homogenization				Evaluation Metric
[103],[55]	Agent-Based Modeling (ABM)				Simulation-Based
[105]	Clustering based model : TF – IDF algorithm (ICDM)				Content Based

Clustering Coefficient, as discussed in [99], measures the degree to which nodes in a network tend to cluster together. High clustering indicates that users are part of tightly-knit communities, which can lead to echo chambers where users are only exposed to content within their group, reinforcing existing viewpoints.

DIS-EUC is mentioned in [27], and defined in Eq. (6). This metric measure the distance between the recommendations of different user groups. Larger distances suggest stronger group segregation and more severe echo chamber effects.

- $d_u \in R^M$: The distribution over item categories in the recommendations for user u.

- $\bar{g}_u \in R^M$:: The average distribution over item categories for the original group $\bar{x}$
- $\hat{g}_u \in R^M$: The average distribution over item categories for the target group $\hat{x}$

$$DIS - EUC = dis(d_u, \hat{g}_u) - (d_u, \bar{g}_u) \quad (6)$$

where, $dis(.)$ represents the Euclidean distance.

Finally, NCI (Normalized Clustering Index) and RWC (Relative Weight of Communities), both mentioned in [36], quantify how users are clustered based on similar opinions and the extent to which users are grouped into distinct communities. High values for these metrics indicate strong echo chambers, where users are more likely to interact with like-minded individuals and less likely to encounter diverse perspectives.

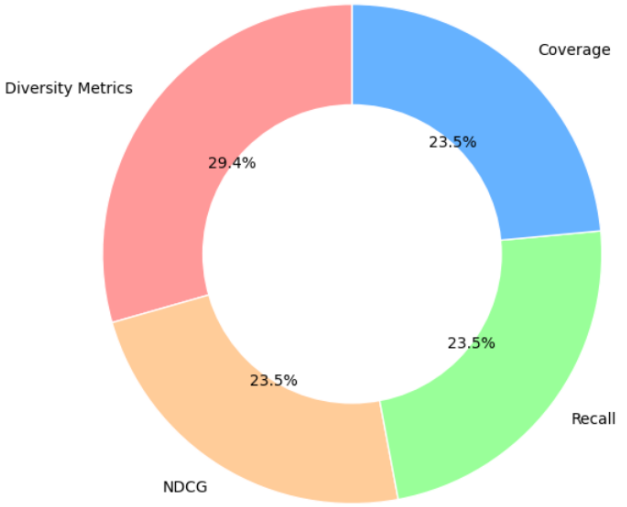

Fig. 5. Proportion of metrics used.

Fig. 5 provides a visual representation of the distribution of metrics used in evaluating recommender systems, particularly in the context of echo chambers. The chart shows that Diversity metrics are the most commonly used, diversity metrics. This distribution suggests a balanced focus on various aspects of recommendation quality, with a particular are also significant but are used slightly less frequently than making up 29.4% of the total. NDCG, Recall, and Coverage metrics each account for 23.5%, indicating that these metrics emphasis on ensuring diversity to combat echo chambers.

4) Summary of the RQ4: The choice of dataset for evaluating echo chamber in recommender systems depends on several factors, including the specific research goals, the characteristics of the recommender system being evaluated, and the availability of suitable data.

Table VII highlights the usage of various datasets in the study of echo chambers in recommender systems. The analysis shows that the MovieLens and Twitter datasets are the most frequently used in research aimed at mitigating echo chambers.

The MovieLens dataset is commonly utilized due to its rich data on user interactions with movies, making it a valuable resource for understanding how recommendation systems can influence user preferences and potentially create echo chambers. Similarly, the Twitter dataset is popular in research because it provides extensive information on social interaction, which is crucial for studying the dynamics of echo chambers in social media environments.

These two datasets play a dominant role in the field, highlighting their central importance in current efforts to investigate the challenges associated with echo chambers in recommender systems. The frequent use of these datasets underscores their importance in developing strategies to ensure that recommendations remain diverse and prevent the reinforcement of narrow user preferences.

Fig. 6 provides a visual representation of the distribution of datasets across different domains in the study of echo chambers in recommender systems. The key observations from the figure are:

Movies represent the most dominant domain, with the largest number of datasets. This suggests that a substantial portion of research on echo chambers focuses on movie recommendation systems, likely due to the widespread use of platforms such as Netflix and MovieLens. The prominence of these systems makes them a key context for examining how echo chambers develop and how they may influence user preferences and viewing habits.

Social media emerges as the second most prominent domain. Given the influence of social platforms on public discourse and user behavior, it is unsurprising that they remain an important focus in studies addressing the dynamics of echo chambers.

E-commerce and News domains each have a moderate representation. This highlights that echo chambers could affect consumer behavior in online shopping platforms and the information people consume from news sources.

Videos, Books, and Music have a smaller but still notable presence in the research. These domains show that echo chamber effects are being studied across various types of content, not just text-based or social media platforms.

Others represents a collection of miscellaneous domains that are less represented individually but still relevant to the overall study of echo chambers.

In summary, Fig. 6 highlights that research on echo chambers in recommender systems is focused on movies and social media with significant attention also given to e-commerce and news platforms. This suggests an interest in understanding how recommendation algorithms influence user behavior across a variety of digital content and platforms.

5) Summary of the RQ5: The last RQ of this SLR addresses future directions on echo chambers in recommender systems. The identified directions suggest various paths to improve how recommender systems function, focusing on mitigating the effects of echo chambers:

TABLE VII. THE DATASETS

Ref.	Dataset	Size of Dataset
[11],[27],[31], [34],[54],[63],[65],],[82],[89],[92], [106],[107]	Movie Lens	6,040 users, 3,702 movies, and 1 million movie ratings [31]: 100,000 ratings of 1682 movies [54] : 6,000 user ratings on 4,000 movies

[92]	Yelp Challenge	N/A
[97]	Own Dataset	317 users registered in the system, and 221 interacted with the news recommendations

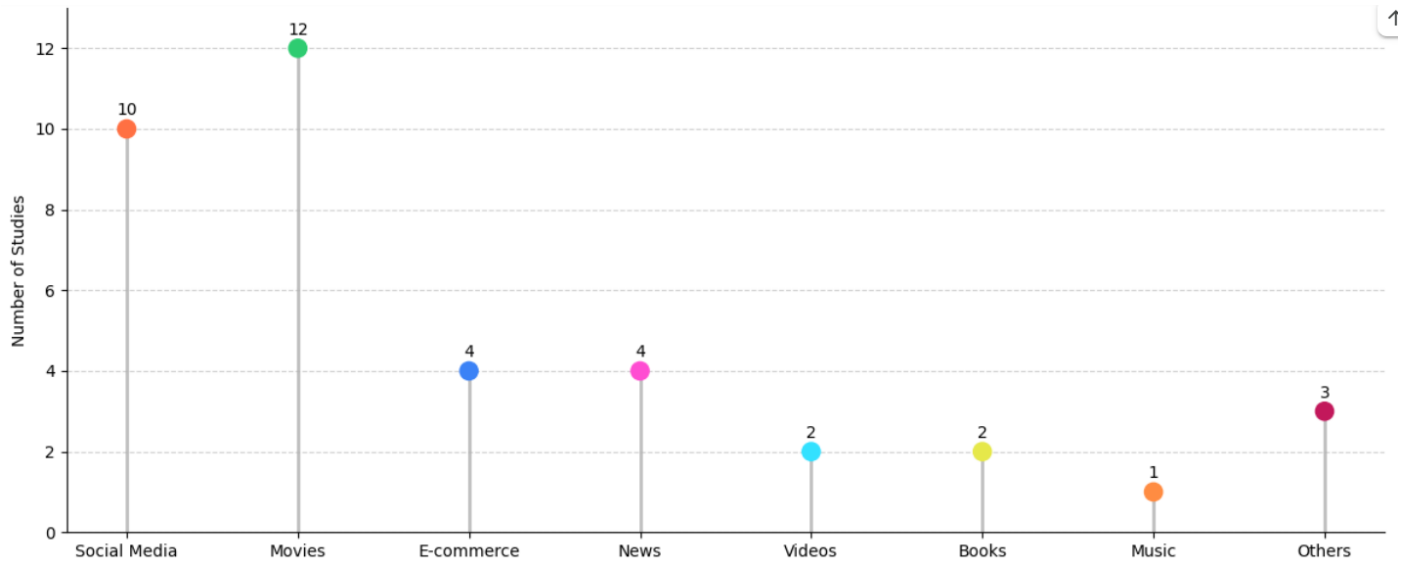

Fig. 6. Count of datasets by domain.

Longitudinal Studies (25%): Conducting long-term studies to track changes in user behavior over time is crucial. Such studies will help understand how echo chambers evolve and the long-term effects of potential interventions [26] [31] [68] [70] [78] [79] [89] [97].

Algorithmic Interventions (15%): Further development and testing of algorithms are necessary to promote diverse viewpoints. These new algorithms will be essential in combating echo chambers by exposing users to a wider range of content [68] [78] [79].

Empirical Validation (5%): A significant direction for future research is the need for more empirical studies that use real-world data from social media platforms to validate computational models. Comparing simulation results with actual user behavior will help determine the real-world impact of echo chambers [55] [69] [79].

Cross-Cutting Content Promotion (5%): Researchers should focus on developing strategies to promote content that bridges different perspectives. Encouraging dialogue between opposing viewpoints is essential for reducing polarization and creating a more balanced user experience [31] [89] [97].

Ethical and Interdisciplinary Approaches (5%): Future research should investigate ethical algorithm design and collaboration across disciplines for a holistic perspective. [26] [76] [78].

User Behavior and Engagement (20%): More research is needed on how users react to diverse content and opposing viewpoints. Understanding user engagement patterns will guide the design of recommender systems that foster more balanced and meaningful interactions [31] [49] [59] [79] [91] [103].

Advanced Technologies and Concepts (15%): Applying AI techniques, like generative AI and deep learning, to improve recommendations [5] [58] [74] [77] [78] [85].

User-Centric Approaches (10%): Designing systems that are tailored to individual users' preferences, behaviors, and feedback will be crucial for creating more personalized and diverse recommendation experiences [26],[78],[89].

An important future direction is the integration of generative AI to enhance content diversity and balance in recommendations. By leveraging generative AI, systems could produce content that represents multiple perspectives or simulate discussions reflecting diverse opinions, fostering a more inclusive and dynamic user experience [74],[101].

VI. Discussion

After following a specific series of detailed steps to collect the most relevant evidence, we now analyze and critique the findings. In addition, Section VI B outlines the limitations of this SLR. A summary of the results for each research question (RQ) is visually presented in the schematic model shown in Fig. 7.

A. Discussion of Findings

Research on echo chambers in recommender systems has consistently highlighted their pervasive influence across various recommendation algorithms, including collaborative, content-based, and hybrid systems. A major limitation of collaborative filtering, for example, is its inherent reliance on past user behavior and preferences of similar users. This often leads to feedback loops where users are repeatedly exposed to the same type of content, reinforcing their preferences and restricting their exposure to diverse perspectives. This absence of diversity keeps users in echo chambers, narrowing their content exploration and contributing to polarization [98].

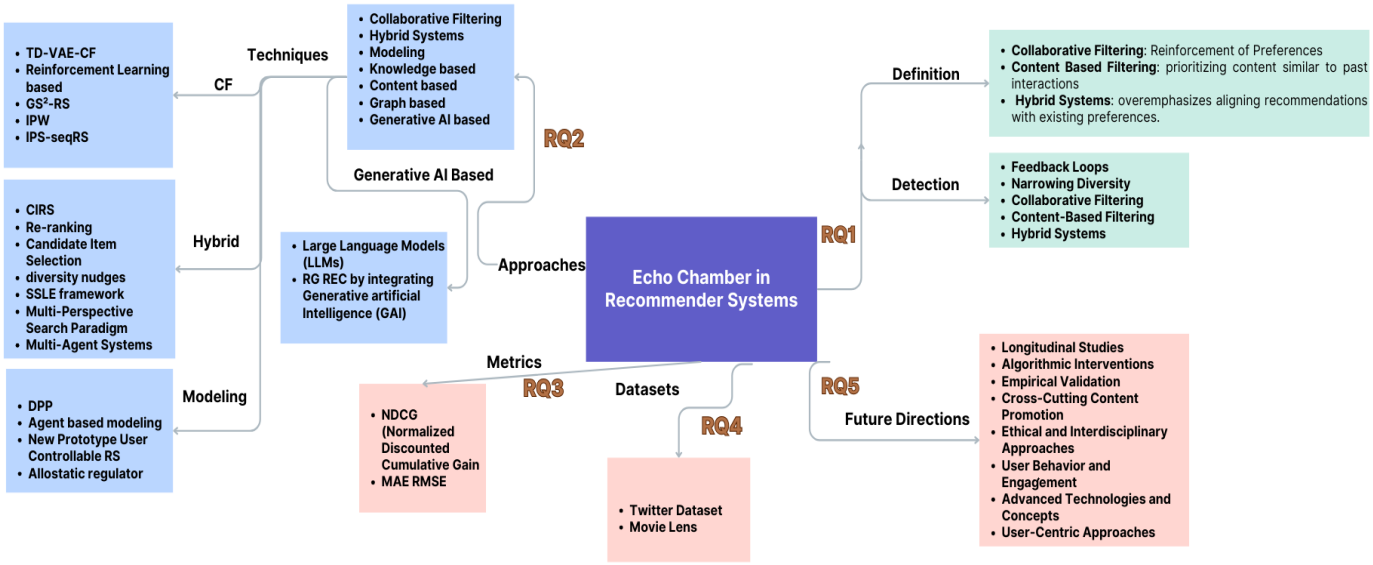

Fig. 7. Overview of findings for the research questions.

To address these limitations, several innovative approaches have been proposed. Targeted Diversification VAE-based Collaborative Filtering (TD-VAE-CF) [60] and Reinforcement Learning-based methods mitigate the feedback loop issue by introducing varied recommendations, diversifying the range of topics and content suggested to users. However, these methods often face challenges in maintaining relevance while enhancing diversity, as balancing the two can sometimes lead to reduce user satisfaction. Community-Aware Models and Contrarian Recommendations attempt to address these issues by integrating social context and intentionally suggesting items that contrast with user preferences. These models break the echo chamber cycle by exposing users to diverse viewpoints and encouraging engagement with content [55]. More advanced approaches, such as the Triple-Filter-Bubble framework utilizing an Agent-Based Model (ABM) [103] tackle systemic challenges like societal fragmentation. ABMs simulate cognitive processes behind echo chambers, including confirmation bias, offering valuable insights into how personalized recommendations contribute to polarization. Yet, their reliance on complex simulations may limit their applicability in real-time systems. Agent4Rec "a recommendation simulator", extends this work by addressing unresolved challenges like causality and user engagement. This approach highlights the importance of understanding the interplay between user behavior and recommendation algorithms, but its use in real-world applications remains questionable [63].

Another valuable direction focusing on maximizing semantic volume and linguistic diversity to enrich content recommendations. Expanding the range of topics and styles, these systems reduce bias and enhance user exposure to new perspectives. RGRec, combining graph-based reasoning, belief nudging, and generative AI, provides an advanced solution by detecting imbalances in user beliefs and nudging users toward diverse content [66]. While the system effectively encourages greater exploration, its reliance on belief manipulation raises ethical concerns about user autonomy. Various scales were used to evaluate these techniques. Diversity Metrics (e.g., ILD, Gini-Simpson Index) are critical for assessing how well systems expose users to a wide variety of content. However, over-reliance on traditional metrics like Precision and Recall, which prioritize accuracy over diversity, can inadvertently reinforce echo chambers. Balancing these metrics with diversity measures remains a key challenge.

Datasets such as MovieLens and Twitter are frequently used to study echo chambers, offering insights into their development across different platforms. However, these datasets primarily focus on entertainment and social media domains, limiting generalizability to contexts like e-commerce or news. Expanding research to incorporate diverse datasets is essential for understanding echo chambers across various sectors.

In summary, while existing methods face challenges such as balancing relevance and diversity or ensuring real-time applicability, newer approaches like graph-based reasoning, semantic diversity, and agent-based simulations offer promising solutions. By addressing these limitations and applying a combination of innovative techniques with evaluation metrics, researchers can more effectively mitigate echo chambers. The continued use of diverse datasets will help ensure that these strategies remain robust and adaptable across multiple domains [40], [66], [83].

B. Limitations of this Systematic Literature Review

A limitation of this review is that, although it covers studies from 2019 to 2025, the analysis only incorporates work published up to early 2025. Any significant research released after this point has not been captured, which may limit the completeness of the findings. Furthermore, despite selecting studies from six major digital libraries, there may still be relevant research from other sources that was not included. The review also focused exclusively on English-language publications, meaning that important non-English studies might

have been overlooked. Additionally, due to time constraints, this review relies on self-reported performance results from the authors of the selected studies, which may introduce bias into the assessment.

VII. Conclusion and Future Works

In this SLR, we have selected 56 research papers, published between 2019 and 2025, to explore how echo chambers appear in recommender systems and the solutions proposed to mitigate them. The main strength of this review is the use of a clear and systematic methodology, including a wide search strategy, predefined keywords, and strict inclusion and exclusion criteria. This ensures that the findings are both reliable and comprehensive. The study not only highlights the influence of echo chambers on user experience and content diversity but also evaluates the effectiveness of existing approaches to reduce polarization. Therefore, this work is valuable for guiding both researchers and practitioners, and it can also support the development of recommender systems that balance personalization with exposure to diverse content. Despite these contributions, this review has several limitations. The analysis focused primarily on studies published in English and indexed in major databases, which may exclude relevant non-English or gray literature. In addition, many included studies relied on simulated or single-platform datasets, limiting the generalizability of conclusions about real-world systems.

As a future work, we plan to build this SLR to address these limitations by conducting cross-platform, longitudinal, and user-centered analyses to better capture the dynamic nature of echo chambers. Promising directions include the integration of natural language processing, state space models, and other advanced AI techniques to design adaptive recommenders that maintain personalization while promoting exposure to diverse and balanced content.

Critical Review of Object Detection Techniques for Traffic Light Detection in Intelligent Transportation Systems

Adhwa Salemi, Muhammad Arif Mohamad
Faculty of Computing, Universiti Malaysia Pahang Al-Sultan Abdullah, 26600 Pekan, Malaysia

***Abstract*—Object detection and tracking play a critical role in intelligent transportation systems (ITS), particularly in recognizing and monitoring traffic lights to ensure safety and improve traffic efficiency. Despite progress in deep learning and optimization algorithms, traffic light detection still faces persistent challenges under varying conditions such as illumination changes, occlusions, and visual clutter. This study provides a critical review of object detection techniques specifically for traffic light detection, evaluating the evolution of machine learning frameworks, deep learning architectures, and hybrid optimization models. The review identifies research gaps in the robustness, real-time adaptability, and generalizability of existing methods. Furthermore, it highlights emerging trends such as multi-camera systems, anchor-free detection, and hybrid optimization techniques that bridge performance trade-offs between accuracy and efficiency. The findings offer a new perspective on integrating multiple approaches to achieve scalable, high-accuracy traffic light detection for future ITS applications.**

***Keywords*—Object detection; traffic light detection; optimization; intelligent transportation systems; review**

I. Introduction

The increasing use of intelligent transportation systems (ITS) and autonomous vehicles has dramatically altered traffic management and road safety paradigms [1]. Several enabling elements of such innovations, such as traffic light detection and tracking, are of pivotal importance. Traffic light signals form the backbone of orderly traffic flow and avoidance of collisions, and hence their detection and tracking with high accuracy is of critical importance to efficient ITS operations and autonomous vehicle capabilities [2].

In spite of their significance, the utilization of traffic light detection systems in real-world settings is beset with difficulties [3]. Such difficulties encompass complicated city landscapes, occlusions caused by other vehicles and roadside installations, variations in the color and pattern of traffic lights across different regions, in addition to the impact of adverse weather conditions such as low lighting, rain, and fog [4]. For example, the significance of deep models for addressing environmental challenges is best illustrated through their ability to detect traffic lights in challenging lighting conditions [5]. These challenges not only compromise detection quality but also hinder smooth tracking between frames, a fundamental element of autonomous decision-making.

Although several review papers have discussed object detection in general contexts, few have specifically addressed the unique challenges of traffic light detection, especially under environmental variations like low illumination, occlusion, and cluttering. Moreover, most existing reviews focus either on traditional image processing or deep learning independently, without synthesizing insights across optimization algorithms and real-time deployment frameworks. This gap highlights the need for a comprehensive review that bridges these areas to support more robust, real-time ITS solutions.

To address these issues, researchers have explored a range of object-detection architectures and optimization methods designed for complex real-world traffic environments. Object detection is a fundamental task within computer vision that enables systems to identify and locate objects within images or video feeds [6]. Traditional approaches relied on hand-designed features, including Haar cascades and histograms of oriented gradients, but the accuracy of detection has significantly increased since the introduction of deep learning techniques [7]. Convolutional neural networks (CNNs) form the foundation of object detection in modern computer vision, wherein the Faster R-CNN and YOLO models are particularly well adapted for real-time use [8]. Vision transformers are being incorporated into detection pipelines through self-attention mechanisms to boost feature extraction [9]. Multi-modal sensor fusion methods that integrate visual with LiDAR or radar data have also increased detection robustness in autonomous systems [10]. Precision, recall, and intersection over union (IoU) metrics remain significant in evaluating model performance [11].

Recent research has also studied progressive multi-modal fusion methods in which object detection is aided through hierarchical feature combination in various sensor modalities [12]. Researchers have also studied the effects of mono-modality feature learning in multi-modal object detection in resolving problems of degradation in fusion [13]. Development of optimal performance assessment frameworks has further improved standards of benchmarking object detection models [14].

As research develops, object detection becomes more advanced with the use of improved architectures and optimisation methods to achieve improved accuracy and efficiency [15]. Growing demand for reliable solutions has driven ample research in traffic light detection and tracking

methods. Conventional methods that include rule-based methods and traditional computer vision methods have been extensively employed; nonetheless, these cannot adequately cope with dynamic and complex environments [16].

Accordingly, this study aims to provide a targeted and critical survey of traffic light detection techniques. The discussion is structured as follows: Section II reviews past and current detection methods, including hybrid and optimization-based approaches. Section III explores recent trends in deep learning and real-time processing frameworks. Section IV evaluates these trends through comparative metrics and radar analysis, and Section V concludes with proposed research directions for more adaptive, scalable detection systems.

II. CRITICAL SURVEY

The studies reviewed in this section primarily utilize diverse datasets such as COCO, BDD100K, and custom traffic-light datasets collected under varied environmental conditions (day/night/rain/fog), ensuring that comparisons account for both real-world and synthetic data sources.

As city life is getting more complex, accurate and efficient traffic-light detection is crucial for maintaining traffic flow and ensuring road safety. Researchers initially used rule-based algorithms and traditional computer vision methods with a focus on colour segmentation, edge detection, and template matching to detect traffic lights from recorded images and video clips [17]. These methods worked well in ideal conditions, but failed in changing conditions. False detection and low confidence typically resulted from challenges such as changing light conditions, various traffic light configurations, and occlusions [18].

The deep learning era has changed how we detect objects, like traffic lights, with more effective models compared to conventional methods. Convolutional neural networks (CNNs) can detect complex features and are the foundation of modern detection systems. Among them, You Only Look Once (YOLO) models like YOLOv4, YOLOv5, and YOLOv7 have excelled in real-time applications. Experiments show how YOLO works together with tracking methods like Kalman filters and DeepSORT in achieving high accuracy for traffic monitoring systems [19]. Similarly, YOLO-based model research highlights their possibilities in solving problems caused by low light and short-time blockages [20] [15].

Mono and hybrid methods that combine optimization algorithms and deep learning have been used intensively in the last several years. These approaches take advantage of the strengths of the two paradigms to improve object detection systems. For example, the Firefly Algorithm (FA) is based on the behaviour of the fireflies [21], to enhance detection performance in difficult conditions. One notable example is KCS-YOLO, an improved YOLOv5n variant that utilizes attention and clustering mechanisms to enhance detection under low-visibility scenes [22]. The Zebra Optimization Algorithm (ZOA) is also a promising optimization algorithm that has been shown to achieve identical and continuous recognition in different video frames with its effectiveness in complex traffic scenes [23].

The demand for real-time processing in ITS applications has also promoted innovations in deployment frameworks. Frameworks such as TensorRT and ONNX streamline the deployment of deep learning models in edge devices to achieve efficient traffic light detection and tracking in real-time applications. For instance, TensorRT is used to speed up YOLOv5-based systems to balance speed and accuracy in autonomous vehicles [15]. Such frameworks are important in helping to meet the computational requirements of ITS applications to allow scalable and robust detection systems.

Recent studies demonstrate the promising work being done in this area. Table I below indicates the total papers that aim at object detection, particularly in traffic signals.

TABLE I. APPROACHES FOR TRAFFIC LIGHT DETECTION IN RECENT YEARS

AUTHOR (YEAR)	TYPE OF APPROACHES
De Guia et al. (2023) [24]	Utilized YOLOv7 for real-time traffic light detection, focusing on improving accuracy under occlusions and poor lighting.
Wu et al. (2023) [15]	Proposed a multi-camera system with YOLOv5 for robust detection and tracking, particularly addressing flashing light states.
Zhou et al. (2023) [22]	Introduced KCS-YOLO, an optimized YOLOv5n model with attention mechanisms to enhance performance under low visibility.
Vedant Singh (2025) [19]	Combined YOLO and SSD with tracking algorithms like DeepSORT for real-time traffic surveillance systems.
Bochkovskiy et al. (2020) [25]	Integrated Firefly Algorithm with YOLOv4 for optimizing object detection in low-light conditions.
Liu et al. (2024) [26]	Developed a GAN-based synthetic dataset for training object detection models, improving generalization for varied traffic environments.
Talaat et al. (2023) [27]	Adopted SSD with Kalman filters for tracking, achieving robust detection across consecutive frames.
Nagendra Rao et al. (2024) [28]	Explored transfer learning using ResNet50, focusing on adapting object tracking models for diverse regional traffic light designs
Chen et al. (2021) [29]	Applied single-shot detector (SSD) models optimized with IoU-based loss functions for better tracking of small objects like traffic lights
Zhang et al. (2021) [30]	Proposed an anchor-free detection technique to simplify tracking and improve inference speed in dense urban traffic scenarios

In spite of the advancements in object detection towards traffic light detection based on the papers above, there are various challenges that persist. Occlusions, illumination, and cluttering continue to plague the detection systems and call for more reliable solutions [24]. Moreover, diversity in traffic light configurations and designs in various regions challenges model flexibility and generalizability [25]. Future work will be required to utilize models that combine multiple algorithms or deep learning for the best solution and investigate the use of synthetic datasets and transfer learning to broaden system flexibility [26][27].

Unlike previous reviews that focus solely on specific algorithms or environments, this study synthesizes cross-disciplinary insights combining deep learning, optimization algorithms, and hardware deployment perspectives. This integrative view positions the study not merely as a compilation, but as an analytical framework for identifying

hybrid approaches that balance accuracy, adaptability, and computational cost.

III. Current Trends in Object Detection for Traffic Light Detection

The research in object detection towards traffic light detection has been significantly improved in recent years with the growing demands of intelligent traffic systems and autonomous vehicles [16]. Current trends manifest in a move to utilize state-of-the-art technologies to overcome challenges in dynamic traffic scenes, variable lighting conditions, and real-time processing requirements [31]. One of the most prominent trends is the use of anchor-free detection models. In contrast to conventional anchor-based methods that use prior bounding box sizes, anchor-free models streamline detection in that they predict object locations and sizes directly [32]. This reduces computational complexity and ensures speed in detection and is hence most applicable in real-time applications. One such example is an anchor-free detection method called DARDet that was proposed to enhance inference speed and accuracy in dense urban traffic environments [30].

Another recent development involves incorporating attention mechanisms into object detection models. They enable the models to focus on the most prominent features in an image, improving detection accuracy even in challenging situations like occlusion or poor lighting. An example is KCS-YOLO, a variant of YOLOv5n that incorporates attention mechanisms to improve detection accuracy in low-light conditions, with significant improvement in tracking precision [22].

Integration of multi-camera systems is gaining traction in traffic light detection. Multi-camera configurations possess a larger field of view and enable the merging of multi-view information, thereby rendering it more precise and robust. A proposed instance is a multi-camera traffic light detection system based on the synergistic application of YOLOv5 along with merged high-definition semantic maps and hidden Markov models. This aims to allow for complicated scenarios, like numerous intersections and various flashing light modes, and more precise outcomes in dynamic environments [15].

Hybrid approaches that combine deep learning and metaheuristic optimization approaches are one of the biggest future trends [35][36]. Such approaches take advantage of the best in the two paradigms to eliminate the limitations of traditional methods. For example, the Firefly Algorithm, inspired by the behaviour of fireflies, has been combined with YOLO-based methods to increase detection accuracy and tracking stability in adverse conditions. Equally, one study illustrated the employment of a GAN-based simulated set of data that offers a controllable environment to train object detection models that achieve generalisation over diverse traffic environments [26].

Synthetic datasets and transfer learning methods also gained popularity. Synthetic datasets, which were developed with generative adversarial networks, allow researchers to mimic various traffic patterns to enhance model adaptability and accuracy. Transfer learning sees models learn from pre-trained weights from large databases to decrease training time and improve performance in other environments. A proposed example used SSD in conjunction with Kalman filters to track objects from one frame to the next, with effective object detection and tracking efficiency [27].

Real-time processing is still a primary need in intelligent transport systems applications and has contributed to the common use of hardware accelerators and optimisation deployment frameworks. TensorRT and ONNX tools have played a significant role in facilitating the implementation of real-time traffic light detection on edge devices. Optimisation frameworks maximise model inference to achieve speed-accuracy balancing. Used TensorRT to speed up YOLOv5-based systems to operate in real-time without degrading detection quality [15].

Finally, the use of three-dimensional localization methods is proving to be a promising area of development in traffic light detection. By pairing camera detections with high-definition maps and methods of depth estimation, developers are creating algorithms that can localize traffic signals with high accuracy in three dimensions. This is especially beneficial in autonomous cars that operate through complicated intersections where multiple traffic signals can be seen in a single image.

Today's trends in object detection in traffic light detection demonstrate a multidisciplinary perspective that unites research in deep learning, optimisation algorithms, and real-time processing technologies. Such innovations continue to open doors to more powerful, efficient, and flexible detection systems that overcome challenges in current traffic conditions and assure higher levels of accuracy of intelligent transport networks and autonomous vehicles, which help encounter the ever-persistent problems of illumination, occlusion, and cluttering.

TABLE II. Trends for Traffic Light Detection

TRENDS	DESCRIPTION
Anchor-Free Detection	Models like DARDet simplify tracking by predicting object locations without predefined bounding boxes, enhancing speed and accuracy.
Attention Mechanisms	Focus on key features in images to improve detection under occlusions and low-light conditions, as demonstrated in KCS-YOLO.
Multi-Camera Systems	Utilize data fusion from multiple cameras to improve robustness in complex scenarios, such as multi-intersection environments.
Hybrid Models	Combine deep learning (e.g., YOLO) with optimization algorithms (e.g., Firefly Algorithm) for better accuracy in dynamic conditions.
Synthetic Datasets	Use GAN-generated datasets to simulate diverse traffic scenarios, enhancing model generalization.
Transfer Learning	Leverage pre-trained weights to adapt models for new environments, reducing training time while maintaining effectiveness.
Real-Time Processing	Employ frameworks like TensorRT to optimize inference speed, enabling real-time tracking on edge devices.
3D Localization	Integrate depth estimation and high-definition maps for accurate traffic light positioning in three-dimensional space.

Table II illustrates on which way these trends are being implemented. It shows descriptively that these trends are usually used for encountering the problems that persist in the field of image processing of traffic light detection in intelligent

transportation systems, which are occlusion, cluttering, and illumination. The comprehensive result review of each trend for resolving the problems is in Section IV.

IV. Evaluation and Discussion

The radar chart in Fig. 1 illustrates the relative weaknesses and strengths of various trends of object detection specifically for traffic lights, providing a sense of how each trend performs according to important criteria, which include Accuracy, Speed, Robustness, Scalability, Simplicity, and Real-Time Processing when occurring with problems that persist in the field of image processing of traffic light detection in intelligent transportation systems which are occlusion, cluttering and illumination.

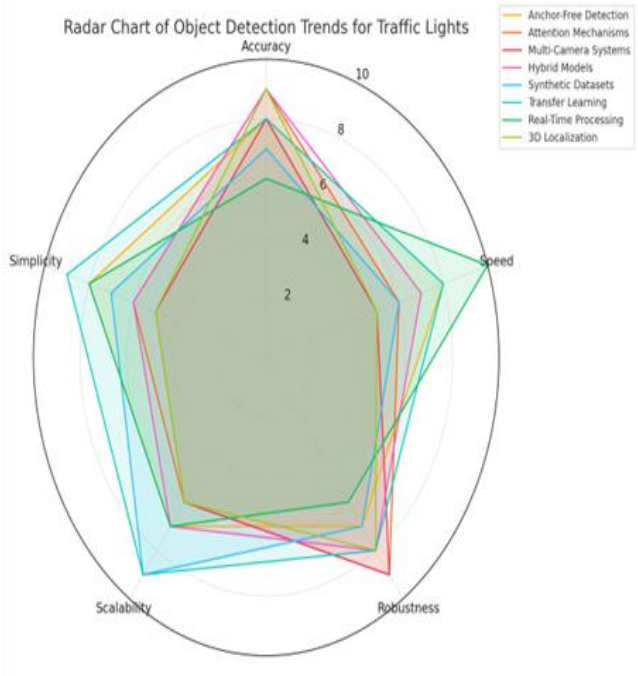

Fig. 1. Evaluation chart of object detection trends.

Anchor-free detection is quicker by eliminating predefined bounding boxes, but less robust under changing conditions. Attention mechanisms prioritize features better, offering balanced performance without excelling in any aspect. Multi-camera systems are spatially more aware and better handle occlusions, but are computationally more expensive. Hybrid models offer the best detection by merging various approaches, but could be challenging to tune. Synthetic datasets are more scalable and flexible but demand high-intensity processing. Transfer learning accelerates deployment with pre-trained models, but is hindered by drastic environment change. Real-time processing ensures fast detection but at the cost of stability in complex scenarios, and 3D localization improves detection accuracy with depth estimation but at the cost of computational efficiency.

It can be deduced from Fig. 2 that the effectiveness score derived from six evaluation criteria indicates strong performance on trends for "Multi-Camera Systems" and "Real-Time Processing", while the second-tier performance is "Anchor-Free Detection", "Hybrid Models", and "Transfer Learning". The bottom three which are "Attention Mechanisms", "3D Localization" and "Synthetic Datasets" gives the least optimum effectiveness score regarding object detection which in future can be a research field for improvement.

Fig. 2. Effectiveness of object tracking trends.

To ensure the probability of the charts, they are aligned with the deduction above. It is therefore appropriate to present the comparative data based on the previous studies with the comparative mean Average Precision (mAP) and Frame per second (FPS). The values presented are drawn from experimental results reported in previous peer-reviewed research papers, and actual performance may vary based on implementation and dataset. Table III shows evaluation metrics in terms of mAP and FPS.

TABLE III. Evaluation Metrics

APPROACH	EXAMPLE	mAP	FPS
Anchor-Free Detection	DARDet [30]	0.85	57.0
Attention Mechanisms	KCS-YOLO [22]	0.78	34.0
Multi-Camera Systems	aUToLights [15]	0.91	35.0
Hybrid Models	YOLOv4 + FA [25]	0.87	37.2
Synthetic Datasets	GAN-based dataset [33]	0.73	41.0
Transfer Learning	ResNet50 TL [28]	0.85	45.0
Real-Time Processing	YOLOv5 + TensorRT [4]	0.91	60.0
3D Localization	HD Maps + Depth Est. [34]	0.76	30.5

The comparative evaluation of trends (see Table III) is based on reported mean Average Precision (mAP) and Frames Per Second (FPS) from peer-reviewed studies, ensuring consistency across methods. For instance, real-time processing frameworks (e.g., YOLOv5 + TensorRT) achieve an average mAP of 0.91 with 60 FPS, indicating superior latency performance under occlusion. In contrast, hybrid models (YOLOv4 + FA) balance performance with mAP $\approx$ 0.87 and improved detection consistency under illumination variance.

It should be noted that the datasets referenced in these studies span diverse conditions, some synthetic (GAN-generated) and others real-world, including different regional signal encodings (e.g., Asia's five-color variant vs. Europe's three-light system) to ensure generalizability. These datasets cover day, night, rain, and fog scenarios, ensuring that each approach is evaluated under consistent environmental diversity. Thus, the comparative rankings are quantitatively grounded in published mAP and FPS benchmarks, representing relative trade-offs rather than subjective judgments.

No single approach is universally optimal; each performs best under specific conditions such as occlusion, illumination, or visual clutter. Anchor-free and real-time methods are better suited for edge deployment and latency-sensitive applications, such as on-device autonomous driving systems (occlusion). Meanwhile, attention-based and hybrid models offer greater robustness and accuracy, making them valuable in complex urban scenarios where precision is critical (occlusion, clutter, or illumination). Synthetic datasets and transfer learning provide scalability and domain adaptability, especially where labelled data is limited (occlusion). Multi-camera systems and 3D localization, while computationally intensive, can significantly enhance spatial awareness at intersections (occlusion, illumination, or clutter). In practice, a modular system that integrates several of these approaches, depending on environmental and application constraints, may offer the best balance of performance, accuracy, and cost-efficiency.

V. Conclusion

Traffic-light object detection plays an important role in intelligent transportation systems and autonomous driving, ensuring safe and smooth traffic flow. Traditional methods could not handle occlusions and illumination variations, leading to a shift toward hybrid models and deep learning. Multi-camera systems, 3D localization, and attention mechanisms are employed to boost detection accuracy, while transfer learning and synthetic datasets are utilized for better adaptability. Regional diversity and real-time implementation remain challenging. Future work must be directed at integrating various trends to develop scalable hybrid models for guaranteeing robust and efficient traffic light detection in continuously changing environments.

Future research should integrate multi-camera systems with real-time processing to achieve low-latency detection (target latency $\leq$ 20 ms) and employ hybrid models enhanced by transfer learning to reach higher precision (target mAP $\geq$ 0.95) in complex environments.

It is also important to distinguish how various environmental factors contribute to detection uncertainty. Occlusion primarily affects visibility consistency across frames, illumination alters color and contrast perception, while cluttering introduces background confusion. Addressing these through probabilistic modeling or uncertainty propagation frameworks (e.g., Bayesian CNNs) can further enhance model robustness.

Collectively, this review underscores the importance of combining complementary trends of hybrid learning, real-time frameworks, and multi-view data to build the next generation of resilient, adaptive traffic light detection systems for intelligent transportation networks.

***Abstract*—Thailand's tourism sector increasingly requires immersive digital innovations that preserve local identity while enhancing visitor engagement. However, there remains a lack of a comprehensive model to guide such developments. This study aims to propose the Conversational AI-powered Virtual Reality Development Model for Tourism Promotion in Thailand, providing an integrated and context-specific framework suitable for practical implementation. A Design and Development Research (DDR) methodology (Type II) was employed in three stages: 1) synthesizing essential components through a scoping review, 2) constructing and validating the model via expert panels using the Content Validity Index (CVI) analysis, and 3) assessing suitability and acceptance through expert evaluation and stakeholder surveys. The model developed in this study, referred to as the 4Ds Model, contributes new knowledge by integrating conversational AI and virtual reality within a four-phase structure—Discover, Design, Develop, and Deploy—supported by five enabling capitals: human, cultural, technological, informational, and financial. The Deploy phase modifies the AISAS communication framework into AICAS (Attention, Interest, Chat, Action, Share) to illustrate the function of conversational AI in improving user interaction and engagement within the context of tourism in Thailand. Results indicated high expert ratings of suitability and strong stakeholder intention to adopt. Multiple regression analysis revealed that technological self-efficacy, perceived interactivity, and perceived tourism benefits were significant predictors, explaining 73.3% of the variance in behavioral intention. The findings demonstrate both the theoretical advancement in AI–VR integration and the practical readiness of the 4Ds Model as a culturally aligned roadmap for digital tourism transformation in Thailand.**

Keywords*—Virtual reality; conversational AI; Model Development; digital tourism; technology adoption

I. Introduction

Tourism is a major economic sector worldwide, playing a vital role in job creation, income generation, and cultural exchange. In recent years, the industry has faced significant challenges, especially due to the COVID-19 pandemic, which accelerated the shift toward digital engagement and virtual-tourism solutions [1]. As a response, technologies such as virtual reality (VR) and conversational artificial intelligence (CAI) have gained prominence as innovative tools for enhancing tourism marketing and traveler engagement [2].

VR allows users to experience simulated environments that replicate real-world tourist destinations. These immersive environments can shape destination image, emotional attachment, and behavioral intention among potential tourists [3], [4]. Multisensory VR—which integrates sound, vision, and other sensory inputs—has been shown to increase emotional engagement and perceived presence, particularly when personalized to specific user groups [4].

CAI plays a complementary role by enabling real-time dialogue and personalized assistance in virtual environments. Services such as language translation, itinerary recommendations, and interactive storytelling help reduce uncertainty and enhance satisfaction for users navigating virtual-tourism experiences [5]. Despite growing global applications of VR and AI in tourism, their integrated use—particularly within culturally diverse and linguistically unique regions like Thailand—remains underexplored [6].

However, existing studies rarely provide a structured model that systematically integrates VR and CAI for tourism promotion, leaving a methodological gap in both research and practice. Without such a structured model, integration efforts risk remaining fragmented, thereby limiting scalability, policy alignment, and long-term impact. For Thailand specifically, aligning immersive technologies with national tourism strategies and embedding local cultural identity are critical considerations, yet current models offer little structured guidance for achieving such alignment.

Research consistently highlights the importance of interactivity, presence, and satisfaction in shaping tourist behavior in VR environments. When VR is combined with conversational systems, emotional immersion is heightened and human-like engagement is created, effectively simulating tour guides or hosts to enrich the tourist's pre-visit experience [4], [7].

This study proposes the Conversational AI-Powered VR Development Model for Tourism Promotion in Thailand as an innovative response to the identified research gap. The model combines immersive virtual environments with conversational

interfaces to enhance engagement and personalization, while remaining aligned with digital tourism strategies. To systematically examine the model, the study focuses on three key aspects: 1) synthesizing its core components, 2) validating its theoretical soundness, and 3) evaluating its suitability and acceptability from expert and stakeholder perspectives. In this study, stakeholders refer not to tourists but to public-sector tourism officers, destination management professionals, and practitioners in provincial tourism promotion units, whose perspectives are essential for policy alignment and implementation. The research also seeks to identify the key factors that predict stakeholders' behavioral intention to adopt the model. These aims directly inform the research objectives and questions outlined in the following section.

II. Research Objectives

1) To synthesize the key components of the conversational AI-powered VR development model for tourism promotion in Thailand.

2) To develop and validate the conversational AI-powered VR development model in terms of theoretical soundness.

3) To evaluate the model's suitability as perceived by domain experts in the tourism sector.

4) To evaluate the model's acceptability as perceived by stakeholders and to identify the key factors predicting their behavioral intention to use the model.

III. Research Questions

1) RQ1: What are the key components of the conversational AI-powered VR development model for tourism promotion in Thailand?

2) RQ2: To what extent is the synthesized model valid in terms of theoretical soundness?

3) RQ3: To what extent do domain experts in the tourism sector perceive the proposed model as suitable?

4) RQ4: To what extent do stakeholders in the tourism sector perceive the proposed model as acceptable, and which overall and specific factors significantly predict their behavioral intention to use it?

IV. Literature Review

A. Virtual Reality in Tourism Promotion

Virtual reality (VR) has been widely adopted as a technology-based marketing tool in the tourism industry because it can simulate real-world experiences. Research indicates that VR enables travellers to pre-experience destinations, which in turn shapes their emotional engagement and travel intentions [8]. The immersive quality of VR—particularly in multisensory formats—enhances presence and enjoyment [9]. Studies further suggest that VR can function as a substitute for real visits to sensitive or remote locations, supporting both destination marketing and conservation goals [10]. Recent reviews emphasise VR's growing relevance in the post-pandemic era, as the technology-maintained destination visibility during periods of restricted travel [11]. Moreover, VR has proven effective in reshaping traveller behaviour and expectations, increasing the potential for its long-term use in destination planning [12].

B. Conversational AI in Tourism Applications

Conversational artificial intelligence (CAI)—including chatbots and virtual assistants—has reshaped tourist services by providing real-time, personalized, and multilingual communication. In tourism and hospitality settings, conversational agents improve user satisfaction, assist with bookings, and reduce staff workload [13]. These systems leverage natural language processing to recognize user intent and adjust responses contextually, creating more natural interactions. Tourists also report positive emotional responses to AI-powered services, especially when these systems are integrated seamlessly across digital platforms. Trust, perceived usefulness, and enjoyment are key factors that drive the continued adoption of AI in tourism [13]. Nevertheless, most existing studies examine AI in isolation, focusing on functional or transactional roles with limited attention to its immersive and experiential potential—particularly in tandem with VR.

C. Integrated Use of VR and Conversational AI

Although VR and CAI have each been applied in tourism, research on their integrated use is still emerging. A combined system offers both immersive visual engagement and interactive verbal communication, effectively simulating local guides or cultural narrators within virtual environments. For instance, integrating speech recognition and natural-language processing into VR environments has been shown to improve user experience and language accessibility, especially for tourists with limited English proficiency [14]. Such systems can adaptively deliver information, answer queries, and provide decision support, making virtual tourism more personalised and engaging. However, there remains a lack of formalized models detailing how these integrated systems should be developed, validated, and deployed—particularly in alignment with national tourism strategies.

D. Cultural and Linguistic Personalization in Tourism

Cultural and linguistic personalization is critical in tourism-technology design, especially in diverse destinations such as Thailand. AI systems that support native-language interactions and culturally relevant content strengthen trust and reduce uncertainty among tourists [13]. In VR environments, weaving culturally nuanced storytelling and symbolic elements—such as temple architecture or local customs—deepens emotional resonance and visitor satisfaction [8]. Recent studies also indicate that tourists perceive greater authenticity and enjoyment when virtual systems reflect their cultural context and accommodate preferred languages [14]. Nevertheless, few development models systematically incorporate cultural and linguistic personalization—particularly those aligned with public-sector objectives for national tourism promotion.

E. Determinants of Technology Adoption in Tourism

The adoption of the proposed Conversational AI-Powered VR Development Model by stakeholders—defined in this study as public-sector tourism officers, destination management professionals, and practitioners in provincial tourism promotion units—depends on several interrelated psychological, organizational, and technological factors. These determinants are consistent with established adoption frameworks such as the Technology Acceptance Model (TAM) [15] and the Unified Theory of Acceptance and Use of Technology (UTAUT) [16],

which highlight perceived usefulness, ease of use, facilitating conditions, and behavioral intention as critical predictors of technology adoption.

One of the most critical factors is technological self-efficacy, referring to stakeholders' confidence in their ability to understand, operate, and apply new technologies in their work. Prior studies confirm that self-efficacy strongly influences the adoption of digital platforms in tourism and hospitality [17], [18]. High self-efficacy supports perceived ease of use and perceived usefulness—core constructs in TAM—and shapes favorable attitudes toward adopting innovative tools [19].

Another determinant is attitude toward tourism technology. Stakeholders who perceive VR and AI as valuable for enhancing tourism experiences and promoting destinations are more willing to support and invest in such tools. This aligns with TAM's emphasis on attitude as a mediator of adoption decisions [20] and with UTAUT's construct of performance expectancy [16].

Facilitating conditions—such as institutional support, infrastructure, budget allocation, and training—either enable or constrain system adoption. As emphasized in UTAUT, strong facilitating conditions increase the likelihood of adoption, especially when coupled with organizational readiness [16], [21].

Perceived accessibility—including ease of use, availability across devices, and language inclusivity—further influences adoption. Systems that minimize technical barriers and support local languages are particularly attractive to public-sector tourism personnel in linguistically diverse contexts [14].

Perceived interactivity is a decisive factor for technologies designed for tourism promotion. Dynamic, real-time engagement (e.g., conversational agents embedded in VR) enhances the perceived quality of communication experiences, encouraging adoption [14].

Finally, perceived tourism benefits reflect beliefs that the system can improve destination image, educate tourists, or stimulate visitation. When stakeholders perceive strong benefits aligned with policy priorities, they are more likely to adopt and champion the system [17].

These determinants—self-efficacy, attitudes, facilitating conditions, accessibility, interactivity, and perceived benefits—reflect validated constructs in TAM and UTAUT while addressing the specific needs of Thailand's public-sector tourism stakeholders. Unlike prior studies that examined these factors in isolation or emphasized tourists as the primary users, this study integrates them into a structured model. The determinants are empirically tested as predictors of stakeholders' perceived acceptability of the model and their behavioral intention to use it, underscoring the study's contribution in bridging technology acceptance theory with the policy and operational realities of tourism promotion in culturally diverse contexts.

V. Methodology

This study employed a Design and Development Research (DDR) Type II methodology, which is well-suited for synthesizing, developing, and evaluating innovative models in real-world contexts where no established models exist. According to Richey and Klein (2014), DDR Type II emphasizes both theoretical rigor and practical applicability. The research proceeded in three stages: 1) Model Synthesis, 2) Model Development and Validation, and 3) Model Evaluation.

A. Stage I: Model Synthesis

In the first stage, a scoping review was conducted to identify and synthesize the key components of the conversational AI-powered VR development model for tourism promotion in Thailand. Following the framework of Arksey and O'Malley [23], searches were performed in Scopus, IEEE Xplore, and ThaiJO databases covering publications between 2019 and 2025. The search strategy combined keywords such as "virtual reality", "conversational AI", "smart tourism", "digital tourism", "cultural communication", and "government tourism innovation". Three instruments supported this stage: a) Study Screening and Eligibility Checklist, b) Data Charting Form, and c) Evidence Synthesis Matrix. The results of this stage provided the preliminary components of the development model.

B. Stage II: Model Development and Validation

The second stage refined and validated the preliminary model. A focus group discussion (FGD) was organized with nine purposively selected experts specializing in tourism technology, VR/AI systems, and Thai cultural media. The FGD followed a semi-structured protocol described in [24]. Insights collected from the discussion were thematically analyzed to enhance the structure, terminology, and contextual alignment of the model. Subsequently, the revised model underwent content validation using the Content Validity Index (CVI). A separate panel of five experts—holding doctoral degrees and with at least five years of relevant experience—rated each component on a four-point relevance scale. All item-level CVIs (I-CVI) exceeded 0.80, and the scale-level CVI/Average (S-CVI/Ave) was 0.94, surpassing the 0.90 threshold recommended in [25]. These results confirmed strong content validity.

C. Stage III: Model Evaluation

This stage evaluated the suitability and acceptability of the proposed model through expert and stakeholder feedback, ensuring both theoretical soundness and practical applicability.

1) Participants: This stage engaged two categories of participants to capture complementary perspectives. The expert category included five purposively selected individuals, each holding a doctoral degree in a relevant discipline, with at least five years of professional or research experience in tourism development, immersive technology, or cultural communication, and recognized contributions such as publications, funded projects, or leadership roles. The stakeholder category comprised 120 participants recruited through a multi-stage sampling process. First, Thailand's four geographical regions—North, Central and East, Northeast, and South—were identified. Next, provincial tourism promotion units within each region were targeted. Finally, thirty participants from each region, including government officials, administrators, and practitioners directly engaged in tourism promotion, were selected.

2) Instruments: Separate instruments were employed for experts and stakeholders, each tailored to its respondent group. Both used a five-point Likert scale (1 = Strongly Disagree, 2 = Disagree, 3 = Neutral, 4 = Agree, and 5 = Strongly Agree). The expert evaluation form consisted of twelve items corresponding to the four phases of the model—Discover, Design, Develop, and Deploy—focusing on practicality, clarity, and policy alignment. The stakeholder survey was divided into two parts: the first part collected demographic and contextual information, and the second part measured six independent variables, namely Technological Self-Efficacy (X_1), Attitude towards Technology in Tourism (X_2), Facilitating Conditions (X_3), Perceived Accessibility (X_4), Perceived Interactivity (X_5), and Perceived Tourism Benefits (X_6), as well as one dependent variable, Behavioral Intention to Use the Model (Y). These constructs were adapted from previously validated studies [15–19] and contextualized for Thai tourism. Both instruments were pilot-tested with thirty respondents, and their quality was confirmed through expert review (CVI ≥ 0.90) and reliability analysis (Cronbach's alpha ≥ 0.80) [25].

3) Data collection procedures: Experts were contacted individually and asked to complete the evaluation form within two weeks. Stakeholders were surveyed in collaboration with regional tourism offices and networks, using both online and in-person administration depending on accessibility. Data collection lasted for one month. Informed consent was obtained from all participants, and confidentiality as well as voluntary participation were assured.

4) Data analysis: Data from the expert group (n = 5) were analyzed using descriptive statistics, including means and standard deviations, combined with qualitative synthesis. Inferential analysis was avoided due to the small sample size. Data from the stakeholder group (n = 120) were analyzed using both descriptive and inferential statistics. Descriptive statistics were applied to summarize responses, Pearson's correlation was used to examine relationships among variables, and Multiple Regression Analysis (MRA) was performed to identify predictors of behavioral intention (Y) from the six independent variables (X_1–X_6). Prior to regression, assumptions were tested for linearity, independence of errors, normality, homoscedasticity, and multicollinearity, with thresholds set at VIF < 10 and Tolerance > 0.1. Sample size adequacy was established based on Green's rule of 15–20 cases per predictor [26], confirming that the sample of 120 participants was sufficient.

5) Ethical considerations: This study adhered to the Declaration of Helsinki, the Belmont Report, the CIOMS Guidelines, and the ICH-GCP framework. Ethical approval was obtained from the Human Research Ethics Committee of Rajamangala University of Technology Thanyaburi, Thailand (COA No. 73, RMUTT_REC No. Exp 73/68) through an expedited review on July 7, 2025. All participants provided written informed consent, with full rights to withdraw at any stage.

VI. Results

A. The Key Components of the Conversational AI-Powered VR Development Model

The conceptual foundation of the Conversational AI-powered VR Development Model for tourism promotion in Thailand was derived from a synthesis of international and local scholarship in virtual tourism, artificial intelligence, human–computer interaction, and cultural experience design. Based on this review, the model is structured around three interrelated domains—Virtual Reality, Conversational AI, and Human-Centered Design—supported by five enabling capitals that ensure sustainable implementation within Thailand's tourism ecosystem.

Virtual Reality (VR) functions as the primary medium for immersive destination simulation. The literature identifies three levels of immersion—non-immersive, semi-immersive, and fully immersive—with the latter two proving most effective in strengthening spatial presence and influencing travel intention [27–29]. Core components include 3D environmental modelling [52], the integration of cultural content, and multisensory feedback systems [30–32]. Scenario design plays a critical role in tourism applications, where meaningful storytelling enhances emotional engagement with cultural landmarks and traditions [33].

Conversational AI adds an intelligent, interactive layer that facilitates real-time dialogue through natural language processing (NLP), automatic speech recognition, and context-aware dialogue management [34], [35]. These capabilities enable virtual agents to act as culturally aligned local guides, providing personalised and linguistically appropriate recommendations [36], [37]. Research highlights that conversational flow should reflect national etiquette, local expressions, and culturally rooted storytelling in order to resonate with diverse audiences [38], [39].

The human-centered design domain focuses on user engagement, perception, and emotional response. This includes modelling diverse tourist personas, designing accessible interfaces, and applying affective strategies to sustain attention [40], [41]. Emphasis on privacy, inclusivity, and cultural accuracy is essential to building trust and ensuring respectful experiences [42], [43]. In the Thai context, systems must not only deliver visual appeal but also convey the symbolic and cultural depth of places, people, and traditions.

Supporting these domains are five enabling capitals identified in tourism innovation literature: human capital (skills and expertise), cultural capital (traditions and narratives), technological capital (infrastructure and platforms), information capital (user data and content libraries), and financial capital (public and private investment) [44–46]. Together, these resources form the foundation for sustainable development, scalability, and policy alignment in Thailand's digital tourism initiatives.

B. The Proposed Model for Tourism Promotion in Thailand

The Conversational AI-powered VR Development Model, hereafter referred to as the 4Ds Model, was developed and validated during Stage II of this study. It comprises four

structured phases—Discover, Design, Develop, and Deploy—as illustrated in Fig. 1. The model translates insights from the synthesis of Stage I into a practical framework, refined through expert input to ensure theoretical grounding, contextual relevance, and alignment with Thailand's public-sector tourism promotion priorities.

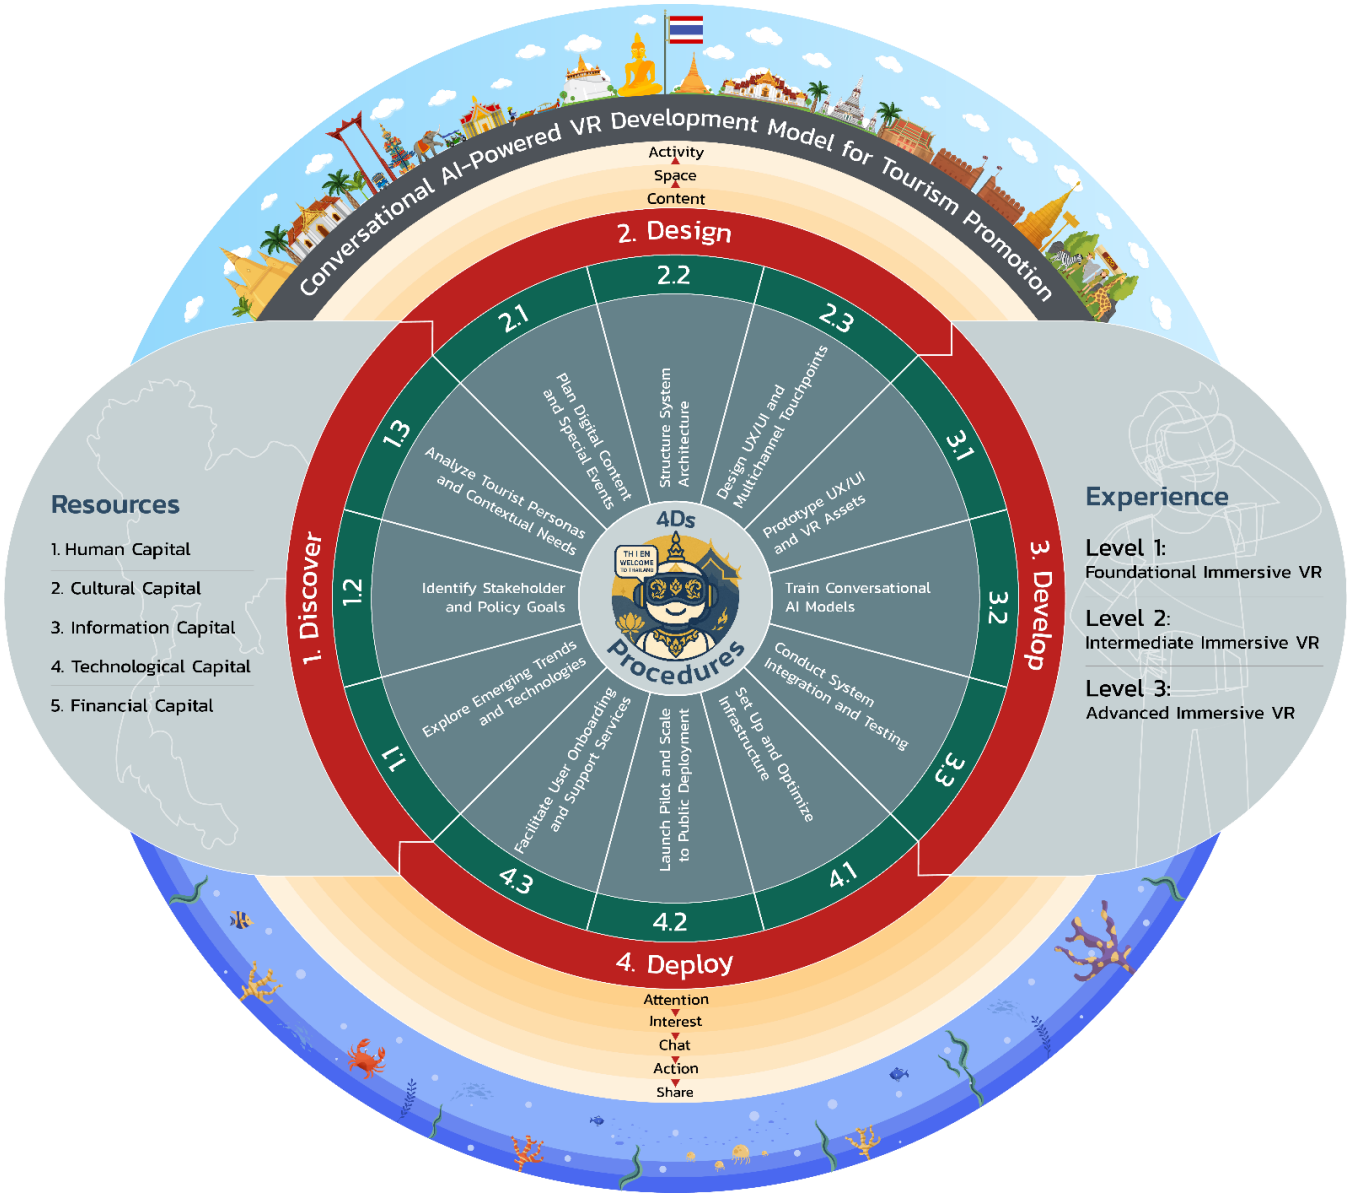

Fig. 1. The conversational AI-powered VR development model for tourism promotion in Thailand.

The Conversational AI-powered VR Development Model for Tourism Promotion in Thailand is structured into four principal phases, comprising a total of twelve systematically organized sub-steps, as follows:

1) Discover (D1): This phase focuses on strategic and contextual exploration to ensure that immersive technology development aligns with stakeholder priorities and destination-specific needs. It involves considering the availability and readiness of five enabling capitals—human, cultural, technological, informational, and financial—while also identifying target user personas and tourism communication goals. This ensures that subsequent phases are grounded in real-world constraints and opportunities. It comprises three sub-steps:

a) Explore emerging trends and technologies: To investigate recent developments in virtual reality, conversational AI, and digital tourism innovations.

b) Identify stakeholder and policy goals: To review national/local tourism policies and align digital initiatives with governmental priorities.

c) Analyze tourist personas and contextual needs: To understand target tourist segments, their motivations, behaviors, and cultural expectations.

2) Design (D2): This phase emphasizes conceptual planning and experience architecture across three core dimensions: content, space, and activity. It translates insights from the Discover phase into an actionable blueprint, detailing narrative structure, spatial navigation, and interactive elements that reflect cultural heritage. The design ensures that immersive tourism experiences are coherent, contextually meaningful, and engaging. It comprises three sub-steps:

a) Plan digital content and special events: To design thematic narratives and cultural programming across physical, digital, and hybrid formats.

b) Structure system architecture: To define the platform's modules, integration flow, and interaction logic.

c) Design UX/UI and Multichannel Touchpoints: To develop user interfaces and engagement pathways across devices and formats.

3) Develop (D3): This phase involves the technical realization of the system, including asset creation, system integration, and iterative testing. It operationalizes three progressive levels of immersive experience—foundational, intermediate, and advanced—each tailored to different user expectations and technological capabilities. It also includes training conversational AI agents to support real-time user interaction. It comprises three sub-steps:

a) Prototype UX/UI and VR assets: To produce visual, spatial, and interactive elements reflecting cultural context.

b) Train conversational AI models: To develop and localize intelligent agents capable of multilingual, context-aware interaction, ensuring that users from diverse linguistic backgrounds—such as Thai, English, Chinese, and regional ASEAN languages—can access tourism content seamlessly. This involves training models not only to handle literal translation but also to adapt cultural nuances, idiomatic expressions, and domain-specific terminology, thereby supporting inclusive, natural, and contextually appropriate communication across different audiences.

c) Conduct system integration and testing: To combine all components into a working prototype and evaluate its functionality and usability.

4) Deploy (D4): This final phase focuses on implementation, public rollout, and ongoing engagement. It adopts the AICAS strategy—Attention, Interest, Chat, Action, and Share—adapted from the AISAS model (Attention, Interest, Search, Action, Share) [47], [48]. In this adaptation, Search is replaced with Chat to reflect dialogic, real-time inquiry within conversational AI–enabled VR environments, where users obtain information through natural-language interaction rather than traditional keyword search. This modification aligns the engagement funnel with CAI-led user journeys while preserving the intent of the original AISAS framework. It comprises three sub-steps:

a) Set up and optimize infrastructure: To ensure technical readiness and system reliability for public deployment.

b) Launch pilot and scale to public deployment: To initiate small-scale trials and refine before wide release.

c) Facilitate user onboarding and support services: To provide orientation, assistance, and ongoing user engagement support.

C. The Suitability of the Proposed Model from Expert Perspectives

Five experts were invited to evaluate the overall suitability of the proposed 4Ds Model for tourism promotion in Thailand, focusing on its twelve sub-steps across the four phases. Their assessments reflected perceptions of the clarity, relevance, and appropriateness of each sub-step within the Thai tourism context. As shown in Table I, mean scores ranged from 4.40 to 4.80, with an overall mean of 4.55. Although these results are based on a small expert panel (n = 5) and should therefore be interpreted as indicative rather than generalizable, the standard deviations remained consistent at 0.53, suggesting strong agreement among the experts.

TABLE I. THE SUITABILITY OF THE CONVERSATIONAL AI-POWERED VR DEVELOPMENT MODEL FOR TOURISM PROMOTION

Assessment Items		M	SD	Suitability Level
Phase	**Sub-steps**			
1. Discover (D1)	1.1 Explore Emerging Trends and Technologies	4.40	0.55	Agree
	1.2 Identify Stakeholder and Policy Goals	4.60	0.55	Strongly Agree
	1.3 Analyze Tourist Personas and Contextual Needs	4.40	0.55	Agree
2. Design (D2)	2.1 Plan Digital Content and Special Events	4.60	0.55	Strongly Agree
	2.2 Structure System Architecture	4.60	0.55	Strongly Agree
	2.3 Design UX/UI and Multichannel Touchpoints	4.40	0.55	Agree
3. Develop (D3)	3.1 Prototype UX/UI and VR Assets	4.40	0.55	Agree
	3.2 Train Conversational AI Models	4.80	0.45	Strongly Agree
	3.3 Conduct System Integration and Testing	4.60	0.55	Strongly Agree
4. Deploy (D4)	4.1 Set Up and Optimize Infrastructure	4.40	0.55	Agree
	4.2 Launch Pilot and Scale to Public Deployment	4.80	0.45	Strongly Agree
	4.3 Facilitate User Onboarding and Support Services	4.60	0.55	Strongly Agree
Overall		4.55	0.53	Strongly Agree

Qualitative feedback reinforced these quantitative results. Experts particularly highlighted the Design phase, which they valued for its structured articulation of content modules, spatial navigation, and interaction logic, and the Deploy phase, which was praised for operationalizing the AICAS strategy (Attention, Interest, Chat, Action, Share) that reflects dialogic, real-time engagement in CAI–VR environments. Collectively, these judgments indicate that the 4Ds Model is conceptually robust, technically coherent, and contextually applicable to Thailand's tourism promotion efforts. Experts further emphasized that the model's flexible procedures make it adaptable across six categories of tourist attractions: 1) wellness and lifestyle tourism (e.g., spas, retreats, health resorts); 2) cultural and heritage tourism (e.g., temples, historical parks, historical museums); 3) nature and ecotourism (e.g., national parks, marine reserves); 4) creative and community-based tourism (e.g., local crafts, village experiences); 5) educational or edutainment tourism (e.g., zoos, aquariums, science centers); and 6) academic and medical tourism (e.g., universities, teaching hospitals, specialty clinics).

D. The Descriptive Statistics and Correlation Analysis of Stakeholders' Responses

A total of 120 stakeholders participated in the survey, comprising 73 females (60.83%) and 47 males (39.17%). Their ages ranged from 18 to 63 years, with a mean of 28.15 years (SD = 10.96) and a median of 24 years, indicating that the majority were young to middle-aged adults. In terms of educational attainment, most respondents held a bachelor's degree (59.17%), followed by those with a master's degree (30.83%) and a doctoral degree (10.00%).

With respect to occupation, the largest group consisted of public-sector tourism officers and staff in provincial tourism promotion units (45.00%). They were followed by private-sector tourism professionals such as tour guides, hotel staff, and travel agency operators (35.00%), and by media professionals or content creators specializing in tourism promotion (20.00%). This composition reflects a balanced mix of public officials, private-sector practitioners, and communication agents, consistent with the study's emphasis on stakeholder perspectives rather than tourists.

Regarding prior experience with technology in tourism, most respondents had never used VR (40.83%), while others had used it once (26.67%), two to three times (20.83%), or four to five times and above (11.67%). In contrast, AI applications for tourism were more widely adopted: 39 respondents (32.50%) had never used them, 28 (23.33%) had used them once, 31 (25.83%) had used them two to three times, and 22 (18.33%) had used them four to five times or more.

The descriptive statistics and Pearson's correlation coefficients of the stakeholder survey responses are presented in Table II. The results show that the mean values of the independent variables ranged from 4.19 to 4.47, while the dependent variable— Behavioral Intention to Use the Conversational AI-powered VR Development Model — had a mean score of 4.33 (SD = 0.65). As all means were above the scale midpoint (3), this indicates a consistently high level of acceptance toward the proposed model among stakeholders. Furthermore, all independent variables were positively and significantly correlated with behavioral intention (Y). The strongest correlations with Y were observed for Perceived Interactivity (r = .806), Perceived Tourism Benefits (r = .800), and Perceived Accessibility (r = .721). Although some intercorrelations were relatively high (e.g., X_5 and X_6), none exceeded problematic thresholds, suggesting that multicollinearity was not severe at this stage. It should also be noted that correlation analysis does not establish causality but provides a statistical foundation for subsequent regression testing.

TABLE II. THE DESCRIPTIVE STATISTICS AND CORRELATION MATRIX

Variable	M	SD	X1	X2	X3	X4	X5	X6	Y
1. Technological Self-Efficacy (X_1)	4.20	0.54	1						
2. Attitude towards Technology in Tourism (X_2)	4.47	0.47	.500	1					
3. Facilitating Conditions (X_3)	4.19	0.64	.596	.438	1				
4. Perceived Accessibility (X_4)	4.28	0.60	.534	.546	.741	1			
5. Perceived Interactivity (X_5)	4.28	0.57	.591	.537	.785	.802	1		
6. Perceived Tourism Benefits (X_6)	4.32	0.54	.517	.510	.675	.741	.821	1	
7. Behavioral Intention to Use the Conversational AI-powered VR Development Model (Y)	4.33	0.65	.602	.509	.703	.721	.806	.800	1

E. Assumption Testing for Multiple Regression

Regression assumptions were tested prior to model estimation. The Durbin–Watson statistic was 1.70, confirming independence of errors. The Shapiro–Wilk test ($p < .001$) indicated some deviation from perfect normality; however, given the adequate sample size (n = 120), residuals were approximately normally distributed, as supported by histogram and Q–Q plots. This meets the robustness criteria for regression with moderate to large samples [49], [50].

Homoscedasticity was supported by residual plots showing no funnel pattern. Variance Inflation Factor (VIF) values ranged between 1.61 and 5.05, below the threshold of 10, indicating no serious multicollinearity, though X_5 showed relatively higher collinearity. Overall, the assumptions were sufficiently met.

F. Multiple Regression Results

As presented in Table III, the multiple regression model significantly predicted stakeholders' behavioral intention to use the Conversational AI-powered VR Development Model, $F(6, 113) = 51.689$, $p < .001$. The six predictors together explained 73.3% of the variance in behavioral intention ($R^2 = .733$), with an adjusted R^2 of .719, indicating strong explanatory power of the model within this dataset.

TABLE III. MODEL SUMMARY OF MULTIPLE REGRESSION

R	R^2	Adjusted R^2	F	Sig. (p)
.856	.733	.719	51.689	< .001

TABLE IV. REGRESSION COEFFICIENTS OF PREDICTORS ON BEHAVIORAL INTENTION TO USE THE CONVERSATIONAL AI-POWERED VR DEVELOPMENT MODEL

Predictor	B	SE	Beta	t	Sig.	95% CI for B	VIF
Constant	-0.507	0.33	–	-1.54	.129	[-1.16, 0.15]	–
1. Technological Self-Efficacy (X_1)	0.174	0.077	0.146	2.25	.027*	[0.02, 0.33]	1.78
2. Attitude towards Technology in Tourism (X_2)	0.029	0.085	0.021	0.34	.736	[-0.14, 0.20]	1.61
3. Facilitating Conditions (X_3)	0.085	0.087	0.084	0.98	.328	[-0.09, 0.26]	3.07
4. Perceived Accessibility (X_4)	0.068	0.097	0.063	0.70	.484	[-0.12, 0.25]	3.40
5. Perceived Interactivity (X_5)	0.313	0.124	0.277	2.53	.013*	[0.07, 0.55]	5.05
6. Perceived Tourism Benefits (X_6)	0.461	0.106	0.384	4.36	.000***	[0.25, 0.67]	3.29

Note: *p < .05, ***p < .001

As shown in Table IV, three variables emerged as significant predictors: Technological Self-Efficacy (X_1), Perceived Interactivity (X_5), and Perceived Tourism Benefits (X_6). The remaining predictors—Attitude towards Technology in Tourism (X_2), Facilitating Conditions (X_3), and Perceived Accessibility (X_4)—did not reach statistical significance.

The regression equation is presented in Eq. (1):

$$Y = 0.507 + 0.174X_1 + 0.029X_2 + 0.085X_3 + 0.068X_4 + 0.313X_5 + 0.461X_6 \quad (1)$$

where, Y represents behavioral intention, X_1 denotes technological self-efficacy, X_2 denotes attitude towards technology in tourism, X_3 denotes facilitating conditions, X_4 denotes perceived accessibility, X_5 denotes perceived interactivity, and X_6 denotes perceived tourism benefits.

A simplified model with only significant predictors is shown in Eq. (2):

$$Y = 0.507 + 0.174X_1 + 0.313X_5 + 0.461X_6 \quad (2)$$

From the stakeholder perspective, multiple regression analysis indicated that X_1 (technological self-efficacy), X_5 (perceived interactivity), and X_6 (perceived tourism benefits) were significant predictors of Y (behavioral intention). Collectively, these three factors accounted for 73.3% of the variance in behavioral intention, demonstrating the model's strong explanatory power and practical relevance for tourism promotion in Thailand. However, the findings should be interpreted as context-specific evidence drawn from the surveyed stakeholder group—public-sector tourism officers, destination management professionals, and provincial tourism practitioners—and therefore may not be directly generalizable to tourists or to broader populations beyond the study sample.

VII. DISCUSSION

This study set out to design, validate, and evaluate the Conversational AI-powered VR Development Model for tourism promotion. The results provided convergent evidence across expert evaluations and stakeholder responses, confirming both theoretical soundness and practical feasibility. In the following discussion, the findings are organized around the four research questions (RQ1 to RQ4) and further interpreted in relation to existing theories and empirical studies in VR, AI, and technology adoption.

Addressing RQ1, which investigated the key components of the model, the study confirmed that the Conversational AI-powered VR Development Model can be systematically structured around three interrelated domains—Virtual Reality, Conversational AI, and Human-Centered Design—supported by five enabling capitals: human, cultural, technological, informational, and financial. This configuration echoes the systematic reviews of Calisto and Sarkar [11] and Mariani et al. [34], who highlighted the need for integrated frameworks that unify immersive technologies with user-centered design principles, and resonates with broader system design methodologies that emphasize iterative cycles of requirements analysis, architectural specification, and prototyping [22], [37]. A distinctive feature of the model is its explicit articulation of three progressive levels of immersion—non-immersive, semi-immersive, and fully immersive—corresponding respectively to foundational, intermediate, and advanced experiences. This dual framing bridges technical VR typologies with operational deployment categories, aligning with Slater and Sanchez-Vives [28] and with Anaya-Sánchez et al. [51], who empirically demonstrated that immersion moderates the impact of VR experiences on destination image and visit intentions. Furthermore, the model structures immersive experiences across content, space, and activity dimensions, offering developers a blueprint that is both flexible and technically rigorous, ensuring applicability across diverse organizational and user contexts [15], [16].

In relation to RQ2, which examined theoretical validity, both content validity testing and expert review indicated strong soundness (I-CVI≥ .80; S-CVI/Ave = .94), following guidelines by Yusoff [25]. Experts noted that the phased, modular structure is consistent with Thailand's policy directions for technology-enhanced tourism promotion. This contextual applicability reflects Wu and Zhang [39], who emphasized that immersive technologies must reflect policy and cultural conditions to achieve sustainable adoption. It also resonates with Guttentag [10] and Phoong et al. [29], who stressed that VR initiatives must consider real-world constraints and tourism development trajectories to evolve from novelty to mainstream adoption. By embedding system design within both technological and policy

contexts, the 4Ds Model demonstrates theoretical rigor while preserving contextual relevance.

For RQ3, concerning suitability, experts rated the model highly across phases (M = 4.55, SD = 0.53). The Design phase was valued for its structured articulation of content modules, spatial navigation, and interaction logic, consistent with UX principles in VR system design [37], [42]. The Deploy phase was praised for operationalizing the AICAS strategy (Attention, Interest, Chat, Action, Share), adapted in this study from the AISAS model originally proposed by Dentsu [47]. By substituting "Search" with "Chat," the model reflects dialogic, real-time inquiry in CAI–VR environments. These judgments are reinforced by Anaya-Sánchez et al. [51], who confirmed that the clarity of immersive structuring and intensity directly shape user perceptions of destination image and travel intention. Similarly, these technical elements are consistent with Rafi et al. [31], who demonstrated that navigability and UI quality strongly influence behavioral outcomes, and with Calisto and Sarkar [11], who underscored the necessity of embedding interactivity into coherent system architectures.

Turning to RQ4, the findings revealed high stakeholder intention to adopt the model (M = 4.33, SD = 0.65) among both public-sector officials and private-sector practitioners. Regression analysis identified technological self-efficacy, perceived interactivity, and perceived tourism benefits as significant predictors, collectively explaining 73.3% of the variance ($R^2 = .733$). These predictors align with Davis [15] on TAM, Venkatesh et al. [16] on UTAUT, and the self-efficacy construct developed by Compeau and Higgins [19] and later refined by Compeau et al. [21]. They also echo Anaya-Sánchez et al. [51], who showed that perceived immersion strengthens both destination image and behavioral intention, underscoring why interactivity and perceived benefits emerged as significant predictors in this study. Together, these findings confirm that stakeholder acceptance of the 4Ds Model is firmly grounded in both classical and contemporary theories of technology adoption.

Beyond answering the research questions, this study contributes more broadly to academic discourse and system design practice. Theoretically, it integrates VR, CAI, and human-centered design into a unified process model that links requirements analysis, architectural specification, iterative development, and deployment strategy, consistent with system design methodologies [22], [37]. This integration responds to Mariani et al. [34] and Slater and Sanchez-Vives [28], who emphasized bridging immersive depth with structured frameworks. Practically, the 4Ds Model provides policymakers and developers with a technically actionable roadmap to translate contextual needs into architectural components, immersive experiences, and engagement strategies. Its graded immersion levels [28], [51] and conversational engagement design [47], [48] illustrate operational feasibility while preserving adaptability across contexts.

Nevertheless, limitations remain. The stakeholder survey excluded tourists, limiting direct insights into consumer adoption. While the sample was adequate for regression analysis [26], broader sampling across diverse user groups would strengthen generalizability. Future research should conduct pilot implementations across Thailand's four regions to test system performance, scalability, and integration with analytics platforms [29], [31]. Parallel prototyping with tourists as end-users will provide usability evidence, while cross-border application in ASEAN will test adaptability across diverse cultural and policy environments.

VIII. Conclusion

This study proposed the Conversational AI-powered VR Development Model, referred to as the 4Ds Model, as a structured framework for integrating immersive technologies into Thailand's tourism promotion. The model integrates conversational AI, virtual reality, and human-centered design, supported by five enabling capitals: human, cultural, technological, informational, and financial. It is organized into four sequential phases—Discover, Design, Develop, and Deploy—comprising twelve sub-steps. Specifically, the Discover phase mobilizes enabling capitals to ensure contextual readiness; the Design phase structures experiential elements across content, space, and activity; the Develop phase specifies immersion levels and operationalizes interactive features; and the Deploy phase incorporates the AICAS strategy (Attention, Interest, Chat, Action, Share) to sustain engagement through conversational interaction.

The key contribution of this study lies in establishing a unified, culturally grounded framework that bridges conversational AI and virtual reality for digital tourism development in Thailand. The findings confirm that the 4Ds Model is both theoretically robust and practically applicable. Expert evaluations underscored its contextual relevance, while assessments by public-sector tourism officers, destination management professionals, and practitioners in provincial tourism units indicated strong acceptance. Regression analysis revealed that technological self-efficacy, perceived interactivity, and perceived tourism benefits significantly predict stakeholders' behavioral intention to adopt the model.

Theoretically, this research advances digital tourism and AI–VR integration literature by articulating how immersive communication and user-centered design can co-exist in culturally sensitive contexts. Practically, it provides policymakers and practitioners with a replicable roadmap for designing, implementing, and sustaining immersive tourism initiatives that reflect local identity and community values.

Nevertheless, the study acknowledges certain limitations, including the representativeness of the expert sample, the limited scope of stakeholder testing, and the absence of longitudinal validation in real-world deployments. Future research should pilot and refine the 4Ds Model in live tourism projects, explore cross-cultural applicability within ASEAN, and integrate emerging AI capabilities such as generative agents and multimodal interfaces. Thus, the 4Ds Model serves not only as a validated framework for Thailand's digital tourism transformation but also as a transferable reference for immersive tourism innovation across the ASEAN region.

Acknowledgment

This research was supported by the National Science, Research and Innovation Fund, Thailand Science Research and Innovation (TSRI), through Rajamangala University of

Technology Thanyaburi (FRB67E0913) (Grant No. FRB670027/0168). The authors also gratefully acknowledge Mahidol University for their valuable support in providing personnel and access to critical research databases.

APPENDIX: QUESTIONNAIRE REGARDING FACTORS INFLUENCING THE INTENTION TO USE THE CONVERSATIONAL AI-POWERED VR DEVELOPMENT MODEL FOR TOURISM PROMOTION IN THAILAND

Instructions: Before completing this questionnaire, respondents were required to watch a short video presentation introducing the Conversational AI-Powered VR Development Model for Tourism Promotion in Thailand. The video outlined the model's purpose, structure, and potential applications to ensure that participants clearly understood the context before responding. Responses were measured on a 5-point Likert scale: 1 = Strongly Disagree, 2 = Disagree, 3 = Neutral, 4 = Agree, 5 = Strongly Agree.

Variable	Item	Scale
Part 1: General Information		
Demographics	Gender, Age, Region, Education, Occupation, Experience with VR, Experience with AI	Categorical
Part 2: Independent Variable (IV)		
Technological Self-Efficacy (X1)	1. I am confident that I can learn to use new technologies on my own. 2. I can troubleshoot basic technical problems when using devices or software. 3. I can apply technology to support my work or activities. 4. I believe that I have sufficient skills to maximize the benefits of technology. 5. I can adapt quickly to technological changes.	1–5
Attitude towards Technology in Tourism (X2)	1. I believe technology makes tourism more attractive. 2. I feel that technology use in tourism should be encouraged. 3. I have a positive view of integrating technology into tourism businesses. 4. I think technology enhances tourism experiences in Thailand. 5. I support the use of technology in tourism promotion.	1–5
Facilitating Conditions (X3)	1. My organization has the necessary devices (e.g., computers, VR headsets). 2. My organization provides sufficient internet connectivity for smooth system use. 3. I receive technical support when needed. 4. My organization offers training or manuals to learn how to use technology. 5. My organization encourages the use of technology in tourism work.	1–5
Perceived Accessibility (X4)	1. The Conversational AI-powered VR system can be accessed anytime and anywhere for tourism purposes. 2. The system is easy to use for tourism personnel. 3. I can use the system even with limited technical knowledge. 4. The system can be accessed through multiple devices for tourism experiences. 5. The system requires minimal time to start using in tourism work.	1–5
Perceived Interactivity (X5)	1. The system interacts appropriately when presenting tourism information. 2. The system responds immediately to my actions. 3. Using the system feels like two-way communication between providers and tourists. 4. The system can adjust content based on tourist behaviors or interests. 5. The system makes tourism experiences more realistic and engaging.	1–5
Perceived Tourism Benefits (X6)	1. The system increases the attractiveness and value of destinations. 2. The system helps tourists decide on destinations more easily. 3. The system allows providers to deliver more in-depth information to customers. 4. The system motivates actual visits and service use. 5. The system supports tourism revenue and sustainable community development.	1–5
Part 3: Dependent Variable (DV)		
Behavioral Intention to Use (Y)	1. I am interested in learning more to develop skills for using the system effectively. 2. I intend to use the system to support my tourism-related work in the future. 3. I plan to continuously use the system in my organization if given the opportunity and resources. 4. I am committed to applying the system to enhance tourist experiences. 5. I would recommend the system to partners or networks in the tourism industry.	1–5

Roadmap for Emerging Cyberbullying Mitigation: Integrating AI-Based Solutions, Ethics, and Policy

***Abstract*—Cyberbullying is one of these challenges that are most found among the younger users of social media which affects the mental health. Artificial Intelligence (AI) is rapidly developing and has enormous potential to mitigate cyberbullying. Therefore, this chapter will talk about the role AI has started playing in strengthening the efforts to combat cyberbullying. Cyberbullying includes all forms of deliberate aggressive behaviour that aims to inflict social, psychological or physical pain in a digital space and AI detection technologies have a lot of potential to detect, predict and prevent cyberbullying in real time. Other critical components of the chapter are how the advances in Natural Language Processing (NLP) technologies, machine learning, images and videos, behavioural analytics make AI an emerging innovation to prevent cyberbullying and provide better services in a timely manner. There are positive trends that make it clear how Safer AI can help in improving the safety of future digital environments. More advanced NLP models will be able to identify the nuances of cyberbullying involving indirect attacks and sarcasm. The chapter will also discuss the hazards associated with AI-based solutions, such as privacy, the zero-sum game of AI morality against AI effectiveness, and the importance of explaining and assigning responsibility for every AI decision. It shows how AI is changing our approach to online safety and helps us identify cyberbullying in a variety of media, including text, video and images. This article gives an overview of roadmap for cyberbullying mitigation with the assistance of AI and ethical practices.**

Keywords*—*Cyberbullying; human computer interaction; artificial intelligence; natural language processing; machine learning; content moderation; predictive analytics; online safety; youth protection; mental health; mental illness; cybercrime

I. Understanding Cyberbullying

A. Definition and Categories of Cyberbullying

Cyberbullying is the intentional use of internet communication to harass, menace or humiliate another person. Unlike conventional bullying, cyberbullying originates in the digital space and is thereby widespread and persistent since it can cross boundaries of geography and time [1]. Anonymity of online sites can sometimes give abusers more confidence. Lack of face-to-face contact makes the problem worse because the offenders may not consider the emotional impact of their actions on the victim.

Several studies have looked into the issue in depth; others have broken down the broad term "cyberbullying" into specific types including flaming, harassment, impersonation, cyberstalking, flooding, masquerade, denigration, outing and stalking [2,3].

1) Sending offensive or threatening messages repeatedly is harassment. For example, sending hate emails or messages every day.

2) Flaming means participating in rude internet arguments. For instance, commenting offensive things in comment sections.

3) Impersonation is when you assume the identity of another person to harm their reputation. For example, setting up a fake social media account and posting inappropriate content under someone else's name.

4) Cyberstalking is when you continuously monitor or follow someone online with malicious intent to intimidate or control them from their social media activity.

5) Flooding in digital worlds is when someone sends too many unwanted messages, emails or comments to someone. Intended to scare, annoy or silence the target, this is another form of harassment.

6) Masquerade is when someone pretends to be another online to damage relationships or reputation. This can be creating fake profiles, forwarding damaging messages pretending to be someone else, or acting dishonestly to undermine the trust or reputation of the victim.

7) Denigration is the spreading of false or defamatory online information to discredit someone. This can be abusive comments, lies or gossip sent on posts, comments or messages.

8) Outing is when you publicly share private, sensitive or personal information without consent. This can affect the victim's personal or professional life or shame and distress.

9) Cyberstalking is continuous, invasive monitoring or harassment of a person online. It usually means monitoring the victim's activity, sending continuous negative messages or instilling fear through digital means.

*Corresponding authors.

B. Social, Psychological and Physical Effects of Cyberbullying in Digital Spaces

Cyberbullying has a huge impact on people's social, psychological and physical lives [4]. Often those who are socially isolated retreat from both online and offline events because of fear of being ridiculed or more harassment. This disengagement can ruin personal and professional reputation, and affect jobs and social networks and other areas. You can find many more negative psychological effects. Many times, victims suffer from low self-esteem, anxiety and depression. Studies show that cyberbullying victims show symptoms of depression twice as much as non-victims [5]. Persistent long-term stress from cyberbullying can lead to mental health problems like headaches, fatigue, sleep disturbances, high blood pressure and heart conditions. Extreme cyberbullying can increase the risk of suicidal thoughts and self-harm especially in younger population. In extreme cases cyberbullying has led to suicides [6].

These social, psychological and physical effects are more harmful to vulnerable groups, that's why we need to address and prevent cyberbullying to protect ourselves.

C. Impact of Cyberbullying on Younger Social Media Users

Cyberbullying is particularly common among younger social media users, such as teens and preteens, due to their developmental stage and reliance on social recognition [7]. Negative online interaction can have a significant impact on such individuals. Bullied children may skip school to avoid encountering their oppressors, which could result in a decline in academic performance and an increase in absenteeism [8]. Negative online behaviour including creating fake profiles to avoid being found out could be due to fear of rejection or exclusion. Teenagers' growing brains make them more susceptible to mental illness from internet addiction [9]. Public humiliation on sites like Instagram can totally crush people's self-esteem. Studies show that because of its focus on visual content and social validation, sites like Instagram and TikTok are hotspots for cyberbullying [10,11]. A 2021 survey found that almost 60% of kids said they experienced some form of online harassment [12].

D. Current Global Efforts to Combat Cyberbullying

Among the many approaches to cyberbullying are legislative actions, technological innovations, educational programs and support systems. These programs help victims and reduce online abuse.

Legislative actions are needed to combat cyberbullying globally and nationally. The US, UK and Australia have already passed laws on this. The Australian "e-Safety Commissioner" can help reduce online abuse by removing harmful internet content [13]. Meanwhile the European Union's Digital Services Act has a comprehensive plan to increase member internet security. This proposal requires online platforms to limit harmful content so they are accountable in keeping the digital space healthy [14,15].

Partially technology has helped reduce cyberbullying. On social media networks like Facebook, content moderation tools and reporting mechanisms allow users to flag objectionable content. Facebook uses artificial intelligence to aggressively search for hate speech and inflammatory language [16]. Meanwhile artificial intelligence-powered platforms like Rethink give consumers quick cues to rethink before they share potentially dangerous content [17].

The fight against cyberbullying is mostly focused on educational activities. Non-governmental organisations (NGOs) and educational institutions are implementing projects to increase digital literacy and empathy among young people. The "Delete Cyberbullying" project teaches teens about the effects of online harassment (https://www.endcyberbullying.net/). Meanwhile events like Safer Internet Day brings together educators, politicians and tech companies to discuss practical solutions and raise awareness on cyberbullying.

Support systems are needed for cyberbullying victims to manage their psychological and emotional response to online harassment. Helplines and initiatives like Childline (https://childline.org.uk/) in the UK are available for victims. Meanwhile social media platforms have introduced tools like Instagram's "Restrict" feature which allows users to block interactions with potential attackers so victims have some sense of security [16]. These combined strategies are a total solution to cyberbullying.

E. Limitations of Current Approaches

Despite all the work, current approaches to cyberbullying have big flaws that make them not work. Legislative is a main challenge. Cyberbullying is global, law enforcement projects are across borders. Tracking down anonymous offenders across different countries is a real challenge for law enforcement.

To make it worse, many social media platforms rely on users to report cyberbullying. This means delays in response to incidents [18]. Many times, victims complain about platforms not responding to objectionable content. Many times, algorithms used to detect negative behaviour can't understand context, sarcasm or cultural sensitivity. AI systems can flag innocent banter as harassment so making it harder to detect cyberbullying.

The shame of cyberbullying stops victims from seeking help. Many delay reporting because of fear of being labelled as "oversensitive" or retaliation. This stigma stops victims from getting the help and support they need [13]. Plus, there are no educational initiatives to increase awareness and stop cyberbullying. Many projects don't keep up with the fast pace of digital interactions so new online environments like BeReal don't have enough security and user services. These limitations highlight the need for continuous work to reduce cyberbullying.

F. The Importance/Potential of AI in Mitigating Cyberbullying

As cyberbullying has emerged as a significantly widespread problem, it is required to adopt the efficient detection and prevention measures. Artificial intelligence is essential in tackling cyberbullying. It provides innovative and adaptable solutions that are scalable as well. It facilitates in real-time monitoring and reviewing the content for automated detection and classification of hazardous messages. Thus, assisting in the identification and reduction of cyberbullying events.

Furthermore, AI can also help to increase awareness among digital space to combat with cyberbullying.

This paper discusses the importance of AI in cyberbullying mitigation in Section I followed AI-powered solutions for prevention of cyberbullying in Sections II and III respectively. The future recommendations and directives have been elaborately discussed in Section IV followed by concluding remarks in Section V.

II. AI-Powered Solutions for Cyberbullying Prevention

AI can be utilized to identify cyberbullying in social networks. It can offer a range of solutions to combat cyberbullying. Such solutions are comprised of real-time detection and intervention, predictive modelling and risk assessment, content moderation and filtering and victim support. Moreover, AI-based educational tools and personalized learning approaches could be incorporated to spread awareness and educate individuals to address such situations and make decisions [19].

AI solutions are made up of text analysis, multimedia content analysis and user behaviour analysis as depicted in Fig. 1. Natural language processing (NLP), machine learning and data mining are used in AI powered cyberbullying solutions. These can help build a robust cyberbullying detection system.

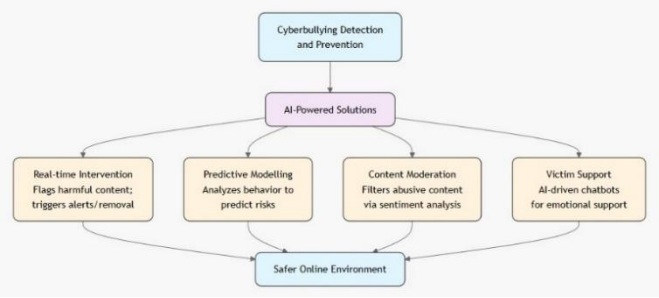

Fig. 1. AI powered solution.

A. Real-Time Intervention Mechanisms

For text analysis, linguistic insights can be extracted using NLP. It will help identify taunts, insults, threats and other harsh or abusive language in the text.

Multimedia content is audio, video and image content so cyberbullying can be detected through various methods. Images and videos can be analysed by AI algorithms involving facial expression recognition, body language analysis, object recognition and image manipulation detection [20]. Audios can be analysed for tone, pitch and volume variation and recognising sound relevant to violence or distress. Combining text, audio and visual indicators in multimodal analysis helps to understand the background and intention of the content [16].

Datamining can help to reveal the broader context of human behaviour to uncover hidden patterns related to cyberbullying. It involves examining user profiles, posting behaviour of the user, interaction pattern and social contacts to identify possible victims or cyberbullies [21].

In this way text messages, online comments and social media posts could be automatically flagged by the AI-powered system. Moreover, several interventions could be triggered to combat cyberbullying like sending alerts to the human reviewers or moderators, warning notifications to the offenders, automatic removal of the hazardous content, connecting the victims to the support channels, helplines or counselling services [22].

B. Predictive Modelling and Risk Assessment

Proactive prevention of cyberbullying relies much on the AI-driven predictive modelling and risk assessment strategies. These strategies observe the online activities and interaction pattern to analyse user behaviour. Based on the analysis, system can predict who would be more likely to engage in cyberbullying as an offender or a victim. Such proactive approach enables platforms to take necessary measures to minimise the damage thus fostering a safer online community.

Machine learning could help to develop predictive models based on predefined labels and large datasets that can classify and detect cyberbullying based on word frequency, the use of particular emojis, or the overall message sentiment [23]. Nevertheless, the scarcity of publicly available dataset, especially having multimedia content and the limitation of several studies based on only textual data poses a significant challenge in the development of cyberbullying detection systems capable of analysing images and videos [20]. Furthermore, there is no standardized definition of cyberbullying and are no specified rules or guidelines for data labelling as well. This could also lead to inefficient cyberbullying detection algorithm.

III. Advances in AI Technologies for Cyberbullying Prevention

Artificial intelligence has emerged as a powerful tool in combating the growing problem of cyberbullying [24]. Recent developments in deep learning and natural language processing have enabled the creation of sophisticated models that can effectively detect and mitigate the impact of cyberbullying incidents [25]. One key area of focus is the use of sentiment analysis and behavioural analytics to identify potential cyberbullying threats. By analysing the tone, context, and language patterns of online interactions, AI-powered systems can flag concerning content and alert authorities or community moderators, allowing for timely intervention.

Moreover, machine learning algorithms have garnered attention for their ability to moderate user-generated content, filtering out harmful or abusive material and curbing the spread of cyber-violence. Beyond detection, AI techniques are being leveraged to enhance the proactive prevention of cyberbullying. Intelligent agents and chatbots, powered by natural language generation, can engage with users at risk, offering emotional support, guidance, and strategies to build resilience.

A. Natural Language Processing (NLP)

1) Text analysis and sentiment analysis: Utilizing NLP techniques to identify bullying language patterns, tone, and context. Recognition and classification of dangerous or abusive content on websites and social media [26]. Creating sophisticated deep learning models to decipher the subtleties of

language used in online conversations, such as transformer models and recurrent neural networks [26]. Although natural language processing has been a major area of interest, scientists are investigating a variety of cutting-edge strategies in the quickly growing field of artificial intelligence for cyberbullying prevention [27].

2) Identifying cyberbullying patterns and language: Examining textual data to find signs of cyberbullying, including aggressive exchanges, derogatory language, and emotional trends [24,26]. Recent developments in deep learning architectures, like transformer models and recurrent neural networks, have shown impressive potential in precisely identifying and categorising cyberbullying content. Researchers have been able to build systems that can detect and distinguish cyberbullying from regular online interactions by using these models with big data [28, 29,56].

3) Recognizing sarcasm and indirect attacks: One of the challenges in detecting cyberbullying is finding indirect or sarcastic forms of harassment which can be more subtle and harder to identify. To detect these more advanced forms of cyber aggression AI powered systems are being developed to detect contextual information and subtle language cues.

To better understand the cyberbullying landscape some studies have looked into multifaceted approaches, combining text analysis with other sources of information like images and videos [24].

B. Machine Learning

Machine learning is being used more and more in risk identification and content moderation to prevent cyberbullying. By looking at user generated content these algorithms can identify and remove offensive or dangerous content and stop cyberviolence from spreading.

By looking at online trends and interactions behavioural analytics has also been explored as a way to predict who will experience cyberviolence. Scientists have looked at various feature sets to develop strong machine learning models for early detection of cyberbullying incidents - content driven, profile based, mobile app data etc [30].

More precise and effective cyberbullying detection systems have been made possible by machine learning. To use the power of neural networks in text data analysis and cyberbullying pattern recognition researchers have tried out various deep learning algorithms - Gated Recurrent Units, Long Short-Term Memory, Bidirectional LSTM.

1) Predictive modelling to prevent cyberbullying: Machine learning-based predictive models were also implemented to the cyberbullying prevention system. These models can help predict people at risk of being-involved in CB from past patterns and information.

Based on this group of at-risk individuals, targeted interventions, such as AI-based interventions, including personalised support, counselling, and education materials, can be provided to help them build resilience and encourage positive online behaviours [25, 30].

One promising approach to address the challenging problem of cyberbully prevention is integrating the proactive intervention techniques and AI-based predictive modelling [29].

2) Data analysis-based methods for user behaviour study: In order to obtain better cyberbullying detection, researchers have been studying data-driven approaches that exploit peer influence and per user feature set beyond the well-known detection and classification strategies. In order to offer a more accurate and personalised detection of cyberbullying, these tailored models can also take into account a user's individual online activity, social media profile and interaction specificity [31].

These AI-based systems can recognize new trends in cyber-heists and also act more quickly by incorporating more granular data about users as well as peer-to-peer dynamics. This could halt the dynamics of the situation from exacerbating and reduce harm to victims [30].

C. Image and Video Analysis

While most AI-based cyberbullying prevention related work has focused on text analysis, it is increasingly recognized that these approaches need to be extended to other modalities, like images and videos. The emerging area of computer vision and multi\-media analysis have been employed by researchers to address visual facets of cyberbullying such as circulation of embarrassing or humiliating images and videos. Deep-learning algorithms also trained on massive numbers of cyberbullying-related photos and videos can help locate and flag harmful media, leading to pre-emptive measures and better content moderation.

AI-powered systems that integrate sophisticated text analysis and visual recognition capabilities provide a more complete method for tackling the complexity of cyberbullying by covering both written and visual aspects [32].

1) Detecting harmful content in multimedia: The increased presence of user-generated multimedia content, such as videos and images, has also provided a new challenge in detecting instances of cyberbullying. To address this issue, researchers have several projects that develop AI solutions to analyse visual data to identify or detect potentially harmful or abusive content. These systems can use various computer vision approaches including object detection, face recognition or detection, and scene understanding to detect and identify images or videos that could potentially be representative of a cyberbullying related incident.

2) Detecting cyberbullying through visual cues (e.g., body language, facial expressions): In addition to identifying harmful media, there are a few AI-powered systems that are currently investigating using visual cues to detect cyberbullying behaviour. By analysing the context, body language, and emotional expressions in images and video, these AI models can be leveraged to identify patterns of behaviour that can act as indicators of cyber-aggression, even when there is no text content [27][57].

The combination of visual-based analysis with a traditional text-based approach may result in a more comprehensive picture of the cyberbullying phenomenon, which can help inform more effective detection and intervention protocols [33].

D. Behavioural Analytics

Behavioural analytics have taken root as an instrumental resource in the prevention of cyberbullying by utilizing AI to assess patterns of online interactions and behaviour. Algorithms focused on behavioural analytics consider the frequency of communication, tone of communication, and social networks, which are valuable predictors of whether individuals are defenceless or if their behaviour is a risk for cyberbullying. The combination of AI-driven behavioural analytics and personalized intervention approaches has potential to empower victims, support positive online communities and encourage citizenship online.

1) Analysing user behaviour patterns to find at-risk cyberbullying victims or perpetrators: Research has been done which aims to harness AI-powered behavioural analytics to discover early warning signs of cyberbullying such as changes in online activities, communications, and social network interactions. AI can help monitor and analyse user behaviour data to discover individuals who may be prone to cyberbullying victimhood or may display concerning behaviours which could escalate into cyber-aggression.

In even a preliminary use of behavioural analytics to detect potential for harm, early identification of these behaviour patterns could facilitate timely interventions with at-risk individuals leading to connection with appropriate supports and resources to help them build resilience and positive online engagement.

2) Tracking digital interactions to identify aggression and conflict: More than just identifying victims and offenders - AI behavioural analytics can be used to track interactions in digital spaces for signs of aggression, conflict, and rising tensions. If AI systems analyse tone, sentiment and dynamics of the digital conversation, they may show early warning signals for cyberbullying so the inventible mechanism can kick in. This proactive data-driven model to moderation and community management can completely alter how we consider - and respond to - cyberbullying and increase levels of acceptability of online spaces.

To summarize, where there is great potential for preventing cyberbullying is through radical data taking using AI-powered solutions. More specifically, there are an unlimited number of opportunities for real-time monitoring of online environments whether through imaginative text analysis methods, multimedia recognitions or through developing personalized behavioural analytics and access to the patterns of users across platforms, AI holds a lot of promise to help detect, prevent, and intervene, when being victimized online [24,25,34].

Practitioners and scientists may want to consider how they can leverage AI in developing digital wellbeing interventions that may result in much more efficient, scalable, and adaptable services. They can also bring some responsibility back to owners of digital spaces to create more inclusive and safer online communities and places where it is safe to innovate [24, 34, 35, 36].

E. Challenges and Considerations

There is tremendous promise in AI-Supported cyberbullying prevention, although researchers and practitioners have found several important challenges and considerations. Among the most important are ethical issues, privacy implications, and needing different disciplines to work together to substantiate responsible and effective uses of these technologies.

F. Privacy Considerations

The collection and analysis of user data for the detection of cyberbullying and for intervention raise serious privacy implications. AI systems need to have strong privacy and security protocols in place to protect personal information, particularly for minors who could be vulnerable to cyberbullying [37].

In order to establish user trust, and ensure compliance with privacy laws, it is important to deliberately consider the processes for collecting, storing, processing, and being transparent and accountable about how data is collected and used by these systems [24].

1) Data collection and use for AI models: When developing AI-based cyberbullying prevention and detection tools, it is often important to collect and analyse user data, such as information from online chats, online social networking communications, and patterns of digital behaviour [38].

This information has to be processed with utmost care and vigilance to protect personal privacy and avoid possible abuse or exploitation—even if it is critical for training and validating these AI systems. In order to ensure that personal information is only used for lawful and ethical purposes, developers and researchers must implement strict data management frameworks that provide clear rules on data collection, user consent, and data de-identification [39].

2) Safeguarding user privacy and online anonymity: Consideration for personal safety and online anonymity should be explored when developing AI systems to prevent cyberbullying, especially in regard to children and youth (i.e., vulnerable users). It is important chatbot and AI systems do not breach user privacy and jeopardize the anonymity many users need to feel safe, secure and empowered to navigate their online lives [34].

Developers must provide a fair balance in protecting user privacy and online safety while identifying and addressing cyberbullying incidents.

G. Ethical Considerations

The use of AI-powered solutions to combat cyberbullying raise a variety of ethics-related questions that will need to be taken seriously. One question to consider is the obligation to ensure that these advancements are developed and deployed in ways that honour the fundamental rights of individuals and cultural norms, along with requisite algorithmic calculation, and the concern of unintended consequences.

1) Algorithmic bias and fairness: Cyberbullying prevention measures must be thoroughly assessed for bias and fairness to ensure that they do not unjustly single out or disfavour specific people or groups. Discriminatory judgements that further disenfranchise already marginalised groups and perpetuate complaints can be caused by biases in algorithmic decision-making, model design, or training datasets [40].

2) Transparency and accountability in AI-enabled decision-making: AI-enabled cyberbullying control or prevention systems must be transparent and accountable to users, stakeholders, and regulators for its decisions and actions. Processes and procedures must be put in place, and detailed, to evidence, show, and or demonstrate the workings of the system, the decision processes, and how the system responds to instances of cyberbullying.

In the absence of similar transparency and accountability, these technologies may be perceived as opaque, unreliable, and perhaps subject to abuse or inappropriate misuse [41].

3) The potential for AI to be repurposed for malicious ends: The aim of the AI-powered cyberbullying prevention programs is to render online spaces safer and comparatively friendly, but there is a possibility for them to be misappropriated for illegal ends such as censorship, surveillance, or to purposely harass certain individuals or groups. To ensure that these technologies are utilized for appropriate and ethical purposes and do not infringe upon fundamental human rights or democratic freedoms, protections and governance structures must exist [42].

H. The "Zero-Sum Game" of AI Morality and Effectiveness

There might be a disjunction between the moral and ethical consequences of AI's expanding abilities to detect and respond to cyberbullying and the efficiency of systems employed to address this issue. In employing AI-enabled cyberbullying surveillance systems, there must be a cognitive divorce between AI tools preventing cyberbullying with moral and ethical soundness with high expectations of privacy, equity, and protection of human rights on one side and the use of AI tools for efficacy and convenience against cyberbullying on the other side.

However, the more successful these systems are at detecting and addressing instances of cyberbullying, the greater amount of user information may be required to gather and examine, which could cause privacy issues. This "zero-sum game" between AI efficacy and morality is a serious issue that needs to be resolved by careful, multi-stakeholder cooperation and the creation of strong governance structures.

AI-powered preventative cyberbullying methods that are socially conscious and have an impact on safer online environments will only be successful if the proper balance is struck between ethical considerations and technological efficacy [24, 25, 43, 44].

In the end, preventing cyberbullying with AI will need a multipronged strategy that emphasises both modern technology and moral user-centred design. Researchers and developers can endeavour to create solutions based on AI that are not only successful at recognising and reducing cyberbullying but also in line with fundamental liberties and societal values by tackling the important issues concerning information privacy, bias within algorithms, and transparent accountability [24, 44, 45, 46].

1) Balancing the need for accurate detection with the risk of false positives: There is always a chance of false positives, in which innocuous or normal interactions are mistakenly reported as cyberbullying, even though AI-powered cyberbullying detection systems can be very successful at spotting potentially harmful content or behaviours.

The AI-based cyberbullying solutions could additionally restrict applicable people or groups or unintentionally over-censor acceptable behaviours suppressing acceptable amounts of online expression.

In order to more effectively identify cyberbullying while avoiding false positives that may limit rights and liberties of users, developers must maximize the sensitivity and specificity of their AI outcomes.

To find the right balance and ensure that AI-based cyberbullying prevention solutions are effective and socially responsible will require, significant and extensive user testing, iterative model improvement, and close collaboration with a broad range of stakeholder groups [47].

2) Striking a balance between user privacy and the effectiveness of AI: While a simple conceptual model of a cyberbullying detection and intervention system based on AI could be developed, the "effective" part of a system likely requires access to a more extensive data set including social networking activity, online communications and perhaps even personal data.

Even if it is done to increase online safety, users might think that their private data has been inappropriately used or excessively exposed, which is why the gathering and utilization of such sensitive data impacts serious privacy concerns.

As a result, developers must carefully balance the requirement for efficient AI-powered cyberbullying detection with users' fundamental right to privacy and control over their personal information. This could entail creating privacy-preserving strategies like federated learning or differential privacy in addition to strong data governance frameworks that give users the ability to control how their data is used. The future of AI-powered cyberbullying prevention may be one of greater efficacy, social responsibility, and user trust if these major issues are resolved [25]. The summary of findings for AI-powered Cyberbullying mitigation has been tabulated in Table I.

TABLE I. SUMMARY OF FINDINGS: AI-POWERED CYBERBULLYING MITIGATION

Aspect	Key Technologies/Methods	Primary Applications & Capabilities	Identified Challenges & Considerations
AI Modalities & Solutions			
Natural Language Processing (NLP)	- Transformer Models (e.g., BERT, GPT) - Recurrent Neural Networks (RNN, LSTM) - Sentiment & Contextual Analysis	- Analysis text to detect abusive language, threats, and insults. - Identifies patterns of harassment and denigration. - Aims to understand sarcasm and indirect attacks.	- Difficulty with linguistic nuance, cultural context, and sarcasm. - High risk of false positives/negatives without deep contextual understanding.
Machine Learning (ML) / Predictive Analytics	- Supervised & Deep Learning (GRU, Bi-LSTM) - Behavioural Pattern Analysis - Peer Influence Modelling (e.g., PI-Bully)	- Classifies cyberbullying based on word frequency, emojis, and sentiment. - Predicts at-risk users (potential victims or perpetrators). - Enables proactive, targeted interventions.	- Scarcity of large, labelled, and multi-modal (text, image, video) datasets. - Lack of a standardized definition of cyberbullying for data labelling.
Image & Video Analysis	- Computer Vision - Facial Expression & Body Language Recognition - Object & Scene Recognition	- Detects harmful visual content (embarrassing images/videos). - Identifies visual cues of aggression or distress. - Multimodal analysis combines visual and textual context.	- A relatively under-explored area compared to text analysis. - Requires complex models to integrate visual and contextual data.
Behavioural Analytics	- User Interaction Analysis - Social Network Analysis	- Tracks digital interactions to identify early signs of aggression and conflict. - Analyses user profiles, posting frequency, and social connections to flag risky behaviour.	- Raises significant privacy concerns due to continuous monitoring. - Requires balancing intrusion with effectiveness.
Core Challenges			
Ethical & Privacy	- Data Governance Frameworks - Transparency Protocols	- Ensures user data is protected, especially for minors. - Aims for accountable and explainable AI decision-making.	- Privacy Risk: Collection of sensitive personal data. - "Zero-Sum Game": Tension between AI efficacy (needing more data) and user privacy/morality (protecting data).
Algorithmic Bias & Fairness	- Bias Mitigation Strategies - Fairness Audits	- Seeks to create equitable systems that do not disproportionately target or harm marginalized groups.	- Biased training data can lead to discriminatory outcomes and reinforce existing societal inequalities.
Effectiveness & Accuracy	- Model Optimization - Iterative Testing	- Aims to maximize accurate detection of true cyberbullying incidents.	- False Positives: Risk of censoring innocent banter or legitimate speech. - False Negatives: Risk of missing sophisticated or novel forms of harassment.
Future Directions			
Technical Innovations	- Advanced NLP for subtlety - Real-time monitoring dashboards (e.g., AI Ally) - Personalized AI (e.g., CAPTAIN chatbot) - Cross-platform tools (e.g., Bullstop)	- Improve detection of nuanced attacks. - Enable immediate intervention. - Provide tailored support to victims. - Create a unified defence across social media, messaging apps, and forums.	- Requires significant R&D investment and interdisciplinary collaboration.
Policy & Collaboration	- Multi-stakeholder Frameworks	- Bridges the gap between researchers (evidence), policymakers (regulation), and industry (implementation).	- Creating effective, enforceable, and adaptable policies that keep pace with technological change.
Education & Awareness	- AI-Powered Chatbots & Serious Games - Data-Driven Educational Content	- Provides interactive, personalized learning about cyberbullying effects and resilience. - Empowers users with knowledge and coping strategies.	- Ensuring widespread adoption and cultural relevance of educational programs.

IV. FUTURE DIRECTIONS AND RECOMMENDATIONS

A. Innovations Required to Make AI More Effective in Cyberbullying Prevention

Considerable advancements in the field of artificial intelligence (AI) have been recorded over the past few years, but none of them are sufficient in preventing cyberbullying. The main weakness is in the area of natural language processing (NLP). Modern AI may notice the boldest attacks, but even it will always fail to realize the milder strategies- particular moments that foster bullying or understated sarcasm that is implemented with the expressive intention to harm. NLP improvement would thus play a critical role towards addressing such blind spots. It is empirically proved that, under such exposure to a large set of examples, the AI models are shown to have an increased ability not only to detect blatantly inappropriate expressions but also to identify the malicious patterns that are repeatedly used by harassers [48].

One of the most telling developments is the ability of AI systems to follow real-time online activity and act in a timely manner. Continuously tracking what happens, computational agents are now able to identify dangerous interactions and act before things go out of control. One such example is AI Ally dashboard that monitors Discord and other platforms. It allows users to identify the wrong exchange and to collect proof of the cyberbullying [49]. This is a tool that will then allow more effective counteractions and this will enhance defences against abuse. In a more practical sense, cyberbullying is alleviated

through AI personalisation: the use of individualized assistance that would be shaped to suit specific victims has proven to be significantly more efficient as compared to uniform, one-size-fits-all interventions. The case of CAPTAIN chatbot demonstrates this concept because the chatbot adjusts discourse on the fly and supports victims who fight against cyberbullying. Since these AI tools are environment-dependent and tuned to the requirements of respective users, such a tool poses a significantly greater resource than generic, standardized alternatives [50].

Colleagues and students, first, it can be noted that there is nothing exceptional with the urgency of developing effective technology to mitigate cyberbullying in a particular social-media ecosystem; instead, what is necessary is that the robust solution be platform-agnostic. Stated differently, the tool has to work harmoniously with a variety of social-networking platforms, instant messaging programs, and Internet message boards. A distinctive suggestion that has been made in this area is the Bullstop application, which will attach to already existing social-media sites and will build a shield against online bullying. Constantly scanning user feeds checking on objectionable content, Bullstop can use this to give warnings and can recommend ways that a bullying event can be defused before it escalates [48].

Ethical imperatives form a preset prerequisite in the academic field of enquiry of creating Artificial Intelligence capable of preventing cyberbullying. The transparent interface, privacy of the user, and maintaining ethical standards require careful implementation into a technological solution. The informed consent, the maintenance of clear and transparent data-management procedures, and the adoption of the mechanisms to help eliminate the misuse or the interruption of the system itself, are essential. AI systems can only be trusted to work effectively against cyberbullying when these ethical dimensions are comfortably tackled.

With the help of prioritizing such forward-thinking of ethical approaches, modern AI technologies will be able to improve their potential to maximize the possibilities of harmful online behaviour identification, alleviation, and elimination. Such development of AI would allow at once to increase the safety and supportiveness of online environments to all users in addition to enhancing the capacity of the system to identify and address potentially dangerous conduct.

B. Collaboration Between Researchers, Policymakers, and Industry Stakeholders

Researchers, stakeholders in the industry, and policymakers need to work together in order to reduce cyberbullying with the help of artificial intelligence in our modern world. Practical approach to the problem of online harassment detection and prevention is entirely in the domain of research organizations. In this case, the academic community also needs to develop a new architecture of algorithmic solutions, conduct empirical studies, and provide evidence-based recommendations on the responsible use of AI-powered technologies [48]. Legislators, however, play a pivotal role in the development of regulation governing the application of AI in the online environment. They would be responsible to oversee the actions of AI systems in terms of moral regulations, user privacy, and taking ownership of the possible negative consequences [49]. There are ethical dilemmas or an abuse issue that can occur without a proper policy framework of using AI assistance from AI-based tools.

The wide acceptance of AI technologies will be based on the stakeholders in the industry, especially those belonging to the tech companies' section, messaging, and social media platforms. They will be in charge of incorporating these technologies in their systems and making sure that they can be used. The efficiency of cyberbullying prevention using AI will rely on the implementation of the results of the studies and the compliance of the stakeholders of the industry to the policies [50]. These stakeholders can assist in achieving a safer online space by making sure AI solutions are practical, scalable to a reasonable degree and meet the legal requirements.

This cooperation results in a strategy to stop cyberbullying made up of the various areas. Policymakers make sure that ethical and legal issues are considered, scientists deliver the groundbreaking information and researches, and industry authorities implement these solutions. In collaboration, they can create the system which will help to popularise AI technologies and make them both ethically right and productive.

C. Education and Awareness Programs for Users and Online Communities

Cyberbullying needs sufficient education and awareness programs to provide users and online communities with awareness of cyberbullying, and related knowledge to approach and respond to it. Besides creating awareness, such programs should be crafted to impart the needed skills in users on how to handle bullying in online environments. Such efforts have a potential to attract a substantial number of people and leave a lasting impact on the reduction of cyberbullying behaviour through the use of state-of-the-art strategies, such as artificial intelligence (AI).

One of the AI tools which is rapidly becoming an effective means of avoiding cyberbullying is the CAPTAIN (Cyberbullying Awareness and Prevention Through Artificial Intelligence) chatbot.

The CAPTAIN chatbot provides users with personalised knowledge on the negative effects of cyberbullying and is available on-demand when the user requires assistance. They can also practise the responses and perfect it as through simulations of actual cyber bullying instances, the users can become more prepared and confident to handle should it arise online [50]. Having conversational AI in the educational program, the users will be offered with a personalised experience in which they will be able to receive preliminary measures that will match their unique needs and, therefore, will shift towards higher effectiveness.

The application of AI-enabled serious games is another good strategy since they present an entertaining approach to learning about the negative effects of cyberbullying. It is possible to achieve high-levels of user engagement (an extended interaction) through the use of serious games because, by incorporating game mechanics to educate people on relevant social topics in an entertaining, interactive form; they advance engagement with greater results. Such games can also employ AI to customise the experience of each player by either varying

the content or changing the level of difficulty depending on the actions of the player. Such interactive learning also allows users to understand the practical effects of cyber bullying as well as promoting empathies and respect in online communication [51]. Moreover, the games give room to the players to practice different scenarios and create an emotional intelligence they would require in events of being cyberbullied.

AI can also have a high level of utility in the creation of specific educational materials through the analysis of user activity and preferences. This will be a data-driven measure, which makes the content that is going to be used valid and suitable to the requirements of people with different users, which allows creating the educational content that will be appealing to this or that demographic group. As an example, a gamified learning content might be of greater value to younger users, and case studies and detailed discussions might be of greater value to senior users [52]. Optimizing the educational contents based on the user data, AI guarantees that awareness campaigns will reach a broad audience, not confined to users of a particular age group and cultural background.

Combined with these AI-based tools, outreach to social networks is a crucial part of achieving education and awareness campaigns. Campaigns can be promoted through the social media platforms, online forums and other virtual platforms, educational materials can be disseminated and positive online behaviour can be empowered. Peer-to-peer support is also another very important element of these networks since users may provide each other with tips and techniques to be successfully introduced to fight cyber bullying. Ensuring the community-based approach to education, awareness campaigns could be more open and effective and allow users to participate in some proactive steps in cyber bullying prevention.

Finally, AI can be implemented in an educational and awareness program, which offers new solutions to cyberbullying. Chatbots and serious games are examples of the AI-guided technologies that provide scalable, personalised and engaging solutions that not only created awareness but also grant users confidence to act. Focusing on the needs of users and tailoring information to fit their needs, AI could contribute to making the online world safer and more respectful so that individuals would recognise the harmful effects of cyberbullying and possess the skills and knowledge needed to combat it.

D. Ethical Frameworks and Guidelines for Responsible AI Deployment

Due to the rise in AI technologies deployment, it is crucial to make sure that these systems are developed and implemented responsibly. Ethical principles play a pivotal role in eliminating the abuse of AI in delicate fields such as the elimination of cyberbullying. Such frameworks could act as a guideline to the legislators as well as the developers in coming up with systems that put emphasis on privacy, justice, accountability and transparency.

AI systems, especially the ones preventing cyberbullying should adhere to the principles of ethics in order to safeguard the users. Fairness is one of the keys of these structures. The AI algorithms should also be open and are not supposed to accidentally affirm built-in prejudices. As demonstrated by study [53], ethical AI laws must be able to tackle the issue of fairness by ensuring that AI systems avoid discrimination against certain people based on race, gender, as well as, the socioeconomic status. Based on their observation, AI models trained with biassed data tend to strengthen such biases, which may harm the under-represented population. According to them, the frameworks of ethical AI must have provisions to reduce biases and have ethically fair returns to all users.

User privacy is another basic value of successful AI implementation. The increased interest in data privacy, including the social media, has evinced an issue of handling personal data with care by AI systems. [54] highlighted the importance of data collection and processing transparency and considered the ethical issues of AI used in moderating social media. They suggest that the AI-based platforms can provide more control over the user data and guarantee privacy without interfering with the system in terms of identifying harmful behaviour, i.e., cyberbullying. It [54] states that their paradigm promotes a compromise between protection of user rights and effectiveness of an AI system.

Moreover, responsibility is crucial even when it comes to the creation and implementation of AI systems. The systems developed by AI frameworks should have systems that demand responsibility of the makers of the systems. Developers should make their systems explicable to both users and external auditors in order to be able to understand the decision-making process, according to a study conducted on ethical AI of online platforms by [55]. They stress that since there is a role of AI system developers in the designing of the technology and its consequences, they should also be blamed.

We also need ethical rules which would make sure that we implement AI system in a manner which cannot be misused especially among the already vulnerable groups. As an example, to fight the issue of cyberbullying, one would have to design AI that would be able to detect the harmful behaviour without violating the freedom of expression of users. Guidelines have to consider the need of ensuring that the freedom of expression of the users is not infringed upon and the need to regulate the contents. This is of particular concern to social media sites which, are habitually accused of censoring content in a manner that is discriminative to certain groups of users.

Such structures should be adaptable and versatile due to the development of AI technologies. In the development of AI, as well as enhancing these ethical frameworks, systematic work by the researchers, legislators, and business executives is necessary as stakeholders of the current development of AI. This will ensure that AI remains a good influence that brings about a fairer and a more just digital society.

V. CONCLUSION

The multifaceted nature of cyberbullying, with its considerable social, psychological, and physical effects, particularly on younger social media users, calls for more effective intervention strategies than what global efforts presently can provide. While these measures are quite essential and provide a good foundation, their inadequacy calls for new solutions. With AI, the possibilities are endless to fight

cyberbullying via AI-powered solutions to directly take action in real-time and forecasting models to determine risk. Breakthrough advances in AI-related technologies, such as Natural Language Processing, Machine Learning, Image & Video Analysis, and Behavioural Analytics are providing mind-blowing tools that can be used to comprehend and address this pervasive problem.

However, if the transformative potential of AI is to be truly unlocked in cyberbullying prevention, key areas will require targeted development and innovation. These areas include fostering strong collaboration between researchers, policymakers, and industry stakeholders to ensure that best possible solutions are designed and implemented ethically. Meanwhile, in parallel with the collaboration, there will need to be extensive education and awareness initiatives targeting users and online communities to empower them with knowledge on the identification and administration of cyberbullying. Finally, establishing ethical frameworks and guidelines for the responsible use of AI must take priority to address challenging questions around privacy, bias, and accountability; ultimately paving the way for a safer and more positive online environment for all.

Intelligent Visualization and Knowledge Graph Analysis for Trend Detection

Evidence from Industry–Education Collaborative Innovation

Sunan Lv
Jiuzhou Polytechic, Xuzhou 221116, Jiangsu, China

***Abstract*—This research employs scientometric examination and visual analytics techniques anchored in the Web of Science (WoS) repository to methodically delineate predominant research themes, foundational academic works, and emerging scholarly directions within industry-education integration studies. The investigation seeks to elucidate the discipline's epistemological framework and longitudinal transformation patterns while offering innovative analytical lenses and methodological paradigms to advance theoretical conceptualization and operational innovation in industry-education convergence initiatives. This investigation employs scientometric techniques to systematically map and examine 500 scholarly works on industry-education integration from the Web of Science (WoS) database (2010–2023) using VOSviewer. Through co-occurrence mapping, thematic clustering, and temporal trend analysis, the study identifies dominant research foci, influential contributors, and collaborative networks. This quantitative approach is further supplemented by case study investigations to delineate operational strategies and innovative frameworks for industry-academia synergy. Analysis reveals that research concentration spans five domains: higher education reform, Industry 4.0 alignment, engineering pedagogy enhancement, innovation ecosystems, and sustainability integration. Temporal evolution tracking demonstrates a paradigm shift from foundational theoretical debates to applied technological and implementation studies in recent cycles. Cluster analytics highlight the interdisciplinary nature of industry-education convergence, emphasizing tripartite collaboration among academic institutions, corporate entities, and governmental bodies as pivotal to systemic advancement. By synthesizing research trajectories and thematic priorities, this work establishes a structured knowledge foundation for both theoretical refinement and practical implementation in industry-education integration.**

Keywords*—*Reviewer; industry-education integration; hotspot visualization and analysis

I. Introduction

Amidst the backdrop of globalization and the profound integration of information technology, collaborative innovation between higher education and industry has emerged as a critical driver for advancing socioeconomic development [1]. As an innovative educational paradigm, the integration of industry and education seeks to establish organic linkages among the education chain, talent chain, industrial chain, and innovation chain through strategic university-enterprise partnerships, thereby fostering high-quality, application-oriented professionals aligned with societal demands [2]. In recent years, the rapid growth of the knowledge economy has elevated both scholarly research and practical initiatives on industry-education integration to a shared priority within academic and industrial communities [3]. Nevertheless, despite the escalating volume of related studies, comprehensive analyses of research hotspots, evolutionary trajectories, and innovation pathways within this domain remain notably deficient [4]. Particularly with advancements in big data and visualization technologies, the application of scientometric tools to conduct holistic mapping and in-depth exploration of the industry-education integration research field—uncovering its intrinsic mechanisms and developmental logic—has become a pivotal focus in contemporary scholarship.

Through visualization analysis leveraging the Web of Science (WoS) database, this study systematically maps hot topics, foundational literature, and academic frontiers within the research field of integration of industry and education, offering theoretical and practical guidance for future investigations [5]. Firstly, at the theoretical level, it clarifies the developmental trajectory of industry-education integration research, uncovers its knowledge architecture and evolutionary patterns, and supports the establishment of a robust theoretical framework for this domain. Secondly, at the practical level, visualizing and analyzing research hotspots furnishes evidence-based insights for universities, enterprises, and governmental bodies to formulate targeted policies and advance the implementation of industry-education integration initiatives [6]. Additionally, this research explores innovative pathways for synergizing education and industry, proposing novel solutions to address the persistent "two skins" dilemma in current practices, thereby fostering deeper alignment between the education chain and industrial chain and enabling bidirectional empowerment of education and industry [7].

This study aims to systematically map and rigorously investigate the research domain of integration of education and industry by employing the WoS Reviewer tool alongside scientometric and visualization analysis methodologies [8]. Specifically, it addresses three focal dimensions: first, leveraging econometric analysis of WoS-indexed literature to delineate temporal trends, geographic distributions, and core authorship networks in this field, thereby sketching its research landscape; second, applying visualization techniques such as co-occurrence and clustering analyses to pinpoint hot topics, frontier directions, knowledge structures, and evolutionary trajectories within integration of education and industry studies; lastly, building on these analytical outcomes, the research explores innovation pathways and strategic frameworks tailored

to address critical challenges in current industry-education integration practices, offering theoretical and actionable insights for future endeavors [9]. Through this multidimensional inquiry, the study seeks to advance academic discourse and practical innovation in the integration of education and industry while fostering sustainable progress in the field.

Section II of the paper is a literature review, which examines the research progress in the integration of industry and education with visual analytics. Section III is the research methodology, which introduces the research methods such as bibliometric analysis of econometrics. Section IV is the results and discussion, which examines author visualization, visual analysis of keywords, etc., and Section V concludes the paper.

II. Literature Review

A. Theoretical Research Progress of Industry-Education Integration

As an emerging educational paradigm, theoretical research on the integration of industry and education has achieved significant advancements in recent years [10]. Initial studies predominantly centered on conceptual definitions and connotation analyses of this integration, with scholars examining its essential characteristics and core components through multidisciplinary lenses spanning pedagogy, economics, and management [11]. Certain researchers posit that industry-education integration serves as a vital platform for collaborative innovation between higher education and industries, emphasizing resource sharing and complementary strengths to achieve profound synergies between the two sectors. As research deepened, scholarly attention gradually shifted toward the dynamic mechanisms and implementation pathways of this integration [12]. From a systems theory perspective, some scholars have identified policy support, market demand, and technological innovation as critical drivers propelling industry-education collaboration. Concurrently, others have investigated its role in facilitating university research commercialization and enterprise technological advancement through the lens of knowledge transfer and innovation [13]. Collectively, existing theoretical studies have laid a foundational framework for practical applications of industry-education integration. However, gaps persist in systemic, dynamic, and interdisciplinary analyses, particularly under the dual pressures of globalization and digital transformation, necessitating further expansion and refinement of its theoretical architecture.

As theoretical research advances, scholars increasingly recognize that the integration of industry and education constitutes not merely an educational model but a multifaceted ecosystem. This system encompasses governmental bodies, universities, enterprises, students, and other stakeholders, requiring scrutiny of its operational mechanisms and underlying logic from a broader systemic perspective. From an ecosystem viewpoint, scholars emphasize that successful industry-education integration hinges on synergistic collaboration and dynamic equilibrium among diverse actors [14]. Concurrently, globalization has amplified interest in cross-border approaches to this integration, prompting efforts to synthesize international best practices with localized contexts to forge a theoretical framework with Chinese characteristics. Despite theoretical progress, challenges persist in aligning abstract models with practical realities. For instance, certain idealized theoretical constructs overlook real-world complexities and uncertainties, diminishing their practical utility. Consequently, future research must prioritize practice-oriented theoretical refinement to bolster applicability and operational viability, ensuring theories effectively guide real-world implementation.

Recent advancements in emerging technologies like big data and artificial intelligence have increasingly intertwined theoretical research on industry-education integration with technological innovation [15]. Scholars now investigate how digital tools and platforms can enhance resource allocation and operational efficiency within this integration [16]. For instance, blockchain-based trust frameworks have been proposed to address information asymmetry and trust deficits in collaborative processes. Simultaneously, researchers leverage educational and industrial big data to develop data-driven monitoring and evaluation systems, enabling real-time assessment of integration dynamics [17]. While these technological approaches inject novel perspectives into theoretical advancements, they also reveal challenges such as ethical dilemmas in technology deployment and vulnerabilities in data privacy safeguards. Consequently, future studies must prioritize ethical frameworks and regulatory safeguards alongside technological empowerment to ensure sustainable and responsible progress in industry-education integration.

B. Practical Exploration and Challenges of Industry-Education Integration

At the practical level, the implementation of industry-education integration has evolved from singular cooperation models to diversified and multilayered collaborative frameworks [18]. Domestic and international universities and enterprises have engaged in extensive collaborative initiatives through joint laboratories, co-established R&D centers, and industry-academia institutions. Globally recognized paradigms include Germany's "dual system" educational model and the U.S. "cooperative education" program [19]. In China, policy-driven initiatives such as the "New Engineering" reforms and the "Excellence in Engineer Education and Cultivation Program" have significantly advanced university-industry innovation synergies. Nevertheless, persistent challenges hinder effective integration [20]. First, disparities in institutional objectives, cultural mismatches, and uneven resource distribution between universities and enterprises often result in superficial collaboration. Second, insufficient policy incentives and institutional safeguards undermine the long-term viability of integration efforts. Third, the digital transformation era demands innovative applications of emerging technologies like big data and artificial intelligence to reconfigure industry-education collaboration models, posing both opportunities and complexities for practical implementation.

Domestic and international practical explorations have gathered both successful experiences and revealed recurring challenges [21]. While Germany's "dual system" model is globally acclaimed, its effectiveness hinges on advanced socio-economic infrastructures and robust legal frameworks—conditions not universally replicable. Similarly, the U.S. "cooperative education" initiative, despite enhancing graduate employability and corporate growth, faces scalability limitations

due to significant financial investments and intricate coordination structures [22]. In China, despite amplified policy backing, industry-education integration encounters persistent challenges. For instance, universities often prioritize short-term gains over long-term educational objectives in partnerships, while enterprises emphasize economic returns at the expense of talent development investments [23]. Such misaligned priorities hinder genuine collaborative synergies.

Furthermore, inadequate policy enforcement and institutional safeguards critically constrain integration efforts. National-level policy frameworks often suffer from fragmented implementation or inefficacy at regional and corporate levels [24]. Local governments frequently lack cohesive strategies and resource allocation for sustaining collaborative programs, while enterprises grapple with insufficient incentives and underdeveloped risk-mitigation mechanisms. Consequently, establishing multi-tiered policy support systems remains pivotal for future progress.

Digital transformation simultaneously catalyzes opportunities and complexities for industry-education integration. Technologies like big data and artificial intelligence enable enhanced resource optimization and operational efficiency through digital platforms, fostering transparent, data-driven university-industry collaborations [25]. Conversely, this shift demands urgent resolutions to data security risks, ethical dilemmas in technological deployment, and the cultivation of digitally competent professionals [26]. Future practices must therefore integrate ethical governance with technological innovation to ensure sustainable, equitable advancement in industry-education integration.

C. Review of the Study

In summary, while significant advancements have been achieved in theoretical and practical domains of industry-education integration, persisting gaps require urgent resolution [27]. Theoretically, despite extensive scholarly exploration of its conceptual foundations, driving mechanisms, and implementation strategies, existing frameworks demonstrate limited adaptability and foresight amid globalized and digitized contexts [28]. Practically, while domestic and international initiatives offer valuable insights, critical challenges persist—including resolving superficial collaboration (“two skins” phenomenon), strengthening policy infrastructures, and addressing technology-driven disruptions. This study employs visual analytics grounded in the WoS database to systematically map research hotspots and emerging trends, thereby offering novel theoretical perspectives and methodological tools to advance sustainable development in industry-education integration [29].

III. Research Method

A. Bibliometric Analysis of Econometrics

This study employs scientometric methods to systematically examine the literature on industry-education integration within the Web of Science (WoS) database, aiming to uncover research hotspots, developmental trajectories, and knowledge frameworks in this domain. Utilizing the WoS advanced search function, 500 core publications (2010–2023) were retrieved using keywords including "Integration of Industry and Education" and related terms, ensuring data comprehensiveness through the inclusion of journal articles, conference papers, and monograph chapters [30]. Visualization and analysis were conducted via CiteSpace and VOSviewer. Co-word analysis identified high-frequency keywords and their co-occurrence networks, elucidating research themes and structural relationships [31]. Cluster analysis categorized keywords to delineate thematic correlations and distinctions, while time-series analysis tracked keyword evolution to map developmental trends and emerging frontiers. Bibliographic coupling and co-citation analyses further identified influential literature and authors, clarifying academic impact and knowledge dissemination pathways in industry-education integration research.

This study prioritizes data cleaning and standardization during processing to ensure analytical accuracy and reliability. Synonyms were consolidated and keywords standardized to minimize terminological inconsistencies, while citation data were refined and calibrated to enhance citation network precision [32]. By implementing these methodologies, the research not only systematically outlines the knowledge architecture and evolutionary patterns in industry-education integration but also furnishes data-driven foundations and methodological frameworks for future investigations. The scientometric approach ensures rigorous objectivity and scientific validity in findings, delivering actionable insights for academic and industrial stakeholders.

B. Exploring the Practical Path of Case Study

This study integrates case study methodology with scientometric analysis to investigate practical pathways and innovative models in industry-education integration. As a qualitative approach, case studies enable in-depth examination of typical cases to unravel underlying mechanisms and operational logics of complex phenomena [33]. Representative domestic and international cases are selected, including Germany’s "dual system" (legal frameworks, corporate engagement mechanisms, curriculum design), the U.S. "cooperative education" program (school-industry collaboration models, student internship systems, evaluation frameworks), and China’s "New Engineering" initiative (policy support mechanisms, institutional reforms, enterprise-academia collaborative innovations). These cases demonstrate proven success in industry-education integration practices. Through document reviews, fieldwork, and interviews, the study systematically evaluates their achievements and challenges, offering insights into effective strategies and implementation barriers across diverse contexts.

This study employs multi-source data triangulation during case analysis to ensure research reliability and validity. Specifically, case background details and historical data are collected via literature analysis; operational dynamics are observed through field investigations to gather primary evidence; and stakeholder perspectives (academic administrators, industry representatives, students) are captured using in-depth interviews. Cross-case comparative analysis is also conducted to contrast similarities and differences among cases, thereby extracting universal principles and localized innovation pathways for industry-education integration. This approach strengthens methodological rigor while maintaining

contextual specificity in examining collaborative mechanisms. The case study samples of "integration of industry and education" and their characterization are shown in Table I.

TABLE I. SAMPLE OF CASE STUDIES ON "INTEGRATION OF INDUSTRY AND EDUCATION" AND THEIR CHARACTERIZATION

Case Name	Nations	Main features	Success stories	Challenges faced
The German "dual system" model	German	Joint cultivation between enterprises and schools, close integration of theory and practice	Comprehensive legal protection system, in-depth participation of enterprises, flexible course design	High dependence on firms and limited adaptability when generalized to other countries
United States "Cooperative Education" program	United States of America	Students alternate between schooling and internships, emphasizing the development of practical skills.	Close school-enterprise cooperation, perfect student internship mechanism, scientific assessment system	High costs and complex coordination mechanisms make large-scale replication difficult.
China's "New Engineering Science" Construction	Sino	Policy-driven, collaborative innovation between universities and enterprises, focusing on emerging technologies and industry needs	Strong policy support, active university reforms, high business participation	Inconsistency between the goals and demands of universities and enterprises, and fragmentation of policy implementation

IV. RESULTS AND DISCUSSION

A. Author Visualization and Analysis

This study illustrates author distribution and temporal engagement patterns in industry-education integration research from 2019 to 2024 through Fig. 1. The timeline visualization clarifies researchers' activity durations and contribution periods within this field. Analysis reveals 2020-2023 as the peak phase for scholarly participation, with notable surges in new researcher emergence during 2021-2022 [34]. This pattern suggests intensified academic interest in industry-education integration during these years, potentially influenced by accelerated global digital transformation initiatives post-2020. Regarding research persistence, recurring authorship across multiple years demonstrates sustained scholarly engagement, indicating continuous contributions through theoretical advancements, practical implementations, or technological innovations [35]. Conversely, single-year author appearances may reflect focused investigations on time-bound projects or specialized thematic studies within the discipline.

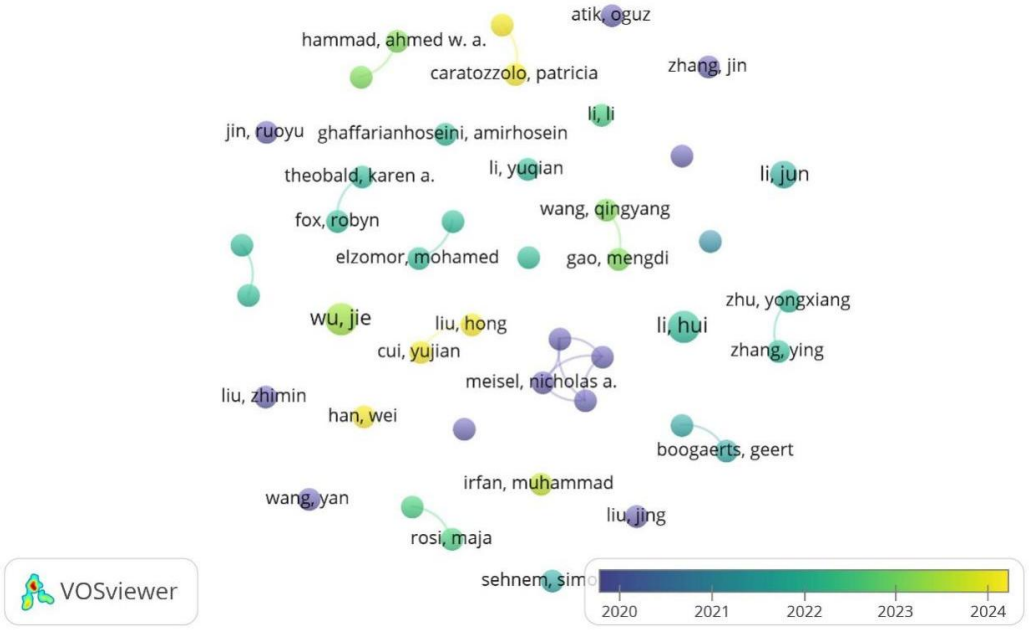

Fig. 1. Visual analysis of author appearance time.

In addition, the relatively small number of authors in 2024 may reflect the time constraints of data collection and maybe a preliminary signal of future research trends. Overall, the visual analysis of the temporal distribution in Fig. 1 reveals the dynamic evolution process of the research field of industry-education integration, reflecting the changes in academic activity and research hotspots of the field in different periods. This analysis, can provide a time dimension reference for future research and help scholars better grasp the research trends and frontier directions.

Fig. 2 demonstrates the correlation between groups of authors and their research topics in the field of research on the integration of industry and education through cluster analysis. Cluster analysis is a method of grouping similar objects, which can reveal the cooperation between authors and the concentration of their research themes. As can be seen from the picture, the authors are categorized into multiple clustered groups, each representing a specific research direction or collaborative network. Some of the authors formed a cluster, which may indicate that they have in-depth cooperation and

research on a particular topic (technology application of industry-education integration or internationalization cooperation).

Another notable clustering group whose research may be focused on ecosystem building or sustainable development in the field of industry-education integration. The large number of authors in this cluster and their close collaborative relationship indicate that this research direction occupies an important position in the research on the integration of industry and education. In addition, the clusters formed by some authors may represent the practical exploration or case study of the integration of industry and education, and their research may focus more on empirical analysis and summarization of practical experience. Through clustering analysis, Fig. 2 not only reveals the cooperative relationship between authors but also reflects the multidisciplinary intersection and thematic diversity in the field of research on the integration of industry and education. For example, some clusters may involve the intersection of education, management, and engineering research, while others may focus on technological innovation or policy analysis [36]. This visualization provides an important reference for researchers to identify potential collaboration opportunities and research hotspots and also provides policymakers and practitioners with an intuitive understanding of the overall landscape of the research field of industry-education integration.

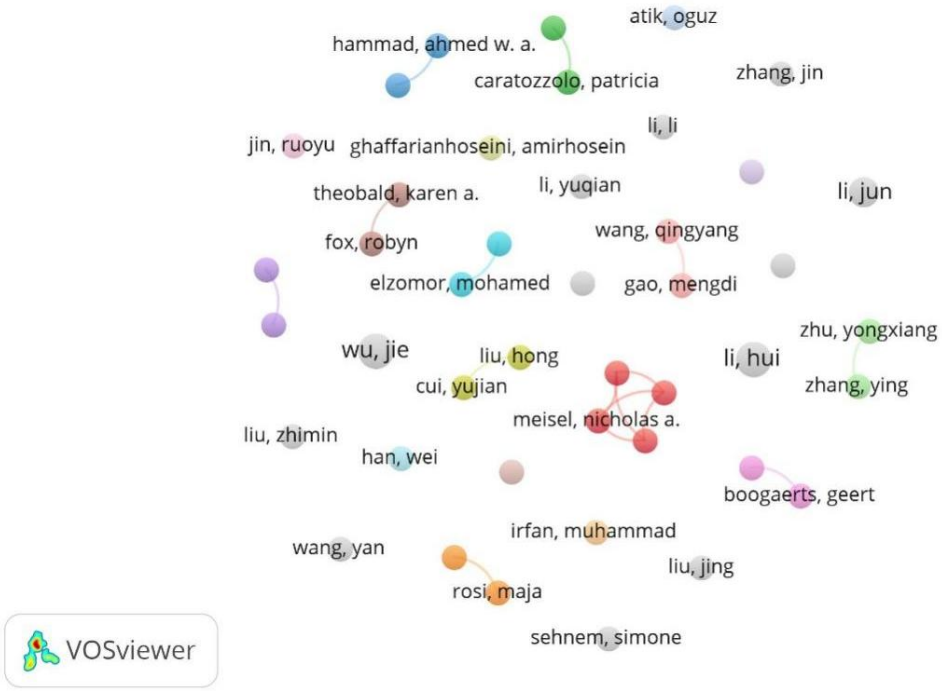

Fig. 2. Analysis of author clustering.

B. Visual Analysis of Keywords

Table II shows the centrality and number of occurrences of core keywords in 500 documents based on the Web of Science (WoS) database of research related to the Integration of Industry and Education [37]. By analyzing these keywords, the hot topics, research trends and academic concerns in the field of Integration of Industry and Education can be revealed. The following is a detailed analysis of the keywords in terms of their centrality, number of occurrences, and the research trends they reflect.

Centrality quantifies a keyword's structural significance within research networks, with higher values indicating stronger conceptual connections to other terms in industry-education integration studies. Table II reveals "Model" as the most central keyword (0.26 centrality), highlighting its fundamental role in conceptualizing collaborative frameworks between academia and industry. This prominence likely stems from the field's reliance on model-driven approaches for both theoretical frameworks and practical implementations, where scholars develop analytical, collaborative, and evaluative models to advance research and application. The secondary-ranked keyword "Higher education" (0.18 centrality) demonstrates academia's critical function as both an implementation platform and research focus within industry-education integration initiatives. The elevated centrality of these terms underscores their interconnectedness with adjacent research themes, reflecting their capacity to bridge disciplinary boundaries and operational challenges in collaborative education systems. As the main implementation body of industry-education integration, the reform and innovation of higher education have been the key direction of research. In contrast, the centrality of "Artificial intelligence" and "Engineering education" is lower, with 0.01 and 0.03 respectively. 0.03. This indicates that although these keywords have gradually gained attention in recent years, their influence in the research network of industry-education integration is still relatively limited. This may be because the research on AI and engineering education has focused more on the technical level and is not yet closely integrated with the overall framework of industry-teaching integration.

TABLE II. INTEGRATION OF INDUSTRY AND EDUCATION CORE KEYWORD CENTRALITY AND NUMBER OF OCCURRENCES

Word	Particular year	Centrality	Ordinal number
Industry4.0	2016	0.12	14
Higher education	2015	0.18	14
Model	2017	0.26	13
Impact	2018	0.15	13
Management	2015	0.14	9
University	2015	0.07	9
Technology	2021	0.08	8
Engineering education	2018	0.03	7
Artificial intelligence	2022	0.01	7
Innovation	2019	0.04	6
Education	2016	0.03	6
Digital transformation	2020	0.05	6
Industry4	2020	0.04	6
Knowledge	2016	0.06	5
Sustainable development	2015	0.06	5

The number of occurrences reflects the frequency of the keyword in the literature, and the higher the frequency, the more attention the topic receives in the research on the integration of industry and education. As can be seen in Table II, the number of occurrences of "Higher education" and "Industry4.0" (Industry 4.0) are both tied for the first place with 14 occurrences. This indicates that higher education and Industry 4.0 are the most popular themes in the research on the integration of industry and education. Higher education, as the main implementation body of industry-education integration, its reform and innovation have been the key direction of research; while Industry 4.0, as the core of the new round of industrial revolution, has also attracted much attention for its promotion of industry-education integration. Scholars have explored how to optimize the resource allocation and operational efficiency of industry-education integration through Industry 4.0 technologies (Internet of Things, big data, artificial intelligence,). In addition, the number of occurrences of "Model" and "Impact" are both 13 times, indicating that model construction and impact assessment are important directions in the research of industry-industry integration. Modeling provides a framework to support the theory and practice of UI, while impact assessment helps researchers and policymakers to understand the actual effects and room for improvement of UI. The number of occurrences of "Management" and "University" are both nine, indicating that the roles of management and universities are important topics in the research of University-Industry Integration. For example, scholars have discussed how to promote in-depth cooperation between universities and enterprises through effective management mechanisms, as well as the positioning and role of universities in the integration of industry and education. It is worth noting that "Artificial intelligence" and "Digital transformation" appear 7 and 6 times respectively, although the number of times is relatively low. Low, but their appearances reflect a new trend in the research of industry-education integration. With the rapid development of AI and digital transformation, scholars have begun to pay attention to the potential impact of these emerging technologies on the integration of education and industry, how to optimize the talent training mode by using AI, or how to improve the efficiency and transparency of the integration of education and industry through digital transformation.

The chronological distribution of keywords in Table II spans 2015-2022, revealing thematic progression within industry-education integration research. Initial investigations (2015-2017) prioritized foundational concepts including "Higher education", "Management", and "University", reflecting institutional-level examinations of collaborative mechanisms between academia and industry. The emergence of "Industry 4.0" as a prominent keyword from 2016 onward, peaking in 2020, demonstrates scholarly responses to technological advancements reshaping educational-industrial synergies. This period witnessed systematic explorations of Industry 4.0's capacity to align educational systems with industrial innovation cycles, particularly through curriculum modernization and talent development strategies [38]. Contemporary research (2020-2022) incorporates emerging technological paradigms, evidenced by the inclusion of "Artificial intelligence" and "Digital Transformation". While these novel concepts currently exhibit lower frequency and centrality metrics, their upward trajectory signals a paradigm shift toward technology-enhanced pedagogical frameworks and innovation-driven collaboration models in future studies.

Fig. 3 shows the distribution of high-frequency keywords in the research field of integration of industry and education through keyword density analysis. The density analysis can visually reflect the concentration and importance of keywords in the research. From the figure, it can be seen that "Industry 4.0" (Industry 4.0) and "Higher Education" (Higher Education) are the keywords with the highest density, indicating that these two topics occupy a core. The keywords of "Industry 4.0" and "Higher Education" are the most dense, indicating that these two topics occupy a central position in the research of industry-education integration. As the core concept of the fourth industrial revolution, the combination of Industry 4.0 and higher education is a hot topic in current research, and scholars are concerned about how to promote the innovation and development of industry-education integration through Industry 4.0 technology. In addition, the densities of "Collaboration" and "Universities" are also high, indicating that the cooperation mode between universities and enterprises and its role in the integration of industry and education is a key direction of research. Other high-frequency keywords such as "Sustainability", "Training", "Curriculum", etc., reflect the importance of industry-industry integration. （ reflect the multidimensional nature of research on the integration of industry and education [39]. For example, Sustainability indicates that researchers are concerned about the impact of UI on the environment and society, while Training and Curriculum highlight the importance of reforming educational content and methods in UI. In addition, the emergence of keywords such as "Artificial Intelligence" and "Engineering Education" suggests that the integration of emerging technologies with discipline-specific education is also an important research direction. Education integration is also an important direction for research. Overall, the keyword density analysis in Fig. 3 reveals the hot topics and core concerns in the research field of industry-education integration, providing researchers with an intuitive understanding of the research priorities in this field.

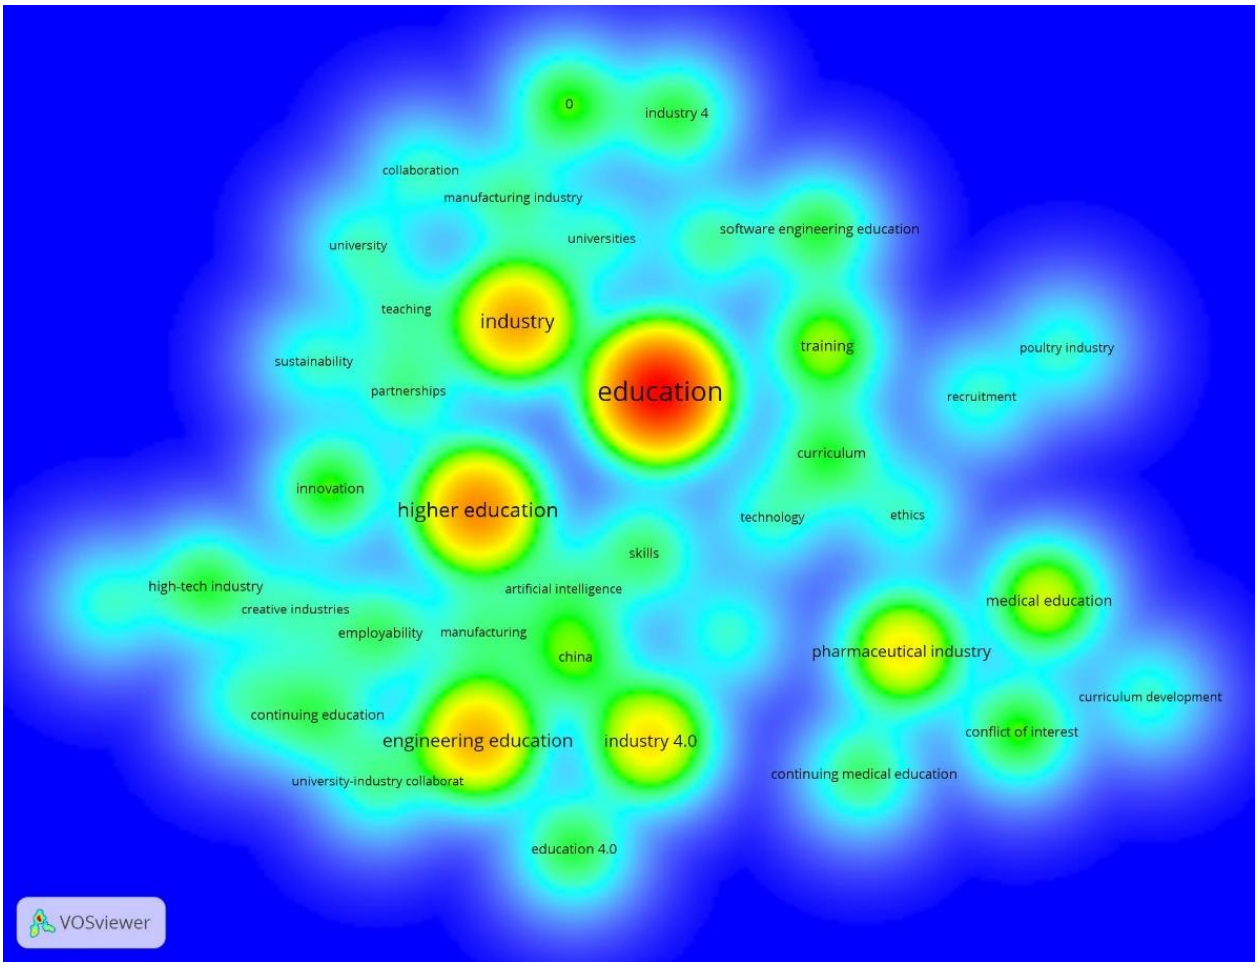

Fig. 3. Density analysis of keyword occurrences.

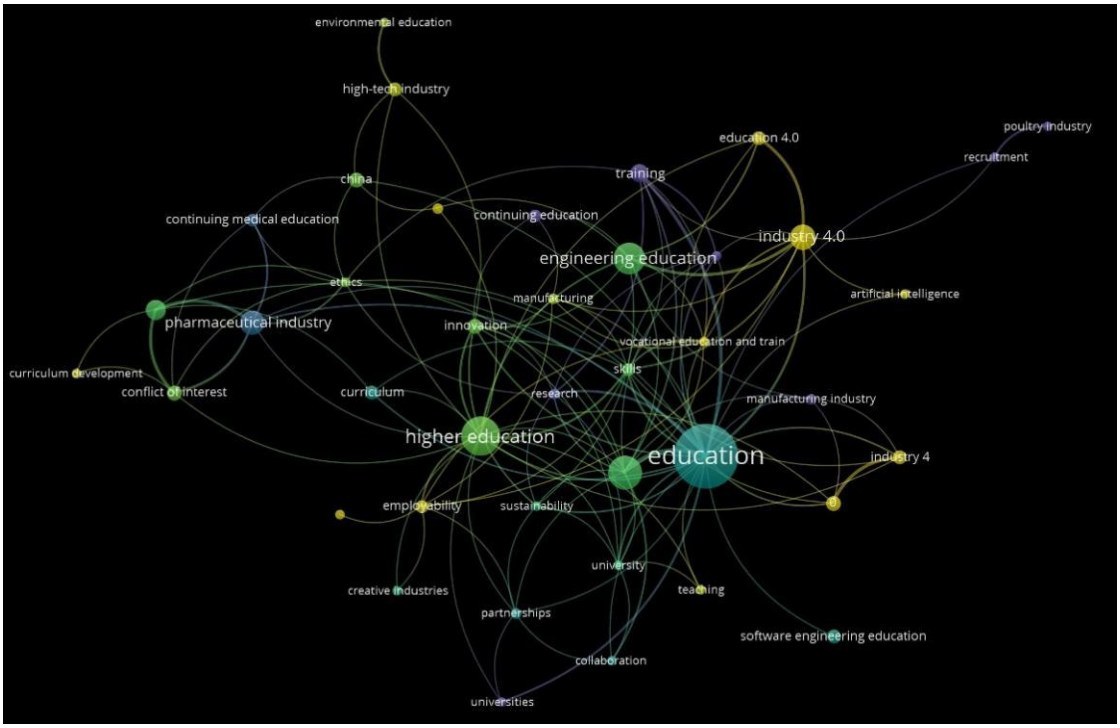

Fig. 4. Analysis of the time of first appearance of keywords.

Fig. 4 illustrates the chronological progression of keywords in industry-education integration research through their initial occurrence timelines. This temporal mapping enables scholars to track thematic emergence and disciplinary evolution. Early-phase keywords like "Environmental Education" and "High-Tech Industry" denote foundational explorations aligning ecological awareness with advanced manufacturing synergies. Subsequent appearances of "Industry 4.0" and "Artificial Intelligence" demonstrate technology's catalytic influence on modernizing collaborative education-industry frameworks. Recent expansions feature specialized terms including "Education 4.0" and "Continuing Medical Education", signaling domain-specific adaptations of integration principles – the former addressing digital pedagogy alignment with industrial automation, the latter showcasing healthcare sector applications. Parallel developments reveal operational challenges through keywords like "Curriculum Development" and "Conflict of Interest", highlighting implementation complexities in reconciling academic objectives with industrial partnerships. The longitudinal analysis confirms three evolutionary phases: initial conceptual groundwork (2015-2017), technology-driven transformation (2018-2020), and current specialized diversification (2021-2024). Such temporal patterns provide critical insights into emerging research frontiers while maintaining coherence with core integration mechanisms. The visualization effectively captures how macro-level technological shifts (Industry 4.0 adoption) and micro-level operational demands (curriculum alignment) collectively shape this interdisciplinary field's trajectory.

In addition, this paper also demonstrates the basic clustering analysis of keywords through Fig. 5. The basic clustering can show the most basic linkage relationship between keywords. It is specifically shown in Fig. 5.

Fig. 6 presents the temporal distribution of 13 keywords exhibiting citation bursts in industry-education integration research. Citation bursts denote sharp surges in keyword citations during specific periods, signaling heightened scholarly attention to particular themes. Analysis of these temporal patterns reveals evolving research priorities and emerging frontiers. Between 2015-2017, "Sustainable Development" demonstrated the strongest citation surge (0.75 burst strength), coinciding with an intensified academic focus on aligning industry-education synergies with global sustainability initiatives. This period simultaneously witnessed "Higher Education" achieving notable citation prominence (0.58 burst intensity), underscoring universities' pivotal role as laboratories for collaborative educational-industrial reforms. The dual emergence of these keywords reflects early-stage research priorities: institutional capacity-building through higher education systems and sustainability-oriented partnership frameworks. The sustained burst duration (2015-2017) for both terms indicates prolonged scholarly engagement with foundational implementation mechanisms before technological paradigm shifts. These findings confirm higher education institutions' dual function as both enablers and subjects of industry-education integration during the field's formative research phase, while simultaneously highlighting sustainability's cross-cutting relevance across collaborative models. The temporal alignment of these bursts with UN Sustainable Development Goal adoptions (2015) further contextualizes their academic prominence within broader policy landscapes.

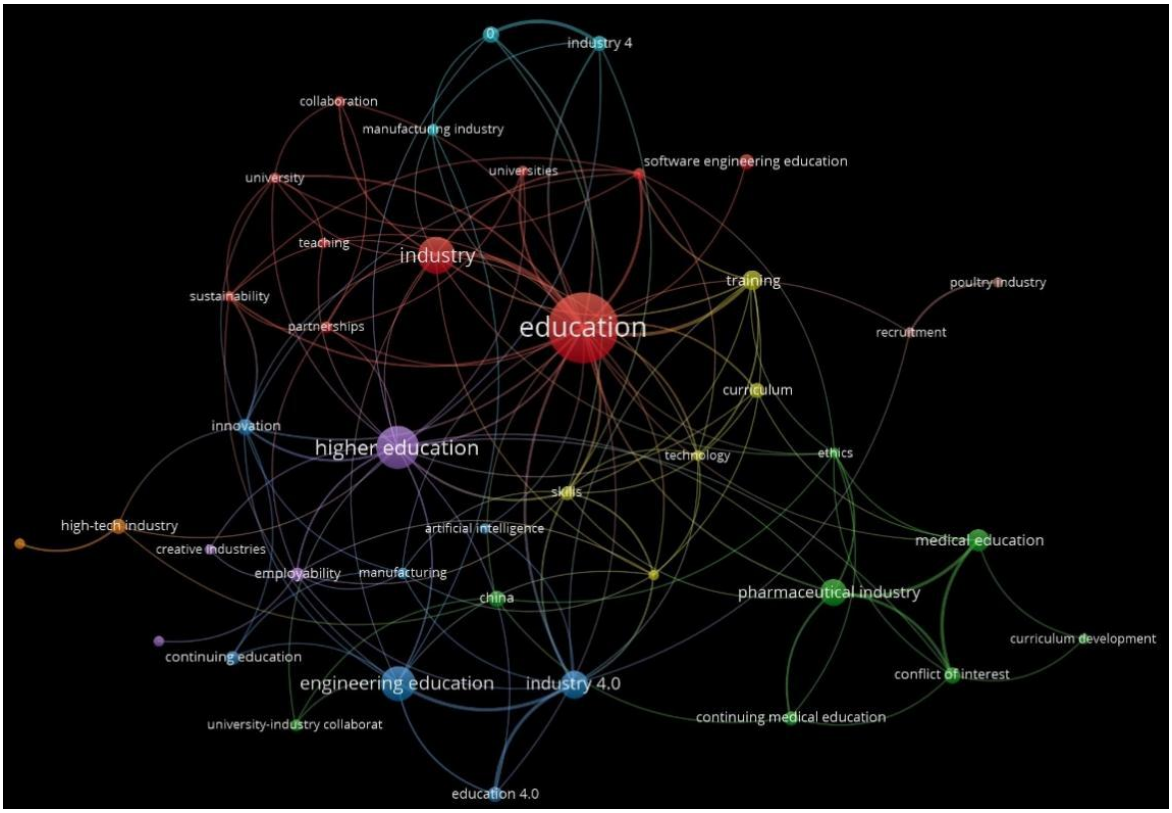

Fig. 5. Basic clustering of keywords.

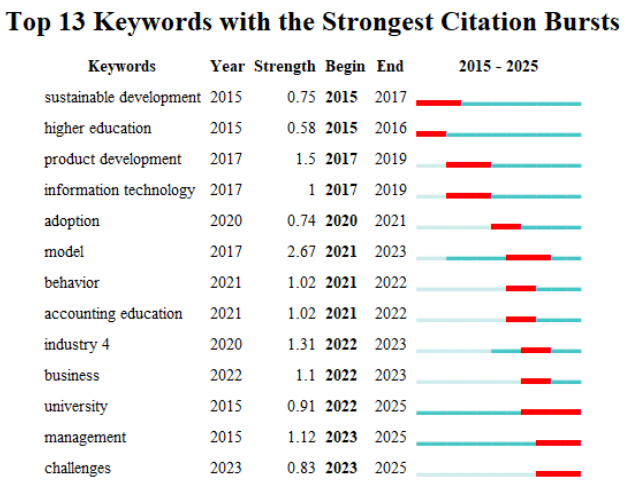

Fig. 6. Keyword highlighting timeline.

The period from 2020 to 2023 is a period of hot concentration in the field of research on the integration of education and industry, with several keywords showing significant citation explosiveness. "Adoption" (Adoption) （Adoption）showed a strong citation explosion (strength of 0.74) between 2020 and 2021, reflecting the researchers' concern about the adoption and promotion of the model of industry-teaching fusion in practical applications. "Model" showed the strongest citation burst (intensity of 2.67) between 2021 and 2023, indicating that model construction became the focus of research in this period. Scholars explore the realization path and optimization strategy of the integration of industry and education by constructing theoretical models and practical models. During the period from 2023 to 2025, "University", "Management" and "Challenges Challenges" show a strong citation explosion. The citation explosion of "University" continues from 2022 to 2025 (strength of 0.91), indicating that the role and function of universities in industry-industry integration remains a central focus of research. "Management" shows a high citation explosion from 2023 to 2025 (intensity of 1.12), reflecting the researchers' attention to the management mechanism and governance structure in the integration of industry and education. "Challenges " shows a high citation burst (intensity of 0.83) between 2023 and 2025, indicating that researchers have begun to systematically explore the problems and challenges in the practice of University-Industry Integration and provide solutions for its future development.

C. Keyword Information Node Study

Tables III and IV list the main keywords and their related statistical information in the research field of integration of education and industry, including the number of occurrences (occurrences) and total link strength (total link strength) of each keyword. These data are analyzed by scientometric tools such as VOSviewer, which can help researchers understand the hot topics and their interrelationships in the research field of integration of education and industry.

The number of occurrences (Occurrences) reflects how often a keyword appears in the literature, and the higher the frequency, the more attention the topic receives in the research on the integration of industry and education. As can be seen from the table, "Education" (Education) has the highest number of occurrences, reaching 62 times, indicating that education is the core theme of the research on the integration of industry and education. This is followed by "Engineering Education" and "Industry", which appear 23 and 25 times respectively, reflecting the combination of engineering education and industry in the research on the integration of industry and education. This reflects the importance of combining engineering education and industry in the research of industry-education integration. In addition, "Pharmaceutical Industry" and "Innovation" appear 16 times and 8 times respectively, indicating that these themes are also hot directions for research.

TABLE III. ANALYSIS OF THE NUMBER OF OCCURRENCES OF MAJOR KEYWORDS AND CONNECTION STRENGTH (I)

Id	Keyword	Occurrences	Total link strength
51	artificial intelligence	4	2
137	collaboration	4	5
194	continuing medical education	6	6
213	creative industries	4	2
227	curriculum	7	5
300	education	62	63
369	engineering education	23	17
385	environmental education	4	3

Total Link Strength reflects the degree of association between a keyword and other keywords, and the higher the strength, the more the keyword is at the center of the research network. From the table, it can be seen that "Education" has the highest total link strength of 63, indicating that education has the strongest correlation with other keywords and is the core node in the research network of industry-education integration. The total link strengths of "Industry" and "Engineering Education" are 27 and 17 respectively, indicating that they are also more relevant to other keywords and are important nodes in the research network. In addition, "Innovation" has a total link strength of 14, indicating that innovation has a strong correlation with other topics in the research of industry-education integration.

The keyword co-occurrence analysis reveals multidimensional research foci within industry-education integration studies. Core thematic clusters encompass educational frameworks, industrial systems, engineering pedagogy, innovation ecosystems, and sustainability paradigms. Quantitative metrics demonstrate differential research maturity across domains: "Sustainability" appears with a frequency of 4 and aggregate linkage strength of 9, suggesting its emergence as an underexplored dimension requiring deeper investigation. Similarly, "Artificial Intelligence" exhibits equivalent frequency (4) but lower connectivity (strength=2), confirming its nascent application stage despite significant transformative potential. Network connectivity analysis identifies key relational patterns - "Collaboration" demonstrates moderate network strength (5), revealing its interdisciplinary connections with educational reform, industrial adaptation, and innovation management. The strongest connectivity emerges in "Partnerships" (strength=7), highlighting its central role in operationalizing university-

industry collaboration models, particularly through curriculum co-design and resource-sharing mechanisms. These quantitative relationships collectively map the field's epistemological structure, illustrating both established knowledge nodes and emerging conceptual bridges. The data further delineate research intensity gradients, with partnership mechanisms receiving sustained scholarly attention compared to technologically-driven innovations requiring further conceptual development [40]. Such network characteristics inform strategic research prioritization while maintaining thematic coherence across disciplinary boundaries.

TABLE IV. ANALYSIS OF THE NUMBER OF OCCURRENCES OF MAJOR KEYWORDS AND CONNECTION STRENGTH (II)

Id	Keyword	Occurrences	Total link strength
540	industry	25	27
595	innovation	8	14
681	manufacturing	5	7
779	partnerships	5	7
788	pharmaceutical industry	16	19
874	recruitment	4	5
996	sustainability	4	9
1026	teaching	4	3
1126	vocational education and training	4	11

V. CONCLUSION

This study systematically examines research priorities, evolutionary trajectories, and innovation mechanisms in industry-education integration through scientometric analysis of Web of Science (WoS) data. The analysis identifies five core research clusters: higher education reform, Industry 4.0 adaptation, engineering education modernization, innovation ecosystems, and sustainable development frameworks. Temporal mapping demonstrates the field's progression from foundational theoretical debates (2010-2015) to technology-enhanced practical implementations (2016-2020), culminating in current interdisciplinary convergence (2021-2024). Emerging technologies like Industry 4.0 and Artificial Intelligence emerge as critical enablers for digital transformation in collaborative education-industry models. Network analysis reveals strong multidisciplinary intersections, particularly in university-industry-government collaboration mechanisms that drive curriculum innovation and workforce development. Methodological limitations include the WoS database's exclusive coverage, potentially overlooking regionally significant studies from platforms like Scopus or CNKI. While the scientometric approach effectively maps knowledge structures and citation patterns, it lacks a granular examination of implementation challenges – a gap future studies could address through mixed-methods research combining bibliometric analysis with empirical investigations of sector-specific applications. The findings underscore the necessity for expanded data inclusivity and context-specific case analyses to strengthen both theoretical frameworks and practical implementation strategies in this evolving interdisciplinary domain.

An Efficient and Scalable Reinforcement Learning-Driven Intelligent Resource Management and Secure Framework for LoRaWAN

Shaista Tarannum[1], Usha S.M[2]
Department of Electronics and Communication Engineering, JSS Academy of Technical Education, Bengaluru, India[1]
Visvesvaraya Technological University, Belagavi-590018, Karnataka, India[2]

***Abstract*—This study proposes a Q-learning-based adaptive duty cycle scheduling algorithm for LoRaWAN in a smart city eco-system to enhance the energy efficiency, reduce transmission delay, and handle dynamic traffic conditions. Additionally, it also incorporates an intelligent and efficient channel utilization scheme for LoRaWAN-enabled IoT networks and also integrates a lightweight security strategy at the edge (gateways), making it suitable for low-power, low-computation LoRaWAN environments. In this adaptive and intelligent LoRaWAN framework Q-learning agent dynamically selects various transmission actions based on the contextual states, including buffer size, energy levels, and channel conditions, which optimizes energy efficiency and also enhances the reliability of data transmission in LoRaWAN. The light-weight intrusion detection mechanism also filters suspicious packets using trust scores and payload analysis to ensure secure data delivery and adaptive, scalable, and proactive protection against several prevalent threats in LoRaWAN-driven IoT. It also incorporates a channel-aware scheduling to avoid congestion and improve overall transmission performance. Experimental outcome further confirms improvement over throughput, delay, bandwidth utilization, energy conservation, and resilience against malicious or faulty transmissions, demonstrating the framework's ability to optimize the resource allocation performance while balancing the above metrics adaptively.**

***Keywords*—LoRa; LoRaWAN; Q-learning; adaptive duty cycle; channel scheduling; energy efficiency; intrusion detection; trust score; resource management; IoT security**

I. Introduction

The rapid advancement of the Internet of Things (IoT) has created a demand for low-power, long-range wireless communication technologies. IoT involves connecting a wide range of end-devices, which are battery-powered sensor nodes, to the Internet and also enabling communication and data exchange between them [1] [2]. Therefore, the need arises to design the power usage profile carefully in order to extend the battery's lifetime. Also, the communication range needs to go from several hundred meters up to several kilometers as IoT end devices are distributed over a large area of operation. Considering all the aforementioned characteristics, this can be only realized by using the low power wide area network (LPWAN) technologies as LPWAN technologies can support resource management, throughput, and delay constraints in IoT [3]. There exist several LPWAN technologies present in the market, such as SigFox [4], Narrow Band (NB)-IoT [5], or Long-Range Wide Area Networks (LoRaWAN) [6] and Long-Term Evolution for Machines (LTE-M) [7]. The maximum data rate in SigFox is ~100 bps, whereas in NB-IoT it is ~250 kbps. On the other hand, in LoRaWAN, it is approximately ~50 kbps, and in the case of LTE-M, the maximum data rate is approximately ~1 Mbps. LoRaWAN [6] is among the leading LPWAN technologies as it offers the possibility for private network deployments and easy integration with a number of worldwide network platforms and has the ability to provide long-range communication with low power consumption. Due to this and its open access specification, LoRaWAN have gained significant attention from academia and industries for IoT [8] [9]. The LoRa physical layer has been patented by Semtech in the year 2014 [10]. LoRa is a radio frequency (RF) modulation technology that defines the physical layer features for long-range communications. However, the LoRaWAN medium access control (MAC) protocol is an open-source protocol standardized by the LoRa Alliance that runs on the top of LoRa physical layer.

LoRaWAN is also popular in smart city applications as it provides cost-effective, scalable, and power-efficient solutions for connecting thousands of widely distributed and low-data-rate devices. It supports long-range communication while covering ~2-15 km in rural areas and 1-5 km in urban settings. The end devices in LoRaWAN can last upto 5 to 10 years on battery, that reduces the need for frequent maintenance. It also offers low-cost unlicensed spectrum (ISM) bands, whereas LoRaWAN gateways are also affordable and can support thousands of devices. It also supports municipalities to deploy and control their own infrastructures in smart city applications. LoRaWAN also supports flexible network architecture with public, private, and hybrid networks, whereas designed for massive IoT deployments. Also, it uses AES-128 encryption schemes at the network and application layers while ensuring end-to-end security for data transmitted from sensors to applications [9] [10]. LoRaWAN is a popular communication protocol designed for low-power wide-area IoT deployments. While it excels in range and energy efficiency for small data transfers but it faces several inherent limitations and challenges due to its design trade-offs [20] [21]. The challenges arise due to low data rates, inefficient resource allocation, energy consumption, and network congestion problems [22]. It has also been observed that traditional fixed-duty cycle mechanisms suffer from suboptimal bandwidth utilization, increased transmission delays, and energy wastage, especially

in dynamic environments where real-time data transmission is crucial [23]. The root cause for the low data rate transmissions is chrip spread spectrum modulation, which prioritizes robustness and range over speed, and also spreading factor (SF) that results in long transmission time and poor latency [24]. LoRaWAN uses a pure ALOHA channel access method that also increases the chances of retransmissions. collisions and unfair resource usage. The frequent transmissions (TX), collisions, and high SF factors result in reduced battery life. LoRaWAN gateways operate in licensed ISM bands (868 MHz in EU, 915 MHz in US) with strict duty cycle limitations. As the network of IoT end devices grows with limited channel availability, that also results in frequent packet drops, low QoS, and scalability problems [25]. It is also observed that the LoRaWAN protocol suffers from security vulnerabilities to jamming and intrusions. No such in-built mechanism is found in LoRaWAN for intrusion detection or anomaly classification [15].

Machine Learning (ML) is a popularly growing field with many applications, including wireless communications [26] [27]. There are various studies which claim that ML could be used to improve the performance, efficiency, and security of LoRaWAN [28]. ML algorithms empower LoRaWAN networks to dynamically allocate resources, predict network traffic, mitigate interference, and optimize energy consumption, thereby enhancing network capacity, reliability, and battery life. With ML-driven insights, operators can proactively plan network expansions and ensure better quality of service (QoS), and also achieve self-optimizing networks that autonomously adapt to changing conditions. However, popular supervised learning approaches such as SVM, Decision Trees, Random Forest, and Logistic Regression models rely on a large amount of labelled data, which is often scarce and expensive in LoRaWAN due to limited sensing and reporting capability [29]. Also, models trained on static datasets may fail to generalize in dynamic, noisy environments with high traffic variability. Traditional supervised approaches also do not adapt well to real-time changes in topology or energy levels. These models also suffer from scalability issues and security bias limitations. It has been also observed that existing Deep Learning (DL) models, such as CNN, LSTM, DNN, auto encoders, require significant resources for training and interference which is not practical for low-powered LoRa nodes. DL models heavily rely on large datasets which is often unavailable in LoRaWAN due to low data rates and sparse feedback. Also, these DL models suffer from latency issues, overfitting problems, black-box nature, and deployment complexities [29] [30]. It has been also observed that the existing unsupervised ML techniques suffer from poor contextual awareness, false positives, and parameter tuning issues in large-scale LoRaWAN deployments.

The proposed system, therefore, aims to optimize the throughput, minimize transmission delay, and preserve energy while meeting the criteria for secure transmission, thereby enhancing the overall performance of LoRaWAN. However, the proposed work also finds the popularity of RL strategies and their scope towards improving the performance of LoRaWAN and further formulates a unique form of light-weight computational and analytical framework for Q-learning based adaptive duty cycle management in LoRaWAN, which is also further integrated with a security modeling. Here, the framework aims to optimize the LoRaWAN resources in dynamic conditions and also offers resiliency against different forms of adversaries in LoRaWAN, which affects the energy and QoS performance in LoRaWAN.

The key contribution of this work is listed as follows:

- Unlike traditional fixed duty cycling and static scheduling strategies, the proposed work employs Q-learning to dynamically adapt transmission decisions based on real-time network conditions and also significantly improves energy efficiency and throughput. Here Q-learning based adaptive duty-cycling dynamically adjusts transmission slots considering buffer, energy, channel, and duty cycle constraints.
- In contrast to the generic ML models that require extensive training data and centralized models, the proposed approach offers a light-weight and model-free reinforcement learning strategy that enables distributed and online learning at individual IoT nodes in LoRaWAN.
- The integration of trust-based intrusion detection modeling enhances the security by proactively filtering malicious data packets, a feature that is missing in existing standard ML approaches for resource management in LoRaWAN that focus solely on performance optimization without considering security. The framework also can be extended to incorporate trust scores from gateway-based intrusion detection, allowing the RL agent to make security-aware scheduling decision without compromising resource optimization.
- It offers an effective RL-driven approach for selecting transmission strategies that adaptively optimizes throughput, bandwidth utilization in response to dynamic traffic patterns. The proposed work shows superior performance in terms of delay, energy conservation, and secure transmission under variable traffic and channel conditions compared to popular baseline schemes.
- Unlike existing RL-based LoRaWAN studies, our framework uniquely integrates a Q-learning-driven adaptive duty cycle with trust-aware security with trust-aware security feedback. It combines Q-learning driven adaptive duty cycle for efficient resource management with a trust-aware security module. While the Q-learning agent optimizes transmission slots and power levels, the security layer independently evaluates trust scores from gateway-based intrusion detection that ensure reliable and secure data transmission alongside optimized network performance.
- In future work, the Q-learning agent could be extended to incorporate trust scores from gateway-based intrusion detection, which will enable joint resource management and security-aware decision making.

The aforementioned contributions are presented in a structured manner. The organization of the study is as follows: Section II reviews the existing methodologies, while the identified limitations are outlined in Section III. Section IV describes the system model, followed by the discussion of results in Section V. Finally, Section VI concludes the study with a summary of key findings.

II. Review of Literature

There exist various forms of related research studies that have also focused on improving the performance of LoRaWAN using ML approaches. The authors in [11] have proposed a load-balancing method for dense IoT networks such as smart city scenarios. The authors basically performed training of various ML techniques such as Multiple Linear Regression (MLR), Gaussian Naïve Bayes (GNB), Linear Discriminant Analysis (LDA), Decision Tree (DT), Random Forest (RF), and few others. These classifiers are applied to an urban IoT network, where the simulation results showed performance improvement over packet success ratio (PSR), and the framework also offered optimized energy consumption in the LoRaWAN network. In [12], the authors have introduced an SF allocation scheme considering SVM and DT that aims to resolve the collision issue in the LoRaWAN network. The training dataset was generated using simulator for LoRa SimLoRaSF, and a custom simulator was also designed for LoRaWAN using Python. The authors in [13] also emphasizes toward resource classification problem for static EDs in LoRaWAN using various ML techniques. Such as RF, SVM, logistic regression (LR), K-Nearest Neighbour (KNN), and few more others. The experimental outcome shows that the RF method accomplished the highest accuracy of 92% compared to other ML techniques. It has been observed that various DL methods were applied to improve the performance of LoRaWAN by optimizing resource parameters, predicting network traffic, mitigating inter-intra interferences, and optimizing energy constraints.

An extended Kalman Filter-based LSTM method based on regression is proposed for predicting collisions in the LoRaWAN network, which is introduced in the study of [14]. As a collision in the LoRa network is directly linked with the SF, hence SF has not been considered for adaptive configuration. As a result, the presented LSTM approach leads to underperformance when applied in a dynamic LoRaWAN network. The study in [15] proposed DeepLoRa, which is an environment-aware path loss model. On the other hand, in [16], a DL method is proposed for managing the transmission interval of IoT devices in LoRa networks by utilizing Intel Berkeley Research Lab Data. The paper [17] proposed a DL method for joint collision detection and resource management. Here, the presented work considers two DL methods: fully connected neural networks (FCNNs) for collision detection and CNN for SF management. The experimental results show improved prediction performance and energy consumption when compared with traditional ML methods. The paper [18] proposed an RL-based approach for optimizing and updating LoRa communication parameters. The authors utilized the RL method to derive optimal disseminating policies by aiming to maximize the accumulated average node throughput. The authors claim that their approach to the LoRaWAN has given a remarkable increase in the accumulated average per-node throughput of 147%.

The authors in [19] presented a novel method for resource allocation in LoRaWAN networks. Here, the method used Q-learning strategy of RL to learn the optimal resource allocation policy for each ED in the network. In the presented method, GW acts as an agent of Q-learning, where the Q-reward is based on the weighted sum of the number of successfully received packets in the proposed method. The Q-learning method was evaluated using simulation, and the outcome shows that the proposed method achieves PSR by ~20% compared to a random resource allocation scheme.

III. Research Problem

LoRaWAN networks significantly face challenges in balancing energy efficiency, reliable data transmission, and security against malicious activities. Traditional static duty cycle mechanism in LoRaWAN leads to inefficient bandwidth utilization and energy wastage, especially under dynamic traffic and channel conditions. Furthermore, LoRaWAN's lightweight nature makes it susceptible to various security threats, including spoofing and packet injection. The research addresses the need for an adaptive secure scheduling mechanism by formulating a Q-learning-based framework that can dynamically adjust the transmission duty cycle based on real-time state conditions. However, the challenge also arises to design a light-weight trust-aware intrusion detection system to block malicious packets in LoRaWAN. Despite the popularity, existing AI/ML-based optimization techniques often fail to adapt to the variability in network traffic, dynamic occupancy patterns, and energy constraints in large-scale LoRaWAN deployments.

IV. Research Method

The proposed work, therefore, aims to develop a novel, highly efficient, and scalable AI/ML-driven adaptive resource management and secure framework for LoRaWAN in a smart city eco-system where the resource management strategy is well-capable of optimizing the duty cycle allocation, bandwidth utilization, and energy-efficient transmission while maintaining high data throughput and minimal latency. The proposed framework of LoRaWAN operates in the MAC layer that effectively defines how LoRa devices communicate with the gateway and network servers. In the proposed work, the adaptive LoRaWAN framework (Fig. 1) is structured into three primary components, which are Q-learning-based scheduling, channel-aware management, and lightweight edge security. Here, Fig. 1 also shows a typical LoRa network deployment scenario. Before delving into algorithmic details, the section outlines the operational flow of these core components in LoRaWAN.

A. LoRaWAN-Based IoT Deployment

Let, $D = \{d_1, d_2, \ldots, d_n\} \in \mathbb{Z}^+$ be the set of n LoRa IoT devices in a LoRaWAN environment. The LoRa-based IoT network also consists of m LoRa gateways such as $G = \{g_1, g_2, \ldots, g_m\} \in \mathbb{Z}^+$. It is also assumed during the analytical modeling that the network should also consist of a central network server S. The total time steps for simulation is considered to be T. Therefore, each IoT device $d_i \in D$ is

located at position of $\mathrm{Loc}(d_i) \in \mathbb{R}^2$. And also, each gateway $g_j \in G$ has a coverage radius of R_j. The deployment assumption also considers that the devices and gateways are randomly distributed in a 2D space, and coverage check can be validated considering the following Eq. (1).

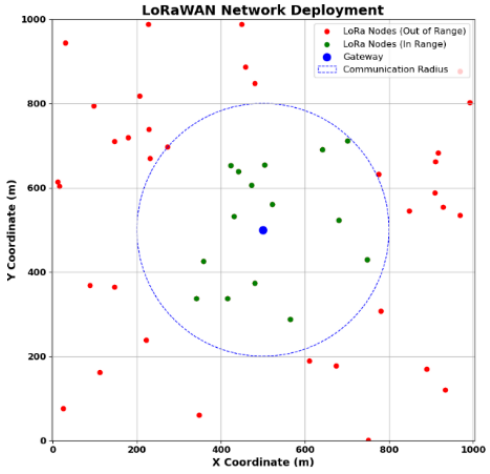
$$\left\|\mathrm{Loc}(d_i) - \mathrm{Loc}(g_j\right\| \leq R_j \quad (1)$$

At each time step of $t_i \in T$ each device d_i generates a data packet in the form of $P_i^{(t)} = \langle temp_i^{(t)}, hum_i^{(t)}, \tau_i^{(t)}, id_i \rangle$ where $temp_i^{(t)}$ represents the temperature readings, $hum_i^{(t)}$ represents the humidity readings, $\tau_i^{(t)}$ represents the current time stamp and id_i refers to the unique device ID. It also assumes that the packet $P_i^{(t)}$ is sent to a randomly selected gateway $g_j \in G$. Here it is assumed that IoT end devices periodically generate data packets, and that are transmitted to randomly selected gateways. The packet loss model also considers that each gateway g_j has a probability of packet loss of 0.05 and success of 0.95. The condition of data transmission is modeled using Eq. (2). If it is found that $X_{ij}^{(t)} = 1$, then the gateway forwards the packet to the server $P_i^{(t)} \rightarrow S$. The server further stores and processes the packets in Eq. (3).

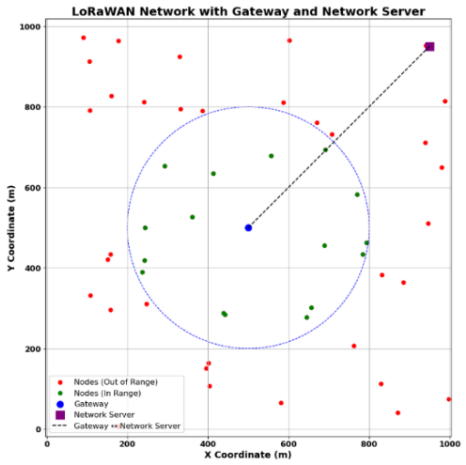
$$X_{ij}^{(t)} = \begin{cases} 1, & \text{if } g_j \text{ succesfully receives } P_i^{(t)} \\ 0 & \text{Otherwise} \end{cases} \quad (2)$$

$$\xi_s = \cup_{t=1}^{T} \left\{ P_i^{(t)} | X_{ij}^{(t)} = 1 \right\} \quad (3)$$

Here, in the above Eq. (3), ξ_s represents the cumulative set of successfully received packets over time from all IoT end devices in the LoRaWAN-enabled smart city eco-system. The proposed work emphasizes towards designing and developing a novel adaptive duty cycle slot allocation mechanism using Reinforcement Learning (RL) to enhance the performance of large-scale LoRaWAN in smart city eco-system. The following Fig. 1(a) shows the LoRaWAN network deployment scenario without a network server, and Fig. 1(b) shows the LoRaWAN network deployment scenario with the inclusion of a network server in the proposed work.



(a)



(b)

B. Improving LoRaWAN Performance Using Reinforcement Learning (RL) Algorithms

The proposed study emphasizes towards improving the performance of LoRaWAN via ML-based decision making for adaptive duty cycle slot allocation. The proposed work leverages RL techniques in LoRaWAN to intelligently manage the network resources and aims to maximize efficiency along with optimal delivery performance. Reinforcement Learning (RL) is a data-driven approach where it learns rules and policies from experience by interacting with the network and observing the results. RL is a dynamic approach that has the capability to adapt to the environmental changes. LoRaWAN networks are constantly changing owing to the dynamic scenarios and due to the underlying propagation environment. As a result, RL algorithms can be used to learn how to optimize the network parameters for these changes, ensuring that the network remains reliable and efficient. As RL is a scalable approach, it can be used to optimize large and complex networks [21]. Therefore, the proposed work realizes that in LoRaWAN, RL could be used to optimize resources by training agents for making decisions to maximize overall network efficiency and minimize interference, along with energy consumption. The proposed work in the first phase of design, therefore, introduces a novel and cost-effective adaptive duty cycle slot allocation using Q-learning modeling and also ensures dynamic slot assignment. In the second phase of design, it incorporates a scheme for bandwidth and efficiency optimization, followed by a security analysis in the third phase.

1) Adaptive duty cycle with RL in LoRaWAN: Duty cycle in LoRaWAN determines how often a device is capable of transmitting data packets. It has been observed that the static allocation paradigms often lead to congestion, collisions, or under-utilization of resources. Therefore, the proposed work introduces an approach of adaptive duty cycling using Q-learning to dynamically choose the best time slot based on traffic, battery, and buffer status, which in longer run reduces contention and also improves energy efficiency.

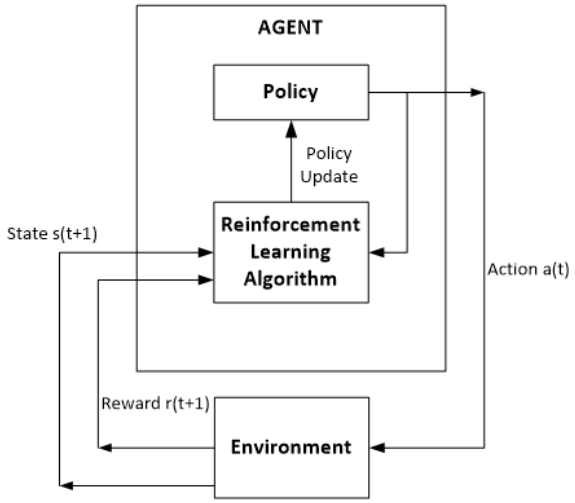

Fig. 2. Reinforcement learning in LoRaWAN.

2) State representation for Q-learning agent: In the proposed analytical modeling of LoRaWAN, each end device state in the context of IoT smart city is defined as a tuple of $s_t = \langle b_t, E_t, l_t, D_t, c_t \rangle$. Here, b_t refers to buffer size at time t, E_t implies the battery level at time t, whereas l_t implies time since last transmission. D_t on the other hand, implies current duty cycle slot and c_t represents channel status (i.e 0=idle, 1 = busy). Fig. 2 shows baseline RL concept which is adopted in the proposed LoRaWAN framework designing.

3) Action space definition in LoRaWAN: The proposed analytical strategy further defines the action space $A = \{TX_{high}, TX_{low}, wait\}$ as a set of high power transmission, which require high energy usage and lower delay denoted with TX_{high}, low power transmission, which require low energy usage but higher delay denoted with TX_{low}, and $wait$ implies skip transmission where the buffer grows and battery is conserved. The prime reason behind considering TX_{high} is that it is used for urgent data or poor channel conditions. It aims to minimize the delay and improve packet delivery probability (stronger signal) for urgent packets or unreliable channel conditions in LoaRaWAN. On the other hand, the action corresponds to TX_{low} imply when channel conditions are good or delay is tolerable for packet transmission. This action also conserves battery life while still sending data. Here, the action $wait$ refers to preserve battery or adhere to duty cycle limits. This action has got importance when the network is highly congested or data is not urgent. This approach not only conserve energy but also helps avoiding duty cycle violation. In the RL perspective the proposed work decides the action space to support light-weight decision model in resource constrained devices with three discrete actions. The learning agent learns a policy to select the best action at each time step depending on the above state space criteria highlighted in $s_t = \langle b_t, E_t, l_t, D_t, c_t \rangle$ to enhance the performance and resource management in LoRaWAN. In the proposed work Q-learning helps managing the resources and LoRaWAN traffic and enables adaptive traffic handling.

4) Q-learning in adaptive traffic handling: In the proposed approach of performance improvement of LoRaWAN the states encode the traffic contexts in the form of s_t. Here, the buffer size implies traffic backlog, which means how much data is waiting to be sent. On the other hand, E_t refers to the remaining battery level of end IoT devices. On the other hand, l_t helps controlling the latency factor. The factor of D_t is used as a duty cycle slot that measures the compliance constraint. These states help the learning agent understand the traffic load and network status accordingly RL mechanism effectively manages the resources. TX_{high} is learned when urgent traffic and high buffer build-up occur. On the other hand, TX_{low} is learned by the agent when traffic is moderate and conditions are favourable. The Q-learning learns to skip Tx for the action $wait$ and avoid penalty and transmit later when the condition improves. In the case of learning$wait$, the Q-learning model realizes that the traffic is low, that means there is no urgency to transmit, whereas transmission at that point might waste energy or duty cycle. $wait$ allows agents to accumulate more data and possibly send it together later. Q-learning learns that delaying when the buffer is small and doesn't incur a big penalty, and also may result in higher future rewards. The $wait$ is useful as it helps avoiding duty cycle violation, helps when the channel is busy ($c_t = 1$) and also useful in the case of battery E_t is critically low. The agent learns to wait for better conditions. Here, via Q-learning, the agent chooses the optimal actions to balance delay, energy usage, and duty cycle compliance, which also positively influence the throughput and data delivery outcome. The Q-Function updating is represented with Eq. (4).

$$Q(s_t, a_t) = Q(s_t, a_t) + \alpha \left[r_t + \gamma \max_{a'} Q(s_{t+1}, a') - Q(s_t, a_t) \right] \quad (4)$$

Here, α represents the learning rate, whereas γ implies the discount factor, and also r_t refers to the intermediate rewards at time t. Also, in the above expression, a' represents the next action, and further it leads to the Q-value for state action pair in $Q(s_t, a_t)$. While iteratively updating the above expression (4), the agent progressively learns when to transmit and at what power in LoRaWAN, and also learns when to wait to avoid congestion or conserve resources. It also adapts to dynamic traffic patterns in real-time. The agent evaluates b_t and if it is high, then it immediately sends in TX_{high} or TX_{low} depending upon the channel conditions. If E_t is low, then the agent prefers to conserve energy, so either it chooses or TX_{low} or $wait$. If l_t is high, then it avoids excessive delay and prefer any Tx. If D_t is found near max, then it avoids sending and prefers $wait$. Also, if $c_t = 1$ that implies the channel is busy and prefers $wait$. Here, $D_t \sim 1$ indicates that the end IoT node has used almost all of its allowed transmission time for the current regulatory duty cycle window. That's why it is safer to avoid transmitting until the cycle resets. In LoRaWAN, especially in the EU 868 MHz band is subject to strict regulatory duty cycle limits. If $D_t \sim 1$ in max and the learning agent still chooses to transmit that means it may get penalty, drop the packet and delay can occur for future transmissions. This results in low or negative reward, so over time the agent

learns that $wait$ is the optimal action, when $D_t \sim 1$. With approach the Q-table find which action yields the best long-term return and balances throughput, energy and reliability.

5) Reward function modeling: The design of reward function modeling encourages high rewards for timely transmission with low power. And also penalizes the agent for buffer overflows, delays, or duty violations. It is modeled using Eq. (5). Here, e = 5 for TX_{high} and e = 2 for TX_{low}:

$$r_t = \begin{cases} 10 - e & If\ TX\ succesful \\ -0.5 & if\ wait \\ -2 & if\ TX\ failed\ or\ battery\ low \end{cases} \quad (5)$$

The reward modeling in LoRaWAN encourages the learning agent with a high reward if fast delivery is needed. On the other hand, TX_{low} also gets a higher reward despite a higher delay, which promotes energy efficiency. Whereas TX_{high} is used when speed is critical but very less frequently. $wait$ is not rewarded, but the penalty is low, allowing it to be chosen in risky or sub-optimal states. The proposed Q-learning in LoRaWAN also penalizes risky transmissions, such as if Tx is fails or Tx when the battery is low. In such cases, the agent gets negative rewards, and further, this reward structure also pushes the agent to avoid such states.

6) LoRaWAN adaptive duty cycle mechanism: In the proposed work, the time is divided into 10 discrete duty cycle slots in the form of D_t. Here, each slot might represent a fixed duration, and the model cycles through them as time advances. The update rule for adaptive duty cycle is given using Eq. (6):

$$D_{t+1} = D_t + 1\ mod\ 10 \quad (6)$$

This equation shows that after each decision step (time step), the slot automatically advances to the next. In the proposed system content of LoRaWAN, the model behaviour simulates a rolling time window where duty cycle behaviour resets periodically, matching regulatory constraints (e.g. 1% per hour transmission time in EU868). In the proposed Q-learning-based adaptive duty cycling-based strategy, agents learn which slots are best for transmission based on success rate (i.e., whether Tx is successful), energy cost (TX_{high}, TX_{low}) , and channel conditions (e.g., fewer collisions). Through Q-learning, LoRaWAN builds state-action values $Q(s_t, a_t)$ that include D_t as a state component. It has to be noted that with this approach, the agent doesn't learn what to do, but it learns when to do it. The benefit of this adaptive duty cycling approach is that the agent learns to adapt to traffic patterns, interference, and energy constraints over time.

It has to be noted that the proposed framework operates in three phases: 1) Q-learning-based adaptive duty cycle assignment, 2) efficient channel scheduling, and 3) security-aware packet evaluation. Algorithm 1 to Algorithm 3 together represent the complete operational procedure in which the RL agent selects optimal transmission actions while considering energy levels, buffer status, and channel conditions, thereby achieving adaptive, secure, and efficient resource management in LoRaWAN. The RL agent is also capable of selecting optimal transmission actions while considering trust scores as well. The following algorithm shows Q-learning for adaptive duty cycle in LoRaWAN.

Algorithm 1: Q-learning for Adaptive Duty Cycle in LoRaWAN

Initialize $Q(s_t, a_t)$ arbitrarily for $\forall \langle s_t, a_t \rangle$ pairs
For each episode:
  Initialize environment (E) and state $s_t = \langle b_t, E_t, l_t, D_t, c_t \rangle$
  Repeat for each time step
    With probability ε select random action
    $a_t \in \{TX_{high}, TX_{low}, wait\}$
    Otherwise select $a_t = \arg\max_{a'} Q(s, a)$
    Execute action a, observe
      reward r_t,
      next state s_{t+1}.
      $D_{t+1} = D_t + 1 \bmod 10$ ← Adaptive Duty Cycle slot update
    Update Q(s,a) using:
      $Q(s_t, a_t) = Q(s_t, a_t) + \alpha \left[r_t + \gamma \max_{a'} Q(s_{t+1}, a') - Q(s_t, a_t) \right]$
      $s \rightarrow s'$
      If terminal condition is met, break

The algorithm design and modeling ensure that the Q-learning agent adapts based on the dynamic state s_t. It also offers a duty cycle slot allocation where the reward strategy is encouraged for optimal time. Here, Q-learning automatically adapts policy using reward signals.

7) Optimization of bandwidth and data efficiency in LoRaWAN: It has to be noted that LoRaWAN in smart city eco-system suffers from collisions and idle listening as many IoT end devices share the same channel. Therefore, optimizing channel utilization (bandwidth) and efficient data scheduling can significantly improve the performance of LoRaWAN. If there are N number of end devices (ED) and P_t indicates the packets the successfully transmitted packets at time t ,whereas $\mathcal{U}_t$ represents the bandwidth utilization at time t. Then the bandwidth utilization can be modelled using Eq. (7) and Throughput T_t is measured using Eq. (8). The proposed work further evaluated the transmission delay using Eq. (9). Here, P_t represents the set of packets receiver at t and t_{rx}^p, t_{gen}^p represents the generation time and reception time of packets. The system also computes the battery energy level of IoT nodes or end devices in the form of E_i^t. Here, E_i^t represents the battery level of device i at step t.

$$\mathcal{U}_t = {}^{P_t}/_{N} \quad (7)$$

$$T_t = \sum_{i=1}^{N} \delta_i^t \text{ where } \delta_i^t = \begin{cases} 1 & if\ node\ i\ transsmission\ was\ succesful\ at\ t \\ 0 & otherwie \end{cases} \quad (8)$$

$$Delay_t = {}^{1}/_{|P_t|} \sum_{p \in P_t} (t_{rx}^p - t_{gen}^p) \quad (9)$$

In the proposed LoRaWAN framework Q-learning chooses TX_{high} and TX_{low} based on the congestion and energy. The bandwidth utilization is also tracked via $\mathcal{U}_t$ whereas the

proposed reward structure and simulation loop encourages maximized throughput. The proposed Algorithm 2 for efficient channel scheduling is represented as follows:

Algorithm 2: Efficient Channel Scheduling in LoRaWAN

For each time slot t:
  For each IoT node i:
    Estimate channel status c_t
    If $b_t > \phi$ and energy sufficient:
      Select TX_{high} and TX_{low} via Q-learning
    Else:
      Choose the $'wait'$ action
    Update packet success/failure
    Update metrics:
      Throughput, delay, bandwidth utilization

It has to be noted that the proposed work in LoRaWAN approximates an efficient channel scheduling (ECS) strategy by using a Q-learning agent to dynamically decide on transmission power or WAIT based on local buffer status, energy, duty cycle, and channel status. However, full-fledged ECS features like multi-channel assignment, real-time congestion estimation are marked as future extensions.

C. Security-Aware RL Approach in LoRaWAN

The extensive analysis on LoRaWAN shows that it is vulnerable to different forms of attacks, such as spoofing, flooding, and data injection. Here, in the proposed system, a security-aware RL strategy can detect malicious data patterns, it can also maintain trust scores, and drop packets based on suspicious behaviour. It also ensures secure routing and packet forwarding. The security modeling considers a functional strategy of malicious packet indicator $\phi(P_i^{(t)})$ which generates binary flags if packet $P_i \in s$ is spoofed or malicious, else it flags to 0. It can be represented using Eq. (10). If s_t denotes the set of received packets at time t. Then the intrusion detection rate is computed using Eq. (11):

$$\phi(P_i^{(t)}) = \begin{cases} 1 & if\ P_i^{(t)}\ is\ malicious \\ 0 & otherwise \end{cases} \quad (10)$$

$$I_t = {}^{1}\!/_{s_t} \sum_{P_i^{(t)} \in s_t} \phi(P_i^{(t)}) \quad (11)$$

The intrusion detection rate basically measures how many suspicious packets were found in the current time window. The value of I_t implies that the network is under attack or faulty devices are sensing data. In this proposed security-aware reinforcement learning approach, each IoT device is continuously monitored. And also, the system learns patterns of normal versus suspicious behavior. The devices that behave badly get low trust scores, and their packets are blocked. Here, the system scans the packets from all the IoT devices, and it incorporates a model to spot unusual behavior in a packet, such strange timing or values. The proposed work also implements a security filter in this adaptive resource management framework of LoRaWAN. Here, each gateway uses a rule-based intrusion detection function using Eq. (12). Here, T_d indicates the temperature reading, H_d indicates the humidity reading, whereas T_{max} = 100 degrees and H_{min} is ~5%. The trust score τ_i for IoT device i is evaluated using Eq. (13). The τ_i ranges between 0 and 1. Here 1 means fully trusted device, whereas 0 indicate highly suspicious device. When too many of a device's packets are flagged, then the trust score drops. The packet drop rate δ-drop is also estimated using Eq. (14). This mathematical model evaluates how many packets are rejected as the proposed framework could not trust the source device.

$$Detect(d) = \begin{cases} 1 & \text{if } T_d > T_{max}\ or\ H_d < H_{min} \\ 0 & otherwise \end{cases} \quad (12)$$

$$\tau_i = 1 - {}^{\text{Flagged } P_i^{(t)} \text{ from i}}\!/_{\text{Total } P_i^{(t)} \text{ from i}} \quad (13)$$

$$\delta_{drop} = {}^{P_i^{(t)} \text{ dropped due to low } \tau_i}\!/_{\text{Total received } P_i^{(t)}} \quad (14)$$

In the proposed work and security strategy, the model simulates malicious behavior in LoRaWAN while injecting fake data. It also simulates malicious IoT devices sending falsified or abnormal data, which represents active attacks like data injection. The proposed security filtering and black listing formulation is well capable of defending network flooding attacks or data corruption with fake sensor values. It also prevents the adversaries from resending previously valid packets. As the gateway/server could be extended to discard old or replayed packets by checking if the timestamp is within a valid range or not. If a node continuously refuses to transmit data, then the proposed security framework could be extended with a Q-learning agent that discourages excessive wait or non-transmitting states via negative rewards and mitigates routing blackhole by adapting duty cycles and penalizing inactivity in LoRaWAN. The system is also well capable of resisting Grayhole attack, Jamming attack, Sybil, and DoS intrusions in LoRaWAN. The next segment of the study further illustrates the results and discussion on the outcome obtained from simulating the above analytical algorithms through numerical computing and analysis.

Algorithm 3: Intrusion Detection and Secure Transmission in LoRaWAN

For each received $P_i^{(t)}$ from device i
  1. Extract key info: device_id, timestamp, data content (payload)
  2. Run anomaly or unusual behaviour detector on $P_i^{(t)}$
    - If $P_i^{(t)}$ is suspicious or trust_score $[i] < 0.6$
      Drop the packet
      Reduce trust_score$[i]$ by a penalty value.
      Blacklist ← Blacklist ∪ {Device$_i$}
    - Else
      Accept the $P_i^{(t)}$
      Increase trust_score $[i]$ by a reward value.

It has to be noted that in the proposed framework the security layer operates synergistically with the Q-learning agent, in which the trust score of each device is periodically updated considering packet consistency and transmission success rate. These trust updates in longer run will indirectly influence the agent's state vector and also enable adaptive scheduling decisions that prioritize reliable and trusted nodes within LoRaWAN. While the Q-learning agent primarily handles the scheduling, the trust mechanism ensures that

unreliable or malicious nodes are filtered that indirectly support more effective and reliable network operations.

V. Results and Discussion

The proposed adaptive duty cycle management framework using Q-learning for LoRaWAN is analytically modeled and scripted in Python 3.10. The simulations are carried out considering a Python-based environment using Jupyter IDE/Notebook. The simulation framework considers a custom discrete-event simulation modeling in Python for LoRaWAN. It also implements a custom implementation of Q-learning, considering visualization libraries, data handling libraries, and machine learning (ML) libraries. The security module also incorporates custom filtering and blacklist logic. The simulation system configuration considers an Intel Core i5 processor with 12 GB RAM and a Windows operating system. The custom Q-learning is CPU-light for conceptual modeling, so it doesn't require GPU processing.

The experimental evaluation considered a custom discrete-event simulation model developed in Python to emulate LoRaWAN communication under varying traffic and channel conditions. The proposed framework also includes realistic parameters such as bandwidth (125 kHz), transmission power levels consistent with LoRa Class-A devices. For comparison, the popular baseline schemes such as Static (fixed duty-cycle allocation), Random (stochastic transmission slot selection), and Round Robin (cyclic slot assignment) were implemented. All metrics, such as throughput (packets/sec) and energy (mJ), are normalized averages derived from the simulation experiments. The network topology configuration is shown in Table I.

TABLE I. Simulation Configuration

Parameters	Values
Number of IoT Devices	10-100
Number of LoRa gateways	1-2
Simulation Time Step	50
No. of Episodes	1000
Coverage Radius (per Gateway)	1000 meters
Device Transmission Slots	10 slot cyclic duty schedule
Random Packet Loss Probability	10-15%
Attack Injection Rate	10% (Fake Sensor Values)
Initial Battery Level	100 Joule
$\boldsymbol{TX_{high}}$ Energy Consumption	5 units
$\boldsymbol{TX_{low}}$ Energy Consumption	2 units
$\boldsymbol{wait}$ Energy Impact	0 (only incurs delay penalty)
Learning Rate α	0.1
Discount Factor $\boldsymbol{\gamma}$	0.9
Exploration Rate $\boldsymbol{\varepsilon}$	0.1

The proposed work observes the trends from the plots after implementing the strategy of adaptive duty cycle operation in LoRaWAN. The observed trends from Q-learning is illustrated in Fig. 3. Fig. 3(a) shows that trend in cumulative reward per episode is initially low, but improves and stabilizes over episodes. This indicates the Q-learning agent in the proposed system learns effective actions to maximize successful transmission and conserve energy while also avoids unnecessary transmissions as the encouragement with higher reward in proposed Q-learning leads to better decision policy.

The analysis of the buffer size also implies that the buffers remain within mid to low ranges, which clearly shows high variability as buffer size fluctuates significantly from episode to episode. The buffer size ranges from 0-4 packets [see Fig. 3(b)]. The high-frequency fluctuations across the episode range suggest that the buffer size is dynamic and frequently changing. The buffer size is rarely remains zero or maxim indicating the system is actively transmitting and receiving data. Values between 1 and 3 dominate suggest a moderately filled buffer across the learned period. The observed variability also indicates that the system adapts dynamically to changes in network load channel availability and energy constraints. Since learning policy involves exploration using ε-greedy policy hence fluctuations are expected as the agent explores different transmission strategies. Overtime although no clear smoothing is visible, the agent avoids extreme buffer overflows or starvation indicating policy convergence. The observed variation suggests a balance between energy and throughput.

Here, Fig. 4 indicates the number of successfully transmitted packets received by the gateway at each time step. Here, the throughput values fluctuate based on agent's learned behavior and environmental dynamics such as channel congestion or blacklist filtering. The Q-learning agent gradually improves its decision-making strategy between TX_{high} , TX_{low} and $wait$ to prioritize successful transmissions when the channel is idle and the battery is sufficient. This adaptive learning process prevents excessive collision or batter drain and ensure stable throughput over time. It also shows good responsiveness and adaptive behavior with increasing number of IoT End Devices (EDs).

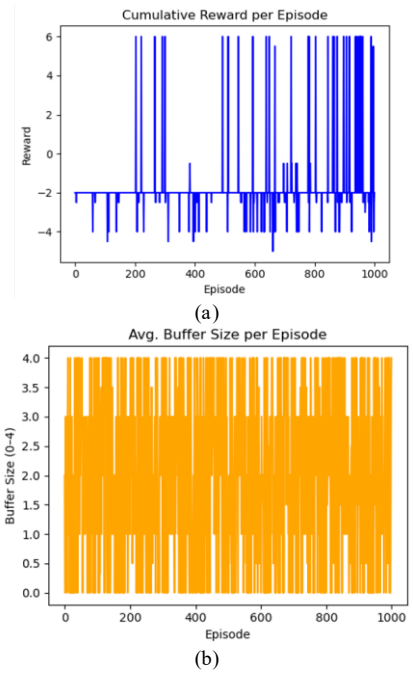

Fig. 3. Observed trends from Q-learning: a) analysis of cumulative rewards and b) average buffer size per episode.

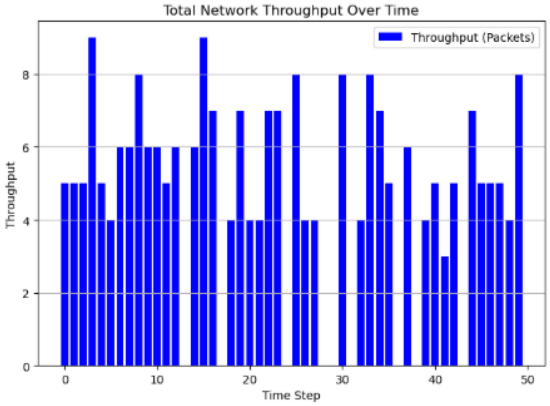

Fig. 4. Analysis of throughput in LoRaWAN.

The observed trends from Q-learning is illustrated in Fig. 5. The interpretation of the [Fig. 5(a)] plot shows ratio of packets successfully transmitted relative to total number of active devices at each time step. The proposed Q-learning based algorithm in LoRaWAN shows moderately efficient bandwidth utilization trend that clearly depicts the fact that the Q-agent balances the aggressive and conservative transmission attempts. Low utilization at certain intervals correlates with high interference (channel status busy) or conservative WAIT actions, which the agent learns to apply when risk is high or energy is low. This approach significantly helped reducing the congestion and packet loss. It offers ~65% utilization and the algorithm with this approach avoids overloading the network while maintains consistent data delivery and indicate balanced usage of resources. Fig. 5(b) captures the average battery level of all IoT devices over simulation steps. It highlights decreasing but controlled energy curve that signifies an energy-aware strategy in LoRaWAN. It also depicts that learning agent adaptively decide and favor low power transmission or defer transmission when essential as guided by the Q-learning optimal policy. The gradual descent also reflects sustainable energy usage rather than rapid depletion which verify the framework's suitability for long term operation in large-scale and constrained LoRaWAN.

The comparison of throughput for proposed Q-learning in (Fig. 6) shows that it achieves highest throughput in initial steps in LoRaWAN. Slowly it starts adapting to the environment dynamics and select transmission times that maximizes rewards. This leads to higher and smarter throughput over time. However, in random policy inconsistency is observed in the throughput outcome as it occasionally performs well by chance but lacks reliability and wastes resources due to frequent collisions or poor timing. However Round Robin offers stable but low throughput as it underutilizes idle slots and cannot adapt to traffic or channel conditions. Static duty cycle paradigms are fragile in dynamic environments and result poor reliability and wasted capacity. The Q-learning approach also occasionally yields zero throughput at specific time steps these reflect intelligent decision making such as avoiding unfavorable transmission slots or conserving energy. Here, Q-learning adapts its policy to maximize long-term throughput leading to overall superior performance despite transient dips in LoRaWAN.

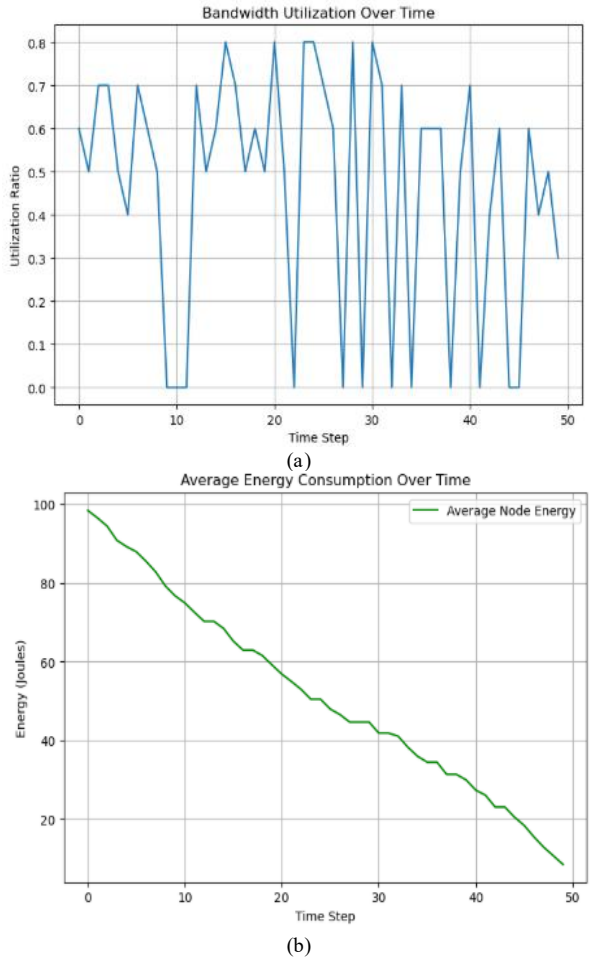

Fig. 5. Observed trends from Q-learning: a) analysis of bandwidth utilization ratio, and b) average energy consumption over time.

The delay outcome is found highly stable in the case of Q-learning strategy, as it learns from the reward feedback to choose actions (transmission slots) that minimizes delay. After brief learning phase, it converges to an efficient schedule with minimal delay. However, other methods such as Random, Round Robin and Static either transmit blindly or without adaption to repeated conflicts therefore, suffers from instability, higher delay variance (see Fig. 7).

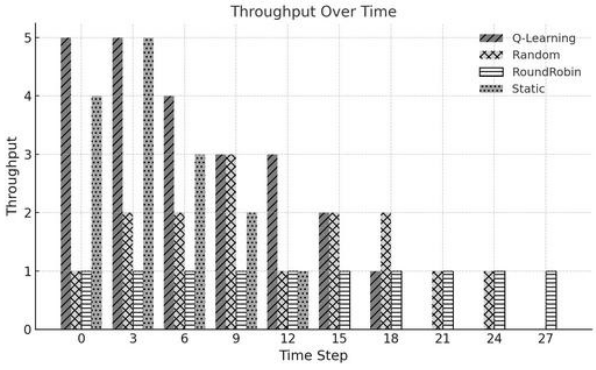

Fig. 6. Comparison of throughput with different approaches.

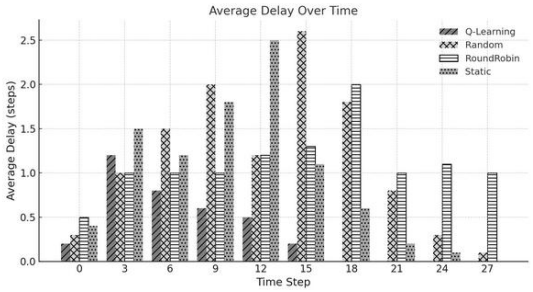

Fig. 7. Comparison of delay outcome with different approaches.

It can be seen from Fig. 8 that Q-learning rapidly explores its action space in early stages which consumes energy. However, once it learns the optimal transmission pattern then energy consumption of IoT devices significantly drops and remains stable. However, it also outperforms others by minimizing the energy use once the optimal policy is learned which static and non-adaptive schemes fail to achieve in LoRaWAN.

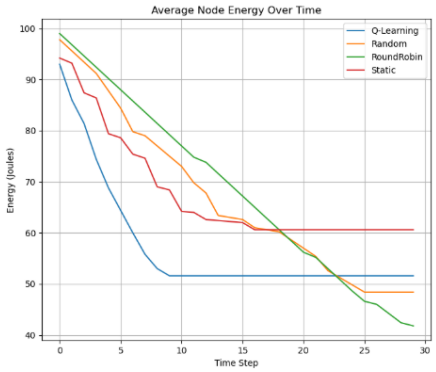

Fig. 8. Comparison of energy outcome with different approaches.

Fig. 9 reveals how many devices are being blacklisted throughout the system's operation in LoRaWAN. The blacklist count increases gradually which suggests that the security system is capable of detecting and isolating misbehaving or low-trust devices which mostly forward suspicious packets in LoRaWAN environment. Here, Q-learning plays a crucial role towards evaluating device behavior and taking penalizing actions over time. The trust-driven approach in the proposed scheme not only improves security and reliability but also contributes towards optimal throughput, lower delay and stable energy consumption.

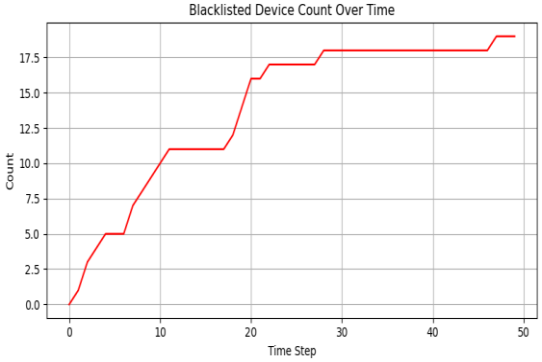

Fig. 9. Analysis of security in LoRaWAN.

VI. Conclusion

The proposed work introduces a Q-learning-based adaptive scheduling and duty cycle strategy to enhance the performance of LoRaWAN. Here, the proposed adaptive duty cycling approach incorporates Q-learning to dynamically choose the best time slot based on traffic, battery and buffer status reducing congestion and improving energy efficiency. Additionally, the unified framework also offers dynamic energy management and optimized transmission under traffic variability. An efficient channel scheduling algorithm is also proposed to enhance the bandwidth utilization, throughput and delay performance in LoRaWAN. The performance of the proposed Q-learning is also evaluated against Static, Random, and Round Robin approaches. The experimental results show that the Q-learning significantly improves the throughput performance (peak: 5 units), and also ensure lower average delay (converging to 0 within 10 steps), and improved energy efficiency (stabilizing at ~52J, ~15% better than Round Robin). It also offers a security analysis strategy that effectively identifies up to 19 malicious or underperforming devices via dynamic blacklisting. The outcome also conceptually justifies that the learning-based approach adapts well to traffic variations and security threats, outperforming static and randomized methods. The proposed framework demonstrates how reinforcement learning and lightweight edge security can jointly enhance LoRaWAN performance and ensure adaptive, energy-efficient, and secure communication in large-scale IoT deployments. In future work, we aim to extend this framework using deep reinforcement learning, multi-agent collaboration, and trust-aware reward models, with validation on more extensive LoRaWAN deployments.

***Abstract*—Real-time surveillance systems require accurate and efficient object detection to ensure safety and situational awareness. Existing methods, such as YOLOv5 and Vision Transformer-based detectors, often struggle to reliably identify small, distant, or occluded objects while maintaining real-time inference, limiting their applicability in complex surveillance environments. To address these challenges, this study proposes PRISM, a hybrid Transformer–YOLOv8 framework that integrates fast local feature extraction with global contextual refinement. The method introduces two novel components: i) a Context-Aware Feed Forward Network (CA-FFN) within the Vision Transformer (ViT), which dynamically weights channel features to reduce redundancy and enhance global context modeling, and ii) Cross-Scale Attention Skip Connections (CSASC) for selective fusion of multi-scale YOLOv8 and ViT features, improving detection of small or occluded objects. The model is implemented in PyTorch and trained on a comprehensive surveillance dataset consisting of pedestrians, vehicles, bicycles, bags, and miscellaneous objects. Experimental evaluation demonstrates that PRISM achieves 96% accuracy, a significant improvement of ~4–5% over baseline methods, with robust performance across all object categories. Key performance indicators verify the reliability of the model to real-time usage, and the lightweight design makes it edge deployable. These findings imply that PRISM can be used to provide a speed-accuracy balance in a complex and dynamic setting, which is more efficient than the current methods. The study also notes the partial extensions, such as the incorporation of multi-sensors and continuous video streams to do time modeling as an extension, which will offer a good base to the next-generation intelligent surveillance systems.**

***Keywords*—Real-time object detection; hybrid transformer–YOLOv8; Context-Aware Feed Forward Network (CA-FFN); Cross-Scale Attention Skip Connections (CSASC); surveillance video analytics; multi-scale feature fusion**

I. Introduction

Real-time surveillance has turned into an inseparable component of the contemporary governance of the city, social security and management of vital infrastructure [1]. Since the idea of smart cities has entered a new phase and the necessity of automated monitoring devices [2] is growing, the ability to properly distinguish and classify objects in dynamic and complicated environments has received primary importance [3]. These traditional computer vision algorithms have been largely reliant on handcrafted features that are sensitive to varying light conditions, occlusion, and size, and hence limit their application in real-world surveillance [4]. With the emergence of deep learning (DL) algorithms, and in particular convolutional neural networks (CNNs) [5], object detection has gotten a significant boost due to automated feature extraction and strong recognition features. The You Only Look Once (YOLO) family of CNN-based [6] detection methods has become one of the most popular frameworks in real-time detection because it operates in a single stage, and all images are processed in a single pass, having an impressive inference speed [7]. However, the YOLO-based models are mostly centered on the local spatial information, disregarding the contextual relationships at a large scale, which may worsen the performance of the model on the detection of small, hidden, or distant objects [8]. ViTs, on the other hand, make use of self-attention mechanisms to learn global dependencies [9], which give a better representation of more complex scenes and greater detection of difficult-to-detect object classes. However, ViTs are computationally expensive and latency-prone, which makes them less ideal for real-time execution on edge devices [10]. Hybrid models using CNN backbones and transformers have also been studied, but most existing methods are inclined to excessive computational cost or non-optimal multi-scale feature integration, which leads to a trade-off between efficiency and accuracy [11], [12].

To address these challenges, this study presents PRISM, a new hybrid system of scalable real-time monitoring of surveillance objects. PRISM combines the property of extracting features of objects within a short time frame used in YOLOv8 with a lightweight ViT module, with an addition of a Context-Aware Feed-Forward Network (CA-FFN) that boosts the network's understanding of the objects in their entirety. This is done using a Cross-Scale Attention Skip Connection (CSASC) mechanism that is effective in producing local and global features at multiple scales without compromising speed and accuracy. The framework integrates powerful preprocessing, data augmentation, and CIoU-based optimization to achieve maximum performance in the detection of various categories of objects such as pedestrians, vehicles, bicycles, and miscellaneous objects. PRISM aims to work around the shortcomings of the current method, combining the strengths of YOLOv8 and ViTs to provide a better detection of small, occluded, and distant objects, preserving the performance of real-time detection. The proposed framework would be applicable to both edge and cloud deployments and would be flexible, scaled, and robust in the present-day surveillance applications.

A. Research Motivation

The increased complexity of urban observation contexts (i.e., occlusion, changing light, and object size variability) requires detection systems to achieve high accuracy while meeting real-time demands [13]. Existing models rely on speed or are not generalizable when faced with challenging situations, which creates the need to develop a generalizable, scalable hybrid approach to robust object recognition.

B. Significance of the Study

This study addresses important gaps in present-day surveillance object detection by utilizing multi-scale contextual learning and fast inference. The proposed framework improves the detection of small, occluded, and distant objects to collect reliable data for a better and more effective public safety, traffic management, and infrastructure protection. Lastly, this solution is deployable across edge and cloud devices.

C. Recent Innovation and Challenges

Recent advancements, such as transformer-based models and hybrid CNN-transformers, have increased the quality of representation of global features. However, there are still difficulties in achieving a balance between computational efficiency, multi-scale feature fusion, and real-time operation. Integrating lightweight attention mechanisms effectively is still a primary challenge to implement practical, scalable surveillance solutions in changing, dynamic environments.

D. Key Contributions

- Hybrid Framework Design: Development of PRISM, a scalable object detection framework that combines fast local feature extraction with global contextual refinement for robust real-time surveillance.
- Novel Fusion Mechanism: Innovation of CSASC to improve multi-scale feature fusion while ensuring computational efficiency.
- Transformer Optimization: Addition of a CA-FFN to the lightweight ViT module to enhance global feature learning on small, occluded, and faraway objects.
- Robust Preprocessing Pipeline: Use of a systematic data cleaning, augmentation, normalization, and adaptive training approach to achieve model generalization in various surveillance environments.

The remaining section of this study will follow the below organization. In Section II, prior research in real-time detection in the transfer application will be explored, examining findings and restrictions of YOLO and Transformer-based models. In Section III, the most notable challenges in surveillance object detection are identified. These are small object recognition, occlusions, and computational efficiency. The proposed Scalable Transformer-YOLO Model methodology is discussed in Section IV and includes preprocessing of the dataset, architecture of the model, and training methodologies. Section V presents results from experimentation, performance metrics, and comparisons to other conventional models. Section VI concludes with a few conclusions, along with some major discussion and potential future improvement work for the real-time surveillance detection system outcomes.

II. Related Works

Ouyang [14] was proposed as a hybrid system, which combines the concepts of DETR and YOLO to become more robust and more accurate. It is a two-stage pipeline architecture in which the bounding boxes of objects were predicted by YOLO extremely quickly. Then, to add high precision transformer-based model refinement was employed. On the COCO dataset, DEYO has achieved an achievement of 52.1 AP and has surpassed the traditional YOLO models in both detection and performance. The combination of YOLO and transformers assists in the local and global contexts, which progresses the object recognition in difficult scenes. Although DEYO improved the accuracy, it had a negative response as it took a long time to converge and was computationally too costly to use in real-time. The principal disadvantage was its accompanying downside of preparing a large amount of training data and adjusting hyperparameters, consuming resources. Additionally, the transformer-based refinement added even more latencies, restricting its capacity for real-time surveillance applications.

Song et al. [15] proposed ViDT, a novel object detection model based solely on the ViTs, which has subsequently improved detection accuracy. ViDT, in contrast to earlier CNN-based models, fabricates a mechanism for retrieving long-range image dependencies, which has improved object recognition. The model has displayed an AP of 49.2 on the COCO dataset; thereby, it outperforms conventional object detection models. The capacity to learn contextual relationships was one of the main benefits of this model and proved useful in situations when objects were interacting. It is, however, a resource-consumptive and, therefore, not applicable to near-real-time edge solutions that require improved resource utilization. The other weakness is that it is based on training on large datasets, and this usually translates to the transformers requiring much more labeled data in order to perform optimally. The necessity to have lightweight models of transformers that would create a

reasonable balance between accuracy and efficiency in computation has been mentioned in the work.

Wang et al. [16] suggested Mamba YOLO, a state-of-the-art model for object detection, which incorporated the use of SSMs in the YOLO to enhance efficiency and accuracy. Mamba YOLO, which makes use of SSMs in the continuity of its one-step thinking process, allows tracking of objects through time. In this way, it greatly aids by reducing the complexity of computation and hence completely enables the applications of Real-time in autonomous systems and surveillance. The model demonstrated huge progress on the COCO and VOC datasets with large improvements compared to classical YOLO versions on both precision and recall. Another weakness was the inability to perform better in extreme light conditions because objects with poor contrast were hard to notice. Nonetheless, Mamba YOLO had potential for making a valuable contribution to the real-time detection area, given the blend of YOLO's speed with SSMs' sequential page processing abilities.

G. and B. [17] created YoloTransformer-TransDetect, a hybrid in that their framework merges YOLO with transformer-based attention mechanisms to implement defect detection. The sequence included first using YOLO to quickly identify defects, followed by the transformer module that worked to extract features at a finer level of grain to improve accuracy. There was better performance of the model in detecting defects in steel tubes, as well as an increase in the detection rates. The technique was not able to work with extremely complicated or visually similar defect patterns in a single pass and had to undergo additional post-processing. A tiny defect and occlusion, one of the common problems in industry, was classically privileged when the method could reliably, if not efficiently, identify. The research found that some feature learning and localization were realized using transformer-based techniques along with YOLO. Its operation efficiency, however, was questioned, and restricted its use in real-time. The future research undertakes the aim of optimization of transformer block to offer convenience in shortcomings.

Li, Yan, and Shi [18] introduced PP-YOLOE, a new version of YOLO for object detection, which comes with a multi-scale attention mechanism. The adaptive scaling method improves feature extraction to better specify fine distinction details in every scale of any object. Application of these mechanisms significantly enhanced the total accuracy of detection on the COCO data set, mainly on small objects, thus are highly overlooked in previous traditional YOLO models. This network, with the help of attention-based techniques, was rather a skilled object localizer in cluttered and occluded scenes, where it provided fewer false positives. Latency can limit applications in which real-time decision-making is required as video surveillance or even autonomous driving. It is also suggested in the study that lightweight models of transformer should be followed up in order to achieve a good speed-accuracy trade-off.

Su et al. [19] came up with a different model of breast mass detection as they divided the mass into LOGO and applied the strengths of YOLOv5 to it. The algorithm is a two-step process and involves both segmentation and detection of breast masses. First, the image is segmented and cropped with the help of a YOLOv5L6 model on high-resolution mammograms; then, the image and the area with breast masses are processed by various global and local transformer branches; finally, they are combined to yield the final segmentation output. Although these are encouraging figures, integration of transformers has computational difficulties, and it is not an easy task to implement it in a regular hospital system that has low computing capabilities. The study revealed that fusing transformers with YOLO improves boundary refinement and lesion detection but requires excessive data augmentation for generalization onto other imaging datasets.

Shah and Tembhurne [20] developed Defect Transformer, a hybrid architecture utilizing transformers, set to leverage surface defects in industrial applications, which is based on attention-based feature extraction for localization and classification of defects, as well as other aspects. The model was reported to be more accurate in detecting microscopic defects compared to the traditional CNN models. It is however, limited in application when it comes to real-time monitoring due to extremely high levels of computational complexity. This study demonstrated that perceiving the world context can be useful in bettering the process of defect classification. Although it can have multiple applications, there are major limitations to its implementation in real-time applications because of the memory and processing requirements of embedded systems.

Shang et al. [21] presented the Defect-Aware Transformer Network, a deep learning framework designed for intelligent defect detection in modern industrial applications. The model integrated a self-attention mechanism to improve feature representation, which helps to detect those defects that were considered subtle and fine-grained, as is often missed with traditional convolutional models. This was in addition to the mix that was the transformer-based feature extraction and the conventional DL methodologies, which offered good learning of both local and global defect patterns. The experimental tests have demonstrated that the model resulted in a significant improvement of the trade-off between the accuracy and robustness of the classification, in particular, against defects with low contrast and textured backgrounds. In spite of these strengths, the authors also mentioned that their method is computationally expensive and thus not practical in real-time use in the automation of industry.

Current object detection studies highlight hybrid models, where YOLO is combined with transformers to make a balance between speed and precision. Hybrid methods enhance accuracy, but are computationally expensive. Pure transformer-based models detect long-range dependencies and contextual associations, but depend on large datasets and intensive resources. Some models combine sequential modules or multi-scale attention to achieve real-time efficiency and identify fine details. Although refinements based on transformers improve overall detection performance and localization, they also increase latency and computational requirements, which reduces their feasibility in real-world applications such as surveillance, autonomous systems, and industrial defect detection.

III. Problem Statement

Real-time object detection forms are one of the core components of surveillance systems where accuracy, flexibility, and efficiency are of equal significance. YOLO-based models are appreciated due to their lightweight architecture and fast inference that allows them to be deployed in edge cases and real-time systems. However, they do not properly identify small, distant, or hidden objects that usually appear in crowded and dynamic surveillance conditions [16]. Transformer-based models, on the other hand, are good at capturing global spatial context and enhance the quality of detection, but are costly to compute, and thus are restricted in their use in resource limited or real-time environments [22]. Hybrid architectures that integrate YOLO with transformer-based architectures have been reached to overcome those drawbacks, but they are generally accompanied by additional issues such as slow convergence, large memory complexity, and scalability constraints in the field environment. These drawbacks leave a research gap that hinders the development of smart surveillance. This is dealt with in the present work by the development of an optimized hybrid framework that trades accuracy, contextual learning, and efficiency of inference both in edge and cloud-based environments.

IV. Proposed PRISM Framework for Real-Time Object Detection

The suggested PRISM framework is modelled as the powerful and scalable object-detecting built-in surveillance system in real-time that is able to take into account the challenges of crowded scenes, changing illumination, partiality, and small sizes of items. The architecture is a hybrid between the convolutional and transformer-based architecture to trade local detail speech and global contextual reasoning. YOLOv8 is essentially the backbone network, and is effective at extracting multi-scale local features giving spatial precision and fast inference, which are essential to real time implementation. Following the extraction step, a lightweight ViT fine-tunes them by capturing long-range dependencies and high-level semantic relationships across the scene. The ViT component is enhanced with a CA-FFN to perform efficient channel-wise recalibration of the features as well as minimizing redundancy in the output. In order to fill the gap between local spatial information and global context, a new CSASC mechanism is added for enabling the proper merging of YOLOv8 features with ViT-refined results. The combined detection head subsequently executes bounding box regression and classification, which is optimized using CIoU-based loss and adaptive learning policies. Overall, this hybrid architecture provides a high-accuracy real-time system that is still computationally lightweight and well-suited for cloud and edge deployments in surveillance systems.

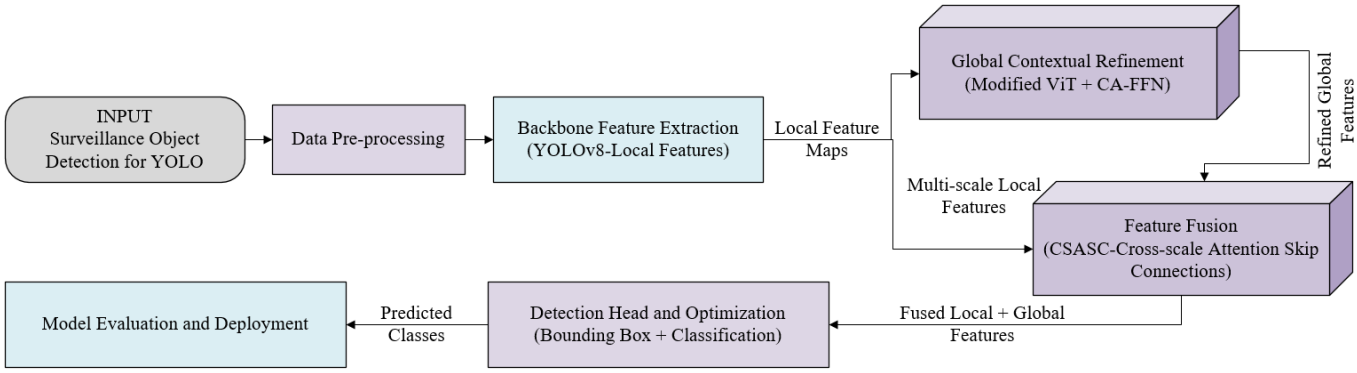

Fig. 1. Proposed PRISM framework.

Fig. 1 shows the process used to detect by the proposed system. The preprocessing of input video streams is followed by feature extraction by means of the YOLOv8 backbone and a lightweight ViT. The extracted features are then used to perform object detection and classification after which the outputs undergo post-processing to give a higher caliber. Evidence is formed to evaluate the quality of detection. The framework is then capable of implementing real-time decision-making or deployment on edge and cloud platforms, which guarantees scalability, efficiency, and flexibility in various settings of surveillance

A. Dataset Overview

The "Surveillance Object Detection Dataset for YOLO" [23] from Kaggle aims to create a training and test dataset with labeled training images specifically for surveillance real-time object detection applications. Approximately, 1,000 annotated images were taken based on real-world surveillance footage, and they depict vehicles and pedestrians, as well as objects of interest, the images are annotated with bounding boxes in the YOLO format that can be used with YOLOv8 models. In every annotation file, there are the class IDs, and coordinates of the bounding box in normalized form (0 to 1) which implies that it is resolution-independent. The dataset is most suitable in the real-time security applications including smart monitoring, anomaly detection, and traffic monitoring whereby strong object detection is a must. It has a great foundation with its formal annotation format and core object types that offer a strong and realistic platform to train YOLOv8 based surveillance models with better accuracy and reliability. The dataset parameters were given in Table I.

TABLE I. DATASET ATTRIBUTES

Attribute	Description	Attribute
Total Images	~1,000 images (varies based on dataset version)	Total Images
Image Resolution	Varies; normalized to 640×640 pixels	Image Resolution
Object Classes	Vehicles, pedestrians, suspicious objects	Object Classes
Annotation Format	YOLO format (TXT files with bounding box details)	Annotation Format
Data Source	Surveillance camera feeds	Data Source

B. Dataset Preprocessing

The input data required for the YOLOv8 model must be acquired using preprocessing techniques for higher precision, generalization, and stability in real-world applications of surveillance. The preprocessing techniques include data cleaning, conversion of format, data augmentation, normalization, and data splitting. These are all important in improving the dataset and the performance of the model.

1) Data cleaning: Cleaning data involves finding and fixing errors, inconsistencies, gaps, or duplicate entries in a dataset. It is important for verifying the accuracy, consistency, and reliability, all of which are required in order to construct effective and trustworthy machine learning models.

a) Identification and removal of corrupt and damaged images: Images that have been corrupted by the files, have an encoding problem, or have been incompletely downloaded are filtered out of the dataset before training [24]. Corrupt files lead to loading errors, higher overhead of computation, or non-batch processing, and therefore instability during model training. The images in the dataset that cannot be read might cause the model to drop out some training examples, and this can also lead to inconsistency in the learning of features and disrupt gradient changes.

Corrupt images are those that fail the image integrity checks. It ensures that all files are complete, well-formatted, and can be accessed. Such images should be deleted, particularly for programs, such as DL models like YOLOv8, where model performance can degrade due to missing or incomplete data. Suppose I_c refers to the number of corrupt images, and I_t to the total number of images in the dataset. The percentage of corrupt image removal can be calculated as in Eq. (1):

$$P_c = \left(\frac{I_c}{I_t}\right) \times 100 \quad (1)$$

b) Filtering mislabelled or empty annotations: Every image in the dataset should ideally have a YOLO annotation file containing bounding box coordinates and class labels. If an annotation file is missing, empty, or incorrectly labeled, the affected images will be adjusted or removed accordingly. Mislabelled annotations could lead to incorrect detections, misclassifications, and an increase in the model's false positive rate, thereby lowering overall detection accuracy.

c) Identification and elimination of duplicate images: Duplicate images lead to bias in the dataset, whereby the model overfits to the frequently seen samples. It follows when the model picks redundant sonic patterns and reduces its generalization ability to unseen test data of the surveillance system. Duplicates are mostly generated if datasets were joined, for example, in cases of automatic image gathering into surveillance systems, or data augmentation errors.

As in Table II, the removal of these problematic images makes way for a better dataset, thereby leading to improved model efficacy, lesser false detection, and improved generalizations in real surveillance environments. This refined dataset is now improved and made apt for preprocessing, augmenting, and training for the YOLOv8 model.

TABLE II. DATA CLEANING OPERATIONS

Issue Identified	Issue Identified	Percentage of Dataset (%)
Corrupt/Damaged Images	120	2.40%
Mislabeled/Empty Annotations	340	6.80%
Duplicate Images	215	4.30%
Total Removed	675	13.50%

2) Format conversion: To ensure conformity, all the images are also transformed into JPEG (.jpg) or PNG (.png) file format. The bounding box annotations are also YOLO format, representing the objects by normalized coordinates in the image frame. The normalizing equation of the bounding box is in Eq. (2):

$$\mathrm{x}' = \frac{x}{W}, \mathrm{y}' = \frac{y}{H}, \mathbf{w}' = \frac{w}{W}, \mathrm{h}' = \frac{h}{H} \quad (2)$$

To make the model more robust and diverse in terms of data, augmentation is done. These changes enable the model to train to identify items in many different situations of low light, motion blur and occlusions.

3) Data augmentation: In order to increase the dataset diversity and robustness of the model, augmentation is applied. Such transformations allow the model to learn to recognize objects in various conditions ranging from low light, motion blur, and occlusions.

The augmentations are used randomly to prevent overfitting, thereby, preserving model generalization in real-world surveillance environments, as provided in Table III.

TABLE III. AUGMENTATION TECHNIQUES AND THEIR EFFECTS

Augmentation Technique	Effect on Model Performance
Scaling (Zoom in/out)	Helps recognize objects at varying distances
Rotation (±15°)	Improves robustness to different camera angles
Flipping (Horizontal)	Enhances ability to detect objects in flipped views
Contrast Adjustment	Compensates for poor lighting conditions
Gaussian Noise Addition	Improves robustness to real-world noise

4) Normalization: This process of normalizing pixel intensities is highly significant as preprocessing and allows making the training of the model stable and efficient. The 0 to 255 raw pixel values in DL typically cause certain wild variation in the weight update in back propagation. These variations can lead to the unstableness of gradient descent, sluggish convergence, and model optimization. In order to solve these issues, pixel intensity is modified, and the intensity values are scaled within a fixed range between 0 and 1 in order to ensure a uniform intensity distribution across all images for the model to learn.

This enables the model to learn features more robustly by diminishing variances in brightness and contrast across the various images. It also allows for faster convergence that will help mitigate the effects of vanishing and exploding gradients. Generally, the normalization can be mathematically expressed, as in Eq. (3):

$$\mathrm{I}' = \frac{\mathrm{I} - I_{min}}{I_{max} - I_{miin}} \tag{3}$$

where, the original pixel value is denoted by I, while I_{min} and I_{miin} represent the minimum and maximum pixel intensities, typically 0 and 255, respectively. The normalized pixel value, I', is scaled within the range [0, 1]. This normalization ensures that the input distributions across all images are consistent, enabling the model to train more effectively. As a result, the model achieves better generalization, leading to improved accuracy in real-time object detection tasks.

5) Dataset splitting: As soon as preprocessing is done, the dataset is separated into orderly and effective subsets: training, validation, and testing for testing model performance in a balanced way. A balanced separation of the dataset is very crucial to avoid overfitting, optimized the learning of the model, and accurate evaluation of unseen data. The above dataset is split with reference to the standard splitting into 70% of the entire data for training, and allows learning the shapes, object features, and positions of the bounding box,20% for validation to ensure hyperparameter tuning and performance monitoring during the training process. The validation dataset helps in ensuring that the model generalizes well while protecting against overfitting onto the training dataset.10% set aside for testing to give unbiased feedback about the model's detection accuracy on data it has not seen. The details of the distribution of this dataset into different test sets are shown in Table IV.

TABLE IV. DATASET PARTITIONING

Dataset Partition	Number of Images	Percentage (%)
Training Set	700	70%
Validation Set	200	20%
Test Set	100	10%

C. Feature Extraction

The YOLOv8 is used in the PRISM framework as the base of rapid local feature detection in the frames of surveillance video. The processing of every frame is done separately by convolutional layers of the YOLOv8 that identify low- and mid-level spatial features, including edges, textures, and contours of objects. These characteristics are essential in the detection of small, remote or partially obscured objects that are major problems in real-time video surveillance images. The architecture of YOLOv8 produces multi-scale feature maps, with multi-resolution detection heads which find objects proficiently. This feature enables precise identification of large, clearly defined objects, including vehicles, and smaller, less obvious objects, such as bicyclists or pedestrians. Formally, the extraction at each layer is given as Eq. (4):

$$F_l = \sigma(W_l * F_{l-1} + b_l) \tag{4}$$

where, F_l is feature map at layer l, W_l and b_l are convolutional kernel and bias, $*$ is convolution, and σ is the activation function. This allows YOLOv8 to obtain spatial and contextual information in every frame of the video due to the hierarchical feature map aggregation. The heads of detection make predictions of bounding boxes and class likelihoods at scales of different sizes at detection time, where larger objects are more sensitive.

YOLOv8 is a real-time, high-throughput spatial fidelity sequentially processing in the case of video datasets. The learned feature maps are subsequently fed to the small ViT, which learns the long-range dependencies and the intrinsic frame contextual relations. Such a mix is what guarantees that PRISM can guarantee the good performance of detecting the dynamic scenes and can handle the application of support to the use of occlusions, motion blur, and varying object sizes without reducing its real-time performance.

D. Global Contextual Refinement

After the local feature extraction stage, which is the YOLOv8, the PRISM framework adopts a lightweight ViT to refine the global context, i.e., long-range dependencies across the extracted robustly feature maps. Unlike the existing ViTs, the proposed architecture presents a novel addition to the traditional FFN layer with the CA-FFN that offers a higher efficiency level, less redundancy of features, and better edge correctness. The modified ViT framework is given in Fig. 2.

The CA-FFN functions by initially performing a regular linear transformation on the input feature $X \in \mathbb{R}^{N \times D}$, where N represents the number of tokens extracted from the YOLOv8 feature map, and D is the dimension for embeddings. Rather than a simple MLP, the transformed feature is subject to channel-wise attention, selectively amplifying informative features while suppressing irrelevant or redundant patterns:

$$A = Softmax\left(\frac{QK^T}{\sqrt{d_k}}\right), \quad X' = AV \tag{5}$$

In Eq. (5), Q, K, V are the query, key, and value matrices from X, and d_k is the scaling factor. The attention output $X'$is next fed into dynamic feature gating, where a learnable gating vector $G \in \mathbb{R}^D$ is used to control the flow of information, given in Eq. (6):

$$X_{CA-FFN} = G \odot GELU(X'W_1 + b_1)W_2 + b_2 \tag{6}$$

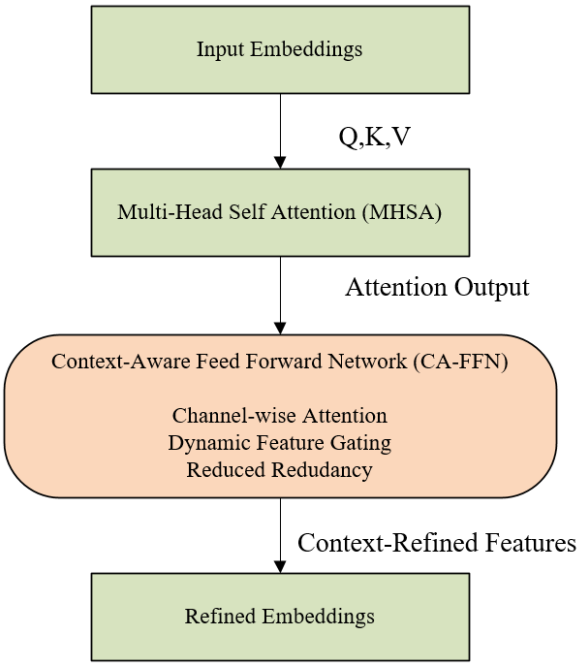

Fig. 2. Global contextual refinement.

where, W_1, W_2 and b_1, b_2 are the trainable weights and biases of the FFN, $\odot$ represents element-wise multiplication, and GELU applies non-linear activation. The gating mechanism enables the network to suppress less useful channels and concentrate computational resources on important features, leading to a significant improvement in efficiency, particularly for edge deployment applications with limited resources.

The PRISM framework, through the inclusion of CA-FFN, makes sure that global contextual information is narrowed without over-inflating computational complexity. The novelty can be easily stated: instead of the traditional ViTs, the FFN is substituted by the context-aware, attention-driven, gated module, which is, at the same time, more effective in terms of feature representation, redundancy, and lightweight architecture to fit into real-time video surveillance. The given step is essential to make sure that the fused YOLOv8 features have contextualized information, increasing the ability to find small, obscured, or visually challenging objects without making real-time performance worse.

E. Feature Fusion Mechanism

The PRISM framework uses representations by taking local feature representations provided by YOLOv8 and contextually enriched global feature representations provided by the CA-FFN-enhanced ViT, integrating them with a Feature Fusion Mechanism. Conventional skip-connections only concatenate, or add, feature maps across layers, which can tend to dilute salient information and cannot prioritize important multi-scale cues that are necessary to detect small, distant, or occluded objects. In order to address this limitation, the proposed framework includes a Cross-Scale Attention Skip Connection (CSASC), a new selective integration feature; its architecture is given in Fig. 3.
